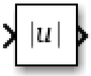
Blocks — Alphabetical List

Abs

Output absolute value of input
Library: Simulink / Math Operations



Description

The Abs block outputs the absolute value of the input.

For signed-integer data types, the absolute value of the most negative value is not representable by the data type. In this case, the **Saturate on integer overflow** check box controls the behavior of the block.

If you...	The block...	And...
Select this check box	Saturates to the most positive value of the integer data type	• For 8-bit signed integers, -128 maps to 127. • For 16-bit signed integers, -32768 maps to 32767. • For 32-bit signed integers, -2147483648 maps to 2147483647.
Do not select this check box	Wraps to the most negative value of the integer data type	• For 8-bit signed integers, -128 remains -128. • For 16-bit signed integers, -32768 remains -32768. • For 32-bit signed integers, -2147483648 remains -2147483648.

The Abs block supports zero-crossing detection. However, when you select **Enable zero-crossing detection** on the dialog box, the block does not report the simulation minimum or maximum in the Fixed-Point Tool. If you want to use the Fixed-Point Tool to analyze a model, disable zero-crossing detection for all Abs blocks in the model first.

Ports

Input

`Port_1` — Input signal

scalar | vector

Input signal to the absolute value block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Absolute value output signal

scalar | vector

Absolute value of the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

`Sample time` — Specify sample time as a value other than -1

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

`Output minimum` — Minimum output value for range checking

`[ ]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Same as input` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `int32` | `uint32` | `fixdt(1,16,2^0,0)` | `<data type expression>` | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Same as input'`, `'Inherit: Inherit via back propagation'`, `'single'`, `'int8'`, `'uint8'`, `int16`, `'uint16'`, `'int32'`, `'uint32'`, `fixdt(1,16,0)`, `fixdt(1,16,2^0,0)`, `fixdt(1,16,2^0,0)`. `'<data type expression>'`
Default: `'Inherit: Same as input'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB® rounding function into the mask field.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Choose the behavior when integer overflow occurs

`off` (default) | `on`

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Action	Reason for Taking This Action	What Happens	Example
Select this check box.	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to the maximum value that the data type can represent.	The number 130 does not fit in a signed 8-bit integer and saturates to 127.
Do not select this check box.	You want to optimize efficiency of your generated code.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`Yes`

Action Port

Add control port for action signal to subsystem
Library: Ports & Subsystems

Description

The Action Port block controls the execution of these subsystem blocks:

- If Action Subsystem blocks connected to If blocks.
- Switch Case Action Subsystem blocks connected to Switch Case blocks.
- Simulink based states in Stateflow®charts. See "Create and Edit Simulink Based States" (Stateflow).

Parameters

`States when execution is resumed` — Select handling of internal states

`held` (default) | `reset`

Select how to handle internal states when a subsystem with an Action Port block reenables.

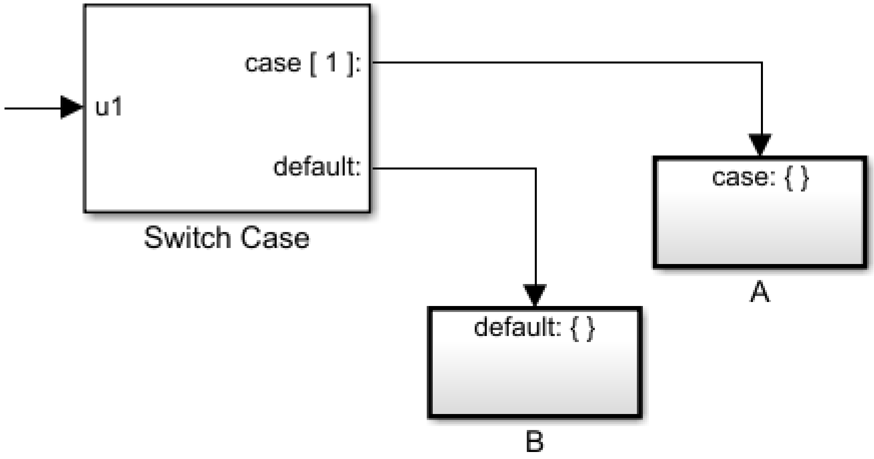
`held`

When the subsystem reenables, retain the previous state values of the subsystem. Previous state values between calls are retained even if you call other subsystem blocks connected to the If or Switch Case block.

`reset`

When the subsystem reenables, reinitialize the state values.

A subsystem reenables when the logical expression for its action port evaluates to true after having been previously false. In the following example, the Action Port blocks for both subsystems A and B have the **States when execution is resumed** parameter set to `reset`.



When **case[1]** is `true`, subsystem **A** is executed. Because the condition of **case[1]** was not previously false, repeated calls to subsystem **A**, while **case [1]** continues to be `true`, does not reset its state values. . The same behavior applies to subsystem **B**.

Programmatic Use
Block Parameter: `InitializeStates`
Type: character vector
Value: `'held'` | `'reset'`
Default: `'held'`

`Propagate sizes of variable-size signals` — Select when to propagate a variable-size signal

`Only when execution is resumed` (default) | `During execution`

Select when to propagate a variable-size signal.

`Only when execution is resumed`

Propagate variable-size signals only when reenabling the subsystem containing the Action Port block.

`During execution`

Propagate variable-size signals at each time step.

Programmatic Use
Block Parameter: `PropagateVarSize`

Type: character vector
Values: `'Only when execution is resumed'` | `'During execution'`
Default: `'Only when execution is resumed'`

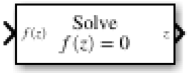
Algebraic Constraint

Constrain input signal

Library: Simulink / Math Operations



Description

The Algebraic Constraint block constrains the input signal f(*z*) to *z* or 0 and outputs an algebraic state *z*. The block outputs a value that produces 0 or *z* at the input. The output must affect the input through a direct feedback path. In other words, the feedback path only contains blocks with direct feedthrough. For example, you can specify algebraic equations for index 1 differential-algebraic systems (DAEs).

Ports

Input

`f(z)` — Input signal
real scalar or vector

Signal is subjected to the constraint *f(z) = 0* or *f(z) = z* to solve the algebraic loop.

Data Types: `double`

Output

z — Output state
real scalar or vector

Solution to the algebraic loop when the input signal **f(z)** is subjected to the constraint *f(z) = 0* or *f(z) = z*.

Data Types: `double`

Parameters

`Constraint` — Constraint on input signal

`f(z) = 0` (default) | `f(z) = z`

Type of constraint for which to solve. You can solve for `f(z) = 0` or `f(z) = z`

Programmatic Use
Block Parameter: `Constraint`
Type: character vector
Values: `'f(z) = 0' | 'f(z) = z'`
Default: `'f(z) = 0'`

`Solver` — Algebraic Loop Solver

`auto` (default) | `Trust region` | `Line search`

Choose between the Trust region [1], [2] or Line search [3] algorithms to solve the algebraic loop. By default this value is set to `auto`, which selects the solver based on the model configuration

Programmatic Use
Block Parameter: `Solver`
Type: character vector
Values: `'auto' | 'Trust region' | 'Line search'`
Default: `'auto'`

`Tolerance` — Solver Tolerance

`auto` (default) | positive scalar

This option is visible when you explicitly specify a solver to be used (Trust region or Line Search) in the **Solver** dropdown menu. Specify a smaller value for higher accuracy or a larger value for faster execution. By default it is set to `auto`.

Programmatic Use
Block Parameter: `Tolerance`
Type: character vector
Values: `'auto' |` positive scalar
Default: `'auto'`

`Initial Guess` — Initial guess of solution value

0 (default) | scalar

Initial guess for the algebraic state *z* that is close to the expected solution value to improve the efficiency of the algebraic loop solver. By default, this value is set to 0

Programmatic Use
Block Parameter: `InitialGuess`
Type: character vector
Values: scalar
Default: `'0'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

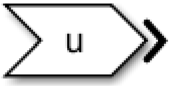
Argument Inport

Argument input port for Simulink Function block
Library: User-Defined Functions



Description

This block is an argument input port for a function that you define in the Simulink Function block.

Ports

Input

u — Argument input
scalar | vector | matrix

The Argument Inport block accepts complex or real signals of any data type that Simulink supports, including fixed-point and enumerated data types. The Argument Inport block also accepts a bus object as a data type.

The complexity and data type of the block output are the same as the argument input. You can specify the signal type and data type of an input argument to an Argument Inport block using the **Signal type** and **Data type** parameters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

out — Block output
scalar | vector | matrix

Block output signal from this block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Port number` — Specify port number of block

`1` (default) | integer

Specify the order in which the port that corresponds to the block appears in the parent subsystem or model block.

`1`

Specify the first port location for this block.

integer

Specify location of port.

Programmatic Use

Block parameter: `Port`
Type: character vector
Value: `'1'` | `'<integer>'`
Default: `'1'`

`Argument name` — Spedify input argument name

`u` (default) | character vector

Specify input argument name for the function prototype displayed on the face of the Simulink Function block.

`u`

Defaut name for the input argument.

character vactor

Name of the input argument.

Programmatic Use

Block parameter: `ArgumentName`
Type: character vector
Value: `'u'` | `'<character vector>'`
Default: `'u'`

`Minimum` — Specify minimum value for block output

`[]` (default) | number

Specify the minimum value for the block output signal.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking and automatic scaling of fixed-point data types.

`[]`

Minimum value not specified.

number

Finite real double scalar value.

Programmatic Use
Block parameter: `OutMin`
Type: character vector
Value: `'[]'` | `'<number>'`
Default: `'[]'`

`Maximum` — Specify maximum value for block output

`[]` (default) | number

Specify the maximum value for the block output signal.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking and automatic scaling of fixed-point data types.

[]

Maxmum value not specified.

number

Finite real double scalar value.

Programmatic Use
Block parameter: OutMax
Type: character vector
Value: '[]' | '<number>'
Default: '[]'

Data type — Specify block output data type
double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | boolean | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^,0) | Enum: <class name> | Bus: <object name> | <data type expression>

Specify the block output data type.

double

Data type is double.

single

Data type is single.

int8

Data type is int8.

uint8

Data type is uint8.

int16

Data type is int16.

uint16

Data type is uint16.

int32

Data type is int32.

uint32

Data type is uint32.

`boolean`

Data type is `boolean`.

`fixdt(1,16,0)`

Data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Data type is fixed point `fixdt(1,16,2^0,0)`.

`Enum: <class name>`

Data type is enumerated, for example, `Enum: Basic Colors`.

`Bus: <object name>`

Data type is a bus object.

`<data type expression>`

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

Programmatic Use
Block parameter: `OutDataTypeStr`
Type: character vector
Value: `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'boolean'` | `'<fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'double'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data type

off (default) | on

Control changes to data type settings from the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

☑ On

Locks all data type settings for this block.

□ Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

Programmatic Use
Block parameter: `LockScale`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

`Port dimensions` — Specify port dimensions

`1` (default) | `n` | `[m n]`

Specify the dimensions of the argument input signal to the block. For more information, see Outport.

`1`

Inherit port dimensions.

`n`

Vector signal of width `n`.

`[m n]`

Matrix signal having `m` rows and `n` columns.

Programmatic Use
Block parameter: `PortDimensions`
Type: character vector
Value: `'1'` | `'n'` | `'[m n]'`
Default: `'1'`

`Signal type` — Select real or complex signal

`real` (default) | `complex`

Select real or complex signal.

`real`

Specify the singnal type as a real number.

`complex`

Specify the signal type as a complex number.

Programmatic Use
Block parameter: `SignalType`
Type: character vector
Value: `'real'` | `'complex'`

Default: `'real'`

Argument Outport | Simulink Function

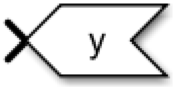
Topics

“Simulink Functions”
“Argument Specification for Simulink Function Blocks”

Introduced in R2014b

Argument Outport

Argument output port for Simulink Function block
Library: User-Defined Functions



Description

This block is an output argument port for a function that you define in the Simulink Function block.

Ports

Input

in — Block input
scalar | vector | matrix

Block input signal to this block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

y — Argument output
scalar | vector | matrix

The Argument Outport block accepts real or complex signals of any data type that Simulink supports. An Argument Outport block can also accept fixed-point and enumerated data types when the block is not a root-level output port. The Argument Outport block also accepts a bus object as a data type.

The complexity and data type of the block input are the same as the argument output. You can specify the signal type and data type of an output argument from an Argument

Outport block using the **Signal type** and **Data type** parameters. For more information, see "Data Types Supported by Simulink".

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Port number` — Specify port number of block

`1` (default) | integer

Specify the order in which the port that corresponds to the block appears in the parent subsystem or model block.

`1`

Specify the first port location for this block.

integer

Specify location of port.

Programmatic Use
Block parameter: `Port`
Type: character vector
Value: `'1'` | `'<integer>'`
Default: `'1'`

`Argument name` — Specify output argument name

`u` (default) | character vector

Specify output argument name for the function prototype displayed on the face of the Simulink Function block.

`u`

Default name of the output argument.

character vector

Name of the output argument.

Programmatic Use
Block parameter: `ArgumentName`
Type: character vector

Value: `'u'` | `'<character vector>'`
Default: `'u'`

`Minimum` — Specify minimum value for block input

`[ ]` (default) | number

Specify the minimum value for the block input signal.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking (see “Signal Ranges”) and automatic scaling of fixed-point data types.

`[ ]`

Minimum value not specified.

number

Finite real double scalar value.

Programmatic Use
Block parameter: `OutMin`
Type: character vector
Value: `'[ ]'` | `'<number>'`
Default: `'[ ]'`

`Maximum` — Specify maximum value for block input

`[ ]` (default) | number

Specify the maximum value for the block input signal.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses this value to perform Simulation range checking (see “Signal Ranges”) and automatic scaling of fixed-point data types.

`[]`

Max mum value not specified.

number

Finite real double scalar value.

Programmatic Use
Block parameter: `OutMax`
Type: character vector
Value: `'[]'` | `'<number>'`
Default: `'[]'`

Data type — Specify block input data type
`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^,0)` | `Enum: <class name>` | `Bus: <object name>` | `<data type expression>`

Specify block input data type. For more information. For more information, see

- Outport
- “Specify Data Types Using Data Type Assistant”

`double`

Data type is `double`.

`single`

Data type is `single`.

`int8`

Data type is `int8`.

`uint8`

Data type is `uint8`.

`int16`

Data type is `int16`.

`uint16`

Data type is `uint16`.

`int32`

Data type is `int32`.

`uint32`

Data type is `uint32`.

`boolean`

Data type is `boolean`.

`fixdt(1,16,0)`

Data type is fixed point `fixdt(1,16,0)`.

`fixdt(1,16,2^0,0)`

Data type is fixed point `fixdt(1,16,2^0,0)`.

`Enum: <class name>`

Data type is enumerated, for example, `Enum: Basic Colors`.

`Bus: <object name>`

Data type is a bus object.

`<data type expression>`

The name of a data type object, for example `Simulink.NumericType`

Do not specify a bus object as the expression.

Programmatic Use
Block parameter: `OutDataTypeStr`
Type: character vector
Value: `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'boolean'` | `'<fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'double'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data type
off (default) | on

Control changes to data type settings from the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

☑ On

Locks all data type settings for this block.

□ Off

Allows the Fixed-Point Tool and the Fixed-Point Advisor to change data type settings for this block.

Programmatic Use
Block parameter: `LockScale`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

`Port dimensions` — Specify port dimensions

`1` (default) | `n` | `[m n]`

Specify the dimensions of the output argument signal from the block. For more information, see Outport.

`1`

Inherit port dimensions.

`n`

Vector signal of width `n`.

`[m n]`

Matrix signal having `m` rows and `n` columns.

Programmatic Use
Block parameter: `PortDimensions`
Type: character vector
Value: `'1'` | `'n'` | `'[m n]'`
Default: `'1'`

`Signal type` — Select real or complex signal

`real` (default) | `complex`

Select real or complex signal. For more information, see Outport.

`real`

Specify the signal type as a real number.

`complex`

Specify the signal type as a complex number.

Programmatic Use
Block parameter: `SignalType`
Type: character vector
Value: `'real'` | `'complex'`
Default: `'real'`

ASCII to String

Uint8 vector signal to string signal
Library: Simulink / String

Description

The ASCII to String block converts uint8 vector signals to string signals. The block treats each element in the input vector as an ASCII value during the conversion. For example, the block converts an input vector of `[72 101 108 108 111]` to the string `"Hello"`.

Ports

Input

`Port_1` — ASCII signal
vector

ASCII signal, specified as a vector.

While using dynamic strings, if the length of the input vector exceeds the number of characters specified in the configuration parameter **Buffer size of dynamically-sized string (bytes)** (`256` by default), the ASCII to String block truncates the string output to the buffer size-1 (for example, `255`), for generated code. To avoid truncation, increase the value of the **Buffer size of dynamically-sized string (bytes)** configuration parameter.

Example: [088 099]

Data Types: `uint8`

Output

`Port_1` — Converted string signal
scalar

Converted string signal from input ASCII signal, specified as a scalar. The block converts each ASCII element in the vector into its alphanumeric equivalent and outputs all elements concatenated into one string.

Data Types: `string`

Block Characteristics

Data Types	`base integer` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

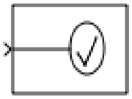
Assertion

Check whether signal is zero
Library: Simulink / Model Verification



Description

The Assertion block checks whether any of the elements of the input signal are zero. If all elements are nonzero, the block does nothing. If any element is zero, the block halts the simulation, by default, and displays an error message. Use the block parameter dialog box to:

- Specify that the block displays a warning message when the assertion fails but allows the simulation to continue.
- Specify a MATLAB expression to evaluate when the assertion fails.
- Enable or disable the assertion.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal to the assertion check.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

`Enable assertion` — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For information about how Simulink Coder™ generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Not recommended for production code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

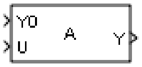
Assignment

Assign values to specified elements of signal

Library: Simulink / Math Operations



Description

The Assignment block assigns values to specified elements of the signal. You specify the indices of the elements to be assigned values either by entering the indices in the block dialog box or by connecting an external indices source or sources to the block. The signal at the block data port, `U`, specifies values to be assigned to `Y`. The block replaces the specified elements of `Y` with elements from the data signal.

Based on the value you enter for the **Number of output dimensions** parameter, a table of index options is displayed. Each row of the table corresponds to one of the output dimensions in **Number of output dimensions**. For each dimension, you can define the elements of the signal to work with. Specify a vector signal as a 1-D signal and a matrix signal as a 2-D signal. To enable an external index port, in the corresponding row of the table, set **Index Option** to `Index vector (port)`.

For example, assume a 5-D signal with a one-based index mode. The table in the Assignment block dialog changes to include one row for each dimension. If you define each dimension with the following entries:

Row	Index Option	Index
1	`Assign all`	
2	`Index vector (dialog)`	`[1 3 5]`
3	`Starting index (dialog)`	`4`
4	`Starting index (port)`	
5	`Index vector (port)`	

The assigned values are `Y(1:end,[1 3 5],4:3+size(U,3),Idx4:Idx4+size(U,4)-1,Idx5)=U`, where `Idx4` and `Idx5` are the input ports for dimensions 4 and 5.

When using the Assignment block in normal mode, Simulink initializes block outputs to zero even if the model does not explicitly initialize them. In accelerator mode, Simulink converts the model into an S-Function. This involves code generation. The code generated may not do implicit initialization of block outputs. In such cases, you must explicitly initialize the model outputs.

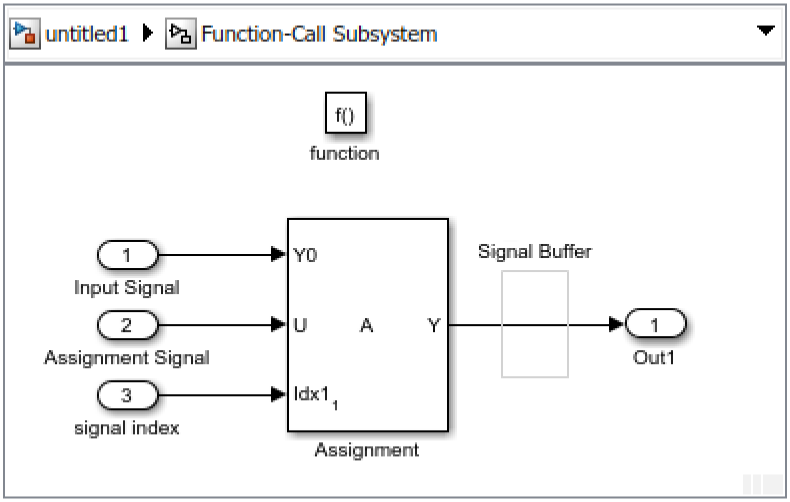
You can use the block to assign values to vector, matrix, or multidimensional signals.

You can use an array of buses as an input signal to an Assignment block.

Assignment Block in Conditional Subsystem

If you place an Assignment block in a conditional subsystem block, a signal buffer can be inserted in many cases, and merging of signals from Assignment blocks with partial writes can cause an error.

However, if you select the **Ensure outport is virtual** check box for the conditional subsystem Outport block, such cases are supported and partial writes to arrays using Assignment blocks are possible.



Ports

Input

`Y0` — Input initialization signal

scalar | vector

The initialization signal for the output signal. If an element is not assigned another value, then the value of the output element matches this input signal value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `Boolean` | `enumerated` | `bus`

`U` — Input data port

scalar | vector

Value assigned to the output element when specified.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `Boolean` | `enumerated` | `bus`

`IndxN` — `N`th index signal

scalar | vector

External port specifying an index for the assignment of the corresponding output element.

Dependencies

To enable an external index port, in the corresponding row of the **Index Option** table, set **Index Option** to `Index vector (port)` or `Starting index (port)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `enumerated`

Output

`Y` — Output signal with assigned values

scalar | vector

The output signal with assigned values for the specified elements.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point | enumerated | bus

Parameters

Number of output dimensions — Number of dimensions of the output signal

1 (default) | integer

Enter the number of dimensions of the output signal.

Command-Line Information
Parameter: NumberOfDimensions
Type: character vector
Values: integer
Default: '1'

Index mode — Index mode

One-based (default) | Zero-based

Select the indexing mode. If One-based is selected, an index of 1 specifies the first element of the input vector. If Zero-based is selected, an index of 0 specifies the first element of the input vector.

Command-Line Information
Parameter: IndexMode
Type: character vector
Values: 'Zero-based' | 'One-based'
Default: 'One-based'

Index Option — Index method for elements

Index vector (dialog) (default) | Assign all | Index vector (port) | Starting index (dialog) | Starting index (port)

Define, by dimension, how the elements of the signal are to be indexed. From the list, select:

Menu Item	Action
Assign all	This is the default. All elements are assigned.

Menu Item	Action
`Index vector (dialog)`	Enables the **Index** column. Enter the indices of elements.
`Index vector (port)`	Disables the **Index** column. The index port defines the indices of elements.
`Starting index (dialog)`	Enables the **Index** column. Enter the starting index of the range of elements to be assigned values.
`Starting index (port)`	Disables the **Index** column. The index port defines the starting index of the range of elements to be assigned values.

If you choose `Index vector (port)` or `Starting index (port)` for any dimension in the table, you can specify one of these values for the **Initialize output (Y)** parameter:

- `Initialize using input port <Y0>`
- `Specify size for each dimension in table`

Otherwise, `Y0` always initializes output port `Y`.

The **Index** and **Output Size** columns are displayed as relevant.

Command-Line Information
Parameter: `IndexOptionArray`
Type: character vector
Values: `'Assign all'` | `'Index vector (dialog)'` | `'Index option (port)'` | `'Starting index (dialog)'` | `'Starting index (port)'`
Default: `'Index vector (dialog)'`

Index — Index of elements

1 (default) | integer

If the **Index Option** is `Index vector (dialog)`, enter the index of each element you are interested in.

If the **Index Option** is `Starting index (dialog)`, enter the starting index of the range of elements to be selected. The number of elements from the starting point is determined by the size of this dimension at `U`.

Command-Line Information
Parameter: `IndexParamArray`
Type: character vector
Values: cell array
Default: `'{ }'`

`Output Size` — Width of the block output signal

1 (default) | integer

Enter the width of the block output signal.

Dependencies

To enable this column, select `Specify size for each dimension in table` for the **Initialize output (Y)** parameter.

Command-Line Information
Parameter: `OutputSizeArray`
Type: character vector
Values: cell array
Default: `'{ }'`

`Initialize output (Y)` — How to initialize the output signal

`Initialize using input port <Y0>` (default) | `Specify size for each dimension in the table`

Specify how to initialize the output signal.

- `Initialize using input port <Y0>` – Signal at the input port `Y0` initializes the output.
- `Specify size for each dimension in table` – Requires you to specify the width of the block's output signal in the **Output Size** parameter. If the output has unassigned elements, the value of those elements is undefined.

Dependency

Enabled when you set **Index Option** to `Index vector (port)` or `Starting index (port)`.

Command-Line Information
Parameter: `OuputInitialize`
Type: character vector

Values: `'Initialize using input port <Y0>'` | `'Specify size for each dimension in table'`
Default: `'Initialize using input port <Y0>'`

`Action if any output element is not assigned` — Specify whether to produce a warning or error if you have not assigned all output elements

`Error` (default) | `Warning` | `None`

Specify whether to produce a warning or error if you have not assigned all output elements. Options include:

- `Error` — Simulink software terminates the simulation and displays an error.
- `Warning` — Simulink software displays a warning and continues the simulation.
- `None` — Simulink software takes no action.

Command-Line Information
Parameter: `DiagnosticForDimensions`
Type: character vector
Values: `'Error'` | `'Warning'` | `'None'`
Default: `'None'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point | enumerated
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No

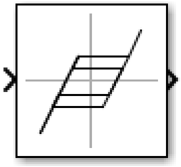
Backlash

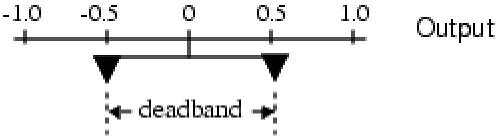
Model behavior of system with play

Library: Simulink / Discontinuities



Description

The Backlash block implements a system in which a change in input causes an equal change in output, except when the input changes direction. When the input changes direction, the initial change in input has no effect on the output. The amount of side-to-side play in the system is referred to as the *deadband*. The deadband is centered about the output. This figure shows an initial state, with the default deadband width of 1 and initial output of 0.



A system with play can be in one of three modes.

Mode	Input	Output
Disengaged	Inside deadband zone.	Remains constant.
Engaged-positive direction	Outside deadband zone and increasing.	Equals input *minus* half of deadband width.
Engaged-negative direction	Outside deadband zone and decreasing.	Equals input *plus* half of deadband width.

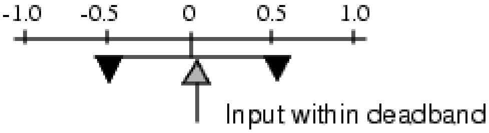
The **Initial output** parameter value defines the initial center of the deadband zone.

This table shows output values when initial conditions are: **Deadband width** = 2 and **Initial output** = 5.

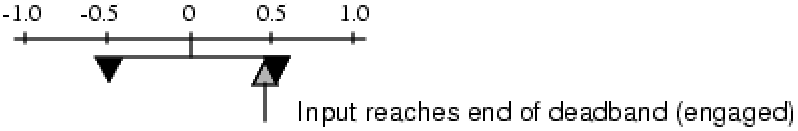
Output Value	Condition
5	4 < input < 6
input + 1	input < 4
input - 1	input > 6

For example, you can use the Backlash block to model the meshing of two gears. The input and output are both shafts with a gear on one end, and the input shaft drives the output shaft. Extra space between the gear teeth introduces *play*. The width of this spacing is the **Deadband width** parameter. If the system is disengaged initially, the **Initial output** parameter defines the output.

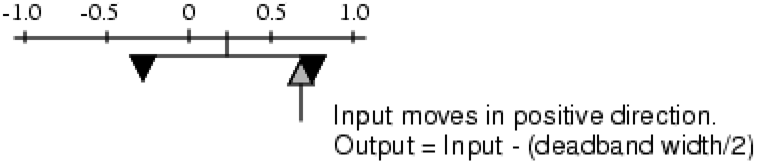
These figures illustrate operation when the initial input is within the deadband and the system begins in disengaged mode.



When the input increases and reaches the end of the deadband, it engages the output. The output remains at its previous value.



After the input engages the output, the output changes by the same amount as the input.



-1.0
-0.5
0
0.5
1.0
Input moves in positive direction.
Output = Input - (deadband width/2)

If the input reverses direction, it disengages from the output. The output remains constant until the input reaches the end of the deadband and engages again.

Ports

Input

Port_1 — Input signal
scalar | vector

Input signal to the backlash algorithm. The value of this signal is either in the deadband or engaging the output in a positive or negative direction.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32

Output

Port_1 — Output signal
scalar | vector

Output signal after the backlash algorithm is applied to the input signal. When the input is in the deadband, then the output remains unchanged. If the input is engaged with the output, then the output changes an equal amount as the input.

Data Types: double | single | int8 | int16 | int32 | uint8 | uint16 | uint32

Parameters

Deadband width — Specify the width of the deadband
1 (default) | scalar | vector

Specify the size of the deadband zone centered on the output value. When the input signal is inside the deadband, then a change in input does not cause a change in output. When the input signal is outside of the deadband, then the output changes an equal amount as the input.

Programmatic Use
Block Parameter: `BacklashWidth`
Type: character vector
Values: real scalar or vector
Default: `'1'`

`Initial output` — Specify the initial output value

0 (default) | scalar | vector

Specify the initial center of the deadband zone. If the initial input value is in the deadband zone, then the output value is equal to **Initial output**. If the initial input value is outside of the deadband zone, then the output value is **Initial output** plus or minus half of the deadzone width.

Programmatic Use
Block Parameter: `InitialOutput`
Type: character vector
Values: real scalar or vector
Default: `'0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox™ license.

  For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `base integer`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`

Zero-Crossing Detection	`Yes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` function (`string.h`) in certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information on HDL code generation, see Backlash.

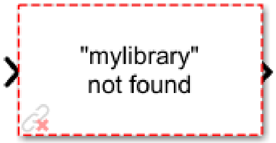
Unresolved Link

Indicate unresolved reference to library block



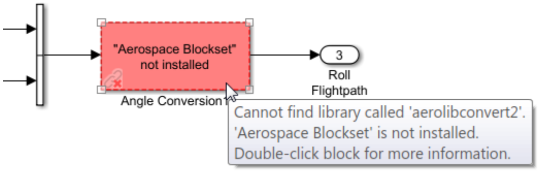
Description

This block indicates an unresolved reference to a library block (see “Linked Blocks”). You can use this block's parameter dialog box to fix the reference to point to the actual location of the library block.

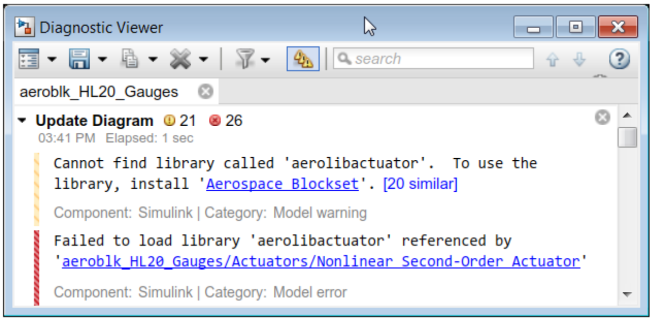
Parameters

Details

The **Details** field contains a description of the cause of the unresolved link. Simulink tries to help you find and install missing products that a model needs to run. For missing products, the block description provides a link. Click the link to open Add-On Explorer and install the missing products.



Cannot find library called 'aerolibconvert2'.
'Aerospace Blockset' is not installed.
Double-click block for more information.



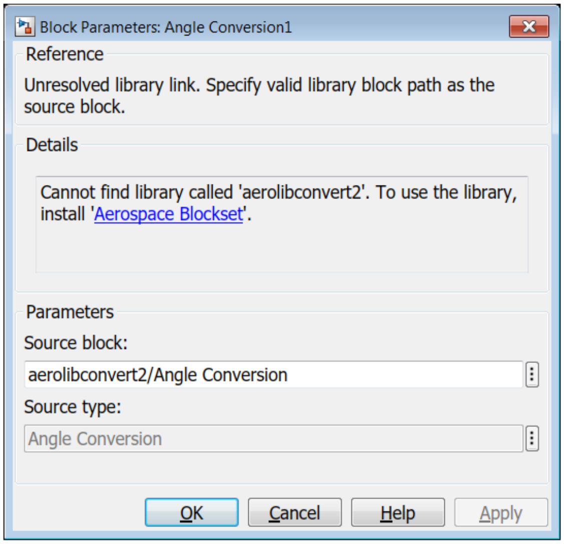
Update Diagram 21 26
03:41 PM Elapsed: 1 sec

```
Cannot find library called 'aerolibactuator'.  To use the
library, install 'Aerospace Blockset'. [20 similar]
```

Component: Simulink | Category: Model warning

```
Failed to load library 'aerolibactuator' referenced by
'aeroblk_HL20_Gauges/Actuators/Nonlinear Second-Order Actuator'
```

Component: Simulink | Category: Model error



Reference

Unresolved library link. Specify valid library block path as the source block.

Details

Cannot find library called 'aerolibconvert2'. To use the library, install 'Aerospace Blockset'.

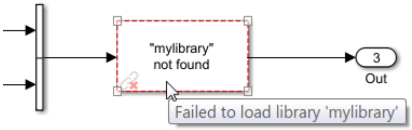
Parameters

Source block:

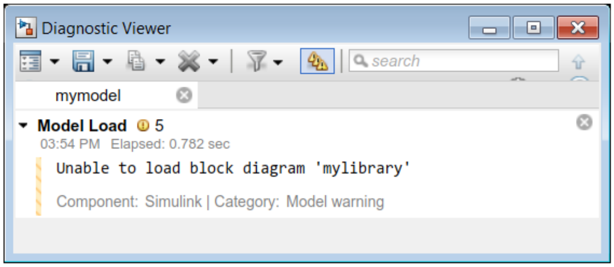
aerolibconvert2/Angle Conversion

Source type:

Angle Conversion



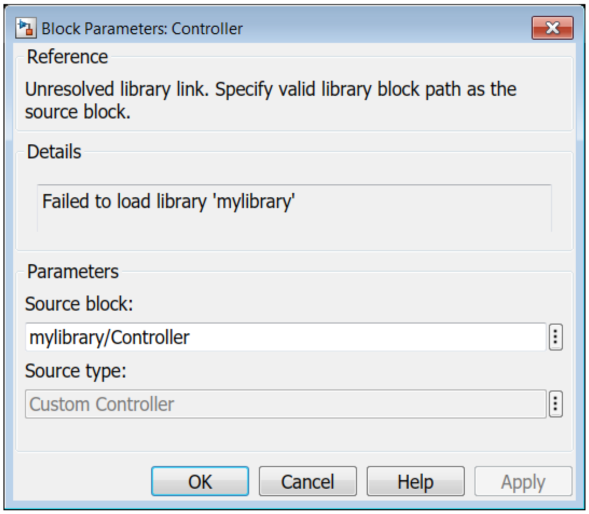
Failed to load library 'mylibrary'



Model Load 5
03:54 PM Elapsed: 0.782 sec

```
Unable to load block diagram 'mylibrary'
```

Component: Simulink | Category: Model warning



Reference

Unresolved library link. Specify valid library block path as the source block.

Details

Failed to load library 'mylibrary'

Parameters

Source block:

mylibrary/Controller

Source type:

Custom Controller

You can customize the Unresolved Link block description for your library to include URLs as follows:

```
set_param(library1,'libraryinfo','https://www.mathworks.com');
```

Here, `library1` is the name of the library for which you want to change the description, and `libraryinfo` is the property that provides the description of the unresolved link.

Source block

Path of the library block that this link represents. To fix a bad link, either click the link in the description to open Add-On Explorer and install a missing product, or edit the **Source block** field to the correct path of the library block. Then select Apply or OK to apply the fix and close the dialog box.

Alternatively, to fix an unresolved link, you can:

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and select either **Simulation > Update Diagram** or **Diagram > Refresh Blocks**.

Source type

Type of library block that this link represents.

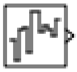
Introduced in R2014a

Band-Limited White Noise

Introduce white noise into continuous system
Library: Simulink / Sources



Description

The Band-Limited White Noise block generates normally distributed random numbers that are suitable for use in continuous or hybrid systems.

Simulation of White Noise

Theoretically, continuous white noise has a correlation time of 0, a flat power spectral density (PSD), and a total energy of infinity. In practice, physical systems are never disturbed by white noise, although white noise is a useful theoretical approximation when the noise disturbance has a correlation time that is very small relative to the natural bandwidth of the system.

In Simulink software, you can simulate the effect of white noise by using a random sequence with a correlation time much smaller than the shortest time constant of the system. The Band-Limited White Noise block produces such a sequence. The correlation time of the noise is the sample rate of the block. For accurate simulations, use a correlation time much smaller than the fastest dynamics of the system. You can get good results by specifying

$$tc \approx \frac{1}{100}\frac{2\pi}{f_{max}},$$

where f_{max} is the bandwidth of the system in rad/sec.

Comparison with the Random Number Block

The primary difference between this block and the Random Number block is that the Band-Limited White Noise block produces output at a specific sample rate. This rate is related to the correlation time of the noise.

Usage with the Averaging Power Spectral Density Block

The Band-Limited White Noise block specifies a two-sided spectrum, where the units are Hz. The Averaging Power Spectral Density block specifies a one-sided spectrum, where the units are the square of the magnitude per unit radial frequency: mag^2/(rad/sec). When you feed the output of a Band-Limited White Noise block into an Averaging Power Spectral Density block, the average PSD value is π times smaller than the **Noise power** of the Band-Limited White Noise block. This difference is the result of converting the units of one block to the units of the other, 1/(1/2)(2π) = 1/π, where:

- 1/2 is the factor for converting from a two-sided to one-sided spectrum.
- 2π is the factor for converting from Hz to rad/sec.

Ports

Output

`Port_1` — Normally distributed random numbers
scalar | vector | matrix | N-D array

Normally distributed random numbers specified as a scalar, vector, matrix, or N-D array.

Data Types: `double`

Parameters

`Noise power` — Height of PSD of white noise
`[0.1]` (default) | scalar | vector | matrix | N-D array

Specify the height of the PSD of the white noise as a scalar, vector, matrix, or N-D array of positive values.

Programmatic Use
Block Parameter: `Cov`
Type: character vector
Values: `scalar | vector | matrix | N-D array`
Default: `'[0.1]'`

`Sample time` — Correlation time of noise

`0.1` (default) | scalar | vector

Correlation time of the noise. For more information, see “Specify Sample Time”.

Programmatic Use
Block Parameter: `Ts`
Type: character vector
Values: `scalar | vector`
Default: `'0.1'`

Seed — Starting seed

`[23341]` (default) | scalar | vector | matrix | N-D array

Specify the starting seed for the random number generator as a scalar, vector, matrix, or N-D array. Values must be positive, real-valued, and finite.

Programmatic Use
Block Parameter: `seed`
Type: character vector
Values: `scalar | vector | matrix | N-D array`
Default: `'[23341]'`

`Interpret vector parameters as 1-D` — Treat vector parameters as 1-D

`on` (default) | `off`

Select to output a 1-D array when the block parameters are vectors. Otherwise, output a 2-D array one of whose dimensions is `1`. For more information, see “Determining the Output Dimensions of Source Blocks”.

Programmatic Use
Block Parameter: `VectorParams1D`
Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Algorithms

To produce the correct intensity of this noise, the covariance of the noise is scaled to reflect the implicit conversion from a continuous PSD to a discrete noise covariance. The appropriate scale factor is *1/tc*, where *tc* is the correlation time of the noise. This scaling ensures that the response of a continuous system to the approximate white noise has the same covariance as the system would have to true white noise. Because of this scaling, the covariance of the signal from the Band-Limited White Noise block is not the same as the **Noise power** (intensity) parameter. This parameter is actually the height of the PSD of the white noise. This block approximates the covariance of white noise as the **Noise power** divided by *tc*.

Bias

Add bias to input

Library: Simulink / Math Operations

Description

The Bias block adds a bias, or offset, to the input signal according to

$$Y = U + bias$$

where *U* is the block input and *Y* is the output.

Ports

Input

`Port_1` — Input signal
scalar | vector

Input signal to which the bias is added to create the output signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector

Output signal resulting from adding the bias to the input signal.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Parameters

Bias — Offset to add to the input signal

0.0 (default) | scalar | vector

Specify the value of the offset to add to the input signal.

Programmatic Use
Block Parameter: Bias
Type: character vector
Values: real, finite
Default: '0.0'

Saturate on integer overflow — Choose the behavior when integer overflow occurs

on (default) | boolean

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the int8 (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Value: `'off'` | `'on'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`

Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

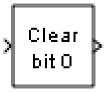
Bit Clear

Set specified bit of stored integer to zero
Library: Simulink / Logic and Bit Operations



Description

The Bit Clear block sets the specified bit, given by its index, of the stored integer to zero. Scaling is ignored.

You can specify the bit to be set to zero with the **Index of bit** parameter, where bit zero is the least significant bit.

Ports

The Bit Clear block supports Simulink integer, fixed-point, and Boolean data types. The block does not support true floating-point data types or enumerated data types.

Input

`Port_1` — Input signal
scalar or vector

The input signal is the specified bit of the stored integer.

Data Types: `single` | `double` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal
scalar or vector

The output consists of the specified bit set to zero.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Index of bit` — Index of bit

0 (default) | scalar or vector

Index of bit where bit 0 is the least significant bit.

Programmatic Use
Block Parameter: `iBit`
Type: scalar or vector
Values: {'0'}
Default: '0'

Block Characteristics

Data Types	`Boolean`[a] | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

[a] Bit operations are not recommended for use with Boolean signals.

Extended Capabilities

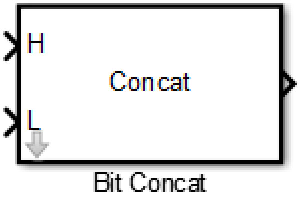
Bit Concat

Concatenates up to 128 input words into single output



Library

HDL Coder / HDL Operations

Description

The Bit Concat block concatenates up to 128 input words into a single output. The input port labeled `L` designates the lowest-order input word. The port labeled `H` designates the highest-order input word. The right-to-left ordering of words in the output follows the low-to-high ordering of input signals.

How the block operates depends on the number and dimensions of the inputs, as follows:

- Single input: The input is a scalar or a vector. When the input is a vector, the coder concatenates the individual vector elements.
- Two inputs: Inputs are any combination of scalar and vector. When one input is scalar and the other is a vector, the coder performs scalar expansion. Each vector element is concatenated with the scalar, and the output has the same dimension as the vector. When both inputs are vectors, they must have the same size.
- Three or more inputs (up to a maximum of 128 inputs): Inputs are uniformly scalar or vector. All vector inputs must have the same size.

Parameters

Number of Inputs: Enter an integer specifying the number of input signals. The number of block input ports updates when you change **Number of Inputs**.

- Default: 2
- Minimum: 1
- Maximum: 128

Caution Make sure that the **Number of Inputs** is equal to the number of signals you connect to the block. If the block has unconnected inputs, an error occurs at code generation time.

Ports

The block has up to 128 input ports, with H representing the highest-order input word, and L representing the lowest-order input word. The maximum concatenated output word size is 128 bits.

Supported Data Types

- Input: Fixed-point, integer (signed or unsigned), Boolean
- Output: Unsigned fixed-point or integer

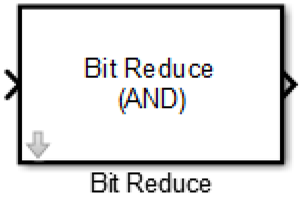
Bit Shift | Bit Reduce | Bit Rotate | Bit Slice

Introduced in R2014a

Bit Reduce

AND, OR, or XOR bit reduction on all input signal bits to single bit



Library

HDL Coder / HDL Operations

Description

The Bit Reduce block performs a selected bit-reduction operation (AND, OR, or XOR) on all the bits of the input signal, for a single-bit result.

Parameters

Reduction Mode

Specifies the reduction operation:

- AND (default): Perform a bitwise AND reduction of the input signal.
- OR: Perform a bitwise OR reduction of the input signal.
- XOR: Perform a bitwise XOR reduction of the input signal.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

Output

Supported data type: `ufix1`

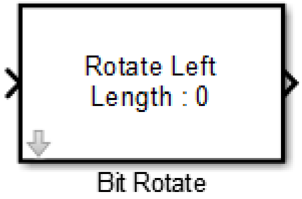
See Also

Bit Shift | Bit Concat | Bit Rotate | Bit Slice

Introduced in R2014a

Bit Rotate

Rotate input signal by bit positions



Library

HDL Coder / HDL Operations

Description

The Bit Rotate block rotates the input signal left or right by the specified number of bit positions.

Parameters

Rotate Mode: Specifies direction of rotation, left or right. The default is `Rotate Left`.

Rotate Length: Specifies the number of bits to rotate. Specify a value greater than or equal to zero. The default is 0.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

Output

Has the same data type as the input signal.

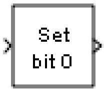
Bit Set

Set specified bit of stored integer to one

Library: Simulink / Logic and Bit Operations



Description

The Bit Set block sets the specified bit of the stored integer to one. Scaling is ignored.

You can specify the bit to be set to one with the **Index of bit** parameter, where bit zero is the least significant bit.

Ports

Input

`Port_1` — Input signal
scalar or vector

Input signal with the specified bit of the stored integer.

Data Types: `single` | `double` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal
scalar or vector

Output signal with the specified bit set to 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Index of bit` — Index of bit

0 (default) | scalar or vector

Index of bit where bit 0 is the least significant bit.

Programmatic Use
Block Parameter: `iBit`
Type: character vector
Values: positive integer
Default:`'0'`

Block Characteristics

Data Types	`Boolean`[a] | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

[a] Bit operations are not recommended for use with Boolean signals.

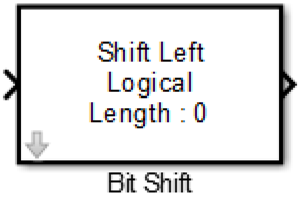
Bit Clear | Bit Rotate | Bit Shift | Bitwise Operator

Introduced before R2006a

Bit Shift

Logical or arithmetic shift of input signal



Library

HDL Coder / HDL Operations

Description

The Bit Shift block performs a logical or arithmetic shift on the input signal.

Parameters

Shift Mode

Default: `Shift Left Logical`

Specifies the type and direction of shift:

- `Shift Left Logical` (default)
- `Shift Right Logical`
- `Shift Right Arithmetic`

Shift Length

Specifies the number of bits to be shifted. Specify a value greater than or equal to zero. The default is 0.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Minimum bit width: 2
- Maximum bit width: 128

Output

Has the same data type and bit width as the input signal.

See Also

Bit Rotate | Bit Concat | Bit Reduce | Bit Slice

Introduced in R2014a

Bit Slice

Return field of consecutive bits from input signal

Slice
(7 downto 0)
Bit Slice

Library

HDL Coder / HDL Operations

Description

The Bit Slice block returns a field of consecutive bits from the input signal. Specify the lower and upper boundaries of the bit field by using zero-based indices in the **LSB Position** and **MSB Position** parameters.

Parameters

MSB Position

Specifies the bit position (zero-based) of the most significant bit (MSB) of the field to extract. The default is 7.

For an input word size `WS`, **LSB Position** and **MSB Position** must satisfy the following constraints:

```
WS > MSB Position >= LSB Position >= 0;
```

The word length of the output is computed as `(MSB Position - LSB Position) + 1`.

LSB Position

Specifies the bit position (zero-based) of the least significant bit (LSB) of the field to extract. The default is 0.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), Boolean
- Maximum bit width: 128

Output

Supported data types: unsigned fixed-point or unsigned integer.

See Also

Bit Rotate | Bit Concat | Bit Reduce | Bit Shift

Introduced in R2014a

Bitwise Operator

Specified bitwise operation on inputs
Library: Simulink / Logic and Bit Operations

Description

The Bitwise Operator block performs the bitwise operation that you specify on one or more operands. Unlike logic operations of the Logical Operator block, bitwise operations treat the operands as a vector of bits rather than a single value.

Restrictions on Block Operations

The Bitwise Operator block does not support shift operations. For shift operations, use the Shift Arithmetic block.

When configured as a multi-input XOR gate, this block performs modulo-2 addition according to the IEEE® Standard for Logic Elements.

Ports

Input

`Port_1` — Input signal

scalar | vector

Input signal, specified as a scalar or vector.

- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the bitwise logical complements of the input vector elements.

- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector.
- For two or more inputs, the block performs the operation between all of the inputs. If the inputs are vectors, the block performs the operation between corresponding elements of the vectors to produce a vector output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector

The output signal specified as the output data type, which the block inherits from the driving block, must represent zero exactly. Data types that satisfy this condition include signed and unsigned integer data types.

The size of the block output depends on the number of inputs, the vector size, and the operator you select. If you do not specify a bit mask, the output is a scalar. If you do specify a bit mask, the output is a vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Operator` — Bitwise logical operator

AND (default) | OR | NOR | NAND | XOR | NOT

Specify the bitwise logical operator for the block operands.

You can select one of these bitwise operations:

Bitwise Operation	Description
AND	TRUE if the corresponding bits are all TRUE
OR	TRUE if at least one of the corresponding bits is TRUE
NAND	TRUE if at least one of the corresponding bits is FALSE

Bitwise Operation	Description
NOR	TRUE if no corresponding bits are TRUE
XOR	TRUE if an odd number of corresponding bits are TRUE
NOT	TRUE if the input is FALSE (available only for single input)

Programmatic Use

Block Parameter: `logicop`
Type: character vector
Values: `'AND'|'OR' |'NAND'|'NOR' |'XOR' |'NOT'`
Default: `'AND'`

`Use bit mask` — Select to use bit mask

checked (default) | unchecked

Select to use the bit mask. Clearing this check box enables **Number of input ports** and disables **Bit Mask** and **Treat mask as**.

Programmatic Use

Block Parameter: `UseBitMask`
Type: character vector
Values: `'off'|'on'`
Default: `'on'`

`Number of input ports` — Number of input signals

1 (default) | integer

Specify the number of inputs. You can have more than one input ports.

Dependency

Clearing the **Use bit mask** check box enables **Number of input ports** and disables **Bit Mask** and **Treat mask as**.

Programmatic Use

Block Parameter: `NumInputPorts`
Type: character vector
Values: positive integer
Default: `'1'`

`Bit Mask` — Bit mask to associate with a single input

bin2dec (default)

Specify the bit mask to associate with a single input.

You can use the bit mask to set or clear a bit on the input.

To perform a...	Set the Operator parameter to...	And create a bit mask with...
Bit set	OR	A 1 for each corresponding input bit that you want to set to 1
Bit clear	AND	A 0 for each corresponding input bit that you want to set to 0

Suppose you want to set the fourth bit of an 8-bit input vector. The bit mask would be 00010000, which you can specify as `2^4` for the **Bit Mask** parameter. To clear the bit, the bit mask would be 11101111, which you can specify as `2^7+2^6+2^5+2^3+2^2+2^1+2^0` for the **Bit Mask** parameter.

Tip Do not use a mask greater than 53 bits. Otherwise, an error message appears during simulation.

Dependency

This parameter is available only when you select **Use bit mask**.

Programmatic Use
Block Parameter: `BitMask`
Type: character vector
Values: positive integer
Default: `'bin2dec('11011001')'`

`Treat mask as` — Treat the mask as a real-world value or a stored integer

`Stored Integer` (default) | `Real World Value`

Specify whether to treat the mask as a real-world value or a stored integer.

The encoding scheme is $V = SQ + B$, as described in “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer™ documentation. `Real World Value` treats the mask as V. `Stored Integer` treats the mask as Q.

Dependency

This parameter is available only when you select **Use bit mask**.

Programmatic Use
Block Parameter: `BitMaskRealWorld`
Type: character vector
Values: `'Real World Value'` | `'Stored Integer'`
Default: `'Stored Integer'`

Block Characteristics

Data Types	`Boolean`[a] | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

[a] Bit operations are not recommended for use with Boolean signals.

Block Support Table

View data type support for Simulink blocks
Library: Simulink / Model-Wide Utilities

Description

The Block Support Table block helps you access a table that lists the data types that Simulink blocks support. To view the table, double-click the block.

Block Characteristics

Data Types	
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Tips

There are two alternate ways to open the Block Support Table:

- To access the Simulink Block Support Table from the model menu, select **Help > Simulink > Block Data Types & Code Generation Support > Simulink**.

- To open the Block Support Table from the command line, you can enter `showblockdatatypetable` at the MATLAB command prompt.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Block Support Table block is ignored during code generation.

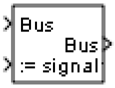
Bus Assignment

Replace specified bus elements
Library: Simulink / Signal Routing



Description

The Bus Assignment block assigns the values of a signal to bus elements. Use a Bus Assignment block to change bus element values without adding Bus Selector and Bus Creator blocks that select bus elements and reassemble them into a bus.

Connect the bus signal to the first input port. To other input ports, connect one or more signals whose values you want to assign to a bus element. Use the Block Parameters dialog box to specify the bus elements to be replaced. The block displays an assignment input port for each such element. For an example of a model that uses a Bus Assignment block, see “Assign Signal Values to a Bus”.

By default, Simulink repairs broken selections in the Bus Assignment Block Parameters dialog boxes that are due to upstream bus hierarchy changes. Simulink generates a warning to highlight that it modified the model. To prevent Simulink from making these repairs automatically, in the **Model Configuration Parameters** > **Diagnostics** > **Connectivity** pane, set the “Repair bus selections” diagnostic to `Error without repair`.

Limitations

When using arrays of buses with a Bus Assignment block, these limitations apply:

- You can assign or replace a subbus that is an array of buses. For a nested bus that is nested inside an array of buses, see “Assign into Array of Buses Signals”.
- To replace a signal in an array of buses, use a Selector block to select the index for the bus element that you want to use with the Bus Assignment block. Then, use that selected bus element with the Bus Assignment block.

Ports

Input

Bus — Accept bus signal for bus element value assignment

real or complex values of any data type supported by Simulink

Input bus signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see Simulink, “Data Types Supported by Simulink”.

The signal connected to the assignment port must have the same structure, data type, and sample time as the bus element to which it corresponds. You can use a Rate Transition block to change the sample time of an individual signal or signals in a bus, to include the signal or bus in a nonvirtual bus. See “Virtual and Nonvirtual Buses” for more information.

:= — Accept signals whose value are assigned to bus elements

real or complex values of any data type supported by Simulink

Assignment input ports can accept signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. You cannot use the Bus Assignment block to replace a bus that is nested within an array of buses. For details about data types, see Simulink, “Data Types Supported by Simulink”.

The Bus Assignment block assigns signals connected to its assignment input ports to specified elements of the bus connected to its bus input port. The block replaces the signals previously assigned to those elements. The change does not affect the composition of the bus; it affects only the values of the signals themselves. Signals not replaced are unaffected by the replacement of other signals.

Output

Bus — Output bus signal

virtual or nonvirtual bus

Bus that includes the assigned bus element values and the values of the bus elements of the input bus that you did not assign values to.

Parameters

`Signals in the bus` — Bus element signals of input bus

list of signal names

List of the bus element signals of the input bus signal. An arrow next to a signal name indicates that the input signal is a bus. To display the signals in an input bus, click the arrow.

Click any item in the list to select it. To find the source of the selected signal, click **Find**. Simulink opens and highlights the system containing the signal source. To move the currently selected signal into the adjacent list of signals to be assigned values (see **Signals that are being assigned** below), click **Select>>**. To refresh the display to reflect modifications to the bus connected to the block, click **Refresh**.

`Filter by name` — Filter set of displayed signals

text

Specify a search term to use for filtering a long list of input signals. Do not enclose the search term in quotation marks. The filter does a partial string search. To access filtering options, including using a regular expression for specifying the search term, click the ⌄ button on the right of the **Filter by name** edit box.

`Enable regular expression` — Filter set of displayed input signals

off (default) | on

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering `t$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the ⌄ button on the right of the **Filter by name** edit box.

`Show filtered results as a flat list` — Filter set of displayed input signals

off (default) | on

By default, the list displays as a tree list of filtered signals, based on the search text in the **Filter by name** edit box. To use a flat list format that uses dot notation to reflect the hierarchy of bus signals, select this parameter.

Dependencies

To access this parameter, click the ⏬ button on the right of the **Filter by name** edit box

`Signals that are being assigned` — Bus element signals to be assigned

list of signal names

Names of bus elements to be assigned values. This block displays an assignment input port for each bus element in this list. The label of the corresponding input port contains the name of the element. You can order the signals by using the **Up**, **Down**, or **Remove**. Port connectivity is maintained when you change the signal order.

If an input bus no longer contains a bus element, three question marks (`???`) appear before the name of that bus element The reason for this event is that the bus has changed since the last time you refreshed the Bus Assignment block input and bus element assignment lists. To address this issue, either modify the bus to include a signal of the specified name or remove the name from the list of bus elements designated to be assigned values.

Programmatic Use

Block Parameter: `OutputSignals`
Type: character vector
Values: `'signal1'|'signal2'`
Default: none

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block has a single, default HDL architecture. See Bus Assignment.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

Introduced before R2006a

Bus Creator

Create bus signal from input signals

Library: Simulink / Commonly Used Blocks
Simulink / Signal Routing

Description

The Bus Creator block combines a set of signals into a bus. To bundle a group of signals with a Bus Creator block, set the block parameter **Number of inputs** to the number of signals in the group. The block displays the number of inport ports that you specify. Connect to the resulting input ports the signals that you want to group.

You can connect any type of signal to the inputs, including other bus signals. To access individual signals in a bus signal, connect the output port of the block to a Bus Selector block port.

The signals in the bus are ordered from the top input port to the bottom input port. See "Port Location After Rotating or Flipping" for a description of the port order for various block orientations. To rearrange the signals in the output bus signal, use buttons such as **Up** or **Down** buttons.

Simulink hides the name of a Bus Creator block when you copy it from the Simulink library to a model.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.

- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

Ports

Input

`Port_1` — Accept signal to include in bus

real or complex values of any data type supported by Simulink

Input signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see Simulink, “Data Types Supported by Simulink”.

Output

`Port_1` — Output bus signal

virtual or nonvirtual bus

Bus that combines the input signals.

Parameters

`Number of inputs` — Number of input ports

2 (default) | integer

Number of inputs, not fewer than two. Increasing the number of connected ports adds empty ports below the connected ports. Before you simulate the model, make sure that an input signal is connected to each input port.

Tip As you draw a new signal line close to input side of a virtual Bus Creator block, if all input ports are already connected, the:

- Adds another input port to the Bus Creator block
- Updates the **Number of inputs** parameter

- Add to the list of bus signals a signal name for the new signal

---

Programmatic Use

Block Parameter: `Inputs`
Type: character vector
Values: integer greater than or equal to 2
Default: `'2'`

`Signals in the bus` — Input signals

list of signal names

List of input signals to combine into a bus signal. An arrow next to a signal name indicates that the input signal is a bus. To display the signals in an input bus, click the arrow. For information about working with the signals in the list, see “Bus Creation Using Bus Creator Blocks”.

`Filter by name` — Search term used to filter input signals

text

Search term used to filter a long list of input signals. Do not enclose the search term in quotation marks. The filter does a partial string search. To access filtering options, including using a regular expression to specify the search term, click the ⌄ button to the right of the **Filter by name** edit box.

`Enable regular expression` — Option to filter with regular expressions

off (default) | on

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering `t$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the ⌄ button to the right of the **Filter by name** edit box.

`Show filtered results as a flat list` — Option to display filtered results as a flat list

off (default) | on

Enable the flat list format that uses dot notation to reflect the hierarchy of bus signals based on the search text in the **Filter by name** edit box. By default, a tree list displays the filtered signals.

Dependencies

To access this parameter, click the ⏬ button to the right of the **Filter by name** edit box

`Output data type` — Data type of output signal

`'Inherit: auto'` (default) | `'Bus: <object name>'` | `<datatype expression>`

Data type of the output bus signal.

Determine whether you want the Bus Creator block to output a virtual or nonvirtual bus.

- For a virtual bus, use the **Output data type** parameter default (`Inherit: auto`) or set the parameter to specify a bus object using `Bus: <object name>`.
- For a nonvirtual bus, set the **Output data type** parameter to specify a bus object using `Bus: <object name>` and click **Output as nonvirtual bus**.

If you select `'Bus: <object name>'`, specify a bus object in the edit box. The bus object must be in the base workspace when you perform an update diagram or simulate the model. To define a bus object using the Bus Editor, click **Show data type assistant** and then click **Edit**. For details, see “Create Bus Objects with the Bus Editor”.

If you select `'<data type expression>'`, specify an expression that evaluates to a data type. Do not specify a bus object as the expression.

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: auto'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'boolean'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'Enum: <class name>'` | `'Bus: <object name>'`
Default: `'Inherit: auto'`

`Require input signal names to match signals above` — Option to require input signal names to match names listed in dialog box

off (default) | on

Optional check that input signal names match signal names in the Bus Creator Block Parameters dialog box.

Tip The **Require input signal names to match signals above** parameter might be removed in a future release. To enforce strong data typing, consider using the **Override bus signal names from inputs** parameter.

If you select **Override bus signal names from inputs**, Simulink software ignores the **Require input signal names to match signals above** setting.

If you change the **Number of inputs** programmatically, this parameter reverts to `'off'`.

`Rename selected signal` — Name for currently selected signal

`''` (default) | character vector

Name for the currently selected input signal. See “Signal Names and Labels” for signal name guidelines.

Dependencies

To display this parameter, enable the **Require input signal names to match signals above** parameter.

`Override bus signal names from inputs` — Bus input signal name override

on (default) | off

By default, the Bus Creator block overrides bus signal names from inputs.

To inherit bus signal names from a bus object, clear this parameter. Clearing the parameter:

- Enforces strong data typing.
- Avoids having to enter a signal name multiple times: in the bus object and in the model. Entering the name multiple times can accidentally create signal name mismatches.
- Supports the array of buses requirement to have consistent signal names across array elements.

Alternatively, you can enforce strong data typing by checking that input signal names match the bus object element names.

- Keep the **Override bus signal names from inputs** check box selected.
- Set the **Element name mismatch** parameter to `error`.

Dependencies

To display this parameter, set the **Output data type** parameter to a bus object.

Programmatic Use
Block Parameter: `InheritFromInputs`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output as nonvirtual bus` — Nonvirtual bus output

off (default) | on

Nonvirtual bus output from the Bus Creator block. All signals in a nonvirtual bus must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation resulting in a nonvirtual bus that violates this requirement generates an error. To change the sample time of a signal or bus that has a different sample time than the other nonvirtual bus input signals, use a Rate Transition block. For details, see "Specify Bus Signal Sample Times".

To generate code that uses a C structure to define the structure of the bus signal output by this block, enable this parameter.

Dependencies

To display this parameter, set the **Output data type** parameter to a bus object.

Programmatic Use
Block Parameter: `NonVirtualBus`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`

Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block has a single, default HDL architecture. See Bus Creator.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

Bus Selector

Select signals from incoming bus

Library: Simulink / Commonly Used Blocks
Simulink / Signal Routing

Description

The Bus Selector block outputs a specified subset of the elements of the bus at its input. The block can output the specified elements as separate signals or as a new bus.

By default, Simulink implicitly converts a nonbus signal to a bus signal to support connecting the signal to a Bus Selector block. To prevent Simulink from performing that conversion, set the “Non-bus signals treated as bus signals” diagnostic to `warning` or `error`.

When the block outputs multiple elements, it outputs each element from a separate port from top to bottom of the block. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

In the Simulink Editor, as you draw a new signal line close to output side of a Bus Selector block and all output ports are already connected, Simulink Editor:

- Adds a port
- Prompts you to specify the signal to be selected

You cannot use this automatic port addition approach in either of these cases if:

- There is no bus input signal connected to the Bus Selector block.
- You do not specify a signal in response to the prompt that appears when you draw a signal line close to the Bus Selector block icon.
- You select the **Output as virtual bus** parameter.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. You can use these bus element port blocks instead of Inport with Bus Selector blocks for inputs, and Outport with Bus Creator blocks for outputs. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

Ports

Input

`Port_1` — Input bus signal

real or complex values of any data type supported by Simulink except for arrays of buses

Input bus signals can have real or complex values of any data type supported by Simulink except for arrays of buses. To work with an array of buses signal, use a Selector block to select the index for the bus element that you want to use with the Bus Selector block. Then use that selected bus element with the Bus Selector block.

Output

`Port_1` — Selected bus elements of input bus signal

standalone signal (default) | virtual bus | nonvirtual bus | array of buses

Selected bus element signals of an input bus signal. For each output signal, this block uses a separate port from top to bottom of the block. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

If you select the **Output as virtual bus** parameter, the output bus is virtual. To produce nonvirtual bus output, insert a Signal Conversion block after the Bus Selector block. Set the Signal Conversion block **Output** parameter to `Nonvirtual bus` and use a `Simulink.Bus` bus object for the **Data type** parameter. For an example, see the Signal Conversion documentation.

Parameters

`Signals in the bus` — Element signals in input bus

list of signal names

List of bus element signals of the input bus, from which to select signals to output. To select a signal to output, click the signal in the list and then click **Select>>**.

To refresh the display to reflect modifications to the bus connected to the block, click **Refresh**.

To find the source of a signal entering the block, select the signal in the list and click **Find**. The Simulink software highlights the signal source in the block diagram.

Programmatic Use

Block Parameter: `InputSignals`
Type: matrix
Values: signal name
Default: `{'[]'}`

`Filter by name` — Filter set of displayed input signals

text

Specify a search term to use for filtering a long list of input signals. Do not enclose the search term in quotation marks. The filter does a partial string search. To access filtering options, including using a regular expressionto specify the search term, click the ⌄ button on the right side of the **Filter by name** edit box.

`Enable regular expression` — Filter set of displayed input signals

off (default) | on

Enable the use of MATLAB regular expressions for filtering signal names. For example, entering `t$` in the **Filter by name** edit box displays all signals whose names end with a lowercase `t` (and their immediate parents). For details, see “Regular Expressions” (MATLAB).

Dependencies

To access this parameter, click the ⌄ button on the right side of the **Filter by name** edit box.

`Show filtered results as a flat list` — Filter set of displayed input signals

off (default) | on

By default, a tree displays the filtered signals, based on the search text in the **Filter by name** edit box. Select this parameter to use a flat list format that uses dot notation to reflect the hierarchy of bus signals.

Dependencies

To access this parameter, click the ⌄ button on the right side of the **Filter by name** edit box

`Selected signals` — Selected bus elements signals

list of signal names

If an output signal listed in the **Selected signals** list box is not an input to the Bus Selector block, the signal name starts with three question marks (`???`).

You can change the list by using the **Up**, **Down**, and **Remove** buttons. To save your changes, click **Apply**. You can select multiple contiguous signals to move or remove. You cannot rearrange leaf signals within a bus. For example, you can move bus signal `Bus1` up or down in the list, but you cannot reorder any of the bus elements of `Bus1`. Port connectivity is maintained when you change the signal order.

Programmatic Use

Block Parameter: `OutputSignals`
Type: character vector
Values: character vector in the form of `'signal1,signal2'`
Default: none

`Output as virtual bus` — Output selected elements as bus

on (default) | off

By default, the block outputs the selected elements as standalone signals, each from an output port that is labeled with the corresponding bus element name. To output the selected bus element signals as a bus, select this parameter.

The output bus is virtual. To produce nonvirtual bus output, insert a Signal Conversion block after the Bus Selector block. Set the Signal Conversion block **Output** parameter to `Nonvirtual bus` and use a `Simulink.Bus` bus object for the **Data type** parameter. For an example, see the Signal Conversion documentation.

When the **Selected signals** list includes only one signal and you enable **Output as virtual bus**, then if the selected signal is:

- A nonbus signal, it is treated as a nonbus signal (it is not wrapped in a bus).
- A bus signal, then the output is that bus signal.

Programmatic Use
Block Parameter: `OutputAsBus`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block has a single, default HDL architecture. See Bus Selector.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

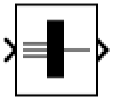
Bus to Vector

Convert virtual bus to vector
Library: Simulink / Signal Attributes



Description

The Bus to Vector block converts a virtual bus signal to a vector signal. The input bus signals must consist of scalars or 1-D, row, or column vectors that have the same data type, signal type, and sampling mode. If the input bus contains row or column vectors, the output is a row or column vector, respectively. Otherwise, the output is a 1-D array.

Use the Bus to Vector block only to replace an implicit bus-to-vector conversion with an explicit conversion. To identify and correct buses used as vectors without manually inserting Bus to Vector blocks, you can use the Simulink Model Advisor **“Check bus signals treated as vectors” on page 9-29** check. Alternatively, you can use the `Simulink.BlockDiagram.addBusToVector` function, which automatically inserts Bus to Vector blocks wherever needed.

Note If you use **Save As** to save a model in a version of the Simulink product before R2007a, Simulink replaces each Bus to Vector block with a null subsystem that outputs nothing. Before you can use the model, reconnect or otherwise correct each path that used to contain a Bus to Vector block but now is interrupted by a null subsystem.

Ports

Input

`Port_1` — Accept signal to convert to vector
virtual bus | nonbus signal

The input bus signals must consist of scalars or 1-D, row, or column vectors that have the same data type, signal type, and sampling mode. If the input is a nonbus signal, the block does no conversion.

Output

`Port_1` — Output vector signal
vector | 1-D array

Output a vector signal, based on input bus signal. If the input bus contains row or column vectors, the block output is a row or column vector, respectively. Otherwise, the output is a 1-D array.

Parameters

This block has no user-accessible parameters.

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block has a single, default HDL architecture. See Bus to Vector.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

Callback Button

Execute MATLAB code based on user input
Library: Simulink / Dashboard

Description

The Callback Button block executes MATLAB code based on user input. The Callback Button block reacts to clicks and presses from the user. You can specify separate code to execute for each action. The Callback Button block repeats the code specified for the press action at a specified rate as long as you continue to press the button.

The Callback Button block registers a click when you release the left mouse button with the cursor on the Callback Button. The code for a press executes when you click the Callback Button and hold for the specified **Press Delay**.

Double-clicking the Callback Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Parameters

`Button Text` — Text on button

'Callback Button' (default) | character array

Text that appears on the button.

`Mouse Action` — Mouse action to run code

'ClickFcn' (default) | 'PressFcn'

Mouse action that causes the MATLAB code to execute.

- Select `ClickFcn` to view and edit the code that executes when the Callback Button block is clicked.

- Select `PressFcn` to view and edit the code that executes when the button is pressed.

`MATLAB Code` — Code to execute based on user input

empty (default) | MATLAB Code

MATLAB code that executes based on user input.

Dependency

The MATLAB code displayed depends on the Mouse Action parameter selection.

- Select `ClickFcn` to view and edit the code that executes when the Callback Button block is clicked.
- Select `PressFcn` to view and edit the code that executes when the button is pressed.

`Press Delay (ms)` — Time to hold button for press

500 (default) | scalar

Amount of time required to cause the `PressFcn` code to execute.

Dependency

Press Delay (ms) is only visible when `PressFcn` is selected as the Mouse Action.

`Repeat Interval (ms)` — Time interval to repeat PressFcn code

0 (default) | scalar

Time interval after which the `PressFcn` code executes again if the Callback Button block is still pressed.

Dependency

Repeat Interval (ms) is only visible when `PressFcn` is selected as the Mouse Action.

C Caller

Integrate C code in Simulink
Library: Simulink / User-Defined Functions

Description

The C Caller block integrates your external C code into Simulink. This block imports and lists the functions in your external C code, and allows you to select your resolved C functions to integrate in your Simulink models. The C Caller block standalone supports code generation. For more complex models, code generation depends on the capabilities of your Simulink model.

To use C Caller block, define your source code and any supporting files using **Simulation Target** under **Configuration Parameters**. Then, bring a C Caller block to Simulink canvas, using **Library Browser > Simulink > User Defined Functions**. To change the defined source code file and its dependencies, go to **Simulation Target** tab in **Configuration Parameters** by clicking the ⚙ from the block dialog. After changing your source code or any of its dependencies, refresh the list of functions by clicking the ↻ on the block dialog. To browse and modify the list of functions in your source code, use the » icon to easily access to your header files.

Ports

Input

`Input argument` — Input argument for the corresponding C caller block
scalar | vector | matrix

Input argument to the C Caller block.

Number of input arguments and their names are inferred through the selected function in your externaI C code. To receive data to your block, connect an input signal to the input ports.

Input label has the same name as your input argument unless changed by editing the **Label** column under **Port Specification** from the **Block Dialog**. If you rename the label to an input port, the C Caller block changes the name of the port.

For input variables, you can change the input scope to parameters or constants using the **Scope** column.

Data types supported in MATLAB, but not supported in Simulink cannot be passed between C Caller and other MATLAB blocks.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Output argument` — Output argument for the corresponding C Caller block

scalar | vector | matrix

Output argument from the C Caller block.

Number of output arguments and their names are inferred through the selected function in your externaI C code. To send data from your C Caller block, connect a block to the output port of your C Caller block.

Output port label has the same name as your output argument unless you change it by editing the **Label** column under **Port Specification** from the **Block Dialog**. If you rename the label to an input port, the C Caller block changes the name of the port.

Data types supported in MATLAB, but not supported in Simulink cannot be passed between C Caller and other MATLAB blocks.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `enumerated` | `bus`

Parameters

`Function name` — Name of the functions in source code

character vector

The C Caller block in your model imports all functions in your external source code, and shows the names of functions under `Function name` in block dialog. To select and use a function in your block, confirm that their names appear at the `Function name`. In case you are missing one of the functions, reload the source code by clicking ↻ on the block dialog box. To change the name of your functions, modify your source code and click the refresh button to reload your functions.

`Port specification` — Specify port properties

string

`Port specification` table indicates the attributes of each input and output element for the selected block. These properties include Argument name, scope, input/output label, type and size of the input/output variables. Argument name, scope, type, and size are inferred from your source code. If the type of scope is an input, you can modify this variable to a parameter or a constant.

Arg name — Demonstrates the variable name inferred from your source code.

Scope — Indicates the role of the variables from your source code. If the variable is an input argument in the C Caller block source code, you can change the scope type to a constant or a parameter. If the variable is an output argument in the source code, you cannot change the scope type.

Label — Labels the input or output variable for the Simulink model. You can change the labels using this table. If the scope is a parameter, enter the parameter name in this field. If the scope is a constant, enter the constant value.

Type — Indicates the data type coming from the ports.

Size — Indicates the size of the input and output data.

Block Characteristics

Data Types	`double`[a] | `single`[a] | `Boolean`[a] | `base integer`[a] | `fixed point`[a] | `enumerated`[a] | `bus`[a]
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`[a]
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

[a] Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

"Integrate C Code Using C Caller Blocks"

Introduced in R2018b

Check Box

Select parameter or variable value
Library: Simulink / Dashboard

Description

The Check Box block allows you to set the value of a parameter or variable during simulation by checking or clearing the box. Use the Check Box block with other Dashboard blocks to create an interactive dashboard for your model.

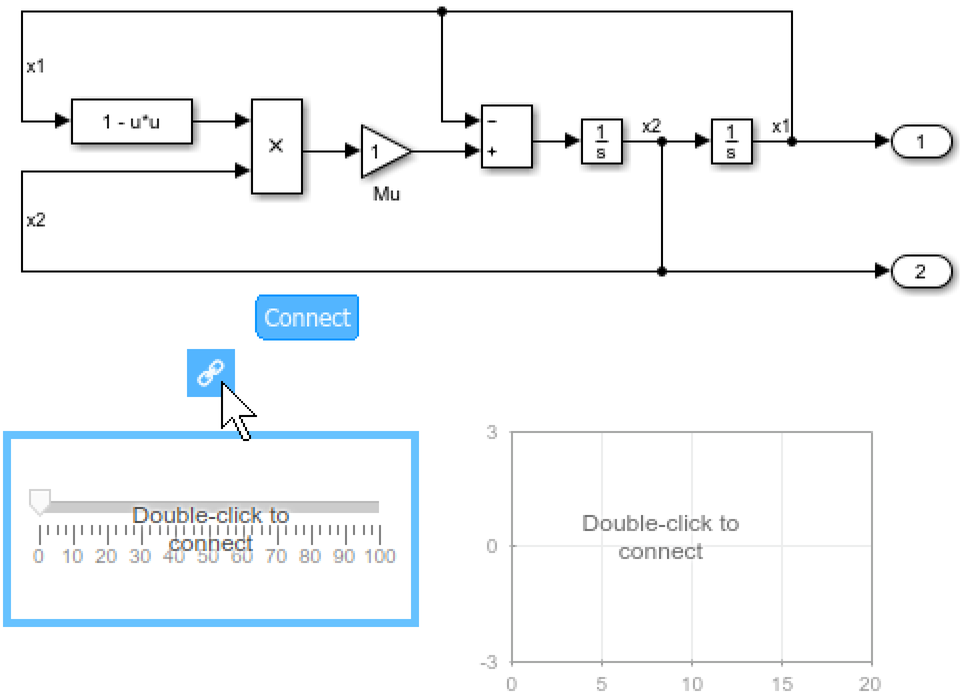
Double-clicking the Check Box block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connecting Dashboard Blocks

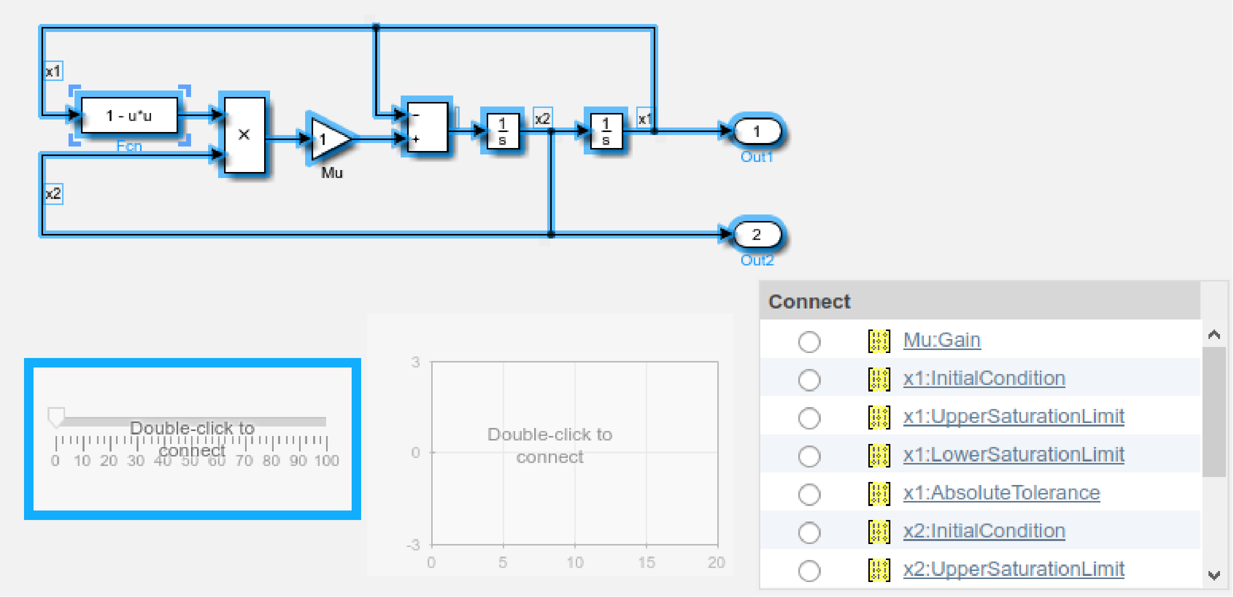
Dashboard blocks do not use ports to make connections. To connect Dashboard blocks to variables and block parameters in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

Note Dashboard blocks cannot connect to variables until you update your model diagram. To connect Dashboard blocks to variables or modify variable values between opening your model and running a simulation, update your model diagram using **Ctrl+D**.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

- ○ Mu:Gain
- ○ x1:InitialCondition
- ○ x1:UpperSaturationLimit
- ○ x1:LowerSaturationLimit
- ○ x1:AbsoluteTolerance
- ○ x2:InitialCondition
- ○ x2:UpperSaturationLimit

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Parameter Logging

Tunable parameters connected to Dashboard blocks are logged to the Simulation Data Inspector, where you can view parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector UI or by using the `Simulink.sdi.exportRun` function. For more information about exporting data with the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using

connect mode, the Dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. Populate the **Connection** table by selecting one or more blocks in your model. Select the radio button next to the variable or parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

States

`Value (Unchecked)` — Value when unchecked

0 (default) | scalar

Value assigned to the connected parameter when the Check Box block is not checked.

`Value (Checked)` — Value when checked

0 (default) | scalar

Value assigned to the connected parameter when the Check Box block is checked.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

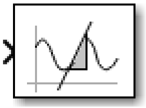
Introduced in R2017b

Check Discrete Gradient

Check that absolute value of difference between successive samples of discrete signal is less than upper bound

Library: Simulink / Model Verification



Description

The Check Discrete Gradient block checks each signal element at its input to determine whether the absolute value of the difference between successive samples of the element is less than an upper bound. Specify the value of the upper bound (1 by default) by setting the **Maximum gradient** parameter. If the verification condition is true, the block does nothing. Otherwise, the block halts the simulation, by default, and displays an error in the Diagnostic Viewer.

Enable or disable all model verification blocks by changing the **Model Verification block enabling** setting in the Configuration Parameters.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

Input signal the block checks to determine if the difference of each element between sucessive samples is less than the upper bound. Specify the upper bound by setting the **Maximum gradient** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

`Maximum gradient` — Upper bound of allowed differences

`1` (default) | scalar

Specify the upper bound on the allowed gradient of the input signal.

Command-Line Information
Parameter: `gradient`
Type: character vector
Values: real scalar
Default: `'1'`

`Enable assertion` — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the

Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

`Select icon type` — Select icon type

`graphic` | `text`

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: `icon`
Type: character vector
Values: `'graphic'` | `'text'`
Default: `'graphic'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

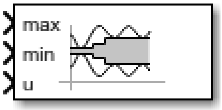
Check Dynamic Gap | Check Dynamic Range

Introduced before R2006a

Check Dynamic Gap

Check that gap of possibly varying width occurs in range of signal's amplitudes
Library: Simulink / Model Verification



Description

The Check Dynamic Gap block checks that a gap of possibly varying width occurs in the range of a signal's amplitudes. The test signal is connected to **u**. The inputs **min** and **max** specify the lower and upper bounds of the dynamic gap. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`max` — Upper bound of dynamic gap
scalar | vector | matrix

Signal specifying the upper bound of the gap. All three input signals must be the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

`min` — Lower bound of dynamic gap

scalar | vector | matrix

Signal specifying the lower bound of the gap. All three input signals must be the same data type and dimension.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

`u` — Input signal

scalar | vector | matrix

Input signal checked for a gap of width specified by **max** and **min**. All three input signals must be the same data type and dimension.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

`Enable assertion` — Enable or disable the check

on (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the

Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

`Select icon type` — Select icon type

`graphic` | `text`

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: `icon`
Type: character vector
Values: `'graphic'` | `'text'`
Default: `'graphic'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

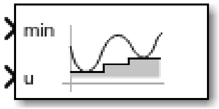
Check Dynamic Lower Bound | Check Dynamic Range | Check Dynamic Upper Bound

Introduced before R2006a

Check Dynamic Lower Bound

Check that one signal is always less than another signal
Library: Simulink / Model Verification



Description

The Check Dynamic Lower Bound block checks that the amplitude of a reference signal, **min**, is less than the amplitude of a test signal, **u**, at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`min` — Lower bound of check
scalar | vector | matrix

Signal specifying the lower bound of the check against the input signal **u** amplitude. Signal data type and dimension must be the same as **u**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

u — Input signal
scalar | vector | matrix

Input signal checked against the lower bound specified by **min**. Both input signals must be the same data type and dimension.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a Boolean. Otherwise the data type of the signal is a double.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: double | Boolean

Parameters

Enable assertion — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: enabled
Type: character vector
Values: 'on' | 'off'
Default: 'on'

Simulation callback when assertion fails (optional) — Expression to evaluate when assertion fails

' ' (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

`Select icon type` — Select icon type

`graphic` | `text`

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the

icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: `icon`
Type: character vector
Values: `'graphic'` | `'text'`
Default: `'graphic'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

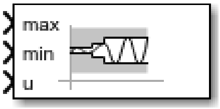
Check Dynamic Range

Check that signal falls inside range of amplitudes that varies from time step to time step

Library: Simulink / Model Verification



Description

The Check Dynamic Range block checks that a test signal falls inside a range of amplitudes at each time step. The width of the range can vary from time step to time step. The input labeled **u** is the test signal. The inputs labeled **min** and **max** are the lower and upper bounds of the valid range at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`max` — Upper bound of dynamic range check
scalar | vector | matrix

Signal specifying the upper bound of the range that the block checks the input signal **u** amplitude. All three input signals must be the same data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

`min` — Lower bound of dynamic range check

scalar | vector | matrix

Signal specifying the lower bound of the range that the block checks the input signal **u** amplitude. All three input signals must be the same data type and dimension.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

u — Input signal

scalar | vector | matrix

Input signal checked against the range specified by **max** and **min**. All three input signals must be the same data type and dimension.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

`Enable assertion` — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the

Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

`Select icon type` — Select icon type

`graphic` | `text`

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: `icon`
Type: character vector
Values: `'graphic'` | `'text'`
Default: `'graphic'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

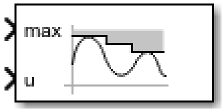
Check Dynamic Upper Bound

Check that one signal is always greater than another signal

Library: Simulink / Model Verification



Description

The Check Dynamic Upper Bound block checks that the amplitude of a reference signal, **max**, is greater than the amplitude of a test signal, **u**, at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Note For information about how Simulink Coder generated code handles Model Verification blocks, see “Debug” (Simulink Coder).

Ports

Input

max — Upper bound of range check

scalar | vector | matrix

Signal specifying the lower bound of the range that the block checks the input signal **u** amplitude. Signal data type and dimension must be the same as **u**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

u — Input signal
scalar | vector | matrix

Input signal checked against the lower bound specified by **min**. Both input signals must be the same data type and dimension.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Assertion output signal
scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

`Enable assertion` — Enable or disable the check
`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector

Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`

Default: 'off'

Select icon type — Select icon type
graphic | text

Specify the type of icon used to display this block in a block diagram. The graphic option displays a graphical representation of the assertion condition on the icon. The text option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: icon
Type: character vector
Values: 'graphic' | 'text'
Default: 'graphic'

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point | enumerated
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

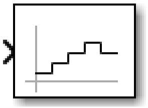
Check Input Resolution

Check that input signal has specified resolution
Library: Simulink / Model Verification



Description

The Check Input Resolution block checks whether the input signal has a specified scalar or vector resolution. If the resolution is a scalar, the input signal must be a multiple of the resolution within a `10e-3` tolerance. If the resolution is a vector, the input signal must equal an element of the resolution vector. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal that the block checks the resolution specified by the **Resolution** parameter.

Data Types: `double`

Output

Port_1 — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

Resolution — Resolution

scalar

Specify the resolution requirement for the input signal.

Command-Line Information

Parameter: `resolution`
Type: character vector
Values: `'1'` | `real value`
Default: `'1'`

Enable assertion — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information

Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`

Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

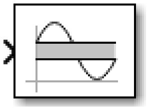
Check Static Gap

Check that gap exists in signal's range of amplitudes
Library: Simulink / Model Verification



Description

The Check Static Gap block checks that each element of the input signal is less than (or optionally equal to) a static lower bound or greater than (or optionally equal to) a static upper bound at the current time step. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`Port_1` — Input
scalar | vector | matrix

Input signal the block checks if the signal value is less than a static lower bound or greater than a static upper bound.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, set the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

`Upper bound` — Upper boundary value

scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Command-Line Information
Parameter: `max`
Type: character vector
Values: `scalar` | `vector` | `matrix`
Default: `'0'`

`Inclusive upper bound` — Include the upper bound in range

`on` (default) | `off`

Select this check box to make the range of valid input amplitudes include the upper bound.

Command-Line Information
Parameter: `max_included`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Lower bound` — Lower boundary value

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Command-Line Information
Parameter: `min`
Type: character vector
Values: `scalar` | `vector` | `matrix`
Default: `'0'`

`Inclusive lower bound` — Include the lower bound in range

`on` (default) | `off`

Select this check box to make the range of valid input amplitudes include the lower bound.

Command-Line Information
Parameter: `min_included`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Enable assertion` — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

`Select icon type` — Select icon type

`graphic` | `text`

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the

icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: `icon`
Type: character vector
Values: `'graphic'` | `'text'`
Default: `'graphic'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

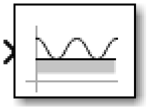
Check Dynamic Range | Check Static Lower Bound | Check Static Upper Bound

Introduced before R2006a

Check Static Lower Bound

Check that signal is greater than (or optionally equal to) static lower bound

Library: Simulink / Model Verification



Description

The Check Static Lower Bound block checks that each element of the input signal is greater than (or optionally equal to) a specified lower bound at the current time step. Specify the value of the lower bound with the **Lower bound** parameter. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal checked against the lower bound specified by the **Lower bound** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

`Lower bound` — Lower boundary value

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Command-Line Information
Parameter: `min`
Type: character vector
Values: `scalar` | `vector` | `matrix`
Default: `'0'`

`Inclusive boundary` — Include the lower bound in range

`on` (default) | `off`

Select this check box to make the range of valid input amplitudes include the lower bound.

Command-Line Information
Parameter: `min_included`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Enable assertion` — Enable or disable the check

on (default) | off

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

on (default) | off

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

off (default) | on

Selecting this check box causes the block to output a Boolean signal that is true (1) at each time step if the assertion succeeds and false (0) if the assertion fails. The data type of the output signal is Boolean if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is double.

Command-Line Information
Parameter: export
Type: character vector
Values: 'on' | 'off'
Default: 'off'

Select icon type — Select icon type

graphic | text

Specify the type of icon used to display this block in a block diagram. The graphic option displays a graphical representation of the assertion condition on the icon. The text option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: icon
Type: character vector
Values: 'graphic' | 'text'
Default: 'graphic'

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point | enumerated
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No

Zero-Crossing Detection	No

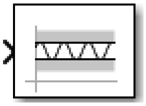
Introduced before R2006a

Check Static Range

Check that signal falls inside fixed range of amplitudes

Library: Simulink / Model Verification



Description

The Check Static Range block checks that each element of the input signal falls inside the same range of amplitudes at each time step. Specify the upper and lower bounds with the parameters **Upper bound** and **Lower bound**. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

Input signal checked against the range specified by the **Upper bound** and **Lower bound** parameters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Assertion output signal
scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, set the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

`Upper bound` — Upper boundary value
scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Command-Line Information
Parameter: `max`
Type: character vector
Values: `scalar` | `vector` | `matrix`
Default: `'0'`

`Inclusive upper boundary` — Include the upper bound in range
on (default) | `off`

Select this check box to make the range of valid input amplitudes include the lower bound.

Command-Line Information
Parameter: `min_included`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Lower bound` — Lower boundary value

scalar | vector | matrix

Specify the lower bound on the range of amplitudes that the input signal can have.

Command-Line Information
Parameter: `min`
Type: character vector
Values: `scalar` | `vector` | `matrix`
Default: `'0'`

`Inclusive lower bound` — Include the lower bound in range

`on` (default) | `off`

Select this check box to make the range of valid input amplitudes include the lower bound.

Command-Line Information
Parameter: `min_included`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Enable assertion` — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

`Select icon type` — Select icon type

`graphic` | `text`

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the

icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: `icon`
Type: character vector
Values: `'graphic'` | `'text'`
Default: `'graphic'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

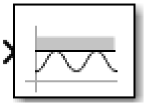
Check Static Upper Bound

Check that signal is less than (or optionally equal to) static upper bound

Library: Simulink / Model Verification



Description

The Check Static Upper Bound block checks that each element of the input signal is less than (or optionally equal to) a specified upper bound at the current time step. Use the block parameter dialog box to specify the value of the upper bound and whether the bound is inclusive. If the verification condition is true, the block does nothing. If not, the block halts the simulation, by default, and displays an error message.

Use the blocks in the Model Verification library to facilitate creation of self-validating models. For example, you can use model verification blocks to test that signals do not exceed specified limits during simulation. When you are satisfied that a model is correct, you can turn error checking off by disabling the verification blocks. You do not have to remove them from the model. If you need to modify a model, you can temporarily turn the verification blocks back on to ensure that your changes do not break the model.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal checked against the upper bound specified by the **Lower bound** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Assertion output signal

scalar

Output signal at each time step that is true (1) if the assertion succeeds, and false (0) if the assertion fails. If, in the Configuration Parameters, you select **Implement logic signals as Boolean data**, then the output data type is a `Boolean`. Otherwise the data type of the signal is a `double`.

Dependencies

To enable this output port, select the **Output assertion signal** parameter check box.

Data Types: `double` | `Boolean`

Parameters

`Upper bound` — Upper boundary value

scalar | vector | matrix

Specify the upper bound on the range of amplitudes that the input signal can have.

Command-Line Information
Parameter: `max`
Type: character vector
Values: `scalar` | `vector` | `matrix`
Default: `'0'`

`Inclusive boundary` — Include the upper bound in range

`on` (default) | `off`

Select this check box to make the range of valid input amplitudes include the upper bound.

Command-Line Information
Parameter: `max_included`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Enable assertion` — Enable or disable the check

`on` (default) | `off`

Clearing this check box disables the block and causes the model to behave as if the block does not exist. You can set the **Model Verification block enabling** setting in the Configuration Parameters to enable or disable all model verification blocks in a model regardless of the setting of this option.

Command-Line Information
Parameter: `enabled`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Simulation callback when assertion fails (optional)` — Expression to evaluate when assertion fails

`' '` (default) | MATLAB expression

Specify a MATLAB expression to evaluate when the assertion fails. Because the expression is evaluated in the MATLAB workspace, define all variables used in the expression in that workspace.

Command-Line Information
Parameter: `callback`
Type: character vector
Values: MATLAB expression
Default: `' '`

`Stop simulation when assertion fails` — Halt simulation when check fails

`on` (default) | `off`

Select this check box to indicate that the block halts simulation when the check fails. Clear to indicate that the software displays a warning and continues the simulation.

Command-Line Information
Parameter: `stopWhenAssertionFail`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output assertion signal` — Create output signal

`off` (default) | `on`

Selecting this check box causes the block to output a Boolean signal that is true (`1`) at each time step if the assertion succeeds and false (`0`) if the assertion fails. The data type of the output signal is `Boolean` if you have selected the **Implement logic signals as Boolean data** check box on the Configuration Parameters dialog box. Otherwise the data type of the output signal is `double`.

Command-Line Information
Parameter: `export`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

`Select icon type` — Select icon type

`graphic` | `text`

Specify the type of icon used to display this block in a block diagram. The `graphic` option displays a graphical representation of the assertion condition on the icon. The `text` option displays a mathematical expression that represents the assertion condition. If the icon is too small to display the expression, the text icon displays an exclamation point. To see the expression, enlarge the block.

Command-Line Information
Parameter: `icon`
Type: character vector
Values: `'graphic'` | `'text'`
Default: `'graphic'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`

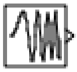
Chirp Signal

Generate sine wave with increasing frequency

Library: Simulink / Sources



Description

The Chirp Signal block generates a sine wave whose frequency increases at a linear rate with time. You can use this block for spectral analysis of nonlinear systems. The block generates a scalar or vector output.

The parameters, **Initial frequency**, **Target time**, and **Frequency at target time**, determine the block's output. You can specify any or all of these variables as scalars or arrays. All the parameters specified as arrays must have the same dimensions. The block expands scalar parameters to have the same dimensions as the array parameters. The block output has the same dimensions as the parameters unless you select the **Interpret vector parameters as 1-D** check box. If you select this check box and the parameters are row or column vectors, the block outputs a vector (1-D array) signal.

Limitations

- The start time of the simulation must be 0. To confirm this value, go to the **Solver** pane in the Configuration Parameters dialog box and view the **Start time** field.
- Suppose that you use a Chirp Signal block in an enabled subsystem. Whenever the subsystem is enabled, the block output matches what would appear if the subsystem were enabled throughout the simulation.

Ports

Output

`Port_1` — Chirp signal

scalar | vector | matrix | N-D array

Sine wave whose frequency increases at a linear rate with time. The chirp signal can be a scalar, vector, matrix, or N-D array.

Data Types: `double`

Parameters

`Initial frequency` — Initial frequency (Hz)

`0.1` (default) | scalar | vector | matrix | N-D array

The initial frequency of the signal, specified as a scalar, vector, matrix, or N-D array.

Programmatic Use
Block Parameter: `f1`
Type: character vector
Values: scalar | vector | matrix | N-D array
Default: `'0.1'`

`Target time` — Target time (seconds)

`100` (default) | scalar | vector | matrix | N-D array

Time, in seconds, at which the frequency reaches the **Frequency at target time** parameter value. You specify the **Target time** as a scalar, vector, matrix, or N-D array. After the target time is reached, the frequency continues to change at the same rate.

Programmatic Use
Block Parameter: `T`
Type: character vector
Values: scalar | vector | matrix | N-D array
Default: `'100'`

`Frequency at target time` — Frequency (Hz)

`1` (default) | scalar | vector | matrix | N-D array

Frequency, in Hz, of the signal at the target time, specified as a scalar, vector, matrix, or N-D array.

Programmatic Use
Block Parameter: `f2`
Type: character vector
Values: scalar | vector | matrix | N-D array
Default: `'1'`

`Interpret vector parameters as 1-D` — Treat vector parameters as 1-D

`on` (default) | `off`

When you select this check box, any column or row matrix values you specify for the **Initial frequency**, **Target time**, and **Frequency at target time** parameters result in a vector output whose elements are the elements of the row or column. For more information, see “Determining the Output Dimensions of Source Blocks”.

Programmatic Use
Block Parameter: `VectorParams1D`
Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Clock

Display and provide simulation time
Library: Simulink / Sources

Description

The Clock block outputs the current simulation time at each simulation step. This block is useful for other blocks that need the simulation time.

When you need the current time within a discrete system, use the Digital Clock block.

Ports

Output

`Port_1` — Sample time
scalar

Sample time, specified as the current simulation time at each simulation time step.

Data Types: `double`

Parameters

`Display time` — Display simulation time on block icon
`off` (default) | `on`

Select this check box to display the simulation time as part of the Clock block icon. When you clear this check box, the simulation time does not appear on the block icon.

Programmatic Use
Block Parameter: `DisplayTime`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Decimation` — Interval at which to update block icon

`10` (default) | positive integer

Specify the interval at which Simulink updates the Clock icon as a positive integer.

Suppose that the decimation is 1000. For a fixed integration step of 1 millisecond, the Clock icon updates at 1 second, 2 seconds, and so on.

Dependencies

To display the simulation time on the block icon, you must select the **Display time** check box.

Programmatic Use
Block Parameter: `Decimation`
Type: character vector
Value: scalar
Default: `'10'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

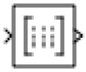
Combinatorial Logic

Implement truth table
Library: Simulink / Logic and Bit Operations



Description

The Combinatorial Logic block implements a standard truth table for modeling programmable logic arrays (PLAs), logic circuits, decision tables, and other Boolean expressions. You can use this block in conjunction with Memory blocks to implement finite-state machines or flip-flops.

Ports

Input

`Port_1` — Input signal
vector

Input signal, specified as a vector. The type of signals accepted by a Combinatorial Logic block depends on whether you selected the Boolean logic signals option (see “Implement logic signals as Boolean data (vs. double)”). If this option is enabled, the block accepts real signals of type `Boolean` or `double`.

Data Types: `double` | `Boolean`

Output

`Port_2` — Output signal
scalar | vector

Output signal, `double` if the truth table contains non-Boolean values of type `double`; `Boolean` otherwise. The type of the output is the same as that of the input except that the block outputs `double` if the input is `Boolean` and the truth table contains non-Boolean values.

Data Types: `double` | `Boolean`

Parameters

`Truth table` — Matrix of outputs

matrix

You specify a matrix that defines all possible block outputs as the **Truth table** parameter. Each row of the matrix contains the output for a different combination of input elements. You must specify outputs for every combination of inputs. The number of columns is the number of block outputs.

The **Truth table** parameter can have Boolean values (0 or 1) of any data type, including fixed-point data types. If the table contains non-Boolean values, the data type of the table must be `double`.

The relationship between the number of inputs and the number of rows is:

$$\texttt{number of rows} = 2^{\texttt{(number of inputs)}}$$

Simulink returns a row of the matrix by computing the row's index from the input vector elements. Simulink computes the index by building a binary number where input vector elements having zero values are 0 and elements having nonzero values are 1, then adding 1 to the result. For an input vector, `u`, of `m` elements:

$$\texttt{row index} = 1 + \texttt{u(m)}*2^{0} + \texttt{u(m-1)}*2^{1} + \ldots + \texttt{u(1)}*2^{m-1}$$

Programmatic Use
Block Parameter: `TruthTable`
Type: character vector
Values: matrix
Default: `'[0 0;0 1;0 1;1 0;0 1;1 0;1 0;1 1]'`

Block Characteristics

Data Types	`double` | `Boolean`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Combo Box

Select parameter value from drop-down menu
Library: Simulink / Dashboard

Description

The Combo Box block lets you set the value of a parameter to one of several values. You can define each selectable value and its label through the Combo Box block parameters. Use the Combo Box block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

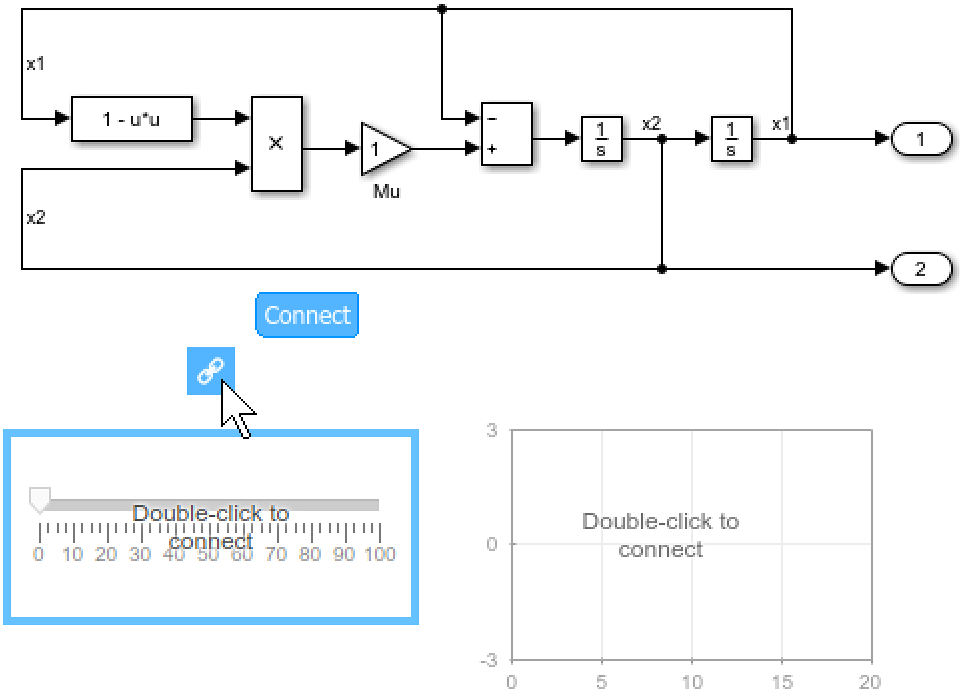
Double-clicking the Combo Box block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connecting Dashboard Blocks

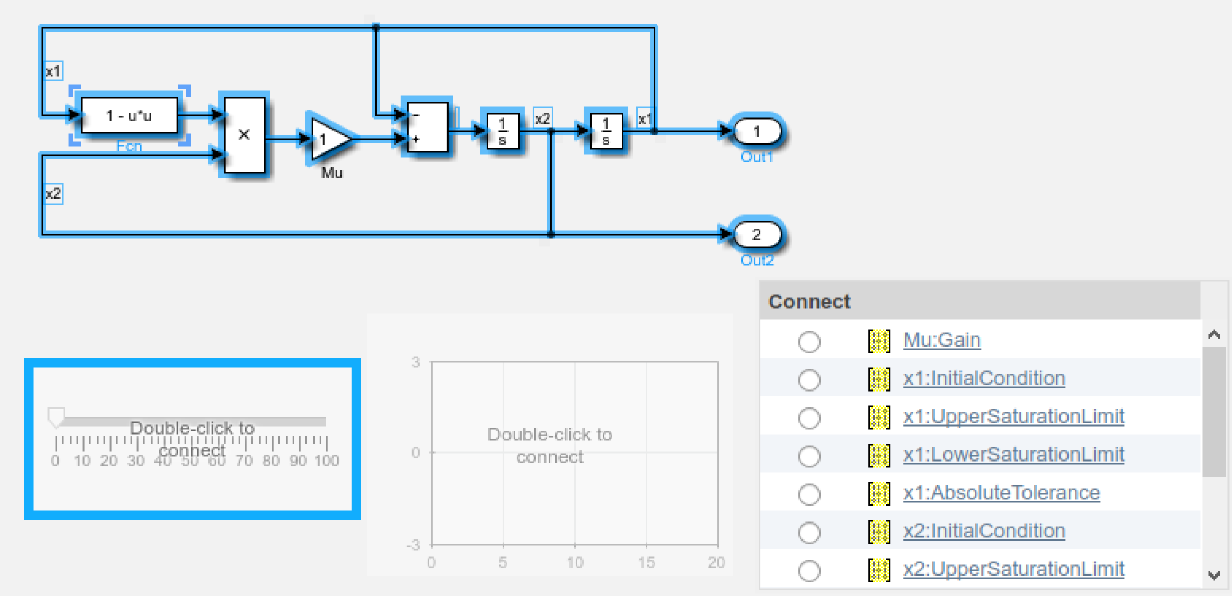
Dashboard blocks do not use ports to make connections. To connect Dashboard blocks to variables and block parameters in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

Note Dashboard blocks cannot connect to variables until you update your model diagram. To connect Dashboard blocks to variables or modify variable values between opening your model and running a simulation, update your model diagram using **Ctrl+D**.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

○ Mu:Gain
○ x1:InitialCondition
○ x1:UpperSaturationLimit
○ x1:LowerSaturationLimit
○ x1:AbsoluteTolerance
○ x2:InitialCondition
○ x2:UpperSaturationLimit

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Parameter Logging

Tunable parameters connected to Dashboard blocks are logged to the Simulation Data Inspector, where you can view parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector UI or by using the `Simulink.sdi.exportRun` function. For more information about exporting data with the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using

connect mode, the Dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. Populate the **Connection** table by selecting one or more blocks in your model. Select the radio button next to the variable or parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

States

`Value` — Values for selected option

0/1/2 (default) | scalar

Values assigned to the connected parameter when you select the option with the corresponding **Label**. Click the **+** button to add options.

`Label` — Option labels

'Label1'/'Label2'/'Label3' (default) | character vector

Label for each option. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a text label.

Example: `Gain = 1`

`Label` — Block label position
'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

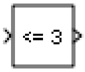
Introduced in R2017b

Compare To Constant

Determine how signal compares to specified constant
Library: Simulink / Logic and Bit Operations



Description

The Compare To Constant block compares an input signal to a constant. Specify the constant in the **Constant value** parameter. Specify how the input is compared to the constant value with the **Operator** parameter.

Ports

Input

`Port_1` — Input signal
scalar

Input signal, specified as a scalar, is compared with zero.The block first converts its **Constant value** parameter to the input data type, and then performs the specified operation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Output signal
0 | 1

The output is `0` if the comparison is false, and `1` if it is true.

Data Types: `uint8` | `Boolean`

Parameters

`Operator` — Logical operator

<= (default) | == | ~= | < | >= | >

This parameter can have these values:

- == — Determine whether the input is equal to the specified constant.
- ~= — Determine whether the input is not equal to the specified constant.
- < — Determine whether the input is less than the specified constant.
- <= — Determine whether the input is less than or equal to the specified constant.
- > — Determine whether the input is greater than the specified constant.
- >= — Determine whether the input is greater than or equal to the specified constant.

Programmatic Use
Block Parameter: `relop`
Type: character vector
Values: `'=='` | `'~='`| `'<'` |`'<='`| `'>='`| `'>'`
Default: `'<='`

`Constant value` — Constant to compare with

constant

Specify the constant value to which the input is compared.

Programmatic Use
Block Parameter: `const`
Type: character vector
Value: scalar | vector | matrix | N-D array
Default: `'3.0'`

`Output data type` — Data type of the output

`boolean` (default) | `uint8`

Specify the data type of the output, `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values:`'boolean'` | `'uint8'`
Default: `'boolean'`

`Enable zero-crossing detection` — Select to enable zero-crossing detection

check (default) | uncheck

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector
Values: `'off'` | `'on'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`Yes`

Extended Capabilities

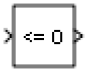
Combinatorial Logic | Compare To Zero | Logical Operator

Introduced before R2006a

Compare To Zero

Determine how signal compares to zero
Library: Simulink / Logic and Bit Operations



Description

The Compare To Zero block compares an input signal to zero. Specify how the input is compared to zero with the **Operator** parameter.

The output is `0` if the comparison is false, and `1` if it is true.

Ports

Input

`Port_1` — Input signal
scalar

Input signal, specified as scalar, is compared with zero. If the input data type cannot represent zero, parameter overflow occurs. To detect this overflow, go to the **Diagnostics > Data Validity** pane of the Configuration Parameters dialog box and set **Parameters > Detect overflow** to `warning` or `error`.

In this case, the block compares the input signal to the *ground value* of the input data type. For example, if you have an input signal of type `fixdt(0,8,2^0,10)`, the input data type can represent unsigned 8-bit integers from 10 to 265 due to a bias of 10. The ground value is 10, instead of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal
0 | 1

The output is `0` if the comparison is false, and `1` if it is true.

The block output is `uint8` or `boolean`, depending on your selection for the **Output data type** parameter.

Data Types: `uint8` | `Boolean`

Parameters

`Operator` — Logical operator
<= (default) | == | ~= | < | >= | >

This parameter can have the following values:

- == — Determine whether the input is equal to zero.
- ~= — Determine whether the input is not equal to zero.
- < — Determine whether the input is less than zero.
- <= — Determine whether the input is less than or equal to zero.
- > — Determine whether the input is greater than zero.
- >= — Determine whether the input is greater than or equal to zero.

Programmatic Use
Block Parameter: `relop`
Type: character vector
Values: `'=='` | `'~='`| `'<'` |`'<='`| `'>='`| `'>'`
Default: `'<='`

`Output data type` — Data type of the output
`boolean` (default) | `uint8`

Specify the data type of the output, `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`

Type: character vector
Values:'boolean' | 'uint8'
Default: 'boolean'

Enable zero-crossing detection — Select to enable zero-crossing detection
on (default) | off

Select to enable zero-crossing detection. For more information, see "Zero-Crossing Detection" in the Simulink documentation.

Programmatic Use
Block Parameter: ZeroCross
Type: character vector
Values: 'off' | 'on'
Default: 'on'

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	Yes

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

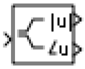
Complex to Magnitude-Angle

Compute magnitude and/or phase angle of complex signal
Library: Simulink / Math Operations



Description

The Complex to Magnitude-Angle block outputs the magnitude and/or phase angle of the input signal, depending on the setting of the **Output** parameter. The outputs are real values of the same data type as the block input. The input can be an array of complex signals, in which case the output signals are also arrays. The magnitude signal array contains the magnitudes of the corresponding complex input elements. The angle output similarly contains the angles of the input elements.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Complex input signal that the block computes and outputs the magnitude and/or the phase angle.

Data Types: `single` | `double`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output signal that is the magnitude and/or phase angle of the input signal. To choose the output, set the **Output** parameter.

Data Types: `single` | `double`

Parameters

`Output` — Magnitude and/or phase angle output specification

`Magnitude and angle` (default) | `Magnitude` | `Angle`

Specify if the output is the magnitude and/or the phase angle in radians of the input signal.

Command-Line Information
Parameter: `Output`
Type: character vector
Values: `'Magnitude and angle'` | `'Magnitude'` | `'Angle'`
Default: `'Magnitude and angle'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single`

Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

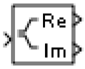
Complex to Real-Imag | Real-Imag to Complex

Introduced before R2006a

Complex to Real-Imag

Output real and imaginary parts of complex input signal
Library: Simulink / Math Operations



Description

The Complex to Real-Imag block outputs the real and/or imaginary part of the input signal, depending on the setting of the **Output** parameter. The real outputs are of the same data type as the complex input. The input can be an array (vector or matrix) of complex signals, in which case the output signals are arrays of the same dimensions. The real array contains the real parts of the corresponding complex input elements. The imaginary output similarly contains the imaginary parts of the input elements.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Complex input signal that the block computes and outputs the real and/or imaginary part.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output signal that is the real and/or imaginary part of the input signal. To choose which part is output, set the **Output** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

`Output` — Real and/or imaginary output specification

`Real and imag` (default) | `Real` | `Imag`

Specify if the output is the real and/or imaginary part of the input signal.

Command-Line Information
Parameter: `Output`
Type: character vector
Values: `'Real and imag'` | `'Real'` | `'Imag'`
Default: `'Real and imag'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`

Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

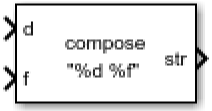
Compose String

Compose output string signal based on specified format and input signals

Library: Simulink / String



Description

The Compose String block composes output string signal based on the format specifier listed in the **Format** parameter. The **Format** parameter determines the number of input signals. If there are multiple inputs, the block constructs the string by combining these multiple inputs in order, and applying the associated format specifier, one format specifier for each input. Each format specifier starts with a percent sign, `%`, followed by the conversion character. For example, `%f` formats the input as a floating point output. To supplement the string output, you can also add a character to the format specification. Use this block to compose and format an output string signal from a multiple inputs.

For example, if the **Format** parameter contains `"%s is %f"`, the block expects two inputs, a string signal and a single or double signal. If the first input is the string `"Pi"` and the second input is a double value `3.14`, the output is `"Pi is 3.14"`.

When a MinGW® compiler compiles code generated from the block, running the compiled code may produce nonstandard results for floating-point inputs. For example, a numeric input of `501.987` returns the string `"5.019870e+002"` instead of the expected string `"5.019870e+02"`.

Ports

Input

d — Data for first part of string

scalar

Data for the first part of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the first item in the **Format** parameter is `%d`, the port label is d.

The data type of the input signal must be compatible with the format specifier in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean`

`f` — Data for second part of string

scalar

Data for the second part of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the first item in the **Format** parameter is `%f`, the port label is f.

The data type of the input signal must be compatible with the format specifier specified in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`Port_N` — Data for N parts of string

scalar (default)

Data for *N* parts of string, specified as a scalar. The **Format** parameter determines the port label and the format of the input data. For example, if the corresponding item in the **Format** parameter is `%f`, the port label is f.

The data type of the input signal must be compatible with the format specifier in the **Format** parameter. For more information, see the **Format** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`str` — Output string

scalar

Output string composed of inputs, specified as a scalar.

Data Types: `string`

Parameters

`Format` — Format input data
"%d %f" (default) | scalar

Format of input data, specified as a scalar.

For more information about acceptable format specifiers, see the Algorithms section.

`Output data type` — Output data type
`string` (default) | `scalar`

Output data type, specified using the string data type to specify a string with no maximum length.

To specify a string data type with a maximum length, specify `stringtype(`*`N`*`)`. For example, `stringtype(31)` creates a string data type with a maximum length of 31 characters.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. See “Specify Data Types Using Data Type Assistant” in the *Simulink User's Guide* for more information.

Block Characteristics

Data Types	`double` | `single` | `base integer` | `string`
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No

Zero-Crossing Detection	No

Algorithms

A formatting specifier starts with a percent sign, %, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier, flags, field width, precision, and subtype specifiers between % and the conversion character. (Spaces are invalid between specifiers and are shown here only for readability).

The Compose String block uses this format specifier prototype:

```
%[flags][width][.precision][length]specifier
```

Conversion Character

This table shows conversion characters to format numeric and character data as text.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a–f
	%X	Same as %x, uppercase letters A–F
Floating-point number	%f	Floating-point notation (Use a precision operator to specify the number of digits after the decimal point.)
	%e	Exponential notation, such as 3.141593e+00 (Use a precision operator to specify the number of digits after the decimal point.)

Value Type	Conversion	Details
	`%E`	Same as `%e`, but uppercase, such as `3.141593E+00` (Use a precision operator to specify the number of digits after the decimal point.)
	`%g`	The more compact of `%e` or `%f`, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
	`%G`	The more compact of `%E` or `%f`, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
String	`%s`	The type of the output text is the same as the type of **Format**.

Optional Operators

The optional identifier, flags, field width, precision, and operators further define the format of the output text.

- **Flags**

`'–'`	Left-justify. Works with all specifiers. **Example:** `%-5.2f` **Example:** `%-10s`
`'+'`	Always print a sign character (+ or –) for any numeric value. Works with all specifiers except `u`, `o`, `x`, `X`, and `s`. **Example:** `%+5.2f` Right-justify text. **Example:** `%+10s`
`' '`	Insert a space before the value. Works with all specifiers except `u`, `o`, `x`, `X`, and `s`. **Example:** `% 5.2f`

`'0'`	Pad to field width with zeros before the value. Works with all specifiers except `s`. **Example:** `%05.2f`
`'#'`	Modify selected numeric conversions: • For `%o`, `%x`, or `%X`, print `0`, `0x`, or `0X` prefix. • For `%f`, `%e`, or `%E`, print decimal point even when precision is 0. • For `%g` or `%G`, do not remove trailing zeros or decimal point. Works with all specifiers except `d`, `i`, `u`, and `s`. **Example:** `%#5.0f`

- **Field Width**

  Minimum number of characters to print.

  The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

For `%f`, `%e`, or `%E`	Number of digits to the right of the decimal point **Example:** `'%.4f'` prints `pi` as `'3.1416'`
d, i, o, u, x, X	Minimum number of digits to be written. Outputs shorter than the specified precision are padded with leading zeros. **Example**: `"%.4d"` prints 5 as `'0005'`
For `%g` or `%G`	Number of significant digits **Example:** `'%.4g'` prints `pi` as `'3.142'`
s	Maximum number of characters to be written to the output. **Example:** `"%.2s"` prints `"Hello!"` as `"He"`

Note If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

Text Before or After Formatting Operators

Special Character	Representation
Single quotation mark	''
Percent character	%%
Backslash	\\
Alarm	\a
Backspace	\b
Form feed	\f
New line	\n
Carriage return	\r
Horizontal tab	\t
Vertical tab	\v
Character whose Unicode® numeric value can be represented by the hexadecimal number, N	\xN **Example:** sprintf('\x5A') returns 'Z'
Character whose Unicode numeric value can be represented by the octal number, N	\N **Example:** sprintf('\132') returns 'Z'

Format can also include additional text before a percent sign, %, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in formatSpec.

Length Specifiers

The Format String block supports the h and l length subspecifiers. These specifiers can change according to the **Configuration Parameters > Hardware Implementation > Number of bits** settings

Length	d i	u o x X	f e E g G	s
No length specifier	`int`	`unsigned int`	`double` (default), `single`	`string`
`h`	`short`	`unsigned short`	—	—
`l`	`long`	`unsigned long`	—	—

Note for Specifiers that Specify Integer Data Types (`d`, `i`, `u`, `o`, `x`, `X`)

Target `int`, `long`, and `short` type sizes are controlled by settings in the **Configuration Parameters** > **Hardware Implementation** pane. For example, if the target `int` is 32 bits and the specifier is `%u`, then the expected input type will be `uint32`. However, the input port accepts any built-in integer type of that size or smaller with the `%u` specifier

Notes for Specifiers that Specify Floating Point Data Types (`f`, `e`, `E`, `g`, `F`)

- Do not use `l` and `h` with these specifiers. Do not use the length subspecifier (for example, `%f` is allowed, but `%hf` and `%lf` are not allowed) .
- Ports that correspond with these specifiers accept both `single` and `double` data types.

Note for Specifiers that Specify the String Data Type (`s`)

- The `s` specifier does not work with the `l` or `h` subspecifiers, and only accepts a string input data type.

Extended Capabilities

Introduced in R2018a

Configurable Subsystem

Represent any block selected from user-specified library of blocks

Library: Simulink / Ports & Subsystems

Description

The Configurable Subsystem block represents one of a set of blocks contained in a specified library of blocks. The context menu of the Configurable Subsystem block lets you choose which block the configurable subsystem represents.

Configurable Subsystem blocks simplify creation of models that represent families of designs. For example, suppose that you want to model an automobile that offers a choice of engines. To model such a design, you would first create a library of models of the engine types available with the car. You would then use a Configurable Subsystem block in your car model to represent the choice of engines. To model a particular variant of the basic car design, a user need only choose the engine type, using the configurable engine block's dialog box.

To create a configurable subsystem in a model, you must first create a library containing a master configurable subsystem and the blocks that it represents. You can then create configurable instances of the master subsystem by dragging copies of the master subsystem from the library and dropping them into models.

You can add any type of block to a master configurable subsystem library. Simulink derives the port names for the configurable subsystem by making a unique list from the port names of all the choices. However, Simulink uses default port names for non-subsystem block choices.

You cannot break library links in a configurable subsystem because Simulink uses those links to reconfigure the subsystem when you choose a new configuration. Breaking links would be useful only if you do not intend to reconfigure the subsystem. In this case, you can replace the configurable subsystem with a nonconfigurable subsystem that implements the permanent configuration.

Creating a Master Configurable Subsystem

To create a master configurable subsystem:

1. Create a library of blocks representing the various configurations of the configurable subsystem.
2. Save the library.
3. Create an instance of the Configurable Subsystem block in the library.

   To do so, drag a copy of the Configurable Subsystem block from the Simulink Ports & Subsystems library into the library you created in the previous step.
4. Display the Configurable Subsystem block dialog box by double-clicking it. The dialog box displays a list of the other blocks in the library.
5. Under **List of block choices** in the dialog box, select the blocks that represent the various configurations of the configurable subsystems you are creating.
6. To apply the changes and close the dialog box, click the **OK** button.
7. Select **Block Choice** from the context menu of the Configurable Subsystem block.

   The context menu displays a submenu listing the blocks that the subsystem can represent.
8. Select the block that you want the subsystem to represent by default.
9. Save the library.

Note If you add or remove blocks from a library, you must recreate any Configurable Subsystem blocks that use the library.

If you modify a library block that is the default block choice for a configurable subsystem, the change does not immediately propagate to the configurable subsystem. To propagate this change, do one of the following:

- Change the default block choice to another block in the subsystem, then change the default block choice back to the original block.
- Recreate the configurable subsystem block, including the selection of the updated block as the default block choice.

If a configurable subsystem in your model contains a broken link to a library block, editing the link and saving the model does not fix the broken link the next time you open the model. To fix a broken library link in your configurable subsystem, use one of the following approaches.

- Convert the configurable subsystem to a variant subsystem. Right-click the configurable subsystem, and select **Subsystem and Model Reference > Convert Subsystem to > Variant Subsystem**.
- Remove the library block from the master configurable subsystem library, add the library block back to the master configurable subsystem library, and then resave the master configurable subsystem library.

Creating an Instance of a Configurable Subsystem

To create an instance of a configurable subsystem in a model:

1. Open the library containing the master configurable subsystem.
2. Drag a copy of the master into the model.
3. Select **Block Choice** from the context menu of that Configurable Subsystem instance.
4. Select the block that you want the configurable subsystem to represent.

The instance of the configurable system displays the icon and parameter dialog box of the block that it represents.

Setting Instance Block Parameters

As with other blocks, you can use the parameter dialog box of a configurable subsystem instance to set its parameters interactively and the `set_param` command to set the parameters from the MATLAB command line or in a MATLAB file. If you use `set_param`, you must specify the full path name of the configurable subsystem's current block choice as the first argument of `set_param`, for example:

```
curr_choice = get_param('mymod/myconfigsys', 'BlockChoice');
curr_choice = ['mymod/myconfigsys/' curr_choice];
set_param(curr_choice, 'MaskValues', ...);
```

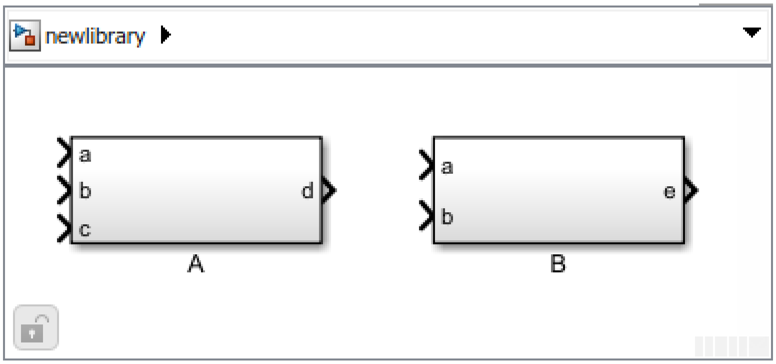
Mapping I/O Ports

A configurable subsystem displays a set of input and output ports corresponding to input and output ports in the selected library. Simulink uses the following rules to map library ports to Configurable Subsystem block ports:

- Map each uniquely named input/output port in the library to a separate input/output port of the same name on the Configurable Subsystem block.
- Map all identically named input/output ports in the library to the same input/output ports on the Configurable Subsystem block.
- Terminate any input/output port not used by the currently selected library block with a Terminator/Ground block.

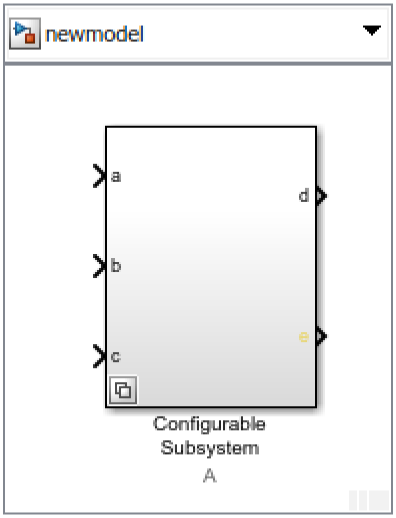
This mapping allows a user to change the library block represented by a Configurable Subsystem block without having to rewire connections to the Configurable Subsystem block.

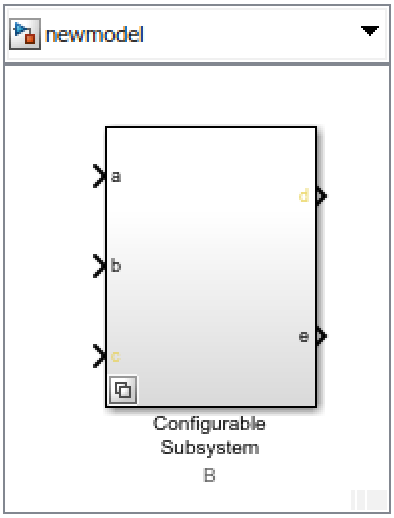
For example, suppose that a library contains two blocks A and B and that block A has input ports labeled a, b, and c and an output port labeled d and that block B has input ports labeled a and b and an output port labeled e.



A Configurable Subsystem block based on this library would have three input ports labeled a, b, and c, respectively, and two output ports labeled d and e.

In this example, port a on the Configurable Subsystem block connects to port a of the selected library block no matter which block is selected. Port c on the Configurable Subsystem block functions only if library block A is selected. Otherwise, it simply terminates.





Note A Configurable Subsystem block does not provide ports that correspond to non-I/O ports, such as the trigger and enable ports on triggered and enabled subsystems. Thus, you cannot use a Configurable Subsystem block directly to represent blocks that have such ports. You can do so indirectly, however, by wrapping such blocks in subsystem blocks that have input or output ports connected to the non-I/O ports.

Convert to Variant Subsystem

Right-click a configurable subsystem and select **Subsystems and Model Reference > Convert Subsystem To > Variant Subsystem**.

During conversion, Simulink performs the following operations:

- Replaces the Subsystem block with a Variant Subsystem block, preserving ports and connections.
- Adds the original subsystem as a variant choice in the Variant Subsystem block.
- Overrides the Variant Subsystem block to use the subsystem that was originally the active choice.
- Preserves links to libraries. For linked subsystems, Simulink adds the linked subsystem as a variant choice.

> Simulink also preserves the subsystem block masks, and it copies the masks to the variant choice.

See Variant Subsystem for more information on variant choices.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix | N-D array | bus

Input signal to the Configurable Subsystem. The block that the Configurable Subsystem represents determines the supported data types and dimensions of the input signal.

Dependencies

The number of input ports depends on the blocks in the library that the Configurable Subsystem represents. For more information, see “Mapping I/O Ports” on page 1-214.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Output signal

scalar | vector | matrix | N-D array | bus

Output signal from the Configurable Subsystem. The block that the Configurable Subsystem represents determines the output data types and dimensions.

Dependencies

The number of output ports depends on the blocks in the library that the Configurable Subsystem represents. For more information, see “Mapping I/O Ports” on page 1-214.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

List of block choices — Block members of the configurable subsystem

no default

Select the blocks you want to include as members of the configurable subsystem. You can include user-defined subsystems as blocks.

Programmatic Use
Block Parameter: MemberBlocks
Type: cell array of character vectors
Values: cell array of block names as character vectors
Default: {''}

Port names — Port names

no default

Lists of input and output ports of member blocks. In the case of multiports, you can rearrange selected port positions by clicking the **Up** and **Down** buttons.

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a] | string[a]
Direct Feedthrough	No
Multidimensional Signals	Yes[a]
Variable-Size Signals	Yes[a]
Zero-Crossing Detection	No

a. Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type support depends on block implementation.

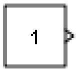
Constant

Generate constant value

Library: Simulink / Commonly Used Blocks
Simulink / Sources



Description

The Constant block generates a real or complex constant value. The block generates scalar, vector, or matrix output, depending on:

- The dimensionality of the **Constant value** parameter
- The setting of the **Interpret vector parameters as 1-D** parameter

The output of the block has the same dimensions and elements as the **Constant value** parameter. If you specify for this parameter a vector that you want the block to interpret as a vector, select the **Interpret vector parameters as 1-D** check box. Otherwise, if you specify a vector for the **Constant value** parameter, the block treats that vector as a matrix.

Tip To output a constant enumerated value, consider using the Enumerated Constant block instead. The Constant block provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**.

Using Bus Objects as the Output Data Type

The Constant block supports nonvirtual buses as the output data type. Using a bus object as the output data type can help simplify your model. If you use a bus object as the output data type, set the **Constant value** to `0` or to a MATLAB structure that matches the bus object.

Using Structures for the Constant Value of a Bus

The structure you specify must contain a value for every element of the bus represented by the bus object. The block output is a nonvirtual bus signal.

You can use the `Simulink.Bus.createMATLABStruct` to create a full structure that corresponds to a bus.

You can use `Simulink.Bus.createObject` to create a bus object from a MATLAB structure.

If the signal elements in the output bus use numeric data types other than `double`, you can specify the structure fields by using typed expressions such as `uint16(37)` or untyped expressions such as `37`. To control the field data types, you can use the bus object as the data type of a `Simulink.Parameter` object. To decide whether to use typed or untyped expressions, see “Control Data Types of Initial Condition Structure Fields”.

Setting Configuration Parameters to Support Using a Bus Object Data Type

To enable the use of a bus object as an output data type, before you start a simulation, set **Configuration Parameters** > **Diagnostics** > **Data Validity** > **Advanced parameters** > **Underspecified initialization detection** to `Simplified`. For more information, see “Underspecified initialization detection”.

Ports

Output

`Port_1` **— Constant value**
scalar | vector | matrix | N-D array

Constant value, specified as a real or complex valued scalar, vector, matrix, or N-D array. By default, the Constant block outputs a signal whose dimensions, data type, and complexity are the same as those of the **Constant value** parameter. However, you can specify the output to be any data type that Simulink supports, including fixed-point and enumerated data types.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For more information, see `Simulink.BusElement`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

`Constant value` — Constant output value

`1` (default) | scalar | vector | matrix | N-D array

Specify the constant value output of the block.

- You can enter any expression that MATLAB evaluates as a matrix, including the Boolean keywords `true` and `false`.
- If you set the **Output data type** to be a bus object, you can specify one of these options:

  - A full MATLAB structure corresponding to the bus object
  - `0` to indicate a structure corresponding to the ground value of the bus object

  For details, see “Using Bus Objects as the Output Data Type” on page 1-220.
- For nonbus data types, Simulink converts this parameter from its value data type to the specified output data type offline, using a rounding method of nearest and overflow action of saturate.

Programmatic Use
Block Parameter: `Value`
Type: character vector
Value: scalar | vector | matrix | N-D array
Default: `'1'`

`Interpret vector parameters as 1-D` — Treat vectors as 1-D

`on` (default) | `off`

Select this check box to output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

- When you select this check box, the block outputs a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector. For example, the block outputs a matrix of dimension 1-by-N or N-by-1.
- When you clear this check box, the block does not output a vector of length N if the **Constant value** parameter evaluates to an N-element row or column vector.

Programmatic Use
Block Parameter: VectorParams1D
Type: character vector
Values: 'on' | 'off'
Default: 'on'

Sample time — Sampling interval

inf (default) | scalar | vector

Specify the interval between times that the Constant block output can change during simulation (for example, due to tuning the **Constant value** parameter).

The default value of inf indicates that the block output can never change. This setting speeds simulation and generated code by avoiding the need to recompute the block output.

See “Specify Sample Time” for more information.

Programmatic Use
Block Parameter: SampleTime
Type: character vector
Values: scalar | vector
Default: 'inf'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Specify the lower value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[ ]` (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[ ]'`

`Output data type` — Output data type

`Inherit: Inherit from 'Constant value'` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class name>` | `Bus: <object name>` | `<data type expression>`

Specify the output data type. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector

Values: 'Inherit: Inherit from 'Constant value'' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>'
Default: 'Inherit: Inherit from 'Constant value''

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: LockScale
Type: character vector
Values: 'off' | 'on'
Default: 'off'

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point | enumerated | bus
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

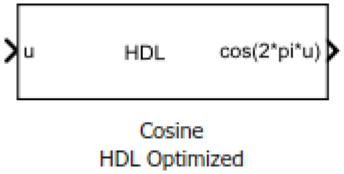
Cosine HDL Optimized

Implement fixed-point cosine wave optimized for HDL code generation



Library

HDL Coder™ / Lookup Tables

Description

The Cosine HDL Optimized block implements a fixed-point cosine wave by using a lookup table method that exploits quarter-wave symmetry.

You define the number of lookup table points in the **Number of data points** parameter. The block implementation is most efficient for HDL code generation when you specify the lookup table data points to be `(2^`*n*`)`, where *n* is an integer. For information about the behavior of this block in HDL Coder, see Cosine HDL Optimized.

Depending on your selection of the **Output formula** parameter, the blocks can output these functions of the input signal:

- sin(2π*u*)
- cos(2π*u*)
- exp(*i*2π*u*)
- sin(2π*u*) and cos(2π*u*)

Use the **Table data type** parameter to specify the word length of the fixed-point output data type. The fraction length of the output is the output word length minus 2.

Data Type Support

The Cosine HDL Optimized block accepts signals of these data types:

- Floating point
- Built-in integer
- Fixed point
- Boolean

The output of the block is a fixed-point data type.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Output formula

Select the signal(s) to output.

Number of data points

Specify the number of data points to retrieve from the lookup table. The implementation is most efficient when you specify the lookup table data points to be `(2^`*`n`*`)`, where *n* is an integer.

Table data type

Specify the table data type. You can specify an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the table data type.

Show data type assistant

Select the mode of data type specification. If you select `Expression`, enter an expression that evaluates to a data type, for example, `fixdt(1,16,0)`.

If you select `Fixed point`, you can use the options in the **Data Type Assistant** to specify the fixed-point data type. In the `Fixed point` mode, you can choose binary point scaling, and specify the signedness, word length, fraction length, and the data type override setting.

Characteristics

Data Types	Double | Single | Boolean | Base Integer | Fixed-Point
Sample Time	Inherited from driving block
Direct Feedthrough	Yes
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No
Code Generation	Yes

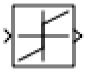
Introduced in R2016b

Coulomb and Viscous Friction

Model discontinuity at zero, with linear gain elsewhere
Library: Simulink / Discontinuities



Description

The Coulomb and Viscous Friction block models Coulomb (static) and viscous (dynamic) friction. The block models a discontinuity at zero and a linear gain otherwise.

The block output matches the MATLAB result for:

```
y = sign(x) .* (Gain .* abs(x) + Offset)
```

where `y` is the output, `x` is the input, `Gain` is the signal gain for nonzero input values, and `Offset` is the Coulomb friction.

The block accepts one input and generates one output. The input can be a scalar, vector, or matrix with real and complex elements.

- For a scalar input, `Gain` and `Offset` can have dimensions that differ from the input. The output is a scalar, vector, or matrix depending on the dimensions of `Gain` and `Offset`.
- For a vector or matrix input, `Gain` and `Offset` must be scalar or have the same dimensions as the input. The output is a vector or matrix of the same dimensions as the input.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

The input signal to the model of Coulomb and viscous friction.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector | matrix

The output signal calculated by applying the friction models to the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

To edit the parameters for the Coulomb and Viscous Friction block, double-click the block icon.

`Coulomb friction value` — Static friction offset

`[1320]` (default) | real values

Specify the offset that applies to all input values.

Programmatic Use
Block Parameter: `offset`
Type: character vector
Value: real values
Default: `'[1 3 2 0]'`

`Coefficient of viscous friction` — Dynamic friction coefficient

1 (default) | real values

Specify the signal gain for nonzero input values.

Programmatic Use
Block Parameter: `gain`
Type: character vector
Value: real values
Default: `'1'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information on HDL code generation, see Coulomb and Viscous Friction.

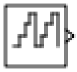
Backlash | Dead Zone

Introduced before R2006a

Counter Free-Running

Count up and overflow back to zero after reaching maximum value for specified number of bits

Library: Simulink / Sources



Description

The Counter Free-Running block counts up until reaching the maximum value, $2^{Nbits} - 1$, where *Nbits* is the number of bits. Then the counter overflows to zero and begins counting up again.

After overflow, the counter always initializes to zero. However, if you select the global doubles override, the Counter Free-Running block does not wrap back to zero.

Note This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Output

`Port_1` — Count value
scalar

Count value, specified as an unsigned integer of 8 bits, 16 bits, or 32 bits.

Data Types: `uint8` | `uint16` | `uint32`

Parameters

`Number of Bits` — Number of bits

16 (default) | scalar

Specify the number of bits as a finite, real-valued. When you specify:

- A positive integer, for example `8`, the block counts up to $2^8 - 1$, which is `255`.
- An unsigned integer expression, for example `uint8(8)`, the block counts up to `uint8(`$2^{\mathtt{uint8(8)}} - 1$`)`, which is `254`.

Programmatic Use
Block Parameter: `NumBits`
Type: character vector
Values: scalar
Default: `'16'`

`Sample time` — Interval between samples

`-1` (default) | scalar | vector

Specify the time interval between samples as a scalar (`sampling period`), or a two-element vector (`[sampling period, initial offset]`). To inherit the sample time, set this parameter to `-1`. For more information, see "Specify Sample Time".

Programmatic Use
Block Parameter: `tsamp`
Type: character vector
Values: scalar | vector
Default: `'-1'`

Block Characteristics

Data Types	`base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`

Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see Counter Free-Running.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

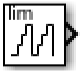
Counter Limited | MATLAB Function

Introduced before R2006a

Counter Limited

Count up and wrap back to zero after outputting specified upper limit
Library: Simulink / Sources



Description

The Counter Limited block counts up until the specified upper limit is reached. Then the counter wraps back to zero, and restarts counting up. The counter always initializes to zero.

Note This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Output

`Port_1` — Count value
scalar

Count value, specified as an unsigned integer of 8 bits, 16 bits, or 32 bits. The block uses the smallest number of bits required to represent the upper limit.

Data Types: `uint8` | `uint16` | `uint32`

Parameters

`Upper limit` — Upper limit
7 (default) | scalar

Specify the upper limit for the block to count to as a finite, real-valued scalar.

Programmatic Use
Block Parameter: `uplimit`
Type: character vector
Values: scalar
Default: `'7'`

`Sample time` — Interval between samples

`-1` (default) | scalar | vector

Specify the time interval between samples as a scalar (`sampling period`), or a two-element vector (`sampling period, initial offset`). To inherit the sample time, set this parameter to `-1`. For more information, see “Specify Sample Time”.

Programmatic Use
Block Parameter: `tsamp`
Type: character vector
Values: scalar | vector
Default: `'-1'`

Block Characteristics

Data Types	`Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
- Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

Counter Free-Running

Introduced before R2006a

Custom Gauge

Display an input value on a customized gauge

Library: Simulink / Dashboard

Description

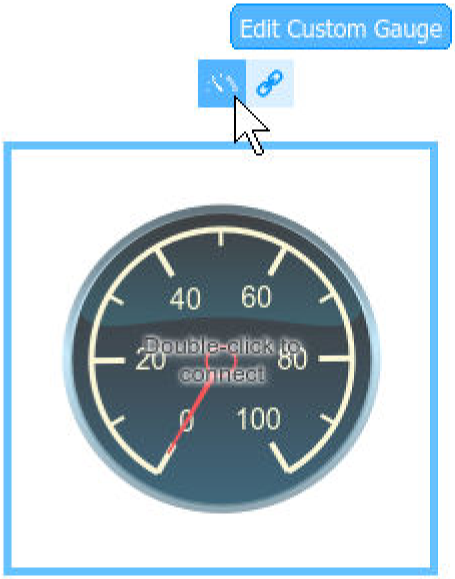
The Custom Gauge block displays the value of the connected signal on a gauge face that you can customize to look like a gauge in a real system. For example, you could create an engine rpm gauge or fuel indicator for an automotive model.

1
2
3
4
5
6
7
8
9
10
x1000

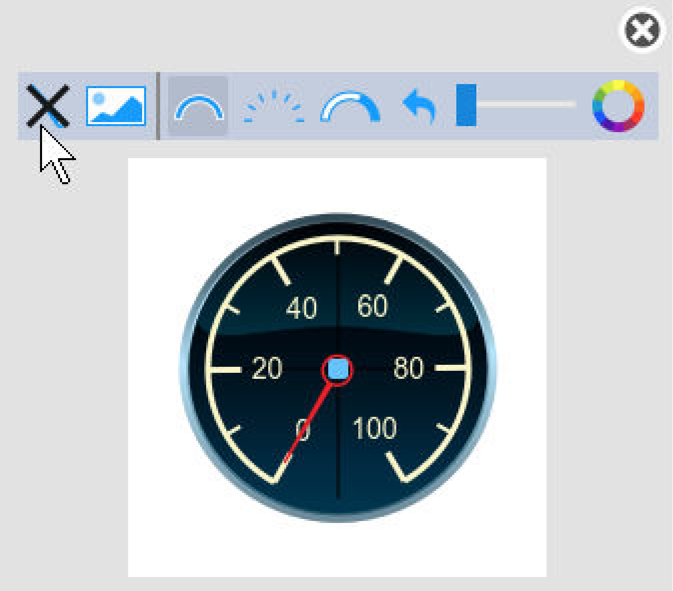
The Custom Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range and tick values on the Custom Gauge block to fit your data. Use the Custom Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Create A Custom Gauge

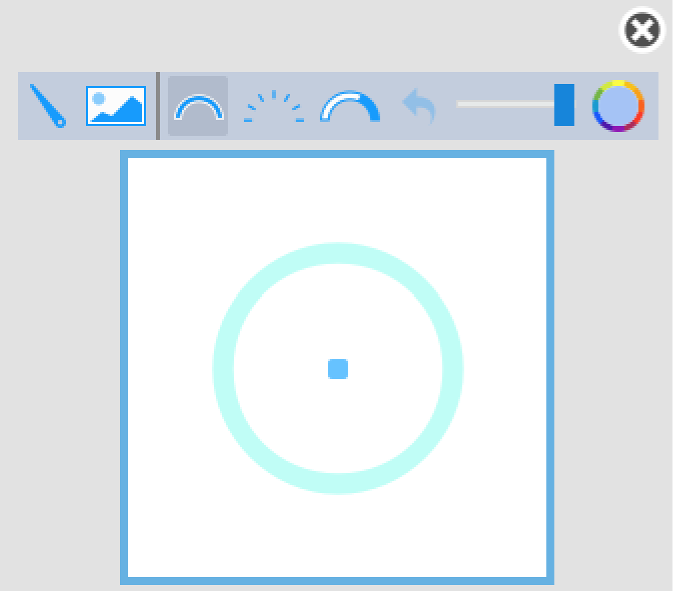
When you add a Custom Gauge block to your model, the block is preconfigured with a default design. You can use the preconfigured Custom Gauge block like you would other Dashboard blocks, or you can enter Custom Gauge edit mode to customize the appearance. The **Edit Custom Gauge** button appears above the Custom Gauge block when you pause on it.



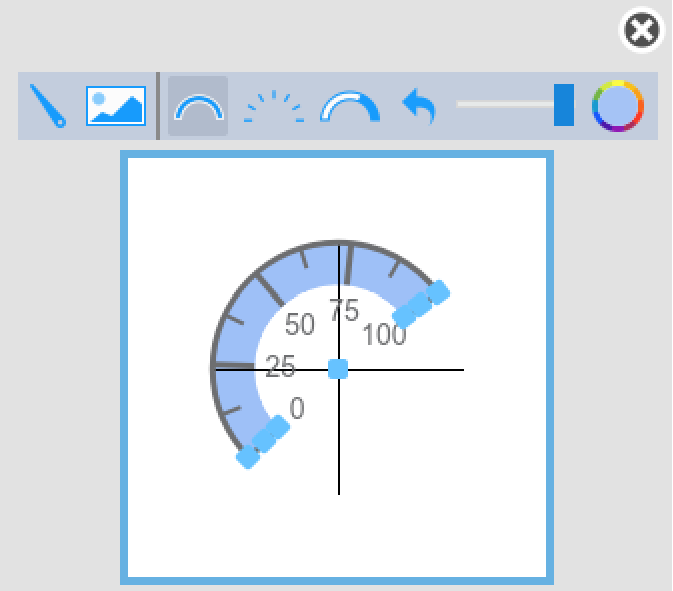
In Custom Gauge edit mode, the customization menu appears above the block. Separate images specify the appearance of the needle and the background. You can also customize the size of the dial arc and the color and transparency of the arc and tick marks. To build from the default design, you can individually select the needle image, background image, and arc to reposition and resize each feature. If you want to start from a blank canvas, you can remove the arc with the **Clear Arc** ↶ button. You can remove the needle and background images by clicking the **X** that appears when you pause on the needle or background image buttons.



The blank canvas for the Custom Gauge block shows a circle with its center marked to help guide alignment as you build your customized gauge. You can drag the center marker to align the center of your arc with the center of the arc in your background image. To add an image for the needle or the gauge background, click the button for the type of image you want to add. Then, select the image you want to use. When you add a gauge background image, the Custom Gauge block **Lock Aspect Ratio** parameter is selected. You can resize the block without distorting the image. If you want to change the aspect ratio of the block after adding a gauge background image, clear the **Lock Aspect Ratio** parameter.



To draw the arc for your gauge, click and drag along the guide circle. As you draw the arc, crosshairs appear to assist you with aligning the start and end points of the arc. After you release the mouse, you can continue to adjust the arc position and size. The arc options on the toolbar control the appearance of the arc, tick marks, and the value arc that indicates the value of the connected signal or parameter during simulation. The slider adjusts the transparency of the selected feature, and the color wheel allows you to specify the color. You can configure the arc as fully transparent when your background image includes the representation of the gauge face you want to use.

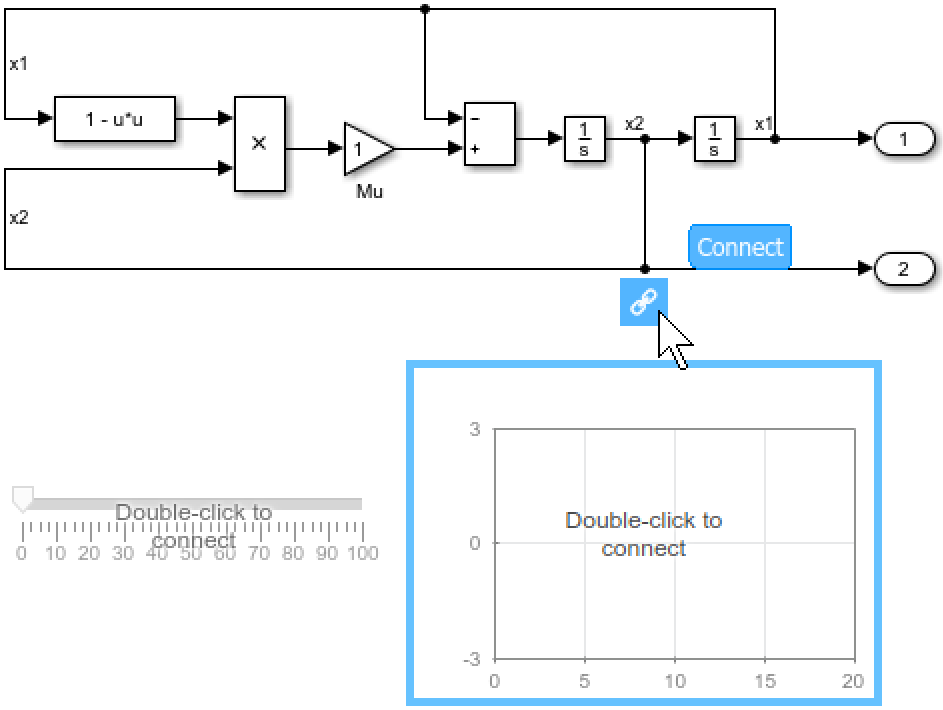


When you finish editing the appearance of your Custom Gauge block, click the **Exit** button in the upper-right of the model canvas or press **Esc** to exit Custom Gauge edit mode.

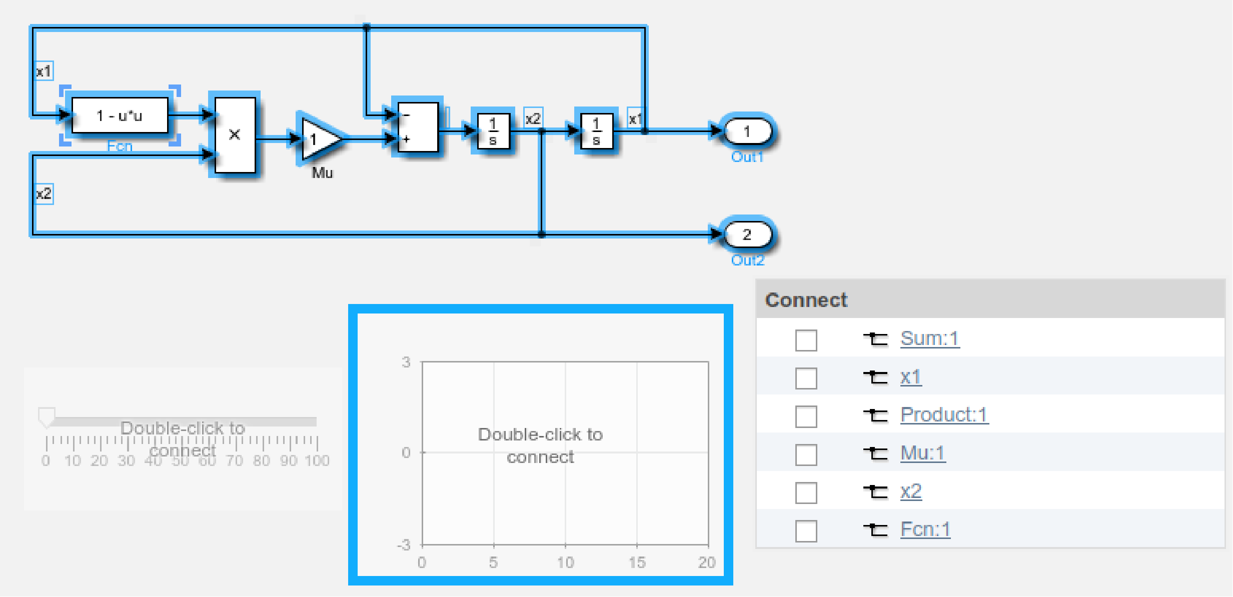
Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect	
□	Sum:1
□	x1
□	Product:1
□	Mu:1
□	x2
□	Fcn:1

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.

Parameters

`Connection` — Select a signal to connect and display

signal connection options

Select the signal to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the radio button next to the signal you want to display. Click **Apply** to connect the signal.

`Minimum` — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the arc. The minimum must be less than the value entered for the maximum.

`Maximum` — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the arc. The maximum must be greater than the value entered for the minimum.

`Tick Interval` — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the arc. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

`Scale Colors` — Color indications on gauge arc

colors for arc ranges

Color specifications for ranges on the arc. Press the **+** button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

`Lock Aspect Ratio` — Maintain background image aspect ratio

`on` (default) | `off`

Maintain the background image aspect ratio when resizing the block. By default, when you specify a background image for the block, the **Lock Aspect Ratio** check box is selected.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

Dashboard Scope

Trace signals during simulation
Library: Simulink / Dashboard

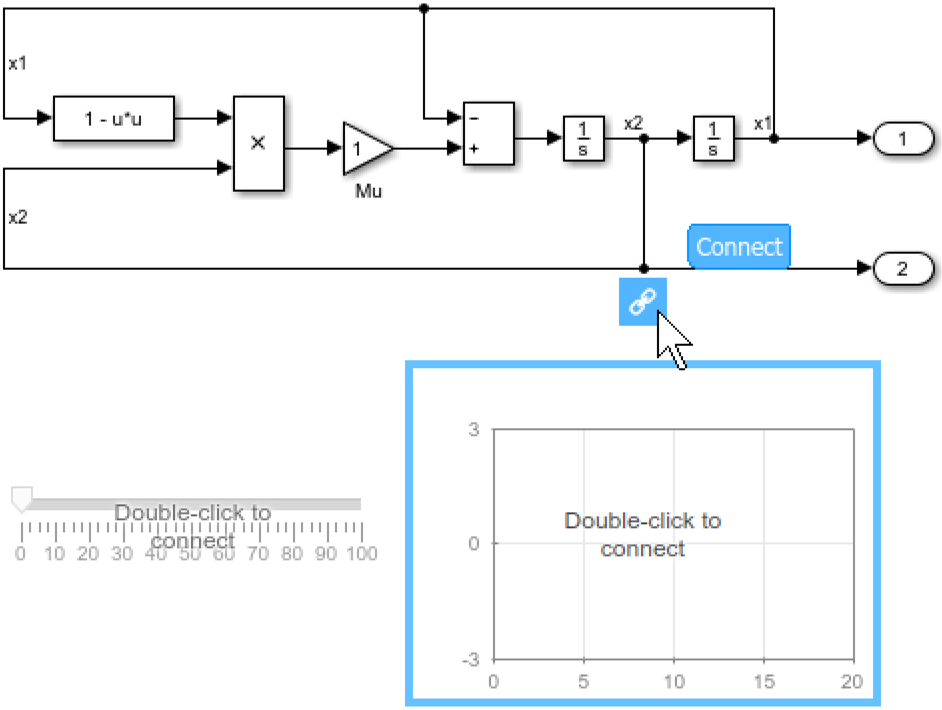
Description

The Dashboard Scope block shows connected signals during simulation on a scope display. You can use the Dashboard Scope block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Dashboard Scope block provides a complete picture of a signal's behavior over the course of the simulation. Use the Dashboard Scope block to display signals of any data type that Simulink supports, including enumerated data types. The Dashboard Scope block can display up to eight signals from a matrix or bus.

