
Change the data type setting for the two input signals and the output signal for the Sub32 block to `uint32`.

9 Regenerate code. Use the Code Replacement Viewer trace information to verify that your model or code replacement table entry corrects the code replacement issue. In the following display, the trace information shows a hit for block Sub32.

Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

1. Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.
2. Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.
3. Register the library customizations or restart MATLAB.
4. Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.
5. Inform users that the libraries are available and provide direction on when and how to apply them.

Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the `sin` function programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_sinfcn2()
%CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```
% Create entry for sin function replacement
fcn_entry = RTW.TflCFunctionEntry;
```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(fcn_entry, ...
                               'Key',                    'sin', ...
                               'Priority',               30, ...
                               'ImplementationName',     'mySin', ...
                               'ImplementationHeaderFile', 'basicMath.h',...
                               'ImplementationSourceFile', 'basicMath.c');
```

5. Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
                          'Name',         'y1',...
                          'IOType',       'RTW_IO_OUTPUT',...
                          'DataTypeMode', 'double');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
                          'Name',         'u1', ...
                          'IOType',       'RTW_IO_INPUT',...
                          'DataTypeMode', 'double');
```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_memcpy()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   % Create entry for void* memcpy(void*, void*, size_t)
   fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   % Set SideEffects to 'true' for function returning void to prevent it from
   % being optimized away.
   setTflCFunctionEntryParameters(fcn_entry, ...
                                  'Key',                    'memcpy', ...
                                  'Priority',               90, ...
                                  'ImplementationName',     'memcpy_int', ...
                                  'ImplementationHeaderFile', 'memcpy_int.h',...
                                  'SideEffects',            true);
   ```

5. Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'void*');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u2', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u3', 'size_t');
   addConceptualArg(fcn_entry, arg);
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the

`copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

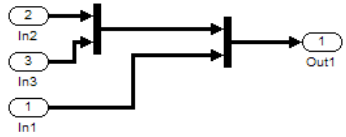
8 Save the table definition file. Use the name of the table definition function to name the file.

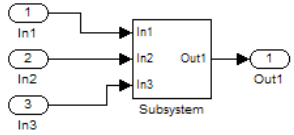
To test this example:

1 Register the code replacement mapping.

2 Create a model that uses the `memcpy` function for vector assignments. For example, use In, Out, and Mux blocks to create the following model. (Alternatively, open the example model `rtwdemo_crlmath` and copy the contents of Subsystem1 to a new model.)



3 Select the diagram and use **Edit** > **Subsystem** to make it a subsystem.



4 Configure the subsystem with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Optimization** pane, select **Use memcpy for vector assignment** and set **Memcpy threshold (bytes)** to 64.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your memory function entry.

5 In the Model Explorer, configure the **Signal Attributes** for the `In1`, `In2`, and `In3` source blocks. For each, set **Port dimensions** to `[1,100]`, and set **Data type** to `int32`. Apply the changes. Save the model.

6 Generate code and a code generation report.

7 Review the code replacements.

Nonfinite Function Code Replacement

This example shows how to define a code replacement mapping for nonfinite utility functions.

1. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_nonfinite()
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3. Create entries for the function mappings. To minimize the size of this function, the example uses a local function, `locAddFcnEnt`, to group lines of code repeated for each entry. A call to the `RTW.TflCFunctionEntry` function creates an entry for the collection of local function entry definitions.

```
%% Create entries for nonfinite utility functions
% locAddFcnEnt(hTable, key, implName, out, in1, hdr)

locAddFcnEnt(hTable, 'getNaN', 'getNaN', 'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getNaN', 'getNaNF', 'single', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getInf', 'getInf',  'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getInf', 'getInfF', 'single', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInf', 'double', 'void', 'nonfin.h');
locAddFcnEnt(hTable, 'getMinusInf', 'getMinusInfF', 'single', 'void', 'nonfin.h');

%% Local Function
function locAddFcnEnt(hTable, key, implName, out, in1, hdr)
  if isempty(hTable)
    return;
  end

 fcn_entry = RTW.TflCFunctionEntry;
```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
 setTflCFunctionEntryParameters(fcn_entry, ...
                                'Key', key, ...
                                'Priority', 90, ...
                                'ImplementationName', implName, ...
                                'ImplementationHeaderFile', hdr);
```

5. Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
  arg = getTflArgFromString(hTable, 'y1', out);
  arg.IOType = 'RTW_IO_OUTPUT';
  addConceptualArg(fcn_entry, arg);
```

```
arg = getTflArgFromString(hTable, 'u1', in1);
addConceptualArg(fcn_entry, arg);
```

6 Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

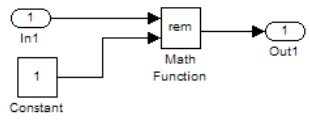
```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that uses a nonfinite function. For example, create a model that includes a Math Function block that is set to the `rem` function. For example:



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your memory function entry and select **Support: non-finite numbers**.

4 In the Model Explorer, configure the **Signal Attributes** for the `In1` and `Constant` source blocks. For each source block, set **Data type** to `double`. Apply the changes. Save the model.

5 Generate code and a code generation report.

6 Review the code replacements.

Semaphore and Mutex Function Replacement

You can create a code replacement table for a custom target that supports concurrent execution. Create table entries that specify custom implementations of semaphore or mutex operations. The table must have four semaphore entries, four mutex entries, or both, and include the table in a custom code replacement library. (The semaphore or mutex entries are mutually dependent. Provide them in complete sets of four.)

Note A custom target that supports concurrent multitasking must set the target configuration parameter `ConcurrentExecutionCompliant`. For more information, see "Support Concurrent Execution of Multiple Tasks" (Simulink Coder).

If the build process generates semaphore or mutex function calls for data transfer between tasks during code generation for a multicore target environment, use a custom library. The library can specify code replacements for custom semaphore or mutex implementations that are optimal for your target environment. Using the Code Replacement Tool (`crtool`) or equivalent code replacement functions, you can:

- Configure code replacement table entries for custom semaphore or mutex functions. During system startup, execution of the code for data transfer between tasks, and system shutdown the generated code calls these functions.
- Configure DWork arguments that represent global data, which the semaphore or mutex functions access. A DWork pointer is passed to the model entry functions.

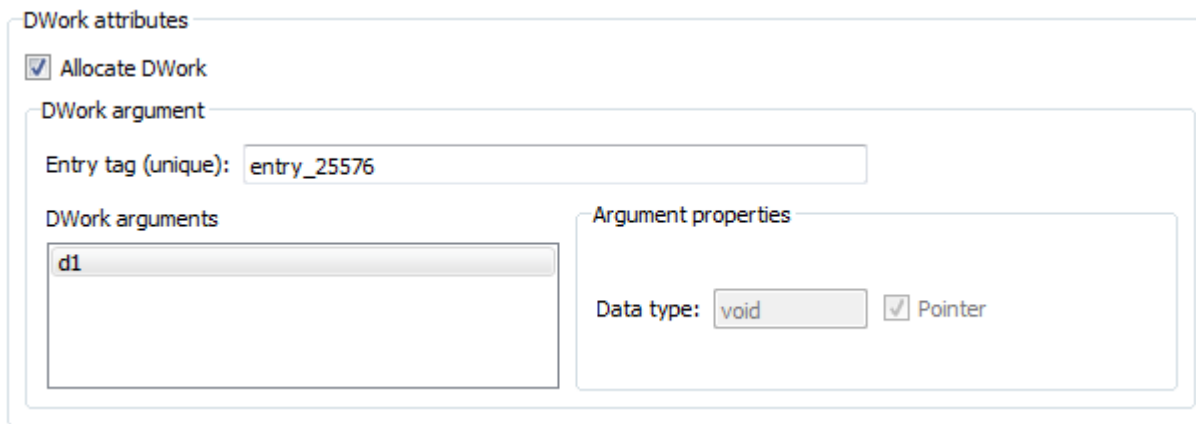
Generated mutex and semaphore code typically consists of these elements:

Code	Generated Code
Model initialization	Initialization function call that creates a mutex or semaphore function to control entry to a critical section of code.
Model step	• Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls reserve the critical section of code. • After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls release the critical section of code.

Code	Generated Code
Model termination	Optional destroy function call to delete the mutex or semaphore explicitly.

This example shows how to create code replacement table entries for a mutex replacement scenario. You configure a multicore target model for concurrent execution and for data transfer between tasks of differing rates, which Rate Transition blocks handle. In the generated code for the model, each Rate Transition block has a separate, unique mutex. Mutex lock and unlock operations within the Rate Transition block generated code share access to the same global data. They achieve this by using the unique mutex created for that Rate Transition block.

1. Open the **Code Replacement Tool**.
2. Create and open a new table.
3. Name the table `crl_table_rt_mutex`.
4. Create an entry for a mutex initialization function replacement.
   a. Select **File > New entry > Semaphore entry** to open a new table entry for configuring a semaphore or mutex replacement.
   b. In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Init`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.
   c. In the **DWork attributes** section, the **Allocate DWork** option is selected. The dialog box provides a unique entry tag for the DWork argument `d1`.



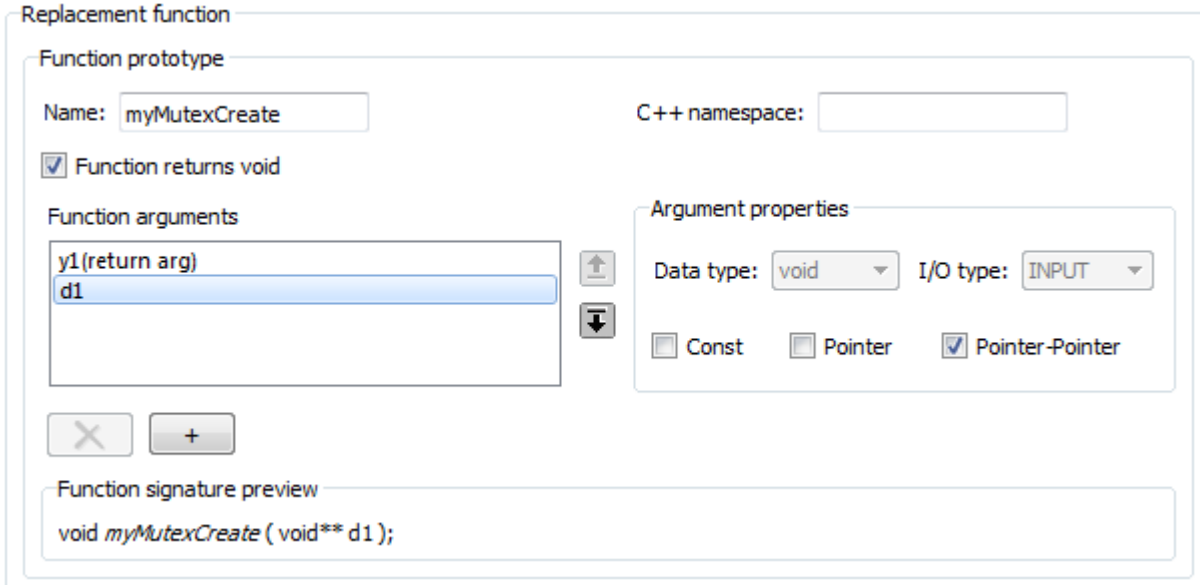
On the **DWork attributes** pane, configure a DWork argument to the replacement function. The DWork argument supports sharing of a semaphore or mutex between:

- Code that creates the semaphore or mutex
- Code that requests and relinquishes access
- Code that deletes the semaphore or mutex

In this example, the DWork argument for the `Mutex Init` function defines a unique entry tag, `entry_25576`. That function also defines DWork arguments for `Mutex Lock`, `Mutex Unlock`, and `Mutex Destroy`, which reference the entry tag to share the DWork data.

The only data type supported for the DWork **Data type** parameter is `void*`.

d In the **Replacement function** section, enter a function name in the **Name** field. This example uses `myMutexCreate`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void**`.



The C function signature preview is:

```
void myMutexCreate (void** d1);
```

e In the **Replacement function** section, select **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values. Click **Apply**. Optionally, you can click **Validate entry** to validate the information entered in the **Mapping Information** tab.

   To create a sample table entry, configure the replacement function signature without the replacement function and its build information. If header and source files for these functions are available, select the **Build Information** table to specify them.

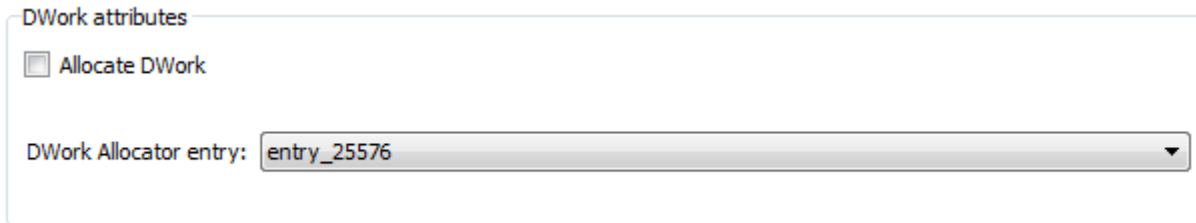
f The `Mutex Init` table entry is complete. Optionally, you can save the table to a file, and inspect the MATLAB code created for the table definition so far.

5 Repeat the following sequence to create the table entries for the mutex lock, unlock, and destroy function replacements. Each table entry references the DWork unique tag entry, `entry_25576`, defined in the `Mutex Init` table entry.

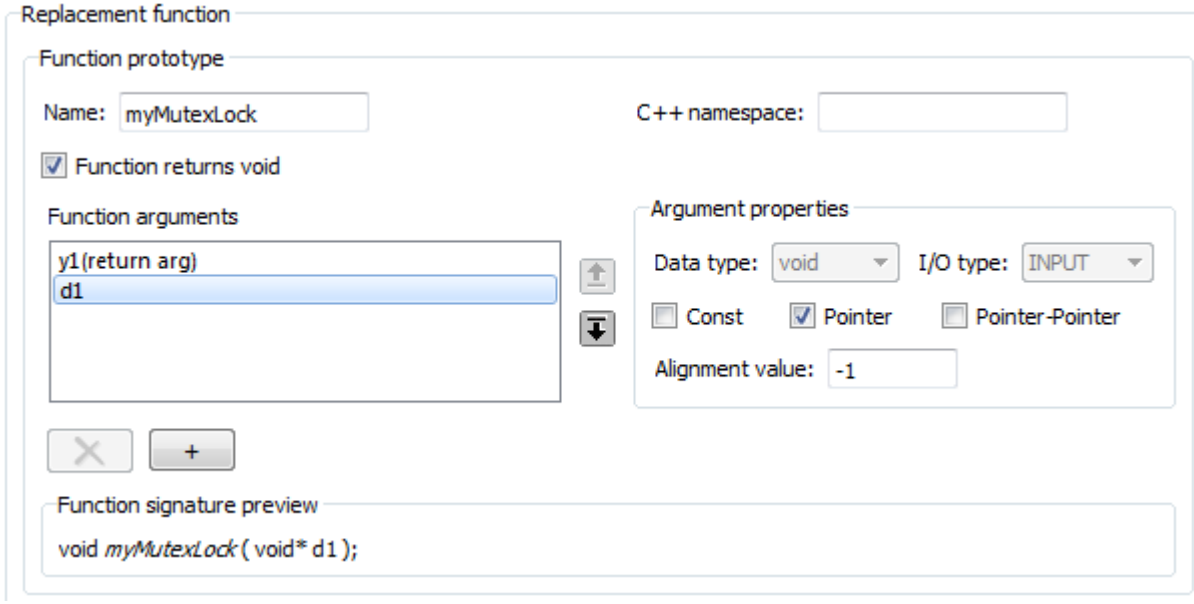
a Select **File** > **New entry** > **Semaphore entry**.

b In the **Mapping Information** tab, use the **Function** parameter to select `Mutex Lock`, `Mutex Unlock`, or `Mutex Destroy`. Initial default values for the table entry appear. In the **Conceptual function** section, typically you can leave the argument settings at their defaults.

c For a Rate Transition block mutex, the wait, post, and destroy functions operate on the DWork allocated at system startup by the mutex initialization function. In the **DWork attributes** section, verify that the **Allocate DWork** option is cleared. From the **DWork Allocator entry** drop-down list, select the entry tag matching the value in the `Mutex Init` table entry. In this example, the entry tag is `entry_25576`.



d In the **Replacement function** section, **Name** field, enter a function name. This example uses `myMutexLock`, `myMutexUnlock`, and `myMutexDelete`. In the list of **Function arguments**, leave the DWork argument `d1` data type as `void*`.

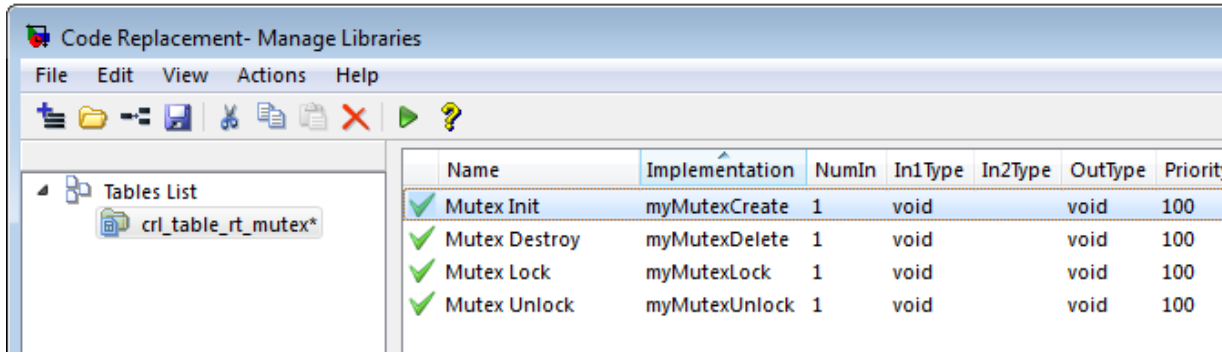


e In the **Implementation attributes** section, select the option **Function modifies internal or global state**. This option instructs the code generator not to optimize away the implementation function described by this entry because it accesses global memory values.

f Optionally, supply build information for the replacement function on the **Build Information** tab.

g Click **Apply**. In the middle pane, right-click the table entry and select **Validate entry(s)**.

6 When you have added the table entries for `Mutex Lock`, `Mutex Unlock`, and `Mutex Destroy` to the entry for `Mutex Init`, the rate transition mutex replacement table is complete. In the left-most pane, right-click the table name and select **Validate table**. Address errors and repeat the table validation.

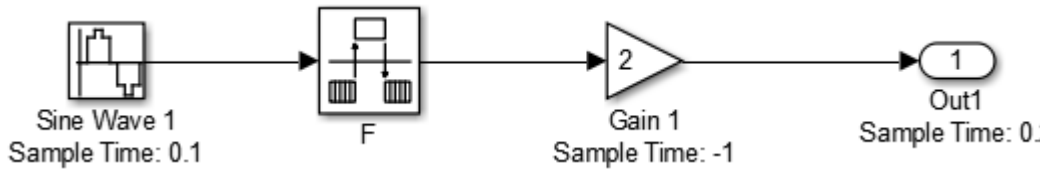


7 Save the table to a MATLAB file in your working folder, for example, using **File** > **Save table**. The name of the saved file is the table name, `crl_table_rt_mutex`, with an `.m` extension. Optionally, you can open the saved file and examine the MATLAB code for the code replacement table definition.

To test this example:

1 Register the code replacement mapping.

2 Create a model that contains a rate transition for which the build process generates mutex function calls. For example:



3 Configure the model for a multicore target environment and the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your mutex entry.

Algorithm-Based Code Replacement

For some math function blocks, you can control code replacement based on the computation or approximation algorithm configured for that block. For example, you can configure:

- The Reciprocal Sqrt block to use the `Newton-Raphson` or `Exact` computation method.
- The Trigonometric Function block, with **Function** set to `sin`, `cos`, or `sincos`, to use the approximation method `CORDIC` or `None`.

You can define code replacement entries to replace these functions for one or all of the available computation methods. For example, you can define an entry to replace only `Newton-Raphson` instances of the `rSqrt` function.

To set the algorithm for a function in an entry definition, use the `EntryInfoAlgorithm` property in a call to the function `setTflCFunctionEntryParameters`. The following table lists arguments for specifying the computation method to match during code generation.

Function	Argument
`rSqrt`	• `'RTW_DEFAULT'` (match the default computation method, `Exact`) • `'RTW_NEWTON_RAPHSON'` • `'RTW_UNSPECIFIED'` (match any computation method)

`sin`
`cos`
`sincos`
	• `'RTW_CORDIC'`
	• `'RTW_DEFAULT'` (match the default approximation method, `None`)
	• `'RTW_UNSPECIFIED'` (match any approximation method)

For example, to replace only `Newton-Raphson` instances of the `rSqrt` function, create an entry as follows:

1. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_rsqrt()
%CRL_TABLE_RSQRT - Define function entry for code replacement table.
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```
% Create entry for rsqrt function replacement
fcn_entry = RTW.TflCFunctionEntry;
```

4 Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(fcn_entry, ...
  'Key',                    'rSqrt', ...
  'Priority',               80, ...
  'ImplementationName',     'rsqrt_newton', ...
  'ImplementationHeaderFile', 'rsqrt.h', ...
  'EntryInfoAlgorithm',     'RTW_NEWTON_RAPHSON');
```

5 Create conceptual arguments `y1` and `u1`. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
  'Name',         'y1', ...
  'IOType',       'RTW_IO_OUTPUT', ...
  'DataTypeMode', 'double');

createAndAddConceptualArg(e, 'RTW.TflArgNumeric', ...
  'Name',         'u1', ...
  'DataTypeMode', 'double');
```

6 Copy the conceptual arguments to the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

The generated code for a `Newton-Raphson` instance of the `rSqrt` function looks like the following code:

```
/* Model step function */
void mrsqrt_step(void)
{
```

```
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
   *  Sqrt:   '<Root>/rSqrtBlk'
   */
  mrsqrt_Y.Out1 = rsqrt_newton(mrsqrt_U.In1);
}
```

Lookup Table Function Code Replacement

You can configure the algorithm for table lookup operations and index searches to better meet your application code requirements. Use the **Algorithm** tab of lookup table blocks. For example, you can specify the interpolation, extrapolation, and index search methods.