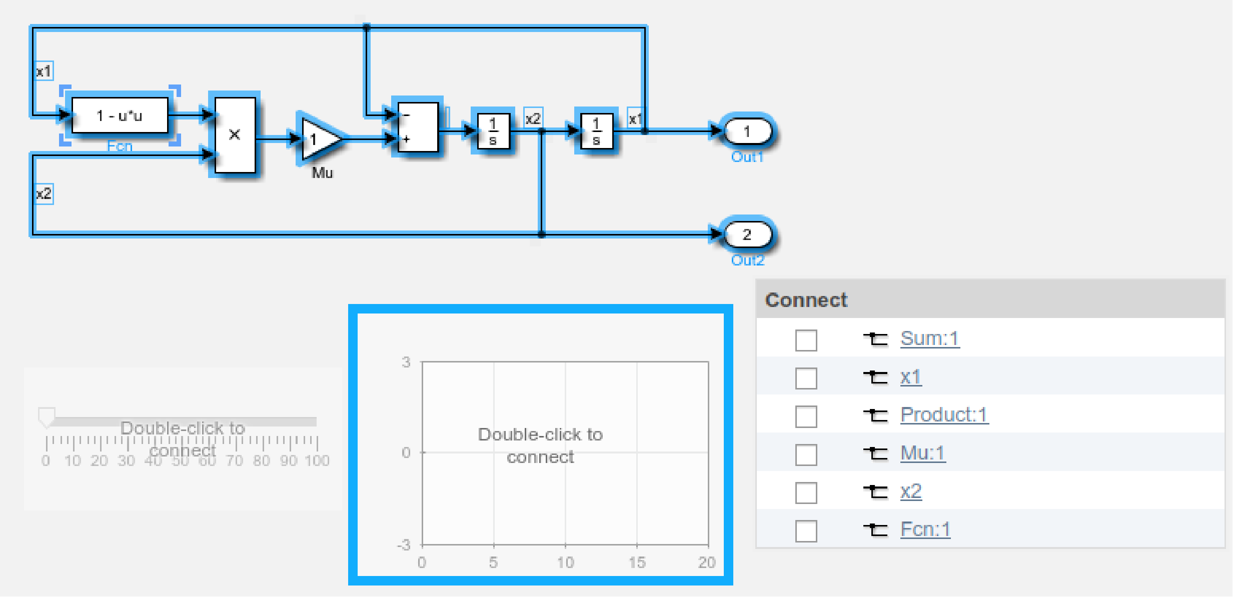
Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



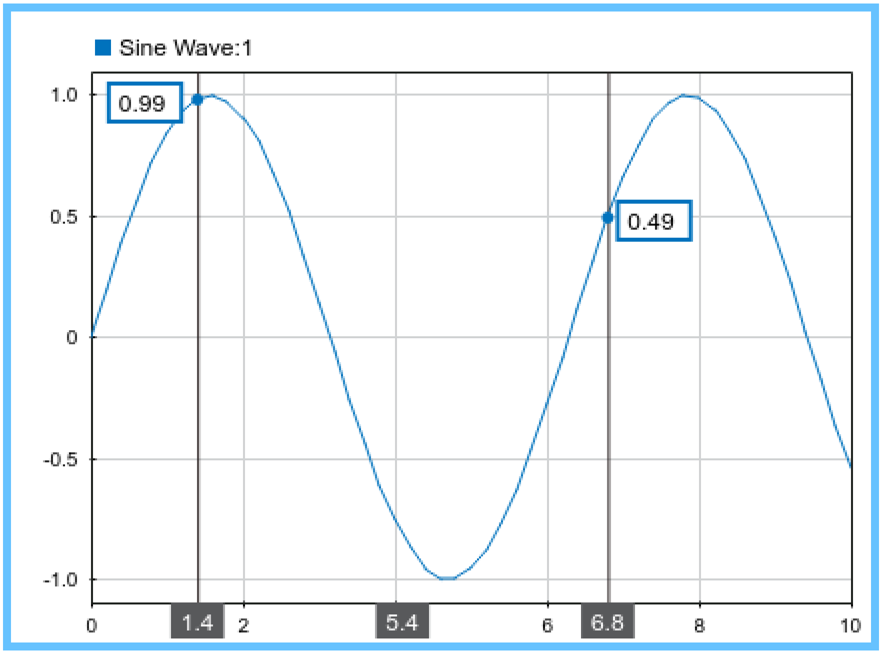
In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Data Cursors

You can add data cursors to the Dashboard Scope to inspect the displayed signals. The data cursors show when the Dashboard Scope block is selected. With the Dashboard Scope block selected, you can move cursors along the displayed signals to see the data values corresponding to each time sample. When you display two cursors, a box between the cursors along the time axis displays the time difference between the two cursors.



To add data cursors, right-click the Dashboard Scope block. Under the **Data Cursors** menu, select the number of cursors you want to add.

Zoom and Pan

You can also zoom and pan to inspect your signals. To change zoom and pan modes, right-click the Dashboard Scope block, and select the zoom or pan mode you want.

Complex Signals

The Dashboard Scope block displays complex signals according to their **Complex Format**. You can configure the **Complex Format** for a signal using the **Instrumentation Properties** dialog box, accessible when you right-click the logging badge for the signal and select **Properties**. A signal can have a **Complex Format** of **Real-Imaginary**, **Magnitude-Phase**, **Magnitude**, or **Phase**. When you set the **Complex Format** for a signal to **Real-Imaginary** or **Magnitude-Phase**, the Dashboard Scope block displays both components of the signal together. The real or magnitude component displays in the color indicated in the **Connection** table. The imaginary or phase component displays in a different shade of the color indicated in the **Connection** table.

Limitations

- You cannot save the block connections or properties in model files that use the `MDL` format.

  To save connections and properties, save the model file in the `SLX` format.
- Dashboard blocks cannot connect to blocks that are commented out.
- Dashboard blocks cannot connect to signals inside reference models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.

Parameters

`Connection` — Select signals to connect and display

signal connection options

Select one or more signals to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the check box next to the signal you want to display. Click **Apply** to connect the signal.

`Time Span` — Set horizontal axis span

auto (default) | scalar

A finite, real, double, scalar value that sets the time span of the scope display.

When **Time Span** is set to `auto`, the block sets its time span to the model's simulation stop time.

`Min` — Set y-axis minimum

-3 (default) | scalar

A finite, real, double, scalar value that sets the minimum of the vertical axis on the scope display.

The **Min** value must be less than the **Max** value.

`Max` — Set y-axis maximum
3 (default) | scalar

A finite, real, double, scalar value that sets the maximum of the vertical axis on the scope display.

The **Max** value must be greater than the **Min** value.

Legend — Set position of legend
'Top' (default) | 'Right' | 'Hide'

Options from the drop-down menu specify the position of the legend in the scope display. The legend shows the color chosen for each connected signal next to the signal's name.

`Scale axes limits at stop` — Autoscale axes limits when simulation finishes
on (default) | off

When on, performs a fit-to-view operation on the data displayed in the scope when the simulation stops.

`Show "Double-click to connect" message` — Show or hide message
on (default) | off

When on, shows instructional text if the block is not connected. When the block is not connected, you can turn this parameter off to hide the text.

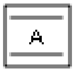
Data Store Memory

Define data store

Library: Simulink / Signal Routing



Description

The Data Store Memory block defines and initializes a named shared data store, which is a memory region usable by Data Store Read and Data Store Write blocks that specify the same data store name.

The location of the Data Store Memory block that defines a data store determines which Data Store Read and Data Store Write blocks can access the data store:

- If the Data Store Memory block is in the *top-level system*, Data Store Read and Data Store Write blocks anywhere in the model can access the data store.
- If the Data Store Memory block is in a *subsystem*, Data Store Read and Data Store Write blocks in the same subsystem or in any subsystem below it in the model hierarchy can access the data store.

Data Store Read or Data Store Write blocks cannot access a Data Store Memory block that is either in a model that contains a Model block or in a referenced model.

Do not include a Data Store Memory block in a For Each subsystem.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see:

- “Order Data Store Access”
- “Data Store Diagnostics”
- “Log Data Stores”

You can use `Simulink.Signal` objects in addition to, or instead of, Data Store Memory blocks to define data stores. A data store defined in the *base* workspace with a signal object is a *global* data store. Global data stores are accessible to every model, including all referenced models. See “Data Stores” for more information.

Parameters

Main

`Data store name` — Name for the data store

A (default) | character vector | string

Specify a name for the data store you are defining with this block. Data Store Read and Data Store Write blocks with the same name can read from, and write to, the data store initialized by this block. The name can represent a Data Store Memory block or a sign object defined to be a data store.

Programmatic Use
Block Parameter: `DataStoreName`
Type: character vector
Values: `'A' | ...`
Default: `'A'`

`Rename All` — Rename this data store throughout the model

button

Rename this data store everywhere the Data Store Read and Data Store Write blocks use it in a model.

Limitations

You cannot use **Rename All** to rename a data store if you:

- Use a `Simulink.Signal` object in a workspace to control the code generated for the data store
- Use a `Simulink.Signal` object instead of a Data Store Memory block to define the data store

You must instead rename the corresponding `Simulink.Signal` object from Model Explorer. For an example, see “Rename Data Store Defined by Signal Object”.

`Corresponding Data Store Read/Write blocks` — Path to connected Data Store Read/Write blocks

block path

List all the Data Store Read and Data Store Write blocks that have the same data store name as the current block, and that are in the current system or in any subsystem below it in the model hierarchy. Clicking a block path displays and highlights that block in your model.

Signal Attributes

`Initial value` — Initial value of data store

`0` (default) | scalar | vector | matrix | N-D array

Specify the initial value or values of the data store. The **Minimum** parameter specifies the minimum value for this parameter, and the **Maximum** parameter specifies the maximum value.

If you specify a nonscalar value and set **Dimensions** to `-1` (the default), the data store has the same dimensions as the array. Data that you write to the data store (by using Data Store Write blocks) must have these dimensions.

If you set the **Dimensions** parameter to a value other than `-1`, the initial value dimensions must match the dimensions that you specify, unless the initial value is a scalar or a MATLAB structure. If you specify a scalar, each element of the data store uses the scalar as the initial value. Use this technique to apply the same initial value (the scalar that you specify) to each element without manually matching the dimensions of the initial value with the dimensions of the data store.

To use this block to initialize a nonvirtual bus signal, specify the initial value as a MATLAB structure and set the model configuration parameter “Underspecified initialization detection” to `Simplified`. For more information about initializing nonvirtual bus signals using structures, see “Specify Initial Conditions for Bus Signals”.

Programmatic Use

Block Parameter: `InitialValue`
Type: character vector
Values: scalar | vector | matrix | N-D array
Default: `'0'`

`Minimum` — Minimum output value for range checking

`[]` (default) | scalar

Specify the minimum value that the block should output. The default value is `[]` (unspecified). This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink uses the minimum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: scalar
Default: `'[ ]'`

`Maximum` — Maximum output value for range checking

`[]` (default) | scalar

Specify the maximum value that the block should output. The default value is `[]` (unspecified). This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[ ]'`

`Data type` — Output data type

`Inherit: auto` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class name>`

Specify the output data type. You can set it to:

- A rule that inherits a data type (for example, `Inherit: auto`).
- The name of a built-in data type (for example, `single`).
- The name of a data type object (for example, a `Simulink.NumericType` object).
- An expression that evaluates to a data type (for example, `fixdt(1,16,0)`). Do not specify a bus object as the data type in an expression; use `Bus: <object name>` to specify a bus data type.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>'`

Default: `'Inherit: auto'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Dimensions (-1 to infer from Initial value)` — Dimensions of data store

`-1` (default) | scalar | vector | matrix

Dimensions of the data store. The default value, `-1`, enables you to set the dimensions of the data store by using the **Initial value** parameter. However, in this case, you cannot use scalar expansion with the initial value. You must specify the initial value by using an array that has the dimensions that you want.

If you use a value other than `-1`, specify the same dimensions as the dimensions of the **Initial value** parameter, unless you specify the initial value as a scalar (for scalar expansion) or a MATLAB structure. If the data store represents an array of buses, and if you use a MATLAB structure for the initial value, you can specify dimensions to initialize the array of buses with this structure.

Programmatic Use
Block Parameter: `Dimensions`
Type: character vector
Values: scalar | vector | matrix
Default: `'-1'`

`Interpret vector parameters as 1-D` — Interpret vectors as 1-D

`on` (default) | `off`

Specify that the data store interpret vector initial values as one-dimensional.

By default, MATLAB represents vector data as matrices, which have two dimensions. For example, MATLAB represents the vector `[1 2 3]` as a 1-by-3 matrix.

When you select this parameter, the data store represents vector data by using only one dimension instead of two. For example, if you specify an initial value of `[1 2 3]`, the data store stores a one-dimensional vector with three elements.

For more information, see “Determining the Output Dimensions of Source Blocks”.

Programmatic Use

Block Parameter: `VectorParams1D`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Signal type` — Complexity of data store values

`auto` (default) | `real` | `complex`

Specify the numeric type, real or complex, of the values in the data store.

Programmatic Use

Block Parameter: `SignalType`
Type: character vector
Values: `'auto' | 'real' | 'complex'`
Default: `'auto'`

`Share across model instances` — Allow Model blocks to read from the same data store

`off` (default) | `on`

In a single model reference hierarchy, when you use multiple Model blocks to refer to a model that contains a Data Store Memory block, by default, each instance of the referenced model (each Model block) reads from and writes to a separate copy of the data store. When you select **Share across model instances**, instead of interacting with a separate copy, all of the instances read from and write to the same data store.

When you set the model configuration parameter **Code interface packaging** to `Reusable function` to generate reentrant code from a model (Simulink Coder), a data store with **Share across model instances** selected appears in the code as a global symbol that the generated entry-point functions access directly. For example, a global symbol is a global variable or a field of a global structure variable. Therefore, each call that your code makes to the entry-point functions (each instance of the model) shares the data.

For an example, see “Share Data Store Between Instances of a Reusable Algorithm”. For more information, see “Share Data Among Referenced Model Instances”.

Programmatic Use
Block Parameter: `ShareAcrossModelInstances`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Data store name must resolve to Simulink signal object` — Require data store name resolve to Simulink signal object

`off` (default) | `on`

Specify that Simulink software, when compiling the model, searches the model and base workspace for a `Simulink.Signal` object having the same name, as described in "Symbol Resolution". If Simulink does not find such an object, the compilation stops with an error. Otherwise, Simulink compares the attributes of the signal object to the corresponding attributes of the Data Store Memory block. If the block and the object attributes are inconsistent, Simulink halts model compilation and displays an error.

Programmatic Use
Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Signal object class` — Custom storage class package

`Simulink.Signal` (default) | object of a class that is derived from `Simulink.Signal`

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder® software, custom storage classes do not affect the generated code.

For information about storage classes, see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder). For information about custom storage classes, see "Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements" (Embedded Coder).

Programmatic Use
Block Parameter: `StateSignalObject`
Type: character vector
Values: `'Simulink.Signal' | ...`
Default: `'Simulink.Signal'`

Storage class — Storage class for code generation

Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Volatile (Custom) | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | AutoScope (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Applies the storage class or custom storage class that you select from the list. For information about storage classes, see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder). For information about custom storage classes, see "Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements" (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

To programmatically set this parameter, use `StateStorageClass` or `StateSignalObject`. See "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder).

Programmatic Use

Block Parameter: `StateStorageClass`
Type: character vector
Values: `'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...`
Default: `'Auto'`

TypeQualifier — Storage type qualifier

'' (default) | const | volatile | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved

- Min and Max values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use
Block Parameter: `RTWStateStorageTypeQualifier`
Type: character vector
Values: `'' | 'const' | 'volatile' | ...`
Default: `''`

Diagnostics

`Detect Read Before Write` — Action when model attempts to read data before writing in current time step

`warning` (default) | `none` | `error`

Select the diagnostic action to take if the model attempts to read data from a data store to which it has not written data in this time step. See also the “Detect read before write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters** > **Diagnostics** > **Data Validity** pane.

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use
Block Parameter: `ReadBeforeWriteMsg`
Type: character vector
Values: `'none' | 'warning' | 'error'`
Default: `'warning'`

`Detect Write After Read` — Action when block attempts to write after reading in same time step

`warning` (default) | `none` | `error`

Select the diagnostic action to take if the model attempts to write data to the data store after previously reading data from it in the current time step. See also the “Detect write after read” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters** > **Diagnostics** > **Data Validity** pane.

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use
Block Parameter: `WriteAfterReadMsg`
Type: character vector
Values: `'none' | 'warning' | 'error'`
Default: `'warning'`

`Detect Write After Write` — Action when model writes twice in same time step

`warning` (default) | `none` | `error`

Select the diagnostic action to take if the model attempts to write data to the data store twice in succession in the current time step. See also the “Detect write after write” diagnostic in the **Data Store Memory block** section of the **Model Configuration Parameters** > **Diagnostics** > **Data Validity** pane.

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use
Block Parameter: `WriteAfterWriteMsg`
Type: character vector
Values: `'none' | 'warning' | 'error'`
Default: `'warning'`

Logging

`Log data store data` — Log data store data

`off` (default) | `on`

Select this option to save the values of this signal to the MATLAB workspace during simulation. See “Signal Logging” for details.

Programmatic Use
Block Parameter: `DataLogging`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Logging name` — Name associated with logged signal data

`Use data store name` (default) | `Custom`

Use this pair of controls, consisting of a list box and an edit field, to specify the name associated with logged signal data.

Simulink uses the signal name as its logging name by default. To specify a custom logging name, select `Custom` from the list box and enter the custom name in the adjacent edit field.

Programmatic Use
Block Parameter: `DataLoggingNameMode`
Type: character vector
Values: `'SignalName' | 'Custom'`
Default: `''`

Note If you set `DataLoggingNameMode` to `Custom`, you must specify the name associated with logged signal data using the `DataLoggingName` parameter.

Block Parameter: `DataLoggingName`
Type: character vector
Values: character vector
Default: `''`

`Limit data points to last` — Discard all but the last N data points

`5000` | non-zero integer

Discard all but the last `N` data points, where `N` is the number that you enter in the adjacent edit field. For more information, see “Log Data Stores”.

Programmatic Use
Block Parameter: `DataLoggingMaxPoints`
Type: character vector
Values: nonzero integer

Default: `'5000'`

Decimation — Log every Nth data point

2 (default) | integer

Log every `N`th data point, where `N` is the number that you enter in the adjacent edit field. For example, suppose that your model uses a fixed-step solver with a step size of `0.1` s. If you select this option and accept the default decimation value (2), Simulink records data points for this signal at times `0.0`, `0.2`, `0.4`, and so on. For more information, see “Log Data Stores”.

Programmatic Use
Block Parameter: `DataLoggingLimitDataPoints`
Type: character vector
Values: non-zero integer
Default: `'2'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

To generate PLC code for a model that uses a Data Store Memory block, first define a `Simulink.Signal` in the base workspace. Then in the **Signal Attributes** tab of the block parameters, set the data store name to resolve to that of the `Simulink.Signal` object.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

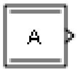
Introduced before R2006a

Data Store Read

Read data from data store
Library: Simulink / Signal Routing



Description

The Data Store Read block copies data from the named data store to its output. More than one Data Store Read block can read from the same data store.

The data store from which the data is read is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. See “Order Data Store Access” and “Data Store Diagnostics” for details.

Ports

Output

`Port_1` — Values from specified data store
scalar | vector | matrix | N-D array

Values from the specified data store, output with the same data type and dimensions as in the data store. The block supports both real and complex signals. You can choose whether to output the entire data store, or only selected elements from the data store.

You can use arrays of buses with a Data Store Read block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Arguments

`Data store name` — Name of data store from which this block reads

`A` (default) | name of data store

Specifies the name of the data store from which this block reads data. The adjacent drop-down list provides the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Read block or at higher levels. The list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the list or enter the name directly in the edit field.

When Simulink software compiles the model containing this block, Simulink searches the model upwards from this block's level for a Data Store Memory block having the specified data store name. If Simulink software does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. See “Symbol Resolution” for more information about the search path.

If Simulink finds the signal object, it creates a hidden Data Store Memory block at the model's root level having the properties specified by the signal object and an initial value of `0`. If Simulink software finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error.

Programmatic Use
Block Parameter: `DataStoreName`
Type: character vector
Values: data store name
Default: `'A'`

`Data store memory block` — Data Store Memory block name

block path

This field lists the Data Store Memory block that initialized the store from which this block reads.

`Data store write blocks` — Corresponding Data Store Write blocks

block path

This field lists the path to all Data Store Write blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Click any entry in this list to highlight the corresponding block in your model.

`Sample time` — Sample time

-1 (default) | scalar | vector

The sample time, which controls when the block reads from the data store. A value of `-1` indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'-1'`

Element Selection

`Elements in the array (Signals in the bus)` — Elements in the associated data store

no default

List of elements in the associated data store. For data stores containing arrays, you can read the whole data store, or you can specify one or more elements of the data store. For bus signals, lists the elements in the associated data store. The list displays the maximum dimensions for each element, in parentheses.

You can select an element and then use one of the following approaches:

- Click **Select>>** to display that element (and all its subelements) in the **Selected element(s)** list.
- Use the **Specify element(s) to select** edit box to specify the elements that you want to select for reading. Then click **Select>>**.

To refresh the display and reflect modifications to the array or bus used in the data store, click **Refresh**.

Dependencies

The prompt for this section (**Elements in the array** or **Signals in the bus**) depends on the type of data in the data store.

Programmatic Use

Block Parameter: `DataStoreElements`
Type: character vector
Values: pound-delimited list of elements (See “Specification using the command line”.)
Default: `''`

`Specify element(s) to select` — MATLAB expression defining the elements to select

no default

Enter a MATLAB expression to define the specific element that you want to read. For example, for a data store named `DSM` that has maximum dimensions of `[3,5]`, you could enter expressions such as `DSM(2,4)` or `DSM([1 3],2)` in the edit box and then click **Select>>**.

To apply the element selection, click **OK** or **Apply**.

Programmatic Use

Block Parameter: `DataStoreElements`
Type: character vector
Values: pound-delimited list of elements (See “Specification using the command line”.)
Default: `''`

`Selected element(s)` — List of selected elements

no default

Displays the elements that you select from the data store. The Data Store Read block icon displays a port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

Programmatic Use

Block Parameter: `DataStoreElements`
Type: character vector
Values: pound-delimited list of elements (See “Specification using the command line”.)

Default: `''`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

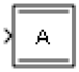
Data Store Write

Write data to data store

Library: Simulink / Signal Routing



Description

The Data Store Write block copies the value at its input to the named data store. Each write operation performed by a Data Store Write block writes over the data store, replacing the previous contents.

The data store to which this block writes is determined by the location of the Data Store Memory block or signal object that defines the data store. For more information, see “Data Stores” and Data Store Memory. The size of the data store is set by the signal object or the Data Store Memory block that defines and initializes the data store. Each Data Store Write block that writes to that data store must write the same amount of data.

More than one Data Store Write block can write to the same data store. However, if two Data Store Write blocks attempt to write to the same data store during the same simulation step, results are unpredictable.

Obtaining correct results from data stores requires ensuring that data store reads and writes occur in the expected order. For details, see “Order Data Store Access” and “Data Store Diagnostics”.

You can log the values of a local or global data store data variable for all the steps in a simulation. For details, see “Log Data Stores”.

Ports

Input

`Port_1` — Values to write to data store

scalar | vector | matrix | N-D array

Values to write to the specified data store. The Data Store Write block accepts a real or complex signal.

You can use an array of buses with a Data Store Write block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

To assign a subset of the bus or matrix elements to the associated data store, use the **Element Assignment** pane. The Data Store Write block icon reflects the elements that you specify. For details, see “Accessing Specific Bus and Matrix Elements”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Arguments

`Data store name` — Name of data store from which this block writes

A (default) | name of data store

Specifies the name of the data store to which this block writes data. The adjacent drop-down list provides the names of Data Store Memory blocks that exist at the same level in the model as the Data Store Write block or at higher levels. The drop-down list also includes all `Simulink.Signal` objects in the base and model workspaces. To change the name, select a name from the drop-down or enter the name directly in the edit field.

When Simulink software compiles the model containing this block, Simulink searches the model upwards from this block's level for a Data Store Memory block having the specified data store name. If Simulink does not find such a block, it searches the model workspace and the MATLAB workspace for a `Simulink.Signal` object having the same name. If Simulink finds neither the Data Store Memory block nor the signal object, it halts the compilation and displays an error. See “Symbol Resolution” for more information about the search path.

If Simulink finds a signal object, it creates a hidden Data Store Memory block at the model's root level having the properties specified by the signal object and an initial value set to a matrix of zeros. The dimensions of that matrix are inherited from the `Dimensions` property of the signal object.

Programmatic Use
Block Parameter: `DataStoreName`
Type: character vector
Values: data store name
Default: `'A'`

`Data store memory block` — Data Store Memory block name

block path

This field lists the Data Store Memory block that initialized the store to which this block writes.

`Data store read blocks` — Corresponding Data Store Read blocks

block path

This field lists the path to all Data Store Read blocks with the same data store name as this block that are in the same (sub)system or in any subsystem below it in the model hierarchy. Click any entry in this list to highlight the corresponding block in your model.

`Sample time` — Sample time

-1 (default) | scalar | vector

The sample time, which controls when the block writes to the data store. A value of `-1` indicates that the sample time is inherited. See “Specify Sample Time” for more information.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'-1'`

Element Assignment

`Elements in the array (Signals in the bus)` — Elements in the associated data store

no default

List of elements in the associated data store. For data stores with arrays, you can write the whole data store, or you can assign one or more elements to the whole data store. For data stores with a bus data type, you can expand the tree to view the bus elements. The list displays the maximum dimensions for each element, in parentheses.

You can select an element and then use one of the following approaches:

- Click **Select>>** to display that element (and all its subelements) in the **Selected element(s)** list.
- Use the **Specify element(s) to select** edit box to specify the elements that you want to select for writing. Then click **Select>>**.

To refresh the display and reflect modifications to the array or bus used in the data store, click **Refresh**.

Dependencies

The prompt for this section (**Elements in the array** or **Signals in the bus**) depends on the type of data in the data store.

Programmatic Use
Block Parameter: `DataStoreElements`
Type: character vector
Values: pound-delimited list of elements (See “Specification using the command line”.)
Default: `''`

`Specify element(s) to assign` — MATLAB expression defining the elements to assign

no default

Enter a MATLAB expression to define the specific element that you want to write. For example, for a data store named `DSM` that has maximum dimensions of `[3,5]`, you could enter expressions such as `DSM(2,4)` or `DSM([1 3],2)` in the edit box. Then click **Select>>**.

To apply the element selection, click **OK** or **Apply**.

Programmatic Use
Block Parameter: `DataStoreElements`
Type: character vector
Values: pound-delimited list of elements (See “Specification using the command line”.)
Default: `''`

`Assigned element(s)` — List of selected elements

no default

Displays the elements that you selected for assignment. The Data Store Write block icon displays a port for each element that you specify.

To change the order of bus or matrix elements in the list, select the element in the list and click **Up** or **Down**. Changing the order of the elements in the list changes the order of the ports. To remove an element, click **Remove**.

Programmatic Use
Block Parameter: `DataStoreElements`
Type: character vector
Values: pound-delimited list of elements (See “Specification using the command line”.)
Default: `''`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Data Type Conversion

Convert input signal to specified data type

Library: Simulink / Commonly Used Blocks
Simulink / Signal Attributes

Description

The Data Type Conversion block converts an input signal of any Simulink data type to the data type that you specify.

Note To control the output data type by specifying block parameters, or to inherit a data type from a downstream block, use the Data Type Conversion block. To inherit a data type from a different signal in the model, use the Data Type Conversion Inherited block.

Convert Fixed-Point Signals

When you convert between fixed-point data types, the **Input and output to have equal** parameter controls block behavior. This parameter does not change the behavior of the block when:

- The input and output do not have a fixed-point data type.
- The input or output has a fixed-point data type with trivial scaling.

For more information about fixed-point numbers, see “Fixed-Point Numbers in Simulink” (Fixed-Point Designer).

To convert a signal from one data type to another by attempting to preserve the real-world value of the input signal, select `Real World Value (RWV)`, the default setting. The block accounts for the limits imposed by the scaling of the input and output and attempts to generate an output of equal real-world value.

To change the real-world value of the input signal by performing a scaling reinterpretation of the stored integer value, select `Stored Integer (SI)`. Within the limits of the specified data types, the block attempts to preserve the stored integer value of the signal during conversion. A best practice is to specify input and output data types using the same word length and signedness. Doing so ensures that the block changes only the scaling of the signal. Specifying a different signedness or word length for the input and output could produce unexpected results such as range loss or unexpected sign extensions. For an example, see “Convert Data Types in Simulink Models” on page 14-136.

If you select `Stored Integer (SI)`, the block does not perform a lower-level bit reinterpretation of a floating-point input signal. For example, if the input is `single` and has value `5`, the bits that store the input in memory are given in hexadecimal by the following command.

```
num2hex(single(5))
```

```
40a00000
```

However, the Data Type Conversion block does not treat the stored integer value as `40a00000`, but instead as the real-world value, `5`. After conversion, the stored integer value of the output is `5`.

Cast Enumerated Signals

Use a Data Type Conversion block to cast enumerated signals as follows:

1. To cast a signal of enumerated type to a signal of any numeric type.

   The underlying integers of all enumerated values input to the Data Type Conversion block must be within the range of the numeric type. Otherwise, an error occurs during simulation.
2. To cast a signal of any integer type to a signal of enumerated type.

   The value input to the Data Type Conversion block must match the underlying value of an enumerated value. Otherwise, an error occurs during simulation.

   You can enable the **Saturate on integer overflow** parameter so that Simulink uses the default value of the enumerated type when the value input to the block does not match the underlying value of an enumerated value. See “Type Casting for Enumerations” (Simulink Coder).

You cannot use a Data Type Conversion block in these cases:

- To cast a noninteger numeric signal to an enumerated signal.
- To cast a complex signal to an enumerated signal, regardless of the data types of the real and imaginary parts of the complex signal.

See “Simulink Enumerations” for information on working with enumerated types.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The input can be any real- or complex-valued signal. If the input is real, the output is real. If the input is complex, the output is complex. The block converts the input signal to the **Output data type** you specify.

When you are converting fixed-point data types, use the **Input and output to have equal** parameter to determine whether the conversion happens based on the `Real World Value (RWV)` or `Stored Integer (SI)` value of the signal. For more information, see “Convert Fixed-Point Signals” on page 1-284.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Output signal

scalar | vector | matrix | N-D array

Output signal, converted to the data type you specify, with the same dimensions as the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

`Output minimum` — Minimum output value for range checking

[ ] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Output data type

`Inherit: Inherit via back propagation` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class name>` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'`, `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'Enum: <class name>''<data type expression>'`
Default: `'Inherit: Inherit via back propagation'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Input and output to have equal` — Constraint for converting fixed-point data types

`Real World Value (RWV)` (default) | `Stored Integer (SI)`

Specify which type of input and output must be equal, in the context of fixed-point data representation.

- `Real World Value (RWV)` — Specifies the goal of making the `Real World Value (RWV)` of the input equal to the `Real World Value (RWV)` of the output.
- `Stored Integer (SI)` — Specifies the goal of making the `Stored Integer (SI)` value of the input equal to the `Stored Integer (SI)` value of the output.

Programmatic Use
Block Parameter: `ConvertRealWorld`
Type: character vector
Values: `'Real World Value (RWV)' | 'Stored Integer (SI)'`
Default: `'Real World Value (RWV)'`

`Integer rounding mode` — Specify the rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Choose one of these rounding modes.

`Ceiling`

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

See Also

For more information, see “Rounding” (Fixed-Point Designer).

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Data Type Conversion Inherited

Convert from one data type to another using inherited data type and scaling

Library: Simulink / Signal Attributes

Description

The Data Type Conversion Inherited block forces dissimilar data types to be the same. The first input is used as the reference signal. The second input, **u**, is converted to the reference type by inheriting the data type and scaling information. (For a description of the port order for various block orientations, see “Port Location After Rotating or Flipping”.)

Inheriting the data type and scaling provides these advantages:

- It makes reusing existing models easier.
- It allows you to create new fixed-point models with less effort since you can avoid the detail of specifying the associated parameters.

Ports

Input

`Port_1` — Reference signal
scalar | vector | matrix | N-D array

Reference signal, defining the data type used to convert input signal **u**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

u — Input signal to convert
scalar | vector | matrix | N-D array

Input signal to convert to the reference data type, specified as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

y — Output signal
scalar | vector | matrix | N-D array

Output is the input signal **u**, converted to the reference data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

`Input and Output to have equal` — Constraint for converting fixed-point data types
`Real World Value (RWV)` (default) | `Stored Integer (SI)`

Specify which type of input and output must be equal, in the context of fixed-point data representation.

- `Real World Value (RWV)` — Specifies the goal of making the `Real World Value (RWV)` of the input equal to the `Real World Value (RWV)` of the output.
- `Stored Integer (SI)` — Specifies the goal of making the `Stored Integer (SI)` value of the input equal to the `Stored Integer (SI)` value of the output.

Programmatic Use
Block Parameter: `ConvertRealWorld`
Type: character vector
Values: `'Real World Value (RWV)' | 'Stored Integer (SI)'`
Default: `'Real World Value (RWV)'`

`Integer rounding mode` — Rounding mode for fixed-point operations
`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate to max or min when overflows occur` — Method of overflow action

`off` (default) | `on`

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `DoSatur`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

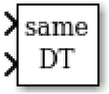
Data Type Duplicate

Force all inputs to same data type

Library: Simulink / Signal Attributes



Description

The Data Type Duplicate block forces all inputs to have the same data type. Other attributes of input signals, such as dimension, complexity, and sample time, are independent.

You can use the Data Type Duplicate block to check for consistency of data types among blocks. If all signals do not have the same data type, the block returns an error message.

The Data Type Duplicate block is typically used such that one signal to the block controls the data type for all other blocks. The other blocks are set to inherit their data types via backpropagation.

The block can also be useful in a user created library. These library blocks can be placed in any model, and the data type for all library blocks are configured according to the usage in the model. To create a library block with more complex data type rules than duplication, use the Data Type Propagation block.

Ports

Input

`Port_1` — First input signal

scalar | vector | matrix | N-D array

First input signal, specified as a scalar, vector, matrix, or N-D array. If all signals do not have the same data type, the block returns an error message.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

`Port_N` — Nth input signal

scalar | vector | matrix | N-D array

Nth input signal, specified as a scalar, vector, matrix, or N-D array. If all signals do not have the same data type, the block returns an error message.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

`Number of input ports` — Number of block inputs

2 (default) | real-valued positive integer

Specify the number of inputs to this block as a real-valued positive integer.

Programmatic Use
Block Parameter: `NumInputPorts`
Type: character vector
Values: real-valued positive integer
Default: `'2'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

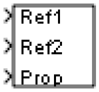
Data Type Propagation

Set data type and scaling of propagated signal based on information from reference signals

Library: Simulink / Signal Attributes



Description

The Data Type Propagation block allows you to control the data type and scaling of signals in your model. You can use this block along with fixed-point blocks that have their **Output data type** parameter configured to `Inherit: Inherit via back propagation`.

The block has three inputs: **Ref1** and **Ref2** are the reference inputs, while the **Prop** input back-propagates the data type and scaling information gathered from the reference inputs. This information is then passed on to other fixed-point blocks.

The block provides many choices for propagating data type and scaling information. For example, you can use:

- The number of bits from the **Ref1** reference signal or the number of bits from widest reference signal
- The range from the **Ref2** reference signal or the range of the reference signal with the greatest range
- A bias of zero, regardless of the biases used by the reference signals
- The precision of the reference signal with the least precision

You specify how data type information is propagated using the **Propagated data type** parameter:

- If you select `Specify via dialog`, then you manually specify the data type via the **Propagated data type** edit field.

- If you select `Inherit via propagation rule`, then you must use the parameters described in “Parameters” on page 1-304.

You specify how scaling information is propagated using the **Propagated scaling** parameter:

- If you select `Specify via dialog`, then you manually specify the scaling via the **Propagated scaling** edit field.
- If you select `Inherit via propagation rule`, then you must use the parameters described in “Parameters” on page 1-304.

After you use the information from the reference signals, you can apply a second level of adjustments to the data type and scaling. To do so, use individual multiplicative and additive adjustments. This flexibility has various uses. For example, if you are targeting a DSP, then you can configure the block so that the number of bits associated with a multiply and accumulate (MAC) operation is twice as wide as the input signal, and has a specific number of guard bits added to it.

The Data Type Propagation block also provides a mechanism to force the computed number of bits to a useful value. For example, if you are targeting a 16-bit micro, then the target C compiler is likely to support sizes of only 8 bits, 16 bits, and 32 bits. The block forces these three choices to be used. For example, suppose that the block computes a data type size of 24 bits. Since 24 bits is not directly usable by the target chip, the signal is forced up to 32 bits, which is natively supported.

There is also a method for dealing with floating-point reference signals. This method makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

The Data Type Propagation block allows you to set up libraries of useful subsystems that are properly configured based on the connected signals. Without this data type propagation process, subsystems from a library are unlikely to work as desired with most integer or fixed-point signals. Manual intervention would be required to configure the data type and scaling. In many situations, this block can eliminate the manual intervention.

Precedence Rules

The precedence of the dialog box parameters decreases from top to bottom. Also:

- Double-precision reference inputs have precedence over all other data types.
- Single-precision reference inputs have precedence over integer and fixed-point data types.
- Multiplicative adjustments are carried out before additive adjustments.
- The number of bits is determined before the precision or positive range is inherited from the reference inputs.
- `PosRange` is one bit higher than the exact maximum positive range of the signal.
- The computed number-of-bits are promoted to the smallest allowable value that is greater than or equal to the computation. If none exists, then the block returns an error.

Ports

Input

`Ref1` — First reference signal

scalar | vector | matrix | N-D array

First reference signal, from which to gather data type and scaling information.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Ref2` — Second reference signal

scalar | vector | matrix | N-D array

Second reference signal from which to gather data type and scaling information.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Prop` — Propagated data type and scaling

data type and scaling

Data type and scaling information, back-propagated to the model. After the block gathers data type and scaling information from the reference signals, you can apply a second level of adjustments to the data type and scaling. To do so, specify individual multiplicative and additive adjustments in the block dialog box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Propagated Type

`1. Propagated data type` — Mode of specifying propagated data type

`Inherit via propagation rule` (default) | `Specify via dialog`

Specify whether to propagate the data type via the dialog box, or inherit the data type from the reference signals.

Dependencies

Setting this parameter to `Specify via dialog` enables the **1.1. Propagated data type (e.g. fixdt(1,16), fixdt('single'))**.

Programmatic Use
Block Parameter: `PropDataTypeMode`
Type: character vector
Values: `'Specify via dialog' | 'Inherit via propagation rule'`
Default: `'Inherit via propagation rule'`

`1.1. Propagated data type (e.g. fixdt(1,16), fixdt('single'))` — Propagated data type

`fixdt(1,16)` (default) | data type string

Specify the data type to propagate.

Dependencies

To enable this parameter, set **1. Propagated data type** to `Specify via dialog`.

Programmatic Use
Block Parameter: `PropDataTypeMode`
Type: character vector
Values: `'Specify via dialog' | 'Inherit via propagation rule'`
Default: `'Inherit via propagation rule'`

1.1 If any reference input is double, output is — Output data type when a reference input is double

double (default) | single

Specify the output data type as single or double. This parameter makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

Dependencies

To enable this parameter, set **Propagated data type** to Inherit via propagation rule.

Programmatic Use

Block Parameter: IfRefDouble
Type: character vector
Values: 'double' | 'single'
Default: 'double'

1.2 If any reference input is single, output is — Output data type when a reference input is single

single (default) | double

Specify the output data type as single or double. This parameter makes it easier to create designs that are easily retargeted between fixed-point chips and floating-point chips.

Dependencies

To enable this parameter, set **Propagated data type** to Inherit via propagation rule.

Programmatic Use

Block Parameter: IfRefSingle
Type: character vector
Values: 'double' | 'single'
Default: 'single'

1.3 Is-Signed — Signedness of propagated data type

IsSigned1 or IsSigned2 (default) | IsSigned1 | IsSigned2 | TRUE | FALSE

Specify the sign of **Prop** as one of the following values.

Parameter Value	Description
IsSigned1	**Prop** is a signed data type if **Ref1** is a signed data type.
IsSigned2	**Prop** is a signed data type if **Ref2** is a signed data type.
IsSigned1 or IsSigned2	**Prop** is a signed data type if either **Ref1** or **Ref2** are signed data types.
TRUE	**Ref1** and **Ref2** are ignored, and Prop is always a signed data type.
FALSE	**Ref1** and **Ref2** are ignored, and Prop is always an unsigned data type.

For example, if the **Ref1** signal is `ufix(16)`, the **Ref2** signal is `sfix(16)`, and the **IsSigned** parameter is `IsSigned1 or IsSigned2`, then **Prop** is forced to be a signed data type.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit via propagation rule`.

Programmatic Use

Block Parameter: `IsSigned`
Type: character vector
Values: `'IsSigned1' | 'IsSigned2' | 'IsSigned1 or IsSigned2' | 'TRUE' | 'FALSE'`
Default: `'IsSigned1 or IsSigned2'`

1.4.1 `Number-of-bits: Base` — Number of bits for the base of the propagated data type

`max([NumBits1 NumBits2])` (default) | `NumBits1` | `NumBits2` | `min([NumBits1 NumBits2])` | `NumBits1+NumBits2`

Specify the number of bits used by **Prop** for the base data type as one of the following values.

Parameter Value	Description
NumBits1	The number of bits for **Prop** is given by the number of bits for **Ref1**.

Parameter Value	Description
NumBits2	The number of bits for **Prop** is given by the number of bits for **Ref2**.
max([NumBits1 NumBits2])	The number of bits for **Prop** is given by the reference signal with largest number of bits.
min([NumBits1 NumBits2])	The number of bits for **Prop** is given by the reference signal with smallest number of bits.
NumBits1+NumBits2	The number of bits for **Prop** is given by the sum of the reference signal bits.

For more information about the base data type, refer to Targeting an Embedded Processor (Fixed-Point Designer).

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit via propagation rule`.

Programmatic Use
Block Parameter: `NumBitsBase`
Type: character vector
Values: `'NumBits1' | 'NumBits2' | 'max([NumBits1 NumBits2])' | 'min([NumBits1 NumBits2])' | 'NumBits1+NumBits2'`
Default: `'max([NumBits1 NumBits2])'`

1.4.2 Number-of-bits: Multiplicative adjustment — Number of bits for multiplicative adjustment of propagated data type

1 (default) | positive integer

Specify the number of bits used by **Prop** by including a multiplicative adjustment that uses a data type of `double`. For example, suppose that you want to guarantee that the number of bits associated with a multiply and accumulate (MAC) operation is twice as wide as the input signal. To do this, set this parameter to 2.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit via propagation rule`.

Programmatic Use
Block Parameter: `NumBitsMult`

Type: character vector
Values: positive integer
Default: `'1'`

1.4.3 `Number-of-bits: Additive adjustment` — Number of bits for additive adjustment of propagated data type

`0` (default) | positive integer

Specify the number of bits used by **Prop** by including an additive adjustment that uses a data type of `double`. For example, if you are performing multiple additions during a MAC operation, the result could overflow. To prevent overflow, you can associate guard bits with the propagated data type. To associate four guard bits, you specify the value `4`.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit via propagation rule`.

Programmatic Use
Block Parameter: `NumBitsAdd`
Type: character vector
Values: scalar
Default: `'0'`

1.4.4 `Number-of-bits: Allowable final values` — Allowable number of bits in propagated data type

`'1:128'` (default) | scalar or vector of positive integers

Force the computed number of bits used by **Prop** to a useful value. For example, if you are targeting a processor that supports only 8 bits, 16 bits, and 32 bits, then you configure this parameter to `[8,16,32]`. The block always propagates the smallest specified value that fits. If you want to allow all fixed-point data types, you would specify the value `1:128`.

Dependencies

To enable this parameter, set **Propagated data type** to `Inherit via propagation rule`.

Programmatic Use
Block Parameter: `NumBitsAllowFinal`
Type: character vector
Values: scalar or vector of positive integers

Default: '1:128'

Propagated Scaling

2. `Propagated scaling` — Propagated scaling mode

`Inherit via propagation rule` (default) | `Specify via dialog` | `Obtain via best precision`

Choose to propagate the scaling via the dialog box, inherit the scaling from the reference signals, or calculate the scaling to obtain best precision.

Programmatic Use
Block Parameter: `PropScalingMode`
Type: character vector
Values: `Inherit via propagation rule` | `Specify via dialog` | `Obtain via best precision`
Default: `Inherit via propagation rule`

2.1. `Propagated scaling (Slope or [Slope Bias])` — Slope or slope and bias

`2^-10` | `Slope` | `[Slope Bias]`

Specify the scaling as either a slope or a slope and bias.

Dependencies

To enable this parameter, set **Propagated scaling** to `Specify via dialog`.

Programmatic Use
Block Parameter: `PropScaling`
Type: character vector
Values: `Slope` | `[Slope Bias]`
Default: '2^-10'

2.1. `Values used to determine best precision scaling` — Values to constrain precision

`[5 -7]` (default)

Specify any values to be used to constrain the precision, such as the upper and lower limits on the propagated input. Based on the data type, the block selects a scaling such that these values can be represented with no overflow error and minimum quantization error.

Dependencies

To enable this parameter, set **Propagated scaling** to `Obtain via best precision`.

Programmatic Use
Block Parameter: `ValuesUsedBestPrec`
Type: character vector
Values: vector of values
Default: `'[5 -7]'`

2.1.1. Slope: Base — Slope for base of the propagated data type

`min([Slope1 Slope2])` (default) | `Slope1` | `Slope2` | `min([Slope1 Slope2])` | `max([Bias1 Bias2])` | `Slope1*Slope2` | `Slope1/Slope2` | `PosRange1` | `PosRange2` | `max([PosRange1 PosRange2])` | `min([PosRange1 PosRange2])` | `PosRange1*PosRange2` | `PosRange1/PosRange2`

Specify the slope used by **Prop** for the base data type as one of the following values.

Parameter Value	Description
`Slope1`	The slope of **Prop** is given by the slope of **Ref1**.
`Slope2`	The slope of **Prop** is given by the slope of **Ref2**.
`max([Slope1 Slope2])`	The slope of **Prop** is given by the maximum slope of the reference signals.
`min([Slope1 Slope2])`	The slope of **Prop** is given by the minimum slope of the reference signals.
`Slope1*Slope2`	The slope of **Prop** is given by the product of the reference signal slopes.
`Slope1/Slope2`	The slope of **Prop** is given by the ratio of the **Ref1** slope to the **Ref2** slope.
`PosRange1`	The range of **Prop** is given by the range of **Ref1**.
`PosRange2`	The range of **Prop** is given by the range of **Ref2**.
`max([PosRange1 PosRange2])`	The range of **Prop** is given by the maximum range of the reference signals.
`min([PosRange1 PosRange2])`	The range of **Prop** is given by the minimum range of the reference signals.
`PosRange1*PosRange2`	The range of **Prop** is given by the product of the reference signal ranges.

Parameter Value	Description
PosRange1/PosRange2	The range of **Prop** is given by the ratio of the **Ref1** range to the **Ref2** range.

You control the precision of **Prop** with Slope1 and Slope2, and you control the range of **Prop** with PosRange1 and PosRange2. Also, PosRange1 and PosRange2 are one bit higher than the maximum positive range of the associated reference signal.

Dependencies

To enable this parameter, set **Propagated scaling** to Inherit via propagation rule.

Programmatic Use
Block Parameter: SlopeBase
Type: character vector
Values: 'Slope1' | 'Slope2' | 'max([Slope1 Slope2])' | 'min([Slope1 Slope2])' | 'Slope1*Slope2' | 'Slope1/Slope2' | 'PosRange1' | 'PosRange2' | 'max([PosRange1 PosRange2])' | 'min([PosRange1 PosRange2])' | 'PosRange1*PosRange2' | 'PosRange1/PosRange2'
Default: 'min([Slope1 Slope2])'

2.1.2. Slope: Multiplicative adjustment — Slope of multiplicative adjustment of propagated data type

1 (default) | scalar

Specify the slope used by **Prop** by including a multiplicative adjustment that uses a data type of double. For example, if you want 3 bits of additional precision (with a corresponding decrease in range), the multiplicative adjustment is 2^-3.

Dependencies

To enable this parameter, set **Propagated scaling** to Inherit via propagation rule.

Programmatic Use
Block Parameter: SlopeMult
Type: character vector
Values: scalar
Default: '1'

2.1.3. Slope: Additive adjustment — Slope of additive adjustment of propagated data type

0 (default) | scalar

Specify the slope used by **Prop** by including an additive adjustment that uses a data type of `double`. An additive slope adjustment is often not needed. The most likely use is to set the multiplicative adjustment to `0`, and set the additive adjustment to force the final slope to a specified value.

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit via propagation rule`.

Programmatic Use
Block Parameter: `SlopeAdd`
Type: character vector
Values: scalar
Default: `'0'`

2.2.1. Bias: Base — Base bias for Prop

Bias1 (default) | Bias2 | max([Bias1 Bias2]) | min([Bias1 Bias2]) | Bias1*Bias2 | Bias1/Bias2 | Bias1+Bias2 | Bias1-Bias2

Specify the bias used by **Prop** for the base data type. The parameter values are described as follows:

Parameter Value	Description
`Bias1`	The bias of **Prop** is given by the bias of **Ref1**.
`Bias2`	The bias of **Prop** is given by the bias of **Ref2**.
`max([Bias1 Bias2])`	The bias of **Prop** is given by the maximum bias of the reference signals.
`min([Bias1 Bias2])`	The bias of **Prop** is given by the minimum bias of the reference signals.
`Bias1*Bias2`	The bias of **Prop** is given by the product of the reference signal biases.
`Bias1/Bias2`	The bias of **Prop** is given by the ratio of the **Ref1** bias to the **Ref2** bias.
`Bias1+Bias2`	The bias of **Prop** is given by the sum of the reference biases.

Parameter Value	Description
`Bias1-Bias2`	The bias of **Prop** is given by the difference of the reference biases.

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit via propagation rule`.

Programmatic Use
Block Parameter: `BiasBase`
Type: character vector
Values: `'Bias1' | 'Bias2' | 'max([Bias1 Bias2])' | 'min([Bias1 Bias2])' | 'Bias1*Bias2' | 'Bias1/Bias2' | 'Bias1+Bias2' | 'Bias1-Bias2'`
Default: `'Bias1'`

2.2.2. `Bias: Multiplicative adjustment` — Multiplicative bias for propagated data type

`1` (default) | scalar

Specify the bias used by Prop by including a multiplicative adjustment that uses a data type of `double`.

This parameter is visible only when you set **Propagated scaling** to `Inherit via propagation rule`.

Programmatic Use
Block Parameter: `BiasMult`
Type: character vector
Values: scalar
Default: `'0'`

2.3.2. `Bias: Additive adjustment` — Additive bias for propagated data type

`0` (default) | scalar

Specify the bias used by **Prop** by including an additive adjustment that uses a data type of `double`.

If you want to guarantee that the bias associated with **Prop** is zero, configure both the multiplicative adjustment and the additive adjustment to `0`.

Dependencies

To enable this parameter, set **Propagated scaling** to `Inherit via propagation rule`.

Programmatic Use
Block Parameter: `BiasAdd`
Type: character vector
Values: scalar
Default: `'0'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

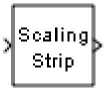
Data Type Scaling Strip

Remove scaling and map to built in integer
Library: Simulink / Signal Attributes



Description

The Data Type Scaling Strip block strips the scaling off a fixed-point signal. It maps the input data type to the smallest built-in data type that has enough data bits to hold the input. The stored integer value of the input is the value of the output. The output always has nominal scaling (slope = 1.0 and bias = 0.0), so the output does not distinguish between real world value and stored integer value.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix. The block strips the scaling off a fixed-point input signal, and outputs the stored integer value with the smallest possible built-in data type.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Output

Port_1 — Input signal mapped to built-in data type
scalar | vector | matrix

Stored integer value of the input signal with the smallest possible built-in data type, and the same dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

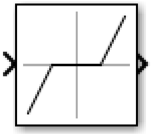
Dead Zone

Provide region of zero output

Library: Simulink / Discontinuities



Description

The Dead Zone block generates zero output within a specified region, called its dead zone. You specify the lower limit (LL) and upper limit (UL) of the dead zone as the **Start of dead zone** and **End of dead zone** parameters. The block output depends on the input (U) and the values for the lower and upper limits.

Input	Output
U >= LL and U <= UL	Zero
U > UL	U – UL
U < LL	U – LL

Ports

Input

Port_1 — Input signal
scalar | vector

Input signal to the dead-zone algorithm.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Output

`Port_1` — Output signal

scalar | vector

Output signal after the dead-zone algorithm is applied to the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Start of dead zone` — Specify the lower bound of the dead zone

`'-0.5'` (default) | scalar | vector

Specify dead zone lower limit. Set the value for **Start of dead zone** less than or equal to **End of dead zone**. When the input value is less than **Start of dead zone**, then the block shifts the output value down by the **Start of dead zone** value.

Programmatic Use
Block Parameter: `LowerValue`
Type: character vector
Value: scalar or vector less than or equal to `UpperValue`.
Default: `'-0.5'`

`End of dead zone` — Specify the upper limit of the dead zone

`'0.5'` (default) | scalar | vector

Specify dead zone upper limit. Set the value for **End of dead zone** greater than or equal to **Start of dead zone**. When the input value is greater than **End of dead zone**, then the block shifts the output value down by the **End of dead zone** value.

Programmatic Use
Block Parameter: `UpperValue`
Type: character vector
Value: scalar or vector greater than or equal to `LowerValue`.
Default: `'0.5'`

`Saturate on integer overflow` — Choose the behavior when integer overflow occurs

`on` (default) | boolean

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Value: `'off'` | `'on'`
Default: `'on'`

`Treat as gain when linearizing` — Specify the gain value

`On` (default) | boolean

The linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the commands to treat the gain as 1. Clear the box to have the commands treat the gain as 0.

Programmatic Use
Block Parameter: `LinearizeAsGain`
Type: character vector
Value: `'off'` | `'on'`
Default: `'on'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

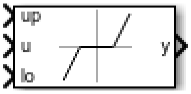
Backlash | Dead Zone Dynamic

Introduced before R2006a

Dead Zone Dynamic

Provide dynamic region of zero output
Library: Simulink / Discontinuities



Description

The Dead Zone Dynamic block generates a region of zero output based on dynamic input signals that specify the upper and lower limit. The block output depends on the input **u**, and the values of the input signals **up** and **lo**.

Input	Output
`u >= lo` and `u <= up`	Zero
`u > up`	`u` – `up`
`u < lo`	`u` – `lo`

The Dead Zone Dynamic block is a masked subsystem and does not have any parameters.

Ports

Input

u — Input signal
scalar | vector

Input signal to the dead zone algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`lo` — Lower limit for the dead zone
scalar | vector

Dynamic value providing the lower bound of the region of zero output. When the input is less than **lo** then the output value is shifted down by value of **lo**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

up — Upper limit for the dead zone
scalar

Dynamic value providing the upper bound of the region of zero output. When the input is greater than **up** then the output value is shifted down by value of **up**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

y — Output signal
scalar | vector

Output signal after the dynamic dead zone algorithm is applied to the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information on HDL code generation, see Dead Zone Dynamic.

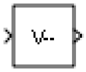
Decrement Real World

Decrease real-world value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math: Increment - Decrement



Description

The Decrement Real World block decreases the real-world value of the signal by one. Overflows always wrap.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector | matrix

Output is the real-world value of the input signal decreased by one. Overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Block Characteristics

Data Types	double | single | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

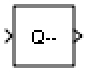
Decrement Stored Integer

Decrease stored integer value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math: Increment - Decrement



Description

The Decrement Stored Integer block decreases the stored integer value of a signal by one.

Floating-point signals also decrease by one, and overflows always wrap.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output is the stored integer value of the input signal decreased by one. Floating-point signals also decrease by one, and overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

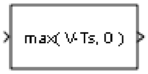
Decrement Time To Zero

Decrease real-world value of signal by sample time, but only to zero

Library: Simulink / Additional Math & Discrete / Additional Math: Increment - Decrement



Description

The Decrement Time To Zero block decreases the real-world value of the signal by the sample time, `Ts`. The output never goes below zero.

Limitations

The Decrement Time To Zero block works only with fixed sample rates and does not work inside a triggered subsystem.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output is the real-world value of the input signal decreased by the sample time, `Ts`. The output never goes below zero. The output has the same data type and dimensions as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

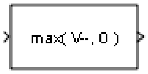
Decrement To Zero

Decrease real-world value of signal by one, but only to zero

Library: Simulink / Additional Math & Discrete / Additional Math: Increment - Decrement



Description

The Decrement To Zero block decreases the real-world value of the signal by one. The output never goes below zero.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output is the real-world value of the input signal decreased by one. The output never goes below zero. The output has the same data type and dimensions as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

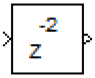
Delay

Delay input signal by fixed or variable sample periods

Library: Simulink / Commonly Used Blocks
Simulink / Discrete



Description

The Delay block outputs the input of the block after a delay. The block determines the delay time based on the value of the **Delay length** parameter. The block supports:

- Variable delay length
- Specification of the initial condition from an input port
- State storage
- Using a circular buffer instead of an array buffer for state storage
- Resetting the state to the initial condition with an external reset signal
- Controlling execution of the block at every time step with an external enable signal

The initial block output depends on several factors such as the **Initial condition** parameter and the simulation start time. For more information, see “Initial Block Output” on page 1-340. The **External reset** parameter determines if the block output resets to the initial condition on triggering. The **Show enable port** parameter determines if the block execution is controlled in every time step by an external enable signal.

Initial Block Output

The output in the first few time steps of the simulation depends on the block sample time, the delay length, and the simulation start time. The block supports specifying or inheriting discrete sample times to determine the time interval between samples. For more information, see “Specify Sample Time”.

The table shows the Delay block output for the first few time steps with these settings. The block inherits a discrete sample time as `[*Tsampling*,*Toffset*]`, where *`Tsampling`* is the sampling period and *`Toffset`* is the initial time offset. *n* is the value of the **Delay length** parameter and *`Tstart`* is the simulation start time for the model

Simulation Time Range	Block Output
(*Tstart*) to (*Tstart + Toffset*)	Zero
(*Tstart + Toffset*) to (*Tstart + Toffset + n * Tsampling*)	**Initial condition** parameter
After (*Tstart + Toffset + n * Tsampling*)	Input signal

Variable-Size Support

The Delay block provides the following support for variable-size signals:

- The data input port u accepts variable-size signals. The other input ports do not accept variable-size signals.
- The output port has the same signal dimensions as the data input port u for variable-size inputs.

The rules that apply to variable-size signals depend on the input processing mode of the Delay block.

Input Processing Mode	Rules for Variable-Size Signal Support
`Elements as channels (sample based)`	• The signal dimensions change only during state reset when the block is enabled. • The initial condition must be scalar.
`Columns as channels (frame based)`	• No support
`Inherited` (where input is a sample-based signal)	• The signal dimensions change only during state reset when the block is enabled. • The initial condition must be scalar.
`Inherited` (where input is a frame-based signal)	• The channel size changes only during state reset when the block is enabled. • The initial condition must be scalar. • The frame size must be constant.

Bus Support

The Delay block provides the following support for bus signals:

- The data input port u accepts virtual and nonvirtual bus signals. The other input ports do not accept bus signals.
- The output port has the same bus type as the data input port u for bus inputs.
- Buses work with:
  - Sample-based and frame-based processing
  - Fixed and variable delay length
  - Array and circular buffers

To use a bus signal as the input to a Delay block, specify the initial condition on the dialog box. The initial condition cannot come from the input port x0. Support for virtual and nonvirtual buses depends on the initial condition that you specify and whether the **State name** parameter is empty or not.

Initial Condition	State Name	
	Empty	Not Empty
Zero	Virtual and nonvirtual bus support	Nonvirtual bus support only
Nonzero scalar	Virtual and nonvirtual bus support	No bus support
Nonscalar	No bus support	No bus support
Structure	Virtual and nonvirtual bus support	Nonvirtual bus support only
Partial structure	Virtual and nonvirtual bus support	Nonvirtual bus support only

Ports

Input

u — Data input signal

scalar | vector

Input data signal delayed according to parameters settings.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

d — Delay length

scalar

Delay length specified as inherited from an input port. Enabled when you select the **Delay length: Source** parameter as `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Enable` — External enable signal

scalar

Enable signal that enables or disables execution of the block. To create this port, select the **Show enable port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`External reset` — External reset signal

scalar

External signal that resets execution of the block to the initial condition. To create this port, select the **External reset** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`x0` — Initial condition

scalar | vector

Initial condition specified as inherited from an input port. Enabled when you select the **Initial Condition: Source** parameter as `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector

Output signal that is the input signal delayed by the length of time specified by the parameter **Delay length**. The initial value of the output signal depends on several conditions. See “Initial Block Output” on page 1-340.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

`Delay length` — Delay length

`Dialog` (default) | `Input port`

Specify whether to enter the delay length directly on the dialog box (fixed delay) or to inherit the delay from an input port (variable delay).

- If you set **Source** to `Dialog`, enter the delay length in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies a delay length for the `d` input port. You can also specify its maximum value by specifying the parameter **Upper limit**.

Specify the scalar delay length as a real, non-negative integer. An out-of-range or non-integer value in the dialog box (fixed delay) returns an error. An out-of-range value from an input port (variable delay) casts it into the range. A noninteger value from an input port (variable delay) truncates it to the integer.

Programmatic Use
Block Parameter: `DelayLengthSource`
Type: character vector
Values: `'Dialog'` | `'Input port'`
Default: `'Dialog'`
Block Parameter: `DelayLength`
Type: character vector
Values: scalar
Default: `'2'`
Block Parameter: `DelayLengthUpperLimit`
Type: character vector
Values: scalar

Default: `'100'`

`Initial condition` — Initial condition

`Dialog` (default) | `Input port`

Specify whether to enter the initial condition directly on the dialog box or to inherit the initial condition from an input port.

- If you set **Source** to `Dialog`, enter the initial condition in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies an initial condition for the `x0` input port.

Simulink converts offline the data type of **Initial condition** to the data type of the input signal `u` using a round-to-nearest operation and saturation.

Note When **State name must resolve to Simulink signal object** is selected on the **State Attributes** pane, the block copies the initial value of the signal object to the **Initial condition** parameter. However, when the source for **Initial condition** is `Input port`, the block ignores the initial value of the signal object.

Programmatic Use

Block Parameter: `InitialConditionSource`
Type: character vector
Values: `'Dialog'` | `'Input port'`
Default: `'Dialog'`
Block Parameter: `InitialCondition`
Type: character vector
Values: scalar
Default: `'0.0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use

Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Use circular buffer for state` — Circular buffer for storing state

`off` (default) | `on`

Select to use a circular buffer for storing the state in simulation and code generation. Otherwise, an array buffer stores the state.

Using a circular buffer can improve execution speed when the delay length is large. For an array buffer, the number of copy operations increases as the delay length goes up. For a circular buffer, the number of copy operations is constant for increasing delay length.

If one of the following conditions is true, an array buffer always stores the state because a circular buffer does not improve execution speed.

- For sample-based signals, the delay length is 1.
- For frame-based signals, the delay length is no larger than the frame size.

Programmatic Use

Block Parameter: `UseCircularBuffer`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Prevent direct feedthrough` — Prevent direct feedthrough

`off` (default) | `on`

Select to increase the delay length from zero to the lower limit for the **Input processing** mode.

- For sample-based signals, increase the minimum delay length to 1.
- For frame-based signals, increase the minimum delay length to the frame length.

Selecting this check box prevents direct feedthrough from the input port, `u`, to the output port. However, this check box cannot prevent direct feedthrough from the initial condition port, `x0`, to the output port.

Dependency

To enable this parameter, set **Delay length: Source** to `Input port`.

Programmatic Use

Block Parameter: `PreventDirectFeedthrough`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Remove delay length check in generated code` — Remove delay length out-of-range check

`off` (default) | `on`

Select to remove code that checks for out-of-range delay length.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range delay length.	For code efficiency
Cleared	Generated code includes conditional statements to check for out-of-range delay length.	For safety-critical applications

Dependency

To enable this parameter, set **Delay length: Source** to `Input port`.

Programmatic Use

Block Parameter: `RemoveDelayLengthCheckInGeneratedCode`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Diagnostic for delay length` — Diagnostic checks for delay length

`None` (default) | `Warning` | `Error`

Specify whether to produce a warning or error when the input `d` is less than the lower limit or greater than the **Delay length: Upper limit**. The lower limit depends on the setting for **Prevent direct feedthrough**.

- If the check box is cleared, the lower limit is zero.
- If the check box is selected, the lower limit is 1 for sample-based signals and frame length for frame-based signals.

Options for the diagnostic include:

- `None` — Simulink software takes no action.
- `Warning` — Simulink software displays a warning and continues the simulation.
- `Error` — Simulink software terminates the simulation and displays an error.

Dependency

To enable this parameter, set **Delay length: Source** to `Input port`.

Programmatic Use
Block Parameter: `DiagnosticForDelayLength`
Type: character vector
Values: `'None'` | `'Warning'` | `'Error'`
Default: `'None'`

`Show enable port` — Create enable port

`off` (default) | `on`

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is `0`. The value of the input is checked at the same time step as the block execution.

Programmatic Use
Block Parameter: `ShowEnablePort`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`External reset` — External state reset

`None` (default) | `Rising` | `Falling` | `Either` | `Level` | `Level hold`

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
`None`	No reset.
`Rising`	Reset on a rising edge.
`Falling`	Reset on a falling edge.
`Either`	Reset on either a rising or falling edge.
`Level`	Reset in either of these cases: • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
`Level hold`	Reset when the reset signal is nonzero at the current time step

Programmatic Use
Block Parameter: `ExternalReset`
Type: character vector
Values: `'None'` | `'Rising'` | `'Falling'` | `'Either'` | `'Level'` | `'Level hold'`
Default: `'None'`

`Sample time (-1 for inherited)` — Discrete interval between sample time hits

`-1` (default) | `scalar`

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. This block supports discrete sample time, but not continuous sample time.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Value: real scalar
Default: `'-1'`

State Attributes

`State name` — Unique name for block state

`''` (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use
Block Parameter: `StateName`
Type: character vector

Values: unique name
Default: `''`

`State name must resolve to Simulink signal object` — Require state name resolve to a signal object

`off` (default) | `on`

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Signal object class` — Custom storage class package name

`Simulink.Signal` (default) | `<StorageClass.PackageName>`

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: `StateSignalObject`
Type: character vector
Values: `'Simulink.Signal' | '<StorageClass.PackageName>'`

Default: `'Simulink.Signal'`

`Code generation storage class` — State storage class for code generation

`Auto` (default) | `Model default` | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer` | `BitField (Custom)` | `Model default` | `ExportToFile (Custom)` | `ImportFromFile (Custom)` | `FileScope (Custom)` | `AutoScope (Custom)` | `Struct (Custom)` | `GetSet (Custom)` | `Reusable (Custom)`

Select state storage class for code generation.

- `Auto` is the appropriate storage class for states that you do not need to interface to external code.
- *`StorageClass`* applies the storage class or custom storage class that you select from the list. For information about storage classes, see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder). For information about custom storage classes, see "Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements" (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use

Block Parameter: `StateStorageClass`
Type: character vector
Values: `'Auto' | 'SimulinkGlobal' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...`
Default: `'Auto'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`Yes`

Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Consider using the Model Discretizer to map these continuous blocks into discrete equivalents that support code generation. From a model, select **Analysis** > **Control Design** > **Model Discretizer**.

Not recommended for production code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see Delay.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Demux

Extract and output elements of virtual vector signal

Library: Simulink / Commonly Used Blocks
Simulink / Signal Routing

Description

The Demux block extracts the components of an input vector signal and outputs separate signals. The output signal ports are ordered from top to bottom. See “Mux Signals” for information about creating and decomposing vectors.

Ports

Input

`Port_1` — Accept nonbus vector signal to extract and output signals from
real or complex values of any nonbus data type supported by Simulink

Vector input signal from which the Demux block selects scalar signals or smaller vectors.

Output

`Port_1` — Output signals extracted from input vector signal
nonbus signal with real or complex values of any data type supported by Simulink

Output signals extracted from the input vector. The output signal ports are ordered from top to bottom. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

Parameters

`Number of outputs` — Number of outputs

2 (default) | scalar | vector

Specify the number and, optionally, the dimensionality of each output port. If you do not specify the dimensionality of the outputs, the block determines the dimensionality of the outputs.

The value can be a scalar specifying the number of outputs or a vector whose elements specify the widths of the block output ports. The block determines the size of its outputs from the size of the input signal and the value of the **Number of outputs** parameter.

If you specify a scalar for the **Number of outputs** parameter and all of the output ports are connected, as you draw a new signal line close to output side of a Demux block, Simulink adds a port and updates the **Number of outputs** parameter.

For an input vector of width `n`, here is what the block outputs.

Parameter Value	Block outputs...	Examples and Comments
`p = n`	`p` scalar signals	If the input is a three-element vector and you specify three outputs, the block outputs three scalar signals.
`p > n`	Error	This value is not supported.

`p < n`
`n mod p = 0`
	`p` vector signals each having `n/p` elements	If the input is a six-element vector and you specify three outputs, the block outputs three two-element vectors.

`p < n`
`n mod p = m`
	`m` vector signals each having `(n/p)+1` elements and `p-m` signals having `n/p` elements	If the input is a five-element vector and you specify three outputs, the block outputs two two-element vector signals and one scalar signal.

Parameter Value	Block outputs...	Examples and Comments
`[`p_1 p_2 `...` p_m`]` $p_1+p_2+...+p_m=n$ $p_i > 0$	m vector signals having widths p_1, p_2, ... p_m	If the input is a five-element vector and you specify `[3, 2]` as the output, the block outputs three of the input elements on one port and the other two elements on the other port.
An array that has one or more of m elements with a value of `-1`, which specifies that Simulink infers the size for the element. For example, suppose that you have a four-element array with a total width of 14 and you specify the parameter to be `[`p_1 p_2 `-1` p_4`]`. The value for the third element (the `-1` element) is `14 - (`p_1 + p_2 + p_4`)`	m vector signals	If p_i is greater than zero, the corresponding output has width p_i. If p_i is -1, the width of the corresponding output is computed dynamically.
`[`p_1 p_2 `...` p_m`]` $p_1+p_2+...+p_m!=n$ $p_i = > 0$	Error	This value is not supported

If you specify the number of outputs that is smaller than the number of input elements, the block distributes the elements as evenly as possible over the outputs. For examples, see “Extract Vector Elements and Distribute Evenly Across Outputs” on page 14-171 and “Extract Vector Elements Using the Demux Block” on page 14-172.

Programmatic Use
Block Parameter: `Outputs`
Type: scalar or vector
Values: character vector
Default: `{'2'}` or vector

`Display option` — Displayed block icon

`bar` (default) | `none`

By default, the block icon is a solid bar of the block foreground color. To display the icon as a box containing the block type name, select `none`.

Programmatic Use
Block Parameter: `Display option`
Type: character vector
Values: `'bar'` | `'none'`
Default: `'bar'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block has a single, default HDL architecture. See Demux.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

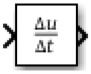
Derivative

Output time derivative of input
Library: Simulink / Continuous



Description

The Derivative block approximates the derivative of the input signal *u* with respect to the simulation time *t*. You obtain the approximation of

$$\frac{du}{dt},$$

by computing a numerical difference $\Delta u/\Delta t$, where Δu is the change in input value and Δt is the change in time since the previous simulation (major) time step.

This block accepts one input and generates one output. The initial output for the block is zero.

The precise relationship between the input and output of this block is:

$$y(t) = \frac{\Delta u}{\Delta t} = \left.\frac{u(t) - u(T_{previous})}{t - T_{previous}}\right| t > T_{previous},$$

where *t* is the current simulation time and $T_{previous}$ is the time of the last output time of the simulation. The latter is the same as the time of the last major time step.

The Derivative block output might be sensitive to the dynamics of the entire model. The accuracy of the output signal depends on the size of the time steps taken in the simulation. Smaller steps allow for a smoother and more accurate output curve from this block. However, unlike with blocks that have continuous states, the solver does not take smaller steps when the input to this block changes rapidly. Depending on the dynamics of the driving signal and model, the output signal of this block might contain unexpected fluctuations. These fluctuations are primarily due to the driving signal output and solver step size.

Because of these sensitivities, structure your models to use integrators (such as Integrator blocks) instead of Derivative blocks. Integrator blocks have states that allow solvers to adjust the step size and improve simulation accuracy. See “Circuit Model” for an example of choosing the best-form mathematical model to avoid using Derivative blocks in your models.

If you must use the Derivative block with a variable step solver, set the solver maximum step size to a value such that the Derivative block can generate answers with adequate accuracy. To determine this value, you might need to repeatedly run the simulation using different solver settings.

If the input to this block is a discrete signal, the continuous derivative of the input exhibits an impulse when the value of the input changes. Otherwise, it is 0. Alternatively, you can define the discrete derivative of a discrete signal using the difference of the last two values of the signal:

$$y(k) = \frac{1}{\Delta t}(u(k) - u(k-1))$$

.

Taking the *z*-transform of this equation results in:

$$\frac{Y(z)}{u(z)} = \frac{1 - z^{-1}}{\Delta t} = \frac{z-1}{\Delta t \cdot z}.$$

The Discrete Derivative block models this behavior. Use this block instead of the Derivative block to approximate the discrete-time derivative of a discrete signal.

Ports

Input

`Port_1` — Input signal

real scalar or vector

Signal to be differentiated, specified as a real scalar or vector.

Data Types: `double`

Output

`Port_1` — Time derivative of input signal
real scalar or vector

Time derivative of input signal, specified as a real scalar or vector. The input signal is differentiated with respect to time as:

$$y(t) = \frac{\Delta u}{\Delta t} = \left.\frac{u(t) - u(T_{previous})}{t - T_{previous}}\right| t > T_{previous},$$

where t is the current simulation time and $T_{previous}$ is the time of the last output time of the simulation. The latter is the same as the time of the last major time step.

Data Types: `double`

Parameters

`Coefficient c in the transfer function approximation s/(c*s + 1) used for linearization` — Specify the time constant *c* to approximate the linearization of your system
`inf` (default)

The exact linearization of the Derivative block is difficult because the dynamic equation for the block is $y = \dot{u}$, which you cannot represent as a state-space system. However, you can approximate the linearization by adding a pole to the Derivative block to create a transfer function $s/(c*s+1)$. The addition of a pole filters the signal before differentiating it, which removes the effect of noise.

The default value `inf` corresponds to a linearization of `0`.

Tips

- As a best practice, change the value of c to $\frac{1}{f_b}$, where f_b is the break frequency of the filter.
- The parameter must be a finite positive value.

Programmatic Use
Block Parameter: `CoefficientInTFapproximation`
Type: character vector, string
Values: `'inf'`
Default: `'inf'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Consider using the Model Discretizer to map the continuous blocks into discrete equivalents that support code generation. From a model, select **Analysis** > **Control Design** > **Model Discretizer** to access the Model Discretizer

Not recommended for production code.

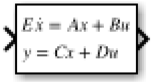
Descriptor State-Space

Model linear implicit systems

Library: Simulink / Continuous



Description

The Descriptor State-Space block allows you to model linear implicit systems that can be expressed in the form $E\dot{x} = Ax + Bu$ where *E* is the mass matrix of the system. When *E* is nonsingular and therefore invertible, the system can be written in its explicit form $\dot{x} = E^{-1}Ax + E^{-1}Bu$ and modeled using the State-Space block.

When the mass matrix *E* is singular, one or more derivatives of the dependent variables of the system are not present in the equations. These variables are called algebraic variables. Differential equations that contain such algebraic variables are called differential algebraic equations. Their state space representation is of the form

$$\begin{aligned} E\dot{x} &= Ax + Bu \\ y &= Cx + Du \end{aligned}$$

where the variables have the following meanings:

- *x* is the state vector
- *u* is the input vector
- *y* is the output vector

Ports

Input

`Input 1` — Input signal

scalar | vector

Real-valued input vector of type `double` whose width is the number of columns in the **B** and **D** matrices.

Data Types: `double`

Output

`Output 1` — Output vector

scalar | vector

Real-valued input vector of type `double` whose width is the number of rows in the **C** and **D** matrices.

Data Types: `double`

Parameters

E — Mass matrix

1 (default) | scalar | matrix | sparse matrix

Specify the mass matrix *E* as a real-valued *n*-by-*n* matrix, where *n* is the number of states in the system. **E** must be the same size as **A**. **E** can be singular or non-singular.

Programmatic Use
Block Parameter: `E`
Type: character vector, string
Values: scalar | matrix
Default: `'1'`

A — Matrix coefficient, A

1 (default) | scalar | matrix | sparse matrix

Specify the matrix coefficient *A* as a real-valued *n*-by-*n* matrix, where *n* is the number of states in the system. **A** must be the same size as **E**.

Programmatic Use
Block Parameter: `A`
Type: character vector, string
Values: scalar | matrix
Default: `'1'`

`B` — Matrix coefficient, B

1 (default) | scalar | vector | matrix | sparse matrix

Specify the matrix coefficient *B* as a real-valued *n*-by-*m* matrix, where *n* is the number of states in the system and *m* is the number of inputs.

Programmatic Use
Block Parameter: `B`
Type: character vector, string
Values: scalar | vector | matrix
Default: `'1'`

`C` — Matrix coefficient, C

1 (default) | scalar | vector | matrix | sparse matrix

Specify the matrix coefficient *C* as a real-valued *r*-by-*n* matrix, where *n* is the number of states in the system and *r* is the number of outputs.

Programmatic Use
Block Parameter: `C`
Type: character vector, string
Values: scalar | vector | matrix
Default: `'1'`

`D` — Matrix coefficient, D

1 (default) | scalar | vector | matrix | sparse matrix

Specify the matrix coefficient *D* as a real-valued *r*-by-*m* matrix, where *r* is the number of outputs of the system and *m* is the number of inputs to the system.

Programmatic Use
Block Parameter: `D`
Type: character vector, string
Values: scalar | vector | matrix

Default: `'1'`

`Initial conditions` — Initial state vector

`0` (default) | scalar | vector

Specify the initial state vector.

Limitations

The initial conditions of this block cannot be `inf` or `NaN`.

Programmatic Use

Block Parameter: `X0`
Type: character vector
Values: scalar | vector
Default: `'0'`

`Direct feedthrough` — Set output signal dependency on input

true (default) | false

Specify whether the output of the block directly depends on the input signal. Use this parameter for systems having more than 500 continuous states in order to speed up simulation. For systems with 500 continuous states or less, Simulink automatically determines this setting.

Programmatic Use

Block Parameter: `DirectFeedthrough`
Type: character vector, string
Values: 'True' | 'False'
Default: `'True'`

`Absolute tolerance` — Absolute tolerance for computing block states

`auto` (default) | scalar | vector

Absolute tolerance for computing block states, specified as a positive, real-valued, scalar or vector. To inherit the absolute tolerance from the Configuration Parameters, specify `auto` or `-1`.

- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

- If you enter `auto` or –1, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.

Programmatic Use
Block Parameter: `AbsoluteTolerance`
Type: character vector, string
Values: `'auto'` | `'-1'` | any positive real-valued scalar or vector
Default: `'auto'`

`State Name (e.g., 'position')` — Assign unique name to each state

`' '` (default) | `'position'` | `{'a', 'b', 'c'}` | `a` | ...

Assign a unique name to each state. If this field is blank (`' '`), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, `'position'`.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

  For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Programmatic Use
Block Parameter: `ContinuousStateAttributes`
Type: character vector, string
Values: `' '` | user-defined
Default: `' '`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

1. Consider using the Model Discretizer to map these continuous blocks into discrete equivalents that support code generation. From a model, select **Analysis** > **Control Design** > **Model Discretizer** to access the Model Discretizer.
2. Not recommended for production code.

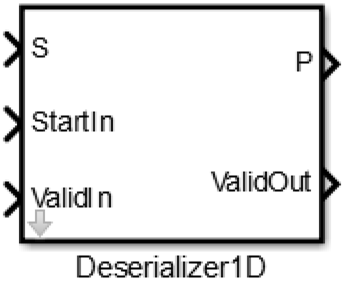
Deserializer1D

Convert scalar stream or smaller vectors to vector signal



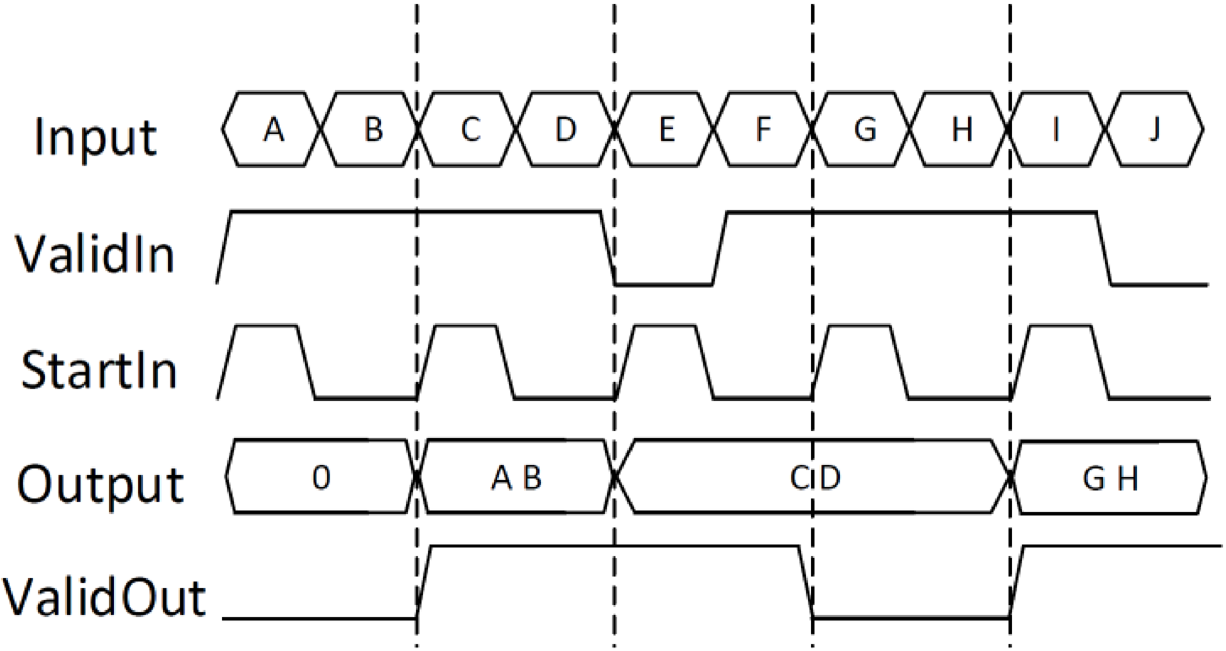
Library

HDL Coder / HDL Operations

Description

The Deserializer1D block buffers a faster, scalar stream or vector signals into a larger, slower vector signal. The faster input signal is converted to a slower signal based on the **Ratio** and **Idle Cycle** values, the conversion changes sample time. Also, the output signal is delayed one slow signal cycle because the serialized data needs to be collected before it can be output as a vector. See the examples below for more details.

You can configure the deserialization to depend on a valid input signal ValidIn and a start signal StartIn. If the **ValidIn** and **StartIn** block parameters are both selected, data collection starts only if both ValidIn and StartIn signals are true. Consider this example:

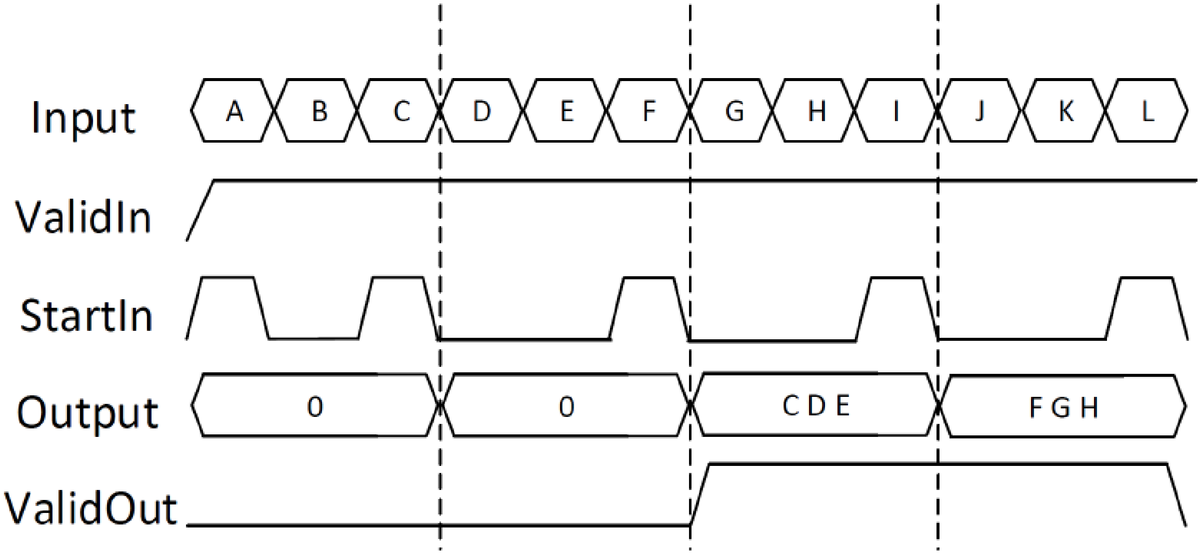


- **Ratio** is 2 and **Idle Cycles** is 0, so each output cycle is two input signals long with all data points considered.
- **ValidIn** and **StartIn** are selected, so data collection can begin only when both StartIn and ValidIn signals are true.
- **ValidOut** is selected.

In the first cycle, ValidIn and StartIn are true, so data collection begins for A and B. The block outputs the deserialized vector in the next valid cycle, so the AB vector is output in the next cycle. This is also true in the second cycle for C and D.

In the third cycle, starting at E, StartIn is true, but ValidIn is not. E is dropped. At F, ValidIn is true, but StartIn is not, so F is also dropped. Since it cannot collect data for E or F, Deserializer1D outputs the previous cycle vector, CD, but ValidOut changes to false.

Another scenario to consider is when the StartIn signal arrives too early. If the length between two StartIn signals is not long enough to collect a full ratio cycle, the insufficient signal data is dropped. Consider this example:



- **Ratio** is 3, so each cycle is two sections long.
- **Idle Cycles** is 0, so all data inputs are considered.
- **ValidIn** and **StartIn** are selected, so data collection can begin only when both StartIn and ValidIn signals are true.
- **ValidOut** is selected.

In the first cycle, ValidIn and StartIn are true, so data collection can begin for A and B. However, at C another StartIn signal arrives before three signals can be collected. Because the StartIn arrived early, A and B are dropped and no valid vector is collected during the first cycle. Therefore, the output of the second cycle is still zero. Deserialization begins at the StartIn at C, for C, D, and E. This vector is output at the next valid cycle, which is cycle 3. Similarly, deserialization starts again at the StartIn at F, and outputs the FGH vector in the fourth cycle.

You specify the block output for the first sampling period with the value of the **Initial condition** parameter.

Parameters

Ratio

Enter the deserialization ratio. Default is `1`.

The ratio is the output vector size, divided by the input vector size. The ratio must be divisible by the input vector size.

Idle Cycles

Enter the number of idle cycles added to the end of each serialized input. Default is `0`.

The value of **Idle Cycles** affects the deserialized output rate. For example, if **Ratio** is `2` and the input signal is `A, B, B, C, D, D, ...`, without idle cycles the output would be `AB, BC, DD...`. However for the same input and ratio with **Idle Cycles** set to `1`, the output is `AB, CD...`. The idle cycles, `B` and `D`, are dropped.

The Deserializer1D behavior changes if **Idle Cycles** is not zero, and **ValidIn** or **StartIn** are on. The idle cycles value affects only the output rate, while **ValidIn** and **StartIn** control what input data is deserialized.

Initial condition

Specify the initial output of the simulation. Default is 0.

StartIn

Select to activate the StartIn port. Default is off.

ValidIn

Select to activate the ValidIn port. Default is off.

ValidOut

Select to activate ValidOut port. Default is off.

Input data port dimensions (-1 for inherited)

Enter the size of the input data signal. The input size must be divisible by the ratio plus the number of idle cycles. By default, the block inherits size based on context within the model.

Input sample time (-1 for inherited)

Enter the time interval between sample time hits or specify another appropriate sample time such as continuous. By default, the block inherits its sample time based on context within the model. For more information, see “Sample Time”.

Input signal type

Specify the input signal type of the block as `auto`, `real`, or `complex`.

Ports

`S`

Input signal to deserialize. Bus data types are not supported.

`ValidIn`

Indicates valid input signal. Use with the Serializer1D block. This port is available when you select the **ValidIn** check box.

Data type: Boolean

`StartOut`

Indicates where to start deserialization. Use with the Serializer1D block. This port is available when you select the **StartOut** check box.

Data type: Boolean

`P`

Deserialized output signal. Bus data types are not supported.

`ValidOut`

Indicates valid output signal. This port is available when you select the **ValidOut** check box.

Data type: Boolean

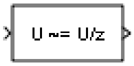
Detect Change

Detect change in signal value
Library: Simulink / Logic and Bit Operations



Description

The Detect Change block determines if an input signal does not equal its previous value. The initial condition determines the initial value of the previous input U/z.

Ports

Input

`Port_1` — Input signal
signal value

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `built-in integer` | `floating point`

Output

`Port_1` — Output signal
0 | 1

Output signal, true (equal to 1) when the input signal does not equal its previous value; false (equal to 0) when the input signal equals its previous value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Initial condition` — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition for the previous input U/z.

Programmatic Use
Block Parameter: `vinit`
Type: character vector
Values: scalar | vector
Default:`'0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see "Sample- and Frame-Based Concepts" (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Output data type` — Data type of the output

`boolean` (default) | `uint8`

Set the output data type to `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean'` | `'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`

Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

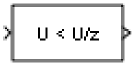
Detect Decrease

Detect decrease in signal value

Library: Simulink / Logic and Bit Operations



Description

The Detect Decrease block determines if an input is strictly less than its previous value.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Output signal

0 | 1

Output signal, true (equal to 1) when the input signal is less than its previous value; false (equal to 0) when the input signal is greater than or equal to its previous value.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

Initial condition — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition for the previous input U/z.

Programmatic Use
Block Parameter: vinit
Type: character vector
Values: scalar | vector
Default: '0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see "Sample- and Frame-Based Concepts" (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Output data type` — Data type of the output
`boolean` (default) | `uint8`

Set the output data type to `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean'` | `'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`

Zero-Crossing Detection	`No`

Extended Capabilities

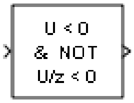
Detect Fall Negative

Detect falling edge when signal value decreases to strictly negative value, and its previous value was nonnegative

Library: Simulink / Logic and Bit Operations



Description

The Detect Fall Negative block determines if the input is less than zero, and its previous value is greater than or equal to zero.

Ports

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Input

`Port_1` — Input signal
signal value

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Output signal
0 | 1

Output signal, true (equal to 1) when the input signal is less than zero, and its previous value was greater than or equal to zero; false (equal to 0) when the input signal is greater than or equal to zero, or if the input signal is negative, its previous value was also negative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Initial condition` — Initial condition for the previous input

0 (default) | scalar | vector

Set the initial condition of the Boolean expression U/z < 0.

Programmatic Use
Block Parameter: `vinit`
Type: character vector
Values: scalar | vector
Default:`'0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Output data type` — Data type of the output

`boolean` (default) | `uint8`

Set the output data type to `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean'` | `'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`

Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

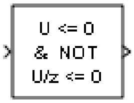
Detect Change | Detect Decrease | Detect Fall Nonpositive | Detect Increase | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Fall Nonpositive

Detect falling edge when signal value decreases to nonpositive value, and its previous value was strictly positive

Library: Simulink / Logic and Bit Operations



Description

The Detect Fall Nonpositive block determines if the input is less than or equal to zero, and its previous value was greater than zero.

- The output is true (equal to `1`) when the input signal is less than or equal to zero, and its previous value was greater than zero.
- The output is false (equal to `0`) when the input signal is greater than zero, or if it is nonpositive, its previous value was also nonpositive.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector | matrix

Output signal that detects a falling edge, specified as a scalar, vector, or matrix.

- The output is true (equal to `1`) when the input signal is less than or equal to zero, and its previous value was greater than zero.
- The output is false (equal to `0`) when the input signal is greater than zero, or if it is nonpositive, its previous value was also nonpositive.

Data Types: `uint8` | `Boolean`

Parameters

`Initial condition` — Initial condition of Boolean expression `U/z <= 0`

0 (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression `U/z <= 0`.

Programmatic Use
Block Parameter: `vinit`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see "Sample- and Frame-Based Concepts" (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Output data type` — Output data type

`boolean` (default) | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean' | 'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

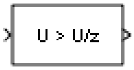
Detect Change | Detect Decrease | Detect Fall Negative | Detect Increase | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Increase

Detect increase in signal value

Library: Simulink / Logic and Bit Operations



Description

The Detect Increase block determines if an input is strictly greater than its previous value.

- The output is true (equal to `1`) when the input signal is greater than its previous value.
- The output is false (equal to `0`) when the input signal is less than or equal to its previous value.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output signal, detecting an increase in signal value, specified as a scalar, vector, or matrix.

- The output is true (equal to `1`) when the input signal is greater than its previous value.
- The output is false (equal to `0`) when the input signal is less than or equal to its previous value.

Data Types: `uint8` | `Boolean`

Parameters

`Initial condition` — Initial condition of previous input

`0.0` (default) | scalar | vector | matrix

Set the initial condition for the previous input `U/z`.

Programmatic Use
Block Parameter: `vinit`
Type: character vector
Values: scalar | vector | matrix
Default: `'0.0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Output data type` — Output data type

`boolean` (default) | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean' | 'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`

Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For information on HDL code generation support, see Detect Increase.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

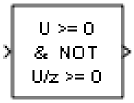
Detect Change | Detect Decrease | Detect Fall Negative | Detect Fall Nonpositive | Detect Rise Nonnegative | Detect Rise Positive

Introduced before R2006a

Detect Rise Nonnegative

Detect rising edge when signal value increases to nonnegative value, and its previous value was strictly negative

Library: Simulink / Logic and Bit Operations



Description

The Detect Rise Nonnegative block determining if the input is greater than or equal to zero, and its previous value was less than zero.

- The output is true (equal to `1`) when the input signal is greater than or equal to zero, and its previous value was less than zero.
- The output is false (equal to `0`) when the input signal is less than zero, or if the input signal is nonnegative, its previous value was also nonnegative.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector | matrix

Output signal that indicates a rising edge whenever the signal value increases to a nonnegative value, and its previous value was strictly negative. The output can be a scalar, vector, or matrix.

- The output is true (equal to `1`) when the input signal is greater than or equal to zero, and its previous value was less than zero.
- The output is false (equal to `0`) when the input signal is less than zero, or if the input signal is nonnegative, its previous value was also nonnegative.

Data Types: `uint8` | `Boolean`

Parameters

`Initial condition` — Initial condition of Boolean expression `U/z >= 0`

`0` (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression `U/z >= 0`.

Programmatic Use
Block Parameter: `vinit`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Output data type` — Output data type

`boolean` (default) | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean' | 'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

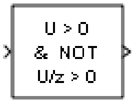
Detect Change | Detect Decrease | Detect Fall Negative | Detect Fall Nonpositive | Detect Increase | Detect Rise Positive

Introduced before R2006a

Detect Rise Positive

Detect rising edge when signal value increases to strictly positive value, and its previous value was nonpositive

Library: Simulink / Logic and Bit Operations



Description

The Detect Rise Positive block detects a rising edge by determining if the input is strictly positive, and its previous value was nonpositive.

- The output is true (equal to `1`) when the input signal is greater than zero, and the previous value was less than or equal to zero.
- The output is false (equal to `0`) when the input is negative or zero, or if the input is positive, the previous value was also positive.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output signal that detects a rising edge whenever the input is strictly positive, and its previous value was nonpositive. The output can be a scalar, vector, or matrix.

- The output is true (equal to `1`) when the input signal is greater than zero, and the previous value was less than or equal to zero.
- The output is false (equal to `0`) when the input is negative or zero, or if the input is positive, the previous value was also positive.

Data Types: `uint8` | `Boolean`

Parameters

`Initial condition` — Initial condition of Boolean expression `U/z > 0`
`0` (default) | scalar | vector | matrix

Set the initial condition of the Boolean expression `U/z > 0`.

Programmatic Use
Block Parameter: `vinit`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`Input processing` — Specify sample- or frame-based processing
`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Output data type` — Output data type

`boolean` (default) | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean' | 'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

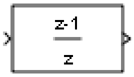
Difference

Calculate change in signal over one time step
Library: Simulink / Discrete



Description

The Difference block outputs the current input value minus the previous input value.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Dependencies

When you set **Input processing** to `Columns as channels (frame based)`, the input signal must have two dimensions or less.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Current input minus previous input
scalar | vector | matrix | N-D array

Current input minus previous input, specified as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Initial condition for previous input` — Initial condition

`0.0` (default) | scalar | vector | matrix | N-D array

Set the initial condition for the previous input.

Programmatic Use
Parameter: `ICPrevInput`
Type: character vector
Values: scalar | vector | matrix | N-D array
Default: `'0.0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see "Sample- and Frame-Based Concepts" (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

Signal Attributes

`Output minimum` — Minimum output value for range checking

[ ] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[ ]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output data type` — Output data type

`Inherit: Inherit via internal rule` (default) | `Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate to max or min when overflows occur` — Method of overflow action

`off` (default) | `on`

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `DoSatur`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	double | single | Boolean[a] | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	Yes

Zero-Crossing Detection	No

a. This block is not recommended for use with Boolean signals.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the Treat as atomic unit option.
- Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Digital Clock

Output simulation time at specified sampling interval
Library: Simulink / Sources

Description

The Digital Clock block outputs the simulation time only at the specified sampling interval. At other times, the block holds the output at the previous value. To control the precision of this block, use the **Sample time** parameter in the block dialog box.

Use this block rather than the Clock block (which outputs continuous time) when you need the current simulation time within a discrete system.

Ports

Output

`Port_1` — Sample time
scalar

Sample time, in seconds, at the specified sampling interval. At other times, the block holds the output at the previous value.

Data Types: `double`

Parameters

`Sample time` — Sampling interval
`1` (default) | scalar | vector

Specify the sampling interval in seconds. You can specify the sampling interval in one of two ways:

- As the period, specified as a real-valued scalar with data type double.
- As the period and offset, specified as a real-valued vector of length 2 with data type double. The period and offset must be finite and non-negative, and the offset value must be less than the period.

For more information, see Specifying Sample Time.

Tip Do not specify a continuous sample time, either `0` or `[0,0]`. Also, avoid specifying `-1` (inheriting the sample time) because this block is a source.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'1'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

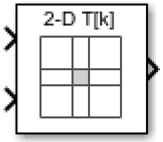
Direct Lookup Table (n-D)

Index into n-dimensional table to retrieve element, vector, or 2-D matrix

Library: Simulink / Lookup Tables



Description

The Direct Lookup Table (n-D) block indexes into an n-dimensional table to retrieve an element, vector, or 2-D matrix. The first selection index corresponds to the top (or left) input port. You can choose to provide the table data as an input to the block, or define the table data on the block dialog box. The number of input ports and the size of the output depend on the number of table dimensions and the output slice you select.

If you select a vector from a 2-D table, the output vector can be a column or a row, depending on the model configuration parameter setting **Math and Data Types > Use algorithms optimized for row-major array layout**. The block inputs are zero-based indices (for more information, see the **Inputs select this object from table** parameter.

The Direct Lookup Table block supports symbolic dimensions.

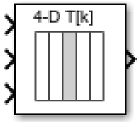
Block Inputs and Outputs

The Direct Lookup Table (n-D) block uses inputs as zero-based indices into an *n*-dimensional table. The number of inputs varies with the shape of the output: an element, vector, or 2-D matrix.

You define a set of output values as the **Table data** parameter. For the default column-major algorithm behavior, the first input specifies the zero-based index to the table dimension that is one higher than the output dimensionality. The next input specifies the zero-based index to the next table dimension, and so on.

Output Shape	Output Dimensionality	Table Dimension that Maps to the First Input
Element	0	1
Vector	1	2
Matrix	2	3

Suppose that you want to select a vector of values from a 4-D table.



The following mapping of block input port to table dimension applies.

This input port...	Is the index for this table dimension...
1	2
2	3
3	4

Changes in Block Icon Appearance

Depending on parameters you set, the block icon changes appearance. For table dimensions higher than 4, the icon matches the 4-D version but shows the exact number of dimensions at the top.

When you use the **Table data** parameter, you see these icons for the default column-major behavior. Some icons are different when you select the configuration parameter **Math and Data Types > Use algorithms optimized for row-major array layout**.

Object that Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				Vector				2-D Matrix	Not applicable			
When you use the table input port, you see these icons.

Object that Inputs Select from the Table	Number of Table Dimensions			
	1	2	3	4
Element				Vector				
Object that Inputs Select from the Table	**Number of Table Dimensions**			
	1	**2**	**3**	**4**
2-D Matrix	Not applicable			
Ports

Input

`Port_1` — Index `i1` input values

scalar | vector

For the default column-major algorithm, the first input port, specifying the zero-based index to the table dimension that is one higher than the output dimensionality (0, 1, or 2). The next input specifies the zero-based index to the next table dimension, and so on. All index inputs must be real-valued.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `enumerated`

`Port_N` — Index `N` input values

scalar | vector

For the default column-major algorithm, the N-th input port, specifying the zero-based index to the table dimension that is N higher than the output dimensionality (0, 1, or 2). The number of inputs varies with the shape of the output. All index inputs must be real-valued.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `enumerated`

`T` — Table data

vector | matrix | N-D array

Table data, specified as a vector, matrix, or N-D array. The table size must match the dimensions of the **Number of dimensions** parameter. The block's output data type is the same as the table data type.

Dependencies

To enable this port, select the **Make table an input** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Output element, vector, or 2-D matrix

scalar | vector | 2-D matrix

Output slice, provided as a scalar, vector, or 2-D matrix. The size of the block output is determined by the setting of the **Inputs select this object from table** parameter. The output data type is the same as the table data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

Main

Table

`Number of table dimensions` — Number of dimensions of table data

2 (default) | 1 | 3 | 4

Number of dimensions that the **Table data** parameter must have. This value determines the number of independent variables for the table and the number of inputs to the block.

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.

To specify...	Do this...
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use
Block Parameter: `NumberOfTableDimensions`
Type: character vector
Values: `'1' | '2' | '3' | '4' | ... |'30'|`
Default: `'2'`

`Make table an input` — Provide table data as a block input

`off` (default) | `on`

Select this check box to provide table data to the Direct Lookup Table (n-D) block as a block input. When you select this check box, a new input port, `T`, appears. Use this port to input the table data.

Programmatic Use
Block Parameter: `TableIsInput`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Table data` — Table of output values

`[4 5 6; 16 19 20; 10 18 23]` (default) | `scalar, vector, matrix, or N-D array`

Specify the table of output values. The table size must match the dimensions of the **Number of table dimensions** parameter.

Tip During block diagram editing, you can leave the **Table data** field empty. But for simulation, you must match the number of dimensions in **Table data** to the **Number of table dimensions**. For details on how to construct multidimensional MATLAB arrays, see “Multidimensional Arrays” (MATLAB).

Click **Edit** to open the Lookup Table Editor. For more information, see “Edit Lookup Tables”.

Dependencies

To enable the **Table data** field, clear the **Make table an input** check box.

Programmatic Use
Block Parameter: `Table`
Type: character vector
Values: `scalar, vector, matrix, or N-D array`
Default: `'[4 5 6;16 19 20;10 18 23]'`

Algorithm

`Inputs select this object from table` — Specify whether output is an element, vector, or 2-D matrix

`Element` (default) | `Vector` | `2-D Matrix`

Specify whether the output data is a single element, a vector, or a 2-D matrix. The number of input ports for indexing depends on your selection.

Selection	Number of Input Ports for Indexing
`Element`	Number of table dimensions
`Vector`	Number of table dimensions -1
`2-D Matrix`	Number of table dimensions -2

This numbering matches MATLAB indexing. For example, if you have a 4-D table of data, follow these guidelines.

To access...	Specify...	As in...
An element	Four indices	`array(1,2,3,4)`
A vector	Three indices	`array(:,2,3,4)` (default column-major algorithm)
A 2-D matrix	Two indices	`array(:,:,3,4)` (default column-major algorithm)

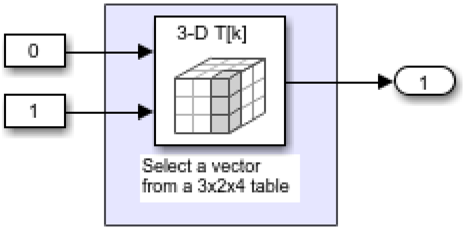
Tips

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the Direct Lookup Table block behavior changes from column-major to row-major. For this block, the column-major and row-major algorithms may differ semantically in output calculations, resulting in different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For example, assume that **Inputs select this object from table** parameter is set to `Vector`. The elements of the selected vector are contiguous in the table storage memory. This table shows the column-major and row-major algorithm depending on the table dimension:

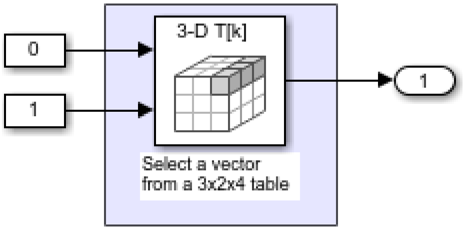
Table Dimension	Column-Major Algorithm	Row-Major Algorithm
2-D table	Column vector is selected	Row vector is selected
3-D and higher table	Output vector is selected from the first dimension of the table	Output vector is selected from the last dimension of the table

Consider the row-major and column-major direct lookup algorithms with vector output from a 3-D table. The last dimension is the third dimension of a 3-D table. Due to semantic changes, column-major and row-major direct lookup may output different vector size and numerical values.

This figure shows a Direct Lookup Table (n-D) block configured with a 3-D table and a vector output. When the model that contains this block is configured for column-major layout, the block icon shows the column-major algorithm.



To have the same block use the row-major algorithm, change the **Use algorithms optimized for row-major array layout** configuration parameter of the model and recompile. The block icon changes to reflect the change to the algorithm optimized for row-major layout.



For more information on row-major support, see “Row-Major Array Layout: Simplify integration with external C/C++ code for Lookup Table and other blocks” (Simulink Coder).

Programmatic Use
Block Parameter: `InputsSelectThisObjectFromTable`
Type: character vector
Values: `'Element' | 'Vector' | '2-D Matrix'`
Default: `'Element'`

`Diagnostic for out-of-range input` — Block action when input is out of range

`Warning` (default) | `None` | `Error`

Specify whether to show a warning or error when an index is out of range with respect to the table dimension. Options include:

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

When you select `None` or `Warning`, the block clamps out-of-range indices to fit table dimensions. For example, if the specified index is 5.3 and the maximum index for that table dimension is 4, the block clamps the index to 4.

Programmatic Use
Block Parameter: `DiagnosticForOutOfRangeInput`
Type: character vector
Values: `'None' | 'Warning' | 'Error'`
Default: `'Warning'`

`Sample time` — Specify sample time as a value other than -1

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Table Attributes

Note The parameters in the **Table Attributes** pane are not available if you select **Make table an input**. In this case, the block inherits all table attributes from the input port with the label `T`.

`Table minimum` — Minimum value table data can have

`[]` (default) | `finite, real, double, scalar`

Specify the minimum value for table data. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `TableMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Table maximum` — Maximum value table data can have

`[]` (default) | `finite, real, double, scalar`

Specify the maximum value for table data. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `TableMax`
Type: character vector
Values: scalar

Default: `'[]'`

`Table data type` — Data type of table data

`Inherit: Inherit from 'Table data'` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class name>` | `<data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit from 'Table data'`
- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see "Specify Data Types Using Data Type Assistant".

Programmatic Use
Block Parameter: `TableDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit from 'Table data'' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'Enum: <class name>'|'<data type expression>'`
Default: `'Inherit: Inherit from 'Table data''`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see "Lock the Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`

Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `enumerated`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see Direct Lookup Table (n-D).

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

This block supports fixed-point data types for **Table data** only.

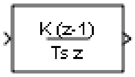
Discrete Derivative

Compute discrete-time derivative
Library: Simulink / Discrete



Description

The Discrete Derivative block computes an optionally scaled discrete time derivative as follows

$$y(t_n) = \frac{Ku(t_n)}{T_s} - \frac{Ku(t_{n-1})}{T_s}$$

where

- $u(t_n)$ and $y(t_n)$ are the block's input and output at the current time step, respectively.
- $u(t_{n-1})$ is the block's input at the previous time step.
- K is a scaling factor.
- T_s is the simulation's discrete step size, which must be fixed.

Note Do not use this block in subsystems with a nonperiodic trigger (for example, nonperiodic function-call subsystems). This configuration produces inaccurate results.

Ports

Input

Port_1 — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Output

Port_1 — Scaled discrete time derivative

scalar | vector | matrix

Optionally scaled discrete-time derivative, specified as a scalar, vector, or matrix. For more information on how the block computes the discrete-time derivative, see “Description” on page 1-433. You specify the data type of the output signal with the **Output data type** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Parameters

Main

Gain value — Scaling factor

1.0 (default) | scalar

Scaling factor used to weight the block's input at the current time step, specified as a real-valued scalar.

Programmatic Use
Block Parameter: gainval
Type: character vector

Values: scalar
Default: '1.0'

Initial condition for previous weighted input K*u/Ts — Initial condition

0.0 (default) | scalar

Initial condition for the previous scaled input, specified as a scalar.

Programmatic Use
Block Parameter: ICPrevScaledInput
Type: character vector
Values: scalar
Default: '0.0'

Input processing — Specify sample- or frame-based processing

Elements as channels (sample based) (default) | Columns as channels (frame based)

Specify whether the block performs sample- or frame-based processing:

- Columns as channels (frame based) — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see "Sample- and Frame-Based Concepts" (DSP System Toolbox).

- Elements as channels (sample based) — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input u. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes

Input Signal u	Input Processing Mode	Block Works?
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

Signal Attributes

`Output minimum` — Minimum output value for range checking

[ ] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'`
Default: `'Inherit: Inherit via internal rule'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate to max or min when overflows occur` — Method of overflow action

`off` (default) | `on`

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `DoSatur`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`

Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Depends on absolute time when used inside a triggered subsystem hierarchy.
- Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

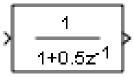
Discrete Filter

Model Infinite Impulse Response (IIR) filters

Library: Simulink / Discrete



Description

The Discrete Filter block independently filters each channel of the input signal with the specified digital IIR filter. You can specify the filter structure as `Direct form I`, `Direct form I transposed`, `Direct form II`, or `Direct form II transposed`. The block implements static filters with fixed coefficients. You can tune the coefficients of these static filters.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify how the block treats each element of the input. You can specify treating input elements as an independent channel (sample-based processing), or treating each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Numerator coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

Use the **Numerator coefficients** parameter to specify the coefficients of the discrete filter numerator polynomial. Use the **Denominator coefficients** parameter to specify the coefficients of the denominator polynomial of the function. The **Denominator coefficients** parameter must be a vector of coefficients.

Specify the coefficients of the numerator and denominator polynomials in ascending powers of z^{-1}. The Discrete Filter block lets you use polynomials in z^{-1} (the delay operator) to represent a discrete system. This method is the one that signal processing engineers typically use. Conversely, the Discrete Transfer Fcn block lets you use polynomials in z to represent a discrete system. This method is the one that control engineers typically use.

When the numerator and denominator polynomials have the same length, the two methods are identical.

Specifying Initial States

In **Dialog parameters** and **Input port(s)** modes, the block initializes the internal filter states to zero by default, which is equivalent to assuming past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial states for the filter delays.

To determine the number of initial state values you must specify, and how to specify them, see the following table on Valid Initial States and Number of Delay Elements (Filter States). The **Initial states** parameter can take one of four forms as described in the following table.

Valid Initial States

Initial state	Examples	Description
Scalar	5 Each delay element for each channel is set to 5.	The block initializes all delay elements in the filter to the scalar value.
Vector (for applying the same delay elements to each channel)	For a filter with two delay elements: $[d_1 d_2]$ The delay elements for all channels are d1 and d2.	Each vector element specifies a unique initial condition for a corresponding delay element. The block applies the same vector of initial conditions to each channel of the input signal. The vector length must equal the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)).
Vector or matrix (for applying different delay elements to each channel)	For a three-channel input signal and a filter with two delay elements: $[d_1 d_2 D_1 D_2 d_1 d_2]$ or $\begin{bmatrix} d_1 & D_1 & d_1 \\ d_2 & D_2 & d_2 \end{bmatrix}$ • The delay elements for channel 1 are d_1 and d_2. • The delay elements for channel 2 are D_1 and D_2. • The delay elements for channel 3 are $d_1$and d_2.	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: • The vector length must be equal to the product of the number of input channels and the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)). • The matrix must have the same number of rows as the number of delay elements in the filter (specified in the table Number of Delay Elements (Filter States)), and must have one column for each channel of the input signal.
Empty matrix	[ ] Each delay element for each channel is set to 0.	The empty matrix, [], is equivalent to setting the **Initial conditions** parameter to the scalar value 0.

The number of delay elements (filter states) per input channel depends on the filter structure, as indicated in the following table.

Number of Delay Elements (Filter States)

Filter Structure	Number of Delay Elements Per Channel

`Direct form I`
`Direct form I transposed`
	• `number of zeros - 1`
	• `number of poles - 1`

`Direct form II`
`Direct form II transposed`
	`max(number of zeros, number of poles)-1`

The following tables describe the valid initial states for different sizes of input and different number of channels. These tables provide this information according to whether you set the **Input processing** parameter to frame based or sample based.

Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
• Column vector (*K*-by-1) • Unoriented vector (*K*)	1	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*)	• Scalar • Column vector (*M*-by-1)
• Row vector (1-by-*N*) • Matrix (*K*-by-*N*)	*N*	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*) • Matrix (*M*-by-*N*)	• Scalar • Matrix (*M*-by-*N*)

Sample-Based Processing

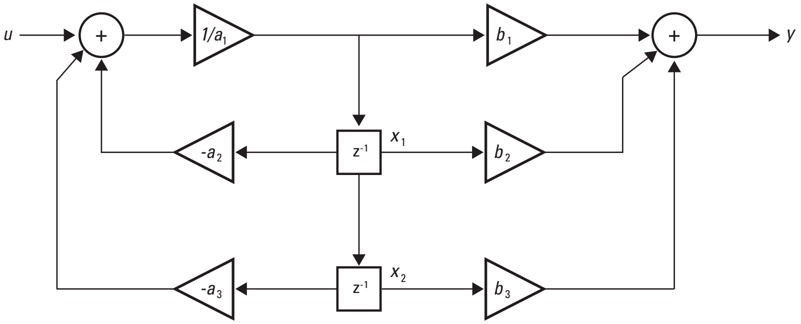
Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
• Scalar	1	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*)	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*)
• Row vector (1-by-*N*) • Column vector (*N*-by–1) • Unoriented vector (*N*)	*N*	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*) • Matrix (*M*-by-*N*)	• Scalar
• Matrix (*K*-by-*N*)	*K* × *N*	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*) • Matrix (*M*-by-(*K*×*N*))	• Scalar

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. Enter `0` to initialize all states to zero. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state. This unique state corresponds to a delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter, `M = max(number of zeros, number of poles)`.
- The matrix must have the same number of rows as the number of delay elements in the filter, `M = max(number of zeros, number of poles)`. The matrix must also have one column for each channel of the input signal.

The following example shows the relationship between the initial filter output and the initial input and state. Given an initial input u_1, the first output y_1 is related to the initial state [x_1, x_2] and initial input by:

$$y_1 = b_1 \left[\frac{(u_1 - a_2 x_1 - a_3 x_2)}{a_1} \right] + b_2 x_1 + b_3 x_2$$



Ports

Input

u — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Dependencies

The name of this port depends on the source you specify for the numerator coefficients, denominator coefficients and initial states. When you set **Numerator**, **Denominator**, and **Initial states** to `Dialog`, there is only one input port, and the port is unlabeled. When you set **Numerator**, **Denominator**, or **Initial states** to `Input port`, this port is labeled **u**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

`Num` — Numerator coefficients

scalar | vector | matrix

Numerator coeffcients of the discrete filter, specified as descending powers of *z*. Use a row vector to specify the coefficients for a single numerator polynomial.

Dependencies

To enable this port, set **Numerator** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

`Den` — Denominator coefficients

scalar | vector

Specify the denominator coefficients of the discrete filter as descending powers of z. Use a row vector to specify the coefficients for a single denominator polynomial.

Dependencies

To enable this port, set **Denominator** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

`x0` — Initial states

scalar | vector | matrix

Initial states, specified as a scalar, vector, or matrix. For more information about specifying states, see “Specifying Initial States” on page 1-442.

Dependencies

To enable this port, set the **Filter structure** to `Direct form II` or `Direct form II transposed`, and set **Initial states** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Output

`Port_1` — Filtered output signal

scalar | vector | matrix

Filtered output signal. The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Numerator coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Parameters

Main

Filter structure — Filter structure

Direct form II (default) | Direct form I transposed | Direct form I | Direct form II transposed

Specify the discrete IIR filter structure.

Dependencies

To use any filter structure other than Direct form II, you must have an available DSP System Toolbox license.

Programmatic Use
Block Parameter: FilterStructure
Type: character vector
Values: 'Direct form II' | 'Direct form I transposed' | 'Direct form I' | 'Direct form II transposed'
Default: 'Direct form II'

Numerator Source — Source of numerator coeffcients

Dialog (default) | Input port

Specify the source of the numerator coefficients as Dialog or Input port.

Programmatic Use
Block Parameter: NumeratorSource
Type: character vector
Values: 'Dialog' | 'Input port'
Default: 'Dialog'

Numerator Value — Numerator coefficients

[1] (default) | scalar | vector | matrix

Specify the numerator coefficients of the discrete filter as descending powers of z. Use a row vector to specify the coefficients for a single numerator polynomial.

Dependencies

To enable this parameter, set the **Numerator Source** to Dialog.

Programmatic Use
Block Parameter: `Numerator`
Type: character vector
Values: scalar | vector | matrix
Default: `'[1]'`

`Denominator Source` — Source of denominator coefficients

`Dialog` (default) | `Input port`

Specify the source of the denominator coefficients as `Dialog` or `Input port`.

Programmatic Use
Block Parameter: `DenominatorSource`
Type: character vector
Values: `'Dialog' | 'Input port'`
Default: `'Dialog'`

`Denominator Value` — Denominator coeffcients

`[1 0.5]` (default) | vector

Specify the denominator coefficients of the discrete filter as descending powers of z. Use a row vector to specify the coefficients for a single denominator polynomial.

Dependencies

To enable this parameter, set the **Denominator Source** to `Dialog`.

Programmatic Use
Block Parameter: `Denominator`
Type: character vector
Values: scalar | vector
Default: `'[1 0.5]'`

`Initial states Source` — Source of initial states

`Dialog` (default) | `Input port`

Specify the source of the initial states as `Dialog` or `Input port`.

Programmatic Use
Block Parameter: `InitialStatesSource`
Type: character vector
Values: `'Dialog' | 'Input port'`
Default: `'Dialog'`

`Initial states Value` — Initial filter states

`0` (default) | scalar | vector | matrix

Specify the initial filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-442.

Dependencies

To enable this parameter, set the **Filter structure** to `Direct form II` or `Direct form II transposed`, and set **Initial states Source** to `Dialog`.

Programmatic Use

Block Parameter: `InitialStates`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`Initial states on numerator side` — Initial numerator states

`0` (default) | scalar | vector | matrix

Specify the initial numerator filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-442.

Dependencies

To enable this port, set the **Filter structure** to `Direct form I` or `Direct form I transposed`.

Programmatic Use

Block Parameter: `InitialStates`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`Initial states on denominator side` — Initial denominator states

`0` (default) | scalar | vector | matrix

Specify the initial denominator filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-442.

Dependencies

To enable this port, set the **Filter structure** to `Direct form I` or `Direct form I transposed`.

Programmatic Use
Block Parameter: `InitialDenominatorStates`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`External reset` — External state reset

`None` (default) | `Rising` | `Falling` | `Either` | `Level` | `Level hold`

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
`None`	No reset.
`Rising`	Reset on a rising edge.
`Falling`	Reset on a falling edge.
`Either`	Reset on either a rising or falling edge.
`Level`	Reset in either of these cases: • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
`Level hold`	Reset when the reset signal is nonzero at the current time step

Programmatic Use
Block Parameter: `ExternalReset`
Type: character vector
Values: `'None'` | `'Rising'` | `'Falling'` | `'Either'` | `'Level'` | `'Level hold'`
Default: `'None'`

`Input processing` — Sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing.

- `Elements as channels (sample based)` — Process each element of the input as an independent channel.

- `Columns as channels (frame based)` — Process each column of the input as an independent channel.

Dependencies

Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)' | 'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

Optimize by skipping divide by leading denominator coefficient (a0) — Skip divide by a0

`off` (default) | `on`

Select when the leading denominator coefficient, a_0, equals one. This parameter optimizes your code.

When you select this check box, the block does not perform a divide-by-a_0 either in simulation or in the generated code. An error occurs if a_0 is not equal to one.

When you clear this check box, the block is fully tunable during simulation. It performs a divide-by-a_0 in both simulation and code generation.

Programmatic Use
Block Parameter: `a0EqualsOne`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Sample time (-1 for inherited) — Interval between samples

`-1` (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. For more information, see “Specify Sample Time”.

Programmatic Use
Block Parameter: `SampleTime`

Type: character vector
Values: scalar | vector
Default: `'-1'`

Data Types

`State` — State data type

`Inherit: Same as input` (default) | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the state data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `StateDataTypeStr`
Type: character vector
Values: `'Inherit: Same as input'` | `'int8'` | `'int16'` | `'int32'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Same as input'`

`Numerator coefficients` — Numerator coefficient data type

`Inherit: Inherit via internal rule` (default) | `int8` | `int16` | `int32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>`

Specify the numerator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in signed integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `NumCoeffDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'int8'` | `'int16'` | `'int32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Numerator coefficient minimum` — Minimum value of numerator coefficients

`[]` (default) | scalar

Specify the minimum value that a numerator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `NumCoeffMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Numerator coefficient maximum` — Maximum value of numerator coefficients

`[]` (default) | scalar

Specify the maximum value that a numerator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `NumCoeffMax`

Type: character vector
Values: scalar
Default: `'[]'`

`Numerator product output` — Numerator product output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the product output data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `NumProductDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via interal rule'`

`Numerator accumulator` — Numerator accumulator data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the accumulator data type for the numerator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`

- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `NumAccumDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via interal rule'`

`Denominator coefficients` — Denominator coefficient data type
`Inherit: Inherit via internal rule` (default) | `int8` | `int16` | `int32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>`

Specify the denominator coefficient data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `DenCoeffDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

Denominator coefficient minimum — Minimum value of denominator coefficients

[] (default) | scalar

Specify the minimum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: DenCoeffMin
Type: character vector
Values: scalar
Default: '[]'

Denominator coefficient maximum — Maximum value of denominator coefficients

[] (default) | scalar

Specify the maximum value that a denominator coefficient can have. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: DenCoeffMax
Type: character vector
Values: scalar
Default: '[]'

Denominator product output — Denominator product output data type

Inherit: Inherit via internal rule (default) | Inherit: Same as input | int8 | int16 | int32 | fixdt(1,16,0) | <data type expression>

Specify the product output data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `DenProductDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Denominator accumulator` — Denominator accumulator data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the accumulator data type for the denominator coefficients. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `DenAccumDataTypeStr`

Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'Inherit: Same as product output' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Output` — Output data type

`Inherit: Inherit via internal rule` (default) | `int8` | `int16` | `int32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>`

Specify the output data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Output minimum` — Minimum value of output

`[]` (default) | scalar

Specify the minimum value that the block can output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: `OutMin`

Type: character vector
Values: scalar
Default: `'[]'`

`Output maximum` — Maximum value of output

`[]` (default) | scalar

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Multiplicand data type` — Multiplcand data type

`Inherit: Same as input` (default) | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the multiplicand data type. You can set this parameter to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set the **Filter structure** to `Direct form I transposed`

Programmatic Use

Block Parameter: `MultiplicandDataTypeStr`

Type: character vector
Values: `'Inherit: Same as input'` | `'int8'` | `'int16'` | `'int32'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Same as input'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see "Lock the Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Values: `'off'` | `'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see "Rounding" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Check for Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

State Attributes

`State name` — Assign unique name to each state

`' '` (default) | `'position'` | `{'a', 'b', 'c'}` | `a` | ...

Assign a unique name to each state. If this field is blank (`' '`), no name assignment occurs.

- To assign a name to a single state, enter the name between quotes, for example, `'position'`.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, cell array, or structure.

Limitations

- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

  For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II`.

Programmatic Use
Block Parameter: `StateName`
Type: character vector
Values: `' '` | user-defined
Default: `' '`

`State name must resolve to Simulink signal object` — Require state name resolve to a signal object

`off` (default) | `on`

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II` and specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Signal object class` — Signal object class

`Simulink.Signal` (default) | object of a class that is derived from `Simulink.Signal`

Specify the signal object class.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II` and specify a value for **State name**.

Programmatic Use

Block Parameter: `StateSignalObject`
Type: character vector
Values: object of a class that is derived from `Simulink.Signal`
Default: `'Simulink.Signal'`

`Code generation storage class` — State storage class for code generation

`Auto` (default) | `Model default` | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer` | `BitField (Custom)` | `Volatile (Custom)` | `ExportToFile (Custom)` | `ImportFromFile (Custom)` | `FileScope (Custom)` | `Localizable (Custom)` | `Struct (Custom)` | `GetSet (Custom)` | `Reusable (Custom)`

Select state storage class for code generation.

- `Auto` is the appropriate storage class for states that you do not need to interface to external code.
- *`StorageClass`* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II`, and specify a value for **State name**.

Programmatic Use

Block Parameter: `StateStorageClass`
Type: character vector
Values:`'Auto' | 'Model default' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...`
Default: `'Auto'`

`Code generation storage type qualifier` — Storage type qualifier

`''` (default)

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Filter structure** to `Direct form II`. This parameter is hidden unless you previously set its value.

Programmatic Use
Block Parameter: `RTWStateStorageTypeQualifier`
Type: character vector
Values: `'' | 'const' | 'volatile' | ...`
Default: `''`

Block Characteristics

Data Types	`double` | `single` | `base integer`[a] | `fixed point`[a]
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

[a] This block only supports signed fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

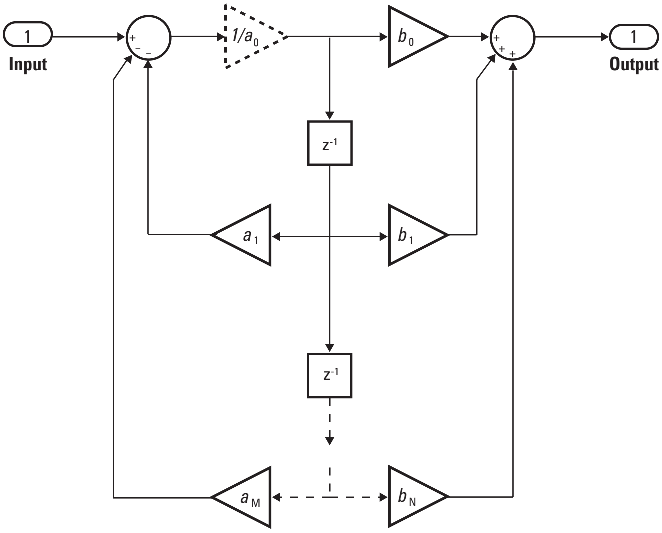
Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

This block only supports signed fixed-point data types.

The Discrete Filter block accepts and outputs real and complex signals of any signed numeric data type that Simulink supports. The block supports the same types for the numerator and denominator coefficients.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

The following diagrams show the filter structure and the data types used within the Discrete Filter block for fixed-point signals.



The block omits the dashed divide when you select the **Optimize by skipping divide by leading denominator coefficient (a0)** parameter.

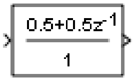
Discrete FIR Filter

Model FIR filters
Library: Simulink / Discrete



Description

The Discrete FIR Filter block independently filters each channel of the input signal with the specified digital FIR filter. The block can implement static filters with fixed coefficients, and time-varying filters with coefficients that change over time. You can tune the coefficients of a static filter during simulation.

This block filters each channel of the input signal independently over time. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an independent channel (sample-based processing), or each column of the input as an independent channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

The output dimensions equal the input dimensions, except when you specify a matrix of filter taps for the **Coefficients** parameter. When you do so, the output dimensions depend on the number of different sets of filter taps you specify.

The outputs of this block numerically match the outputs of the DSP System Toolbox Digital Filter Design block.

This block supports the Simulink state logging feature. For more information, see “States”.

Filter Structure Support

You can change the filter structure implemented with the Discrete FIR Filter block by selecting one of the following from the **Filter structure** parameter:

- `Direct form`
- `Direct form symmetric`
- `Direct form antisymmetric`
- `Direct form transposed`
- `Lattice MA`

You must have an available DSP System Toolbox license to run a model with any of these filter structures other than `Direct form`.

Specifying Initial States

The Discrete FIR Filter block initializes the internal filter states to zero by default, which has the same effect as assuming that past inputs and outputs are zero. You can optionally use the **Initial states** parameter to specify nonzero initial conditions for the filter delays.

To determine the number of initial states you must specify and how to specify them, see the table on valid initial states. The **Initial states** parameter can take one of the forms described in the next table.

Valid Initial States

Initial Condition	Description
Scalar	The block initializes all delay elements in the filter to the scalar value.
Vector or matrix (for applying different delay elements to each channel)	Each vector or matrix element specifies a unique initial condition for a corresponding delay element in a corresponding channel: • The vector length equal the product of the number of input channels and the number of delay elements in the filter, `#_of_filter_coeffs-1` (or `#_of_reflection_coeffs` for `Lattice MA`). • The matrix must have the same number of rows as the number of delay elements in the filter, `#_of_filter_coeffs-1` (`#_of_reflection_coeffs` for `Lattice MA`), and must have one column for each channel of the input signal.

Ports

Input

In — Input signal

scalar | vector | matrix

Input signal to filter, specified as a scalar, vector, or matrix.

Dependencies

When you set **Coefficient source** to `Dialog parameters`, the port for the input signal is unlabeled. When you set **Coefficient source** to `Input port`, the port for the input signal is labeled **In**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Num — Filter coefficients

scalar | vector | matrix

Specify the filter coefficents as a scalar, vector, or matrix. When you specify a row vector of filter taps, the block applies a single filter to the input. To apply multiple filters to the same input, specify a matrix of coefficients, where each row represents a different set of filter taps.

Dependencies

To enable this port, set **Coefficient source** to `Input port`.

To implement multiple filters, **Filter structure** must be `Direct form`, and the input must be a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

External reset — External reset signal

scalar

External reset signal, specified as a scalar. When the specified trigger event occurs, the block resets the states to their initial conditions.

Tip The icon for this port changes based on the value of the **External reset** parameter.

Dependencies

To enable this port, set **External reset** to `Rising`, `Falling`, `Either`, `Level`, or `Level hold`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

□ — Enable signal
scalar

Enable signal, specified as a scalar. This port can control execution of the block. The block is enabled when the input to this port is nonzero, and is disabled when the input is `0`. The value of the input is checked at the same time step as the block execution.

Dependencies

To enable this port, select the **Show enable port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Filtered output signal
scalar | vector | matrix

Filtered output signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

`Coefficient source` — Source of coefficients
`Dialog parameters` (default) | `Input port`

Choose to specify the filter coefficients using tunable dialog parameters or through an input port, which is useful for time-varying cofficients.

Programmatic Use
Block Parameter: `CoefSource`
Type: character vector
Values: `'Dialog parameters' | 'Input port'`
Default: `'Dialog parameters'`

`Filter structure` — Filter structure

`Direct form` (default) | `Direct form symmetric` | `Direct form antisymmetric` | `Direct form transposed` | `Lattice MA`

Select the filter structure you want the block to implement.

Dependencies

You must have an available DSP System Toolbox license to run a model with a Discrete FIR Filter block that implements any filter structure other than `Direct form`.

Programmatic Use
Block Parameter: `FilterStructure`
Type: character vector
Values: `'Direct form' | 'Direct form symmetric' | 'Direct form antisymmetric' | 'Direct form transposed' | 'Lattice MA'`
Default: `'Direct form'`

`Coefficients` — Filter coefficients

`[0.5 0.5]` (default) | vector | matrix

Specify the coefficient vector for the transfer function. Filter coefficients must be specified as a row vector. When you specify a row vector of filter taps, the block applies a single filter to the input. To apply multiple filters to the same input, specify a matrix of coefficients, where each row represents a different set of filter taps.

Dependencies

To enable this parameter, set **Coefficient source** to `Dialog parameters`.

To implement multiple filters, **Filter structure** must be `Direct form`, and the input must be a scalar.

Programmatic Use
Block Parameter: `Coefficients`
Type: character vector
Values: vector
Default: `'[0.5 0.5]'`

`Input processing` — Sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing. You can select one of the following options:

- `Elements as channels (sample based)` — Treat each element of the input as an independent channel (sample-based processing).
- `Columns as channels (frame based)` — Treat each column of the input as an independent channel (frame-based processing).

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)' | 'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Initial states` — Initial conditions of filter states

`0` (default) | scalar | vector | matrix

Specify the initial conditions of the filter states. To learn how to specify initial states, see “Specifying Initial States” on page 1-470.

Programmatic Use
Block Parameter: `InitialStates`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`Show enable port` — Create enable port

`off` (default) | `on`

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is `0`. The value of the input is checked at the same time step as the block execution.

Programmatic Use
Block Parameter: `ShowEnablePort`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`External reset` — External state reset

`None` (default) | `Rising` | `Falling` | `Either` | `Level` | `Level hold`

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
`None`	No reset.
`Rising`	Reset on a rising edge.
`Falling`	Reset on a falling edge.
`Either`	Reset on either a rising or falling edge.
`Level`	Reset in either of these cases: • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
`Level hold`	Reset when the reset signal is nonzero at the current time step

Programmatic Use
Block Parameter: `ExternalReset`
Type: character vector
Values: `'None'` | `'Rising'` | `'Falling'` | `'Either'` | `'Level'` | `'Level hold'`
Default: `'None'`

`Sample time (-1 for inherited)` — Time interval between samples

`-1` (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. For more information, see “Specify Sample Time”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'-1'`

Data Types

`Tap sum` — Tap sum data type

`Inherit: Same as input` (default) | `Inherit: Inherit via internal rule` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the tap sum data type of a direct form symmetric or direct form antisymmetric filter, which is the data type the filter uses when it sums the inputs prior to multiplication by the coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter is only visible when you set the **Filter structure** to `Direct form symmetric` or `Direct form antisymmetric`.

Programmatic Use
Block Parameter: `TapSumDataTypeStr`

Type: character vector
Values: `'Inherit: Same as input' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Same as input'`

`Coefficients` — Coefficient data type

`Inherit: Same wordlength as input` (default) | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same word length as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `CoeffDataTypeStr`
Type: character vector
Values: `'Inherit: Same word length as input'| 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Same wordlength as input'`

`Coefficients minimum` — Minimum value of coefficients

`[]` (default) | scalar

Specify the minimum value that a filter coefficient should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `CoeffMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Coefficients maximum` — Maximum value of coefficients

`[]` (default) | scalar

Specify the maximum value that a filter coefficient should have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `CoeffMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Product output` — Product output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the product output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `ProductDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as input'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Accumulator` — Accumulator data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the accumulator data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `AccumDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as input'` | `'Inherit: Same as product output'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`State` — State data type

`Inherit: Same as accumulator` (default) | `Inherit: Same as input` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Dependencies

To enable this parameter, set the **Filter structure** to `Lattice MA`.

Programmatic Use
Block Parameter: `StateDataTypeStr`
Type: character vector
Values: `'Inherit: Same as accumulator'` | `'Inherit: Same as input'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Same as accumulator'`

`Output` — Output data type

`Inherit: Same as accumulator` (default) | `Inherit: Same as input` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as accumulator`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Same as accumulator'` | `'Inherit: Same as input'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'<data type expression>'`

Default: `'Inherit: Same as accumulator'`

`Output minimum` — Minimum output value for range checking

`[ ]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[ ]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock data type settings of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when

overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

This block supports custom state attributes to customize and generate code more efficiently. To access or set these attributes, in the Simulink editor, select **View > Model Data Editor** or press **Ctrl+Shift+E**. For an example, see “Custom State Attributes in Discrete FIR Filter block”.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL Coder provides additional configuration options that affect HDL implementation and synthesized logic. For more information on implementations, properties, and restrictions for HDL code generation, see Discrete FIR Filter.

For hardware-friendly valid and reset control signals, and to model exact hardware latency behavior in Simulink, use the Discrete FIR Filter HDL Optimized block instead.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

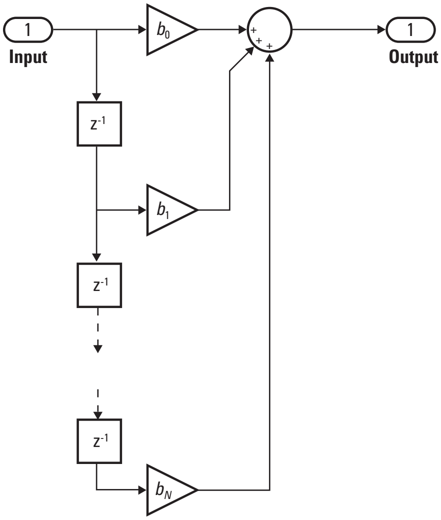
Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

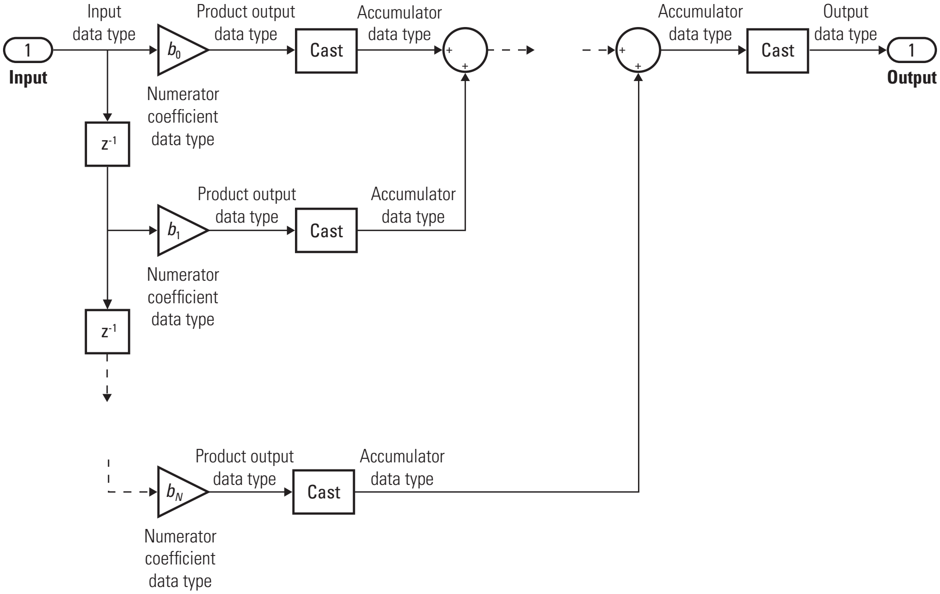
The Discrete FIR Filter block accepts and outputs real and complex signals of any numeric data type supported by Simulink. The block supports the same types for the coefficients.

The following diagrams show the filter structure and the data types used within the Discrete FIR Filter block for fixed-point signals.

Direct Form

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

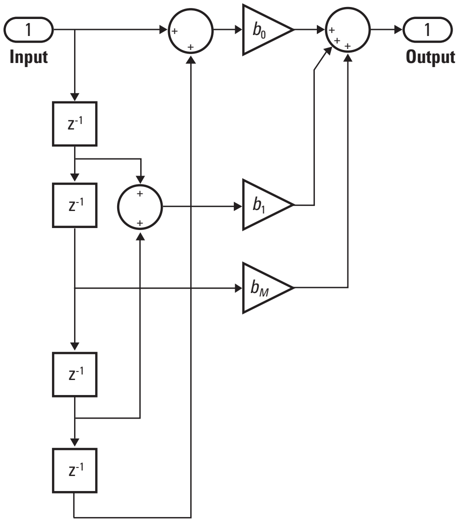




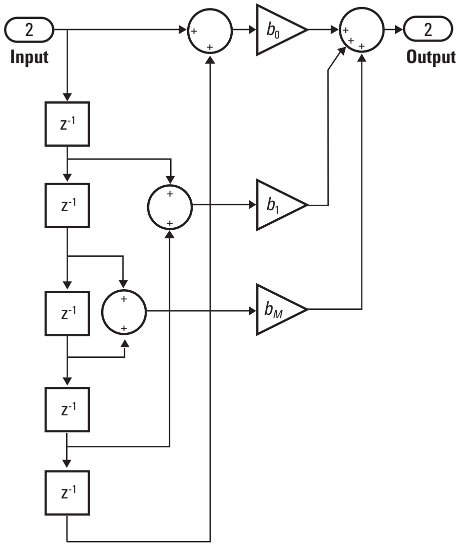
Direct Form Symmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

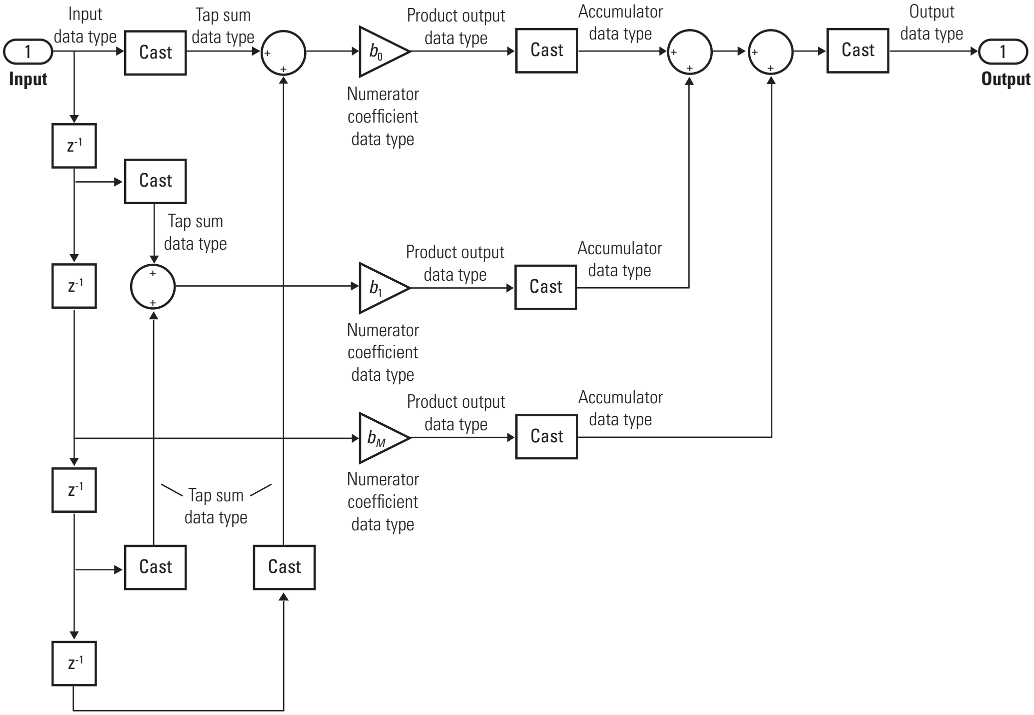
It is assumed that the filter coefficients are symmetric. The block only uses the first half of the coefficients for filtering.



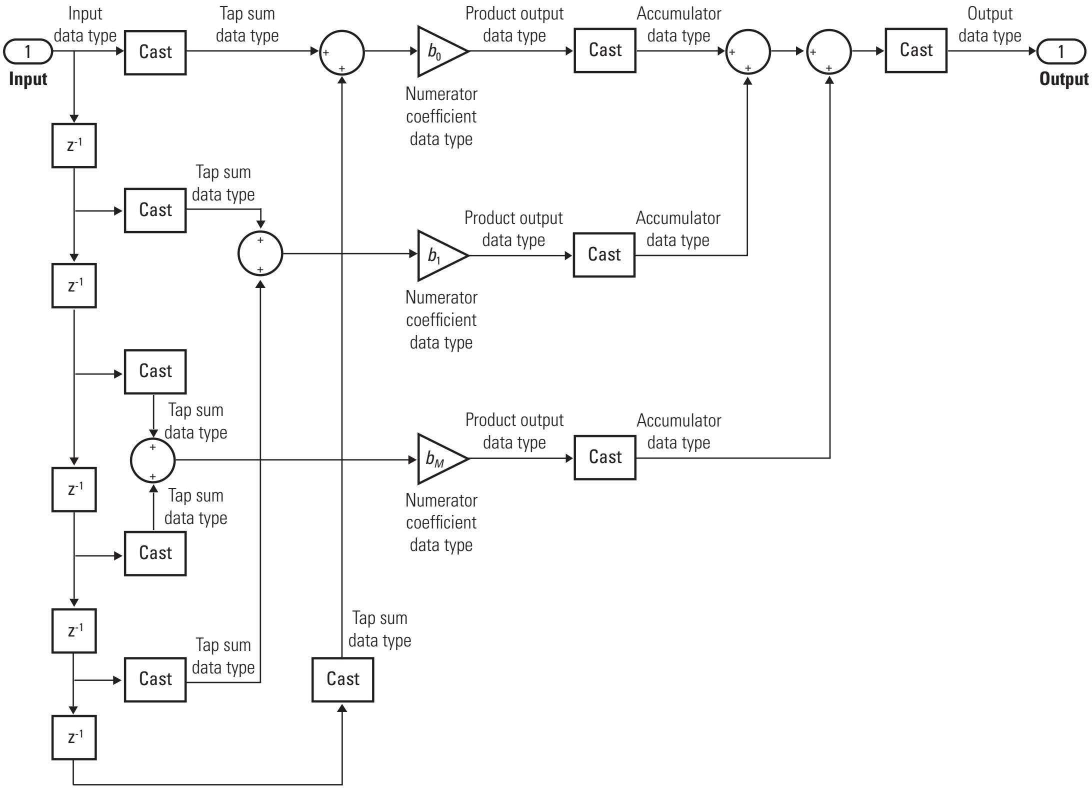
Even Order - Type I



Odd Order - Type II



Even Order - Type I

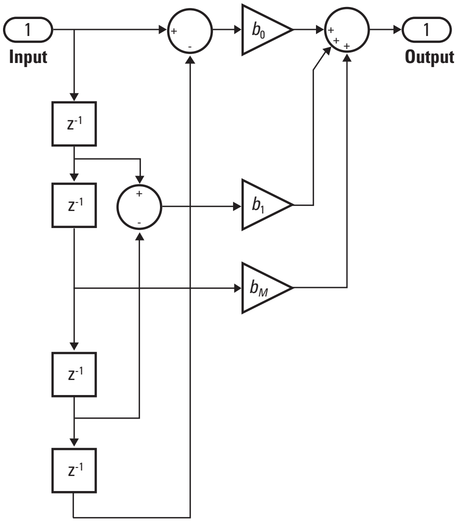


Odd Order - Type II

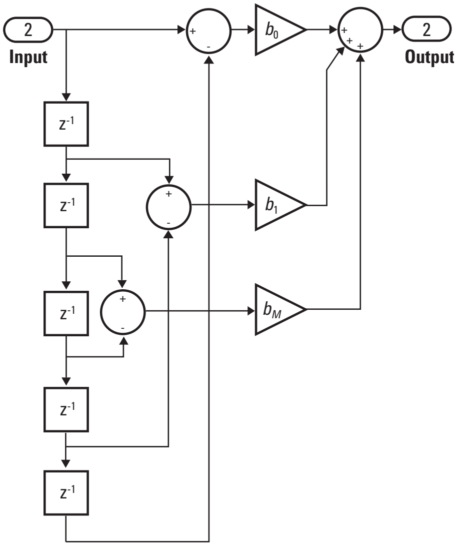
Direct Form Antisymmetric

You cannot specify the state data type on the block mask for this structure because the input states have the same data types as the input.

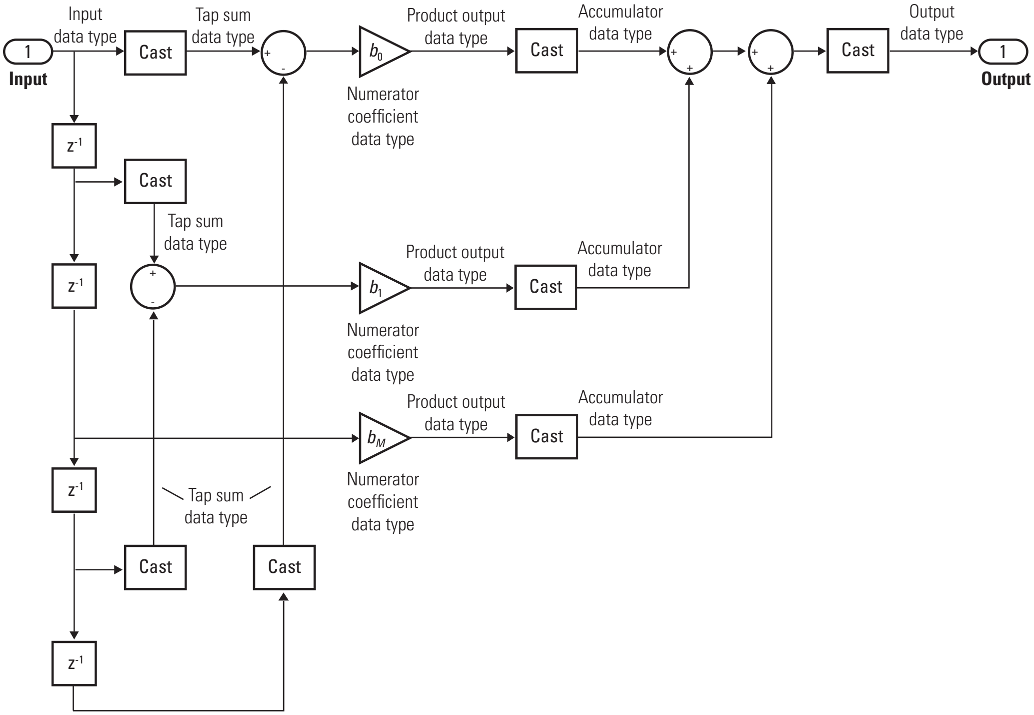
It is assumed that the filter coefficients are antisymmetric. The block only uses the first half of the coefficients for filtering.



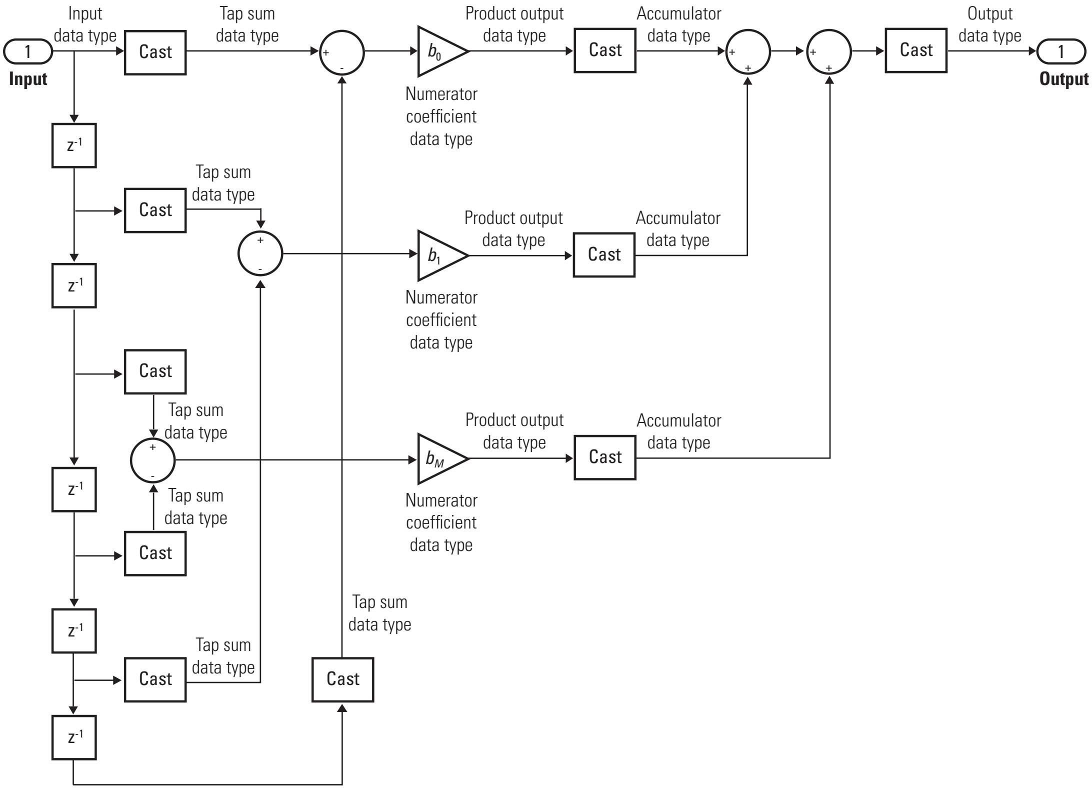
Even Order - Type III



Odd Order - Type IV



Even Order - Type III



Odd Order - Type IV

Direct Form Transposed

States are complex when either the inputs or the coefficients are complex.

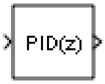
Discrete PID Controller

Discrete-time or continuous-time PID controller
Library: Simulink / Discrete



Description

The Discrete PID Controller block implements a PID controller (PID, PI, PD, P only, or I only). The block is identical to the PID Controller block with the **Time domain** parameter set to `Discrete-time`.

The block output is a weighted sum of the input signal, the integral of the input signal, and the derivative of the input signal. The weights are the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action.

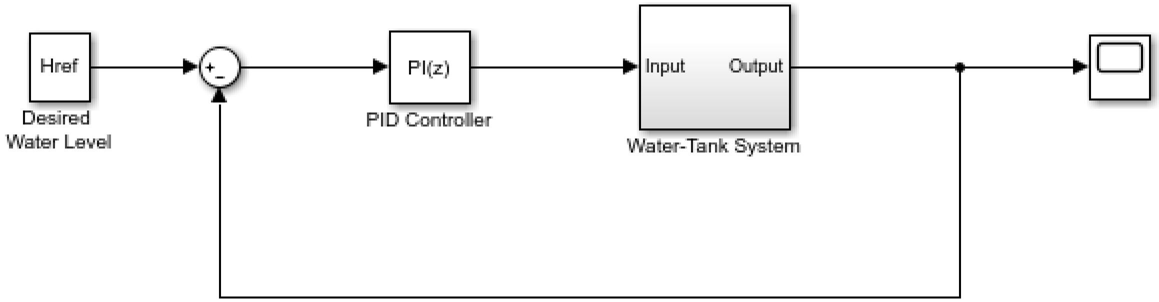
The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, PD, P only, or I only) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (For more information, see “Variant Subsystems”). To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.



The input of the block is typically an error signal, which is the difference between a reference signal and the system output. For a two-input block that permits setpoint weighting, see Discrete PID Controller (2DOF).

PID Gain Tuning

The PID controller gains are tunable either manually or automatically. Automatic tuning requires Simulink Control Design™ software. For more information about automatic tuning, see the **Select tuning method** parameter.

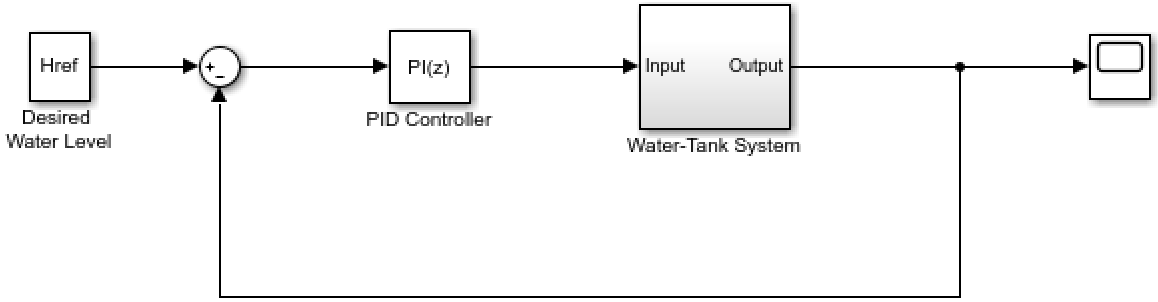
Ports

Input

`Port_1( u )` — Error signal input

scalar | vector

Difference between a reference signal and the output of the system under control, as shown.



Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`D` — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`N` — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

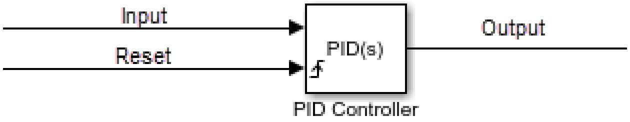
To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Reset — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. The value of the **External reset** parameter determines whether reset occurs on a rising signal, a falling signal, or a level signal. The port icon indicates the selected trigger type. For example, the following illustration shows a continuous-time PID block with **External reset** set to `rising`.



When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the $\mathbf{I_0}$ and $\mathbf{D_0}$ ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA®) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than `none`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `Boolean`

I_0 — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

D_0 — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1( y )` — Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as *N* independent PID controllers, where *N* is the number of signals in the input vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Controller` — Controller type

`PID` (default) | `PI` | `PD` | `P` | `I`

Specify which of the proportional, integral, and derivative terms are in the controller.

`PID`

Proportional, integral, and derivative action.

`PI`

Proportional and integral action only.

`PD`

Proportional and derivative action only.

`P`

Proportional action only.

`I`

Integral action only.

Tip The controller transfer function for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use
Block Parameter: `Controller`
Type: string, character vector
Values: `"PID"`, `"PI"`, `"PD"`, `"P"`, `"I"`
Default: `"PID"`

`Form` — Controller structure

`Parallel` (default) | `Ideal`

Specify whether the controller structure is parallel or ideal.

`Parallel`

The controller output is the sum of the proportional, integral, and derivative actions, weighted independently by **P**, **I**, and **D**, respectively. For example, for a continuous-time parallel-form PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

`Ideal`

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time ideal-form PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $a(z)$ and $b(z)$, respectively.

Tip The controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use
Block Parameter: `Controller`
Type: string, character vector
Values: `"Parallel"`, `"Ideal"`
Default: `"Parallel"`

`Time domain` — Specify discrete-time or continuous-time controller

`Discrete-time` (default) | `Continuous-time`

When you select `Discrete-time`, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting `Discrete-time` also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select `Continuous-time`.

Note The PID Controller and Discrete PID Controller blocks are identical except for the default value of this parameter.

Programmatic Use
Block Parameter: `TimeDomain`
Type: string, character vector
Values: `"Continuous-time"`, `"Discrete-time"`
Default: `"Continuous-time"`

`Sample time (-1 for inherited)` — Discrete interval between samples

–1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of –1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to `Continuous-time`.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to –1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`.

Programmatic Use
Block Parameter: `SampleTime`
Type: scalar
Values: `-1`, positive scalar
Default: `-1`

`Integrator method` — Method for computing integral in discrete-time controller

`Forward Euler` (default) | `Backward Euler` | `Trapezoidal`

In discrete time, the integral term of the controller transfer function is $I\alpha(z)$, where $\alpha(z)$ depends on the integrator method you specify with this parameter.

`Forward Euler`

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z - 1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1}.$$

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Bilinear approximation,

$$\alpha(z) = \frac{T_s}{2}\frac{z+1}{z-1}.$$

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Note For the `BackwardEuler` or `Trapezoidal` methods, you cannot generate HDL code for the block if either:

- **Limit output** is selected and **Anti-Windup Method** is anything other than `none`.
- **Enable tracking mode** is selected.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to `Discrete-time` and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: `IntegratorMethod`
Type: string, character vector
Values: `"Forward Euler"`, `"Backward Euler"`, `"Trapezoidal"`
Default: `"Forward Euler"`

`Filter method` — Method for computing derivative in discrete-time controller

`Forward Euler` (default) | `Backward Euler` | `Trapezoidal`

In discrete time, the derivative term of the controller transfer function is:

$$D\left[\frac{N}{1+N\alpha(z)}\right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

`Forward Euler`

Forward rectangular (left-hand) approximation,

$$\alpha(z)=\frac{T_s}{z-1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Backward rectangular (right-hand) approximation,

$$\alpha(z)=\frac{T_s z}{z-1}.$$

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Bilinear approximation,

$$\alpha(z)=\frac{T_s}{2}\frac{z+1}{z-1}.$$

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to `Discrete-time` and set **Controller** to a controller type with derivative action.

Programmatic Use

Block Parameter: `FilterMethod`
Type: string, character vector
Values: `"Forward Euler"`, `"Backward Euler"`, `"Trapezoidal"`
Default: `"Forward Euler"`

Main

`Source` — Source for controller gains and filter coefficient

internal (default) | external

Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

`internal`

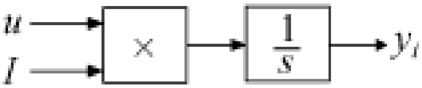
Specify the controller gains and filter coefficient using the block parameters **P**, **I**, **D**, and **N**.

`external`

Specify the PID gains and filter coefficient externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.



Within the block, the input signal *u* is multiplied by the externally supplied integrator gain, *I*, before integration. This implementation yields:

$$y_i = \int uI\,dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain *D* to be differentiated.

Programmatic Use
Block Parameter: `ControllerParametersSource`
Type: string, character vector
Values: `"internal"`, `"external"`
Default: `"internal"`

`Proportional (P)` — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- `Parallel` — Proportional action is independent of the integral and derivative actions. For instance, for a continuous-time parallel PID controller, the transfer function is:

  $$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right).$$

  For a discrete-time parallel-form controller, the transfer function is:

  $$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1+N\beta(z)}\right],$$

  where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- `Ideal` — The proportional gain multiples the integral and derivative terms. For instance, for a continuous-time ideal PID controller, the transfer function is:

  $$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right)\right].$$

  For a discrete-time ideal-form controller, the transfer function is:

  $$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1 + N\beta(z)}\right],$$

  where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to `PID`, `PD`, `PI`, or `P`.

Programmatic Use

Block Parameter: `P`
Type: scalar, vector
Default: 1

`Integral (I)` — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `I`
Type: scalar, vector

Default: 1

`Derivative (D)` — Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: `D`
Type: scalar, vector
Default: 0

`Use filtered derivative` — Apply filter to derivative term

`on` (default) | `off`

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller transfer function becomes:

$$D\frac{z-1}{zT_s}.$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`, and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: `UseFilter`
Type: string, character vector
Values: `"on"`, `"off"`
Default: `"on"`

`Filter coefficient (N)` — Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is `Continuous-time`, the pole location is `s = -N`.
- When **Time domain** is `Discrete-time`, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
`Forward Euler`	$z_{pole} = 1 - NT_s$
`Backward Euler`	$z_{pole} = \dfrac{1}{1 + NT_s}$
`Trapezoidal`	$z_{pole} = \dfrac{1 - NT_s / 2}{1 + NT_s / 2}$

The block does not support `N = Inf` (ideal unfiltered derivative). When the **Time domain** is `Discrete-time`, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: `N`
Type: scalar, vector
Default: 100

`Select tuning method` — Tool for automatic tuning of controller coefficients

`Transfer Function Based (PID Tuner App)` (default) | `Frequency Response Based`

If you have Simulink Control Design software, you can automatically tune the PID coefficients. To do so, use this parameter to select a tuning tool, and click **Tune**.

`Transfer Function Based (PID Tuner App)`

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Introduction to Model-Based PID Tuning in Simulink” (Simulink Control Design).

`Frequency Response Based`

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

`Enable zero-crossing detection` — Detect zero crossings on reset and on entering or leaving a saturation state

`on` (default) | `off`

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use

Block Parameter: `ZeroCross`
Type: string, character vector
Values: `"on"`, `"off"`

Default: `"on"`

Initialization

`Source` — Source for integrator and derivative initial conditions

`internal` (default) | `external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

`internal`

> Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

`external`

> Specify the initial conditions externally using block inputs. Additional input ports $\mathbf{I_o}$ and $\mathbf{D_o}$ appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at $\mathbf{D_o}$ instead of a filter initial condition.

Programmatic Use
Block Parameter: `InitialConditionSource`
Type: string, character vector
Values: `"internal"`, `"external"`
Default: `"internal"`

`Integrator` — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `InitialConditionForIntegrator`
Type: scalar, vector
Default: 0

`Filter` — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: `InitialConditionForFilter`
Type: scalar, vector
Default: 0

`Differentiator` — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, set **Time domain** to `Discrete-time`, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to `internal`.

Programmatic Use
Block Parameter: `DifferentiatorICPrevScaledInput`
Type: scalar, vector
Default: 0

`Initial condition setting` — Location at which initial condition is applied

`State (most efficient)` (default) | `Output`

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

`State (most efficient)`

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

`Output`

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use
Block Parameter: `InitialConditionSetting`
Type: string, character vector
Values: `"state"`, `"output"`
Default: `"state"`

`External reset` — Trigger for resetting integrator and filter values

`none` (default) | `rising` | `falling` | `either` | `level`

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than `none` enables the **Reset** port on the block for the external reset signal.

`none`

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

`rising`

Reset the outputs when the reset signal has a rising edge.

`falling`

Reset the outputs when the reset signal has a falling edge.

`either`

Reset the outputs when the reset signal either rises or falls.

`level`

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use
Block Parameter: `ExternalReset`
Type: string, character vector
Values: `"none"`, `"rising"`, `"falling"`, `"either"`,`"level"`
Default: `"none"`

`Ignore reset when linearizing` — Force linearization to ignore reset

`off` (default) | `on`

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use
Block Parameter: `IgnoreLimit`
Type: string, character vector
Values: `"off"`, `"on"`

Default: `"off"`

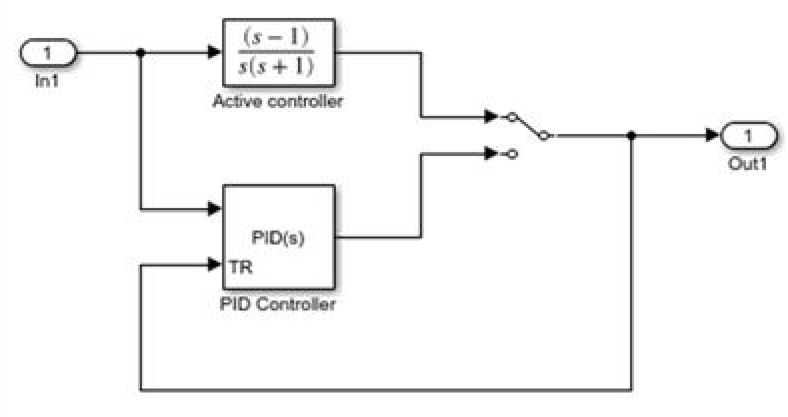
`Enable tracking mode` — Activate signal tracking

`off` (default) | `on`

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain `Kt`, specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

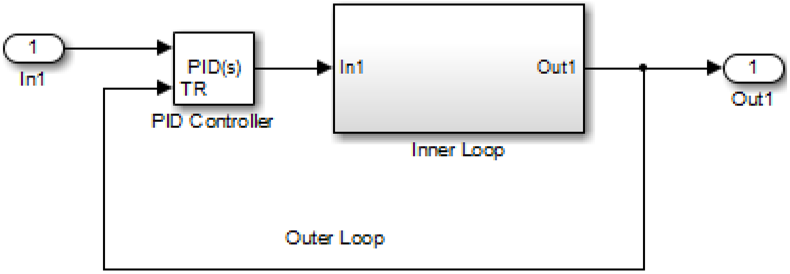
Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.



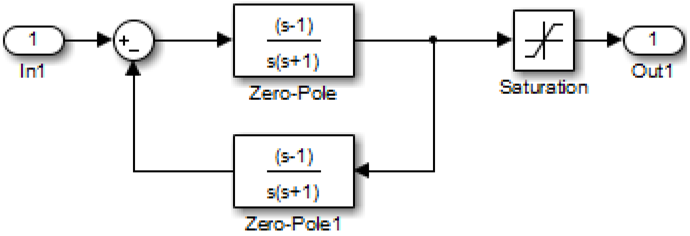
For more information, see “Bumpless Control Transfer” on page 14-111.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches, as in the following model.



The Inner Loop subsystem contains the blocks shown in the following diagram.



Because the PID controller tracks the output of the inner loop, its output never exceeds the saturated inner-loop output. For more details, see "Prevent Block Windup in Multiloop Control" on page 14-110.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `TrackingMode`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Tracking coefficient (Kt)` — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain `Kt`. Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use

Block Parameter: `Kt`
Type: scalar
Default: 1

Output saturation

`Limit Output` — Limit block output to specified saturation values

`off` (default) | `on`

Activating this option limits the block output internally to the block, so that you do not need a separate Saturation on page 1-1607 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the saturation limits using the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use

Block Parameter: `LimitOutput`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Upper limit` — Upper saturation limit for block output

`Inf` (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: `UpperSaturationLimit`
Type: scalar
Default: `Inf`

`Lower limit` — Lower saturation limit for block output

`-Inf` (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: `LowerSaturationLimit`
Type: scalar
Default: `-Inf`

`Ignore saturation when linearizing` — Force linearization to ignore output limits

`off` (default) | `on`

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: `LinearizeAsGain`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Anti-windup method` — Integrator anti-windup method

`none` (default) | `back-calculation` | `clamping`

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

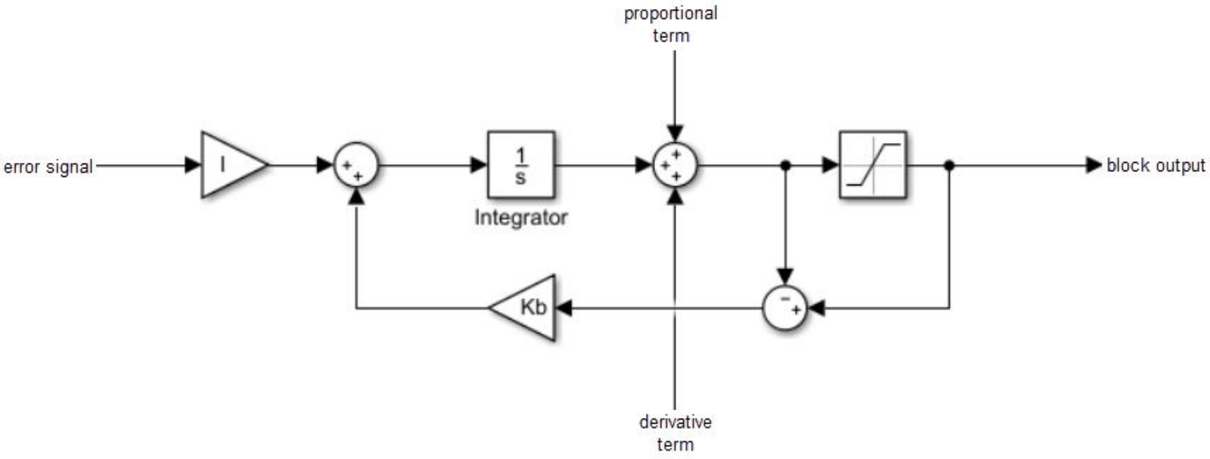
In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

`none`

Do not use an anti-windup mechanism.

`back-calculation`

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.



Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set `Kb = I`, or for controllers with derivative action, `Kb = sqrt(I*D)`. Back-calculation can be effective for plants with relatively large dead time [1].

`clamping`

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use
Block Parameter: `AntiWindupMode`
Type: string, character vector
Values: `"none"`, `"back-calculation"`,`"clamping"`
Default: `"none"`

`Back-calculation coefficient (Kb)` — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The `back-calculation` anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to `back-calculation`.

Programmatic Use
Block Parameter: `Kb`
Type: scalar

Default: 1

Data Types

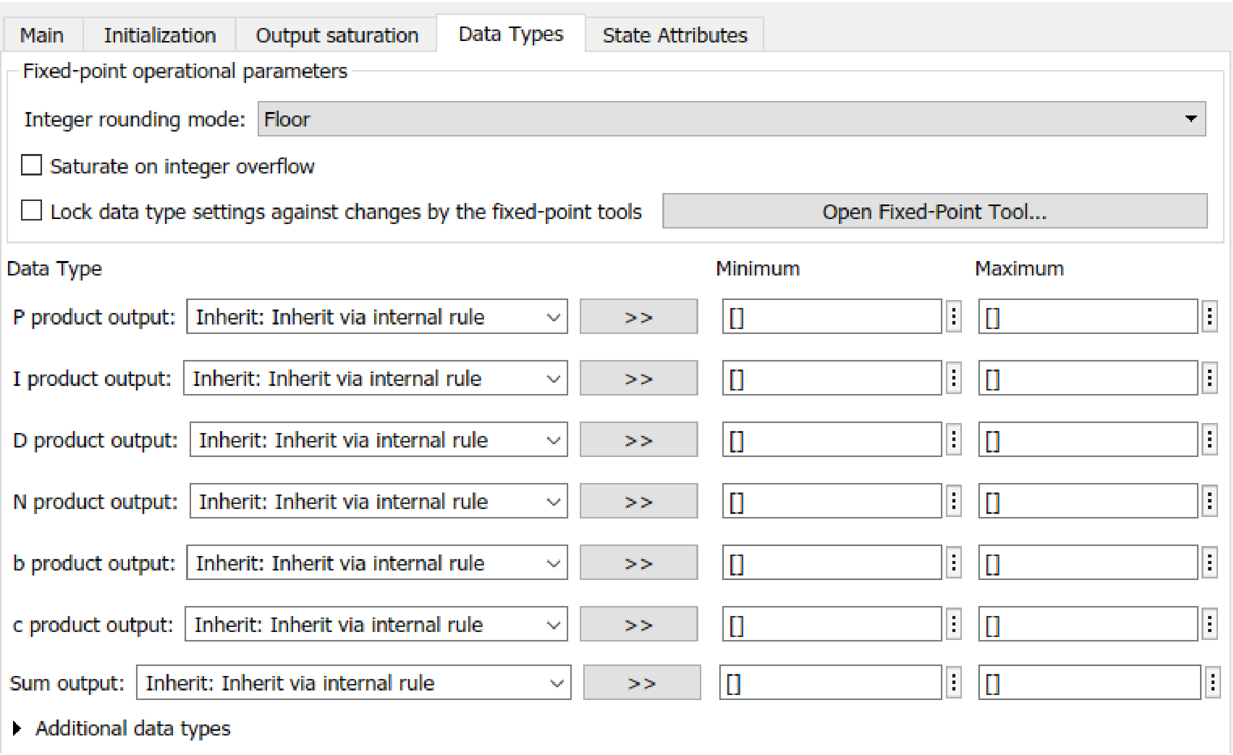
The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click >> to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.



Fixed-point operational parameters

Integer rounding mode: Floor

□ Saturate on integer overflow

□ Lock data type settings against changes by the fixed-point tools

Data Type		Minimum	Maximum
P product output:	Inherit: Inherit via internal rule	[]	[]
I product output:	Inherit: Inherit via internal rule	[]	[]
D product output:	Inherit: Inherit via internal rule	[]	[]
N product output:	Inherit: Inherit via internal rule	[]	[]
b product output:	Inherit: Inherit via internal rule	[]	[]
c product output:	Inherit: Inherit via internal rule	[]	[]
Sum output:	Inherit: Inherit via internal rule	[]	[]

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block

SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as `SumI2`. (See “Search and Edit Using Model Explorer”.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector

Values: `'off' | 'on'`
Default: `'off'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

State Attributes

The parameters in this tab are primarily of use in code generation.

`State name (e.g., 'position')` — Name for continuous-time filter and integrator states

`''` (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to `Continuous-time`.

Programmatic Use

Parameter: `IntegratorContinuousStateAttributes`, `FilterContinuousStateAttributes`
Type: character vector
Default: `''`

`State name` — Names for discrete-time filter and integrator states

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`.

Programmatic Use

Parameter: `IntegratorStateIdentifier`, `FilterStateIdentifier`
Type: string, character vector
Default: `""`

`State name must resolve to Simulink signal object` — Require that state name resolve to a signal object

`off` (default) | `on`

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

1. Set **Time domain** to `Discrete-time`.
2. Specify a value for the integrator or filter **State name**.
3. Set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class** for the corresponding integrator or filter state.

Programmatic Use

Block Parameter: `IntegratorStateMustResolveToSignalObject`, `FilterStateMustResolveToSignalObject`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Code generation storage class` — Storage class for code generation

`Auto` (default) | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer`

Select state storage class for code generation. If you do not need to interface to external code, select `Auto`.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

1. Set **Time domain** to `Discrete-time`.
2. Specify a value for the integrator or filter **State name**.
3. Set the model configuration parameter **Signal resolution** to a value other than `None`.

Programmatic Use

Block Parameter: `IntegratorRTWStateStorageClass`, `FilterRTWStateStorageClass`
Type: string, character vector
Values: `"Auto"`, `"ExportedGlobal"`, `"ImportedExtern"` | `"ImportedExternPointer"`
Default: `"Auto"`

Code generation storage type qualifier — Storage type qualifier

empty string (default) | character vector | "const" | "volatile" | ...

Specify a storage type qualifier such as `const` or `volatile`.

> **Note** This parameter will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to any value other than `Auto`.

Programmatic Use

Block Parameter: `IntegratorRTWStateStorageTypeQualifier`,`FilterRTWStateStorageTypeQualifier`
Type: string, character vector
Values:`""`,`"const"`,`"volatile"`
Default: `""`

Block Characteristics

Data Types	double | single | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to `Continuous-time`):

- Consider using “Model Discretizer” to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, from your model, select **Analysis** > **Control Design** > **Analysis** > **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to `Discrete-time`):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

If the **Integrator method** is set to `BackwardEuler` or `Trapezoidal`, you cannot generate HDL code for the block under either of the following conditions:

- **Limit output** is selected and the **Anti-Windup Method** is anything other than `none`.
- **Enable tracking mode** is selected.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

Introduced in R2009b

Discrete PID Controller (2DOF)

Discrete-time or continuous-time two-degree-of-freedom PID controller
Library: Simulink / Discrete

Description

The Discrete PID Controller (2DOF) block implements a two-degree-of-freedom PID controller (PID, PI, or PD). The block is identical to the PID Controller (2DOF) block with the **Time domain** parameter set to `Discrete-time`.

The block generates an output signal based on the difference between a reference signal and a measured system output. The block computes a weighted difference signal for the proportional and derivative actions according to the setpoint weights (**b** and **c**) that you specify. The block output is the sum of the proportional, integral, and derivative actions on the respective difference signals, where each action is weighted according to the gain parameters **P**, **I**, and **D**. A first-order pole filters the derivative action.

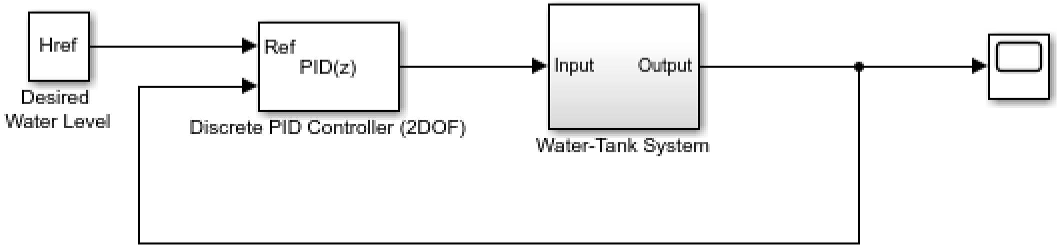
The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, or PD) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (discrete or continuous) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Variant Subsystems”.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.



For a single-input block that accepts an error signal (a difference between a setpoint and a system output), see Discrete PID Controller.

PID Gain Tuning

The PID controller coefficients and the setpoint weights are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

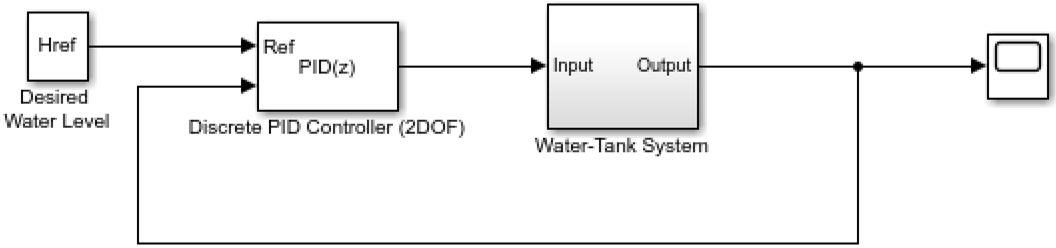
Ports

Input

`Ref` — Reference signal

scalar | vector

Reference signal for plant to follow, as shown.



When the reference signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Port_1( y )` — Measured system output

scalar | vector

Feedback signal for the controller, from the plant output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`I` — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`D` — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`N` — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

b — Proportional setpoint weight

scalar | vector

Proportional setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

c — Derivative setpoint weight

scalar | vector

Derivative setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

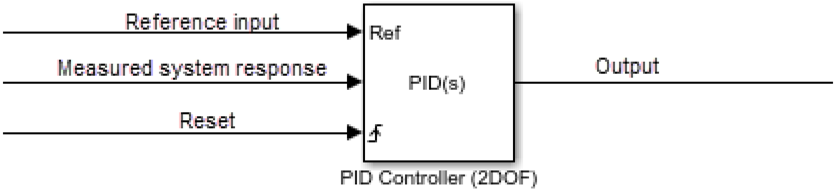
To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Reset — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. Use the **External reset** parameter to specify what kind of signal triggers a reset. The port icon indicates the trigger type specified in that parameter. For example, the following illustration shows a continuous-time PID Controller (2DOF) block with **External reset** set to `rising`.



When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the $\mathbf{I_0}$ and $\mathbf{D_0}$ ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than `none`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `Boolean`

$\mathbf{I_0}$ — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

D_0 — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1( u )` — Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the setpoint weights and by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as *N* independent PID controllers, where *N* is the number of signals in the input vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Controller` — Controller type

`PID` (default) | `PI` | `PD`

Specify which of the proportional, integral, and derivative terms are in the controller.

`PID`

Proportional, integral, and derivative action.

`PI`

Proportional and integral action only.

`PD`

Proportional and derivative action only.

Tip The controller output for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: `Controller`
Type: string, character vector
Values: `"PID"`, `"PI"`, `"PD"`
Default: `"PID"`

Form — Controller structure

Parallel (default) | Ideal

Specify whether the controller structure is parallel or ideal.

Parallel

The proportional, integral, and derivative gains **P**, **I**, and **D**, are applied independently. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output *u* is:

$$u = P(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y),$$

where *r* is the reference signal, *y* is the measured plant output signal, and *b* and *c* are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Ideal

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P\left[(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y)\right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P\left[(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y)\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tip The controller output for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use
Block Parameter: `Controller`
Type: string, character vector
Values: `"Parallel"`, `"Ideal"`
Default: `"Parallel"`

`Time domain` — Specify discrete-time or continuous-time controller

`Discrete-time` (default) | `Continuous-time`

When you select `Discrete-time`, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting `Discrete-time` also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select `Continuous-time`.

Note The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks are identical except for the default value of this parameter.

Programmatic Use
Block Parameter: `TimeDomain`
Type: string, character vector
Values: `"Continuous-time"`, `"Discrete-time"`
Default: `"Discrete-time"`

`Sample time (-1 for inherited)` — Discrete interval between samples

–1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of –1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the

controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to `Continuous-time`.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to –1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`.

Programmatic Use
Block Parameter: `SampleTime`
Type: scalar
Values: `-1`, positive scalar
Default: `-1`

`Integrator method` — Method for computing integral in discrete-time controller

`Forward Euler` (default) | `Backward Euler` | `Trapezoidal`

In discrete time, the integral term of the controller transfer function is *Ia*(*z*), where *a*(*z*) depends on the integrator method you specify with this parameter.

`Forward Euler`

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z-1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z - 1}.$$

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Bilinear approximation,

$$\alpha(z) = \frac{T_s}{2} \frac{z + 1}{z - 1}.$$

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to `Discrete-time` and set **Controller** to a controller type with integral action.

Programmatic Use
Block Parameter: `IntegratorMethod`
Type: string, character vector
Values: `"Forward Euler"`, `"Backward Euler"`, `"Trapezoidal"`
Default: `"Forward Euler"`

`Filter method` — Method for computing derivative in discrete-time controller

`Forward Euler` (default) | `Backward Euler` | `Trapezoidal`

In discrete time, the derivative term of the controller transfer function is:

$$D\left[\frac{N}{1+N\alpha(z)}\right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

`Forward Euler`

Forward rectangular (left-hand) approximation,

$$\alpha(z)=\frac{T_s}{z-1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Backward rectangular (right-hand) approximation,

$$\alpha(z)=\frac{T_s z}{z-1}.$$

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Bilinear approximation,

$$\alpha(z)=\frac{T_s}{2}\frac{z+1}{z-1}.$$

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to `Discrete-time` and set **Controller** to a controller type with derivative action.

Programmatic Use

Block Parameter: `FilterMethod`
Type: string, character vector
Values: `"Forward Euler"`, `"Backward Euler"`, `"Trapezoidal"`
Default: `"Forward Euler"`

Main

`Source` — Source for controller gains and filter coefficient

internal (default) | external

`internal`

Specify the controller gains, filter coefficient, and setpoint weights using the block parameters **P**, **I**, **D**, **N**, **b**, and **c** respectively.

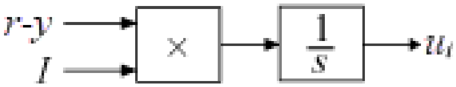
`external`

Specify the PID gains, filter coefficient, and setpoint weights externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

Enabling external inputs for the parameters allows you to compute their values externally to the block and provide them to the block as signal inputs.

External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. The derivative setpoint weight *c* is also differentiated. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.



Within the block, the input signal *u* is multiplied by the externally supplied integrator gain, *I*, before integration. This implementation yields:

$$u_i = \int (r - y) I \, dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain *D* and the derivative setpoint weight *c* to be differentiated.

Programmatic Use
Block Parameter: `ControllerParametersSource`
Type: string, character vector
Values: `"internal"`, `"external"`
Default: `"internal"`

`Proportional (P)` — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- `Parallel` — Proportional action is independent of the integral and derivative actions. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output *u* is:

  $$u = P(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y),$$

  where *r* is the reference signal, *y* is the measured plant output signal, and *b* and *c* are the setpoint weights.

  For a discrete-time 2-DOF controller in parallel form, the controller output is:

  $$u = P(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- `Ideal` — The proportional gain multiples the integral and derivative terms. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P\left[(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y)\right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P\left[(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y)\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, set the Controller parameters **Source** to `internal`.

Programmatic Use

Block Parameter: `P`
Type: scalar, vector
Default: 1

`Integral (I)` — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use
Block Parameter: `I`
Type: scalar, vector
Default: 1

`Derivative (D)` — Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to `PID` or `PD`.

Programmatic Use
Block Parameter: `D`
Type: scalar, vector
Default: 0

`Use filtered derivative` — Apply filter to derivative term

`on` (default) | `off`

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller output becomes:

$$D\frac{z-1}{zT_s}(cr-y).$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`, and set **Controller** to a type that has a derivative term.

Programmatic Use
Block Parameter: `UseFilter`
Type: string, character vector
Values: `"on"`, `"off"`

Default: `"on"`

`Filter coefficient (N)` — Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is `Continuous-time`, the pole location is `s = -N`.
- When **Time domain** is `Discrete-time`, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
`Forward Euler`	$z_{pole} = 1 - NT_s$
`Backward Euler`	$z_{pole} = \frac{1}{1 + NT_s}$
`Trapezoidal`	$z_{pole} = \frac{1 - NT_s / 2}{1 + NT_s / 2}$

The block does not support `N = Inf` (ideal unfiltered derivative). When the **Time domain** is `Discrete-time`, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: `N`
Type: scalar, vector
Default: 100

`Setpoint weight (b)` — Proportional setpoint weight

1 (default) | scalar | vector

Setpoint weight on the proportional term of the controller. The proportional term of a 2-DOF controller output is *P*(*br*–*y*), where *r* is the reference signal and *y* is the measured plant output. Setting *b* to 0 eliminates proportional action on the reference signal, which can reduce overshoot in the system response to step changes in the setpoint. Changing the relative values of *b* and *c* changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

Programmatic Use
Block Parameter: `b`
Type: scalar, vector
Default: 1

`Setpoint weight (c)` — Derivative setpoint weight

1 (default) | scalar | vector

Setpoint weight on the derivative term of the controller. The derivative term of a 2-DOF controller acts on *cr*–*y*, where *r* is the reference signal and *y* is the measured plant output. Thus, setting *c* to 0 eliminates derivative action on the reference signal, which can reduce transient response to step changes in the setpoint. Setting *c* to 0 can yield a controller that achieves both effective disturbance rejection and smooth setpoint tracking without excessive transient response. Changing the relative values of *b* and *c* changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to a type that has derivative action.

Programmatic Use
Block Parameter: `c`
Type: scalar, vector
Default: 1

`Select tuning method` — Tool for automatic tuning of controller coefficients

`Transfer Function Based (PID Tuner App)` (default) | `Frequency Response Based`

If you have Simulink Control Design software, you can automatically tune the PID coefficients when they are internal to the block. To do so, use this parameter to select a tuning tool, and click **Tune**.

`Transfer Function Based (PID Tuner App)`

> Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. **PID Tuner** can tune all the coefficients **P**, **I**, **D**, and **N**, and the setpoint coefficients **b** and **c**. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Design Two-Degree-of-Freedom PID Controllers” (Simulink Control Design).

`Frequency Response Based`

> Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. **Frequency Response Based PID Tuner** tunes the coefficients **P**, **I**, **D**, and **N**, but does not tune the setpoint coefficients **b** and **c**. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

`Enable zero-crossing detection` — Detect zero crossings on reset and on entering or leaving a saturation state

`on` (default) | `off`

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use
Block Parameter: `ZeroCross`
Type: string, character vector
Values: `"on"`, `"off"`
Default: `"on"`

Initialization

`Source` — Source for integrator and derivative initial conditions

`internal` (default) | `external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

`internal`

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

`external`

Specify the initial conditions externally using block inputs. Additional input ports $\mathbf{I_o}$ and $\mathbf{D_o}$ appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at $\mathbf{D_o}$ instead of a filter initial condition.

Programmatic Use
Block Parameter: `InitialConditionSource`

Type: string, character vector
Values: `"internal"`, `"external"`
Default: `"internal"`

`Integrator` — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `InitialConditionForIntegrator`
Type: scalar, vector
Default: 0

`Filter` — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: `InitialConditionForFilter`
Type: scalar, vector
Default: 0

`Differentiator` — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, set **Time domain** to `Discrete-time`, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to `internal`.

Programmatic Use
Block Parameter: `DifferentiatorICPrevScaledInput`
Type: scalar, vector
Default: 0

`Initial condition setting` — Location at which initial condition is applied

`State (most efficient)` (default) | `Output`

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

`State (most efficient)`

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

`Output`

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use
Block Parameter: `InitialConditionSetting`

Type: string, character vector
Values: "state", "output"
Default: "state"

External reset — Trigger for resetting integrator and filter values

none (default) | rising | falling | either | level

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than none enables the **Reset** port on the block for the external reset signal.

none

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

rising

Reset the outputs when the reset signal has a rising edge.

falling

Reset the outputs when the reset signal has a falling edge.

either

Reset the outputs when the reset signal either rises or falls.

level

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: ExternalReset
Type: string, character vector
Values: "none", "rising", "falling", "either","level"
Default: "none"

`Ignore reset when linearizing` — Force linearization to ignore reset

`off` (default) | `on`

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: `IgnoreLimit`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

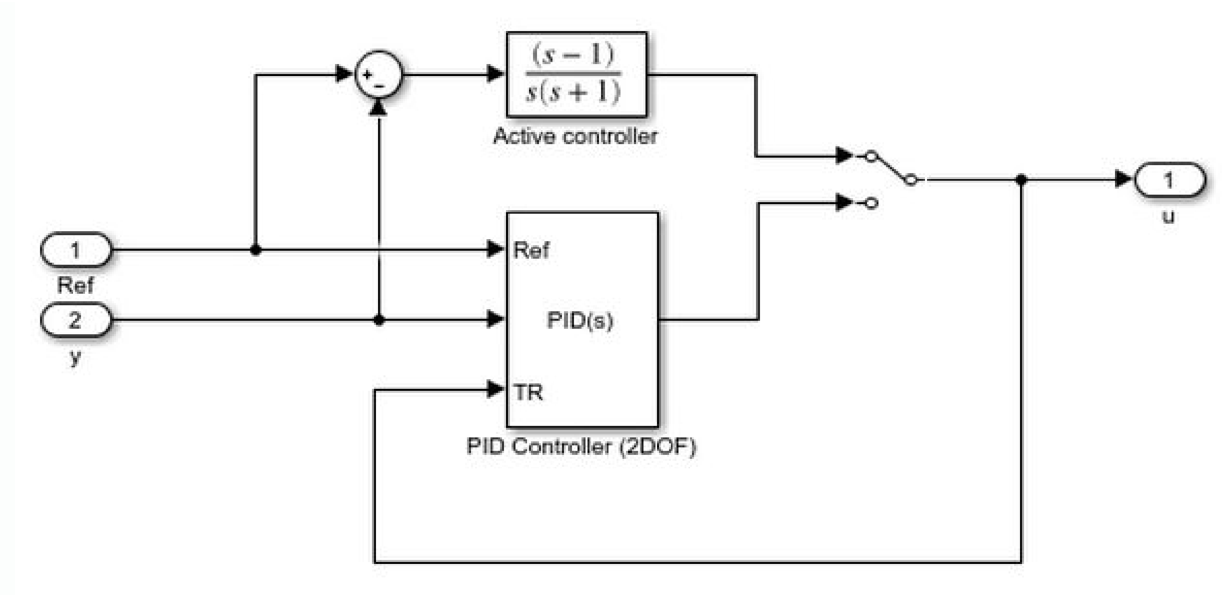
`Enable tracking mode` — Activate signal tracking

`off` (default) | `on`

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain `Kt`, specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.



For more information, see “Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller” on page 14-112.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches. For an example illustrating this approach with a 1DOF PID controller, see “Prevent Block Windup in Multiloop Control” on page 14-110.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use
Block Parameter: `TrackingMode`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Tracking coefficient (Kt)` — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain `Kt`. Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use
Block Parameter: `Kt`
Type: scalar
Default: 1

Output saturation

`Limit Output` — Limit block output to specified saturation values

`off` (default) | `on`

Activating this option limits the block output internally to the block, so that you do not need a separate Saturation on page 1-1607 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the saturation limits using the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use
Block Parameter: `LimitOutput`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Upper limit` — Upper saturation limit for block output

`Inf` (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use
Block Parameter: `UpperSaturationLimit`

Type: scalar
Default: `Inf`

`Lower limit` — Lower saturation limit for block output

`-Inf` (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: `LowerSaturationLimit`
Type: scalar
Default: `-Inf`

`Ignore saturation when linearizing` — Force linearization to ignore output limits

`off` (default) | `on`

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: `LinearizeAsGain`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Anti-windup method` — Integrator anti-windup method

`none` (default) | `back-calculation` | `clamping`

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the signal entering the integrator never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the signal entering the integrator changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

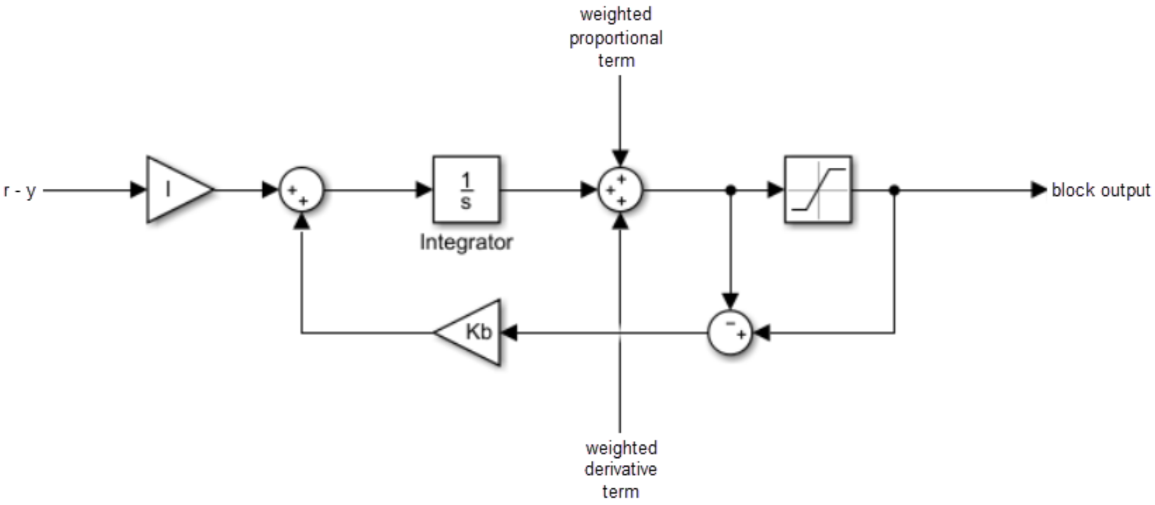
In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

`none`

Do not use an anti-windup mechanism.

`back-calculation`

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.



Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set `Kb = I`, or for controllers with derivative action, `Kb = sqrt(I*D)`. Back-calculation can be effective for plants with relatively large dead time [1].

`clamping`

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use
Block Parameter: `AntiWindupMode`
Type: string, character vector
Values: `"none"`, `"back-calculation"`,`"clamping"`

Default: `"none"`

`Back-calculation coefficient (Kb)` — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The `back-calculation` anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to `back-calculation`.

Programmatic Use

Block Parameter: `Kb`
Type: scalar
Default: 1

Data Types

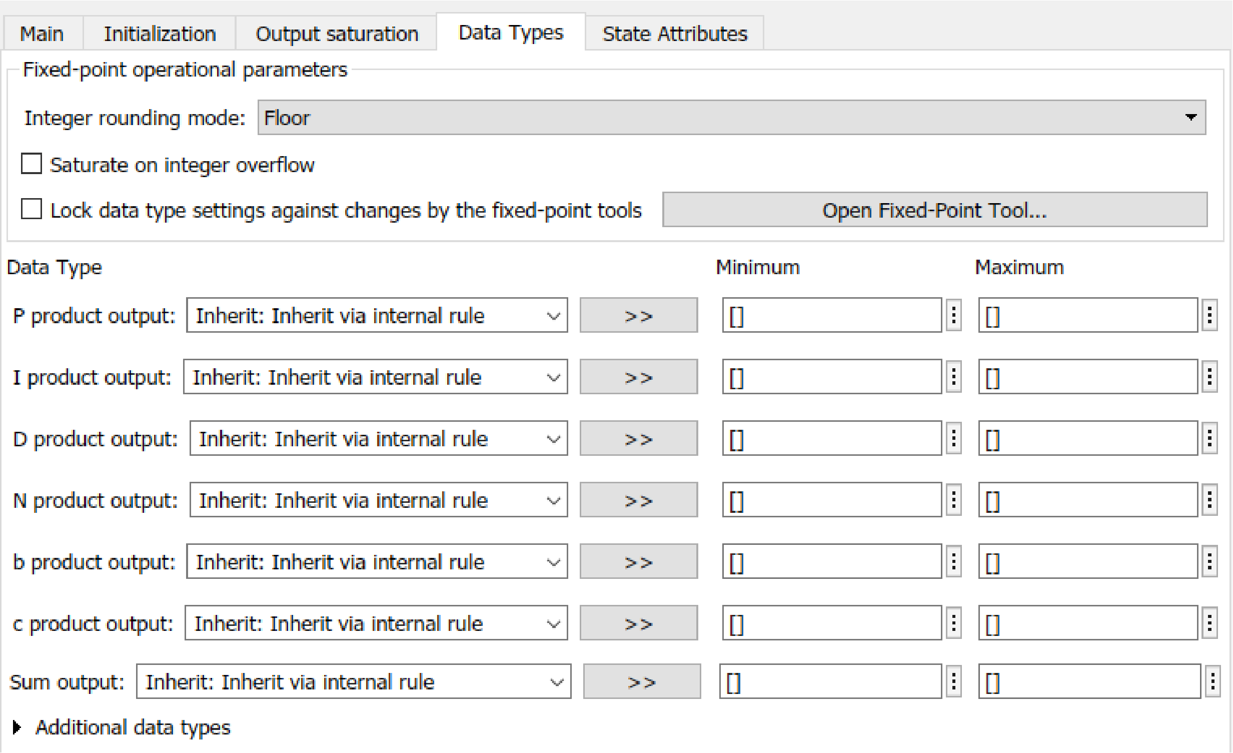
The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click >> to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.



Fixed-point operational parameters

Integer rounding mode: Floor

□ Saturate on integer overflow

□ Lock data type settings against changes by the fixed-point tools

Data Type			Minimum	Maximum
P product output:	Inherit: Inherit via internal rule	>>	[]	[]
I product output:	Inherit: Inherit via internal rule	>>	[]	[]
D product output:	Inherit: Inherit via internal rule	>>	[]	[]
N product output:	Inherit: Inherit via internal rule	>>	[]	[]
b product output:	Inherit: Inherit via internal rule	>>	[]	[]
c product output:	Inherit: Inherit via internal rule	>>	[]	[]
Sum output:	Inherit: Inherit via internal rule	>>	[]	[]

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the

output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.

- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as `SumI2`. (See “Search and Edit Using Model Explorer”.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see "Rounding" (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see "Check for Signal Range Errors".
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see "Lock the Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

State Attributes

The parameters in this tab are primarily of use in code generation.

`State name (e.g., 'position')` — Name for continuous-time filter and integrator states

`''` (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to `Continuous-time`.

Programmatic Use
Parameter: `IntegratorContinuousStateAttributes`, `FilterContinuousStateAttributes`
Type: character vector
Default: `''`

`State name` — Names for discrete-time filter and integrator states

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`.

Programmatic Use
Parameter: `IntegratorStateIdentifier`, `FilterStateIdentifier`
Type: string, character vector
Default: `""`

`State name must resolve to Simulink signal object` — Require that state name resolve to a signal object

`off` (default) | `on`

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

1. Set **Time domain** to `Discrete-time`.
2. Specify a value for the integrator or filter **State name**.
3. Set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class** for the corresponding integrator or filter state.

Programmatic Use
Block Parameter: `IntegratorStateMustResolveToSignalObject`, `FilterStateMustResolveToSignalObject`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Code generation storage class` — Storage class for code generation

`Auto` (default) | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer`

Select state storage class for code generation. If you do not need to interface to external code, select `Auto`.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

1. Set **Time domain** to `Discrete-time`.
2. Specify a value for the integrator or filter **State name**.
3. Set the model configuration parameter **Signal resolution** to a value other than `None`.

Programmatic Use
Block Parameter: `IntegratorRTWStateStorageClass`, `FilterRTWStateStorageClass`
Type: string, character vector
Values: `"Auto"`, `"ExportedGlobal"`, `"ImportedExtern"` | `"ImportedExternPointer"`
Default: `"Auto"`

Code generation storage type qualifier — Storage type qualifier

empty string (default) | character vector | "const" | "volatile" | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note This parameter will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to any value other than `Auto`.

Programmatic Use
Block Parameter: `IntegratorRTWStateStorageTypeQualifier`,`FilterRTWStateStorageTypeQualifier`
Type: string, character vector
Values:`""`,`"const"`,`"volatile"`
Default: `""`

Block Characteristics

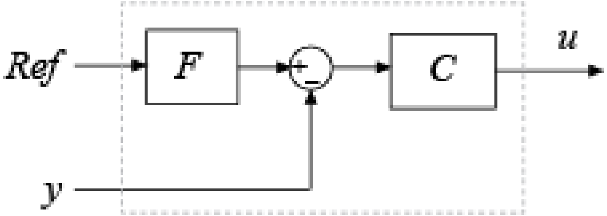
Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Definitions

Decomposition of 2-DOF PID Controllers

A 2-DOF PID controller can be interpreted as a PID controller with a prefilter, or a PID controller with a feedforward element.

In parallel form, a two-degree-of-freedom PID controller can be equivalently modeled by the following block diagram, where *C* is a single degree-of-freedom PID controller and *F* is a prefilter on the reference signal.



Ref is the reference signal, *y* is the feedback from the measured system output, and *u* is the controller output. For a continuous-time 2-DOF PID controller in parallel form, the transfer functions for *F* and *C* are

$$F_{par}(s) = \frac{(bP + cDN)s^2 + (bPN + I)s + IN}{(P + DN)s^2 + (PN + I)s + IN},$$

$$C_{par}(s) = \frac{(P + DN)s^2 + (PN + I)s + IN}{s(s + N)},$$

where *b* and *c* are the setpoint weights.

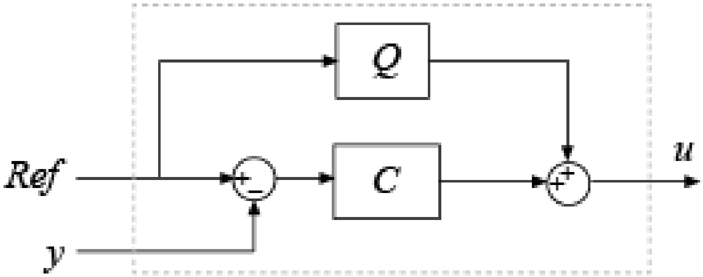
For a 2-DOF PID controller in ideal form, the transfer functions are

$$F_{id}(s) = \frac{(b + cDN)s^2 + (bN + I)s + IN}{(1 + DN)s^2 + (N + I)s + IN},$$

$$C_{id}(s) = P\,\frac{(1 + DN)s^2 + (N + I)s + IN}{s(s + N)}.$$

A similar decomposition applies for a discrete-time 2-DOF controller.

Alternatively, the parallel two-degree-of-freedom PID controller can be modeled by the following block diagram.



In this realization, *Q* acts as feed-forward conditioning on the reference signal. For a continuous-time 2-DOF PID controller in parallel form, the transfer function for *Q* is

$$Q_{par}(s) = \frac{\big((b-1)P + (c-1)DN\big)s + (b-1)PN}{s + N}.$$

For a 2-DOF PID controller in ideal form, the transfer function is

$$Q_{id}(s) = P\,\frac{\big((b-1) + (c-1)DN\big)s + (b-1)N}{s + N}.$$

The transfer functions for *C* are the same as in the filter decomposition.

A similar decomposition applies for a discrete-time 2-DOF controller.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to `Continuous-time`):

- Consider using “Model Discretizer” to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, from your model, select **Analysis** > **Control Design** > **Analysis** > **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to `Discrete-time`):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

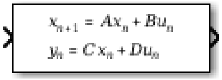
Discrete State-Space

Implement discrete state-space system
Library: Simulink / Discrete



Description

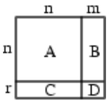
Block Behavior for Non-Empty Matrices

The Discrete State-Space block implements the system described by

$$\begin{aligned} x(n+1) &= Ax(n) + Bu(n) \\ y(n) &= Cx(n) + Du(n), \end{aligned}$$

where *u* is the input, *x* is the state, and *y* is the output. The matrix coefficients must have these characteristics, as illustrated in the following diagram:

- **A** must be an *n*-by-*n* matrix, where *n* is the number of states.
- **B** must be an *n*-by-*m* matrix, where *m* is the number of inputs.
- **C** must be an *r*-by-*n* matrix, where *r* is the number of outputs.
- **D** must be an *r*-by-*m* matrix.



The block accepts one input and generates one output. The width of the input vector is the number of columns in the **B** and **D** matrices. The width of the output vector is the number of rows in the **C** and **D** matrices. To define the initial state vector, use the **Initial conditions** parameter.

To specify a vector or matrix of zeros for **A**, **B**, **C**, **D**, or **Initial conditions**, use the `zeros` function.

Block Behavior for Empty Matrices

When the matrices **A**, **B**, and **C** are empty (for example, `[]`), the functionality of the block becomes `y(n) = Du(n)`. If the **Initial conditions** vector is also empty, the block uses an initial state vector of zeros.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input vector, where the width equals the number of columns in the **B** and **D** matrices. For more information, see "Description" on page 1-576.

Tip For integer and fixed-point input signals, use the Fixed-Point State-Space block.

Data Types: `single` | `double`

Output

`Port_1` — Output vector
scalar | vector | matrix

Output vector, with width equal to the number of rows in the **C** and **D** matrices. For more information, see "Description" on page 1-576.

Data Types: `single` | `double`

Parameters

Main

`A` — Matrix coefficient A
`1` (default) | scalar | vector | matrix

Specify the matrix coefficient A, as a real-valued *n*-by-*n* matrix, where *n* is the number of states. For more information on the matrix coefficients, see “Description” on page 1-576.

Programmatic Use
Block Parameter: A
Type: character vector
Values: scalar | vector | matrix
Default: '1'

B — Matrix coefficient B

1 (default) | scalar | vector | matrix

Specify the matrix coefficient B, as a real-valued *n*-by-*m* matrix, where *n* is the number of states, and *m* is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-576.

Programmatic Use
Block Parameter: B
Type: character vector
Values: scalar | vector | matrix
Default: '1'

C — Matrix coefficient, C

1 (default) | scalar | vector | matrix

Specify the matrix coefficient **C**, as a real-valued *r*-by-*n* matrix, where *r* is the number of outputs, and *n* is the number of states. For more information on the matrix coefficients, see “Description” on page 1-576.

Programmatic Use
Block Parameter: C
Type: character vector
Values: scalar | vector | matrix
Default: '1'

D — Matrix coefficient, D

1 (default) | scalar | vector | matrix

Specify the matrix coefficient **D**, as a real-valued *r*-by-*m* matrix, where *r* is the number of outputs, and *m* is the number of inputs. For more information on the matrix coefficients, see “Description” on page 1-576.

Programmatic Use

Block Parameter: `D`
Type: character vector
Values: scalar | vector | matrix
Default: `'1'`

`Initial conditions` — Initial state vector

0 (default) | scalar | vector | matrix

Specify the initial state vector as a scalar, vector, or matrix. Simulink does not allow the initial states of this block to be `inf` or `NaN`.

Programmatic Use

Block Parameter: `InitialCondition`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`Sample time (–1 for inherited)` — Interval between samples

`-1` (default) | scalar | vector

Specify the time interval between samples. See “Specify Sample Time”.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'-1'`

State Attributes

`State name` — Unique name for block state

`''` (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use
Block Parameter: `StateName`
Type: character vector
Values: unique name
Default: `''`

`State name must resolve to Simulink signal object` — Require state name resolve to a signal object

`off` (default) | `on`

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Programmatic Use
Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Signal object class` — Custom storage class package name

`Simulink.Signal` (default) | `<StorageClass.PackageName>`

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Programmatic Use
Block Parameter: `StateSignalObject`
Type: character vector
Values: `'Simulink.Signal' | '<StorageClass.PackageName>'`
Default: `'Simulink.Signal'`

`Code generation storage class` — State storage class for code generation

`Auto` (default) | `Model default` | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer` | `BitField (Custom)` | `Model default` | `ExportToFile (Custom)` | `ImportFromFile (Custom)` | `FileScope (Custom)` | `AutoScope (Custom)` | `Struct (Custom)` | `GetSet (Custom)` | `Reusable (Custom)`

Select state storage class for code generation.

- `Auto` is the appropriate storage class for states that you do not need to interface to external code.
- *`StorageClass`* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use
Block Parameter: `StateStorageClass`
Type: character vector
Values: `'Auto' | 'SimulinkGlobal' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...`
Default: `'Auto'`

`TypeQualifier` — Storage type qualifier

`''` (default) | `const` | `volatile` | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use

Block Parameter: `RTWStateStorageTypeQualifier`
Type: character vector
Values: `'' | 'const' | 'volatile' | ...`
Default: `''`

Block Characteristics

Data Types	`double` | `single`
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No

Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

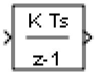
Discrete-Time Integrator

Perform discrete-time integration or accumulation of signal

Library: Simulink / Commonly Used Blocks
Simulink / Discrete



Description

Use the Discrete-Time Integrator block in place of the Integrator block to create a purely discrete model. With the Discrete-Time Integrator block, you can:

- Define initial conditions on the block dialog box or as input to the block
- Define an input gain (K) value
- Output the block state
- Define upper and lower limits on the integral
- Reset the state with an additional reset input

Output Equations

With the first time step, block state `n = 0`, with either initial output `y(0) = IC` or initial state `x(0) = IC`, depending on the **Initial condition setting** parameter value.

For a given step `n > 0` with simulation time `t(n)`, Simulink updates output `y(n)` as follows:

- Forward Euler method:

  ```
  y(n) = y(n-1) + K*[t(n) - t(n-1)]*u(n-1)
  ```
- Backward Euler method:

  ```
  y(n) = y(n-1) + K*[t(n) - t(n-1)]*u(n)
  ```
- Trapezoidal method:

```
   y(n) = y(n-1) + K*[t(n)-t(n-1)]*[u(n)+u(n-1)]/2
```

Simulink automatically selects a state-space realization of these output equations depending on the block sample time, which can be explicit or triggered. When using explicit sample time, `t(n)-t(n-1)` reduces to the sample time `T` for all `n > 0`.

Integration and Accumulation Methods

This block can integrate or accumulate a signal using a forward Euler, backward Euler, or trapezoidal method. Assume that `u` is the input, `y` is the output, and `x` is the state. For a given step `n`, Simulink updates `y(n)` and `x(n+1)`. In integration mode, `T` is the block sample time (delta `T` in the case of triggered sample time). In accumulation mode, `T = 1`. The block sample time determines when the output is computed but not the output value. `K` is the gain value. Values clip according to upper or lower limits.

Forward Euler method (default), also known as forward rectangular, or left-hand approximation

The software approximates `1/s` as `T/(z-1)`. The expressions for the output of the block at step `n` are:

```
x(n+1) = x(n) + K*T*u(n)
y(n)   = x(n)
```

The block uses these steps to compute the output:

```
Step 0:         y(0)   = IC (clip if necessary)
                x(1)   = y(0) + K*T*u(0)

Step 1:         y(1)   = x(1)
                x(2)   = x(1) + K*T*u(1)

Step n:         y(n)   = x(n)
                x(n+1) = x(n) + K*T*u(n) (clip if necessary)
```

Using this method, input port 1 does not have direct feedthrough.

Backward Euler method, also known as backward rectangular or right-hand approximation

The software approximates `1/s` as `T*z/(z-1)`. The resulting expression for the output of the block at step `n` is

```
y(n) = y(n-1) + K*T*u(n).
```

Let `x(n) = y((n)-1)`. The block uses these steps to compute the output.

- If the parameter **Initial condition setting** is set to `Output` or `Auto` for triggered and function-call subsystems:

  ```
  Step 0:          y(0) = IC (clipped if necessary)
                   x(1) = y(0)
  ```
- If the parameter **Initial condition setting** is set to `Auto` for non-triggered subsystems:

  ```
  Step 0:          x(0)   = IC (clipped if necessary)
                   x(1)   = y(0) = x(0) + K*T*u(0)

  Step 1:          y(1)   = x(1) + K*T*u(1)
                   x(2)   = y(1)

  Step n:          y(n)   = x(n) + K*T*u(n)
                   x(n+1) = y(n)
  ```

Using this method, input port 1 has direct feedthrough.

For this method, the software approximates `1/s` as `T/2*(z+1)/(z-1)`.

When `T` is fixed (equal to the sampling period), the expressions to compute the output are:

```
x(n) = y(n-1) + K*T/2*u(n-1)
y(n) = x(n) + K*T/2*u(n)
```

- If the parameter **Initial condition setting** is set to `Output` or `Auto` for triggered and function-call subsystems:

  ```
  Step 0:          y(0)   = IC (clipped if necessary)
                   x(1)   = y(0) + K*T/2*u(0)
  ```
- If the parameter **Initial condition setting** is set to `Auto` for non-triggered subsystems:

  ```
  Step 0:          x(0)   = IC (clipped if necessary)
                   y(0)   = x(0) + K*T/2*u(0)
  ```

```
                 x(1)   = y(0) + K*T/2*u(0)

Step 1:          y(1)   = x(1) + K*T/2*u(1)
                 x(2)   = y(1) + K*T/2*u(1)

Step n:          y(n)   = x(n) + K*T/2*u(n)
                 x(n+1) = y(n) + K*T/2*u(n)
```

Here, `x(n+1)` is the best estimate of the next output. It is not the same as the state, in that `x(n)` is not equal to `y(n)`.

Using this method, input port 1 has direct feedthrough.

When`T` is a variable (for example, obtained from the triggering times), the block uses these steps to compute the output.

- If the parameter **Initial condition setting** is set to `Output` or `Auto` for triggered and function-call subsystems:

```
Step 0:          y(0)   = IC (clipped if necessary)
                 x(1)   = y(0)
```

- If the parameter **Initial condition setting** is set to `Auto` for non-triggered subsystems:

```
Step 0:          x(0)   = IC (clipped if necessary)
                 x(1)   = y(0) = x(0) + K*T/2*u(0)

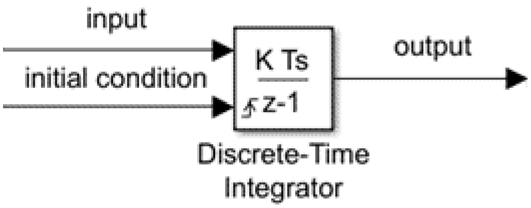
Step 1:          y(1)   = x(1) + T/2*(u(1) + u(0))
                 x(2)   = y(1)

Step n:          y(n)   = x(n) + T/2*(u(n) + u(n-1))
                 x(n+1) = y(n)
```

Define Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, set the **Initial condition source** parameter to `internal` and enter the value in the **Initial condition** text box.
- To provide the initial conditions from an external source, set the **Initial condition source** parameter to `external`. An additional input port appears on the block.

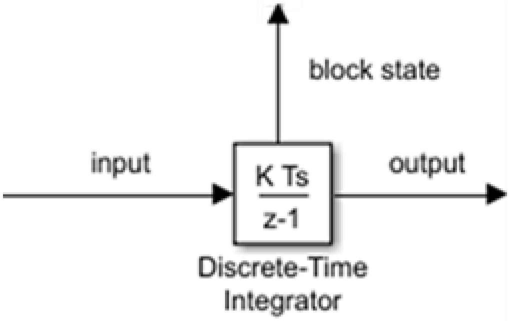


When to Use the State Port

Use the state port instead of the output port:

- When the output of the block is fed back into the block through the reset port or the initial condition port, causing an algebraic loop. For an example, see the `sldemo_bounce_two_integrators` model.
- When you want to pass the state from one conditionally executed subsystem to another, which can cause timing problems. For an example, see the `sldemo_clutch` model.

You can work around these problems by passing the state through the state port rather than the output port. Simulink generates the state at a slightly different time from the output, which protects your model from these problems. To output the block state, select the **Show state port** check box. The state port appears on the top of the block.

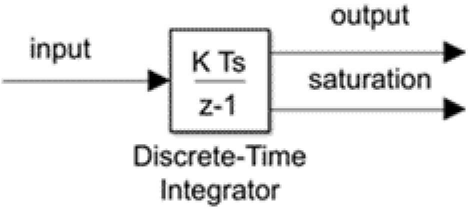


Limit the Integral

To keep the output within certain levels, select the **Limit output** check box and enter the limits in the corresponding text box. Doing so causes the block to function as a limited integrator. When the output reaches the limits, the integral action turns off to prevent integral windup. During a simulation, you can change the limits but you cannot change whether the output is limited. The table shows how the block determines output.

Integral	Output
Less than or equal to the **Lower saturation limit** and the input is negative	Held at the **Lower saturation limit**
Between the **Lower saturation limit** and the **Upper saturation limit**	The integral
Greater than or equal to the **Upper saturation limit** and the input is positive	Held at the **Upper saturation limit**

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A new saturation port appears below the block output port.

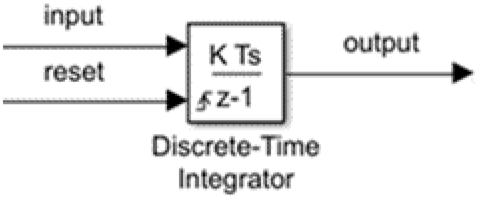


The saturation signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- -1 indicates that the lower limit is being applied.

Reset the State

The block resets its state to the specified initial condition, based on an external signal. To cause the block to reset its state, select one of the **External reset** parameter options. A reset port appears that indicates the reset trigger type.

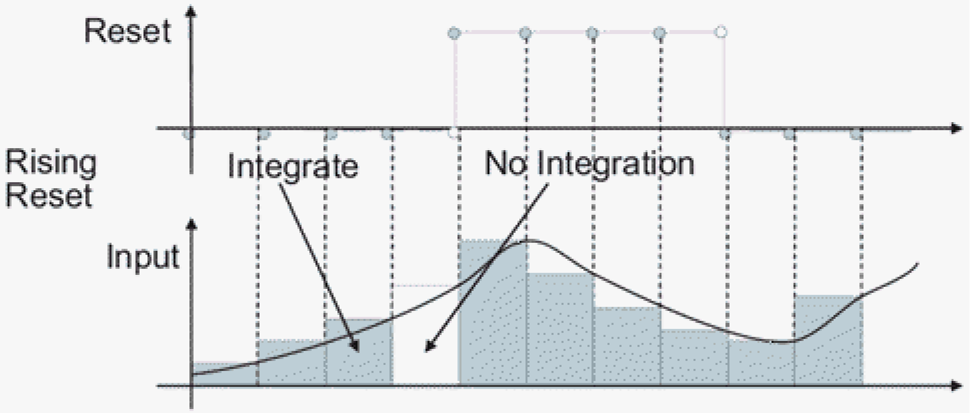


The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results. To resolve this loop, feed the output of the block state port into the reset port instead. To access the block state, select the **Show state port** check box.

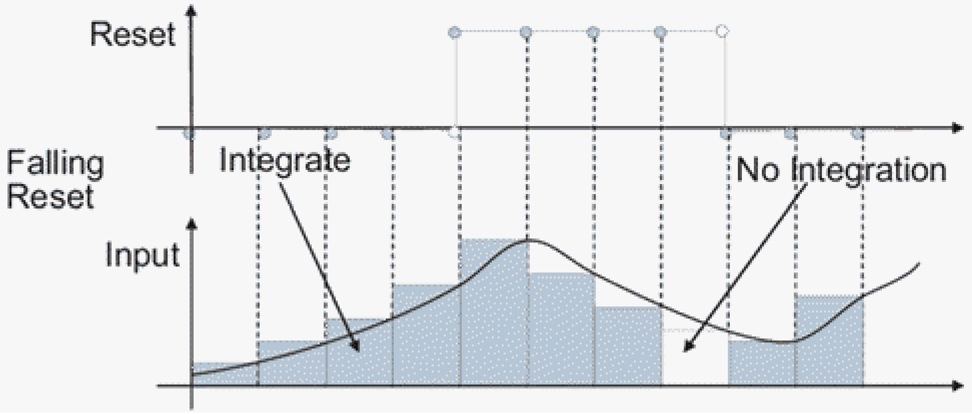
Reset Trigger Types

The **External reset** parameter lets you determine the attribute of the reset signal that triggers the reset. The trigger options include:

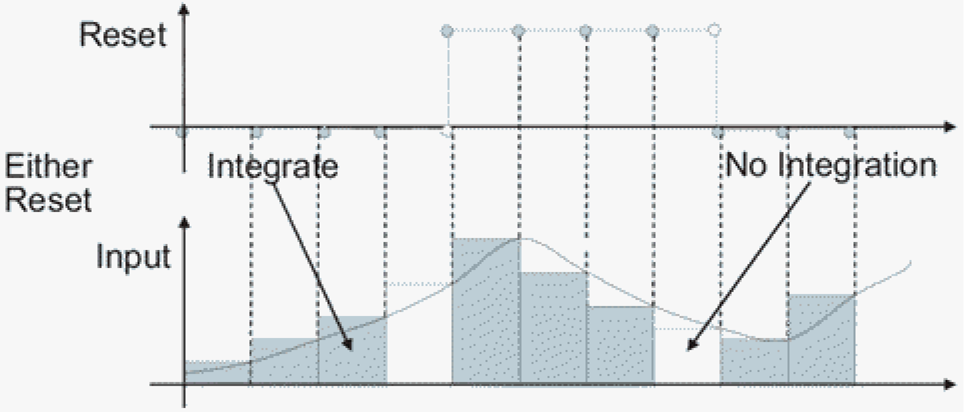
- `rising` – Resets the state when the reset signal has a rising edge. For example, this figure shows the effect that a rising reset trigger has on backward Euler integration.



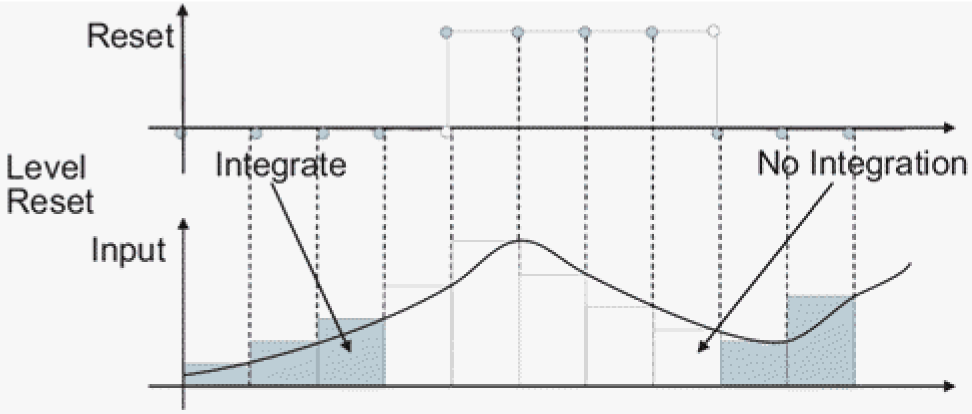
- `falling` — Resets the state when the reset signal has a falling edge. For example, this figure shows the effect that a falling reset trigger has on backward Euler integration.



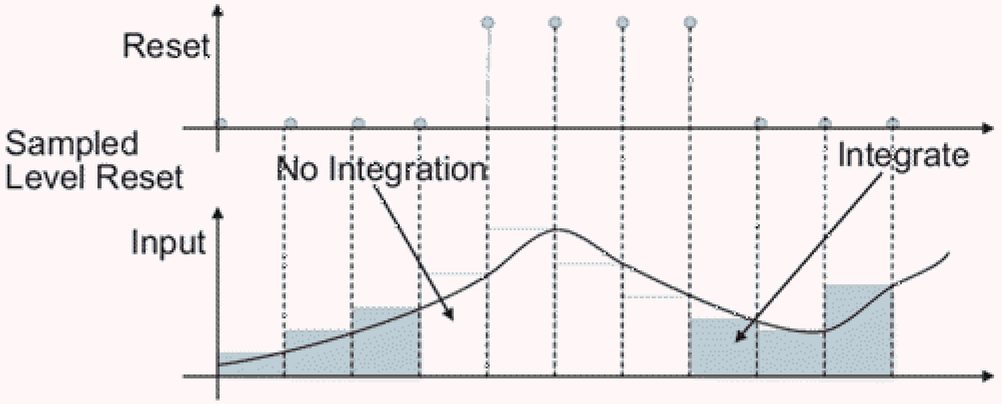
- `either` — Resets the state when the reset signal rises or falls. For example, the following figure shows the effect that an either reset trigger has on backward Euler integration.



- `level` — Resets and holds the output to the initial condition while the reset signal is nonzero. For example, this figure shows the effect that a level reset trigger has on backward Euler integration.



- `sampled level` — Resets the output to the initial condition when the reset signal is nonzero. For example, this figure shows the effect that a sampled level reset trigger has on backward Euler integration.



The `sampled level` reset option requires fewer computations, making it more efficient than the `level` reset option.

Note For the Discrete-Time Integrator block, all trigger detections are based on signals with positive values. For example, a signal changing from -1 to 0 is not considered a rising edge, but a signal changing from 0 to 1 is.

Behavior in Simplified Initialization Mode

Simplified initialization mode is enabled when you set **Underspecified initialization detection** to `Simplified` in the Configuration Parameters dialog box. If you use simplified initialization mode, the behavior of the Discrete-Time Integrator block differs from classic initialization mode. The new initialization behavior is more robust and provides more consistent behavior in these cases:

- In algebraic loops
- On enable and disable
- When comparing results using triggered sample time against explicit sample time, where the block is triggered at the same rate as the explicit sample time

Simplified initialization mode enables easier conversion from Continuous-Time Integrator blocks to Discrete-Time Integrator blocks, because the initial conditions have the same meaning for both blocks.

For more information on classic and simplified initialization modes, see “Underspecified initialization detection”.

When you use simplified initialization mode with **Initial condition setting** set to `Output` for triggered and function-call subsystems, the enable and disable behavior of the block is simplified as follows.

At disable time t_d:

$y(t_d) = y(t_d-1)$

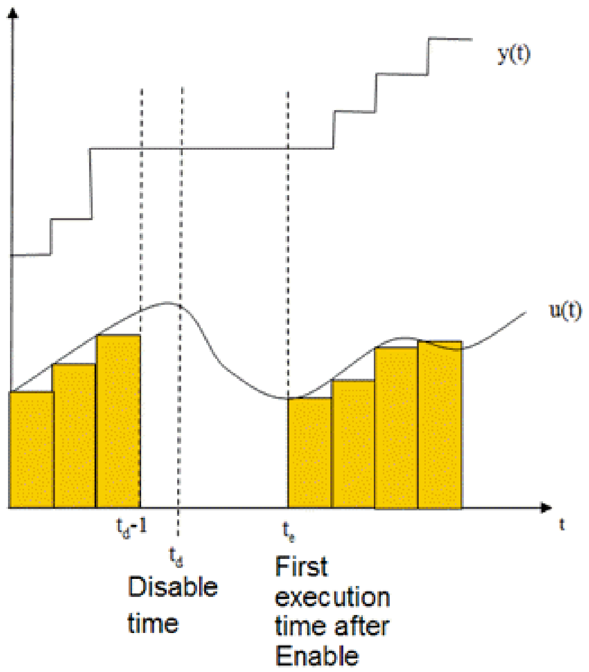
At enable time t_e:

- If the parent subsystem control port has **States when enabling** set to `reset`:

  $y(t_e) = IC$.
- If the parent subsystem control port has **States when enabling** set to `held`:

  $y(t_e) = y(t_d)$.

  The following figure shows this condition.



When using simplified initialization mode, you cannot place the Discrete-Time Integrator block in an iterator subsystem block.

In simplified initialization mode, Iterator subsystems do not maintain elapsed time. Thus, if a Discrete-Time Integrator block, which needs elapsed time, is placed inside an iterator subsystem block, Simulink reports an error.

Behavior in an Enabled Subsystem Inside a Function-Call Subsystem

Suppose you have a function-call subsystem that includes an enabled subsystem, which contains a Discrete-Time Integrator block. The following behavior applies.

Integrator Method	Sample Time Type of Function-Call Trigger Port	Value of `delta T` When Function-Call Subsystem Executes for the First Time After Enabled	Reason for Behavior
Forward Euler	Triggered	`t – tstart`	When the function-call subsystem executes for the first time, the integrator algorithm uses `tstart` as the previous simulation time.
Backward Euler and Trapezoidal	Triggered	`t – tprevious`	When the function-call subsystem executes for the first time, the integrator algorithm uses `tprevious` as the previous simulation time.
Forward Euler, Backward Euler, and Trapezoidal	Periodic	Sample time of the function-call generator	In periodic mode, the Discrete-Time Integrator block uses sample time of the function-call generator for `delta T`.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

IC — Initial conditions of the states

scalar | vector | matrix

Initial conditions of the states, specified as a finite scalar, vector, or matrix.

Dependencies

To enable this port, set **Initial condition source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Port_1 — Discrete-time integration or accumulation of input

scalar | vector | matrix

Discrete-time integration or accumulation of the input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Port_2 — Saturation output

scalar | vector | matrix

Signal indicating when the state is being limited, specified as a scalar, vector, or matrix. The signal has one of three values:

- `1` indicates that the upper limit is being applied.
- `0` indicates that the integral is not limited.
- `-1` indicates that the lower limit is being applied.

Dependencies

To enable this port, select the **Show saturation port** check box.

Data Types: `single` | `double` | `int8`

Port_3 — State output

scalar | vector | matrix

Block states, output as a scalar, vector, or matrix. By default, the block adds this port to the top of the block icon. Use the state port when:

- The output of the block is fed back into the block through the reset port or the initial condition port, causing an algebraic loop. For an example, see the `sldemo_bounce_two_integrators` model.
- You want to pass the state from one conditionally executed subsystem to another, which can cause timing problems. For an example, see the `sldemo_clutch` model.

For more information, see “When to Use the State Port” on page 1-588.

Dependencies

To enable this port, select the **Show state port** check box.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

`Integrator method` — Accumulation method

`Integration: Forward Euler` (default) | `Integration: Backward Euler` | `Integration: Trapezoidal` | `Accumulation: Forward Euler` | `Accumulation: Backward Euler` | `Accumulation: Trapezoidal`

Specify the integration or accumulation method. See “Output Equations” on page 1-584 and “Integration and Accumulation Methods” on page 1-585 for more information.

Programmatic Use
Block Parameter: `IntegratorMethod`
Type: character vector
Values: `'Integration: Forward Euler'` | `'Integration: Backward Euler'` | `'Integration: Trapezoidal'` | `'Accumulation: Forward Euler'` | `'Accumulation: Backward Euler'` | `'Accumulation: Trapezoidal'`
Default: `'Integration: Forward Euler'`

`Gain value` — Value to multiply with integrator input

`1.0` (default) | scalar | vector

Specify a scalar, vector, or matrix by which to multiply the integrator input. Each element of the gain must be a positive real number.

- Specifying a value other than 1.0 (the default) is semantically equivalent to connecting a Gain block to the input of the integrator.
- Valid entries include:
  - `double(1.0)`
  - `single(1.0)`
  - `[1.1 2.2 3.3 4.4]`
  - `[1.1 2.2; 3.3 4.4]`

Tip Using this parameter to specify the input gain eliminates a multiplication operation in the generated code. However, this parameter must be nontunable to realize this benefit. If you want to tune the input gain, set this parameter to 1.0 and use an external Gain block to specify the input gain.

Programmatic Use
Block Parameter: `gainval`
Type: character vector
Values: scalar | vector
Default: `'1.0'`

`External reset` — Select when to reset states to initial conditions

`none` (default) | `rising` | `falling` | `either` | `level` | `sampled level`

Select the type of trigger event that resets the states to their initial conditions:

- `none` — Do not reset the state to initial conditions.
- `rising` — Reset the state when the reset signal has a rising edge.
- `falling` — Reset the state when the reset signal has a falling edge.
- `either` — Reset the state when the reset signal rises or falls.
- `level` — Reset and hold the output to the initial condition while the reset signal is nonzero.
- `sampled level` — Reset the output to the initial condition when the reset signal is nonzero.

For more information, see “Reset the State” on page 1-589 and “Reset Trigger Types” on page 1-590.

Programmatic Use
Block Parameter: `ExternalReset`
Type: character vector
Values: `'none'` | `'rising'` | `'falling'` | `'either'` | `'level'` | `'sampled level'`
Default: `'none'`

`Initial condition source` — Select source of initial condition

`internal` (default) | `external`

Select source of initial condition:

- `internal` — Get the initial conditions of the states from the **Initial condition** block parameter.
- `external` — Get the initial conditions of the states from an external block, via the **IC** input port.

Dependencies

Selecting `internal` enables the **Initial condition** parameter.

Selecting `external` disables the **Initial condition** parameter and enables the **IC** input port.

Programmatic Use
Block Parameter: `InitialConditionSource`
Type: character vector, string
Values: `'internal'` | `'external'`
Default: `'internal'`

`Initial condition` — Initial condition of states

`0` (default) | scalar | vector | matrix

Specify initial condition of the block states. The minimum and maximum values are bound by the **Output minimum** and **Output maximum** block parameters.

Tip Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

To enable this parameter, set the **Initial condition source** to `internal`.

Programmatic Use
Block Parameter: `InitialCondition`
Type: character vector, string
Values: scalar | vector | matrix
Default: `'0'`

`Initial condition setting` — Select where to apply the initial condition

`Auto` (default) | `Output` | `Compatibility`

Select whether to apply the value of the **Initial condition** parameter to the block state or block output. The initial condition is also the reset value.

- `Auto` — Block chooses where to apply the **Initial condition** parameter.

  - If the block is in a non-triggered subsystem and **Integrator method** is set to an integration method, set initial conditions:

    ```
    x(0) = IC
    ```

    At reset:

    ```
    x(n) = IC
    ```
  - If the block is in a triggered or function-call subsystem and **Integrator method** is set to an integration method, set initial conditions as if `output` was selected.
- `Output` — Use this option when the block is in a triggered or a function-call subsystem and **Integrator method** is set to an integration method.

  Set initial conditions:

  ```
  y(0) = IC
  ```

  At reset:

  ```
  y(n) = IC
  ```
- `Compatibility` — This option is present to provide backward compatibility. You cannot select this option for Discrete-Time Integrator blocks in Simulink models but you can select it for Discrete-Time Integrator blocks in a library. Use this option to maintain compatibility with Simulink models created before R2014a.

  Prior to R2014a, the option `Auto` was known as `State only (most efficient)`. The option `Output` was known as `State and output`. The behavior of the block with the option `Compatibility` is as follows.

- If **Underspecified initialization detection** is set to `Classic`, the **Initial condition setting** parameter behaves as `Auto`.
- If **Underspecified initialization detection** is set to `Simplified`, the **Initial condition setting** parameter behaves as `Output`.

Note This parameter was named **Use initial condition as initial and reset value for** in Simulink before R2014a.

Programmatic Use
Block Parameter: `InitialConditionSetting`
Type: character vector
Value: `'Auto'` | `'Output'` | `'Compatibility'`
Default: `'Auto'`

`Sample time (-1 for inherited)` — Interval between samples

`-1` (default) | scalar | vector

Enter the discrete time interval between steps.

By default, the block uses a discrete sample time of `1`. To set a different sample time, enter another discrete value, such as 0.1.

See “Specify Sample Time” for more information.

Tips

- Do not specify a sample time of 0. This value specifies a continuous sample time, which the Discrete-Time Integrator block does not support.
- Do not specify a sample time of `inf` or `NaN` because these values are not discrete.
- If you specify -1 to inherit the sample time from an upstream block, verify that the upstream block uses a discrete sample time. For example, the Discrete-Time Integrator block cannot inherit a sample time of 0.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'-1'`

`Limit output` — Limit block output values to specified range

`off` (default) | `on`

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block's output values.

Dependencies

Selecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use
Block Parameter: `LimitOutput`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Upper saturation limit` — Upper limit for the integral

`inf` (default) | scalar | vector | matrix

Specify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use
Block Parameter: `UpperSaturationLimit`
Type: character vector, string
Values: scalar | vector | matrix
Default: `'inf'`

`Lower saturation limit` — Lower limit for the integral

`-inf` (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: `LowerSaturationLimit`
Type: character vector , string
Values: scalar | vector | matrix
Default: `'-inf'`

`Show saturation port` — Enable saturation output port

`off` (default) | `on`

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use

Block Parameter: `ShowSaturationPort`
Type: character vector , string
Values: `'off'` | `'on'`
Default: `'off'`

`Show state port` — Enable state output port

`off` (default) | `on`

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use

Block Parameter: `ShowStatePort`
Type: character vector , string
Values: `'off'` | `'on'`
Default: `'off'`

`Ignore limit and reset when linearizing` — Treat block as not resettable

`off` (default) | `on`

Select this check box to have Simulink linearization commands treat this block as not resettable and as having no limits on its output, regardless of the settings of the block reset and output limitation options.

Tip Ignoring the limit and resetting allows you to linearize a model around an operating point. This point may cause the integrator to reset or saturate.

Programmatic Use
Block Parameter: `IgnoreLimit`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

Signal Attributes

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Data type` — Output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- `Inherit: Inherit via internal rule` — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and `ASIC/FPGA` is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, i.e., a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

  It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

  - Specify the output data type explicitly.
  - Use the simple choice of `Inherit: Same as input`.
  - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
  - To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'`, `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Specify the rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Choose one of these rounding modes.

`Ceiling`

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

See Also

For more information, see “Rounding” (Fixed-Point Designer).

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

State Attributes

`State name` — Unique name for block state

`''` (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

For more information, see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder).

Dependencies

When you specify a value for **State name** and click **Apply**, you enable the **State name must resolve to Simulink signal object** parameter.

Programmatic Use
Parameter: `StateName`
Type: character vector
Values: unique name
Default: `''`

`State name must resolve to Simulink signal object` — Require state names resolve to signal object

`Off` (default) | Boolean

Specify if requiring that state name resolve to Simulink signal objects or not. If selected, the software generates an error at run time if you specify a state name that does not match the name of a Simulink signal object.

Dependency

Enabled when you give the parameter **State name** a value and set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Signal object class` — Custom storage class package name

`Simulink.Signal` (default)

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: `StateSignalObject`
Type: character vector
Values: `'Simulink.Signal' | '<StorageClass.PackageName>'`
Default: `'Simulink.Signal'`

`Code generation storage class` — Storage class for code generation

`Auto` (default) | `Model default` | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer` | `Bitfield (Custom)` | `Volatile (Custom)` | `ExportToFile (Custom)` | `ImportFromFile (Custom)` | `FileScope (Custom)` | `Struct (Custom)` | `GetSet (Custom)` | `Reusable (Custom)`

Select state storage class for code generation. If you do not need to interface to external code, select `Auto`.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Programmatic Use
Block Parameter: `StateStorageClass`
Type: character vector
Values: `'Auto'` | `'Model default'` | `'ExportedGlobal''` | `'ImportedExtern'` | `'ImportedExternPointer'` | `'Custom'`
Default: `'Auto'`

`TypeQualifier` — Storage type qualifier

`''` (default) | `const` | `volatile` | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use
Block Parameter: `RTWStateStorageTypeQualifier`
Type: character vector
Values:`'' | 'const' | 'volatile' | ...`
Default: `''`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`Yes`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Depends on absolute time when used inside a triggered subsystem hierarchy.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see Discrete-Time Integrator.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

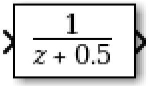
Introduced before R2006a

Discrete Transfer Fcn

Implement discrete transfer function

Library: Simulink / Discrete



Description

The Discrete Transfer Fcn block implements the *z*-transform transfer function:

$$H(z) = \frac{num(z)}{den(z)} = \frac{num_0 z^m + num_1 z^{m-1} + ... + num_m}{den_0 z^n + den_1 z^{n-1} + ... + den_n}$$

where *m+1* and *n+1* are the number of numerator and denominator coefficients, respectively. *num* and *den* contain the coefficients of the numerator and denominator in descending powers of *z*. *num* can be a vector or matrix, *den* must be a vector. The order of the denominator must be greater than or equal to the order of the numerator.

Specify the coefficients of the numerator and denominator polynomials in descending powers of *z*. This block lets you use polynomials in *z* to represent a discrete system, a method that control engineers typically use. Conversely, the Discrete Filter block lets you use polynomials in z^{-1} (the delay operator) to represent a discrete system, a method that signal processing engineers typically use. The two methods are identical when the numerator and denominator polynomials have the same length.

The Discrete Transfer Fcn block applies the *z*-transform transfer function to each independent channel of the input. The **Input processing** parameter allows you to specify whether the block treats each element of the input as an individual channel (sample-based processing), or each column of the input as an individual channel (frame-based processing). To perform frame-based processing, you must have a DSP System Toolbox license.

Specifying Initial States

Use the **Initial states** parameter to specify initial filter states. To determine the number of initial states you must specify and how to specify them, see the following tables.

Frame-Based Processing

Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
• Column vector (*K*-by-1) • Unoriented vector (*K*)	1	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*)	• Scalar • Column vector (*M*-by-1)
• Row vector (1-by-*N*) • Matrix (*K*-by-*N*)	*N*	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*) • Matrix (*M*-by-*N*)	• Scalar • Matrix (*M*-by-*N*)

Sample-Based Processing

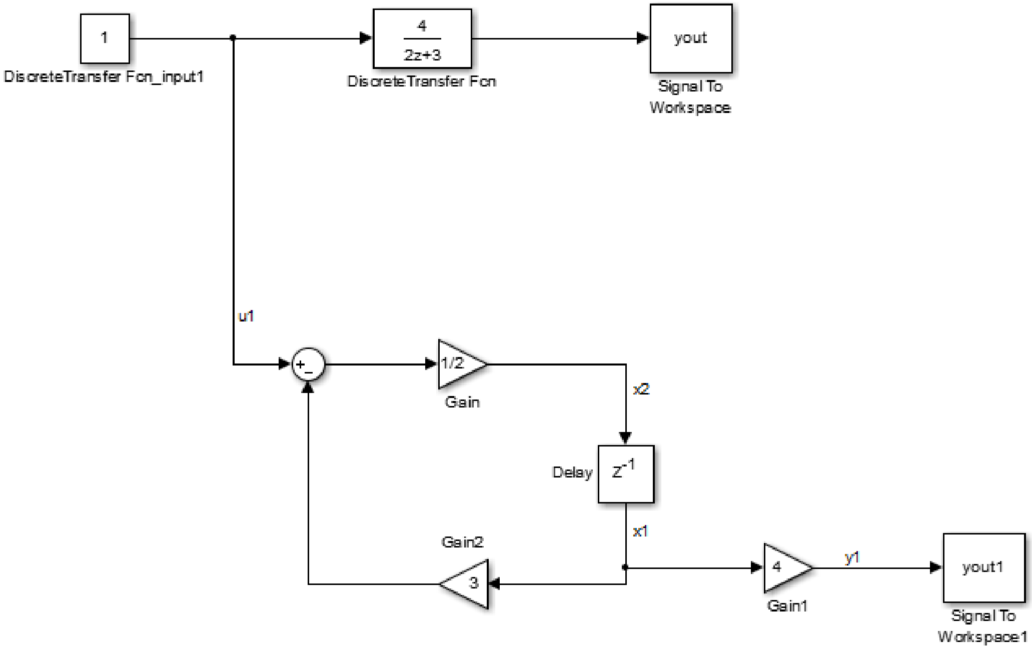
Input	Number of Channels	Valid Initial States (Dialog Box)	Valid Initial States (Input Port)
• Scalar	1	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*)	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*)
• Row vector (1-by-*N*) • Column vector (*N*-by-1) • Unoriented vector (*N*)	*N*	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*) • Matrix (*M*-by-*N*)	• Scalar
• Matrix (*K*-by-*N*)	*K* × *N*	• Scalar • Column vector (*M*-by-1) • Row vector (1-by-*M*) • Matrix (*M*-by-(*K*×*N*))	• Scalar

When the **Initial states** is a scalar, the block initializes all filter states to the same scalar value. To initialize all states to zero, enter `0`. When the **Initial states** is a vector or a matrix, each vector or matrix element specifies a unique initial state for a corresponding delay element in a corresponding channel:

- The vector length must equal the number of delay elements in the filter, `M = max(number of zeros, number of poles)`.
- The matrix must have the same number of rows as the number of delay elements in the filter, `M = max(number of zeros, number of poles)`. The matrix must also have one column for each channel of the input signal.

The following example shows the relationship between the initial filter output and the initial input and state. Given an initial input u_1, the first output y_1 is related to the initial state [x_1, x_2] and initial input by:

$$y_1 = 4x_1$$
$$x_2 = 1/2(u_1 - 3x_1)$$



Ports

Input

u — Input signal

scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

`Num` — Numerator coefficients

scalar | vector | matrix

Coefficients of the numerator polynomial specified as a vector or matrix in descending powers of *z*. Use a row vector to specify the coefficients for a single numerator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps. The order of the denominator must be greater than or equal to the order of the numerator.

Dependencies

To enable this port, set **Numerator Source** to `Input port`.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

`Den` — Denominator coefficients

scalar | vector | matrix

Coefficients of the denominator polynomial specified as a vector in descending powers of *z*. Use a row vector to specify the coefficients for a single denominator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps. The order of the denominator must be greater than or equal to the order of the numerator.

Dependencies

To enable this port, set **Denominator Source** to `Input port`.

Numerator and denominator coefficients must have the same complexity. They can have different word lengths and fraction lengths.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

`External reset` — External reset signal
scalar

External reset signal, specified as a scalar. When the specified trigger event occurs, the block resets the states to their initial conditions.

Tip The icon for this port changes based on the value of the **External reset** parameter.

Dependencies

To enable this port, set **External reset** to `Rising`, `Falling`, `Either`, `Level`, or `Level hold`.

Limitations

The reset signal must be a scalar of type single, double, boolean, or integer. Fixed-point data types, except for `ufix1`, are not supported.

Data Types: `single` | `double` | `Boolean` | `int8` | `int16` | `int32` | `fixed point`

`x0` — Initial states
scalar | vector | matrix

Initial states, specified as a scalar, vector, or matrix. For more information about specifying states, see “Specifying Initial States” on page 1-614. States are complex when either the input or the coefficients are complex.

Dependencies

To enable this port, set **Initial states Source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output signal specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `fixed point`

Parameters

Main

`Numerator Source` — Source of numerator coefficients

`Dialog` (default) | `Input port`

Specify the source of the numerator coefficients as `Dialog` or `Input port`.

Programmatic Use
Block Parameter: `NumeratorSource`
Type: character vector
Values: `'Dialog' | 'Input port'`
Default: `'Dialog'`

`Numerator Value` — Numerator coefficients

`[1]` (default) | scalar | vector | matrix

Numerator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to `Dialog`. Then enter the coefficients in **Value** as descending powers of *z*. Use a row vector to specify the coefficients for a single numerator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

Dependencies

To enable this parameter, set the **Numerator Source** to `Dialog`.

Programmatic Use
Block Parameter: `Numerator`
Type: character vector
Values: scalar | vector | matrix
Default: `'[1]'`

`Denominator Source` — Source of denominator coefficients

`Dialog` (default) | `Input port`

Specify the source of the denominator coefficients as `Dialog` or `Input port`.

Programmatic Use

Block Parameter: `DenominatorSource`
Type: character vector
Values: `'Dialog' | 'Input port'`
Default: `'Dialog'`

`Denominator Value` — Denominator coefficients

`[1 0.5]` (default) | scalar | vector | matrix

Denominator coefficients of the discrete transfer function. To specify the coefficients, set the **Source** to `Dialog`. Then, enter the coefficients in **Value** as descending powers of z. Use a row vector to specify the coefficients for a single denominator polynomial. Use a matrix to specify coefficients for multiple filters to be applied to the same input. Each matrix row represents a set of filter taps.

Dependencies

To enable this parameter, set the **Denominator Source** to `Dialog`.

Programmatic Use

Block Parameter: `Denominator`
Type: character vector
Values: scalar | vector | matrix
Default: `'[1 0.5]'`

`Initial states Source` — Source of initial states

`Dialog` (default) | `Input port`

Specify the source of the initial states as `Dialog` or `Input port`.

Programmatic Use

Block Parameter: `InitialStatesSource`
Type: character vector
Values: `'Dialog' | 'Input port'`
Default: `'Dialog'`

`Initial states Value` — Initial filter states

`0` (default) | scalar | vector | matrix

Specify the initial filter states as a scalar, vector, or matrix. To learn how to specify initial states, see “Specifying Initial States” on page 1-614.

Dependencies

To enable this parameter, set **Initial states Source** to `Dialog`.

Programmatic Use
Block Parameter: `InitialStates`
Type: character vector
Values: scalar | vector | matrix
Default: `'0'`

`External reset` — External state reset

`None` (default) | `Rising` | `Falling` | `Either` | `Level` | `Level hold`

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
`None`	No reset.
`Rising`	Reset on a rising edge.
`Falling`	Reset on a falling edge.
`Either`	Reset on either a rising or falling edge.
`Level`	Reset in either of these cases: • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
`Level hold`	Reset when the reset signal is nonzero at the current time step

Programmatic Use
Block Parameter: `ExternalReset`
Type: character vector
Values: `'None'` | `'Rising'` | `'Falling'` | `'Either'` | `'Level'` | `'Level hold'`
Default: `'None'`

`Input processing` — Sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing.

- `Elements as channels (sample based)` — Process each element of the input as an independent channel.
- `Columns as channels (frame based)` — Process each column of the input as an independent channel.

Note Frame-based processing requires a DSP System Toolbox license.

For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Elements as channels (sample based)' | 'Columns as channels (frame based)'`
Default: `'Elements as channels (sample based)'`

Optimize by skipping divide by leading denominator coefficient (a0) — Skip divide by a0

`off` (default) | `on`

Select when the leading denominator coefficient, a_0, equals one. This parameter optimizes your code.

When you select this check box, the block does not perform a divide-by-a_0 either in simulation or in the generated code. An error occurs if a_0 is not equal to one.

When you clear this check box, the block is fully tunable during simulation, and performs a divide-by-a_0 in both simulation and code generation.

Programmatic Use
Block Parameter: `a0EqualsOne`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Sample time (-1 for inherited) — Interval between samples

`-1` (default) | scalar | vector

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. For more information, see “Specify Sample Time”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'-1'`

Data Types

`State` — State data type

`Inherit: Same as input` (default) | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the state data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

`Numerator coefficients` — Numerator coefficient data type

`Inherit: Inherit via internal rule` (default) | `int8` | `int16` | `int32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>`

Specify the numerator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see "Specify Data Types Using Data Type Assistant".

Programmatic Use
Block Parameter: `NumCoeffDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Numerator coefficient minimum` — Minimum value of numerator coefficients

[ ] (default) | scalar

Specify the minimum value that a numerator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see "Specify Minimum and Maximum Values for Block Parameters")
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `NumCoeffMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Numerator coefficient maximum` — Maximum value of numerator coefficients

[ ] (default) | scalar

Specify the maximum value that a numerator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see "Specify Minimum and Maximum Values for Block Parameters")
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `NumCoeffMax`
Type: character vector

Values: scalar
Default: `'[]'`

`Numerator product output` — Numerator product output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the product output data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `NumProductDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via interal rule'`

`Numerator accumulator` — Numerator accumulator data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the accumulator data type for the numerator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `NumAccumDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as input'` | `'Inherit: Same as product output'` | `'int8'` | `'int16'` | `'int32'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via interal rule'`

`Denominator coefficients` — Denominator coefficient data type

`Inherit: Inherit via internal rule` (default) | `int8` | `int16` | `int32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>`

Specify the denominator coefficient data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in integer, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `DenCoeffDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'int8'` | `'int16'` | `'int32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Same wordlength as input'`

`Denominator coefficient minimum` — Minimum value of denominator coefficients

`[]` (default) | scalar

Specify the minimum value that a denominator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `DenCoeffMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Denominator coefficient maximum` — Maximum value of denominator coefficients

`[]` (default) | scalar

Specify the maximum value that a denominator coefficient can have. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `DenCoeffMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Denominator product output` — Denominator product output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the product output data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `DenProductDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as input'` | `'int8'` | `'int16'` | `'int32'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via interal rule'`

`Denominator accumulator` — Denominator accumulator data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Same as product output` | `int8` | `int16` | `int32` | `fixdt(1,16,0)` | `<data type expression>`

Specify the accumulator data type for the denominator coefficients. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `DenAccumDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as input'` | `'Inherit: Same as product output'` | `'int8'` | `'int16'` | `'int32'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via interal rule'`

`Output` — Output data type
`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `int8` | `int16` | `int32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- A built-in data type, for example, `int8`
- A data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as input' | 'int8' | 'int16' | 'int32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | '<data type expression>'`
Default: `'Inherit: Inherit via interal rule'`

`Output minimum` — Minimum value of output
`[]` (default) | scalar

Specify the minimum value that the block can output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Output maximum` — Maximum value of output
`[]` (default) | scalar

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Simulation range checking (see “Signal Ranges”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

Saturate on integer overflow — Method of overflow action

off (default) | on

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (on).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the int8 (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (off).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the int8 (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as int8, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as int8, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when

overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

State Attributes

`State name` — Unique name for block state

`''` (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use
Block Parameter: `StateName`
Type: character vector
Values: unique name
Default: `''`

`State name must resolve to Simulink signal object` — Require state name resolve to a signal object

`off` (default) | `on`

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Programmatic Use

Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Signal object class` — Custom storage class package name

`Simulink.Signal` (default) | `<StorageClass.PackageName>`

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: `StateSignalObject`
Type: character vector
Values: `'Simulink.Signal' | '<StorageClass.PackageName>'`
Default: `'Simulink.Signal'`

`Code generation storage class` — State storage class for code generation

`Auto` (default) | `Model default` | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer` | `BitField (Custom)` | `Model default` | `ExportToFile (Custom)` | `ImportFromFile (Custom)` | `FileScope (Custom)` | `AutoScope (Custom)` | `Struct (Custom)` | `GetSet (Custom)` | `Reusable (Custom)`

Select state storage class for code generation.

- `Auto` is the appropriate storage class for states that you do not need to interface to external code.
- *`StorageClass`* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use

Block Parameter: `StateStorageClass`
Type: character vector
Values: `'Auto' | 'SimulinkGlobal' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...`
Default: `'Auto'`

`TypeQualifier` — Storage type qualifier

`''` (default) | `const` | `volatile` | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use
Block Parameter: `RTWStateStorageTypeQualifier`
Type: character vector
Values: `'' | 'const' | 'volatile' | ...`
Default: `''`

Block Characteristics

Data Types	`double` | `single` | `base integer`[a] | `fixed point`[a]
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

[a] This block only supports signed fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see Discrete Transfer Fcn.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

This block only supports signed fixed-point data types.

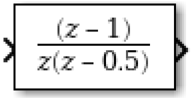
Discrete Zero-Pole

Model system defined by zeros and poles of discrete transfer function

Library: Simulink / Discrete



Description

The Discrete Zero-Pole block models a discrete system defined by the zeros, poles, and gain of a *z*-domain transfer function. This block assumes that the transfer function has the following form:

$$H(z) = K\frac{Z(z)}{P(z)} = K\frac{(z-Z_1)(z-Z_2)\ldots(z-Z_m)}{(z-P_1)(z-P_2)\ldots(z-P_n)},$$

where *Z* represents the zeros vector, *P* the poles vector, and *K* the gain. The number of poles must be greater than or equal to the number of zeros ($n \geq m$). If the poles and zeros are complex, they must be complex conjugate pairs.

The block displays the transfer function depending on how the parameters are specified. See Zero-Pole for more information.

Modeling a Single-Output System

For a single-output system, the input and the output of the block are scalar time-domain signals. To model this system:

1. Enter a vector for the zeros of the transfer function in the **Zeros** field.
2. Enter a vector for the poles of the transfer function in the **Poles** field.
3. Enter a 1-by-1 vector for the gain of the transfer function in the **Gain** field.

Modeling a Multiple-Output System

For a multiple-output system, the block input is a scalar and the output is a vector, where each element is an output of the system. To model this system:

1. Enter a matrix of zeros in the **Zeros** field.

   Each *column* of this matrix contains the zeros of a transfer function that relates the system input to one of the outputs.
2. Enter a vector for the poles common to all transfer functions of the system in the **Poles** field.
3. Enter a vector of gains in the **Gain** field.

   Each element is the gain of the corresponding transfer function in **Zeros**.

Each element of the output vector corresponds to a column in **Zeros**.

Ports

Input

`Port_1` — Input signal

scalar

Input signal specified as a real-valued scalar.

Data Types: `single` | `double`

Output

`Port_1` — Model of discrete system

scalar | vector

Model of system as defined by zeros, poles, and gain of discrete transfer function. The width of the output is equal to the number of columns in the **Zeros** matrix, or one if **Zeros** is a vector.

Data Types: `single` | `double`

Parameters

Main

`Zeros` — Matrix of zeros

`[1]` (default) | vector | matrix

Specify the vector or matrix of zeros. The number of zeros must be less than or equal to the number of poles. If the poles and zeros are complex, they must be complex conjugate pairs.

- For a single-output system, enter a vector for the zeros of the transfer function.
- For a multiple-output system, enter a matrix. Each column of the matrix contains the zeros of a transfer function that relates the system input to one of the outputs.

Programmatic Use
Block Parameter: `Zeros`
Type: character vector
Values: vector
Default: `'[1]'`

`Poles` — Vector of poles

`[0 0.5]` (default) | vector

Specify the vector of poles. The number of poles must be greater than or equal to the number of zeros. If the poles and zeros are complex, they must be complex conjugate pairs.

- For a single-output system, enter a vector for the poles of the transfer function.
- For a multiple-output system, enter a vector for the poles common to all transfer functions of the system.

Programmatic Use
Block Parameter: `Poles`
Type: character vector
Values: vector
Default: `'[0 0.5]'`

`Gain` — Gain value

`1` (default) | scalar | vector

Specify vector of gain values.

- For a single-output system, enter a scalar or 1-by-1 vector for the gain of the transfer function.
- For a multiple-output system, enter a vector of gains. Each element is the gain of the corresponding transfer function in **Zeros**.

Programmatic Use
Block Parameter: `Gain`
Type: character vector
Values: scalar | vector
Default: `'1'`

`Sample time (-1 for inherited)` — Interval between samples

`-1` | scalar | vector

Specify the time interval between samples. For more information, see Specifying Sample Time.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'-1'`

State Attributes

`State name` — Unique name for block state

`''` (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use
Block Parameter: `StateName`
Type: character vector
Values: unique name
Default: `''`

`State name must resolve to Simulink signal object` — Require state name resolve to a signal object

`off` (default) | `on`

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Programmatic Use
Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Signal object class` — Custom storage class package name

`Simulink.Signal` (default) | `<StorageClass.PackageName>`

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Programmatic Use
Block Parameter: `StateSignalObject`
Type: character vector
Values: `'Simulink.Signal' | '<StorageClass.PackageName>'`
Default: `'Simulink.Signal'`

`Code generation storage class` — State storage class for code generation

`Auto` (default) | `Model default` | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer` | `BitField (Custom)` | `Model default` | `ExportToFile (Custom)` | `ImportFromFile (Custom)` | `FileScope (Custom)` | `AutoScope (Custom)` | `Struct (Custom)` | `GetSet (Custom)` | `Reusable (Custom)`

Select state storage class for code generation.

- `Auto` is the appropriate storage class for states that you do not need to interface to external code.
- *`StorageClass`* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use
Block Parameter: `StateStorageClass`
Type: character vector
Values: `'Auto' | 'SimulinkGlobal' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...`
Default: `'Auto'`

`TypeQualifier` — Storage type qualifier

`''` (default) | `const` | `volatile` | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use

Block Parameter: `RTWStateStorageTypeQualifier`
Type: character vector
Values: `'' | 'const' | 'volatile' | ...`
Default: `''`

Block Characteristics

Data Types	`double` | `single`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

Display

Display signal value during simulation

Library: Simulink / Dashboard

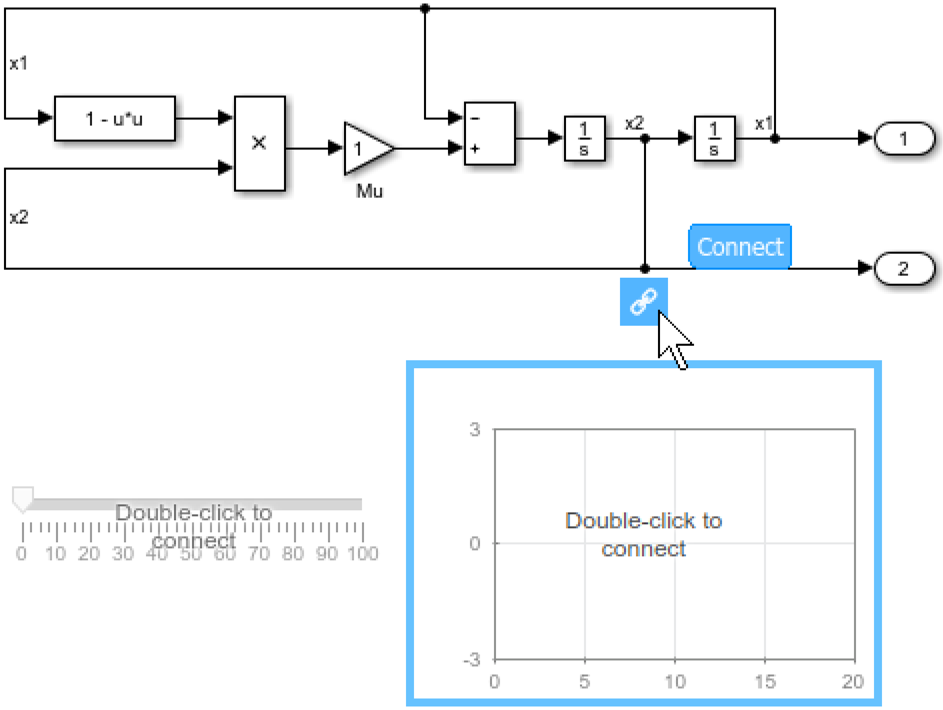
Description

The Display block connects to a signal in your model and displays its value during simulation. You can edit the parameters of the Display block while a simulation runs. Use the Display block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.

□ Fcn:1

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a signal to connect and display

signal connection options

Select the signal to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the radio button next to the signal you want to display. Click **Apply** to connect the signal.

`Format` — Format for displaying numerical values

long (default) | long_e

Format for displaying numerical values.

- When you select `long`, the block displays numeric signal values using up to 15 digits with a fixed decimal point that displays up to four decimal places.
- When you select `long_e`, the block displays numeric signal values in scientific notation using up to 16 digits with a floating decimal point.

`Alignment` — Text alignment in block

'Center' (default) | 'Left' | 'Right'

Text alignment in Display block.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

Introduced in R2017b

Display

Show value of input

Library: Simulink / Sinks

Description

The Display block shows the value of the input data. You can specify the format and the frequency of display.

If the block input is an array, you can resize the block vertically or horizontally to show more than just the first element. If the block input is a vector, the block sequentially adds display fields from left to right and top to bottom. The block displays as many values as possible. A black triangle indicates that the block is not displaying all input array elements.

The Display block shows the first 200 elements of a vector signal and the first 20 rows and 10 columns of a matrix signal.

Display Abbreviations

The following abbreviations appear on the Display block to help you identify the format of the value.

When You See...	The Value That Appears Is...
`(SI)`	The stored integer value **Note** `(SI)` does not appear when the signal is of an integer data type.
`hex`	In hexadecimal format
`bin`	In binary format

When You See...	The Value That Appears Is...
`oct`	In octal format

Displaying Strings

When working with strings, the Display block displays:

- Strings with double quotes.
- Special characters such as newline are shown as escaped sequences, for example `'\n'`.
- Non-displayable characters as escaped octal number, for example `'\201'`.

If the incoming signal is of type string, the **Format** parameter selection does not affect the display of the string.

Ports

Input

`Port_1` — Input data
scalar | vector

Input data to display.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

`Format` — Format to display input data
`short` (default) | `long` | `short_e` | `long_e` | `bank` | `hex (Stored Integer)` | `binary (Stored Integer)` | `decimal (Stored Integer)` | `octal (Stored Integer)`

Specify the format of the data that appears.

If You Select...	The Block Displays...
`short`	A 5-digit scaled value with fixed decimal point
`long`	A 15-digit scaled value with fixed decimal point
`short_e`	A 5-digit value with a floating decimal point
`long_e`	A 16-digit value with a floating decimal point
`bank`	A value in fixed dollars and cents format (but with no $ or commas)
`hex (Stored Integer)`	The stored integer value of a fixed-point input in hexadecimal format
`binary (Stored Integer)`	The stored integer value of a fixed-point input in binary format
`decimal (Stored Integer)`	The stored integer value of a fixed-point input in decimal format
`octal (Stored Integer)`	The stored integer value of a fixed-point input in octal format

If the input to a Display block has an enumerated data type (see “Simulink Enumerations” and “Define Simulink Enumerations”):

- The block displays enumerated values, not the values of underlying integers.
- Setting **Format** to any of the `Stored Integer` settings causes an error.

If the incoming signal is of type string, the selection of the **Format** parameter does not affect the display of the string.

Programmatic Use
Block Parameter: `Format`
Type: character vector
Values: `'short'` | `'long'` | `'short_e'` | `'long_e'` | `'bank'` | `'hex (Stored Integer)'` | `'binary (Stored Integer)'` | `'decimal (Stored Integer)'` | `'octal (Stored Integer)'`
Default: `'short'`

Decimation — Display rate

`1` (default) | `integer`

Specify how often to display data.

The amount of data that appears and the time steps at which the data appears depend on the **Decimation** block parameter and the `SampleTime` property.

- The **Decimation** parameter enables you to display data at every *n*th sample, where *n* is the decimation factor. The default decimation, `1`, displays data at every time step.

  Note The Display block updates its display at the initial time, even when the **Decimation** value is greater than one.

- The `SampleTime` property, which you can set with `set_param`, enables you to specify a sampling interval at which to display points. This property is useful when you are using a variable-step solver where the interval between time steps is not the same. The default sample time, `-1`, causes the block to ignore the sampling interval when determining the points to display.

  Note If the block inherits a sample time of `Inf`, the **Decimation** parameter is ignored.

Programmatic Use
Block Parameter: `Decimation`
Type: character vector
Values: `'1'` | integer
Default: `'1'`

`Floating display` — Floating display

`off` (default) | `on`

To use the block as a floating display, select the **Floating display** check box. The block input port disappears and the block displays the value of the signal on a selected line.

If you select **Floating display**:

- Turn off signal storage reuse for your model. See “Signal storage reuse” in the Simulink documentation for more information.
- Do not connect a multidimensional signal to a floating display.

Programmatic Use
Block Parameter: `Floating`

Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

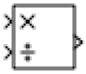
Divide

Divide one input by another

Library: Simulink / Math Operations



Description

The Divide block outputs the result of dividing its first input by its second. The inputs can be scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The Divide block is functionally a Product block that has two block parameter values preset:

- **Multiplication —** `Element-wise(.*)`
- **Number of Inputs —** `*/`

Setting nondefault values for either of those parameters can change a Divide block to be functionally equivalent to a Product block or a Product of Elements block.

Ports

Input

X — Input signal to multiply

scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more **X** ports, specify one or more * characters for the **Number of inputs** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

÷ — Input signal to divide or invert

scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more ÷ ports, specify one or more `/` characters for the **Number of inputs** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Port_1` — First input to multiply or divide

scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Port_N` — Nth input to multiply or divide

scalar | vector | matrix | N-D array

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output computed by multiplying, dividing, or inverting inputs

scalar | vector | matrix | N-D array

Output computed by multiplying, dividing, or inverting inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Number of inputs` — Control number of inputs and type of operation

`*/` (default) | positive integer scalar | `*` or `/` for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

  The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is `1` or `*`, the block outputs the input value. If the value is `/`, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See "Element-Wise Mode" on page 1-1448 and "Matrix Mode" on page 1-1449 for more information.
- **Integer value > 1**

  The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See "Element-Wise Mode" on page 1-1448 and "Matrix Mode" on page 1-1449 for more information.
- **Unquoted string of two or more * and / characters**

  The block has the number of inputs given by the length of the character vector. Each input that corresponds to a `*` character is multiplied into the output. Each input that corresponds to a `/` character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See "Element-Wise Mode" on page 1-1448 and "Matrix Mode" on page 1-1449 for more information.

Programmatic Use
Block Parameter: `Inputs`

Type: character vector
Values: `'2' | '*' | '**' | '*/' | '*/*' | ...`
Default: `'*/'`

`Multiplication` — Element-wise (.*) or Matrix (*) multiplication

`Element-wise(.*)` (default) | `Matrix(*)`

Specify whether the block performs `Element-wise(.*)` or `Matrix(*)` multiplication.

Programmatic Use

Block Parameter: `Multiplication`
Type: character vector
Values: `'Element-wise(.*)' | 'Matrix(*)'`
Default: `'Element-wise(.*)'`

`Multiply over` — All dimensions or specified dimension

`All dimensions` (default) | `Specified dimension`

Specify the dimension to multiply over as `All dimensions`, or `Specified dimension`. When you select `Specified dimension`, you can specify the **Dimension** as `1` or `2`.

Dependencies

To enable this parameter, set **Number of inputs** to `*` and **Multiplication** to `Element-wise (.*)`.

Programmatic Use

Block Parameter: `CollapseMode`
Type: character vector
Values: `'All dimensions' | 'Specified dimension'`
Default: `'All dimensions'`

`Dimension` — Dimension to multiply over

`1` (default) | `2` | `...` | `N`

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to `*`

- **Multiplication** to `Element-wise (.*)`
- **Multiply over** to `Specified dimension`

Programmatic Use
Block Parameter: `CollapseDim`
Type: character vector
Values: `'1' | '2' | ...`
Default: `'1'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

`Require all inputs to have the same data type` — Require that all inputs have the same data type

`off` (default) | `on`

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use
Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `Inherit: Same as first input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- `Inherit: Inherit via internal rule` — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and `ASIC/FPGA` is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

  It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn’t meet your specific needs for numerical accuracy or performance, use one of the following options:

  - Specify the output data type explicitly.
  - Use the simple choice of `Inherit: Same as input`.
  - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

  - To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as first input` — Use data type of first input signal.

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule`|`'Inherit: Same as first input'`|`'Inherit: Inherit via back propagation'`|`'double'`|`'single'`|`'int8'`|`'uint8'`|`'int16'`|`'uint16'`|`'int32'`|`'uint32'`|`'fixdt(1,16)'`|`'fixdt(1,16,0)'`|`'fixdt(1,16,2^0,0)'`|`'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations. You can select:

`Ceiling`

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see "Rounding" (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Check for Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

These conditions may yield different results between simulation and the generated code:

- The Divide block inputs contain a `NaN` or `inf` value
- The Divide block generates `NaN` or `inf` during execution

This difference is due to the nonfinite `NaN` or `inf` values. In such cases, inspect your model configuration and eliminate the conditions that produce `NaN` or `inf`.

The Simulink Coder build process provides efficient code for matrix inverse and division operations. This table describes the benefits and when each benefit is available.

Benefit	Small Matrices (2-by-2 to 5-by-5)	Medium Matrices (6-by-6 to 20-by-20)	Large Matrices (larger than 20-by-20)
Faster code execution time, compared to R2011a and earlier releases	Yes	No	Yes
Reduced ROM and RAM usage, compared to R2011a and earlier releases	Yes, for real values	Yes, for real values	Yes, for real values
Reuse of variables	Yes	Yes	Yes
Dead code elimination	Yes	Yes	Yes
Constant folding	Yes	Yes	Yes
Expression folding	Yes	Yes	Yes
Consistency with MATLAB Coder results	Yes	Yes	Yes

For blocks that have three or more inputs of different dimensions, the code might include an extra buffer to store temporary variables for intermediate results.

DocBlock

Create text that documents model and save text with model
Library: Simulink / Model-Wide Utilities

Description

The DocBlock allows you to create and edit text that documents a model, and save that text with the model. Double-clicking an instance of the block creates a temporary file containing the text associated with this block and opens the file in an editor. Use the editor to modify the text and save the file. Simulink software stores the contents of the saved file in the model file.

The DocBlock supports HTML, Rich Text Format (RTF), and ASCII text document types. The default editors for these different document types are

- HTML — Microsoft® Word (if available). Otherwise, the DocBlock opens HTML documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- RTF — Microsoft Word (if available). Otherwise, the DocBlock opens RTF documents using the editor specified on the **Editor/Debugger Preferences** pane of the Preferences dialog box.
- Text — The DocBlock opens text documents using the editor specified on the **Editor/ Debugger Preferences** pane of the Preferences dialog box.

Use the `docblock` command to change the default editors.

Tip To edit the block parameters of the DocBlock, right-click the block icon and select **Mask > Mask Parameters...**.

Parameters

`Code generation template symbol` — Template symbol for generated code

`' '` | `Abstract` | `Description` | `History` | `Modified History` | `Notes`

Enter a template symbol name in this field. Embedded Coder software uses this symbol to add comments to the code generated from the model. For more information, see “Add Global Comments” (Embedded Coder).

Dependencies

For comments to appear in the generated code, you must also set the **Document type** to `Text`.

Programmatic Use
Block Parameter: `ECoderFlag`
Type: character vector
Values: `Abstract | Description | History | Modified History | Notes`
Default: `'0'`

`Document type` — Type of document

`Text` (default) | `RTF` | `HTML`

Select the type of document associated with the DocBlock. The options are:

- `Text`
- `RTF`
- `HTML`

Dependencies

If you are using a DocBlock to add comments to your code during code generation, ensure that you set the **Document Type** as `Text`. If you set the **Document Type** as `RTF` or `HTML`, your comments will not appear in the code.

Programmatic Use
Block Parameter: `DocumentType`
Type: character vector
Values: `Text | RTF | HTML`
Default: `'Text'`

Block Characteristics

Data Types	
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Uses the template symbol you specify for the Embedded Coder Flag block parameter to add comments to generated code. Requires an Embedded Coder license. For more information, see “Use a Simulink DocBlock to Add a Comment” (Embedded Coder).

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see DocBlock.

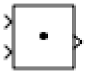
Introduced before R2006a

Dot Product

Generate dot product of two vectors
Library: Simulink / Math Operations



Description

The Dot Product block generates the dot product of the input vectors. The scalar output, `y`, is equal to the MATLAB operation

```
y = sum(conj(u1) .* u2 )
```

where `u1` and `u2` represent the input vectors. The inputs can be vectors, column vectors (single-column matrices), or scalars. If both inputs are vectors or column vectors, they must be the same length. If `u1` and `u2` are both column vectors, the block outputs the equivalent of the MATLAB expression `u1'*u2`.

The elements of the input vectors can be real- or complex-valued signals. The signal type (complex or real) of the output depends on the signal types of the inputs.

Input 1	Input 2	Output
real	real	real
real	complex	complex
complex	real	complex
complex	complex	complex

Ports

Input

`Port_1` — First operand input signal

scalar | vector

Signal representing the first operand to the dot product calculation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Port_2` — Second operand input signal

scalar | vector

Signal representing the second operand to the dot product calculation.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Dot product output signal

scalar | vector

Output signal resulting from the dot product calculation of the two input signals.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Require all inputs to have the same data type` — Require all inputs to have the same data type

`on` (default) | `off`

Clear this check box for all the inputs to have different data types.

Programmatic Use

Block Parameter: `InputSameDT`

Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Output minimum` — Minimum output value for range checking

[ ] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Specify the upper value of the output range that Simulink checks as a finite, real, double, scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum parameter for a bus element, see `Simulink.BusElement`.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `Inherit: Same as first input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- `Inherit: Inherit via internal rule` — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and `ASIC/FPGA` is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn’t meet your specific needs for numerical accuracy or performance, use one of the following options:

  - Specify the output data type explicitly.
  - Use the simple choice of `Inherit: Same as input`.
  - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
  - To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.

- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as first input` — Use data type of first input signal.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see "Use Lock Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see "Rounding" (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`

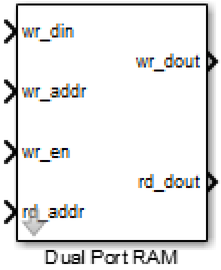
Product | Product of Elements

Introduced before R2006a

Dual Port RAM

Dual port RAM with two output ports



Library

HDL Coder / HDL Operations

Description

The Dual Port RAM block models a RAM that supports simultaneous read and write operations, and has both a read data output port and write data output port. You can use this block to generate HDL code that maps to RAM in most FPGAs.

If you do not need to use the write output data, `wr_dout`, you can achieve better RAM inference with synthesis tools by using the Simple Dual Port RAM block.

Read-During-Write Behavior

During a write, new data appears at the output of the write port (`wr_dout`) of the Dual Port RAM block. If a read operation occurs simultaneously at the same address as a write operation, old data appears at the read output port (`rd_dout`).

Parameters

Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 29. The default is 8.

Ports

The block has the following ports:

`wr_din`

Write data input. The data can be any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`wr_addr`

Write address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of `0`

`wr_en`

Write enable.

Data type: Boolean

`rd_addr`

Read address.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of `0`

`wr_dout`

Output data from write address, `wr_addr`.

`rd_dout`

Output data from read address, `rd_addr`.

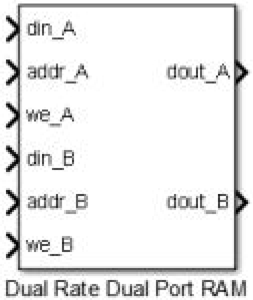
See Also

Dual Rate Dual Port RAM | Simple Dual Port RAM | Single Port RAM

Introduced in R2014a

Dual Rate Dual Port RAM

Dual Port RAM that supports two rates



Library

HDL Coder / HDL Operations

Description

The Dual Rate Dual Port RAM block models a RAM that supports simultaneous read and write operations to different addresses at two clock rates. Port A of the RAM can run at one rate, and port B can run at a different rate.

In high-performance hardware applications, you can use this block to access the RAM twice per clock cycle. If you generate HDL code, this block maps to a dual-clock dual-port RAM in most FPGAs.

Simultaneous Access

You can access different addresses from ports A and B simultaneously. You can also read the same address from ports A and B simultaneously.

However, do not access an address from one RAM port while it is being written from the other RAM port. During simulation, if you access an address from one RAM port at the same time as you write that address from the other RAM port, the software reports an error.

Read-During-Write Behavior

The RAM has write-first behavior. When you write to the RAM, the new write data is immediately available at the output port.

HDL Code Generation

For simulation results that match the generated HDL code, in the Solver pane of the Configuration Parameters dialog box, clear the checkbox for **Treat each discrete rate as a separate task**. When the checkbox is cleared, single-tasking mode is enabled.

If you simulate this block with **Treat each discrete rate as a separate task** selected, multitasking mode is enabled. The output data can update in the same cycle but in the generated HDL code, the output data is updated one cycle later.

Parameters

Address port width

Address bit width. Minimum bit width is 2, and maximum bit width is 28. The default value is 8.

Ports

The block has the following ports:

`din_A`

Write data input for RAM port A. The data can be any width. It inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`addr_A`

Write address for RAM port A.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of `0`

`we_A`

Write enable for RAM port A. Set `we_A` to `true` for a write operation, or `false` for a read operation.

Data type: Boolean

`din_B`

Write data input for RAM port B. The data can be of any width, and inherits the width and data type from the input signal.

Data type: scalar fixed point, integer, or complex

`addr_B`

Write address for RAM port B.

Data type: scalar unsigned integer (`uintN`) or unsigned fixed point (`ufixN`) with a fraction length of `0`

`we_B`

Write enable for RAM port B. Set `we_B` to `true` for a write operation, or `false` for a read operation.

Data type: Boolean

`dout_A`

Output data from RAM port A address, `addr_A`.

`dout_B`

Output data from RAM port B address, `addr_B`.

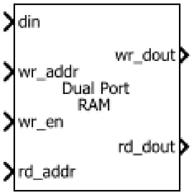
Dual Port RAM | HDL FIFO | Simple Dual Port RAM | Single Port RAM

Introduced in R2014a

Dual Port RAM System, Simple Dual Port RAM System, Single Port RAM System

RAM blocks based on the hdl.RAM system object with ability to provide initial value

Library: HDL Coder / HDL RAMs



Dual Port RAM System

Description

The blocks are MATLAB System blocks that use the `hdl.RAM` System object™. You can specify the RAM type as `Dual port`, `Simple dual port`, or `Single port`. In terms of simulation behavior, the Dual Port RAM System block behaves similar to the Dual Port RAM, the Single Port RAM System behaves similar to the Single Port RAM, and so on. With the MATLAB System blocks, you can:

- Specify an initial value for the RAM. In the Block Parameters dialog box, enter a value for **Specify the RAM initial value**.
- Obtain faster simulation results when you use these blocks in your Simulink model.

Limitations

- The block does not support `boolean` inputs. Cast any `boolean` types to `ufix1` for input to the block.

Ports

Input

din — Write data input

Scalar (default) | Vector

Data that you write into the RAM memory location when wrEn is true. This value can be double, single, integer, or a fixed-point (fi) object, and can be real or complex.

Data Types: single | double | int8 | int16 | uint8 | uint16 | fixed point

addr — Write or Read address

Scalar (default) | Vector

Address that you write the data into when wrEn is true. The RAM reads the value in memory location **addr** when wrEn is false. This value can be either fixed-point (fi) or integer, and must be real and unsigned.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to Single port.

Data Types: uint8 | uint16 | fixed point

wr_addr — Write address

Scalar (default) | Vector

RAM address that you write the data into. This value can be either fixed-point (fi) or integer, and must be real and unsigned.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to Simple dual port or Dual port.

Data Types: uint8 | uint16 | fixed point

wr_en — Write enable

Scalar (default) | Vector

When wrEn is true, the RAM writes the data into the memory location that you specify. If you set the **Specify the type of RAM** to Single port, the RAM reads the value in the memory location addr when wrEn is false.

Data Types: `Boolean`

`rd_addr` — Read address
`Scalar` (default) | `Vector`

Address that you read the data from the RAM. This value can be either `fixed-point (fi)` or `integer`, and must be real and unsigned.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Simple dual port` or `Dual port`.

Data Types: `uint8` | `uint16` | `fixed point`

Output

`dout` — Output data
`Scalar` (default) | `Vector`

Output data that the RAM reads from the memory location `addr` when `wrEn` is false.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Single port`.

`rd_dout` — Read data
`Scalar` (default) | `Vector`

Old output data that the RAM reads from the memory location `rd_addr`.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Simple dual port` or `Dual port`.

`wr_dout` — Write data output
`Scalar` (default) | `Vector`

New or old output data that the RAM reads from the memory location `wr_addr`.

Dependencies

To enable this port, set the **Specify the type of RAM** parameter to `Dual port`.

Parameters

`Specify the type of RAM` — RAM type

`Dual port` (default) | `Simple dual port` | `Single port`

Type of RAM, specified as either:

- `Single port` — Create a single port RAM with Write data, Address, and Write enable as inputs and Read data as the output.
- `Simple dual port` — Create a simple dual port RAM with Write data, Write address, Write enable, and Read address as inputs and data from read address as the output.
- `Dual port` — Create a dual port RAM with Write data, Write address, Write enable, and Read address as inputs and data from read address and write address as the outputs.

The code generator dynamically configures the input and output ports of the block based on the RAM type that you specify.

`Specify the output data for a write operation` — Write output behavior

`New data` (default) | `Old data`

Behavior for Write output, specified as either:

- `'New data'` — Send out new data at the address to the output.
- `Old data'` — Send out old data at the address to the output.

`Specify the RAM initial value` — Initial simulation output of RAM

`'0.0'` (default) | `Scalar` | `Vector`

Initial simulation output of the System object, specified as either:

- A scalar value.
- A vector with one-to-one mapping between the initial value and the RAM words.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

If have HDL Coder installed, you can generate HDL code for the blocks. For more information, see Dual Port RAM System, Simple Dual Port RAM System, and Single Port RAM System.

Edit

Enter new value for parameter
Library: Simulink / Dashboard

Description

The Edit block allows you to type in new values for block parameters during simulation. Use the Edit block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

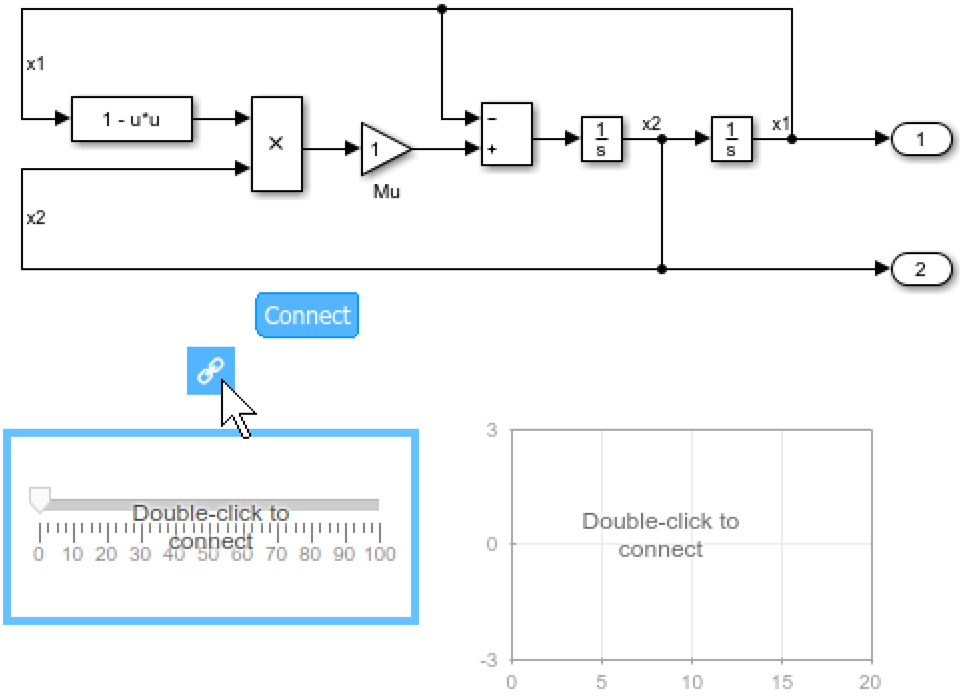
Double-clicking the Edit block does not open its dialog box during simulation and when the block is selected. To edit the block parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connecting Dashboard Blocks

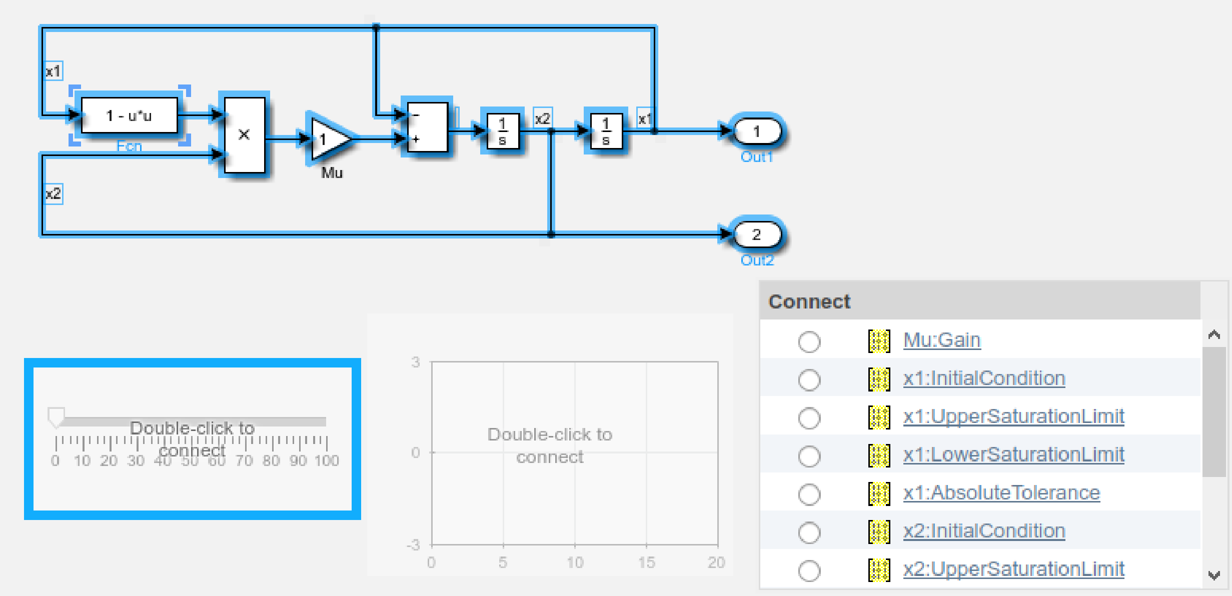
Dashboard blocks do not use ports to make connections. To connect Dashboard blocks to variables and block parameters in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

Note Dashboard blocks cannot connect to variables until you update your model diagram. To connect Dashboard blocks to variables or modify variable values between opening your model and running a simulation, update your model diagram using **Ctrl+D**.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

○ Mu:Gain

○ x1:InitialCondition

○ x1:UpperSaturationLimit

○ x1:LowerSaturationLimit

○ x1:AbsoluteTolerance

○ x2:InitialCondition

○ x2:UpperSaturationLimit

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Parameter Logging

Tunable parameters connected to Dashboard blocks are logged to the Simulation Data Inspector, where you can view parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector UI or by using the `Simulink.sdi.exportRun` function. For more information about exporting data with the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using

connect mode, the Dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. Populate the **Connection** table by selecting one or more blocks in your model. Select the radio button next to the variable or parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

`Align` — Text alignment

'Center' (default) | 'Left' | 'Right'

Alignment of the text in the Edit block.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

Enable

Add enable port to subsystem or model
Library: Simulink / Ports & Subsystems

Description

The Enable block allows an external signal to control execution of a subsystem or a model. To enable this functionality, add the block to a Subsystem block or at the root level of a model that is referenced in a Model block.

If you use an enable port at the root-level of a model:

- For multi-rate models, set the solver to single-tasking.
- For models with a fixed-step size, at least one block in the model must run at the specified fixed-step size rate.

Ports

Output

`Enable signal` — External enable signal for a subsystem or model
scalar

Enable signal attached externally to the outside of an Enable Subsystem block and passed to the inside of the subsystem. An enable signal port is added to an Enable block when you select the **Show output port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `expression`

Parameters

`States when enabling` — Select block states when subsystem or model is disabled

`held` (default) | `reset`

When a Subsystem block or Model block is disabled, select what happens to block states for the blocks within the subsystem or model.

`held`

Hold block states at their previous values.

`reset`

Reset block states to their initial conditions (zero if not defined).

Programmatic Use

Block parameter: `StatesWhenEnabling`
Type: character vector
Values: `'held'` | `'reset'`
Default: `'held'`

`Propagate sizes of variable-size signals` — Select when to propagate a variable-size signal

`Only when enabling` (default) | `During execution`

Select when to propagate a variable-size signal.

`Only when enabling`

Propagate a variable-size signal when reenabling a Subsystem block or Model block containing an Enable port block. When you select this option, sample time must be periodic.

`During execution`

Propagate variable-size signals at each time step.

Programmatic Use

Block parameter: `PropagateVarSize`
Type: character vector
Values: `'Only when enabling'` | `'During execution'`
Default: `'Only when enabling'`

`Show output port` — Control display of output port for enable signal

off (default) | on

The output port passes the enable signal attached externally to the outside of an Enable Subsystem block or enabled Model block to the inside.

□ off

Remove the output port on the Enable port block.

☑ on

Display an output port on the Enable port block. Selecting this option allows the subsystem or model to process the enable signal.

Programmatic Use
Block parameter: `ShowOutputPort`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Enable zero-crossing detection` — Control zero-crossing detection

on (default) | off

Control zero-crossing detection for a model.

☑ on

Detect zero crossings.

□ off

Do not detect zero crossings.

Programmatic Use
Block parameter: `ZeroCross`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Port dimensions` — Specify dimensions for the enable signal

`1` (default) | `[n]` | `[m n]`

Specify dimensions for the enable signal attached externally to a Model block and passed to the inside of the block.

`1`

Scalar signal.

`[n]`

Vector signal of width `n`.

`[m n]`

Matrix signal having `m` rows and `n` columns.

Programmatic Use
Block parameter: `PortDimensions`
Type: character vector
Values: `'1'` | `'[n]'` | `'[m n]'`
Default: `'1'`

`Sample time` — Specify time interval

`-1` (default) | `Ts` | `[Ts, To]`

Specify time interval between block method execution. See “Specify Sample Time”.

`-1`

Sample time inherited from the model.

`Ts`

Scalar where Ts is the time interval.

`[Ts, To]`

Vector where Ts is the time interval and To is the initial time offset.

Programmatic Use
Block parameter: `SampleTime`
Type: character vector
Values: `'-1'` | `'Ts'`| `'[Ts, To]'`
Default: `'-1'`

`Minimum` — Specify minimum output value for the enable signal

`[ ]` (default) | real scalar

Specify minimum value for the enable signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values” (Simulink Coder).

`[]`

Unspecified minimum value.

real scalar

Real double scalar value.

Programmatic Use
Block parameter: `OutMin`
Type: character vector
Values: `'[]'|'<real scalar>'`
Default: `'[]'`

`Maximum` — Specify maximum output value for the enable signal

`[ ]` (default) | real scalar

Specify maximum value for the enable signal attached externally to a Model block and passed to the inside of the block.

Simulink uses this value to perform:

- Simulation range checking. See “Signal Ranges”.
- Automatic scaling of fixed-point data types.
- Optimization of generated code. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. See “Optimize using the specified minimum and maximum values” (Simulink Coder).

`[]`

Unspecified maximum value.

real scalar

Real double scalar value.

Programmatic Use
Block parameter: `OutMax`

Type: character vector
Values: `'[]'` | `'<real scalar>'`
Default: `'[]'`

`Data type` — Specify output data type for the enable signal

`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^,0)` | `<data type expression>`

Specify data type for the enable signal attached externally to a Model block and passed to the inside of the block.

`double`

Double-precision floating point.

`single`

Single-precision floating point.

`int8`

Signed 8-bit integer.

`uint8`

Unsigned 8-bit integer.

`int16`

Signed 16-bit integer.

`uint16`

Unsigned 16-bit integer.

`int32`

Signed 32-bit integer.

`uint32`

Unsigned 32-bit integer.

`boolean`

Boolean with a value of `true` or `false`.

`fixdt(1,16)`

Signed 16-bit fixed point number with binary point undefined.

`fixdt(1,16,0)`

Signed 16-bit fixed point number with binary point set to zero.

`fixdt(1,16,2^,0)`

Signed 16-bit fixed point number with slope set to `2^0` and bias set to `0`.

`<data type expression>`

Data type object, for example `Simulink.NumericType`. Do not specify a bus object as the expression.

Programmatic Use

b
Block parameter: `OutDataTypeStr`
Type: character vector
Values: `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'boolean'` | `'<fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'double'`

`Mode` — Select data type category

`Build in` (default) | `Fixed point` | `Expression`

Select data type category and display drop-down lists to help you define the data type.

`Build in`

Display drop-down lists for data type and Data type override.

`Fixed point`

Display drop-down lists for Signedness, Scaling, and Data type override.

`Expression`

Display text box for entering an expression.

Dependency

To enable this parameter, select the Show data type assistant button.

Programmatic Use

No equivalent command-line parameter.

`Interpolate data` — Specify value of missing workspace data

on (default) | off

Specify value of missing workspace data when loading data from the workspace.

☑ on

Linearly Interpolate output at time steps for which no corresponding workspace data exists.

□ off

Do not interpolate output at time steps. The current output equals the output at the most recent time step for which data exists.

Programmatic Use
Block parameter: `Interpolate`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`

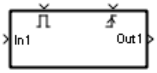
Enabled and Triggered Subsystem

Subsystem whose execution is enabled and triggered by external input

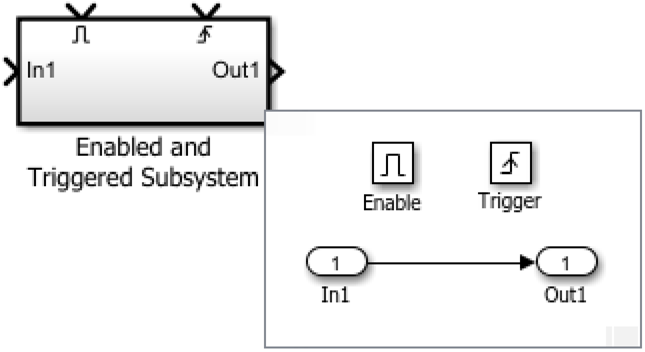
Library: Simulink / Ports & Subsystems



Description

The Enabled and Triggered Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when both of these conditions occur:

- Enable control signal has a positive value.
- Trigger control signal has a trigger event.



Use Enabled and Triggered Subsystem blocks to model:

- Optional functionality that runs with the detection of an event.
- Alternative functionality that runs with the detection of an event.

Ports

Input

`In` — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`Enable` — Control signal input to a subsystem block

scalar

Placing an Enable block in a subsystem block adds an external input port to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Trigger` — Control signal input to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Out` — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a] | string[a]
Direct Feedthrough	No
Multidimensional Signals	Yes[a]
Variable-Size Signals	Yes[a]
Zero-Crossing Detection	No

[a] Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

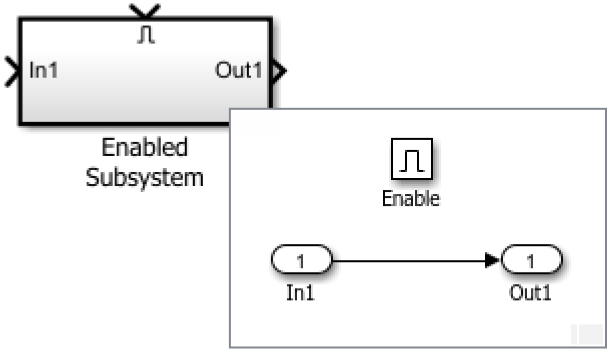
Enabled Subsystem

Subsystem whose execution is enabled by external input

Library: Simulink / Ports & Subsystems

Description

The Enabled Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when a control signal has a positive value.



Use Enable Subsystem blocks to model:

- Discontinuities
- Optional functionality
- Alternative functionality

Ports

Input

`In` — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`Enable` — Control signal input to a subsystem block

scalar | vector | matrix

Placing an Enable block in a subsystem block adds an external input port to the block and changes the block to an Enable Subsystem block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Out` — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a] | string[a]
Direct Feedthrough	No
Multidimensional Signals	Yes[a]
Variable-Size Signals	Yes[a]
Zero-Crossing Detection	No

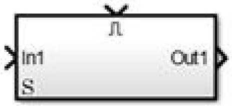
Enabled Synchronous Subsystem

Represent enabled subsystem that has synchronous reset and enable behavior



Library

HDL Coder / HDL Subsystems

Description

An Enabled Synchronous Subsystem is an Enabled Subsystem that uses the `Synchronous` mode of the State Control block. If an **S** symbol appears in the subsystem, then it is synchronous.

To create an Enabled Synchronous Subsystem block, add the block to your Simulink model from the HDL Subsystems block library. You can also add a State Control block with **State control** set to `Synchronous` inside an Enabled subsystem.

For more information, see State Control and “Using Enabled Subsystems”.

Data Type Support

See Inport for information on the data types accepted by a subsystem's input ports. See Outport for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show port labels

Cause Simulink software to display labels for the subsystem's ports on the subsystem's icon.

Default: `FromPortIcon`

`none`

Does not display port labels on the subsystem block.

`FromPortIcon`

If the corresponding port icon displays a signal name, display the signal name on the subsystem block. Otherwise, display the port block's name.

`FromPortBlockName`

Display the name of the corresponding port block on the subsystem block.

`SignalName`

If a name exists, display the name of the signal connected to the port on the subsystem block; otherwise, the name of the corresponding port block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Read/Write permissions

Control user access to the contents of the subsystem.

Default: `ReadWrite`

`ReadWrite`

Enables opening and modification of subsystem contents.

`ReadOnly`

Enables opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem and can make and modify local copies of the subsystem but cannot change the permissions or modify the contents of the original library instance.

`NoReadOrWrite`

Disables opening or modification of subsystem. If the subsystem resides in a library, you can create links to the subsystem in a model but cannot open, modify, change permissions, or create local copies of the subsystem.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Name of error callback function

Enter name of a function to be called if an error occurs while Simulink software is executing the subsystem.

Default: `' '`

Simulink software passes two arguments to the function: the handle of the subsystem and a character vector that specifies the error type. If no function is specified, Simulink software displays a generic error message if executing the subsystem causes an error.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

Default: `All`

`All`

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, `Simulink.Signal` objects).

`ExplicitOnly`

Resolve only names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked as “must resolve”.

`None`

Do not resolve any workspace variable names.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as atomic unit

Causes Simulink software to treat the subsystem as a unit when determining the execution order of block methods.

Default: Off

☑ On

Cause Simulink software to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

□ Off

Cause Simulink software to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause execution of methods of blocks in the subsystem to be interleaved with execution of methods of blocks outside the subsystem.

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-0 .
- “Sample time” on page 1-0
- “Function packaging” on page 1-0 (requires a Simulink Coder license)

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

Default: On

☑ On

> Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all the blocks in the subsystem.

□ Off

> Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

“Treat as grouped when propagating variant conditions” on page 1-0 enables this parameter.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

Default: `Auto`

`Auto`

> Simulink Coder software chooses the optimal format for you based on the type and number of instances of the subsystem that exist in the model.

`Inline`

> Simulink Coder software inlines the subsystem unconditionally.

`Nonreusable function`

> Simulink Coder software explicitly generates a separate function in a separate file. Subsystems with this setting generate functions that might have arguments

depending on the “Function interface” on page 1-0 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-0 and “File name (no extension)” on page 1-0 . These functions are not reentrant.

`Reusable function`

Simulink Coder software generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

This option also generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy that includes multiple instances of a subsystem across referenced models. In this case, the subsystem must be in a library.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Double | Single | Boolean | Base Integer | Fixed-Point | Enumerated | Bus

Introduced in R2016a

Enumerated Constant

Generate enumerated constant value
Library: Simulink / Sources

Description

The Enumerated Constant block outputs a scalar, array, or matrix of enumerated values. You can also use the Constant block to output enumerated values, but it provides block parameters that do not apply to enumerated types, such as **Output minimum** and **Output maximum**. When you need a block that outputs only constant enumerated values, use Enumerated Constant rather than Constant. For more information, see “Simulink Enumerations”.

Ports

Output

`Port_1` — Enumerated constant
scalar | vector | matrix

Enumerated constant value, specified as a scalar, vector, or matrix.

Data Types: `enumerated`

Parameters

`Output data type` — Output data type
`Enum: SlDemoSign` (default) | `Enum:<ClassName>`

Specify the enumerated type from which you want the block to output one or more values. The initial value, `Enum:SlDemoSign`, is a dummy enumerated type that prevents a newly cloned block from causing an error. To specify the desired enumerated type, select it from the drop-down list or enter `Enum:`*`ClassName`* in the **Output data type** field, where *`ClassName`* is the name of the MATLAB class that defines the type.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Enum:<ClassName>'`
Default: `'Enum: SlDemoSign'`

`Mode` — Category of data to specify

`Enumerated` (default)

Select the category of data to specify.

`Enumerated`

Enumerated data types. Selecting `Enumerated` enables a second menu/text box to the right, where you can enter the class name.

`Value` — Enumerated value

`SlDemoSign.Positive` (default) | `Enum:<ClassName.Value>`

Specify the value or values that the block outputs. The output of the block has the same dimensions and elements as the **Value** parameter. The initial value, `SlDemoSign.Positive`, is a dummy enumerated value that prevents a newly cloned block from causing an error.

To specify the desired enumerated values, select from the drop-down list or enter any MATLAB expression that evaluates to the desired result, including an expression that uses tunable parameters. All specified values must be of the type indicated by the **Output data type**. To specify an array that includes every value in the enumerated type, use the `enumeration` function.

Programmatic Use
Block Parameter: `Value`
Type: character vector
Values: `'Enum:<ClassName.Value>'`
Default: `'SlDemoSign.Positive'`

`Sample time` — Sample time

`inf` (default) | scalar | vector

Specify the interval between times that the block output can change during simulation (for example, due to tuning the **Value** parameter). The default value of `inf` indicates that the block output can never change. A sample time of `inf` speeds the simulation and generated code by avoiding the need to recompute the block output. For more information, see “Specify Sample Time”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'inf'`

Block Characteristics

Data Types	`enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

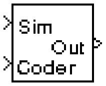
Environment Controller

Create branches of block diagram that apply only to simulation or only to code generation
Library: Simulink / Signal Routing



Description

The Environment Controller block outputs the signal at its **Sim** port only if the model that contains it is being simulated. It outputs the signal at its **Coder** port only if code is being generated from the model. This option enables you to create branches of a block diagram that apply only to simulation or code generation. This table describes various scenarios where either the **Sim** or **Coder** port applies.

Scenario	Output
Normal mode simulation	**Sim**
Accelerator mode simulation	**Sim**
Rapid accelerator mode simulation	**Sim**
Simulation of a referenced model in normal or accelerator modes	**Sim**
Simulation of a referenced model in processor-in-the-loop (PIL) mode	**Coder** (uses the same code generated for a referenced model)
External mode simulation	**Coder**
Standard code generation	**Coder**
Code generation of a referenced model	**Coder**

Simulink Coder software does not generate code for blocks connected to the **Sim** port if these conditions hold:

- On the **Code Generation > Optimization** pane of the Configuration Parameters dialog box, you set **Default parameter behavior** to `Inlined`.

- The blocks connected to the Sim port do not have external signals.
- The Sim port input path does not contain an S-function or an Interpreted MATLAB Function block.

If you enable block reduction optimization, Simulink eliminates blocks in the branch connected to the Coder port when compiling the model for simulation. For more information, see “Block reduction”.

Note Simulink Coder code generation eliminates the blocks connected to the Sim branch only if the Sim branch has the same signal dimensions as the Coder branch. Regardless of whether it eliminates the Sim branch, Simulink Coder uses the sample times on the Sim branch as well as the Coder branch to determine the fundamental sample time of the generated code and might, in some cases, generate sample-time handling code that applies only to sample times specified on the Sim branch.

Ports

Input

`Sim` — Simulation input

scalar | vector | matrix

Simulation input values, specified as a scalar, vector, or matrix. Input signal must have the same width as the input to the **Coder** port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`Coder` — Code generation input

scalar | vector | matrix

Code generation input values, specified as a scalar, vector, or matrix. Input signal must have the same width as the input to the **Sim** port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Out` — Values from Sim or Coder input port
scalar | vector | matrix

Values from the **Sim** or **Coder** input port, depending on the current environment. For more information on what the block outputs in various simulation and code generation modes, see “Description” on page 1-724.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Event Listener

Add event port to a subsystem block
Library: Ports & Subsystems

Description

Add event port to a Subsystem block.

Parameters

`Event type` — Select event type for subsystem
`Initialize` (default) | `Terminate` | `Reset`

Select event type for subsystem to execute initialize, reset, or terminate algorithms.

`Initialize`

Select to trigger the execution of an Initialize Function block with an initialize event.

`Terminate`

Select to trigger the execution of a Terminate Function block with a terminate event.

`Reset`

Select to trigger the execution of an Initialize Function block reconfigured as a Reset Function block with a reset event.

Programmatic Use
Block Parameter: `EventType`
Type: character vector
Value: `'Initialize'` | `'Terminate'` | `'Reset'`
Default: `'Initialize'`

`Event name` — Specify event name
`Reset` (default) | event name

Specify event name for Reset Function block

`Reset`

Default name on the face of the Reset Function block.

event name

User entered name displayed on the face of the Reset Function block, and the name of the reset event port on the Model block containing the Reset Function block.

When tying the name for a reset function, the auto-completion list provides some suggestions. The list is not complete.

Dependency

To enable this parameter, set the **Event** parameter to `Reset`.

Programmatic Use

Block Parameter: `EventName`
Type: character vector
Value: `'reset'` | `'<event name>'`
Default: `'reset'`

`Enable variant condition` — Control activating the variant control (condition)

off (default) | on

Control activating the variant control (condition) defined with the **Variant Control** parameter.

□ off

Deactivate variant control of subsystem.

☑ on

Activate variant control of subsystem.

Dependency

Selecting this parameter, enables the **Variant control** and **Generate preprocessor conditionals** parameters.

Programmatic Use

Block Parameter: `Variant`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

Note

- The Reset event port of a Model block can be conditional and propagates the net Variant conditions defined on the corresponding Reset Function block(s) in the referenced model.
- Initialize and Terminate event ports are always unconditional because they control both the model default and block-specific initialize and terminate events of the referenced model. If you define an Initialize function block in the referenced model, it corresponds to an explicit initialize event.

`Variant control` — Specify variant control (condition) expression

`Variant` (default) | logical expression

Specify variant control (condition) expression that executes a variant Initialize function, Reset function, or Terminate function block when the expression evaluates to `true`.

`Variant`

Default name for a logical (Boolean) expression.

logical expression

A logical (Boolean) expression or a `Simulink.Variant` object representing a boolean expression.

If you want to generate code for your model, define the variables in the expression as `Simulink.Parameter` objects.

Dependency

To enable this parameter, select the **Enable variant condition** parameter.

Programmatic Use

Block Parameter: `VariantControl`
Type: character vector
Value: `'Variant'` | `'<logical expression>'`
Default: `'Variant'`

`Generate preprocessor conditionals` — Select if variant choices are enclosed within C preprocessor conditional statements

off (default) | on

Select if variant choices are enclosed within C preprocessor conditional statements.