Lookup Table Algorithm Replacement

If the code generated for available algorithm options does not meet requirements for your application, create custom code replacement table entries to replace generated algorithm code. You can create the table entries programmatically or interactively by using the Code Replacement Tool.

For more information about using lookup table blocks, see “Nonlinearity” (Simulink).

Lookup Table Function Signatures

To create code replacement table entries for a function corresponding to a lookup table algorithm, you must have:

- Information about the conceptual function signature.
- Relevant algorithm parameters.

The following table provides the conceptual function signature information.

Conceptual Function Signature	Argument Summary
`y1 = interp1D(u1, u2, u3, u4)`	`y1` – output `u1` – index `u2` – fraction `u3` – table data `u4` – table dimension length
`y1 = interp2D(u1, u2, u3, u4, u5, u6, u7)`	`y1` – output `u1, u3` – index `u2, u4` – fraction `u5` – table data `u6, u7` – table dimension lengths

Conceptual Function Signature	Argument Summary
`y1 = interp3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10)`	`y1` – output `u1, u3, u5` – index `u2, u4, u6` – fraction `u7` – table data `u8, u9, u10` – table dimension lengths
`y1 = interp4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)`	`y1` – output `u1, u3, u5, u7` – index `u2, u4, u6, u8` – fraction `u9` – table data `u10, u11, u12, u13` – table dimension lengths
`y1 = interp5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16)`	`y1` – output `u1, u3, u5, u7, u9` – index `u2, u4, u6, u8, u10` – fraction `u11` – table data `u12, u13, u14, u15, u16` – table dimension lengths
`y1 = interpND({u`*`i`*`, u`*`f`*`,}... u`*`t`*`, u`*`n`*`...)`	`y1` – output u*i*, u*f* is an index and fraction pair per dimension u*t* – table data u*n* – table dimension lengths
Explicit values `y1 = lookup1D(u1, u2, u3, u4)`	`y1` – output `u1` – input `u2` – breakpoint data `u3` – table data `u4` – table dimension length
Even spacing `y1 = lookup1D(u1, u2, u3, u4, u5)`	`y1` – output `u1` – input `u2` – first point of breakpoint data `u3` – spacing of breakpoints `u4` – table data `u5` – table dimension length

Conceptual Function Signature	Argument Summary
Explicit values `y1 = lookup2D(u1, u2, u3, u4, u5, u6, u7)`	`y1` – output `u1, u2` – input `u3, u4` – breakpoint data `u5` – table data `u6, u7` – table dimension lengths
Even spacing `y1 = lookup2D(u1, u2, u3, u4, u5, u6, u7, u8, u9)`	`y1` – output `u1, u2` – input `u3, u5` – first point of breakpoint data `u4, u6` – spacing of breakpoints `u7` – table data `u8, u9` – table dimension lengths
Explicit spacing `y1 = lookup3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10)`	`y1` – output `u1, u2, u3` – input `u4, u5, u6` – breakpoint data `u7` – table data `u8, u9, u10` – table dimension lengths
Even spacing `y1 = lookup3D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)`	`y1` – output `u1, u2, u3` – input `u4, u6, u8` – first point of breakpoint data `u5, u7, u9` – spacing of breakpoints `u10` – table data `u11, u12, u13` – table dimension lengths
Explicit values `y1 = lookup4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13)`	`y1` – output `u1, u2, u3, u4` – input `u5, u6, u7, u8` – breakpoint data `u9` – table data `u10, u11, u12, u13` – table dimension lengths

Conceptual Function Signature	Argument Summary
Even spacing `y1 = lookup4D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16, u17)`	`y1` – output `u1, u2, u3, u4` – input `u5, u7, u9, u11` – first point of breakpoint data `u6, u8, u10, u12` – spacing of breakpoints `u13` – table data `u14, u15, u16, u17` – table dimension lengths
Explicit values `y1 = lookup5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16)`	`y1` – output `u1, u2, u3, u4, u5` – input `u6, u7, u8, u9, u10` – breakpoint data `u11` – table data `u12, u13, u14, u15, u16` – table dimension lengths
Even spacing `y1 = lookup5D(u1, u2, u3, u4, u5, u6, u7, u8, u9, u10, u11, u12, u13, u14, u15, u16, u17, u18, u19, u20, u21)`	`y1` – output `u1, u2, u3, u4, u5` – input `u6, u8, u10, u12, u14` – first point of breakpoint data `u7, u9, u11, u13, u15` – spacing of breakpoints `u16` – table data `u17, u18, u19, u20, u21` – table dimension lengths
Explicit values `y1 = lookupND(u`*n*`,..., u`*b*`,..., u`*t*`, u`*n*`...)`	`y1` – output u*n*, input per dimension u*b*, breakpoint per dimension u*t* – table data u*n* – table dimension lengths

Conceptual Function Signature	Argument Summary
Even spacing `y1 = lookupND(u`*`n`*`,..., {u`*`fn`*`, u`*`sn`*`,}... u`*`t`*`, u`*`n`*`...)`	`y1` – output u*`n`* – input per dimension u*`fn`* – first point of breakpoint data per dimension u*`sn`* – spacing of breakpoint per dimension u*`t`* – table data u*`n`* – table dimension lengths
`y1 = lookupND_Direct(u1, u2,...ui, ui+1)`	`y1` – output `u1...ui` – input `ui+1` – table data
Explicit values `y1, y2 = prelookup(u1, u2, u3)`	`y1` – index `y2` – fraction `u1` – input `u2` – breakpoint data `u3` – number of breakpoints
Evenly spaced `y1, y2 = prelookup(u1, u2, u3, u4)`	`y1` – index `y2` – fraction `u1` – input `u2` – first point of breakpoint data `u3` – spacing of breakpoints `u4` – number of breakpoints

When defining a table entry programmatically, you might also need to change the values of required (primary) and optional algorithm parameters.

- Set values for required parameters to achieve code replacement.
- If you do not set a value for an optional parameter, the algorithm parameter software applies `don't care`. The code replacement software ignores the parameter while searching for matches.

To look up algorithm parameter information for a lookup table function:

1 Create a table entry for a function.

```
tableEntry = RTW.TflCFunctionEntry;
```

2. Identify the lookup table function in the table entry. Use the `Key` table entry parameter in a call to `setTflCFunctionEntryParameters`. The following example identifies an entry for the `prelookup` function.

```
setTflCFunctionEntryParameters(tableEntry, ...
    'Key', 'prelookup', ...
    'Priority', 100, ...
    'ImplementationName', 'myPrelookup');
```

3. Get the algorithm parameter set for the entry with a call to `getAlgorithmParameters`.

```
algParams = getAlgorithmParameters(tableEntry);
```

```
algParams =

  Prelookup with properties:

            ExtrapMethod: [1x1 coder.algorithm.parameter.ExtrapMethod]
                 RndMeth: [1x1 coder.algorithm.parameter.RndMeth]
       IndexSearchMethod: [1x1 coder.algorithm.parameter.IndexSearchMethod]
       UseLastBreakpoint: [1x1 coder.algorithm.parameter.UseLastBreakpoint]
    RemoveProtectionInput: [1x1 coder.algorithm.parameter.RemoveProtectionInput]
```

4. Examine information available for each parameter.

```
algParams.ExtrapMethod
```

```
ans =

  ExtrapMethod with properties:

       Name: 'ExtrapMethod'
    Options: {'Linear'  'Clip'}
    Primary: 1
      Value: {'Linear'}
```

```
algParams.RndMeth
```

```
ans =

  RndMeth with properties:

       Name: 'RndMeth'
    Options: {1x7 cell}
    Primary: 0
      Value: {1x7 cell}
```

```
algParams.RndMeth.Value
```

```
ans =

  Columns 1 through 6

    'Ceiling'    'Convergent'    'Floor'    'Nearest'    'Round'    'Simplest'

  Column 7

    'Zero'
```

```
algParams.IndexSearchMethod
```

```
ans =

  IndexSearchMethod with properties:

       Name: 'IndexSearchMethod'
    Options: {'Linear search'  'Binary search'  'Evenly spaced points'}
    Primary: 0
      Value: {'Binary search'  'Evenly spaced points'  'Linear search'}

algParams.UseLastBreakpoint

ans =

  UseLastBreakpoint with properties:

       Name: 'UseLastBreakpoint'
    Options: {'off'  'on'}
    Primary: 0
      Value: {'off'  'on'}

algParams.RemoveProtectionInput

ans =

  RemoveProtectionInput with properties:

       Name: 'RemoveProtectionInput'
    Options: {'off'  'on'}
    Primary: 0
      Value: {'off'  'on'}
```

Interactive Mapping with Code Replacement Tool

This example shows how to specify a code replacement table entry for a lookup table algorithm by using the Code Replacement Tool.

Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder `matlab/toolbox/rtw/rtwdemos/crl_demo`:

- `myLookup1D.h`
- `myLookup1D.c`

Place a copy of these files in your working folder.

Open and examine the code for `myLookup1D.h`.

```
#include "rtwtypes.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl);
```

Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```
#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
{
  real_T y;
  uint16_T frac;
  uint32_T bpIdx;
  uint32_T maxIndex=tdl-1;

  if (u0 <= bp0[0U]) {
    bpIdx = 0U;
    frac = 0U;
  } else if (u0 < bp0[maxIndex]) {
    bpIdx = maxIndex >> 1U;
    while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
      bpIdx--;
    }

    while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
      bpIdx++;
    }

    frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
      bp0[bpIdx]) * 32768.0);
  } else {
    bpIdx = maxIndex;
    frac = 0U;
  }

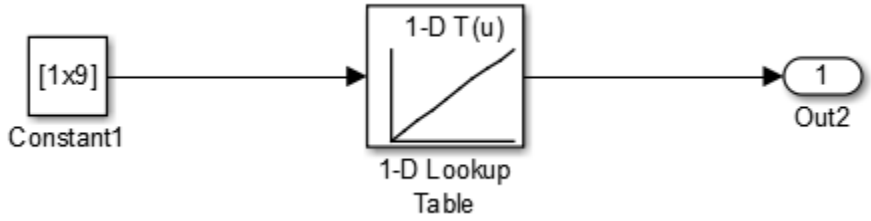
  if (bpIdx == maxIndex) {
    y = table[bpIdx];
  } else {
    y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
      table[bpIdx];
  }

  return y;
}
```

Open and Examine the Example Model

This example uses the model rtwdemo_crllookup1D to test your code replacement specification. Place a copy of the model in your working folder and name it `my_lookup1d.slx`.

Open and examine the model. Note input and output specifications and block parameter settings. To achieve a match, you must specify conceptual arguments based on how the 1-D Lookup Table block is configured in the example model.



Create Code Replacement Table

1. At the command prompt, enter `crtool` to open the Code Replacement Tool.
2. Add a new table, select that table, and add a new function entry.
3. On the **Mapping Information** tab, select `Custom` for the **Function** parameter.
4. Look up the call signature and algorithm parameter information for the lookup table function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 65-116.

   For this example, you replace the algorithm for the conceptual function associated with the 1-D Lookup Table block. The signature for that function is:

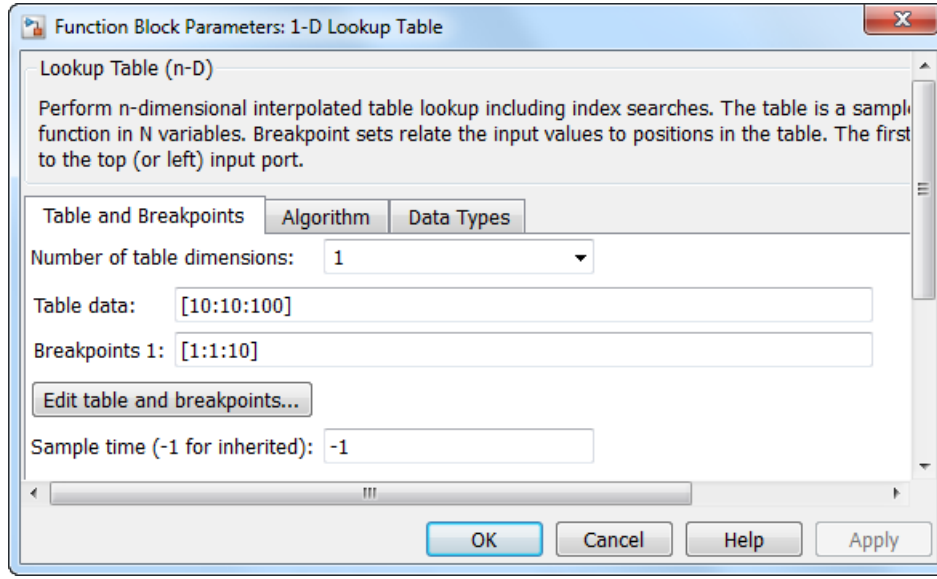
   ```
   y1 = lookup1D(u1, u2, u3, u4)
   ```

   Arguments `u1`, `u2`, `u3`, `u4` represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to `y1`.
5. To the right of the **Function** drop-down list, in the function-name text box, enter the name of the Simulink lookup table function. For this example, type the name `lookup1D`. Type the name exactly as it appears in the documented signature, including character casing. Press **Enter**.

   The tool displays algorithm parameter settings that trigger a match for the 1-D Lookup Table block in the example model. Required parameters appear with only one value. For this example, do not change the values. Optional parameters appear with multiple values. Changes to optional parameters do not affect the match process.
6. Specify the conceptual arguments. Under the **Conceptual arguments** list box, click **+** to add the arguments that are in the documented function signature. The `lookup1D` function takes one output argument and four input arguments. Click **+** five times.

The tool creates an output argument *y1* and four input arguments *u1*, *u2*, *u3*, and *u4*. By default, the four arguments are scalars of type `double`.

You can adjust the conceptual argument properties. For this example, you do not make changes for `y1` and `u1`. However, as the block parameter dialog box for the example model shows, you must adjust the argument properties for the breakpoint and table data arguments.



Adjust the conceptual argument properties by using the following table. Click **Apply**.

Signature Argument Name	Conceptual Argument Name	Data type	I/O type	Argument type	Lower range	Upper range
`y`	`y1`	`double`	`OUTPUT`	`Scalar`	Not applicable	Not applicable
`u1`	`u1`	`double`	`INPUT`	`Scalar`	Not applicable	Not applicable
`bp1`	`u2`	`double`	`INPUT`	`Matrix`	`[0 0]`	`[Inf Inf]`
`table`	`u3`	`double`	`INPUT`	`Matrix`	`[0 0]`	`[Inf Inf]`

Signature Argument Name	Conceptual Argument Name	Data type	I/O type	Argument type	Lower range	Upper range
`tdl`	`u4`	`uint32`	`INPUT`	`Scalar`	Not applicable	Not applicable

7. Enter information for the replacement function prototype. The prototype for the example function is:

   ```
   real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
   ```

   In the **Replacement function > Function prototype** section, type the function name `my_Lookup1D_Repl` in the **Name** text box.

8. Specify the arguments for the replacement function. Under the **Function arguments** list box, click **+** five times to add five implementation arguments.

   You might need to adjust the function argument properties. As the replacement function signature shows, adjust the argument properties for the breakpoint, table data, and table dimension length arguments. For `u2` (breakpoints) and `u3` (table), select the **Const** check box. For `u4`, set **Data type** to `uint32`.

   The function signature preview should appear as follows:

   ```
   double my_Lookup1D_Repl(double u1, const double* u2, const double* u3, uint32 u4)
   ```

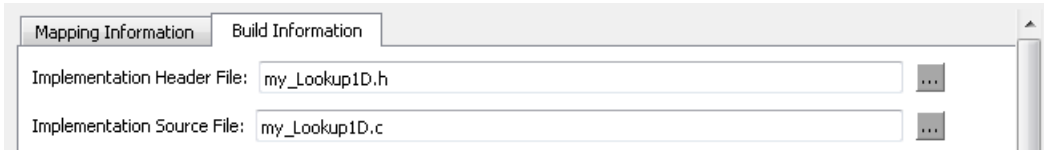
9. Set relevant implementation attributes. Use the default settings.

10. Validate the entry. If the tool reports errors, fix them, and retry the validation. Repeat the procedure until the tool does not report errors.

11. Save the code replacement table in your working folder as `my_lookup_replacement_table.m`.

Specify Build Information

On the **Build Information** tab, specify information relevant to generating C or C++ code and building an executable from the model. Enter `myLookup1D.h` for **Implementation Header File** and `myLookup1D.c` for **Implementation Source File**.



If you copied the example files to a folder other than the working folder containing the test model, `lookup1d.slx`, specify the source and header file paths. Otherwise, leave the other **Build Information** parameters set to default values. Click **Apply**.

Test the Entry

To test this example:

1. Register the code replacement mapping.
2. Use the example model rtwdemo_crllookup1D.
3. Configure the model with the following settings:
   - On the **Solver** pane, select a fixed-step solver.
   - On the **Code Generation** pane, select an ERT-based system target file.
   - On the **Code Generation** > **Interface** pane, select the code replacement library that contains your lookup table function entry.

Programmatic Specification

This example shows how to specify code replacement table entries for lookup table functions programmatically.

Open and Examine Example Replacement Function

Identify or create the C or C++ replacement function for the algorithm that you want to use in place of a Simulink software algorithm.

This example uses the following C replacement function header and source files, which are in the folder `matlab/toolbox/rtw/rtwdemos/crl_demo`:

- `myLookup1D.h`
- `myLookup1D.c`

Place a copy of these files in your working folder.

Open and examine the code for `myLookup1D.h`.

```
#include "rtwtypes.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl);
```

Open and examine the code in `myLookup1D.c`. Note the function signature. When you enter the implementation argument specification in the Code Replacement Tool, specify argument properties.