□ off

Does not enclose variant choices within C preprocessor conditional statements.

☑ on

When generating code for an ERT target, encloses variant choices within C preprocessor conditional statements (#if).

Dependency

To enable this parameter, select the **Enable variant condition** parameter.

Programmatic Use

Block Parameter: `GeneratePreprocessorConditionals`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

Extract Bits

Output selection of contiguous bits from input signal
Library: Simulink / Logic and Bit Operations

Description

The Extract Bits block allows you to output a contiguous selection of bits from the stored integer value of the input signal. Use the **Bits to extract** parameter to define the method for selecting the output bits.

- Select `Upper half` to output the half of the input bits that contain the most significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation

  number of output bits = ceil(number of input bits/2)
- Select `Lower half` to output the half of the input bits that contain the least significant bit. If there is an odd number of bits in the input signal, the number of output bits is given by the equation

  number of output bits = ceil(number of input bits/2)
- Select `Range starting with most significant bit` to output a certain number of the most significant bits of the input signal. Specify the number of most significant bits to output in the **Number of bits** parameter.
- Select `Range ending with least significant bit` to output a certain number of the least significant bits of the input signal. Specify the number of least significant bits to output in the **Number of bits** parameter.
- Select `Range of bits` to indicate a series of contiguous bits of the input to output in the **Bit indices** parameter. You indicate the range in `[start end]` format, and the indices of the input bits are labeled contiguously starting at 0 for the least significant bit.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. Floating-point inputs are passed through the block unchanged. `Boolean` inputs are treated as `uint8` signals.

Note Performing bit operations on a signed integer is difficult. You can avoid difficulty by converting the data type of your input signals to unsigned integer types.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Extracted bits

scalar | vector | matrix | N-D array

Contiguous selection of extracted bits, specified as a scalar, vector, matrix, or N-D array. Floating-point inputs are passed through the block unchanged.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Bits to extract` — Method for extracting bits

`Upper half` (default) | `Lower half` | `Range starting with most significant bit` | `Range ending with least significant big` | `Range of bits`

Select the method for extracting bits from the input signal.

Consider an input signal that is represented in binary by `110111001`:

- If you select `Upper half` for the **Bits to extract** parameter, the output is `11011` in binary.
- If you select `Lower half` for the **Bits to extract** parameter, the output is `11001` in binary.
- If you select `Range starting with most significant bit` for the **Bits to extract** parameter, and specify `3` for the **Number of bits** parameter, the output is `110` in binary.
- If you select `Range ending with least significant bit` for the **Bits to extract** parameter, and specify `8` for the **Number of bits** parameter, the output is `10111001` in binary.
- If you select `Range of bits` for the **Bits to extract** parameter, and specify `[4 7]` for the **Bit indices** parameter, the output is `1011` in binary.

Programmatic Use

Block Parameter: `bitsToExtract`
Type: character vector
Values: `'Upper half' | 'Lower half' | 'Range starting with most significant bit' | 'Range ending with least significant bit' | 'Range of bits'`
Default: `'Upper half'`

`Number of bits` — Number of bits to output

8 (default) | positive integer

Select the number of bits to output from the input signal. Signed integer data types must have at least two bits. Unsigned data integer types can be as short as a single bit.

Dependencies

To enable this parameter, set **Bits to extract** to `Range starting with most significant bit` or `Range ending with least significant bit`.

Programmatic Use

Block Parameter: `numBits`
Type: character vector
Values: positive integer
Default: `'8'`

`Bit indices` — Contiguous range of bits to output

[0 7] (default) | contiguous range

Specify a contiguous range of bits of the input signal to output. Specify the range in `[start end]` format. The indices are assigned to the input bits starting with 0 at the least significant bit.

Dependencies

To enable this parameter, set **Bits to extract** to `Range of bits`.

Programmatic Use
Block Parameter: `bitIdxRange`
Type: character vector
Values: contiguous range
Default: `'[0 7]'`

`Output scaling mode` — Output scaling mode

`Preserve fixed-point scaling` (default) | `Treat bit field as an integer`

Select the scaling mode to use on the output bit selection:

- When you select `Preserve fixed-point scaling`, the fixed-point scaling of the input is used to determine the output scaling during the data type conversion.
- When you select `Treat bit field as an integer`, the fixed-point scaling of the input is ignored, and only the stored integer is used to compute the output data type.

Programmatic Use
Block Parameter: `outScalingMode`
Type: character vector
Values: `'Preserve fixed-point scaling' | 'Treat bit field as an integer'`
Default: `'Preserve fixed-point scaling'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`

Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

Introduced before R2006a

Fcn

Apply specified expression to input

Library: Simulink / User-Defined Functions

Description

The Fcn block applies the specified mathematical expression to its input. The expression can include one or more of these components:

- `u` — The input to the block. If `u` is a vector, `u(i)` represents the `i`th element of the vector; `u(1)` or `u` alone represents the first element.
- Numeric constants.
- Arithmetic operators (+ - * / ^).
- Relational operators (`== != > < >= <=`) — The expression returns 1 if the relation is true; otherwise, it returns 0.
- Logical operators (&& || !) — The expression returns 1 if the relation is true; otherwise, it returns 0.
- Parentheses.
- Mathematical functions — `abs`, `acos`, `asin`, `atan`, `atan2`, `ceil`, `cos`, `cosh`, `exp`, `floor`, `hypot`, `log`, `log10`, `power`, `rem`, `sgn` (equivalent to `sign` in MATLAB), `sin`, `sinh`, `sqrt`, `tan`, and `tanh`.

  Note The Fcn block does not support `round` and `fix`. Use the Rounding Function block to apply these rounding modes.

- Workspace variables — Variable names that are not recognized in the preceding list of items are passed to MATLAB for evaluation. Matrix or vector elements must be specifically referenced (e.g., `A(1,1)` instead of `A` for the first element in the matrix).

The Fcn block observes the following rules of operator precedence:

1. `( )`
2. `^`
3. `+ -` (unary)
4. `!`
5. `* /`
6. `+ -`
7. `> < <= >=`
8. `== !=`
9. `&&`
10. `||`

The expression differs from a MATLAB expression in that the expression cannot perform matrix computations. Also, this block does not support the colon operator (:).

Block input can be a scalar or vector. The output is always a scalar. For vector output, consider using the Math Function block. If a block input is a vector and the function operates on input elements individually (for example, the `sin` function), the block operates on only the first vector element.

Limitations

- You cannot tune the expression during simulation in Normal or Accelerator mode (see “How Acceleration Modes Work”), or in generated code. To implement tunable expressions, tune the expression outside the Fcn block. For example, use the Relational Operator block to evaluate the expression outside.
- The Fcn block does not support custom storage classes. See “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Ports

Input

In — Input to a Fcn block
scalar | matrix | vector

The Fcn block accepts and outputs signals of type `single` or `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Data Types: `single` | `double`

Output

`Out` — Output from a Fcn block

scalar | matrix | vector

The Fcn block accepts and outputs signals of type `single` or `double`.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Data Types: `single` | `double`

Parameters

`Expression` — Specify the mathematical expression

mathematical expression

Specify the mathematical expression to apply to the input. Expression components are listed above. The expression must be mathematically well-formed (uses matched parentheses, proper number of function arguments, and so on). The expression has restrictions on tunability (see “Limitations” on page 1-738).

Programmatic Use
Block Parameter: `Expr`
Type: character vector
Value: mathematical expression
Default: `'sin(u(1)*exp(2.3*(-u(2))))'`

`Sample time` — Specify sample time in the block

scalar

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Block Characteristics

Data Types	`double` | `single`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Introduced before R2006a

Find Nonzero Elements

Find nonzero elements in array
Library: Simulink / Math Operations

Description

The Find Nonzero Elements block locates all nonzero elements of the input signal and returns the linear indices of those elements. If the input is a multidimensional signal, the Find Nonzero Elements block can also return the subscripts of the nonzero input elements. In both cases, you can show an output port with the nonzero input values.

The Find Nonzero Elements block outputs a variable-size signal. The sample time for any variable-size signal must be discrete. If your model does not already use a fixed-step solver, you may need to select a fixed-step solver in the Configuration Parameters dialog. For more information, see “Solvers” and “Choose a Solver”.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix | N-D array

Input signal from which the block finds all nonzero elements.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Indices of nonzero elements
variable-size signal

The Find Nonzero Elements block outputs the indices of nonzero elements as a variable-size signal. You control the data type of the output using the **Output data type** block parameter.

Dependencies

By default, the block outputs linear indices from the first output port. When you change the **Index output format** to `Subscripts`, the block instead provides the element indices of a two-dimension or larger signal in a subscript form. In this mode, you must specify the **Number of input dimensions**, and the block creates a separate output port for each dimension.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Port_2` — Values of nonzero elements

variable-size signal

The Find block can optionally output the values of all nonzero elements as a variable-size signal.

Dependencies

To enable this port, select **Show output port for nonzero input values**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Index output format` — Format for indices of nonzero elements

`Linear indices` (default) | `Subscripts`

Select the output format for the indices of the nonzero input values.

- Selecting `Linear indices` provides the element indices of any dimension signal in a vector form. For one dimension (vector) signals, indices correspond to the position of nonzero values within the vector. For signals with more than one dimension, the conversion of subscripts to indices is along the first dimension. You do not need to know the signal dimension of the input signal.

- Selecting `Subscripts` provides the element indices of a two-dimension or larger signal in a subscript form. Because the block shows an output port for each dimension, this option requires you to specify the **Number of input dimensions**.

Programmatic Use
Block Parameter: `IndexOutputFormat`
Type: character vector
Values: `'Linear indices'` | `'Subscripts'`
Default: `'Linear indices'`

`Number of input dimensions` — Number of dimensions for the input signal

`1` (default) | scalar

Specify the number of dimensions for the input signal as a positive integer value from 1 to 32.

Dependencies

To enable this parameter, set **Index output format** to `Subscripts`.

Programmatic Use
Block Parameter: `NumberOfInputDimensions`
Type: character vector
Values: scalar
Default: `'1'`

`Index mode` — Specify zero- or one-based indexing

`Zero-based` (default) | `One-based`

Specify the indexing mode as `Zero-based` or `One-based`.

- For `Zero-based` indexing, an index of `0` specifies the first element of the input vector. An index of `1` specifies the second element, and so on.
- For `One-based` indexing, an index of `1` specifies the first element of the input vector. An index of `2`, specifies the second element, and so on.

Programmatic Use
Block Parameter: `IndexMode`
Type: character vector
Values: `'Zero-based'` | `'One-based'`
Default: `'Zero-based'`

`Show output port for nonzero input values` — Enable output port for nonzero values

`off` (default) | `on`

Show or hide the output port for nonzero input values.

- When you clear this check box (`off`), the block hides the output port for nonzero input values.
- When you select this check box (`on`), the block displays the output port for nonzero input values. The additional output port provides values of the nonzero input elements.

Programmatic Use
Block Parameter: `ShowOutputPortForNonzeroInputValues`
Type: character vector
Values: `'on'` | `'off'`
Default: `'off'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Data Types

`Output data type` — Output data type

`Inherit: Inherit via internal rule` (default) | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `<data type expression>`

Specify the output data type.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

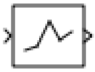
First-Order Hold

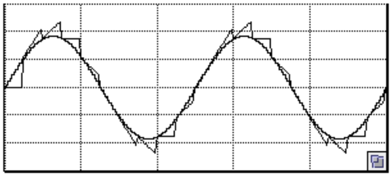
Implement first-order sample-and-hold
Library: Simulink / Discrete



Description

The First-Order Hold block implements a first-order sample-and-hold that operates at the specified sampling interval. This block has little value in practical applications and is included primarily for academic purposes.

This figure compares the output from a Sine Wave block and a First-Order Hold block.



Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `double`

Output

`Port_1` — First-order sample-and-hold
scalar | vector | matrix

First-order sample and hold applied to the input signal.

Data Types: `double`

Parameters

`Sample time` — Time interval between samples
1 (default) | scalar | vector

The time interval between samples. See “Specify Sample Time” for more information.

Programmatic Use
Block Parameter: `Ts`
Type: character vector
Values: scalar | vector
Default: `'1'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Fixed-Point State-Space

Implement discrete-time state space

Library: Simulink / Additional Math & Discrete / Additional Discrete

Description

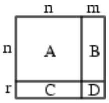
The Fixed-Point State-Space block implements the system described by

$$y(n) = \mathrm{C}x(n) + \mathrm{D}u(n)$$

$$x(n+1) = \mathrm{A}x(n) + \mathrm{B}u(n)$$

where *u* is the input, *x* is the state, and *y* is the output. Both equations have the same data type.

- **A** must be an *n*-by-*n* matrix, where *n* is the number of states.
- **B** must be an *n*-by-*m* matrix, where *m* is the number of inputs.
- **C** must be an *r*-by-*n* matrix, where *r* is the number of outputs.
- **D** must be an *r*-by-*m* matrix.



In addition:

- The state x must be an *n*-by-1 vector.
- The input u must be an *m*-by-1 vector.
- The output y must be an *r*-by-1 vector.

The block accepts one input and generates one output. The width of the input vector is the number of columns in the **B** and **D** matrices. The width of the output vector is the number of rows in the **C** and **D** matrices. To define the initial state vector, use the **Initial conditions** parameter.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

Input vector, where the width equals the number of columns in the **B** and **D** matrices. For more information, see “Description” on page 1-750.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector | matrix

Output signal, with width equal to the number of rows in the **C** and **D** matrices. For more information, see “Description” on page 1-750.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`State Matrix A` — Matrix of states

`[2.6020 -2.2793 0.6708; 1 0 0; 0 1 0]` (default) | scalar | vector | matrix

Specify the matrix of states as a real-valued *n*-by-*n* matrix, where *n* is the number of states. For more information on the matrix coefficients, see “Description” on page 1-750.

Programmatic Use
Block Parameter: `A`
Type: character vector
Values: scalar | vector | matrix
Default: `'[2.6020 -2.2793 0.6708; 1 0 0; 0 1 0]'`

`Input Matrix B` — Column vector of inputs

`[ 1; 0; 0]` (default) | scalar | vector | matrix

Specify the column vector of inputs as a real-valued *n*-by-*m* matrix, where *n* is the number of states, and *m* is the number of inputs. For more information on the matrix coefficients, see "Description" on page 1-750.

Programmatic Use
Block Parameter: `B`
Type: character vector
Values: scalar | vector | matrix
Default: `'[ 1; 0; 0]'`

`Output Matrix C` — Column vector of outputs

`[0.0184 0.0024 0.0055]` (default) | scalar | vector | matrix

Specify the column vector of outputs as a real-valued *r*-by-*n* matrix, where *r* is the number of outputs, and *n* is the number of states. For more information on the matrix coefficients, see "Description" on page 1-750.

Programmatic Use
Block Parameter: `C`
Type: character vector
Values: scalar | vector | matrix
Default: `'[0.0184 0.0024 0.0055]'`

`Direct Feedthrough Matrix D` — Matrix for direct feedthrough

`[0.0033]` (default) | scalar | vector | matrix

Specify the matrix for direct feedthrough as a real-valued *r*-by-*m* matrix, where *r* is the number of outputs, and *m* is the number of inputs. For more information on the matrix coefficients, see "Description" on page 1-750.

Programmatic Use
Block Parameter: `D`
Type: character vector

Values: scalar | vector | matrix
Default: `'[0.0033]'`

`Initial condition for state` — Initial state vector

`0.0` (default) | scalar | vector | matrix

Specify the initial condition for the state.

Limitations

The initial state cannot be `inf` or `NaN`.

Programmatic Use
Block Parameter: `X0`
Type: character vector
Values: scalar | vector | matrix
Default: `'0.0'`

Signal Attributes

`Data type for internal calculations` — Data type for internal calculations

`fixdt('double')` (default) | data type string

Specify the data type the block uses for internal calculations.

Programmatic Use
Block Parameter: `InternalDataType`
Type: character vector
Values: data type string
Default: `'fixdt('double')'`

`Scaling for State Equation AX+BU` — Scaling for state equations

`2^0` (default) | scalar

Specify the scaling for the state equation **AX+BU**.

Programmatic Use
Block Parameter: `StateEqScaling`
Type: character vector
Values: scalar
Default: `'2^0'`

`Scaling for Output Equation CX+DU` — Scaling for output equations

`2^0` (default) | scalar

Specify the scaling for the output equation **CX+DU**.

Programmatic Use
Block Parameter: `InternalDataType`
Type: character vector
Values: scalar
Default: `'2^0'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate to max or min when overflows occur` — Method of overflow action

`off` (default) | `on`

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `DoSatur`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean`[a] | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

a. This block is not recommended for use with Boolean signals.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

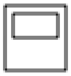
Floating Scope and Scope Viewer

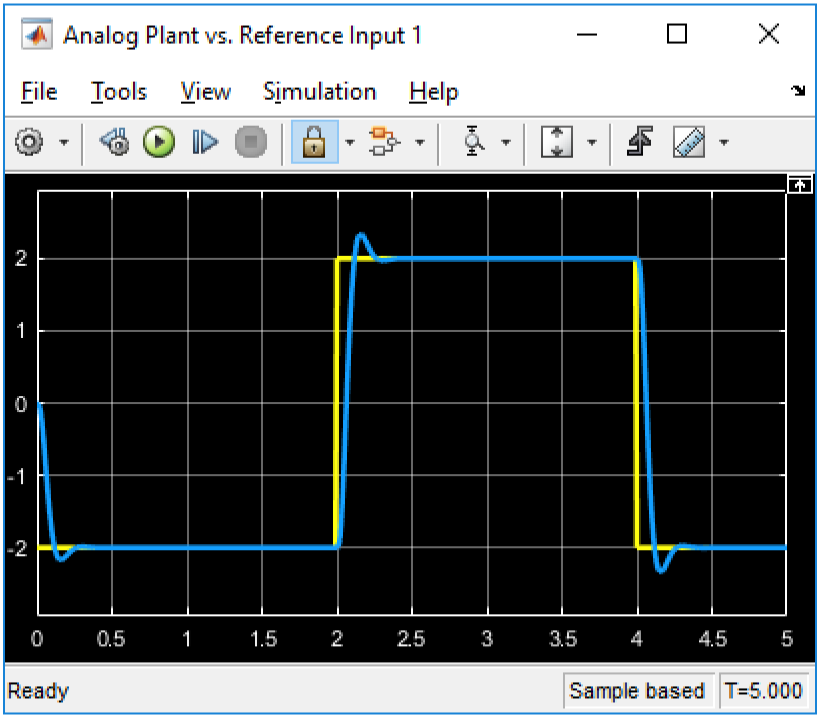
Display signals generated during simulation without signal lines

Library: Simulink / Sinks



Description

The Simulink Scope Viewer and Floating Scope block display time domain signals with respect to simulation time. The Scope Viewer and Floating Scope block have the same functionality as the Scope block, but they are not connected to signal lines. Use the button to add and display signals on a Floating Scope or Scope Viewer.



- Multiple *y*-axes (displays) — Display multiple *y*-axes with multiple input ports. All the *y*-axes have a common time range on the *x*-axis.
- Multiple signals — Show multiple signals on the same *y*-axis (display) from one or more input ports.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Display data after simulation — If a scope is closed at the start of a simulation, scope data is still written to the scope during the simulation. If you open the scope after a simulation, the scope displays simulation results for input signals.

Oscilloscope features:

- Triggers — Set triggers on repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.

- Peak Finder — Find maxima, showing the *x*-axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

You must have a Simscape™ or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

For information on controlling a Floating Scope block from the command line, see “Control Scope Blocks Programmatically” in the Simulink documentation.

Limitations

When you use model configuration parameters that optimize the simulation, such as **Signal storage reuse** and **Block reduction**, Simulink eliminates storage for some signals during simulation. You are unable to apply a Floating Scope to these eliminated signals. To work around this issue, configure an eliminated signal as a test point. You can then apply a Floating Scope to the signal regardless of optimization settings. To configure test points, see “Test Points”.

- If you step back the simulation after adding or removing a signal, the Floating Scope clears the existing data. New data does not appear until the simulation steps forward again.
- When connected to a constant signal, the Scope Viewer plots a single point.
- Simulink messages are not supported for Floating Scope block and Scope Viewer.
- You cannot connect signals from ForEach subsystems.
- You cannot connect testpointed Stateflow signals to a Floating Scope. To connect these signals to a Scope Viewer, use the “Signal Selector”.

Ports

Input

`Port_1` — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink”.
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” and “Determine Output Signal Dimensions”.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope block. To display the bus signals, use normal or accelerator simulation mode. The scope block displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope block, set the **Save format** block parameter to `Dataset`. You can use any **Save format** to log virtual bus signals.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View** > **Configuration Properties**.

Main

`Open at simulation start` — Specify when scope window opens

off (default) | on

Select this check box to open the scope window when simulation starts.

Programmatic Use

See OpenAtSimulationStart.

`Display the full path` — Display block path on scope title bar

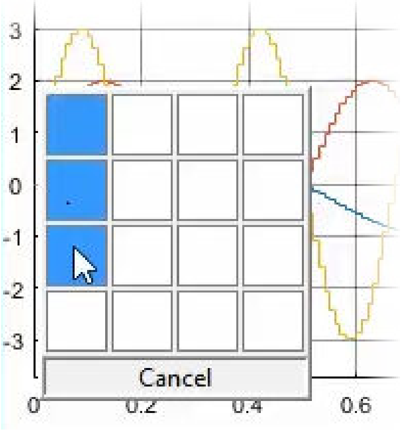
off (default) | on

Select this check box to display the block path in addition to the block name.

Layout — Number and arrangement of displays

1-by-1 display (default) | an arrangement of *m*-by-*n* displays

Specify number and arrangement of displays. To expand the layout grid beyond 4 by 4, click within the dialog box and drag. The maximum layout is 16 rows by 16 columns.



If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down and then across.

Programmatic Use

See LayoutDimensions.

`Input processing` — Channel or element signal processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

- `Elements as channels (sample based)` — Process each element as a unique sample.
- `Columns as channels (frame based)` — Process signal values in a column as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See FrameBasedProcessing.

`Maximize axes` — Maximize size of plots

`Off` (default) | `Auto` | `On`

- `Auto` — If “Title” on page 1-0 and “Y-label” on page 1-0 properties are not specified, maximize all plots.
- `On` — Maximize all plots. Values in **Title** and **Y-label** are hidden.
- `Off` — Do not maximize plots.

Programmatic Use

See MaximizeAxes.

Time

`Time span` — Length of *x*-axis to display

`Auto` (default) | `User defined`

- `Auto` — Difference between the simulation start and stop times.

  The block calculates the beginning and end times of the time range using the “Time display offset” on page 1-0 and “Time span” on page 1-0 properties. For example, if you set the **Time display offset** to `10` and the **Time span** to `20`, the scope sets the time range from `10` to `30`.
- `User defined` — Enter any value less than the total simulation time.

Programmatic Use

See TimeSpan.

`Time span overrun action` — Display data beyond visible *x*-axis

`Wrap` (default) | `Scroll`

Specify how to display data beyond the visible *x*-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- `Wrap` — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.

- `Scroll` — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See TimeSpanOverrunAction.

`Time units` — *x*-axis units

`None` (default for Scope) | `Metric` (default for Time Scope) | `Seconds`

- `Metric` — Display time units based on the length of “Time span” on page 1-0 .
- `Seconds` — Display time in seconds.
- `None` — Do not display time units.

Programmatic Use

See TimeUnits.

`Time display offset` — *x*-axis offset

`0` (default) | scalar | vector

Offset the *x*-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- Scalar — Offset all channels of an input signal by the same time value.
- Vector — Independently offset the channels.

Programmatic Use

See TimeDisplayOffset.

`Time-axis labels` — Display of *x*-axis labels

`Bottom Displays Only` (default for Scope) | `All` (default for Time Scope) | `None`

Specify how *x*-axis (time) labels display:

- `All` — Display *x*-axis labels on all *y*-axes.
- `None` — Do not display labels. Selecting `None` also clears the **Show time-axis label** check box.

- `Bottom displays only` — Display *x*-axis label on the bottom *y*-axis.

Dependencies

To activate this property, set:

- "Show time-axis label" on page 1-0 to on.
- "Maximize axes" on page 1-0 to off.

The "Active display" on page 1-0 property determines which display is affected.

Programmatic Use

See TimeAxisLabels.

`Show time-axis label` — Display or hide *x*-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the *x*-axis label for the active display

Dependencies

To activate this property, set "Time-axis labels" on page 1-0 to `All` or `Bottom Displays Only`.

The "Active display" on page 1-0 property determines which display is affected.

Programmatic Use

See ShowTimeAxisLabel.

Display

`Active display` — Selected display

1 (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

Programmatic Use

See “Active display” on page 1-0 .

`Title` — Display name

`%<SignalLabel>` (default) | character vector | string

Title for a display, specified as a character vector or string. The default value `%<SignalLabel>` uses the input signal name for the title.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See Title.

`Show legend` — Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowLegend.

`Show grid` — Show internal grid lines

on (default) | off

Select this check box to show grid lines.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowGrid.

`Plot signals as magnitude and phase` — Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same *y*-axis.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See PlotAsMagnitudePhase.

`Y-limits (Minimum)` — Minimum y-axis value

`-10` (default) | real scalar

Specify the minimum value of the *y*-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The *y*-axis limits of the phase plot are always `[-180 180]`.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See YLimits.

`Y-limits (Maximum)` — Maximum y-axis value

`10` (default) | real scalar

Specify the maximum value of the *y*-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The *y*-axis limits of the phase plot are always `[-180 180]`.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See YLimits.

`Y-label` — Y-axis label

none (default for Scope) | `'Amplitude'` (default for Time Scope) | character vector | string

Specify the text to display on the *y*-axis. To display signal units, add `(%<SignalUnits>)` to the label. At the beginning of a simulation, Simulink replaces `(%SignalUnits)` with the units associated with the signals.

Example: For a velocity signal with units of `m/s`, enter `Velocity (%<SignalUnits>)`.

Dependency

If you select **Plot signals as magnitude and phase**, this property does not apply. The *y*-axes are labeled `Magnitude` and `Phase`.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See YLabel.

Logging

`Limit data points to last` — Limit buffered data values

off (default) | on

Limit buffered data values before plotting and saving signals. Data values are from the end of a simulation. To use this property, you must also specify the number of data values by entering a positive integer in the text box.

- On — Specify the number of data values saved for each signal (5000 by default). If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

  For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

  Sometimes, selecting this parameter cause signals to be plotted for less than the entire time range of a simulation. For example, where the sample time is small. If a scope plots a portion of your signals, consider increasing the number of data values the simulation saves.
- Off — Save and plot all data values. Clearing **Limit data points to last** can cause an out-of-memory error for simulations that generate a large amount of data or for systems without enough available memory.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See DataLoggingLimitDataPoints and DataLoggingMaxPoints.

`Decimation` — Reduce amount of scope data to display and save

off (default) | on

- On — Plot and log (save) scope data every N^{th} data point, where N is the decimation factor entered in the text box. The default decimation factor is 2. A value of 1 buffers all data values.
- Off — Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See `DataLoggingDecimateData` and `DataLoggingDecimation`.

`Log/Unlog Viewed Signals to Workspace` — Toggle logging

on | off

For signals selected with the Signal Selector, clicking this button toggles the state of the **Log signal data** check boxes in the Signals Properties dialog boxes.

Axes Scaling Properties

The Axes Scaling Properties dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools** > **Axes Scaling** > **Axes Scaling Properties**.

`Axes scaling` — Y-axis scaling mode

`Manual` (default) | `Auto` | `After N Updates`

- `Manual` — Manually scale the *y*-axis range with the **Scale Y-axis Limits** toolbar button.
- `Auto` — Scale the *y*-axis range during and after simulation. Selecting this option displays the “Do not allow Y-axis limits to shrink” on page 1-0 check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to `Auto` and clear the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Scale *y*-axis after the number of time steps specified in the “Number of updates” on page 1-0 text box (`10` by default). Scaling occurs only once during each run.

Programmatic Use

See AxesScaling.

`Do not allow Y-axis limits to shrink` — When y-axis limits can change

on (default) | off

Allow *y*-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set “Axes scaling” on page 1-0 to `Auto`.

`Number of updates` — Number of updates before scaling

`10` (default) | integer

Set this property to delay auto scaling the *y*-axis.

Dependency

To use this property, set “Axes scaling” on page 1-0 to `After N Updates`.

Programmatic Use

See AxesScalingNumUpdates.

`Scale axes limits at stop` — When y-axis limits can change

on (default) | off

- On — Scale axes when simulation stops.
- Off — Scale axes continually.

Dependency

To use this property, set “Axes scaling” on page 1-0 to `Auto`.

`Y-axis Data range (%)` — Percent of *y*-axis to use for plotting

`80` (default) | integer between [1, 100]

Specify the percentage of the *y*-axis range used for plotting data. If you set this property to `100`, the plotted data uses the entire *y*-axis range.

`Y-axis Align` — Alignment along *y*-axis

`Center` (default) | `Top` | `Bottom`

Specify where to align plotted data along the *y*-axis data range when **Y-axis Data range** is set to less than 100 percent.

- `Top` — Align signals with the maximum values of the *y*-axis range.
- `Center` — Center signals between the minimum and maximum values.
- `Bottom` — Align signals with the minimum values of the *y*-axis range.

`Autoscale X-axis limits` — Scale *x*-axis range limits
off (default) | on

Scale *x*-axis range to fit all signal values. If **Axes scaling** is set to `Auto`, the data currently within the axes is scaled, not the entire signal in the data buffer.

`X-axis Data range (%)` — Percent of *x*-axis to use for plotting
`100` (default) | integer in the range [1, 100]

Specify the percentage of the *x*-axis range to plot data on. For example, if you set this property to `100`, plotted data uses the entire *x*-axis range.

`X-axis Align` — Alignment along *x*-axis
`Center` (default) | `Top` | `Bottom`

Specify where to align plotted data along the *x*-axis data range when **X-axis Data range** is set to less than 100 percent.

- `Top` — Align signals with the maximum values of the *x*-axis range.
- `Center` — Center signals between the minimum and maximum values.
- `Bottom` — Align signals with the minimum values of the *x*-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View** > **Style**.

`Figure color` — Background color for window
black (default) | color

Background color for the scope.

`Plot type` — How to plot signal
`Auto` (default for Scope) | `Line` (default for Time Scope) | `Stairs` | `Stem`

When you select `Auto`, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

`Axes colors` — Background and axes color for individual displays
black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

`Preserve colors for copy to clipboard` — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

`Properties for line` — Line to change

`Channel 1` (default)

Select active line for setting line style properties.

`Visible` — Line visibility

on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

`Line` — Line style

solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

`Marker` — Data point marker style

`None` (default) | marker shape

Select marker shape.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Float Typecast

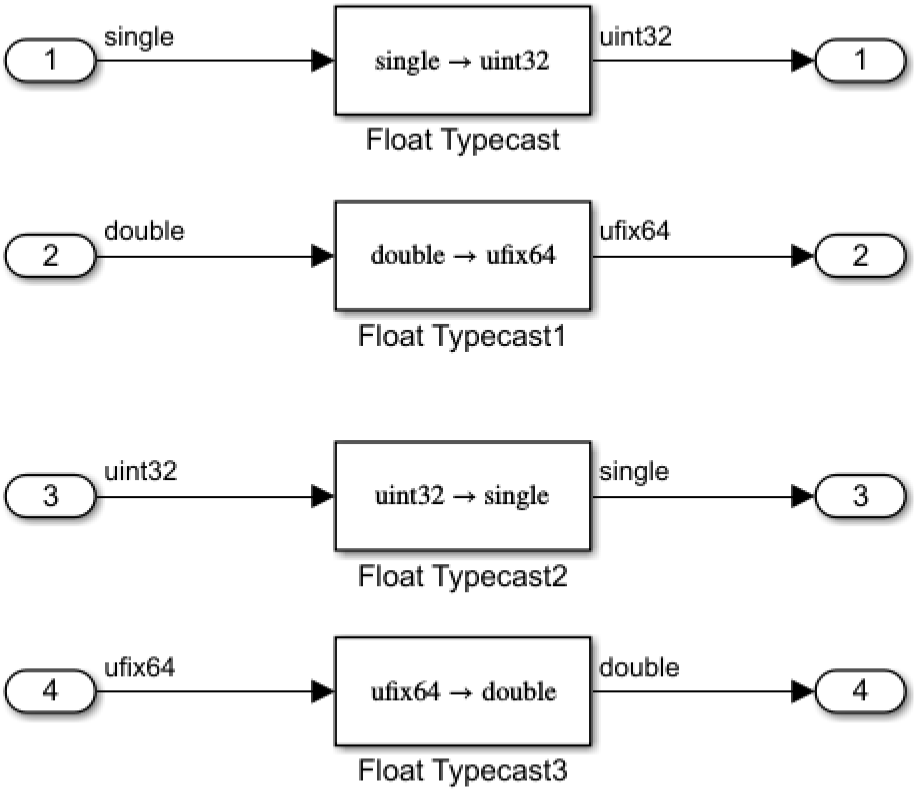
Typecast a floating-point type to an unsigned integer or vice versa

Library: HDL Coder / HDL Floating Point Operations / Float Typecast

Float Typecast

Description

The block casts the underlying bits of the input to the corresponding fixed-point or floating point representation. The input and output of the block contain the same number of bits. This figure shows how the block mask, behavior, and output data type changes dynamically depending on the input data type that you specify.



Ports

Input

`Port_1(u)` — Input signal

`scalar` | `vector`

Port to provide input to the block.

Data Types: `single` | `double` | `uint32` | `fixed point`

Output

`Port_1(y)` — Output signal
`scalar` | `vector`

Port to obtain calculated output from the block.

Data Types: `single` | `double` | `uint32` | `fixed point`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point` | `bus`
Sample Time	`Inherit`

For Each

Process elements or subarrays of a mask parameter or input signal independently
Library: Ports & Subsystems

Description

The For Each block serves as a control block for the For Each Subsystem block. Specifically, the For Each block enables the blocks inside the For Each Subsystem to process the elements of input signals or mask parameters independently. Each block inside this subsystem that has states maintains a separate set of states for each element or subarray that it processes. As the set of blocks in the subsystem processes the elements or subarrays, the subsystem concatenates the results to form output signals.

You can use a For Each subsystem to iteratively compute output after changing inputs or mask parameters. To do so, you configure the partitioning of input signals or mask parameters in the For Each block dialog box.

Partition Input Signals to the Subsystem

In a For Each subsystem, you can specify which input signals to partition for each iteration using the **Input Partition** tab in the dialog box of the For Each block. When specifying a signal to be partitioned, you also have to specify the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

Partition Parameters in the For Each block

You can partition the mask parameters of a For Each Subsystem block. Partitioning is useful for systems that have identical structures in each iteration but different parameter values. In this case, changing the model to partition extra input signals for each parameter is cumbersome. Instead, add a mask parameter to a For Each subsystem. For more information, see “Create a Simple Mask”. To select the mask parameter for partitioning, use the Parameter Partition tab on the For Each block dialog box. For more information, see “Select Partition Parameters” on page 1-780

Concatenate Output

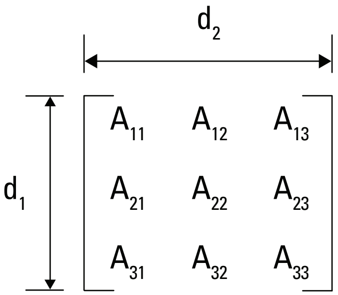
You define the dimension along which to concatenate the results by specifying the **Concatenation Dimension** in the Output Concatenation tab.

The results generated by the block for each subarray stack along the concatenation dimension, d_1 (*y*-axis). Whereas, if you specify d_2 by setting the concatenation dimension to 2, the results concatenate along the d_2 direction (*x*-axis). Thus if the process generates row vectors, then the concatenated result is a row vector.

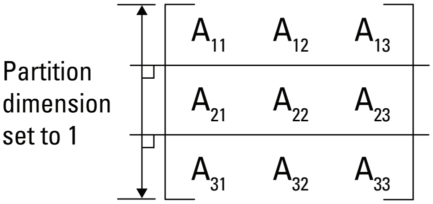
Select Partition Parameters

When selecting an input signal or subsystem mask parameter for partitioning, you need to specify how to decompose it into elements or subarrays for each iteration. Do this by setting integer values for the **Partition Dimension**, **Partition Width**, and **Partition Offset** parameters.

As an illustration, consider an input signal matrix A of the form:



The labels d_1 and d_2, respectively, define dimensions 1 and 2. If you retain the default setting of `1` for both the partition dimension and the partition width, and `0` for the partition offset, then Simulink slices perpendicular to partition dimension d_1 at a width equal to the partition width, that is one element.



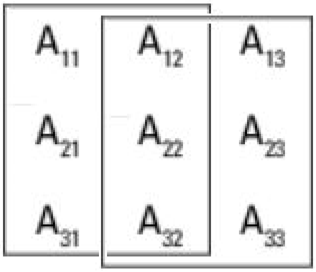
Matrix A decomposes into these three row vectors.

$$\begin{bmatrix} A_{11} & A_{12} & A_{13} \end{bmatrix}$$
$$\begin{bmatrix} A_{21} & A_{22} & A_{23} \end{bmatrix}$$
$$\begin{bmatrix} A_{31} & A_{32} & A_{33} \end{bmatrix}$$

If instead you specify d_2 as the partition dimension by entering the value 2, Simulink slices perpendicular to d_2 to form three column vectors.

$$\begin{bmatrix} A_{11} \\ A_{21} \\ A_{31} \end{bmatrix} \quad \begin{bmatrix} A_{12} \\ A_{22} \\ A_{32} \end{bmatrix} \quad \begin{bmatrix} A_{13} \\ A_{23} \\ A_{33} \end{bmatrix}$$

In addition to setting the **Partition Dimension** to 2, if you set the **Partition Width** to 2 and the **Partition Offset** to -1, Simulink uses two overlapping 3x2 partitions for processing.



For an example using the **Partition Offset** parameter, open the Simulink model slexForEachOverlapExample.

Note Only signals are considered one-dimensional in Simulink. Mask parameters are row or column vectors, according to their orientation. To partition a row vector, specify the partition dimension as 2 (along the columns). To partition a column vector, specify the partition dimension as 1 (along the rows).

Ports

Input

`In` — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Out` — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Input Partition Tab

Select each input signal you want to partition and to specify the corresponding **Partition Dimension** and **Partition Width** parameters. See the Inport block reference page for more information.

`Port` — List of input ports

no default (default) | input port name

List of input ports connected to the For Each Subsystem block.

`Partition` — Select input port signals to partition

off (default) | on

Select input ports signals connected to the For Each Subsystem block to partition into subarrays or elements.

off

Clear input port signals.

on

Select input port signals to partition.

Dependency

Selecting this parameter enables the **Partition Dimension** and **Partition Width** parameters for the selected input port signal.

Programmatic Use
Block Parameter: `InputPartition`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Partition Dimension` — Specify dimension

`1` (default) | integer

Specify the dimension through which to slice the input signal array. The resulting slices are perpendicular to the dimension that you specify. The slices also partition the array into subarrays or elements, as appropriate.

`1`

Specify a dimension of `1`.

integer

Specify dimension. Minimum value `1`.

Programmatic Use
Block Parameter: `InputPartitionDimension`
Type: character vector
Values: `'1'` | `'<integer>'`
Default: `'1'`

`Partition Width` — Specify width

`1` (default) | integer

Specify the width of each partition slice of the input signal.

`1`

Width of one element.

integer

Specify width. Minimum value `1`.

Programmatic Use
Block Parameter: `InputPartitionWidth`
Type: character vector
Values: `'1'` | `'<integer>'`
Default: `'1'`

`Partition Offset` — Specify partition offset

`0` (default) | integer

Specify the offset for each partition slice of the input signal.

`0`

No offset between partition slices.

integer

Specify partition offset where the sum of the partition width and the partition offset is a positive integer.

For example, a **Partition Width** of `3` and a **Partition Offset** of `-2` indicates that each 3 element slice overlaps its neighboring slices by 2 elements.

Programmatic Use
Block Parameter: `SubsysMaskParameterOffset`
Type: character vector
Values: `'0'` | `'<integer>'`
Default: `'0'`

Output Concatenation Tab

For each output port, specify the dimension along which to stack (concatenate) the For Each Subsystem block results. See the Outport block reference page for more information.

`Port` — List of output ports

none (default) | output port name

List of output ports connected to the For Each Subsystem block.

`Concatenation Dimension` — Specify dimension

`1` (default) | `integer`

Specify the dimension along which to stack the results of the For Each Subsystem block.

`1`

  The results stack in the d_1 direction. If the block generates column vectors, the concatenation process results in a single column vector.

`integer`

  The results stack in the d_2 direction. If the block generates row vectors, the concatenation process results in a single row vector. Minimum value `1`

Programmatic Use
Block Parameter: `OutputConcatenationDimension`
Type: character vector
Values: `'1'` | `'<integer>'`
Default: `'1'`

Parameter Partition Tab

Select each mask parameter to partition and to specify the corresponding **Partition Dimension** and **Partition Width** parameters. Parameters appear in the list only if you have added an editable parameter to the mask of the parent For Each subsystem.

`Parameter` — List of mask parameters

parameter name

List of mask parameters for the For Each Subsystem block.

`Partition` — Select mask parameters to partition

off (default) | on

Select mask parameters for the For Each Subsystem block to partition into subarrays or elements.

off

Clear mask parameters.

on

Select mask parameters to partition.

Dependency

Selecting this parameter enables the **Partition Dimension** and **Partition Width** parameters for the selected mask parameter.

Programmatic Use

Block Parameter: `SubsysMaskParameterPartition`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Partition Dimension` — Specify dimension

1 (default) | integer

Specify the dimension through which to slice the input signal array as an integer greater than or equal to one. The resulting slices are perpendicular to the dimension that you specify. The slices also partition the array into subarrays or elements, as appropriate.

Programmatic Use

Block Parameter: `SubsysMaskParameterPartitionDimension`
Type: character vector
Values: `'1'` | `'<integer>'`
Default: `'1'`

`Partition Width` — Specify partition width

1 (default) | integer

Specify the width of each partition slice of the input signal as an integer greater than or equal to one.

Programmatic Use
Block Parameter: `SubsysMaskParameterPartitionWidth`
Type: character vector
Values: `'1'` | `'<integer>'`
Default: `'1'`

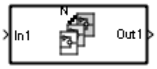
For Each Subsystem

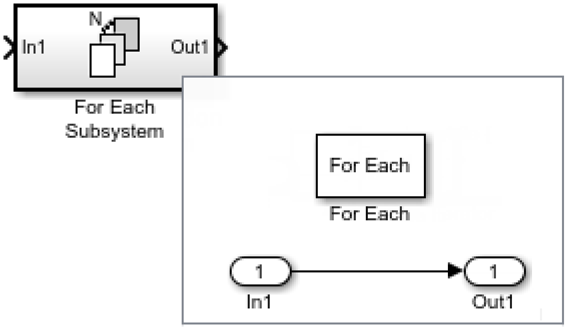
Subsystem that repeats execution on each element or subarray of input signal and concatenates results

Library: Simulink / Ports & Subsystems



Description

The For Each Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step on each element or subarray of an input signal.



The set of blocks within the subsystem represents the algorithm applied to a single element or subarray of the original signal. The For Each block inside the subsystem allows you to configure the decomposition of the subsystem inputs into elements or subarrays, and to configure the concatenation of the individual results into output signals.

Inside this subsystem, each block that has states maintains separate sets of states for each element or subarray that it processes. Consequently, the operation of this subsystem is similar in behavior to copying the contents of the subsystem for each element in the original input signal and then processing each element using its respective copy of the subsystem.

An additional benefit of the For Each Subsystem block is that, for certain models, it improves the code reuse in SimulinkCoder generated code. Consider a model containing two reusable Atomic Subsystem blocks with the same scalar algorithm applied to each element of the signal. If the input signal dimensions of these subsystems are different, Simulink Coder generated code includes two distinct functions. You can replace these two subsystems with two identical For Each Subsystem blocks that are configured to process each element of their respective inputs using the same algorithm. For this case, Simulink Coder generated code consists of a single function parameterized by the number of input signal elements. This function is invoked twice — once for each unique instance of the For Each Subsystem block in the model. For each of these cases, the input signal elements have different values.

S-Function Support

The For Each Subsystem block supports both C-MEX S-functions and Level-2 MATLAB S-functions, provided that the S-function supports multiple execution instances using one of the following techniques:

- A C-MEX S-function must declare `ssSupportsMultipleExecInstances(S, true)` in the `mdlSetWorkWidths` method.
- A Level-2 MATLAB S-function must declare `block.SupportsMultipleExecInstances = true` in the setup method.

If you use the above specifications:

- Do not cache run-time data, such as DWork and Block I/O, using global or persistent variables or within the user data of the S-function.
- Every S-function execution method from `mdlStart` up to `mdlTerminate` is called once for each element processed by the S-function, when it is in a For Each Subsystem block. Consequently, you need to be careful not to free the same memory on repeated calls to `mdlTerminate`. For example, consider a C-MEX S-function that allocates memory for a run-time parameter within `mdlSetWorkWidths`. The memory only needs to be freed once in `mdlTerminate`. As a solution, set the pointer to be empty after the first call to `mdlTerminate`.

Limitations

The For Each Subsystem block has these limitations, and these are the workarounds.

Limitation	Workaround
You cannot log bus or an array of bus signals directly in the For Each subsystem.	Use one of these approaches: • Use a Bus Selector block to select the signals you want to log and mark those signals for signal logging. • Attach the signal to an Outport block and log the signal outside the For Each subsystem.
You cannot log a signal inside a referenced model that is inside a For Each subsystem if either of these conditions exists: • The For Each subsystem is in a model simulating in Rapid Accelerator mode. • The For Each subsystem itself is in a model referenced by a Model block in Accelerator mode.	For the first condition, use Accelerator mode. For the second condition, use Normal or Rapid Accelerator mode.
You cannot log the states of the blocks in a For Each subsystem .	Save and restore the simulation state.
You cannot use Normal mode to simulate a Model block inside a For Each subsystem.	Use Accelerator or Rapid Accelerator mode.
Reusable code is generated for two For Each Subsystems with identical contents if their input and output signals are vectors (1-D or 2-D row or column vector). For n-D input and output signals, reusable code is generated only when the dimension along which the signal is partitioned is the highest dimension.	Permute the signal dimensions to transform the partition dimension and the concatenation dimension to the highest nonsingleton dimension for n-D signals.

The For Each Subsystem block does not support these features:

- You cannot include these blocks or S-functions inside a For Each Subsystem:
  - Data Store Memory, Data Store Read, or Data Store Write blocks inside the subsystem

  - The From Workspace block if the input is a `Structure with Time` that has an empty time field
  - The To Workspace and To File data saving blocks
  - Goto and From blocks that cross the subsystem boundary
  - Model Reference block with simulation mode set to Normal
  - Shadow Inports
  - ERT S-functions

  For a complete list of the blocks that support the For Each Subsystem, type `showblockdatatypetable` at the MATLAB command line.

- You cannot use these types of signals:

  - Test-pointed signals or signals with an external storage class inside the system
  - Frame signals on subsystem input and output boundaries
  - Variable-size signals
  - Function-call signals crossing the boundaries of the subsystem
- Creation of a linearization point inside the subsystem
- Propagating the Jacobian flag for the blocks inside the subsystem. You can check this condition in MATLAB using `J.Mi.BlockAnalyticFlags.jacobian`, where `J` is the Jacobian object. To verify the correctness of the Jacobian of the For Each Subsystem block, perform these steps:

  - Look at the tag of the For Each Subsystem Jacobian. If it is `“not_supported”`, then the Jacobian is incorrect.
  - Move each block out of the For Each Subsystem and calculate its Jacobian. If any block is " not_supported " or has a warning tag, the For Each Subsystem Jacobian is incorrect.
- You cannot perform these types of code generation:

  - Generation of a Simulink Coder S-function target
  - Simulink Coder code generation under both of the following conditions:

    - A Stateflow or MATLAB Function block resides in the subsystem.
    - This block tries to access global data outside the subsystem, such as Data Store Memory blocks or `Simulink.Signal` objects of `ExportedGlobal` storage class.

- PLC code generation

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

Out — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a]
Direct Feedthrough	No

Multidimensional Signals	Yes[a]
Variable-Size Signals	No
Zero-Crossing Detection	No

[a] Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

For Iterator

Repeat execution of a subsystem during a time step for a specified number of iterations
Library: Ports & Subsystems

Description

The For Iterator block, when placed in a Subsystem block, repeats the execution of a subsystem during the current time step until an iteration variable exceeds the specified iteration limit. You can use this block to implement the block diagram equivalent of a `for` loop in a programming language.

The output of a For Iterator Subsystem block cannot be a function-call signal. Simulink displays an error message when the model updates.

Ports

Input

`Number of Iterations` — External value for iterator variable
scalar | vector, size 1 | matrix, size 1x1

- The input port accepts data of mixed numeric types.
- If the input port value is non-integer, it is first truncated to an integer.
- Internally, the input value is cast to an integer of the type specified for the iteration variable output port.
- If no output port is specified, the input port value is cast to type `int32`.
- If the input port value exceeds the maximum value of the output port type, the overflow wraps around.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

`Iterator value` — Value of iterator variable during time step
scalar | vector, size 1 | matrix, size 1x1

Selecting the **Show iteration variable** parameter check box adds an output port to this block

Data Types: `double` | `int8` | `int16` | `int32`

Parameters

`States when starting` — Select block states between time steps
`held` (default) | `reset`

Select how to handle block states between time steps.

`held`

Hold block states between time steps. Block state values persist across time steps.

`reset`

Reset block states to their initial values at the beginning of each time step and before the first iteration loop.

Programmatic Use
Block Parameter: `ResetStates`
Type: character vector
Values: `'held'` | `'reset'`
Default: `'held'`

`Iteration limit source` — Select source for number of iterations
`internal` (default) | `external`

Select source for number of iterations.

`internal`

Value of the **Iteration limit** parameter determines the number of iterations.

`external`

Value of the signal at the **N** port determines the number of iterations. The signal source must reside outside the For Iterator Subsystem block.

Dependencies

Selecting `internal` displays and enables the **Iteration limit** parameter. Selecting `external` adds an input port labeled **N**.

Programmatic Use

Block Parameter: `IterationSource`
Type: character vector
Values: `'internal'` | `'external'`
Default: `'internal'`

`Iteration limit` — Specify number of iterations

5 (default) | integer

Specify the number of iterations. This parameter supports storage classes. You can define the named constant in the base workspace of the Model Explorer as a `Simulink.Parameter` object of the built-in storage class `Define (custom)` type.

`5`

Iterate blocks in the For Iterator Subsystem block `5` times.

integer

Specify an integer or a named constant variable.

Dependencies

To enable this parameter, select `internal` from the **Iteration limit source** drop-down list.

Programmatic Use

Block Parameter: `IterationLimit`
Type: character vector
Values: `'5'` | `'<integer>'`
Default: `'5'`

`Set Next i (iteration variable) externally` — Control display of input port

off (default) | on

Control display of an input port.

off

Remove input port.

on

Add input port labeled **Next_i** for connecting to an external iteration variable source. The value of the input at the current iteration is used as the value of the iteration variable at the next iteration.

Dependencies

To enable this parameter, select the **Show iteration variable** parameter which also displays an output port labeled **1:N**.

Programmatic Use

Block Parameter: `ExternalIncrement`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Show iteration variable` — Control display of output port

on (default) | off

Control the display of an output port with the current iterator value for a loop.

on

Add output port labeled **1:N** to the For Iterator block.

off

Remove output port.

Dependencies

Selecting this parameter enables the **Set next i (iteration variable) externally** parameter.

Programmatic Use

Block Parameter: `ShowIterationPort`
Type: character vector
Value: `'on'` | `'off'`
Default: `'on'`

`Index mode` — Select initial iteration number

`One-based` (default) | `Zero-based`

Select an initial iteration number of `0` or `1`.

`One-based`

Iteration number starts at one.

`Zero-based`

Iteration number starts at zero.

Programmatic Use
Block Parameter: `IndexMode`
Type: character vector
Values: `'One-based'` | `'Zero-based'`
Default: `'One-based'`

`Iteration variable data type` — Select data type

`int32` (default) | `int16` | `int8` | `double`

Set the data type for the iteration value output from the iteration number port.

`int32`

Set data type to `int32`.

`int16`

Set data type to `int16`.

`int8`

Set data type to `int8`.

`double`

Set data type to `double`.

Programmatic Use
Block Parameter: `IterationVariableDataType`
Type: character vector
Value: `'int32'` | `'int16'` | `'int8'` | `'double'`
Default: `'int32'`

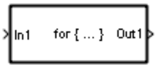
Iterator Subsystem Execution

Introduced before R2006a

For Iterator Subsystem

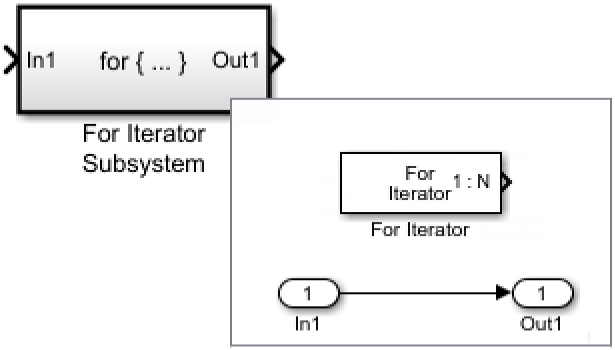
Subsystem that repeats execution during a simulation time step

Library: Simulink / Ports & Subsystems



Description

The For Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats the execution during a simulation time step for a specified number of iterations.



When using simplified initialization mode, if you place a block that needs elapsed time (such as a Discrete-Time Integrator block) in a While Iterator Subsystem block, Simulink displays an error.

Ports

Input

In — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Out` — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a Subsystem block adds an output port from the block. The port label on the Subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a] | string[a]
Direct Feedthrough	No
Multidimensional Signals	Yes[a]
Variable-Size Signals	Yes[a]
Zero-Crossing Detection	No

[a] Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

Fixed-Point Conversion

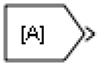
From

Accept input from Goto block

Library: Simulink / Signal Routing

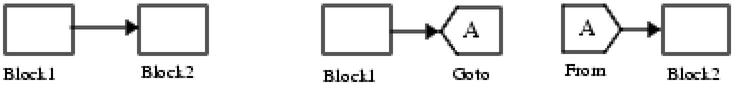


Description

The From block accepts a signal from a corresponding Goto block, then passes it as output. The data type of the output is the same as that of the input from the Goto block. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them. To associate a Goto block with a From block, enter the Goto block's tag in the **Goto Tag** parameter.

A From block can receive its signal from only one Goto block, although a Goto block can pass its signal to more than one From block.

This figure shows that using a Goto block and a From block is equivalent to connecting the blocks to which those blocks are connected. In the model at the left, Block1 passes a signal to Block2. That model is equivalent to the model at the right, which connects Block1 to the Goto block, passes that signal to the From block, then on to Block2.



The visibility of a Goto block tag determines the From blocks that can receive its signal. For more information, see Goto and Goto Tag Visibility. The block indicates the visibility of the Goto block tag:

- A local tag name is enclosed in brackets ([]).
- A scoped tag name is enclosed in braces ({}).
- A global tag name appears without additional characters.

The From block supports signal label propagation.

Ports

Output

`Port_1` — Signal from connected Goto block

scalar | vector | matrix | N-D array

Signal from connected Goto block, output with the same dimensions and data type as the input to the Goto block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Goto Tag` — Tag of the Goto block that forwards its signal to this block

A (default) | `<More Tags...>` | ...

Specify the tag of the Goto block that forwards its signal to this From block. To change the tag, select a new tag from the drop-down list.

The drop-down list displays the Goto tags that the From block can currently see. An item labeled `<More Tags...>` appears at the end of the list the first time you display the list in a Simulink session. Selecting this item causes the block to update the tags list to include the tags of Goto blocks residing in library subsystems referenced by the model containing this From block. Simulink software displays a progress bar while building the list of library tags. Simulink saves the updated tags list for the duration of the Simulink session or until the next time you select the adjacent **Update Tags** button. You need to update the tags list again in the current session only if the libraries referenced by the model have changed since the last time you updated the list.

Tip If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. To do so, use the **Rename All** button in the Goto block dialog box.

To find the relevant Goto block, use the **Goto Source** hyperlink in the From block dialog box.

Programmatic Use
Block Parameter: `GotoTag`
Type: character vector
Values: `'A'` | `...`
Default: `'A'`

`Update Tags` — Update list of visible tags

Updates the list of tags visible to this From block, including tags residing in libraries referenced by the model containing this From block. Update the tags list again in the current session only if the libraries referenced by the model have changed since the last time you updated the list.

`Goto Source` — Path to connected Goto block

block path

Path of the Goto block connected to this From block. Clicking the path displays and highlights the Goto block in your model.

`Icon Display` — Text to display on block icon

`Tag` | `Tag and signal name` | `Signal name`

Specifies the text to display on the From block icon. The options are the block tag, the name of the signal that the block represents, or both the tag and the signal name.

Programmatic Use
Block Parameter: `IconDisplay`
Type: character vector
Values: `'Signal name'` | `'Tag'` | `'Tag and signal name'`
Default: `'Tag'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`

Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

“Signal Label Propagation”

Introduced before R2006a

From File

Load data from MAT-file
Library: Simulink / Sources

untitled.mat

Description

The From File block loads data from a MAT-file to a model and outputs the data as a signal. The data is a sequence of samples. Each sample consists of a time stamp and an associated data value. The data can be in array format or MATLAB `timeseries` format.

The From File block icon shows the name of the MAT-file that supplies the data to the block.

You can have multiple From File blocks that load from the same MAT-file.

The supported MAT-file versions are Version 7.0 or earlier and Version 7.3. The From File block incrementally loads data from Version 7.3 files.

You can specify how the data is loaded, including:

- Sample time
- How to handle data for missing data points
- Whether to use zero-crossing detection

For more information, see “Load Data Using the From File Block”.

Ports

Output

`Port_1` — File data
scalar | vector | matrix | N-D array

MAT-file data, specified as a sequence of samples. Each sample consists of a time stamp and an associated data value. The data can be in array format or MATLAB `timeseries` format.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`File name` — Path or file name

`untitled.mat` (default) | path, or MAT-file name

Path or file name of the MAT-file that contains the input data. Specify a path or file name in one of these ways:

- Browse to a folder that contains a valid MAT-file.

  On UNIX® systems, the path name can start with a tilde (~) character, which means your home folder.
- Enter the path for the file in the text box.

The default file name is `untitled.mat`. If you specify a file name without path information, Simulink loads the file in the current folder or on the MATLAB path. (To determine the current folder, at the MATLAB command prompt enter `pwd`.)

After you specify the **File name**, you can use the view button ( ) to preview the signal from the MAT-file. For more information, see “Preview Signal Data”.

Dependencies

Code generation for RSim target provides identical support as Simulink; all other code generation targets support only double, one-dimensional, real signals in array with time format.

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, the MAT-file must contain a nonempty, finite, real matrix with at least two rows.

For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-821.

Programmatic Use
Block Parameter: `FileName`
Type: character vector
Values: MAT-file name
Default: `'untitled.mat'`

`Output data type` — Output data type

`Inherit: auto` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class_name>` | `Bus: <bus_object>` | `<data type expression>`

The data type for the data that the From File block outputs. For nonbus types, you can use `Inherit: auto` to skip any data type verification. If you specify an output data type, then the From File block verifies that the data in the file matches the specified data type. For more information, see “Control Signal Data Types”.

If you set **Output data type** as a bus object, the bus object must be available when you compile the model. For each signal in bus data, the From File block verifies that data type, dimensions, and complexity are the same for the data and for the bus object.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: auto' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'Enum: <class name>' | 'Bus: <object name>' | '<data type expression>'`
Default: `'Inherit: auto'`

`Sample time` — Sampling period and offset

`0` | scalar | vector

Specify the sample period and offset.

The From File block loads data from a MAT-file, using a sample time that either:

- You specify for the From File block.

- The From File block inherits from the blocks into which the From File block feeds data.

The default sample time is `0`, which specifies a continuous sample time. The MAT-file is loaded at the base (fastest) rate of the model. For details, see “Specify Sample Time”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'0'`

`Data extrapolation before first data point` — Extrapolation method for simulation times before initial time stamp in MAT-file

`Linear extrapolation` (default) | `Hold first value` | `Ground value`

Extrapolation method for a simulation time hit that occurs before the initial time stamp in the MAT-file. Choose one of the following extrapolation methods.

Method	Description
`Linear extrapolation`	(Default) If the MAT-file contains only one sample, then the From File block outputs the corresponding data value. If the MAT-file contains more than one sample, then the From File block linearly extrapolates using the first two samples: • For `double` data, linearly extrapolates the value using the first two samples • For `Boolean` data, outputs the first data value • For a built-in data type other than `double` or `Boolean`, the From File block: • Upcasts the data to `double` • Performs linear extrapolation (as described for `double` data) • Downcasts the extrapolated data value to the original data type You cannot use the `Linear extrapolation` option with enumerated (`enum`) data. All signals in a bus use the same extrapolation setting. If any signal in a bus uses `enum` data, then you cannot use the `Linear extrapolation` option.
`Hold first value`	Uses the first data value in the file
`Ground value`	Uses a value that depends on the data type of MAT-file sample data values: • Fixed-point data types — Uses the ground value • Numeric types other than fixed point —Uses `0` • `Boolean` — Uses `false` • Enumerated data types — Uses default value

Dependencies

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, you must set this parameter to `Linear extrapolation`. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-821.

Programmatic Use
Block Parameter: `ExtrapolationBeforeFirstDataPoint`
Type: character vector
Values: `'Linear extrapolation' | 'Hold first value' | 'Ground value'`
Default: `'Linear extrapolation'`

`Data interpolation within time range` — Interpolation method for simulation times that fall between two time stamps in the MAT-file
`Linear interpolation` (default) | `Zero order hold`

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the MAT-file. Choose one of these interpolation methods.

Method	Description
`Linear interpolation`	(Default) The From File block interpolates using the two corresponding MAT-file samples: • For `double` data, linearly interpolates the value using the two corresponding samples • For `Boolean` data, uses `false` for the first half of the sample and `true` for the second half. • For a built-in data type other than `double` or `Boolean`, the From File block: • Upcasts the data to `double` • Performs linear interpolation, as described for `double` data • Downcasts the interpolated value to the original data type
`Zero order hold`	Uses the data from the first of the two samples

Limitations

You cannot use the `Linear interpolation` option with enumerated (`enum`) data. All signals in a bus use the same interpolation setting. If any signal in a bus uses `enum` data, then you cannot use the `Linear interpolation` option.

Dependencies

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, you must set this parameter to `Linear interpolation`. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-821.

Programmatic Use

Block Parameter: `InterpolationWithinTimeRange`
Type: character vector
Values: `'Linear interpolation' | 'Zero order hold'`
Default: `'Linear interpolation'`

`Data extrapolation after last data point` — Extrapolation method for simulation times after last time stamp in MAT-file

`Linear extrapolation` (default) | `Hold last value` | `Ground value`

The extrapolation method for a simulation time hit that occurs after the last time stamp in the MAT-file. Choose one of these extrapolation methods.

Method	Description
`Linear extrapolation`	(Default) If the MAT-file contains only one sample, then the From File block outputs the corresponding data value. If the MAT-file contains more than one sample, then the From File block linearly extrapolates using data values of the last two samples: • For `double` data, extrapolates the value using the last two samples. • For `Boolean` data, outputs the first data value. • For built-in data types other than double or `Boolean`: • Upcasts the data to `double` • Performs linear extrapolation, as described for `double` data • Downcasts the extrapolated value to the original data type
`Hold last value`	Uses the last data value in the file
`Ground value`	Uses a value that depends on the data type of MAT-file sample data values: • Fixed-point data types — Uses the ground value • Numeric types other than fixed point —Uses `0` • `Boolean` — Uses `false` • Enumerated data types — Uses default value

Limitations

You cannot use the `Linear extrapolation` option with enumerated (`enum`) data. All signals in a bus use the same extrapolation setting. If any signal in a bus uses `enum` data, then you cannot use the `Linear extrapolation` option.

Dependencies

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, you must set this parameter to `Linear extrapolation`. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-821.

Programmatic Use

Block Parameter: `ExtrapolationAfterLastDataPoint`
Type: character vector
Values: `'Linear extrapolation' | 'Hold last value' | 'Ground value'`
Default: `'Linear extrapolation'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`off` (default) | `on`

Enables zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to `0` (continuous).

Simulink uses a technique known as zero-crossing detection to locate a discontinuity in time stamps, without resorting to excessively small time steps. “Zero-crossing” represents a discontinuity.

For the From File block, zero-crossing detection occurs only at time stamps in the file. Simulink examines only the time stamps, not the data values.

For bus signals, Simulink detects zero-crossings across all leaf bus elements.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at those time stamps. For example, suppose that the input array has this data.

```
time:     0 1 2 2 3
signal:   2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For nonduplicate time stamps, zero-crossing detection depends on the settings of these parameters:

- **Data extrapolation before first data point**

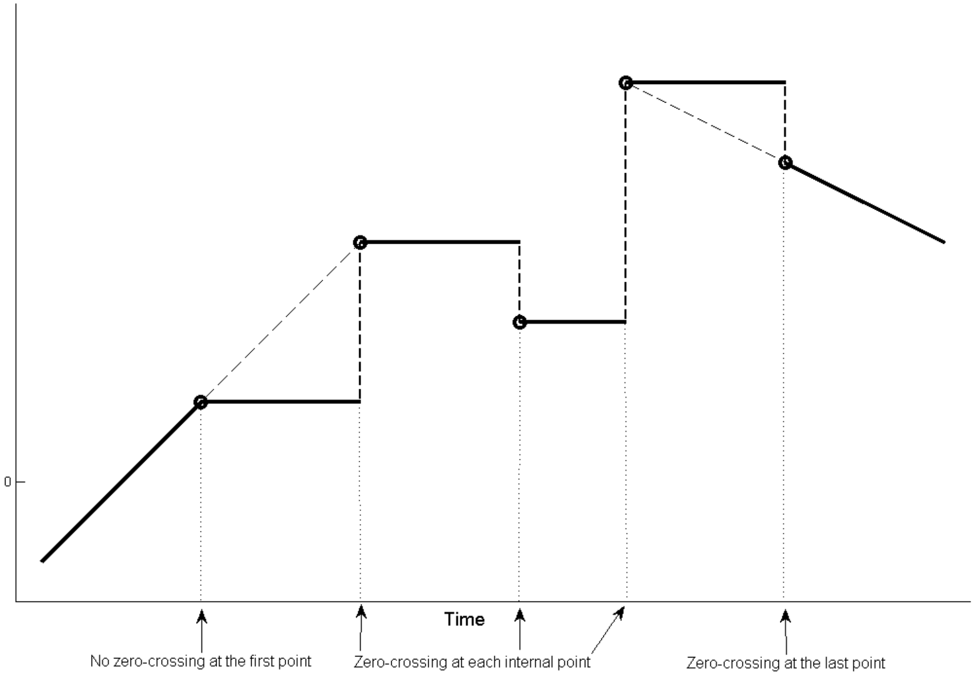
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The From File block determination of when zero-crossing occurs depends on the time stamp.

Time Stamp	Setting
First	**Data extrapolation before first data point** is set to `Ground value`.
Between first and last	**Data interpolation within time range** is set to `Zero-order hold`.
Last	One or both of these settings apply: • **Data extrapolation after last data point** is set to `Ground value`. • **Data interpolation within time range** is set to `Zero-order hold`.

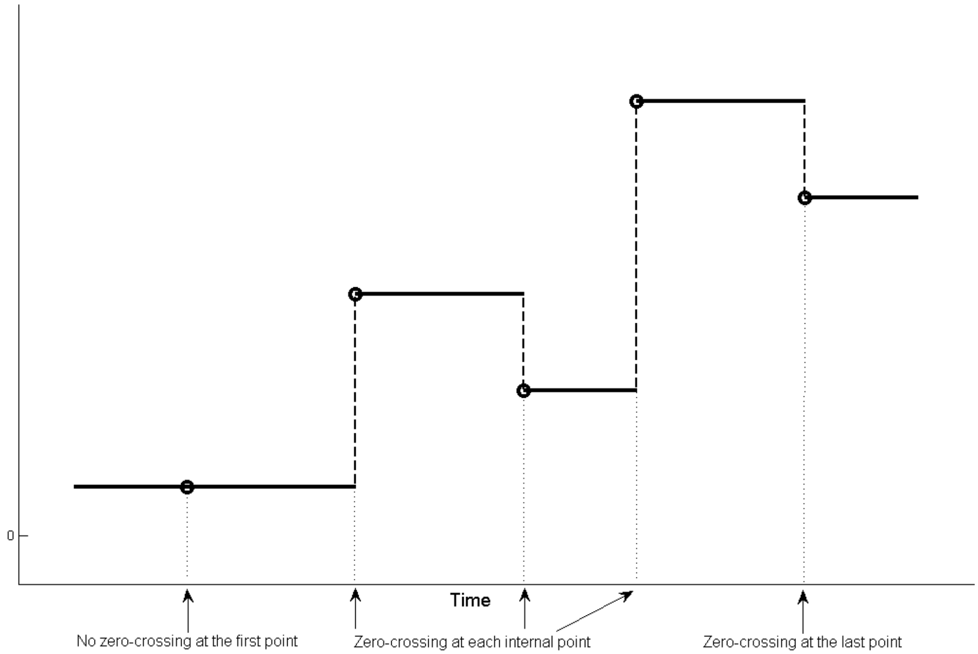
This figure illustrates zero-crossing detection for data accessed by a From File block that has these settings:

- **Data extrapolation before first data point** — `Linear extrapolation`
- **Data interpolation within time range** (for internal points) — `Zero order hold`
- **Data extrapolation after last data point** — `Linear extrapolation`



This figure is another illustration of zero-crossing detection for data accessed by a From File block. The block has the following settings for the time stamps (points):

- **Data extrapolation before first data point** — `Hold first value`
- **Data interpolation within time range** — `Zero order hold`
- **Data extrapolation after last data point** — `Hold last value`



Dependencies

To generate code that builds ERT or GRT targets or uses SIL or PIL simulation modes, clear this check box. For more information on C/C++ code generation with the From File block, see “Code Generation” on page 1-821.

Programmatic Use

Block Parameter: `ZeroCross`
Type: character vector
Values: `'off'` | `'on'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`[a] | `enumerated` | `bus`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

[a] Supports up to 32-bit fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Not recommended for production code.
- Code generation for RSim target provides identical support as Simulink; all other code generation targets support only double, one-dimensional, real signals in array with time format.
- For a From File block, generating code that builds ERT or GRT targets or uses SIL or PIL simulation modes requires that:
  - The MAT-file contains a nonempty, finite, real matrix with at least two rows.
    - Use a data type of `double` for the matrix.
    - Do not include any NaN, Inf, or -Inf elements in the matrix.
  - In the From File block parameters dialog box:
    - Set the **Data extrapolation before first data point** and **Data extrapolation after last data point** parameters to `Linear extrapolation`.

- Set the **Data interpolation within time range** parameter to `Linear interpolation`.
- Clear the **Enable zero-crossing detection** parameter.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Supports up to 32-bit fixed-point data types.

From Spreadsheet

Read data from spreadsheet
Library: Simulink / Sources

untitled.xlsx
Sheet1

Description

The From Spreadsheet block reads data from Microsoft Excel® (all platforms) or CSV (MicrosoftWindows® platform with Microsoft Office installed only) spreadsheets and outputs the data as a signal. The From Spreadsheet block does not support Microsoft Excel spreadsheet charts.

The From Spreadsheet icon displays the spreadsheet file name and sheet name specified in the block **File name** and **Sheet name** parameters.

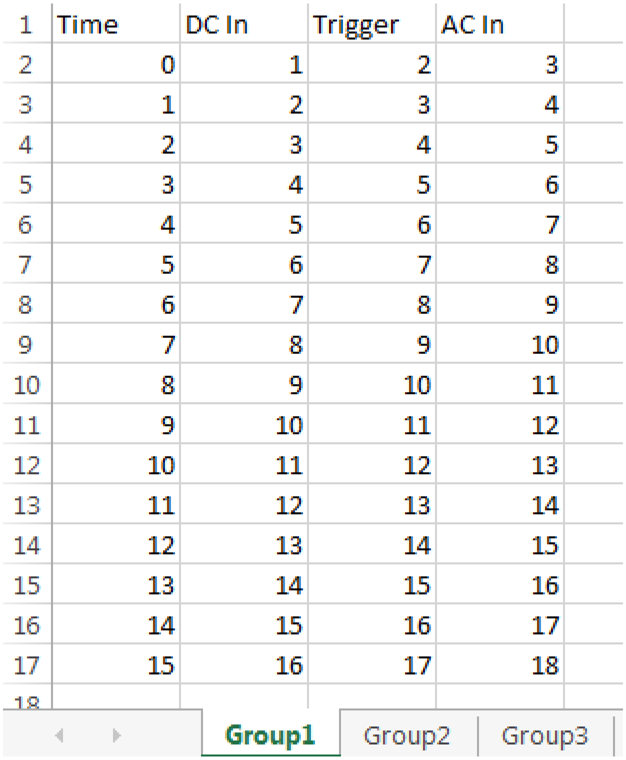
Storage Formats

The data that the From Spreadsheet block reads from a spreadsheet must be appropriately formatted.

For Microsoft Excel spreadsheets:

- The From Spreadsheet block interprets the first row as a signal name. If you do not specify a signal name, the From Spreadsheet block assigns a default one with the format `Signal #`, where `#` increments with each additional unnamed signal.
- The From Spreadsheet block interprets the first column as time. In this column, the time values must monotonically increase.
- The From Spreadsheet block interprets the remaining columns as signals.

This example shows an acceptably formatted Microsoft Excel spreadsheet. The first column is Time and the first row contains signal names. Each worksheet contains a signal group.



1	Time	DC In	Trigger	AC In
2	0	1	2	3
3	1	2	3	4
4	2	3	4	5
5	3	4	5	6
6	4	5	6	7
7	5	6	7	8
8	6	7	8	9
9	7	8	9	10
10	8	9	10	11
11	9	10	11	12
12	10	11	12	13
13	11	12	13	14
14	12	13	14	15
15	13	14	15	16
16	14	15	16	17
17	15	16	17	18
18				

For CSV text files (Microsoft platform with Microsoft Office installed only):

- The From Spreadsheet block interprets the first column as time. In this column, the time values must increase.
- The From Spreadsheet block interprets the remaining columns as signals.
- Each column must have the same number of entries.
- The From Spreadsheet block interprets each file as one signal group.

This example shows an acceptably formatted CSV file. The contents represent one signal group.

```
0,0,0,5,0
1,0,1,5,0
2,0,1,5,0
3,0,1,5,0
4,5,1,5,0
```

```
5,5,1,5,0
6,5,1,5,0
7,0,1,5,0
8,0,1,5,1
9,0,1,5,1
10,0,1,5,0
```

Block Behavior During Simulation

The From Spreadsheet block incrementally reads data from the spreadsheet during simulation.

The **Sample time** parameter specifies the sample time that the From Spreadsheet block uses to read data from the spreadsheet. For details, see “Parameters” on page 1-827. The time stamps in the file must be monotonically nondecreasing.

For each simulation time hit for which the spreadsheet contains no matching time stamp, Simulink software interpolates or extrapolates to obtain the needed data using the selected method. For details, see “Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps” on page 1-825.

Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps

If the simulation time hit does not have a corresponding spreadsheet time stamp, the From Spreadsheet block output depends on:

- Whether the simulation time hit occurs before the first time stamp, within the range of time stamps, or after the last time stamp
- The interpolation or extrapolation methods that you select
- The data type of the spreadsheet data

For details about interpolation and extrapolation options, see the descriptions of these parameters:

- “Data extrapolation before first data point” on page 1-0
- “Data interpolation within time range” on page 1-0
- “Data extrapolation after last data point” on page 1-0

Sometimes the spreadsheet includes two or more data values that have the same time stamp. In such cases, the From Spreadsheet block action depends on when the simulation time hit occurs, relative to the duplicate time stamps in the spreadsheet.

For example, suppose that the spreadsheet contains this data. Three data values have a time stamp value of 2.

```
time stamps:    0 1 2 2 2 3 4
data values:    2 3 6 4 9 1 5
```

The table describes the From Spreadsheet block output.

Simulation Time, Relative to Duplicate Time Stamp Values in Spreadsheet	From Spreadsheet Block Action
Before the duplicate time stamps	Performs the same actions as when the time stamps are distinct, using the first of the duplicate time stamp values as the basis for interpolation. (In this example, the time stamp value is 6.)
At or after the duplicate time stamps	Performs the same actions as when the times stamps are distinct, using the last of the duplicate time stamp values as the basis for interpolation. (In this example, that time stamp value is 9.)

Rounding Mode

The From Spreadsheet block rounds positive and negative numbers toward negative infinity. This mode is equivalent to the MATLAB `floor` function.

Saturation on Integer Overflow

For data type conversion, the From Spreadsheet block deals with saturation overflow by wrapping to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to –126.

Ports

Output

`Port_1` — Data from spreadsheet

scalar | vector | matrix

Incremental data from the specified spreadsheet.

The **Sample time** parameter specifies the sample time that the From Spreadsheet block uses to read data from the spreadsheet. For details, see “Parameters” on page 1-827. The time stamps in the file must be monotonically nondecreasing.

For each simulation time hit for which the spreadsheet contains no matching time stamp, Simulink software interpolates or extrapolates to obtain the needed data using the selected method. For details, see “Simulation Time Hits That Have No Corresponding Spreadsheet Time Stamps” on page 1-825.

The From Spreadsheet block accepts data type specifications at a block level. If you want to specify different data types for each signal, consider selecting **Output Data Type > Inherit: Auto**. This option resolves back signal data types using back propagation. For example, assume that there are two signals in the From Spreadsheet block, In1 and In2, which the block sends to ports that have int8 and Boolean data types. With back propagation, the block recasts In1 as int8 and In2 as Boolean.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

`File name` — Full path and file name

`untitled.xlsx` (default) | full path and file name

Enter full path and file name of a spreadsheet file.

This block supports non-English full paths and file names only on Microsoft platforms.

Programmatic Use
Block Parameter: `FileName`

Type: character vector
Value: full path and file name
Default: `'untitled.xlsx'`

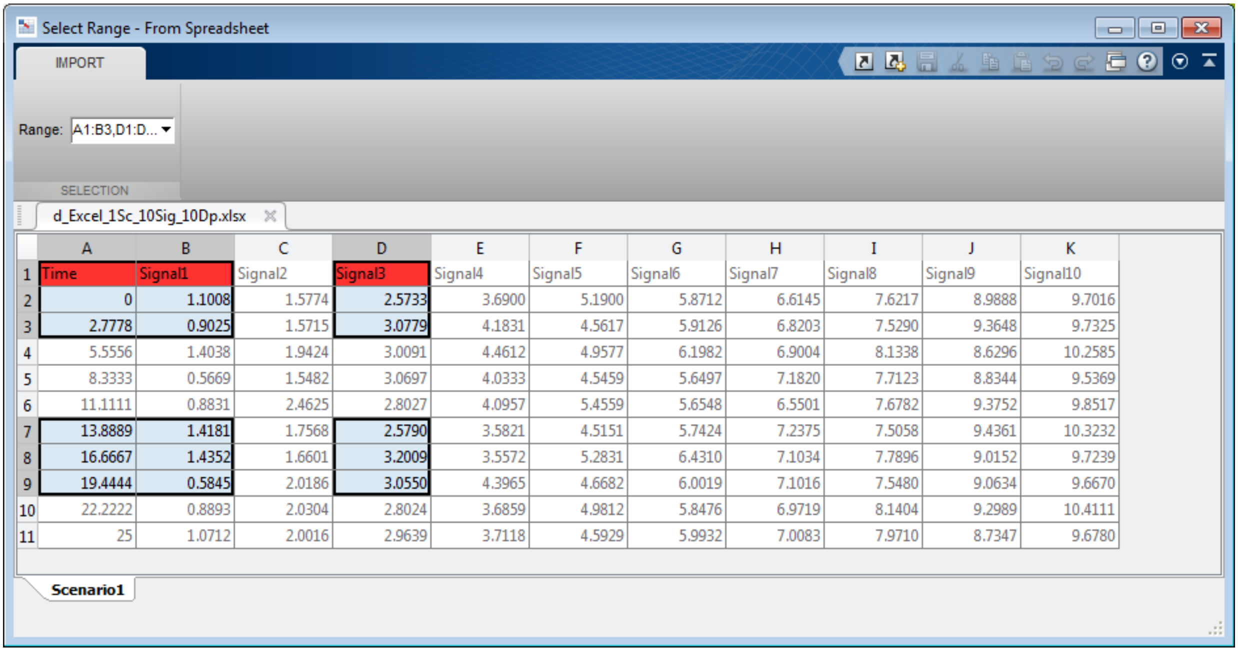
Sheet name — Name of sheet in spreadsheet

`Sheet1` (default) | sheet name

Enter the name of the sheet in the spreadsheet. You can type the sheet name in this edit box or select the sheet name after you open the sheet.

If your spreadsheet is the CSV format, the block populates this parameter with the name of the CSV file without the extension. Do not change this value.

To open the sheet, click . In the sheet, you can select the range of data by dragging over the desired range of values.



Range: A1:B3,D1:D...

	A	B	C	D	E	F	G	H	I	J	K
1	Time	Signal1	Signal2	Signal3	Signal4	Signal5	Signal6	Signal7	Signal8	Signal9	Signal10

8	16.6667	1.4352	1.6601	3.2009	3.5572	5.2831	6.4310	7.1034	7.7896	9.0152	9.7239
9	19.4444	0.5845	2.0186	3.0550	4.3965	4.6682	6.0019	7.1016	7.5480	9.0634	9.6670
10	22.2222	0.8893	2.0304	2.8024	3.6859	4.9812	5.8476	6.9719	8.1404	9.2989	10.4111
11	25	1.0712	2.0016	2.9639	3.7118	4.5929	5.9932	7.0083	7.9710	8.7347	9.6780

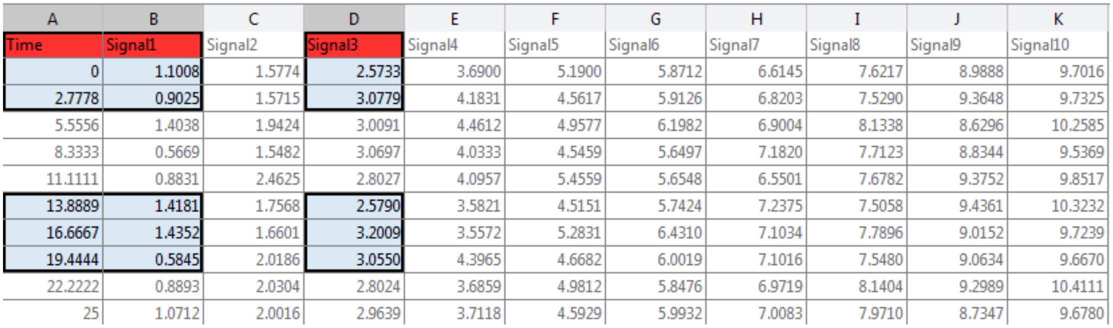
Alternatively, you can select the range of data by specifying the range of values in the **Range** parameter.

Programmatic Use
Block Parameter: `SheetName`
Type: character vector
Value: Sheet name
Default: `'Sheet1'`

Range — Cell range

entire range of used cells in sheet (default) | `A1:B3,D1:D3,A7:B9,D7:D9` | comma-separated list of *`column`*`:`*`row`*

To specify the range, use the format *`column`*`:`*`row`*, with multiple specifications separated by commas. For example, `A1:B3,D1:D3,A7:B9,D7:D9`. If unspecified, or empty, the block automatically detects the used range, which is all the data in the sheet.



A	B	C	D	E	F	G	H	I	J	K
Time	Signal1	Signal2	Signal3	Signal4	Signal5	Signal6	Signal7	Signal8	Signal9	Signal10
0	1.1008	1.5774	2.5733	3.6900	5.1900	5.8712	6.6145	7.6217	8.9888	9.7016
2.7778	0.9025	1.5715	3.0779	4.1831	4.5617	5.9126	6.8203	7.5290	9.3648	9.7325
5.5556	1.4038	1.9424	3.0091	4.4612	4.9577	6.1982	6.9004	8.1338	8.6296	10.2585
8.3333	0.5669	1.5482	3.0697	4.0333	4.5459	5.6497	7.1820	7.7123	8.8344	9.5369
11.1111	0.8831	2.4625	2.8027	4.0957	5.4559	5.6548	6.5501	7.6782	9.3752	9.8517
13.8889	1.4181	1.7568	2.5790	3.5821	4.5151	5.7424	7.2375	7.5058	9.4361	10.3232
16.6667	1.4352	1.6601	3.2009	3.5572	5.2831	6.4310	7.1034	7.7896	9.0152	9.7239
19.4444	0.5845	2.0186	3.0550	4.3965	4.6682	6.0019	7.1016	7.5480	9.0634	9.6670
22.2222	0.8893	2.0304	2.8024	3.6859	4.9812	5.8476	6.9719	8.1404	9.2989	10.4111
25	1.0712	2.0016	2.9639	3.7118	4.5929	5.9932	7.0083	7.9710	8.7347	9.6780

If the selections overlap, the block resolves the selection information as appropriate. For example, if you specify multiple ranges that overlap, such as `A1:B4,B1:E7`, the block resolves the selection to A1 to E7, inclusive.

An alternate to using the **Range** parameter is to open the sheet, by clicking . In the sheet, you can select the range of data by dragging over the desired range of values.

Programmatic Use
Block Parameter: `Range`
Type: character vector
Value: Cell range
Default: `''`

`Output data type` — Output data type

`Inherit: auto` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class_name>` | `Bus: <bus_object>` | `<data type expression>`

The data type for the From Spreadsheet block output. The From Spreadsheet block accepts spreadsheets that contain many data types. However, the block reads the spreadsheet data type as doubles. It then outputs the data type according to the value of **Output data type**.

If you want to specify different data types for each signal, consider selecting **Output Data Type** > **Inherit: auto**. This option resolves back signal data types using back propagation. For example, assume that there are two signals in the From Spreadsheet block, In1 and In2, which the block sends to ports that have int8 and Boolean data types. With back propagation, the block recasts In1 as int8 and In2 as boolean.

To allow the block to cast the output data type to match that of the receiving block, use `Inherit: auto`.

For more information, see “Control Signal Data Types”.

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: auto'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'boolean'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'Enum: <class name>'` | `'Bus: <object name>'` | `'<data type expression>'`
Default: `'Inherit: auto'`

`Treat first column as` — Time or data

`Time` (default) | `Data`

Select how the block should treat the first column of the spreadsheet:

- `Time` — Treat first column as time.
- `Data` — Treat first column as data.

Dependencies

When you select `Data`, the block disables:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

And enables:

- **Output after last data point**

Programmatic Use
Block Parameter: `TreatFirstColumnAs`
Type: character vector
Value: `'Time' | 'Data'`
Default: `'Time'`

`Sample time` — Sampling period and offset

`0` (default) | scalar | vector

The sample period and offset.

The From Spreadsheet block reads data from a spreadsheet using a sample time that either:

- You specify for the From Spreadsheet block
- The From Spreadsheet block inherits from the blocks into which the From Spreadsheet block feeds data

The default is `0`, which specifies a continuous sample time. The spreadsheet is read at the base (fastest) rate of the model. For details, see "Specify Sample Time".

Programmatic Use
Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'0'`

`Data extrapolation before first data point` — Extrapolation method for simulation times before initial time stamp in MAT-file

`Linear extrapolation` (default) | `Hold first value` | `Ground value`

Extrapolation method that Simulink uses for a simulation time hit that is before the first time stamp in the spreadsheet. Choose one of these extrapolation methods.

Method	Description
`Linear extrapolation`	(Default) If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value. If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using the first two samples: • For `double` data, linearly extrapolates the value using the first two samples • For `Boolean` data, outputs the first data value • For a built-in data type other than `double` or `Boolean`: • Upcasts the data to `double` • Performs linear extrapolation (as described above for `double` data) • Downcasts the extrapolated data value to the original data type You cannot use the `Linear extrapolation` option with enumerated (`enum`) data.
`Hold first value`	Uses the first data value in the file
`Ground value`	Uses a value that depends on the data type of spreadsheet sample data values: • Fixed-point data types — Uses the ground value • Numeric types other than fixed–point — Uses `0` • `Boolean` — Uses `false` • Enumerated data types — Uses default value

Dependencies

To enable this parameter, set **Treat first column as** to `Time`.

Programmatic Use
Parameter: `ExtrapolationBeforeFirstDataPoint`

Type: character vector
Values: `'Linear extrapolation' | 'Hold first value' | 'Ground value'`
Default: `'Linear extrapolation'`

`Data interpolation within time range` — Interpolation method for simulation times that fall between two time stamps in the MAT-file

`Linear interpolation` (default) | `Zero order hold`

The interpolation method that Simulink uses for a simulation time hit between two time stamps in the spreadsheet. Choose one of the following interpolation methods.

Method	Description
`Linear interpolation`	(Default) The From Spreadsheet block interpolates using the two corresponding spreadsheet samples: • For `double` data, linearly interpolates the value using the two corresponding samples • For `Boolean` data, uses `false` for the first half of the sample and `true` for the second half • For a built-in data type other than `double` or `Boolean`: • Upcasts the data to `double` • Performs linear interpolation (as described above for `double` data) • Downcasts the interpolated value to the original data type You cannot use the `Linear interpolation` option with enumerated (`enum`) data.
`Zero order hold`	Uses the data from the first of the two samples

Dependencies

To enable this parameter, set **Treat first column as** to `Time`.

Programmatic Use

Parameter: `InterpolationWithinTimeRange`
Type: character vector

Values: `'Linear interpolation' | 'Zero order hold'`
Default: `'Linear interpolation'`

`Data extrapolation after last data point` — Extrapolation method for simulation times after last time stamp in MAT-file
`Linear extrapolation` (default) | `Hold last value` | `Ground value`

The extrapolation method that Simulink uses for a simulation time hit that is after the last time stamp in the spreadsheet. Choose one of the following extrapolation methods.

Method	Description
`Linear extrapolation`	(Default) If the spreadsheet contains only one sample, the From Spreadsheet block outputs the corresponding data value. If the spreadsheet contains more than one sample, the From Spreadsheet block linearly extrapolates using data values of the last two samples: • For `double` data, extrapolates the value using the last two samples • For `Boolean` data, outputs the last data value • For a built-in data type other than `double` or `Boolean`: • Upcasts the data to `double`. • Performs linear extrapolation (as described above for `double` data). • Downcasts the extrapolated value to the original data type. You cannot use the `Linear extrapolation` option with enumerated (`enum`) data.
`Hold last value`	Uses the last data value in the file

Method	Description
`Ground value`	Uses a value that depends on the data type of spreadsheet sample data values: • Fixed-point data types — Uses the ground value • Numeric types other than fixed-point — uses `0` • `Boolean` — Uses `false` • Enumerated data types — Uses default value

Dependencies

To enable this parameter, set **Treat first column as** to `Time`.

Programmatic Use
Parameter: `ExtrapolationAfterLastDataPoint`
Type: character vector
Values: `'Linear extrapolation' | 'Hold last value' | 'Ground value'`
Default: `'Linear extrapolation'`

`Output after last data point` — Action after last data point

`Repeating sequence` (default) | `Hold final value` | `Ground value`

Select action after last data point:

- `Repeating sequence` — Repeat the sequence by reading the data from the first row of the range specified in **Range**
- `Hold final value` — Output the last defined value for the remainder of the simulation.
- `Ground value` — Output a ground value depending on the data type value specified in **Output data type**.

Dependencies

To enable this parameter, set **Treat first column as** to `Data`.

Programmatic Use
Parameter: `OutputAfterLastPoint`
Type: character vector
Values: `'Repeating sequence' | 'Hold final value' | 'Ground value'`
Default: `'Repeating sequence'`

Enable zero-crossing detection — Enable zero-crossing detection

off (default) | on

Select to enable zero-crossing detection.

The “Zero-Crossing Detection” parameter applies only if the **Sample time** parameter is set to 0 (continuous).

Simulink uses a technique known as zero-crossing detection to locate accurately a discontinuity, without resorting to excessively small time steps. In this context, zero-crossing is used to represent discontinuities.

For the From Spreadsheet block, zero-crossing detection can only occur at time stamps in the file. Simulink examines only the time stamps, not the data values.

If the input array contains duplicate time stamps (more than one entry with the same time stamp), Simulink detects a zero crossing at that time stamp. For example, suppose that the input array has this data.

```
time:     0 1 2 2 3
signal:   2 3 4 5 6
```

At time 2, there is a zero crossing from the input signal discontinuity.

For data with nonduplicate time stamps, zero-crossing detection depends on the settings of the following parameters:

- **Data extrapolation before first data point**
- **Data interpolation within time range**
- **Data extrapolation after last data point**

The block applies the following rules when determining when:

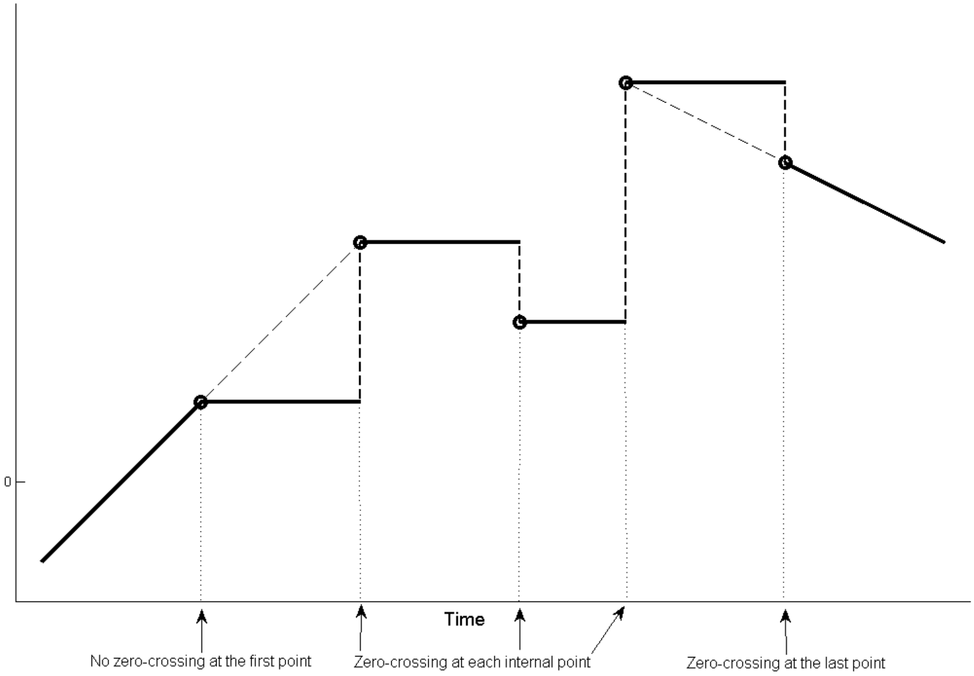
- Zero-crossing occurs for the first time stamp
- For time stamps between the first and last time stamp
- For the last time stamp

Time Stamp	When Zero-Crossing Detection Occurs
First	**Data extrapolation before first data point** is set to Ground value.

Time Stamp	When Zero-Crossing Detection Occurs
Between first and last	**Data interpolation within time range** is set to `Zero-order hold`.
Last	One or both of these settings occur: • **Data extrapolation after last data point** is set to `Ground value`. • **Data interpolation within time range** is set to `Zero-order hold`.

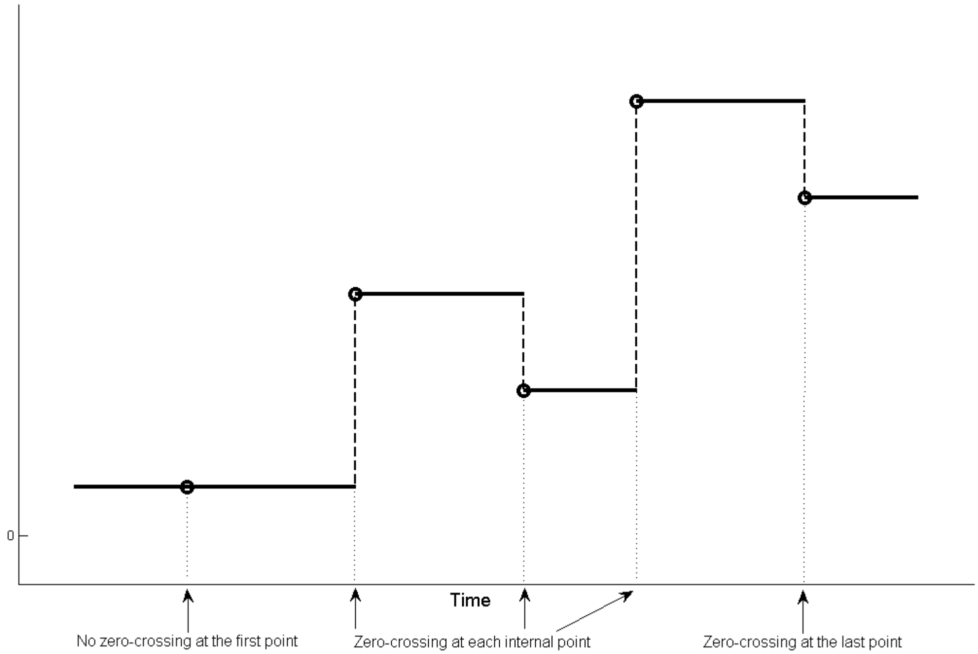
The following figure illustrates zero-crossing detection for data accessed by a From Spreadsheet block that has these settings:

- **Data extrapolation before first data point** — `Linear extrapolation`
- **Data interpolation within time range** (for internal points) — `Zero order hold`
- **Data extrapolation after last data point** — `Linear extrapolation`



The following figure is another illustration of zero-crossing detection for data accessed by a From Spreadsheet block. The block has these settings for the time stamps (points):

- **Data extrapolation before first data point** — `Hold first value`
- **Data interpolation within time range** — `Zero order hold`
- **Data extrapolation after last data point** — `Hold last value`



Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`[a] | `enumerated`
Direct Feedthrough	`No`

Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

[a] Supports up to 32-bit fixed-point data types.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Not recommended for production code.
- Code generation for RSim target provides identical support as Simulink; all other code generation targets support only double, one-dimensional, real signals in array with time format.
- Simulating in accelerator, rapid accelerator, model reference accelerator mode, or model reference rapid accelerator mode behaves the same way, and has the same requirements, as simulating in normal mode.
- The From Spreadsheet block does not support generating code that involves building ERT or GRT targets, or using SIL or PIL simulation modes.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Supports up to 32-bit fixed-point data types.

Introduced in R2015b

From Workspace

Load signal data from workspace
Library: Simulink / Sources

Description

The From Workspace block reads signal data from a workspace and outputs the data as a signal.

The block displays the expression specified in the **Data** parameter. For details about how Simulink software evaluates this expression, see "Symbol Resolution".

You can specify how the data is loaded, including sample time, how to handle data for missing data points, and whether to use zero-crossing detection. For more information, see "Load Data Using the From Workspace Block".

Specifying Workspace Data

In the From Workspace block dialog box, use the **Data** parameter to specify the workspace data to load. You can specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of these options:

- A MATLAB `timeseries` object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

For additional information, see "Load Data Using the From Workspace Block".

Use with Data Dictionary

When you link a model to a data dictionary, you:

- Store design data, which contributes to the fundamental design of the model in the Design Data section of the dictionary. Design data includes numeric variables and `Simulink.Parameter` objects that you use to set block parameter values.
- Store simulation input data, which you use to stimulate and experiment with the model, in the base workspace. Typically, you create simulation input data as MATLAB `timeseries` objects.

For more information about storing variables, objects, and other data that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models”.

- To access design data by using a From Workspace block, store the target variable in the Design Data section of the dictionary and set the **Data** parameter of the block to the name of the variable.
- To access simulation input data, store the target variable in the base workspace and set the **Data** parameter by using a call to the `evalin` function. In the call to `evalin`, specify the `ws` argument as `'base'` so that the block seeks the variable in the base workspace instead of the data dictionary. For example, if the name of the variable is `myTimeseriesObject`, set **Data** to `evalin('base','myTimeseriesObject')`.

Ports

Output

`Port_1` — Workspace data

scalar | vector | matrix

Signal created from workspace data. The block outputs real or complex signals of any type that Simulink supports, including fixed-point and enumerated data types.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Data` — Workspace data to load

`simin` (default) | `timeseries` object | structure of `timeseries` objects | structure | 2-D matrix

In the **Data** parameter, specify the workspace data to load. Specify a MATLAB expression (for example, the name of a variable in the MATLAB workspace) that evaluates to one of the following:

- A MATLAB `timeseries` object
- A structure of MATLAB `timeseries` objects
- A structure, with or without time
- A two-dimensional matrix

The From Workspace block also accepts a bus object as a data type. To load bus data, use a structure of MATLAB `timeseries` objects. For details, see "Load Bus Data to Root-Level Input Ports".

Real signals of type `double` can be in any data format that the From Workspace block supports. For complex signals and real signals of a data type other than `double`, use any format except `Array`.

For additional information, see "Specify the Workspace Data".

Programmatic Use
Block Parameter: `VariableName`
Type: character vector
Values: `timeseries` object | structure of `timeseries` objects | structure | 2-D matrix
Default: `'simin'`

`Output data type` — Output data type

`Inherit: auto` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class_name>` | `Bus: <bus_object>` | `<data type expression>`

Required data type for the workspace data that the From Workspace block loads. For non-bus types, to skip any data type verification, you can use `Inherit: auto`. For more information, see "Control Signal Data Types".

To load bus data, use a structure of MATLAB timeseries objects. For details, see "Load Bus Data to Root-Level Input Ports".

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector

Values: `'Inherit: auto'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'boolean'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'Enum: <class name>'` | `'Bus: <object name>'` | `'<data type expression>'`
Default: `'Inherit: auto'`

`Sample time` — Sample rate of loaded data

`0` (default) | scalar | vector

Sample rate of loaded workspace data. For details, see "Specify Sample Time".

Command-Line Information
Block Parameter: `SampleTime`
Type: character vector
Values: scalar | vector
Default: `'0'`

`Interpolate data` — Interpolate or use last known data point

`on` (default) | `off`

When you select this option, the block performs linear interpolation at time hits for which no corresponding workspace data exist. Otherwise, the current output equals the output at the most recent time for which data exists.

The From Workspace block interpolates by using the two corresponding workspace samples:

- For `double` data, linearly interpolates the value by using the two corresponding samples
- For `Boolean` data, uses `false` for the first half of the time between two time values and `true` for the second half
- For a built-in data type other than `double` or `Boolean`:
  - Upcasts the data to `double`
  - Performs linear interpolation (as described for `double` data)
  - Downcasts the interpolated value to the original data type

You cannot use linear interpolation with enumerated (`enum`) data.

The block uses the value of the last known data point as the value of time hits that occur after the last known data point.

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

For details, see the **Form output after final data value by** parameter.

Programmatic Use
Block Parameter: `Interpolate`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | `off`

When you select **Enable zero-crossing detection**, and the input array contains multiple entries for the same time hit, Simulink detects a zero crossing. For example, suppose that the input array has this data.

```
time:     0 1 2 2 3
signal:   2 3 4 5 6
```

At time 2, there is a zero crossing from input signal discontinuity. For more information, see “Zero-Crossing Detection”.

For bus signals, Simulink detects zero crossings across all leaf bus elements.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Form output after final data value by` — Determine block output after final time hit

`Extrapolation` (default) | `Setting to zero` | `Holding final value` | `Cyclic repetition`

To determine the block output after the last time hit for which workspace data is available, combine the settings of these parameters:

- **Interpolate data**
- **Form output after final data value by**

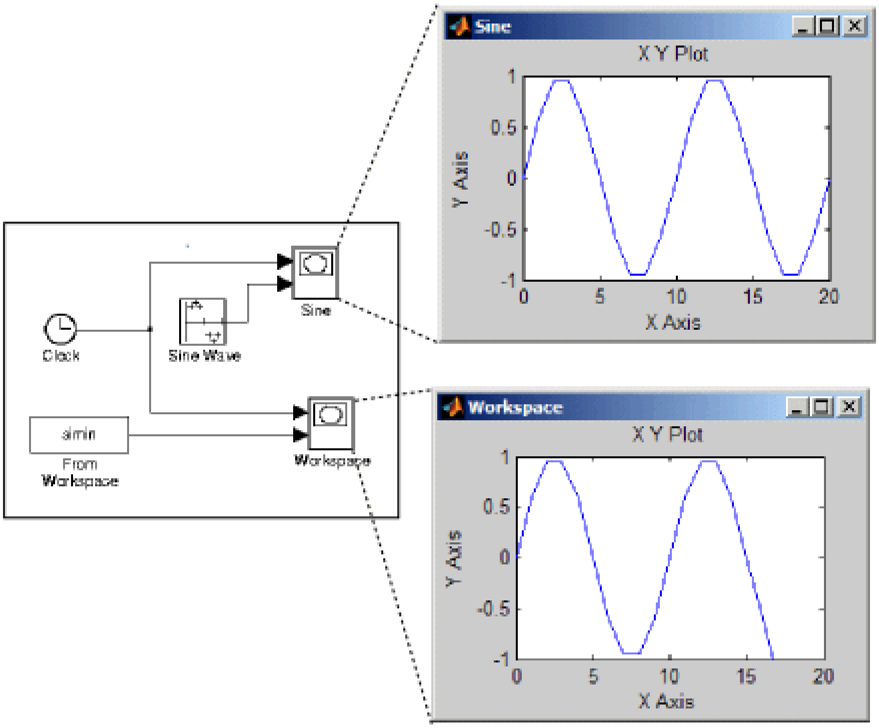
This table lists the block output, based on the values of the two options.

Setting for Form Output After Final Data Value By	Setting for Interpolate Data	Block Output After Final Data
Extrapolation	On	Extrapolated from final data value
	Off	Error
Setting to zero	On	Zero
	Off	Zero
Holding final value	On	Final value from workspace
	Off	Final value from workspace
Cyclic repetition	On	Error
	Off	Repeated from workspace if the workspace data is in structure-without-time format. Error otherwise.

For example, the block uses the last two known data points to extrapolate data points that occur after the last known point if you:

- Select **Interpolate data**.
- Set **Form output after final data value by** to `Extrapolation`.

Consider this model.



The From Workspace block reads data from the workspace. The data consists of the output of the Simulink Sine Wave block sampled at one-second intervals. The workspace contains the first 16 samples of the output. The top and bottom X-Y plots display the output of the Sine Wave and From Workspace blocks, respectively, from 0 to 20 seconds. The straight line in the output of the From Workspace block reflects the linear extrapolation of missing data points at the end of the simulation.

Programmatic Use
Block Parameter: `OutputAfterFinalValue`
Type: character vector
Values: `'Extrapolation'` | `'Setting to zero'` | `'Holding final value'` | `'Cyclic repetition'`
Default: `'Extrapolation'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`[a] | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`Yes`

[a] Supports input via fi objects created using Fixed-Point Designer.

Extended Capabilities

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Supports input via `fi` objects created using Fixed-Point Designer.

Function-Call Feedback Latch

Break feedback loop involving data signals between function-call blocks

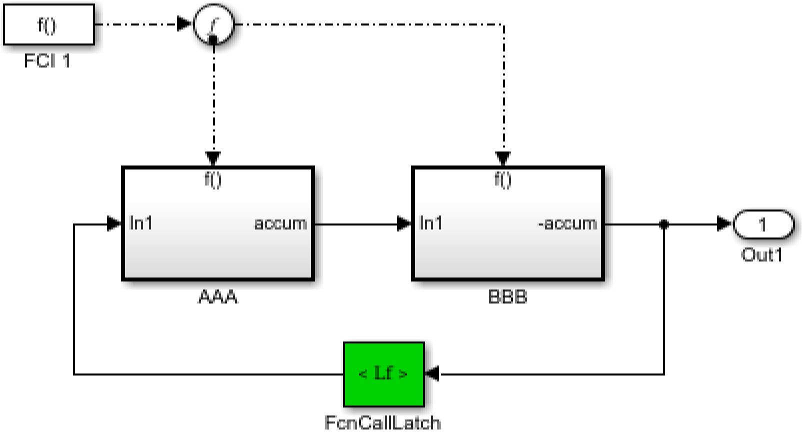
Library: Simulink / Ports & Subsystems

Description

Use the Function-Call Feedback Latch block to break a feedback loop of data signals between one or more function-call blocks. Specifically, break a feedback loop formed in one of the following ways.

- **When function-call blocks connect to branches of the same function-call signal**

  Place the Function-Call Feedback Latch block on the feedback signal between the branched blocks. As a result, the latch block delays the signal at the input of the destination function-call block, and the destination function-call block executes prior to the source function-call block of the latch block.



To run this model, see "Function-Call Blocks Connected to Branches of the Same Function-Call Signal" on page 14-179.

- **When the loop involves parent and child function-call blocks, where the child initiator is inside the parent**

  Place the Function-Call Feedback Latch block on the feedback signal between the child and the parent. This arrangement prevents the signal value, read by the parent (FCSS1), from changing during execution of the child. In other words, the parent reads the value from the previous execution of the child (FCSS2).

  To run this model, see “Function-Call Feedback Latch on Feedback Signal Between Child and Parent” on page 14-180.

Using the latch block is equivalent to selecting the **Latch input for function-call feedback signals** check box on the Inport block in the destination function-call subsystem or model. However, an advantage of the latch block over using the dialog parameter is that one can design the destination function-call subsystem or model in a modular fashion and then use it either in or out of the context of loops.

The Function-Call Feedback Latch block is better suited than Unit Delay or Memory blocks in breaking function-call feedback loops for the following reasons:

- The latch block delays the feedback signal for exactly one execution of the source function-call block. This behavior is different from the Unit Delay or Memory blocks for cases where the function-call subsystem blocks may execute multiple times in a given simulation step.

- Unlike the Unit Delay or Memory blocks, the latch block may be used to break loops involving asynchronous function-call subsystems.
- The latch block can result in better performance, in terms of memory optimization, for generated code.

Ports

Input

`In` — Signal from a function-call subsystem block
scalar | vector | matrix

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Out` — Signal to a function-call subsystem
scalar | vector | matrix

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`

Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Introduced in R2011a

Function-Call Generator

Provide function-call signal to control execution of a subsystem or model

Library: Simulink / Ports & Subsystems

Description

The Function-Call Generator block provides a function-call signal to execute a function-call subsystem or function-call model at the rate that you specify with the **Sample time** parameter. To iteratively execute each function-call block multiple times at each time step, use the **Number of Iterations** parameter.

To execute multiple function-call subsystems or models in a specified order, use the Function-Call Generator block with a Function-Call Split block. For an example, see the Function-Call Split block documentation.

Ports

Output

`Function Call` — Function-call signal to a function-call subsystem or function-call model

scalar

Parameters

`Sample time` — Specify time interval

`-1` (default) | `Ts` | `[Ts, To]`

Specify the time interval between function calls to a subsystem or model containing a Trigger block with **Trigger type** set to `function-call`. If the actual calling rate for the subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

Settings

`-1`

Inherit time interval from the trigger signal.

`Ts`

Scalar where `Ts` is the time interval.

`[Ts, To]`

Vector where `Ts` is the time interval and `To` is the initial time offset.

Programmatic Use

Block Parameter: `sample_time`
Type: character vector
Values: `'-1'` | `'Ts'` | `'[Ts, To]'`
Default: `'-1'`

`Number of iterations` — Specify number of times to provide a function-call at each time step

`1` (default) | integer

The value of this parameter can be a vector where each element of the vector specifies a number of times to execute a function-call subsystem. The total number of times that a function-call subsystem executes per time step equals the sum of the values of the elements of the generator signal entering its control port.

Suppose that you specify the number of iterations to be `[2 2]` and connect the output of this block to the control port of a function-call subsystem. In this case, the function-call subsystem executes four times at each time step.

Settings

`1`

Provide function-call once during each time step.

integer

Signed or unsigned integer number. Provide the specified number of function calls at each time step.

Programmatic Use
Block Parameter: `numberOfIterations`
Type: character vector
Values: `'1'` | `'<integer>'`
Default: `'1'`

Block Characteristics

Data Types	
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Function-Call Split

Provide junction for splitting function-call signal
Library: Simulink / Ports & Subsystems

Description

The Function-Call Split block allows a function-call signal to branch and connect to several function-call subsystems or function-call models.

A Function-Call Split outputs multiple function-call signals to create multiple branches from a single function-call signal. In some cases, when you use this block, you do not need the function-call initiator to create multiple function-call signals to invoke a set of function-call subsystems or function-call models.

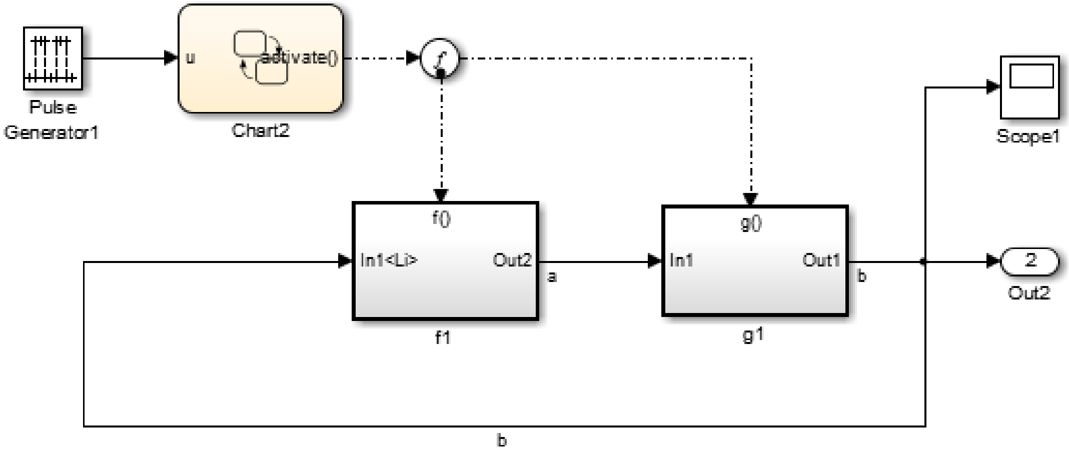
The function-call subsystem or function-call model connected to the output port of the Function-Call Split block that is marked with a dot execute before the subsystems or models connected to other output ports. If data dependencies between subsystems or models do not support the specified execution order, the Function-Call Split block returns an error. To eliminate this error, consider selecting the **Latch input for feedback signals of function-call subsystem outputs** parameter on one or more Inport blocks of the function-call subsystems models involved in a data-dependency loop. Selecting this option delays the corresponding input signal, thereby eliminating the data-dependency loop.

For a model to contain Function-Call Split blocks, you must set the following diagnostic to `error`: **Model Configuration Parameters > Diagnostics > Connectivity > Invalid function-call connection**.

If you select the model menu option **Display > Blocks > Sorted Execution Order**, then the execution order of function-call subsystems connected to branches of a given function-call signal appears on the blocks . Each subsystem has an execution order of the form `s:[B#]` where # is a number that ranges from 0 to one less than the total number of subsystems or models connected to branches of a given signal. The subsystems execute in ascending order based on this number.

The Function-Call Split block supports “Signal Label Propagation”.

The following model shows how to apply the **Latch input for feedback signals of function-call subsystem outputs** parameter to work around a data-dependency error caused by using a Function-Call Split block. By turning this parameter on in the f1 subsystem Inport block, the Function-Call Split block ignores the data dependency of signal b. The block breaks the loop of data dependencies between subsystems f1 and g1. The model achieves the behavior of consistently calling f1 to execute before g1. For a given execution step, subsystem f1 uses the g1 output computed at the previous execution step.



Limitations

The Function-Call Split block has these limitations:

- All function-call subsystems and models connected to a given function-call signal must reside within the same nonvirtual layer of the model hierarchy.
- You cannot connect branched function-call subsystems or models and their children directly back to the function-call initiator.
- Function-call subsystems and models connected to branches of a function-call signal cannot have multiple (muxed) initiators.

- A Function-Call Split block cannot have its input from a signal with multiple function-call elements.

Ports

Input

`Function Call` — Function-call signal
scalar

A Function-Call Generator block or a Stateflowchart can provide function-call signals.

Output

`Function Call` — Function-call signal
scalar

Function-call signal connected to a function-call subsystem or function-call model.

Parameters

`Icon shape` — Select block icon shape
`distinctive` (default) | `round`

Select block icon shape.

Settings

`distinctive`

Rectangular block icon.

`round`

Circular block icon.

Programmatic Use
Block Parameter: `IconShape`
Type: character vector
Values: `'distinctive'` | `'round'`

Default: `'distinctive'`

`Number of output ports` — Specify number of output ports

2 (default) | integer

Specify number of function-call signal output ports.

Settings

`2`

Two function-call signal output ports.

integer

Integer number

Programmatic Use
Block Parameter: `NumOutputPorts`
Type: character vector
Values: `'2'` | `'<integer>'`
Default: `'2'`

`Output port layout` — Select order of output ports

`default` (default) | `reverse`

Select the order of output ports with respect to which port provides a function-call first.

Settings

`default`

Top port provides function-call signal first.

`reverse`

Bottom port provides function-call signal first.

Programmatic Use
Block Parameter: `OutputPortLayout`
Type: character vector
Values: `'default'` | `'reverse'`
Default: `'default'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

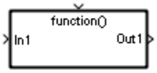
Topics

“Using Function-Call Subsystems”

Introduced in R2010a

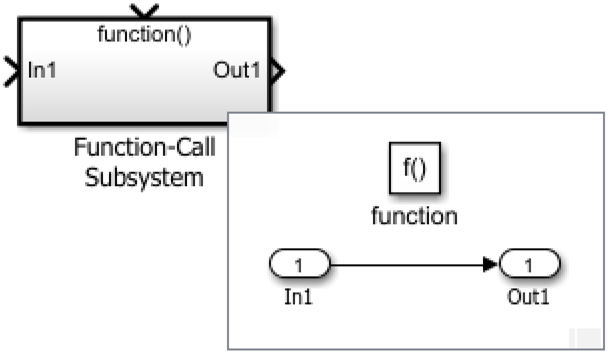
Function-Call Subsystem

Subsystem whose execution is triggered by external function call input
Library: Simulink / Ports & Subsystems



Description

The Function-Call Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that executes when a control signal has a function call event.



Use Function-Call Subsystem blocks to:

- Schedule the execution order of model components.
- Control the rate of model component execution.

For an explanation of Function-Call Subsystem blocks parameters, see Subsystem, Atomic Subsystem, Nonvirtual Subsystem, CodeReuse Subsystem

Ports

Input

`In` — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`Function Call` — Function-call control signal to a subsystem block

scalar

Placing a Trigger block in a subsystem block adds an external input port to the block. Selecting `function-call` from the **Trigger type** list, allows the Trigger block to accept function-call signals.

Output

`Out` — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	`double`[a] | `single`[a] | `Boolean`[a] | `base integer`[a] | `fixed point`[a] | `enumerated`[a] | `bus`[a] | `string`[a]
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`[a]
Variable-Size Signals	`Yes`[a]
Zero-Crossing Detection	`No`

[a] Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type support depends on block implementation.

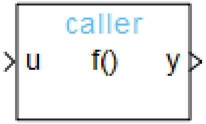
Function Caller

Call Simulink or exported Stateflow function

Library: Simulink / User-Defined Functions



Function Caller

Description

A Function Caller block calls and executes a function defined with a Simulink Function block or an exported Stateflow function. Using Function Caller blocks, you can call a function from anywhere in a model or chart hierarchy.

Ports

Input

`Input argument` — Input signal for an input argument

scalar | vector | matrix

Input signal for an input argument that is sent to the function.

The function prototype determines the number and name of input ports that appear on the Function Caller block. Connect signal lines to the input ports to send data to a function through the function input arguments.

For example, `y = myfunction(u)` creates one input port (`u`) on the Function Caller block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Output argument` — Output signal for an output argument

scalar | vector | matrix

Output signal for an output argument that the function returns.

The function prototype determines the number and name of output ports that appear on the Function Caller block. Connect signal lines to the output ports to receive data from a function through the function output arguments.

For example, `y = myfunction(u)` creates one output port (`y`) on the Function Caller block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Function prototype` — Specify function interface

`y=f(u)` (default) | <function prototype>

Specify the function interface between a Function Caller block and a Simulink function. A Simulink function can be a Simulink Function block, an exported Stateflow graphical function, or an exported Stateflow MATLAB function. For a call to a Simulink Function block:

- Function call argument names must match the function arguments.
- Function names, input arguments, and output arguments must be valid MATLAB identifiers.

Programmatic Use
Block Parameter: `FunctionPrototype`
Type: character vector
Values: `'y=f(u)'` | `'<function prototype>'`
Default: `'y=f(u)'`

`Input argument specifications` — Specify input argument data type, dimensions, and complexity

`<Enter example>` (default) | <MATLAB expression>

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each input argument. For examples, see “Argument Specification for Simulink Function Blocks”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Inport block.

Programmatic Use
Block Parameter: `'InputArgumentSpecifications'`
Type: character vector
Values: `''` | `'<MATLAB expression>'`
Default: `''`

`Output argument specifications` — Specify output argument data type, dimensions, and complexity

`<Enter example>` (default) | `<MATLAB Expression>`

Specify a comma-separated list of MATLAB expressions that combine data type, dimensions, and complexity (real or imaginary) for each output argument. For examples, see “Argument Specification for Simulink Function Blocks”.

This specification must match the Simulink Function block data type specified with the **Data type** parameter of the Argument Outport Block.

Programmatic Use
Block Parameter: `'OutputArgumentSpecifications'`
Type: character vector
Values: `''` | `'<MATLAB expression>'`
Default: `''`

`Sample time` — Time interval between function calls

`-1` (default) | `Ts` | `[Ts, To]`

Specify the time interval between function calls to a subsystem or model containing this Trigger block. If the actual calling rate for the subsystem or model differs from the time interval this parameter specifies, Simulink displays an error.

Settings

`-1`

Inherit time interval from the trigger signal.

`Ts`

Scalar where Ts is the time interval.

`[Ts, To]`

Vector where Ts is the time interval and To is the initial time offset.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: `'-1'` | `'Ts'` | `'[Ts, To]'`
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

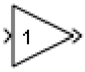
Gain

Multiply input by constant
Library: Simulink / Commonly Used Blocks
Simulink / Math Operations



Description

The Gain block multiplies the input by a constant value (gain). The input and the gain can each be a scalar, vector, or matrix.

You specify the value of gain in the **Gain** parameter. The **Multiplication** parameter lets you specify element-wise or matrix multiplication. For matrix multiplication, this parameter also lets you indicate the order of the multiplicands.

Gain is converted from doubles to the data type specified in the block mask offline using round-to-nearest and saturation. The input and gain are then multiplied, and the result is converted to the output data type using the specified rounding and overflow modes.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

The Gain block accepts real or complex-valued scalar, vector, or matrix input. The Gain block supports fixed-point data types. If the input of the Gain block is real and gain is complex, the output is complex.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

Port_1 — Input multiplied by gain

scalar | vector | matrix

The Gain block outputs the input multiplied by a constant gain value. When the input to the Gain block is real and gain is complex, the output is complex.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

Parameters

Main

Gain — Value by which to multiply the input

1 (default) | real or complex-valued scalar, vector, or matrix

Specify the value by which to multiply the input. Gain can be a real or complex-valued scalar, vector, or matrix.

Programmatic Use
Block Parameter: Gain
Type: character vector
Values: '1' | real- or complex-valued scalar, vector, or matrix
Default: '1'

Multiplication — Specify the multiplication mode

Element-wise(K.*u) (default) | Matrix(K*u) | Matrix(u*K) | Matrix(K*u) (u vector)

Specify one of these multiplication modes:

- Element-wise(K.*u) — Each element of the input is multiplied by each element of the gain. The block performs expansions, if necessary, so that the input and gain have the same dimensions.
- Matrix(K*u) — The input and gain are matrix-multiplied with the input as the second operand.
- Matrix(u*K) — The input and gain are matrix-multiplied with the input as the first operand.

- Matrix(K*u) (u vector) — The input and gain are matrix multiplied with the input as the second operand. This mode is identical to Matrix(K*u), except for how dimensions are determined.

  Suppose that K is an m-by-n matrix. Matrix(K*u)(u vector) sets the input to a vector of length n and the output to a vector of length m. In contrast, Matrix(K*u) uses propagation to determine dimensions for the input and output. For an m-by-n gain matrix, the input can propagate to an n-by-q matrix, and the output becomes an m-by-q matrix.

Programmatic Use
Parameter: Multiplication
Type: character vector
Value: 'Element-wise(K.*u)' | 'Matrix(K*u)' | 'Matrix(u*K)' | 'Matrix(K*u) (u vector)'
Default: 'Element-wise(K.*u)'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: SampleTime
Type: character vector
Values: scalar
Default: '-1'

Signal Attributes

Output minimum — Minimum output value for range checking

[] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `Inherit: Same as input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block exhibits these behaviors:

- `Inherit: Inherit via internal rule` — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and `ASIC/FPGA` is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

  It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn’t meet your specific needs for numerical accuracy or performance, use one of the following options:

  - Specify the output data type explicitly.
  - Use the simple choice of `Inherit: Same as input`.
  - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.

  - To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as input` — Use data type of input signal.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule` | `'Inherit: Same as input'` | `'Inherit: Inherit via back propagation'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'`, `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Parameter Attributes

`Parameter minimum` — Specify the minimum value of gain

`[]` (default) | scalar

Specify the minimum value of gain. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)

- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `ParamMin`
Type: character vector
Value: scalar
Default: `'[ ]'`

`Parameter maximum` — Specify the maximum value of gain

`[]` (default) | scalar

Specify the maximum value of gain. The default value is `[]` (unspecified). Simulink uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”)
- Automatic scaling of fixed-point data types

Programmatic Use
Block Parameter: `ParamMax`
Type: character vector
Value: scalar
Default: `'[ ]'`

`Parameter data type` — Specify the data type of the Gain parameter

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as input` | `Inherit: Inherit from 'Gain'` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the data type of the **Gain** parameter.

Programmatic Use
Block Parameter: `ParamDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule` | `'Inherit: Same as input'` | `'Inherit: Inherit via back propagation'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'`, `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

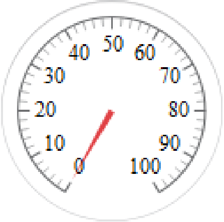
“Model a Continuous System”

Introduced before R2006a

Gauge

Display input value on circular scale
Library: Simulink / Dashboard



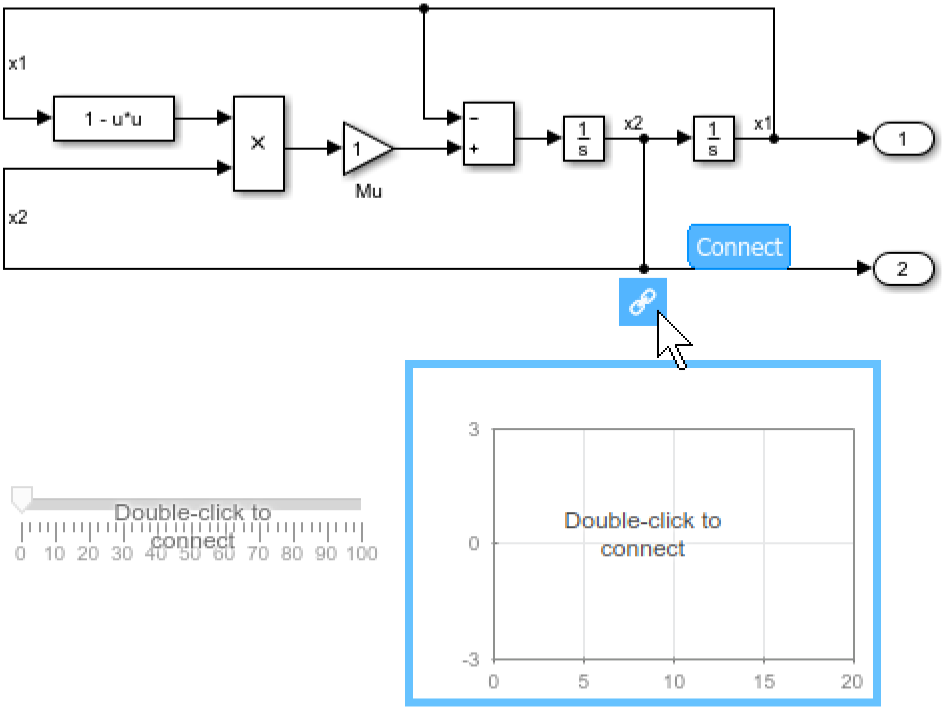
Description

The Gauge block displays the connected signal on a circular scale during simulation. You can use the Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Gauge block to fit your data. You can also change the appearance of the dial to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

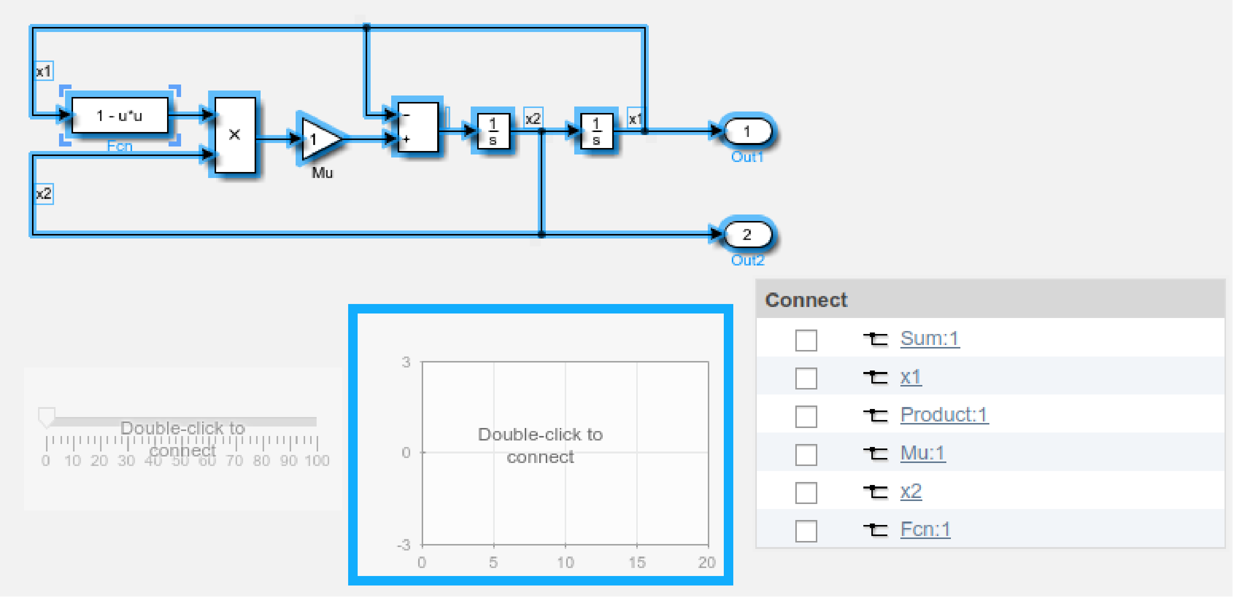
Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect	
□	Sum:1
□	x1
□	Product:1
□	Mu:1
□	x2
□	Fcn:1

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.

Parameters

`Connection` — Select a signal to connect and display

signal connection options

Select the signal to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the radio button next to the signal you want to display. Click **Apply** to connect the signal.

`Minimum` — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the arc. The minimum must be less than the value entered for the maximum.

`Maximum` — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the arc. The maximum must be greater than the value entered for the minimum.

`Tick Interval` — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the arc. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

`Scale Colors` — Color indications on gauge arc

colors for arc ranges

Color specifications for ranges on the arc. Press the **+** button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

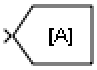
Goto

Pass block input to From blocks
Library: Simulink / Signal Routing



Description

The Goto block passes its input to its corresponding From blocks. The input can be a real- or complex-valued signal or vector of any data type. From and Goto blocks allow you to pass a signal from one block to another without actually connecting them.

A Goto block can pass its input signal to more than one From block, although a From block can receive a signal from only one Goto block. The input to that Goto block is passed to the From blocks associated with it as though the blocks were physically connected. Goto blocks and From blocks are matched by the use of Goto tags.

The **Tag Visibility** parameter determines whether the location of From blocks that access the signal is limited:

- `local` (default) — From and Goto blocks that use the same tag must be in the same subsystem. A local tag name is enclosed in brackets (`[]`).
- `scoped` — From and Goto blocks that use the same tag must be in the same subsystem or at any level in the model hierarchy below the Goto Tag Visibility block that does not entail crossing a nonvirtual subsystem boundary, in other words, the boundary of an atomic, conditionally executed, or function-call subsystem or a model reference. A scoped tag name is enclosed in braces (`{}`).
- `global` — From and Goto blocks using the same tag can be anywhere in the model except in locations that span nonvirtual subsystem boundaries.

The rule that From-Goto block connections cannot cross nonvirtual subsystem boundaries has the following exception. A Goto block connected to a state port in one conditionally executed subsystem is visible to a From block inside another conditionally executed subsystem.

Note A `scoped` Goto block in a masked system is visible only in that subsystem and in the nonvirtual subsystems it contains. Simulink generates an error if you run or update a diagram that has a Goto Tag Visibility block at a higher level in the block diagram than the corresponding `scoped` Goto block in the masked subsystem.

Use local tags when the Goto and From blocks using the same tag name reside in the same subsystem. You must use global or scoped tags when the Goto and From blocks using the same tag name reside in different subsystems. When you define a tag as global, all uses of that tag access the same signal. A tag defined as scoped can be used in more than one place in the model.

The Goto block supports signal label propagation.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix | N-D array

Input signal to be passed to the corresponding From block, specified as a scalar, vector, matrix, or N-D array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Goto tag` — Block identifier

A (default) | ...

The Goto block identifier. This parameter identifies the Goto block whose scope is defined in this block.

Programmatic Use
Block Parameter: `GotoTag`
Type: character vector

Values: `'A'` | `...`
Default: `'A'`

`Tag visibility` — Scope of the Goto block tag

`local` (default) | `scoped` | `global`

The scope of the Goto block tag, specified as `local`, `scoped`, or `global`. When you set this parameter to `scoped`, you must use a Goto Tag Visibility block to define the scope of tag visibility.

Programmatic Use
Block Parameter: `TagVisibility`
Type: character vector
Values: `'local' | 'scoped' | 'global'`
Default: `'local'`

`Icon display` — Text to display on block icon

`Tag` (default) | `Signal name` | `Tag and signal name`

Specifies the text to display on the block icon. The options are the block tag, the name of the signal that the block represents, or both the tag and the signal name.

Programmatic Use
Block Parameter: `IconDisplay`
Type: character vector
Values: `'Signal name' | 'Tag' | 'Tag and signal name'`
Default: `'Tag'`

`Rename All` — Propagate name throughout model

button

Rename the Goto tag. The new name propagates to all From and Goto Tag Visibility blocks that are listed in the **Corresponding blocks** box.

`Corresponding blocks` — Blocks connected to this Goto block

block path | ...

List of the From blocks and Goto Tag Visibility blocks connected to this Goto block. Click an entry in the list to display and highlight the corresponding From or Goto Tag Visibility block.

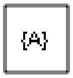
“Signal Label Propagation”

Introduced before R2006a

Goto Tag Visibility

Define scope of Goto block tag
Library: Simulink / Signal Routing



Description

The Goto Tag Visibility block defines the accessibility of Goto block tags that have `scoped` visibility. The value you specify for the **Goto tag** block parameter is accessible by From blocks in the same subsystem that contains the Goto Tag Visibility block and in subsystems below it in the model hierarchy.

A Goto Tag Visibility block is required for Goto blocks whose **Tag Visibility** parameter value is `scoped`. No Goto Tag Visibility block is needed if the tag visibility is either `local` or `global`. The block shows the tag name enclosed in braces (`{}`).

Note A `scoped` Goto block in a masked system is visible only in that subsystem and in the nonvirtual subsystems it contains. Simulink generates an error if you run or update a diagram that has a Goto Tag Visibility block at a higher level in the block diagram than the corresponding `scoped` Goto block in the masked subsystem.

Parameters

`Goto tag` — Goto block tag whose visibility is defined by the location of this block

A (default) | ...

The Goto block tag whose visibility is defined by the location of this block. From and Goto blocks using the specified tag must be in the same subsystem or at any level in the model hierarchy below the Goto Tag Visibility block that does not entail crossing a nonvirtual subsystem boundary, in other words, the boundary of an atomic, conditionally executed, or function-call subsystem or a model reference. A scoped tag name is enclosed in braces ({}).

Tip If you use multiple From and Goto Tag Visibility blocks to refer to the same Goto tag, you can simultaneously rename the tag in all of the blocks. Use the **Rename All** button in the Goto block dialog box.

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point | enumerated | bus
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Ground

Ground unconnected input port

Library: Simulink / Commonly Used Blocks
Simulink / Sources

Description

The Ground block connects to blocks whose input ports do not connect to other blocks. If you run a simulation with blocks that have unconnected input ports, Simulink issues warnings. Using a Ground block to ground those unconnected blocks can prevent these warnings.

Working with Fixed-Point Data Types

When working with fixed-point data types, there may be instances where the fixed-point data type cannot represent zero exactly. In these cases, the Ground block outputs a nonzero value that is the closest possible value to zero. This behavior applies only to fixed-point data types with nonzero bias. These expressions are examples of fixed-point data types that cannot represent zero:

- `fixdt(0, 8, 1, 1)` — an unsigned 8-bit type with slope of 1 and bias of 1
- `fixdt(1, 8, 6, 3)` — a signed 8-bit type with slope of 6 and bias of 3

Working with Enumerated Data Types

When working with enumerated data types, the Ground block outputs the default value of the enumeration. This behavior applies whether:

- The enumeration can represent zero
- The default value of the enumeration is zero

If the enumerated type does not have a default value, the Ground block outputs the first enumeration value in the type definition.

Ports

Output

`Port_1` — Ground signal
scalar

The Ground block outputs a scalar signal with zero value, and the same data type as the port to which it connects.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

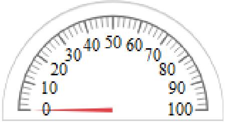
“Unconnected block input ports”

Introduced before R2006a

Half Gauge

Display input value on semicircular scale
Library: Simulink / Dashboard



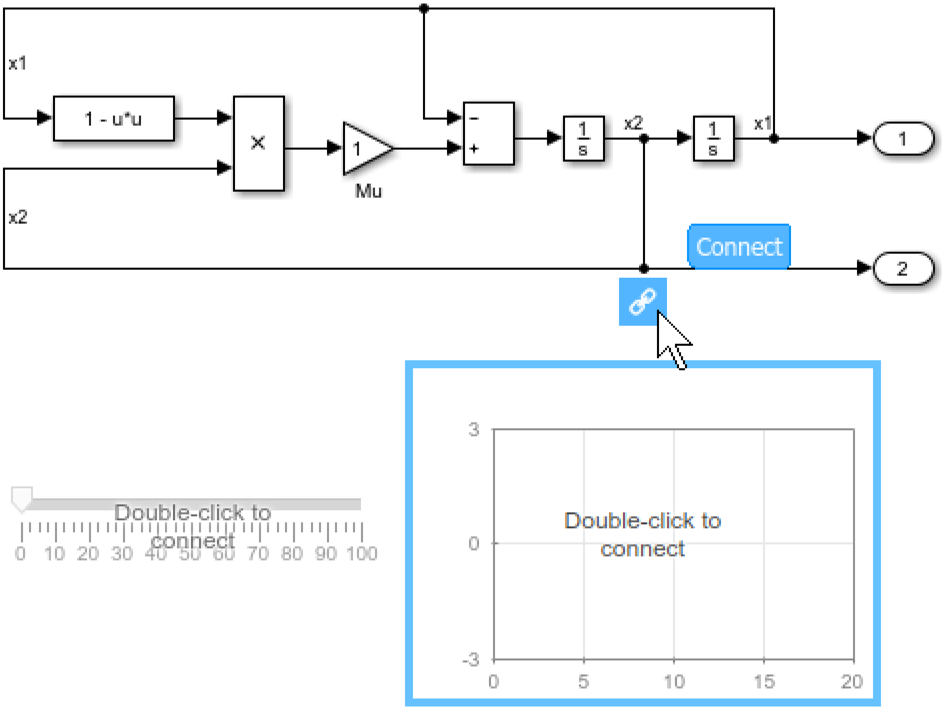
Description

The Half Gauge block displays the connected signal on a semicircular scale during simulation. You can use the Half Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Half Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Half Gauge block to fit your data. You can also customize the appearance of the Half Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

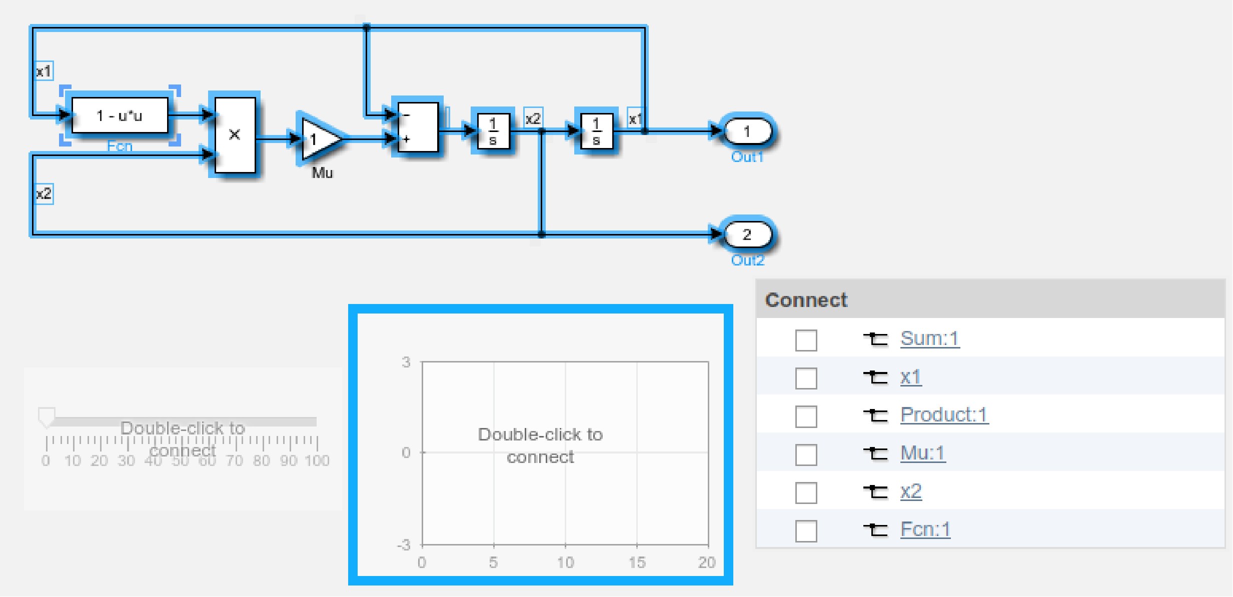
Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect	
□	Sum:1
□	x1
□	Product:1
□	Mu:1
□	x2
□	Fcn:1

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.

Parameters

`Connection` — Select a signal to connect and display

signal connection options

Select the signal to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the radio button next to the signal you want to display. Click **Apply** to connect the signal.

`Minimum` — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the arc. The minimum must be less than the value entered for the maximum.

`Maximum` — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the arc. The maximum must be greater than the value entered for the minimum.

`Tick Interval` — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the arc. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

`Scale Colors` — Color indications on gauge arc

colors for arc ranges

Color specifications for ranges on the arc. Press the **+** button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

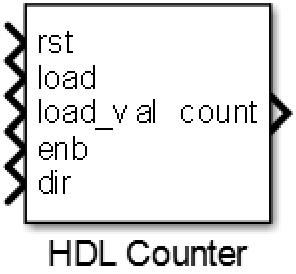
HDL Counter

Free-running or count-limited hardware counter



Library

HDL Coder / HDL Operations

Description

The HDL Counter block models a free-running or count-limited hardware counter that supports signed and unsigned integer and fixed-point data types.

The counter emits its value for the current sample time.

This block does not report wrap on overflow warnings during simulation. To report these warnings, see the `Simulink.restoreDiagnostic` reference page. The block does report errors due to wrap on overflow.

Control Ports

By default, the counter does not have input ports. Optionally, you can add control ports that enable, disable, load, reset or set the direction of the counter.

The table shows the priority of the control signals and how the counter value is updated in relation to the control signals.

Local reset, `rst`	Load trigger, `load`	Count enable, `enb`	Count direction, `dir`	Next Counter Value
1	–	–	–	initial value
0	1	–	–	`load_val` value
0	0	0	–	current value
0	0	1	1	current value + step value
0	0	1	0	current value - step value

Count direction

The **Step value** parameter and optional count direction port, `dir`, interact to determine the actual count direction.

`dir` Signal Value	Step Value Sign	Actual Count Direction
1	+ (positive)	Up
1	- (negative)	Down
0	+ (positive)	Down
0	- (negative)	Up

Parameters

Counter type

Counter behavior.

- `Free running` (default): The counter continues to increment or decrement by the **Step value** until reset.
- `Count limited`: The counter increments or decrements by the **Step value** until it is exactly equal to the **Count to value**.

Initial value

Counter value after reset. The default is 0.

Step value

Value added to counter at each sample time. The default is 1.

Count to value

When the count is exactly equal to **Count to value**, the count restarts at the **Initial value**. This option is available when **Counter type** is set to `Count limited`. The default is 100.

Count from

Specifies the parameter that sets the start value after rollover. When set to `Specify`, the **Count from value** parameter is the start value after rollover. The default is `Initial value`.

Count from value

Counter value after rollover when **Count from** is set to `Specify`. The default is 0.

Local reset port

When selected, creates a local reset port, `rst`.

Load ports

When selected, creates a load data port, `load_val`, and load trigger port, `load`.

Count enable port

When selected, creates a count enable port, `enb`.

Count direction port

When selected, creates a count direction port, `dir`.

Counter output data is

Output data type signedness. The default is `Unsigned`.

Word length

Bit width, including sign bit, for an integer counter; word length for a fixed-point data type counter. The minimum value if Output data type is `Unsigned` is 1, 2 if `Signed`. The maximum value is 125. The default is 8.

Fraction length

Fixed-point data type fraction length. The default is 0.

Sample time

Sample time. The default is 1.

This parameter is not available, and the block inherits its sample time from the input ports when any of these parameters is selected:

- **Local reset port**
- **Load ports**
- **Count enable port**
- **Count direction port**

Ports

The block has the following ports:

`rst`

Resets the counter value. Active-high.

This port is available when you select **Local reset port**.

Data type: Boolean

`load`

Sets the counter to the load value, `load_val`. Active-high.

This port is available when you select **Load ports**.

Data type: Boolean

`load_val`

Data value to load.

This port is available when you select **Load ports**.

Data type: Same as `count`.

`enb`

Enables counter operation. Active-high.

This port is available when you select **Count enable port**.

Data type: Boolean

`dir`

Count direction. This port interacts with **Step value** to determine count direction.

- `1`: **Step value** is added to the current counter value to compute the next value.
- `0`: **Step value** is subtracted from the current counter value to compute the next value.

This port is available when you select **Count direction port**.

Data type: Boolean

`count`

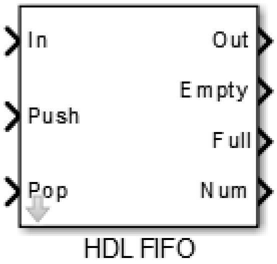
Counter value.

Data type: Determined automatically based on **Counter output data is**, **Word length**, and **Fraction length**.

Introduced in R2014a

HDL FIFO

Stores sequence of input samples in first in, first out (FIFO) register



Library

HDL Coder / HDL Operations

Description

The HDL FIFO block stores a sequence of input samples in a first in, first out (FIFO) register.

HDL Code Generation

For simulation results that match the generated HDL code, in the Solver pane of the Configuration Parameters dialog box, clear the checkbox for **Treat each discrete rate as a separate task**. When the checkbox is cleared, single-tasking mode is enabled.

If you simulate this block with **Treat each discrete rate as a separate task** selected, multitasking mode is enabled. The output data can update in the same cycle but in the generated HDL code, the output data is updated one cycle later.

Parameters

Register size

Specify the number of entries that the FIFO register can hold. The minimum is 4. The default is 10.

The ratio of output sample time to input sample time

Inputs (`In`, `Push`) and outputs (`Out`, `Pop`) can run at different sample times. Enter the ratio of output sample time to input sample time. Use a positive integer or `1/N`, where `N` is a positive integer. The default is 1.

For example:

- If you enter `2`, the output sample time is twice the input sample time, meaning the outputs run slower.
- If you enter `1/2`, the output sample time is half the input sample time, meaning the outputs run faster.

The `Full`, `Empty`, and `Num` signals run at the faster rate.

Push onto full register

Response (`Ignore`, `Error`, or `Warning`) to a trigger received at the Push port when the register is full. The default is `Warning`.

Pop empty register

Response (`Ignore`, `Error`, or `Warning`) to a trigger received at the Pop port when the register is empty. The default is `Warning`.

Show empty register indicator port (Empty)

Enable the Empty output port, which is high (1) when the FIFO register is empty and low (0) otherwise.

Show full register indicator port (Full)

Enable the Full output port, which is high (1) when the FIFO register is full and low (0) otherwise.

Show number of register entries port (Num)

Enable the Num output port, which tracks the number of entries currently in the queue.

Ports

The block has the following ports:

`In`

Data input signal.

`Push`

Control signal. When this port receives a value of `1`, the block pushes the input at the `In` port onto the end of the FIFO register.

`Pop`

Control signal. When this port receives a value of `1`, the block pops the first element off the FIFO register and holds the `Out` port at that value.

`Out`

Data output signal.

`Empty`

The block asserts this signal when the FIFO register is empty. This port is optional.

`Full`

The block asserts this signal when the FIFO register is full. This port is optional.

`Num`

Current number of data values in the FIFO register. This port is optional.

If two or more of the control input ports are triggered in the same time step, the operations execute in the following order:

1. Pop
2. Push

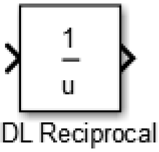
Dual Rate Dual Port RAM

Introduced in R2014a

HDL Reciprocal

Calculate reciprocal with Newton-Raphson approximation method



Library

HDL Coder / HDL Operations

Description

The HDL Reciprocal block uses the Newton-Raphson iterative method to compute the reciprocal of the block input. The Newton-Raphson method uses linear approximation to successively find better approximations to the roots of a real-valued function.

The reciprocal of a real number a is defined as a zero of the function:

$$f(x) = \frac{1}{x} - a$$

HDL Coder chooses an initial estimate in the range $0 < x_0 < \frac{2}{a}$ as this is the domain of convergence for the function.

To successively compute the roots of the function, specify the **Number of iterations** parameter in the Block Parameters dialog box. The process is repeated as:

$$x_{i+1} = x_i - \frac{f(x_i)}{f'(x_i)} = x_i + (x_i - a{x_i}^2) = x_i.(2 - ax_i)$$

$f'(x)$ is the derivative of the function $f(x)$.

Following table shows comparison of simulation behavior of HDL Reciprocal with Math Reciprocal block:

Math Reciprocal	HDL Reciprocal
Computes the reciprocal as 1/N by using the HDL divide operator (/) to implement the division.	Uses the Newton-Raphson iterative method. The block computes an approximate value of reciprocal of the block input and can yield different simulation results compared to the Math Reciprocal block. To match the simulation results with the Math Reciprocal block, increase the number of iterations for the HDL Reciprocal block.

Parameters

Number of iterations

Number of Newton-Raphson iterations. The default is 3.

Ports

The block has the following ports:

Input

- Supported data types: Fixed-point, integer (signed or unsigned), double, single
- Minimum bit width: 2
- Maximum bit width: 128

Output

Input data type	Output data type
double	double
single	single

Input data type	Output data type
built-in integer	built-in integer
built-in fixed-point	built-in fixed-point
`fi` (*value*, 0, *word_length*, *fraction_length*)	`fi` (*value*, 0, *word_length*, *word_length*–*fraction_length*–1)
`fi` (*value*, 1, *word_length*, *fraction_length*)	`fi` (*value*, 1, *word_length*, *word_length*–*fraction_length*–2)

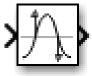
Divide | Math Function

Introduced in R2014b

Hit Crossing

Detect crossing point

Library: Simulink / Discontinuities



Description

The Hit Crossing block detects when the input reaches the **Hit crossing offset** parameter value in the direction specified by the **Hit crossing direction** property.

You can configure the block to output a 1 or 0 `signal` or a SimEvents® `message`. See “Output” on page 1-916 for more information.

Ports

Input

`Port_1` — Input signal
scalar | vector

Input signal that the block detects when it reaches the offset in the specified direction.

Data Types: `double`

Output

`Port_1` — Output signal
scalar | vector | SimEvents message

Output indicating if the input signal crossed the hit offset. This port is only visible when you select the **Show output port** parameter check box.

Signal Output

If you select the **Show output port** check box and set the `Output type` parameter to `Signal`, the block output indicates when the crossing occurs.

- If the input signal is exactly the value of the offset value after the hit crossing is detected in the specified direction, the block continues to output a value of 1.
- If the input signals at two adjacent points brackets the offset value, the block outputs a value of 1 at the second time step.
- If the **Show output port** check box is *not* selected, the block ensures that the simulation finds the crossing point but does not generate output.
- If the initial signal is equal to the offset value, the block outputs 1 only if the **Hit crossing direction** property is set to `either`.
- If Boolean logic signals are enabled, then the output is a `Boolean`.

SimEvents Message Output

The Hit Crossing block can also output a SimEvents message when the `Output Type` is set to `Message`.

- If the input signal crosses the offset value in the specified direction, the block outputs a message.
- If the input signal reaches the offset value in the specified direction and remains there, block outputs one message at the hit time and one message when the signal leaves the offset value.
- If the initial input signal is equal to the offset value, the block outputs a message with `Crossing Type` value `None` only if the **Hit crossing direction** is set to `either`.

The SimEvents message output signal is a `struct` with four fields.

`CrossingType` — Direction of zero-crossing

`None` | `NegativeToPositive` | `NegativeToZero` | `ZeroToPositive` | `PositiveToNegative` | `PositiveToZero` | `ZeroToNegative`

This field shows the direction in which the signal crosses the **Hit crossing offset** value. Negative, Zero, and Positive are defined relative to the offset value. The data type is `slHitCrossingType` which is an enumerated data type. See “Use Enumerated Data in Simulink Models” for more information. For example, if `HitCrossingOffset` is set to 2, a rising signal crossing this offset value would be recorded as a `NegativeToPositive` hit crossing.

Note A hit crossing is recorded based on the **Hit crossing direction** setting. In other words, if you set **Hit crossing direction** to detect a `falling` hit crossing, a `NegativeToPositive` hit is not recorded.

Note In a SimEvents block, if the `Crossing Type` of an entity is a `NegativeToPositive` hitcrossing then `entity.CrossingType == slHitCrossingType.NegativeToPositive` returns logical 1 `(true)`.

If the signal reaches the `HitCrossingOffset` value and holds it, a single `NegativeToZero` or `PositiveToZero`, depending on the direction, hit is registered at the time of the hit crossing.

Data Types: `slHitCrossingType`

Index — Index of the input signal at which the hit crossing event occurs
nonnegative integer

For *n* signals being passed to the Hit Crossing block, this field denotes which signal had a hit crossing event. For a matrix input, this field follows MATLAB linear indexing. See “Array Indexing” (MATLAB).

Data Types: `uint32`

Time — Time of hit crossing event
real, finite

Time *T* of the hit crossing event.

Data Types: `double`

`Offset` — Hit crossing value for detection
`0` (default) | real values

Hit crossing offset value as specified by the “Hit crossing offset” on page 1-0 parameter.

Data Types: `double`

Data Types: `double` | `Boolean` | `struct`

Note If the SimEvents message output signal crosses model reference boundaries or is used as an input to a Stateflow chart, you need to create a bus object for the message. See “Tips” on page 1-921.

Parameters

`Hit crossing offset` — Hit crossing value for detection

`0` (default) | real values

Specify the value the block detects when the input crosses in the direction specified by **Hit crossing direction**.

Programmatic Use
Block Parameter: `HitCrossingOffset`
Type: character vector
Values: real values
Default: `'0'`

`Hit crossing direction` — Input signal direction to hit crossing

`either` (default) | `falling` | `rising`

Direction from which the input signal approaches the hit crossing offset for a crossing to be detected.

When set to `either`, the block serves as an *almost equal* block, useful in working around limitations in finite mathematics and computer precision. Used for these reasons, this block might be more convenient than adding logic to your model to detect this condition.

When the **Hit crossing direction** property is set to `either` and the model uses a fixed-step solver, the block has the following behavior. If the output signal is 1, the block sets the output signal to 0 at the next time step, unless the input signal equals the offset value.

Programmatic Use
Block Parameter: `HitCrossingDirection`
Type: character vector
Values: `'either'` | `'rising'` |`'falling'`
Default: `'either'`

`Show output port` — Display an output port

`off` (default) | `on`

If selected, create an output port on the block icon.

Programmatic Use
Block Parameter: `ShowOutputPort`
Type: character vector
Values: `'off'` | `'on'`
Default: `'on'`

`Output type` — Choose signal or message output

signal (default for Simulink) | message (default for SimEvents)

When **Output type** is set to `Signal`, the output signal is set to one whenever the input signal crosses the **Hit crossing offset** value in the **Hit crossing direction** and is zero at other times.

When the **Output type** is set to `Message`, the output signal becomes a SimEvents message.

Programmatic Use
Block Parameter: `HitCrossingOutputType`
Type: character vector
Values: `'Signal'` | `'Message'`
Default: `'Signal'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

`Sample time` — Specify sample time as a value other than -1

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

Tips

If the Hit Crossing block is configured to output a SimEvents message and the output signal:

- Crosses into or out of a referenced model
- Is fed to the input of a Stateflow chart

then you need to create a bus object for the message signal. In the MATLAB Command Window, run `Simulink.createHitCrossMessage` to check for and, if needed, create a hit crossing message bus object in the base workspace.

Set the data type of the corresponding port to `Bus: HitCrossMessage`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

Does not support non-floating data type for ert targets.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

Not supported for SimEvents messages.

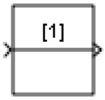
Introduced before R2006a

IC

Set initial value of signal
Library: Simulink / Signal Attributes



Description

The IC block sets the initial condition of the signal at its input port, for example, the value of the signal at the simulation start time (t_{start}). To do so, the block outputs the specified initial condition when you start the simulation, regardless of the actual value of the input signal. Thereafter, the block outputs the actual value of the input signal.

The IC block is useful for providing an initial guess for the algebraic state variables in a loop. For more information, see “Algebraic Loops”.

Behavior for Nonzero Sample Time Offset

If an IC block has a nonzero sample time offset (t_{offset}), the IC block outputs its initial value at time t,

$$t = n * t_{period} + t_{offset}$$

where n is the smallest integer such that $t \geq t_{start}$.

That is, the IC block outputs its initial value the first-time blocks with sample time $[t_{period}, t_{offset}]$ execute, which can be after t_{start}.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The block sets the initial condition of this signal to the **Initial value** you specify.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Output signal

scalar | vector | matrix | N-D array

Output signal provided as the **Initial value** you specify, followed by the actual values of the input signal. See “Behavior for Nonzero Sample Time Offset” on page 1-923 for more information.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Initial value` — Initial value

`1` (default) | real, finite scalar, vector, matrix, or N-D array

Specify the initial value of the input signal as a finite, real-valued scalar, vector, matrix, or N-D array. The value must be a scalar, or have the same dimensions as the input signal.

Programmatic Use
Block Parameter: `Value`
Type: character vector
Values: scalar | vector | matrix | N-D array
Default: `'1'`

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: SampleTime
Type: character vector
Values: scalar
Default: '-1'

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point | enumerated
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

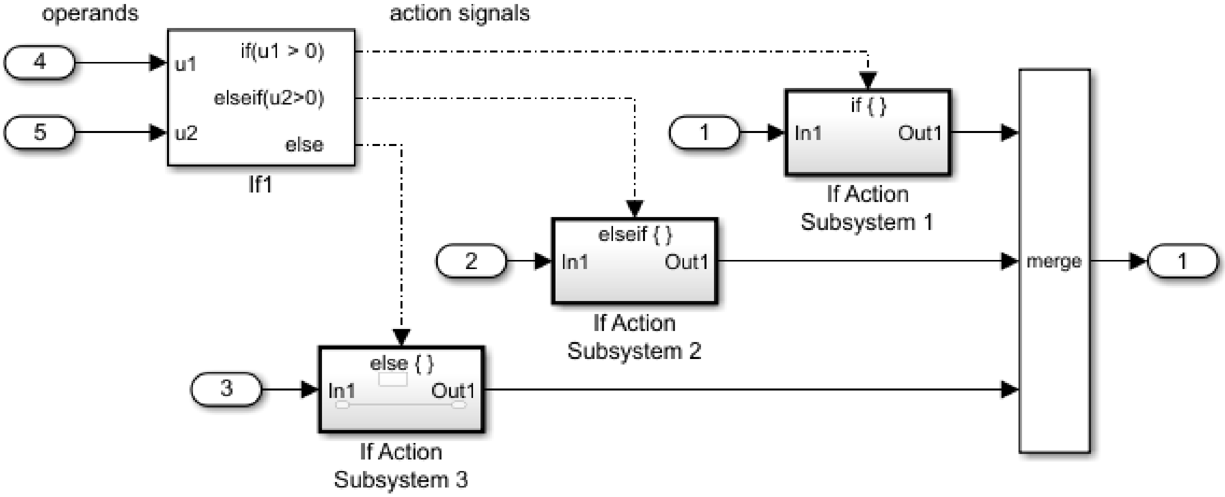
If

Select subsystem execution using logic similar to if-else statement
Library: Simulink / Ports & Subsystems

Description

The If block, along with If Action Subsystem blocks containing an Action Port block, implements if-else logic to control subsystem execution. For an example using the If block, see If Action Subsystems.



Limitations

The If block has the following limitations:

- It does not support tunable parameters. Values for an `if` or `elseif` expression cannot be tuned during a simulation in normal or accelerator mode, or when running generated code.

  To implement tunable if-else expressions, tune the expression outside the If block. For example, use the Relational Operator block to evaluate the expression outside of the If block or add the tunable parameter as an input to the If block.
- It does not support custom storage classes. See “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).
- The **If expression** and **Elseif expressions** cannot accept certain operators, such as `+, -, *`, and `/`.

Ports

Input

`Logical operands` — Values for evaluating logical expressions

scalar | vector

Inputs `u1,u2,...,un` must have the same data type. The inputs cannot be of any user-defined type, such as an enumerated type.

The If block does not directly support fixed-point data types. However, you can use the Compare To Constant block to work around this limitation. See Support for Fixed-Point Data Type in If Action Subsystems.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

Output

`Action` — Action signal for an If Action Subsystem block

scalar

Outputs from the `if`, `else`, and `elseif` ports are action signals to If Action Subsystem blocks.

Support for Fixed-Point Data Type

Parameters

`Number of inputs` — Specify number of input ports

1 (default) | integer

1

Specify one input port.

integer

Specify the number of input ports. Block ports are labeled with a `'u'` character followed by a number, `1,2,...,n`, where `n` equals the number of inputs that you specify.

Programmatic Use
Block Parameter: `NumInputs`
Type: character vector
Values: `'1'` | `'<integer>'`
Default: `'1'`

`if expression` — Specify logical expression

`u1 > 0` (default) | logical expression

The If Action Subsystem attached to the `if` port executes when its associated expression evaluates to true.

`u1 > 0`

Specify sending an action signal on the output port when the input `u1` is greater than `0`.

logical expression

Specify logical expression. This expression appears on the If block adjacent to the **if** output port.

The expression can include only the operators `<, <=, ==, ~=, >, >=, &, |, ~, (), unary-minus`. Operators such as `+, -, *, /`, and `^` are not allowed. The expression must not contain data type expressions, for example, `int8(6)`, and must not reference workspace variables whose data type is other than `double` or `single`.

Programmatic Use
Block Parameter: `IfExpression`
Type: character vector
Values: `'u1 > 0'` | `'<logical expression>'`
Default: `'u1 > 0'`

`Elseif expressions` — Specify logical expression

empty (default) | list of logical expressions

The If Action Subsystem attached to an **elseif** port executes when its expression evaluates to `true` and all `if` and `elseif` expressions are false.

empty

Logical expressions not specified.

list of logical expressions

Specify a list of logical expressions delimited by commas. The expressions appear on the If block below the **if** port and above the **else** port when you select the **Show else condition** check box.

Expressions can include only the operators `<, <=, ==, ~=, >, >=, &, |, ~, (), unary-minus`. Operators such as `+, -, *, /`, and `^` are not allowed. The expressions must not contain data type expressions, for example, `int8(6)`, and must not reference workspace variables whose data type is other than `double` or `single`.

Programmatic Use
Block Parameter: `ElseIfExpressions`
Type: character vector
Values: `''` | `'<list of logical expressions>'`
Default: `''`

`Show else condition` — Control display of else port

on (default) | off

When the **if** port and all **elseif** port expressions are `false`, the **else** port sends an action signal to execute the attached If Action Subsystem block.

☑ on

Display **else** port.

□ off

Hide **else** port.

Programmatic Use
Block Parameter: `ShowElse`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

`Enable zero-crossing detection` — Control zero-crossing detection

on (default) | off

Control zero-crossing detection.

☑ on

Detect zero crossings.

□ off

Do not detect zero crossings.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector
Values: `'on'` | `'off'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Blocks

Action Port | If Action Subsystem | Subsystem

Topics

Select Subsystem Execution

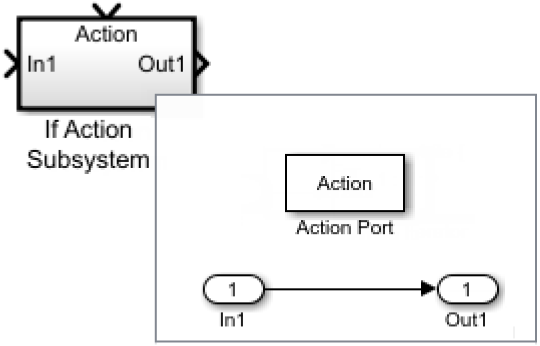
Introduced before R2006a

If Action Subsystem

Subsystem whose execution is enabled by an If block
Library: Simulink / Ports & Subsystems

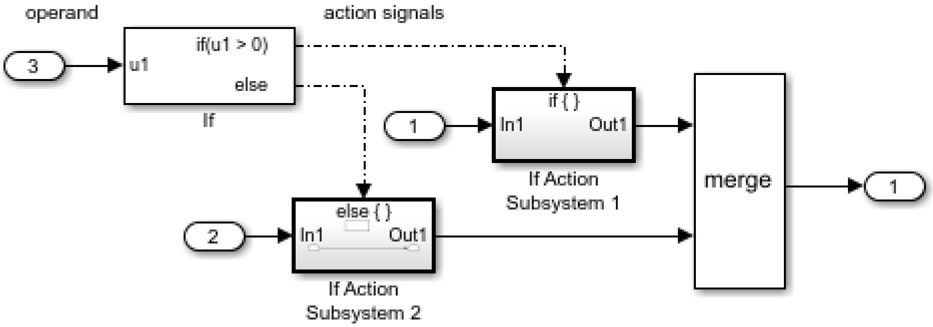
Description

The If Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is controlled by an If block. The If block evaluates a logical expression and then, depending on the result of the evaluation, outputs an action signal.



Merge signals from If Action Subsystem blocks

This example shows how to merge signals controlled by an If block. The If block selects the execution of an If Action Subsystem block from a set of subsystems. Regardless of which subsystem the If block selects, you can create a single signal with a Merge block.
Open model

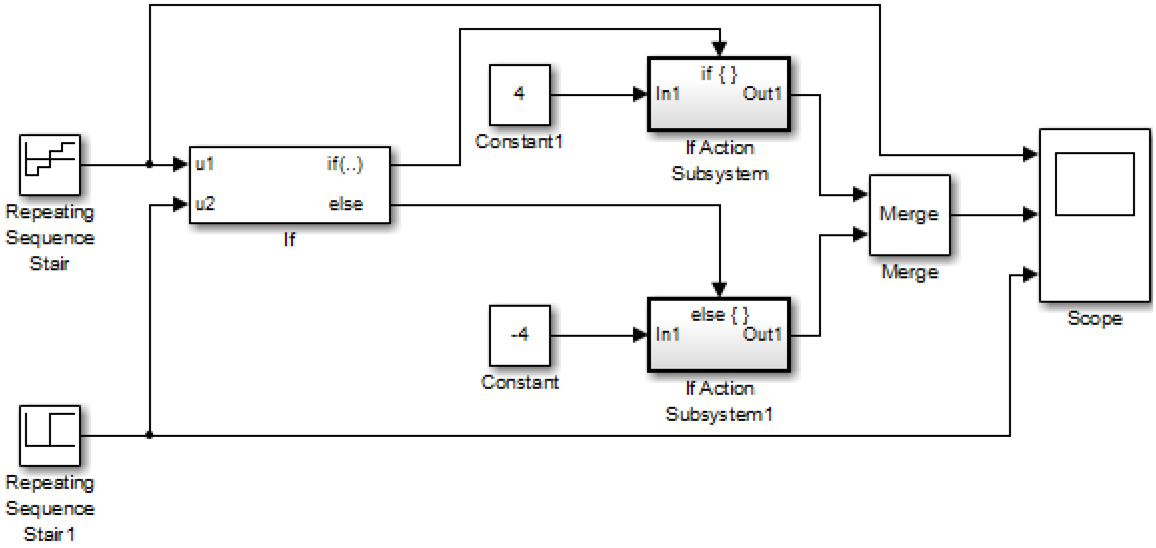


All blocks in an If Action Subsystem block must execute at the same rate as the driving If block. You can satisfy this requirement by setting the sample time parameter for each block to either inherited (-1) or the same value as the If block sample time.

Support for Fixed-Point Data Type

The If block does not directly support fixed-point data types. However, you can use the Compare To Constant block to work around this limitation.

Consider the following floating-point model without fixed-point data types:



In this model, the If Action Subsystem blocks use their default configurations. The simulation parameters are set to their default values except for the parameters listed in the following table.

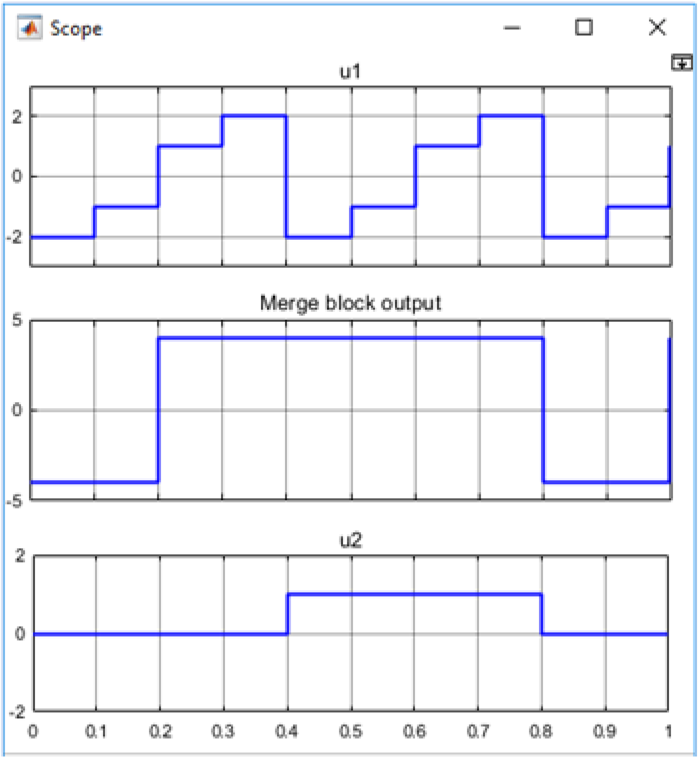
Configuration Parameter Pane	Parameter	Setting
Solver	**Start time**	`0.0`
	Stop time	`1.0`
	Type	`Fixed-step`
	Solver	`discrete (no continuous states)`
	Fixed-step size	`0.1`

The block parameters are set to their default values except for the parameters listed in the following table.

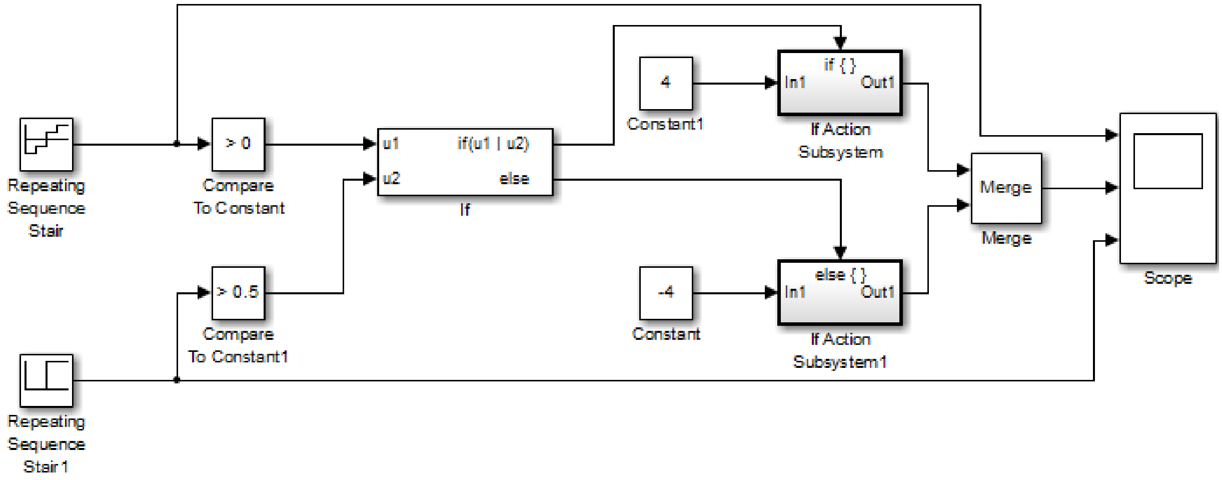
Block	Parameter	Setting
Repeating Sequence Stair	**Vector of output values**	`[-2 -1 1 2].'`

Block	Parameter	Setting
Repeating Sequence Stair1	**Vector of output values**	`[0 0 0 0 1 1 1 1].'`
If	**Number of inputs**	`2`
	If expression	`(u1 > 0) | (u2 > 0.5)`
	Show else condition	Selected
Constant	**Constant value**	`-4`
Constant1	**Constant value**	`4`
Scope	**Number of axes**	`3`
	Time range	`1`

For this model, when input `u1` is greater than `0` or input `u2` is greater than `0.5`, the output is `4`. Otherwise, the output is `-4`. The Scope block displays the output from the Merge block with inputs `u1`, and `u2`.



You can implement this block diagram as a model with fixed-point data types:



The Repeating Sequence Stair blocks output fixed-point data types.

The Compare To Constant blocks implement two parts of the **If expression** that is used in the If block in the floating-point version of the model, `(u1 > 0)` and `(u2 > 0.5)`. The `OR` operation, `(u1|u2)`, can still be implemented inside the If block. For a fixed-point model, the expression must be partially implemented outside of the If block as it is in this model.

The block and simulation parameters for the fixed-point model are the same as for the floating-point model with the following exceptions and additions:

Block	Parameter	Setting
Compare To Constant	**Operator**	`>`
	Constant value	`0`
	Output data type mode	`Boolean`
	Enable zero-crossing detection	off
Compare To Constant1	**Operator**	`>`
	Constant value	`0.5`
	Output data type mode	`Boolean`

Block	Parameter	Setting
	Enable zero-crossing detection	off
If	**Number of inputs**	2
	If expression	`u1|u2`

Ports

Input

`In` — Signal input to a subsystem block

scalar | vector | matrix

Placing an Inport block in a subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`Action` — Control signal input to a subsystem block

scalar | vector | matrix

Placing an Action Port block in a subsystem block adds an external input port to the block and changes the block to an If Action Subsystem.

Dot-dash lines from a Switch Case block to an Switch Case Action Subsystem block represent *action* signals. An action signal is a control signal connected to the action port of a Switch Case Action Subsystem block. A message on the action signal initiates execution of the subsystem.

Data Types: `action`

Output

`Out` — Signal output from a subsystem

scalar | vector | matrix

Placing an Outport block in a subsystem block adds an output port from the block. The port label on the subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Block Characteristics

Data Types	`double`[a] | `single`[a] | `Boolean`[a] | `base integer`[a] | `fixed point`[a] | `enumerated`[a] | `bus`[a] | `string`[a]
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`[a]
Variable-Size Signals	`Yes`[a]
Zero-Crossing Detection	`No`

[a] Actual data type or capability support depends on block implementation.

Select Subsystem Execution

Introduced before R2006a

In Bus Element

Select bus element or entire bus that is connected to subsystem input port

Library: Simulink / Ports & Subsystems
Simulink / Sources

Description

Note This block has two different names, depending on the library in which it appears. The functionality of both blocks is the same.

- In the Sources library and the Ports & Subsystems library — In Bus Element
- In the Signal Routing library — Bus Element In

Select an element from a bus (or the entire bus) that is connected to the input port of the subsystem. This block integrates into one block the functionality of using an Inport block and a Bus Selector block. The In Bus Element block is of the Inport block type. There are no specifications allowed on an In Bus Element block, which supports only an inherited workflow. You cannot use the Block Parameters dialog box of an In Bus Element block to specify bus element attributes, such as data type or dimensions.

To work with buses at subsystem interfaces, consider using In Bus Element and Out Bus Element blocks. This bus element port block combination:

- Reduces signal line complexity and clutter in a block diagram.
- Makes it easy to change the interface incrementally.
- Allows access to a bus element closer to the point of usage.
  - For input, avoid a duplicate Inport blocks and a Bus Selector, Goto, and From block configuration.
  - For output, avoid a Goto, From, and Bus Creator block configuration.

The In Bus Element block selects signals from a subsystem input port. Feed the output of the In Bus Element block to another block in the subsystem.

For bus input signals, either specify the signal that you want to select from the input port or to pass through the whole bus signal, leave the element empty. For a nonbus input signal for a subsystem, leave the element section of the block icon text empty. The block passes through the value of the nonbus signal. To select multiple signals from an input bus signal, create multiple In Bus Element blocks, one for each selected signal.

To reduce the number of bus element signals displayed in the Block Parameters dialog box, use the **Filter** box. The **Filter** box supports regular expressions. To use a regular expression character as a literal, include an escape character (\). For example, to use a question mark: `sig\?1`.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box **Set color** option. This action sets the color of blocks associated with selected elements, or to all blocks if you do not select elements.

Ports

The block does not have an input port. Use the Block Parameters dialog box or Property Inspector to specify the subsystem input port from which the block receives its input signal.

Output

`Port_1` — Pass selected signal to another block

signal

The output port passes the value of the selected input signal to another block. The signal can have a real or complex value of any data type that Simulink supports.

Parameters

`Port name` — Name of associated subsystem input port

`InBus` (default) | text

Specify a name for a subsystem port. That name appears on the Subsystem and In Bus Element block icons. If you specify a port name, that name cannot already be in use by another In Bus Element block or port. All In Bus Element blocks that access the same subsystem input port reflect the port name that you specify.

Programmatic Use
Block Parameter: `PortName`
Type: text
Default: `InBus`

`Port number` — Position in which port appears for subsystem input ports
1 (default) | integer

Specify the order in which the port appears on the subsystem, with 1 being the top port, 2 the second port down, and so on.

- If you specify a number that exceeds the number of subsystem input ports, new ports are added above the port associated with the In Bus Element block.
- If you add an In Bus Element block that creates another subsystem input port, the port number is the next available number.
- If you delete all In Bus Element blocks associated with a port, other port numbers are renumbered so that the blocks are in sequence and that no numbers are omitted.

Programmatic Use
Block Parameter: `Port`
Value: integer
Default: `1`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

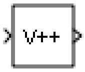
Increment Real World

Increase real-world value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math: Increment - Decrement



Description

The Increment Real World block increases the real-world value of the signal by one.

Overflows always wrap.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output is the real-world value of the input signal increased by one. Overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Block Characteristics

Data Types	double | single | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

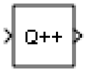
Increment Stored Integer

Increase stored integer value of signal by one

Library: Simulink / Additional Math & Discrete / Additional Math: Increment - Decrement



Description

The Increment Stored Integer block increases the stored integer value of a signal by one.

Floating-point signals also increase by one, and overflows always wrap.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output is the stored integer value of the input signal increased by one. Floating-point signals also increase by one, and overflows always wrap. The output has the same data type and dimensions as the input.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Block Characteristics

Data Types	double | single | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	Yes
Zero-Crossing Detection	No

Extended Capabilities

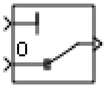
Introduced before R2006a

Index Vector

Switch output between different inputs based on value of first input
Library: Simulink / Signal Routing



Description

The Index Vector block is a special configuration of the Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is `[18 15 17 10]` and the control input is `3`, the element that matches the index of 3 (zero-based) is `10`, and that becomes the output value.

To configure a Multiport Switch block to work as an Index Vector block set **Number of data ports** to `1` and **Data port order** to `Zero-based contiguous`.

For more information about the Multiport Switch block, see the Multiport Switch block reference page.

Ports

Input

`Port_1` — Control signal
scalar

Control signal, specified as a scalar. The control signal can be of any data type that Simulink supports, including fixed-point and enumerated types. When the control input is not an integer value, the block truncates the value to an integer by rounding to zero.

For information on control signals of enumerated type, see “Guidelines on Setting Parameters for Enumerated Control Port” on page 1-1288 on the Multiport Switch block ref page.

Limitations

- If the control signal is numeric, the control signal cannot be complex.
- If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port.
- If the underlying integer does not correspond to a data input, an error occurs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`0 or 1` — First data input

scalar | vector

First data input, specified as a scalar or vector. The port is labeled **0** when you set **Data port order** to `Zero-based contiguous`, and labeled **1** when you set **Data port order** to `One-based contiguous`. The input data signal can be of any data type that Simulink supports.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Selected data input, based on control signal value

scalar | vector | matrix | N-D array

The block outputs the selected value from the input data vector, according to the control signal value. The output is a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

Data port order — Type of ordering for data input ports

Zero-based contiguous (default) | One-based contiguous | Specify indices

Specify the type of ordering for your data input ports.

- Zero-based contiguous — Block uses zero-based indexing for ordering contiguous data ports. This is the default value of the Index Vector block.
- One-based contiguous — Block uses one-based indexing for ordering contiguous data ports. This is the default value of the Multiport Switch block.
- Specify indices — Block uses noncontiguous indexing for ordering data ports. This value is supported only for configurations with two or more input data ports.

Tips

- When the control port is of enumerated type, select Specify indices.
- If you select Zero-based contiguous or One-based contiguous, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.
- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs:

If the block has unused data ports and data port order is:	The block produces:
Zero-based contiguous or One-based contiguous	A warning
Specify indices	An error

Dependencies

Selecting Zero-based contiguous or One-based contiguous enables the **Number of data ports** parameter.

Selecting `Specify indices` enables the **Data port indices** parameter.

Programmatic Use
Block Parameter: `DataPortOrder`
Type: character vector
Values: `'Zero-based contiguous' | 'One-based contiguous' | 'Specify indices'`
Default: `'Zero-based contiguous'`

`Number of data ports` — Number of data input ports

`1` (default) | integer between 1 and 65536

Specify the number of data input ports to the block.

Dependencies

To enable this parameter, set **Data port order** to `Zero-based contiguous` or `One-based contiguous`.

Programmatic Use
Block Parameter: `Inputs`
Type: character vector
Values: integer between 1 and 65536
Default: `'1'`

Signal Attributes

`Require all data port inputs to have the same data type` — Require all inputs to have the same data type

`off` (default) | `on`

Select this check box to require that all data input ports have the same data type. When you clear this check box, the block allows data port inputs to have different data types.

Programmatic Use
Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block behaves as follows:

- `Inherit: Inherit via internal rule`—Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn’t meet your specific needs for numerical accuracy or performance, use one of the following options:

  - Specify the output data type explicitly.
  - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
  - To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Uses the data type of the driving block.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule`|`'Inherit: Inherit via back propagation'`|`'double'`|`'single'`|`'int8'`|`'uint8'`|`'int16'`|`'uint16'`, `'int32'`|`'uint32'`|`'fixdt(1,16)'`|`'fixdt(1,16,0)'`|`'fixdt(1,16,2^0,0)'`|`'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off'`|`'on'`
Default: `'off'`

`Integer rounding mode` — Specify the rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Choose one of these rounding modes.

`Ceiling`

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

See Also

For more information, see "Rounding" (Fixed-Point Designer).

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.

- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Allow different data input sizes (Results in variable-size output signal)` — Allow input signals with different sizes
`off` (default) | `on`

Select this check box to allow input signals with different sizes.

- `On` — Allows input signals with different sizes, and propagate the input signal size to the output signal. In this mode, the block produces a variable-size output signal.
- `Off` — Requires that all nonscalar data input signals be the same size.

Programmatic Use
Parameter: `AllowDiffInputSizes`
Type: character vector
Value: `'on'` | `'off'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`

Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

“Variable-Size Signal Basics”

Introduced before R2006a

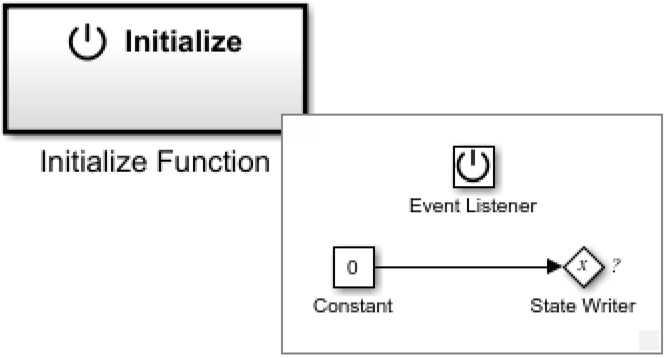
Initialize Function

Executes contents on a model initialize event

Library: Simulink / User-Defined Functions

Description

The Initialize Function block is a pre-configured subsystem block that executes on a model initialize event. By default, the Initialize Function block includes an Event Listener block with **Event** set to `Initialize`, a Constant block with **Constant value** set to `0`, and a State Writer block.



Replace the Constant block with blocks that generate the state value for the State Writer block.

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

The input and output ports of a component containing Initialize Function and Terminate Function blocks must connect to input and output port blocks.

The code generated from this block is part of the `model_initialize` function that is called once at the beginning of model execution.

Block Characteristics

Data Types	`double`[a] | `single`[a] | `Boolean`[a] | `base integer`[a] | `fixed point`[a] | `enumerated`[a] | `bus`[a] | `string`[a]
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`[a]
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

[a] Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Inport

Create input port for subsystem or external input

Library: Simulink / Commonly Used Blocks
Simulink / Ports & Subsystems
Simulink / Sources

Description

Inport blocks link signals from outside a system into the system.

Simulink software assigns Inport block port numbers according to these rules:

- It automatically numbers the Inport blocks within a top-level system or subsystem sequentially, starting with 1.
- If you add an Inport block, the label is the next available number.
- If you delete an Inport block, other port numbers are automatically renumbered to ensure that the Inport blocks are in sequence and that no numbers are omitted.
- If you copy an Inport block into a system, its port number is *not* renumbered unless its current number conflicts with an inport already in the system. If the copied Inport block port number is not in sequence, renumber the block. Otherwise, you get an error message when you run the simulation or update the block diagram.

Inport Blocks in a Top-Level System

You can use an Inport block in a top-level system to:

- Supply external inputs from the workspace using one of these approaches. If no external outputs are supplied, then the default output is the ground value.
    - Use the **Configuration Parameters > Data Import/Export > Input** parameter. See “Load Data to Root-Level Input Ports”.

Tip To import many signals to root-level input ports, consider using the Root Inport Mapper tool. For more information, see “Map Data Using Root Inport Mapper Tool”.

  - Use the `ut` argument of the `sim` command to specify the inputs.
- Provide a means for perturbation of the model by the `linmod` and `trim` analysis functions.
  - Use Inport blocks to inject inputs into the system. See “Linearizing Models”.
- To load logged signal data using root Inport blocks, use the `createInputDataset` function to create a `Dataset` object that contains elements corresponding to root-level Inport blocks.

Inport Blocks in a Subsystem

Inport blocks in a subsystem represent inputs to the subsystem. A signal arriving at an input port on a Subsystem block flows out of the associated Inport block in that subsystem. The Inport block associated with an input port on a Subsystem block is the block whose **Port number** parameter matches the relative position of the input port on the Subsystem block. For example, the Inport block whose **Port number** parameter is `1` gets its signal from the block connected to the topmost port on the Subsystem block.

If you renumber the **Port number** of an Inport block, the block becomes connected to a different input port. The block continues to receive its signal from the same block outside the subsystem.

Inport blocks inside a subsystem support signal label propagation, but root-level Inport blocks do not.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The Out Bus Element block is of block type Outport. However, there are no specifications allowed on bus element port blocks, which support inherited workflows. You cannot use the Block Parameters dialog box of an Out Bus Element block to specify bus element attributes, such as data type or dimensions.

Creating Duplicate Inports

You can create any number of duplicates of an Inport block. The duplicates are graphical representations of the original intended to simplify block diagrams by eliminating unnecessary lines. The duplicate has the same port number, properties, and output as the original.

To create a duplicate of an Inport block:

1. In the block diagram, select the block that you want to duplicate.
2. In the Model Editor menu bar, select **Edit** > **Copy**.
3. In the block diagram, place your cursor where you want to place the duplicate.
4. Select **Edit** > **Paste Duplicate Inport**.

Connecting Buses to Root-Level Inports

If you want a root-level Inport of a model to produce a bus signal, set the **Data type** parameter to the name of a bus object that defines the bus that the Inport produces. For more information, see “When to Use Bus Objects”.

Ports

Output

`Port_1` — Inport signal

scalar | vector

Input signal that flows through the inport into the system.

You can use a subsystem inport to supply fixed-point data in a structure or any other format.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

`Port number` — Port number of block

`1` (default)

Specify the port number of the block. This parameter controls the order in which the port that corresponds to the block appears on the parent subsystem or model block.

Programmatic Use
Block Parameter: `Port`
Type: character vector
Values: real integer
Default: `'1'`

`Icon display` — Icon display

`Port number` (default) | `Signal name` | `Port number and signal name`

Specify the information to be displayed on the icon of this port.

Programmatic Use
Block Parameter: `IconDisplay`
Type: character vector
Values: `'Signal name'` | `'Port number'` | `'Port number and signal name'`
Default: `'Port number'`

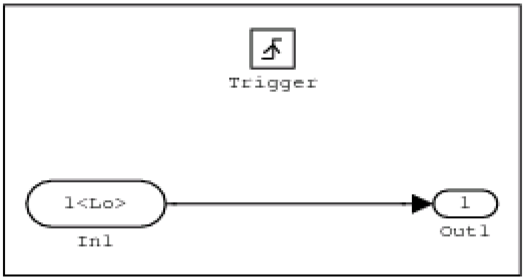
`Latch input by delaying outside signal` — Latch signal by delay

`off` (default) | `on`

Select to specify the block outputs the value of the input signal at the previous time step.

Selecting this check box enables Simulink to resolve data dependencies among triggered subsystems that are part of a loop.

The Inport block indicates that this option is selected by displaying `<Lo>`.



Dependency

Enabled in a triggered subsystem.

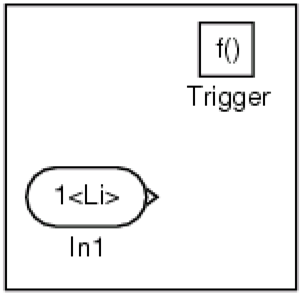
Programmatic Use
Block Parameter: `LatchByDelaying OutsideSignal`
Type: character vector
Values: `'on' | 'off'`
Default: `'off'`

`Latch input for feedback signals of function-call subsystem outputs` — Latch signal from changing

`off` (default) | `on`

Select to specify the block latches the value of the input to this subsystem and prevents this value from changing during the execution of the subsystem. For a single function call that is branched to invoke multiple function-call subsystems, this option breaks a loop formed by a signal fed back from one of these function-call subsystems into the other. This option prevents any change to the values of a feedback signal from a function-call subsystem that is invoked during the execution of this subsystem.

The Inport block indicates that this option is selected by displaying `<Li>`.



Dependency

Enabled when Inport block is in a function-call subsystem.

Programmatic Use
Block Parameter: `LatchInputFor FeedbackSignals`
Type: character vector
Values: `'on' | 'off'`
Default: `'off'`

`Interpolate data` — Interpolate output data

on (default) | ogg

When loading data from the workspace to a root-level Inport block, specify whether the block linearly interpolates and extrapolates output at time steps for which no corresponding data exists.

To load discrete signal data from the workspace, in the Inport block dialog box:

1. Set the **Sample time** parameter to a discrete value, such as 2.
2. Clear the **Interpolate data** parameter.

Specifying the discrete sample time causes the simulation to have hit times exactly at those instances when the discrete data is sampled. You specify the data values, not time values.

Turning interpolation off avoids unexpected data values at other simulation time points as a result of double precision arithmetic processing. For more information, see “Load Data to Test a Discrete Algorithm”.

Simulink uses the following interpolation and extrapolation:

- For time steps between the first specified data point and the last specified data point — zero-order hold
- For time steps before the first specified data point and after the last specified data point — ground value
- For variable-size signals for time steps before the first specified data point — a NaN is logged for single or double data types and ground for other data types. For time steps after the last specified data point, uses ground values.

Programmatic Use
Block Parameter: `Interpolate`
Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

`Connect Input` — Tool to help map signals to inports

button

To import, visualize, and map signal and bus data to root-level inports, click this button. The Root Inport Mapper tool displays.

Dependency

This button appears only if this block is a root inport block.

Signal Attributes

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

`Output function call` — Output function-call trigger signal

`off` (default) | `on`

Specify that the input signal outputs a function-call trigger signal.

Select this option if it is necessary for a current model to accept a function-call trigger signal when referenced in the top model.

Dependency

Enabled in an asynchronous function call.

`Minimum` — Minimum output value

[ ] (default) | scalar

Lower value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Maximum` — Maximum output value

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Data type` — Output data type

`Inherit: auto` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class name>` | `Bus: <object name>` | `<data type expression>`

Specify the output data type of the external input. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. Do not specify a bus object as the expression.

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Output as nonvirtual bus in parent model` — Outport as nonvirtual bus in parent model

`off` (default) | `on`

Specify the outport bus to be nonvirtual in the parent model. Select this parameter if you want the bus emerging in the parent model to be nonvirtual. The bus that is input to the port can be virtual or nonvirtual, regardless of the setting of **Output as nonvirtual bus in parent model**.

Clear this parameter if you want the bus emerging in the parent model to be virtual.

Tips

- In a nonvirtual bus, all signals must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. For details, see “Connect Multirate Buses to Referenced Models”.
- For a virtual bus, to use a multirate signal, in the root-level Outport block, set the **Sample time** parameter to inherited (`-1`).
- For the top model in a model reference hierarchy, code generation creates a C structure to represent the bus signal output by this block.
- For referenced models, select this option to create a C structure. Otherwise, code generation creates an argument for each leaf element of the bus.

Dependency

To enable this parameter, select **Data type** > `Bus: <object name>`.

Programmatic Use

Block Parameter: `BusOutputAsStruct`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Unit (e.g., m, m/s^2, N*m)` — Physical unit of the input signal to the block

`inherit` (default) | `<Enter unit>`

Specify the physical unit of the input signal to the block. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.

- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

Programmatic Use
Block Parameter: `Unit`
Type: character vector
Values: `'inherit'` | `'<Enter unit>'`
Default: `'inherit'`

`Port dimensions (-1 for inherited)` — Port dimensions

`-1` (default) | integer | [integer, integer]

Specify the dimensions that a signal must have to be connected to this Outport block.

`-1`	A signal of any dimensions can be connected to this port.
`N`	The signal connected to this port must be a vector of size `N`.
`[R C]`	The signal connected to this port must be a matrix having `R` rows and `C` columns.

Programmatic Use
Block Parameter: `PortDimensions`
Type: character vector
Values: `'-1'` | integer | [integer, integer]
Default: `'-1'`

`Variable-size signal` — Allow variable-size signals

`Inherit` (default) | `No` | `Yes`

Specify the type of signals allowed out of this port. To allow variable-size and fixed-size signals, select `Inherit`. To allow only variable-size signals, select `Yes`. Not to allow variable-size signals, select `No`.

Dependencies

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

Command-Line Information
Parameter: `VarSizeSig`
Type: character vector

Value: `'Inherit'` | `'No'` | `'Yes'`
Default: `'Inherit'`

`Sample time (-1 for inherited)` — Specify sample time

`-1` (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

`Signal type` — Output signal type

`auto` (default) | `real` | `complex`

Specify the numeric type of the signal output. To choose the numeric type of the signal that is connected to its input, select `auto`. Otherwise, choose a real or complex signal type.

Programmatic Use
Block Parameter: `SignalType`
Type: character vector
Values: `'auto'` | `'real'` | `'complex'`
Default: `'auto'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`

Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

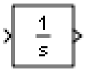
Integrator

Integrate signal
Library: Simulink / Commonly Used Blocks
Simulink / Continuous



Description

The Integrator block outputs the value of the integral of its input signal with respect to time.

Simulink treats the Integrator block as a dynamic system with one state. The block dynamics are given by:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(t_0) = x_0$$

where:

- u is the block input.
- y is the block output.
- x is the block state.
- x_0 is the initial condition of x.

While these equations define an exact relationship in continuous time, Simulink uses numerical approximation methods to evaluate them with finite precision. Simulink can use several different numerical integration methods to compute the output of the block, each with advantages in particular applications. Use the **Solver** pane of the Configuration Parameters dialog box (see “Solver Pane”) to select the technique best suited to your application.

The selected solver computes the output of the Integrator block at the current time step, using the current input value and the value of the state at the previous time step. To support this computational model, the Integrator block saves its output at the current time step for use by the solver to compute its output at the next time step. The block also provides the solver with an initial condition for use in computing the block's initial state at the beginning of a simulation. The default value of the initial condition is 0. Use the block parameter dialog box to specify another value for the initial condition or create an initial value input port on the block.

Use the parameter dialog box to:

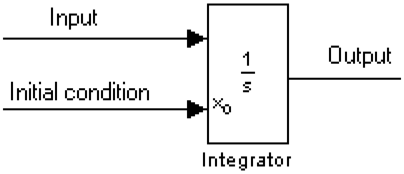
- Define upper and lower limits on the integral
- Create an input that resets the block's output (state) to its initial value, depending on how the input changes
- Create an optional state output so that the value of the block's output can trigger a block reset

Use the Discrete-Time Integrator block to create a purely discrete system.

Defining Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, specify the **Initial condition source** parameter as `internal` and enter the value in the **Initial condition** field.
- To provide the initial conditions from an external source, specify the **Initial condition source** parameter as `external`. An additional input port appears under the block input.



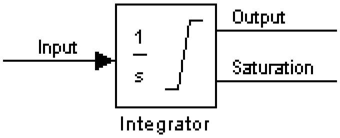
Note If the integrator limits its output (see “Limiting the Integral” on page 1-982), the initial condition must fall inside the integrator's saturation limits. If the initial condition is outside the block saturation limits, the block displays an error message.

Limiting the Integral

To prevent the output from exceeding specifiable levels, select the **Limit output** check box and enter the limits in the appropriate parameter fields. This action causes the block to function as a limited integrator. When the output reaches the limits, the integral action is turned off to prevent integral wind up. During a simulation, you can change the limits but you cannot change whether the output is limited. The block determines output as follows:

- When the integral is less than or equal to the **Lower saturation limit**, the output is held at the **Lower saturation limit**.
- When the integral is between the **Lower saturation limit** and the **Upper saturation limit**, the output is the integral.
- When the integral is greater than or equal to the **Upper saturation limit**, the output is held at the **Upper saturation limit**.

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A saturation port appears below the block output port.



The signal has one of three values:

- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- –1 indicates that the lower limit is being applied.

When you select this check box, the block has three zero crossings: one to detect when it enters the upper saturation limit, one to detect when it enters the lower saturation limit, and one to detect when it leaves saturation.

Note For the Integrator Limited block, by default, **Limit output** is selected, **Upper saturation limit** is set to `1`, and **Lower saturation limit** is set to `0`.

Wrapping Cyclic States

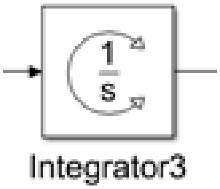
Several physical phenomena are cyclic, periodic, or rotary in nature. Objects or machinery that exhibit rotational movement and oscillators are examples of such phenomena.

Modeling these phenomena in Simulink involves integrating the rate of change of the periodic or cyclic signals to obtain the state of the movement.

The drawback with this approach, however, is that over long simulation time spans, the states representing periodic or cyclic signals integrate to large values. Further, computing the sine or cosine of these signals takes an increasingly large amount of time because of angle reduction. The large signals values also negatively impact solver performance and accuracy.

One approach for overcoming this drawback is to reset the angular state to `0` when it reaches 2π (or to –π when it reaches π, for numerical symmetry). This approach improves the accuracy of sine and cosine computations and reduces angle reduction time. But it also requires zero-crossing detection and introduces solver resets, which slow down the simulation for variable step solvers, particularly in large models.

To eliminate solver resets at wrap points, the Integrator block supports wrapped states that you can enable by checking **Wrap state** on the block parameter dialog box. When you enable **Wrap state**, the block icon changes to indicate that the block has wrapping states.



Simulink allows wrapping states that are bounded by upper and lower values parameters of the wrapped state. The algorithm for determining wrapping states is given by:

$$y = \begin{cases} x & x \in [x_l, x_u) \\ x - (x_u - x_l)\left\lfloor \dfrac{x - x_l}{x_u - x_l} \right\rfloor & \text{otherwise} \end{cases}$$

where:

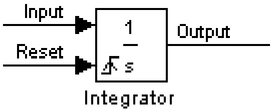
- x_l is the lower value of the wrapped state.
- x_u is the upper value of the wrapped state.
- y is the output.

The support for wrapping states provides these advantages.

- It eliminates simulation instability when your model approaches large angles and large state values.
- It reduces the number of solver resets during simulation and eliminates the need for zero-crossing detection, improving simulation time.
- It eliminates large angle values, speeding up computation of trigonometric functions on angular states.
- It improves solver accuracy and performance and enables unlimited simulation time.

Resetting the State

The block can reset its state to the specified initial condition based on an external signal. To cause the block to reset its state, select one of the **External reset** choices. A trigger port appears below the block's input port and indicates the trigger type.



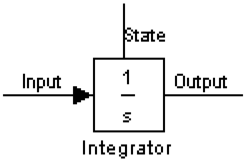
- Select `rising` to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select `falling` to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select `either` to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select `level` to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select `level hold` to reset the state when the reset signal is nonzero at the current time step.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loops”). Use the Integrator block's state port to feed back the block's output without creating an algebraic loop.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of Integrator blocks.

About the State Port

Selecting the **Show state port** check box on the Integrator block's parameter dialog box causes an additional output port, the state port, to appear at the top of the Integrator block.



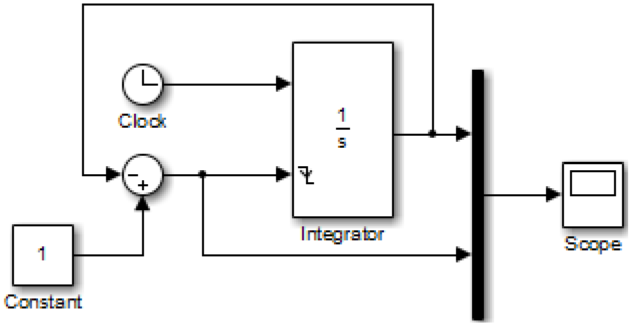
The output of the state port is the same as the output of the block's standard output port except for the following case. If the block is reset in the current time step, the output of the state port is the value that would have appeared at the block's standard output if the block had not been reset. The state port's output appears earlier in the time step than the output of the Integrator block's output port. Use the state port to avoid creating algebraic loops in these modeling scenarios:

- Self-resetting integrators (see “Creating Self-Resetting Integrators” on page 1-986)
- Handing off a state from one enabled subsystem to another (see “Handing Off States Between Enabled Subsystems” on page 1-987)

Note When updating a model, Simulink checks that the state port applies to one of these two scenarios. If not, an error message appears. Also, you cannot log the output of this port in a referenced model that executes in Accelerator mode. If logging is enabled for the port, Simulink generates a "signal not found" warning during execution of the referenced model.

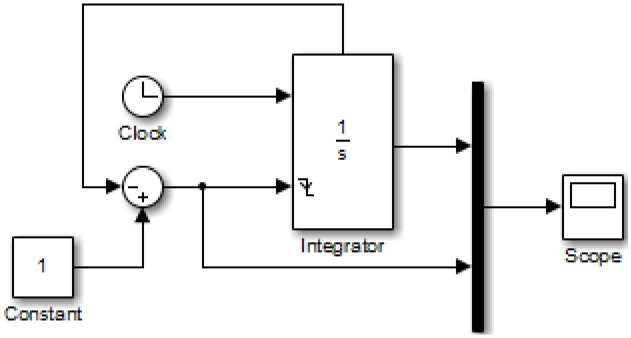
Creating Self-Resetting Integrators

The Integrator block's state port helps you avoid an algebraic loop when creating an integrator that resets itself based on the value of its output. Consider, for example, the following model.



This model tries to create a self-resetting integrator by feeding the integrator's output, subtracted from 1, back into the integrator's reset port. However, the model creates an algebraic loop. To compute the integrator block's output, Simulink software needs to know the value of the block's reset signal, and vice versa. Because the two values are mutually dependent, Simulink software cannot determine either. Therefore, an error message appears if you try to simulate or update this model.

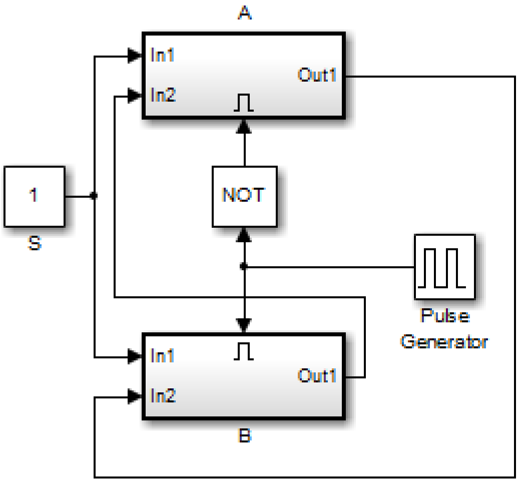
The following model uses the integrator's state port to avoid the algebraic loop.



In this version, the value of the reset signal depends on the value of the state port. The value of the state port is available earlier in the current time step than the value of the integrator block's output port. Therefore, Simulink can determine whether the block needs to be reset before computing the block's output, thereby avoiding the algebraic loop.

Handing Off States Between Enabled Subsystems

The state port helps you avoid an algebraic loop when passing a state between two enabled subsystems. Consider, for example, the following model.



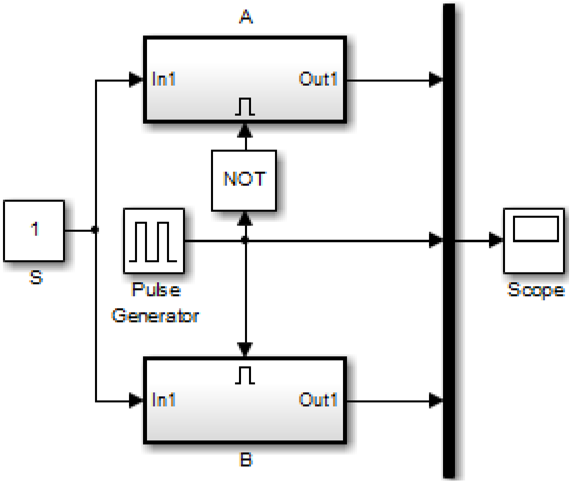
The enabled subsystems, A and B, contain the following blocks:

Subsystem A	Subsystem B
 Enable 1 In1 2 In2 1/s x0 Integrator 1 Out1	 Enable 1 In1 -1 Gain 2 In2 1/s x0 Integrator 1 Out1

In this model, a constant input signal drives two enabled subsystems that integrate the signal. A pulse generator generates an enabling signal that causes execution to alternate between the two subsystems. The enable port of each subsystem is set to reset, which causes the subsystem to reset its integrator when it becomes active. Resetting the integrator causes the integrator to read the value of its initial condition port. The initial condition port of the integrator in each subsystem is connected to the output port of the integrator in the other subsystem.

This connection is intended to enable continuous integration of the input signal as execution alternates between two subsystems. However, the connection creates an algebraic loop. To compute the output of A, Simulink needs to know the output of B, and vice versa. Because the outputs are mutually dependent, Simulink cannot compute the output values. Therefore, an error message appears if you try to simulate or update this model.

The following version of the same model uses the integrator state port to avoid creating an algebraic loop when handing off the state.



The enabled subsystems, A and B, contain the following blocks:

Subsystem A	Subsystem B
 Enable 1 In1 B From 1/s xo Integrator A Goto 1 Out1	 Enable 1 In1 -1 Gain A From 1/s xo Integrator B Goto 1 Out1

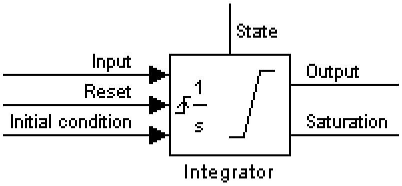
In this model, the initial condition of the integrator in A depends on the value of the state port of the integrator in B, and vice versa. The values of the state ports are updated earlier in the simulation time step than the values of the integrator output ports. Therefore, Simulink can compute the initial condition of either integrator without knowing the final output value of the other integrator. For another example of using the state port to hand off states between conditionally executed subsystems, see the `sldemo_clutch` model.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the Integrator block. If this value does not provide sufficient error control, specify a more appropriate value in the **Absolute tolerance** field of the Integrator block dialog box. The value that you specify is used to compute all the block outputs.

Selecting All Options

When you select all options, the block icon looks like this.



Ports

The Integrator block accepts and outputs signals of type `double` on its data ports. The external reset port accepts signals of type `double` or `Boolean`.

Input

`Port_1` — Integrand signal

real scalar or array

Signal that needs to be integrated.

Data Types: `double`

`External Reset` — Reset state to initial conditions

real scalar or array

Reset the state to the specified initial conditions based on an external signal. See "Resetting the State" on page 1-984.

Dependencies

To enable this port, enable the **External Reset** parameter.

Data Types: `Boolean`

x_0 — Initial condition

real scalar or array

Set the initial condition of the block's state from an external signal.

Dependencies

To enable this port, set the **Initial Conditions** parameter to `external`.

Data Types: `double`

Output

`Port_1` — Output signal

real scalar or array

Output the integrated state.

Data Types: `double`

`Port_2` — Show output saturation

-1 | 0 | 1

Indicate when the state is being limited. The signal has a value of `1` when the integral is limited by the specified **Upper saturation limit**. When the signal is limited by the **Lower saturation limit**, the signal value is `-1`. When the integral is between the saturation limits, the signal value is `0`. See “Limiting the Integral” on page 1-982.

Data Types: `double`

`Port_3` — State

real scalar or array

Output the state of the block. See “About the State Port” on page 1-985.

Dependencies

Enable this port by enabling the **Show state port** parameter.

Data Types: `double`

Parameters

`External reset` — Reset states to their initial conditions

`none` (default) | `rising` | `falling` | `either` | `level` | `level hold`

Specify the type of trigger to use for the external reset signal.

- Select `rising` to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select `falling` to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select `either` to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select `level` to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select `level hold` to reset the state when the reset signal is nonzero at the current time step.

Programmatic Use
Block Parameter: `ExternalReset`
Type: character vector , string
Values: `'none'` | `'rising'` | `'falling'` | `'either'` | `'level'` | `'level hold'`
Default: `'none'`

`Initial condition source` — Select source of initial condition

`internal` (default) | `external`

Select source of initial condition:

- `internal` — Get the initial conditions of the states from the **Initial condition** block parameter.
- `external` — Get the initial conditions of the states from an external block, via the **IC** input port.

Dependencies

Selecting `internal` enables the **Initial condition** parameter.

Selecting `external` disables the **Initial condition** parameter and enables the **IC** input port.

Programmatic Use
Block Parameter: `InitialConditionSource`
Type: character vector, string
Values: `'internal'` | `'external'`
Default: `'internal'`

`Initial condition` — Initial state

0 (default) | real scalar or array

Set the initial state of the Integrator block.

Tips

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

Setting **Initial condition source** to `internal` enables this parameter.

Setting **Initial condition source** to `external` disables this parameter.

Programmatic Use

Block Parameter: `InitialCondition`
Type: scalar or vector
Default: `'0'`

`Limit output` — Limit block output values to specified range

`off` (default for Integrator) | `on` (default for Integrator Limited)

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block output values.

Dependencies

Selecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use

Block Parameter: `LimitOutput`
Type: character vector , string
Values: `'off'` | `'on'`
Default: `'off'`

`Upper saturation limit` — Upper limit for the integral

`inf` (default) | scalar | vector | matrix

Specify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: `UpperSaturationLimit`
Type: character vector, string
Values: scalar | vector | matrix
Default: `'inf'`

`Lower saturation limit` — Lower limit for the integral

`-inf` (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: `LowerSaturationLimit`
Type: character vector , string
Values: scalar | vector | matrix
Default: `'-inf'`

`Wrap state` — Enable wrapping of states

`off` (default) | `on`

Enable wrapping of states between the **Wrapped state upper value** and **Wrapped state lower value** parameters. Enabling wrap states eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped state upper value** as `inf` and **Wrapped state lower value** as `-inf`, wrapping does not occur.

Dependencies

Selecting this parameter enables **Wrapped state upper value** and **Wrapped state lower value** parameters.

Programmatic Use

Block Parameter: `WrapState`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'off'`

`Wrapped state upper value` — Specify upper value for wrapped state

`pi` (default) | scalar or vector

Upper limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use
Block Parameter: `WrappedStateUpperValue`
Type: scalar or vector
Values: `'2*pi'`
Default: `'pi'`

`Wrapped state lower value` — Specify lower value for wrap state

`-pi` (default) | scalar or vector

Lower limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use
Block Parameter: `WrappedStateLowerValue`
Type: scalar or vector
Values: `'0'`
Default: `'-pi'`

`Show saturation port` — Enable saturation output port

`off` (default) | `on`

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use
Block Parameter: `ShowSaturationPort`
Type: character vector , string
Values: `'off'` | `'on'`
Default: `'off'`

`Show state port` — Enable state output port

`off` (default) | `on`

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use

Block Parameter: `ShowStatePort`
Type: character vector , string
Values: `'off'` | `'on'`
Default: `'off'`

`Absolute tolerance` — Absolute tolerance for block states

`auto` (default) | `real scalar or vector`

- If you enter `auto` or –1, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use

Block Parameter: `AbsoluteTolerance`
Type: character vector, string, scalar, or vector
Values: `'auto'` | `'-1'` | any positive real scalar or vector
Default: `'auto'`

`Ignore limit and reset when linearizing` — Treat block as unresettable and output unlimited

`off` (default) | `on`

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the reset and output limitation options of the block.

Tip

Use this check box to linearize a model around an operating point that causes the integrator to reset or saturate.

Programmatic Use

Block Parameter: `IgnoreLimit`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'off'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

`State Name (e.g., 'position')` — Assign unique name to each state

`' '` (default) | character vector | string

- To assign a name to a single state, enter the name between quotes, for example, `'velocity'`.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

  For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Programmatic Use

Block Parameter: `ContinuousStateAttributes`
Type: character vector, string
Values: `' '` | user-defined

Default: `' '`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`Yes`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

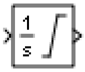
Integrator Limited

Integrate signal

Library: Simulink / Continuous



Description

The Integrator Limited block is identical to the Integrator block with the exception that the output of the block is limited based on the upper and lower saturation limits. See “Limiting the Integral” on page 1-1002 for details.

Simulink treats the Integrator block as a dynamic system with one state. The block dynamics are given by:

$$\begin{cases} \dot{x}(t) = u(t) \\ y(t) = x(t) \end{cases} \quad x(t_0) = x_0$$

where:

- *u* is the block input.
- *y* is the block output.
- *x* is the block state.
- x_0 is the initial condition of *x*.

While these equations define an exact relationship in continuous time, Simulink uses numerical approximation methods to evaluate them with finite precision. Simulink can use several different numerical integration methods to compute the output of the block, each with advantages in particular applications. Use the **Solver** pane of the Configuration Parameters dialog box (see “Solver Pane”) to select the technique best suited to your application.

The selected solver computes the output of the Integrator block at the current time step, using the current input value and the value of the state at the previous time step. To support this computational model, the Integrator block saves its output at the current time step for use by the solver to compute its output at the next time step. The block also provides the solver with an initial condition for use in computing the block's initial state at the beginning of a simulation. The default value of the initial condition is 0. Use the block parameter dialog box to specify another value for the initial condition or create an initial value input port on the block.

Use the parameter dialog box to:

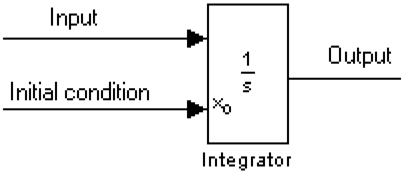
- Define upper and lower limits on the integral
- Create an input that resets the block's output (state) to its initial value, depending on how the input changes
- Create an optional state output so that the value of the block's output can trigger a block reset

Use the Discrete-Time Integrator block to create a purely discrete system.

Defining Initial Conditions

You can define the initial conditions as a parameter on the block dialog box or input them from an external signal:

- To define the initial conditions as a block parameter, specify the **Initial condition source** parameter as `internal` and enter the value in the **Initial condition** field.
- To provide the initial conditions from an external source, specify the **Initial condition source** parameter as `external`. An additional input port appears under the block input.



Note If the integrator limits its output (see "Limiting the Integral" on page 1-1002), the initial condition must fall inside the integrator's saturation limits. If the initial condition is outside the block saturation limits, the block displays an error message.

Wrapping Cyclic States

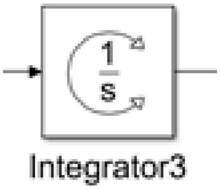
Several physical phenomena are cyclic, periodic, or rotary in nature. Objects or machinery that exhibit rotational movement and oscillators are examples of such phenomena.

Modeling these phenomena in Simulink involves integrating the rate of change of the periodic or cyclic signals to obtain the state of the movement.

The drawback with this approach, however, is that over long simulation time spans, the states representing periodic or cyclic signals integrate to large values. Further, computing the sine or cosine of these signals takes an increasingly large amount of time because of angle reduction. The large signals values also negatively impact solver performance and accuracy.

One approach for overcoming this drawback is to reset the angular state to `0` when it reaches 2π (or to –π when it reaches π, for numerical symmetry). This approach improves the accuracy of sine and cosine computations and reduces angle reduction time. But it also requires zero-crossing detection and introduces solver resets, which slow down the simulation for variable step solvers, particularly in large models.

To eliminate solver resets at wrap points, the Integrator block supports wrapped states that you can enable by checking **Wrap state** on the block parameter dialog box. When you enable **Wrap state**, the block icon changes to indicate that the block has wrapping states.



Simulink allows wrapping states that are bounded by upper and lower values parameters of the wrapped state. The algorithm for determining wrapping states is given by:

$$y = \begin{cases} x & x \in [x_l, x_u) \\ x - (x_u - x_l)\left\lfloor \dfrac{x - x_l}{x_u - x_l} \right\rfloor & \text{otherwise} \end{cases}$$

where:

- x_l is the lower value of the wrapped state.
- x_u is the upper value of the wrapped state.
- y is the output.

The support for wrapping states provides these advantages.

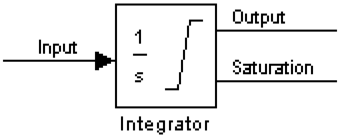
- It eliminates simulation instability when your model approaches large angles and large state values.
- It reduces the number of solver resets during simulation and eliminates the need for zero-crossing detection, improving simulation time.
- It eliminates large angle values, speeding up computation of trigonometric functions on angular states.
- It improves solver accuracy and performance and enables unlimited simulation time.

Limiting the Integral

To prevent the output from exceeding specifiable levels, select the **Limit output** check box and enter the limits in the appropriate parameter fields. This action causes the block to function as a limited integrator. When the output reaches the limits, the integral action is turned off to prevent integral wind up. During a simulation, you can change the limits but you cannot change whether the output is limited. The block determines output as follows:

- When the integral is less than or equal to the **Lower saturation limit**, the output is held at the **Lower saturation limit**.
- When the integral is between the **Lower saturation limit** and the **Upper saturation limit**, the output is the integral.
- When the integral is greater than or equal to the **Upper saturation limit**, the output is held at the **Upper saturation limit**.

To generate a signal that indicates when the state is being limited, select the **Show saturation port** check box. A saturation port appears below the block output port.



The signal has one of three values:

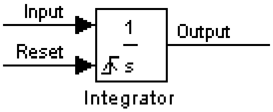
- 1 indicates that the upper limit is being applied.
- 0 indicates that the integral is not limited.
- –1 indicates that the lower limit is being applied.

When you select this check box, the block has three zero crossings: one to detect when it enters the upper saturation limit, one to detect when it enters the lower saturation limit, and one to detect when it leaves saturation.

Note For the Integrator Limited block, by default, **Limit output** is selected, **Upper saturation limit** is set to `1`, and **Lower saturation limit** is set to `0`.

Resetting the State

The block can reset its state to the specified initial condition based on an external signal. To cause the block to reset its state, select one of the **External reset** choices. A trigger port appears below the block's input port and indicates the trigger type.



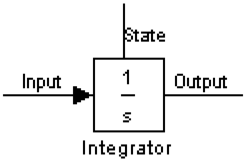
- Select `rising` to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select `falling` to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select `either` to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select `level` to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select `level hold` to reset the state when the reset signal is nonzero at the current time step.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loops”). Use the Integrator block's state port to feed back the block's output without creating an algebraic loop.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of Integrator blocks.

About the State Port

Selecting the **Show state port** check box on the Integrator block's parameter dialog box causes an additional output port, the state port, to appear at the top of the Integrator block.



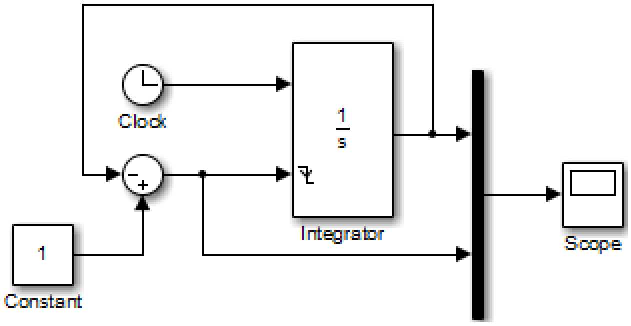
The output of the state port is the same as the output of the block's standard output port except for the following case. If the block is reset in the current time step, the output of the state port is the value that would have appeared at the block's standard output if the block had not been reset. The state port's output appears earlier in the time step than the output of the Integrator block's output port. Use the state port to avoid creating algebraic loops in these modeling scenarios:

- Self-resetting integrators (see “Creating Self-Resetting Integrators” on page 1-1005)
- Handing off a state from one enabled subsystem to another (see “Handing Off States Between Enabled Subsystems” on page 1-1006)

Note When updating a model, Simulink checks that the state port applies to one of these two scenarios. If not, an error message appears. Also, you cannot log the output of this port in a referenced model that executes in Accelerator mode. If logging is enabled for the port, Simulink generates a "signal not found" warning during execution of the referenced model.

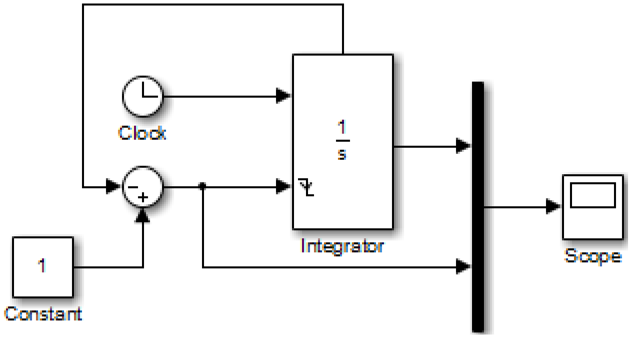
Creating Self-Resetting Integrators

The Integrator block's state port helps you avoid an algebraic loop when creating an integrator that resets itself based on the value of its output. Consider, for example, the following model.



This model tries to create a self-resetting integrator by feeding the integrator's output, subtracted from 1, back into the integrator's reset port. However, the model creates an algebraic loop. To compute the integrator block's output, Simulink software needs to know the value of the block's reset signal, and vice versa. Because the two values are mutually dependent, Simulink software cannot determine either. Therefore, an error message appears if you try to simulate or update this model.

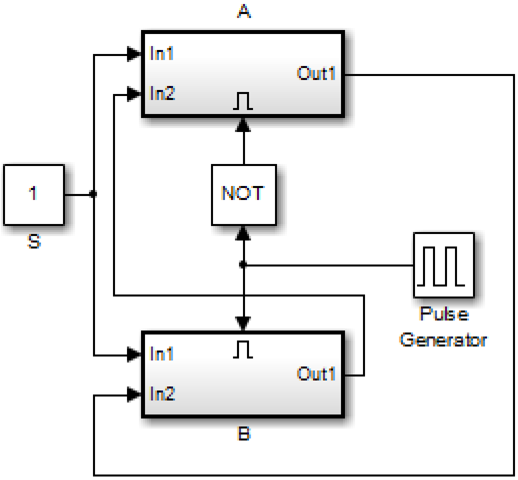
The following model uses the integrator's state port to avoid the algebraic loop.



In this version, the value of the reset signal depends on the value of the state port. The value of the state port is available earlier in the current time step than the value of the integrator block's output port. Therefore, Simulink can determine whether the block needs to be reset before computing the block's output, thereby avoiding the algebraic loop.

Handing Off States Between Enabled Subsystems

The state port helps you avoid an algebraic loop when passing a state between two enabled subsystems. Consider, for example, the following model.



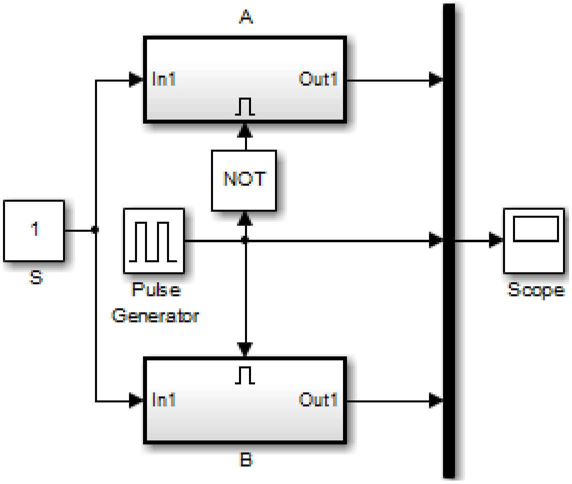
The enabled subsystems, A and B, contain the following blocks:

Subsystem A	Subsystem B
 Enable 1 In1 2 In2 1/s x0 Integrator 1 Out1	 Enable 1 In1 -1 Gain 2 In2 1/s x0 Integrator 1 Out1

In this model, a constant input signal drives two enabled subsystems that integrate the signal. A pulse generator generates an enabling signal that causes execution to alternate between the two subsystems. The enable port of each subsystem is set to reset, which causes the subsystem to reset its integrator when it becomes active. Resetting the integrator causes the integrator to read the value of its initial condition port. The initial condition port of the integrator in each subsystem is connected to the output port of the integrator in the other subsystem.

This connection is intended to enable continuous integration of the input signal as execution alternates between two subsystems. However, the connection creates an algebraic loop. To compute the output of A, Simulink needs to know the output of B, and vice versa. Because the outputs are mutually dependent, Simulink cannot compute the output values. Therefore, an error message appears if you try to simulate or update this model.

The following version of the same model uses the integrator state port to avoid creating an algebraic loop when handing off the state.



The enabled subsystems, A and B, contain the following blocks:

Subsystem A	Subsystem B
 Enable 1 In1 B From 1 s x0 Integrator A Goto 1 Out1	 Enable 1 In1 -1 Gain A From 1 s x0 Integrator B Goto 1 Out1

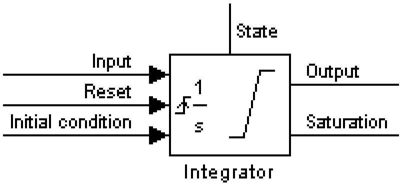
In this model, the initial condition of the integrator in A depends on the value of the state port of the integrator in B, and vice versa. The values of the state ports are updated earlier in the simulation time step than the values of the integrator output ports. Therefore, Simulink can compute the initial condition of either integrator without knowing the final output value of the other integrator. For another example of using the state port to hand off states between conditionally executed subsystems, see the `sldemo_clutch` model.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the Integrator block. If this value does not provide sufficient error control, specify a more appropriate value in the **Absolute tolerance** field of the Integrator block dialog box. The value that you specify is used to compute all the block outputs.

Selecting All Options

When you select all options, the block icon looks like this.



Ports

Input

`Port_1` — Integrand signal

real scalar or array

Signal that needs to be integrated.

Data Types: `double`

`External Reset` — Reset state to initial conditions

real scalar or array

Reset the state to the specified initial conditions based on an external signal. See "Resetting the State" on page 1-1003.

Dependencies

To enable this port, enable the **External Reset** parameter.

Data Types: `Boolean`

x_0 — Initial condition

real scalar or array

Set the initial condition of the block's state from an external signal.

Dependencies

To enable this port, set the **Initial Conditions** parameter to `external`.

Data Types: `double`

Output

`Port_1` — Output signal

real scalar or array

Output the integrated state.

Data Types: `double`

`Port_2` — Show output saturation

-1 | 0 | 1

Indicate when the state is being limited. The signal has a value of `1` when the integral is limited by the specified **Upper saturation limit**. When the signal is limited by the **Lower saturation limit**, the signal value is `-1`. When the integral is between the saturation limits, the signal value is `0`. See “Limiting the Integral” on page 1-1002.

Data Types: `double`

`Port_3` — State

real scalar or array

Output the state of the block. See “About the State Port” on page 1-1004.

Dependencies

Enable this port by enabling the **Show state port** parameter.

Data Types: `double`

Parameters

`External reset` — Reset states to their initial conditions

`none` (default) | `rising` | `falling` | `either` | `level` | `level hold`

Specify the type of trigger to use for the external reset signal.

- Select `rising` to reset the state when the reset signal rises from a negative or zero value to a positive value.
- Select `falling` to reset the state when the reset signal falls from a positive value to a zero or negative value.
- Select `either` to reset the state when the reset signal changes from zero to a nonzero value, from a nonzero value to zero, or changes sign.
- Select `level` to reset the state when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.
- Select `level hold` to reset the state when the reset signal is nonzero at the current time step.

Programmatic Use

Block Parameter: `ExternalReset`
Type: character vector , string
Values: `'none'` | `'rising'` | `'falling'` | `'either'` | `'level'` | `'level hold'`
Default: `'none'`

`Initial condition source` — Select source of initial condition

`internal` (default) | `external`

Select source of initial condition:

- `internal` — Get the initial conditions of the states from the **Initial condition** block parameter.
- `external` — Get the initial conditions of the states from an external block, via the **IC** input port.

Dependencies

Selecting `internal` enables the **Initial condition** parameter.

Selecting `external` disables the **Initial condition** parameter and enables the **IC** input port.

Programmatic Use

Block Parameter: `InitialConditionSource`
Type: character vector, string
Values: `'internal'` | `'external'`
Default: `'internal'`

`Initial condition` — Initial state

0 (default) | real scalar or array

Set the initial state of the Integrator block.

Tips

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

Setting **Initial condition source** to `internal` enables this parameter.

Setting **Initial condition source** to `external` disables this parameter.

Programmatic Use

Block Parameter: `InitialCondition`
Type: scalar or vector
Default: `'0'`

`Limit output` — Limit block output values to specified range

`off` (default for Integrator) | `on` (default for Integrator Limited)

Limit the block's output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.

- Selecting this check box limits the block output to a value between the **Lower saturation limit** and **Upper saturation limit** parameters.
- Clearing this check box does not limit the block output values.

Dependencies

Selecting this parameter enables the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use

Block Parameter: `LimitOutput`
Type: character vector , string
Values: `'off'` | `'on'`
Default: `'off'`

`Upper saturation limit` — Upper limit for the integral

`inf` (default) | scalar | vector | matrix

Specify the upper limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: `UpperSaturationLimit`
Type: character vector, string
Values: scalar | vector | matrix
Default: `'inf'`

`Lower saturation limit` — Lower limit for the integral

`-inf` (default) | scalar | vector | matrix

Specify the lower limit for the integral as a scalar, vector, or matrix. You must specify a value between the **Output minimum** and **Output maximum** parameter values.

Dependencies

To enable this parameter, select the **Limit output** check box.

Programmatic Use

Block Parameter: `LowerSaturationLimit`
Type: character vector , string
Values: scalar | vector | matrix
Default: `'-inf'`

`Wrap state` — Enable wrapping of states

`off` (default) | `on`

Enable wrapping of states between the **Wrapped state upper value** and **Wrapped state lower value** parameters. Enabling wrap states eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped state upper value** as `inf` and **Wrapped state lower value** as `-inf`, wrapping does not occur.

Dependencies

Selecting this parameter enables **Wrapped state upper value** and **Wrapped state lower value** parameters.

Programmatic Use

Block Parameter: `WrapState`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'off'`

`Wrapped state upper value` — Specify upper value for wrapped state

`pi` (default) | scalar or vector

Upper limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use
Block Parameter: `WrappedStateUpperValue`
Type: scalar or vector
Values: `'2*pi'`
Default: `'pi'`

`Wrapped state lower value` — Specify lower value for wrap state

`-pi` (default) | scalar or vector

Lower limit of the block output.

Dependencies

Selecting **Wrap state** enables this parameter.

Programmatic Use
Block Parameter: `WrappedStateLowerValue`
Type: scalar or vector
Values: `'0'`
Default: `'-pi'`

`Show saturation port` — Enable saturation output port

`off` (default) | `on`

Select this check box to add a saturation output port to the block. When you clear this check box, the block does not have a saturation output port.

Dependencies

Selecting this parameter enables a saturation output port.

Programmatic Use
Block Parameter: `ShowSaturationPort`
Type: character vector , string
Values: `'off'` | `'on'`
Default: `'off'`

`Show state port` — Enable state output port

`off` (default) | `on`

Select this check box to add a state output port to the block. When you clear this check box, the block does not have a state output port.

Dependencies

Selecting this parameter enables a state output port.

Programmatic Use

Block Parameter: `ShowStatePort`
Type: character vector , string
Values: `'off'` | `'on'`
Default: `'off'`

`Absolute tolerance` — Absolute tolerance for block states

`auto` (default) | `real scalar or vector`

- If you enter `auto` or –1, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see "Solver Pane") to compute block states.
- If you enter a real scalar, then that value overrides the absolute tolerance in the Configuration Parameters dialog box for computing all block states.
- If you enter a real vector, then the dimension of that vector must match the dimension of the continuous states in the block. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use

Block Parameter: `AbsoluteTolerance`
Type: character vector, string, scalar, or vector
Values: `'auto'` | `'-1'` | any positive real scalar or vector
Default: `'auto'`

`Ignore limit and reset when linearizing` — Treat block as unresettable and output unlimited

`off` (default) | `on`

Cause Simulink linearization commands to treat this block as unresettable and as having no limits on its output, regardless of the settings of the reset and output limitation options of the block.

Tip

Use this check box to linearize a model around an operating point that causes the integrator to reset or saturate.

Programmatic Use

Block Parameter: `IgnoreLimit`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'off'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

`State Name (e.g., 'position')` — Assign unique name to each state

`' '` (default) | character vector | string

- To assign a name to a single state, enter the name between quotes, for example, `'velocity'`.
- To assign names to multiple states, enter a comma-delimited list surrounded by braces, for example, `{'a', 'b', 'c'}`. Each name must be unique.
- The state names apply only to the selected block.
- The number of states must divide evenly among the number of state names.
- You can specify fewer names than states, but you cannot specify more names than states.

  For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, cell array, or structure.

Programmatic Use
Block Parameter: `ContinuousStateAttributes`
Type: character vector, string
Values: `' '` | user-defined

Default: `' '`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`Yes`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Consider discretizing the model
- Not recommended for production code

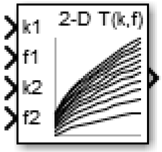
Interpolation Using Prelookup

Use precalculated index and fraction values to accelerate approximation of N-dimensional function

Library: Simulink / Lookup Tables



Description

The Interpolation Using Prelookup block is most efficient when used with the Prelookup block. The Prelookup block calculates the index and interval fraction that specify how its input value `u` relates to the breakpoint data set. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an *n*-dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n-D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility that can provide more efficient simulation and code generation. For more information, see “Efficiency of Performance”.

Supported Block Operations

To use the Interpolation Using Prelookup block, you specify a set of table data values directly on the dialog box or feed values into the **T** input port. Typically, these table values correspond to the breakpoint data sets specified in Prelookup blocks. The Interpolation Using Prelookup block generates output by looking up or estimating table values based on index and interval fraction values fed from Prelookup blocks. Labels for the index and interval fraction appear as `k` and `f` on the Interpolation Using Prelookup block icon.

When inputs for index and interval fraction...	The Interpolation Using Prelookup block...
Map to values in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not map to values in breakpoint data sets, but are within range	Interpolates appropriate table values using the **Interpolation method** you select
Do not map to values in breakpoint data sets, and are out of range	Extrapolates the output value using the **Extrapolation method** you select

How The Block Interpolates a Subset of Table Data

You can use the **Number of sub-table selection dimensions** parameter to specify that interpolation occur only on a subset of the table data. To activate this interpolation mode, set this parameter to a positive integer. This value defines the number of dimensions to select, starting from the highest dimension of table data for the default column-major algorithm. Therefore, the value must be less than or equal to the **Number of table dimensions**.

For row-major algorithms, the interpolation starts from the first or lowest dimension of the table data.

For nonzero values, the subtable selection behavior is optimized for row-major layout when you select the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter.

Suppose that you have 3-D table data in your Interpolation Using Prelookup block. This behavior applies for the column-major algorithm.

Number of Selection Dimensions	Action by the Block	Block Appearance
0	Interpolates the entire table and does not activate subtable selection	Does not change
1	Interpolates the first two dimensions and selects the third dimension	Displays an input port with the label `s3` that you use to select and interpolate 2-D tables

Number of Selection Dimensions	Action by the Block	Block Appearance
2	Interpolates the first dimension and selects the second and third dimensions	Displays two input ports with the labels s2 and s3 that you use to select and interpolate 1-D tables

Subtable selection uses zero-based indexing. For an example of interpolating a subset of table data, type `sldemo_bpcheck` at the MATLAB command prompt.

For 2-D or n-D interpolation without subtable selection, the column-major and row-major algorithms may differ in the order of output calculations, causing slight different numerical results.

Ports

Input

k1 — Index, k, for the first dimension of the table
scalar | vector | matrix

Zero-based index, k, specifying the interval containing the input u for the first dimension of the table.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

f1 — Fraction, f, for the first dimension of the table
scalar | vector | matrix

Fraction, f, representing the normalized position of the input within the interval, k, for the first dimension of the table.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

kn — Index, k, for the n-th dimension of the table
scalar | vector | matrix

Zero-based index, k, specifying the interval containing the input u for the n-th dimension of the table.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

fn — Fraction, f, for the n-th dimension of the table

scalar | vector | matrix

Fraction, f, representing the normalized position of the input within the interval, k, for the n-th dimension of the table.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

kf1 — Input containing index k and fraction f

bus object

Inputs to the **kf1** port contain index k and fraction f specified as a bus object.

Dependencies

To enable this port, select the **Require index and fraction as a bus** check box.

The number of available kf input ports depends on the value of the **Number of dimensions** and **Number of sub-table selection dimensions** parameters.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point | bus

kfn — Input containing index k and fraction f

bus object

Inputs to the **kfn** port contain index k and fraction f for the n-th dimension of the input, specified as a bus object.

Dependencies

To enable this port, select the **Require index and fraction as a bus** check box.

The number of available **kf** input ports depends on the value of the **Number of dimensions** and **Number of sub-table selection dimensions** parameters.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point | bus

`sm` — Select and interpolate a subset of the table data

scalar | vector | matrix

The block uses inputs to the s*m*, s*m*-1... port to perform selection and interpolation within the subtables. *m* equals the **Number of dimensions - Number of sub-table selection dimensions**.

Dependencies

To enable this port, the **Number of sub-table selection dimensions** must be a positive integer less than or equal to the **Number of dimensions**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`T` — Table data

scalar | vector | matrix | n-d array

Table data values provided as input to port **T**. Typically, these table values correspond to the breakpoint data sets specified in Prelookup blocks. The Interpolation Using Prelookup block generates output by looking up or estimating table values based on index (`k`) and interval fraction (`f`) values fed from Prelookup blocks.

Dependencies

To enable this port, set **Source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Approximation of N-dimensional function

scalar | vector | matrix

Approximation of N-dimensional function, computed by interpolating (or extrapolating) table data using values from the input index, `k`, and fraction, `f`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

Table data

`Number of dimensions` — Number of table data dimensions

2 (default) | integer between 1 and 30

Specify the number of dimensions that the table data must have. The **Number of dimensions** defines the number of independent variables for the table.

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use
Block Parameter: `NumberOfTableDimensions`
Type: character vector
Values: `'1' | '2' | '3' |'4' | ... | '30'`
Default: `'2'`

`Require index and fraction as bus` — Index and fraction inputs can be combined in a bus

`off` (default) | `on`

If you select this parameter, subtable selection ports continue to work in nonbus mode.

To enable the Prelookup block to supply input to the Interpolation Using Prelookup block, set:

- **Output selection** to `Index and fraction as bus`
- **Output** to `Bus: <object name>`, where `<object name>` must be a valid bus object name accessible to the model

Programmatic Use
Block Parameter: `RequireIndexFractionAsBus`

Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Specification` — Choose how to enter table data

`Explicit values` (default) | `Lookup table object`

Specify whether to enter table data directly or use a lookup table object. If you set this parameter to:

- `Explicit values`, the **Source** and **Value** parameters are visible on the dialog box.
- `Lookup table object`, the **Name** parameter is visible on the dialog box.

Programmatic Use

Block Parameter: `TableSpecification`
Type: character vector
Values: `'Explicit values' | 'Lookup table object'`
Default: `'Explicit values'`

`Source` — Source of table data

`Dialog` (default) | `Input port`

Specify whether to enter table data in the dialog box or to inherit the data from an input port. If you set **Source** to:

- `Dialog`, enter table data in the text box under **Value**
- `Input port`, verify that an upstream signal supplies table data to the table input port

Dependencies

To enable this parameter, set **Specification** to `Explicit values`.

Programmatic Use

Block Parameter: `TableSource`
Type: character vector
Values: `'Dialog' | 'Input port'`
Default: `'Dialog'`

`Value` — Specify table data values

`sqrt([1:11]' * [1:11])` (default) | multidimensional array of table data

Specify table data as an `N`-D array, where `N` is the value of the **Number of dimensions** parameter. You can edit the block diagram without specifying a correctly dimensioned matrix by entering an empty matrix (`[]`) or an undefined workspace variable in the **Value** edit field. For information about how to construct multidimensional arrays in MATLAB, see “Multidimensional Arrays” (MATLAB).

If you set **Source** to `Input port`, verify that an upstream signal supplies table data to the **T** input port. The size of table data must match the **Number of table dimensions**. For this option, the block inherits table attributes from the **T** input port.

To edit lookup tables using the Lookup Table Editor, click **Edit** (see “Edit Lookup Tables”).

Dependencies

To enable this parameter and explicitly specify table values on the dialog box, you must set **Specification** to `Explicit values` and **Source** to `Dialog`.

Programmatic Use

Block Parameter: `Table`
Type: character vector
Values: `scalar, vector, matrix, or N-D array`
Default: `'sqrt([1:11]' * [1:11])'`

Name — Name of an existing `Simulink.LookupTable` object

`Simulink.LookupTable object`

Specify the name of an existing `Simulink.LookupTable` object. An existing lookup table object references Simulink breakpoint objects.

Dependencies

To enable this parameter, set **Specification** to `Lookup table object`.

Programmatic Use

Block Parameter: `LookupTableObject`
Type: character vector
Value: `Simulink.LookupTable object`
Default: `''`

Algorithm

Interpolation method — Select `Linear point-slope`, `Flat`, `Nearest`, or `Linear Lagrange`

`Linear point-slope` (default) | `Nearest` | `Flat` | `Linear Lagrange`

Specify the method the block uses to interpolate table data. You can select `Linear point-slope`, `Flat`, `Nearest`, or `Linear Lagrange`. See “Interpolation Methods” for more information.

Programmatic Use
Block Parameter: `InterpMethod`
Type: character vector
Values: `'Flat' | 'Linear point-slope' | 'Nearest' | 'Linear Lagrange'`
Default: `'Linear point-slope'`

`Extrapolation method` — Method of handling input that falls outside the range of the breakpoint data set

`Linear` (default) | `Clip`

Specify the method the block uses to extrapolate values for all inputs that fall outside the range of the breakpoint data set. You can select `Clip` or `Linear`. See “Extrapolation Methods” for more information.

If the extrapolation method is `Linear`, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is Linear Lagrange, the extrapolation method inherits the Linear Lagrange equation to compute the extrapolated value.

Dependencies

To enable the **Extrapolation method** parameter, set the **Interpolation method** to `Linear`.

The Interpolation Using Prelookup block does not support `Linear` extrapolation when the input or output signals specify integer or fixed-point data types.

Programmatic Use
Block Parameter: `ExtrapMethod`
Type: character vector
Values: `'Clip' | 'Linear'`
Default: `'Linear'`

`Valid index input may reach last index` — Allow inputs to access the last elements of table data

`off` (default) | `on`

Specify how block inputs for index (`k`) and interval fraction (`f`) access the last elements of *n*-dimensional table data. Index values are zero based.

Check Box	Block Behavior
on	Returns the value of the last element in a dimension of its table when: • k indexes the last table element in the corresponding dimension • f is 0
off	Returns the value of the last element in a dimension of its table when: • k indexes the next-to-last table element in the corresponding dimension • f is 1

Dependencies

This check box is visible only when:

- **Interpolation method** is `Linear`
- **Extrapolation method** is `Clip`

Tip When you select **Valid index input may reach last index** for an Interpolation Using Prelookup block, you must also select **Use last breakpoint for input at or above upper limit** for all Prelookup blocks that feed it. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

Programmatic Use

Block Parameter: `ValidIndexMayReachLast`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Diagnostic for out-of-range input` — Block action when input is out of range

`None` (default) | `Warning` | `Error`

Specify whether to produce a warning or error when the input is out of range. Options include:

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use
Block Parameter: `DiagnosticForOutOfRangeInput`
Type: character vector
Values: `'None' | 'Warning' | 'Error'`
Default: `'None'`

`Number of sub-table selection dimensions` — Number of dimensions of the output computation subtable

`0` (default) | positive integer, less than or equal to the number of table dimensions

Specify the number of dimensions of the subtable that the block uses to compute the output. Follow these rules:

- To enable subtable selection, enter a positive integer.

  This integer must be less than or equal to the **Number of table dimensions**.
- To disable subtable selection, enter `0` to interpolate the entire table.

For nonzero values, the subtable selection behavior is optimized for row-major layout when you select the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter.

For more information, see “How The Block Interpolates a Subset of Table Data” on page 1-1019.

Programmatic Use
Block Parameter: `NumSelectionDims`
Type: character vector
Values: `'0' | '1' | '2' | '3' | '4' | ... | Number of table dimensions`
Default: `'0'`

Code generation

`Remove protection against out-of-range index in generated code` — Remove code that checks for out-of-range index inputs

`off` (default) | `on`

Check Box	Result	When to Use
`on`	Generated code does not include conditional statements to check for out-of-range index inputs. When the input `k` or `f` is out of range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
`off`	Generated code includes conditional statements to check for out-of-range index inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

1. Clear the **Remove protection against out-of-range index in generated code** check box.
2. Set the **Diagnostic for out-of-range input** parameter to `Error`.
3. Simulate the model in normal mode.
4. If there are out-of-range errors, fix them to be in range and run the simulation again.
5. When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input `k` or `f` is out of range, the behavior is undefined for generated code and simulations using accelerator mode.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks”.

This check box has no effect on the generated code when one of the following is true:

- The Prelookup block feeds index values to the Interpolation Using Prelookup block.

  Because index values from the Prelookup block are always valid, no check code is necessary.
- The data type of the input `k` restricts the data to valid index values.

  For example, unsigned integer data types guarantee nonnegative index values. Therefore, unsigned input values of `k` do not require check code for negative values.

Programmatic Use

Block Parameter: `RemoveProtectionIndex`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Data Types

`Table data` — Data type of table values

`Inherit: Same as output` (default) | `Inherit: Inherit from 'Table data'` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the table data type.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
- Sharing of prescaled table data between two Interpolation Using Prelookup blocks with different output data types
- Sharing of custom storage table data in Simulink Coder generated code for blocks with different output data types

---

Programmatic Use

Block Parameter: `TableDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit from table data'` | `'Inherit: Same as output'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Same as input'`

`Table minimum` — Minimum value of table data

`[]` (default) | scalar

Specify the minimum value for table data as a finite, real, double, scalar. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `TableMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Table maximum` — Maximum value of table data

`[]` (default) | scalar

Specify the maximum value for table data as a finite, real, double, scalar. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `TableMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Intermediate results` — Data type of intermediate results

`Inherit: Inherit via internal rule` (default) | `Inherit: Same as output` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher precision for internal computations than for table data or output data.

Programmatic Use
Block Parameter: `IntermediateResultsDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`
Default: `'Inherit: Same as input'`

`Output` — Output data type

`Inherit: Inherit from 'Table data'` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the output data type.

See “Control Signal Data Types” in the *Simulink User*'s *Guide* for more information.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'`
Default: `'Inherit: Inherit from table data'`

`Output minimum` — Minimum value the block can output

`[]` (default) | scalar

Specify the minimum value that the block should output as a finite, real-valued scalar. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Output maximum` — Maximum value the block can output

`[]` (default) | scalar

Specify the maximum value that the block should output as a finite, real-valued scalar. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Internal rule priority` — Internal rule for intermediate calculations

`Speed` (default) | `Precision`

Specify the internal rule for intermediate calculations. Select Speed for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use
Block Parameter: `InternalRulePriority`
Type: character vector
Values: `'Speed' | 'Precision'`
Default: `'Speed'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Convergent` | `Ceiling` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function in the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see “Supported Blocks” (HDL Coder).

Interpreted MATLAB Function

Apply MATLAB function or expression to input

Library: Simulink / User-Defined Functions

Description

The Interpreted MATLAB Function block applies the specified MATLAB function or expression to the input. The output of the function must match the output dimensions of the block.

Some valid expressions for this block are:

```
sin
atan2(u(1), u(2))
u(1)^u(2)
```

Note This block is slower than the Fcn block because it calls the MATLAB parser during each integration step. Consider using built-in blocks (such as the Fcn block or the Math Function block) instead. Alternatively, you can write the function as a MATLAB S-function or MEX-file S-function, then access it using the S-Function block.

Ports

Input

In — Input of a Interpreted MATLAB function

scalar | vector | matrix

The Interpreted MATLAB Function block accepts one real or complex input of type `double` and generates real or complex output of type `double`, depending on the setting of the **Output signal type** parameter.

Data Types: `double`

Output

`Out` — Output of a Interpreted MATLAB function

scalar | vector | matrix

The Interpreted MATLAB Function block accepts one real or complex input of type `double` and generates real or complex output of type `double`, depending on the setting of the **Output signal type** parameter.

Data Types: `double`

Parameters

`MATLAB Function` — Specify the function or expression

function (default)

Specify the function or expression. If you specify a function only, it is not necessary to include the input argument in parentheses.

`Output dimensions` — Specify the dimensions of the block output signal

scalar | matrix | vector | inherited

Specify the dimensions of the block output signal, for example, `2` for a two-element vector. The output dimensions must match the dimensions of the value returned by the function or expression in the **MATLAB function** field.

Specify `-1` to inherit the dimensions from the output of the specified function or expression. To determine the output dimensions, Simulink runs the function or expression once before simulation starts.

Note If you specify `-1` for this parameter and your function has persistent variables, then the variables might update before the simulation starts. If you need to use persistent variables, consider setting this parameter to a value other than `-1`.

`Output signal type` — Specify the block output signal type

auto (default) | real | complex

Specify the output signal type of the block as `real`, `complex`, or `auto`. A value of `auto` sets the output type to be the same as the type of the input signal.

`Collapse 2-D results to 1-D` — Output a 2-D array as a 1-D array
off (default) | on

Select this check box to output a 2-D array as a 1-D array containing the 2-D array's elements in column-major order.

`Sample time` — Specify sample time in the block
scalar

Note This parameter is not visible in the block dialog box unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

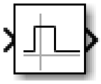
Fcn | MATLAB Function | MATLAB System

Introduced in R2011a

Interval Test

Determine if signal is in specified interval
Library: Simulink / Logic and Bit Operations



Description

The Interval Test block outputs true (1) if the input is between the values specified by the **Lower limit** and **Upper limit** parameters. The block outputs false (0) if the input is outside those values. The output of the block when the input is equal to the **Lower limit** or the **Upper limit** is determined by whether you select the **Interval closed on left** and **Interval closed on right** check boxes.

Ports

Input

Port_1 — Input signal
scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **Upper limit** and **Lower limit** values must be of the same enumerated type.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated

Output

Port_1 — Output signal
scalar | vector | matrix | N-D array

Output signal indicating whether the input values fall within the specified interval. You can specify the **Output data type** as `boolean` or `uint8`.

Data Types: `uint8` | `Boolean`

Parameters

`Interval closed on right` — Include upper limit value

`on` (default) | `off`

When you select this check box, the **Upper limit** is included in the interval for which the block outputs true (`1`).

Programmatic Use
Block Parameter: `IntervalClosedRight`
Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

`Upper limit` — Upper limit of interval

`0.5` (default) | scalar | vector | matrix | N-D array

The upper limit of the interval for which the block outputs true (`1`).

Programmatic Use
Block Parameter: `uplimit`
Type: character vector
Values: scalar | vector | matrix | N-D array
Default: `'0.5'`

`Interval closed on left` — Include lower limit value

`on` (default) | `off`

When you select this check box, the **Lower limit** is included in the interval for which the block outputs true (`1`).

Programmatic Use
Block Parameter: `IntervalClosedLeft`
Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

`Lower limit` — Lower limit of interval

`-0.5` (default) | scalar | vector | matrix | N-D array

The lower limit of the interval for which the block outputs true (`1`).

Programmatic Use
Block Parameter: `lowlimit`
Type: character vector
Values: scalar | vector | matrix | N-D array
Default: `'-0.5'`

`Output data type` — Output data type

`boolean` (default) | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean' | 'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

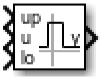
Interval Test Dynamic

Introduced before R2006a

Interval Test Dynamic

Determine if signal is in specified interval
Library: Simulink / Logic and Bit Operations



Description

The Interval Test Dynamic block outputs true (`1`) if the input is between the values of the external signals **up** and **lo**. The block outputs false (`0`) if the input is outside those values. To control how the block handles input values that are equal to the signal **lo** or the signal **up**, use the **Interval closed on left** and **Interval closed on right** check boxes.

Ports

Input

up — Upper limit of interval
scalar | vector | matrix | N-D array

Upper limit of interval, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

u — Input signal
scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

`lo` — Lower limit of interval

scalar | vector | matrix | N-D array

Lower limit of interval, specified as a scalar, vector, matrix, or N-D array.

Limitations

When the input signal is an enumerated type, the **up** and **lo** signals must be of the same enumerated type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

y — Output signal

scalar | vector | matrix | N-D array

Output signal indicating whether the input values fall within the specified interval. You can specify the **Output data type** as `boolean` or `uint8`.

Data Types: `uint8` | `Boolean`

Parameters

`Interval closed on right` — Include upper limit value

on (default) | `off`

When you select this check box, the value of the signal connected to the **up** input port is included in the interval for which the block outputs true (1).

Programmatic Use

Block Parameter: `IntervalClosedRight`
Type: character vector

Values: `'on' | 'off'`
Default: `'on'`

`Interval closed on left` — Include lower limit value

`on` (default) | `off`

When you select this check box, the value of the signal connected to the **lo** input port is included in the interval for which the block outputs true (`1`).

Programmatic Use
Block Parameter: `IntervalClosedLeft`
Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

`Output data type` — Output data type

`boolean` (default) | `uint8`

Specify the output data type as `boolean` or `uint8`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'boolean' | 'uint8'`
Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

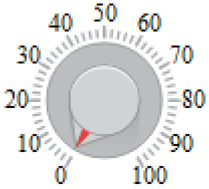
Interval Test

Introduced before R2006a

Knob

Tune parameter value with dial

Library: Simulink / Dashboard



Description

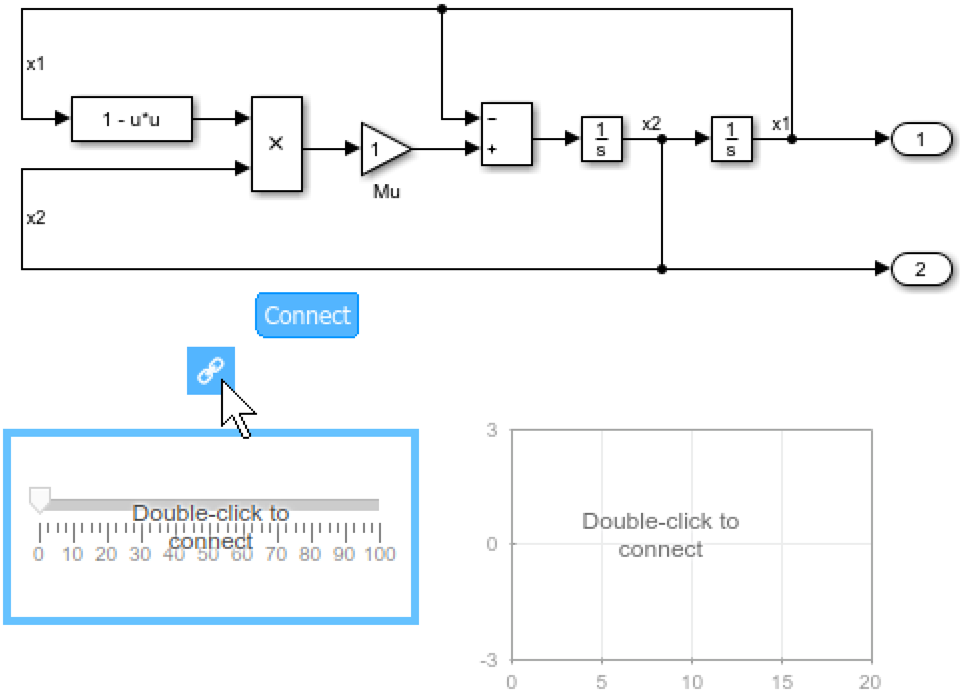
The Knob block tunes the value of the connected block parameter to during simulation. For example, you can connect the Knob block to a Gain block in your model and adjust its value during simulation. You can modify the range of the Knob block's scale to fit your data. Use the Knob block with other Dashboard blocks to create an interactive dashboard to control your model.

Connecting Dashboard Blocks

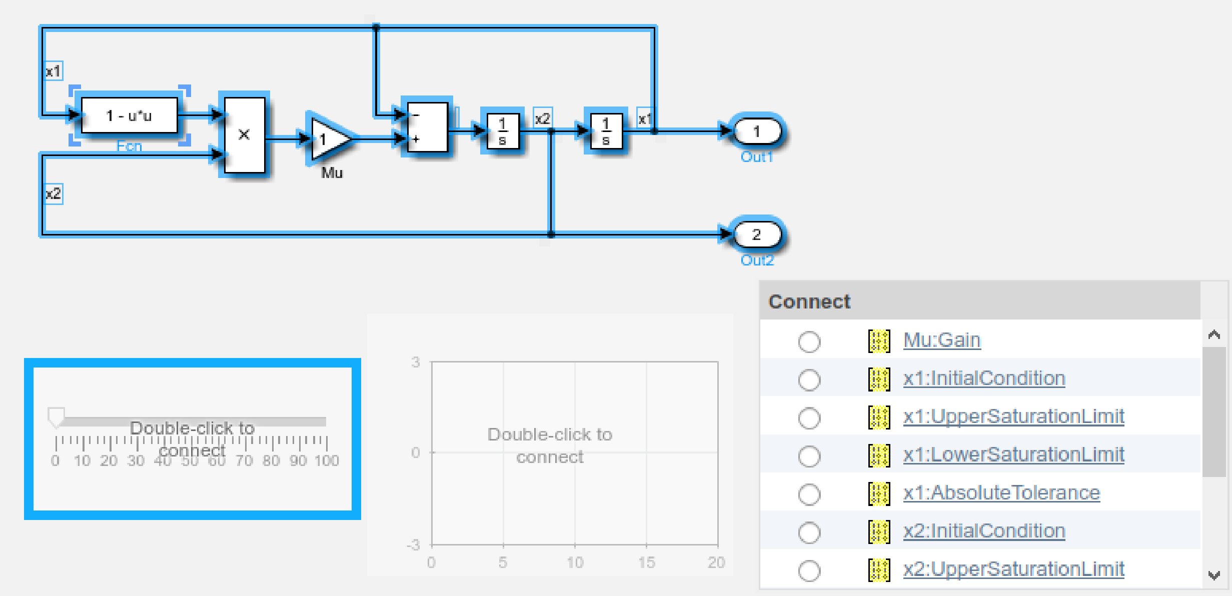
Dashboard blocks do not use ports to make connections. To connect Dashboard blocks to variables and block parameters in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

Note Dashboard blocks cannot connect to variables until you update your model diagram. To connect Dashboard blocks to variables or modify variable values between opening your model and running a simulation, update your model diagram using **Ctrl+D**.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

○	Mu:Gain
○	x1:InitialCondition
○	x1:UpperSaturationLimit
○	x1:LowerSaturationLimit
○	x1:AbsoluteTolerance
○	x2:InitialCondition
○	x2:UpperSaturationLimit

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Parameter Logging

Tunable parameters connected to Dashboard blocks are logged to the Simulation Data Inspector, where you can view parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector UI or by using the `Simulink.sdi.exportRun` function. For more information about exporting data with the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using

connect mode, the Dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. Populate the **Connection** table by selecting one or more blocks in your model. Select the radio button next to the variable or parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

`Scale Type` — Type of scale

'Linear' (default) | 'Log'

Type of scale displayed on the control. **Linear** specifies a linear scale, and **Log** specifies a logarithmic scale.

`Minimum` — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the arc. The minimum must be less than the value entered for the maximum.

`Maximum` — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the arc. The maximum must be greater than the value entered for the minimum.

`Tick Interval` — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the arc. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

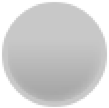
Lamp

Display color reflecting input value
Library: Simulink / Dashboard



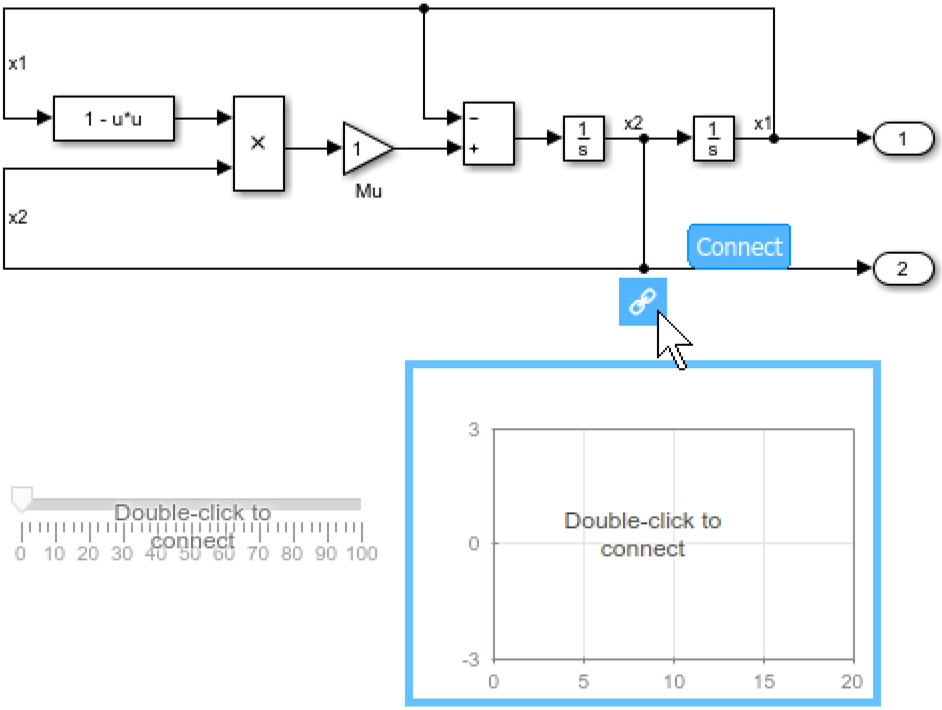
Description

The Lamp block displays a color indicating the value of the input signal. You can use the Lamp block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. You can specify pairs of input values and colors to provide the information you want during simulation.

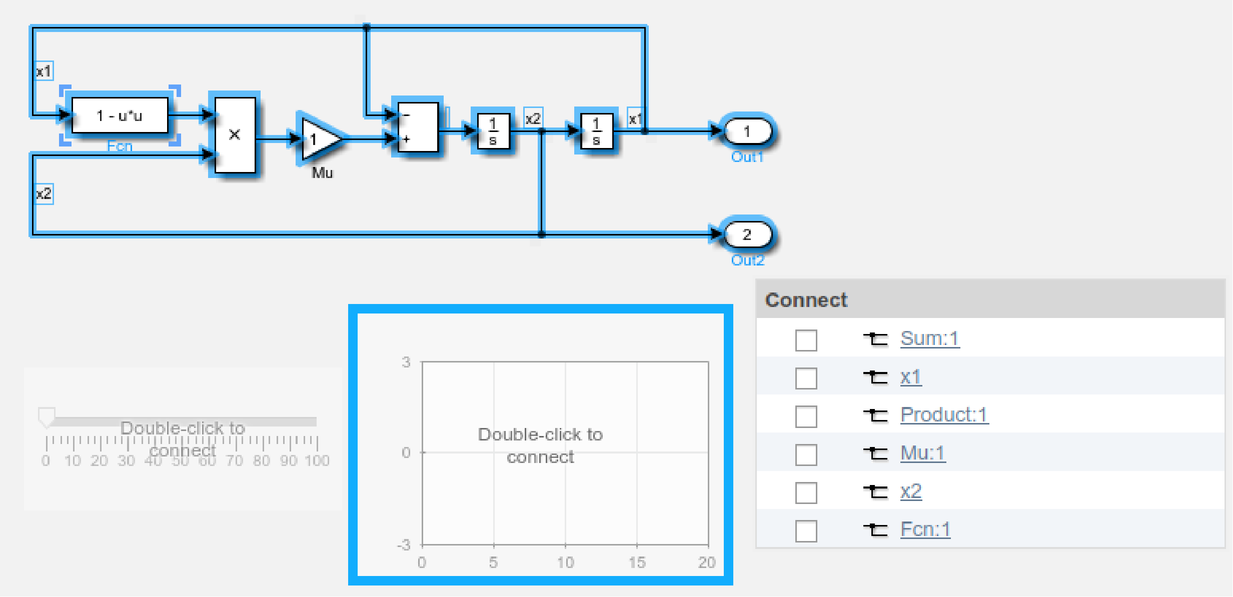
Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect	
□	Sum:1
□	x1
□	Product:1
□	Mu:1
□	x2
□	Fcn:1

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.

Parameters

`Connection` — Select a signal to connect and display

signal connection options

Select the signal to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the radio button next to the signal you want to display. Click **Apply** to connect the signal.

States

`State` — Input value corresponding to a color

0 (default) | scalar

Input value that causes the specified color indication. The `[undefined]` state specifies the Lamp block's behavior when the input value is anything other than values specified in the **States** table. Click the **+** button to add another state.

`Color` — Color of lamp indicating input value

green (default)

Color indicating the input value specified in the corresponding **State**. You can select from a palette of standard colors or specify a custom color with `RGB` values. The Lamp block displays the color specified for the `[undefined]` state when the input's value does not correspond to a value in the **States** table. Click the **+** button to add another state.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

Level-2 MATLAB S-Function

Use Level-2 MATLAB S-function in model

Library: Simulink / User-Defined Functions

Description

This block allows you to use a Level-2 MATLAB S-function (see “Write Level-2 MATLAB S-Functions”) in a model. To do this, create an instance of this block in the model. Then enter the name of the Level-2 MATLAB S-function in the **S-function name** field of the block's parameter dialog box.

Note Use the S-Function block to include a Level-1 MATLAB S-function in a block.

If the Level-2 MATLAB S-function defines any additional parameters, you can enter them in the **Parameters** field of the block's parameter dialog box. Enter the parameters as MATLAB expressions that evaluate to their values in the order defined by the MATLAB S-function. Use commas to separate each expression.

If a model includes a Level-2 MATLAB S-Function block, and an error occurs in the S-function, the Level-2 MATLAB S-Function block displays MATLAB stack trace information for the error in a dialog box. Click **OK** to close the dialog box.

Parameters

S-Function Name — Specify S-Function name

matlabfile (default) | S-Function name

Specify the name of a MATLAB function that defines the behavior of this block. The MATLAB function must follow the Level-2 standard for writing MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” for details).

Programmatic Use
Block Parameter: `FunctionName`
Type: character vector
Values: `'matlabfile'` | S-Function name
Default: `'matlabfile'`

`Parameters` — Specify values of parameters for this block
no default (default)

Specify values of parameters for this block.

Programmatic Use
Block Parameter: `Parameters`
Type: character vector
Values: values of block parameters
Default: `' '`

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a]
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	Yes
Zero-Crossing Detection	No

[a] Level-1 MATLAB S-functions support only the double data type. Level-2 MATLAB S-functions support all data types that Simulink supports.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- If a corresponding TLC file is available, the Level-2 MATLAB S-Function block uses the TLC file to generate code, otherwise code generation throws an error.
- Real-time code generation does not support S-functions that call MATLAB.
- Actual data type or capability support depends on block implementation.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Level-1 MATLAB S-functions support only the `double` data type. Level-2 MATLAB S-functions support all data types that Simulink supports.

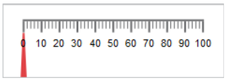
Linear Gauge

Display input value on linear scale
Library: Simulink / Dashboard



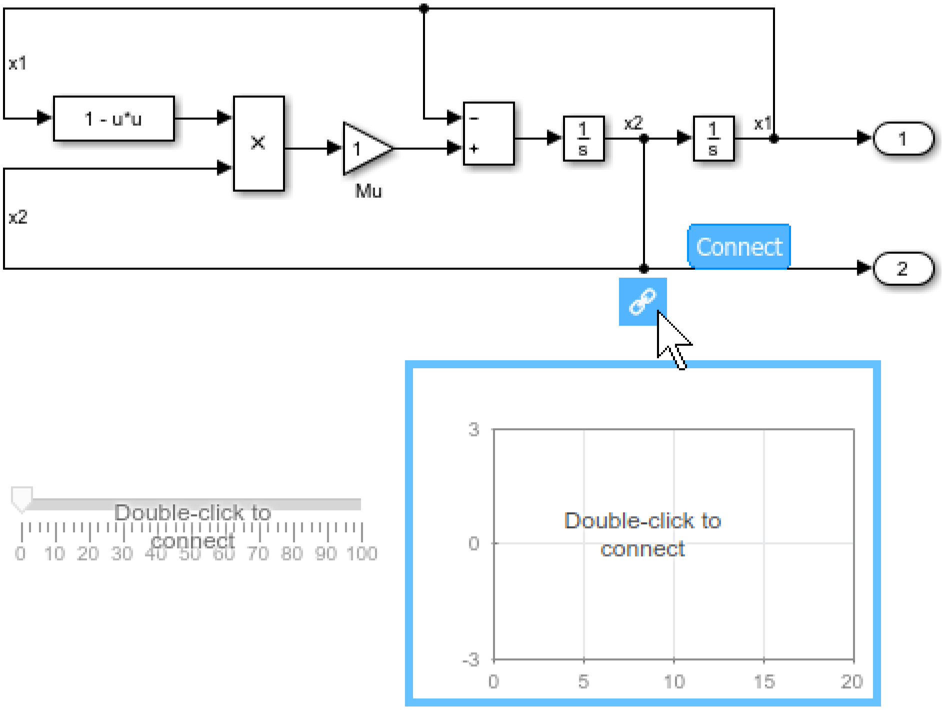
Description

The Linear Gauge block displays the connected signal on a straight linear scale during simulation. Use the Linear Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Linear Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Linear Gauge block to fit your data. You can also customize the appearance of the Linear Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

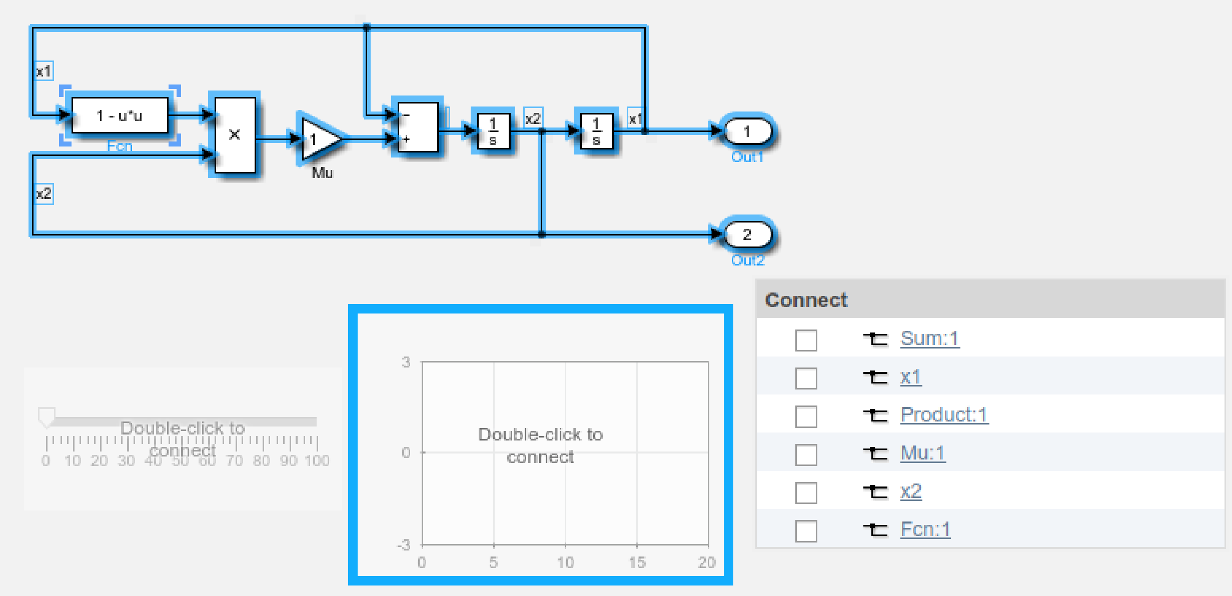
Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

☐	Sum:1
☐	x1
☐	Product:1
☐	Mu:1
☐	x2
☐	Fcn:1

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.

Parameters

`Connection` — Select a signal to connect and display

signal connection options

Select the signal to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the radio button next to the signal you want to display. Click **Apply** to connect the signal.

`Minimum` — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the arc. The minimum must be less than the value entered for the maximum.

`Maximum` — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the arc. The maximum must be greater than the value entered for the minimum.

`Tick Interval` — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the arc. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

`Scale Colors` — Color indications on gauge arc

colors for arc ranges

Color specifications for ranges on the arc. Press the **+** button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

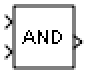
Logical Operator

Perform specified logical operation on input

Library: Simulink / Commonly Used Blocks
Simulink / Logic and Bit Operations



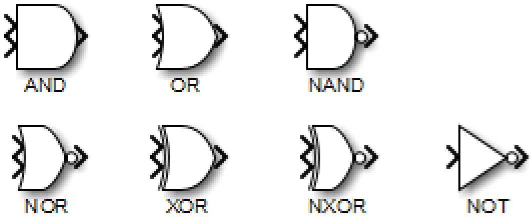
Description

The Logical Operator block performs the specified logical operation on its inputs. An input value is true (1) if it is nonzero and false (0) if it is zero.

You select the Boolean operation connecting the inputs with the **Operator** parameter list. If you select rectangular as the **Icon shape** property, the block updates to display the name of the selected operator. The supported operations are:

Operation	Description
AND	TRUE if all inputs are TRUE
OR	TRUE if at least one input is TRUE
NAND	TRUE if at least one input is FALSE
NOR	TRUE when no inputs are TRUE
XOR	TRUE if an odd number of inputs are TRUE
NXOR	TRUE if an even number of inputs are TRUE
NOT	TRUE if the input is FALSE

If you select distinctive as the **Icon shape**, the block appearance indicates its function. Simulink software displays a distinctive shape for the selected operator, conforming to the IEEE Standard Graphic Symbols for Logic Functions:



The number of input ports is specified with the **Number of input ports** parameter. The output type is specified with the **Output data type** parameter. An output value is `1` if TRUE and `0` if FALSE.

Note The output data type should represent zero exactly. Data types that satisfy this condition include signed and unsigned integers, and any floating-point data type.

The size of the output depends on input vector size and the selected operator:

- If the block has more than one input, any nonscalar inputs must have the same dimensions. For example, if any input is a 2-by-2 array, all other nonscalar inputs must also be 2-by-2 arrays.

  Scalar inputs are expanded to have the same dimensions as the nonscalar inputs.

  If the block has more than one input, the output has the same dimensions as the inputs (after scalar expansion) and each output element is the result of applying the specified logical operation to the corresponding input elements. For example, if the specified operation is AND and the inputs are 2-by-2 arrays, the output is a 2-by-2 array whose top left element is the result of applying AND to the top left elements of the inputs, etc.
- For a single vector input, the block applies the operation (except the NOT operator) to all elements of the vector. The output is always a scalar.
- The NOT operator accepts only one input, which can be a scalar or a vector. If the input is a vector, the output is a vector of the same size containing the logical complements of the input vector elements.

When configured as a multi-input XOR gate, this block performs an addition- modulo-two operation as mandated by the IEEE Standard for Logic Elements.

Ports

Input

`Port_1` — First input signal

scalar | vector | matrix

First input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Port_2` — Second input signal

scalar | vector | matrix

Second input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`Port_N` — Nth input signal

scalar | vector | matrix

Nth input signal, specified as a scalar, vector, or matrix.

Dependencies

To enable additional input ports, use the **Number of input ports** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector | matrix

Output signal, consisting of zeros and ones, with the same dimensions as the input. You control the output data type with the **Require all inputs and output to have the same data type** and **Output data type** parameters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Operator` — Logical operator

AND (default) | OR | NAND | NOR | XOR | NXOR | NOT

Select the logical operator to apply to block inputs.

- `AND` — TRUE if all inputs are TRUE
- `OR` — TRUE if at least one input is TRUE
- `NAND` — TRUE if at least one input is FALSE
- `NOR` — TRUE when no inputs are TRUE
- `XOR` — TRUE if an odd number of inputs are TRUE
- `NXOR` — TRUE if an even number of inputs are TRUE
- `XOR` — TRUE if the input is FALSE

Programmatic Use
Block Parameter: `Operator`
Type: character vector
Values: `'AND' | 'OR' | 'NAND' | 'NOR' | 'XOR' | 'NXOR' | 'NOT'`
Default: `'AND'`

`Number of input ports` — Number of inputs

2 (default) | positive integer

Specify the number of block inputs as a positive integer.

Programmatic Use
Block Parameter: `Inputs`
Type: character vector
Values: positive integer
Default: `'2'`

Dependencies

This parameter is not available when you set the **Operator** to `NOT`.

`Icon shape` — Icon shape

`rectangular` (default) | `distinctive`

Specify the shape of the block icon.

- `rectangular` — Results in a rectangular block that displays the name of the selected operator.
- `distinctive` — Use the graphic symbol for the selected operator as specified by the IEEE standard.

Programmatic Use
Block Parameter: `IconShape`
Type: character vector
Values: `'rectangular' | 'distinctive'`
Default: `'rectangular'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Data Type

`Require all inputs and output to have the same data type` — Require all ports to have same data type

`off` (default) | `on`

To require that all block inputs and the output have the same data type, select this check box. When you clear this check box, the inputs and output can have different data types.

Programmatic Use
Block Parameter: `AllPortsSameDT`
Type: character vector

Values: `'off' | 'on`
Default: `'off'`

`Output data type` — Output data type

`boolean` (default) | `Inherit: Logical (see Configuration Parameters: Optimization)` | `fixdt(1,16)` | `<data type expression>`

Specify the output data type. When you select:

- `boolean` — the block output has data type `boolean`.
- `Inherit: Logical (see Configuration Parameters: Optimization)` — the block uses the **Implement logic signals as Boolean data** configuration parameter (see “Implement logic signals as Boolean data (vs. double)”) to specify the output data type.

  Note This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.
- `fixdt(1,16)` — the block output has the specified fixed-point data type `fixdt(1,16)`.

  Tip Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.
- `<data type expression>` — the block output has the data type you specify as a data type expression, for example, `Simulink.NumericType`.

  Tip To enter a built-in data type (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`), enclose the expression in single quotes. For example, enter `'double'` instead of `double`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Logical (see Configuration Parameters: Optimization)' | 'boolean' | 'fixdt(1,16)' | '<data type expression>'`

Default: `'boolean'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see Logical Operator.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

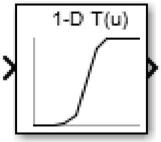
Introduced before R2006a

1-D Lookup Table

Approximate one-dimensional function

Library: Simulink / Lookup Tables



Description

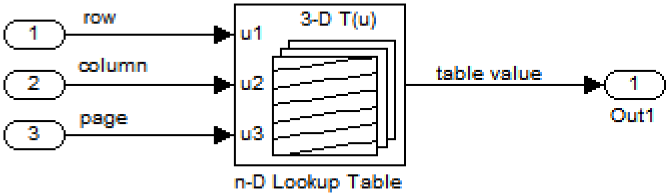
Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \ldots, x_N)$$

where the function *F* can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (Linear point-slope), Lagrange (Linear Lagrange), nearest, and cubic-spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.



See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and “Identify questionable fixed-point operations” (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the **Interpolation method** you select

When block inputs...	The n-D Lookup Table block...
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the **Extrapolation method** you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value `k` and you want the `k`th element of a table, `y = table(k)`, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs

scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output computed by looking up or estimating table values

scalar | vector | matrix

Output generated by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the **Interpolation method** you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the **Extrapolation method** you select

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Table and Breakpoints

`Number of table dimensions` — Number of lookup table dimensions

1 (default) | 2 | 3 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use

Block Parameter: `NumberOfTableDimensions`
Type: character vector
Values: `'1' | '2' | '3' | '4' | ... | 30`
Default: `'1'`

`Data specification` — Method of table and breakpoint specification

`Table and breakpoints` (default) | `Lookup table object`

From the list, select:

- `Table and breakpoints` — Specify the table data and breakpoints. Selecting this option enables these parameters:
  - **Table data**
  - **Breakpoints specification**
  - **Breakpoints 1**
  - **Edit table and breakpoints**
- `Lookup table object` — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use
Block Parameter: `DataSpecification`
Type: character vector
Values: `'Table and breakpoints' | 'Lookup table object'`
Default: `'Table and breakpoints'`

`Name` — Name of the lookup table object

`[]` (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object.

Dependencies

To enable this parameter, set **Data specification** to `Lookup table object`.

Programmatic Use
Block Parameter: `LookupTableObject`
Type: character vector
Values: name of a `Simulink.LookupTable` object
Default: `''`

`Table data` — Define the table of output values

`tanh([-5:5])` (default) | vector of values

Enter the table of output values.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as `[]`) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `Table`
Type: character vector
Values: vector of table values
Default: `'tanh([-5:5])'`

`Breakpoints specification` — Method of breakpoint specification

`Explicit values` (default) | `Even spacing`

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsSpecification`
Type: character vector
Values: `'Explicit values' | 'Even spacing'`
Default: `'Explicit values'`

`Breakpoints` — Explicit breakpoint values, or first point and spacing of breakpoints

`[10,22,31]` (default) | 1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1`
Type: character vector
Values: 1-by-n or n-by-1 vector of monotonically increasing values
Default: `'[10, 22, 31]'`

`First point` — First point in evenly spaced breakpoint data

1 (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite, scalar. This parameter is available when **Breakpoints specification** is set to `Even spacing`.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1FirstPoint`
Type: character vector
Values: real-valued, finite, scalar
Default: `'1'`

Spacing — Spacing between evenly spaced breakpoints

1 (default) | scalar

Specify the spacing between points in your evenly spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1Spacing`
Type: character vector
Values: positive, real-valued, finite, scalar
Default: `'1'`

`Edit table and breakpoints` — Launch Lookup Table Editor dialog box

button

Click this button to open the Lookup Table Editor. For more information, see "Edit Lookup Tables" in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm

Lookup method

`Interpolation method` — Method of interpolation between breakpoint values

`Linear point-slope` (default) | `Flat` | `Nearest` | `Linear Lagrange` | `Cubic spline`

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see "Interpolation Methods".

Dependencies

If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.

Programmatic Use

Block Parameter: `InterpMethod`
Type: character vector

Values: `'Linear point-slope' | 'Flat' | 'Nearest' | 'Linear Lagrange' | 'Cubic spline'`
Default: `'Linear point-slope'`

`Extrapolation method` — Method of handling input values that fall outside the range of a breakpoint data set

`Clip` (default) | `Linear` | `Cubic spline`

Select `Clip`, `Linear`, or `Cubic spline`. See “Extrapolation Methods” for more information.

If the extrapolation method is `Linear`, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is Linear Lagrange, the extrapolation method inherits the Linear Lagrange equation to compute the extrapolated value.

Dependencies

To select `Cubic spline` for **Extrapolation method**, you must also select `Cubic spline` for **Interpolation method**.

Programmatic Use

Block Parameter: `ExtrapMethod`
Type: character vector
Values: `'Linear' | 'Clip' | 'Cubic spline'`
Default: `'Linear'`

`Index search method` — Method of calculating table indices

`Evenly spaced points` (default) | `Linear search` | `Binary search`

Select `Evenly spaced points`, `Linear search`, or `Binary search`. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices.

  This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

  Note Set **Index search method** to `Evenly spaced points` when using the `Simulink.LookupTable` object to specify table data and the **Breakpoints**

Specification parameter of the referenced `Simulink.LookupTable` object is set to `Even spacing`.

- For unevenly spaced breakpoint sets, follow these guidelines:
  - If input signals do not vary much between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
  - If input signals jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
- The index search method is `Evenly spaced points`.

Programmatic Use
Block Parameter: `IndexSearchMethod`
Type: character vector
Values: `'Binary search' | 'Evenly spaced points' | 'Linear search'`
Default: `'Binary search'`

`Begin index search using previous index result` — Start using the index from the previous time step

`off` (default) | `on`

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to `Linear search` or `Binary search`.

Programmatic Use
Block Parameter: `BeginIndexSearchUsing PreviousIndexResult`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Diagnostic for out-of-range input` — Block action when input is out of range

`None` (default) | `Warning` | `Error`

Specify whether to produce a warning or error when the input is out of range. Options include:

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use
Block Parameter: `DiagnosticForOutOfRangeInput`
Type: character vector
Values: `'None' | 'Warning' | 'Error'`
Default: `'None'`

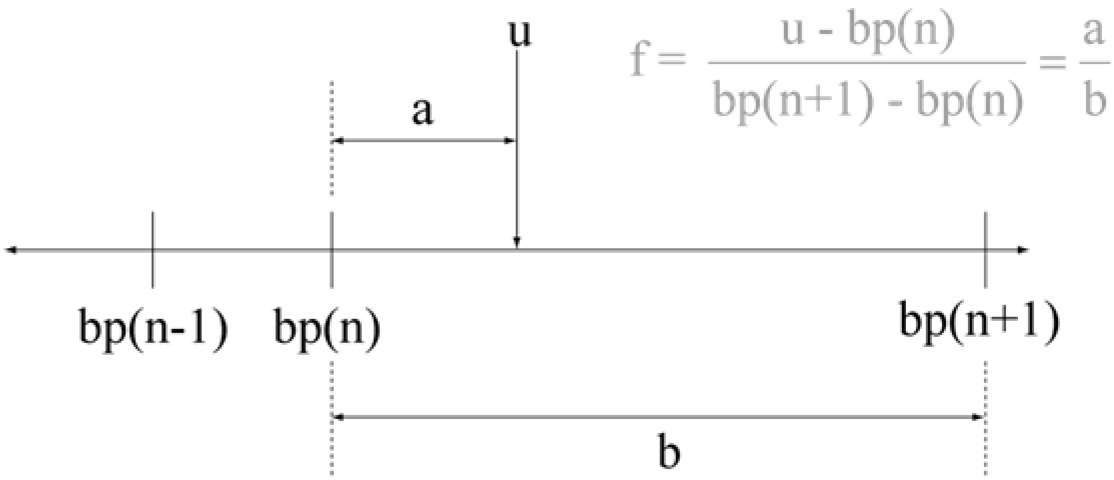
`Use last table value for inputs at or above last breakpoint` — Method for computing output for inputs at or above last breakpoint

`off` (default) | `on`

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is larger than the last element of the breakpoint data.

Check Box	Block Uses Index Of The...	Interval Fraction
Selected	Last element of breakpoint data on the **Table and Breakpoints** tab	0
Cleared	Next-to-last element of breakpoint data on the **Table and Breakpoints** tab	1

Given an input *u* within range of a breakpoint set *bp*, the interval fraction *f*, in the range 0 *f* 1, is computed as shown below.



Suppose the breakpoint set is `[1 4 5]` and input *u* is `5.5`. If you select this check box, the index is that of the last element (`5`) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (`4`) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to `Linear`.
- **Extrapolation method** to `Clip`.

Programmatic Use

Block Parameter: `UseLastTableValue`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Input settings

`Use one input port for all input data` — Use only one input port

`off` (default) | `on`

Select this check box to use only one input port that expects a signal that is `n` elements wide for an n-dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label `u` appears on the block.

Programmatic Use
Block Parameter: `UseOneInputPortForAllInputData`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Code generation

Remove protection against out-of-range input in generated code — Remove code that checks for out-of-range input values

`off` (default) | `on`

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
`on`	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
`off`	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

1. Clear the **Remove protection against out-of-range index in generated code** check box.
2. Set the **Diagnostic for out-of-range input** parameter to `Error`.
3. Simulate the model in normal mode.
4. If there are out-of-range errors, fix them to be in range and run the simulation again.
5. When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

> **Note** When you select the **Remove protection against out-of-range index in generated code** check box and the input `k` or `f` is out of range, the behavior is undefined for generated code and simulations using accelerator mode.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks”.

Programmatic Use

Block Parameter: `RemoveProtectionInput`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Support tunable table size in code generation` — Enable tunable table size in the generated code

`off` (default) | `on`

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code.

Dependencies

If you set **Interpolation method** to `Cubic spline`, this check box is not available.

Programmatic Use

Block Parameter: `SupportTunableTableSize`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see "Specify Sample Time".

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see "Blocks for Which Sample Time Is Not Recommended".

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

`Maximum indices for each dimension` — Maximum index value for each table dimension

`[]` (default) | `scalar or vector of positive integer values`

Example: `[4 6]` for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Examples of valid specifications include:

- `[4 6]` for a 5-by-7 table
- `[int8(2) int16(5) int32(9)]` for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see "Tunable Table Size in the Generated Code" on page 1-1100.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use
Block Parameter: `MaximumIndicesForEachDimension`
Type: character vector
Values: scalar or vector of positive integer values
Default: `'[]'`

Data Types

`Table data` — Data type of table data

`Inherit: Same as output` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
- Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
- Sharing of custom storage table data in the generated code for blocks with different output data types

Programmatic Use
Block Parameter: `TableDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit from 'Table data'' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`
Default: `'Inherit: Same as output'`

`Table data Minimum` — Minimum value of the table data

`[]` | `scalar`

Specify the minimum value for table data. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `TableMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Table data Maximum` — Maximum value of the table data

`[]` | `scalar`

Specify the maximum value for table data. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `TableMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Breakpoints` — Breakpoint data type

`Inherit: Same as corresponding input` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class name>` | `<data type expression>`

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as corresponding input`
- The name of a built-in data type, for example, `single`

- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.
- If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
- For enumerated data, **Extrapolation method** must be `Clip`.
- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
- Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
- Sharing of custom storage breakpoint data in the generated code for blocks with different input data types

Programmatic Use
Block Parameter: `BreakpointsForDimension1DataTypeStr | BreakpointsForDimension2DataTypeStr| ... | BreakpointsForDimension30DataTypeStr`
Type: character vector
Values: `'Inherit: Same as corresponding input' | 'Inherit: Inherit from 'Breakpoint data'' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`
Default: `'Inherit: Same as corresponding input'`

`Breakpoints Minimum` — Minimum value breakpoint data can have

`[]` | `scalar`

Specify the minimum value that a set of breakpoint data can have. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `BreakpointsForDimension1Min | BreakpointsForDimension2Min | ... | BreakpointsForDimension30Min`
Type: character vector
Values: scalar
Default: `'[]'`

`Breakpoints Maximum` — Maximum value breakpoint data can have

`[]` | `scalar`

Specify the maximum value that a set of breakpoint data can have. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `BreakpointsForDimension1Max | BreakpointsForDimension2Max | ... | BreakpointsForDimension30Max`
Type: character vector
Values: scalar
Default: `'[]'`

`Fraction` — Fraction data type

`Inherit: Inherit via internal rule` (default) | `double` | `single` | `fixdt(1,16,0)` | `<data type expression>`

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `FractionDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'double' | 'single' | 'fixdt(1,16,0)'|'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Intermediate results` — Intermediate results data type

`Inherit: Same as output` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use
Block Parameter: `IntermediateResultsDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`
Default: `'Inherit: Same as output'`

Output — Output data type

`Inherit: Same as input` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see "Specify Data Types Using Data Type Assistant".

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression'`
Default: `'Inherit: Same as first input'`

Output Minimum — Minimum value the block can output

`[]` | `scalar`

Specify the minimum value that the block outputs. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Output Maximum` — Maximum value the block can output

`[]` | `scalar`

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Internal rule priority` — Internal rule for intermediate calculations

`Speed` (default) | `Precision`

Specify the internal rule for intermediate calculations. Select `Speed` for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use
Block Parameter: `InternalRulePriority`
Type: character vector
Values: `'Speed' | 'Precision'`
Default: `'Speed'`

`Require all inputs to have the same data type` — Require all inputs to have the same data type

`on` (default) | `off`

Select to require all inputs to have the same data type.

Programmatic Use
Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Simplest` (default) | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Zero`

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see "Rounding" (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Simplest'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (`on`).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Check for Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Definitions

Tunable Table Size in the Generated Code

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

  ```
  p = Simulink.Parameter;
  p.Value.MaxIdx = [2 2];
  p.Value.BP1 = [1 2 3];
  p.Value.BP2 = [1 4 16];
  p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
  p.DataType = 'Bus: slLookupTable';
  p.CoderInfo.StorageClass = 'ExportedGlobal';

  % Create bus object slBus1 from MATLAB structure
  Simulink.Bus.createObject(p.Value);
  slLookupTable = slBus1;
  slLookupTable.Elements(1).DataType = 'uint32';
  ```
- These block parameters apply in the n-D Lookup Table block dialog box.

Parameter	Value
Number of table dimensions	2
Table data	`p.Table`
Breakpoints 1	`p.BP1`
Breakpoints 2	`p.BP2`
Support tunable table size in code generation	`on`
Maximum indices for each dimension	`p.MaxIdx`

The generated *`model`*`_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
  uint32_T MaxIdx[2];
  real_T BP1[3];
  real_T BP2[3];
  real_T Table[9];
} slLookupTable;
```

The generated *`model`*`.c` file contains code that looks something like this.

```
/* Exported block parameters */
slLookupTable p = {
  { 2U, 2U },
```

```
  { 1.0, 2.0, 3.0 },

  { 1.0, 4.0, 16.0 },

  { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
} ;

/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
  /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   */
  Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

  /* Outport: '<Root>/Out1' */
  ex_lut_nd_tunable_table_Y.Out1 = Y;

  /* tid is required for a uniform function interface.
   * Argument tid is not used in the function. */
  UNUSED_PARAMETER(tid);
}
```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

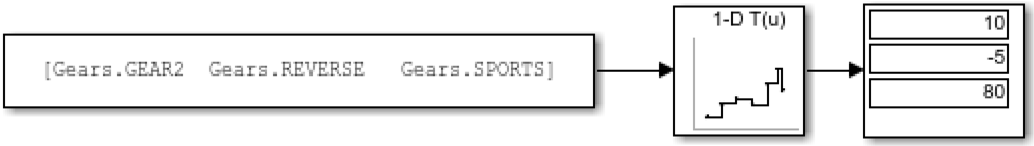
Suppose that you have a lookup table with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end
```

n-D Lookup block has these settings:

- **Number of dimensions** to `1`.
- **Table data** value is `[5 10 20 40 80 -5 0]`.
- **Breakpoints 1** value is `enumeration('Gears')`.
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to `Linear search` and clear the **Begin index search using previous index result** check box.

Simulation produces a vector `[10 -5 80]`, which correspond to `GEAR2`, `REVERSE`, and `SPORTS`.



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

The 1-D, 2-D, and N-D Lookup Table blocks have restrictions for HDL code generation. For more information, see “Restrictions” (HDL Coder).

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

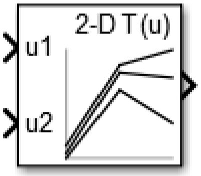
2-D Lookup Table

Approximate two-dimensional function

Library: Simulink / Lookup Tables



Description

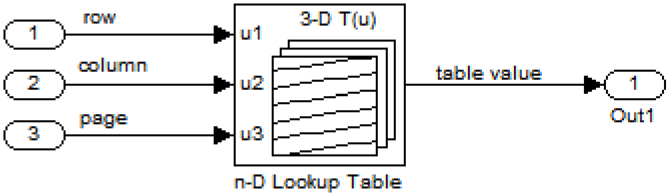
Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \ldots, x_N)$$

where the function *F* can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (Linear point-slope), Lagrange (Linear Lagrange), nearest, and cubic-spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.



See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and “Identify questionable fixed-point operations” (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints

When block inputs...	The n-D Lookup Table block...
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the **Interpolation method** you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the **Extrapolation method** you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value `k` and you want the `k`th element of a table, `y = table(k)`, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs
scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

u2 — Second-dimension (column) inputs
scalar | vector | matrix

Real-valued inputs to the **u2** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Output

Port_1 — Output computed by looking up or estimating table values
scalar | vector | matrix

Output generated by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the **Interpolation method** you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the **Extrapolation method** you select

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Parameters

Table and Breakpoints

Number of table dimensions — Number of lookup table dimensions
2 (default) | 1 | 3 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.

To specify...	Do this...
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use
Block Parameter: `NumberOfTableDimensions`
Type: character vector
Values: `'1' | '2' | '3' | '4' | ... | 30`
Default: `'2'`

`Data specification` — Method of table and breakpoint specification

`Table and breakpoints` (default) | `Lookup table object`

From the list, select:

- `Table and breakpoints` — Specify the table data and breakpoints. Selecting this option enables these parameters:
  - **Table data**
  - **Breakpoints specification**
  - **Breakpoints 1**
  - **Breakpoints 2**
  - **Edit table and breakpoints**
- `Lookup table object` — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use
Block Parameter: `DataSpecification`
Type: character vector
Values: `'Table and breakpoints' | 'Lookup table object'`
Default: `'Table and breakpoints'`

Name — Name of the lookup table object

`[]` (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object.

Dependencies

To enable this parameter, set **Data specification** to `Lookup table object`.

Programmatic Use

Block Parameter: `LookupTableObject`
Type: character vector
Values: name of a `Simulink.LookupTable` object
Default: `''`

`Table data` — Define the table of output values

`[4 5 6; 16 19 20; 10 18 23]` (default) | matrix of values

Enter the table of output values.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as `[]`) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `Table`
Type: character vector
Values: matrix of table values
Default: `'[4 5 6; 16 19 20; 10 18 23]'`

`Breakpoints specification` — Method of breakpoint specification

`Explicit values` (default) | `Even spacing`

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsSpecification`
Type: character vector
Values: `'Explicit values' | 'Even spacing'`
Default: `'Explicit values'`

`Breakpoints` — Explicit breakpoint values, or first point and spacing of breakpoints

`[1:3]` (default) | 1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly-spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1`
Type: character vector
Values: 1-by-n or n-by-1 vector of monotonically increasing values
Default: `'[1:3]'`

`First point` — First point in evenly spaced breakpoint data

`1` (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite, scalar. This parameter is available when **Breakpoints specification** is set to `Even spacing`.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1FirstPoint | BreakpointsForDimension2FirstPoint`
Type: character vector
Values: real-valued, finite, scalar
Default: `'1'`

`Spacing` — Spacing between evenly spaced breakpoints

1 (default) | scalar

Specify the spacing between points in your evenly-spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1Spacing | BreakpointsForDimension2Spacing`
Type: character vector
Values: positive, real-valued, finite, scalar
Default: `'1'`

`Edit table and breakpoints` — Launch Lookup Table Editor dialog box

button

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm

Lookup method

`Interpolation method` — Method of interpolation between breakpoint values

`Linear point-slope` (default) | `Flat` | `Nearest` | `Linear Lagrange` | `Cubic spline`

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Dependencies

If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.

Programmatic Use
Block Parameter: `InterpMethod`
Type: character vector
Values: `'Linear point-slope' | 'Flat' | 'Nearest' | 'Linear Lagrange' | 'Cubic spline'`
Default: `'Linear point-slope'`

`Extrapolation method` — Method of handling input values that fall outside the range of a breakpoint data set

`Clip` (default) | `Linear` | `Cubic spline`

Select `Clip`, `Linear`, or `Cubic spline`. See “Extrapolation Methods” for more information.

If the extrapolation method is `Linear`, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is Linear Lagrange, the extrapolation method inherits the Linear Lagrange equation to compute the extrapolated value.

Dependencies

To select `Cubic spline` for **Extrapolation method**, you must also select `Cubic spline` for **Interpolation method**.

Programmatic Use
Block Parameter: `ExtrapMethod`

Type: character vector
Values: `'Linear' | 'Clip' | 'Cubic spline'`
Default: `'Linear'`

`Index search method` — Method of calculating table indices

`Evenly spaced points` (default) | `Linear search` | `Binary search`

Select `Evenly spaced points`, `Linear search`, or `Binary search`. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices.

  This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

  Note Set **Index search method** to `Evenly spaced points` when using the `Simulink.LookupTable` object to specify table data and the **Breakpoints Specification** parameter of the referenced `Simulink.LookupTable` object is set to `Even spacing`.

- For unevenly spaced breakpoint sets, follow these guidelines:

  - If input signals do not vary much between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
  - If input signals jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
- The index search method is `Evenly spaced points`.

Programmatic Use
Block Parameter: `IndexSearchMethod`
Type: character vector
Values: `'Binary search' | 'Evenly spaced points' | 'Linear search'`
Default: `'Binary search'`

`Begin index search using previous index result` — Start using the index from the previous time step

`off` (default) | `on`

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to `Linear search` or `Binary search`.

Programmatic Use
Block Parameter: `BeginIndexSearchUsing PreviousIndexResult`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Diagnostic for out-of-range input` — Block action when input is out of range

`None` (default) | `Warning` | `Error`

Specify whether to produce a warning or error when the input is out of range. Options include:

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use
Block Parameter: `DiagnosticForOutOfRangeInput`
Type: character vector
Values: `'None' | 'Warning' | 'Error'`
Default: `'None'`

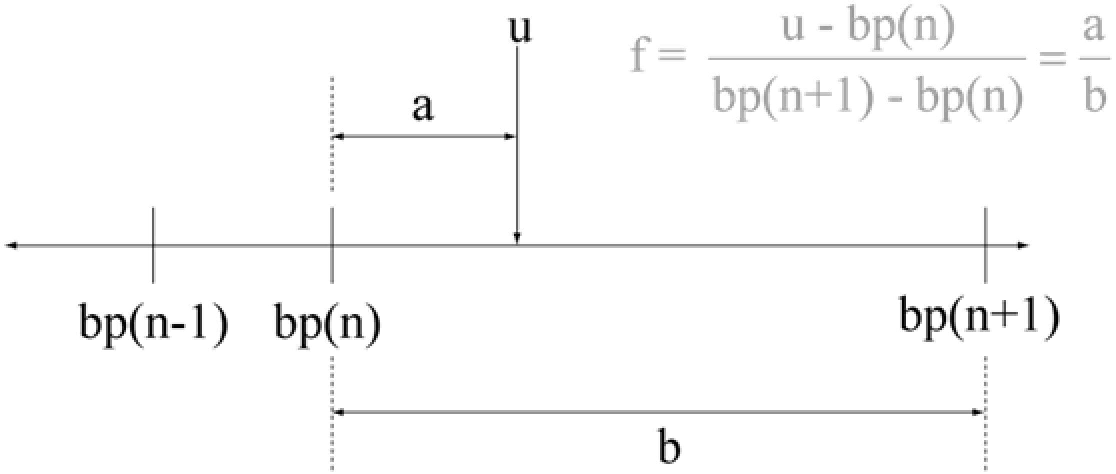
`Use last table value for inputs at or above last breakpoint` — Method for computing output for inputs at or above last breakpoint

`off` (default) | `on`

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is larger than the last element of the breakpoint data.

Check Box	Block Uses Index Of The...	Interval Fraction
Selected	Last element of breakpoint data on the **Table and Breakpoints** tab	0
Cleared	Next-to-last element of breakpoint data on the **Table and Breakpoints** tab	1

Given an input *u* within range of a breakpoint set *bp*, the interval fraction *f*, in the range 0 *f* 1, is computed as shown below.



Suppose the breakpoint set is `[1 4 5]` and input *u* is `5.5`. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (4) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to `Linear`.
- **Extrapolation method** to `Clip`.

Programmatic Use

Block Parameter: `UseLastTableValue`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Input settings

`Use one input port for all input data` — Use only one input port

`off` (default) | `on`

Select this check box to use only one input port that expects a signal that is `n` elements wide for an n-dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label `u` appears on the block.

Programmatic Use

Block Parameter: `UseOneInputPortForAllInputData`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Code generation

`Remove protection against out-of-range input in generated code` — Remove code that checks for out-of-range input values

`off` (default) | `on`

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
`on`	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
`off`	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

1. Clear the **Remove protection against out-of-range index in generated code** check box.
2. Set the **Diagnostic for out-of-range input** parameter to `Error`.
3. Simulate the model in normal mode.
4. If there are out-of-range errors, fix them to be in range and run the simulation again.
5. When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input `k` or `f` is out of range, the behavior is undefined for generated code and simulations using accelerator mode.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks”.

Programmatic Use
Block Parameter: `RemoveProtectionInput`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Support tunable table size in code generation` — Enable tunable table size in the generated code

`off` (default) | `on`

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code.

Dependencies

If you set **Interpolation method** to `Cubic spline`, this check box is not available.

Programmatic Use
Block Parameter: `SupportTunableTableSize`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

`Maximum indices for each dimension` — Maximum index value for each table dimension

`[]` (default) | `scalar or vector of positive integer values`

Example: `[4 6]` for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Examples of valid specifications include:

- `[4 6]` for a 5-by-7 table
- `[int8(2) int16(5) int32(9)]` for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-1130.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use
Block Parameter: `MaximumIndicesForEachDimension`
Type: character vector
Values: scalar or vector of positive integer values
Default: `'[]'`

Data Types

`Table data` — Data type of table data

`Inherit: Same as output` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
- Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
- Sharing of custom storage table data in the generated code for blocks with different output data types

Programmatic Use

Block Parameter: `TableDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit from 'Table data'' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`
Default: `'Inherit: Same as output'`

Table data Minimum — Minimum value of the table data

[] | scalar

Specify the minimum value for table data. The default value is [] (unspecified).

Programmatic Use
Block Parameter: TableMin
Type: character vector
Values: scalar
Default: '[]'

Table data Maximum — Maximum value of the table data

[] | scalar

Specify the maximum value for table data. The default value is [] (unspecified).

Programmatic Use
Block Parameter: TableMax
Type: character vector
Values: scalar
Default: '[]'

Breakpoints — Breakpoint data type

Inherit: Same as corresponding input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as corresponding input
- The name of a built-in data type, for example, single
- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.

- If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
- For enumerated data, **Extrapolation method** must be `Clip`.
- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
- Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
- Sharing of custom storage breakpoint data in the generated code for blocks with different input data types

---

Programmatic Use
Block Parameter: `BreakpointsForDimension1DataTypeStr | BreakpointsForDimension2DataTypeStr| ... | BreakpointsForDimension30DataTypeStr`
Type: character vector
Values: `'Inherit: Same as corresponding input' | 'Inherit: Inherit from 'Breakpoint data'' | 'double' | 'single' | 'int8' | 'uint8' |`

'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'
Default: 'Inherit: Same as corresponding input'

Breakpoints Minimum — Minimum value breakpoint data can have

[] | scalar

Specify the minimum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use
Block Parameter: BreakpointsForDimension1Min | BreakpointsForDimension2Min | ... | BreakpointsForDimension30Min
Type: character vector
Values: scalar
Default: '[]'

Breakpoints Maximum — Maximum value breakpoint data can have

[] | scalar

Specify the maximum value that a set of breakpoint data can have. The default value is [] (unspecified).

Programmatic Use
Block Parameter: BreakpointsForDimension1Max | BreakpointsForDimension2Max | ... | BreakpointsForDimension30Max
Type: character vector
Values: scalar
Default: '[]'

Fraction — Fraction data type

Inherit: Inherit via internal rule (default) | double | single | fixdt(1,16,0) | <data type expression>

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via internal rule
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `FractionDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'double' | 'single' | 'fixdt(1,16,0)'|'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Intermediate results` — Intermediate results data type

`Inherit: Same as output` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use
Block Parameter: `IntermediateResultsDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`

Default: `'Inherit: Same as output'`

`Output` — Output data type

`Inherit: Same as input` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see "Specify Data Types Using Data Type Assistant".

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression'`
Default: `'Inherit: Same as first input'`

`Output Minimum` — Minimum value the block can output

`[]` | `scalar`

Specify the minimum value that the block outputs. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see "Specify Minimum and Maximum Values for Block Parameters").
- Simulation range checking (see "Signal Ranges").
- Automatic scaling of fixed-point data types.

- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Output Maximum` — Maximum value the block can output

`[]` | `scalar`

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Internal rule priority` — Internal rule for intermediate calculations

`Speed` (default) | `Precision`

Specify the internal rule for intermediate calculations. Select `Speed` for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use
Block Parameter: `InternalRulePriority`
Type: character vector

Values: `'Speed' | 'Precision'`
Default: `'Speed'`

`Require all inputs to have the same data type` — Require all inputs to have the same data type

`on` (default) | `off`

Select to require all inputs to have the same data type.

Programmatic Use
Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Simplest` (default) | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Zero`

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Simplest'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (`on`).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	double | single | base integer | fixed point | enumerated
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

Definitions

Tunable Table Size in the Generated Code

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to configure lookup table data for calibration in the generated code, use the `SupportTunableSize` property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a `Simulink.Parameter` structure in the preload function of your model:

```
p = Simulink.Parameter;
p.Value.MaxIdx = [2 2];
p.Value.BP1 = [1 2 3];
p.Value.BP2 = [1 4 16];
p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
```

```
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- These block parameters apply in the n-D Lookup Table block dialog box.