```
#include "myLookup1D.h"
real_T my_Lookup1D_Repl(real_T u0, const real_T *bp0, const real_T *table, uint32_T tdl)
{
  real_T y;
  uint16_T frac;
  uint32_T bpIdx;
  uint32_T maxIndex=tdl-1;

  if (u0 <= bp0[0U]) {
    bpIdx = 0U;
    frac = 0U;
  } else if (u0 < bp0[maxIndex]) {
    bpIdx = maxIndex >> 1U;
    while ((u0 < bp0[bpIdx]) && (bpIdx > 0U)) {
      bpIdx--;
    }

    while ((bpIdx < maxIndex - 1U) && (u0 >= bp0[bpIdx + 1U])) {
      bpIdx++;
    }

    frac = (uint16_T)((u0 - bp0[bpIdx]) / (bp0[bpIdx + 1U] -
      bp0[bpIdx]) * 32768.0);
  } else {
    bpIdx = maxIndex;
    frac = 0U;
  }

  if (bpIdx == maxIndex) {
    y = table[bpIdx];
  } else {
    y = (table[bpIdx + 1U] - table[bpIdx]) * ((real_T)frac * 3.0517578125E-5) +
      table[bpIdx];
  }

  return y;
}
```

Review Lookup Function Signature

Look up the call signature information for the lookup function that you want to update with an algorithm replacement. See “Lookup Table Function Signatures” on page 65-116.

Replace the algorithm for the function associated with the 1–D Lookup Table block. The signature for that function is:

```
y1 = lookup1D(u1, u2, u3, u4)
```

Arguments `u1`, `u2`, `u3`, and `u4` represent input, breakpoint data, table data, and table dimension length, respectively. The function returns output to `y1`.

Create Code Replacement Entry

Create a code replacement table file as a MATLAB function, that describes the lookup table function code replacement table entries. Place a copy of the file `matlab/toolbox/rtw/rtwdemos/crl_demo/crl_table_lookup1D.m` in your working folder. This file defines a code replacement table for the C function `my_Lookup1D_Repl`.

Open `crl_table_lookup1D.m` and examine the definition.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hLib = my_lookup_replacement_table
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hLib = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function. The function key, implementation name, and header and source files in the function call identify the Simulink lookup table function name, `lookup1D`, and the following information for replacement function `my_Lookup1D_Repl`:

   - Function name
   - Header file
   - Source file

   Specify the Simulink lookup table function name exactly as it appears in the documented signature, including character casing (see “Lookup Table Function Signatures” on page 65-116). If you copied the example files to a folder other than the working folder that contains the test model, rtwdemo_crllookup1D, specify the source and header file paths.

   ```
   setTflCFunctionEntryParameters(hEnt, ...
             'Key',                    'lookup1D', ...
             'Priority',               100, ...
             'ImplementationName',     'my_Lookup1D_Repl', ...
             'ImplementationHeaderFile', 'myLookup1D.h', ...
             'ImplementationSourceFile', 'myLookup1D.c', ...
             'GenCallback',            'RTW.copyFileToBuildDir');
   ```

5 Create conceptual arguments and add them to the entry. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

The example defines five conceptual arguments for the `lookup1D` function, one output argument *y1* and four input arguments *u1*, *u2*, *u3*, and *u4*. Arguments *y1* and *u1* are defined as scalar `double` data. Arguments *u2* and *u3* represent *bp1* and *table* in the signature and are defined as 1x10 matrices of `double` data. Argument *u4* represents *tdl* and is defined as scalar of `uint32` data. This definition triggers a match with the example model.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u1','double');
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT',  'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = RTW.TflArgMatrix('u3', 'RTW_IO_INPUT',  'double');
arg.DimRange = [0 0; Inf Inf];
addConceptualArg(hEnt, arg);

arg = hEnt.getTflArgFromString('u4','uint32');
addConceptualArg(hEnt, arg);
```

6 Review the algorithm parameter information for the lookup function that you want to update with an algorithm replacement. Use the `getAlgorithmParameters` function to display the parameter information.

```
algParams = getAlgorithmParameters(hEnt)

algParams =

  Lookup with properties:

               InterpMethod: [1x1 coder.algorithm.parameter.InterpMethod]
               ExtrapMethod: [1x1 coder.algorithm.parameter.ExtrapMethod]
       UseRowMajorAlgorithm: [1x1 coder.algorithm.parameter.UseRowMajorAlgorithm]
                    RndMeth: [1x1 coder.algorithm.parameter.RndMeth]
          IndexSearchMethod: [1x1 coder.algorithm.parameter.IndexSearchMethod]
          UseLastTableValue: [1x1 coder.algorithm.parameter.UseLastTableValue]
      RemoveProtectionInput: [1x1 coder.algorithm.parameter.RemoveProtectionInput]
   SaturateOnIntegerOverflow: [1x1 coder.algorithm.parameter.SaturateOnIntegerOverflow]
     SupportTunableTableSize: [1x1 coder.algorithm.parameter.SupportTunableTableSize]
             BPPower2Spacing: [1x1 coder.algorithm.parameter.BPPower2Spacing]
```

Examine the information for each parameter. The `Options` property lists possible values. `Primary` indicates whether a parameter is required (1) or optional (0). The

`Value` property specifies the current value. For required parameters, initially, `Value` is set to the default value for a given lookup table function.

```
algParams.InterpMethod

ans =

  InterpMethod with properties:

       Name: 'InterpMethod'
    Options: {'Linear'  'Flat'  'Nearest'}
    Primary: 1
      Value: {'Linear'}

algParams.RndMeth

ans =

  RndMeth with properties:

       Name: 'RndMeth'
    Options: {1x7 cell}
    Primary: 0
      Value: {1x7 cell}

algParams.RndMeth.Options

ans =

  Columns 1 through 5

    'Ceiling'    'Convergent'    'Floor'    'Nearest'    'Round'

  Columns 6 through 7

    'Simplest'    'Zero'
```

7 Set the algorithm properties for the `lookup1D` table entry. Assign a value to each parameter. Update the parameter settings for the entry by calling the function `setAlgorithmParameters`. The following parameter settings trigger a match with the example model.

```
algParams.InterpMethod = 'Linear';
algParams.ExtrapMethod = 'Clip';
algParams.UseRowMajorAlgorithm: = 'off';
algParams.RndMeth = 'Round';
```

```
algParams.IndexSearchMethod = 'Linear search';
algParams.UseLastTableValue = 'Evenly spaced point';
algParams.RemoveProtectionInput = 'off';
algParams.SaturateOnIntegerOverflow = 'off';
algParams.SupportTunableTableSize = 'off';
algParams.BPPower2Spacing = 'off';
setAlgorithmParameters(hEnt, algParams);
```

To verify your changes, call `getAlgorithmParameters` to get the parameter set for the table entry. Examine the value of each parameter.

```
getAlgorithmParameters(hEnt, algParams);
algParams.InterpMethod.Value

ans =

    'Linear'

algParams.ExtrapMethod.Value

ans =

    'Clip'

algParams.UseRowMajorAlgorithm.Value

ans =

    'off'
.
.
.
```

8 Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create five implementation arguments that map to arguments in the replacement function prototype: one output argument *y1* and four input arguments *u1*, *u2*, *u3*, and *u4*. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. The `addArgument` function also adds each argument to the entry's array of implementation arguments.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
```

```
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','uint32');
hEnt.Implementation.addArgument(arg);
```

9 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

Test the Entry

To test this example:

1 Register the code replacement mapping.

2 Use the example model rtwdemo_crllookup1D.

3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your lookup table function entry.

Sample Code Replacement Definition for the lookup2D Function

The following code shows a replacement definition for the `lookup2D` function.

```
function hLib = my_2dlookup_replacement_table

hLib = RTW.TflTable;

hEnt = RTW.TflCFunctionEntry;
setTflCFunctionEntryParameters(hEnt, ...
          'Key',                      'lookup2D', ...
```

```

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance. To configure data alignment for a function implementation:

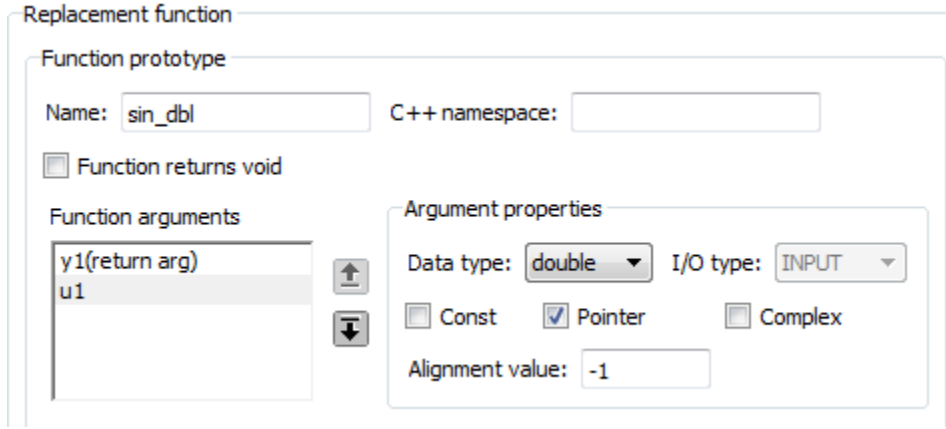
1. Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 65-137.
2. Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the `rtwTargetInfo.m` file. See “Provide Data Alignment Specifications for Compilers” on page 65-139.
3. Register the library containing the table entry and alignment specification object.
4. Configure the code generator to use the code replacement library and generate code. Observe the results.

For examples, see “Basic Example of Code Replacement Data Alignment” on page 65-144 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®” example page.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (`RTW.ArgumentDescriptor`). Use its `AlignmentBoundary` property to specify the required alignment boundary and assign the object to the argument `Descriptor` property.
- If you are defining a replacement function using the **Code Replacement Tool**, on the **Mapping Information** tab, in the **Argument properties** section for the replacement function, enter a value for the **Alignment value** parameter.



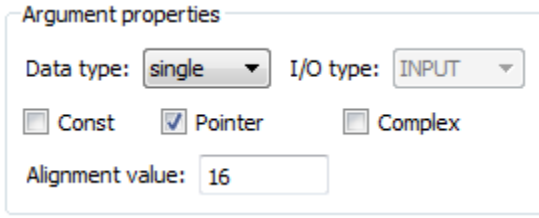
The `AlignmentBoundary` property (or **Alignment value** parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The `AlignmentBoundary` property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- `-1` (default) — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.
- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the `AlignmentBoundary` for an argument as 16 bytes.

```
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.



Note If your model imports `Simulink.Bus`, `Simulink.Parameter`, or `Simulink.Signal` objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see `Simulink.Bus`, `Simulink.Parameter`, and `Simulink.Signal`.

Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

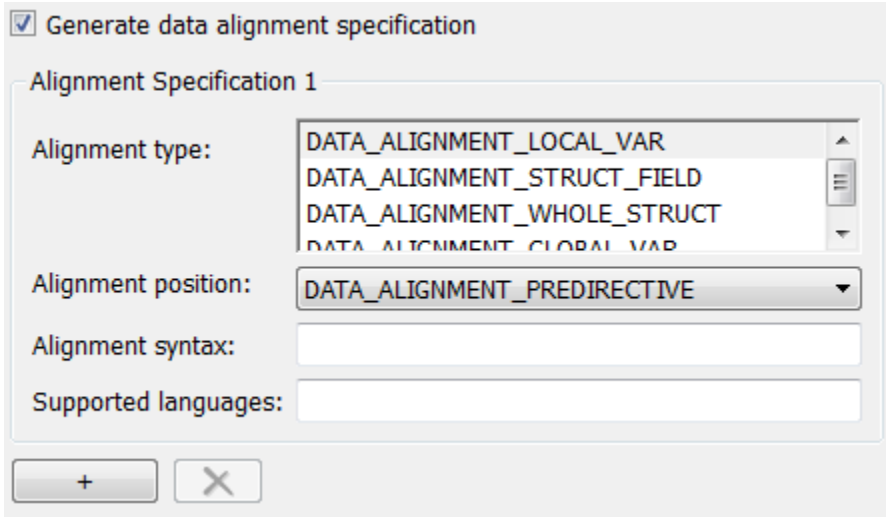
To describe the data alignment capabilities and syntax for a compiler:

- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

  The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is `-1`, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.



Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.

Alignment-Specification Property	Dialog Box Parameter	Description
`AlignmentType`	**Alignment type**	Cell array of predefined enumerated strings, specifying which types of alignment this specification supports. • `DATA_ALIGNMENT_LOCAL_VAR` — Local variables. • `DATA_ALIGNMENT_GLOBAL_VAR` — Global variables. • `DATA_ALIGNMENT_STRUCT_FIELD` — Individual structure fields. • `DATA_ALIGNMENT_WHOLE_STRUCT` — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment). Each alignment specification must specify at least `DATA_ALIGNMENT_GLOBAL_VAR` and `DATA_ALIGNMENT_STRUCT_FIELD`.

Alignment-Specification Property	Dialog Box Parameter	Description
AlignmentPosition	**Alignment position**	Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type DATA_ALIGNMENT_WHOLE_STRUCT: • DATA_ALIGNMENT_PREDIRECTIVE — The alignment directive is emitted before struct st_tag{…}, as part of the type definition statement (for example, MSVC). • DATA_ALIGNMENT_POSTDIRECTIVE — The alignment directive is emitted after struct st_tag{…}, as part of the type definition statement (for example, gcc). • DATA_ALIGNMENT_PRECEDING_STATEMENT — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. • DATA_ALIGNMENT_FOLLOWING_STATEMENT — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. For alignment types other than DATA_ALIGNMENT_WHOLE_STRUCT, code generation uses alignment position DATA_ALIGNMENT_PREDIRECTIVE.

Alignment-Specification Property	Dialog Box Parameter	Description
`AlignmentSyntax-Template`	**Alignment syntax**	Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported: • `%n` — Replaced by the alignment boundary for the replacement function argument. • `%s` — Replaced by the aligned symbol, usually the identifier of a variable. For example, for the gcc compiler, you can specify `__attribute__((aligned(%n)))`, or for the MSVC compiler, `__declspec(align(%n))`.
`SupportedLanguages`	**Supported languages**	Cell array specifying the languages to which this alignment specification applies, among `c` and `c++`. Sometimes alignment syntax and position differ between languages for a compiler.

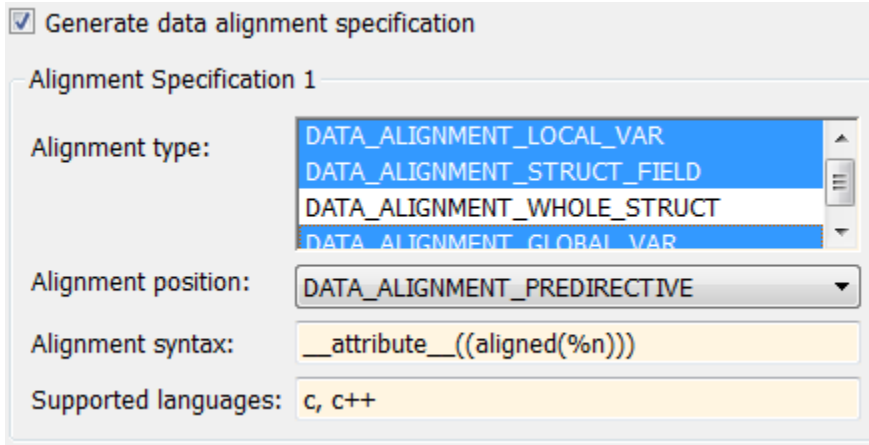
Here is a data alignment specification for the GCC compiler:

```
da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
                    'DATA_ALIGNMENT_STRUCT_FIELD', ...
                    'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.



Basic Example of Code Replacement Data Alignment

A simple example of the complete workflow for data alignment specified for code replacement is:

1 Create and save the following code replacement table definition file, `crl_table_mmul_4x4_single_align.m`. This table defines a replacement entry for the * (multiplication) operator, the `single` data type, and input dimensions `[4,4]`. The entry also specifies a data alignment boundary of 16 bytes for each replacement function argument. The entry expresses the requirement that the starting memory address for the data allocated for the function arguments during code generation is a multiple of 16.

```
function hLib = crl_table_mmul_4x4_single_align
%CRL_TABLE_MMUL_4x4_SINGLE_ALIGN - Describe matrix operator entry with data alignment

hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(entry, ...
    'Key',                  'RTW_OP_MUL', ...
    'Priority',             90, ...
    'ImplementationName',   'matrix_mul_4x4_s');

% conceptual arguments
createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
                                 'Name',         'y1', ...
                                 'IOType',       'RTW_IO_OUTPUT', ...
                                 'BaseType',     'single', ...
                                 'DimRange',     [4 4]);
```

```
createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
                                 'Name',          'u1', ...
                                 'BaseType',     'single', ...
                                 'DimRange',     [4 4]);

createAndAddConceptualArg(entry, 'RTW.TflArgMatrix',...
                                 'Name',          'u2', ...
                                 'BaseType',     'single', ...
                                 'DimRange',     [4 4]);

% implementation arguments
arg = getTflArgFromString(hLib, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hLib, 'y1','single*');
arg.IOType = 'RTW_IO_OUTPUT';
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hLib, 'u2','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);

hLib.addEntry(entry);
```

2. Create and save the following registration file, `rtwTargetInfo.m`. If you want to compile the code generated in this example, first modify the `AlignmentSyntaxTemplate` property for the compiler that you use. For example, for the MSVC compiler, replace the gcc template specification `__attribute__((aligned(%n)))` with `__declspec(align(%n))`.

```
function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)
% for use with  code generation

  % Register the CRL defined in local function locCrlRegFcn
  cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_mmul_4x4_single_align
function thisCrl = locCrlRegFcn
```

```
    % create an alignment specification object, assume gcc
    as = RTW.AlignmentSpecification;
    as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
                        'DATA_ALIGNMENT_GLOBAL_VAR', ...
                        'DATA_ALIGNMENT_STRUCT_FIELD'};
    as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
    as.SupportedLanguages={'c', 'c++'};

    % add the alignment specification object
    da = RTW.DataAlignment;
    da.addAlignmentSpecification(as);

    % add the data alignment object to target characteristics
    tc = RTW.TargetCharacteristics;
    tc.DataAlignment = da;

    % Instantiate a CRL registry entry
    thisCrl = RTW.TflRegistry;

    % Define the CRL properties
    thisCrl.Name = 'Data Alignment Example';
    thisCrl.Description = 'Example of replacement with data alignment';
    thisCrl.TableList = {'crl_table_mmul_4x4_single_align'};
      thisCrl.TargetCharacteristics = tc;

end % End of LOCCRLREGFCN
```

3. To register your library with code generator without having to restart MATLAB, enter this command:

   ```
   RTW.TargetRegistry.getInstance('reset');
   ```

4. Configure the code generator to use your code replacement library.
5. Generate code and a code generation report.
6. Review the code replacements. For example, check whether a multiplication operation is replaced with a `matrix_mul_4x4_s` function call. In `mmalign.h`, check whether the gcc alignment directive `__attribute__((aligned(16)))` is generated to align the function variables.

Replace MATLAB Functions with Custom Code Using coder.replace

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

Replace coder.ceval Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

Example Files

For the examples in “Interactive External Function Call Replacement Specification with Code Replacement Tool” on page 66-113 and “Programmatic External Function Call Replacement Specification” on page 66-115 you must have set up the following:

- Custom C function `my_add.c`.

```
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
  return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```
function y = call_my_add(in1, in2)  %#codegen

y=0.0;

if ~coder.target('Rtw')
```

```
% Executing in MATLAB, call MATLAB equivalent of C function my_add
  y= in1+in2;
else
% Executing in generated code, call C function my_add
  y = coder.ceval('my_add', in1, in2);
end
```

- MATLAB test function `call_my_add_test.m`, which calls `call_my_add.m`.

```
in1=10;
in2=20;

y = call_my_add(in1, in2);

disp('Output')
disp('y =')
disp(y);
```

- Replacement C function `my_add_replacement.c`.

```
/* my_add_replacement.c */

#include "my_add_replacement.h"

double my_add_replacement(double in1, double in2)
{
  return in1 + in2;
}
```

- Replacement C header file `my_add_replacement.h`.

```
/* my_add_replacement.h */

double my_add_replacement(double in1, double in2);
```

Interactive External Function Call Replacement Specification with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval`, a MATLAB test function, and the source and header files for

your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 66-112.

2. In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see “Define Code Replacement Mappings” on page 66-30.
3. On the **Mapping Information** tab, select `Custom` for the **Function** parameter.
4. In the **function-name** text box, type the custom function name. For this example, type the name `my_add`.
5. Under the **Conceptual arguments** list box, click **+** to add three arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`.
6. In the **Replacement function** > **Function prototype** section, type the name `my_add_replacement` in the **Name** text box.
7. Under the **Function arguments** list box, click **+** to add three function implementation arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type double. Use the default settings.
8. In the **Function signature preview** box, if you see the expected function signature, click **Apply**. The function signature for this example, appears as:

   ```
   double my_add_replacement(double u1, double u2);
   ```

9. On the **Build Information** tab, specify `my_add_replacement.h` for the **Implementation header file** parameter and `my_add_replacement.c` for the **Implementation source file**.
10. Click **Validate entry**.
11. Save the code replacement table in the same folder as `my_add_replacement.c`. Name the file `crl_table_my_add.m`.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programmatically.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 66-112.
2. Create a table definition file that contains a function definition. For example:

   ```
   function hLib = crl_table_my_add
   ```
3. Within the function body, create the table by calling the function `RTW.TflTable`.
4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```
5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   hEnt.setTflCFunctionEntryParameters( ...
             'Key', 'my_add', ...
             'Priority', 100, ...
             'ImplementationName', 'my_add_replacement', ...
             'ImplementationHeaderFile', 'my_add_replacement.h', ...
             'ImplementationSourceFile', 'my_add_replacement.c');
   ```
6. Create conceptual arguments `y1`, `u1`, and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.addConceptualArg(arg);
   ```

7 Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```
arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double');
hEnt.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
hLib.addEntry(hEnt);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate code and the report.

4 Review the code replacements.

Replace MATLAB Functions Specified in MATLAB Function Blocks

This example shows how to use code replacement to replace a **MATLAB** function specified in a MATLAB Function block.

1. Open the `ex_replace` model. At the command prompt, enter:

   ```
   addpath(fullfile(docroot,'toolbox','ecoder','examples'))
   ex_replace
   ```

2. View the MATLAB Function Block code. In the model, double-click the MATLAB Function block to view the code in the MATLAB editor.

   ```
   function y = customFcn(u1, u2) %#codegen
   % This block supports MATLAB for code generation.

   % Replace this MATLAB function with CRL replacement function and if no
   % CRL replacement is found, generate an error during code generation.
   coder.replace('-errorifnoreplacement');

   assert(isa(u1,'int32'));
   assert(isa(u2,'int32'));

   y = power(u1,u2);
   ```

   The `coder.replace('-errorifnoreplacement')` statement instructs the code generator to replace this MATLAB function with a code replacement library function. The code generator produces an error if it does not find a match.

3. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_coderreplace()
   ```

4. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

5. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```

6. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(hEnt, ...
    'Key',                      'customFcn', ...
    'Priority',                 100, ...
    'ImplementationName',       'scalarFcnReplacement', ...
    'ImplementationHeaderFile', 'MyMath.h', ...
    'ImplementationSourceFile', 'MyMath.c')
```

7 Create conceptual arguments `y1`, `u1`, and `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hEnt, 'y1','int32');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','int32');
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u2','int32');
addConceptualArg(hent, arg);
```

8 Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument *`void`*, input arguments *`u1`* and *`u2`*, and output argument *`y1`*. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. The `addArgument` function also adds each argument to the entry's array of implementation arguments.

```
arg = getTflArgFromString(hEnt, 'void','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = getTflArgFromString(hEnt, 'u1','int32');
hEnt.Implementation.addArgument(arg);

arg = getTflArgFromString(hEnt, 'u2','int32');
hEnt.Implementation.addArgument(arg);

arg = getTflArgFromString(hEnt, 'y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);
```

9 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the code replacement mapping.
2. Create files `MyMath.c` and `MyMath.h` that define the replacement function, `scalarFcnReplacement`, which has two `int32` inputs and one `int32` output.

   `MyMath.c`

   ```
   #include "MyMath.h"

   void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1 ) {
       *y1 = u1^u2;
   }
   ```

   `MyMath.h`

   ```
   #ifndef _ScalarMath_h
   #define _ScalarMath_h

   #include "rtwtypes.h"

   #ifdef __cplusplus
   extern "C" {
   #endif

   extern void scalarFcnReplacement(int32_T u1, int32_T u2, int32_T* y1);

   #ifdef __cplusplus
   }
   #endif

   #endif
   ```
3. Open the `ex_replace` model.
4. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
5. Generate the replacement code and a code generation report.
6. Review the code replacements. In the code generation report, view the generated code for `ex_replace.c`.

   ```
   void ex_replace_step(void)
   {
      int32_T y;
   ```

```
    scalarFcnReplacement(ex_replace_U.In1, ex_replace_U.In2, &y);
    ex_replace_Y.Out1 = y;
}
```

Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function `RTW.TargetRegistry.getInstance.getTflReservedIdentifiers`. For example:

```
crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```
d{1}.LibraryName = 'ANSI_C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

- “Customize Match and Replacement Process” on page 65-160
- “Define Code Replacement Mappings” on page 65-44
- “Develop a Code Replacement Library” on page 65-27

Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

1. Create a custom code replacement entry class, derived from `RTW.TflCFunctionEntryML (for function replacement) or RTW.TflCOperationEntryML` (for operator replacement).
2. In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:

    - Add match criteria that the base class does not provide. The base class provides a match based on:

        - Argument number
        - Argument name
        - Signedness
        - Word size
        - Slope (if not specified with wildcards)
        - Bias (if not specified with wildcards)

    - Math modes, such as saturation and rounding
    - Operator or function key
  - Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.
3. Create code replacement entries that instantiate the custom entry class.
4. Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

Customize Code Match and Replacement for Functions

This example shows how to use custom code replacement table entries to refine the match and replacement logic for functions. The example shows how to:

- Modify a sine function replacement only if the integer size on the current target platform is 32 bits.
- Change the replacement such that the implementation function passes in a degrees-versus-radians flag as an input argument.

1. To exercise the table entries that you create in this example, create an ERT-based model with a sine function block. For example:

   In the Inport block parameters, set the signal **Data type** to `double`. If the value selected for **Configuration Parameters** > **Hardware Implementation** > **Device type** supports an integer size other than 32, do one of the following:

   - Select a temporary target platform with a 32-bit integer size.
   - Modify the code to match the integer size of your target platform.
2. Create a class, for example `TflCustomFunctionEntry`, that is derived from the base class `RTW.TflCFunctionEntryML`. The derived class defines a `do_match` method with the signature:

```
function ent = do_match(hThis, ...
        hCSO, ...
        targetBitPerChar, ...
        targetBitPerShort, ...
        targetBitPerInt, ...
        targetBitPerLong, ...
        targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned either as empty (indicating that the match failed) or as a `TflCFunctionEntry` handle.
- `hThis` is a handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method:

- Adds required additional match criteria that the base class does not provide.
- Makes required modifications to the implementation signature.

In this case, the `do_match` method must match only `targetBitPerInt`, representing the number of bits in the C `int` data type for the current target, to the value 32. If the code generator finds a match, the method sets the return handle and creates and adds an input argument. The input argument represents whether units are expressed as degrees or radians, to the replacement function signature.

Alternatively, create and add the additional implementation function argument for passing a units flag in each code replacement table definition file that instantiates this class. In that case, this class definition code does not create the argument. That code sets only the argument value. For an example of creating and adding additional implementation function arguments in a table definition file, see “Customize Code Match and Replacement for Scalar Operations” on page 65-168.

```
classdef TflCustomFunctionEntry < RTW.TflCFunctionEntryML
  methods
    function ent = do_match(hThis, ...
        hCSO, ... %#ok
        targetBitPerChar, ... %#ok
        targetBitPerShort, ... %#ok
        targetBitPerInt, ... %#ok
```

```
        targetBitPerLong, ... %#ok
        targetBitPerLongLong) %#ok
      % DO_MATCH - Create a custom match function. The base class
      % checks the types of the arguments prior to calling this
      % method. This will check additional data and perhaps modify
      % the implementation function.

      ent = []; % default the return to empty, indicating the match failed.

      % Match sine function only if the target int size is 32 bits
      if targetBitPerInt == 32
        % Need to modify the default implementation, starting from a copy
        % of the standard TflCFunctionEntry.
        ent = RTW.TflCFunctionEntry(hThis);

        % If the target int size is 32 bits, the implementation function
        % takes an additional input flag argument indicating degress vs.
        % radians. The additional argument can be created and added either
        % in the CRL table definition file that instantiates this class, or
        % here in the class definition, as follows:
        createAndAddImplementationArg(ent, 'RTW.TflArgNumericConstant', ...
                                      'Name',           'u2', ...
                                      'IsSigned',       true, ...
                                      'WordLength',     32, ...
                                      'FractionLength', 0, ...
                                      'Value',          1);
      end
    end
  end
end
```

Exit the class folder and return to the previous working folder.

3 Create and save the following code replacement table definition file, `crl_table_custom_sinfcn_double.m`. This file defines a code replacement table that contains a function table entry for sine with `double` input and output. This entry instantiates the derived class from the previous step, `TflCustomFunctionEntry`.

```
function hTable = crl_table_custom_sinfcn_double

hTable = RTW.TflTable;

%% Add TflCustomFunctionEntry
fcn_entry = TflCustomFunctionEntry;
setTflCFunctionEntryParameters(fcn_entry, ...
    'Key',                      'sin', ...
    'Priority',                 30, ...
    'ImplementationName',       'mySin', ...
    'ImplementationHeaderFile', 'mySin.h', ...
    'ImplementationSourceFile', 'mySin.c');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
     'Name',         'y1', ...
     'IOType',       'RTW_IO_OUTPUT', ...
```

```
        'DataTypeMode', 'double');

    createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
        'Name',         'u1', ...
        'IOType',       'RTW_IO_INPUT', ...
        'DataTypeMode', 'double');

    % TflCustomFunctionEntry class do_match method will create and add
    % an implementation function argument during code generation if
    % the supported integer size on the current target is 32 bits.
    copyConceptualArgsToImplementation(fcn_entry);

    addEntry(hTable, fcn_entry);
```

4 Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.

  ```
  tbl = crl_table_custom_sinfcn_double
  ```

- In the Code Replacement Viewer, view the table definition file.

  ```
  crviewer(crl_table_custom_sinfcn_double)
  ```

Customize Code Match and Replacement for Nonscalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a nonscalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

This example restricts the match criteria for an element-wise multiplication replacement to entries with a specific dimension range. When a match occurs, the custom `do_match` method modifies the replacement signature to pass the number of elements into the function.

Files for developing and testing this code replacement library example are available in `matlab/help/toolbox/ecoder/examples/code_replacement/custom_elemmult`:

- `do_match` method — `@MyElemMultEntry/MyElemMultEntry.m`
- Replacement function source and header files — `src/myMulImplLib.c` and `src/myMulImplLib.h`
- Model — `myElemMul.slx`

- Code replacement table definition — `myElemMultCrlTable.m`
- Registration file — `rtwTargetInfo.m`

To create custom code replacement entries that add logic to the code replacement match and replacement process:

1 Create a class, for example `MyElemMultEntry`, which is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
    hCSO, ...
    targetBitPerChar, ...
    targetBitPerShort, ...
    targetBitPerInt, ...
    targetBitPerLong, ...
    targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the derived instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method:

- Adds match criteria that the base class does not provide.
- Makes changes to the implementation signature.

The `do_match` method relies on the base class for checking data types and dimension ranges. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Uses the conceptual arguments to compute the number of elements in the array. In the replacement entry returned, sets the value of the constant implementation argument as the number of elements of the array.

- Updates the code replacement entry such that it matches CSOs that have the same argument dimensions.

```
classdef MyElemMultEntry < RTW.TflCOperationEntryML
    methods
        function obj = MyElemMultEntry(varargin)
            mlock;
            obj@RTW.TflCOperationEntryML(varargin{:});
        end

        function ent = do_match(hThis, ...
            hCSO, ... %#ok
            targetBitPerChar, ... %#ok
            targetBitPerShort, ... %#ok
            targetBitPerInt, ... %#ok
            targetBitPerLong, ... %#ok
            targetBitPerLongLong ) %#ok

            %  Fourth implementation arg represents number of elements for producing matches.
            assert(strcmp(hThis.Implementation.Arguments(4).Name,'numElements'));

            ent = RTW.TflCOperationEntry(hThis);

            % Calculate number of elements and set value of injected constant.
            ent.Implementation.Arguments(4).Value = prod(hCSO.ConceptualArgs(1).DimRange(1,:));

            % Since implementation has been modified for specific DimRange, update
            % returned entry to match similar CSOs only.
            for idx =1:3
                ent.ConceptualArgs(idx).DimRange = hCSO.ConceptualArgs(idx).DimRange;
            end
        end
    end
end
```

2 Create and save the following code replacement table definition file, `myElemMultCrlTable.m`. This file defines a code replacement table that contains an operator entry generator for element-wise multiplication. The table entry:

- Instantiates the derived class `myElemMultEntry` from the previous step.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Creates conceptual arguments `y1`, `u1`, and `u2`. The argument class `RTW.TflArgMatrix` specifies matrix arguments to match. The three arguments are set up to match 2-dimensional matrices with at least two elements in each dimension.
- Calls the `getTflArgFromString` function to create a return value and four implementation arguments. Arguments `u1` and `u2` are the operands, `y1` is the product, and the fourth argument is the number of elements.

Alternatively, the `do_match` method of the derived class `myElemMultEntry` can create and add the implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.

- Calls `addEntry` to add the entry to a code replacement table.

```
function hLib = myElemMultCrlTable

libPath = fullfile(fileparts(which(mfilename)),'src');

hLib = RTW.TflTable;
%---------- entry: RTW_OP_ELEM_MUL -----------
hEnt = MyElemMultEntry;
hEnt.setTflCOperationEntryParameters( ...
          'Key', 'RTW_OP_ELEM_MUL', ...
          'Priority', 100, ...
          'SaturationMode', 'RTW_WRAP_ON_OVERFLOW', ...
          'ImplementationName', 'myElemMul_s32', ...
          'ImplementationSourceFile', 'myMulImplLib.c', ...
          'ImplementationSourcePath', libPath, ...
          'ImplementationHeaderFile', 'myMulImplLib.h', ...
          'ImplementationHeaderPath', libPath, ...
          'SideEffects', true, ...
          'GenCallback','RTW.copyFileToBuildDir');

% Conceptual Args

arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT',  'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT',  'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT',  'int32');
arg.DimRange = [2 2; Inf Inf];
hEnt.addConceptualArg(arg);

% Implementation Args

arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);
```

```
arg = hEnt.getTflArgFromString('u1','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','int32*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','int32*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('numElements','uint32',0);
hEnt.Implementation.addArgument(arg);

hLib.addEntry( hEnt );
```

3 Check the validity of the code replacement table entry.

- At the command prompt, invoke the table definition file.

  ```
  tbl = myElemMultCrlTable
  ```

- In the Code Replacement Viewer, view the table definition file.

  ```
  crviewer(myElemMultCrlTable)
  ```

Customize Code Match and Replacement for Scalar Operations

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

- When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
- When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

1 Create a class, for example `TflCustomOperationEntry`, that is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
        hCSO, ...
        targetBitPerChar, ...
        targetBitPerShort, ...
        targetBitPerInt, ...
        targetBitPerLong, ...
        targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them

to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
  methods
    function ent = do_match(hThis, ...
        hCSO, ... %#ok
        targetBitPerChar, ... %#ok
        targetBitPerShort, ... %#ok
        targetBitPerInt, ... %#ok
        targetBitPerLong, ... %#ok
        targetBitPerLongLong) %#ok

      % DO_MATCH - Create a custom match function. The base class
      % checks the types of the arguments prior to calling this
      % method. This class will check additional data and can
      % modify the implementation function.

      % The base class checks word size and signedness. Slopes and biases
      % have been wildcarded, so the only additional checking to do is
      % to check that the biases are zero and that there are only three
      % conceptual arguments (one output, two inputs)

      ent = []; % default the return to empty, indicating the match failed

      if length(hCSO.ConceptualArgs) == 3 && ...
          hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
          hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
          hCSO.ConceptualArgs(3).Type.Bias == 0

        % Modify the default implementation. Since this is a
        % generator entry, a concrete entry is created using this entry
        % as a template. The type of entry being created is a standard
        % TflCOperationEntry. Using the standard operation entry
        % provides required information, and you do not need
        % a custom match function.
        ent = RTW.TflCOperationEntry(hThis);

        % Since this entry is modifying the implementation for specific
        % fraction-length values (arguments 3, 4, and 5), the conceptual argument
        % wild cards must be removed (the wildcards were inherited from the
        % generator when it was used as a template for the concrete entry).
        % This concrete entry is now for a specific slope and bias.
        % hCSO holds the slope and bias values (created by the code generator).
        for idx=1:3
          ent.ConceptualArgs(idx).CheckSlope = true;
          ent.ConceptualArgs(idx).CheckBias = true;

          % Set the specific Slope and Biases
          ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
          ent.ConceptualArgs(idx).Type.Bias = 0;
        end

        % Set the fraction-length values in the implementation function.
        ent.Implementation.Arguments(3).Value = ...
```

```
            -1.0*hCSO.ConceptualArgs(2).Type.FixedExponent;
          ent.Implementation.Arguments(4).Value = ...
            -1.0*hCSO.ConceptualArgs(3).Type.FixedExponent;
          ent.Implementation.Arguments(5).Value = ...
            -1.0*hCSO.ConceptualArgs(1).Type.FixedExponent;
        end
      end
    end
end
```

Exit the class folder and return to the previous working folder.

2 Create and save the following code replacement table definition file, `crl_table_custom_add_ufix32.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```
function hTable = crl_table_custom_add_ufix32

hTable = RTW.TflTable;
```

```
% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
    'Key',                    'RTW_OP_ADD', ...
    'Priority',               30, ...
    'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes',          {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName',     'myFixptAdd', ...
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',       'y1', ...
     'IOType',     'RTW_IO_OUTPUT', ...
     'CheckSlope', false, ...
     'CheckBias',  false, ...
     'DataType',   'Fixed', ...
     'Scaling',    'BinaryPoint', ...
     'IsSigned',   false, ...
     'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
      'Name',       'u1', ...
      'IOType',     'RTW_IO_INPUT', ...
      'CheckSlope', false, ...
      'CheckBias',  false, ...
      'DataType',   'Fixed', ...
      'Scaling',    'BinaryPoint', ...
      'IsSigned',   false, ...
      'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
       'Name',       'u2', ...
       'IOType',     'RTW_IO_INPUT', ...
       'CheckSlope', false, ...
       'CheckBias',  false, ...
       'DataType',   'Fixed', ...
       'Scaling',    'BinaryPoint', ...
       'IsSigned',   false, ...
       'WordLength', 32);

% Specify replacement function signature
```

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'IsSigned',     false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'u1', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',     false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'u2', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',     false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',         'fl_in1', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',     false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',         0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',         'fl_in2', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',     false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',         0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',         'fl_out', ...
    'IOType',       'RTW_IO_INPUT', ...
    'IsSigned',     false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
```

```
    'Value',       0);

addEntry(hTable, op_entry);
```

3 Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.

  ```
  tbl = crl_table_custom_add_ufix32
  ```

- In the Code Replacement Viewer, view the table definition file.

  ```
  crviewer(crl_table_custom_add_ufix32)
  ```

Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set function entry parameters with a call to the `setTflCOperationEntryParameters` function.

   ```
   % Define addition operation of built-in uint8 data type
   % Saturation on, Rounding unspecified
   setTflCOperationEntryParameters(op_entry, ...
                       'Key',                    'RTW_OP_ADD', ...
                       'Priority',               90, ...
                       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
                       'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
                       'ImplementationName',     'u8_add_u8_u8', ...
                       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
                       'ImplementationSourceFile', 'u8_add_u8_u8.c' );
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'uint8');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'uint8');
   addConceptualArg(op_entry, arg );

   arg = getTflArgFromString(hTable, 'u2', 'uint8');
   addConceptualArg(op_entry, arg );
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the

`copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(op_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

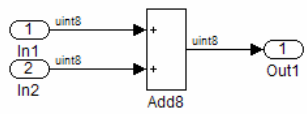
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that includes an Add block, such as this model.



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

4 Generate code and a code generation report.

5 Review the code replacements.

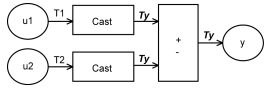
Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

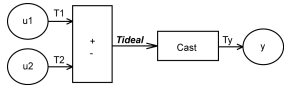
Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.



- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.



Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an **Algorithm** menu. Use that menu to specify the `Cast before operation` or `Cast after operation` algorithm for that entry.

Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTflCOperationEntryParameters`, set at least these parameters:

- `Key` to `RTW_OP_ADD` or `RTW_OP_MINUS`
- `ImplementationName` to the name of your replacement function
- `EntryInfoAlgorithm` to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                  'Key',                      'RTW_OP_ADD', ...
                  'EntryInfoAlgorithm',       'RTW_CAST_AFTER_OP', ...
                  'ImplementationName',       'u8_add_u8_u8');
```

For more information, see `setTflCOperationEntryParameters`.

Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
`double`	`double`	`double`	`double`	CBO, CAO
`double`	`double`	`double`	`single`	—
`double`	`double`	`single`	`double`	—
`double`	`double`	`single`	`single`	CBO
`double`	`single`	`double`	`double`	CBO, CAO

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
`double`	`single`	`double`	`single`	—
`double`	`single`	`single`	`double`	—
`double`	`single`	`single`	`single`	CBO
`single`	`single`	`single`	`single`	CBO, CAO
`single`	`single`	`single`	`double`	—
`single`	`single`	`double`	`single`	—
`single`	`single`	`double`	`double`	CBO, CAO

- Floating-point and fixed-point types on the immediate addition or subtraction operation

Algorithm	Conditions
CBO	One of the following is true: • Operation type is `double`. • Operation type is `single` and input types are `single` or fixed-point.
CAO	Operation type is a superset of input types—that is, output type can represent values of input types without loss of data.

- Fixed-point types only

Algorithm	Conditions
CBO	At least one of the following is true: • Accumulator type equals output type (`Tacc == Tout`). • Output type is a superset of input types (`Tacc >= {Tin1, Tin2}`) and accumulator type is a superset of output type (`Tacc >= Tout`). • Operation does not incur range or precision loss.

Algorithm	Conditions
CAO	Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see “Addition” or “Subtraction” in “Fixed-Point Operator Code Replacement” on page 66-155 (for MATLAB code) or “Fixed-Point Operator Code Replacement” on page 65-205 (for Simulink models).