Parameter	Value
Number of table dimensions	2
Table data	`p.Table`
Breakpoints 1	`p.BP1`
Breakpoints 2	`p.BP2`
Support tunable table size in code generation	`on`
Maximum indices for each dimension	`p.MaxIdx`

The generated *`model`*`_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
  uint32_T MaxIdx[2];
  real_T BP1[3];
  real_T BP2[3];
  real_T Table[9];
} slLookupTable;
```

The generated *`model`*`.c` file contains code that looks something like this.

```
/* Exported block parameters */
slLookupTable p = {
  { 2U, 2U },

  { 1.0, 2.0, 3.0 },

  { 1.0, 4.0, 16.0 },

  { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
} ;
```

```
/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
  /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   */
  Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

  /* Outport: '<Root>/Out1' */
  ex_lut_nd_tunable_table_Y.Out1 = Y;

  /* tid is required for a uniform function interface.
   * Argument tid is not used in the function. */
  UNUSED_PARAMETER(tid);
}
```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

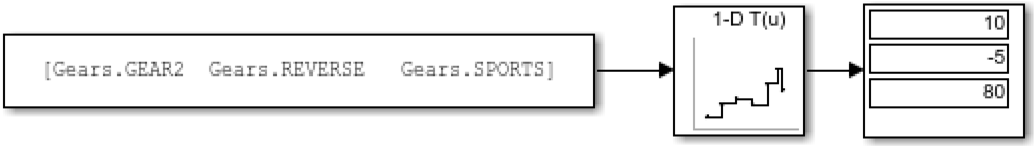
Suppose that you have a lookup table with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end
```

n-D Lookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is `[5 10 20 40 80 -5 0]`.
- **Breakpoints 1** value is `enumeration('Gears')`.
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to `Linear search` and clear the **Begin index search using previous index result** check box.

Simulation produces a vector `[10 -5 80]`, which correspond to `GEAR2`, `REVERSE`, and `SPORTS`.



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

The 1-D, 2-D, and N-D Lookup Table blocks have restrictions for HDL code generation. For more information, see “Restrictions” (HDL Coder).

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

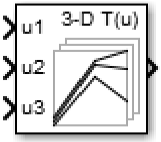
n-D Lookup Table

Approximate n-dimensional function

Library: Simulink / Lookup Tables



Description

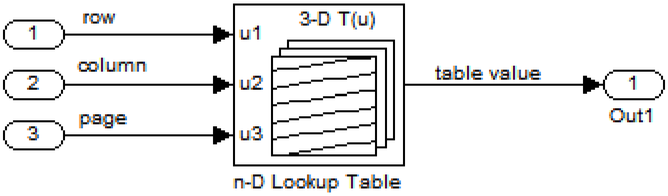
Supported Block Operations

The 1-D, 2-D, and n-D Lookup Table blocks evaluate a sampled representation of a function in N variables

$$y = F(x_1, x_2, x_3, \ldots, x_N)$$

where the function *F* can be empirical. The block maps inputs to an output value by looking up or interpolating a table of values you define with block parameters. The block supports flat (constant), linear (Linear point-slope), Lagrange (Linear Lagrange), nearest, and cubic-spline interpolation methods. You can apply these methods to a table of any dimension from 1 through 30.

In the following block, the first input identifies the first dimension (row) breakpoints, the second input identifies the second dimension (column) breakpoints, and so on.



See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

When the **Math and Data Types > Use algorithms optimized for row-major array layout** configuration parameter is set, the 2-D and n-D Lookup Table block behavior changes from column-major to row-major. For these blocks, the column-major and row-major algorithms may differ in the order of the output calculations, possibly resulting in slightly different numerical values. This capability requires a Simulink Coder or Embedded Coder license. For more information on row-major support, see "Code Generation of Matrices and Arrays" (Simulink Coder).

Specification of Breakpoint and Table Data

These block parameters define the breakpoint and table data.

Block Parameter	Purpose
Number of table dimensions	Specifies the number of dimensions of your lookup table.
Breakpoints	Specifies a breakpoint vector that corresponds to each dimension of your lookup table.
Table data	Defines the associated set of output values.

Tip Evenly spaced breakpoints can make the generated code division-free. For more information, see `fixpt_evenspace_cleanup` and "Identify questionable fixed-point operations" (Embedded Coder).

How the Block Generates Output

The n-D, 1-D and 2-D Lookup Table blocks generate output by looking up or estimating table values based on the input values.

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the **Interpolation method** you select

When block inputs...	The n-D Lookup Table block...
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the **Extrapolation method** you select

Other Blocks that Perform Equivalent Operations

You can use the Interpolation Using Prelookup block with the Prelookup block to perform the equivalent operation of one n-D Lookup Table block. This combination of blocks offers greater flexibility that can result in more efficient simulation performance for linear interpolations.

When the lookup operation is an array access that does not require interpolation, use the Direct Lookup Table (n-D) block. For example, if you have an integer value `k` and you want the `k`th element of a table, `y = table(k)`, interpolation is unnecessary.

Ports

Input

u1 — First-dimension (row) inputs
scalar | vector | matrix

Real-valued inputs to the **u1** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

uN — n-th dimension input values
scalar | vector | matrix

Real-valued inputs to the **uN** port, mapped to an output value by looking up or interpolating the table of values that you define.

Example: `0:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

Port_1 — Output computed by looking up or estimating table values
scalar | vector | matrix

Output generated by looking up or estimating table values based on the input values:

When block inputs...	The n-D Lookup Table block...
Match the values of indices in breakpoint data sets	Outputs the table value at the intersection of the row, column, and higher dimension breakpoints
Do not match the values of indices in breakpoint data sets, but are within range	Interpolates appropriate table values, using the **Interpolation method** you select
Do not match the values of indices in breakpoint data sets, and are out of range	Extrapolates the output value, using the **Extrapolation method** you select

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Parameters

Table and Breakpoints

Number of table dimensions — Number of lookup table dimensions
3 (default) | 1 | 2 | 4 | ... | 30

Enter the number of dimensions of the lookup table. This parameter determines:

- The number of independent variables for the table and the number of block inputs
- The number of breakpoint sets to specify

To specify...	Do this...
1, 2, 3, or 4	Select the value from the drop-down list.

To specify...	Do this...
A higher number of table dimensions	Enter a positive integer directly in the field. The maximum number of table dimensions that this block supports is 30.

Programmatic Use
Block Parameter: `NumberOfTableDimensions`
Type: character vector
Values: `'1' | '2' | '3' | '4' | ... | 30`
Default: `'3'`

`Data specification` — Method of table and breakpoint specification

`Table and breakpoints` (default) | `Lookup table object`

From the list, select:

- `Table and breakpoints` — Specify the table data and breakpoints. Selecting this option enables the following parameters:
  - **Table data**
  - **Breakpoints specification**
  - **Breakpoints 1**
  - **Breakpoints 2**
  - **Breakpoints 3**
  - **Edit table and breakpoints**
- `Lookup table object` — Use an existing lookup table (`Simulink.LookupTable`) object. Selecting this option enables the **Name** field and **Edit table and breakpoints** button.

Programmatic Use
Block Parameter: `DataSpecification`
Type: character vector
Values: `'Table and breakpoints' | 'Lookup table object'`
Default: `'Table and breakpoints'`

`Name` — Name of the lookup table object

`[]` (default) | `Simulink.LookupTable` object

Enter the name of the lookup table (`Simulink.LookupTable`) object.

Dependencies

To enable this parameter, set **Data specification** to `Lookup table object`.

Programmatic Use
Block Parameter: `LookupTableObject`
Type: character vector
Values: name of a `Simulink.LookupTable` object
Default: `''`

`Table data` — Define the table of output values

`reshape(repmat([4 5 6;16 19 20;10 18 23],1,2),[3,3,2])` (default) | matrix of values with dimensions that match the **Number of table dimensions**

Enter the table of output values.

During simulation, the matrix size must match the dimensions defined by the **Number of table dimensions** parameter. However, during block diagram editing, you can enter an empty matrix (specified as `[]`) or an undefined workspace variable. This technique lets you postpone specifying a correctly dimensioned matrix for the table data and continue editing the block diagram.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use
Block Parameter: `Table`
Type: character vector
Values: matrix of table values
Default: `'reshape(repmat([4 5 6;16 19 20;10 18 23],1,2),[3,3,2])'`

`Breakpoints specification` — Method of breakpoint specification

`Explicit values` (default) | `Even spacing`

Specify whether to enter data as explicit breakpoints or as parameters that generate evenly spaced breakpoints.

- To explicitly specify breakpoint data, set this parameter to `Explicit values` and enter breakpoint data in the text box next to the **Breakpoints** parameters.
- To specify parameters that generate evenly spaced breakpoints, set this parameter to `Even spacing` and enter values for the **First point** and **Spacing** parameters for

each dimension of breakpoint data. The block calculates the number of points to generate from the table data.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsSpecification`
Type: character vector
Values: `'Explicit values' | 'Even spacing'`
Default: `'Explicit values'`

`Breakpoints` — Explicit breakpoint values, or first point and spacing of breakpoints

`[10,22,31]` (default) | 1-by-n or n-by-1 vector of monotonically increasing values

Specify the breakpoint data explicitly or as evenly-spaced breakpoints, based on the value of the **Breakpoints specification** parameter.

- If you set **Breakpoints specification** to `Explicit values`, enter the breakpoint set that corresponds to each dimension of table data in each **Breakpoints** row. For each dimension, specify breakpoints as a 1-by-n or n-by-1 vector whose values are strictly monotonically increasing.
- If you set **Breakpoints specification** to `Even spacing`, enter the parameters **First point** and **Spacing** in each **Breakpoints** row to generate evenly-spaced breakpoints in the respective dimension. Your table data determines the number of evenly spaced points.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1 | BreakpointsForDimension2 | ... | BreakpointsForDimension30 |`
Type: character vector
Values: 1-by-n or n-by-1 vector of monotonically increasing values
Default: `'[10, 22, 31]'`

`First point` — First point in evenly spaced breakpoint data

`1` (default) | scalar

Specify the first point in your evenly spaced breakpoint data as a real-valued, finite, scalar. This parameter is available when **Breakpoints specification** is set to `Even spacing`.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1FirstPoint | BreakpointsForDimension2FirstPoint | ... | BreakpointsForDimension30FirstPoint |`
Type: character vector
Values: real-valued, finite, scalar
Default: `'1'`

Spacing — Spacing between evenly spaced breakpoints

1 (default) | scalar

Specify the spacing between points in your evenly-spaced breakpoint data.

Dependencies

To enable this parameter, set **Data specification** to `Table and breakpoints`, and **Breakpoints specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsForDimension1Spacing | BreakpointsForDimension2Spacing | ... | BreakpointsForDimension30Spacing |`
Type: character vector
Values: positive, real-valued, finite, scalar
Default: `'1'`

`Edit table and breakpoints` — Launch Lookup Table Editor dialog box

button

Click this button to open the Lookup Table Editor. For more information, see “Edit Lookup Tables” in the Simulink documentation.

Clicking this button for a lookup table object lets you edit the object and save the new values for the object.

Algorithm

Lookup method

`Interpolation method` — Method of interpolation between breakpoint values

`Linear point-slope` (default) | `Flat` | `Nearest` | `Linear Lagrange` | `Cubic spline`

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. For more information on interpolation methods, see “Interpolation Methods”.

Dependencies

If you select `Cubic spline`, the block supports only scalar signals. The other interpolation methods support nonscalar signals.

Programmatic Use
Block Parameter: `InterpMethod`
Type: character vector
Values: `'Linear point-slope' | 'Flat' | 'Nearest' | 'Linear Lagrange' | 'Cubic spline'`
Default: `'Linear point-slope'`

`Extrapolation method` — Method of handling input values that fall outside the range of a breakpoint data set

`Clip` (default) | `Linear` | `Cubic spline`

Select `Clip`, `Linear`, or `Cubic spline`. See “Extrapolation Methods” for more information.

If the extrapolation method is `Linear`, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is Linear Lagrange, the extrapolation method inherits the Linear Lagrange equation to compute the extrapolated value.

Dependencies

To select `Cubic spline` for **Extrapolation method**, you must also select `Cubic spline` for **Interpolation method**.

Programmatic Use
Block Parameter: `ExtrapMethod`

Type: character vector
Values: `'Linear' | 'Clip' | 'Cubic spline'`
Default: `'Linear'`

`Index search method` — Method of calculating table indices

`Evenly spaced points` (default) | `Linear search` | `Binary search`

Select `Evenly spaced points`, `Linear search`, or `Binary search`. Each search method has speed advantages in different circumstances:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices.

  This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.

  Note Set **Index search method** to `Evenly spaced points` when using the `Simulink.LookupTable` object to specify table data and the **Breakpoints Specification** parameter of the referenced `Simulink.LookupTable` object is set to `Even spacing`.

- For unevenly spaced breakpoint sets, follow these guidelines:

  - If input signals do not vary much between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
  - If input signals jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
- The index search method is `Evenly spaced points`.

Programmatic Use
Block Parameter: `IndexSearchMethod`
Type: character vector
Values: `'Binary search' | 'Evenly spaced points' | 'Linear search'`
Default: `'Binary search'`

`Begin index search using previous index result` — Start using the index from the previous time step

`off` (default) | `on`

Select this check box when you want the block to start its search using the index found at the previous time step. For inputs that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Dependencies

To enable this parameter, set **Index search method** to `Linear search` or `Binary search`.

Programmatic Use
Block Parameter: `BeginIndexSearchUsing PreviousIndexResult`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Diagnostic for out-of-range input` — Block action when input is out of range

`None` (default) | `Warning` | `Error`

Specify whether to produce a warning or error when the input is out of range. Options include:

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use
Block Parameter: `DiagnosticForOutOfRangeInput`
Type: character vector
Values: `'None' | 'Warning' | 'Error'`
Default: `'None'`

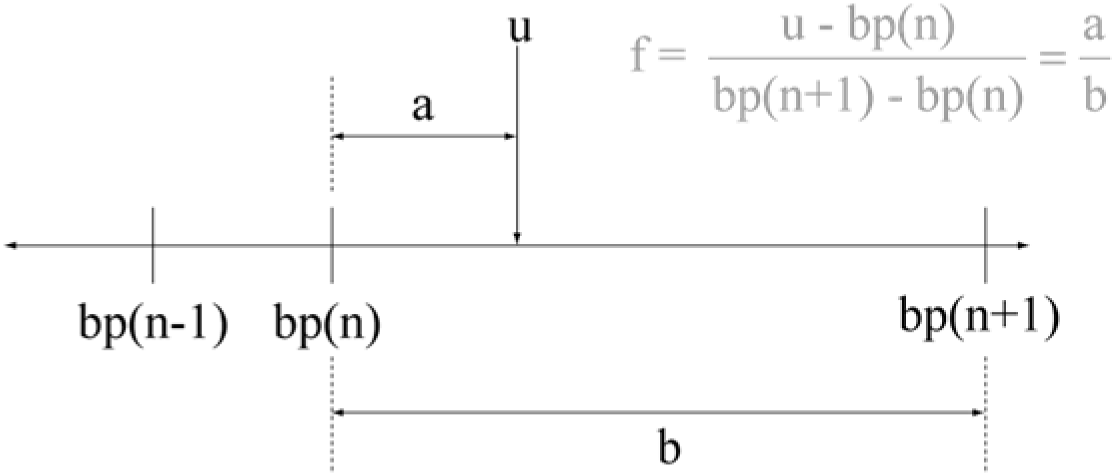
`Use last table value for inputs at or above last breakpoint` — Method for computing output for inputs at or above last breakpoint

`off` (default) | `on`

Using this check box, specify the indexing convention that the block uses to address the last element of a breakpoint set and its corresponding table value. This check box is relevant if the input is larger than the last element of the breakpoint data.

Check Box	Block Uses Index Of The...	Interval Fraction
Selected	Last element of breakpoint data on the **Table and Breakpoints** tab	0
Cleared	Next-to-last element of breakpoint data on the **Table and Breakpoints** tab	1

Given an input *u* within range of a breakpoint set *bp*, the interval fraction *f*, in the range 0 *f* 1, is computed as shown below.



Suppose the breakpoint set is `[1 4 5]` and input *u* is `5.5`. If you select this check box, the index is that of the last element (5) and the interval fraction is 0. If you clear this check box, the index is that of the next-to-last element (4) and the interval fraction is 1.

Dependencies

To enable this parameter, set:

- **Interpolation method** to `Linear`.
- **Extrapolation method** to `Clip`.

Programmatic Use

Block Parameter: `UseLastTableValue`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Input settings

`Use one input port for all input data` — Use only one input port

`off` (default) | `on`

Select this check box to use only one input port that expects a signal that is `n` elements wide for an n-dimensional table. This option is useful for removing line clutter on a block diagram with many lookup tables.

Note When you select this check box, one input port with the label `u` appears on the block.

Programmatic Use

Block Parameter: `UseOneInputPortForAllInputData`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Code generation

`Remove protection against out-of-range input in generated code` — Remove code that checks for out-of-range input values

`off` (default) | `on`

Specify whether or not to include code that checks for out-of-range input values.

Check Box	Result	When to Use
`on`	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
`off`	Generated code includes conditional statements to check for out-of-range inputs.	For safety-critical applications

If your input is not out of range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

1. Clear the **Remove protection against out-of-range index in generated code** check box.
2. Set the **Diagnostic for out-of-range input** parameter to `Error`.
3. Simulate the model in normal mode.
4. If there are out-of-range errors, fix them to be in range and run the simulation again.
5. When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

> **Note** When you select the **Remove protection against out-of-range index in generated code** check box and the input `k` or `f` is out of range, the behavior is undefined for generated code and simulations using accelerator mode.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks”.

Programmatic Use
Block Parameter: `RemoveProtectionInput`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Support tunable table size in code generation` — Enable tunable table size in the generated code

`off` (default) | `on`

Select this check box to enable tunable table size in the generated code. This option enables you to change the size and values of the lookup table and breakpoint data in the generated code without regenerating or recompiling the code.

Dependencies

If you set **Interpolation method** to `Cubic spline`, this check box is not available.

Programmatic Use
Block Parameter: `SupportTunableTableSize`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

`Maximum indices for each dimension` — Maximum index value for each table dimension

`[]` (default) | `scalar or vector of positive integer values`

Example: `[4 6]` for a 5-by-7 table

Specify the maximum index values for each table dimension using zero-based indexing. You can specify a scalar or vector of positive integer values using the following data types:

- Built-in floating-point types: `double` and `single`
- Built-in integer types: `int8`, `int16`, `int32`, `uint8`, `uint16`, and `uint32`

Examples of valid specifications include:

- `[4 6]` for a 5-by-7 table
- `[int8(2) int16(5) int32(9)]` for a 3-by-6-by-10 table
- A `Simulink.Parameter` whose value on generating code is one less than the dimensions of the table data. For more information, see “Tunable Table Size in the Generated Code” on page 1-1160.

Dependencies

To enable this parameter, select **Support tunable table size in code generation**. On tuning this parameter in the generated code, provide the new table data and breakpoints along with the tuned parameter value.

Programmatic Use
Block Parameter: `MaximumIndicesForEachDimension`
Type: character vector
Values: scalar or vector of positive integer values
Default: `'[]'`

Data Types

`Table data` — Data type of table data

`Inherit: Same as output` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the table data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a table data type different from the output data type for these cases:

- Lower memory requirement for storing table data that uses a smaller type than the output signal
- Sharing of prescaled table data between two n-D Lookup Table blocks with different output data types
- Sharing of custom storage table data in the generated code for blocks with different output data types

Programmatic Use

Block Parameter: `TableDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit from 'Table data'' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`
Default: `'Inherit: Same as output'`

Table data Minimum — Minimum value of the table data

[] | scalar

Specify the minimum value for table data. The default value is [] (unspecified).

Programmatic Use
Block Parameter: TableMin
Type: character vector
Values: scalar
Default: '[]'

Table data Maximum — Maximum value of the table data

[] | scalar

Specify the maximum value for table data. The default value is [] (unspecified).

Programmatic Use
Block Parameter: TableMax
Type: character vector
Values: scalar
Default: '[]'

Breakpoints — Breakpoint data type

Inherit: Same as corresponding input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | Enum: <class name> | <data type expression>

Specify the data type for a set of breakpoint data. You can set it to:

- A rule that inherits a data type, for example, Inherit: Same as corresponding input
- The name of a built-in data type, for example, single
- The name of a data type class, for example, an enumerated data type class
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Tip

- Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.

- If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
- For enumerated data, **Extrapolation method** must be `Clip`.
- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

This is a limitation for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Specify a breakpoint data type different from the corresponding input data type for these cases:

- Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal
- Sharing of prescaled breakpoint data between two n-D Lookup Table blocks with different input data types
- Sharing of custom storage breakpoint data in the generated code for blocks with different input data types

---

Programmatic Use
Block Parameter: `BreakpointsForDimension1DataTypeStr | BreakpointsForDimension2DataTypeStr| ... | BreakpointsForDimension30DataTypeStr`
Type: character vector
Values: `'Inherit: Same as corresponding input' | 'Inherit: Inherit from 'Breakpoint data'' | 'double' | 'single' | 'int8' | 'uint8' |`

`'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`
Default: `'Inherit: Same as corresponding input'`

`Breakpoints Minimum` — Minimum value breakpoint data can have

`[]` | `scalar`

Specify the minimum value that a set of breakpoint data can have. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `BreakpointsForDimension1Min | BreakpointsForDimension2Min | ... | BreakpointsForDimension30Min`
Type: character vector
Values: scalar
Default: `'[]'`

`Breakpoints Maximum` — Maximum value breakpoint data can have

`[]` | `scalar`

Specify the maximum value that a set of breakpoint data can have. The default value is `[]` (unspecified).

Programmatic Use
Block Parameter: `BreakpointsForDimension1Max | BreakpointsForDimension2Max | ... | BreakpointsForDimension30Max`
Type: character vector
Values: scalar
Default: `'[]'`

`Fraction` — Fraction data type

`Inherit: Inherit via internal rule` (default) | `double` | `single` | `fixdt(1,16,0)` | `<data type expression>`

Specify the fraction data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via internal rule`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `FractionDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'double' | 'single' | 'fixdt(1,16,0)'|'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Intermediate results` — Intermediate results data type

`Inherit: Same as output` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the intermediate results data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as output`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip Use this parameter to specify higher (or lower) precision for internal computations than for table data or output data.

Programmatic Use
Block Parameter: `IntermediateResultsDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule' | 'Inherit: Same as output' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`

Default: 'Inherit: Same as output'

Output — Output data type

Inherit: Same as input (default) | double | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | fixdt(1,16) | fixdt(1,16,0) | fixdt(1,16,2^0,0) | <data type expression>

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, Inherit: Inherit via back propagation
- The name of a built-in data type, for example, single
- The name of a data type object, for example, a Simulink.NumericType object
- An expression that evaluates to a data type, for example, fixdt(1,16,0)

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: OutDataTypeStr
Type: character vector
Values: 'Inherit: Inherit via back propagation' | 'Inherit: Inherit from table data' | 'Inherit: Same as first input' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression'
Default: 'Inherit: Same as first input'

Output Minimum — Minimum value the block can output

[] | scalar

Specify the minimum value that the block outputs. The default value is [] (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.

- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: scalar
Default: `'[]'`

`Output Maximum` — Maximum value the block can output

`[]` | `scalar`

Specify the maximum value that the block can output. The default value is `[]` (unspecified). Simulink software uses this value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”).
- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: scalar
Default: `'[]'`

`Internal rule priority` — Internal rule for intermediate calculations

`Speed` (default) | `Precision`

Specify the internal rule for intermediate calculations. Select `Speed` for faster calculations. If you do, a loss of accuracy might occur, usually up to 2 bits.

Programmatic Use
Block Parameter: `InternalRulePriority`
Type: character vector

Values: `'Speed' | 'Precision'`
Default: `'Speed'`

`Require all inputs to have the same data type` — Require all inputs to have the same data type

`on` (default) | `off`

Select to require all inputs to have the same data type.

Programmatic Use
Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Simplest` (default) | `Ceiling` | `Convergent` | `Floor` | `Nearest` | `Round` | `Zero`

Specify the rounding mode for fixed-point lookup table calculations that occur during simulation or execution of code generated from the model. For more information, see “Rounding” (Fixed-Point Designer).

This option does not affect rounding of values of block parameters. Simulink rounds such values to the nearest representable integer value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the edit field on the block dialog box.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Simplest'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box (`on`).	Your model has possible overflow and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	An overflow associated with a signed 8-bit integer can saturate to -128 or 127.
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tip If you save your model as version R2009a or earlier, this check box setting has no effect and no saturation code appears. This behavior preserves backward compatibility.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`

Type: character vector
Values: 'off' | 'on'
Default: 'off'

Block Characteristics

Data Types	double | single | base integer | fixed point | enumerated
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

Definitions

Tunable Table Size in the Generated Code

Suppose that you have a lookup table and want to make the size tunable in the generated code. When you use Simulink.LookupTable and Simulink.Breakpoint objects to configure lookup table data for calibration in the generated code, use the SupportTunableSize property of the objects to enable a tunable table size. When you do not use these classes, use the **Support tunable table size in code generation** parameter in an n-D Lookup Table block to enable a tunable table size.

Assume that:

- You define a Simulink.Parameter structure in the preload function of your model:

  ```
  p = Simulink.Parameter;
  p.Value.MaxIdx = [2 2];
  p.Value.BP1 = [1 2 3];
  p.Value.BP2 = [1 4 16];
  p.Value.Table = [4 5 6; 16 19 20; 10 18 23];
  ```

```
p.DataType = 'Bus: slLookupTable';
p.CoderInfo.StorageClass = 'ExportedGlobal';

% Create bus object slBus1 from MATLAB structure
Simulink.Bus.createObject(p.Value);
slLookupTable = slBus1;
slLookupTable.Elements(1).DataType = 'uint32';
```

- These block parameters apply in the n-D Lookup Table block dialog box.

Parameter	Value
Number of table dimensions	`2`
Table data	`p.Table`
Breakpoints 1	`p.BP1`
Breakpoints 2	`p.BP2`
Support tunable table size in code generation	`on`
Maximum indices for each dimension	`p.MaxIdx`

The generated `*model*_types.h` header file contains a type definition that looks something like this.

```
typedef struct {
  uint32_T MaxIdx[2];
  real_T BP1[3];
  real_T BP2[3];
  real_T Table[9];
} slLookupTable;
```

The generated `*model*.c` file contains code that looks something like this.

```
/* Exported block parameters */
slLookupTable p = {
  { 2U, 2U },

  { 1.0, 2.0, 3.0 },

  { 1.0, 4.0, 16.0 },

  { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
} ;
```

```
/* More code */

/* Model output function */
static void ex_lut_nd_tunable_table_output(int_T tid)
{
  /* Lookup_n-D: '<Root>/n-D Lookup Table' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   */
  Y = look2_binlcpw(U1, U2, p.BP1, p.BP2, p.Table, ...
p.MaxIdx, p.MaxIdx[0] + 1U);

  /* Outport: '<Root>/Out1' */
  ex_lut_nd_tunable_table_Y.Out1 = Y;

  /* tid is required for a uniform function interface.
   * Argument tid is not used in the function. */
  UNUSED_PARAMETER(tid);
}
```

The highlighted line of code specifies a tunable table size for the lookup table. You can change the size and values of the lookup table and breakpoint data without regenerating or recompiling the code.

Enumerated Values in Lookup Tables

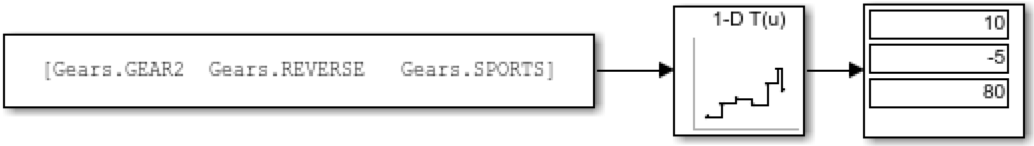
Suppose that you have a lookup table with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end
```

n-D Lookup block has these settings:

- **Number of dimensions** to 1.
- **Table data** value is `[5 10 20 40 80 -5 0]`.
- **Breakpoints 1** value is `enumeration('Gears')`.
- Interpolation method is Flat.
- For an unordered search, set **Index search method** to `Linear search` and clear the **Begin index search using previous index result** check box.

Simulation produces a vector `[10 -5 80]`, which correspond to `GEAR2`, `REVERSE`, and `SPORTS`.



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL Code Generation, see n-D Lookup Table.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Simulink PLC Coder™ has limited support for lookup table blocks. The coder does not support:

- Number of dimensions greater than 2
- Cubic spline interpolation method
- Begin index search using a previous index mode
- Cubic spline extrapolation method

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

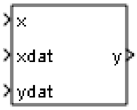
Lookup Table Dynamic

Approximate a one-dimensional function using dynamic table
Library: Simulink / Lookup Tables



Description

How This Block Differs from Other Lookup Table Blocks

The Lookup Table Dynamic block computes an approximation of a function `y = f(x)` using `xdat` and `ydat` vectors. The lookup method can use interpolation, extrapolation, or the original values of the input.

Using the Lookup Table Dynamic block, you can change the table data without stopping the simulation. For example, you can incorporate new table data if the physical system you are simulating changes.

Inputs for Breakpoint and Table Data

The `xdat` vector is the breakpoint data, which must be *strictly monotonically increasing*. The value of the next element in the vector must be greater than the value of the preceding element after conversion to a fixed-point data type. Due to quantization, `xdat` can be strictly monotonic for a floating-point data type, but not after conversion to a fixed-point data type.

The `ydat` vector is the table data, which is an evaluation of the function at the breakpoint values.

Note The inputs to `xdat` and `ydat` cannot be scalar (one-element array) values. If you provide a scalar value to either of these inputs, you see an error upon simulation. Provide a 1-by-n vector to both the `xdat` and `ydat` inputs.

Lookup Table Definition

You define the lookup table by feeding `xdat` and `ydat` as 1-by-n vectors to the block. To reduce ROM usage in the generated code for this block, you can use different data types for `xdat` and `ydat`. However, these restrictions apply:

- The `xdat` breakpoint data and the `x` input vector must have the same sign, bias, and fractional slope. Also, the precision and range for `x` must be greater than or equal to the precision and range for `xdat`.
- The `ydat` table data and the `y` output vector must have the same sign, bias, and fractional slope.

Tip Breakpoints with even spacing can make Simulink Coder generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and "Identify questionable fixed-point operations" (Embedded Coder) in the Simulink Coder documentation.

How the Block Generates Output

The block uses the input values to generate output using the method you select for **Lookup Method**:

Lookup Method	Block Action
`Interpolation-Extrapolation`	Performs linear interpolation and extrapolation of the inputs. • If the input matches a breakpoint, the output is the corresponding element in the table data. • If the input does not match a breakpoint, the block performs linear interpolation between two elements of the table to determine the output. If the input falls outside the range of breakpoint values, the block extrapolates using the first two or last two points. **Note** If you select this lookup method, Simulink Coder software cannot generate code for this block.

Lookup Method	Block Action
`Interpolation-Use End Values` (default)	Performs linear interpolation but does not extrapolate outside the end points of the breakpoint data. Instead, the block uses the end values.
`Use Input Nearest`	Finds the element in `xdat` nearest the current input. The corresponding element in `ydat` is the output.
`Use Input Below`	Finds the element in `xdat` nearest and below the current input. The corresponding element in `ydat` is the output. If there is no element in `xdat` below the current input, the block finds the nearest element.
`Use Input Above`	Finds the element in `xdat` nearest and above the current input. The corresponding element in `ydat` is the output. If there is no element in `xdat` above the current input, the block finds the nearest element.

Note The `Use Input Nearest`, `Use Input Below`, and `Use Input Above` methods perform the same action when the input `x` matches a breakpoint value.

Some continuous solvers subdivide the simulation time span into major and minor time steps. A minor time step is a subdivision of the major time step. The solver produces a result at each major time step and uses results at minor time steps to improve the accuracy of the result at the major time step. For continuous solvers, the output of the Lookup Table Dynamic block can appear like a stair step because the signal is fixed in minor time step to avoid incorrect results. For more information about the effect of solvers on block output, see “Solvers” in the Simulink documentation.

Ports

Input

x — input vector

`n-dimensional array`

The block accepts real-valued or complex-valued multidimensional inputs.

Example: `2:12`

Dependencies

The `x` input vector and the `xdat` breakpoint data must have the same sign, bias, and fractional slope. Also, the precision and range for `x` must be greater than or equal to the precision and range for `xdat`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `bus`

`xdat` — breakpoint data

`1-by-n vector of strictly monotonically increasing values`

The `xdat` vector is the breakpoint data, which must be strictly monotonically increasing. The value of the next element in the vector must be greater than the value of the preceding element after conversion to a fixed-point data type. Due to quantization, `xdat` can be strictly monotonic for a floating-point data type, but not after conversion to a fixed-point data type.

Tip Breakpoints with even spacing can make Simulink Coder generated code division-free. For more information, see `fixpt_evenspace_cleanup` in the Simulink documentation and “Identify questionable fixed-point operations” (Embedded Coder) in the Simulink Coder documentation.

Example: `1:10`

Dependencies

The `xdat` breakpoint data and the `x` input vector must have the same sign, bias, and fractional slope. Also, the precision and range for `x` must be greater than or equal to the precision and range for `xdat`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `bus`

`ydat` — table data

`1-by-n vector`

The `ydat` input is a 1-by-n vector of real-valued or complex-valued table data, which is an evaluation of the function at the breakpoint values.

Example: `[0 3 12 27 48 75 108 147 192 243 300]`

Dependencies

The ydat table data and the y output vector must have the same sign, bias, and fractional slope.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | bus

Output

y — Approximation of y = f(x) using dynamic table data

1-by-n vector

The block computes an approximation of a function y = f(x) using the xdat and ydat input vectors. The lookup method can use interpolation, extrapolation, or the original values of the input.

Dependencies

The ydat table data and the y output vector must have the same sign, bias, and fractional slope.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Parameters

Main Tab

Lookup Method — Specify the lookup method

Interpolation-Use End Values (default) | Interpolation-Extrapolation | Use Input Nearest | Use Input Below | Use Input Above

The block computes output by applying the **Lookup Method** you select to the input vectors of breakpoint data (xdat) and table data (ydat). For details, see “How the Block Generates Output” on page 1-1166.

Programmatic Use

Block Parameter: LookUpMeth
Type: character vector

Values: `'Interpolation-Extrapolation' | 'Interpolation-Use End Values' | 'Use Input Nearest' | 'Use Input Below' | 'Use Input Above'`
Default: `'Interpolation-Use End Values'`

Signal Attributes Tab

`Output data type` — Output data type

`double` (default) | `'Inherit: Inherit via back propagation'` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the data type of the output signal `y`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

The `ydat` table data and the `y` output vector must have the same sign, bias, and fractional slope.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via back propagation' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'boolean' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|<data type expression>`
Default: `'double'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`

Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see "Rounding" (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate to max or min when overflows occur` — Method of overflow action

`off` (default) | `on`

When you select this check box, overflows saturate to the maximum or minimum value that the data type can represent. Otherwise, overflows wrap.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `DoSatur`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

The Simulink PLC Coder software does not support the SimulinkSimulink Lookup Table Dynamic block. For your convenience, the plclib/Simulink/Lookup Tables library contains an implementation of a dynamic table lookup block using the Prelookup and Interpolation Using Prelookup blocks.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

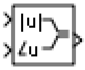
Magnitude-Angle to Complex

Convert magnitude and/or a phase angle signal to complex signal
Library: Simulink / Math Operations



Description

Supported Operations

The Magnitude-Angle to Complex block converts magnitude and phase angle inputs to a complex output. The angle input must be in rad.

The block supports the following combinations of input dimensions when there are two block inputs:

- Two inputs of equal dimensions
- One scalar input and the other an n-dimensional array

If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

Effect of Out-of-Range Input on CORDIC Approximations

If you use the CORDIC approximation method (see “Definitions” on page 1-1181), the block input for phase angle has the following restrictions:

- For signed fixed-point types, the input angle must fall within the range [–2π, 2π) rad.
- For unsigned fixed-point types, the input angle must fall within the range [0, 2π) rad.

The following table summarizes what happens for an out-of-range input:

Block Usage	Effect of Out-of-Range Input
Simulation	An error appears.
Generated code	Undefined behavior occurs.
Accelerator modes	

Ensure that you use an in-range input for the Magnitude-Angle to Complex block when you use the CORDIC approximation. Avoid relying on undefined behavior for generated code or accelerator modes.

Ports

Input

|u| — Magnitude

scalar | vector | matrix

Magnitude, specified as a real-valued scalar, vector, or matrix.

Dependencies

- To enable this port, set **Input** to `Magnitude and angle`.

Limitations

- If one input has a floating-point data type, the other input must use the same data type. For example, both signals must be `double` or `single`.
- Fixed-point data types are supported only when you set the **Approximation method** to `CORDIC`. When one input has a fixed-point data type, the other input must also have a fixed-point data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

∠u — Radian phase angle

scalar | vector | matrix

Radian phase angle, specified as a real-valued scalar, vector, or matrix. To compute the CORDIC approximation, the input angle must be between:

- [–2π, 2π) rad, for signed fixed-point types
- [0, 2π) rad, for unsigned fixed-point types

For more information, see “Effect of Out-of-Range Input on CORDIC Approximations” on page 1-1174.

Dependencies

- To enable this port, set **Input** to `Magnitude and angle`.

Limitations

- If one input has a floating-point data type, the other input must use the same data type. For example, both signals must be `double` or `single`.
- Fixed-point data types are supported only when you set the **Approximation method** to `CORDIC`. If one input has a fixed-point data type, the other input must also have a fixed-point data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Port_1` — Magnitude or radian phase angle

scalar | vector | matrix

Magnitude, or radian phase angle, specified as a real-valued scalar, vector, or matrix.

- When you set **Input** to `Magnitude`, you specify the magnitude at the input port, and the angle on the dialog box.
- When you set **Input** to `Angle`, you specify the angle at the input port, and the magnitude on the dialog box.

Dependencies

To enable this port, set **Input** to `Magnitude` or `Angle`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Complex signal

scalar | vector | matrix

Complex signal, formed from the magnitude and phase angle you specify.

If the block input is an array, the output is an array of complex signals. The elements of a magnitude input vector map to the magnitudes of the corresponding complex output elements. Similarly, the elements of an angle input vector map to the angles of the corresponding complex output elements. If one input is a scalar, it maps to the corresponding component (magnitude or angle) of all the complex output signals.

Data Types: `single` | `double` | `fixed point`

Parameters

`Input` — Type of input

`Magnitude` (default) | `Angle` | `Magnitude and angle`

Specify the kind of input: a magnitude input, an angle input, or both.

Programmatic Use

Block Parameter: `Input`
Type: character vector
Values: `'Magnitude' | 'Angle' | 'Magnitude and angle'`
Default: `'Magnitude and angle'`

`Angle` — Phase angle of output

`0` (default) | real-valued scalar, vector, or matrix

Constant phase angle of the output signal, in rad. To compute the CORDIC approximation, the input angle must be between:

- [–2π, 2π) rad, for signed fixed-point types
- [0, 2π) rad, for unsigned fixed-point types

For more information, see “Effect of Out-of-Range Input on CORDIC Approximations” on page 1-1174.

Dependencies

To enable this parameter, set **Input** to `Magnitude`.

Programmatic Use

Block Parameter: `ConstantPart`

Type: character vector
Values: constant scalar
Default: `'0'`

`Magnitude` — Magnitude of output

`0` (default) | real-valued scalar, vector, or matrix

Constant magnitude of the output signal, specified as a real-valued scalar, vector, or matrix.

Dependencies

To enable this parameter, set **Input** to `Angle`.

Programmatic Use

Block Parameter: `ConstantPart`
Type: character vector
Values: constant scalar
Default: `'0'`

`Approximation method` — CORDIC or none

`None` (default) | `CORDIC`

Specify the type of approximation for computing output.

Approximation Method	Data Types Supported	When to Use This Method
`None` (default)	Floating point	You want to use the default Taylor series algorithm.
`CORDIC`	Floating point and fixed point	You want a fast, approximate calculation.

When you use the CORDIC approximation, follow these guidelines for the input angle:

- For signed fixed-point types, the input angle must fall within the range [–2π, 2π) rad.
- For unsigned fixed-point types, the input angle must fall within the range [0, 2π) rad.

The block uses the following data type propagation rules:

Data Type of Magnitude Input	Approximation Method	Data Type of Complex Output
Floating point	`None` or `CORDIC`	Same as input
Signed, fixed point	`CORDIC`	`fixdt`(1, *`WL`* + 2, *`FL`*) where *`WL`* and *`FL`* are the word length and fraction length of the magnitude
Unsigned, fixed point	`CORDIC`	`fixdt`(1, *`WL`* + 3, *`FL`*) where *`WL`* and *`FL`* are the word length and fraction length of the magnitude

Programmatic Use
Block Parameter: `ApproximationMethod`
Type: character vector
Values: `'None' | 'CORDIC'`
Default: `'None'`

`Number of iterations` — Number of iterations for CORDIC algorithm

`11` (default) | positive integer, less than or equal to word length of fixed-point input

Number of iterations to perform the CORDIC algorithm. The range of possible values depends on the data type of the input:

Data Type of Block Inputs	Value You Can Specify
Floating point	A positive integer
Fixed point	A positive integer that does not exceed the word length of the magnitude input or the word length of the phase angle input, whichever value is smaller

Dependencies

To enable this parameter, set **Approximation method** to `CORDIC`.

Programmatic Use
Block Parameter: `NumberOfIterations`
Type: character vector
Values: positive integer, less than or equal to word length of fixed-point input

Default: '11'

Scale output by reciprocal of gain factor — Scale real and imaginary parts of complex output

on (default) | off

Select this check box to scale the real and imaginary parts of the complex output by a factor of (1/CORDIC gain). This value depends on the number of iterations you specify. As the number of iterations goes up, the value approaches 1.647.

This check box is selected by default, which leads to a more numerically accurate result for the complex output, X + iY. However, scaling the output adds two extra multiplication operations, one for X and one for Y.

Dependencies

To enable this parameter, set **Approximation method** to CORDIC.

Programmatic Use

Block Parameter: ScaleReciprocalGainFactor
Type: character vector
Values: 'on' | 'off'
Default: 'on'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: SampleTime
Type: character vector
Values: scalar
Default: '-1'

Block Characteristics

Data Types	`double` | `single`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Definitions

CORDIC

CORDIC is an acronym for COordinate Rotation DIgital Computer. The Givens rotation-based CORDIC algorithm is one of the most hardware-efficient algorithms available because it requires only iterative shift-add operations (see References). The CORDIC algorithm eliminates the need for explicit multipliers. Using CORDIC, you can calculate various functions, such as sine, cosine, arc sine, arc cosine, arc tangent, and vector magnitude. You can also use this algorithm for divide, square root, hyperbolic, and logarithmic functions.

Increasing the number of CORDIC iterations can produce more accurate results, but doing so also increases the expense of the computation and adds latency.

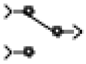
Manual Switch

Switch between two inputs
Library: Simulink / Signal Routing



Description

The Manual Switch block is a toggle switch that selects one of its two inputs to pass through to the output. To toggle between inputs, double-click the block. You control the signal flow by setting the switch before you start the simulation or by changing the switch while the simulation is executing. The Manual Switch block retains its current state when you save the model.

Note Double-clicking the Manual Switch block does not open the block dialog box. Instead, it toggles the input choice.

Ports

Input

Port_1 — First input signal
scalar | vector

First of two inputs to the Manual Switch block. The block propagates the selected input to the output. To select the input signal, toggle the switch by double-clicking the block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Port_2 — Second input signal
scalar | vector

Second of two inputs to the Manual Switch block. The block propagates the selected input to the output. To select which input signal, toggle the switch by double-clicking the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Output signal

scalar | vector

Output signal progagated from either the first or second input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

To view the block parameters, right-click the block and select `Block Parameters (ManualSwitch)`.

`Allow the two inputs to differ in size (Results in variable-size output signal)` — Allow inputs of different sizes

`off` (default) | `on`

Select this check box to allow inputs with different sizes. If you select the box, the block allows inputs with different sizes, and propagates the selected input signal size to the output signal. If you clear the box, the block expands scalar inputs to have the same dimensions as nonscalar inputs. See “Scalar Expansion of Inputs and Parameters”.

Programmatic Use
Parameter: `varsize`
Type: character vector
Value: `'on'` | `'off'`
Default: `'off'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`

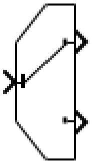
Manual Variant Sink | Manual Variant Source | Multiport Switch | Switch

Introduced before R2006a

Manual Variant Sink

Switch between multiple variant choices at output
Library: Simulink / Signal Routing



Description

The Manual Variant Sink block is a toggle switch that activates one of its variant choices at the output to pass the input.

The block can have two or more output ports and has one input port. Each output port is associated with a variant control. To change the number of output ports, right-click the block and select **Mask Parameters**, then type a value in the **Number of choices** box.

To toggle between the variant choices at output, double-click the block. The block displays the active choice with a line connecting the input to the output. The block propagates the active variant choice at output and discards the blocks connected to inactive output ports during simulation.

Note Double-clicking the Manual Variant Sink block does not open the block dialog box instead it toggles the output choice.

Ports

Input

`Port_1` — Input signal
scalar | vector

Input signal passed to the active output port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — First variant output

scalar | vector

First variant output signal. The block passes the input signal to this output port when you connect the toggle switch to this port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`Port_n` — nth variant output

scalar | vector

`n`th variant output signal. The block passes the input signal to this output port when you connect the toggle switch to this port.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

To access the block parameter, right-click the block and select **Mask > Mask Parameters**.

`Number of choices` — Number of output choices

2 (default) | scalar

Specify the number of variant output ports.

Programmatic Use
Block Parameter: `NumChoices`
Type: character vector
Value: `integer`
Default: `'2'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

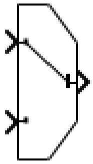
Manual Variant Source

Switch between multiple variant choices at input
Library: Simulink / Signal Routing



Description

The Manual Variant Source block is a toggle switch that activates one of its variant choices at the input to pass through to the output.

A Manual Variant Source block can have two or more input ports and has one output port. Each input port is associated with a variant control. To change the number of input ports, right-click the block and select **Mask Parameters**, then type a value in the **Number of choices** box.

To toggle between the variant choices at input, double-click the block. The block displays the active choice with a line connecting the input to the output. The block propagates the active variant choice at input directly to the output and discards the blocks connected to inactive input ports during simulation.

Note Double-clicking the Manual Variant Source block does not open the block dialog box instead it toggles the output choice.

Ports

Input

`Port_1` — First variant input signal
scalar | vector

First variant input signal. The block passes this input signal to the output port when you connect the toggle switch to this port.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Port_n — nth variant input signal
scalar | vector

nth variant input signal. The block passes this input signal to the output port when you connect the toggle switch to this port.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal
scalar | vector

Output signal passed from the active variant input signal.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Parameters

To access the block parameter, right-click the block and select **Mask** > **Mask Parameters**.

Number of choices — Number of input choices
2 (default) | scalar

Specify the number of variant input ports.

Programmatic Use
Block Parameter: NumChoices
Type: character vector
Value: integer
Default: '2'

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

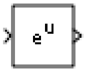
Math Function

Perform mathematical function

Library: Simulink / Math Operations



Description

The Math Function block performs numerous common mathematical functions.

Tip To perform square root calculations, use the Sqrt block.

You can select one of these functions from the **Function** parameter list.

Function	Description	Mathematical Expression	MATLAB Equivalent
exp	Exponential	e^u	exp
log	Natural logarithm	$\ln u$	log
10^u	Power of base 10	10^u	10.^u (see power)
log10	Common (base 10) logarithm	$\log u$	log10
magnitude^2	Complex modulus	$\|u\|^2$	(abs(u)).^2 (see abs and power)
square	Power 2	u^2	u.^2 (see power)
pow	Power	u^v	power
conj	Complex conjugate	$\bar{u}$	conj

Function	Description	Mathematical Expression	MATLAB Equivalent
`reciprocal`	Reciprocal	$1/u$	`1./u` (see `rdivide`)
`hypot`	Square root of sum squares	$(u^2+v^2)^{0.5}$	`hypot`
`rem`	Remainder after division	—	`rem`
`mod`	Modulus after division	—	`mod`
`transpose`	Transpose	u^T	`u.'` (see “Array vs. Matrix Operations” (MATLAB))
`hermitian`	Complex conjugate transpose	u^H	`u'` (see “Array vs. Matrix Operations” (MATLAB))

The block output is the result of the operation of the function on the input or inputs. The functions support these types of operations.

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
`exp`	Yes	Yes	—
`log`	Yes	Yes	—
`10^u`	Yes	Yes	—
`log10`	Yes	Yes	—
`magnitude^2`	Yes	Yes	—
`square`	Yes	Yes	—
`pow`	Yes	Yes	—
`conj`	Yes	Yes	—
`reciprocal`	Yes	Yes	—

Function	Scalar Operations	Element-Wise Vector and Matrix Operations	Vector and Matrix Operations
`hypot`	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
`rem`	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
`mod`	Yes, on two inputs	Yes, on two inputs (two vectors or two matrices of the same size, a scalar and a vector, or a scalar and a matrix)	—
`transpose`	Yes	—	Yes
`hermitian`	Yes	—	Yes

The name of the function appears on the block. The appropriate number of input ports appears automatically.

Tip Use the Math Function block instead of the Fcn block when you want vector or matrix output because the Fcn block produces only scalar output.

Data Type Support

This table shows the input data types that each function of the block can support.

Function	single	double	boolean	built-in integer	fixed point
`exp`	Yes	Yes	—	—	—
`log`	Yes	Yes	—	—	—

Function	single	double	boolean	built-in integer	fixed point
`10^u`	Yes	Yes	—	—	—
`log10`	Yes	Yes	—	—	—
`magnitude^2`	Yes	Yes	—	Yes	Yes
`square`	Yes	Yes	—	Yes	Yes
`pow`	Yes	Yes	—	—	—
`conj`	Yes	Yes	—	Yes	Yes
`reciprocal`	Yes	Yes	—	Yes	Yes
`hypot`	Yes	Yes	—	—	—
`rem`	Yes	Yes	—	Yes	—
`mod`	Yes	Yes	—	Yes	—
`transpose`	Yes	Yes	Yes	Yes	Yes
`hermitian`	Yes	Yes	—	Yes	Yes

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix. All supported modes accept both real and complex inputs, except for `reciprocal`, which does not accept complex fixed-point inputs. See Description on page 1-1195 for more information.

Dependencies

Data type support for this block depends on the **Function** you select and the size of the input(s). For more information, see “Data Type Support” on page 1-1197.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `bus`

`Port_2` — Input signal

scalar | vector | matrix

Input signal specified as a scalar, vector, or matrix. All supported modes accept both real and complex inputs, except for `reciprocal`, which does not accept complex fixed-point inputs.

Dependencies

To enable this port, set **Function** to `hypot`, `rem`, or `mod`.

Data type support for this block depends on the **Function** you select, and the size of the input(s). For more information, see “Data Type Support” on page 1-1197.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `bus`

Output

`Port_1` — Result of the operation of the function on the input or inputs

scalar | vector | matrix

Output signal specified as a scalar, vector, or matrix. The dimensions of the block output depend on the **Function** you select and the size of the inputs. The block output is real or complex, depending on what you select for **Output signal type**. See Description on page 1-1195 for more information.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Function` — Math function

`exp` (default) | `log` | `10^u` | `log10` | `magnitude^2` | `square` | `pow` | `conj` | `reciprocal` | `hypot` | `rem` | `mod` | `transpose` | `hermitian`

Specify the mathematical function. See Description on page 1-1195 for more information about the options for this parameter.

Programmatic Use
Block Parameter: `Operator`
Type: character vector
Values: `'exp' | 'log' | '10^u' | 'log10' | 'magnitude^2' | 'square' | 'pow' | 'conj' | 'reciprocal' | 'hypot' | 'rem' | 'mod' | 'transpose' | 'hermitian'`
Default: `'exp'`

`Output signal type` — Complexity of output signal

`auto` (default) | `real` | `complex`

Specify the output signal type of the Math Function block as `auto`, `real`, or `complex`.

Function	Input Signal Type	Output Signal Type		
		Auto	Real	Complex
`exp`, `log`, `10u`, `log10`, `square`, `pow`, `reciprocal`, `conjugate`, `transpose`, `hermitian`	`real` `complex`	`real` `complex`	`real` `error`	`complex` `complex`
`magnitude squared`	`real` `complex`	`real` `real`	`real` `real`	`complex` `complex`
`hypot`, `rem`, `mod`	`real` `complex`	`real` `error`	`real` `error`	`complex` `error`

Programmatic Use
Block Parameter: `OutputSignalType`
Type: character vector
Values: `'auto' | 'real' | 'complex'`
Default: `'auto'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

`Output minimum` — Minimum output value for range checking

`[ ]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Same as first input` (default) | `Inherit: Inherit via internal rule` | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object

- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Same as first input'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, or `reciprocal`.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Choose the behavior when integer overflow occurs

`on` (default) | boolean

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Dependencies

To enable this parameter, set the **Function** to `magnitude^2`, `square`, `conj`, `reciprocal`, or `hermitian`.

Programmatic Use

Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Value: `'off'` | `'on'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

The Math Function block has HDL code generation restrictions when you set the **Function** to `reciprocal`. For more information, see Math Function.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

The Math Function block only supports fixed-point conversion in certain configurations. For more information, see the Block Support Table.

MATLAB Function

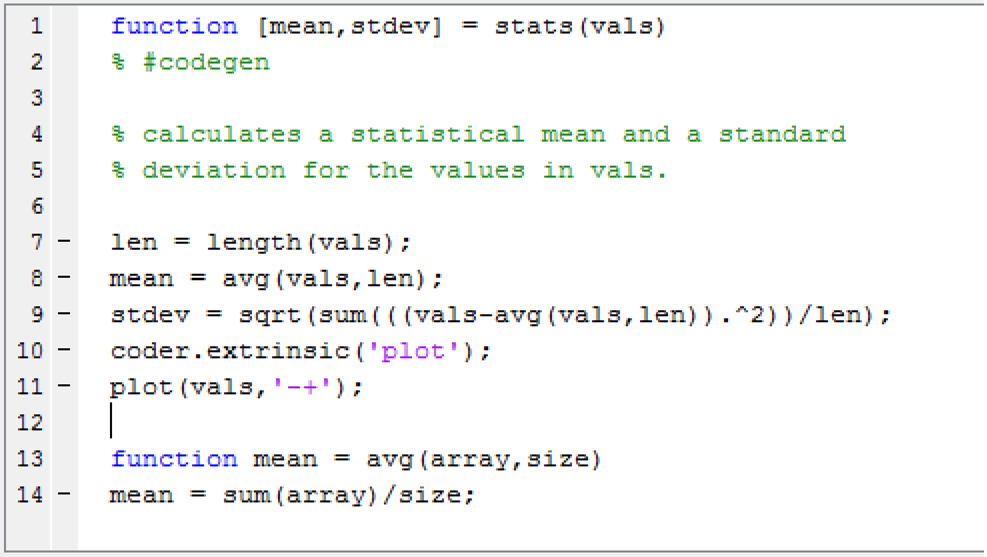
Description

With a MATLAB Function block, you can write a MATLAB function for use in a Simulink model. The MATLAB function you create executes for simulation and generates code for a Simulink Coder target. If you are new to the Simulink and MATLAB products, see “What Is a MATLAB Function Block?” and “Create Model That Uses MATLAB Function Block” for an overview.

Double-clicking the MATLAB Function block opens its editor, where you write the MATLAB function, as in this example:



```
function [mean,stdev] = stats(vals)
% #codegen

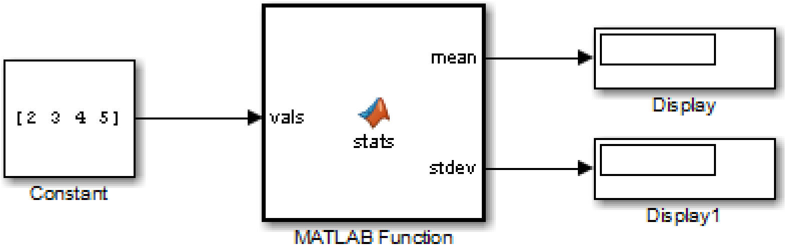
% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
coder.extrinsic('plot');
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

To learn more about this editor, see “MATLAB Function Block Editor”.

You specify input and output data to the MATLAB Function block in the function header as arguments and return values. The argument and return values of the preceding example function correspond to the inputs and outputs of the block in the model:



You can also define data, input triggers, and function call outputs using the Ports and Data Manager, which you access from the MATLAB Function Block Editor by selecting **Edit Data**. See “Ports and Data Manager”.

The MATLAB Function block generates efficient embeddable code based on an analysis that determines the size, class, and complexity of each variable. This analysis imposes the following restrictions:

- The first assignment to a variable defines its, size, class, and complexity.

  See “Best Practices for Defining Variables for C/C++ Code Generation”.
- You cannot reassign variable properties after the initial assignment except when using variable-size data or reusing variables in the code for different purposes.

  See “Reassignment of Variable Properties”.

In addition to language restrictions, the MATLAB Function block supports a subset of the functions available in MATLAB. A list of supported functions is given in “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List”. These functions include functions in common categories, such as:

- Arithmetic operators like `plus`, `minus`, and `power`. For more information, see “Array vs. Matrix Operations” (MATLAB).
- Matrix operations like `size`, and `length`

- Advanced matrix operations like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions like `sin`, `cos`, `sinh`, and `cosh`

See “Functions and Objects Supported for C/C++ Code Generation — Category List” for a complete list of function categories.

Note Although the code for this block attempts to produce exactly the same results as MATLAB, differences might occur due to rounding errors. These numerical differences, which might be a few `eps` initially, can magnify after repeated operations. Reliance on the behavior of `nan` is not recommended. Different C compilers can yield different results for the same computation.

Note In the MATLAB Function block, the `%#codegen` directive is included to emphasize that the block’s MATLAB algorithm is always intended for code generation. The `%#codegen` directive, or the absence of it, does not change the error checking behavior in the context of the MATLAB Function block. For more information see “Compilation Directive %#codegen”.

To support visualization of data, the MATLAB Function block supports calls to MATLAB functions for simulation only. See “Extrinsic Functions” to understand some of the limitations of this capability, and how it integrates with code analysis for this block. If these function calls do not directly affect any of the Simulink inputs or outputs, the calls do not appear in Simulink Coder generated code.

From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions with **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** checked in the chart Properties dialog box.

In the Ports and Data Manager, you can declare a block input to be a Simulink parameter instead of a port. The MATLAB Function block also supports inheritance of types and size for inputs, outputs, and parameters. You can also specify these properties explicitly. See “Type Function Arguments”, “Size Function Arguments”, and “Add Parameter Arguments” for descriptions of variables that you use in MATLAB Function blocks.

Recursive calls are not allowed in MATLAB Function blocks.

By default, MATLAB Function blocks have direct feedthrough enabled. To disable it, in the Ports and Data Manager, clear the **Allow direct feedthrough** check box. Nondirect feedthrough enables semantics to ensure that outputs rely only on current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

Ports

Input

u — Input argument u
scalar | vector | matrix

Input corresponding to the first input argument of the function inside the MATLAB Function block. If you rename the function argument in the editor, the block renames the port correspondingly.

Data types supported by MATLAB but not supported by Simulink may not be passed between the Simulink model and the function within the MATLAB Function block. These types may be used within the MATLAB Function block.

For more information on fixed-point support for this block, refer to “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer) and “MATLAB Function Block with Data Type Override” (Fixed-Point Designer).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

n — Input argument n
scalar | vector | matrix

`n`th input argument to the function in the MATLAB Function block. When you add the argument in the editor, the block adds the port correspondingly.

Data types supported by MATLAB but not supported by Simulink may not be passed between the Simulink model and the function within the MATLAB Function block. These types may be used within the MATLAB Function block.

For more information on fixed-point support for this block, refer to “Fixed-Point Data Types with MATLAB Function Block” (Fixed-Point Designer) and “MATLAB Function Block with Data Type Override” (Fixed-Point Designer).

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

y — Output argument

scalar | vector | matrix

First output argument of the function inside the MATLAB Function block. If you rename the function argument in the editor, the block renames the port correspondingly.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

n — Output argument n

scalar | vector | matrix

nth output argument from the function inside the MATLAB Function block. When you add the argument in the editor, the block adds the port correspondingly.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a]
Direct Feedthrough	No
Multidimensional Signals	Yes[a]
Variable-Size Signals	Yes[a]
Zero-Crossing Detection	No

[a] Actual data type or capability support depends on block implementation.

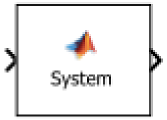
MATLAB System

Include System object in model
Library: Simulink / User-Defined Functions



Description

The MATLAB System block brings existing System objects (based on `matlab.System`) into Simulink. It also enables you to use System object APIs to develop new blocks for Simulink. For more information on this block, see “MATLAB System Block”.

For interpreted execution, the model simulates the block using the MATLAB execution engine.

For code generation, the model simulates the block using code generation (using the subset of MATLAB code supported for code generation). The MATLAB System block supports only a subset of the functions available in MATLAB. See “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” for a complete list of functions. These functions include those in common categories, such as:

- “Array vs. Matrix Operations” (MATLAB), like `plus`, `minus`, and `power`
- Matrix operations, like `size` and `length`
- Advanced matrix operations, like `lu`, `inv`, `svd`, and `chol`
- Trigonometric functions, like `sin`, `cos`, `sinh`, and `cosh`

System Objects

To use the MATLAB System block, you must first have a new System object or use an existing one. For more information, see “Integrate System Objects Using MATLAB System Block”.

Ports

Input

`In` — Signal input to a MATLAB System block

scalar | vector | matrix

The MATLAB System block accepts inputs of most types that Simulink supports. It does not support virtual buses as input or output. It does not support nonvirtual buses that contain variable-size signals. For more information, see "Data Types Supported by Simulink".

For information on fixed-point support for this block, see "Code Acceleration and Code Generation from MATLAB" (Fixed-Point Designer).

The MATLAB System block supports Simulink frames. For more information, see "Sample- and Frame-Based Concepts" (DSP System Toolbox).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Out` — Signal output of a MATLAB System block

scalar | vector | matrix

Signal output of a MATLAB System block that the System objectreturns.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`System Object Name` — Name of the System object

cell array (default)

Specify the full name of the user-defined System object class without the file extension. This entry is case sensitive. The class name must exist on the MATLAB path.

You can specify a System object name in one of these ways:

- Enter the name in the text box.
- Click the list arrow attached to the text box. If valid System objects exist in the current folder, the names appear in the list. Select a System object from this list.
- Browse to a folder that contains a valid System object. If the folder is not on your MATLAB path, the software prompts you to add it.

If you need to create a System object, you can create one from a template by clicking **New**.

After you save the System object, the name appears in the **System object name** text box.

Use the full name of the user-defined System object class name. The block does not accept a MATLAB variable that you have assigned to a System object class name.

Programmatic Use
Block Parameter: `System`
Type: character vector
Value: name of the System object
Default: `' '`

New — Create a System object from a template

`Basic` (default) | `Advanced` | `Simulink Extension`

Select one of the options for a System object template.

`Basic`

Starts MATLAB Editor and displays a template for a simple System object using the fewest System object methods.

`Advanced`

Starts MATLAB Editor and displays a template for a more advanced System object using most of the System object methods.

`Simulink Extension`

Starts MATLAB Editor and displays a file that contains utilities for customizing the block for Simulink. This is the same file available in MATLAB when you select **New > System Object > Simulink Extension**.

After you save the System object, you can enter the name in the **System object name** text box.

`Simulate using` — Select the simulation mode

`Code generation` (default) | `Interpreted Execution`

Select the simulation mode.

`Code generation`

On the first model run, simulate and generate code for MATLAB System block using only MATLAB functions supported for code generation. If the structure of the block does not change, subsequent model runs do not regenerate the code.

If the simulation mode is `Code generation`, System Objects accept a maximum of 32 inputs.

`Interpreted execution`

Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance.

Dependency — Dependency parameter for MATLAB System block

auto (default)

After you assign a valid System object class name to the block, the next time you open the block dialog box, the parameter is visible. This parameter appears for every MATLAB System block. You cannot remove it.

- If the block has no tabs, this parameter appears at the bottom of the dialog box.
- If the block has multiple tabs, this parameter appears at the bottom of the first tab of the dialog box.

`Saturate on integer overflow` — Specify whether overflows saturate

Off (default) | **On**

☑ On

Overflows saturate to either the minimum or maximum value that the data type can represent. For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

□ Off

Overflows wrap to the appropriate value that the data type can represent. For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

Tips

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code. Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

Programmatic Use

Block Parameter:`SaturateOnIntegerOverflow`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

Treat these inherited Simulink signal types as fi objects — Specify fi data types

`Fixed-point` (default) | `Fixed-point & Integer`

Select which inherited data types to treat fi data types,

`Fixed-point`

Treat fixed-point data types as fi data types.

`Fixed-point & Integer`

Treat fixed-point and integer data types as fi data types.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

`MATLAB System fimath` — Specify fixed-point settings to use

Same as MATLAB (default) | **Specify Other**

Select which fixed-point math settings to use.

Same as MATLAB

Use the current MATLAB fixed-point math settings.

Specify Other

Enable the edit box for specifying the desired fixed-point math settings. For information on setting fixed-point math, see `fimath`.

Dependency

This check box appears when you use the `showFiSettingsImpl` method in the System object.

Block Characteristics

Data Types	`double`[a] | `single`[a] | `Boolean`[a] | `base integer`[a] | `fixed point`[a] | `enumerated`[a] | `bus`[b][a]
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`[a]
Variable-Size Signals	`Yes`[c][a]
Zero-Crossing Detection	`No`

a. Actual data type or capability support depends on block implementation.

b. See Nonvirtual Buses and MATLAB System Block for more information.

c. See Variable-Size Signals for more information.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see MATLAB System.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

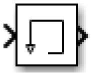
Memory

Output input from previous time step
Library: Simulink / Discrete



Description

The Memory block holds and delays its input by one major integration time step. When placed in an iterator subsystem, it holds and delays its input by one iteration. This block accepts continuous and discrete signals. The block accepts one input and generates one output. Each signal can be a scalar, vector, matrix, or N-D array. If the input is non-scalar, the block holds and delays all elements of the input by the same time step.

You specify the block output for the first time step using the **Initial condition** parameter. Careful selection of this parameter can minimize unwanted output behavior. However, you cannot specify the sample time. This block's sample time depends on the type of solver used, or you can specify to inherit it. The **Inherit sample time** parameter determines whether sample time is inherited or based on the solver.

Tip Avoid using the Memory block when both these conditions are true:

- Your model uses the variable-step solver `ode15s` or `ode113`.
- The input to the block changes during simulation.

When the Memory block inherits a discrete sample time, the block is analogous to the Unit Delay block. However, the Memory block does not support state logging. If logging the final state is necessary, use a Unit Delay block instead.

Comparison with Similar Blocks

The Memory, Unit Delay, and Zero-Order Hold blocks provide similar functionality but have different capabilities. Also, the purpose of each block is different.

This table shows recommended usage for each block.

Block	Purpose of the Block	Reference Examples
Unit Delay	Implement a delay using a discrete sample time that you specify. The block accepts and outputs signals with a discrete sample time.	• `sldemo_enginewc` (Compression subsystem)
Memory on page 1-1222	Implement a delay by one major integration time step. Ideally, the block accepts continuous (or fixed in minor time step) signals and outputs a signal that is fixed in minor time step.	• `sldemo_bounce` • `sldemo_clutch` (Friction Mode Logic/Lockup FSM subsystem)
Zero-Order Hold	Convert an input signal with a continuous sample time to an output signal with a discrete sample time.	• `sldemo_radar_eml` • `aero_dap3dof`

Each block has the following capabilities.

Capability	Memory	Unit Delay	Zero-Order Hold
Specification of initial condition	Yes	Yes	No, because the block output at time t = 0 must match the input value.
Specification of sample time	No, because the block can only inherit sample time from the driving block or the solver used for the entire model.	Yes	Yes
Support for frame-based signals	No	Yes	Yes
Support for state logging	No	Yes	No

Bus Support

The Memory block is a bus-capable block. The input can be a virtual or nonvirtual bus signal subject to the following restrictions:

- **Initial condition** must be zero, a nonzero scalar, or a finite numeric structure.
- If **Initial condition** is zero or a structure, and you specify a **State name**, the input cannot be a virtual bus.
- If **Initial condition** is a nonzero scalar, you cannot specify a **State name**.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

All signals in a nonvirtual bus input to a Memory block must have the same sample time, even if the elements of the associated bus object specify inherited sample times. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus. See “Specify Bus Signal Sample Times” and Bus-Capable Blocks for more information.

You can use an array of buses as an input signal to a Memory block. You can specify the **Initial condition** parameter with:

- The value `0`. In this case, all the individual signals in the array of buses use the initial value `0`.
- An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
- A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Ports

Input

`Port_1` — Input signal

scalar | vector | matrix | N-D array

Input signal, specified as a scalar, vector, matrix, or N-D array. The input can be continuous or discrete, containing real, or complex values of any data type Simulink supports.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Input delayed by one major integration time step

scalar | vector | matrix | N-D array

Output is the input from the previous time step.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

`Initial condition` — Initial condition

0 (default) | scalar | vector | matrix | N-D array

Specify the output at the initial integration step. This value must be 0 when you do not use a built-in input data type. Simulink does not allow the initial output of this block to be `inf` or `NaN`.

Programmatic Use
Block Parameter: `InitialCondition`
Type: character vector

Values: scalar | vector
Default: '0'

Inherit sample time — Inherit sample time

off (default) | on

Select to inherit the sample time from the driving block:

- If the driving block has a discrete sample time, the block inherits the sample time.
- If the driving block has a continuous sample time, selecting this check box has no effect. The sample time depends on the type of solver used for simulating the model.

When this check box is cleared, the block sample time depends on the type of solver used for simulating the model:

- If the solver is a variable-step solver, the block sample time is continuous but fixed in minor time step: [0, 1].
- If the solver is a fixed-step solver, the [0, 1] sample time converts to the solver step size after sample-time propagation.

Programmatic Use
Block Parameter: InheritSampleTime
Type: character vector
Values: 'off' | 'on'
Default: 'off'

Direct feedthrough of input during linearization — Output the input during linearization and trim

off (default) | on

Select to output the input during linearization and trim. This selection sets the block mode to direct feedthrough.

Selecting this check box can cause a change in the ordering of states in the model when using the functions linmod, dlinmod, or trim. To extract this new state ordering, use the following commands.

First compile the model using the following command, where model is the name of the Simulink model.

```
[sizes, x0, x_str] = model([],[],[],'lincompile');
```

Next, terminate the compilation with this command.

```
model([],[],[],'term');
```

The output argument, `x_str`, which is a cell array of the states in the Simulink model, contains the new state ordering. When passing a vector of states as input to the `linmod`, `dlinmod`, or `trim` functions, the state vector must use this new state ordering.

Programmatic Use
Block Parameter: `LinearizeMemory`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Treat as a unit delay when linearizing with discrete sample time` — Linearize to unit delay for discrete inputs

`off` (default) | `on`

Select to linearize the Memory block to a unit delay when the Memory block is driven by a signal with a discrete sample time.

Programmatic Use
Block Parameter: `LinearizeAsDelay`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

State Attributes

`State name` — Unique name for block state

`''` (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use
Block Parameter: `StateName`
Type: character vector
Values: unique name
Default: `''`

`State name must resolve to Simulink signal object` — Require state name resolve to a signal object

`off` (default) | `on`

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Programmatic Use
Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Signal object class` — Custom storage class package name

`Simulink.Signal` (default) | `<StorageClass.PackageName>`

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Programmatic Use

Block Parameter: `StateSignalObject`
Type: character vector
Values: `'Simulink.Signal' | '<StorageClass.PackageName>'`
Default: `'Simulink.Signal'`

`Code generation storage class` — State storage class for code generation

`Auto` (default) | `Model default` | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer` | `BitField (Custom)` | `Model default` | `ExportToFile (Custom)` | `ImportFromFile (Custom)` | `FileScope (Custom)` | `AutoScope (Custom)` | `Struct (Custom)` | `GetSet (Custom)` | `Reusable (Custom)`

Select state storage class for code generation.

- `Auto` is the appropriate storage class for states that you do not need to interface to external code.
- *`StorageClass`* applies the storage class or custom storage class that you select from the list. For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than `Simulink`.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use

Block Parameter: `StateStorageClass`
Type: character vector
Values: `'Auto' | 'SimulinkGlobal' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...`
Default: `'Auto'`

`TypeQualifier` — Storage type qualifier

`''` (default) | `const` | `volatile` | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note **TypeQualifier** will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

During simulation, the block uses the following values:

- The initial value of the signal object to which the state name is resolved
- Min and Max values of the signal object

For more information, see “Data Objects”.

Dependencies

To enable this parameter, set **Code generation storage class** to `ExportedGlobal`, `ImportedExtern`, `ImportedExternPointer`, or `Model default`. This parameter is hidden unless you previously set its value.

Programmatic Use

Block Parameter: `RTWStateStorageTypeQualifier`
Type: character vector
Values: `'' | 'const' | 'volatile' | ...`
Default: `''`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

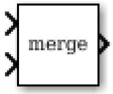
Merge

Combine multiple signals into single signal
Library: Simulink / Signal Routing



Description

The Merge block combines inputs into a single output. The output value at any time is equal to the most recently computed output of its driving blocks. Specify the number of inputs by setting the parameter **Number of inputs** parameter.

Use Merge blocks to interleave input signals that update at different times into a combined signal in which the interleaved values retain their separate identities and times. To combine signals that update at the same time into an array or matrix signal, use a Concatenate block.

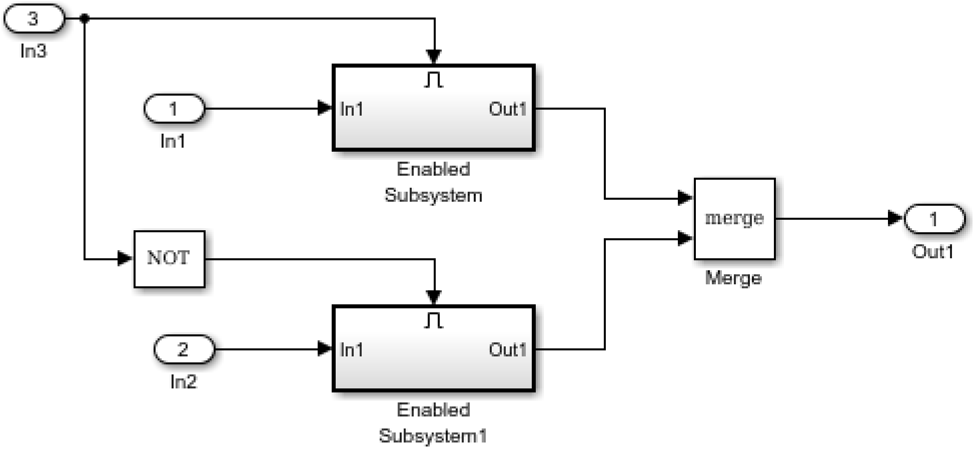
Guidelines for Using the Merge Block

When you use the Merge block, follow these guidelines:

- Always use conditionally executed subsystems to drive Merge blocks.
- Ensure that at most one of the driving conditionally executed subsystems executes at any time step.
- Ensure that all input signals have the same sample time.
- Do not branch a signal that inputs to a Merge block, if you use the default setting of `Classic` for the **Model Configuration Parameters > Diagnostics > Underspecified initialization detection** parameter.
- For all conditionally executed subsystem Outport blocks that drive Merge blocks, set the **Output when disabled** parameter to `held`.
- If the output of a Model block is coming from a MATLAB Function block or a Stateflow chart, do not connect that output port to the input port of the Merge block.

For each input of a Merge block, the topmost nonatomic and nonvirtual source must be a conditionally executed subsystem that is not an Iterator Subsystem.

The next diagram shows valid Merge block usage, merging signals from two conditionally executed subsystems.



Bus Support

The Merge block is a bus-capable block. The inputs can be virtual or nonvirtual bus signals subject to these restrictions:

- The number of inputs must be greater than one.
- **Initial output** must be zero, a nonzero scalar, or a finite numeric structure.
- **Allow unequal port widths** must be disabled.
- All inputs to the merge must be buses and must be equivalent (same hierarchy with identical names and attributes for all elements).

All signals in a nonvirtual bus input to a Merge block must have the same sample time. You can use a Rate Transition block to change the sample time of an individual signal, or of all signals in a bus.

Merging S-Function Outputs

The Merge block can merge a signal from an S-Function block only if the memory used to store the output from the S-Function is reusable. Simulink software displays an error message if you attempt to update or simulate a model that connects a nonreusable port of an S-Function block to a Merge block. See `ssSetOutputPortOptimOpts`.

Limitations

- All signals that connect to a Merge block, are functionally the same signal. Therefore, they are subject to the restriction that a given signal can have at most one associated signal object. See `Simulink.Signal` for more information.
- Run-time diagnostics do not run if the inputs to a merge block are from a single initiator. For example, a single initiator could be a Stateflow chart executing function-call subsystems that are connected to a Merge block.
- Do not set the outports of conditionally executed subsystems being merged to reset when disabled. This action can cause multiple subsystems to update the block at the same time. Specifically, the disabled subsystem updates the Merge block by resetting its output, while the enabled subsystem updates the block by computing its output.

  To prevent this behavior, set the Outport block parameter **Output when disabled** to `held` for each conditionally executed subsystem being merged.

  Note If you are using Simplified Initialization Mode, set the Outport block parameter **Output when disabled** to `held`.
- A Merge block does not accept input signals whose elements have been reordered or partially selected. In addition, do not connect input signals to the block that have been combined outside of a conditionally executed subsystem.

You can use an array of buses as an input signal to a Merge block with these limitations:

- **Allow unequal port widths** — Clear this parameter.
- **Initial condition** — You can specify this parameter using:
  - The value `0`. In this case, each of the individual signals in the array of buses use the initial value `0`.
  - An array of structures that specifies an initial condition for each of the individual signals in the array of buses.
  - A single scalar structure that specifies an initial condition for each of the elements that the bus type defines. Use this technique to specify the same initial conditions for each of the buses in the array.

Ports

Input

Port_1 — First input signal

scalar | vector

First input signal merged with the other input signals.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Port_n — nth input signal

scalar | vector

nth input signal merged with the other input signals.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

Port_1 — Output signal

scalar | vector

Output signal merged from the input signals.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Parameters

Number of inputs — Number of input signals to merge

2 (default) | integer

Specify the number of input signals to merge. The block creates a port for each input signal.

Programmatic Use
Block Parameter: `Inputs`

Type: character vector
Values: integer
Default: `'2'`

`Initial output` — Initial output value

[ ] (default) | scalar | vector

Specify the initial value of the output signal. If you do not specify an initial output value, then initial output depends on the initialization mode and the driving blocks.

In Simplified initialization mode, for an unspecified (empty matrix `[]`) value of **Initial output**, the block uses the default initial value of the output data type. For information on the default initial value, see "Initializing Signal Values". In Classic initialization mode, for an unspecified (empty matrix `[]`) value of **Initial output**, the initial output of the block equals the most recently evaluated initial output of the driving blocks. Since the initialization ordering for these sources can vary, initialization can be inconsistent for the simulation and the code generation of a model.

Programmatic Use
Block Parameter: `InitialOutput`
Type: character vector
Values: scalar | vector
Default: `'[ ]'`

`Allow unequal port widths` — Allow inputs of unequal dimensions

`off` (default) | `on`

Select this check box to allow the block to accept inputs having different numbers of elements. The block allows you to specify an offset for each input signal relative to the beginning of the output signal. The width of the output signal is

$\mathrm{max}(w_1+o_1,\ w_2+o_2,\ ...\ w_n+o_n)$

where w_1, ... w_n are the widths of the input signals and o_1, ... o_n are the offsets for the input signals.

If you clear this check box, the Merge block accepts only inputs of equal dimensions and outputs a signal of the same dimensions as the inputs.

Programmatic Use
Block Parameter: `AllowUnequalInputPortWidths`
Type: character vector

Values: `'off'` | `'on'`
Default: `'off'`

`Input port offsets` — Offset for input signals
`[ ]` (default) | vector

Enter a vector to specify the offset of each input signal relative to the beginning of the output signal.

Programmatic Use
Block Parameter: `InputPortOffsets`
Type: character vector
Values: scalar | vector
Default: `'[ ]'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

In the code generation workflow, when the Merge block receives a constant value and non-constant sample times, one of these conditions must hold. Otherwise Simulink displays an error.

- The source of the constant value is a grounded signal.
- The source of the constant value is a constant block with a non-tunable parameter.
  - There is only one constant block that feeds the Merge block.
  - All other input signals to the Merge block are from conditionally executed subsystems.
  - The Merge block and outport blocks of all conditionally executed subsystems does not specify any initial outputs.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

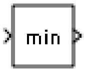
“Conditionally Executed Subsystems Overview”

Introduced before R2006a

MinMax

Output minimum or maximum input value
Library: Simulink / Math Operations



Description

The MinMax block outputs either the minimum or the maximum element or elements of the inputs. You choose whether the block outputs the minimum or maximum values by setting the **Function** parameter.

The MinMax block ignores any input value that is `NaN`, except when every input value is `NaN`. When all input values are `NaN`, the output is `NaN`, either as a scalar or the value of each output vector element.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Provide an input signal from which the block outputs the maximum or minimum values.

- When the block has one input port, the input must be a scalar or a vector. The block outputs a scalar equal to the minimum or maximum element of the input vector.
- When the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Dependencies

To support matrix input, you must set the **Number of input ports** parameter to an integer greater than one. All nonscalar inputs must have the same dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `bus`

`Port_N` — N-th input signal

scalar | vector | matrix

Provide an input signal from which the block outputs the maximum or minimum values.

When the block has multiple input ports, all nonscalar inputs must have the same dimensions. The block expands any scalar inputs to have the same dimensions as the nonscalar inputs. The block outputs a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Dependencies

To provide more than one input signal, set the **Number of input ports** to an integer greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `bus`

Output

`Port_1` — Minimum or maximum values of inputs

scalar | vector | matrix

When the block has one input, the output is a scalar value, equal to the minimum or maximum of the input elements. When the block has multiple inputs, the output is a signal having the same dimensions as the input. Each output element equals the minimum or maximum of the corresponding input elements.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Function` — Specify minimum or maximum

`min` (default) | `max`

Specify whether to apply the function `min` or `max` to the input.

Programmatic Use
Block Parameter: `Function`
Type: character vector
Values: `'min' | 'max'`
Default: `'min'`

`Number of input ports` — Specify number of input ports

`1` (default) | `positive integer`

Specify the number of inputs to the block.

Programmatic Use
Block Parameter: `Inputs`
Type: character vector
Values: `'1'`
Default: `'1'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

`Sample time` — Specify sample time as a value other than -1

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

`Require all inputs to have the same data type` — Inputs must have the same data type

`off` (default) | `on`

Select this check box to require that all inputs have the same data type.

Programmatic Use

Block Parameter: `Inputs`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL

or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note Output minimum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note Output maximum does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'Inherit: Inherit via back propagation'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`

Variable-Size Signals	`Yes`
Zero-Crossing Detection	`Yes`

MinMax Running Resettable

Introduced before R2006a

MinMax Running Resettable

Determine minimum or maximum of signal over time

Library: Simulink / Math Operations

Description

The MinMax Running Resettable block outputs the minimum or maximum of all past inputs u. You specify whether the block outputs the running minimum or maximum with the **Function** parameter.

The block can reset its state based on an external reset signal R. When the reset signal R is nonzero (true), the block resets the output to the value of the **Initial condition** parameter.

The input can be a scalar, vector, or matrix signal. The block outputs a signal having the same dimensions as the input. Each output element equals the running minimum or maximum of the corresponding input elements.

Ports

Input

u — Input signal

scalar | vector | matrix

Input signal as a scalar, vector, or matrix. Based on what you specify for the **Function** parameter, the block outputs the minimum or maximum value of all past inputs u.

If you specify a scalar value for the **Initial condition** parameter, the block expands the parameter to have the same dimensions as nonscalar input u.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | bus

R — Reset signal
scalar | vector | matrix

The input port accepting the reset signal as a scalar, vector, or matrix. When the reset signal is nonscalar, it must have the same dimensions as input signal u. As long as the reset signal has a value of zero, the block outputs the running minimum or maximum value of input u. Whenever the reset signal has a nonzero value (true), the block resets the output to the value of the **Initial condition** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | bus

Output

y — Running minimum or maximum value
scalar | vector | matrix

Output signal, specified as a scalar, vector, or matrix, where each output element equals the running minimum or maximum value of the corresponding input elements. Output signal y has the same data type and dimensions as input signal u.

When the block receives a nonzero (true) reset signal, the block resets the output to the value of the **Initial condition** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Parameters

Function — Specify minimum or maximum
min (default) | max

Specify whether the block outputs the running minimum or maximum value of the corresponding input elements.

Programmatic Use
Block Parameter: Function

Type: character vector
Values: `'min' | 'max'`
Default: `'min'`

`Initial condition` — Value to reset output to

`0.0` (default) | scalar or vector

Specify the initial condition value. When the reset input signal `R` is `true`, the block resets the output to the value you specify.

Programmatic Use
Block Parameter: `vinit`
Type: character vector
Values: scalar or vector
Default: `'0.0'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

Model

Include multiple model implementations as block in another model through model reference

Library: Simulink / Ports & Subsystems

Description

The Model block allows you to include a model as a block in another model. The included model is called a *referenced model*, and the model containing it (using the Model block) is called the *parent model*.

The Model block displays input and output ports corresponding to the top-level input and output ports of the referenced model. Using these ports allow you to connect the referenced model to other blocks in the parent model. See “Model References” for more information.

By default, the contents of a referenced model are user-visible by double-clicking the Model block. However, you can hide the contents of a referenced model by making the model a protected model.

To set the referenced model and simulation parameters, open the **Block Parameters** dialog box and use the **Main** tab. To specify values for model arguments, use the **Arguments** tab.

Ports

Input

`Input_Port_1` — Input port corresponding to root-level Inport, Enable, and Trigger blocks of referenced model

real or complex values of any data type supported by Simulink

The Model block has an input port for each root-level Inport, Enable, or Trigger block in the referenced model. The name of the Model block port matches the name of the corresponding referenced model input block. The Model block input signals must be valid for the corresponding referenced model input blocks. See “Model Reference Interface”.

Input signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see “Data Types Supported by Simulink”.

Output

`Output_Port_1` — Output port corresponding to root-level Outport block of referenced model

real or complex values of any data type supported by Simulink

The Model block has an output port for each root-level Outport block in the referenced model. The name of the Model block port matches the name of the corresponding Outport block. The Model block output signals are the signals from the corresponding referenced model Outport blocks. See “Model Reference Interface”.

Output signals can have real or complex values of any data type supported by Simulink, including bus objects, arrays of buses, fixed-point, and enumerated data types. For details about data types, see “Data Types Supported by Simulink”.

Parameters

Main Tab

`Model name` — File name of referenced model

`''` (default) | character vector

Path to the referenced model. The file name must be a valid MATLAB identifier. The extension, for example, `.slx`, is optional. The file name must contain fewer than 60 characters, exclusive of the `.slx` or `.mdl` suffix.

To navigate to the model that you want to reference, click **Browse**.

To view the model that you specified, click **Open Model**.

Programmatic Use
Parameter: `ModelFile`
Type: character vector
Value: `''` | `'<file name>'`
Default: `''`

`Simulation mode` — Simulation mode for model reference

`Normal` (default) | `Accelerator` | `Software-in-the-loop (SIL)` | `Processor-in-the-loop (PIL)`

Specify the simulation mode for the Model block. The simulation mode for the Model block can be different than the simulation mode of its referenced model and of other models in the model hierarchy.

- `Accelerator` — Create a MEX-file for the referenced model and then executes the referenced model by running the S-function.
- `Normal` — Execute the referenced model interpretively, as if the referenced model is an atomic subsystem implemented directly within the parent model.
- `Software-in-the-loop (SIL)` — This option requires the Embedded Coder software. Generate production code based on the **Code Interface** parameter setting. The code is compiled for, and executed on, the host platform.
- `Processor-in-the-loop (PIL)` — This option requires the Embedded Coder software. Generate production code based on the **Code Interface** parameter setting. This code is compiled for, and executed on, the target platform. A documented target connectivity API supports exchange of data between the host and target at each time step during the PIL simulation.

The corners of the Model block reflect the simulation mode of the Model block. For normal mode, the corners have empty triangles. For accelerator mode, the corner triangles are filled in. For SIL and PIL modes, the corners are filled in and the word `(SIL)` or `(PIL)` appears on the block icon.

While you can set a referenced model to rapid accelerator mode, simulation ignores the referenced model simulation mode. For information about simulation mode precedence in a model hierarchy, see “Simulate Model Hierarchies”.

Programmatic Use
Parameter: `SimulationMode`
Type: character vector

Value: `'Normal'` | `'Accelerator'` | `'Software-in-the-loop'` | `'Processor-in-the-loop'`
Default: `'Normal'`

`Code interface` — Generate code from top model or referenced model

`Model reference` (default) | `Top model`

Specify whether to generate the code from the top model or the referenced model for SIL and PIL simulation modes. To deploy the generated code as part of a larger application that uses the referenced model, specify `Model reference`. To deploy the generated code as a standalone application, specify `Top model`.

`Model reference`

Code generated from referenced model as part of a model hierarchy. Code generation uses the `slbuild('`*`model`*`', 'ModelReferenceRTWTarget')` command.

`Top model`

Code generated from top model with the standalone code interface. Code generation uses the `slbuild('`*`model`*`')` command.

Dependencies

To display and enable this parameter, select either `Software-in-the-loop (SIL)` or `Processor-in-the-loop (SIL)` from the **Simulation mode** drop-down list.

Programmatic Use
Parameter: `CodeInterface`
Type: character vector
Value: `'Model reference'` | `'Top model'`
Default: `'Model reference'`

`Show model initialize port` — Control display of initialize event port

off (default) | on

Control display of initialize event port on the Model block.

□ off

Remove port.

☑ on

Display model initialize event port.

Programmatic Use

Block parameter: `ShowModelInitializePort`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

`Show model reset port` — Control display of reset event ports

off (default) | on

Control display of reset event ports on the Model block.

☐ off

Remove port.

☑ on

Display model reset event ports.

Programmatic Use

Block parameter: `ShowModelResetPorts`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

`Show model terminate port` — Control display of terminate event port

off (default) | on

Control display of terminate event port on Model block.

☐ off

Remove port.

☑ on

Display model block port.

Programmatic Use

Block parameter: `ShowModelTerminatePort`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

`Show model periodic event ports` — Control display of periodic event ports

off (default) | on

Control display of periodic event ports on Model block.

□ off

Hide ports.

☑ on

Display ports for rate-based models. A rate-based model is a model with the **Sample time** for a connected Inport block specified.

If you want to manually specify the port rates, set the parameter `AutoFillPortDiscreteRates` to `'off'`, and then add the port rates to the parameter `PortDiscreteRates`.

Programmatic Use

Block parameter: `ShowModelPeriodicEventPorts`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

Arguments Tab

`Model arguments` — Display model arguments and specify argument values for referenced model

number | workspace variable | mathematical expression | structure or structure field

Display model arguments and specify model argument values. Model arguments enable the referenced model to use a different value for a variable used by a referenced model. To specify model argument values, use the **Value** column in the table. For more information about configuring model arguments in a referenced model and specifying argument values, see “Parameterize Instances of a Reusable Referenced Model”.

When changing argument values, you can use a partial structure, which has fields that correspond to only the arguments whose values you want to change. Arguments not included in the partial structure retain their values. In the structure, include the model argument names and values, represented as character vectors.

Programmatic Use
Block parameter: `ParameterArgumentNames`
Type: character vector
Value: character vector in the form of `'argument1,argument2'`
Default: none

Programmatic Use
Block parameter: `ParameterArgumentValues`
Type: structure
Value: structure
Default: structure with no fields

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a] | string[a]
Direct Feedthrough	No
Multidimensional Signals	Yes[a]
Variable-Size Signals	Yes[a]
Zero-Crossing Detection	No

[a] Actual data type or capability support depends on block implementation.

Compatibility Considerations

Model blocks will no longer support model variants

Warns starting in R2017b

In a future release, Model blocks that contain variant models will convert to Variant Subsystem blocks that reference the variant models. Variant Subsystem blocks provide these advantages:

- Allow you to mix Model blocks and Subsystem blocks as variant systems
- Support flexible I/O, so that variants can have a different number of input and output ports

To convert a Model block that contains variant models to a Variant Subsystem block that contains Model blocks referencing the variant models, use one of these approaches:

- Right-click the Model block and select **Subsystems & Model Reference** > **Convert to** > **Variant Subsystem**.
- Use the `Simulink.VariantManager.convertToVariant` function. Specify the Model block path or block handle.

If you convert a Model block to a Variant Subsystem block, the Model block parameter **Generate preprocessor conditionals** behaves differently from the Variant Subsystem block parameter **Analyze all choices during update diagram and generate preprocessor conditionals**. For Model blocks that contain model variants, enabling the parameter causes simulation and update diagram to compile the active variant only. For Variant Subsystem blocks, enabling the parameter compiles all the variants, which can make simulation and updates slower.

Converting model variants to subsystem variants can require you to update scripts that use the `Variants` command-line parameter.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see Model.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type support depends on block implementation.

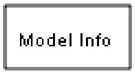
Model Info

Display model properties and text in model

Library: Simulink / Model-Wide Utilities



Description

The Model Info block displays model properties and text about a model on the mask of the block. Use the Model Info block dialog box to specify the content and format of the text that the block displays. You can select model properties to display on the block. In the text displayed on the block mask, Simulink replaces the property name with the current value of the property in the model.

Parameters

`Specify Text and Properties to Display` — Content and format of the text to display

no default

Use the **Enter text and tokens to display on Model Info block** edit box to specify the text and properties to display.

- In the edit box, enter any text you want to display on the block mask. Edit the default text `Model Info`.
- To display a model property on the block mask, select a property in the **Model properties** list and click the right arrow button.

  The block adds a token of the form `%<modelpropertyname>` to the edit box. In the text the block mask displays, Simulink replaces the token with the value of the property.

  1. For example, if you select `Description` in the **Model properties** list and click the right arrow button, then the token

```
%<Description>
```

appears in the right edit box.

2 You could add some explanatory text before the model property, e.g. “`Model description:`”.

3 When you click **Apply** or **OK**, Simulink displays your new text and the current value of the model property on the block mask in the Model Editor.

See “Version Information Properties” for descriptions of the model properties.

If you are interested in source control information, for a flexible interface to source control tools, use Simulink Project. See “Source Control in Simulink Project”.

Block Characteristics

Data Types	
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The Model Info block is ignored during code generation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

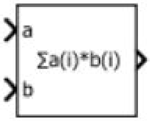
Multiply-Accumulate

Perform a multiply-accumulate operation on the inputs

Library: HDL Coder / HDL Operations / Multiply-Accumulate



Multiply-Accumulate

Description

The Multiply-Accumulate block performs this operation on inputs a and b, and bias c, to compute result dataOut.

```
dataOut = sum(a.* b) + c
```

By default, the block operates in the vector mode. The inputs a and b can be scalars or vectors. The default bias value, c, is equal to zero, and the block computes the dot product of inputs a and b. You can specify a nonzero value for c using Dialog or Input port as the **Source**. The block adds this bias to the dot product of a and b. The multiplication operation is full precision irrespective of the **Output data type** setting. The **Output data type** and **Integer rounding mode** settings apply to the addition operation.

By using the **Operation Mode** setting, you can specify streaming modes of operation for the Multiply-Accumulate block. For HDL code generation, when you use the streaming operation mode, input scalar values to the block. The block has two streaming modes: Streaming - using Start and End ports and Streaming - using Number of Samples. When you select these streaming modes, you can specify the control signals to use with the mode. The control signals specify when to start and end accumulation, and when the output is valid.

Ports

Input

a — Input signal

`vector` | `matrix` | `array` | `bus`

Port to provide input to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

b — Input signal

`scalar` | `vector` | `matrix` | `array` | `bus`

Port to provide input to the block.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

c — Bias signal

`scalar` | `vector` | `matrix` | `array` | `bus`

Port to provide the bias signal to the block. The block adds this bias to the inputs. Make sure that the bias signal data type matches that of the dot product of the inputs.

Dependencies

To enable this port, set **Source** to `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`startIn` — Start of accumulation control signal

`scalar` | `vector` | `matrix` | `array` | `bus`

Port to provide the control signal to start accumulation. It is recommended that you use a `boolean` data type signal as input to the port. To start obtaining the accumulated output value from the **dataOut** signal, both **startIn** and **validIn** signals must be high. The **dataOut** signal produces the accumulated result from the next clock cycle.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Start and End Ports`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`validIn` — Valid input control signal

`scalar` | `vector` | `matrix` | `array` | `bus`

Port to provide the control signal to indicate that the input signal is valid for accumulation. It is recommended that you use a `boolean` data type signal as input to the port. To start obtaining the accumulated output value from the **dataOut** signal, both **validIn** and **startIn** signals must be high. The **dataOut** signal produces the accumulated result from the next clock cycle. The **validIn** signal has higher priority than **startIn** and **endIn** signals.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Start and End Ports` or `Streaming - using Number of Samples`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`endIn` — End of accumulation control signal

`scalar` | `vector` | `matrix` | `array` | `bus`

Port to provide the control signal to indicate end of accumulation. You can use the **startIn** and **endIn** signals with the **validIn** signal to indicate a frame that contains the accumulated output.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Start and End Ports` and then select **End input and output ports**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

dataOut — Output signal

scalar | vector | matrix | array | bus

Port that generates the output data from the multiply-accumulate operation. By default, the block uses the Vector mode of operation and computes the dot product of the input signals, and adds the bias to produce the result. If you specify a streaming mode of operation as **Operation Mode**, the value of the **dataOut** signal depends on the control signals that you provide. The data type of the output signal is same as that of the accumulator.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

startOut — Start of accumulation output control signal

scalar | vector | matrix | array | bus

Port that generates output control signal to indicate the start of accumulation. When both **validIn** and **startIn** are high, the **startOut** signal becomes high in the next clock cycle. The clock cycle at which **startOut** becomes high indicates the start of a frame and that the **dataOut** signal has started producing valid accumulated output.

Dependencies

To enable this port, set **Operation Mode** to Streaming - using Start and End Ports and then select **Start output port**.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

validOut — Valid output control signal

scalar | vector | matrix | array | bus

Port that generates the output control signal to indicate that the **dataOut** signal is valid. When the **validIn** signal becomes high , the **validOut** signal becomes high in the next clock cycle and indicates that the **dataOut** is valid.

Dependencies

To enable this port, set **Operation Mode** to Streaming - using Start and End Ports and then select **Valid output port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`endOut` — End of accumulation output control signal

`scalar` | `vector` | `matrix` | `array` | `bus`

Port that generates the output control signal to indicate the end of accumulation. You can use the clock cycles between when the **startOut** signal becomes high and when the **endOut** signal becomes high to indicate a valid frame that contains the accumulated output.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Start and End Ports` and then select **End input and output ports**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`countOut` — Count output control signal

`scalar` | `vector` | `matrix` | `array` | `bus`

Port that generates the output control signal to indicate number of samples to accumulate. The value of this signal increases from `1` to the value that you specify for **Number of Samples**. As long as the **validIn** signal is high, the **countOut** increments by `1` every clock cycle.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Number of Samples` and then select **Count output port**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Operation Mode` — Mode of accumulation of inputs

`'Vector'` (default) | `'Streaming - using Start and End Ports'` | `'Streaming - using Number of Samples'`

You can specify the **Operation Mode** as:

- `Vector`: You can use scalars or vectors as inputs. The block performs the dot product of the inputs `u1` and `u2` and adds bias `k` to produce the result.
- `Streaming - using Start and End Ports`: Use scalar inputs for HDL code generation. In this mode, you can use the **startIn** and **endIn** control signals to determine when to start and stop accumulation. The output data is valid when **validIn** is high.
- `Streaming - using Number of Samples`: Use scalar inputs for HDL code generation. In this mode, you can specify the **Number of Samples** and use the **countIn** control signal to determine when to start and stop accumulation. The output data is valid when **validIn** is high.

Programmatic Use

Block parameter: `opMode`
Type: character vector
Value: `'Vector'` | `'Streaming - using Start and End Ports'` | `'Streaming - using Number of Samples'`
Default: `'Vector'`

Bias — Offset to add to the input dot product

`{'0.0'}` (default)

You can specify the bias with:

- **Source** as `Dialog`. Then, specify the **Value**.
- **Source** as `Input port`. This setting creates an external input port `c` to input the bias signal to the block.

Programmatic Use

Block parameter: `initValueSetting`
Type: character vector
Value: `'Dialog'` | `'Input port'`
Default: `'Dialog'`

If you set **Source** as `Dialog`, you can specify the initial value by using the `initValue2` setting.
Block parameter: `initValue2`
Type: character vector
Value: An integer greater than or equal to zero
Default: `'0.0'`

`Number of Samples` — Number of samples of valid accumulated output signal

`{'2'}` (default)

You can specify the **Number of Samples** to specify a frame containing the number of samples of valid accumulated output **dataOut**.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Number of Samples`.

Programmatic Use
Block parameter: `num_samples`
Type: character vector
Value: An integer greater than or equal to zero
Default: `'2'`

`Output data type` — Data type of the block output

`Inherit: Inherit via back propagation` (default)

Set the output data type to:

- A rule that inherits a data type, such as `Inherit: Same as first input`.
- A built-in data type, such as `single` or `int16`.
- The name of a data type object. for instance, a `Simulink.NumericType` object.
- An expression that evaluates to a valid data type, for example, `fixdt(1,16,0)`

The streaming modes do not suuport `Inherit: Inherit via internal rule`. When you set the **Output data type**, you can use the **Data Type Assistant**. To display the assistant, click the **Show data type assistant** >>.

Programmatic Use
Block parameter: `OutDataTypeStr`
Type: character vector
Default: `{'Inherit: Inherit via internal rule'}`

To see possible values that you can specify for this parameter, see “Block-Specific Parameters” on page 6-128.

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding action as:

`Ceiling`

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds the number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use
Block parameter: `RndMeth`
Type: character vector
Default: `{'Floor'}`

To see possible values that you can specify for this parameter, see “Block-Specific Parameters” on page 6-128.

`Valid output port` — Control generation of validOut output port

off (default) | on

Control generation of the **validOut** output port. This port indicates whether **dataOut** is valid.

□ off

Does not display the **validOut** output port.

☑ on

Display the **validOut** output port.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Number of Samples` or `Streaming - using Start and End Ports`.

Programmatic Use
Block parameter: `validOut`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`End input and output ports` — Control generation of endIn input port and endOut output port

off (default) | on

Control generation of the **endIn** input port and the **endOut** output port. The ports indicate the end of a frame containing valid accumulation output.

□ off

Does not display the **endIn** input port and the **endOut** output port.

☑ on

Display the **endIn** input port and the **endOut** output port.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Start and End Ports`.

Programmatic Use
Block parameter: `endInandOut`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Start output port` — Control generation of startOut output port

off (default) | on

Control generation of the **startOut** output port. This port generates the **startOut** signal that indicates the start of a frame containing valid accumulated output.

□ off

Does not display the **startOut** output port.

☑ on

Display the **startOut** output port.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Start and End Ports`.

Programmatic Use

Block parameter: `startOut`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Count output port` — Control generation of countOut output port

off (default) | on

Control generation of the **countOut** output port. This port generates the counter that indicates a frame containing valid samples.

□ off

Does not display the **countOut** output port.

☑ on

Display the **countOut** output port.

Dependencies

To enable this port, set **Operation Mode** to `Streaming - using Number of Samples`.

Programmatic Use
Block parameter: `countOut`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point` | `bus`
Sample Time	`Inherit`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Scalar`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Algorithms

Streaming Mode Using Start and End Ports

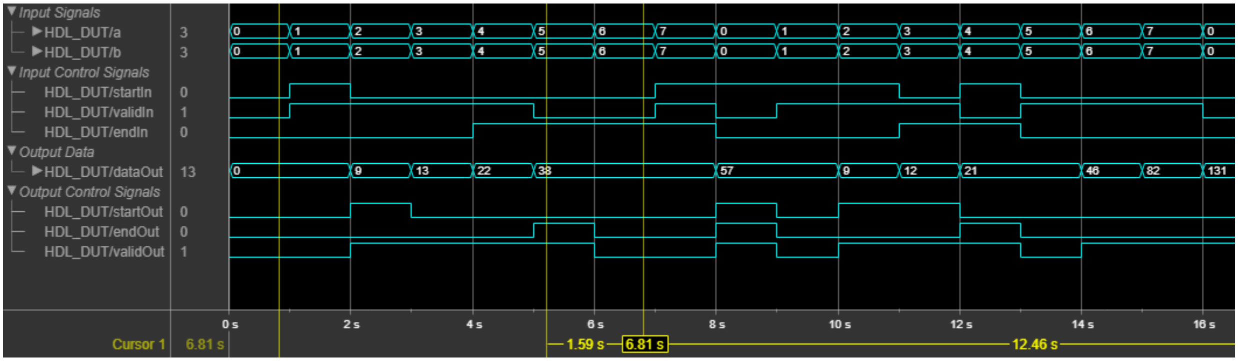
You can use the **Operation Mode** setting for the block to specify a streaming mode of operation. When you select `Streaming - using Start and End Ports`, you see three additional settings enabled by default. The settings include:

- **Valid output port**
- **End input and output ports**
- **Start output port**

It is recommended that you leave these settings enabled. When you apply the settings, three additional input ports and three additional output ports appear:

Input Ports	Output Ports
startIn	**startOut**
validIn	**validOut**
endIn	**endOut**

This figure illustrates the streaming mode of operation using the start and end ports. In this example, the bias value is 8.



Initially, when **validIn** is low, **dataOut** is zero. At time 1s, both **startIn** and **validIn** become high. Therefore, **validOut** becomes high in the next clock cycle and **dataOut** starts producing valid accumulation output. During accumulation, **dataOut** takes the values of **a** and **b** from the previous clock cycle. For example, at time t = 2s, **dataOut** = 1*1 + 8 = 9.

To continue accumulation, make **startIn** low at the next clock cycle and keep **validIn** high. **dataOut** continues accumulating the inputs until **validIn** becomes low. At each time step, **dataOut** computes the product of the inputs from the previous clock cycle and sums the result with the **dataOut** value from the previous clock cycle. For example, at time t = 3s, **dataOut** = 2*2 + 9 = 13.

When **validIn** becomes low, **dataOut** holds the output value as seen at time t = 5s. At t = 5s, **endIn** and **validIn** are high. Therefore, **endOut** becomes high in the next clock cycle, which indicates end of frame. Therefore the frame between t = 2s (when **startOut** is high) and t = 6s (when **endOut** is high) indicates a frame containing valid output.

If **startIn**, **validIn**, and **endIn** are both high at the same time, only the **dataOut** corresponding to those inputs are accumulated as seen at t = 8s. If **startIn** is high for multiple clock cycles, and if **validIn** is high, the accumulator is reset at each clock cycle as seen at t = 10s and t = 11s. The accumulation continues at t = 12s.

Streaming Mode Using Number of Samples

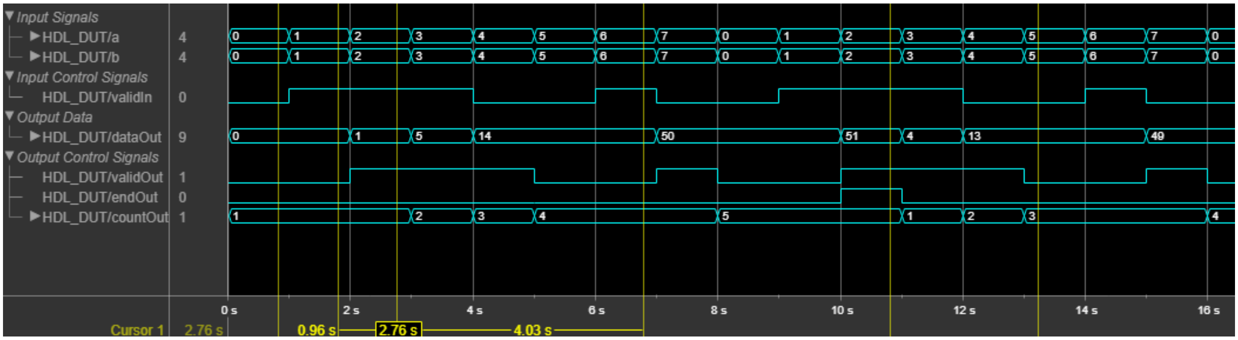
You can use the **Operation Mode** setting for the block to specify a streaming mode of operation. When you select `Streaming - using Number of Samples`, you see two additional settings enabled by default. The settings include:

- **Valid output port**
- **Count output port**

It is recommended that you leave these settings enabled. When you apply the settings, you have an additional input port **validIn** and three additional output ports appear:

- **endOut**
- **validOut**
- **countOut**

This figure illustrates the streaming mode of operation using the number of samples. In this example, the bias value is 8 and the **Number of Samples** is 5.



Initially, when **validIn** is low, **dataOut** is `0` and **countOut** is `1`. At time `1s`, **validIn** becomes high. Therefore, **validOut** becomes high in the next clock cycle, and **dataOut** starts producing valid accumulation output. During accumulation, **dataOut** takes the values of **a** and **b** from the previous clock cycle. For example, at time t = `2s`, **dataOut** = 1*1 = 1. **countOut** increments by `1` at the next clock cycle, that is, at t = `3s`, **countOut** becomes `2`.

To continue accumulation, keep **validIn** high. **dataOut** continues accumulating the inputs until **validIn** becomes low. When five valid outputs are obtained from **dataOut**, **countOut** becomes `5` and **endOut** becomes high, which indicates the end of the frame. Therefore, the time between when **countOut** is `1` and when **countOut** is five indicates a frame containing valid output.

The accumulator counter is now reset and **countOut** starts from `1`. When **validIn** becomes high again, **dataOut** starts accumulating a new set of values and **countOut** starts incrementing for each valid **dataOut**.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

If have HDL Coder installed, you can map the generated HDL code for the block efficiently to DSP slices on the FPGA when you synthesize your design. For more information, see Multiply-Accumulate.

You can use the data types listed above for the ports when you simulate the block. To generate HDL code, make sure that you use `vector` inputs and a `scalar` bias signal. If you use `single` or `double` data types for the inputs, the block may not map the generated code to DSP slices on the FPGA.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

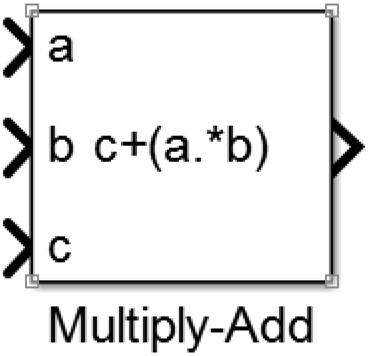
Dot Product | Multiply-Add

Introduced in R2017b

Multiply-Add

Multiply-add combined operation



Library

HDL Coder / HDL Operations

Description

The Multiply-Add block computes the product of the first two inputs, a and b, and adds the result to the third input, c. The inputs can be vectors or scalars.

Operation Precision

The multiplication operation is full precision, regardless of the output type. The **Integer rounding mode**, **Output data type**, and **Saturate on integer overflow** settings apply only to the addition operation.

HDL Code Generation

Use the Multiply-Add block to map a combined multiply-add or a multiply-subtract operation to a DSP unit in your target hardware.

When you generate HDL code for your model, HDL Coder configures the multiply-add operation so that your synthesis tool can map to a DSP unit.

Data Type Support

The Multiply-Add block accepts and outputs signals of any numeric data type that Simulink supports, including fixed-point data types.

For more information, see “Data Types Supported by Simulink”.

Parameters

Function

Specify the function to perform a combined multiply and add or a multiply and subtract operation.

Default: `c+(a.*b)`

You can set the function to:

- `c+(a.*b)`
- `c-(a.*b)`
- `(a.*b)-c`

Output data type

Specify the output data type.

Default: `Inherit: Inherit via internal rule`

Set the output data type to:

- A rule that inherits a data type, for example, `Inherit: Same as input`
- An expression that evaluates to a valid data type, for example, `fixdt([],16,0)`

Click the **Show data type assistant** button >> to display the Data Type Assistant dialog box, which helps you to set the **Output data type** parameter.

For more information, see “Control Signal Data Types” in *Simulink User's Guide* .

Integer rounding mode

Specify the rounding mode for fixed-point operations.

Default: `Floor`

`Ceiling`

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

For more information, see “Rounding” (Fixed-Point Designer).

Saturate on integer overflow

Specify whether overflows saturate.

Default: Off

☑ On

Overflows saturate to either the minimum or maximum value that the data type can represent.

For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

□ Off

Overflows wrap to the appropriate value that the data type can represent.

For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Value: `'off'` | `'on'`
Default: `'off'`

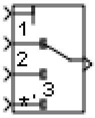
Introduced in R2015b

Multiport Switch

Choose between multiple block inputs
Library: Simulink / Signal Routing



Description

The Multiport Switch block determines which of several inputs to the block passes to the output. The block bases this decision on the value of the first input. The first input is the control input and the remaining inputs are the data inputs. The value of the control input determines which data input passes to the output.

The table summarizes how the block interprets the control input and determines the data input that is passed to the output.

Control Input	Truncation	Setting for Data Port Order	Block Behavior During Simulation	
			Indexing to Select Data Input	Out-of-Range Condition
Integer value	None	`Zero-based contiguous`	Zero-based indexing	The control input is less than `0` or greater than the number of data inputs minus one.
		`One-based contiguous`	One-based indexing	The control input is less than `1` or greater than the number of data inputs.
		`Specify indices`	Indices you specify	The control input does not correspond to any specified data port index.

Control Input	Truncation	Setting for Data Port Order	Block Behavior During Simulation	
			Indexing to Select Data Input	Out-of-Range Condition
Not an integer value	The block truncates the value to an integer by rounding to zero.	`Zero-based contiguous`	Zero-based indexing	The truncated control input is less than `0` or greater than the number of data inputs minus one.
		`One-based contiguous`	One-based indexing	The truncated control input is less than `1` or greater than the number of data inputs.
		`Specify indices`	Indices you specify	The truncated control input does not correspond to any specified data port index.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-1285.

Multiport Switch Configured as an Index Vector Block

An Index Vector is a special configuration of a Multiport Switch block in which you specify one data input and the control input is zero-based. The block output is the element of the input vector whose index matches the control input. For example, if the input vector is `[18 15 17 10]` and the control input is `3`, the element that matches the index of 3 (zero-based) is 10, and that becomes the output value.

To configure a Multiport Switch block to work as an Index Vector block, set **Number of data ports** to `1` and **Data port order** to `Zero-based contiguous`.

How the Block Handles an Out-of-Range Control Input

For an input with an integer value less than `intmax('int32')`, the input is out of range when the value does not match any data port indices. For a control input that is not an integer value, the input is out of range when the *truncated* value does not match any data port indices. In both cases, the block behavior depends on your settings for **Data port for default case** and **Diagnostic for default case**.

Note If the control input is larger than `intmax('int32')`, the block wraps the input value to an integer.

The following behavior applies only to simulation for your model.

Data Port for Default Case	Diagnostic for Default Case		
	None	Warning	Error
`Last data port` 	Use the last data port and do not report any warning or error.	Use the last data port and report a warning.	Report an error and stop simulation.
`Additional data port` 	Use the additional data port with a * label and do not report any warning or error.	Use the additional data port with a * label and report a warning.	Report an error and stop simulation.

The following behavior applies to code generation for your model.

Data Port for Default Case	Diagnostic for Default Case		
	None	Warning	Error
`Last data port`  	Use the last data port.	Use the last data port.	Use the last data port.
`Additional data port`  	Use the additional data port with a * label.	Use the additional data port with a * label.	Use the additional data port with a * label.

Use Data Inputs That Have Different Dimensions

If two signals have a different number of dimensions or different dimension lengths, you can use the signals as data inputs to a Multiport Switch block. In the block dialog box, select the parameter **Allow different data input sizes**. In this case, the output of the block is a variable-size signal. If you do not select this parameter, the block generates an error.

For more information about the parameter, see “Allow different data input sizes (Results in variable-size output signal)” on page 1-0 . For more information about variable-size signals, see “Variable-Size Signal Basics”.

Rules That Determine the Block Behavior

You specify the number of data inputs with **Number of data ports**.

- If you set **Number of data ports** to 1, the block behaves as an *index selector* or *index vector* and not as a multiport switch. For more details, see “Multiport Switch Configured as an Index Vector Block” on page 1-1285.
- If you set **Number of data ports** to an integer greater than 1, the block behaves as a multiport switch. The block output is the data input that corresponds to the value of the control input. If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If all the data inputs are scalar, the output is a scalar.

Guidelines on Setting Parameters for Enumerated Control Port

When the control port on the Multiport Switch block is of enumerated type, follow these guidelines:

Scenario	What to Do	Rationale
The enumerated type contains a value that represents invalid, out-of-range, or uninitialized values.	• Set **Data port order** to `Specify indices`. • Set **Data port indices** to use this value for the last data port. • Set **Data port for default case** to `Last data port`.	This block configuration handles invalid values that the enumerated type explicitly represents.
The enumerated type contains only valid enumerated values. However, a data input port can get invalid values of enumerated type.	• Set **Data port for default case** to `Additional data port`.	This block configuration handles invalid values that the enumerated type does not explicitly represent.

Scenario	What to Do	Rationale
The enumerated type contains only valid enumerated values. Data input ports can never get invalid values of enumerated type.	• Set **Data port for default case** to `Last data port`. • Set **Diagnostic for default case** to `None`.	This block configuration avoids unnecessary diagnostic action.
The block does not have a data input port for every value of the enumerated type.	• Set **Data port for default case** to `Additional data port`.	This block configuration handles enumerated values that do not have a data input port, along with invalid values.

Ports

Input

`Port_1` — Control signal

scalar | vector | matrix | N-D array

The control signal can be of any data type that Simulink supports, including fixed-point and enumerated types. When the control input is not an integer value, the block truncates the value to an integer by rounding to zero.

For information on control signals of enumerated type, see “Guidelines on Setting Parameters for Enumerated Control Port” on page 1-1288.

For information on how the block handles the out-of-range condition, see “How the Block Handles an Out-of-Range Control Input” on page 1-1285.

Limitations

- If the control signal is numeric, the control signal cannot be complex.
- If the control signal is an enumerated signal, the block uses the value of the underlying integer to select a data port.
- If the underlying integer does not correspond to a data port, an error occurs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

1 — First data input

scalar | vector | matrix | N-D array

First data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1287
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

2 — Second data input

scalar | vector | matrix | N-D array

Second data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see “Use Data Inputs That Have Different Dimensions” on page 1-1287
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Dependencies

To enable this port, set **Number of data ports** to an integer greater than 1.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`N` — Nth data input

scalar | vector | matrix | N-D array

Nth data input, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports.

- If all the data inputs are scalar, the output is scalar
- If at least one of the data inputs is a vector, the block output is a vector. In this case, the block expands any scalar inputs to vectors.
- If any two nonscalar signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see "Use Data Inputs That Have Different Dimensions" on page 1-1287
- If any data signal is of an enumerated type, all others must be of the same enumerated type.

Dependencies

To enable the **N**th input port, set **Number of data ports** to an integer value greater than or equal to `N`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

* — Data port for out-of-range inputs

scalar | vector | matrix | N-D array

Input data port for out-of-range control signal inputs, specified as a scalar, vector, matrix, or N-D array. All input data signals can be of any data type that Simulink supports. If any data signal is of an enumerated type, all others must be of the same enumerated type. If any two signals have a different number of dimensions or different dimension lengths, select the **Allow different data input sizes** check box. For more information, see "Use Data Inputs That Have Different Dimensions" on page 1-1287.

Dependencies

To create an additional data port for out-of-range control signal inputs, set **Data port for default case** to `Additional data port`. When you set **Data port for default case** to `Last data port`, the block uses the last data port for output when the control signal value does not match any data port indices.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Selected data input, based on control signal value

scalar | vector | matrix | N-D array

The block outputs one of the data inputs, selected according to the control signal value. The output has the same dimensions as the corresponding data input. When you select the **Allow different data input sizes** check box, the output of the block is a variable size signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

`Data port order` — Type of ordering for data input ports

`One-based contiguous` | `Zero-based contiguous` | `Specify indices`

Specify the type of ordering for your data input ports.

- `Zero-based contiguous` — Block uses zero-based indexing for ordering contiguous data ports. This is the default value of the Index Vector block.
- `One-based contiguous` — Block uses one-based indexing for ordering contiguous data ports. This is the default value of the Multiport Switch block
- `Specify indices` — Block uses noncontiguous indexing for ordering data ports.

Tips

- When the control port is of enumerated type, select `Specify indices`.
- If you select `Zero-based contiguous` or `One-based contiguous`, verify that the control port is not of enumerated type. This configuration is deprecated and produces an error. You can run the Upgrade Advisor on your model to replace each Multiport Switch block of this configuration with a block that explicitly specifies data port indices. See “Model Upgrades”.

- Avoid situations where the block contains unused data ports for simulation or code generation. When the control port is of fixed-point or built-in data type, verify that all data port indices are representable with that type. Otherwise, the following block behavior occurs.

If the Block Has Unused Data Ports and Data Port Order Is:	The Block Produces:
`Zero-based contiguous` or `One-based contiguous`	A warning
`Specify indices`	An error

Dependencies

Selecting `Zero-based contiguous` or `One-based contiguous` enables the **Number of data ports** parameter.

Selecting `Specify indices` enables the **Data port indices** parameter.

Programmatic Use
Block Parameter: `DataPortOrder`
Type: character vector
Values: `'Zero-based contiguous' | 'One-based contiguous' | 'Specify indices'`
Default: `'One-based contiguous'` (Multiport Switch) `'Zero-based contiguous'` (Index Vector)

`Number of data ports` — Number of data input ports

`1` | `3` | integer between 1 and 65536

Specify the number of data input ports to the block. The total number of input ports is the number you specify, plus one for the control signal input port, and plus one more if you set **Data port for default case** to `Additional data port`.

Dependencies

To enable this parameter, set **Data port order** to `Zero-based contiguous` or `One-based contiguous`.

Programmatic Use
Block Parameter: `Inputs`
Type: character vector
Values: integer between 1 and 65536

Default: `'3'` (Multiport Switch) `'1'` (Index Vector)

`Data port indices` — Array of indices for data ports

`{1,2,3}` (default) | array of indices

Specify an array of indices for your data ports. The block icon changes to match the data port indices you specify.

Tips

- To specify an array of indices that correspond to all values of an enumerated type, enter `enumeration('`*`type_name`*`')` for this parameter. Do not include braces.

  For example, `enumeration('MyColors')` is a valid entry.
- To enter specific values of an enumerated type, use the *`type_name.enumerated_name`* format. Do not enter the underlying integer value.

  For example, `{MyColors.Red, MyColors.Green, MyColors.Blue}` is a valid entry.
- To indicate that more than one value maps to a data port, use brackets.

  For example, the following entries are both valid:

  - `{MyColors.Red, MyColors.Green, [MyColors.Blue, MyColors.Yellow]}`
  - `{[3,5],0,18}`
- If the control port is of fixed-point or built-in data type, the values for **Data port indices** must be representable with that type. Otherwise, an error appears at compile time to alert you to unused data ports.
- If the control port is of enumerated data type, the values for **Data port indices** must be enumerated values of that type.
- If **Data port indices** contains values of enumerated type, the control port must be of that data type.

Dependencies

To enable this parameter, set **Data port order** to `Specify indices`.

Programmatic Use
Block Parameter: `DataPortIndices`
Type: character vector

Values: array of indices
Default: `'{1,2,3}'`

`Data port for default case` — Port to use for out-of-range inputs

`Last data port` (default) | `Additional data port`

Specify whether to use the last data port for out-of-range inputs, or to use an additional port. An asterisk (*) next to the port name indicates the port the block uses when the control port value does not match any data port indices.

- `Last data port` — Block uses the last data port for output when the control port value does not match any data port indices.
- `Additional data port` — Block uses an additional data port for output when the control port value does not match any data port indices.

Tip

If you set this parameter to `Additional data port` and **Number of data ports** is `3`, the number of input ports on the block is 5. The first input is the control port, the next three inputs are data ports, and the fifth input is the default port for out-of-range inputs.

Programmatic Use
Block Parameter: `DataPortForDefault`
Type: character vector
Values: `'Last data port' | 'Additional data port'`
Default: `'Last data port'`

`Diagnostic for default case` — Diagnostic action when control port value does not match data port indices

`Error` (default) | `Warning` | `None`

Specify the diagnostic action to take when the control port value does not match any data port indices.

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error. In this case, the **Data port for default case** is used only for code generation and not simulation.

For more information, see “How the Block Handles an Out-of-Range Control Input” on page 1-1285.

Programmatic Use
Block Parameter: `DiagnosticForDefault`
Type: character vector
Values: `'None' | 'Warning' | 'Error'`
Default: `'Error'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

`Require all data port inputs to have the same data type` — Require all inputs to have the same data type

`off` (default) | `on`

Select this check box to require that all data input ports have the same data type. When you clear this check box, the block allows data port inputs to have different data types.

Programmatic Use
Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

When you select an inherited option, the block behaves as follows:

- `Inherit: Inherit via internal rule`—Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn't meet your specific needs for numerical accuracy or performance, use one of the following options:

  - Specify the output data type explicitly.
  - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
  - To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Uses the data type of the driving block.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'`, `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Integer rounding mode` — Specify the rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Choose one of these rounding modes.

`Ceiling`

> Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

> Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

> Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

> Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

See Also

For more information, see “Rounding” (Fixed-Point Designer).

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.

- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Allow different data input sizes (Results in variable-size output signal)` — Allow input signals with different sizes
`off` (default) | `on`

Select this check box to allow input signals with different sizes.

- `On` — Allows input signals with different sizes, and propagate the input signal size to the output signal. In this mode, the block produces a variable-size output signal.
- `Off` — Requires that all nonscalar data input signals be the same size.

Programmatic Use
Parameter: `AllowDiffInputSizes`
Type: character vector
Value: `'on'` | `'off'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`

Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

"Variable-Size Signal Basics"

Introduced before R2006a

MultiStateImage

Display image reflecting input value
Library: Simulink / Dashboard

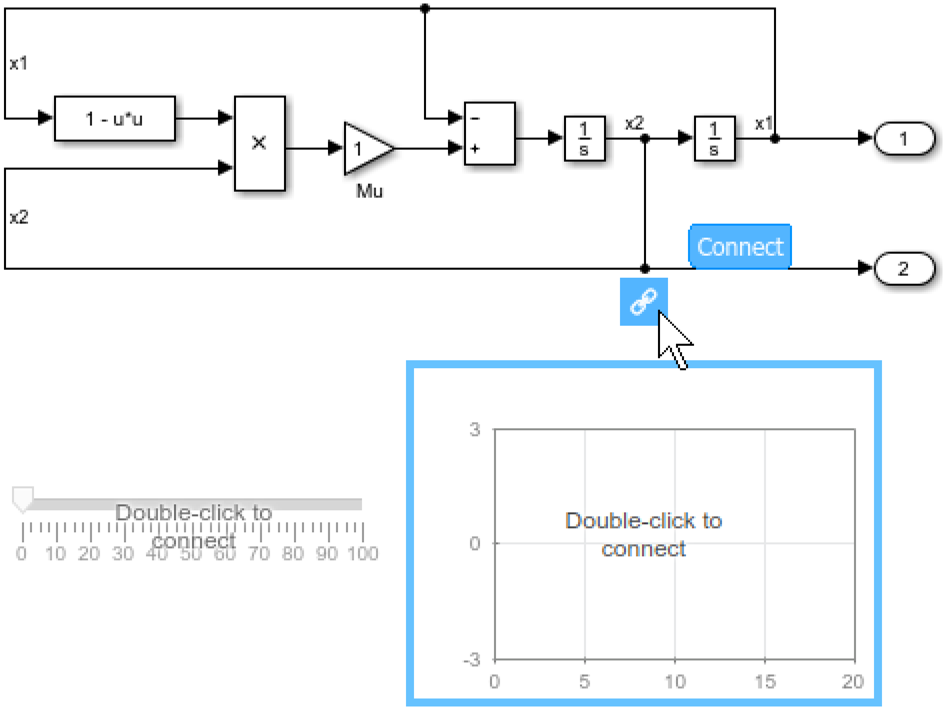
Description

The MultiStateImage block displays an image to indicate the value of the input signal. You can use the MultiStateImage block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. You can specify pairs of input values and images to provide the information you want during simulation.

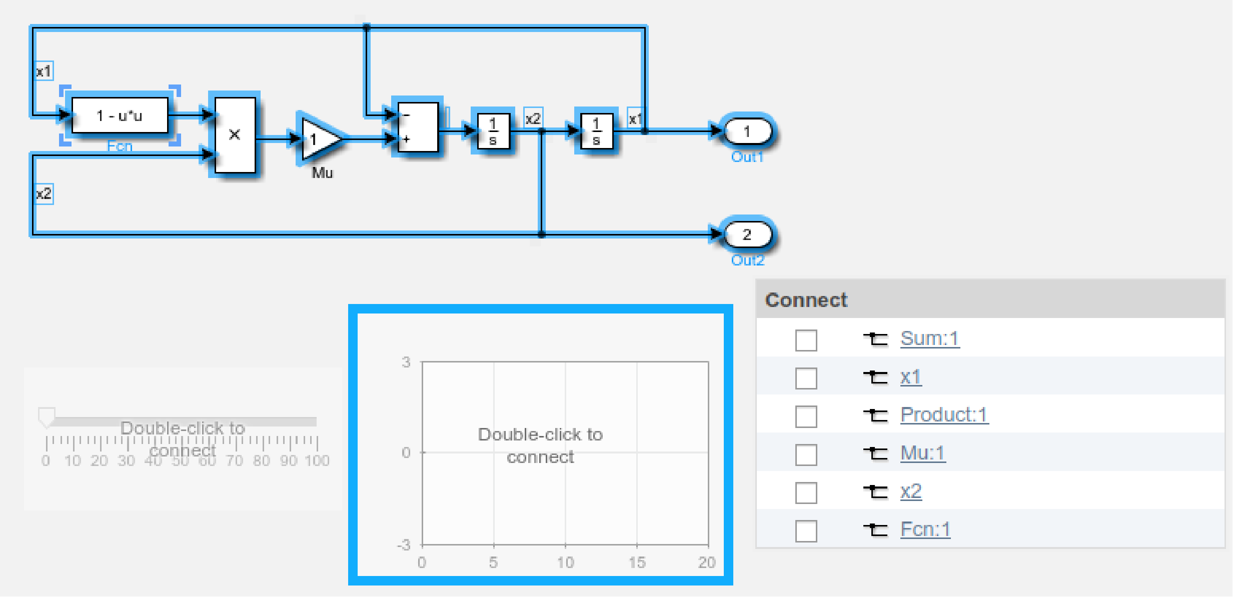
Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

- □ Sum:1
- □ x1
- □ Product:1
- □ Mu:1
- □ x2
- □ Fcn:1

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.

Parameters

`Connection` — Select a signal to connect and display

signal connection options

Select the signal to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the radio button next to the signal you want to display. Click **Apply** to connect the signal.

`Scale Mode` — Specify how to scale image

'Fill with fixed Aspect Ratio' (default) | Fixed | Fill

Specify how to scale the image.

Fill with fixed Aspect Ratio scales the image to the size of the block while retaining its original aspect ratio.

Fixed displays the image with its fixed true size.

Fill adjusts the image to fill the block.

States

`State` — Input signal value

1 (default) | scalar

Input signal value that causes the block to display an image. Click the **+** button to add another state.

`Thumbnail` — Image to display

image file

Image the block displays when the input signal has the value specified in **State**. The MultiStateImage block can display `png`, `jpg`, `tif`, and `bmp` image files.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

Mux

Combine input signals of same data type and numeric type into virtual vector

Library: Simulink / Commonly Used Blocks
Simulink / Signal Routing

Description

The Mux block combines its inputs into a single vector output. An input can be a scalar or vector signal. All inputs must be of the same data type and numeric type. For information about creating and decomposing vectors, see “Mux Signals”.

The elements of the vector output signal take their order from the top to bottom, or left to right, input port signals. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

The nonvirtual components of a virtual signal are called *regions*. A virtual signal can contain the same region more than once. For example, if the same nonvirtual signal is connected to two input ports of a Mux block, the block outputs a virtual signal that has two regions. The regions behave as they would if they had originated in two different nonvirtual signals, even though the resulting behavior duplicates information.

Note Simulink provides several techniques for combining signals into a composite signal. For more information, see “Composite Signal Techniques”.

Ports

Input

`Port_1` — Accept nonbus vector signal to extract and output signals from
real or complex values of any nonbus data type supported by Simulink

Port that accepts the input nonbus vector signal from which to extract and output signals.

Output

`Port_1` — Output signals extracted from input vector signal

nonbus signal with real or complex values of any data type supported by Simulink

Output signals extracted from the input vector. The output signal ports are ordered from top to bottom. See “Port Location After Rotating or Flipping” for a description of the port order for various block orientations.

Parameters

`Number of inputs` — Inputs

2 (default) | scalar | vector | cell array | comma-separated list of signal names

Specify the number of input signals. You can also specify signal names and sizes. Use one of these formats.

Format	Block Behavior
Scalar	Specifies the number of inputs to the Mux block. When you use this format, the block accepts scalar or vector signals of any size. Simulink assigns each input the name `signalN`, where `N` is the input port number.
Vector	The length of the vector specifies the number of inputs. Each element specifies the size of the corresponding input. A positive value specifies that the corresponding port can accept only vectors of that size. For example, `[2 3]` specifies two input ports of sizes `2` and `3`, respectively. If an input signal width does not match the expected width, an error message appears. A value of `-1` specifies that the corresponding port can accept scalars or vectors of any size.

Format	Block Behavior
Cell array	The length of the cell array specifies the number of inputs. The value of each cell specifies the size of the corresponding input. A scalar value `N` specifies a vector of size `N`. A value of `-1` means that the corresponding port can accept scalar or vector signals of any size.
Signal name list	You can enter a list of signal names separated by commas. Simulink assigns each name to the corresponding port and signal. For example, if you enter `position,velocity`, the Mux block has two inputs, named `position` and `velocity`.

Tip If you specify a scalar for the **Number of inputs** parameter and all of the input ports are connected, as you draw a new signal line close to input side of a Mux block, Simulink adds a port and updates the parameter.

Programmatic Use

Block Parameter: `Inputs`
Type: scalar, vector, cell array, signal name list
Values: number, vector of port numbers, cell array, or list of signal names
Default: `{'2'}`

`Display option` — Displayed block icon

`bar` (default) | `nonesignal`

By default, the block icon is a solid bar of the block foreground color. To display the icon as a hollow bar containing input signal names, select `signals`. To display the icon as a box containing the block type name, select `none`.

Programmatic Use

Block Parameter: `DisplayOption`
Type: character vector
Values: `'bar' 'signals' 'none''bar'`
Default: `'bar'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

This block has a single, default HDL architecture. See Mux.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type or capability support depends on block implementation.

"Virtual Signals"
"Composite Signal Techniques"
"Simplify Subsystem Bus Interfaces"

Introduced before R2006a

Out Bus Element

Output signals from a subsystem as a virtual bus

Library: Simulink / Ports & Subsystems
Simulink / Sinks

Description

Note This block has two different names, depending on the library in which it appears. The functionality of both blocks is the same.

- In the Sinks library and the Ports & Subsystems library— Out Bus Element
- In the Signal Routing library — Bus Element Out

To output signals in a virtual bus from a subsystem, use an Out Bus Element block for each signal in the subsystem that you want the bus to contain. This block integrates into one block the functionality of using an Outport block and a Bus Creator block. The Out Bus Element block is of the Outport block type. There are no specifications allowed on an Out Bus Element block, which supports only an inherited workflow. You cannot use the Block Parameters dialog box of an Out Bus Element block to specify bus element attributes, such as data type or dimensions.

To work with buses at subsystem interfaces, consider using In Bus Element and Out Bus Element blocks. This bus element port block combination:

- Reduces signal line complexity and clutter in a block diagram.
- Makes it easy to change the interface incrementally.
- Allows access to a bus element closer to the point of usage.
  - For output, avoid a Goto, From, and Bus Creator block configuration.
  - For input, avoid a duplicate Outport blocks and a Bus Selector, Goto, and From block configuration.

To output multiple signals from a subsystem as a bus signal, create multiple Out Bus Element blocks, one for each signal.

If an Out Bus Element block creates a signal `A`, then another Out Bus Element block for the same port cannot specify signal `A` (or a child of signal `A`) as an element

To add a subbus, in the Block Parameters dialog box, click ☰. To remove blocks associated with selected elements, click 🗑.

To reduce the number of bus element signals displayed in the Block Parameters dialog box, use the **Filter** box. The **Filter** box supports regular expressions. To use a regular expression character as a literal, include an escape character (`\`). For example, to use a question mark: `sig\?1`.

You can reorder bus elements by dragging and dropping a signal in the list of signals in the Block Parameters dialog box.

You can specify the background color for bus element port blocks, using the Block Parameters dialog box **Set color** option. This action sets the color of blocks associated with selected elements, or to all blocks if you do not select elements.

Ports

The block does not have an output port. Use the Block Parameters dialog box to specify the subsystem output port to which the block sends its input signal.

Input

`Port_1` — Input port for bus signal or bus element from within subsystem

signal

The selected input signal is included in a bus signal that the subsystem outputs. The signal can have a real or complex values of any data type that Simulink supports.

Parameters

`Port name` — Name of subsystem output port

`OutBus` (default) | text

Specify a name for a subsystem port. That name appears on the Subsystem and Out Bus Element block icons. If you specify a port name, that name cannot already be in use by another block or port. All Out Bus Element blocks that access the same subsystem output port reflect the port name that you specify.

Programmatic Use
Block Parameter: `PortName`
Type: text
Default: `OutBus`

`Port number` — Order in which port appears for subsystem output ports

1 (default) | integer

Specify the order in which the port appears on the subsystem, with `1` being the top port, `2` the second port down, and so on.

- If you specify a number that exceeds the number of subsystem output ports, new ports are added above the port associated with the Outport Bus Element block.
- If you add an Out Bus Element block that creates another subsystem output port, the port number is the next available number.
- If you delete all Out Bus Element blocks associated with a port, other port numbers are renumbered so that the blocks are in sequence and that no numbers are omitted.

Programmatic Use
Block Parameter: `Port`
Value: integer
Default: `1`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`

Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual data type or capability support depends on block implementation.

Fixed-Point Conversion

Introduced in R2017a

Outport

Create output port for subsystem or external output
Library: Simulink / Commonly Used Blocks
Simulink / Ports & Subsystems
Simulink / Sinks

Description

Outport blocks link signals from a system to a destination outside of the system. They can connect signals flowing from a subsystem to other parts of the model. They can also supply external outputs at the top level of a model hierarchy.

Simulink software assigns Outport block port numbers according to these rules:

- It automatically numbers the Outport blocks within a root-level system or subsystem sequentially, starting with 1.
- If you add an Outport block, it is assigned the next available number.
- If you delete an Outport block, other port numbers are automatically renumbered to ensure that the Outport blocks are in sequence and that no numbers are omitted.

Outport Blocks in a Subsystem

Outport blocks in a subsystem represent outputs from the subsystem. A signal arriving at an Outport block in a subsystem flows out of the associated output port on that Subsystem block. The Outport block associated with an output port is the block whose **Port number** parameter matches the relative position of the output port on the Subsystem block. For example, the Outport block whose **Port number** parameter is 1 sends its signal to the block connected to the topmost output port on the Subsystem block.

If you renumber the **Port number** of an Outport block, the block becomes connected to a different output port. The block continues to send the signal to the same block outside the subsystem.

Tip For models that include bus signals composed of many bus elements that feed subsystems, consider using the In Bus Element and Out Bus Element blocks. These bus element port blocks:

- Reduce signal line complexity and clutter in a block diagram.
- Make it easier to change the interface incrementally.
- Allow access to a bus element closer to the point of usage, avoiding the use of a Bus Selector and Goto block configuration.

The Out Bus Element block is of block type Outport. However, there are no specifications allowed on bus element port blocks, which support inherited workflows. You cannot use the Block Parameters dialog box of an Out Bus Element block to specify bus element attributes, such as data type or dimensions.

Top-Level Outport Block in a Model Hierarchy

Outport blocks at the top level of a model hierarchy have two uses. They can supply external outputs to the base MATLAB workspace, and they provide a means for the `linmod` and `trim` analysis functions to obtain output from the system.

To supply external outputs to the workspace, use the **Configuration Parameters > Data Import/Export** pane (see Exporting Output Data to the MATLAB Workspace) or the `sim` command. For example, if a system has more than one Outport block and the save format is array, the following command

```
[t,x,y] = sim(...);
```

writes `y` as a matrix, with each column containing data for a different Outport block. The column order matches the order of the port numbers for the Outport blocks.

If you specify more than one variable name after the second (state) argument, data from each Outport block is written to a different variable. For example, if the system has two Outport blocks, to save data from Outport block 1 to `speed` and the data from Outport block 2 to `dist`, specify this command:

```
[t,x,speed,dist] = sim(...);
```

Connecting Buses to Root-Level Outports

A root-level Outport of a model can accept a virtual bus only if all elements of the bus have the same data type. The Outport block automatically unifies the bus to a vector having the same number of elements as the bus, and outputs that vector.

If you want a root-level Outport of a model to accept a bus signal that contains mixed types, set Outport block **Data type** to `Bus: <object name>` . If the bus signal is virtual, it is converted to nonvirtual, as described in “Bus Conversion”.

Associate Root-Level Outport Block with `Simulink.Signal` Object

To associate a root-level Outport block with a `Simulink.Signal` object, use the Model Data Editor. See “For Signals”.

Ports

Input

`Port_1` — Outport signal

scalar | vector

Input signal that flows through the outport to an external subsystem or model.

An Outport block can accept fixed-point and enumerated data types when the block is not a root-level output port. The complexity and data type of the block output are the same as its input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

`Port number` — Port number of block

1 (default)

Specify the port number of the block. This parameter controls the order in which the port that corresponds to the block appears on the parent subsystem or model block.

Programmatic Use
Block Parameter: `Port`
Type: character vector
Values: real integer
Default: `'1'`

`Signal name` — Signal name

`' '` (default) | character vector

Specify the name of the corresponding signal data in the generated code. Use this parameter to specify a name for the signal data when you apply a storage class to a root-level Outport block.

Programmatic Use
Block Parameter: `SignalName`
Type: character vector
Values: character vector
Default: `' '`

`Icon display` — Icon display

`Port number` (default) | `Signal name` | `Port number and signal name`

Specify the information to be displayed on the icon of this port.

Programmatic Use
Block Parameter: `IconDisplay`
Type: character vector
Values: `'Signal name'` | `'Port number'` | `'Port number and signal name'`
Default: `'Port number'`

`Specify output when source is unconnected` — Specify unconnected output

`off` (default) | `on`

Specify a constant output value to be displayed when source is not connected.

Dependency

Enabled when a non-driven Outport block is in a Variant Subsystem block.

Programmatic Use
Block Parameter: `OutputWhenUnconnected`
Type: character vector
Values: `'on' | 'off'`
Default: `'off'`

`Constant value` — Specify unconnected output

`0` (default) | scalar | vector

Specify a constant output value to be displayed when source is not connected.

Dependency

Enabled in a Variant Subsystem block on a non-driven Output block.

Programmatic Use
Block Parameter: `OutputWhenUnconnectedValue`
Type: character vector
Values: | `real integer`
Default: `'1`

`Interpret vector parameters as 1-D` — Treat vectors as 1-D

`off` (default) | `on`

Select this check box to output a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector.

Dependency

Enabled in a Variant Subsystem block on a non-driven Output block when you select the **Specify output when source is unconnected** parameter.

Programmatic Use
Block Parameter: `VectorParams1DForOutWhenUnconnected`
Type: character vector
Values: `'on' | 'off'`
Default: `'off'`

`Ensure outport is virtual` — Ensure that outport is virtual

`off` (default) | `on`

Clear this check box to specify that Simulinkuses a signal buffer on output port. This buffer ensures consistent initialization of the Outport block signal.

If you select this check box, Simulink tries to remove the signal buffer.

- If the signal buffer is not needed, Simulink removes the buffer.
- If the signal buffer is needed for data consistency and proper execution, Simulink displays an error indicating the buffer could not be removed.

Allow partial writes through Assignment blocks.

For examples with conditional writes and partial writes, see “Ensure Outport is Virtual”.

Dependencies

This parameter applies to these blocks:

- Conditional subsystem
- Assignment
- Merge
- Model with root Outport block

`Source of initial output value` — Source of initial output value

`Dialog` (default) | `Input signal`

Select the source of the initial output value of the block. Select `Dialog` to specify that the initial output value is the value of the **Initial output** parameter. Select `Input signal` to specify that the initial output value is inherited from the input signal. See “Conditional Subsystem Initial Output Values”.

Tips

- If you are using classic initialization mode, selecting `Input signal` causes an error. To inherit the initial output value from the input signal, set this parameter to `Dialog` and specify `[]` (empty matrix) for the **Initial output** value. For more information, see “Conditional Subsystem Initial Output Values”.

Dependencies

This parameter is enabled when the Outport resides in a Conditional Subsystem.

Selecting `Dialog` enables the following parameters:

- **Output when disabled**
- **Initial output**

Programmatic Use
Block Parameter: `SourceOfInitialOutputValue`
Type: character vector
Values: `'Dialog' | 'Input signal'`
Default: `'Dialog'`

`Output when disabled` — Output when disabled

`held` (default) | `reset`

Specify what happens to the block output when the subsystem is disabled. Select `held` to indicate that the output is held when the subsystem is disabled. Select `reset` to indicate that the output is reset to the value given by **Initial output** when the subsystem is disabled.

Dependencies

To enable this parameter, select `Dialog` in **Source of initial output value** when the outport resides in a conditional sybsystem with valid enabling and disabling semantics.For example, this parameter is disabled when the Outport is placed inside a Triggered Subsystem but is enabled when the Outport is placed inside an Enabled Subsystem.

If an Outport is placed inside a function-call subsystem, this parameter is meaningful only if the function-call subsystem is bound to a state in a Stateflow chart. For more information, see “Bind a Function-Call Subsystem to a State” (Stateflow).

When connecting the output of a conditional subsystem to a Merge block, set this parameter to `held`. Setting it to `reset` returns an error.

Programmatic Use
Block Parameter: `OutputWhenDisabled`
Type: character vector
Values: `'held' | 'reset'`
Default: `'held'`

`Initial output` — Initial output for conditionally executed subsystems

`[ ]` (default) | scalar

For conditionally executed subsystems, specify the block output before the subsystem executes and while it is disabled. Specify `[]` (empty matrix) to inherit the initial output value from the input signal. For more information, see “Conditional Subsystem Initial Output Values”.

For information about specifying an initial condition structure, see “Specify Initial Conditions for Bus Signals”.

Tips

If the conditional subsystem is driving a Merge block, you do not need to specify an Initial Condition (IC) for the Outport block. For more information, see “Underspecified initialization detection”.

Dependencies

To enable this parameter, set **Source of initial output value** to `Dialog` when this block resides in a conditionally executed subsystem.

Limitations

- This block does not allow an initial output of `inf` or `NaN`.
- When the input is a virtual bus, an **Initial output** value `[]` is treated as double(0).
- When the input contains a nonvirtual bus, **Initial output** does not support nonzero scalar values.

Programmatic Use

Block Parameter: `InitialOutput`
Type: character vector
Values: `'[]'` | scalar
Default: `'[]'`

Signal Attributes

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

`Minimum` — Minimum output value

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the minimum value for bus data on the block. Simulink ignores this setting. Instead, set the minimum values for bus elements of the bus object specified as the data type. For information on the Minimum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

Maximum — Maximum output value

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

This number must be a finite real double scalar value.

Note If you specify a bus object as the data type for this block, do not set the maximum value for bus data on the block. Simulink ignores this setting. Instead, set the maximum values for bus elements of the bus object specified as the data type. For information on the Maximum property of a bus element, see `Simulink.BusElement`.

Simulink software uses this value to perform:

- Simulation range checking (see “Signal Ranges”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Data type` — Output data type

`Inherit: auto` (default) | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class name>` | `Bus: <object name>` | `<data type expression>`

Specify the output data type of the external input. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. Do not specify a bus object as the expression.

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Output as nonvirtual bus in parent model` — Outport as nonvirtual bus in parent model

`off` (default) | `on`

Specify the outport bus to be nonvirtual in the parent model. Select this parameter if you want the bus emerging in the parent model to be nonvirtual. The bus that is input to the port can be virtual or nonvirtual, regardless of the setting of **Output as nonvirtual bus in parent model**.

Clear this parameter if you want the bus emerging in the parent model to be virtual.

Tips

- In a nonvirtual bus, all signals must have the same sample time, even if the elements of the associated bus object specify inherited sample times. Any bus operation that would result in a nonvirtual bus that violates this requirement generates an error. For details, see "Connect Multirate Buses to Referenced Models".
- For a virtual bus, to use a multirate signal, in the root-level Outport block, set the **Sample time** parameter to inherited (`-1`).
- For the top model in a model reference hierarchy, code generation creates a C structure to represent the bus signal output by this block.
- For referenced models, select this option to create a C structure. Otherwise, code generation creates an argument for each leaf element of the bus.

Dependency

To enable this parameter, select **Data type** > `Bus: <object name>`.

Programmatic Use

Block Parameter: `BusOutputAsStruct`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Unit (e.g., m, m/s^2, N*m)` — Physical unit of the input signal to the block

`inherit` (default) | `<Enter unit>`

Specify the physical unit of the input signal to the block. To specify a unit, begin typing in the text box. As you type, the parameter displays potential matching units. For a list of supported units, see Allowed Unit Systems.

To constrain the unit system, click the link to the right of the parameter:

- If a Unit System Configuration block exists in the component, its dialog box opens. Use that dialog box to specify allowed and disallowed unit systems for the component.
- If a Unit System Configuration block does not exist in the component, the model Configuration Parameters dialog box displays. Use that dialog box to specify allowed and disallowed unit systems for the model.

Programmatic Use
Block Parameter: `Unit`
Type: character vector
Values: `'inherit'` | `'<Enter unit>'`
Default: `'inherit'`

`Port dimensions (-1 for inherited)` — Port dimensions

`-1` (default) | integer | [integer, integer]

Specify the dimensions that a signal must have to be connected to this Outport block.

`-1`	A signal of any dimensions can be connected to this port.
`N`	The signal connected to this port must be a vector of size `N`.
`[R C]`	The signal connected to this port must be a matrix having `R` rows and `C` columns.

Programmatic Use
Block Parameter: `PortDimensions`
Type: character vector
Values: `'-1'` | integer | [integer, integer]
Default: `'-1'`

`Variable-size signal` — Allow variable-size signals

`Inherit` (default) | `No` | `Yes`

Specify the type of signals allowed out of this port. To allow variable-size and fixed-size signals, select `Inherit`. To allow only variable-size signals, select `Yes`. Not to allow variable-size signals, select `No`.

Dependencies

When the signal at this port is a variable-size signal, the **Port dimensions** parameter specifies the maximum dimensions of the signal.

Command-Line Information
Parameter: `VarSizeSig`
Type: character vector
Value: `'Inherit`'| `'No'` | `'Yes'`
Default: `'Inherit'`

`Sample time (-1 for inherited)` — Specify sample time

`-1` (default) | scalar

Specify the discrete interval between sample time hits or specify another appropriate sample time such as continuous or inherited.

By default, the block inherits its sample time based upon the context of the block within the model. To set a different sample time, enter a valid sample time based upon the table in “Types of Sample Time”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

`Signal type` — Output signal type

`auto` (default) | `real` | `complex`

Specify the numeric type of the signal output. To choose the numeric type of the signal that is connected to its input, select `auto`. Otherwise, choose a real or complex signal type.

Programmatic Use
Block Parameter: `SignalType`
Type: character vector
Values: `'auto'` | `'real'` | `'complex'`
Default: `'auto'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`

Zero-Crossing Detection	No

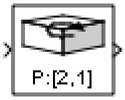
Introduced before R2006a

Permute Dimensions

Rearrange dimensions of multidimensional array dimensions
Library: Simulink / Math Operations



Description

The Permute Dimensions block reorders the elements of the input signal by permuting its dimensions. You specify the permutation to be applied to the input signal using the **Order** parameter.

For example, to transpose a 3-by-5 input signal, specify the permutation vector `[2 1]` for the **Order** parameter. When you do, the block reorders the elements of the input signal and outputs a 3-by-5 matrix.

You can use an array of buses as an input signal to a Permute Dimensions block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix | N-D array

This port accepts scalar, vector, matrix, and N-dimensional signals of any data type that Simulink supports, including fixed-point, enumerated, and nonvirtual bus data types.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_2` — Permutation of input signal
scalar | vector | matrix | N-D array

The block outputs the permutation of the input signal, according to the value of the **Order** parameter. The output has the same data type as the input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Order` — Permutation vector
`[2,1]` (default) | `N`-element vector, where `N` is the number of dimensions of the input signal

Specify the permutation order to apply to the dimensions of the input signal. The value of this parameter must be an `N`-element vector where `N` is the number of dimensions of the input signal. The elements of the permutation vector must be a rearrangement of the values from 1 to `N`.

For example, the permutation vector `[2 1]` applied to a 5-by-3 input signal results in a 3-by-5 output signal, in other words, the transpose of the input signal.

Programmatic Use
Block Parameter: `Order`
Type: character vector
Value: N-element vector
Default: `'[2 1]'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`No`

Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

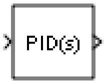
Introduced in R2007a

PID Controller

Continuous-time or discrete-time PID controller
Library: Simulink / Continuous



Description

The PID Controller block implements a PID controller (PID, PI, PD, P only, or I only). The block is identical to the Discrete PID Controller block with the **Time domain** parameter set to `Continuous-time`.

The block output is a weighted sum of the input signal, the integral of the input signal, and the derivative of the input signal. The weights are the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action.

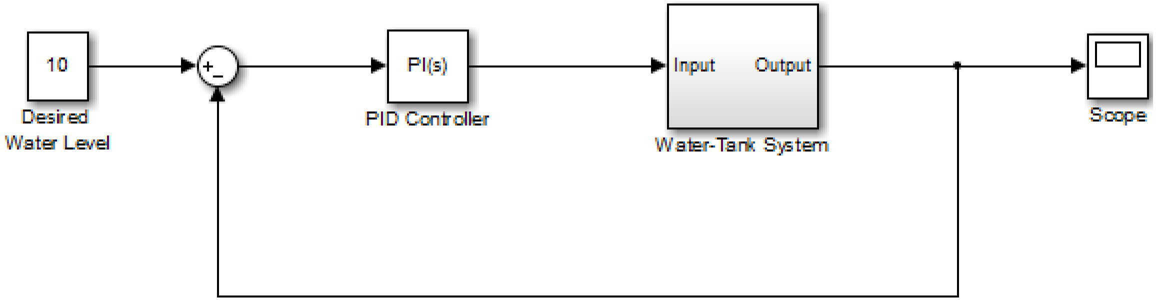
The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, PD, P only, or I only) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Variant Subsystems”.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.



The input of the block is typically an error signal, which is the difference between a reference signal and the system output. For a two-input block that permits setpoint weighting, see PID Controller (2DOF).

PID Gain Tuning

The PID controller coefficients are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

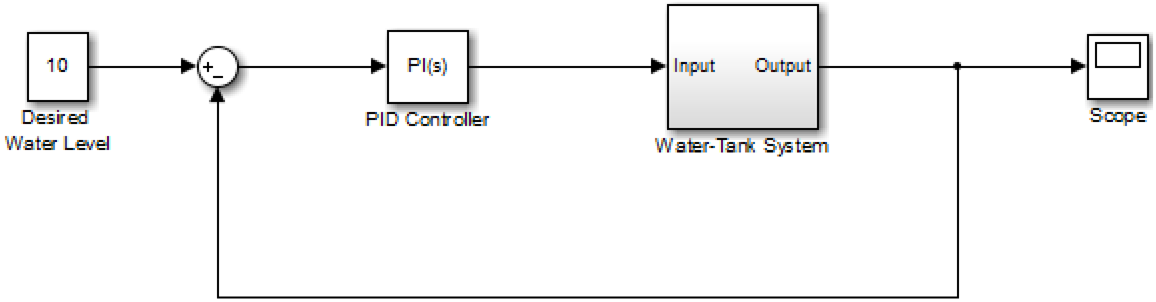
Ports

Input

`Port_1( u )` — Error signal input

scalar | vector

Difference between a reference signal and the output of the system under control, as shown.



When the error signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

I — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control.

In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`D` — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`N` — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

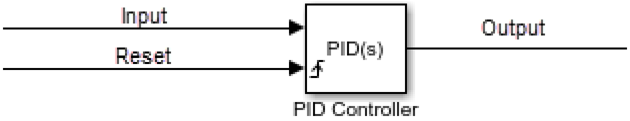
To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Reset` — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. The value of the **External reset** parameter determines whether reset occurs on a rising signal, a falling signal, or a level signal. The port icon indicates the selected trigger type. For example, the following illustration shows a continuous-time PID block with **External reset** set to `rising`.



When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the $\mathbf{I_0}$ and $\mathbf{D_0}$ ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than `none`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `Boolean`

$\mathtt{I_0}$ — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

D_0 — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1( y )` — Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as *N* independent PID controllers, where *N* is the number of signals in the input vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Controller` — Controller type

`PID` (default) | `PI` | `PD` | `P` | `I`

Specify which of the proportional, integral, and derivative terms are in the controller.

`PID`

Proportional, integral, and derivative action.

`PI`

Proportional and integral action only.

`PD`

Proportional and derivative action only.

`P`

Proportional action only.

`I`

Integral action only.

Tip The controller transfer function for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use

Block Parameter: `Controller`
Type: string, character vector
Values: `"PID"`, `"PI"`, `"PD"`, `"P"`, `"I"`
Default: `"PID"`

`Form` — Controller structure

`Parallel` (default) | `Ideal`

Specify whether the controller structure is parallel or ideal.

`Parallel`

The controller output is the sum of the proportional, integral, and derivative actions, weighted independently by **P**, **I**, and **D**, respectively. For example, for a continuous-time parallel-form PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

`Ideal`

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time ideal-form PID controller, the transfer function is:

$$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right)\right].$$

For a discrete-time ideal-form controller, the transfer function is:

$$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $a(z)$ and $b(z)$, respectively.

Tip The controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use
Block Parameter: `Controller`
Type: string, character vector
Values: `"Parallel"`, `"Ideal"`
Default: `"Parallel"`

`Time domain` — Specify continuous-time or discrete-time controller

`Continuous-time` (default) | `Discrete-time`

When you select `Discrete-time`, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting `Discrete-time` also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select `Continuous-time`.

Note The PID Controller and Discrete PID Controller blocks are identical except for the default value of this parameter.

Programmatic Use
Block Parameter: `TimeDomain`
Type: string, character vector
Values: `"Continuous-time"`, `"Discrete-time"`
Default: `"Continuous-time"`

`Sample time (-1 for inherited)` — Discrete interval between samples

–1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of –1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the

controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to `Continuous-time`.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to –1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`.

Programmatic Use

Block Parameter: `SampleTime`
Type: scalar
Values: `-1`, positive scalar
Default: `-1`

`Integrator method` — Method for computing integral in discrete-time controller

`Forward Euler` (default) | `Backward Euler` | `Trapezoidal`

In discrete time, the integral term of the controller transfer function is $I\alpha(z)$, where $\alpha(z)$ depends on the integrator method you specify with this parameter.

`Forward Euler`

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z-1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z-1}.$$

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Bilinear approximation,

$$\alpha(z) = \frac{T_s}{2}\frac{z+1}{z-1}.$$

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Note For the `BackwardEuler` or `Trapezoidal` methods, you cannot generate HDL code for the block if either:

- **Limit output** is selected and **Anti-Windup Method** is anything other than `none`.
- **Enable tracking mode** is selected.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to `Discrete-time` and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: `IntegratorMethod`

Type: string, character vector
Values: `"Forward Euler"`, `"Backward Euler"`, `"Trapezoidal"`
Default: `"Forward Euler"`

`Filter method` — Method for computing derivative in discrete-time controller

`Forward Euler` (default) | `Backward Euler` | `Trapezoidal`

In discrete time, the derivative term of the controller transfer function is:

$$D\left[\frac{N}{1+N\alpha(z)}\right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

`Forward Euler`

Forward rectangular (left-hand) approximation,

$$\alpha(z)=\frac{T_s}{z-1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Backward rectangular (right-hand) approximation,

$$\alpha(z)=\frac{T_s z}{z-1}.$$

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Bilinear approximation,

$$\alpha(z)=\frac{T_s}{2}\frac{z+1}{z-1}.$$

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to `Discrete-time` and set **Controller** to a controller type with derivative action.

Programmatic Use

Block Parameter: `FilterMethod`
Type: string, character vector
Values: `"Forward Euler"`, `"Backward Euler"`, `"Trapezoidal"`
Default: `"Forward Euler"`

Main

Source — Source for controller gains and filter coefficient

internal (default) | external

Enabling external inputs for the parameters allows you to compute PID gains and filter coefficients externally to the block and provide them to the block as signal inputs.

`internal`

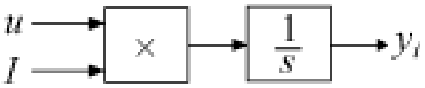
Specify the controller gains and filter coefficient using the block parameters **P**, **I**, **D**, and **N**.

`external`

Specify the PID gains and filter coefficient externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.



Within the block, the input signal *u* is multiplied by the externally supplied integrator gain, *I*, before integration. This implementation yields:

$$y_i = \int uI\,dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain *D* to be differentiated.

Programmatic Use
Block Parameter: `ControllerParametersSource`
Type: string, character vector
Values: `"internal"`, `"external"`
Default: `"internal"`

`Proportional (P)` — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- `Parallel` — Proportional action is independent of the integral and derivative actions. For instance, for a continuous-time parallel PID controller, the transfer function is:

$$C_{par}(s) = P + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right).$$

For a discrete-time parallel-form controller, the transfer function is:

$$C_{par}(z) = P + I\alpha(z) + D\left[\frac{N}{1+N\beta(z)}\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- `Ideal` — The proportional gain multiples the integral and derivative terms. For instance, for a continuous-time ideal PID controller, the transfer function is:

  $$C_{id}(s) = P\left[1 + I\left(\frac{1}{s}\right) + D\left(\frac{Ns}{s+N}\right)\right].$$

  For a discrete-time ideal-form controller, the transfer function is:

  $$C_{id}(z) = P\left[1 + I\alpha(z) + D\frac{N}{1+N\beta(z)}\right],$$

  where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to `PID`, `PD`, `PI`, or `P`.

Programmatic Use

Block Parameter: `P`
Type: scalar, vector
Default: 1

`Integral (I)` — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `I`
Type: scalar, vector
Default: 1

`Derivative (D)` — Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: `D`
Type: scalar, vector
Default: 0

`Use filtered derivative` — Apply filter to derivative term

`on` (default) | `off`

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller transfer function becomes:

$$D\frac{z-1}{zT_s}.$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`, and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: `UseFilter`
Type: string, character vector
Values: `"on"`, `"off"`
Default: `"on"`

`Filter coefficient (N)` — Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is `Continuous-time`, the pole location is `s = -N`.
- When **Time domain** is `Discrete-time`, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
`Forward Euler`	$z_{pole} = 1 - NT_s$
`Backward Euler`	$z_{pole} = \frac{1}{1 + NT_s}$
`Trapezoidal`	$z_{pole} = \frac{1 - NT_s / 2}{1 + NT_s / 2}$

The block does not support `N = Inf` (ideal unfiltered derivative). When the **Time domain** is `Discrete-time`, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to `PID` or `PD`.

Programmatic Use
Block Parameter: `N`
Type: scalar, vector
Default: `100`

`Select tuning method` — Tool for automatic tuning of controller coefficients

`Transfer Function Based (PID Tuner App)` (default) | `Frequency Response Based`

If you have Simulink Control Design software, you can automatically tune the PID coefficients. To do so, use this parameter to select a tuning tool, and click **Tune**.

`Transfer Function Based (PID Tuner App)`

> Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Introduction to Model-Based PID Tuning in Simulink” (Simulink Control Design).

`Frequency Response Based`

> Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

`Enable zero-crossing detection` — Detect zero crossings on reset and on entering or leaving a saturation state

`on` (default) | `off`

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use
Block Parameter: `ZeroCross`
Type: string, character vector
Values: `"on"`, `"off"`
Default: `"on"`

Initialization

`Source` — Source for integrator and derivative initial conditions

`internal` (default) | `external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

`internal`

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

`external`

Specify the initial conditions externally using block inputs. Additional input ports $\mathbf{I_o}$ and $\mathbf{D_o}$ appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at $\mathbf{D_o}$ instead of a filter initial condition.

Programmatic Use
Block Parameter: `InitialConditionSource`
Type: string, character vector
Values: `"internal"`, `"external"`
Default: `"internal"`

`Integrator` — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `InitialConditionForIntegrator`
Type: scalar, vector
Default: 0

`Filter` — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: `InitialConditionForFilter`
Type: scalar, vector
Default: 0

`Differentiator` — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External**

reset). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, set **Time domain** to `Discrete-time`, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to `internal`.

Programmatic Use

Block Parameter: `DifferentiatorICPrevScaledInput`
Type: scalar, vector
Default: 0

`Initial condition setting` — Location at which initial condition is applied

`State (most efficient)` (default) | `Output`

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

`State (most efficient)`

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

`Output`

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use

Block Parameter: `InitialConditionSetting`
Type: string, character vector
Values: `"state"`, `"output"`
Default: `"state"`

`External reset` — Trigger for resetting integrator and filter values

`none` (default) | `rising` | `falling` | `either` | `level`

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than `none` enables the **Reset** port on the block for the external reset signal.

`none`

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

`rising`

Reset the outputs when the reset signal has a rising edge.

`falling`

Reset the outputs when the reset signal has a falling edge.

`either`

Reset the outputs when the reset signal either rises or falls.

`level`

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: `ExternalReset`
Type: string, character vector
Values: `"none"`, `"rising"`, `"falling"`, `"either"`,`"level"`
Default: `"none"`

`Ignore reset when linearizing` — Force linearization to ignore reset

`off` (default) | `on`

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: `IgnoreLimit`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

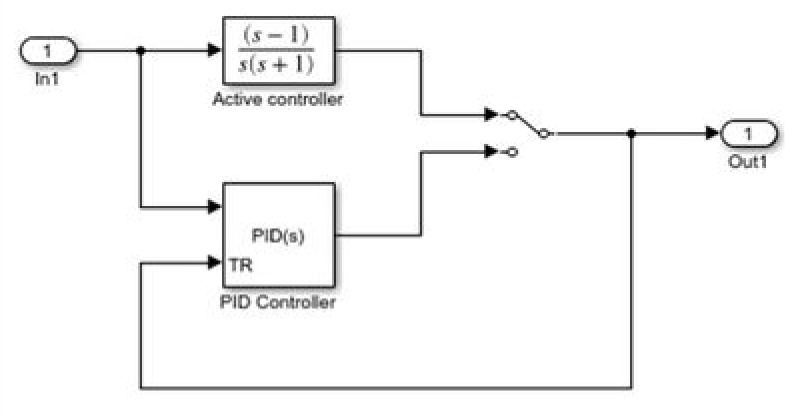
`Enable tracking mode` — Activate signal tracking

`off` (default) | `on`

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain `Kt`, specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

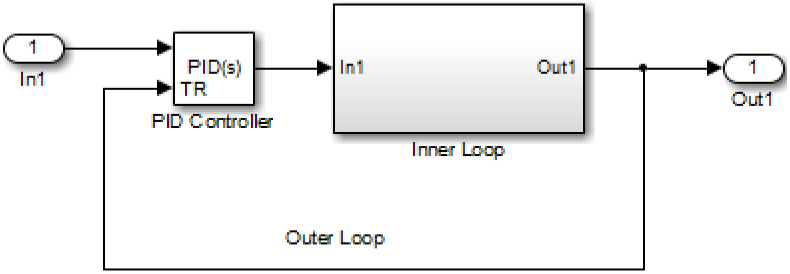
Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.



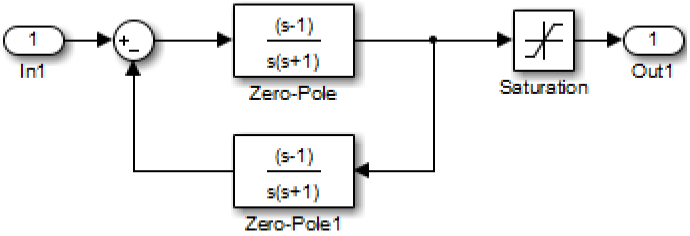
For more information, see "Bumpless Control Transfer" on page 14-111.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches, as in the following model.



The Inner Loop subsystem contains the blocks shown in the following diagram.



Because the PID controller tracks the output of the inner loop, its output never exceeds the saturated inner-loop output. For more details, see “Prevent Block Windup in Multiloop Control” on page 14-110.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use
Block Parameter: `TrackingMode`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Tracking coefficient (Kt)` — Gain of signal-tracking feedback loop
1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain `Kt`. Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use

Block Parameter: `Kt`
Type: scalar
Default: 1

Output saturation

`Limit Output` — Limit block output to specified saturation values

`off` (default) | `on`

Activating this option limits the block output internally to the block, so that you do not need a separate Saturation on page 1-1607 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the saturation limits using the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use

Block Parameter: `LimitOutput`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Upper limit` — Upper saturation limit for block output

`Inf` (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: `UpperSaturationLimit`
Type: scalar
Default: `Inf`

`Lower limit` — Lower saturation limit for block output

`-Inf` (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: `LowerSaturationLimit`
Type: scalar
Default: `-Inf`

`Ignore saturation when linearizing` — Force linearization to ignore output limits

`off` (default) | `on`

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: `LinearizeAsGain`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Anti-windup method` — Integrator anti-windup method

`none` (default) | `back-calculation` | `clamping`

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the input signal never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the input signal changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

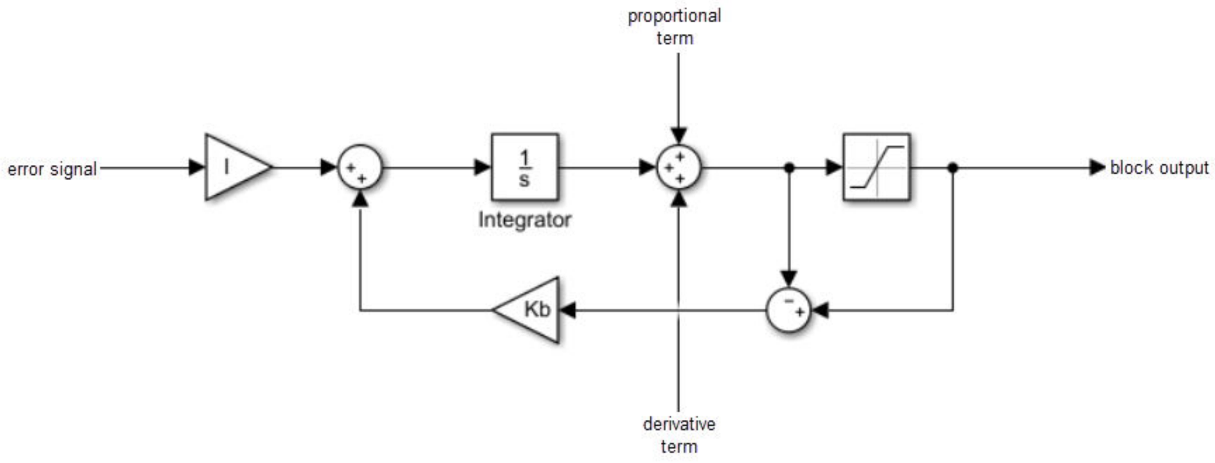
In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

`none`

Do not use an anti-windup mechanism.

`back-calculation`

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.



Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set `Kb = I`, or for controllers with derivative action, `Kb = sqrt(I*D)`. Back-calculation can be effective for plants with relatively large dead time [1].

`clamping`

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use
Block Parameter: `AntiWindupMode`
Type: string, character vector
Values: `"none"`, `"back-calculation"`,`"clamping"`
Default: `"none"`

`Back-calculation coefficient (Kb)` — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The `back-calculation` anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to `back-calculation`.

Programmatic Use
Block Parameter: `Kb`
Type: scalar

Default: 1

Data Types

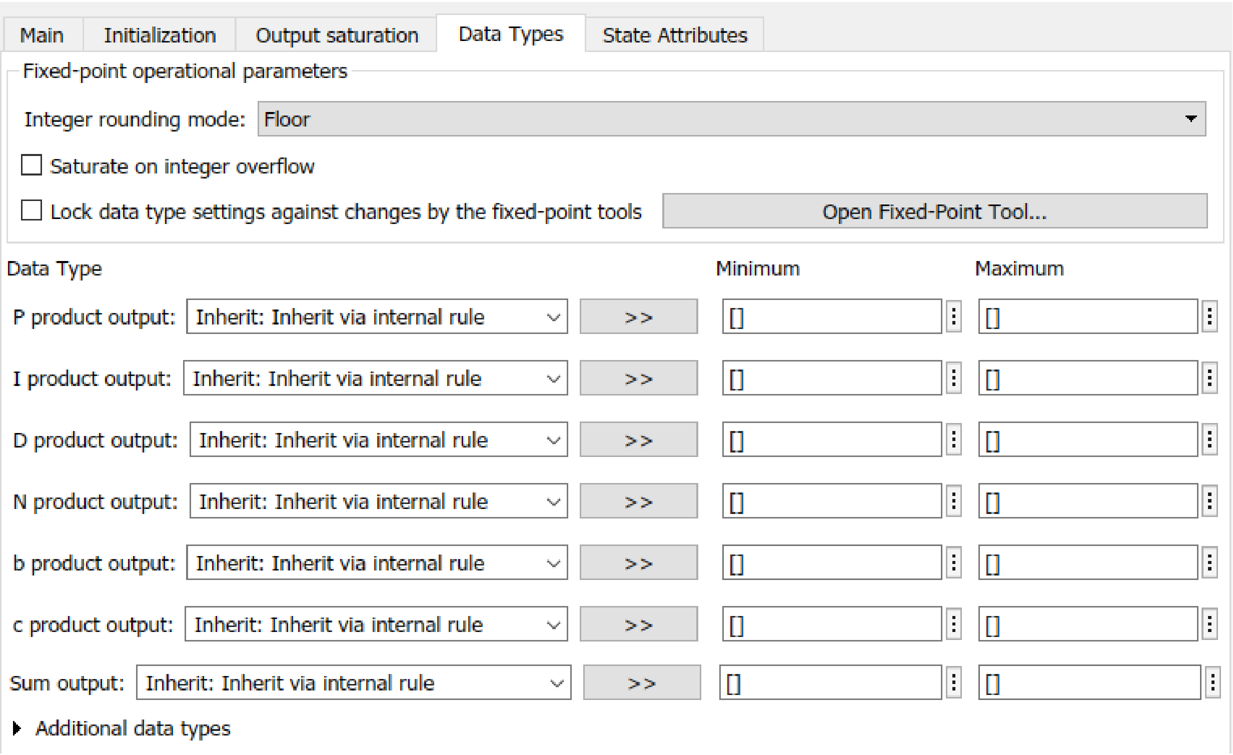
The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see "Autoscaling Data Objects Using the Fixed-Point Tool" (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click >> to open the Data Type Assistant for the corresponding quantity. For more information, see "Specify Data Types Using Data Type Assistant".



Fixed-point operational parameters

Integer rounding mode: Floor

□ Saturate on integer overflow

□ Lock data type settings against changes by the fixed-point tools

Data Type		Minimum	Maximum
P product output:	Inherit: Inherit via internal rule	[]	[]
I product output:	Inherit: Inherit via internal rule	[]	[]
D product output:	Inherit: Inherit via internal rule	[]	[]
N product output:	Inherit: Inherit via internal rule	[]	[]
b product output:	Inherit: Inherit via internal rule	[]	[]
c product output:	Inherit: Inherit via internal rule	[]	[]
Sum output:	Inherit: Inherit via internal rule	[]	[]

▸ Additional data types

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.
- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block

SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as `SumI2`. (See “Search and Edit Using Model Explorer”.)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see "Check for Signal Range Errors".
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector

Values: `'off' | 'on'`
Default: `'off'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

State Attributes

The parameters in this tab are primarily of use in code generation.

`State name (e.g., 'position')` — Name for continuous-time filter and integrator states

`''` (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to `Continuous-time`.

Programmatic Use
Parameter: `IntegratorContinuousStateAttributes`, `FilterContinuousStateAttributes`
Type: character vector
Default: `''`

`State name` — Names for discrete-time filter and integrator states

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`.

Programmatic Use
Parameter: `IntegratorStateIdentifier`, `FilterStateIdentifier`
Type: string, character vector
Default: `""`

`State name must resolve to Simulink signal object` — Require that state name resolve to a signal object

`off` (default) | `on`

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

1. Set **Time domain** to `Discrete-time`.
2. Specify a value for the integrator or filter **State name**.
3. Set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class** for the corresponding integrator or filter state.

Programmatic Use
Block Parameter: `IntegratorStateMustResolveToSignalObject`, `FilterStateMustResolveToSignalObject`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Code generation storage class` — Storage class for code generation

`Auto` (default) | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer`

Select state storage class for code generation. If you do not need to interface to external code, select `Auto`.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder) and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

1. Set **Time domain** to `Discrete-time`.
2. Specify a value for the integrator or filter **State name**.
3. Set the model configuration parameter **Signal resolution** to a value other than `None`.

Programmatic Use
Block Parameter: `IntegratorRTWStateStorageClass`, `FilterRTWStateStorageClass`
Type: string, character vector
Values: `"Auto"`, `"ExportedGlobal"`, `"ImportedExtern"` | `"ImportedExternPointer"`
Default: `"Auto"`

`Code generation storage type qualifier` — Storage type qualifier

empty string (default) | character vector | `"const"` | `"volatile"` | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note This parameter will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to any value other than `Auto`.

Programmatic Use
Block Parameter: `IntegratorRTWStateStorageTypeQualifier`,`FilterRTWStateStorageTypeQualifier`
Type: string, character vector
Values:`""`,`"const"`,`"volatile"`
Default: `""`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to `Continuous-time`):

- Consider using "Model Discretizer" to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, from your model, select **Analysis** > **Control Design** > **Analysis** > **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to `Discrete-time`):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

HDL code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

If the **Integrator method** is set to `BackwardEuler` or `Trapezoidal`, you cannot generate HDL code for the block under either of the following conditions:

- **Limit output** is selected and the **Anti-Windup Method** is anything other than `none`.
- **Enable tracking mode** is selected.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

Introduced in R2009b

PID Controller (2DOF)

Continuous-time or discrete-time two-degree-of-freedom PID controller
Library: Simulink / Continuous

Description

The PID Controller (2DOF) block implements a two-degree-of-freedom PID controller (PID, PI, or PD). The block is identical to the Discrete PID Controller (2DOF) block with the **Time domain** parameter set to `Continuous-time`.

The block generates an output signal based on the difference between a reference signal and a measured system output. The block computes a weighted difference signal for the proportional and derivative actions according to the setpoint weights (**b** and **c**) that you specify. The block output is the sum of the proportional, integral, and derivative actions on the respective difference signals, where each action is weighted according to the gain parameters **P**, **I**, and **D**. A first-order pole filters the derivative action.

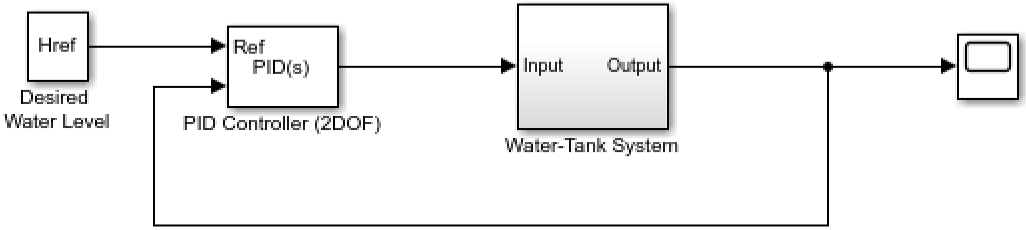
The block supports several controller types and structures. Configurable options in the block include:

- Controller type (PID, PI, or PD) — See the **Controller** parameter.
- Controller form (Parallel or Ideal) — See the **Form** parameter.
- Time domain (continuous or discrete) — See the **Time domain** parameter.
- Initial conditions and reset trigger — See the **Source** and **External reset** parameters.
- Output saturation limits and built-in anti-windup mechanism — See the **Limit output** parameter.
- Signal tracking for bumpless control transfer and multiloop control — See the **Enable tracking mode** parameter.

As you change these options, the internal structure of the block changes by activating different variant subsystems. (See “Variant Subsystems”.) To examine the internal structure of the block and its variant subsystems, right-click the block and select **Mask > Look Under Mask**.

Control Configuration

In one common implementation, the PID Controller block operates in the feedforward path of a feedback loop.



For a single-input block that accepts an error signal (a difference between a setpoint and a system output), see PID Controller.

PID Gain Tuning

The PID controller coefficients and the setpoint weights are tunable either manually or automatically. Automatic tuning requires Simulink Control Design software. For more information about automatic tuning, see the **Select tuning method** parameter.

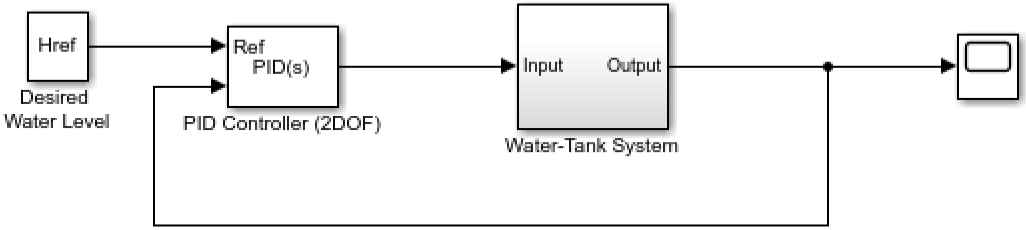
Ports

Input

`Ref` — Reference signal

scalar | vector

Reference signal for plant to follow, as shown.



When the reference signal is a vector, the block acts separately on each signal, vectorizing the PID coefficients and producing a vector output signal of the same dimensions. You can specify the PID coefficients and some other parameters as vectors of the same dimensions as the input signal. Doing so is equivalent to specifying a separate PID controller for each entry in the input signal.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Port_1( y )` — Measured system output

scalar | vector

Feedback signal for the controller, from the plant output.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

P — Proportional gain

scalar | vector

Proportional gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`I` — Integral gain

scalar | vector

Integral gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral gain are also integrated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`D` — Derivative gain

scalar | vector

Derivative gain, provided from a source external to the block. External gain input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the derivative gain are also differentiated. This result occurs because of the way the PID gains are implemented within the block. For details, see the **Controller parameters Source** parameter.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`N` — Filter coefficient

scalar | vector

Derivative filter coefficient, provided from a source external to the block. External coefficient input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has a filtered derivative.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

b — Proportional setpoint weight

scalar | vector

Proportional setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

To enable this port, set **Controller parameters Source** to `external`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

c — Derivative setpoint weight

scalar | vector

Derivative setpoint weight, provided from a source external to the block. External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use the external input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID coefficients by logic or other calculation in your model and feed them to the block.

Dependencies

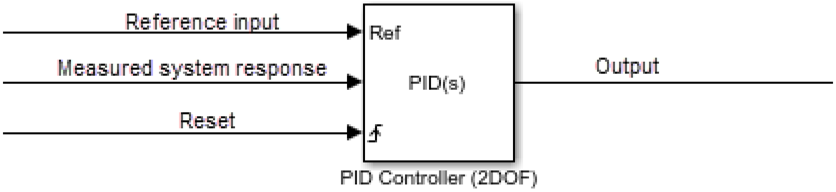
To enable this port, set **Controller parameters Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Reset — External reset trigger

scalar

Trigger to reset the integrator and filter to their initial conditions. Use the **External reset** parameter to specify what kind of signal triggers a reset. The port icon indicates the trigger type specified in that parameter. For example, the following illustration shows a continuous-time PID Controller (2DOF) block with **External reset** set to `rising`.



When the trigger occurs, the block resets the integrator and filter to the initial conditions specified by the **Integrator Initial condition** and **Filter Initial condition** parameters or the $\mathbf{I_0}$ and $\mathbf{D_0}$ ports.

Note To be compliant with the Motor Industry Software Reliability Association (MISRA) software standard, your model must use Boolean signals to drive the external reset ports of the PID controller block.

Dependencies

To enable this port, set **External reset** to any value other than `none`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `Boolean`

I_0 — Integrator initial condition

scalar | vector

Integrator initial condition, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has integral action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

D_0 — Filter initial condition

scalar | vector

Initial condition of the derivative filter, provided from a source external to the block.

Dependencies

To enable this port, set **Initial conditions Source** to `external`, and set **Controller** to a controller type that has derivative action.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

TR — Tracking signal

scalar | vector

Signal for controller output to track. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input. Signal tracking is useful for implementing bumpless control transfer in systems that switch between two controllers. It can also be useful to prevent block windup in multiloop control systems. For more information, see the **Enable tracking mode** parameter.

Dependencies

To enable this port, select the **Enable tracking mode** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1( u )` — Controller output

scalar | vector

Controller output, generally based on a sum of the input signal, the integral of the input signal, and the derivative of the input signal, weighted by the setpoint weights and by the proportional, integral, and derivative gain parameters. A first-order pole filters the derivative action. Which terms are present in the controller signal depends on what you select for the **Controller** parameter. The base controller transfer function for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask. Other parameters modify the block output, such as saturation limits specified by the **Upper Limit** and **Lower Limit** saturation parameters.

The controller output is a vector signal when any of the inputs is a vector signal. In that case, the block acts as *N* independent PID controllers, where *N* is the number of signals in the input vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Controller` — Controller type

`PID` (default) | `PI` | `PD`

Specify which of the proportional, integral, and derivative terms are in the controller.

`PID`

Proportional, integral, and derivative action.

`PI`

Proportional and integral action only.

`PD`

Proportional and derivative action only.

Tip The controller output for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use
Block Parameter: `Controller`
Type: string, character vector
Values: `"PID"`, `"PI"`, `"PD"`
Default: `"PID"`

`Form` — Controller structure

`Parallel` (default) | `Ideal`

Specify whether the controller structure is parallel or ideal.

`Parallel`

The proportional, integral, and derivative gains **P**, **I**, and **D**, are applied independently. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output *u* is:

$$u = P\left(br - y\right) + I\frac{1}{s}\left(r - y\right) + D\frac{N}{1 + N\frac{1}{s}}\left(cr - y\right),$$

where *r* is the reference signal, *y* is the measured plant output signal, and *b* and *c* are the setpoint weights.

For a discrete-time 2-DOF controller in parallel form, the controller output is:

$$u = P\left(br - y\right) + I\alpha\left(z\right)\left(r - y\right) + D\frac{N}{1 + N\beta\left(z\right)}\left(cr - y\right),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

`Ideal`

The proportional gain **P** acts on the sum of all actions. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P\left[\left(br - y\right) + I\frac{1}{s}\left(r - y\right) + D\frac{N}{1 + N\frac{1}{s}}\left(cr - y\right)\right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P\left[\left(br - y\right) + I\alpha\left(z\right)\left(r - y\right) + D\frac{N}{1 + N\beta\left(z\right)}\left(cr - y\right)\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tip The controller output for the current settings is displayed in the **Compensator formula** section of the block parameters and under the mask.

Programmatic Use
Block Parameter: `Controller`
Type: string, character vector
Values: `"Parallel"`, `"Ideal"`
Default: `"Parallel"`

`Time domain` — Specify continuous-time or discrete-time controller

`Continuous-time` (default) | `Discrete-time`

When you select `Discrete-time`, it is recommended that you specify an explicit sample time for the block. See the **Sample time (-1 for inherited)** parameter. Selecting `Discrete-time` also enables the **Integrator method**, and **Filter method** parameters.

When the PID Controller block is in a model with synchronous state control (see the State Control block), you cannot select `Continuous-time`.

Note The PID Controller (2DOF) and Discrete PID Controller (2DOF) blocks are identical except for the default value of this parameter.

Programmatic Use
Block Parameter: `TimeDomain`
Type: string, character vector
Values: `"Continuous-time"`, `"Discrete-time"`
Default: `"Continuous-time"`

`Sample time (-1 for inherited)` — Discrete interval between samples

–1 (default) | positive scalar

Specify a sample time by entering a positive scalar value, such as 0.1. The default discrete sample time of –1 means that the block inherits its sample time from upstream blocks. However, it is recommended that you set the controller sample time explicitly, especially if you expect the sample time of upstream blocks to change. The effect of the

controller coefficients P, I, D, and N depend on the sample time. Thus, for a given set of coefficient values, changing the sample time changes the performance of the controller.

See “Specify Sample Time” for more information.

To implement a continuous-time controller, set **Time domain** to `Continuous-time`.

Tip If you want to run the block with an externally specified or variable sample time, set this parameter to –1 and put the block in a Triggered Subsystem. Then, trigger the subsystem at the desired sample time.

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`.

Programmatic Use
Block Parameter: `SampleTime`
Type: scalar
Values: `-1`, positive scalar
Default: `-1`

`Integrator method` — Method for computing integral in discrete-time controller

`Forward Euler` (default) | `Backward Euler` | `Trapezoidal`

In discrete time, the integral term of the controller transfer function is *Ia*(*z*), where *a*(*z*) depends on the integrator method you specify with this parameter.

`Forward Euler`

Forward rectangular (left-hand) approximation,

$$\alpha(z) = \frac{T_s}{z-1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Backward rectangular (right-hand) approximation,

$$\alpha(z) = \frac{T_s z}{z-1}.$$

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Bilinear approximation,

$$\alpha(z) = \frac{T_s}{2}\frac{z+1}{z-1}.$$

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to `Discrete-time` and set **Controller** to a controller type with integral action.

Programmatic Use

Block Parameter: `IntegratorMethod`
Type: string, character vector
Values: `"Forward Euler"`, `"Backward Euler"`, `"Trapezoidal"`
Default: `"Forward Euler"`

`Filter method` — Method for computing derivative in discrete-time controller

`Forward Euler` (default) | `Backward Euler` | `Trapezoidal`

In discrete time, the derivative term of the controller transfer function is:

$$D\left[\frac{N}{1+N\alpha(z)}\right],$$

where $\alpha(z)$ depends on the filter method you specify with this parameter.

`Forward Euler`

Forward rectangular (left-hand) approximation,

$$\alpha(z)=\frac{T_s}{z-1}.$$

This method is best for small sampling times, where the Nyquist limit is large compared to the bandwidth of the controller. For larger sampling times, the `Forward Euler` method can result in instability, even when discretizing a system that is stable in continuous time.

`Backward Euler`

Backward rectangular (right-hand) approximation,

$$\alpha(z)=\frac{T_s z}{z-1}.$$

An advantage of the `Backward Euler` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result.

`Trapezoidal`

Bilinear approximation,

$$\alpha(z)=\frac{T_s}{2}\frac{z+1}{z-1}.$$

An advantage of the `Trapezoidal` method is that discretizing a stable continuous-time system using this method always yields a stable discrete-time result. Of all available integration methods, the `Trapezoidal` method yields the closest match between frequency-domain properties of the discretized system and the corresponding continuous-time system.

Tip The controller formula for the current setting is displayed in the **Compensator formula** section of the block parameters and under the mask.

For more information about discrete-time integration, see the Discrete-Time Integrator block reference page.

Dependencies

To enable this parameter, set **Time Domain** to `Discrete-time` and set **Controller** to a controller type with derivative action.

Programmatic Use
Block Parameter: `FilterMethod`
Type: string, character vector
Values: `"Forward Euler"`, `"Backward Euler"`, `"Trapezoidal"`
Default: `"Forward Euler"`

Main

`Source` — Source for controller gains and filter coefficient

internal (default) | external

`internal`

Specify the controller gains, filter coefficient, and setpoint weights using the block parameters **P**, **I**, **D**, **N**, **b**, and **c** respectively.

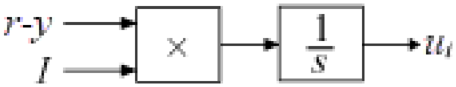
`external`

Specify the PID gains, filter coefficient, and setpoint weights externally using block inputs. An additional input port appears on the block for each parameter that is required for the current controller type.

Enabling external inputs for the parameters allows you to compute their values externally to the block and provide them to the block as signal inputs.

External input is useful, for example, when you want to map a different PID parameterization to the PID gains of the block. You can also use external gain input to implement gain-scheduled PID control. In gain-scheduled control, you determine the PID gains by logic or other calculation in your model and feed them to the block.

When you supply gains externally, time variations in the integral and derivative gain values are integrated and differentiated, respectively. The derivative setpoint weight *c* is also differentiated. This result occurs because in both continuous time and discrete time, the gains are applied to the signal before integration or differentiation. For example, for a continuous-time PID controller with external inputs, the integrator term is implemented as shown in the following illustration.



Within the block, the input signal *u* is multiplied by the externally supplied integrator gain, *I*, before integration. This implementation yields:

$$u_i = \int (r-y) I \, dt.$$

Thus, the integrator gain is included in the integral. Similarly, in the derivative term of the block, multiplication by the derivative gain precedes the differentiation, which causes the derivative gain *D* and the derivative setpoint weight *c* to be differentiated.

Programmatic Use
Block Parameter: `ControllerParametersSource`
Type: string, character vector
Values: `"internal"`, `"external"`
Default: `"internal"`

`Proportional (P)` — Proportional gain

1 (default) | scalar | vector

Specify a finite, real gain value for the proportional gain. When **Controller form** is:

- `Parallel` — Proportional action is independent of the integral and derivative actions. For example, for a continuous-time 2-DOF PID controller in parallel form, the controller output *u* is:

  $$u = P(br-y) + I\frac{1}{s}(r-y) + D\frac{N}{1+N\frac{1}{s}}(cr-y),$$

  where *r* is the reference signal, *y* is the measured plant output signal, and *b* and *c* are the setpoint weights.

  For a discrete-time 2-DOF controller in parallel form, the controller output is:

  $$u = P(br-y) + I\alpha(z)(r-y) + D\frac{N}{1+N\beta(z)}(cr-y),$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

- `Ideal` — The proportional gain multiples the integral and derivative terms. For example, for a continuous-time 2-DOF PID controller in ideal form, the controller output is:

$$u = P\left[(br - y) + I\frac{1}{s}(r - y) + D\frac{N}{1 + N\frac{1}{s}}(cr - y)\right].$$

For a discrete-time 2-DOF PID controller in ideal form, the transfer function is:

$$u = P\left[(br - y) + I\alpha(z)(r - y) + D\frac{N}{1 + N\beta(z)}(cr - y)\right],$$

where the **Integrator method** and **Filter method** parameters determine $\alpha(z)$ and $\beta(z)$, respectively.

Tunable: Yes

Dependencies

To enable this parameter, set the Controller parameters **Source** to `internal`.

Programmatic Use

Block Parameter: `P`
Type: scalar, vector
Default: 1

`Integral (I)` — Integral gain

1 (default) | scalar | vector

Specify a finite, real gain value for the integral gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `I`
Type: scalar, vector
Default: 1

`Derivative (D)` — Derivative gain

0 (default) | scalar | vector

Specify a finite, real gain value for the derivative gain.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`, and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: `D`
Type: scalar, vector
Default: 0

`Use filtered derivative` — Apply filter to derivative term

`on` (default) | `off`

For discrete-time PID controllers only, clear this option to replace the filtered derivative with an unfiltered discrete-time differentiator. When you do so, the derivative term of the controller output becomes:

$$D\frac{z-1}{zT_s}(cr-y).$$

For continuous-time PID controllers, the derivative term is always filtered.

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`, and set **Controller** to a type that has a derivative term.

Programmatic Use

Block Parameter: `UseFilter`
Type: string, character vector
Values: `"on"`, `"off"`

Default: `"on"`

`Filter coefficient (N)` — Derivative filter coefficient

100 (default) | scalar | vector

Specify a finite, real gain value for the filter coefficient. The filter coefficient determines the pole location of the filter in the derivative action of the block. The location of the filter pole depends on the **Time domain** parameter.

- When **Time domain** is `Continuous-time`, the pole location is `s = -N`.
- When **Time domain** is `Discrete-time`, the pole location depends on the **Filter method** parameter.

Filter Method	Location of Filter Pole
`Forward Euler`	$z_{pole} = 1 - NT_s$
`Backward Euler`	$z_{pole} = \frac{1}{1 + NT_s}$
`Trapezoidal`	$z_{pole} = \frac{1 - NT_s / 2}{1 + NT_s / 2}$

The block does not support `N = Inf` (ideal unfiltered derivative). When the **Time domain** is `Discrete-time`, you can clear **Use filtered derivative** to remove the derivative filter.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to `PID` or `PD`.

Programmatic Use

Block Parameter: `N`
Type: scalar, vector
Default: 100

`Setpoint weight (b)` — Proportional setpoint weight

1 (default) | scalar | vector

Setpoint weight on the proportional term of the controller. The proportional term of a 2-DOF controller output is *P*(*br*–*y*), where *r* is the reference signal and *y* is the measured plant output. Setting *b* to 0 eliminates proportional action on the reference signal, which can reduce overshoot in the system response to step changes in the setpoint. Changing the relative values of *b* and *c* changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

Programmatic Use

Block Parameter: `b`
Type: scalar, vector
Default: 1

`Setpoint weight (c)` — Derivative setpoint weight

1 (default) | scalar | vector

Setpoint weight on the derivative term of the controller. The derivative term of a 2-DOF controller acts on *cr*–*y*, where *r* is the reference signal and *y* is the measured plant output. Thus, setting *c* to 0 eliminates derivative action on the reference signal, which can reduce transient response to step changes in the setpoint. Setting *c* to 0 can yield a controller that achieves both effective disturbance rejection and smooth setpoint tracking without excessive transient response. Changing the relative values of *b* and *c* changes the balance between disturbance rejection and setpoint tracking.

Tunable: Yes

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal` and set **Controller** to a type that has derivative action.

Programmatic Use

Block Parameter: `c`
Type: scalar, vector
Default: 1

`Select tuning method` — Tool for automatic tuning of controller coefficients

`Transfer Function Based (PID Tuner App)` (default) | `Frequency Response Based`

If you have Simulink Control Design software, you can automatically tune the PID coefficients when they are internal to the block. To do so, use this parameter to select a tuning tool, and click **Tune**.

`Transfer Function Based (PID Tuner App)`

Use **PID Tuner**, which lets you interactively tune PID coefficients while examining relevant system responses to validate performance. **PID Tuner** can tune all the coefficients **P**, **I**, **D**, and **N**, and the setpoint coefficients **b** and **c**. By default, **PID Tuner** works with a linearization of your plant model. For models that cannot be linearized, you can tune PID coefficients against a plant model estimated from simulated or measured response data. For more information, see “Design Two-Degree-of-Freedom PID Controllers” (Simulink Control Design).

`Frequency Response Based`

Use **Frequency Response Based PID Tuner**, which tunes PID controller coefficients based on frequency-response estimation data obtained by simulation. This tuning approach is especially useful for plants that are not linearizable or that linearize to zero. **Frequency Response Based PID Tuner** tunes the coefficients **P**, **I**, **D**, and **N**, but does not tune the setpoint coefficients **b** and **c**. For more information, see “Design PID Controller from Plant Frequency-Response Data” (Simulink Control Design).

Both of these tuning methods assume a single-loop control configuration. Simulink Control Design software includes other tuning approaches that suit more complex configurations. For information about other ways to tune a PID Controller block, see “Choose a Control Design Approach” (Simulink Control Design).

Dependencies

To enable this parameter, in the **Main** tab, set the controller-parameters **Source** to `internal`.

`Enable zero-crossing detection` — Detect zero crossings on reset and on entering or leaving a saturation state

on (default) | `off`

Zero-crossing detection can accurately locate signal discontinuities without resorting to excessively small time steps that can lead to lengthy simulation times. If you select **Limit output** or activate **External reset** in your PID Controller block, activating zero-crossing detection can reduce computation time in your simulation. Selecting this parameter activates zero-crossing detection:

- At initial-state reset
- When entering an upper or lower saturation state
- When leaving an upper or lower saturation state

For more information about zero-crossing detection, see “Zero-Crossing Detection”.

Programmatic Use
Block Parameter: `ZeroCross`
Type: string, character vector
Values: `"on"`, `"off"`
Default: `"on"`

Initialization

`Source` — Source for integrator and derivative initial conditions

`internal` (default) | `external`

Simulink uses initial conditions to initialize the integrator and derivative-filter (or the unfiltered derivative) output at the start of a simulation or at a specified trigger event. (See the **External reset** parameter.) These initial conditions determine the initial block output. Use this parameter to select how to supply the initial condition values to the block.

`internal`

Specify the initial conditions using the **Integrator Initial condition** and **Filter Initial condition** parameters. If **Use filtered derivative** is not selected, use the **Differentiator** parameter to specify the initial condition for the unfiltered differentiator instead of a filter initial condition.

`external`

Specify the initial conditions externally using block inputs. Additional input ports $\mathbf{I_o}$ and $\mathbf{D_o}$ appear on the block. If **Use filtered derivative** is not selected, supply the initial condition for the unfiltered differentiator at $\mathbf{D_o}$ instead of a filter initial condition.

Programmatic Use
Block Parameter: `InitialConditionSource`

Type: string, character vector
Values: `"internal"`, `"external"`
Default: `"internal"`

`Integrator` — Integrator initial condition

0 (default) | scalar | vector

Simulink uses the integrator initial condition to initialize the integrator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The integrator initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `InitialConditionForIntegrator`
Type: scalar, vector
Default: 0

`Filter` — Filter initial condition

0 (default) | scalar | vector

Simulink uses the filter initial condition to initialize the derivative filter at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the filter initial condition determine the initial output of the PID controller block.

The filter initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, in the **Initialization** tab, set **Source** to `internal`, and use a controller that has a derivative filter.

Programmatic Use

Block Parameter: `InitialConditionForFilter`
Type: scalar, vector
Default: 0

`Differentiator` — Initial condition for unfiltered derivative

0 (default) | scalar | vector

When you use an unfiltered derivative, Simulink uses this parameter to initialize the differentiator at the start of a simulation or at a specified trigger event (see **External reset**). The integrator initial condition and the derivative initial condition determine the initial output of the PID controller block.

The derivative initial condition cannot be `NaN` or `Inf`.

Dependencies

To use this parameter, set **Time domain** to `Discrete-time`, clear the **Use filtered derivative** check box, and in the **Initialization** tab, set **Source** to `internal`.

Programmatic Use

Block Parameter: `DifferentiatorICPrevScaledInput`
Type: scalar, vector
Default: 0

`Initial condition setting` — Location at which initial condition is applied

`State (most efficient)` (default) | `Output`

Use this parameter to specify whether to apply the **Integrator Initial condition** and **Filter Initial condition** parameter to the corresponding block state or output. You can change this parameter at the command line only, using `set_param` to set the `InitialConditionSetting` parameter of the block.

`State (most efficient)`

Use this option in all situations except when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

`Output`

Use this option when the block is in a triggered subsystem or a function-call subsystem and simplified initialization mode is enabled.

For more information about the **Initial condition setting** parameter, see the Discrete-Time Integrator block.

This parameter is only accessible through programmatic use.

Programmatic Use

Block Parameter: `InitialConditionSetting`

Type: string, character vector
Values: `"state"`, `"output"`
Default: `"state"`

`External reset` — Trigger for resetting integrator and filter values

`none` (default) | `rising` | `falling` | `either` | `level`

Specify the trigger condition that causes the block to reset the integrator and filter to initial conditions. (If **Use filtered derivative** is not selected, the trigger resets the integrator and differentiator to initial conditions.) Selecting any option other than `none` enables the **Reset** port on the block for the external reset signal.

`none`

The integrator and filter (or differentiator) outputs are set to initial conditions at the beginning of simulation, and are not reset during simulation.

`rising`

Reset the outputs when the reset signal has a rising edge.

`falling`

Reset the outputs when the reset signal has a falling edge.

`either`

Reset the outputs when the reset signal either rises or falls.

`level`

Reset the outputs when the reset signal either:

- Is nonzero at the current time step
- Changes from nonzero at the previous time step to zero at the current time step

This option holds the outputs to the initial conditions while the reset signal is nonzero.

Dependencies

To enable this parameter, set **Controller** to a type that has derivative or integral action.

Programmatic Use

Block Parameter: `ExternalReset`
Type: string, character vector
Values: `"none"`, `"rising"`, `"falling"`, `"either"`,`"level"`
Default: `"none"`

`Ignore reset when linearizing` — Force linearization to ignore reset

`off` (default) | `on`

Select to force Simulink and Simulink Control Design linearization commands to ignore any reset mechanism specified in the **External reset** parameter. Ignoring reset states allows you to linearize a model around an operating point even if that operating point causes the block to reset.

Programmatic Use

Block Parameter: `IgnoreLimit`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

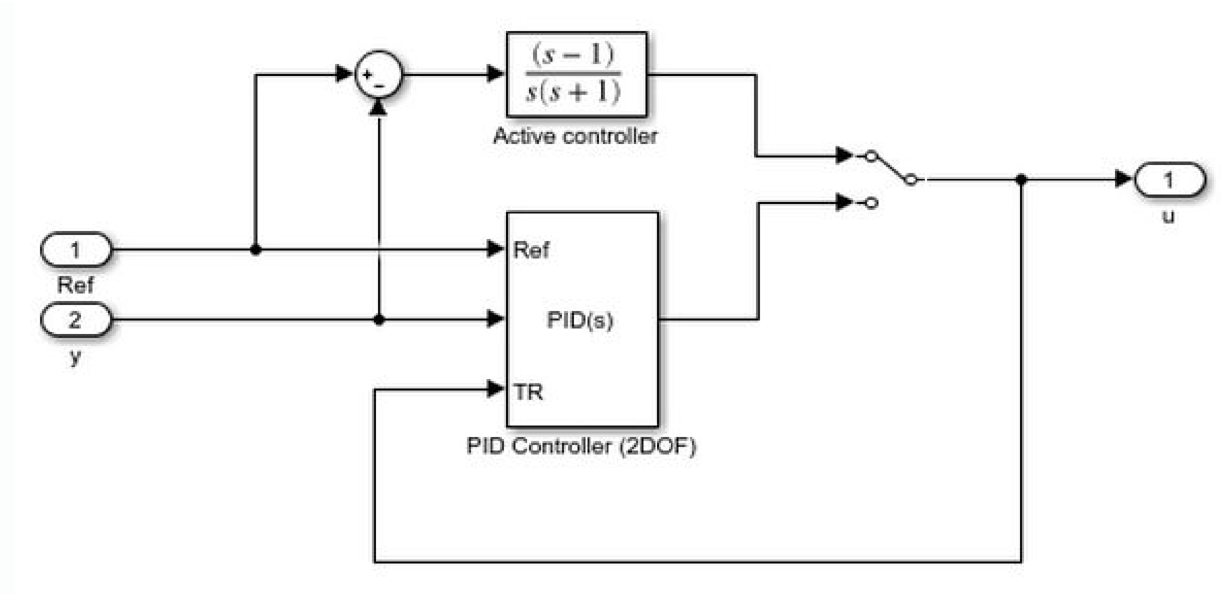
`Enable tracking mode` — Activate signal tracking

`off` (default) | `on`

Signal tracking lets the block output follow a tracking signal that you provide at the **TR** port. When signal tracking is active, the difference between the tracking signal and the block output is fed back to the integrator input with a gain `Kt`, specified by the **Tracking gain (Kt)** parameter. Signal tracking has several applications, including bumpless control transfer and avoiding windup in multiloop control structures.

Bumpless control transfer

Use signal tracking to achieve bumpless control transfer in systems that switch between two controllers. Suppose you want to transfer control between a PID controller and another controller. To do so, connecting the controller output to the **TR** input as shown in the following illustration.



For more information, see “Bumpless Control Transfer with a Two-Degree-of-Freedom PID Controller” on page 14-112.

Multiloop control

Use signal tracking to prevent block windup in multiloop control approaches. For an example illustrating this approach with a 1DOF PID controller, see “Prevent Block Windup in Multiloop Control” on page 14-110.

Dependencies

To enable this parameter, set **Controller** to a type that has integral action.

Programmatic Use

Block Parameter: `TrackingMode`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Tracking coefficient (Kt)` — Gain of signal-tracking feedback loop

1 (default) | scalar

When you select **Enable tracking mode**, the difference between the signal **TR** and the block output is fed back to the integrator input with a gain `Kt`. Use this parameter to specify the gain in that feedback loop.

Dependencies

To enable this parameter, select **Enable tracking mode**.

Programmatic Use
Block Parameter: `Kt`
Type: scalar
Default: 1

Output saturation

`Limit Output` — Limit block output to specified saturation values

`off` (default) | `on`

Activating this option limits the block output internally to the block, so that you do not need a separate Saturation on page 1-1607 block after the controller. It also allows you to activate the anti-windup mechanism built into the block (see the **Anti-windup method** parameter). Specify the saturation limits using the **Lower saturation limit** and **Upper saturation limit** parameters.

Programmatic Use
Block Parameter: `LimitOutput`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Upper limit` — Upper saturation limit for block output

`Inf` (default) | scalar

Specify the upper limit for the block output. The block output is held at the **Upper saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions exceeds that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use
Block Parameter: `UpperSaturationLimit`

Type: scalar
Default: `Inf`

`Lower limit` — Lower saturation limit for block output

`-Inf` (default) | scalar

Specify the lower limit for the block output. The block output is held at the **Lower saturation limit** whenever the weighted sum of the proportional, integral, and derivative actions goes below that value.

Dependencies

To enable this parameter, select **Limit output**.

Programmatic Use

Block Parameter: `LowerSaturationLimit`
Type: scalar
Default: `-Inf`

`Ignore saturation when linearizing` — Force linearization to ignore output limits

`off` (default) | `on`

Force Simulink and Simulink Control Design linearization commands to ignore block output limits specified in the **Upper limit** and **Lower limit** parameters. Ignoring output limits allows you to linearize a model around an operating point even if that operating point causes the block to exceed the output limits.

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: `LinearizeAsGain`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Anti-windup method` — Integrator anti-windup method

`none` (default) | `back-calculation` | `clamping`

When you select **Limit output** and the weighted sum of the controller components exceeds the specified output limits, the block output holds at the specified limit. However, the integrator output can continue to grow (integrator windup), increasing the difference between the block output and the sum of the block components. In other words, the internal signals in the block can be unbounded even if the output appears bounded by saturation limits. Without a mechanism to prevent integrator windup, two results are possible:

- If the sign of the signal entering the integrator never changes, the integrator continues to integrate until it overflows. The overflow value is the maximum or minimum value for the data type of the integrator output.
- If the sign of the signal entering the integrator changes once the weighted sum has grown beyond the output limits, it can take a long time to unwind the integrator and return the weighted sum within the block saturation limit.

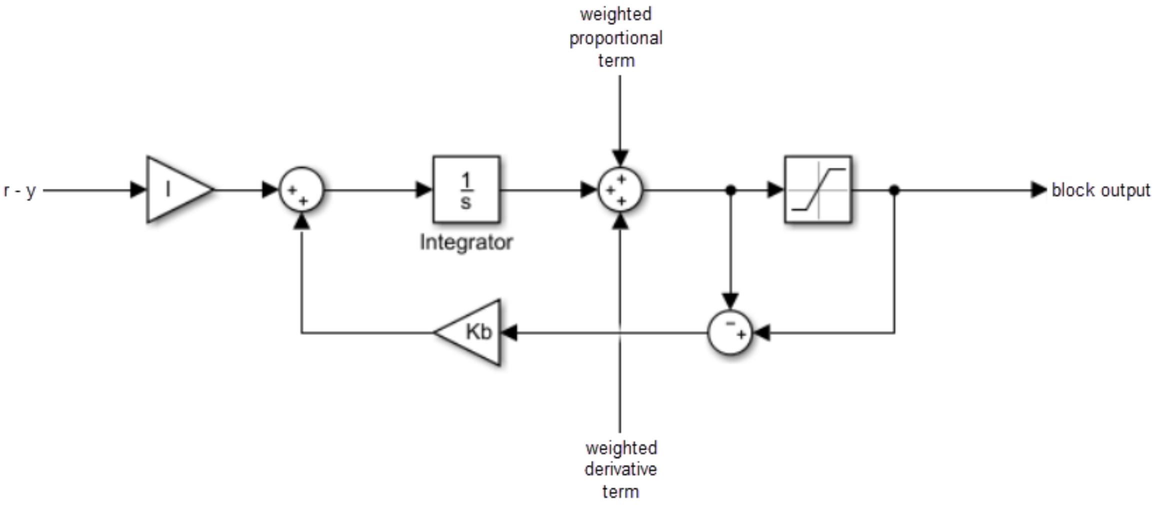
In either case, controller performance can suffer. To combat the effects of windup without an anti-windup mechanism, it may be necessary to detune the controller (for example, by reducing the controller gains), resulting in a sluggish controller. To avoid this problem, activate an anti-windup mechanism using this parameter.

`none`

Do not use an anti-windup mechanism.

`back-calculation`

Unwind the integrator when the block output saturates by feeding back to the integrator the difference between the saturated and unsaturated control signal. The following diagram represents the back-calculation feedback circuit for a continuous-time controller. To see the actual feedback circuit for your controller configuration, right-click on the block and select **Mask > Look Under Mask**.



Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. It is usually satisfactory to set `Kb = I`, or for controllers with derivative action, `Kb = sqrt(I*D)`. Back-calculation can be effective for plants with relatively large dead time [1].

`clamping`

Integration stops when the sum of the block components exceeds the output limits and the integrator output and block input have the same sign. Integration resumes when the sum of the block components exceeds the output limits and the integrator output and block input have opposite sign. Clamping is sometimes referred to as conditional integration.

Clamping can be useful for plants with relatively small dead times, but can yield a poor transient response for large dead times [1].

Dependencies

To enable this parameter, select the **Limit output** parameter.

Programmatic Use

Block Parameter: `AntiWindupMode`
Type: string, character vector
Values: `"none"`, `"back-calculation"`,`"clamping"`

Default: "none"

Back-calculation coefficient (Kb) — Gain coefficient of anti-windup feedback loop

1 (default) | scalar

The back-calculation anti-windup method unwinds the integrator when the block output saturates. It does so by feeding back to the integrator the difference between the saturated and unsaturated control signal. Use the **Back-calculation coefficient (Kb)** parameter to specify the gain of the anti-windup feedback circuit. For more information, see the **Anti-windup method** parameter.

Dependencies

To enable this parameter, select the **Limit output** parameter, and set the **Anti-windup method** parameter to back-calculation.

Programmatic Use

Block Parameter: Kb
Type: scalar
Default: 1

Data Types

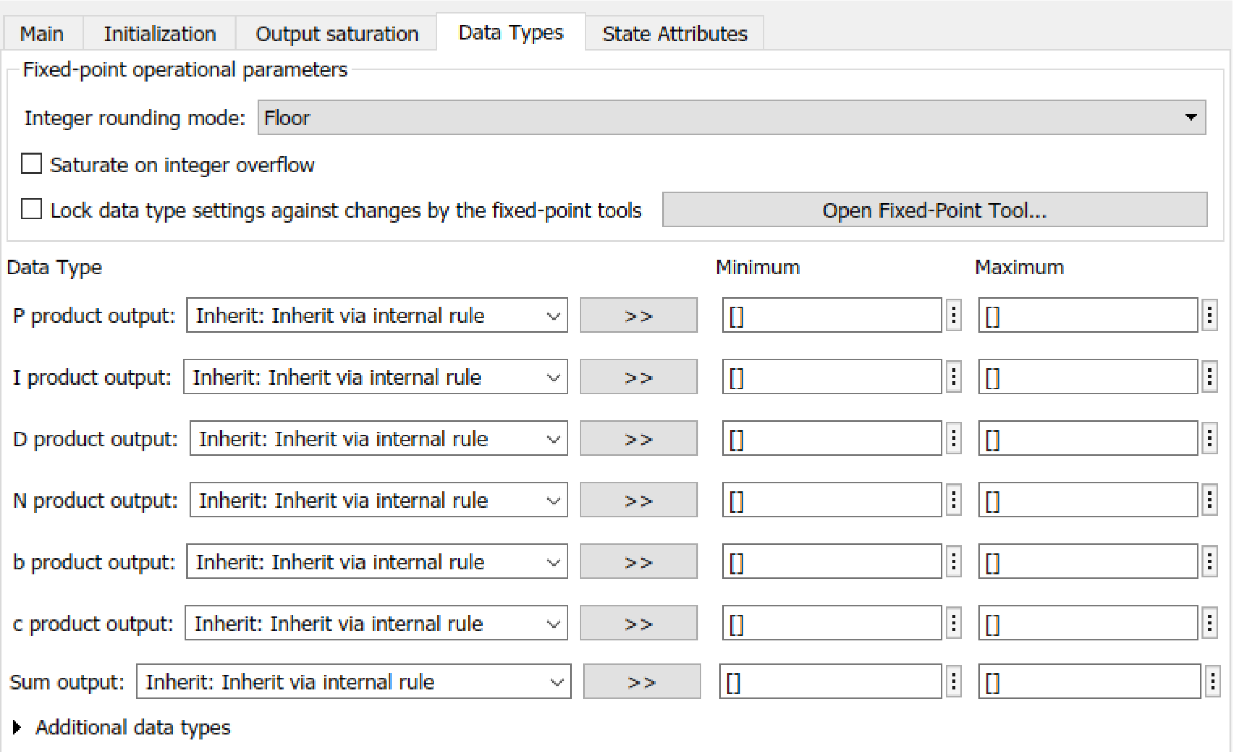
The parameters in this tab are primarily of use in fixed-point code generation using Fixed-Point Designer. They define how numeric quantities associated with the block are stored and processed when you generate code.

If you need to configure data types for fixed-point code generation, click **Open Fixed-Point Tool** and use that tool to configure the rest of the parameters in the tab. For information about using Fixed-Point Tool, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

After you use Fixed-Point Tool, you can use the parameters in this tab to make adjustments to fixed-point data-type settings if necessary. For each quantity associated with the block, you can specify:

- Floating-point or fixed-point data type, including whether the data type is inherited from upstream values in the block.
- The minimum and maximum values for the quantity, which determine how the quantity is scaled for fixed-point representation.

For assistance in selecting appropriate values, click >> to open the Data Type Assistant for the corresponding quantity. For more information, see “Specify Data Types Using Data Type Assistant”.



Main | Initialization | Output saturation | Data Types | State Attributes

Fixed-point operational parameters

Integer rounding mode: Floor

□ Saturate on integer overflow

□ Lock data type settings against changes by the fixed-point tools [Open Fixed-Point Tool...]

Data Type			Minimum	Maximum
P product output:	Inherit: Inherit via internal rule	>>	[]	[]
I product output:	Inherit: Inherit via internal rule	>>	[]	[]
D product output:	Inherit: Inherit via internal rule	>>	[]	[]
N product output:	Inherit: Inherit via internal rule	>>	[]	[]
b product output:	Inherit: Inherit via internal rule	>>	[]	[]
c product output:	Inherit: Inherit via internal rule	>>	[]	[]
Sum output:	Inherit: Inherit via internal rule	>>	[]	[]

▸ Additional data types

The specific quantities listed in the Data Types tab vary depending on how you configure the PID controller block. In general, you can configure data types for the following types of quantities:

- Product output — Stores the result of a multiplication carried out under the block mask. For example, **P product output** stores the output of the gain block that multiplies the block input with the proportional gain **P**.
- Parameter — Stores the value of a numeric block parameter, such as **P**, **I**, or **D**.
- Block output — Stores the output of a block that resides under the PID controller block mask. For example, use **Integrator output** to specify the data type of the

output of the block called Integrator. This block resides under the mask in the Integrator subsystem, and computes integrator term of the controller action.

- Accumulator — Stores values associated with a sum block. For example, **SumI2 Accumulator** sets the data type of the accumulator associated with the sum block SumI2. This block resides under the mask in the Back Calculation subsystem of the Anti-Windup subsystem.

In general, you can find the block associated with any listed parameter by looking under the PID Controller block mask and examining its subsystems. You can also use the Model Explorer to search under the mask for the listed parameter name, such as `SumI2`. (See "Search and Edit Using Model Explorer".)

Matching Input and Internal Data Types

By default, all data types in the block are set to `Inherit: Inherit via internal rule`. With this setting, Simulink chooses data types to balance numerical accuracy, performance, and generated code size, while accounting for the properties of the embedded target hardware.

Under some conditions, incompatibility can occur between data types within the block. For instance, in continuous time, the Integrator block under the mask can accept only signals of type `double`. If the block input signal is a type that cannot be converted to `double`, such as `uint16`, the internal rules for type inheritance generate an error when you generate code.

To avoid such errors, you can use the Data Types settings to force a data type conversion. For instance, you can explicitly set **P product output**, **I product output**, and **D product output** to `double`, ensuring that the signals reaching the continuous-time integrators are of type `double`.

In general, it is not recommended to use the block in continuous time for code generation applications. However, similar data type errors can occur in discrete time, if you explicitly set some values to data types that are incompatible with downstream signal constraints within the block. In such cases, use the Data Types settings to ensure that all data types are internally compatible.

Fixed-Point Operational Parameters

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Specify the rounding mode for fixed-point operations. For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

- `off` — Overflows wrap to the appropriate value that the data type can represent.

  For example, the number 130 does not fit in a signed 8-bit integer and wraps to -126.
- `on` — Overflows saturate to either the minimum or maximum value that the data type can represent.

  For example, an overflow associated with a signed 8-bit integer can saturate to -128 or 127.

Tip

- Consider selecting this check box when your model has a possible overflow and you want explicit saturation protection in the generated code.
- Consider clearing this check box when you want to optimize efficiency of your generated code.

  Clearing this check box also helps you to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.
- When you select this check box, saturation applies to every internal operation on the block, not just the output or result.
- In general, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see "Lock the Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

State Attributes

The parameters in this tab are primarily of use in code generation.

`State name (e.g., 'position')` — Name for continuous-time filter and integrator states

`''` (default) | character vector

Assign a unique name to the state associated with the integrator or the filter, for continuous-time PID controllers. (For information about state names in a discrete-time PID controller, see the **State name** parameter.) The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters.

Dependencies

To enable this parameter, set **Time domain** to `Continuous-time`.

Programmatic Use

Parameter: `IntegratorContinuousStateAttributes`, `FilterContinuousStateAttributes`
Type: character vector
Default: `''`

`State name` — Names for discrete-time filter and integrator states

empty string (default) | string | character vector

Assign a unique name to the state associated with the integrator or the filter, for discrete-time PID controllers. (For information about state names in a continuous-time PID controller, see the **State name (e.g., 'position')** parameter.)

A valid state name begins with an alphabetic or underscore character, followed by alphanumeric or underscore characters. The state name is used, for example:

- For the corresponding variable in generated code
- As part of the storage name when logging states during simulation
- For the corresponding state in a linear model obtain by linearizing the block

For more information about the use of state names in code generation, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Dependencies

To enable this parameter, set **Time domain** to `Discrete-time`.

Programmatic Use

Parameter: `IntegratorStateIdentifier`, `FilterStateIdentifier`
Type: string, character vector
Default: `""`

`State name must resolve to Simulink signal object` — Require that state name resolve to a signal object

`off` (default) | `on`

Select this parameter to require that the discrete-time integrator or filter state name resolves to a Simulink signal object.

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

1. Set **Time domain** to `Discrete-time`.
2. Specify a value for the integrator or filter **State name**.
3. Set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class** for the corresponding integrator or filter state.

Programmatic Use
Block Parameter: `IntegratorStateMustResolveToSignalObject`, `FilterStateMustResolveToSignalObject`
Type: string, character vector
Values: `"off"`, `"on"`
Default: `"off"`

`Code generation storage class` — Storage class for code generation

`Auto` (default) | `ExportedGlobal` | `ImportedExtern` | `ImportedExternPointer`

Select state storage class for code generation. If you do not need to interface to external code, select `Auto`.

For more information, see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder) and "Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements" (Embedded Coder).

Dependencies

To enable this parameter for the discrete-time integrator or filter state:

1. Set **Time domain** to `Discrete-time`.
2. Specify a value for the integrator or filter **State name**.
3. Set the model configuration parameter **Signal resolution** to a value other than `None`.

Programmatic Use
Block Parameter: `IntegratorRTWStateStorageClass`, `FilterRTWStateStorageClass`
Type: string, character vector
Values: `"Auto"`, `"ExportedGlobal"`, `"ImportedExtern"` | `"ImportedExternPointer"`
Default: `"Auto"`

`Code generation storage type qualifier` — Storage type qualifier

empty string (default) | character vector | `"const"` | `"volatile"` | ...

Specify a storage type qualifier such as `const` or `volatile`.

Note This parameter will be removed in a future release. To apply storage type qualifiers to data, use custom storage classes and memory sections. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes and memory sections do not affect the generated code.

Dependencies

To enable this parameter, set **Code generation storage class** to any value other than `Auto`.

Programmatic Use

Block Parameter:
`IntegratorRTWStateStorageTypeQualifier`,`FilterRTWStateStorageTypeQualifier`
Type: string, character vector
Values:`""`,`"const"`,`"volatile"`
Default: `""`

Block Characteristics

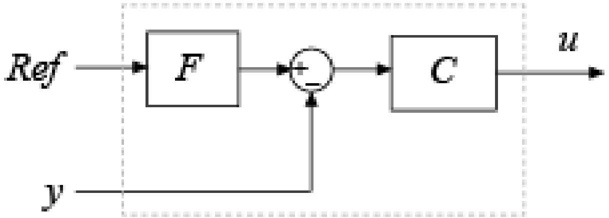
Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Definitions

Decomposition of 2-DOF PID Controllers

A 2-DOF PID controller can be interpreted as a PID controller with a prefilter, or a PID controller with a feedforward element.

In parallel form, a two-degree-of-freedom PID controller can be equivalently modeled by the following block diagram, where *C* is a single degree-of-freedom PID controller and *F* is a prefilter on the reference signal.



Ref is the reference signal, *y* is the feedback from the measured system output, and *u* is the controller output. For a continuous-time 2-DOF PID controller in parallel form, the transfer functions for *F* and *C* are

$$F_{par}(s)=\frac{(bP+cDN)s^2+(bPN+I)s+IN}{(P+DN)s^2+(PN+I)s+IN},$$

$$C_{par}(s)=\frac{(P+DN)s^2+(PN+I)s+IN}{s(s+N)},$$

where *b* and *c* are the setpoint weights.

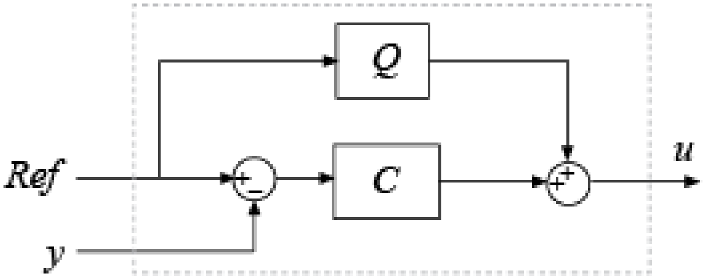
For a 2-DOF PID controller in ideal form, the transfer functions are

$$F_{id}(s) = \frac{(b+cDN)s^2 + (bN+I)s + IN}{(1+DN)s^2 + (N+I)s + IN},$$

$$C_{id}(s) = P\frac{(1+DN)s^2 + (N+I)s + IN}{s(s+N)}.$$

A similar decomposition applies for a discrete-time 2-DOF controller.

Alternatively, the parallel two-degree-of-freedom PID controller can be modeled by the following block diagram.



In this realization, *Q* acts as feed-forward conditioning on the reference signal. For a continuous-time 2-DOF PID controller in parallel form, the transfer function for *Q* is

$$Q_{par}(s) = \frac{\left((b-1)P + (c-1)DN\right)s + (b-1)PN}{s+N}.$$

For a 2-DOF PID controller in ideal form, the transfer function is

$$Q_{id}(s) = P\frac{\left((b-1) + (c-1)DN\right)s + (b-1)N}{s+N}.$$

The transfer functions for *C* are the same as in the filter decomposition.

A similar decomposition applies for a discrete-time 2-DOF controller.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

For continuous-time PID controllers (**Time domain** set to `Continuous-time`):

- Consider using “Model Discretizer” to map continuous-time blocks to discrete equivalents that support code generation. To access Model Discretizer, from your model, select **Analysis** > **Control Design** > **Analysis** > **Model Discretizer**.
- Not recommended for production code.

For discrete-time PID controllers (**Time domain** set to `Discrete-time`):

- Depends on absolute time when placed inside a triggered subsystem hierarchy.
- Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Fixed-point code generation is supported for discrete-time PID controllers only (**Time domain** set to `Discrete-time`).

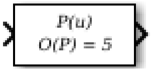
Introduced in R2009b

Polynomial

Perform evaluation of polynomial coefficients on input values
Library: Simulink / Math Operations



Description

The Polynomial block evaluates `P(u)` at each time step for the input *u*. You define a set of polynomial coefficients in the form that the MATLAB `polyval` command accepts.

Ports

Input

`Port_1` — Input signal
real scalar or vector

Value at which to evaluate the polynomial *P(u)*.

Data Types: `single` | `double`

Output

`Port_1` — Evaluated polynomial value
real scalar or vector

Value of the polynomial *P(u)* evaluated at the input signal.

Data Types: `single` | `double`

Parameters

Polynomial coefficients — Coefficients of polynomial to be evaluated
[+2.081618890e-019, -1.441693666e-014, +4.719686976e-010, -8.536869453e-006, +1.621573104e-001, -8.087801117e+001] (default) | real array

Specify polynomial coefficients in MATLAB polyval form. The first coefficient corresponds to x^N and the remaining coefficients correspond to decreasing orders of x. The last coefficient represents the constant for the polynomial.

Programmatic Use
Block Parameter: coefs
Type: real array
Default: [+2.081618890e-019, -1.441693666e-014, +4.719686976e-010, -8.536869453e-006, +1.621573104e-001, -8.087801117e+001]

Block Characteristics

Data Types	double | single
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

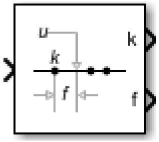
`polyval`

Introduced before R2006a

Prelookup

Compute index and fraction for Interpolation Using Prelookup block
Library: Simulink / Lookup Tables



Description

The Prelookup block calculates the index and interval fraction that specify how its input value `u` relates to the breakpoint dataset. The Prelookup block works best with the Interpolation Using Prelookup block. Feed the resulting index and fraction values into an Interpolation Using Prelookup block to interpolate an *n*-dimensional table. These two blocks have distributed algorithms. When combined together, they perform the same operation as the integrated algorithm in the n-D Lookup Table block. However, the Prelookup and Interpolation Using Prelookup blocks offer greater flexibility and more efficient simulation and code generation than the n-D Lookup Table block. For more information, see “Efficiency of Performance”.

Supported Block Operations

To use the Prelookup block, you must specify a set of breakpoint values. You choose whether to specify the breakpoint values directly on the dialog box or by feeding the values to a `bp` input port by setting the **Source** parameter to `Dialog` or `Input port`. Typically, this breakpoint data set corresponds to one dimension of the table data in an Interpolation Using Prelookup block. The Prelookup block generates a pair of outputs for each input value `u` by calculating:

- The index of the breakpoint set element that is less than or equal to `u` and forms an interval containing `u`
- The interval fraction in the range 0 ≤ f < 1, representing the normalized position of `u` on the breakpoint interval between the index and the next index value for in-range input

For example, if the breakpoint data set is `[0 5 10 20 50 100]` and the input value `u` is 55, the index is 4 and the fractional value is 0.1. Labels for the index and interval fraction appear as **k** and **f** on the Prelookup block icon. The index value is zero based.

The interval fraction can be negative or greater than `1` for out-of-range input. See the **Extrapolation method** block parameter for more information.

Ports

Input

`Port_1` — Input signal, `u`

scalar | vector | matrix

The Prelookup block accepts real-valued signals of any numeric data type that Simulink supports, except Boolean. The Prelookup block supports fixed-point data types for signals and breakpoint data.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `bus`

Output

k — Index of the interval containing the input, `u`

scalar | vector | matrix

The zero-based index, *k*, is a real-valued integer that specifies the interval containing the input, `u`.

Dependencies

To enable this port, set the **Output selection** to `Index and fraction` or `Index only`.

Data Types: `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

f — Fraction representing the normalized position of the input, `u`, within the interval, *k*

scalar | vector | matrix

Fraction, *f*, represents the normalized position of the input, `u`, within the interval *k*.

Dependencies

To enable this port, set the **Output selection** to `Index and fraction`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Port_2` — Bus containing index, *k*, and fraction, *f*
bus

Outputting the index, *k*, and fraction *f*, as a bus object can help simplify the model.

Dependencies

To enable this port, set the **Output selection** to `Index and fraction as bus`.

Data Types: `bus`

Parameters

Main

Breakpoints data

`Specification` — Choose how to enter breakpoint data
`Explicit values` (default) | `Even spacing` | `Breakpoint object`

If you set this parameter to:

- `Explicit values`, the **Source** and **Value** parameters are visible on the dialog box.
- `Even spacing`, the **First point**, **Spacing**, and **Number of points** parameters are visible on the dialog box.
- `Breakpoint object`, the **Name** parameter is visible on the dialog box.

Programmatic Use
Block Parameter: `BreakpointsSpecification`
Type: character vector
Values: `'Explicit values' | 'Even spacing' | 'Breakpoint object'`
Default: `'Explicit values'`

`Source` — Specify source of breakpoint data
`Dialog` (default) | `Input port`

If you set **Source** to:

- `Dialog`, specify breakpoint data under **Value**.
- `Input port`, verify that an upstream signal supplies breakpoint data to the `bp` input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, your block inherits breakpoint attributes from the `bp` input port.

Dependencies

To enable this parameter, set **Specification** to `Explicit values`.

Programmatic Use
Block Parameter: `BreakpointsDataSource`
Type: character vector
Values: `'Dialog' | 'Input port'`
Default: `'Dialog'`

Value — Breakpoint data values

`[10:10:110]` (default)

Explicitly specify the breakpoint data. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, you specify additional breakpoint attributes on the **Data Types** pane.

To open the Lookup Table Editor, click **Edit** (see “Edit Lookup Tables”).

Note When you set **Specification** to `Explicit values` and **Source** to `Input port`, verify that an upstream signal supplies breakpoint data to the `bp` input port. Each breakpoint data set must be a strictly monotonically increasing vector that contains two or more elements. For this option, your block inherits breakpoint attributes (including data type) from the `bp` input port.

Dependencies

To enable this parameter, set **Specification** to `Explicit values` and **Source** to `Dialog`.

Programmatic Use
Block Parameter: `BreakpointsData`

Type: character vector
Values: `'[10:10:110]'`
Default: `'[10:10:110]'`

`First point` — First point in evenly spaced breakpoint data

`10` (default) | `real-valued scalar`

Dependencies

To enable this parameter, set **Specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsFirstPoint`
Type: character vector
Values: `'10'`
Default: `'10'`

`Spacing` — Spacing between evenly spaced breakpoints

`10` (default) | `real-valued, positive scalar`

Dependencies

To enable this parameter, set **Specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsSpacing`
Type: character vector
Values: `'10'`
Default: `'10'`

`Number of points` — Number of evenly spaced points

`11` (default) | `real-valued, positive scalar`

Dependencies

To enable this parameter, set **Specification** to `Even spacing`.

Programmatic Use

Block Parameter: `BreakpointsNumPoints`
Type: character vector
Values: `'11'`
Default: `'11'`

`Name` — Name of an existing `Simulink.Breakpoint` object

`no default` | `Simulink.Breakpoint`

Dependencies

To enable this parameter, set **Specification** to `Breakpoint object`.

Programmatic Use
Block Parameter: `BreakpointObject`
Type: character vector
Values: `Simulink.Breakpoint` object
Default: `''`

Algorithm

`Output selection` — Specify the signals the block outputs

`Index and fraction` (default) | `Index and fraction as bus` | `Index only`

If you want the block to output the index and interval fraction, you can specify whether the block outputs individual signals or a bus signal that includes both the index and fraction signals.

- `Index only` outputs just the index, without the fraction. Typical applications for this option include:
  - Feeding a Direct Lookup Table (n-D) block, with no interpolation on the interval
  - Feeding selection ports of a subtable selection for an Interpolation Using Prelookup block
  - Performing nonlinear quantizations
- `Index and fraction` outputs the index and fraction as individual signals.
- `Index and fraction as bus` outputs a bus signal that includes the index and fraction signals. Using a bus for these signals:
  - Simplifies the model by tying these two related signals together
  - Creates a testpoint `DpResult` structure for the AUTOSAR 4.0 library
  - For the AUTOSAR 4.0 library, avoids the creation of extra copies during code generation when the Prelookup and Interpolation Using Prelookup blocks are in separate models

Note Selecting `Index and fraction as bus` displays the **Output** parameter in the **Data Types** pane and sets the **Output** parameter to `Inherit: auto`. Change this default value to specify a user-defined bus object. For details about defining the bus object, see the **Output** parameter description.

Programmatic Use
Block Parameter: `OutputSelection`
Values: `'Index and fraction' | 'Index and fraction as bus' | 'Index only'`
Type: character vector
Default: `'Index and fraction'`

`Index search method` — Method for searching breakpoint data

`Evenly spaced points` (default) | `Linear search` | `Binary search`

Each search method has speed advantages in different situations:

- For evenly spaced breakpoint sets (for example, 10, 20, 30, and so on), you achieve optimal speed by selecting `Evenly spaced points` to calculate table indices. This algorithm uses only the first two breakpoints of a set to determine the offset and spacing of the remaining points.
- For unevenly spaced breakpoint sets, follow these guidelines:
  - If input values for `u` do not vary significantly between time steps, selecting `Linear search` with **Begin index search using previous index result** produces the best performance.
  - If input values for `u` jump more than one or two table intervals per time step, selecting `Binary search` produces the best performance.

A suboptimal choice of index search method can lead to slow performance of models that rely heavily on lookup tables.

Note The generated code stores only the first breakpoint, the spacing, and the number of breakpoints when:

- The breakpoint data is not tunable.
- The index search method is `Evenly spaced points`.

`Begin index search using previous index result` — Start search using the index found at the previous time step

`off` (default) | `on`

For input values of u that change slowly with respect to the interval size, enabling this option can improve performance. Otherwise, the linear search and binary search methods can take longer, especially for large breakpoint sets.

Programmatic Use
Block Parameter: `IndexSearchMethod`
Values: `'Binary search' | 'Evenly spaced points' | 'Linear search'`
Type: character vector
Default: `'Binary search'`

Extrapolation method — Method for handling out-of-range input values

`Clip` (default) | `Linear`

Options include:

- `Clip`

Block Input	Block Outputs
Less than the first breakpoint	• Index of the first breakpoint (for example, 0) • Interval fraction of 0
Greater than the last breakpoint	• Index of the next-to-last breakpoint • Interval fraction of 1

  Suppose the range is `[1 2 3]` and you select this option. If u is 0.5, the index is 0 and the interval fraction is 0. If u is 3.5, the index is 1 and the interval fraction is 1.

- `Linear`

Block Input	Block Outputs
Less than the first breakpoint	• Index of the first breakpoint (for example, 0) • Interval fraction that represents the linear distance from u to the first breakpoint
Greater than the last breakpoint	• Index of the next-to-last breakpoint • Interval fraction that represents the linear distance from the next-to-last breakpoint to u

Suppose the range is [1 2 3] and you select this option. If u is 0.5, the index is 0 and the interval fraction is -0.5. If u is 3.5, the index is 1 and the interval fraction is 1.5.

Note The Prelookup block supports linear extrapolation only when all of the following conditions are true:

- The input u, breakpoint data, and fraction output use floating-point data types.
- The index uses a built-in integer data type.

Programmatic Use
Block Parameter: ExtrapMethod
Type: character vector
Values: 'Clip' | 'Linear'
Default: 'Clip'

Use last breakpoint for input at or above upper limit — Method of handling inputs at or above upper limit

off (default) | on

Specify how to index input values of u that are greater than or equal to the last breakpoint. The index value is zero based. When input equals the last breakpoint, block outputs differ as follows.

Check Box	Block Outputs
Selected (on)	• Index of the last element in the breakpoint data set • Interval fraction of 0
Cleared (off)	• Index of the next-to-last breakpoint • Interval fraction of 1

Tip When you select **Use last breakpoint for input at or above upper limit** for a Prelookup block, you must also select **Valid index input may reach last index** for the Interpolation Using Prelookup block to which it connects. This action allows the blocks to use the same indexing convention when accessing the last elements of their breakpoint and table data sets.

Dependencies

This check box is visible only when:

- **Output only the index** is cleared
- **Extrapolation method** is `Clip`

However, when **Output only the index** is selected and **Extrapolation method** is `Clip`, the block behaves as if this check box is selected, even though it is invisible.

Programmatic Use
Block Parameter: `UseLastBreakpoint`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Diagnostic for out-of-range input` — Block action when input is out of range

`None` (default) | `Warning` | `Error`

Options include:

- `None` — Produce no response.
- `Warning` — Display a warning and continue the simulation.
- `Error` — Terminate the simulation and display an error.

Programmatic Use
Block Parameter: `DiagnosticForOutOfRangeInput`
Type: character vector
Values: `'None' | 'Warning' | 'Error'`
Default: `'None'`

Code generation

`Remove protection against out-of-range input in generated code` — Remove code that checks for out-of-range breakpoint inputs

`Off` (default) | `On`

Check Box	Result	When to Use
`On`	Generated code does not include conditional statements to check for out-of-range breakpoint inputs. When the input `k` or `f` is out-of-range, it may cause undefined behavior for generated code and simulations using accelerator mode.	For code efficiency
`Off`	Generated code includes conditional statements to check for out-of-range breakpoint inputs.	For safety-critical applications

If your input is not out-of-range, you can select the **Remove protection against out-of-range index in generated code** check box for code efficiency. By default, this check box is cleared. For safety-critical applications, do not select this check box. If you want to select the **Remove protection against out-of-range index in generated code** check box, first check that your model inputs are in range. For example:

1 Clear the **Remove protection against out-of-range index in generated code** check box.

2 Set the **Diagnostic for out-of-range input** parameter to `Error`.

3 Simulate the model in normal mode.

4 If there are out-of-range errors, fix them to be in range and run the simulation again.

5 When the simulation no longer generates out-of-range input errors, select the **Remove protection against out-of-range index in generated code** check box.

Note When you select the **Remove protection against out-of-range index in generated code** check box and the input `k` or `f` is out-of-range, the behavior is undefined for generated code and simulations using accelerator mode.

Depending on your application, you can run the following Model Advisor checks to verify the usage of this check box:

- **By Product > Embedded Coder > Identify lookup table blocks that generate expensive out-of-range checking code**
- **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks > Check usage of lookup table blocks**

For more information about the Model Advisor, see “Run Model Checks”.

Programmatic Use
Block Parameter: `RemoveProtectionInput`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Data Types

`Breakpoint` — Breakpoint data type

`Inherit: Same as input` (default) | `Inherit: Inherit from 'Breakpoint data'` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `Enum: <class name>` | `<data type expression>`

Specify the breakpoint data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Same as input`

- The name of a built-in data type, for example, `single`
- The name of a data type class, for example, an enumerated data type class
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Tip

- Specify a breakpoint data type different from the data type of input `u` for these cases:
  - Lower memory requirement for storing breakpoint data that uses a smaller type than the input signal `u`
  - Sharing of prescaled breakpoint data between two Prelookup blocks with different data types for input `u`
  - Sharing of custom storage breakpoint data in the generated code for blocks with different data types for input `u`
- Enumerated data:
  - Breakpoints support unordered enumerated data. As a result, linear searches are also unordered, which offers flexibility but can impact performance. The search begins from the first element in the breakpoint.
  - If the **Begin index search using previous index result** check box is selected, you must use ordered monotonically increasing data. This ordering improves performance.
  - For enumerated data, **Extrapolation method** must be `Clip`.
  - Because the fraction is `1` or `0`, select **Output selection** > **Index only**.

    If you are using the index only output selection setting with the Interpolation Using Prelookup block, consider using the **Number of sub-table selection dimensions** parameter.

These are limitations for using enumerated data with this block:

- The block does not support out-of-range input for enumerated data. When specifying enumerated data, include the entire enumeration set in the breakpoint data set. For example, use the `enumeration` function.
- When breakpoints data source is set to `Inport port`, the enumeration data type must have `0` as the default value. For example, for this enumeration class, the default value of `GEAR1` must be `0`.

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(32),
        NEUTRAL(0)
    end
end
```

Dependencies

To enable this parameter, set the breakpoints data **Source** to `Dialog`.

Note When you set **Source** to `Input port`, the block inherits all breakpoint attributes (data type, minimum, and maximum) from the `bp` input port.

Programmatic Use

Block Parameter: `BreakpointDataTypeStr`
Type: character vector
Values: `'Inherit: Same as input' | 'Inherit: Inherit from 'Breakpoint data'' | 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)'|'<data type expression>'`
Default: `'Inherit: Same as input'`

Index — Index data type

`uint32` (default) | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `<data type expression>`

Specify a data type that can index all elements in the breakpoint data set. You can:

- Select a built-in integer data type from the list.
- Specify an integer data type using a fixed-point representation.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `IndexDataTypeStr`
Type: character vector
Values:
`'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | '<data type expression>'`
Default: `'uint32'`

`Fraction` — Fraction data type

`Inherit: Inherit via internal rule` (default) | `double` | `single` | `fixdt(1,16,0)` | `<data type expression>`

Specify the data type of the interval fraction. You can:

- Select a built-in data type from the list.
- Specify data type inheritance through an internal rule.
- Specify a fixed-point data type using the [Slope Bias] or binary-point-only scaling representation.
  - If you use the [Slope Bias] representation, the scaling must be trivial — that is, the slope is `1` and the bias is `0`.
  - If you use the binary-point-only representation, the fixed power-of-two exponent must be less than or equal to zero.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter displays only when you set **Output selection** on the **Main** tab to `Index and fraction`.

Programmatic Use
Block Parameter: `FractionDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule'` | `'double'` | `'single'` | `'fixdt(1,16,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Output` — Output data type

`Inherit: auto` (default) | `bus: <object name>`

To output a virtual bus, use the `Inherit: auto` setting. The resulting virtual bus contains two elements, the index and the fraction signals.

To output and specify a nonvirtual bus, use the `Bus: <object name>` template. Replace `<object name>` with the name of a bus object that contains the index and fraction signals.

- The bus object must contain two elements. The first element corresponds to the index signal and the second to the fraction signal.
- The index and fraction bus element signals cannot be bus signals.
- The data type and the complexity of the bus elements must meet the same constraints that apply to the index and fraction signals if you set **Output selection** to `Index and fraction`.

To create the bus object with the index and fraction bus elements, use MATLAB code similar to this, customizing the bus object name and the names and data types of the bus elements.

```
% Bus object: kfBus
elems(1) = Simulink.BusElement;
elems(1).Name = 'Index';
elems(1).DataType = 'int8';

elems(2) = Simulink.BusElement;
elems(2).Name = 'Fraction';
elems(2).DataType = 'double';

kfBus = Simulink.Bus;
kfBus.Elements = elems;
clear elems;
```

Alternatively, you can use the Bus Editor to create or modify the bus object to use with the Prelookup block.

If you feed the bus output signal from this block to an Interpolation Using Prelookup block, select the **Require index and fraction as bus** check box in that block.

Note Use the Fixed-Point Tool data type override option to override bus objects with new bus objects that replace fixed-point data types with floating-point data types.

Overridden bus objects used with the Prelookup block can cause an error because the block does not accept floating-point data types for the first element in the bus.

If you encounter this issue, use the **Fix** button to redefine the original bus object and protect it from being overridden. For example, suppose you define the first element of the bus object to be an `int32`.

```
myBus.Elements(1).DataType
```

```
int32
```

Clicking the **Fix** button redefines the first bus element:

```
myBus.Elements(1).DataType = 'fixdt(''int32'',''DataTypeOverride'',''Off'')'
```

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Dependencies

This parameter displays only when you set **Output selection** on the **Main** tab to `Index and fraction as bus`.

Programmatic Use

Block Parameter: `OutputBusDataTypeStr`
Type: character vector
Values: `'Inherit: auto'` | `'Bus: <object name>'` | `'<data type expression>'`
Default: `'Inherit: auto'`

`Breakpoint Minimum` — Minimum value breakpoint data can have

`[]` (default) | scalar

Specify the minimum value that the breakpoint data can have. The default value is `[]` (unspecified).

Dependencies

To enable this parameter, set the breakpoints data **Source** to `Dialog` on the **Main** tab.

Programmatic Use

Block Parameter: `BreakpointMin`
Type: character vector
Value: scalar
Default: `'[]'`

`Breakpoint Maximum` — Maximum value breakpoint data can have

`[]` (default) | scalar

Specify the maximum value that the breakpoint data can have. The default value is `[]` (unspecified).

Dependencies

To enable this parameter, set the breakpoints data **Source** to `Dialog` on the **Main** tab.

Programmatic Use

Block Parameter: `BreakpointMax`
Type: character vector
Value: scalar
Default: `'[]'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Integer rounding mode — Rounding mode for fixed-point operations
Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Specify the rounding mode for fixed-point operations. For more information, see "Rounding" (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: RndMeth
Type: character vector
Values: 'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'
Default: 'Floor'

Block Characteristics

Data Types	double | single | base integer | fixed point | enumerated
Direct Feedthrough	No
Multidimensional Signals	Yes
Variable-Size Signals	No
Zero-Crossing Detection	No

Definitions

Enumerated Values in Prelookup

Simulate a Prelookup block with enumerated values.

Suppose that you have a Prelookup block with an enumerated class like this defined:

```
classdef(Enumeration) Gears < Simulink.IntEnumType
    enumeration
        GEAR1(1),
        GEAR2(2),
        GEAR3(4),
        GEAR4(8),
        SPORTS(16),
        REVERSE(-1),
        NEUTRAL(0)
    end
end
```

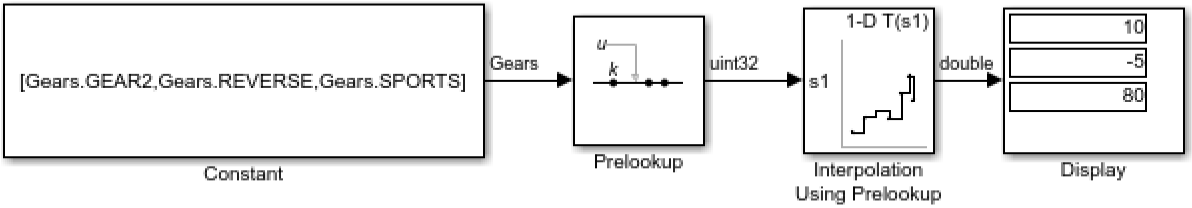
Prelookup block has these settings:

- **Breakpoints data** value is `enumeration('Gears')`.
- **Output selection** is `Index only`.
- For an unordered search, set **Index search method** to `Linear search` and clear the **Begin index search using previous index result** check box.
- **Extrapolation method** is `Clip`.

Interpolation using Prelookup block has these settings:

- **Number of dimensions** to `1`.
- **Table data** value is `[5 10 20 40 80 -5 0]`.
- **Interpolation method** is `Flat`.
- **Number of sub-table selection dimensions** is `1`.

Simulation produces a vector `[10 -5 80]`, which correspond to `GEAR2`, `REVERSE`, and `SPORTS`.



Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL Code Generation, see Prelookup.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Simulink PLC Coder has limited support for lookup table blocks. The coder does not support:

- Number of dimensions greater than 2
- Cubic spline interpolation method
- Begin index search using a previous index mode
- Cubic spline extrapolation method

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

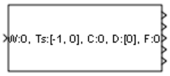
Probe

Output signal attributes, including width, dimensionality, sample time, and complex signal flag

Library: Simulink / Signal Attributes



Description

The Probe block outputs selected information about the signal on its input. The block can output the following attributes of the input signal: width, dimensionality, sample time, and a flag indicating whether the input is a complex-valued signal. The block has one input port. The number of output ports depends on the information that you select for probing, that is, signal dimensionality, sample time, and/or complex signal flag. Each probed value is output as a separate signal on a separate output port, with an independent data type control. During simulation, the block icon displays the probed data.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix | N-D array

Input signal to probe, specified as a scalar, vector, matrix, or N-D array. The block accepts real or complex-valued signals of any built-in data type.

You can use an array of buses as an input signal to a Probe block. For details about defining and using an array of buses, see “Combine Buses into an Array of Buses”.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1 (W)` — Signal width

scalar

Width, or number of elements, in the input signal, specified as a scalar. The width is also displayed on the block icon with the notation `W:`.

Dependencies

To enable this port, select **Probe width**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Port_2 (Ts)` — Sample time

vector

Sample time of the input signal, as a two-element vector that specifies the period and offset of the sample time, respectively. The sample time is also displayed on the block icon with the notation `Ts:`. See “Specify Sample Time” for more information.

Dependencies

To enable this port, select **Probe sample time**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Port_3 (C)` — Signal complexity

scalar

Indication of input signal complexity:

- When the input signal is complex, the block outputs `1`.
- When the input signal is real-valued, the block outputs `0`.

The indication of signal complexity is also displayed on the block icon with the notation `C:`.

Dependencies

To enable this port, select **Detect complex signal**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

`Port_4 (D)` — Signal dimensions

scalar | vector

Dimensions of the input signal, output as a scalar or vector. The signal dimensions are also displayed on the block icon with the notation `D:`.

Dependencies

To enable this port, select **Probe signal dimensions**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

`Probe width` — Output width of the input signal

`on` (default) | `off`

Select to output the width, or number of elements, of the probed signal.

Programmatic Use

Block Parameter: `ProbeWidth`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Probe sample time` — Output sample time of input signal

`on` (default) | `off`

Select to output the sample time of the probed signal. The output is a two-element vector that specifies the period and offset of the sample time, respectively. See “Specify Sample Time” for more information.

Programmatic Use

Block Parameter: `ProbeSampleTime`
Type: character vector

Values: 'off' | 'on'
Default: 'on'

Detect complex signal — Indicate the complexity of input signal

on (default) | off

Select to output 1 if the probed signal is complex; otherwise, 0.

Programmatic Use
Block Parameter: ProbeComplexSignal
Type: character vector
Values: 'off' | 'on'
Default: 'on'

Probe signal dimensions — Output dimensions of input signal

on (default) | off

Select to output the dimensions of the probed signal.

Programmatic Use
Block Parameter: ProbeSignalDimensions
Type: character vector
Values: 'off' | 'on'
Default: 'on'

Signal Attributes

Data type for width — Data type of signal width output

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | Same as input

Select the output data type for the signal width.

Programmatic Use
Block Parameter: ProbeWidthDataType
Type: character vector
Values: 'double' | 'single' | 'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'Same as input'
Default: 'double'

Data type for sample time — Data type of sample time output

double (default) | single | int8 | uint8 | int16 | uint16 | int32 | uint32 | Same as input

Select the output data type for the sample time information.

Programmatic Use
Block Parameter: `ProbeSampleTimeDataType`
Type: character vector
Values: `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'Same as input'`
Default: `'double'`

`Data type for signal complexity` — Data type of complexity output

`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `boolean` | `Same as input`

Select the output data type for the complexity information.

Programmatic Use
Block Parameter: `ProbeComplexityDataType`
Type: character vector
Values: `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'Same as input'`
Default: `'double'`

`Data type for signal dimensions` — Data type for signal dimension output

`double` (default) | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `Same as input`

Select the output data type for the signal dimension output.

Programmatic Use
Block Parameter: `ProbeDimensionsDataType`
Type: character vector
Values: `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'Same as input'`
Default: `'double'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus` | `string`

Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

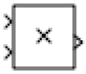
Product

Multiply and divide scalars and nonscalars or multiply and invert matrices

Library: Simulink / Commonly Used Blocks
Simulink / Math Operations



Description

The Product block outputs the result of multiplying two inputs: two scalars, a scalar and a nonscalar, or two nonscalars that have the same dimensions. The default parameter values that specify this behavior are:

- **Multiplication:** `Element-wise(.*)`
- **Number of inputs:** 2

This table shows the output of the Product block for example inputs using default block parameter values.

Inputs and Behavior	Example
Scalar X Scalar Output the product of the two inputs.	
Inputs and Behavior	Example
Scalar X Nonscalar Output a nonscalar having the same dimensions as the input nonscalar. Each element of the output nonscalar is the product of the input scalar and the corresponding element of the input nonscalar.	Nonscalar X Nonscalar Output a nonscalar having the same dimensions as the inputs. Each element of the output is the product of corresponding elements of the inputs.	
The Divide and Product of Elements blocks are variants of the Product block.

- For information on the Divide block, see Divide.
- For information on the Product of Elements block, see Product of Elements.

The Product block (or the Divide block or Product of Elements block, if appropriately configured) can:

- Numerically multiply and divide any number of scalar, vector, or matrix inputs
- Perform matrix multiplication and division on any number of matrix inputs

The Product block performs scalar or matrix multiplication, depending on the value of the **Multiplication** parameter. The block accepts one or more inputs, depending on the **Number of inputs** parameter. The **Number of inputs** parameter also specifies the operation to perform on each input.

The Product block can input any combination of scalars, vectors, and matrices for which the operation to perform has a mathematically defined result. The block performs the specified operations on the inputs, then outputs the result.

The Product block has two modes: *Element-wise mode*, which processes nonscalar inputs element by element, and *Matrix mode*, which processes nonscalar inputs as matrices.

Element-Wise Mode

When you set **Multiplication** to `Element-wise(.*)`, the Product block is in *Element-wise mode*, in which it operates on the individual numeric elements of any nonscalar inputs. The MATLAB equivalent is the `.*` operator. In element-wise mode, the Product block can perform a variety of multiplication, division, and arithmetic inversion operations.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each is multiplied or divided to form the output. When the Product block is in element-wise mode and has only one input, it is functionally equivalent to a Product of Elements block. When the block has multiple inputs, any nonscalar inputs must have identical dimensions, and the block outputs a nonscalar with those dimensions. To calculate the output, the block first expands any scalar input to a nonscalar that has the same dimensions as the nonscalar inputs.

This table shows the output of the Product block for example inputs, using the indicated values for the **Number of inputs** parameter.

Parameter Values	Examples
Number of inputs: 2	Number of inputs: */	Number of inputs: /**/	
Parameter Values	Examples
Number of inputs:**	Number of inputs: */*	 1 2 3 4 2 2 3 4 5 × ÷ × 1 3 6 10

Matrix Mode

When the value of the **Multiplication** parameter is `Matrix(*)`, the Product block is in *Matrix mode*, in which it processes nonscalar inputs as matrices. The MATLAB equivalent is the * operator. In Matrix mode, the Product block can invert a single square matrix, or multiply and divide any number of matrices that have dimensions for which the result is mathematically defined.

The value of the **Number of inputs** parameter controls both how many inputs exist and whether each input matrix is multiplied or divided to form the output. The syntax of **Number of inputs** is the same as in element-wise mode. The difference between the modes is in the type of multiplication and division that occur.

Expected Differences Between Simulation and Code Generation

For element-wise operations on complex floating-point inputs, simulation and code generation results might differ in near-overflow cases. Although **complex numbers** is selected and **non-finite numbers** is not selected on the **Code Generation > Interface** pane of the Configuration Parameters dialog box, the code generator does not emit special case code for intermediate overflows. This method improves the efficiency of embedded operations for the general case that does not include extreme values. If the inputs could include extreme values, you must manage these cases explicitly.

The generated code might not produce the exact same pattern of `NaN` and `inf` values as simulation when these values are mathematically meaningless. For example, if the simulation output contains a NaN, output from the generated code also contains a NaN, but not necessarily in the same place.

Ports

Input

Port_1 — First input to multiply or divide

scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Port_N — Nth input to multiply or divide

scalar | vector | matrix | N-D array

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

X — Input signal to multiply

scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more **X** ports, specify one or more * characters for the **Number of inputs** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

÷ — Input signal to divide or invert

scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more ÷ ports, specify one or more `/` characters for the **Number of inputs** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output computed by multiplying, dividing, or inverting inputs

scalar | vector | matrix | N-D array

Output computed by multiplying, dividing, or inverting inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Number of inputs` — Control number of inputs and type of operation

2 (default) | scalar | * or / for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

  The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is `1` or `*`, the block outputs the input value. If the value is `/`, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1448 and “Matrix Mode” on page 1-1449 for more information.

- **Integer value > 1**

  The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1448 and “Matrix Mode” on page 1-1449 for more information.
- **Unquoted string of two or more * and / characters**

  The block has the number of inputs given by the length of the character vector. Each input that corresponds to a `*` character is multiplied into the output. Each input that corresponds to a `/` character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See “Element-Wise Mode” on page 1-1448 and “Matrix Mode” on page 1-1449 for more information.

Programmatic Use

Block Parameter: `Inputs`
Type: character vector
Values: `'2' | '**' | '*/' | '*/*' | ...`
Default: `'2'`

`Multiplication` — Element-wise (.*) or Matrix (*) multiplication

`Element-wise(.*)` (default) | `Matrix(*)`

Specify whether the block performs `Element-wise(.*)` or `Matrix(*)` multiplication.

Programmatic Use

Block Parameter: `Multiplication`
Type: character vector
Values: `'Element-wise(.*)' | 'Matrix(*)'`
Default: `'Element-wise(.*)'`

`Multiply over` — All dimensions or specified dimension

`All dimensions` (default) | `Specified dimension`

Specify the dimension to multiply over as `All dimensions`, or `Specified dimension`. When you select `Specified dimension`, you can specify the **Dimension** as `1` or `2`.

Dependencies

To enable this parameter, set **Number of inputs** to `*` and **Multiplication** to `Element-wise (.*)`.

Programmatic Use

Block Parameter: `CollapseMode`
Type: character vector
Values: `'All dimensions' | 'Specified dimension'`
Default: `'All dimensions'`

`Dimension` — Dimension to multiply over

`1` (default) | `2` | `...` | `N`

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to `*`
- **Multiplication** to `Element-wise (.*)`
- **Multiply over** to `Specified dimension`

Programmatic Use

Block Parameter: `CollapseDim`
Type: character vector
Values: `'1' | '2' | ...`
Default: `'1'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

`Require all inputs to have the same data type` — Require that all inputs have the same data type

`off` (default) | `on`

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use
Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar

Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `Inherit: Same as first input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- `Inherit: Inherit via internal rule` — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and `ASIC/FPGA` is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

  It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn’t meet your specific needs for numerical accuracy or performance, use one of the following options:

  - Specify the output data type explicitly.
  - Use the simple choice of `Inherit: Same as input`.
  - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
  - To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as first input` — Use data type of first input signal.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` | `'int8'` | `'uint8'` | `'int16'` | `'uint16'` | `'int32'` | `'uint32'` | `'fixdt(1,16)'` | `'fixdt(1,16,0)'` | `'fixdt(1,16,2^0,0)'` | `'<data type expression>'`
Default: `'Inherit: Inherit via internal rule'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Select the rounding mode for fixed-point operations. You can select:

`Ceiling`

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Check for Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`

Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

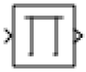
Introduced before R2006a

Product of Elements

Copy or invert one scalar input, or collapse one nonscalar input
Library: Simulink / Math Operations



Description

The Product of Elements block inputs one scalar, vector, or matrix. You can use the block to:

- Copy a scalar input unchanged
- Invert a scalar input (divide 1 by it)
- Collapse a vector or matrix to a scalar by multiplying together all elements or taking successive inverses of the elements
- Collapse a matrix to a vector using one of these options:
  - Multiply together the elements of each row or column
  - Take successive inverses of the elements of each row or column

The Product of Elements block is functionally a Product block that has two preset parameter values:

- **Multiplication**: `Element-wise(.*)`
- **Number of inputs**: `*`

Setting nondefault values for either of those parameters can change a Product of Elements block to be functionally equivalent to a Product block or a Divide block.

Ports

Input

Port_1 — First input to multiply or divide

scalar | vector | matrix | N-D array

First input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Port_N — Nth input to multiply or divide

scalar | vector | matrix | N-D array

Nth input to multiply or divide, provided as a scalar, vector, matrix, or N-D array.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

X — Input signal to multiply

scalar | vector | matrix | N-D array

Input signal to be multiplied with other inputs.

Dependencies

To enable one or more **X** ports, specify one or more * characters for the **Number of inputs** parameter.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

÷ — Input signal to divide or invert

scalar | vector | matrix | N-D array

Input signal for division or inversion operations.

Dependencies

To enable one or more ÷ ports, specify one or more / characters for the **Number of inputs** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output computed by multiplying, dividing, or inverting inputs
scalar | vector | matrix | N-D array

Output computed by multiplying, dividing, or inverting inputs.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Number of inputs` — Control number of inputs and type of operation
`*` (default) | positive integer scalar | `*` or `/` for each input port

Control two properties of the block:

- The number of input ports on the block
- Whether each input is multiplied or divided into the output

When you specify:

- **1 or * or /**

  The block has one input port. In element-wise mode, the block processes the input as described for the Product of Elements block. In matrix mode, if the parameter value is `1` or `*`, the block outputs the input value. If the value is `/`, the input must be a square matrix (including a scalar as a degenerate case) and the block outputs the matrix inverse. See “Element-Wise Mode” on page 1-1448 and “Matrix Mode” on page 1-1449 for more information.
- **Integer value > 1**

  The block has the number of inputs given by the integer value. The inputs are multiplied together in element-wise mode or matrix mode, as specified by the

Multiplication parameter. See "Element-Wise Mode" on page 1-1448 and "Matrix Mode" on page 1-1449 for more information.

- **Unquoted string of two or more * and / characters**

  The block has the number of inputs given by the length of the character vector. Each input that corresponds to a * character is multiplied into the output. Each input that corresponds to a / character is divided into the output. The operations occur in element-wise mode or matrix mode, as specified by the **Multiplication** parameter. See "Element-Wise Mode" on page 1-1448 and "Matrix Mode" on page 1-1449 for more information.

Programmatic Use

Block Parameter: `Inputs`
Type: character vector
Values: `'2' | '*' | '**' | '*/' | '*/*' | ...`
Default: `'*'`

`Multiplication` — Element-wise (.*) or Matrix (*) multiplication

`Element-wise(.*)` (default) | `Matrix(*)`

Specify whether the block performs `Element-wise(.*)` or `Matrix(*)` multiplication.

Programmatic Use

Block Parameter: `Multiplication`
Type: character vector
Values: `'Element-wise(.*)' | 'Matrix(*)'`
Default: `'Element-wise(.*)'`

`Multiply over` — All dimensions or specified dimension

`All dimensions` (default) | `Specified dimension`

Specify the dimension to multiply over as `All dimensions`, or `Specified dimension`.

When you select `All dimensions` and select configuration parameter **Use algorithms optimized for row-major array layout**, Simulink enables row-major algorithms for simulation. To generate row-major code, set configuration parameter **Array layout** (Simulink Coder) to `Row-major` in addition to selecting **Use algorithms optimized for row-major array layout**. The column-major and row-major algorithms differ only in the multiplication order. In some cases, due to different operation order on the same data set, you might experience minor numeric differences in the outputs of column-major and row-major algorithms.

When you select `Specified dimension`, you can specify the **Dimension** as `1` or `2`.

Dependencies

To enable this parameter, set **Number of inputs** to `*` and **Multiplication** to `Element-wise (.*)`.

Programmatic Use

Block Parameter: `CollapseMode`
Type: character vector
Values: `'All dimensions' | 'Specified dimension'`
Default: `'All dimensions'`

`Dimension` — Dimension to multiply over

`1` (default) | `2` | `...` | `N`

Specify the dimension to multiply over as an integer less than or equal to the number of dimensions of the input signal.

Dependencies

To enable this parameter, set:

- **Number of inputs** to `*`
- **Multiplication** to `Element-wise (.*)`
- **Multiply over** to `Specified dimension`

Programmatic Use

Block Parameter: `CollapseDim`
Type: character vector
Values: `'1' | '2' | ...`
Default: `'1'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

`Require all inputs to have the same data type` — Require that all inputs have the same data type

`off` (default) | `on`

Specify if input signals must all have the same data type. If you enable this parameter, then an error occurs during simulation if the input signal types are different.

Programmatic Use
Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see "Specify Minimum and Maximum Values for Block Parameters") for some blocks.
- Simulation range checking (see "Signal Ranges" and "Enable Simulation Range Checking").
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see "Optimize using the specified minimum and maximum values" (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Inherit via internal rule` (default) | `Inherit: Inherit via back propagation` | `Inherit: Same as first input` | `double` | `single` | `int8` | `uint8` | `int16` | `uint16` | `int32` | `uint32` | `fixdt(1,16)` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `<data type expression>`

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`. For more information, see “Control Signal Data Types”.

When you select an inherited option, the block behaves as follows:

- `Inherit: Inherit via internal rule` — Simulink chooses a data type to balance numerical accuracy, performance, and generated code size, while taking into account the properties of the embedded target hardware. If you change the embedded target settings, the data type selected by the internal rule might change. For example, if the block multiplies an input of type `int8` by a gain of `int16` and `ASIC/FPGA` is specified as the targeted hardware type, the output data type is `sfix24`. If `Unspecified (assume 32-bit Generic)`, in other words, a generic 32-bit microprocessor, is specified as the target hardware, the output data type is `int32`. If none of the word lengths provided by the target microprocessor can accommodate the output range, Simulink software displays an error in the Diagnostic Viewer.

  It is not always possible for the software to optimize code efficiency and numerical accuracy at the same time. If the internal rule doesn’t meet your specific needs for numerical accuracy or performance, use one of the following options:

  - Specify the output data type explicitly.
  - Use the simple choice of `Inherit: Same as input`.
  - Explicitly specify a default data type such as `fixdt(1,32,16)` and then use the Fixed-Point Tool to propose data types for your model. For more information, see `fxptdlg`.
  - To specify your own inheritance rule, use `Inherit: Inherit via back propagation` and then use a Data Type Propagation block. Examples of how to use this block are available in the Signal Attributes library Data Type Propagation Examples block.
- `Inherit: Inherit via back propagation` — Use data type of the driving block.
- `Inherit: Same as first input` — Use data type of first input signal.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via internal rule` | `'Inherit: Same as first input'` | `'Inherit: Inherit via back propagation'` | `'double'` | `'single'` |

'int8' | 'uint8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'fixdt(1,16)' | 'fixdt(1,16,0)' | 'fixdt(1,16,2^0,0)' | '<data type expression>'
Default: 'Inherit: Inherit via internal rule'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type
off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see "Use Lock Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: LockScale
Type: character vector
Values: 'off' | 'on'
Default: 'off'

Integer rounding mode — Rounding mode for fixed-point operations
Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Select the rounding mode for fixed-point operations. You can select:

Ceiling

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB ceil function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer convergent function.

Floor

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB floor function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer nearest function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer round function.

`Simplest`

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Block parameters always round to the nearest representable value. To control the rounding of a block parameter, enter an expression using a MATLAB rounding function into the mask field.

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Floor'`

`Saturate on integer overflow` — Method of overflow action

`off` (default) | `on`

Specify whether overflows saturate or wrap.

Action	Rationale	Impact on Overflows	Example
Select this check box (`on`).	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.

Action	Rationale	Impact on Overflows	Example
Do not select this check box (`off`).	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see “Check for Signal Range Errors”.	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output, or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`

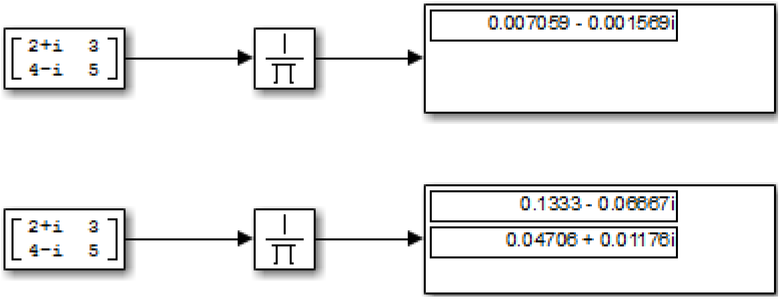
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Algorithms

The Product of Elements block uses these algorithms to perform element-wise operations on inputs of floating-point, built-in integer, and fixed-point types.

Input	Element-Wise Operation	Algorithm
Real scalar, `u`	Multiplication	`y = u`
	Division	`y = 1/u`
Real vector or matrix with elements `u1, u2, u3, ..., uN`	Multiplication	`y = u1*u2*u3*...*uN`
	Division	`y = ((((1/u1)/u2)/u3).../uN)`
Complex scalar, `u`	Multiplication	`y = u`
	Division	`y = 1/u`
Complex vector or matrix with elements `u1, u2, u3, ..., uN`	Multiplication	`y = u1*u2*u3*...*uN`
	Division	`y = ((((1/u1)/u2)/u3).../uN)`

If the specified dimension for element-wise multiplication or division is a row or column of a matrix, the algorithm applies to that row or column. Consider this model.



The top Product of Elements block collapses the matrix input to a scalar by taking successive inverses of the four elements:

- `y = ((((1/2+i)/3)/4-i)/5)`

The bottom Product of Elements block collapses the matrix input to a vector by taking successive inverses along the second dimension:

- `y(1) = ((1/2+i)/3)`
- `y(2) = ((1/4-i)/5)`

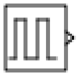
Introduced before R2006a

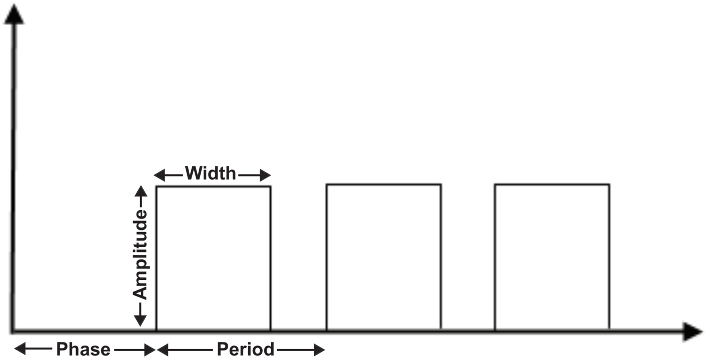
Pulse Generator

Generate square wave pulses at regular intervals
Library: Simulink / Sources



Description

The Pulse Generator block generates square wave pulses at regular intervals. The block waveform parameters, **Amplitude**, **Pulse Width**, **Period**, and **Phase delay**, determine the shape of the output waveform. The following diagram shows how each parameter affects the waveform.



The Pulse Generator block can emit scalar, vector, or matrix signals of any real data type. To cause the block to emit a scalar signal, use scalars to specify the waveform parameters. To cause the block to emit a vector or matrix signal, use vectors or matrices, respectively, to specify the waveform parameters. Each element of the waveform parameters affects the corresponding element of the output signal. For example, the first element of a vector amplitude parameter determines the amplitude of the first element of a vector output pulse. All the waveform parameters must have the same dimensions after scalar expansion. The data type of the output is the same as the data type of the **Amplitude** parameter.

This block output can be generated in time-based or sample-based modes, determined by the **Pulse type** parameter.

Time-Based Mode

In time-based mode, Simulink computes the block output only at times when the output actually changes. This approach results in fewer computations for the block output over the simulation time period. Activate this mode by setting the **Pulse type** parameter to `Time based`.

The block does not support a time-based configuration that results in a constant output signal. Simulink returns an error if the parameters **Pulse Width** and **Period** satisfy either of these conditions:

$$Period^{*}\frac{PulseWidth}{100}=0$$

$$Period^{*}\frac{PulseWidth}{100}=Period$$

Depending on the pulse waveform characteristics, the intervals between changes in the block output can vary. For this reason, a time-based Pulse Generator block has a variable sample time. The sample time color of such blocks is brown (see “View Sample Time Information” for more information).

Simulink cannot use a fixed-step solver to compute the output of a time-based pulse generator. If you specify a fixed-step solver for models that contain time-based pulse generators, Simulink computes a fixed sample time for the time-based pulse generators. Then the time-based pulse generators simulate as sample based.

If you use a fixed-step solver and the **Pulse type** is `Time based`, choose the step size such that the period, phase delay, and pulse width (in seconds) are integer multiples of the solver step size. For example, suppose that the period is `4` seconds, the pulse width is `75%` (that is, `3` s), and the phase delay is `1` s. In this case, the computed sample time is `1` s. Therefore, choose a fixed-step size of `1` or a number that divides `1` exactly (for example, `0.25`). To ensure this setting, select `auto` on the **Solver** pane of the Configuration Parameters dialog box.

Sample-Based Mode

In sample-based mode, the block computes its outputs at fixed intervals that you specify. Activate this mode by setting the **Pulse type** parameter to `Sample based`.

An important difference between the time-based and sample-based modes is that in time-based mode, the block output is based on simulation time, and in sample-based mode, the block output depends only on the simulation start, regardless of elapsed simulation time.

This block supports reset semantics in sample-based mode. For example, if a Pulse Generator block is in a resettable subsystem that hits a reset trigger, the block output resets to its initial condition.

Ports

Output

`Port_1` — Output signal
scalar | vector | matrix

Generated square wave pulse signal specified by the parameters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Pulse type` — Type of pulse
`Time based` (default) | `Sample based`

Specify the type of square wave that this block generates, either time- or sample-based. Some parameters in the dialog box appear depending on whether you select time-based or sample-based.

Programmatic Use
Block Parameter: `PulseType`
Type: character vector
Values: `'Time based'` | `'Sample based'`

Default: `'Time based'`

`Time (t)` — Source of time variable

`Use simulation time` (default) | `Use external signal`

Specifies whether to use simulation time or an external signal as the source of values for the output pulse's time variable. If you specify an external source, the block displays an input port for connecting the source. The output pulse differs as follows:

- `Use simulation time`: The block generates an output pulse where the time variable equals the simulation time.
- `Use external signal`: The block generates an output pulse where the time variable equals the value from the input port, which can differ from the simulation time.

Programmatic Use

Block Parameter: `TimeSource`
Type: character vector
Values: `'Use simulation time'` | `'Use external signal'`
Default: `'Use simulation time'`

`Amplitude` — Signal amplitude

`1` (default) | `scalar`

Specify the amplitude of the signal.

Programmatic Use

Block Parameter: `Amplitude`
Type: character vector
Value: scalar
Default: `'1'`

`Period (secs)` — Pulse period

`10` (default) | `scalar`

Pulse period specified in seconds if the pulse type is time-based. If the pulse type is sample-based, then the period is specified as the number of sample times.

Programmatic Use

Block Parameter: `Period`
Type: character vector
Value: scalar

Default: `'10'`

`Pulse width` — Duty cycle

`5` (default) | `scalar in the range [0,100]`

Duty cycle specified as the percentage of the pulse period that the signal is on if time-based or as number of sample times if sample-based.

Programmatic Use

Block Parameter: `PulseWidth`
Type: character vector
Value: scalar
Default: `'5'`

`Phase delay (secs)` — Delay before pulse

`0` (default) | `scalar`

Delay before the pulse is generated, specified in seconds, if the pulse type is time-based or as number of sample times if the pulse type is sample-based.

Programmatic Use

Block Parameter: `PhaseDelay`
Type: character vector
Value: scalar
Default: `'0'`

`Sample time` — Length of sample time

`0` (default) | `scalar`

Length of the sample time for this block in seconds. This parameter appears only if the block's pulse type is sample-based. See “Specify Sample Time”.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Value: scalar
Default: `'0'`

`Interpret vector parameters as 1-D` — Treat vectors as 1-D

`on` (default) | `off`

Select this check box to output a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector.

- When you select this check box, the block outputs a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector. For example, the block outputs a matrix of dimension `1-by-N` or `N-by-1`.
- When you clear this check box, the block does not output a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector.

Programmatic Use
Block Parameter: `VectorParams1D`
Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`Yes`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Cannot be used inside a triggered subsystem hierarchy.

These blocks do not reference absolute time when configured for sample-based operation. In time-based operation, they depend on absolute time.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Push Button

Set value of parameter when button is pressed
Library: Simulink / Dashboard

Description

When you press the Push Button block during a simulation, the value of the connected block parameter changes to a specified value. Use the Push Button block with other Dashboard blocks to create an interactive dashboard to control your model.

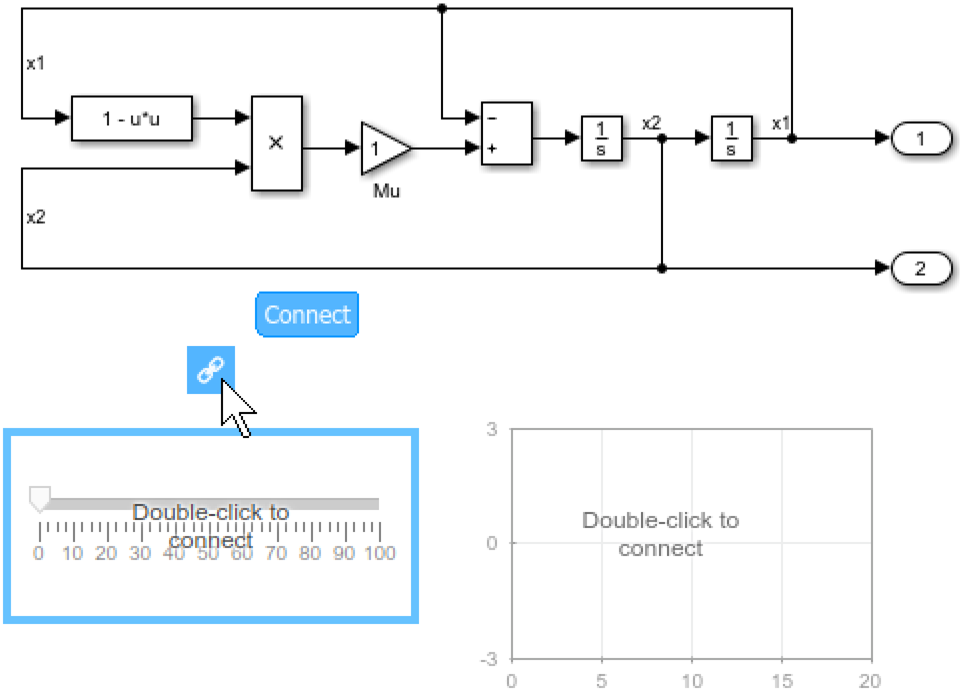
Double-clicking the Push Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connecting Dashboard Blocks

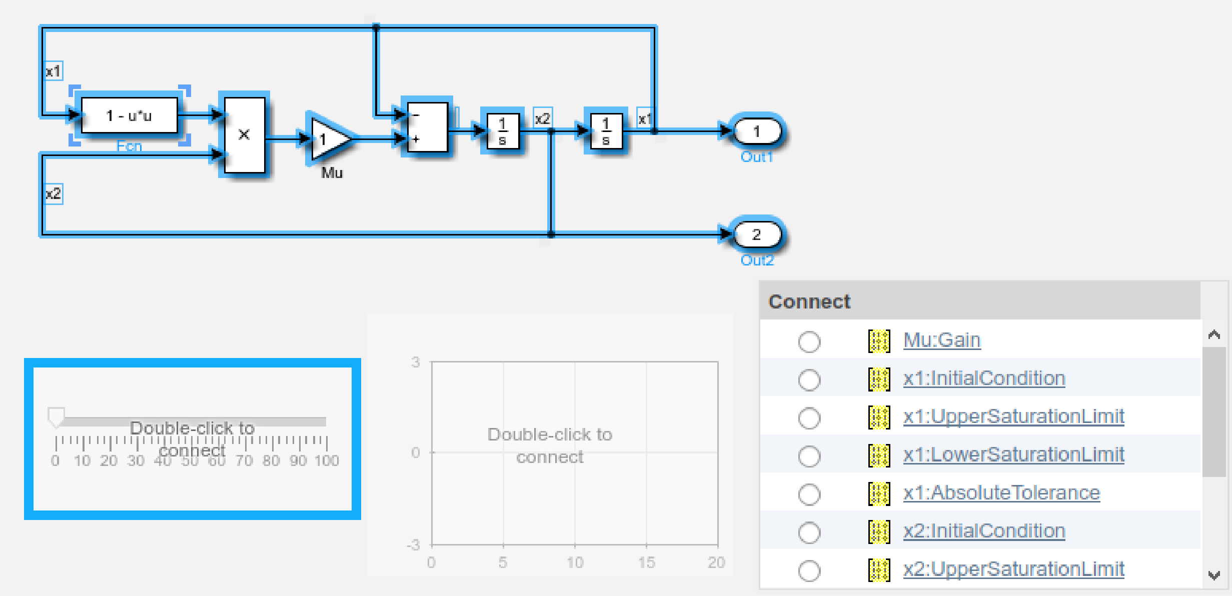
Dashboard blocks do not use ports to make connections. To connect Dashboard blocks to variables and block parameters in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

Note Dashboard blocks cannot connect to variables until you update your model diagram. To connect Dashboard blocks to variables or modify variable values between opening your model and running a simulation, update your model diagram using **Ctrl+D**.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

○	Mu:Gain
○	x1:InitialCondition
○	x1:UpperSaturationLimit
○	x1:LowerSaturationLimit
○	x1:AbsoluteTolerance
○	x2:InitialCondition
○	x2:UpperSaturationLimit

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Parameter Logging

Tunable parameters connected to Dashboard blocks are logged to the Simulation Data Inspector, where you can view parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector UI or by using the `Simulink.sdi.exportRun` function. For more information about exporting data with the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using

connect mode, the Dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. Populate the **Connection** table by selecting one or more blocks in your model. Select the radio button next to the variable or parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

`Button Text` — Text displayed on button

'Button' (default) | character vector

The text displayed on the Push Button block in your model.

`On Value` — Value assigned to parameter when button is pressed

1 (default) | scalar

The value assigned to the connected block parameter when the button is pressed.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

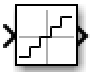
Introduced in R2015a

Quantizer

Discrete input at given interval
Library: Simulink / Discontinuities



Description

The Quantizer block passes the input signal through a stair-step function. Many neighboring points on the input axis are mapped to one point on the output axis. The effect quantizes a smooth signal into a stair-step output. The block uses a round-to-nearest method to produce an output that is symmetric about zero.

```
y = q * round(u/q)
```

where `y` is the output, `u` the input, and `q` the **Quantization interval** parameter.

Ports

Input

`Input 1` — Input signal to quantize

scalar | vector

The input signal to the quantization algorithm.

Data Types: `single` | `double`

Output

`Output 1` — Quantized output signal

real or complex scalar | real or complex vector

Output signal as quantized discrete values.