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of `int8 + int8 –> int16`. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

Limitations

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A)(cast B)(u1+u2)`. If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator (+) are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

Small Matrix Operation to Processor Code Replacement

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the `double` data type. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_matrix_add_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the first operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create table entry for matrix_sum_2x2_double
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTflCOperationEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_ADD', ...
       'Priority',               30, ...
       'SaturationMode',         'RTW_WRAP_ON_OVERFLOW', ...
       'ImplementationName',     'matrix_sum_2x2_double', ...
       'ImplementationHeaderFile', 'MatrixMath.h', ...
       'ImplementationSourceFile', 'MatrixMath.c', ...
       'ImplementationHeaderPath', LibPath, ...
       'ImplementationSourcePath', LibPath, ...
       'AdditionalIncludePaths',   {LibPath}, ...
       'GenCallback',            'RTW.copyFileToBuildDir', ...
       'SideEffects',            true);
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix`. Specify the base type and the dimensions for which the

argument is valid. The first table entry specifies `[2 2]` and the second table entry specifies `[3 3]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` to create the arguments. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Create the entry for the second operator mapping.

```
% Create table entry for matrix_sum_3x3_double
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                    'RTW_OP_ADD', ...
    'Priority',               30, ...
    'SaturationMode',         'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName',     'matrix_sum_3x3_double', ...
    'ImplementationHeaderFile', 'MatrixMath.h', ...
```

```
        'ImplementationSourceFile', 'MatrixMath.c', ...
        'ImplementationHeaderPath', LibPath, ...
        'ImplementationSourcePath', LibPath, ...
        'AdditionalIncludePaths',   {LibPath}, ...
        'GenCallback',              'RTW.copyFileToBuildDir', ...
        'SideEffects',              true);

    % Specify operands and result
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                              'Name',         'y1', ...
                              'IOType',       'RTW_IO_OUTPUT', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                              'Name',         'u1', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);
    createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                              'Name',         'u2', ...
                              'BaseType',     'double', ...
                              'DimRange',     [3 3]);

    % Specify replacement function signature
    arg = getTflArgFromString(hTable, 'y2', 'void');
    arg.IOType = 'RTW_IO_OUTPUT';
    op_entry.Implementation.setReturn(arg);
    arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
    op_entry.Implementation.addArgument(arg);
    arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
    op_entry.Implementation.addArgument(arg);
    arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
    arg.IOType = 'RTW_IO_OUTPUT';
    op_entry.Implementation.addArgument(arg);

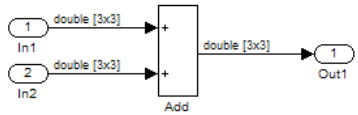
    addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that includes an Add block.



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as `0.1`.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

4 In the Model Explorer, configure the **Signal Attributes** for the `In1` and `In2` source blocks. For each source block, set **Port dimensions** to `[3,3]`, and set **Data type** to `double`. Apply the changes. Save the model.

5 Generate code and a code generation report.

6 Review the code replacements. The code generator replaces the + operator with `matrix_sum_3x3_double` in the generated code.

7 Reconfigure **Port dimensions** for `In1` and `In2` to `[2 2]`, regenerate code. Observe that code containing the + operator is replaced with `matrix_sum_2x2_double`.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to replace floating-point matrix/matrix and matrix/vector multiplication operations with the multiplication functions `dgemm` and `dgemv` defined in the MathWorks BLAS library. If you use a third-party BLAS library for replacement, you will need to change the build requirements in this example to point to your library. This example defines the function mappings programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mappings.

Code replacement libraries only support limited cases from BLAS libraries. BLAS libraries support matrix/matrix multiplication in the form C = a(op(A) * op(B)) + bC. Where the expression op(X) represents either the transposition or Hermitian transposition of X. However, code replacement libraries only support the limited case of C = op(A) * op(B) (a = 1.0, b = 0.0). Additionally, BLAS libraries support matrix/vector multiplication in the form of y = a(op(A) * x) + by, while code replacement libraries only support the limited case of y = op(A) * x (a = 1.0, b = 0.0).

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_tmwblas_mmult_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

   ```
   % Define library path for Windows or UNIX
   arch = computer('arch');
   if ~ispc
       LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
   else
       % Use Stateflow to get the compiler info
       compilerInfo = sf('Private','compilerman','get_compiler_info');
       compilerName = compilerInfo.compilerName;
       if strcmp(compilerName, 'msvc90') || ...
               strcmp(compilerName, 'msvc80') || ...
               strcmp(compilerName, 'msvc71') || ...
               strcmp(compilerName, 'msvc60'), ...
               compilerName = 'microsoft';
       end
       LibPath = fullfile('$(MATLAB_ROOT)', 'extern', 'lib', arch, compilerName);
   end
   ```

4. Create an entry for the first mapping with a call to the `RTW.TflBlasEntryGenerator` function.

```
% Create table entry for dgemm32
op_entry = RTW.TflBlasEntryGenerator;
```

5 Call `setTflCFunctionEntryParameters` to set operator entry parameters. For floating-point nonscalar addition and subtraction, the code generator ignores saturation and rounding modes. For nonscalar addition and subtraction operations that do not involve fixed-point data, specify `SaturationMode` as `'RTW_SATURATE_UNSPECIFIED'` and `RoundingModes` as `{'RTW_ROUND_UNSPECIFIED'}`.

```
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                    'RTW_OP_MUL', ...
    'Priority',               100, ...
    'ImplementationName',     'dgemm32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',     {['libmwblascompat32.' libExt]}, ...
    'AdditionalLinkObjsPaths', {LibPath}, ...
    'SideEffects',            true);
```

6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`, while the conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
```

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf inf]);
```

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` and `RTW.TflArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Using RTW.TflBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
%        type* BETA, type* y, int* LDC)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANSA');
% Possible values for PassByType property are
%  RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
%  RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
```

```
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Create the entry for the second mapping.

```
% Create table entry for dgemv32
op_entry = RTW.TflBlasEntryGenerator;
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
```

```
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'ImplementationName',       'dgemv32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',       {['libmwblascompat32.' libExt]}, ...
    'AdditionalLinkObjsPaths',  {LibPath},...
    'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf 1]);

% Using RTW.TflBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(char* TRANS, int* M, int* N,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* INCX,
%        type* BETA, type* y, int* INCY)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY, and insert them into the
% generated code. TRANS will be set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANS');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
```

```
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX','integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);
```

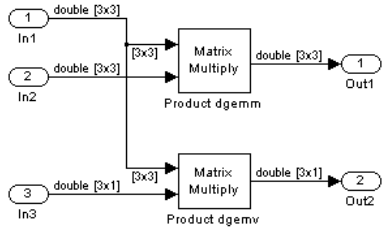
10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that includes two Product blocks.



3 For each Product block, set the block parameter **Multiplication** to the value `Matrix(*)`.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as `0.1`.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

5 In the Model Explorer, configure the **Signal Attributes** for the `In1`, `In2`, and `In3` source blocks. For `In1` and `In2`, set **Port dimensions** to `[3 3]` and set the **Data type** to `double`. For `In3`, set **Port dimensions** to `[3 1]` and set the **Data type** to `double`.

6 Generate code and a code generation report.

7 Review the code replacements.

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions *x*`gemm` and *x*`gemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of C = a(op(A) * op(B)) + bC. op(X) means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of C = op(A) * op(B) (a = 1.0, b = 0.0). Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of y = a(op(A) * x) + by, code replacement libraries support only the limited case of y = op(A) * x (a = 1.0, b = 0.0).

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cblas_mmult_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the CBLAS function library. For example:

   ```
   LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
   ```

4. Create an entry for the first mapping with a call to the `RTW.TflBlasEntryGenerator` function.

   ```
   % Create table entry for cblas_dgemm
   op_entry = RTW.TflCBlasEntryGenerator;
   ```

5. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_MUL', ...
       'Priority',               100, ...
       'ImplementationName',     'cblas_dgemm', ...
       'ImplementationHeaderFile', 'cblas.h', ...
   ```

```
    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);
```

6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`. The conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf inf]);
```

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Using RTW.TflCBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, enum TRANSB, int M, int N, int K,
%        type ALPHA, type* u1, int LDA, type* u2, int LDB,
%        type BETA, type* y, int LDC)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
```

```
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

```
arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Create the entry for the second mapping.

```
% Create table entry for cblas_dgemv
op_entry = RTW.TflCBlasEntryGenerator;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'ImplementationName',       'cblas_dgemv', ...
    'ImplementationHeaderFile', 'cblas.h', ...
    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf 1]);

% Using RTW.TflCBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, int M, int N,
%        type ALPHA, type* u1, int LDA, type* u2, int INCX,
%        type BETA, type* y, int INCY)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY and insert them into the
% generated code.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
```

```
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M','integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

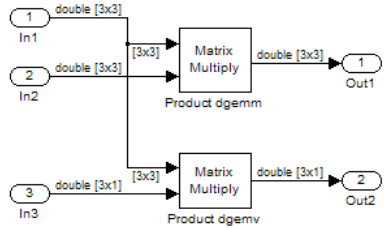
addEntry(hTable, op_entry);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model that includes two Product blocks.



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as `0.1`.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

4 For each Product block, set the block parameter **Multiplication** to the value `Matrix(*)`.

5 In the Model Explorer, configure the **Signal Attributes** for the `In1`, `In2`, and `In3` source blocks. For `In1` and `In2`, set **Port dimensions** to `[3 3]`. Set the **Data type** to `double`. For `In3`, set **Port dimensions** to `[3 1]`. Set the **Data type** to `double`.

6 Generate code and a code generation report.

7 Review the code replacements.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

Note Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
                       'Key',                      'RTW_OP_ADD', ...
                       'Priority',                 90, ...
                       'ImplementationName',       'u8_add_u8_u8', ...
                       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
                       'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
                       'SideEffects',              true );
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg );

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg );
```

6. Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a new `void` output argument, for example, `y2`. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Create new void output y2
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set y1 as first input arg, mark IOType as output, and use pointer type
arg=getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

7. Add the entry to a code replacement table with a call to the `addEntry` function.

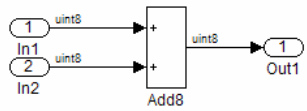
```
addEntry(hTable, op_entry);
```

8. Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1. Register the code replacement mapping.

2 Create a model that includes an Add block.



3 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.
- Set the **Optimize global data access** parameter to `Use global to hold temporary results` to reduce data copies in the generated code.

4 Generate code and a code generation report.

5 Review the code replacements.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

Match	Create entry	Minimally specify parameters
A specific binary-point-only scaling combination on the operator inputs and output.	`RTW.TflCOperationEntry`	`createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `true`. • `CheckBias`: Specify the value `true`. • `DataTypeMode` (or `DataType/Scaling` equivalent): Specify fixed-point binary-point-only scaling. • `FractionLength`: Specify a fraction length (for example, 3).

Match	Create entry	Minimally specify parameters
A specific slope bias scaling combination on the operator inputs and output.	`RTW.TflCOperationEntry`	`createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `true`. • `CheckBias`: Specify the value `true`. • `DataTypeMode` (or `DataType/Scaling` equivalent): Specify fixed-point [slope bias] scaling. • `Slope` (or `SlopeAdjustmentFactor`/`FixedExponent` equivalent): Specify a slope value (for example, `15`). • `Bias`: Specify a bias value (for example, `2`).
Net slope between operator inputs and output (multiplication and division).	`RTW.TflCOperationEntryGenerator_NetSlope`	`setTflCOperationEntryParameters` function: • `NetSlopeAdjustmentFactor`: Specify the slope adjustment factor (`F`) part of the net slope, $F2^E$ (for example, `1.0`). • `NetFixedExponent`: Specify the fixed exponent (`E`) part of the net slope, $F2^E$ (for example, `-3.0`). `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`. • `DataType`: Specify the value `'Fixed'`.

Match	Create entry	Minimally specify parameters
Relative scaling between operator inputs and output (multiplication and division).	`RTW.TflCOperationEntry-Generator`	`setTflCOperationEntryParameters` function: • `RelativeScalingFactorF`: Specify the slope adjustment factor (`F`) part of the relative scaling factor, $F2^E$ (for example, `1.0`). • `RelativeScalingFactorE`: Specify the fixed exponent (`E`) part of the relative scaling factor, $F2^E$ (for example, `-3.0`). `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`. • `DataType`: Specify the value `'Fixed'`.
Equal slope and zero net bias across operator inputs and output (addition and subtraction).	`RTW.TflCOperationEntry-Generator`	`setTflCOperationEntryParameters` function: • `SlopesMustBeTheSame`: Specify the value `true`. • `MustHaveZeroNetBias`: Specify the value `true`. `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`.

Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

$$V = \tilde{V} = SQ + B$$

- V is an arbitrarily precise real-world value.
- $\tilde{V}$ is the approximate real-world value that results from fixed-point representation.
- Q is an integer that encodes $\tilde{V}$, referred to as the quantized integer.
- S is a coefficient of Q, referred to as the slope.
- B is an additive correction, referred to as the bias.

The general equation for an operation between fixed-point operands is:

$$(S_O Q_O + B_O) = (S_1 Q_1 + B_1) < op > (S_2 Q_2 + B_2)$$

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

Addition

The operation $V_0 = V_1 + V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1 + \left(\frac{S_2}{S_0}\right)Q_2 + \left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias

$$\left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all addition conceptual arguments. (For

parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Subtraction

The operation $V_0 = V_1 - V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1 - \left(\frac{S_2}{S_0}\right)Q_2 + \left(\frac{B_1 - B_2 - B_0}{S_0}\right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left(\frac{B_1 - B_2 - B_0}{S_0}\right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all subtraction conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation $V_0 = V_1 * V_2$ implies, for binary-point-only scaling, that

$$S_0Q_0 = (S_1Q_1)(S_2Q_2)$$

$$Q_0 = \left(\frac{S_1S_2}{S_0}\right)Q_1Q_2$$

$$Q_0 = S_nQ_1Q_2$$

where S_n is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all multiplication conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Note When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry (see “Customize Match and Replacement Process” on page 65-160).

The operation $V_0 = (V_1 / V_2)$ implies, for binary-point-only scaling, that

$$S_0Q_0 = \left(\frac{S_1Q_1}{S_2Q_2}\right)$$

$$Q_0 = S_n\left(\frac{Q_1}{Q_2}\right)$$

where S_n is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the

`s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all division conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Note When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Data Type Conversion (Cast)

The data type conversion operation $V_0 = V_1$ implies, for binary-point-only scaling, that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1$$
$$Q_0 = S_n Q_1$$

where S_n is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all cast conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Shift

The shift left or shift right operation $V_0 = (V_1 / 2^n)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left(\frac{S_1 Q_1}{2^n}\right)$$
$$Q_0 = \left(\frac{S_1}{S_0}\right)\left(\frac{Q_1}{2^n}\right)$$
$$Q_0 = S_n\left(\frac{Q_1}{2^n}\right)$$

where S_n is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement,

the biases must be zero for all shift conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_binptscale
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as `s32_mul_s16_s16_binarypoint`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_MUL', ...
       'Priority',               90, ...
       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
       'ImplementationName',     's32_mul_s16_s16_binarypoint', ...
       'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
       'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a

fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     32, ...
    'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 13);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (`int32`). The input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'IsSigned',       true, ...
   'WordLength',     32, ...
   'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
```

```
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

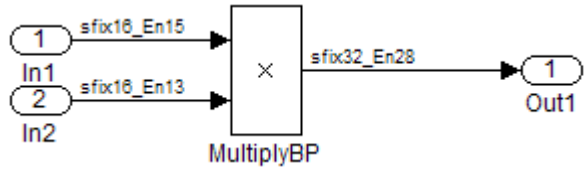
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.



3 For this model:

- Set the Inport 1 **Data type** to `fixdt(1,16,15)`.
- Set the Inport 2 **Data type** to `fixdt(1,16,13)`.
- In the Product block:
  - Set **Output data type** to `fixdt(1,32,28)`.
  - Select the option **Saturate on integer overflow**.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_s16divslopebias
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
      'Key',                    'RTW_OP_DIV', ...
      'Priority',               90, ...
      'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
      'RoundingModes',          {'RTW_ROUND_CEILING'}, ...
      'ImplementationName',     's16_div_s16_s16_slopebias', ...
      'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
      'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          15, ...
   'Bias',           2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          15, ...
   'Bias',           2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'u2', ...
   'IOType',         'RTW_IO_INPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          13, ...
   'Bias',           5);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'FractionLength', 0);
```

```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u2', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

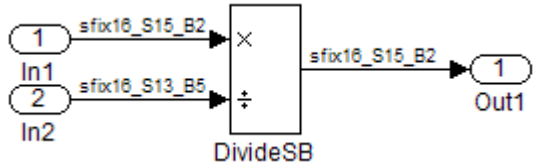
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.



3 For this model:

- Set the Inport 1 **Data type** to `fixdt(1,16,15,2)`.
- Set the Inport 2 **Data type** to `fixdt(1,16,13,5)`.
- In the Divide block:
  - Set **Output data type** to `Inherit: Inherit via back propagation`.
  - Set **Integer rounding mode** to `Ceiling`.
  - Select the option **Saturate on integer overflow**.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.
6 Review the code replacements.

Net Slope Scaling Code Replacement

Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_netslopesaturate
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

   ```
   wv = [16,32];
   for iy = 1:2
     for inum = 1:2
       for iden = 1:2
         hTable = getDivOpEntry(hTable, ...
            fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
       end
     end
   end

   %------------------------------------------------------------
   function hTable = getDivOpEntry(hTable,dty,dtnum,dtden)
   %------------------------------------------------------------
   % Create an entry for division of fixed-point data types where
   % arguments are specified using Slope and Bias scaling
   % Saturation on, Rounding unspecified

   funcStr = sprintf('user_div_%s_%s_%s',...
           typeStrFunc(dty),...
           typeStrFunc(dtnum),...
           typeStrFunc(dtden));
   ```

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
setTflCOperationEntryParameters(op_entry, ...
   'Key',                    'RTW_OP_DIV', ...
   'Priority',               90, ...
   'SaturationMode',         'RTW_WRAP_ON_OVERFLOW',...
   'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'},...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',       0.0, ...
   'ImplementationName',     funcStr, ...
   'ImplementationHeaderFile', [funcStr,'.h'], ...
   'ImplementationSourceFile', [funcStr,'.c']);
```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name',           'y1',...
   'IOType',         'RTW_IO_OUTPUT',...
   'CheckSlope',     false,...
   'CheckBias',      false,...
   'DataTypeMode',   'Fixed-point: slope and bias scaling',...
   'IsSigned',       dty.Signed,...
   'WordLength',     dty.WordLength,...
   'Bias',           0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT',...
   'CheckSlope',     false,...
   'CheckBias',      false,...
   'DataTypeMode',   'Fixed-point: slope and bias scaling',...
   'IsSigned',       dtnum.Signed,...
   'WordLength',     dtnum.WordLength,...
   'Bias',           0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name',           'u2', ...
```

```
    'IOType',          'RTW_IO_INPUT',...
    'CheckSlope',      false,...
    'CheckBias',       false,...
    'DataTypeMode',    'Fixed-point: slope and bias scaling',...
    'IsSigned',        dtden.Signed,...
    'WordLength',      dtden.WordLength,...
    'Bias',            0);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2',typeStrBase(dtden));
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Define functions that determine the data type word length.

```
%------------------------------------------------------------
function str = typeStrFunc(dt)
%------------------------------------------------------------

if dt.Signed
    sstr = 's';
else
    sstr = 'u';
end
str = sprintf('%s%d',sstr,dt.WordLength);

%------------------------------------------------------------
function str = typeStrBase(dt)
%------------------------------------------------------------

if dt.Signed
    sstr = ;
else
    sstr = 'u';
end
str = sprintf('%sint%d',sstr,dt.WordLength);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Multiplication and Division with Rounding Mode and Additional Implementation Arguments

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_netsloperound
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the relative scaling factor $F2^E$.

```
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
   'NetSlopeAdjustmentFactor',   1.0, ...
   'NetFixedExponent',           0.0, ...
```

```
    'ImplementationName',       's16_div_s16_s16', ...
    'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
    'ImplementationSourceFile', 's16_div_s16_s16.c');
```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
                                  'Name',           'y1', ...
                                  'IOType',         'RTW_IO_OUTPUT', ...
                                  'IsSigned',       true, ...
                                  'WordLength',     16, ...
                                  'FractionLength', 0);
```

```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
                                'Name',           'u1', ...
                                'IOType',         'RTW_IO_INPUT', ...
                                'IsSigned',       true, ...
                                'WordLength',     16, ...
                                'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
                                'Name',           'u2', ...
                                'IOType',         'RTW_IO_INPUT', ...
                                'IsSigned',       true, ...
                                'WordLength',     16, ...
                                'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

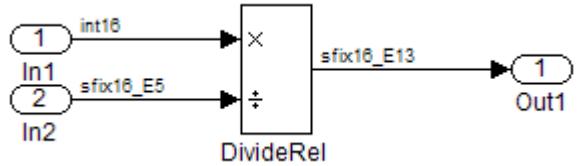
8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.



3 For this model:

- Set the Inport 1 **Data type** to `int16`.
- Set the Inport 2 **Data type** to `fixdt(1,16,-5)`.
- In the Divide block:
  - Set **Output data type** to `fixdt(1,16,-13)`.
  - Set **Integer rounding mode** to `Ceiling`.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.

- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation > Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match the relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values when mapping relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for the addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can also use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_slopeseq_netbiaszero
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator` function, which provides access to the fixed-point parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias`.

   ```
   op_entry = RTW.TflCOperationEntryGenerator;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as `u16_add_SameSlopeZeroBias`. The parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` must be set to `true` to indicate that slopes must be equal and net bias must be zero across the addition (or subtraction) of inputs and output.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_ADD', ...
       'Priority',                90, ...
       'SaturationMode',          'RTW_WRAP_ON_OVERFLOW', ...
       'RoundingModes',           {'RTW_ROUND_UNSPECIFIED'}, ...
       'SlopesMustBeTheSame',     true, ...
       'MustHaveZeroNetBias',     true, ...
       'ImplementationName',      'u16_add_SameSlopeZeroBias', ...
       'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
       'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the

`createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (`uint16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
```

```
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

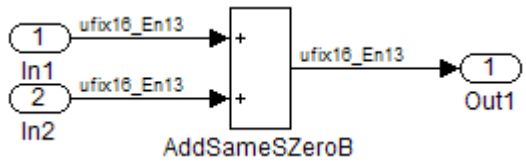
```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

To test this example:

1 Register the code replacement mapping.

2 Create a model.



3 For this model:

- Set the Inport 1 **Data type** to `fixdt(0,16,13)`.
- Set the Inport 2 **Data type** to `fixdt(0,16,13)`.
- In the Add block:
  - Verify that **Output data type** is set to its default, `Inherit via internal rule`.
  - Set **Integer rounding mode** to `Zero`.

4 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

5 Generate code and a code generation report.

6 Review the code replacements.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

Casts from int32 To int16

This example creates a code replacement entry that replaces `int32` to `int16` data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cast_int32_to_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_sat_cast`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_CAST', ...
       'Priority',               50, ...
       'ImplementationName',     'my_sat_cast', ...
       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_FLOOR'}, ...
       'ImplementationHeaderFile', 'some_hdr.h', ...
       'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the

entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
op_entry.Implementation.setReturn(arg);
```

6 Create the `int32` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Casts Using Net Slope

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cast_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_cast`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_CAST', ...
   'Priority',                 50, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',         (OutFL - InFL), ...
   'ImplementationName',       'my_fxp_cast', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
```

5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',         'u1', ...
     'IOType',       'RTW_IO_INPUT', ...
     'CheckSlope',   false, ...
     'CheckBias',    false, ...
     'DataTypeMode', 'Fixed-point: binary point scaling', ...
     'IsSigned',     InSgn, ...
     'WordLength',   InWL, ...
     'FractionLength',InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       InSgn, ...
    'WordLength',     InWL, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

Shift Lefts for int16 Data

This example creates a code replacement entry to replace shift left operations for `int16` data. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_shift_left_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left and the name of the replacement function as `my_shift_left`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_SL', ...
       'Priority',               50, ...
       'ImplementationName',     'my_shift_left', ...
       'ImplementationHeaderFile', 'some_hdr.h', ...
       'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   op_entry.Implementation.setReturn(arg);
   ```

6 Create the `int16` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as an implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function `getTflArgFromString` is called to create an `int8` input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the `addEntry` function.

  ```
  addEntry(hTable, op_entry);
  ```

- Save the table definition file. Use the name of the table definition function to name the file.

Shift Lefts Using Net Slope

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_shift_left_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the F and E parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                     'RTW_OP_SL', ...
   'Priority',                50, ...
   'SaturationMode',          'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',           {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',        (OutFL - InFL),...
   'ImplementationName',      'my_fxp_shift_left', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
```

5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);
```

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',          'u1', ...
    'IOType',        'RTW_IO_INPUT', ...
    'CheckSlope',    false, ...
    'CheckBias',     false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',      InSgn, ...
    'WordLength',    InWL, ...
    'FractionLength',InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',           'u1', ...
     'IOType',         'RTW_IO_INPUT', ...
     'IsSigned',       InSgn, ...
     'WordLength',     InWL, ...
     'FractionLength', 0);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Code Replacement Customization for MATLAB Code

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the **Code Replacement Tool** or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator's match and replacement process for functions

To get started, "Quick Start Code Replacement Library Development - Simulink®" on page 65-28.

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

1. Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
2. Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
   - Conceptual name or key
   - Arguments, including quantity, type, type qualifiers, and complexity
   - Algorithm (computation method)
   - Fixed-point saturation and rounding modes
   - Priority
3. When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.

4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

Code Replacement Customization Limitations

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 66-66.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 66-48.
- Addition and subtraction operation replacements—See “Addition and Subtraction Operator Code Replacement” on page 66-129for relevant limitations.
- `coder.replace` function — See `coder.replace` for relevant limitations.
- `coder.dataAlignment` function — See `coder.dataAlignment` for relevant limitations.

Code You Can Replace from MATLAB Code

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

In this section...

Math Functions

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`abs`[1]	Floating point	Scalar	Real
`acos`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`acosd`	Floating point	Scalar Vector Matrix	Real Complex
`acot`	Floating point	Scalar Vector Matrix	Real Complex
`acotd`	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`acoth`	Floating point	Scalar Vector Matrix	Real Complex
`acsc`	Floating point	Scalar Vector Matrix	Real Complex
`acscd`	Floating point	Scalar Vector Matrix	Real Complex
`acsch`	Floating point	Scalar Vector Matrix	Real Complex
`asec`	Floating point	Scalar Vector Matrix	Real Complex
`asecd`	Floating point	Scalar Vector Matrix	Real Complex
`asech`	Floating point	Scalar Vector Matrix	Real Complex
`asin`	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`asind`	Floating point	Scalar Vector Matrix	Real Complex

[1] Wrap on integer overflow only			

Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`memcmp`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memcpy`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memset`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memset2zero`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

Operators

When generating C/C++ code from MATLAB code, depending on code replacement libraries available in your development environment, you can configure the code

generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates you can specify different data types of different inputs.

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Addition (+)[1]	RTW_OP_ADD	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Subtraction (-)[1]	RTW_OP_MINUS	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Multiplication (*)[2]	RTW_OP_MUL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Division (/)	RTW_OP_DIV	Integer Floating point Fixed-point Mixed	Scalar	Real Complex
Data type conversion (cast)	RTW_OP_CAST	Integer Floating point[3] Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Shift left (<<)	RTW_OP_SL	Integer Fixed-point Mixed	Scalar Vector Matrix	Real
Shift right arithmetic (>>)[4]	RTW_OP_SRA	Integer Fixed-point Mixed	Scalar Vector Matrix	Real

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Shift right logical (>>)	RTW_OP_SRL	Integer Fixed-point Mixed	Scalar Vector Matrix	Real
Element-wise matrix multiplication (.*)[5]	RTW_OP_ELEM_MUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Complex conjugation	RTW_OP_CONJUGATE	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Transposition (.')	RTW_OP_TRANS	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Hermitian (complex conjugate) transposition (')	RTW_OP_HERMITIAN	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with transposition[2]	RTW_OP_TRMUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with Hermitian transposition[2]	RTW_OP_HMMUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication followed by shift right arithmetic (u1*u2>>u3)[6]	RTW_OP_MUL_SRA	Integer Fixed-point	Scalar	Real

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Multiplication followed by division (u1*u2/u3)[7]	RTW_OP_MULDIV	Integer Fixed-point	Scalar	Real
Greater than (>)	RTW_OP_GREATER_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Greater than or equal (>=)	RTW_OP_GREATER_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than (<)	RTW_OP_LESS_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than or equal (<=)	RTW_OP_LESS_THAN_OR_EUQAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Equal (==)	RTW_OP_EUQAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Not equal (!=)	RTW_OP_NOT_EUQAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support

[1] See “Addition and Subtraction Operator Code Replacement” on page 66-129 for details to consider when defining mappings for addition and subtraction code replacements.

[2] Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions.

[3] Scaled floating point is not supported.

[4] Code replacement libraries that provide arithmetic shift right implementations should also provide logical shift right implementations, because some arithmetic shift rights are converted to logical shift rights during code generation.

[5] Use the multiplication (*) operator (`RTW_OP_MUL`) for scalar multiplication.

[6] Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 (`U1_slope * U2_slope == Mul_output_slope` and `Mul_output_slope == output_slope_of_shift_operation`).

[7] Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 (`U1_slope * U2_slope == Mul_output_slope == U3_slope * Div_output_slope`).

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

1. “Identify Code Replacement Requirements” on page 66-25
2. “Prepare for Code Replacement Library Development” on page 66-28
3. “Define Code Replacement Mappings” on page 66-30
4. “Specify Build Information for Replacement Code” on page 66-48
5. “Register Code Replacement Mappings” on page 66-57
6. “Verify Code Replacements” on page 66-66
7. “Deploy Code Replacement Library” on page 66-79

To get started, see “Identify Code Replacement Requirements” on page 66-25.

To experiment with the process and tools, see “Quick Start Library Development” on page 66-16.

- “Identify Code Replacement Requirements” on page 66-25
- “Code You Can Replace from MATLAB Code” on page 66-5
- “Quick Start Library Development” on page 66-16
- “What Is Code Replacement Customization?” on page 66-3

Quick Start Library Development

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function `sin`. You use the **Code Replacement Tool**.

Prerequisites

To complete this example, install the following software:

- MATLAB
- MATLAB Coder
- Embedded Coder
- C compiler

For instructions on installing MathWorks products, see “Installation, Licensing, and Activation”. If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

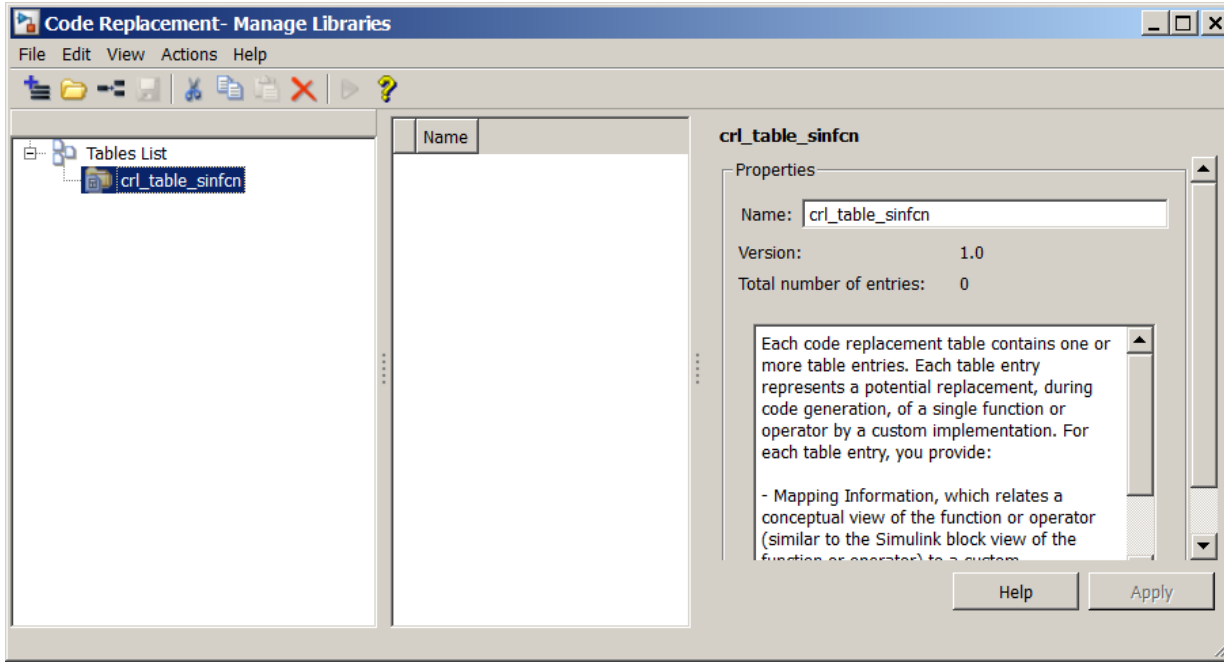
For a list of supported compilers, see `https://www.mathworks.com/support/compilers/current_release/`.

Open the Code Replacement Tool

1. Start a new MATLAB session.
2. Create or navigate (`cd`) to an empty folder.
3. At the command prompt, enter the `crtool` command. The **Code Replacement Tool** window opens.

Create Code Replacement Table

1. In the **Code Replacement Tool** window, select **File** > **New table**.
2. In the right pane, name the table `crl_table_sinfcn` and click **Apply**. Later, when you save the table, the tool saves it with the file name `crl_table_sinfcn.m`.



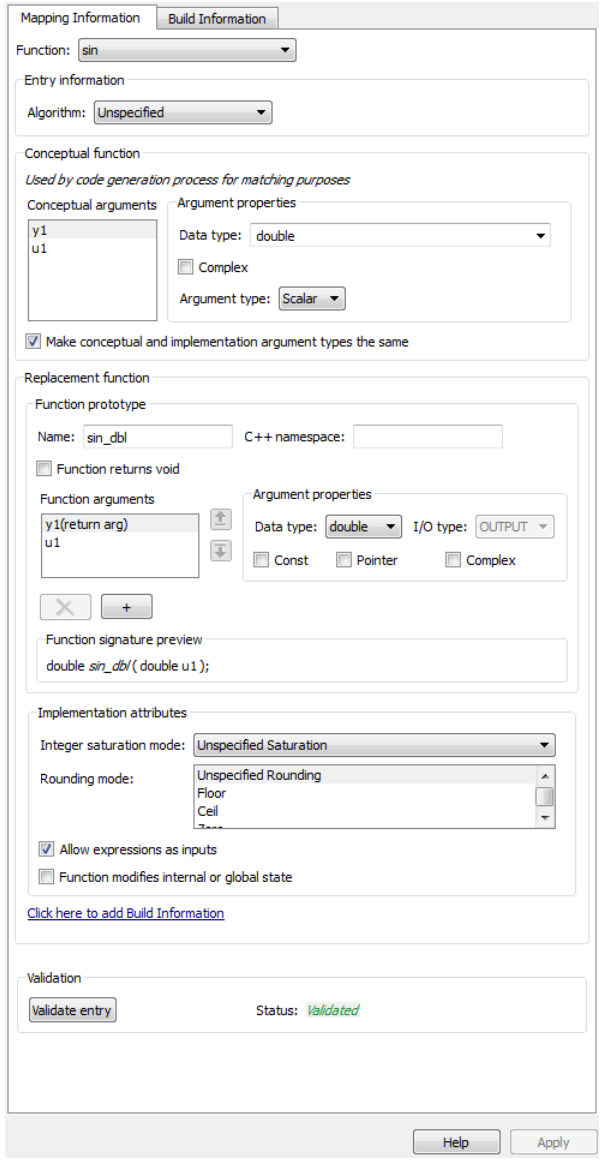
Create Table Entry

Create a table entry that maps a `sin` function with `double` input and `double` output to a custom implementation function.

1. In the left pane, select table `crl_table_sinfcn`. Then, select **File** > **New entry** > **Function**. The new entry appears in the middle pane, initially without a name.
2. In the middle pane, select the new entry.
3. In the right pane, on the **Mapping Information** tab, from the **Function** menu, select `sin`.
4. Leave **Algorithm** set to `Unspecified`, and leave parameters in the **Conceptual function** group set to default values.
5. In the **Replacement function** group, name the replacement function `sin_dbl`.
6. Leave the remaining parameters in the **Replacement function** group set to default values.
7. Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.

8 Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.



Mapping Information
Build Information
Function: sin
Entry information
Algorithm: Unspecified
Conceptual function
Used by code generation process for matching purposes
Conceptual arguments
y1
u1
Argument properties
Data type: double
Complex
Argument type: Scalar
Make conceptual and implementation argument types the same
Replacement function
Function prototype
Name: sin_dbl
C++ namespace:
Function returns void

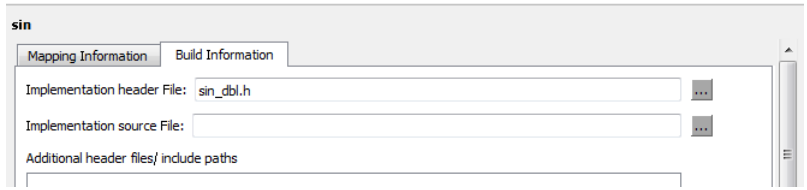
Validation
Validate entry
Status: Validated
Help
Apply

Specify Build Information for Replacement Code

1. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.
2. Leave the remaining parameters set to default values.
3. Click **Apply**.



4. Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

Create Another Table Entry

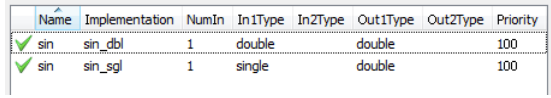
Create an entry that maps a `sin` function with `single` input and `double` output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

1. In the middle pane, select the `sin_dbl` entry.
2. Select **Edit** > **Copy**
3. Select **Edit** > **Paste**
4. On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to `single`.
5. In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to `single`.
6. Click **Apply**. Note the changes that appear for the **Function signature preview**.
7. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

Validate the Code Replacement Table

1. Select **Actions** > **Validate table**.

2 If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.



Name	Implementation	NumIn	In1Type	In2Type	Out1Type	Out2Type	Priority
sin	sin_dbl	1	double		double		100
sin	sin_sgl	1	single		double		100

Save the Code Replacement Table

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

Review the Code Replacement Table Definition

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

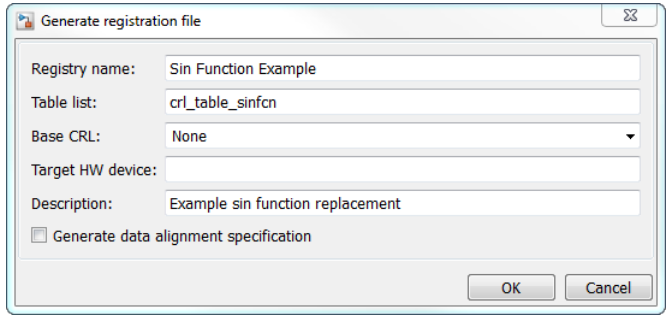
To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

Generate a Registration File

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1 In the Code Replacement Tool, select **File > Generate registration file**.

2 In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and then click **OK**.



3 In the **Select location to save the registration file** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

Register the Code Replacement Table

At the command prompt, enter:

```
RTW.TargetRegistry.getInstance('reset');
```

Review and Test Code Replacements

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1 Check for errors. At the command line, invoke the table definition file. For example:

```
tbl = crl_table_sinfcn

tbl =

  TflTable with properties:

               Version: '1.0'
      ReservedSymbols: []
    StringResolutionMap: []
             AllEntries: [2x1 RTW.TflCFunctionEntry]
           EnableTrace: 1
```

If an error exists in the definition file, the invocation triggers a message to appear. Fix the error and try again.

2 Use the Code Replacement Viewer to check your code replacement entries. For example:

```
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

- Incorrect argument order.
- Conceptual argument names that do not match what is expected by the code generator.

- Incorrect priority settings.

3. Identify existing or create new MATLAB code that calls the `sin` function. For example:

```
function y = my_sin_fnc(x)
  y = sin(x);
end
```

4. Open the MATLAB Coder app.
5. Add the function that includes a call to the `sin` function as an entry-point file. For example, add `my_sin_func.m`. The app creates a project named `my_sin_func.prj`.
6. Click **Next** to go to the **Define Input Type** step. Define the types for the entry-point function inputs.
7. Click **Next** to go to the **Check for Run-Time Issues** step. This step is optional. However, it is a best practice to perform this step. Provide a test file that calls your entry-point function. The app generates a MEX function from your entry-point function. Then, the app runs the test file, replacing calls to the MATLAB function with calls to the generated MEX function.
8. Click **Next** to go to the **Generate Code** step. To open the **Generate** dialog box, click the **Generate** arrow  .
9. Set **Build type** to generate a library or executable.
10. Click **More Settings**.
11. Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For example, `Sin Function Example`.
12. Configure the code generation report. On the **Debug** tab, set the **Always create a code generation report**, **Code replacements**, and **Automatically launch a report if one is generated** parameters.
13. Configure the code generator to generate code only. For **Build type**, select **Source code**. You want to review your code replacements in the generated code before building an executable.
14. Click **Generate** to generate C code and a report.
15. Review code replacement results in the Code Replacements Report section of the code generation report.

    The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

16 Review the code replacements. In the report, click the MATLAB function that triggered the replacement, `my_sin_func.m`. The MATLAB Editor opens and highlights the function call that triggers the code replacement.

Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for your code replacement library.

Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?

Build Information Requirements

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

Registration Information Requirements

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x` device library.

- Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

- “Prepare for Code Replacement Library Development” on page 66-28
- “What Is Code Replacement Customization?” on page 66-3
- “Code You Can Replace from MATLAB Code” on page 66-5

Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the **Code Replacement Tool** or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library. Determine if you would like to use `coder.replace` in your programs to provide warning or error feedback when a code replacement library function cannot be found.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

- “Code You Can Replace from MATLAB Code” on page 66-5
- “Define Code Replacement Mappings” on page 66-30

- “Develop a Code Replacement Library” on page 66-15
- “What Is Code Replacement Customization?” on page 66-3

Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

Situation	Approach
Defining mappings for the first time.	Code Replacement Tool.
Rapid prototyping mappings.	Code Replacement Tool to quickly generate, register, and test mappings.
Developing a mapping as a template or starting point for defining similar mappings.	Code Replacement Tool to generate definition code that you can copy and modify.
Modifying a registration file, including copying and pasting content.	MATLAB Editor to update the programming interface directly.
Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).	Programming interface.
Reusing existing code for new mappings by copying, pasting, and editing existing mappings.	Programming interface.

Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to **Code Generation** pane. In the **Advanced parameters** section, scroll down and click **Custom CRL...** button.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select **View > Show dialog pane** to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select **Hide** to remove the column from the display. (You cannot hide the **Name** column.)

Create a Code Replacement Table

1. In the **Code Replacement Tool** window, select **File > New table**.
2. In the right pane, name the table and click **Apply**. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`.

Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

1. In the left pane, select the table to which you want to add the entry.
2. Select **File** > **New entry** > **entry-type**, where **entry-type** is one of:

   - Math Operation
   - Function
   - BLAS Operation
   - CBLAS Operation
   - Net Slope Fixed-Point Operation
   - Semaphore entry
   - Customization entry

   The new entry appears in the middle pane, initially without a name.
3. In the middle pane, select the new entry.
4. In the right pane, on the **Mapping Information** tab, from the **Function** or **Operation** menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

   Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.
5. If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (`Cast before operation` or `Cast after operation`).
6. Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.

When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have `IOType` of `RTW_IO_INPUT`.

If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the **Make the conceptual and implementation argument types the same** check box. For example, most ANSI-C functions operate on and return `double` data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function `sin` to an implementation representation that specifies an argument and return value of type `single` (`single sin(single)`), of type `double` (`double sin(double)`. In this case, the code generator produces the following code:

```
y = (single) sin(u1);
```

If you select `Custom` for a function entry, specify only conceptual argument information.

7 Specify the name and argument information for your replacement function. As you enter the information and click **Apply**, the tool updates the **Function signature preview**.

When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type `RTW_IO_OUTPUT` requires a compatible implementation argument of type `RTW_IO_OUTPUT` or `RTW_IO_INPUT_OUTPUT`. The default I/O type is `RTW_IO_INPUT`.

8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:

- Integer saturation mode
- Rounding modes
- Whether to allow inputs that include expressions
- Whether a function modifies internal or global state

9 Click **Apply**.

Validate Tables and Entries

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can

address them and retry the validation. Repeat the process until the tool does not report errors.

To	Do
Validate table entries	Select an entry, scroll to the bottom of the **Mapping Information** tab, and click **Validate entry**. Alternatively, select one or more entries, right-click, and select **Validate entries**.
Validate a table	Select the table. Then, select **Actions** > **Validate table**.

Save a Table

When you save a table, the tool validates unvalidated content.

1. Select **File** > **Save table**.
2. In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension `.m`.
3. Click **Save**.

Open and Modify Tables

After saving a code replacement table, to make changes in the table:

1. Select **File** > **Open table**.
2. In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

Define Mappings Programmatically

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for

- Modifying tables that you create with the Code Replacement Tool.
- Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
- Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

- “Create Code Replacement Table” on page 66-35
- “Create Table Entry” on page 66-35
- “Set Entry Parameters” on page 66-37
- “Create Conceptual Arguments” on page 66-39
- “Create Implementation Arguments” on page 66-41
- “Add Entry to Table” on page 66-45
- “Validate Entry” on page 66-45
- “Save Table” on page 66-46

Create Code Replacement Table

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_sinfcn()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

1. Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

Entry Type	Function
Math operation	`RTW.TflCOperationEntry`
Function	`RTW.TflCFunctionEntry`
BLAS operation	`RTW.TflBlasEntryGenerator`

Entry Type	Function
CBLAS operation	`RTW.TflCBlasEntryGenerator`
Fixed-point addition and subtraction operations (support for `SlopesMustBeTheSame` and `MustHaveZeroNetBias` parameters)	`RTW.TflCOperationEntryGenerator`
Net slope fixed-point operation	`RTW.TflCOperationEntryGenerator_NetSlope`
Semaphore or mutex entry	`RTW.TflCSemaphoreEntry`
Custom function entry	*`MyCustomFunctionEntry`* (where *`MyCustomFunctionEntry`* is a class derived from `RTW.TflCFunctionEntryML`)
Custom operation entry	*`MyCustomOperationEntry`* (where *`MyCustomOperationEntry`* is a class derived from `RTW.TflCOperationEntryML`)

For example:

```
hEnt = RTW.TflCFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator's default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `u`*`n`*.

For example:

```
registerCFunctionEntry(hTable, 100, 1, 'sin', 'double', ...
   'sin_dbl', 'double', 'sin_dbl.h','','');
```

As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the `createCRLEntry` function. In this case, specify the conceptual and implementation information as character vector or string scalar specifications.

For example:

```
hEnt = createCRLEntry(hTable, ...
    'double y1 = sin(double u1)', ...
    'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

Set Entry Parameters

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

Entry Type	Function
Math operation	`setTflCOperationEntryParameters`
Function	`setTflCFunctionEntryParameters`
BLAS operation	`setTflCOperationEntryParameters`
CBLAS operation	`setTflCOperationEntryParameters`

Entry Type	Function
Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for `SlopesMustBeTheSame` and `MustHaveZeroNetBias` parameters)	`setTflCOperationEntryParameters`
Net slope fixed-point operation	`setTflCOperationEntryParameters`
Semaphore or mutex entry	`setTflCSemaphoreEntryParameters`
Custom function entry	`setTflCFunctionEntryParameters`
Custom operation entry	`setTflCOperationEntryParameters`

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```
hEnt = RTW.TflCFunctionEntry
```

```
hEnt =

  TflCFunctionEntry with properties:

             Implementation: [1x1 RTW.CImplementation]
         SlopesMustBeTheSame: 0
           BiasMustBeTheSame: 0
             AlgorithmParams: []
                    ImplType: 'FCN_IMPL_FUNCT'
       AdditionalHeaderFiles: {0x1 cell}
       AdditionalSourceFiles: {0x1 cell}
      AdditionalIncludePaths: {0x1 cell}
       AdditionalSourcePaths: {0x1 cell}
          AdditionalLinkObjs: {0x1 cell}
     AdditionalLinkObjsPaths: {0x1 cell}
         AdditionalLinkFlags: {0x1 cell}
      AdditionalCompileFlags: {0x1 cell}
                 SearchPaths: {0x1 cell}
                         Key: ''
                    Priority: 100
                 ArrayLayout: 'COLUMN_MAJOR'
               ConceptualArgs: [0x1 handle]
                    EntryInfo: []
```

```
                GenCallback: ''
                GenFileName: ''
             SaturationMode: 'RTW_SATURATE_UNSPECIFIED'
              RoundingModes: {'RTW_ROUND_UNSPECIFIED'}
         TypeConversionMode: 'RTW_EXPLICIT_CONVERSION'
            AcceptExprInput: 1
                SideEffects: 0
                 UsageCount: 0
       RecordedUsageCount: 0
                Description: ''
  StoreFcnReturnInLocalVar: 0
   AllowShapeAgnosticMatch: 0
              TraceManager: [1x1 RTW.TflTraceManager]
```

To see the implementation parameters, enter:

```
hEnt.Implementation
```

```
ans =

  CImplementation with properties:

           HeaderFile: ''
           SourceFile: ''
           HeaderPath: ''
           SourcePath: ''
               Return: []
        StructFieldMap: []
                 Name: ''
            Arguments: [0x1 RTW.Argument]
    ArgumentDescriptor: []
```

For example, to set entry parameters for the `sin` function and name your replacement function `sin_dbl`, use the following function call:

```
setTflCFunctionEntryParameters(hEnt, ...
          'Key', 'sin', ...
          'ImplementationName', 'sin_dbl');
```

Create Conceptual Arguments

Create conceptual arguments and add them to the entry's array of conceptual arguments.

- Specify output arguments before input arguments.

- Specify argument names that comply with code generator argument naming conventions:
  - `y1` for a return argument
  - `u1`, `u2`, ..., `u`*n* for input arguments
- Specify data types that are familiar to the code generator.
- The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
- The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

1. Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the `sin` function, open the tool, create a table, create a function entry, and in the **Function** menu select `sin`.

   When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have `IOType` of `RTW_IO_INPUT`.

2. Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

If	Then

You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix).	Call the function `createAndAddConceptualArg`. For example:
	`createAndAddConceptualArg(hEnt, ...`
	`'RTW.TflArgNumeric', ...`
	`'Name', 'y1',...`
	`'IOType', 'RTW_IO_OUTPUT',...`
	`'DataTypeMode', 'double');`
	The second argument specifies whether the argument is scalar (`RTW.TflArgNumeric` or`RTW.TflArgMatrix`) .

If	Then

You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar).	Call `getTflArgFromString` to create the argument. Then, call `addConceptualArg` to add the argument to the entry.
	
	`arg = getTflArgFromString(hEnt, 'y1','double');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`addConceptualArg(hEnt, arg);`

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.
	
	`hEnt = createCRLEntry(hTable, ...`
	`'double y1 = sin(double u1)', ...`
	`'mySin');`

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

```
% Conceptual Args

arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.
- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.

- For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition, `y1=u1+u2`, the conceptual arguments are `y1`, `u1`, and `u2`, in that order. If the signature of your implementation function is `t myAdd(t u2, t u1)`, where `t` is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument, `u1`, to the second implementation argument of `myAdd`. The code generator passes the value of the second conceptual argument, `u2`, to the first implementation argument of `myAdd`.
- For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

1. Identify whether the argument is for input or output, the name, and the data type.

   When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type `RTW_IO_OUTPUT` requires a compatible implementation argument of type `RTW_IO_OUTPUT` or `RTW_IO_INPUT_OUTPUT`. The default I/O type is `RTW_IO_INPUT`.
2. Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

If	Then
You want to populate implementation arguments as copies of previously created matching conceptual arguments	Call the function `copyConceptualArgsToImplementation`. For example: `copyConceptualArgsToImplementation(hEnt);`

If	Then

You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order	Call functions `createAndSetCImplementationReturn` and`createAndAddImplementationArg` . For example:
	
	`createAndSetCImplementationReturn(hEnt,`
	`  'RTW.TflArgNumeric', ...`
	`  'Name',  'y1', ...`
	`  'IOType',  'RTW_IO_OUTPUT', ...`
	`  'IsSigned',  true, ...`
	`  'WordLength', 32, ...`
	`  'FractionLength', 0);`
	
	`createAndAddImplementationArg(op_entry,`
	`  'RTW.TflArgNumeric',...`
	`  'Name',  'u1', ...`
	`  'IOType',  'RTW_IO_INPUT',...`
	`  'IsSigned',  true,...`
	`  'WordLength', 32, ...`
	`  'FractionLength', 0 );`

If	Then

You want to minimize the amount of code, or specify constant arguments to pass to the implementation function	Create the argument with a call to the function `getTflArgFromString`. Then, use the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument and to add the argument to the entry's array of implementation arguments. For example:
	
	`arg = getTflArgFromString(hEnt,...`
	`    'y1','double');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`hEnt.Implementation.setReturn(arg);`
	
	`arg = getTflArgFromString(hEnt,...`
	`    'u1','double');`
	`hEnt.Implementation.addArgument(arg);`
	
	The following call to `getTflArgFromString` passes the constant `0` to argument `u2`:
	
	`arg = getTflArgFromString(hEnt,...`
	`    'u2', 'int16', 0)`
	`hEnt.Implementation.addArgument(arg);`
	
	For semaphore and mutex entries, use the functions `getTflDWorkFromString` and `addDWorkArg` to create and add a DWork argument to the entry. Then create implementation arguments as shown above with `getTflArgFromString` and the convenience methods `setReturn` and `addArgument`. For example:
	
	`arg = getTflDWorkFromString(...`
	`    'd1', 'void*')`
	`hEnt.addDWorkArg(arg);`
	
	`arg = hEnt.getTflArgFromString(...`
	`    'y1', 'void');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`hEnt.Implementation.setRetrurn(arg);`
	
	`arg = hEnt.getTflArgFromString(...`
	`    'u1', 'integer');`
	`hEnt.Implementation.addArgument(arg);`

If	Then

	`arg = hEnt.getTflArgFromString(...`
	`    'd1', 'void**');`
	`hEnt.Implementation.addArgument(arg);`

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.
	`hEnt = createCRLEntry(hTable, ...`
	`    'double y1 = sin(double u1)', ...`
	`    'mySin');`

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```
% Implementation Args

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

Add Entry to Table

Add an entry to a code replacement table by calling the function `addEntry`.

```
addEntry(hTable, hEnt);
```

Validate Entry

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```
hTbl = crl_table_sinfcn

hTbl =
```

```
RTW.TflTable
    Version: '1.0'
    AllEntries: [2x1 RTW.TflCFunctionEntry]
    ReservedSymbols: []
    StringResolutionMap: []
```

If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```
hTbl = crl_table_sinfcn

??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Save Table

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

- Interactively, by using the **Build Information** tab in the **Code Replacement Tool**.
- Programmatically, by using a MATLAB programming interface.

Build Information

The build information can include:

- Paths and file names for header files
- Paths and file names for source files
- Paths and file names for object files
- Compile flags
- Link flags

Choose an Approach for Specifying Build Information

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

Situation	Approach
Creating code replacement entries for the first time.	Code Replacement Tool.
You used the Code Replacement Tool to create the entries for which the build information applies.	Code Replacement Tool to specify the build information quickly .

Situation	Approach
Rapid prototyping entries.	Code Replacement Tool to generate, register, and test entries quickly.
Developing an entry to use as a template or starting point for defining similar entries.	Code Replacement Tool to generate entry code that you can copy and modify.
Modifying existing mappings.	MATLAB Editor to update the programming interface directly.

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
- If you specify *additional* header files/include paths or source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
- If you choose to copy files to the build folder and you are using the `packNGo` function to relocate static and generated code files to another development environment:
  - In the call to `packNGo`, specify the property-value pair `'minimalHeaders' true` (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the `packNGo` function finds multiple instances of the same file, the function returns an error.
- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector, cell array of character vectors, or string array in the MATLAB workspace that you enclose with dollar signs (`$`*`variable`*`$`). The code generator evaluates and replaces a token with the defined value. For example, consider the path `$myfolder$\folder1`, where `myfolder` is a character vector or string scalar variable defined in the MATLAB workspace as `'d:\work\source\module1'`. The code generator generates the custom path as `d:\work\source\module1\folder1`.

Specify Build Information Interactively with the Code Replacement Tool

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining

a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.

1. Determine the information that you must specify.
2. Open the Code Replacement Tool.
3. Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
4. In the right pane, select the **Build Information** tab.
5. On the **Build Information** tab, specify your build information.

Parameter	Specify
Implementation header file	File name and extension for the header file the code generator needs to generate the replacement code. For example, `sin_dbl.h`.
Implementation source file	File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, `sin_dbl.c`.
Additional header files/ include paths	Paths and file names for additional header files the code generator needs to generate the replacement code. For example, `C:\libs\headerFiles` and `C:\libs\headerFiles\common.h`. This parameter adds `-I` to the compile line in the generated makefile.
Additional source files/ paths	Paths and file names for additional source files the code generator needs to generate the replacement code. For example, `C:\libs\srcFiles` and `C:\libs\srcFiles\common.c`. This parameter adds `-I` to the compile line in the generated makefile.
Additional object files/ paths	Paths and file names for additional object files the linker needs to build the replacement code. For example, `C:\libs\objFiles` and `C:\libs\objFiles\common.obj`.

Parameter	Specify
Additional link flags	Flags the linker needs to generate an executable file for the replacement code.
Additional compile flags	Flags the compiler needs to generate object code for the replacement code.
Copy files to build directory	Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with **Additional header files/include paths** or **Additional source files/ paths** and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files.

6. Click **Apply**.
7. Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.
8. Save the table that includes the entry that you just modified.

Specify Build Information Programmatically

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

1. Identify or create the code replacement entry that you want to specify the build information.
2. Determine what information to specify.
3. Specify your build information.

Specify	Action

Implementation header file	Use one of the following:
	• Set properties `ImplementationHeaderFile` and `ImplementationHeaderPath` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.h', ...`
	`'ImplementationHeaderPath', 'D:/lib/headerFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl');`
	• Set argument `headerFile` in a call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry`

Implementation source file	Set properties `ImplementationSourceFile` and `ImplementationSourcePath` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.c', ...`
	`'ImplementationHeaderPath', 'D:/lib/sourceFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl');`

Additional header files/include paths	For each file, specify the file name and path in calls to the functions `addAdditionalHeaderFile` and `addAdditionalIncludePath`. For example:
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	`hEnt = RTW.TflCFunctionEntry;`
	`addAdditionalHeaderFile(hEnt, 'common.h');`
	`addAdditionalIncludePath(hEnt, fullfile(libdir, 'include'));`
	These functions add `-I` to the compile line in the generated makefile.

Specify	Action

Additional source files/paths	For each file, specify the file name and path in calls to the functions `addAdditionalSourceFile` and `addAdditionalSourcePath`. For example:
	
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`addAdditionalSourceFile(hEnt, 'common.c');`
	`addAdditionalSourcePath(hEnt, fullfile(libdir, 'src'));`
	
	These functions add `-I` to the compile line in the generated makefile.

Additional object files/paths	For each file, specify the file name and path in calls to the functions `addAdditionalLinkObj` and `addAdditionalLinkObjPath`. For example:
	
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`addAdditionalLinkObj(hEnt, 'sin.o');`
	`addAdditionalLinkObjPath(hEnt, fullfile(libdir, 'bin'));`

Compile flags	Set the entry property `AdditionalCompileFlags` to a cell array of character vectors or string array representing the required compile flags. For example:
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`hEnt.AdditionalCompileFlags = {'-Zi -Wall', '-03'};`

Link flags	Set the entry property `AdditionalLinkFlags` to a cell array of character vectors or string array representing the required link flags. For example:
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`hEnt.AdditionalCompileFlags = {'-MD -Gy', '-T'};`

Specify	Action

Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation	Use one of the following:
	• Set property `GenCallback` to `'RTW.copyFileToBuildDir'` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.h', ...`
	`'ImplementationHeaderPath', 'D:/lib/headerFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl'`
	`'GenCallback', 'RTW.copyFileToBuildDir');`
	• Set argument `genCallback` in a call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` to `'RTW.copyFileToBuildDir'`.
	If a match occurs for a table entry, a call to the function `RTW.copyFileToBuildDir` copies required files to the build folder.
	If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files.

4 Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the `genCallback` property to `'RTW.copyFileToBuildDir'` in the call to the `setTflCOperationEntryParameters` function. In this example, the header file `s32_mul.h` contains an inlined function that invokes assembly functions contained in `s32_mul.s`. If a match occurs for the table entry,

the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```
function hTable = make_my_crl_table

hTable = RTW.TflTable;

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                'Key',                      'RTW_OP_MUL', ...
                'Priority',                 100, ...
                'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
                'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                'ImplementationName',       's32_mul_s32_s32_sat', ...
                'ImplementationHeaderFile', 's32_mul.h', ...
                'ImplementationSourceFile', 's32_mul.s', ...
                'ImplementationHeaderPath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
                'ImplementationSourcePath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
                'GenCallback',              'RTW.copyFileToBuildDir');
.
.
.
addEntry(hTable, op_entry);
```

The following example uses the functions `addAdditionalHeaderFile`, `addAdditionalIncludePath`, `addAdditionalSourceFile`, `addAdditionalSourcePath`, `addAdditionalLinkObj`, and `addAdditionalLinkObjPath` in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```
hTable = RTW.TflTable;

% Path to external source, header, and object files
libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                'Key',                      'RTW_OP_ADD', ...
                'Priority',                 90, ...
                'SaturationMode',           'RTW_SATURATE_UNSPECIFIED', ...
                'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                'ImplementationName',       's32_add_s32_s32', ...
                'ImplementationHeaderFile', 's32_add_s32_s32.h', ...
                'ImplementationSourceFile', 's32_add_s32_s32.c'...
                'GenCallback',              'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, 'addition.o');
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));
.
```