```
y = q * round(u/q)
```

where y is the output, u the input, and q the **Quantization interval** parameter.

Data Types: single | double

Parameters

Quantization interval — Interval around which the block quantizes the output

0.5 (default) | scalar | vector

Specify the quantization interval used in the algorithm. Permissible output values for the Quantizer block are n*q, where n is an integer and q the **Quantization interval**.

Programmatic Use
Block Parameter: QuantizationInterval
Type: character vector
Value: Any real or complex value
Default: '0.5'

Treat as gain when linearizing — Specify the gain value

On (default) | boolean

The linearization commands in Simulink software treat this block as a gain in state space. Select this check box to cause the commands to treat the gain as 1. Clear the box to have the commands treat the gain as 0.

Programmatic Use
Block Parameter: LinearizeAsGain
Type: character vector
Value: 'off' | 'on'
Default: 'on'

Sample time — Specify sample time as a value other than -1

-1 (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than -1. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

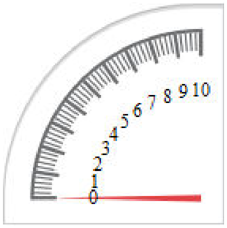
Quarter Gauge

Display input value on quadrant scale
Library: Simulink / Dashboard



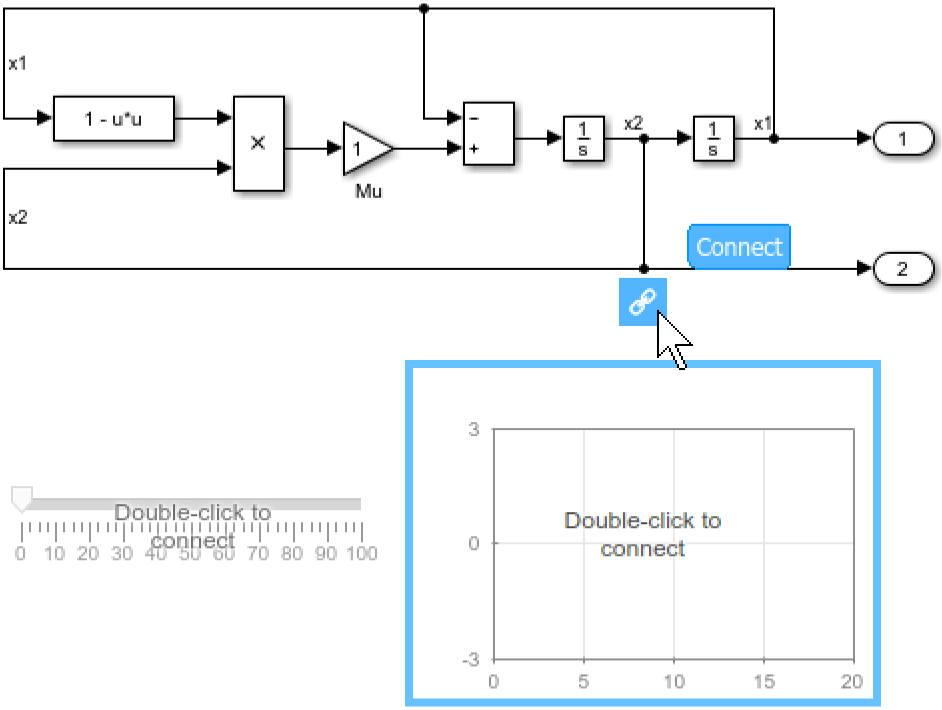
Description

The Quarter Gauge block displays the connected signal on a quadrant scale during simulation. You can use the Quarter Gauge block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model. The Quarter Gauge block provides an indication of the instantaneous value of the connected signal throughout simulation. You can modify the range of the Quarter Gauge block to fit your data. You can also customize the appearance of the Quarter Gauge block to provide more information about your signal. For example, you can color-code in-specification and out-of-specification ranges.

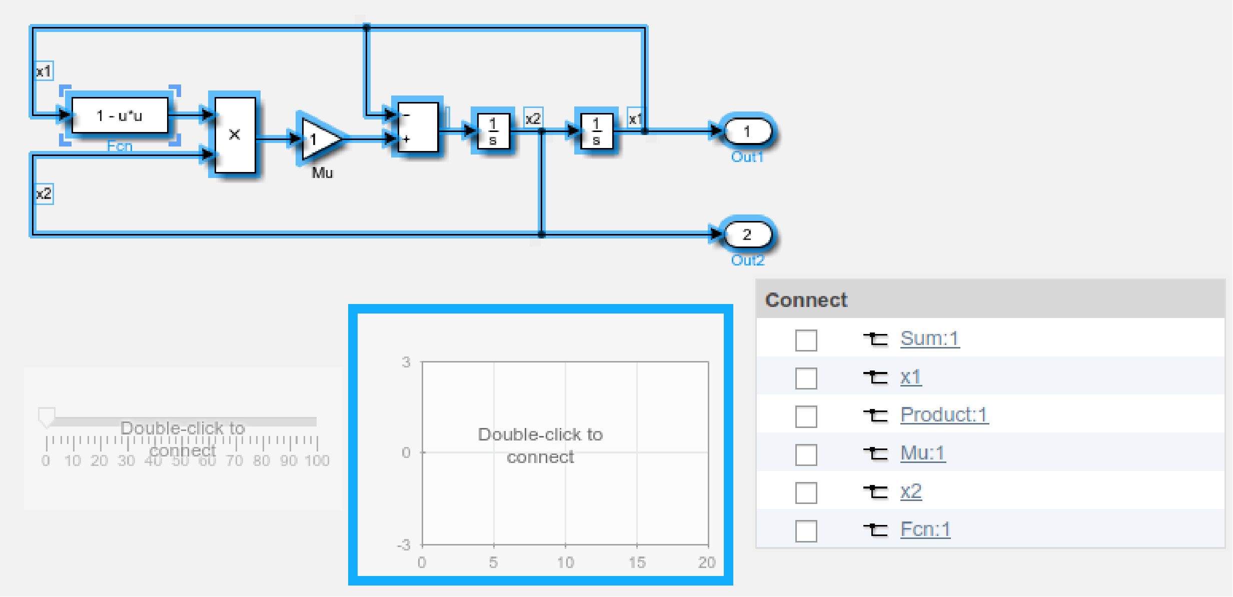
Connecting Dashboard Blocks

Dashboard blocks do not use ports to connect to signals. To connect Dashboard blocks to signals in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect	
□	Sum:1
□	x1
□	Product:1
□	Mu:1
□	x2
□	Fcn:1

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using connect mode, the Dashboard block does not display the connected value until the you uncomment the block.
- Dashboard blocks cannot connect to signals inside referenced models.
- If you turn off logging for a signal connected to a Dashboard block, the model stops sending data from that signal to the block. To view the signal again, reconnect the signal.

Parameters

`Connection` — Select a signal to connect and display

signal connection options

Select the signal to connect using the **Connection** table. Populate the **Connection** table by selecting signals of interest in your model. Select the radio button next to the signal you want to display. Click **Apply** to connect the signal.

`Minimum` — Minimum tick mark value

0 (default) | scalar

A finite, real, double, scalar value specifying the minimum tick mark value for the arc. The minimum must be less than the value entered for the maximum.

`Maximum` — Maximum tick mark value

100 (default) | scalar

A finite, real, double, scalar value specifying the maximum tick mark value for the arc. The maximum must be greater than the value entered for the minimum.

`Tick Interval` — Interval between major tick marks

auto (default) | scalar

A finite, real, positive, integer, scalar value specifying the interval of major tick marks on the arc. When set to `auto`, the block automatically adjusts the tick interval based on the minimum and maximum values.

`Scale Colors` — Color indications on gauge arc

colors for arc ranges

Color specifications for ranges on the arc. Press the **+** button to add a color. For each color added, specify the minimum and maximum values of the range where you want to display that color.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

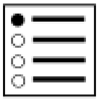
Radio Button

Select parameter value
Library: Simulink / Dashboard



Description

The Radio Button block lets you change the value of the connected parameter during simulation. You can specify a list of values and labels and then select the value for the parameter from that list. Use the Radio Button block with other Dashboard blocks to build an interactive dashboard of controls and indicators for your model.

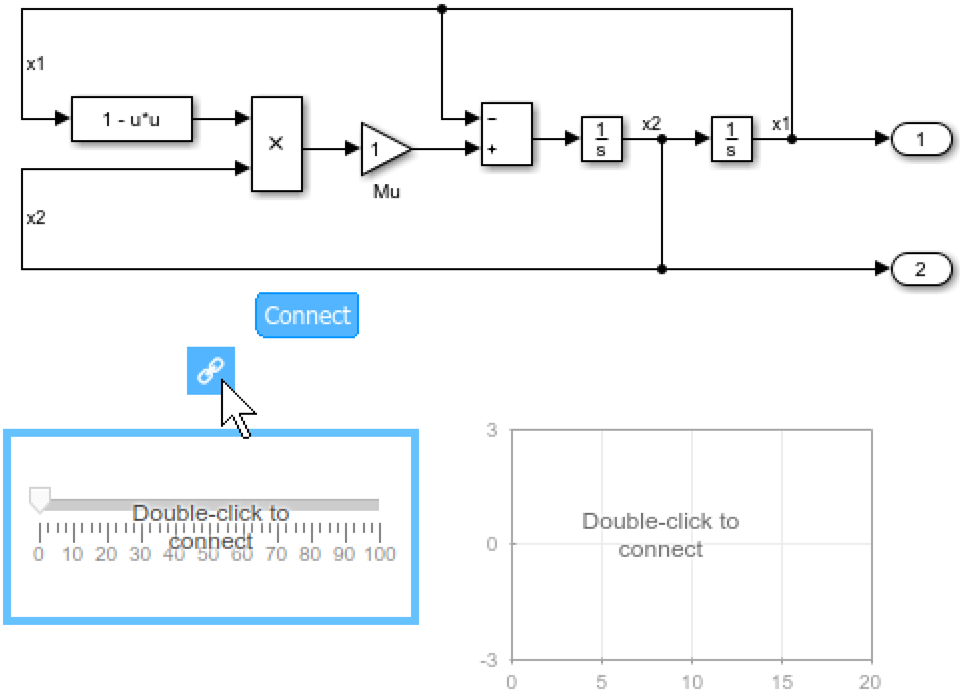
Double-clicking the Radio Button block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connecting Dashboard Blocks

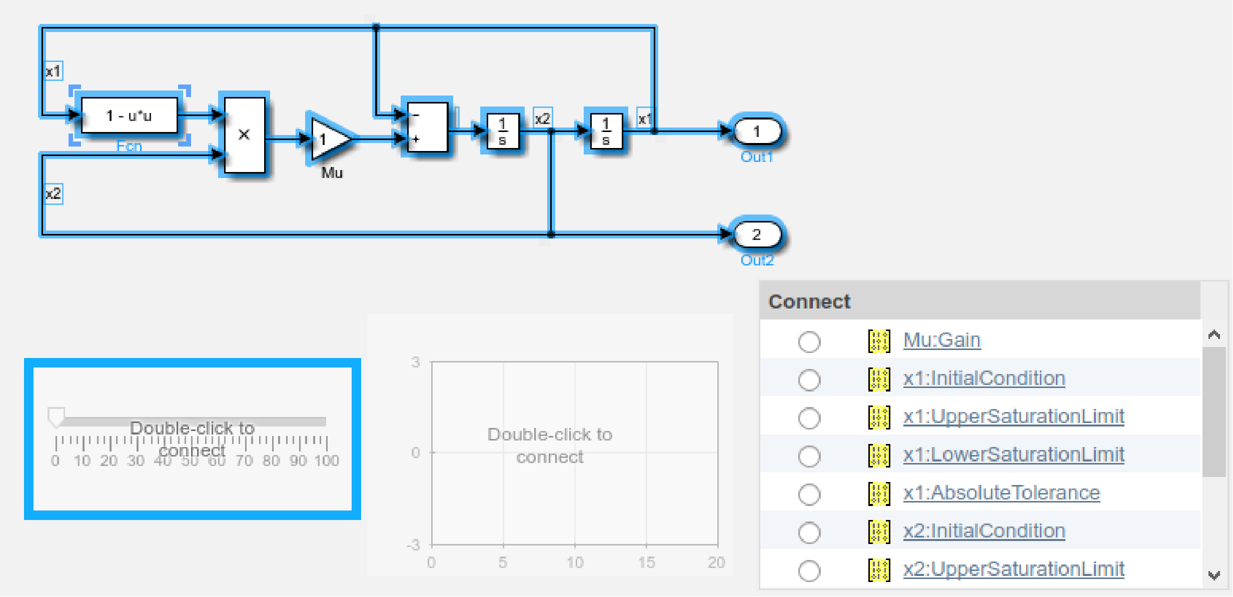
Dashboard blocks do not use ports to make connections. To connect Dashboard blocks to variables and block parameters in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

Note Dashboard blocks cannot connect to variables until you update your model diagram. To connect Dashboard blocks to variables or modify variable values between opening your model and running a simulation, update your model diagram using **Ctrl+D**.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

○ Mu:Gain
○ x1:InitialCondition
○ x1:UpperSaturationLimit
○ x1:LowerSaturationLimit
○ x1:AbsoluteTolerance
○ x2:InitialCondition
○ x2:UpperSaturationLimit

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Parameter Logging

Tunable parameters connected to Dashboard blocks are logged to the Simulation Data Inspector, where you can view parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector UI or by using the `Simulink.sdi.exportRun` function. For more information about exporting data with the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using

connect mode, the Dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. Populate the **Connection** table by selecting one or more blocks in your model. Select the radio button next to the variable or parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

States

`Value` — Values for selected option

0/1/2 (default) | scalar

Values assigned to the connected parameter when you select the option with the corresponding **Label**. Click the **+** button to add options.

`Label` — Option labels

'Label1'/'Label2'/'Label3' (default) | character vector

Label for each option. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a text label.

Example: `Gain = 1`

`Group Name` — Radio Button group name

RadioButtonGroup (default) | character array

Name for the group of values displayed on the Radio Button block. Unlike the **Block Name** and **Label**, the **Group Name** always shows on the Radio Button block.

Example: `Input Amplitude`

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

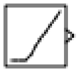
Ramp

Generate constantly increasing or decreasing signal
Library: Simulink / Sources



Description

The Ramp block generates a signal that starts at a specified time and value and changes by a specified rate. The block's **Slope**, **Start time**, and **Initial output** parameters determine the characteristics of the output signal. All must have the same dimensions after scalar expansion.

Ports

Output

`Port_1` — Output signal
scalar | vector | matrix

Generated output ramp signal characterized by the **Slope**, **Start time, and Initial output** parameters.

Data Types: `double`

Parameters

`Slope` — Slope of signal
1 (default) | scalar | vector | matrix

Specify the rate of change of the generated signal.

Programmatic Use

Block Parameter: `slope`
Type: character vector
Values: scalar
Default: `'1'`

`Start time` — Time output begins

0 (default) | scalar

Specify the time at which the block begins generating the signal.

Programmatic Use

Block Parameter: `start`
Type: character vector
Values: scalar
Default: `'0'`

`Initial output` — Initial value of output signal

0 (default) | scalar | vector | matrix

Specify the initial value of the output signal.

Programmatic Use

Block Parameter: `InitialOutput`
Type: character vector
Values: scalar
Default: `'0'`

`Interpret vector parameters as 1-D` — Treat vectors as 1-D

`on` (default) | `off`

Select this check box to output a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector.

- When you select this check box, the block outputs a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector. For example, the block outputs a matrix of dimension `1-by-N` or `N-by-1`.
- When you clear this check box, the block does not output a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector.

Programmatic Use

Block Parameter: `VectorParams1D`

Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

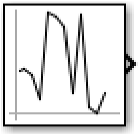
Pulse Generator | Repeating Sequence

Introduced before R2006a

Random Number

Generate normally distributed random numbers
Library: Simulink / Sources



Description

The Random Number block generates normally distributed random numbers. To generate uniformly distributed random numbers, use the Uniform Random Number block.

You can generate a repeatable sequence using any Random Number block with the same nonnegative seed and parameters. The seed resets to the specified value each time a simulation starts. By default, the block produces a sequence that has a mean of 0 and a variance of 1. To generate a vector of random numbers with the same mean and variance, specify the **Seed** parameter as a vector.

Avoid integrating a random signal, because solvers must integrate relatively smooth signals. Instead, use the Band-Limited White Noise block.

The numeric parameters of this block must have the same dimensions after scalar expansion. If you select the **Interpret vector parameters as 1-D** check box, and the numeric parameters are row or column vectors after scalar expansion, the block outputs a 1-D signal. If you clear the **Interpret vector parameters as 1-D** check box, the block outputs a signal of the same dimensionality as the parameters.

Ports

Output

`Port_1` — Output signal
scalar | vector | matrix

Output signal that is the generated random numbers falling within a normal Gaussian distribution. The output is repeatable for a given seed.

Data Types: `double`

Parameters

`Mean` — Mean of random numbers

`0` (default) | scalar

Specify the mean of the random numbers generated.

Programmatic Use
Block Parameter: `Mean`
Type: character vector
Values: scalar
Default: `'0'`

`Variance` — Variance of random numbers

`1` (default) | scalar

Specify the variance of the random numbers.

Programmatic Use
Block Parameter: `Variance`
Type: character vector
Values: scalar
Default: `'1'`

Seed — Starting seed

`0` (default) | positive integer

Specify the starting seed for the random number generator.

The output of number generated is repeatable for a given seed.

Programmatic Use
Block Parameter: `Seed`
Type: character vector
Values: scalar
Default: `'0'`

`Sample time` — Time between intervals

`0.1` (default) | `integer`

Specify the time interval between samples. The default is `0.1`, which matches the default sample time of the Band-Limited White Noise block. See “Specify Sample Time” in the Simulink documentation for more information.

Programmatic Use

Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'0.1'`

`Interpret vector parameters as 1-D` — Treat vectors as 1-D

`on` (default) | `off`

Select this check box to output a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector.

- When you select this check box, the block outputs a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector. For example, the block outputs a matrix of dimension `1-by-N` or `N-by-1`.
- When you clear this check box, the block does not output a vector of length `N` if the **Constant value** parameter evaluates to an `N`-element row or column vector.

Programmatic Use

Block Parameter: `VectorParams1D`
Type: character vector
Values: `'on' | 'off'`
Default: `'on'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`

Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

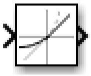
Band-Limited White Noise | Uniform Random Number

Introduced before R2006a

Rate Limiter

Limit rate of change of signal
Library: Simulink / Discontinuities



Description

The Rate Limiter block limits the first derivative of the signal passing through it. The output changes no faster than the specified limit. The derivative is calculated using this equation:

$$rate = \frac{u(i) - y(i-1)}{t(i) - t(i-1)}$$

where *u(i)* and*t(i)* are the current block input and time, and *y(i-1)* and *t(i-1))* are the output and time at the previous step. The output is determined by comparing *rate* to the **Rising slew rate** and **Falling slew rate** parameters:

- If *rate* is greater than the **Rising slew rate** parameter (*R*), the output is calculated as

  $$y(i) = \Delta t \cdot R + y(i-1).$$

- If *rate* is less than the **Falling slew rate** parameter (*F*), the output is calculated as

  $$y(i) = \Delta t \cdot F + y(i-1).$$

- If *rate* is between the bounds of *R* and *F*, the change in output is equal to the change in input:

  $$y(i) = u(i)$$

When the block is running in continuous mode (for example, **Sample time mode** is `inherited` and **Sample time** of the driving block is zero), the **Initial condition** is ignored. The block output at `t = 0` is equal to the initial input:

$$y(0) = u(0)$$

When the block is running in discrete mode (for example, **Sample time mode** is `inherited` and **Sample time** of the driving block is nonzero), the **Initial condition** is preserved:

$$y(-1) = Ic$$

where *Ic* is the initial condition. The block output at `t = 0` is calculated as if *rate* is outside the bounds of *R* and *F*. For `t = 0`, *rate* is calculated as follows:

$$rate = \frac{u(0) - y(-1)}{sampletime}$$

Limitations

- You cannot use a Rate Limiter block inside a Triggered Subsystem. Use the Rate Limiter Dynamic block instead.

Ports

Input

`Port_1` — Input signal
scalar

The input signal to the rate limiter algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `enumerated`

Output

`Port_1` — Output signal
scalar

Output signal from the rate limiter algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `enumerated`

Parameters

`Rising slew rate` — Limit of derivative for increasing input

`1` (default) | real number

Specify the limit of the rising rate of the input signal. This parameter is tunable for fixed-point inputs.

Programmatic Use
Block Parameter: `RisingSlewLimit`
Type: character vector
Values: real number
Default: `'1'`

`Falling slew rate` — Limit of derivative for decreasing input

`-1` (default) | real number

Specify the lower limit on the falling rate of the input signal. This parameter is tunable for fixed-point inputs.

Programmatic Use
Block Parameter: `FallingSlewLimit`
Type: character vector
Values: real number
Default: `'-1'`

`Sample time mode` — Sample time mode

`inherited` (default) | `continuous`

Specify the sample time mode, `continuous` or `inherited` from the driving block.

Programmatic Use
Block Parameter: `SampleTimeMode`
Type: character vector
Values: `'inherited'` | `'continuous'` |
Default: `'inherited'`

`Initial condition` — Initial output

`0` (default) | scalar

Set the initial output of the simulation. Simulink does not allow you to set the initial condition of this block to `inf` or `NaN`.

Programmatic Use
Block Parameter: `InitialCondition`
Type: character vector
Values: `scalar`
Default: `'0'`

`Treat as gain when linearizing` — Specify the gain value

`On` (default) | Boolean

Select this check box to cause the commands to treat the gain as 1. The linearization commands in Simulink software treat this block as a gain in state space. Clear the box to have the commands treat the gain as 0.

Programmatic Use
Block Parameter: `LinearizeAsGain`
Type: character vector
Values: `'off'` | `'on'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Cannot be used inside a triggered subsystem hierarchy.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

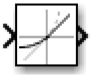
Rate Limiter Dynamic | Saturation

Introduced before R2006a

Rate Limiter Dynamic

Limit rate of change of signal
Library: Simulink / Discontinuities



Description

The Rate Limiter Dynamic block limits the rising and falling rates of the signal.

- The external signal `up` sets the upper limit on the rising rate of the signal.
- The external signal `lo` sets the lower limit on the falling rate of the signal.

Follow these guidelines when using the Rate Limiter Dynamic block:

- Ensure that the data types of `up` and `lo` are the same as the data type of the input signal `u`.

  When the lower limit uses a signed type and the input signal uses an unsigned type, the output signal keeps increasing regardless of the input and the limits.
- Use a fixed-step solver to simulate models that contain this block.

  Because the Rate Limiter Dynamic block does not support continuous sample time, simulation with a variable-step solver causes an error.

Ports

Input

u — Input signal
scalar

Input signal to the rate limiter algorithm.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

lo — Limit of derivative for decreasing input

scalar

Dynamic value providing the limit of the falling rate of the input signal. Make the signal data type of lothe same data type of the input signal u.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

up — Limit of derivative for increasing input

scalar

Dynamic value providing the limit of the rising rate of the input signal. Make the signal data type of upthe same data type of the input signal u.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point

Output

Y — Output signal

scalar

Output signal from the rate limiter algorithm.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | fixed point | enumerated | bus

Block Characteristics

Data Types	double | single | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No

Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

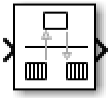
Rate Limiter

Introduced before R2006a

Rate Transition

Handle transfer of data between blocks operating at different rates

Library: Simulink / Signal Attributes



Description

The Rate Transition block transfers data from the output of a block operating at one rate to the input of a block operating at a different rate. Use the block parameters to trade data integrity and deterministic transfer for faster response or lower memory requirements. To learn about data integrity and deterministic data transfer, see “Data Transfer Problems” (Simulink Coder).

Transition Handling Options

Transition Handling Options	Block Parameter Settings
• Data integrity • Deterministic data transfer • Maximum latency	Select: • **Ensure data integrity during data transfer** • **Ensure deterministic data transfer**
• Data integrity • Nondeterministic data transfer • Minimum latency • Higher memory requirements	Select: • **Ensure data integrity during data transfer** Clear: • **Ensure deterministic data transfer**

Transition Handling Options	Block Parameter Settings
• Potential loss of data integrity • Nondeterministic data transfer • Minimum latency • Lower memory requirements	Clear: • **Ensure data integrity during data transfer** • **Ensure deterministic data transfer**

Dependencies

The behavior of the Rate Transition block depends on:

- Sample times of the ports to which the block connects (see “Effects of Synchronous Sample Times” on page 1-1517 and “Effects of Asynchronous Sample Times” on page 1-1519)
- Priorities of the tasks for the source and destination sample times (see “Sample time properties” in the Simulink documentation)
- Whether the model specifies a fixed- or variable-step solver (see “Solvers” in the Simulink documentation)

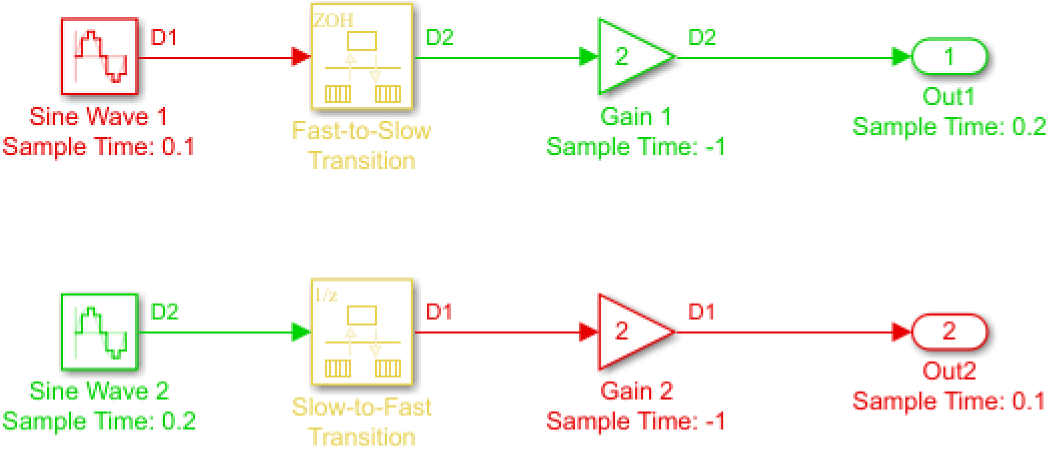
Block Labels

When you update your diagram, a label appears on the Rate Transition block to indicate simulation behavior.

Label	Block Behavior
`ZOH`	Acts as a zero-order hold
`1/z`	Acts as a unit delay
`Buf`	Copies input to output under semaphore control
`Db_buf`	Copies input to output using double buffers
`Copy`	Unprotected copy of input to output
`NoOp`	Does nothing
`Mixed`	Expands to multiple blocks with different behaviors

The block behavior label shows the method that ensures safe transfer of data between tasks operating at different rates. You can use the sample-time colors feature (see “View

Sample Time Information") to display the relative rates that the block bridges. Consider, for example, the following model:



Sample-time colors and the block behavior label show:

- The Rate Transition block at the top of the diagram acts as a zero-order hold in a fast-to-slow transition.
- The Rate Transition block at the bottom of the diagram acts as a unit delay in a slow-to-fast transition.

For more information, see "Handle Rate Transitions" (Simulink Coder).

Effects of Synchronous Sample Times

The following table summarizes how each label appears when the sample times of the input and output ports (inTs and outTs) are periodic, or synchronous.

Block Settings		Block Label		
Rate Transition	**Conditions for Rate Transition Block**	**With Data Integrity and Determinism**	**With Only Data Integrity**	**Without Data Integrity or Determinism**
inTs = outTs	inTsOffset < outTsOffset	None (error)	Buf	Copy or NoOp (see note that

Block Settings		Block Label		
Rate Transition	**Conditions for Rate Transition Block**	**With Data Integrity and Determinism**	**With Only Data Integrity**	**Without Data Integrity or Determinism**
(Equal)	`inTsOffset` = `outTsOffset`	`Copy` or `NoOp` (see note that follows the table)	`Copy` or `NoOp` (see note that follows the table)	follows the table)
	`inTsOffset` > `outTsOffset`	None (error)	`Db_buf`	
`inTs` < `outTs` (Fast to slow)	`inTs` = `outTs / N` `inTsOffset`, `outTsOffset` = 0	`ZOH`	`Buf`	

	`inTs` = `outTs / N`
	`inTsOffset` ≤ `outTsOffset`
		None (error)		

	`inTs` = `outTs / N`
	`inTsOffset` > `outTsOffset`
		None (error)	`Db_buf`	

	`inTs` ≠ `outTs / N`	None (error)		
`inTs` > `outTs` (Slow to fast)	`inTs` = `outTs * N` `inTsOffset`, `outTsOffset` = 0	`1/z`	`Db_buf`	

	`inTs` = `outTs * N`
	`inTsOffset` ≤ `outTsOffset`
		None (error)		

	`inTs` = `outTs * N`
	`inTsOffset` > `outTsOffset`
		None (error)		

	`inTs` ≠ `outTs * N`	None (error)		

KEY

- `inTs, outTs`: Sample times of input and output ports, respectively
- `inTsOffset, outTsOffset`: Sample time offsets of input and output ports, respectively
- `N`: Integer value > 1

When you select the **Block reduction** parameter on the Configuration Parameters dialog box, Copy reduces to NoOp. No code generation occurs for a Rate Transition block with a NoOp label. To prevent a block from being reduced when block reduction is on, add a test point to the block output (see “Test Points” in the Simulink documentation).

Effects of Asynchronous Sample Times

The following table summarizes how each label appears when the sample time of the input or output port (inTs or outTs) is not periodic, or asynchronous.

Block Settings	**Block Label**		
	With Data Integrity and Determinism	**With Only Data Integrity**	**Without Data Integrity or Determinism**
inTs = outTs	Copy	Copy	Copy
inTs ≠ outTs	None (error)	Db_buf	
KEY • inTs, outTs: Sample times of input and output ports, respectively			

Ports

Input

Port_1 — Input signal

scalar | vector | matrix | N-D array

Input signal to transition to a new sample rate, specified as a scalar, vector, matrix, or N-D array. To learn about the block parameters that enable you to trade data integrity and deterministic transfer for faster response or lower memory requirements, see “Transition Handling Options” on page 1-1515.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Output

`Port_1` — Output signal
scalar | vector | matrix | N-D array

Output signal is the input signal converted to the sample rate you specify. The default configuration ensures safe and deterministic data transfer. To learn about the block parameters that enable you to trade data integrity and deterministic transfer for faster response or lower memory requirements, see “Transition Handling Options” on page 1-1515.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Ensure data integrity during data transfer` — Ensure data integrity
on (default) | `off`

Selecting this check box results in generated code that ensures data integrity when the block transfers data. If you select this check box and the transfer is nondeterministic (see **Ensure deterministic data transfer**), depending on the priority of input rate and output rate, the generated code uses a proper algorithm using single or multiple buffers to protect data integrity during data transfer.

Otherwise, the Rate Transition block is either reduced or generates code using a copy operation to affect the data transfer. This unprotected mode consumes less memory. But the copy operation is also interruptible, which can lead to loss of data integrity during data transfers. Select this check box if you want the generated code to operate with maximum responsiveness (that is, nondeterministically) and data integrity. For more information, see “Rate Transition Block Options” (Simulink Coder).

Programmatic Use
Block Parameter: `Integrity`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Ensure deterministic data transfer (maximum delay)` — Ensure deterministic data transfer
on (default) | `off`

Selecting this check box results in generated code that transfers data at the sample rate of the slower block, that is, deterministically. If you do not select this check box, data transfers occur when new data is available from the source block and the receiving block is ready to receive the data. You avoid transfer delays, thus ensuring that the system operates with maximum responsiveness. However, transfers can occur unpredictably, which is undesirable in some applications. For more information, see “Rate Transition Block Options” (Simulink Coder).

Programmatic Use
Block Parameter: `Deterministic`
Type: character vector
Values: `'off' | 'on'`
Default: `'on'`

`Initial conditions` — Initial conditions

`0` (default) | scalar | vector | matrix | N-D array

This parameter applies only to slow-to-fast transitions. It specifies the initial output of the Rate Transition block at the beginning of a transition when there is no output from the slow block connected to the input of the Rate Transition block. Simulink does not allow the initial output of this block to be `Inf` or `NaN`. The value you specify must be a scalar, or have the same dimensions as the input signal.

Programmatic Use
Block Parameter: `InitialCondition`
Type: character vector
Values: finite scalar
Default: `'0'`

`Output port sample time options` — Mode for specifying output port sample time

`Specify` (default) | `Inherit` | `Multiple of input port sample time`

Specifies a mode for setting the output port sample time. The options are:

- `Specify` — Allows you to use the **Output port sample time** parameter to specify the output rate to which the Rate Transition block converts its input rate.
- `Inherit` — Specifies that the Rate Transition block inherits an output rate from the block to which the output port is connected.
- `Multiple of input port sample time` — Allows you to use the **Sample time multiple (>0)** parameter to specify the Rate Transition block output rate as a multiple of its input rate.

If you select `Inherit` and all blocks connected to the output port also inherit sample time, the fastest sample time in the model applies.

Programmatic Use
Block Parameter: `OutPortSampleTimeOpt`
Type: character vector
Values: `'Specify' | 'Inherit' | 'Multiple of input port sample time'`
Default: `'Specify'`

`Output port sample time` — Output rate

`-1` (default) | scalar | vector

Enter a value that specifies the output rate to which the block converts its input rate. The default value (`-1`) specifies that the Rate Transition block inherits the output rate from the block to which the output port is connected. See “Specify Sample Time” in the Simulink documentation for information on how to specify the output rate.

Dependencies

To enable this parameter, set **Output port sample time options** to `Specify`.

Programmatic Use
Block Parameter: `OutPortSampleTime`
Type: character vector
Values: scalar | vector
Default: `'-1'`

`Sample time multiple(>0)` — Sample time multiple

`1` (default) | positive scalar

Enter a positive value that specifies the output rate as a multiple of the input port sample time. The default value (`1`) specifies that the output rate is the same as the input rate. A value of `0.5` specifies that the output rate is half of the input rate. A value of `2` specifies that the output rate is twice the input rate.

Dependencies

To enable this parameter, set **Output port sample time options** to `Multiple of input port sample time`.

Programmatic Use
Block Parameter: `OutPortSampleTimeMultiple`
Type: character vector

Values: scalar
Default: `'1'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

- Generated code relies on `memcpy` or `memset` functions (`string.h`) under certain conditions
- Cannot use inside a triggered subsystem hierarchy

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information about HDL code generation, see Rate Transition.

Fixed-Point Conversion

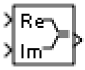
Real-Imag to Complex

Convert real and/or imaginary inputs to complex signal
Library: Simulink / Math Operations



Description

The Real-Imag to Complex block converts real and/or imaginary inputs to a complex-valued output signal.

The inputs can both be arrays (vectors or matrices) of equal dimensions, or one input can be an array and the other a scalar. If the block has an array input, the output is a complex array of the same dimensions. The elements of the real input map to the real parts of the corresponding complex output elements. The imaginary input similarly maps to the imaginary parts of the complex output signals. If one input is a scalar, it maps to the corresponding component (real or imaginary) of all the complex output signals.

Ports

Input

Re — Real part of complex output
scalar | vector | matrix

Real value to be converted to complex-valued output signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `bus`

`Im` — Imaginary part of complex output
scalar | vector | matrix

Imaginary value to be converted to complex-valued output signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `bus`

`Port_1` — Real or imaginary part of complex output
scalar | vector | matrix

Real or imaginary value to convert to complex output signal, specified as a finite scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point` | `bus`

Output

`Port_1` — Complex signal
scalar | vector | matrix

Complex signal, formed from real and imaginary values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

`Input` — Real, imaginary, or both
`Real` (default) | `Imag` | `Real and imag`

Specify the type of input: a real input, an imaginary input, or both.

Programmatic Use
Block Parameter: `Input`
Type: character vector
Values: `'Real and imag' | 'Real' | 'Imag'`
Default: `'Real and imag'`

`Imag part` — Imaginary part of complex output
`0` (default) | finite scalar, vector, or matrix

Specify the imaginary value to use when converting the input to a complex-valued output signal.

Dependencies

To enable this parameter, set **Input** to `Real`.

Programmatic Use
Block Parameter: `ConstantPart`
Type: character vector
Values: imaginary value
Default: `'0'`

`Real part` — Real part of complex output

`0` (default) | finite scalar, vector, or matrix

Specify the constant real value to use when converting the input to a complex-valued output signal.

Dependencies

To enable this parameter, set **Input** to `Imag`.

Programmatic Use
Block Parameter: `ConstantPart`
Type: character vector
Values: finite, real-valued scalar, vector, or matrix
Default: `'0'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar

Default: `'-1'`

Block Characteristics

Data Types	`double` | `single` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

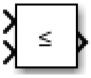
"Complex Signals"

Introduced before R2006a

Relational Operator

Perform specified relational operation on inputs

Library: Simulink / Commonly Used Blocks
Simulink / Logic and Bit Operations



Description

The Relational Operator performs the specified relational operation on the input. The value you choose for the **Relational operator** parameter determines whether the block accepts one or two input signals.

Two-Input Mode

By default, the Relational Operator block compares two inputs using the **Relational operator** parameter that you specify. The first input corresponds to the top input port and the second input to the bottom input port. (See "Port Location After Rotating or Flipping" for a description of the port order for various block orientations.)

You can specify one of the following operations in two-input mode:

Operation	Description
==	TRUE if the first input is equal to the second input
~=	TRUE if the first input is not equal to the second input
<	TRUE if the first input is less than the second input
<=	TRUE if the first input is less than or equal to the second input
>=	TRUE if the first input is greater than or equal to the second input
>	TRUE if the first input is greater than the second input

You can specify inputs as scalars, arrays, or a combination of a scalar and an array.

For...	The output is...
Scalar inputs	A scalar

For...	The output is...
Array inputs	An array of the same dimensions, where each element is the result of an element-by-element comparison of the input arrays
Mixed scalar and array inputs	An array, where each element is the result of a comparison between the scalar and the corresponding array element

The input with the smaller positive range is converted to the data type of the other input offline using round-to-nearest and saturation. This conversion occurs before the comparison.

You can specify the output data type using the **Output data type** parameter. The output equals `1` for true and `0` for false.

Tip Select an output data type that represents zero exactly. Data types that satisfy this condition include signed and unsigned integers and any floating-point data type.

One-Input Mode

When you select one of the following operations for **Relational operator**, the block switches to one-input mode.

Operation	Description
`isInf`	TRUE if the input is `Inf`
`isNaN`	TRUE if the input is `NaN`
`isFinite`	TRUE if the input is finite

For an input that is not floating point, the block produces the following output.

Data Type	Operation	Block Output
• Fixed point • Boolean • Built-in integer	`isInf`	FALSE
	`isNaN`	FALSE
	`isFinite`	TRUE

Rules for Data Type Propagation

The following rules apply for data type propagation when your block has one or more input ports with unspecified data types.

When the block is in...	And...	The block uses...
Two-input mode	Both input ports have unspecified data types	`double` as the default data type for both inputs
	One input port has an unspecified data type	The data type from the specified input port as the default data type of the other port
One-input mode	The input port has an unspecified data type	`double` as the default data type for the input

Ports

Input

`Port_1` — First input signal

scalar | vector | matrix

First input signal, specified as a scalar, vector, or matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

`Port_2` — Second input signal

scalar | vector | matrix

Second input signal, specified as a scalar, vector, or matrix.

Dependencies

To enable this port, set the **Relational operator** to ==, ~=, <, <=, >=, or >.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Output

`Port_1` — Output signal

scalar | vector | matrix

Output signal, consisting of zeros and ones, with the same dimensions as the input. You control the output data type with the **Output data type** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

Main

`Relational operator` — Relational operator

<= (default) | ~= | == | < | >= | > | `isInf` | `isNaN` | `isFinite`

Specify the operation for comparing two inputs or determining the signal type of one input.

- == — TRUE if the first input is equal to the second input
- ~= — TRUE if the first input is not equal to the second input
- < — TRUE if the first input is less than the second input
- <= — TRUE if the first input is less than or equal to the second input
- >= — TRUE if the first input is greater than or equal to the second input
- > — TRUE if the first input is greater than the second input
- `isInf` — TRUE if the input is `Inf`
- `isNaN` — TRUE if the input is `NaN`
- `isFinite` — TRUE if the input is finite

Programmatic Use

Block Parameter: `Operator`
Type: character vector
Values: `'==' | '~=' | '<' | '<=' | '>=' | '>' | 'isInf' | 'isNaN' | 'isFinite'`

Default: `'<='`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | `off`

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use
Parameter:`ZeroCross`
Type: character vector, string
Values: `'on'` | `'off'`
Default: `'on'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Data Type

`Require all inputs to have the same data type` — Require all inputs to have same data type

`off` (default) | `on`

To require that all block inputs have the same data type, select this check box. When you clear this check box, the inputs can have different data types.

Dependencies

This check box is not available when you set **Relational operator** to `isInf`, `isNaN`, or `isFinite` because in those modes, the block only has one input port.

Programmatic Use

Block Parameter: `InputSameDT`
Type: character vector
Values: `'off' | 'on`
Default: `'off'`

`Output data type` — Output data type

`boolean` (default) | `Inherit: Logical (see Configuration Parameters: Optimization)` | `fixdt(1,16)` | `<data type expression>`

Specify the output data type. When you select:

- `boolean` — the block output has data type `boolean`.
- `Inherit: Logical (see Configuration Parameters: Optimization)` — the block uses the **Implement logic signals as Boolean data** configuration parameter (see “Implement logic signals as Boolean data (vs. double)”) to specify the output data type.

  Note This option supports models created before the `boolean` option was available. Use one of the other options, preferably `boolean`, for new models.
- `fixdt(1,16)` — the block output has the specified fixed-point data type `fixdt(1,16)`.

  Tip Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.
- `<data type expression>` — the block output has the data type you specify as a data type expression, for example, `Simulink.NumericType`.

  Tip To enter a built-in data type (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, or `uint32`), enclose the expression in single quotes. For example, enter `'double'` instead of `double`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Logical (see Configuration Parameters: Optimization)' | 'boolean' | 'fixdt(1,16)' | '<data type expression>'`
Default: `'boolean'`

`Integer rounding mode` — Rounding mode for fixed-point operations

`Simplest` (default) | `Convergent` | `Floor` | `Nearest` | `Round` | `Ceiling` | `Zero`

Specify the rounding mode for fixed-point operations. You can select:

`Ceiling`

Rounds positive and negative numbers toward positive infinity. Equivalent to the MATLAB`ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer`convergent` function.

`Floor`

Rounds positive and negative numbers toward negative infinity. Equivalent to the MATLAB`floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer`nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer`round` function.

`Simplest`

Chooses between rounding toward floor and rounding toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB`fix` function.

For more information, see “Rounding” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling' | 'Convergent' | 'Floor' | 'Nearest' | 'Round' | 'Simplest' | 'Zero'`
Default: `'Simplest'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated`
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`Yes`

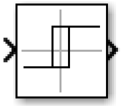
Logical Operator

Introduced before R2006a

Relay

Switch output between two constants
Library: Simulink / Discontinuities



Description

The output for the Relay block switches between two specified values. When the relay is on, it remains on until the input drops below the value of the **Switch off point** parameter. When the relay is off, it remains off until the input exceeds the value of the **Switch on point** parameter. The block accepts one input and generates one output.

Note When the initial input falls *between* the **Switch off point** and **Switch on point** values, the initial output is the value when the relay is off.

Ports

Input

`Port_1` — Input signal
scalar

The input signal that switches the relay on or off.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Output

`Port_1` — Output signal
scalar

The output signal switches between two values determined by the parameters **Output when on** and **Output when off**.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

`Switch on point` — Input value which switches the relay on

`'eps'` (default) | `scalar`

When the input crosses this threshold, the relay switches on. The **Switch on point** value must be greater than or equal to the **Switch off point**. Specifying a **Switch on point** value greater than the **Switch off point** models hysteresis, whereas specifying equal values models a switch with a threshold at that value.

The **Switch on point** parameter is converted to the input data type offline using round-to-nearest and saturation methods.

Programmatic Use
Block Parameter: `OnSwitchValue`
Type: character vector
Values: scalar
Default: `'eps'`

`Switch off point` — Input value which switches the relay off

`'eps'` (default) | `scalar`

When the input crosses this threshold the relay switches off. The value of **Switch off point** must be less than or equal to **Switch on point**. The **Switch off point** parameter is converted to the input data type offline using round-to-nearest and saturation.

Programmatic Use
Block Parameter: `OffSwitchValue`
Type: character vector
Values: scalar
Default: `'eps'`

`Output when on` — Output value when the relay is on

1 (default) | `scalar`

The output value when the relay is on.

Programmatic Use
Block Parameter: `OnOutputValue`
Type: character vector
Values: scalar
Default: `'1'`

`Output when off` — Output value when the relay is off

`0` (default) | `scalar`

The output value when the relay is off.

Programmatic Use
Block Parameter: `OffOutputValue`
Type: character vector
Values: scalar
Default: `'0'`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see "Sample- and Frame-Based Concepts" (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error

Input Signal u	Input Processing Mode	Block Works?
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use
Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`

Type: character vector
Values: scalar
Default: `'-1'`

`Output minimum` — Minimum output value for range checking

[ ] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.

- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Data type of output signal

`Inherit: All ports same datatype` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `int32` | `uint32` | `fixdt(1,16,2^0,0)` | `<data type expression>` | ...

Specify the output data type. You can set it to:

- A rule that inherits a data type, for example, `Inherit: Inherit via back propagation`
- The name of a built-in data type, for example, `single`
- The name of a data type object, for example, a `Simulink.NumericType` object
- An expression that evaluates to a data type, for example, `fixdt(1,16,0)`
- An enumerated data type, for example, `Enum:BasicColors`

  In this case, **Output when on** and **Output when off** must be of the same enumerated type.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the **Output data type** parameter.

See “Control Signal Data Types” in *Simulink User's Guide* for more information.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Same as input'`, `'Inherit: Inherit via back propagation'`, `'single'`, `'int8'`, `'uint8'`, `int16`, `'uint16'`, `'int32'`, `'uint32'`, `fixdt(1,16,0)`, `fixdt(1,16,2^0,0)`, `fixdt(1,16,2^0,0)`. `'<data type expression>'`
Default: `'Inherit: Same as input'`

`Lock data type settings against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types
`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the data types you specify on this block. For more information, see “Lock the Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For more information on HDL code generation, see Relay.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

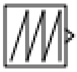
Backlash | Saturation

Introduced before R2006a

Repeating Sequence

Generate arbitrarily shaped periodic signal
Library: Simulink / Sources



Description

The Repeating Sequence block outputs a periodic scalar signal having a waveform that you specify using the **Time values** and **Output values** parameters. The **Time values** parameter specifies a vector of output times. The **Output values** parameter specifies a vector of signal amplitudes at the corresponding output times. Together, the two parameters specify a sampling of the output waveform at points measured from the beginning of the interval over which the waveform repeats (the period of the signal).

By default, both parameters are `[0 2]`. These default settings specify a sawtooth waveform that repeats every `2` seconds from the start of the simulation and has a maximum amplitude of `2`.

Ports

Output

`Port_1` — Periodic output signal
scalar

Output signal specified by the **Time values** and **Output values** parameters to create a periodic scalar signal.

Data Types: `double`

Parameters

`Time values` — Vector of output times

`[0 2]` (default) | vector

Vector of strictly monotonically increasing time values. The period of the generated waveform is the difference of the last and first values of this parameter.

Programmatic Use

Block Parameter: `rep_seq_t`
Type: character vector
Values: vector
Default: `[0 2]`

`Output values` — Vector of output values

`[0 2]` (default) | vector

Vector of output values that specify the output waveform. Each element corresponds to the time value in the **Time values**parameter.

Programmatic Use

Block Parameter: `rep_seq_y`
Type: character vector
Values: vector
Default: `[0 2]`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

Algorithms

The block sets the input period as the difference between the first and last value of the **Time values** parameter. The output at any time `t` is the output at time `t = t-n*period`, where `n` is an integer. The sequence repeats at `t = n*period`. The block uses linear interpolation to compute the value of the waveform between the output times that you specify.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production code.

Consider using Repeating Sequence Stair or Repeating Sequence Interpolated blocks for code generation.

See Also

Repeating Sequence Interpolated | Repeating Sequence Stair

Introduced before R2006a

Repeating Sequence Interpolated

Output discrete-time sequence and repeat, interpolating between data points
Library: Simulink / Sources

Description

The Repeating Sequence Interpolated block outputs a periodic discrete-time sequence based on the values in **Vector of time values** and **Vector of output values** parameters. Between data points, the block uses the method you specify for the **Lookup Method** parameter to determine the output.

Ports

Output

`Port_1` — Periodic output signal
scalar

Output signal generated based on the values in the **Vector of time values** and **Vector of output values** parameters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

Parameters

Main

`Vector of output values` — Vector of output values

`[3 1 4 2 1].'` (default) | vector

Vector of output values that specify the output waveform. Each element corresponds to the time value in the **Time values**parameter.

Programmatic Use

Block Parameter: `OutValues`
Type: character vector
Values: vector
Default: `[3 1 4 2 1].'`

`Vector of time values` — Vector of time values

`[0 0.1 0.5 0.6 1].'` (default) | vector

Specify the column vector containing time values. The time values must be strictly increasing, and the vector must have the same size as the vector of output values.

Programmatic Use

Block Parameter: `TimeValues`
Type: character vector
Values: vector
Default: `[0 0.1 0.5 0.6 1].'`

`Lookup Method` — Lookup method for output

`Interpolation-Use End Values` (default) | `Use Input Nearest` | `Use Input Below` | `Use Input Above`

Specify the lookup method to determine the output between data points.

Programmatic Use

Block Parameter: `LookUpMeth`
Type: character vector
Values: `'Interpolation-Use End Values'` | `'Use Input Nearest'` | `Use Input Below` | `Use Input Above`
Default: `'Interpolation-Use End Values'`

`Sample time` — Time interval between samples

`0.01` (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” for more information.

Programmatic Use
Block Parameter: `tsamp`
Type: character vector
Values: scalar
Default: `'0.01'`

Signal Attributes

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar

Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[ ]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see "Specify Minimum and Maximum Values for Block Parameters") for some blocks.
- Simulation range checking (see "Signal Ranges" and "Enable Simulation Range Checking").
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see "Optimize using the specified minimum and maximum values" (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`double` (default) | `Inherit: Inherit via back propagation` | `single` | `int8` | `int32` | `uint32` | `fixdt(1,16,2^0,0)` | `<data type expression>` | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector

Values: , 'Inherit: Inherit via back propagation', 'single', 'int8', 'uint8', int16, 'uint16', 'int32', 'uint32', fixdt(1,16,0), fixdt(1,16,2^0,0), fixdt(1,16,2^0,0). '<data type expression>'
Default: 'Double'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding data types
off (default) | on

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see "Use Lock Output Data Type Setting" (Fixed-Point Designer).

Programmatic Use
Block Parameter: LockScale
Type: character vector
Values: 'off' | 'on'
Default: 'off'

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Cannot be used inside a triggered subsystem hierarchy.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

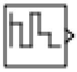
Repeating Sequence | Repeating Sequence Stair

Introduced before R2006a

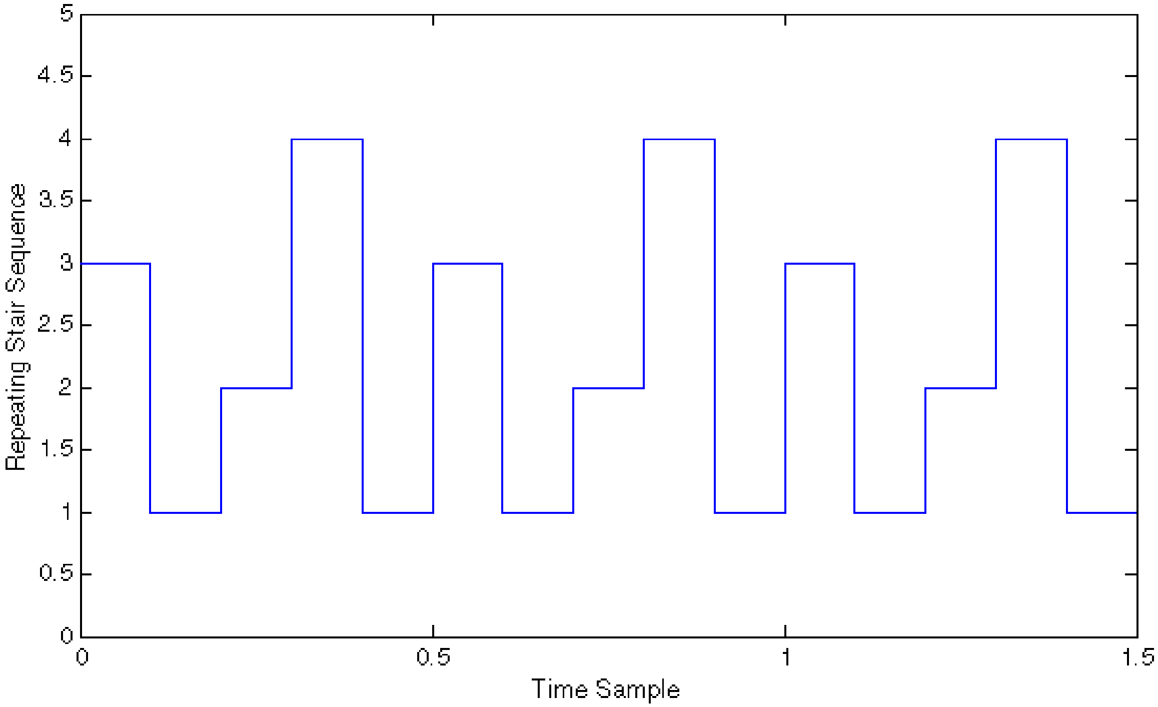
Repeating Sequence Stair

Output and repeat discrete time sequence
Library: Simulink / Sources



Description

The Repeating Sequence Stair block outputs and repeats a stair sequence that you specify with the **Vector of output values** parameter. For example, you can specify the vector as `[3 1 2 4 1]'`. A value in **Vector of output values** is output at each time interval, and then the sequence repeats.



Ports

Output

`Port_1` — Repeating discrete output signal
scalar

Output signal generated based on the values in the **Vector of time values** and **Sample time** parameters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated`

Parameters

Main

`Vector of output values` — Vector of output values

`[3 1 4 2 1].'` (default) | vector

Specify the vector containing values of the repeating stair sequence.

Programmatic Use
Block Parameter: `OutValues`
Type: character vector
Values: vector
Default: `[3 1 4 2 1].'`

`Sample time` — Time interval between samples

`-1` (default) | scalar

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. See “Specify Sample Time” for more information.

Programmatic Use
Block Parameter: `tsamp`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

`Output minimum` — Minimum output value for range checking

`[ ]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).

- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use

Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`double` (default) | `Inherit: Inherit via back propagation` | `single` | `int8` | `int32` | `uint32` | `fixdt(1,16,2^0,0)` | `<data type expression>` | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

Programmatic Use

Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Inherit via back propagation'` | `'single'` | `'int8'` | `'uint8'` | `int16` | `'uint16'` | `'int32'` | `'uint32'` | `fixdt(1,16,0)` | `fixdt(1,16,2^0,0)` | `fixdt(1,16,2^0,0)` | `'<data type expression>'`
Default: `'Double'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding data types

`off` (default) | `on`

Select to lock the output data type setting of this block against changes by the Fixed-Point Tool and the Fixed-Point Advisor. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use

Block Parameter: `LockScale`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

PLC Code Generation

Generate Structured Text code using Simulink® PLC Coder™.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Repeating Sequence | Repeating Sequence Interpolated

Introduced before R2006a

Reset

Add reset port to subsystem
Library: Ports & Subsystems

Description

A Reset block at the root level of a Subsystem block adds a control port to the block. When a reset trigger event occurs on the signal connected to the port, the block states of the subsystem are reset to their initial condition.

Parameters

`Reset trigger type` — Select the type of trigger event

`level` (default) | `rising` | `falling` | `either` | `level hold`

Select the type of trigger event that resets the subsystem block states.

`level`

Reset the block states when the reset signal is nonzero at the current time step or changes from nonzero at the previous time step to zero at the current time step.

`rising`

Reset the block states when the reset signal rises from a zero to a positive value or from a negative to a positive value.

`falling`

Reset the block states when the reset signal falls from a positive value to zero or from a positive to a negative value.

`either`

Reset the block states when the reset signal changes from a zero to a nonzero value or changes sign.

`level hold`

Reset the block states when the reset signal is nonzero at the current time step.

Programmatic Use

Block Parameter: `ResetTriggerType`
Type: character vector
Value: `'level'` | `'rising'` | `'falling'` | `'either'` | `'level hold'`
Default: `'level'`

`Propagate sizes of variable-size signals` — Select when to propagate a variable-size signal

`During execution` (default) | `Only when enabling`

Select when to propagate a variable-size signal.

`During execution`

Propagate variable-size signals at each time step.

`Only when resetting`

Propagate variable-size signals when resetting a Subsystem block containing a Reset port block. When you select this option, sample time must be periodic.

Programmatic Use

Block Parameter: `PropagateVarSize`
Type: character vector
Value: `'During execution'` | `'Only when resetting'`
Default: `'During execution'`

`Enable zero-crossing detection` — Control zero-crossing detection

on (default) | off

Control zero-crossing detection.

☑ on

Detect zero crossings.

□ off

Do not detect zero crossings.

Programmatic Use

Block Parameter: `ZeroCross`
Type: character vector
Value: `'on'` | `'off'`
Default: `'on'`

Blocks

Reset | Resettable Subsystem | Subsystem

Topics

"Use Resettable Subsystems"
"Simulink Block Support for Variable-Size Signals"

Introduced in R2015a

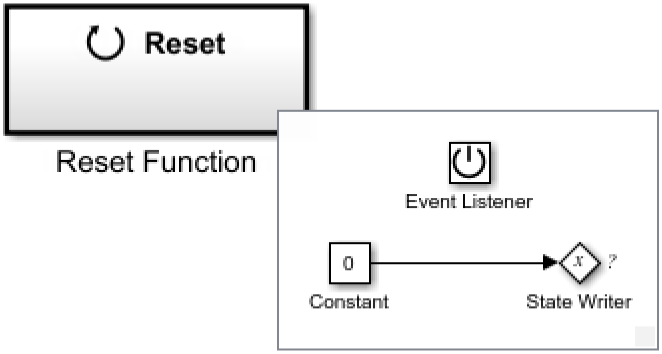
Reset Function

Executes contents on a model reset event

Library: Simulink / User-Defined Functions

Description

The Reset Function block is a pre-configured subsystem block that executes on a model reset event. By default, the Reset Function block includes an Event Listener block with **Event** set to `Reset`, a Constant block with **Constant value** set to `0`, and a State Writer block.



Replace the Constant block with source blocks that generate the state value for the State Writer block.

For a list of unsupported blocks and features, see “Initialize, Reset, and Terminate Function Limitations”.

A model can potentially have multiple Reset Function blocks with each block having a different **Event name**. Each of these reset events appear in the generated code as a different function.

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a] | string[a]
Direct Feedthrough	No
Multidimensional Signals	Yes[a]
Variable-Size Signals	No
Zero-Crossing Detection	No

[a] Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

See Also

Event Listener | Initialize Function | State Reader | State Writer | Terminate Function

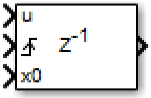
Topics

“Customize Initialize, Reset, and Terminate Functions”
“Create Test Harness to Generate Function Calls”
“Generate Code That Responds to Initialize, Reset, and Terminate Events” (Simulink Coder)

Resettable Delay

Delay input signal by variable sample period and reset with external signal

Library: Simulink / Discrete



Description

The Resettable Delay block is a variant of the Delay block that has the source of the initial condition set to `Input port` and the external reset algorithm set to `Rising`, by default.

Ports

Input

u — Data input signal
scalar | vector

Input data signal delayed according to parameters settings.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

d — Delay length
scalar

Delay length specified as inherited from an input port. Enabled when you select the **Delay length: Source** parameter as `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Enable — External enable signal
scalar

Enable signal that enables or disables execution of the block. To create this port, select the **Show enable port** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`External reset` — External reset signal

scalar

External signal that resets execution of the block to the initial condition. To create this port, select the **External reset** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point`

`x0` — Initial condition

scalar | vector

Initial condition specified as inherited from an input port. Enabled when you select the **Initial Condition: Source** parameter as `Input port`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal

scalar | vector

Output signal that is the input signal delayed by the length of time specified by the parameter **Delay length**. The initial value of the output signal depends on several conditions. See “Initial Block Output” on page 1-340.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

Main

`Delay length` — Delay length

`Dialog` (default) | `Input port`

Specify whether to enter the delay length directly on the dialog box (fixed delay) or to inherit the delay from an input port (variable delay).

- If you set **Source** to `Dialog`, enter the delay length in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies a delay length for the `d` input port. You can also specify its maximum value by specifying the parameter **Upper limit**.

Specify the scalar delay length as a real, non-negative integer. An out-of-range or non-integer value in the dialog box (fixed delay) returns an error. An out-of-range value from an input port (variable delay) casts it into the range. A non-integer value from an input port (variable delay) truncates it to the integer.

Programmatic Use
Block Parameter: `DelayLengthSource`
Type: character vector
Values: `'Dialog'` | `'Input port'` |
Default: `'Dialog'`
Block Parameter: `DelayLength`
Type: character vector
Values: scalar
Default: `'2'`
Block Parameter: `DelayLengthUpperLimit`
Type: character vector
Values: scalar
Default: `'100'`

`Initial condition` — Initial condition

`Input port` (default) | `Dialog`

Specify whether to enter the initial condition directly on the dialog box or to inherit the initial condition from an input port.

- If you set **Source** to `Dialog`, enter the initial condition in the edit field under **Value**.
- If you set **Source** to `Input port`, verify that an upstream signal supplies an initial condition for the `x0` input port.

Simulink converts offline the data type of **Initial condition** to the data type of the input signal `u` using a round-to-nearest operation and saturation.

Note When **State name must resolve to Simulink signal object** is selected on the **State Attributes** pane, the block copies the initial value of the signal object to the **Initial condition** parameter. However, when the source for **Initial condition** is `Input port`, the block ignores the initial value of the signal object.

Programmatic Use
Block Parameter: `InitialConditionSource`
Type: character vector
Values: `'Dialog'` | `'Input port'` |
Default: `'Input Port'`
Block Parameter: `InitialCondition`
Type: character vector
Values: scalar
Default: `''`

`Input processing` — Specify sample- or frame-based processing

`Elements as channels (sample based)` (default) | `Columns as channels (frame based)`

Specify whether the block performs sample- or frame-based processing:

- `Columns as channels (frame based)` — Treat each column of the input as a separate channel (frame-based processing).

  Note Frame-based processing requires a DSP System Toolbox license.

  For more information, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

- `Elements as channels (sample based)` — Treat each element of the input as a separate channel (sample-based processing).

Use **Input processing** to specify whether the block performs sample- or frame-based processing. The block accepts frame-based signals for the input `u`. All other input signals must be sample-based.

Input Signal u	Input Processing Mode	Block Works?
Sample based	Sample based	Yes
Frame based		No, produces an error
Sample based	Frame based	Yes
Frame based		Yes
Sample based	Inherited	Yes
Frame based		Yes

For more information about these two processing modes, see “Sample- and Frame-Based Concepts” (DSP System Toolbox).

Programmatic Use
Block Parameter: `InputProcessing`
Type: character vector
Values: `'Columns as channels (frame based)'` | `'Elements as channels (sample based)'`
Default: `'Elements as channels (sample based)'`

`Use circular buffer for state` — Circular buffer for storing state

`off` (default) | `on`

Select to use a circular buffer for storing the state in simulation and code generation. Otherwise, an array buffer stores the state.

Using a circular buffer can improve execution speed when the delay length is large. For an array buffer, the number of copy operations increases as the delay length goes up. For a circular buffer, the number of copy operations is constant for increasing delay length.

If one of the following conditions is true, an array buffer always stores the state because a circular buffer does not improve execution speed:

- For sample-based signals, the delay length is 1.
- For frame-based signals, the delay length is no larger than the frame size.

Programmatic Use

Block Parameter: `UseCircularBuffer`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Prevent direct feedthrough` — Prevent direct feedthrough

`off` (default) | `on`

Select to increase the delay length from zero to the lower limit for the **Input processing** mode:

- For sample-based signals, increase the minimum delay length to 1.
- For frame-based signals, increase the minimum delay length to the frame length.

Selecting this check box prevents direct feedthrough from the input port, `u`, to the output port. However, this check box cannot prevent direct feedthrough from the initial condition port, `x0`, to the output port.

Dependency

To enable this parameter, set **Delay length: Source** to `Input port`.

Programmatic Use

Block Parameter: `PreventDirectFeedthrough`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Remove delay length check in generated code` — Remove delay length out-of-range check

`off` (default) | `on`

Select to remove code that checks for out-of-range delay length.

Check Box	Result	When to Use
Selected	Generated code does not include conditional statements to check for out-of-range delay length.	For code efficiency

Check Box	Result	When to Use
Cleared	Generated code includes conditional statements to check for out-of-range delay length.	For safety-critical applications

Dependency

To enable this parameter, set **Delay length: Source** to `Input port`.

Programmatic Use
Block Parameter: `RemoveDelayLengthCheckInGeneratedCode`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'`

`Diagnostic for delay length` — Diagnostic checks for delay length

`None` (default) | `Warning` | `Error`

Specify whether to produce a warning or error when the input `d` is less than the lower limit or greater than the **Delay length: Upper limit**. The lower limit depends on the setting for **Prevent direct feedthrough**.

- If the check box is cleared, the lower limit is zero.
- If the check box is selected, the lower limit is 1 for sample-based signals and frame length for frame-based signals.

Options for the diagnostic include:

- `None` — Simulink software takes no action.
- `Warning` — Simulink software displays a warning and continues the simulation.
- `Error` — Simulink software terminates the simulation and displays an error.

Dependency

To enable this parameter, set **Delay length: Source** to `Input port`.

Programmatic Use
Block Parameter: `DiagnosticForDelayLength`
Type: character vector
Values: `'None'` | `'Warning'` | `'Error'`

Default: `'None'`

`Show enable port` — Create enable port

`off` (default) | `on`

Select to control execution of this block with an enable port. The block is considered enabled when the input to this port is nonzero, and is disabled when the input is `0`. The value of the input is checked at the same time step as the block execution.

Programmatic Use

Block Parameter: `ShowEnablePort`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`External reset` — External state reset

`Rising` (default) | `None` | `Falling` | `Either` | `Level` | `Level hold`

Specify the trigger event to use to reset the states to the initial conditions.

Reset Mode	Behavior
`None`	No reset.
`Rising`	Reset on a rising edge.
`Falling`	Reset on a falling edge.
`Either`	Reset on either a rising or falling edge.
`Level`	Reset in either of these cases: • when the reset signal is nonzero at the current time step • when the reset signal value changes from nonzero at the previous time step to zero at the current time step
`Level hold`	Reset when the reset signal is nonzero at the current time step

The reset signal must be a scalar of type `single`, `double`, `boolean`, or `integer`. Fixed point data types, except for `ufix1`, are not supported.

Programmatic Use
Block Parameter: `ExternalReset`
Type: character vector
Values: `'None'` | `'Rising'` | `'Falling'` | `'Either'` | `'Level'` | `'Level hold'`
Default: `'Rising'`

`Sample time (-1 for inherited)` — Discrete interval between sample time hits

`-1` (default) | `scalar`

Specify the time interval between samples. To inherit the sample time, set this parameter to `-1`. This block supports discrete sample time, but not continuous sample time.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Value: real scalar
Default: `'-1'`

State Attributes

`State name` — Unique name for block state

`''` (default) | alphanumeric string

Use this parameter to assign a unique name to the block state. The default is `' '`. When this field is blank, no name is assigned. When using this parameter, remember these considerations:

- A valid identifier starts with an alphabetic or underscore character, followed by alphanumeric or underscore characters.
- The state name applies only to the selected block.

This parameter enables **State name must resolve to Simulink signal object** when you click **Apply**.

For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

Programmatic Use
Block Parameter: `StateName`
Type: character vector

Values: unique name
Default: `''`

`State name must resolve to Simulink signal object` — Require state name resolve to a signal object

`off` (default) | `on`

Select this check box to require that the state name resolves to a Simulink signal object.

Dependencies

To enable this parameter, specify a value for **State name**. This parameter appears only if you set the model configuration parameter **Signal resolution** to a value other than `None`.

Selecting this check box disables **Code generation storage class**.

Programmatic Use
Block Parameter: `StateMustResolveToSignalObject`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Signal object class` — Custom storage class package name

`Simulink.Signal` (default) | `<StorageClass.PackageName>`

Choose a custom storage class package by selecting a signal object class that the target package defines. For example, to apply custom storage classes from the built-in package `mpt`, select `mpt.Signal`. Unless you use an ERT-based code generation target with Embedded Coder, custom storage classes do not affect the generated code.

If the class that you want does not appear in the list, select `Customize class lists`. For instructions, see “Target Class Does Not Appear in List of Signal Object Classes” (Embedded Coder).

For information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder). For information about custom storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder).

Programmatic Use
Block Parameter: `StateSignalObject`
Type: character vector
Values: `'Simulink.Signal' | '<StorageClass.PackageName>'`

Default: 'Simulink.Signal'

Code generation storage class — State storage class for code generation
Auto (default) | Model default | ExportedGlobal | ImportedExtern | ImportedExternPointer | BitField (Custom) | Model default | ExportToFile (Custom) | ImportFromFile (Custom) | FileScope (Custom) | AutoScope (Custom) | Struct (Custom) | GetSet (Custom) | Reusable (Custom)

Select state storage class for code generation.

- Auto is the appropriate storage class for states that you do not need to interface to external code.
- *StorageClass* applies the storage class or custom storage class that you select from the list. For information about storage classes, see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder). For information about custom storage classes, see "Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements" (Embedded Coder).

Use **Signal object class** to select custom storage classes from a package other than Simulink.

Dependencies

To enable this parameter, specify a value for **State name**.

Programmatic Use
Block Parameter: StateStorageClass
Type: character vector
Values: 'Auto' | 'SimulinkGlobal' | 'ExportedGlobal' | 'ImportedExtern' | 'ImportedExternPointer' | 'Custom' | ...
Default: 'Auto'

Block Characteristics

Data Types	double | single | Boolean | base integer | fixed point | enumerated | bus
Direct Feedthrough	Yes

Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Consider using the Model Discretizer to map these continuous blocks into discrete equivalents that support code generation. From a model, select **Analysis > Control Design > Model Discretizer**.

Not reommended for production code.

HDL Code Generation

Generate Verilog and VHDL code for FPGA and ASIC designs using HDL Coder™.

For information about HDL code generation, see Delay.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

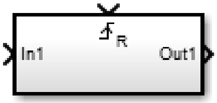
Topics

"Using Enabled Subsystems"

Introduced in R2012b

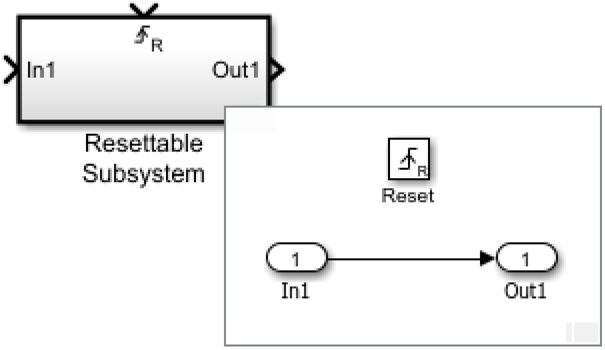
Resettable Subsystem

Subsystem whose block states reset with external trigger
Library: Simulink / Ports & Subsystems



Description

The Resettable Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that resets the block states each time the control signal has a trigger event.



Ports

Input

In — Signal input to a subsystem block
scalar | vector | matrix

Placing an Inport block in a Subsystem block adds an external input port to the block. The port label matches the name of the Inport block.

Use Inport blocks to get signals from the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Reset — Control signal input to a subsystem block
scalar | vector | matrix

Placing a Reset block in a Subsystem block adds an external input port to the block and changes the block to a Resettable Subsystem block.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point

Output

Out — Signal output from a subsystem
scalar | vector | matrix

Placing an Outport block in a Subsystem block adds an output port from the block. The port label on the Subsystem block is the name of the Outport block.

Use Outport blocks to send signals to the local environment.

Data Types: single | double | int8 | int16 | int32 | uint8 | uint16 | uint32 | Boolean | fixed point | enumerated | bus

Block Characteristics

Data Types	double[a] | single[a] | Boolean[a] | base integer[a] | fixed point[a] | enumerated[a] | bus[a] | string[a]
Direct Feedthrough	No
Multidimensional Signals	Yes[a]
Variable-Size Signals	Yes[a]

Zero-Crossing Detection	`No`

a. Actual data type or capability support depends on block implementation.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Actual code generation support depends on block implementation.

Fixed-Point Conversion

Convert floating-point algorithms to fixed point using Fixed-Point Designer™.

Actual data type support depends on block implementation.

Blocks

Reset | Subsystem

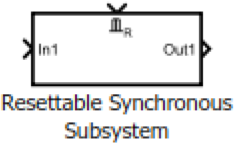
Topics

"Use Resettable Subsystems"

Introduced in R2015a

Resettable Synchronous Subsystem

Represent resettable subsystem that has synchronous reset and enable behavior



Library

HDL Coder / HDL Subsystems

Description

The Resettable Synchronous Subsystem block uses the `Synchronous` mode of the State Control block with the Resettable Subsystem block. If an **S** symbol appears in the subsystem, then it is synchronous. For more information about the block in HDL Coder, see Resettable Synchronous Subsystem.

For more information about the State Control block, see State Control.

Data Type Support

See Inport for information on the data types accepted by a subsystem's input ports. See Outport for information on the data types output by a subsystem's output ports.

For more information, see “Data Types Supported by Simulink” in the Simulink documentation.

Parameters

Show port labels

Display subsystem port labels on the subsystem block.

Default: `FromPortIcon`

`none`

Does not display port labels on the subsystem block.

`FromPortIcon`

If the corresponding port icon displays a signal name, the parameter displays the signal name on the subsystem block. Otherwise, it displays the port block name.

`FromPortBlockName`

Display the name of the corresponding port block on the subsystem block.

`SignalName`

If the signal connected to the subsystem block port is named, this parameter displays the name. Otherwise, it displays the name of the corresponding port block.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Read/Write permissions

Control user access to the contents of the subsystem.

Default: `ReadWrite`

`ReadWrite`

Enables opening and modification of subsystem contents.

`ReadOnly`

Enables the opening but not modification of the subsystem. If the subsystem resides in a block library, you can create and open links to the subsystem, and create and modify local copies of the subsystem. You cannot change the permissions or modify the contents of the original library instance.

`NoReadOrWrite`

Disables the opening or modification of subsystem. If the subsystem resides in a block library, you can create links to the subsystem in a model. You cannot open, modify, change permissions, or create local copies of the subsystem.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Name of error callback function

Enter the name of the function to be called if an error occurs while Simulink software is executing the subsystem.

Default: `' '`

Simulink passes two arguments to the function: the subsystem handle and a character vector that specifies the error type. If no function is specified, you get a generic error message.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Permit hierarchical resolution

Specify whether to resolve names of workspace variables referenced by this subsystem.

Default: `All`

`All`

Resolve all names of workspace variables used by this subsystem, including those used to specify block parameter values and Simulink data objects (for example, `Simulink.Signal` objects).

`ExplicitOnly`

Resolve the names of workspace variables used to specify block parameter values, data store memory (where no block exists), signals, and states marked by using the signal resolution icon.

`None`

Do not resolve any workspace variable names.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as atomic unit

Causes Simulink to treat the subsystem as a unit when determining the execution order of block methods.

Default: Off

☑ On

Cause Simulink to treat the subsystem as a unit when determining the execution order of block methods. For example, when it needs to compute the output of the subsystem, Simulink software invokes the output methods of all the blocks in the subsystem before invoking the output methods of other blocks at the same level as the subsystem block.

□ Off

Cause Simulink to treat all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem when determining block method execution order. This can cause the execution of block methods in the subsystem to be interleaved with the execution of block methods outside the subsystem.

This parameter enables:

- “Minimize algebraic loop occurrences” on page 1-0 .
- “Sample time” on page 1-0
- “Function packaging” on page 1-0 (requires a Simulink Coder license)

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Treat as grouped when propagating variant conditions

Causes Simulink software to treat the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks.

Default: On

☑ On

Simulink treats the subsystem as a unit when propagating variant conditions from Variant Source blocks or to Variant Sink blocks. For example, when Simulink computes the variant condition of the subsystem, it propagates that condition to all blocks in the subsystem.

☐ Off

Simulink treats all blocks in the subsystem as being at the same level in the model hierarchy as the subsystem itself when determining their variant condition.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Function packaging

Specify the code format to be generated for an atomic (nonvirtual) subsystem.

Default: `Auto`

`Auto`

Simulink Coder chooses the optimal format based on the type and number of subsystem instances in the model.

`Inline`

Simulink Coder inlines the subsystem unconditionally.

`Nonreusable function`

Simulink Coder explicitly generates a separate function in a separate file. In some cases, when you apply this setting, the subsystems generate functions with arguments that depend on the “Function interface” on page 1-0 parameter setting. You can name the generated function and file using parameters “Function name” on page 1-0 and “File name (no extension)” on page 1-0 . These functions are not reentrant.

`Reusable function`

Simulink Coder generates a function with arguments that allows reuse of subsystem code when a model includes multiple instances of the subsystem.

> This option generates a function with arguments that allows subsystem code to be reused in the generated code of a model reference hierarchy. In this case, the subsystem must be in a library.

See “Block-Specific Parameters” on page 6-128 for the command-line information.

Characteristics

Data Types	Double | Single | Boolean | Base Integer | Fixed-Point | Enumerated | Bus
Multidimensional Signals	Yes
Variable-Size Signals	Yes
HDL Code Generation	Yes

Introduced in R2016b

Reshape

Change dimensionality of signal
Library: Simulink / Math Operations

Description

The Reshape block changes the dimensionality of the input signal to a dimensionality that you specify, using the **Output dimensionality** parameter. For example, you can use the block to change an *N*-element vector to a 1-by-*N* or *N*-by-1 matrix signal.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal whose dimensions are changed based on the **Output dimensionality** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Output

`Port_1` — Output signal
scalar | vector | matrix

Output signal created with the dimensions specified in the **Output dimensionality** parameter.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Output dimensionality` — Dimensions of output signal

`1-D array` (default) | `Column vector (2-D)` | `Row vector (2-D)` | `Customize` | `Derive from reference input port`

Specify the dimensionality of the output signal.

Output Dimensionality	Description
1-D array	Converts a multidimensional array to a vector (1-D array) array signal. The output vector consists of the first column of the input matrix followed by the second column, and so on. (This option leaves a vector input unchanged.)
Column vector	Converts a vector, matrix, or multidimensional input signal to a column matrix, a *M*-by-1 matrix, where *M* is the number of elements in the input signal. For matrices, the conversion is done in column-major order. For multidimensional arrays, the conversion is done along the first dimension.
Row vector	Converts a vector, matrix, or multidimensional input signal to a row matrix, a 1-by-*N* matrix where *N* is the number of elements in the input signal. For matrices, the conversion is done in column-major order. For multidimensional arrays, the conversion is done along the first dimension.
Customize	Converts the input signal to an output signal whose dimensions you specify, using the **Output dimensions** parameter.
Derive from reference input port	Creates a second input port, **Ref**, on the block. Derives the dimensions of the output signal from the dimensions of the signal input to the Ref input port. Selecting this option disables the **Output dimensions** parameter. When you select this parameter, the input signals for both inport ports, **U** and **Ref**, must have the same sampling mode (sample-based or frame-based).

Programmatic Use
Block Parameter: `OutputDimensionality`
Type: character vector
Value: `'1-D array'` | `'Column vector (2-D)'` | `'Row vector (2-D)'` | `'Customize'` | `'Derive from reference input port'`
Default: `'1-D array'`

`Output dimensions` — Custom dimensions of output signal

`[1,1]` (default) | `[integer]` | `[integer,integer]`

Specify the dimensions for the output signal. The value can be a one- or multi-element vector. A value of `[N]` outputs a vector of size `N`. A value of `[M N]` outputs an `M`-by-`N` matrix. The number of elements of the input signal must match the number of elements specified by the **Output dimensions** parameter. For multidimensional arrays, the conversion is done along the first dimension.

Dependency

To enable this parameter, set **Output dimensionality** to `Customize`.

Programmatic Use
Block Parameter: `OutputDimensions`
Type: character vector
Value: `'[integer,intger]'` |
Default: `'[1,1]'`

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`
Direct Feedthrough	`Yes`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`

Zero-Crossing Detection	No

Topics

"Combine Buses into an Array of Buses"

Introduced before R2006a

Rocker Switch

Toggle parameter between two values
Library: Simulink / Dashboard

Description

The Rocker Switch block toggles the value of the connected block parameter between two values during simulation. For example, you can connect the Rocker Switch block to a Switch block in your model and change its state during simulation. Use the Rocker Switch block with other Dashboard blocks to create an interactive dashboard for your model.

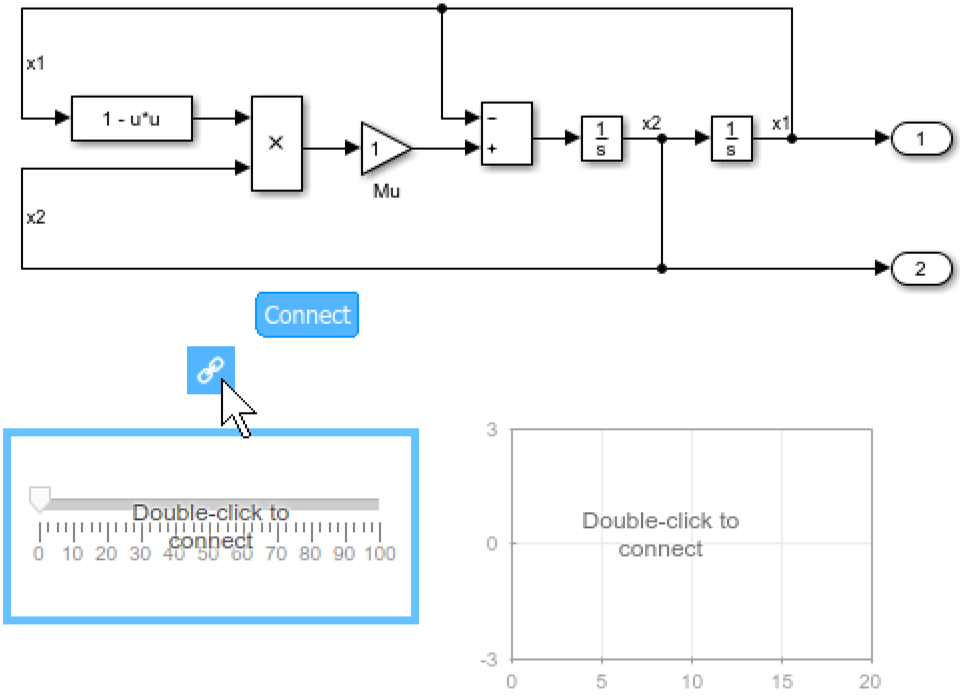
Double-clicking the Rocker Switch block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connecting Dashboard Blocks

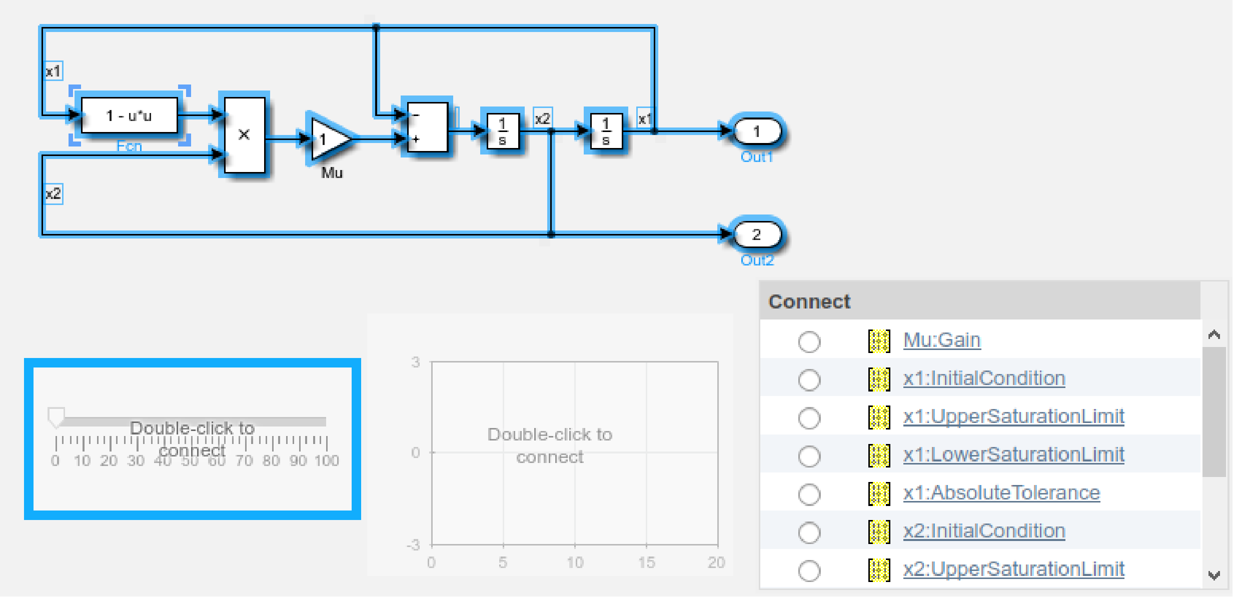
Dashboard blocks do not use ports to make connections. To connect Dashboard blocks to variables and block parameters in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

Note Dashboard blocks cannot connect to variables until you update your model diagram. To connect Dashboard blocks to variables or modify variable values between opening your model and running a simulation, update your model diagram using **Ctrl+D**.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

○ Mu:Gain
○ x1:InitialCondition
○ x1:UpperSaturationLimit
○ x1:LowerSaturationLimit
○ x1:AbsoluteTolerance
○ x2:InitialCondition
○ x2:UpperSaturationLimit

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Parameter Logging

Tunable parameters connected to Dashboard blocks are logged to the Simulation Data Inspector, where you can view parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector UI or by using the `Simulink.sdi.exportRun` function. For more information about exporting data with the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using

connect mode, the Dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. Populate the **Connection** table by selecting one or more blocks in your model. Select the radio button next to the variable or parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

States

`Label (Top)` — Label for top switch position

'On' (default) | character vector

Labels the top switch position. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the top, or you can enter a text label.

Example: `Gain = 2`

`Value (Top)` — Value for top switch position

1 (default) | scalar

The value assigned to the connected parameter when the switch is positioned at the top.

`Label (Bottom)` — Label for bottom switch position

'Off' (default) | character vector

Labels the bottom switch position. You can use the **Label** to display the value the connected parameter takes when the switch is positioned at the bottom, or you can enter a text label.

Example: `Gain = 1`

`Value (Bottom)` — Value for bottom switch position

0 (default) | scalar

The value assigned to the connected parameter when the switch is positioned at the bottom.

`Label` — Block label position

'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

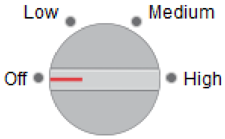
Rotary Switch

Switch parameter to set values on dial
Library: Simulink / Dashboard



Description

The Rotary Switch changes the value of the connected block parameter to several specified values during simulation. For example, you can connect the Rotary Switch block to the amplitude or frequency of an input signal in your model and change its characteristics during simulation. Use the Rotary Switch block with other Dashboard blocks to create an interactive dashboard to control your model.

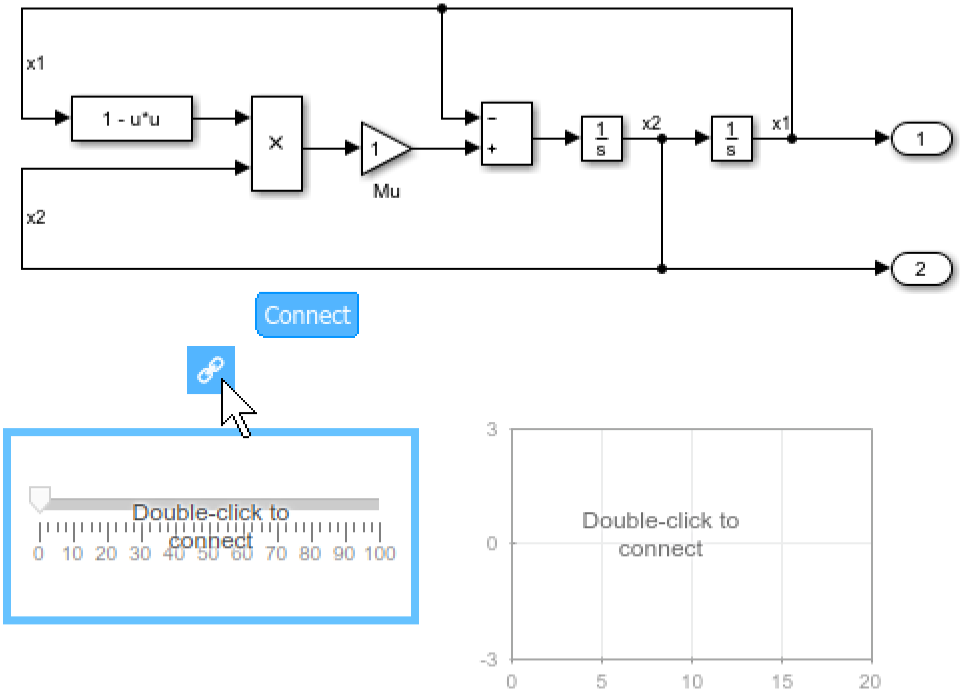
Double-clicking the Rotary Switch block does not open its dialog box during simulation and when the block is selected. To edit the block's parameters, you can use the **Property Inspector**, or you can right-click the block and select **Block Parameters** from the context menu.

Connecting Dashboard Blocks

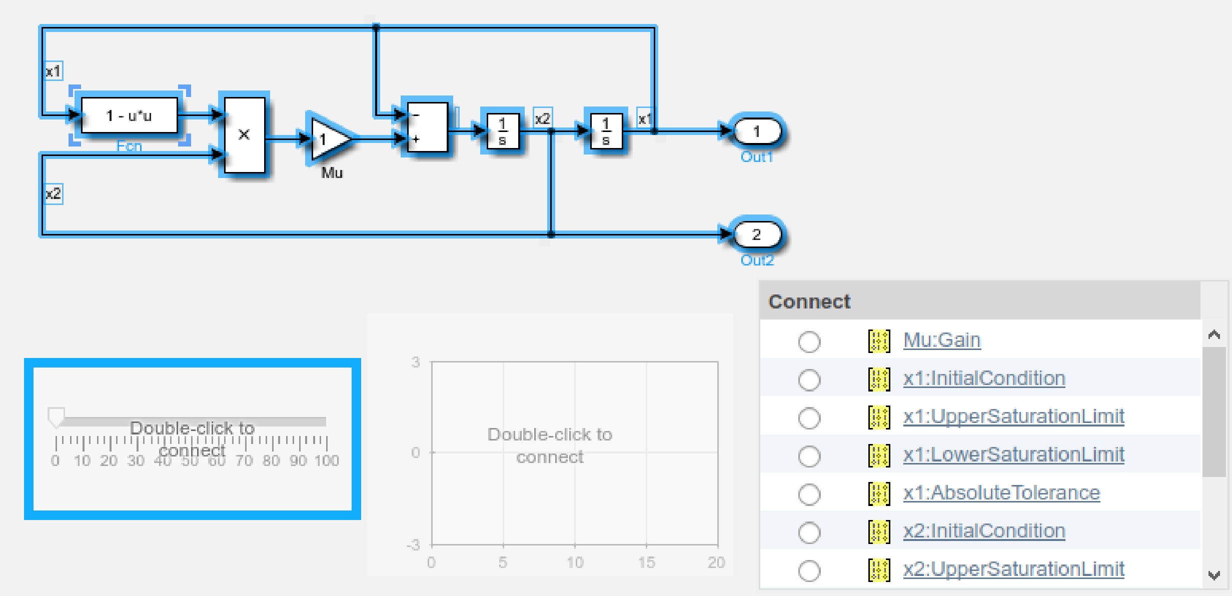
Dashboard blocks do not use ports to make connections. To connect Dashboard blocks to variables and block parameters in your model, use connect mode. Connect mode facilitates the process of connecting Dashboard blocks in your model, especially when you want to connect multiple blocks at once. If you only want to connect a single Dashboard block, you can also use the **Connection** table in the block dialog box to make the connection.

Note Dashboard blocks cannot connect to variables until you update your model diagram. To connect Dashboard blocks to variables or modify variable values between opening your model and running a simulation, update your model diagram using **Ctrl+D**.

To enter connect mode, click the **Connect** button that appears above your unconnected Dashboard block when you pause on it.



In connect mode, when you select one or more signals or blocks, a list of parameters and signals available for connection appears. Select a signal or parameter from the list to connect the selected Dashboard block. To connect another Dashboard block, pause on the block and click the **Connect** button above it. Then, make a selection of signals and blocks in your model, and choose a signal or parameter to connect.



Connect

- ○ Mu:Gain
- ○ x1:InitialCondition
- ○ x1:UpperSaturationLimit
- ○ x1:LowerSaturationLimit
- ○ x1:AbsoluteTolerance
- ○ x2:InitialCondition
- ○ x2:UpperSaturationLimit

When you finish connecting the Dashboard blocks in your model, click the **Exit** button in the upper-right of the canvas to exit connect mode.

Parameter Logging

Tunable parameters connected to Dashboard blocks are logged to the Simulation Data Inspector, where you can view parameter values along with logged signal data. You can access logged parameter data in the MATLAB workspace by exporting the parameter data from the Simulation Data Inspector UI or by using the `Simulink.sdi.exportRun` function. For more information about exporting data with the Simulation Data Inspector UI, see “Export Data from the Simulation Data Inspector”. The parameter data is stored in a `Simulink.SimulationData.Parameter` object, accessible as an element in the exported `Simulink.SimulationData.Dataset`.

Limitations

- Dashboard blocks can only connect to real scalar signals.
- You cannot use the **Connection** table to connect a Dashboard block to a block that is commented out. When you connect a Dashboard block to a commented block using

connect mode, the Dashboard block does not display the connected value until the you uncomment the block.

- Dashboard blocks cannot connect to signals inside referenced models.
- Parameters specified by indexing a variable array do not appear in the **Connection** table. For example, a block parameter defined as `engine(1)` using the variable `engine` does not appear in the table.

  To access the parameter in the **Connection** table, assign the indexed value to a scalar variable, such as `engine_1`. Then, use the scalar variable to define the block parameter.

Parameters

`Connection` — Select a variable or block parameter to connect

variable and parameter connection options

Select the variable or block parameter to control using the **Connection** table. Populate the **Connection** table by selecting one or more blocks in your model. Select the radio button next to the variable or parameter you want to control, and click **Apply**.

Note To see workspace variables in the connection table, update the model diagram using **Ctrl+D**.

States

`Value` — Values for switch positions

0/1/2/3 (default) | scalar

The values assigned to the connected parameter when the switch is positioned at the corresponding **Label**. Click the **+** button to add positions.

`Label` — Labels for switch positions

'Off'/'Low'/'Medium'/'High' (default) | character vector

Labels the switch positions. You can use the **Label** to display the value the connected parameter takes when the switch points to the **Label**, or you can enter a descriptive text label. Click the **+** button to add positions.

Example: `Gain = 2`

`Label` — Block label position
'Top' (default) | 'Bottom' | 'Hide'

Position of the block label. When the block is connected to a signal, the label is the name of the connected signal.

Rounding Function

Apply rounding function to signal
Library: Simulink / Math Operations

Description

The Rounding Function block rounds each element of the input signal to produce the output signal.

You select the type of rounding from the **Function** parameter list. The name of the selected function appears on the block.

Tip Use the Rounding Function block instead of the Fcn block when you want vector or matrix output, because the Fcn block produces only scalar output.

Also, the Rounding Function block provides two more rounding modes. The Fcn block supports `floor` and `ceil`, but does not support `round` and `fix`.

Ports

Input

`Port_1` — Input signal
scalar | vector | matrix

Input signal to which the rounding function is applied.

Data Types: `single` | `double`

Output

Port_1 — Output signal
scalar | vector | matrix

Output signal after the rounding function is applied to the input signal. The output signal has the same dimensions and data type as the input. Each element of the output signal is the result of applying the selected rounding function to the corresponding element of the input signal.

Data Types: `single` | `double`

Parameters

Function — Rounding function
`floor` (default) | `ceil` | `round` | `fix`

Choose the rounding function applied to the input signal.

Rounding function	Rounds each element of the input signal
`floor`	To the nearest integer value towards minus infinity
`ceil`	To the nearest integer towards positive infinity
`round`	To the nearest integer
`fix`	To the nearest integer towards zero

Programmatic Use
Block Parameter: `Operator`
Type: character vector
Values: `'floor'` | `'ceil'` | `'round'` | `'fix'`
Default: `'floor'`

Sample time — Specify sample time as a value other than -1
`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Block Characteristics

Data Types	`double` | `single`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

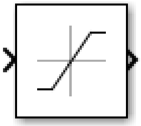
Fcn

Introduced before R2006a

Saturation

Limit input signal to the upper and lower saturation values

Library: Simulink / Commonly Used Blocks
Simulink / Discontinuities



Description

The Saturation block produces an output signal that is the value of the input signal bounded to the upper and lower saturation values. The upper and lower limits are specified by the parameters **Upper limit** and **Lower limit**.

Input	Output
Lower limit ≤ Input value ≤ Upper limit	Input value
Input value < Lower limit	Lower limit
Input value > Upper limit	Upper limit

Ports

Input

`Port_1` — Input signal
scalar | vector

The input signal to the saturation algorithm.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Output

`Port_1` — Output signal
scalar | vector

Output signal that is the value of the input signal, upper saturation limit, or lower saturation limit.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

Main

`Upper limit` — Upper saturation boundary for the input signal
`0.5` (default) | scalar | vector

Specify the upper bound on the input signal. If the input signal is greater than this boundary, then the output signal is set to this saturation value. The **Upper limit** parameter is converted to the output data type using round-to-nearest and saturation. **Upper limit** must be greater than the **Output minimum** parameter and less than the **Output maximum** parameter.

Programmatic Use
Block Parameter: `UpperLimit`
Type: character vector
Value: real scalar or vector
Default: `'0.5'`

`Lower limit` — Lower saturation boundary for the input signal
`-0.5` (default) | scalar | vector

Specify the lower bound on the input signal. If the input signal is less than this boundary, then the output signal is set to this saturation value. The **Lower limit** parameter is converted to the output data type using round-to-nearest and saturation. **Lower limit** must be greater than the **Output minimum** parameter and less than the **Output maximum** parameter.

Programmatic Use

Block Parameter: `LowerLimit`
Type: character vector
Value: real scalar or vector
Default: `'-0.5'`

`Treat as gain when linearizing` — Specify the gain value

`On` (default) | Boolean

Select this check box to cause the commands to treat the gain as 1. The linearization commands in Simulink software treat this block as a gain in state space. Clear the box to have the commands treat the gain as 0.

Programmatic Use

Block Parameter: `LinearizeAsGain`
Type: character vector
Values: `'off'` | `'on'`
Default: `'on'`

`Enable zero-crossing detection` — Enable zero-crossing detection

`on` (default) | Boolean

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection” in the Simulink documentation.

Programmatic Use

Block Parameter: `ZeroCross`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'on'`

`Sample time` — Specify sample time as a value other than `-1`

`-1` (default) | scalar

Specify the sample time as a value other than -1. For more information, see “Specify Sample Time”.

Dependencies

This parameter is not visible unless it is explicitly set to a value other than `-1`. To learn more, see “Blocks for Which Sample Time Is Not Recommended”.

Programmatic Use
Block Parameter: `SampleTime`
Type: character vector
Values: scalar
Default: `'-1'`

Signal Attributes

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

`Output minimum` — Minimum output value for range checking

[ ] (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

`[]` (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Same as input` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `int32` | `uint32` | `fixdt(1,16,2^0,0)` | `<data type expression>` | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Same as input'`, `'Inherit: Inherit via back propagation'`, `'single'`, `'int8'`, `'uint8'`, `int16`, `'uint16'`, `'int32'`, `'uint32'`,

fixdt(1,16,0), fixdt(1,16,2^0,0), fixdt(1,16,2^0,0). '<data type expression>'
Default: 'Inherit: Same as input'

Lock output data type setting against changes by the fixed-point tools — Prevent fixed-point tools from overriding Output data type

off (default) | on

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: LockScale
Type: character vector
Values: 'off' | 'on'
Default: 'off'

Integer rounding mode — Specify the rounding mode for fixed-point operations

Floor (default) | Ceiling | Convergent | Nearest | Round | Simplest | Zero

Choose one of these rounding modes.

Ceiling

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB ceil function.

Convergent

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer convergent function.

Floor

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB floor function.

Nearest

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer nearest function.

Round

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer round function.

`Simplest`

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

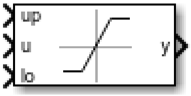
Backlash | Saturation Dynamic

Introduced before R2006a

Saturation Dynamic

Limit input signal to dynamic upper and lower saturation values

Library: Simulink / Discontinuities



Description

The Saturation Dynamic block produces an output signal that is the value of the input signal bounded to the saturation values from the input ports `up` and `lo`.

Input	Output
`lo` ≤ Input value ≤ `hi`	Input value
Input value < `lo`	Lower limit
Input value > `hi`	Upper limit

Ports

Input

u — Input signal
scalar | vector

The input signal to the saturation algorithm.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

up — Signal that provides the upper saturation limit
scalar | vector

Dynamic value providing the upper saturation limit. When the input is greater than **up** then the output value is bound to **up**.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

`lo` — Signal that provides the lower saturation limit

scalar | vector

Dynamic value providing the lower saturation limit. When the input is less than **lo** then the output value is bound to **lo**.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`
Complex Number Support: Yes

Output

`Output 1` — Output signal

scalar | vector

Output signal that is the value of the input signal, upper saturation limit, or lower saturation limit.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `fixed point`

Parameters

To edit the parameters for the Saturation Dynamic block, double-click the block icon.

Click the **Show data type assistant** button >> to display the **Data Type Assistant**, which helps you set the data type attributes. For more information, see “Specify Data Types Using Data Type Assistant”.

`Output minimum` — Minimum output value for range checking

`[]` (default) | scalar

Lower value of the output range that Simulink checks.

Simulink uses the minimum to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output minimum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMin`
Type: character vector
Values: `'[ ]'`| scalar
Default: `'[ ]'`

`Output maximum` — Maximum output value for range checking

[ ] (default) | scalar

Upper value of the output range that Simulink checks.

Simulink uses the maximum value to perform:

- Parameter range checking (see “Specify Minimum and Maximum Values for Block Parameters”) for some blocks.
- Simulation range checking (see “Signal Ranges” and “Enable Simulation Range Checking”).
- Automatic scaling of fixed-point data types.
- Optimization of the code that you generate from the model. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

Note **Output maximum** does not saturate or clip the actual output signal. Use the Saturation block instead.

Programmatic Use
Block Parameter: `OutMax`
Type: character vector
Values: `'[ ]'` | scalar
Default: `'[ ]'`

`Output data type` — Specify the output data type

`Inherit: Same as input` (default) | `Inherit: Inherit via back propagation` | `double` | `single` | `int8` | `int32` | `uint32` | `fixdt(1,16,2^0,0)` | `<data type expression>` | ...

Choose the data type for the output. The type can be inherited, specified directly, or expressed as a data type object such as `Simulink.NumericType`.

Programmatic Use
Block Parameter: `OutDataTypeStr`
Type: character vector
Values: `'Inherit: Same as input'`, `'Inherit: Inherit via back propagation'`, `'single'`, `'int8'`, `'uint8'`, `int16`, `'uint16'`, `'int32'`, `'uint32'`, `fixdt(1,16,0)`, `fixdt(1,16,2^0,0)`, `fixdt(1,16,2^0,0)`. `'<data type expression>'`
Default: `'Inherit: Same as input'`

`Lock output data type setting against changes by the fixed-point tools` — Prevent fixed-point tools from overriding Output data type

`off` (default) | `on`

Select this parameter to prevent the fixed-point tools from overriding the **Output** data type you specify on the block. For more information, see “Use Lock Output Data Type Setting” (Fixed-Point Designer).

Programmatic Use
Block Parameter: `LockScale`
Type: character vector
Values: `'off' | 'on'`
Default: `'off'`

`Integer rounding mode` — Specify the rounding mode for fixed-point operations

`Floor` (default) | `Ceiling` | `Convergent` | `Nearest` | `Round` | `Simplest` | `Zero`

Choose one of these rounding modes.

`Ceiling`

Rounds both positive and negative numbers toward positive infinity. Equivalent to the MATLAB `ceil` function.

`Convergent`

Rounds number to the nearest representable value. If a tie occurs, rounds to the nearest even integer. Equivalent to the Fixed-Point Designer `convergent` function.

`Floor`

Rounds both positive and negative numbers toward negative infinity. Equivalent to the MATLAB `floor` function.

`Nearest`

Rounds number to the nearest representable value. If a tie occurs, rounds toward positive infinity. Equivalent to the Fixed-Point Designer `nearest` function.

`Round`

Rounds number to the nearest representable value. If a tie occurs, rounds positive numbers toward positive infinity and rounds negative numbers toward negative infinity. Equivalent to the Fixed-Point Designer `round` function.

`Simplest`

Automatically chooses between round toward floor and round toward zero to generate rounding code that is as efficient as possible.

`Zero`

Rounds number toward zero. Equivalent to the MATLAB `fix` function.

Programmatic Use

Block Parameter: `RndMeth`
Type: character vector
Values: `'Ceiling'` | `'Convergent'` | `'Floor'` | `'Nearest'` | `'Round'` | `'Simplest'` | `'Zero'`
Default: `'Floor'`

See Also

For more information, see “Rounding” (Fixed-Point Designer).

`Saturate on integer overflow` — Choose the behavior when integer overflow occurs

`on` (default) | boolean

Action	Reasons for Taking This Action	What Happens for Overflows	Example
Select this check box.	Your model has possible overflow, and you want explicit saturation protection in the generated code.	Overflows saturate to either the minimum or maximum value that the data type can represent.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box selected, the block output saturates at 127. Similarly, the block output saturates at a minimum output value of -128.
Do not select this check box.	You want to optimize efficiency of your generated code. You want to avoid overspecifying how a block handles out-of-range signals. For more information, see "Check for Signal Range Errors".	Overflows wrap to the appropriate value that is representable by the data type.	The maximum value that the `int8` (signed, 8-bit integer) data type can represent is 127. Any block operation result greater than this maximum value causes overflow of the 8-bit integer. With the check box cleared, the software interprets the overflow-causing value as `int8`, which can produce an unintended result. For example, a block result of 130 (binary 1000 0010) expressed as `int8`, is -126.

When you select this check box, saturation applies to every internal operation on the block, not just the output or result. Usually, the code generation process can detect when overflow is not possible. In this case, the code generator does not produce saturation code.

Programmatic Use
Block Parameter: `SaturateOnIntegerOverflow`
Type: character vector
Value: `'off'` | `'on'`
Default: `'on'`

Block Characteristics

Data Types	`double` | `single` | `Boolean`[a] | `base integer` | `fixed point`
Direct Feedthrough	`No`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`No`

[a] This block is not recommended for use with Boolean signals.

Introduced before R2006a

Scan String

Scan input string and convert to signals per specified format

Library: Simulink / String

str
scan
"%d %f"
d
f

Description

The Scan String block scans an input string and converts it to signals per the format specified by the **Format** parameter. The block converts values to their decimal (base 10) representation and outputs the results as numeric or string signals. Use this block when you want to deconstruct a string, for example a sentence, into its individual components. For example, if the **Format** parameter is set to `"%s is %f."`, the block outputs two parts, a string signal and a single signal. If the input is the string `"Pi is 3.14"`, the two outputs are `"Pi"` and `"3.14"`.

The Scan String, String to Double, and String to Single blocks are identical blocks. When configured for String to Double, the block converts the input string signal to a double numerical output. When configured for String to Single, the block converts the input string signal to a single numerical output.

For code generation, configure models that contain this block for non-finite number support by selecting the **Configuration Parameters > Code Generation > Interface > Support non-finite numbers** check box.

Ports

Input

`Port_1` — Input string
scalar

Input string, specified as a scalar.

Data Types: `string`

Output

`d` — Output data whose format matches `%d` format

scalar

Output data whose format matches the specified format, defined as a scalar. Total maximum number of outputs is 128.

If the block cannot match an input string to a format operator specified in **Format**, it returns a warning and outputs an appropriate value (`0` or `""`) for each unmatched format operator.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`f` — Output data whose format matches %f format

scalar

Output data whose format matches the `%f` format, specified as a scalar. Total maximum number of outputs is 128.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

`Port_N` — Output data whose format matches N format

scalar

Output data whose format matches *N* format, specified as a scalar. Total maximum number of outputs is 128.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Parameters

`Format` — Format operator for input

`"%d %f"` (default) | scalar

Format operator for input, specified as a scalar. If the block cannot match the input string with the specified format, it returns `0`. The return of `0` differs from the `sscanf` function return, which is an empty matrix if the function cannot match the input with the specified format.

- For the String to Double block, this parameter has a default value of `%lf`.
- For the String to Single block, this parameter has a default value of `%f`.

For more information about acceptable format operators, see the Algorithms section.

Block Characteristics

Data Types	`double | single | base integer | string`
Direct Feedthrough	No
Multidimensional Signals	No
Variable-Size Signals	No
Zero-Crossing Detection	No

Algorithms

The Scan String block uses this format specifier prototype:

```
%[width][length]specifier
```

Numeric Fields

This table lists available conversion specifiers to convert text to numeric outputs. The block converts values to their decimal (base 10) representation.

Output Port Data Type	Conversion Specifier	Description
Integer, signed	%d	Base 10
Integer, unsigned	%u	Base 10

Output Port Data Type	Conversion Specifier	Description
Floating-point number	`%f`, `%e`, or `%g`	Floating-point values. Input fields can contain any of the following (not case sensitive): `Inf`, `-Inf`, `NaN`, or `-NaN`. Input fields that represents floating-point numbers can include leading `+` or `-` symbols and exponential notation using `e` or `E`. The conversion specifiers `%f`, `%e`, and `%g` all treat input fields the same way.

Character Fields

This table lists available conversion specifiers to convert text so that the output is a string.

Character Field Type	Conversion Specifier	Description
String scalar	`%s`	Read the text until the block encounters whitespace.
	`%c`	Read any single character, including whitespace. To read multiple characters at a time, specify field width. For example, `%10c` reads 10 characters at a time.
Pattern-matching	`%[...]`	Read only the characters in the brackets up to the first nonmatching character or whitespace. Example: `%[mus]` reads `'summer'` as `'summ'`.

Character Field Type	Conversion Specifier	Description
	`%[^...]`	Do not read characters in the brackets up to the first nonmatching character or whitespace. Example: `%[m]` reads `'summer'` as `'su'`.

Optional Operators

- Field Width — To specify the maximum number of digits or text characters to read at a time, insert a number after the percent character. For example, `%10s` reads up to 10 characters at a time, including whitespace. `%4f` reads up to four digits at a time, including the decimal point.
- Literal Text to Ignore — This block must match the specified text immediately before or after the conversion specifier.

  Example: `Hell%s` reads `"Hello!"` as `"o!"`.

Length Specifiers

The Scan String block supports the `h` and `l` length subspecifiers. These specifiers can change according to the **Configuration Parameters** > **Hardware Implementation** > **Number of bits** settings.

Length	i	u	f e g	s c [...] [^...]
No length specifier	`int`	`unsigned int`	`single`	`string`
`h`	`short`	`unsigned short`	—	—
`l`	`long`	`unsigned long`	`double`	—

Notes for Specifiers that Specify Integer Data Types (d, u)

- Target `int`, `long`, and `short` type sizes are controlled by settings in the **Configuration Parameters** > **Hardware Implementation** pane. For example, if the target `int` is 32 bits and the specifier is `%u`, then the expected input type will be `uint32`. For this example, the Scan String block requires that the output type be exactly `int32`. It cannot be any other data type.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

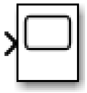
Introduced in R2018a

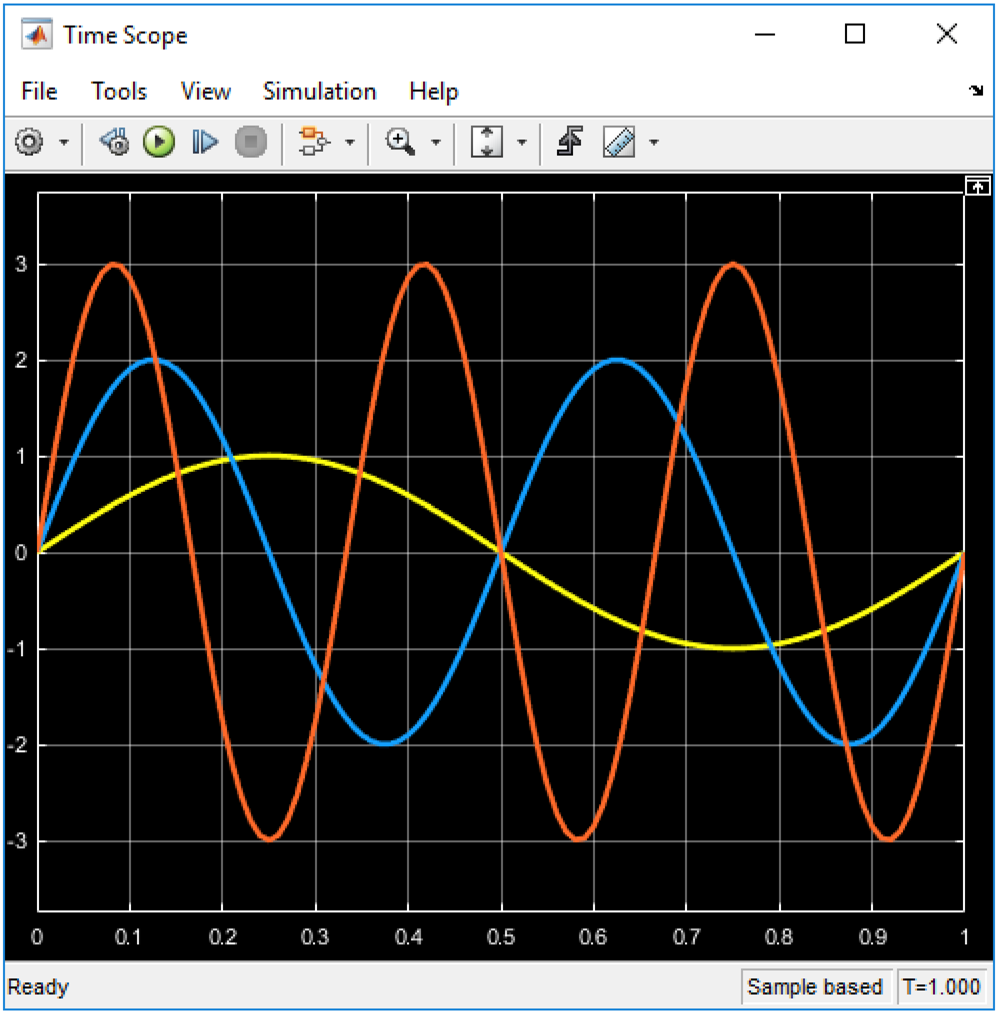
ScopeTime Scope

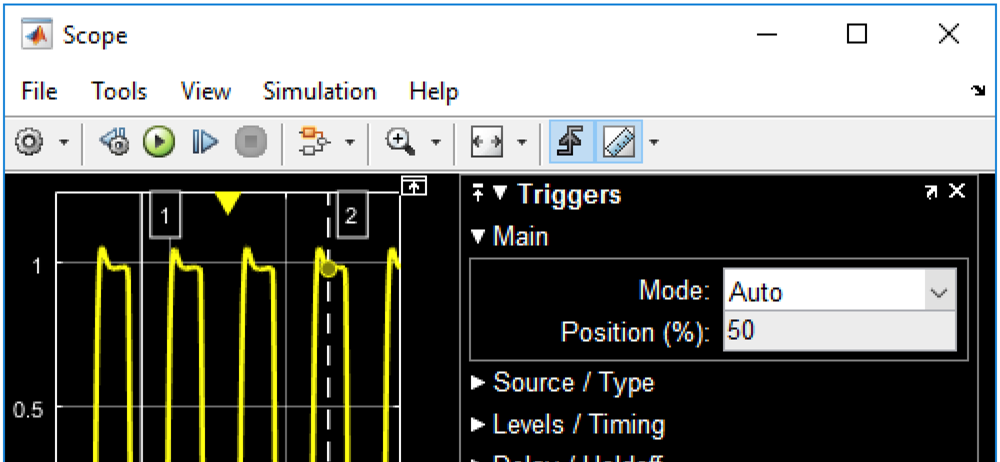
Display signals generated during simulation
Library: Simulink / Commonly Used Blocks
Simulink / Sinks



Description

The Simulink Scope block and DSP System Toolbox Time Scope block display time domain signals.





Mode: Auto

Position (%): 50

The two blocks have identical functionality, but different default settings. The Time Scope is optimized for discrete time processing. The Scope is optimized for general time-domain simulation. For a side-by-side comparison, see “Simulink Scope Versus DSP System Toolbox Time Scope”.

Oscilloscope features:

- Triggers — Set triggers to sync repeating signals and pause the display when events occur.
- Cursor Measurements — Measure signal values using vertical and horizontal cursors.
- Signal Statistics — Display the maximum, minimum, peak-to-peak difference, mean, median, and RMS values of a selected signal.
- Peak Finder — Find maxima, showing the *x*-axis values at which they occur.
- Bilevel Measurements — Measure transitions, overshoots, undershoots, and cycles.

You must have a Simscape or DSP System Toolbox license to use the Peak Finder, Bilevel Measurements, and Signal Statistics.

Scope display features:

- Simulation control — Debug models from a Scope window using **Run**, **Step Forward**, and **Step Backward** toolbar buttons.
- Multiple signals — Plot multiple signals on the same *y*-axis (display) using multiple input ports.
- Multiple y-axes (displays) — Display multiple *y*-axes. All the *y*-axes have a common time range on the *x*-axis.
- Modify parameters — Modify scope parameter values before and during a simulation.
- Axis autoscaling — Autoscale axes during or at the end of a simulation. Margins are drawn at the top and bottom of the axes.
- Display data after simulation — If a Scope is closed at the start of a simulation, scope data is still written to the scope during a simulation. As a result, if you open the Scope after a simulation, the Scope displays simulation results for attached input signals.

For information on controlling a scope programmatically, see “Control Scope Blocks Programmatically”.

Limitations

- Do not use scope blocks in a Library. If you place a scope block inside a library block with a locked link or in a locked library, Simulink displays an error when trying to open the scope window. To display internal data from a library block, add an output port to the library block, and then connect the port to a Scope block in your model.
- A Scope block may plot a single point when connected to a constant signal.

Ports

Input

`Port_1` — Signal or signals to visualize

scalar | vector | matrix | array | bus | nonvirtual bus

Connect the signals you want to visualize. You can have up to 96 input ports. Input signals can have these characteristics:

- **Type** — Continuous (sample-based) or discrete (sample-based and frame-based).
- **Data type** — Any data type that Simulink supports. See “Data Types Supported by Simulink”.
- **Dimension** — Scalar, one dimensional (vector), two dimensional (matrix), or multidimensional (array). Display multiple channels within one signal depending on the dimension. See “Signal Dimensions” and “Determine Output Signal Dimensions”.

Bus Support

You can connect nonvirtual bus and arrays of bus signals to a scope block. To display the bus signals, use normal or accelerator simulation mode. The scope block displays each bus element signal in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened.

To log nonvirtual bus signals with a scope block, set the **Save format** block parameter to `Dataset`. You can use any **Save format** to log virtual bus signals.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32` | `Boolean` | `fixed point` | `enumerated` | `bus`

Properties

Configuration Properties

The Configuration Properties dialog box controls various properties about the scope displays. From the scope menu, select **View** > **Configuration Properties**.

Main

`Open at simulation start` — Specify when scope window opens

off (default for Scope) | on (default for Time Scope)

Select this check box to open the scope window when simulation starts.

Programmatic Use

See OpenAtSimulationStart.

`Display the full path` — Display block path on scope title bar

off (default) | on

Select this check box to display the block path in addition to the block name.

`Number of input ports` — Number of input ports on scope block

1 (default) | integer

Specify number of input ports on a Scope block, specified as an integer. The maximum number of input ports is 96.

Programmatic Use

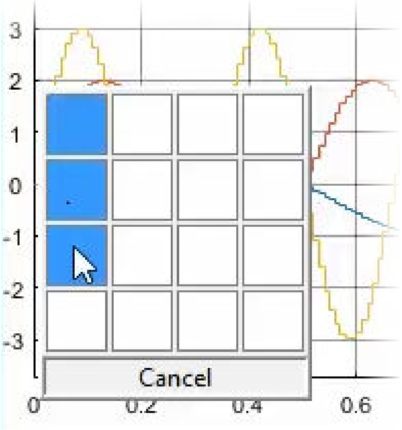
See NumInputPorts.

Layout — Number and arrangement of displays

1-by-1 display (default) | an arrangement of `m`-by-`n` axes

Specify number and arrangement of displays. The maximum layout is 16 rows by 16 columns.

To expand the layout grid beyond 4 by 4, click within the dialog box and drag. Maximum of 16 rows by 16 columns.



If the number of displays is equal to the number of ports, signals from each port appear on separate displays. If the number of displays is less than the number of ports, signals from additional ports appear on the last display. For layouts with multiple columns and rows, ports are mapped down then across.

Programmatic Use

See LayoutDimensions.

`Sample time` — Simulation interval between scope updates

`-1` (for inherited) (default) | positive real number

Specify the time internal between updates of the scope display. This property does not apply to floating scopes and scope viewers.

Programmatic Use

See SampleTime.

`Input processing` — Channel or element signal processing

`Elements as channels (sample based)` (default for Scope) | `Columns as channels (frame based)` (default for Time Scope)

- `Elements as channels (sample based)` - Process each element as a unique sample.
- `Columns as channels (frame based)` - Process signal values in a channel as a group of values from multiple time intervals. Frame-based processing is available only with discrete input signals.

Programmatic Use

See FrameBasedProcessing.

`Maximize axes` — Maximize size of plots

`Off` (default for Scope) | `Auto` (default for Time Scope) | `On`

- `Auto` - If “Title” on page 1-0 and “Y-label” on page 1-0 properties are not specified, maximize all plots.
- `On` - Maximize all plots. Values in **Title** and **Y-label** are hidden.
- `Off` - Do not maximize plots.

Programmatic Use

See MaximizeAxes.

Time

`Time span` — Length of *x*-axis to display

`Auto` (default) | `User defined`

- `Auto` — Difference between the simulation start and stop times.

  The block calculates the beginning and end times of the time range using the “Time display offset” on page 1-0 and “Time span” on page 1-0 properties. For example, if you set the **Time display offset** to `10` and the **Time span** to `20`, the scope sets the time range from `10` to `30`.
- `User defined` — Enter any value less than the total simulation time.

Programmatic Use

See TimeSpan.

`Time span overrun action` — Display data beyond visible *x*-axis

`Wrap` (default) | `Scroll`

Specify how to display data beyond the visible *x*-axis range.

You can see the effects of this option only when plotting is slow with large models or small step sizes.

- `Wrap` — Draw a full screen of data from left to right, clear the screen, and then restart drawing the data from the left.

- `Scroll` — Move data to the left as new data is drawn on the right. This mode is graphically intensive and can affect run-time performance.

Programmatic Use

See TimeSpanOverrunAction.

`Time units` — *x*-axis units

`None` (default for Scope) | `Metric` (default for Time Scope) | `Seconds`

- `Metric` — Display time units based on the length of “Time span” on page 1-0 .
- `Seconds` — Display time in seconds.
- `None` — Do not display time units.

Programmatic Use

See TimeUnits.

`Time display offset` — *x*-axis offset

`0` (default) | scalar | vector

Offset the *x*-axis by a specified time value, specified as a real number or vector of real numbers.

For input signals with multiple channels, you can enter a scalar or vector:

- Scalar — Offset all channels of an input signal by the same time value.
- Vector — Independently offset the channels.

Programmatic Use

See TimeDisplayOffset.

`Time-axis labels` — Display of *x*-axis labels

`Bottom Displays Only` (default for Scope) | `All` (default for Time Scope) | `None`

Specify how *x*-axis (time) labels display:

- `All` — Display *x*-axis labels on all *y*-axes.
- `None` — Do not display labels. Selecting `None` also clears the **Show time-axis label** check box.

- `Bottom displays only` — Display *x*-axis label on the bottom *y*-axis.

Dependencies

To activate this property, set:

- “Show time-axis label” on page 1-0 to on.
- “Maximize axes” on page 1-0 to off.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See TimeAxisLabels.

`Show time-axis label` — Display or hide *x*-axis labels

off (default for Scope) | on (default for Time Scope)

Select this check box to show the *x*-axis label for the active display

Dependencies

To activate this property, set “Time-axis labels” on page 1-0 to `All` or `Bottom Displays Only`.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowTimeAxisLabel.

Display

`Active display` — Selected display

`1` (default) | positive integer

Selected display. Use this property to control which display is changed when changing style properties and axes-specific properties.

Specify the desired display using a positive integer that corresponds to the column-wise placement index. For layouts with multiple columns and rows, display numbers are mapped down and then across.

Programmatic Use

See “Active display” on page 1-0 .

`Title` — Display name

`%<SignalLabel>` (default) | character vector | string

Title for a display, specified as a character vector or string. The default value `%<SignalLabel>` uses the input signal name for the title.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See Title.

`Show legend` — Display signal legend

off (default) | on

Toggle signal legend. The names listed in the legend are the signal names from the model. For signals with multiple channels, a channel index is appended after the signal name. Continuous signals have straight lines before their names, and discrete signals have step-shaped lines.

From the legend, you can control which signals are visible. This control is equivalent to changing the visibility in the **Style** properties. In the scope legend, click a signal name to hide the signal in the scope. To show the signal, click the signal name again. To show only one signal, right-click the signal name, which hides all other signals. To show all signals, press **Esc**.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowLegend.

`Show grid` — Show internal grid lines

on (default) | off

Select this check box to show grid lines.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See ShowGrid.

`Plot signals as magnitude and phase` — Split display into magnitude and phase plots

off (default) | on

- On — Display magnitude and phase plots. If the signal is real, plots the absolute value of the signal for the magnitude. The phase is 0 degrees for positive values and 180 degrees for negative values. This feature is useful for complex-valued input signals. If the input is a real-valued signal, selecting this check box returns the absolute value of the signal for the magnitude.
- Off — Display signal plot. If the signal is complex, plots the real and imaginary parts on the same *y*-axis.

Dependency

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See PlotAsMagnitudePhase.

`Y-limits (Minimum)` — Minimum y-axis value

`-10` (default) | real scalar

Specify the minimum value of the *y*-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The *y*-axis limits of the phase plot are always `[-180 180]`.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See YLimits.

`Y-limits (Maximum)` — Maximum y-axis value

`10` (default) | real scalar

Specify the maximum value of the *y*-axis as a real number.

Tunable: Yes

Dependency

If you select **Plot signals as magnitude and phase**, this property only applies to the magnitude plot. The *y*-axis limits of the phase plot are always `[-180 180]`.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See YLimits.

`Y-label` — Y-axis label

none (default for Scope) | `'Amplitude'` (default for Time Scope) | character vector | string

Specify the text to display on the *y*-axis. To display signal units, add `(%<SignalUnits>)` to the label. At the beginning of a simulation, Simulink replaces `(%SignalUnits)` with the units associated with the signals.

Example: For a velocity signal with units of `m/s`, enter `Velocity (%<SignalUnits>)`.

Dependency

If you select **Plot signals as magnitude and phase**, this property does not apply. The *y*-axes are labeled `Magnitude` and `Phase`.

The “Active display” on page 1-0 property determines which display is affected.

Programmatic Use

See YLabel.

Logging

`Limit data points to last` — Limit buffered data values

off and `5000` (default) | on | positive integer

Specify to limit buffered data values before plotting and saving signals. Data values are from the end of a simulation. To use this property, you must also specify the number of data values by entering a positive integer in the text box.

- On — Save specified number of data values for each signal. If the signal is frame-based, the number of buffered data values is the specified number of data values multiplied by the frame size.

  For simulations with **Stop time** set to `inf`, consider selecting **Limit data points to last**.

  In some cases, for example where the sample time is small, selecting this parameter can have the effect of plotting signals for less than the entire time range of a simulation. If a scope plots a portion of your signals, consider increasing the number of data values to save.
- Off — Save and plot all data values. Clearing **Limit data points to last** can cause an out-of-memory error for simulations that generate a large amount of data or for systems without enough available memory.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See DataLoggingLimitDataPoints and DataLoggingMaxPoints.

`Decimation` — Reduce amount of scope data to display and save

off, 2 (default) | on | positive integer

- On — Plot and log (save) scope data every `N`th data point, where `N` is the decimation factor entered in the text box. A value of `1` buffers all data values.
- Off — Save all scope data values.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

This property limits the data values plotted in the scope and the data values saved to a MATLAB variable specified in “Variable name” on page 1-0 .

Programmatic Use

See DataLoggingDecimateData and DataLoggingDecimation.

`Log data to workspace` — Save data to MATLAB workspace
off (default) | on

Select this check box to activate logging and activate the **Variable name**, **Save format**, and **Decimation** properties. This property does not apply to floating scopes and scope viewers.

For an example of saving signals to the MATLAB Workspace using a Scope block, see “Save Simulation Data Using Floating Scope Block”.

Programmatic Use

See DataLogging.

`Variable name` — Name of saved data variable
`ScopeData` (default) | character vector | string

Specify a variable name for saving scope data in the MATLAB workspace, specified as a character vector or string. This property does not apply to floating scopes and scope viewers.

Dependency

To enable this property, select “Log data to workspace” on page 1-0 .

Programmatic Use

See DataLoggingVariableName.

`Save format` — MATLAB variable format
`Dataset` (default) | `Structure With Time` | `Structure` | `Array`

Select variable format for saving data to the MATLAB workspace. This property does not apply to floating scopes and scope viewers.

- `Dataset` — Save data as a dataset object. Use the **Dataset signal format** configuration parameter to select the dataset object. This format does not support variable-size data, MAT-file logging, or external mode archiving. See `Simulink.SimulationData.Dataset`.

- `Structure With Time` — Save data as a structure with associated time information.
- `Structure` — Save data as a structure.
- `Array` — Save data as an array with associated time information. This format does not support variable-size data.

Dependency

To enable this property, select "Log data to workspace" on page 1-0 .

Programmatic Use

See DataLoggingSaveFormat.

Axes Scaling Properties

The **Axes Scaling** dialog controls the axes limits of the scope. To open the Axes Scaling properties, in the scope menu, select **Tools** > **Axes Scaling** > **Axes Scaling Properties**.

`Axes scaling` — Y-axis scaling mode

`Manual` (default) | `Auto` | `After N Updates`

- `Manual` — Manually scale the *y*-axis range with the **Scale Y-axis Limits** toolbar button.
- `Auto` — Scale the *y*-axis range during and after simulation. Selecting this option displays the "Do not allow Y-axis limits to shrink" on page 1-0 check box. If you want the y-axis range to increase and decrease with the maximum value of a signal, set **Axes scaling** to `Auto` and clear the **Do not allow Y-axis limits to shrink** check box.
- `After N Updates` — Scale *y*-axis after the number of time steps specified in the "Number of updates" on page 1-0 text box (`10` by default). Scaling occurs only once during each run.

Programmatic Use

See AxesScaling.

`Do not allow Y-axis limits to shrink` — When y-axis limits can change

on (default) | off

Allow *y*-axis range limits to increase but not decrease during a simulation.

Dependency

To use this property, set “Axes scaling” on page 1-0 to `Auto`.

`Number of updates` — Number of updates before scaling

`10` (default) | integer

Set this property to delay auto scaling the *y*-axis.

Dependency

To use this property, set “Axes scaling” on page 1-0 to `After N Updates`.

Programmatic Use

See AxesScalingNumUpdates.

`Scale axes limits at stop` — When y-axis limits can change

on (default) | off

- On — Scale axes when simulation stops.
- Off — Scale axes continually.

Dependency

To use this property, set “Axes scaling” on page 1-0 to `Auto`.

`Y-axis Data range (%)` — Percent of *y*-axis to use for plotting

`80` (default) | integer between [1, 100]

Specify the percentage of the *y*-axis range used for plotting data. If you set this property to `100`, the plotted data uses the entire *y*-axis range.

`Y-axis Align` — Alignment along *y*-axis

`Center` (default) | `Top` | `Bottom`

Specify where to align plotted data along the *y*-axis data range when **Y-axis Data range** is set to less than 100 percent.

- `Top` — Align signals with the maximum values of the *y*-axis range.
- `Center` — Center signals between the minimum and maximum values.
- `Bottom` — Align signals with the minimum values of the *y*-axis range.

`Autoscale X-axis limits` — Scale *x*-axis range limits

off (default) | on

Scale *x*-axis range to fit all signal values. If **Axes scaling** is set to `Auto`, the data currently within the axes is scaled, not the entire signal in the data buffer.

`X-axis Data range (%)` — Percent of *x*-axis to use for plotting

`100` (default) | integer in the range [1, 100]

Specify the percentage of the *x*-axis range to plot data on. For example, if you set this property to `100`, plotted data uses the entire *x*-axis range.

`X-axis Align` — Alignment along *x*-axis

`Center` (default) | `Top` | `Bottom`

Specify where to align plotted data along the *x*-axis data range when **X-axis Data range** is set to less than 100 percent.

- `Top` — Align signals with the maximum values of the *x*-axis range.
- `Center` — Center signals between the minimum and maximum values.
- `Bottom` — Align signals with the minimum values of the *x*-axis range.

Style Properties

To open the Style dialog box, from the scope menu, select **View** > **Style**.

`Figure color` — Background color for window

black (default) | color

Background color for the scope.

`Plot type` — How to plot signal

`Auto` (default for Scope) | `Line` (default for Time Scope) | `Stairs` | `Stem`

When you select `Auto`, the plot type is a line graph for continuous signals, a stair-step graph for discrete signals, and a stem graph for Simulink message signals.

`Axes colors` — Background and axes color for individual displays

black (default) | color

Select the background color for axes (displays) with the first color palette. Select the grid and label color with the second color palette.

`Preserve colors for copy to clipboard` — Copy scope without changing colors

off (default) | on

Specify whether to use the displayed color of the scope when copying.

When you select **File > Copy to Clipboard**, the software changes the color of the scope to be printer friendly (white background, visible lines). If you want to copy and paste the scope with the colors displayed, select this check box.

`Properties for line` — Line to change

`Channel 1` (default)

Select active line for setting line style properties.

`Visible` — Line visibility

on (default) | off

Show or hide a signal on the plot.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

`Line` — Line style

solid line (default style) | 0.75 (default width) | yellow (default color)

Select line style, width, and color.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

`Marker` — Data point marker style

`None` (default) | marker shape

Select marker shape.

Dependency

The values of “Active display” on page 1-0 and “Properties for line” on page 1-0 determine which line is affected.

Block Characteristics

Data Types	`double` | `single` | `Boolean` | `base integer` | `fixed point` | `enumerated` | `bus`[a]
Direct Feedthrough	`No`
Multidimensional Signals	`Yes`
Variable-Size Signals	`Yes`
Zero-Crossing Detection	`No`

[a] Virtual bus not supported. Nonvirtual bus supported only in normal and accelerator mode simulation. Data logging for nonvirtual bus supported only in the dataset format

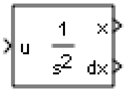
Second-Order Integrator

Integrate input signal twice

Library: Simulink / Continuous



Description

The Second-Order Integrator block and the Second-Order Integrator Limited block solve the second-order initial value problem:

$$\frac{d^2x}{dt^2} = u,$$

$$\left.\frac{dx}{dt}\right|_{t=0} = dx_o,$$

$$\left.x\right|_{t=0} = x_o,$$

where *u* is the input to the system. The block is therefore a dynamic system with two continuous states: *x* and *dx/dt*.

Note These two states have a mathematical relationship, namely, that *dx/dt* is the derivative of *x*. To satisfy this relationship throughout the simulation, Simulink places various constraints on the block parameters and behavior.

The Second-Order Integrator Limited block is identical to the Second-Order Integrator block with the exception that it defaults to limiting the states based on the specified upper and lower limits. For more information, see “Limiting the States” on page 1-1651.

Simulink software can use several different numerical integration methods to compute the outputs of the block. Each has advantages for specific applications. Use the **Solver** pane of the Configuration Parameters dialog box to select the technique best suited to your application. (For more information, see “Solver Types”.) The selected solver computes the states of the Second-Order Integrator block at the current time step using the current input value.

Use the block parameter dialog box to:

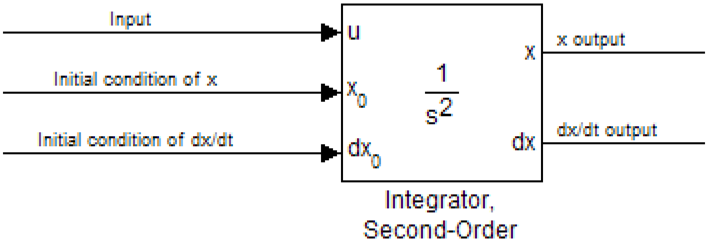
- Specify whether the source of each state initial condition is internal or external
- Specify a value for the state initial conditions
- Define upper and lower limits on either or both states
- Specify absolute tolerances for each state
- Specify names for both states
- Choose an external reset condition
- Enable zero-crossing detection
- Reinitialize dx/dt when x reaches saturation
- Specify that Simulink disregard the state limits and external reset for linearization operations

Defining Initial Conditions

You can define the initial conditions of each state individually as a parameter on the block dialog box or input one or both of them from an external signal.

- To define the initial conditions of state *x* as a block parameter, use the **Initial condition source x** drop-down menu to select `internal` and enter the value in the **Initial condition x** field.
- To provide the initial conditions from an external source for state *x*, specify the **Initial condition source x** parameter as `external`. An additional input port appears on the block.
- To define the initial conditions of state *dx/dt* as a block parameter, use the **Initial condition source dx/dt** drop-down menu to select `internal` and enter the value in the **Initial condition dx/dt** field.
- To provide the initial conditions from an external source for state *dx/dt*, specify **Initial condition source dx/dt** as `external`. An additional input port appears on the block.

If you choose to use an external source for both state initial conditions, your block appears as follows.



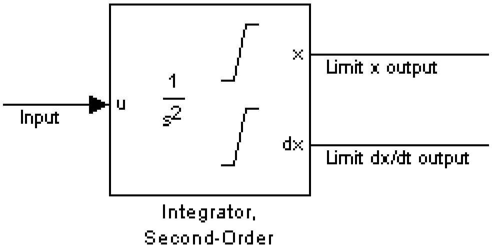
Note

- Simulink does not allow initial condition values of `inf` or `NaN`.
- If you limit state *x* or state *dx/dt* by specifying saturation limits (see "Limiting the States" on page 1-1651) and one or more initial conditions are outside the corresponding limits, then the respective states are initialized to the closest valid value and a set of consistent initial conditions is calculated.

Limiting the States

When modeling a second-order system, you may need to limit the block states. For example, the motion of a piston within a cylinder is governed by Newton's Second Law and has constraints on the piston position (*x*). With the Second-Order Integrator block, you can limit the states *x* and *dx/dt* independent of each other. You can even change the limits during simulation; however, you cannot change whether or not the states are limited. An important rule to follow is that an upper limit must be strictly greater than its corresponding lower limit.

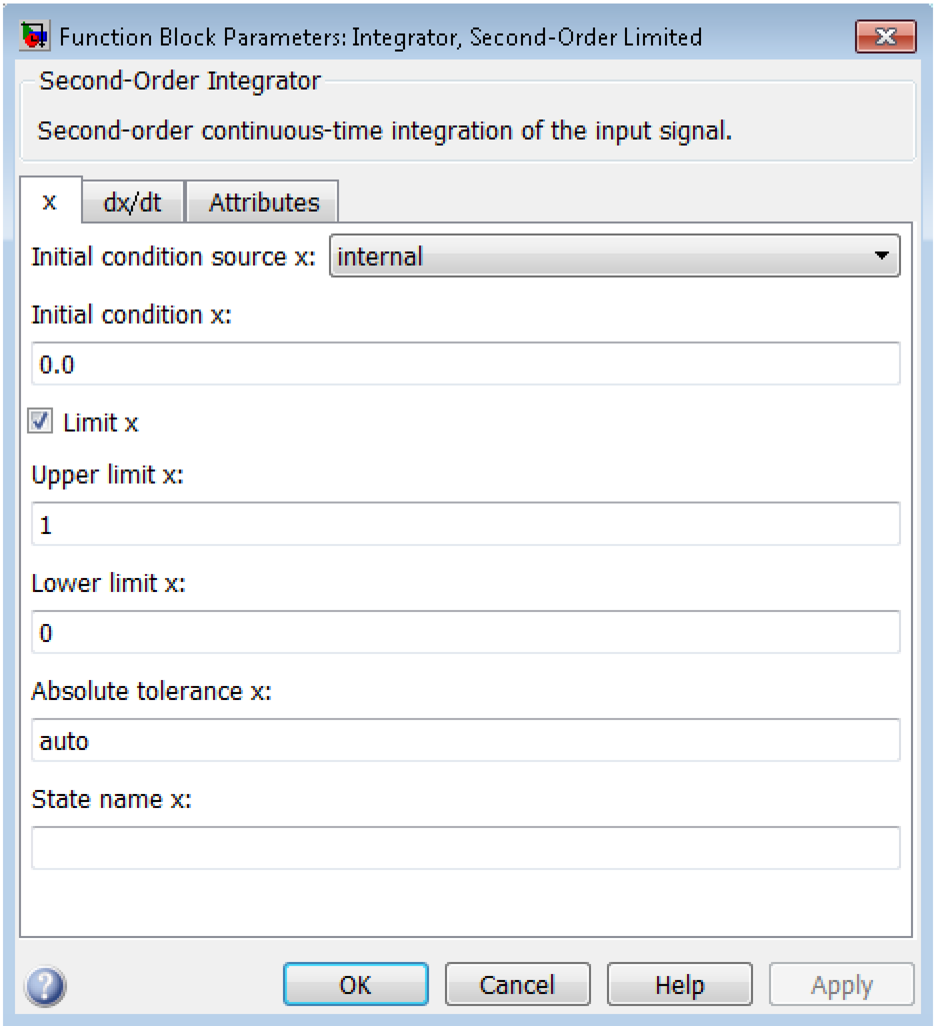
The block appearance changes when you limit one or both states. With both states limited, the block appears as follows.



For each state, you can use the block parameter dialog box to set appropriate saturation limits.

Limiting *x* Only

If you use the Second-Order Integrator Limited block, both states are limited by default. But you can also manually limit state *x* on the Second-Order Integrator block by selecting **Limit x** and entering the limits in the appropriate parameter fields.



Function Block Parameters: Integrator, Second-Order Limited

Second-Order Integrator

Second-order continuous-time integration of the input signal.

Initial condition source x: internal

Initial condition x:

0.0

☑ Limit x

Upper limit x:

1

Lower limit x:

0

Absolute tolerance x:

auto

State name x:

The block then determines the values of the states as follows:

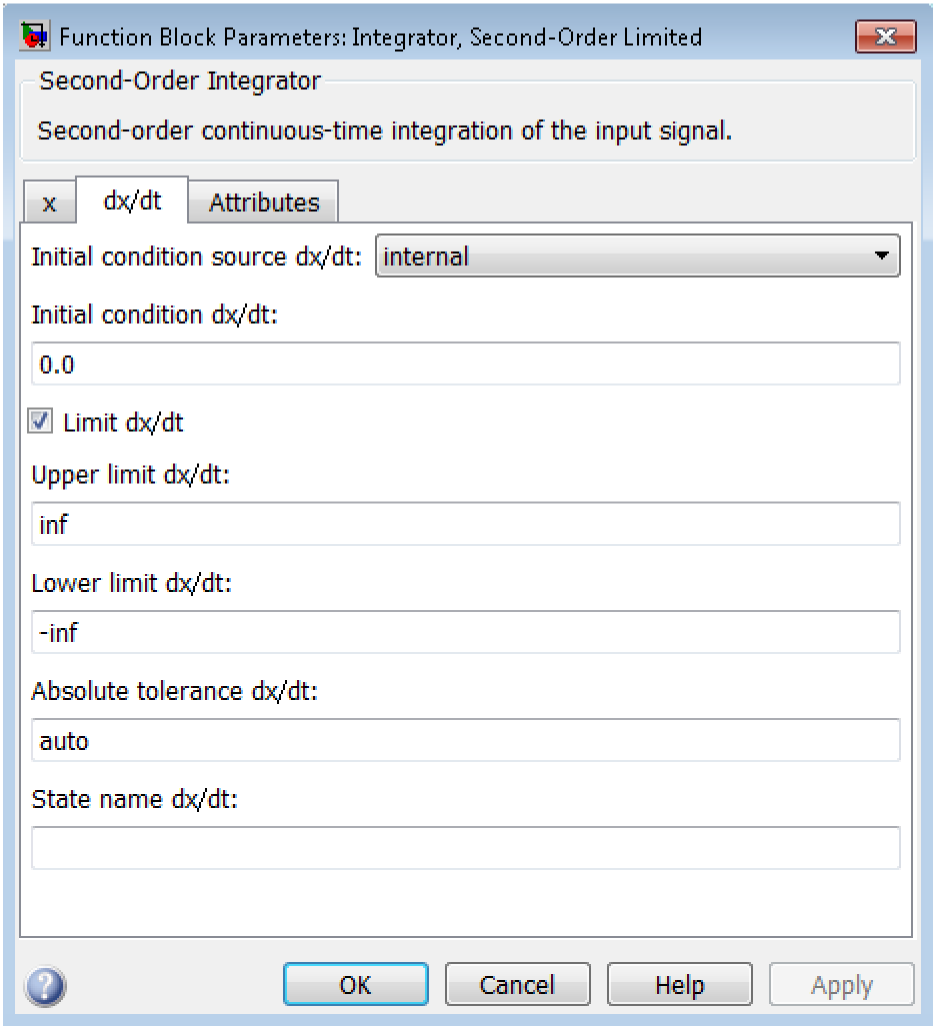
- When *x* is less than or equal to its lower limit, the value of *x* is held at its lower limit and *dx/dt* is set to zero.
- When *x* is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.

- When *x* is greater than or equal to its upper limit, the value of *x* is held at its upper limit and *dx/dt* is set to zero.

You can choose to reinitialize *dx/dt* to a new value at the time when *x* reaches saturation. See "Reinitializing dx/dt When x Reaches Saturation" on page 1-1658.

Limiting *dx/dt* Only

As with state *x*, state *dx/dt* is set as limited by default on the **dx/dt** pane of the Second-Order Integrator Limited block dialog box. You can manually set this parameter, **Limit dx/dt**, on the Second-Order Integrator block. In either case, you must enter the appropriate limits for *dx/dt*.



Function Block Parameters: Integrator, Second-Order Limited

Second-Order Integrator

Second-order continuous-time integration of the input signal.

Initial condition source dx/dt: internal

Initial condition dx/dt: 0.0

☑ Limit dx/dt

Upper limit dx/dt: inf

Lower limit dx/dt: -inf

Absolute tolerance dx/dt: auto

State name dx/dt:

If you limit only the state *dx/dt*, then the block determines the values of *dx/dt* as follows:

- When *dx/dt* is less than or equal to its lower limit, the value of *dx/dt* is held at its lower limit.
- When *dx/dt* is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.

- When *dx/dt* is greater than or equal to its upper limit, the value of *dx/dt* is held at its upper limit.

When state *dx/dt* is held at it upper or lower limit, the value of *x* is governed by the first-order initial value problem:

$$\frac{dx}{dt} = L,$$
$$x(t_L) = x_{L,}$$

where *L* is the *dx/dt* limit (upper or lower), t_L is the time when *dx/dt* reaches this limit, and x_L is the value of state *x* at that time.

Limiting Both States

When you limit both states, Simulink maintains mathematical consistency of the states by limiting the allowable values of the upper and lower limits for *dx/dt*. Such limitations are necessary to satisfy the following constraints:

- When *x* is at its saturation limits, the value of *dx/dt* must be zero.
- In order for *x* to leave the upper limit, the value of *dx/dt* must be strictly negative.
- In order for *x* to leave its lower limit, the value of *dx/dt* must be strictly positive.

For such cases, the upper limit of *dx/dt* must be strictly positive and the lower limit of *dx/dt* must be strictly negative.

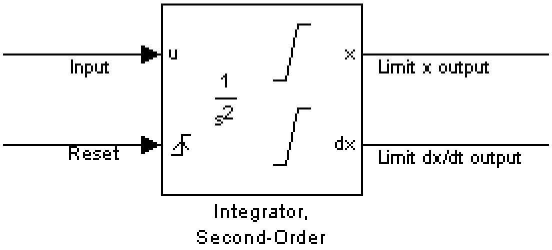
When both states are limited, the block determines the states as follows:

- Whenever *x* reaches its limits, the resulting behavior is the same as that described in "Limiting x only".
- Whenever *dx/dt* reaches one of its limits, the resulting behavior is the same as that described in "Limiting dx/dt only" — including the computation of *x* using a first-order ODE when *dx/dt* is held at one of its limits. In such cases, when *x* reaches one of its limits, it is held at that limit and *dx/dt* is set to zero.
- Whenever both reach their respective limits simultaneously, the state *x* behavior overrides *dx/dt* behavior to maintain consistency of the states.

When you limit both states, you can choose to reinitialize *dx/dt* at the time when state *x* reaches saturation. If the reinitialized value is outside specified limits on *dx/dt*, then *dx/dt* is reinitialized to the closest valid value and a consistent set of initial conditions is calculated. See “Reinitializing dx/dt When x Reaches Saturation” on page 1-1658

Resetting the State

The block can reset its states to the specified initial conditions based on an external signal. To cause the block to reset its states, select one of the **External reset** choices on the **Attributes** pane. A trigger port appears on the block below its input port and indicates the trigger type.



- Select `rising` to reset the states when the reset signal rises from zero to a positive value, from a negative to a positive value, or a negative value to zero.
- Select `falling` to reset the states when the reset signal falls from a positive value to zero, from a positive to a negative value, or from zero to negative.
- Select `either` to reset the states when the reset signal changes from zero to a nonzero value or changes sign.

The reset port has direct feedthrough. If the block output feeds back into this port, either directly or through a series of blocks with direct feedthrough, an algebraic loop results (see “Algebraic Loops”).

Enabling Zero-Crossing Detection

This parameter controls whether zero-crossing detection is enabled for this block. By default, the **Enable zero-crossing detection** parameter is selected on the **Attributes** pane. However, this parameter is only in affect if the **Zero-crossing control**, on the **Solver** pane of the Configuration Parameters dialog box, is set to `Use local settings`. For more information, see “Zero-Crossing Detection”.

Reinitializing *dx/dt* When *x* Reaches Saturation

For certain modeling applications, *dx/dt* must be reinitialized when state *x* reaches its limits in order to pull *x* out of saturation immediately. You can achieve this by selecting **Reinitialize dx/dt when x reaches saturation** on the **Attributes** pane.

If this option is on, then at the instant when *x* reaches saturation, Simulink checks whether the current value of the *dx/dt* initial condition (parameter or signal) allows the state *x* to leave saturation immediately. If so, Simulink reinitializes state *dx/dt* with the value of the initial condition (parameter or signal) at that instant. If not, Simulink ignores this parameter at the current instant and sets *dx/dt* to zero to make the block states consistent.

This parameter only applies at the time when *x* actually reaches saturation limit. It does not apply at any future time when *x* is being held at saturation.

Refer to the sections on limiting the states for more information. For an example, see “Simulation of a Bouncing Ball”.

Disregarding State Limits and External Reset for Linearization

For cases where you simplify your model by linearizing it, you can have Simulink disregard the limits of the states and the external reset by selecting **Ignore state limits and the reset for linearization**.

Specifying the Absolute Tolerance for the Block Outputs

By default Simulink software uses the absolute tolerance value specified in the Configuration Parameters dialog box (see “Error Tolerances for Variable-Step Solvers”) to compute the output of the integrator blocks. If this value does not provide sufficient error control, specify a more appropriate value for state *x* in the **Absolute tolerance x** field and for state *dx/dt* in the **Absolute tolerance dx/dt** field of the parameter dialog box. Simulink uses the values that you specify to compute the state values of the block.

Specifying the Display of the Output Ports

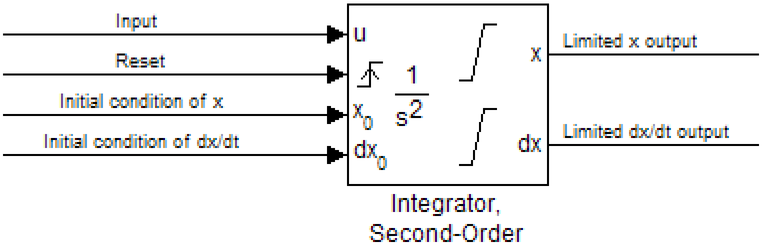
You can control whether to display the *x* or the *dx/dt* output port using the `ShowOutput` parameter. You can display one output port or both; however, you must select at least one.

Specifying the State Names

You can specify the name of *x* states and *dx/dt* states using the `StateNameX` and `StateNameDXDT` parameters. However, you must specify names for both or neither; you cannot specify names for just *x* or just *dx/dt*. Both state names must have identical type and length. Furthermore, the number of names must evenly divide the number of states.

Selecting All Options

When you select all options, the block icon looks like this.



Ports

Input

u — Input signal u
scalar | vector | matrix

Input signal `u` to the integrator system, specified as a scalar, vector, or matrix.

Data Types: `double`

x0 — Initial condition x0
scalar | vector | matrix

External signal specifying the initial condition `x0` to the integrator system. You can specify the initial condition as a scalar, vector, or matrix.

Dependencies

To enable this input port, set the **Initial condition source x** parameter to `external`.

Data Types: `double`

`dx0` — Initial condition `dx0`

scalar | vector | matrix

External signal specifying the initial condition `dx0` to the integrator system. You can specify the initial condition `dx0` as a scalar, vector, or matrix.

Dependencies

To enable this input port, set the **Initial condition source dx/dt** parameter to `external`.

Data Types: `double`

Output

x — Output signal x

scalar | vector | matrix

`x` state output signal, provided as a scalar, vector, or matrix.

Data Types: `double`

dx — Output signal dx

scalar | vector | matrix

`dx` state output signal, specified as a scalar, vector, or matrix.

Data Types: `double`

Parameters

x

`Initial condition source x` — Source of initial condition for state *x*

`internal` (default) | `external`

Specify the source of the initial conditions for state *x*.

- `internal` — Get the initial conditions of state *x* from the **Initial condition x** parameter.
- `external` — Get the initial conditions of state *x* from an external block connected to the $\mathbf{X_0}$ input port.

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

Selecting `internal` enables the **Initial condition x** parameter and removes the $\mathbf{X_0}$ input port.

Selecting `external` disables the **Initial condition x** parameter and enables the $\mathbf{X_0}$ input port.

Programmatic Use

Block Parameter: `ICSourceX`
Type: character vector, string
Values: `'internal'` | `'external'`
Default: `'internal'`

`Initial condition x` — Initial condition of state *x*

`0.0` (default) | scalar | vector | matrix

Specify the initial condition of state *x*.

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

To enable this parameter, set **Initial condition source x** to `internal`.

Setting **Initial condition source x** to `external` disables this parameter and enables the $\mathbf{X_0}$ input port.

Programmatic Use

Block Parameter: `ICX`
Type: character vector, string

Values: scalar | vector | matrix
Default: `'0.0'`

`Limit x` — Limit values of state *x*

`off` | `on`

Limit state *x* of the block to a value between the **Lower limit x** and **Upper limit x** parameters. The default value of the Second-Order Integrator block is `off`. The default value of the Second-Order Integrator Limited is `on`.

- To limit state *x* to a value between the **Lower limit x** and **Upper limit x** parameters, select this check box.
- To remove range limitations on state *x*, clear this check box.

Dependencies

Selecting this check box enables the **Upper limit x** and **Lower limit x** parameters.

Programmatic Use

Block Parameter: `LimitX`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'off'` (Second-Order Integrator) | `'on'` (Second-Order Integrator Limited)

`Upper limit x` — Upper limit of state *x*

`1` | `inf` | scalar | vector | matrix

Specify the upper limit of state *x*. The default value for the Second-Order Integrator block is `inf`. The default value for the Second-Order Integrator Limited block is `1`.

Tips

The upper saturation limit for state *x* must be strictly greater than the lower saturation limit.

Dependencies

To enable this parameter, select the **Limit x** check box.

Programmatic Use

Block Parameter: `UpperLimitX`
Type: character vector, string
Values: `'1' | 'inf' |` scalar | vector | matrix

Default: `'1'` (Second-Order Integrator Limited) | `'inf'` (Second-Order Integrator)

`Lower limit x` — Lower limit of state *x*

`0` (default) | `-inf` | scalar | vector | matrix

Specify the lower limit of state *x*. The default value for the Second-Order Integrator block is `-inf`. The default value for the Second-Order Integrator Limited block is `0`.

Tip

The lower saturation limit for state *x* must be strictly less than the upper saturation limit.

Dependencies

To enable this parameter, select the **Limit x** check box.

Programmatic Use
Block Parameter: `LowerLimitX`
Type: character vector, string
Values: `'0' | '-inf' |` scalar | vector | matrix
Default: `'0'` (Second-Order Integrator Limited) | `'-inf'` (Second-Order Integrator)

`Wrap x` — Enable wrapping of x

`off` (default) | `on`

Enable wrapping of *x* between the **Wrapped upper value x** and **Wrapped lower value x** parameters. Enabling wrapping of *x* eliminates the need for zero-crossing detection, reduces solver resets, improves solver performance and accuracy, and increases simulation time span when modeling rotary and cyclic state trajectories.

If you specify **Wrapped upper value x** as `inf` and **Wrapped lower value x** as `-inf`, wrapping will never occur.

Dependencies

Selecting this check box enables **Wrapped upper value x** and **Wrapped lower value x**.

Programmatic Use
Block Parameter: `WrapX`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'off'`

`Wrapped upper value x` — Upper value for wrapping x

`pi` (default) | scalar | vector | matrix

Specify the upper value for wrapping *x*.

Dependencies

To enable this parameter, select the **Wrap x** check box.

Programmatic Use

Block Parameter: `WrappedUpperValueX`
Type: character vector, string
Values: scalar | vector | matrix
Default: `'pi'`

`Wrapped lower value x` — Lower value for wrapping x

`-pi` (default) | scalar | vector | matrix

Specify the lower value for wrapping *x*.

Dependencies

To enable this parameter, select the **Wrap x** check box.

Programmatic Use

Block Parameter: `WrappedLowerValueX`
Type: character vector, string
Values: scalar | vector | matrix
Default: `'-pi'`

`Absolute tolerance x` — Absolute tolerance for computing state *x*

`auto` (default) | `-1` | scalar | vector

Specify the absolute tolerance for computing state *x*.

- You can enter `auto`, –1, a positive real scalar or vector.
- If you enter `auto` or –1, Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute state *x*.
- If you enter a real scalar value, that value overrides the absolute tolerance in the Configuration Parameters dialog box and is used for computing all *x* states.
- If you enter a real vector, the dimension of that vector must match the dimension of state *x*. These values override the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use

Block Parameter: `AbsoluteToleranceX`
Type: character vector, string
Values: `'auto'` | `'-1'` | any positive real scalar or vector
Default: `'auto'`

`State name x` — Name for state *x*

`''` (default) | character vector | string

Assign a unique name to state *x*.

Tips

- To assign a name to a single state, enter the name between quotes, for example, position'.
- To assign names to multiple *x* states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for *x*, you must also specify a state name for *dx/dt*.
- State names for *x* and *dx/dt* must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than *x* states, but you cannot specify more names than *x* states. For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for *dx/dt*.
- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string or a cell array.

Programmatic Use

Block Parameter: `StateNameX`
Type: character vector, string
Values: `' '` | user-defined
Default: `' '`

dx/dt

`Initial condition source dx/dt` — Source of initial condition for state *dx/dt*

`internal` (default) | `external`

Specify the source of initial conditions for state *dx/dt* as `internal` or `external`.

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

- Selecting `internal` enables the **Initial condition dx/dt** parameter and removes the **$\mathbf{dx_0}$** input port.
- Selecting `external` disables the **Initial condition dx/dt** parameter and enables the **$\mathbf{dx_0}$** input port.

Programmatic Use

Block Parameter: `ICSourceDXDT`
Type: character vector
Values: `'internal'` | `'external'`
Default: `'internal'`

`Initial condition dx/dt` — Initial condition of state *dx/dt*

`0.0` (default) | scalar | vector | matrix

Specify the initial condition of state *dx/dt*.

Limitations

Simulink software does not allow the initial condition of this block to be `inf` or `NaN`.

Dependencies

- Setting **Initial condition source dx/dt** to `internal` enables this parameter.
- Setting **Initial condition source dx/dt** to `external` disables this parameter.

Programmatic Use

Block Parameter: `ICDXDT`
Type: character vector
Values: scalar | vector | matrix
Default: `'0.0'`

`Limit dx/dt` — Limit values of state *dx/dt*

`off` | `on`

Limit the *dx/dt* state of the block to a value between the **Lower limit dx/dt** and **Upper limit dx/dt** parameters. The default value of the Second-Order Integrator block is `off`. The default value of the Second-Order Integrator Limited is `on`.

Tip

If you set saturation limits for *x*, then the interval defined by the **Upper limit dx/dt** and **Lower limit dx/dt** must contain zero.

Dependencies

Selecting this check box enables the **Upper limit dx/dt** and **Lower limit dx/dt** parameters.

Programmatic Use

Parameter: `LimitDXDT`
Type: character vector
Values: `'off'` | `'on'`
Default: `'off'` (Second-Order Integrator) | `'on'` (Second-Order Integrator Limited)

`Upper limit dx/dt` — Upper limit of state *dx/dt*

`inf` (default) | scalar | vector | matrix

Specify the upper limit for state *dx/dt*.

Dependencies

If you limit *x*, then this parameter must have a strictly positive value.

To enable this parameter, select the **Limit dx/dt** check box.

Programmatic Use

Block Parameter: `UpperLimitDXDT`
Type: character vector
Values: scalar | vector | matrix
Default: `'inf'`

`Lower limit dx/dt` — Lower limit of state *dx/dt*

`-inf` (default) | scalar | vector | matrix

Specify the lower limit for state *dx/dt*.

Dependencies

If you limit *x*, then this parameter must have a strictly negative value.

To enable this parameter, select the **Limit dx/dt** check box.

Programmatic Use
Block Parameter: `LowerLimitDXDT`
Type: character vector
Values: scalar | vector | matrix
Default: `'-inf'`

`Absolute tolerance dx/dt` — Absolute tolerance for computing state *dx/dt*

`auto` (default) | `-1` | scalar | vector

Specify the absolute tolerance for computing state *dx/dt*.

- You can enter `auto`, −1, a positive real scalar or vector.
- If you enter `auto` or −1, then Simulink uses the absolute tolerance value in the Configuration Parameters dialog box (see “Solver Pane”) to compute the *dx/dt* output of the block.
- If you enter a numeric value, that value overrides the absolute tolerance in the Configuration Parameters dialog box.

Programmatic Use
Block Parameter: `AbsoluteToleranceDXDT`
Type: character vector, string, scalar, or vector
Values: `'auto'` | `'-1'` | any positive real scalar or vector
Default: `'auto'`

`State name dx/dt` — Name for state *dx/dt*

`' '` (default) | character vector | string

Assign a unique name to state *dx/dt*.

Tips

- To assign a name to a single state, enter the name between quotes, for example, 'velocity'.
- To assign names to multiple *dx/dt* states, enter a comma-delimited list surrounded by braces, for example, {'a', 'b', 'c'}. Each name must be unique.
- The state names apply only to the selected block.
- If you specify a state name for *dx/dt*, you must also specify a state name for *x*.
- State names for *x* and *dx/dt* must have identical types and lengths.
- The number of states must be evenly divided by the number of state names. You can specify fewer names than *dx/dt* states, but you cannot specify more names than *dx/dt*

states. For example, you can specify two names in a system with four states. The first name applies to the first two states and the second name to the last two states. However, you must be consistent and apply the same scheme to the state names for *x*.

- To assign state names with a variable in the MATLAB workspace, enter the variable without quotes. A variable can be a character vector, string, or a cell array.

Programmatic Use
Block Parameter: `StateNameDXDT`
Type: character vector, string
Values: `' '` | user-defined
Default: `' '`

Attributes

`External reset` — Reset states to their initial conditions

`none` (default) | `rising` | `falling` | `either`

Reset the states to their initial conditions when a trigger event occurs in the reset signal.

- `none` — Do not reset the state to initial conditions.
- `rising` — Reset the state when the reset signal rises from a zero to a positive value or from a negative to a positive value.
- `falling` — Reset the state when the reset signal falls from a positive value to zero or from a positive to a negative value.
- `either` — Reset the state when the reset signal changes from zero to a nonzero value or changes sign.

Programmatic Use
Block Parameter: `ExternalReset`
Type: character vector, string
Values: `'none'` | `'rising'` | `'falling'` | `'either'`
Default: `'none'`

`Enable zero-crossing detection` — Enable zero-crossing detection

on (default) | `off`

Select to enable zero-crossing detection. For more information, see “Zero-Crossing Detection”.

Programmatic Use
Parameter:`ZeroCross`
Type: character vector, string
Values: `'on'` | `'off'`
Default: `'on'`

`Reinitialize dx/dt when x reaches saturation` — Reset *dx/dt* when *x* reaches saturation

`off` (default) | `on`

At the instant when state *x* reaches saturation, reset *dx/dt* to its current initial conditions.

Tip

The *dx/dt* initial condition must have a value that enables *x* to leave saturation immediately. Otherwise, Simulink ignores the initial conditions for *dx/dt* to preserve mathematical consistency of block states.

Programmatic Use
Block Parameter: `ReinitDXDTwhenXreachesSaturation`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'off'`

`Ignore state limits and the reset for linearization` — Ignore state limits and external reset for linearization

`off` (default) | `on`

For linearization purposes, have Simulink ignore the specified state limits and the external reset.

Programmatic Use
Block Parameter: `IgnoreStateLimitsAndResetForLinearization`
Type: character vector, string
Values: `'off'` | `'on'`
Default: `'off'`

`Show output` — Output ports to display

`both` (default) | `x` | `dxdt`

Specify the output ports on the block.

- `both` — Show both *x* and *dx/dt* output ports.

- `x` — Show only the *x* output port.
- `dx/dt` — Show only the *dx/dt* output port.

Programmatic Use
Block Parameter: `ShowOutput`
Type: character vector, string
Values: `'both'` | `'x'` | `'dxdt'`
Default: `'both'`

Block Characteristics

Data Types	`double`
Direct Feedthrough	`Yes`
Multidimensional Signals	`No`
Variable-Size Signals	`No`
Zero-Crossing Detection	`Yes`

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using Simulink® Coder™.

Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code.

In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, select `Analysis > Control Design > Model Discretizer`. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

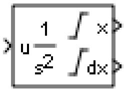
Second-Order Integrator Limited

Integrate input signal twice

Library: Simulink / Continuous



Description

The Second-Order Integrator block and the Second-Order Integrator Limited block solve the second-order initial value problem:

$$\frac{d^2x}{dt^2} = u,$$
$$\left.\frac{dx}{dt}\right|_{t=0} = dx_o,$$
$$\left.x\right|_{t=0} = x_o,$$

where *u* is the input to the system. The block is therefore a dynamic system with two continuous states: *x* and *dx/dt*.

Note These two states have a mathematical relationship, namely, that *dx/dt* is the derivative of *x*. To satisfy this relationship throughout the simulation, Simulink places various constraints on the block parameters and behavior.

The Second-Order Integrator Limited block is identical to the Second-Order Integrator block with the exception that it defaults to limiting the states based on the specified upper and lower limits. For more information, see “Limiting the States” on page 1-1675.

Simulink software can use several different numerical integration methods to compute the outputs of the block. Each has advantages for specific applications. Use the **Solver** pane of the Configuration Parameters dialog box to select the technique best suited to your application. (For more information, see “Solver Types”.) The selected solver computes the states of the Second-Order Integrator block at the current time step using the current input value.

Use the block parameter dialog box to:

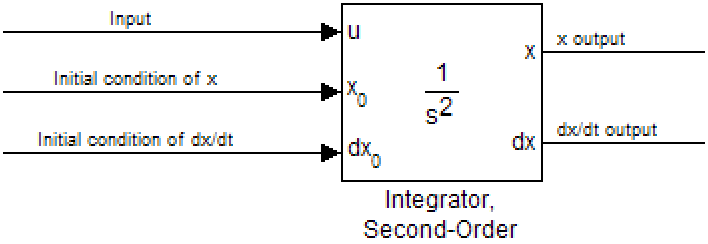
- Specify whether the source of each state initial condition is internal or external
- Specify a value for the state initial conditions
- Define upper and lower limits on either or both states
- Specify absolute tolerances for each state
- Specify names for both states
- Choose an external reset condition
- Enable zero-crossing detection
- Reinitialize dx/dt when x reaches saturation
- Specify that Simulink disregard the state limits and external reset for linearization operations

Defining Initial Conditions

You can define the initial conditions of each state individually as a parameter on the block dialog box or input one or both of them from an external signal.

- To define the initial conditions of state *x* as a block parameter, use the **Initial condition source x** drop-down menu to select `internal` and enter the value in the **Initial condition x** field.
- To provide the initial conditions from an external source for state *x*, specify the **Initial condition source x** parameter as `external`. An additional input port appears on the block.
- To define the initial conditions of state *dx/dt* as a block parameter, use the **Initial condition source dx/dt** drop-down menu to select `internal` and enter the value in the **Initial condition dx/dt** field.
- To provide the initial conditions from an external source for state *dx/dt*, specify **Initial condition source dx/dt** as `external`. An additional input port appears on the block.

If you choose to use an external source for both state initial conditions, your block appears as follows.



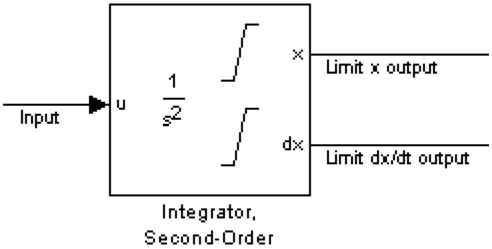
Note

- Simulink does not allow initial condition values of `inf` or `NaN`.
- If you limit state *x* or state *dx/dt* by specifying saturation limits (see “Limiting the States” on page 1-1675) and one or more initial conditions are outside the corresponding limits, then the respective states are initialized to the closest valid value and a set of consistent initial conditions is calculated.

Limiting the States

When modeling a second-order system, you may need to limit the block states. For example, the motion of a piston within a cylinder is governed by Newton's Second Law and has constraints on the piston position (*x*). With the Second-Order Integrator block, you can limit the states *x* and *dx/dt* independent of each other. You can even change the limits during simulation; however, you cannot change whether or not the states are limited. An important rule to follow is that an upper limit must be strictly greater than its corresponding lower limit.

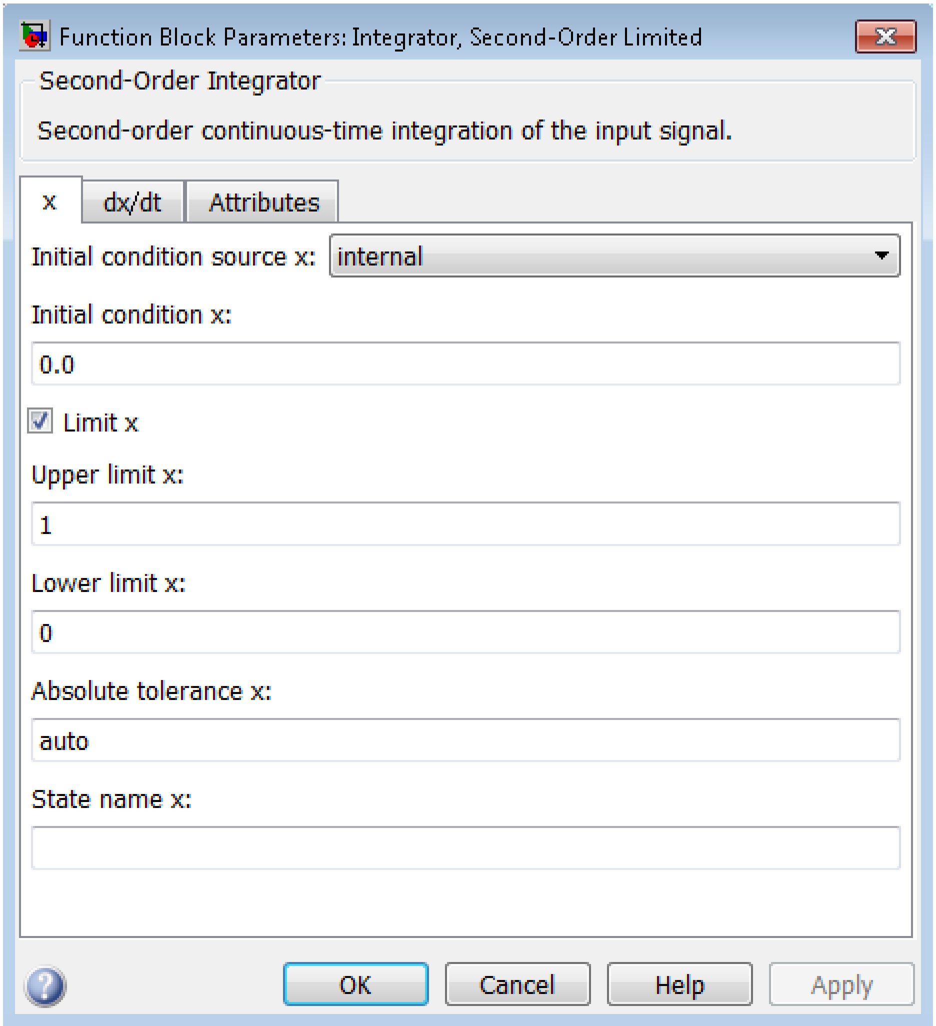
The block appearance changes when you limit one or both states. With both states limited, the block appears as follows.



For each state, you can use the block parameter dialog box to set appropriate saturation limits.

Limiting *x* Only

If you use the Second-Order Integrator Limited block, both states are limited by default. But you can also manually limit state *x* on the Second-Order Integrator block by selecting **Limit x** and entering the limits in the appropriate parameter fields.



Second-Order Integrator

Second-order continuous-time integration of the input signal.

Initial condition source x: internal

Initial condition x: 0.0

☑ Limit x

Upper limit x: 1

Lower limit x: 0

Absolute tolerance x: auto

State name x:

The block then determines the values of the states as follows:

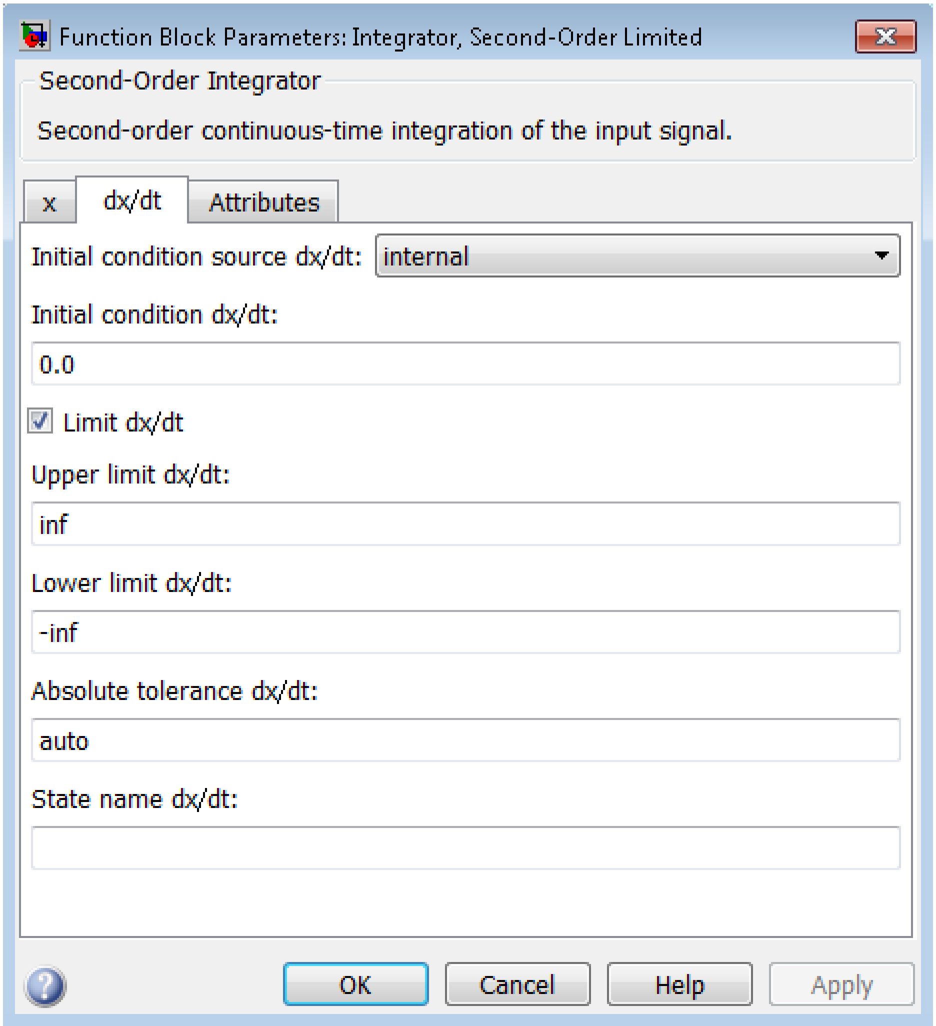
- When *x* is less than or equal to its lower limit, the value of *x* is held at its lower limit and *dx/dt* is set to zero.
- When *x* is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.

- When *x* is greater than or equal to its upper limit, the value of *x* is held at its upper limit and *dx/dt* is set to zero.

You can choose to reinitialize *dx/dt* to a new value at the time when *x* reaches saturation. See “Reinitializing dx/dt When x Reaches Saturation” on page 1-1682.

Limiting *dx/dt* Only

As with state *x*, state *dx/dt* is set as limited by default on the **dx/dt** pane of the Second-Order Integrator Limited block dialog box. You can manually set this parameter, **Limit dx/dt**, on the Second-Order Integrator block. In either case, you must enter the appropriate limits for *dx/dt*.



Function Block Parameters: Integrator, Second-Order Limited

Second-Order Integrator

Second-order continuous-time integration of the input signal.

Initial condition source dx/dt: internal

Initial condition dx/dt: 0.0

☑ Limit dx/dt

Upper limit dx/dt: inf

Lower limit dx/dt: -inf

Absolute tolerance dx/dt: auto

State name dx/dt:

If you limit only the state *dx/dt*, then the block determines the values of *dx/dt* as follows:

- When *dx/dt* is less than or equal to its lower limit, the value of *dx/dt* is held at its lower limit.
- When *dx/dt* is in between its lower and upper limits, both states follow the trajectory given by the second-order ODE.

- When *dx/dt* is greater than or equal to its upper limit, the value of *dx/dt* is held at its upper limit.

When state *dx/dt* is held at it upper or lower limit, the value of *x* is governed by the first-order initial value problem:

$$\frac{dx}{dt} = L,$$
$$x(t_L) = x_{L,}$$

where *L* is the *dx/dt* limit (upper or lower), t_L is the time when *dx/dt* reaches this limit, and x_L is the value of state *x* at that time.

Limiting Both States

When you limit both states, Simulink maintains mathematical consistency of the states by limiting the allowable values of the upper and lower limits for *dx/dt*. Such limitations are necessary to satisfy the following constraints:

- When *x* is at its saturation limits, the value of *dx/dt* must be zero.
- In order for *x* to leave the upper limit, the value of *dx/dt* must be strictly negative.
- In order for *x* to leave its lower limit, the value of *dx/dt* must be strictly positive.

For such cases, the upper limit of *dx/dt* must be strictly positive and the lower limit of *dx/dt* must be strictly negative.

When both states are limited, the block determines the states as follows:

- Whenever *x* reaches its limits, the resulting behavior is the same as that described in “Limiting x only”.
- Whenever *dx/dt* reaches one of its limits, the resulting behavior is the same as that described in “Limiting dx/dt only” — including the computation of *x* using a first-order ODE when *dx/dt* is held at one of its limits. In such cases, when *x* reaches one of its limits, it is held at that limit and *dx/dt* is set to zero.
- Whenever both reach their respective limits simultaneously, the state *x* behavior overrides *dx/dt* behavior to maintain consistency of the states.

When you limit both states, you can choose to reinitialize *dx/dt* at the time when state *x* reaches saturation. If the reinitialized value is outside specified limits on *dx/dt*, then *dx/dt* is reinitialized to the closest valid value and a consistent set of initial conditions is calculated. See “Reinitializing dx/dt When x Reaches Saturation” on page 1-1682

Resetting the State

The block can reset its states to the specified initial conditions based on an external signal. To cause the block to reset its states, select one of the **External reset** choices on the **Attributes** pane. A trigger port appears on the block below its input port and indicates the trigger type.