```
.
.
addEntry(hTable, op_entry);
```

Next, include your code replacement table in a code replacement library and register the library with the code generator.

- “Register Code Replacement Mappings” on page 66-57
- “Develop a Code Replacement Library” on page 66-15
- “What Is Code Replacement Customization?” on page 66-3
- “Code You Can Replace from MATLAB Code” on page 66-5

Register Code Replacement Mappings

After you define code replacement entries in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

Choose an Approach for Creating the Registration File

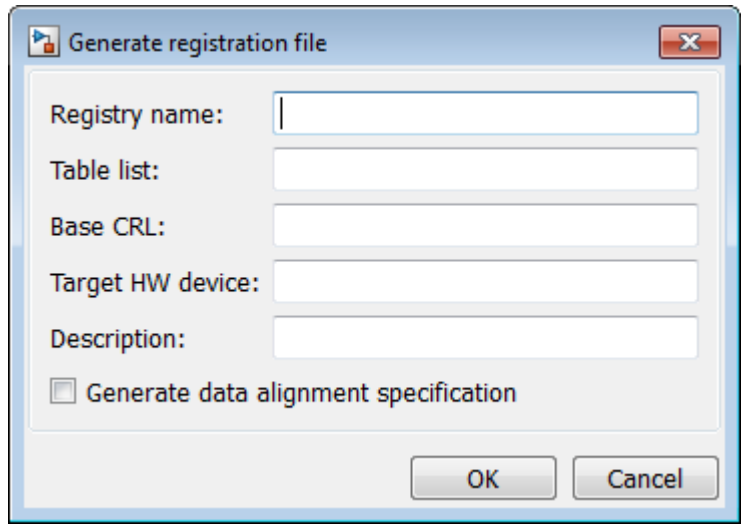
The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

If...	Then...
Registering a code replacement table for the first time	Use the Code Replacement Tool.
You used the Code Replacement Tool to create the table	Use the Code Replacement Tool to quickly register the table.
Rapid prototyping code replacement	Use the Code Replacement Tool to quickly generate, register, and test entries.
Creating registration file to use as a template or starting point for defining similar registration files	Use the Code Replacement Tool to generate code that you can copy and modify.
Modifying existing registration files	Use the MATLAB Editor to update the registration file.
Defining multiple code replacement libraries in one registration file	Use the MATLAB Editor to create a new or extend an existing registration file.
Defining code replacement library hierarchy in a registration file	Use the MATLAB Editor to create a new or extend an existing registration file.

Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

1 After you validate and save a code replacement table, select **File > Generate registration file** to open the **Generate registration file** dialog box.



2 Enter the registration information. Minimally, specify:

For...	Specify...
Registry name	Text naming the code replacement library. For example, `Sin Function Example`.

For...	Specify...
Table list	Text naming one or more code replacement tables to include in the library. Specify each table as one of the following: • Name of a table file on the MATLAB search path • Absolute path to a table file • Path to a table file relative to `$(MATLAB_ROOT)` You can specify multiple tables. If you do, separate the table specifications with a comma. For example: `crl_table_sinfcn, c:/work_crl/crl_table_muldiv` See “Registration Files That Define Multiple Code Replacement Libraries” on page 66-63 for examples of each type of table specification.

Optionally, you can specify:

For...	Specify...
Description	Text that describes the purpose and content of the library.
Target HW device	Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, `TI C28x, TI C62x`.
Base CRL	Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x` device library.
Generate data alignment specification	Flag that enables data alignment specification.

Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

1 Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'crl-name';
this(1).TableList = {'table',...};
```

For...	Replace...
`this(1).Name = '`*`crl-name`*`';`	*`crl-name`* with text naming the code replacement library. For example, `Sin Function Example`.

For...	Replace...
`this(1).TableList = {'table',...};`	*`table`* with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following: • Name of a table file on the MATLAB search path • Absolute path to a table file • Path to a table file relative to `$(MATLAB_ROOT)` You can specify multiple tables. If you do, separate the table specifications with commas.

Optionally, you can specify:

For...	Replace...
`this(1).Description = 'text'`	*`text`* with text that describes the purpose and content of the library.
`this(1).TargetHWDeviceType = {'device-type',...}`	*`device-type`* with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, `TI C28x, TI C62x`. To support all device types, enter an asterisk (*).

For...	Replace...
`this(1).BaseTfl = '`*`base-lib`*`'`	*`base-lib`* with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general `TI device` library as the base library for a `TI C28x device` library. See “Registration Files That Define Code Replacement Library Hierarchies” on page 66-63 for an example.

For example:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'Sin Function Example';
this(1).TableList = {'crl_table_sinfcn'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example - sin function replacement';
```

2. Save the file with the name `rtwTargetInfo.m`.
3. Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

Register a Code Replacement Library

Before you can use the code replacement tables defined in a registration file, you must refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```
RTW.TargetRegistry.getInstance('reset');
```

Registration Files That Define Multiple Code Replacement Libraries

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The `TableList` fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

  % Register a code replacement library for use with model: rtwdemo_crladdsub
  thisCrl(1) = RTW.TflRegistry;
  thisCrl(1).Name = 'Addition & Subtraction Examples';
  thisCrl(1).Description = 'Example of addition/subtraction op replacement';
  thisCrl(1).TableList = {'crl_table_addsub'};
  thisCrl(1).TargetHWDeviceType = {'*'};

  % Register a code replacement library for use with model: rtwdemo_crlmuldiv
  thisCrl(2) = RTW.TflRegistry;
  thisCrl(2).Name = 'Multiplication & Division Examples';
  thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
  thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
  thisCrl(2).TargetHWDeviceType = {'*'};

  % Register a code replacement library for use with model: rtwdemo_crlfixpt
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'Fixed-Point Examples';
  thisCrl(3).Description = 'Example of fixed-point operator replacement';
  thisCrl(3).TableList = {fullfile('$(MATLAB_ROOT)', ...
     'toolbox','rtw','rtwdemos','crl_demo','crl_table_fixpt')};
  thisCrl(3).TargetHWDeviceType = {'*'};
```

Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```
function rtwTargetInfo(cm)
```

```
cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

  % Register a code replacement library that includes common entries
  thisCrl(1) = RTW.TflRegistry;
  thisCrl(1).Name = 'Common Replacements';
  thisCrl(1).Description = 'Common code replacement entries shared by other libraries';
  thisCrl(1).TableList = {'crl_table_general'};
  thisCrl(1).TargetHWDeviceType = {'*'};

  % Register a code replacement library for TI devices
  thisCrl(2) = RTW.TflRegistry;
  thisCrl(2).Name = 'TI Device Replacements';
  thisCrl(2).Description = 'Code replacement entries shared across TI devices';
  thisCrl(2).TableList = {'crl_table_TI_devices'};
  thisCrl(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
  thisCrl(2).BaseTfl = 'Common Replacements';

  % Register a code replacement library for TI c6xx devices
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'TI c6xx Device Replacements';
  thisCrl(3).Description = 'Code replacement entries shared across TI C6xx devices';
  thisCrl(3).TableList = {'crl_table_TIC6xx_devices'};
  thisCrl(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};
  thisCrl(3).BaseTfl = 'TI Device Replacements';

  % Register a code replacement library for the TI c67x device
  thisCrl(4) = RTW.TflRegistry;
  thisCrl(4).Name = 'TI c67x Device Replacements';
  thisCrl(4).Description = 'Code replacement entries for the TI C67x device';
  thisCrl(4).TableList = {'crl_table_TIC67x_device'};
  thisCrl(4).TargetHWDeviceType = {'TI 67x'};
  thisCrl(4).BaseTfl = 'TI c6xx Device Replacements';
```

After registering your code replacement mappings, verify that code replacements occur.

Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (`RTW.TargetRegistry.getInstance('reset');` or for the Simulink environment,`sl_refresh_customizations`).
- See whether the registration file, `rtwTargetInfo.m`, contains an error.

More About

- “Register Code Replacement Mappings” on page 66-57

Verify Code Replacements

After you create or modify a code replacement table, use the following techniques to examine and validate the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.

Validate a Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isvalid` function. For example:

```
isvalid(crl_table_sinfcn)

ans =

      1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```
isvalid(crl_table_sinfcn)

??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Review Library Content

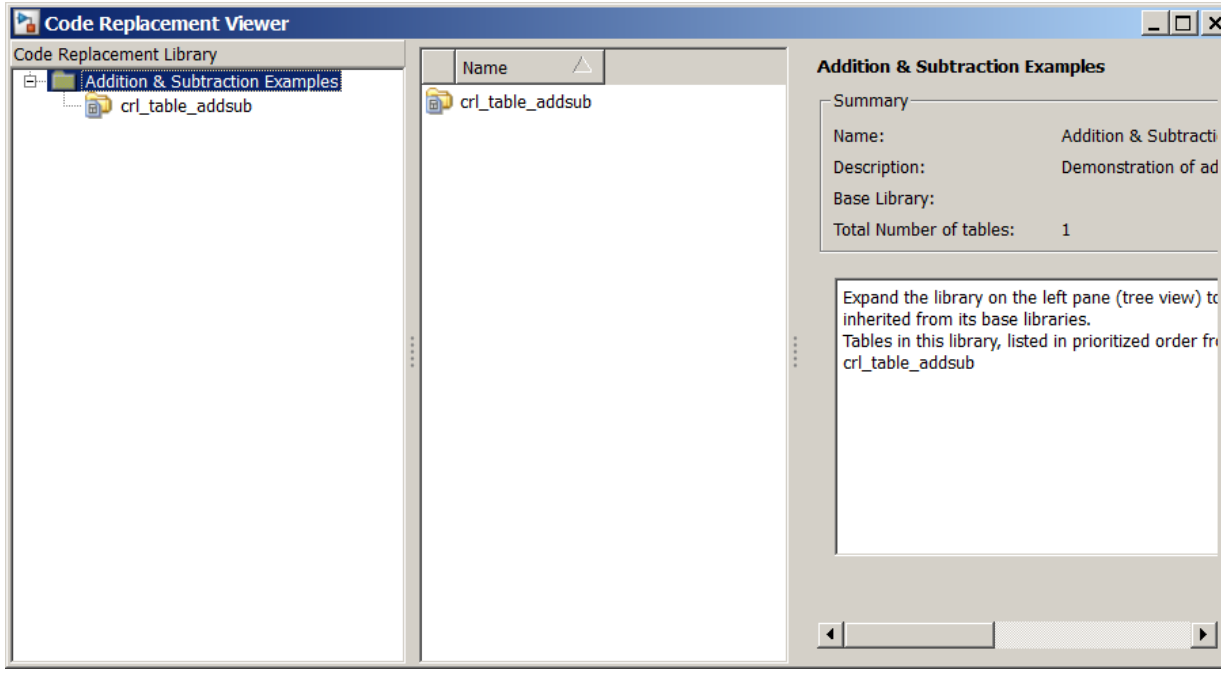
After you create or modify a code replacement library, use the **Code Replacement Viewer** to review and verify the list of tables in the library and the entries in each table.

1. Open the viewer to display the contents of your library. At the command prompt, enter the following command:

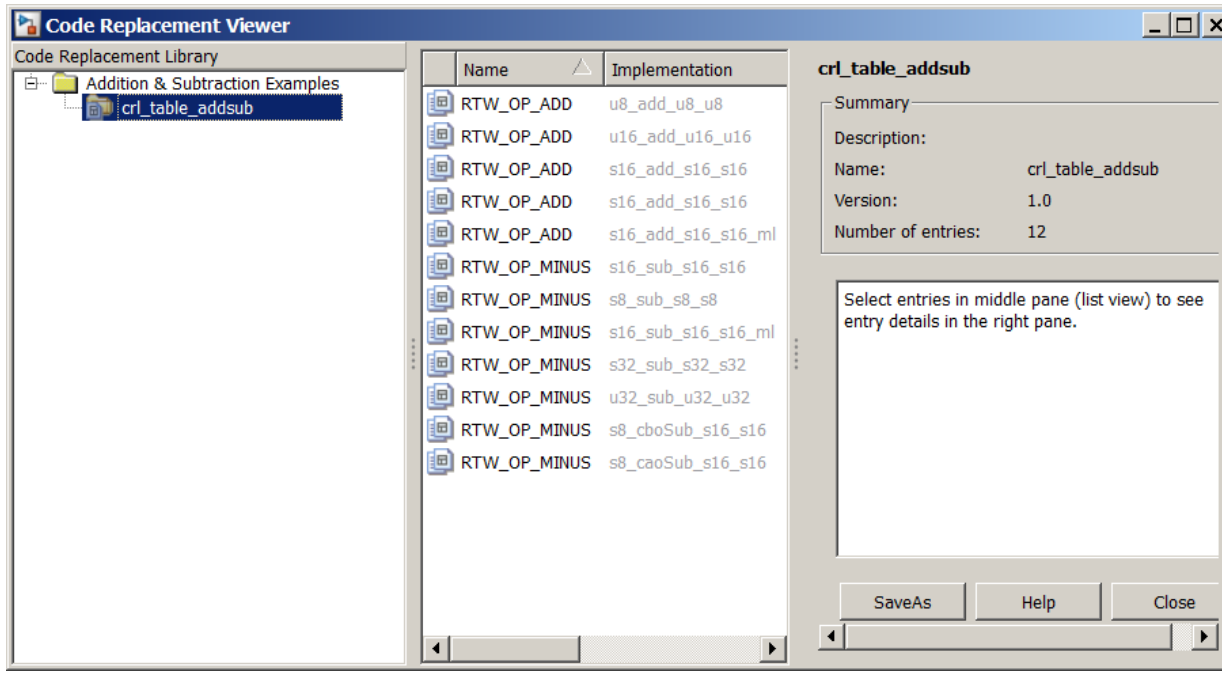
   ```
   crviewer('library')
   ```

   For example:

   ```
   crviewer('Addition & Subtraction Examples')
   ```



2. Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.
3. In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?



Review Table Content

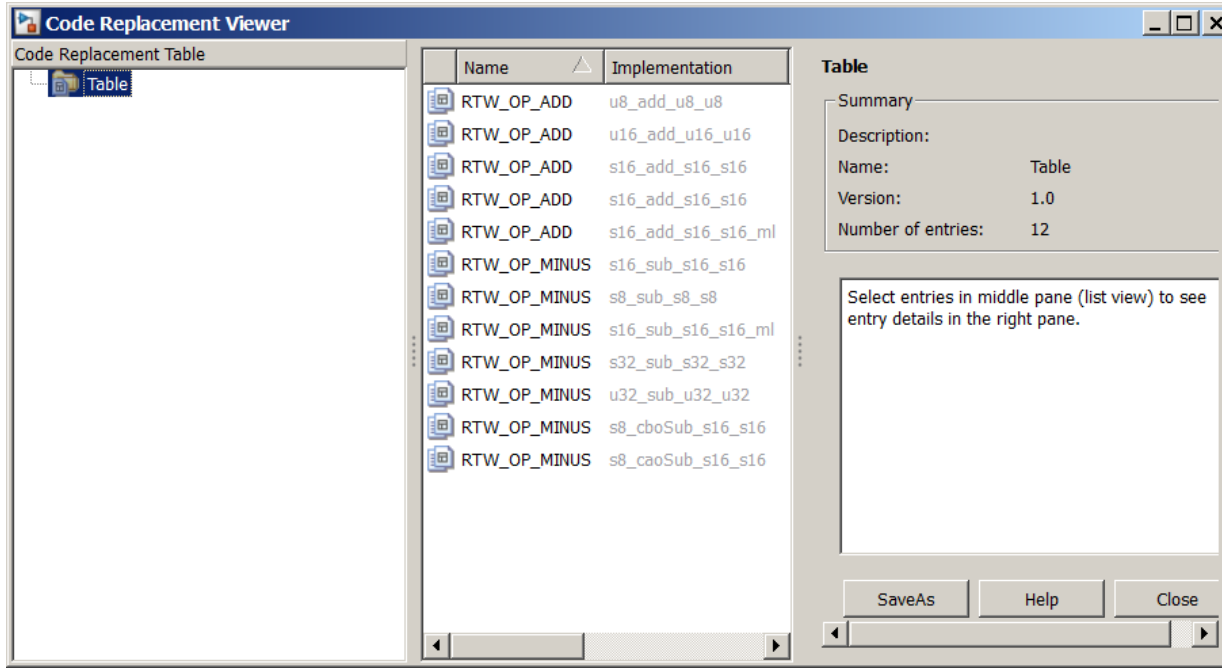
After you create or modify a code replacement table, use the **Code Replacement Viewer** to review and verify table entries.

1. Open the viewer to display the contents of your table. At the command prompt, enter the following command. *`table`* is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

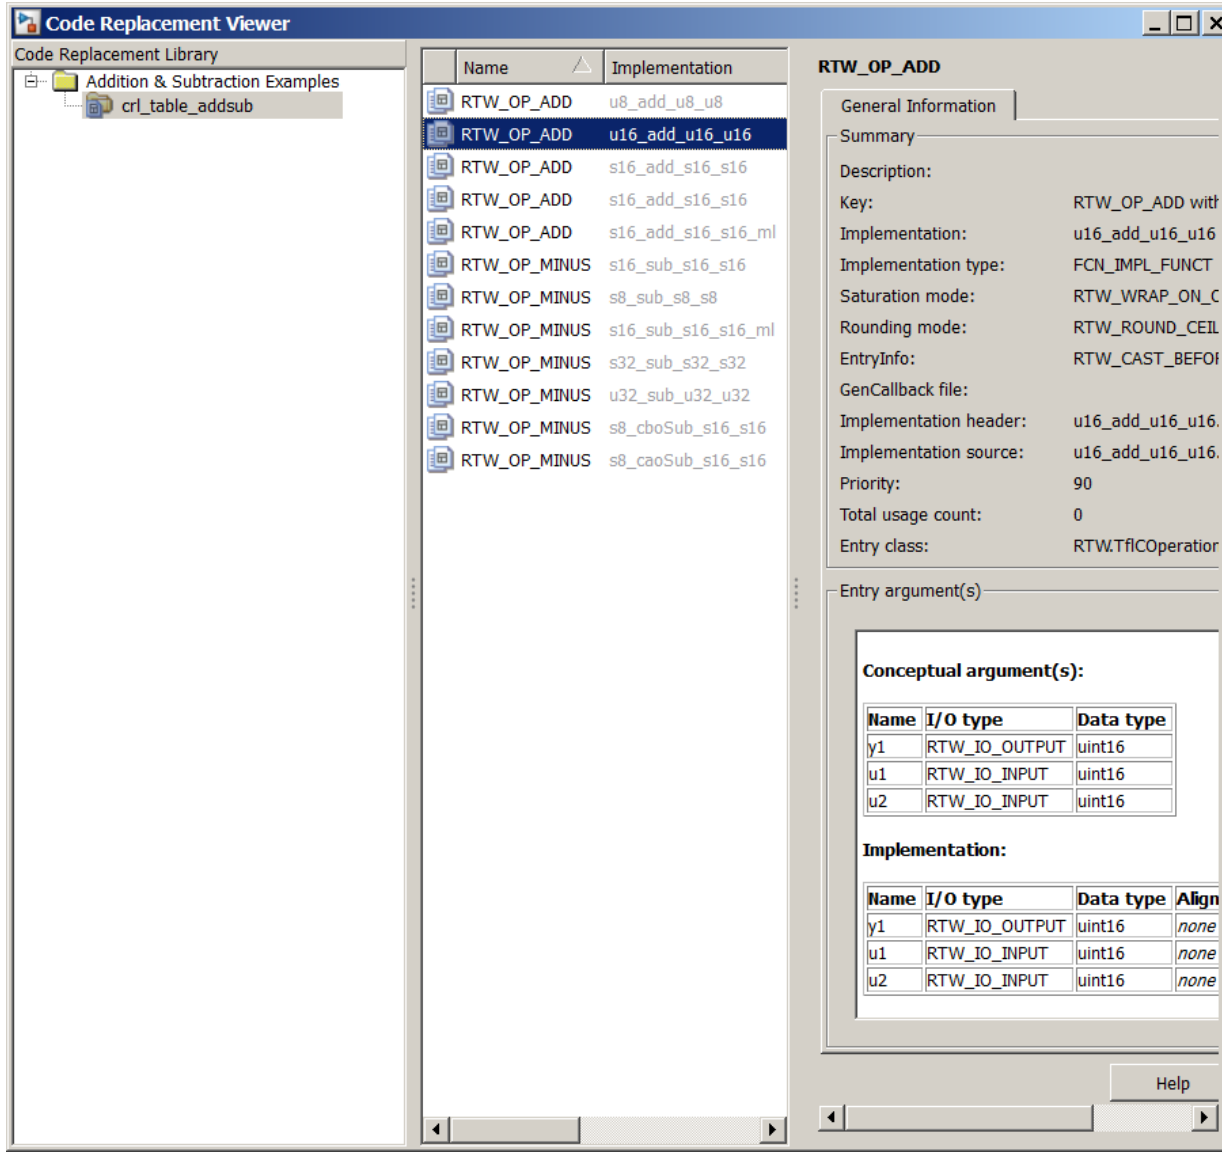
   ```
   crviewer(table)
   ```

   For example:

   ```
   crviewer(crl_table_addsub)
   ```



2. Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.
3. In the center pane, click each entry and verify the entry information in the right pane.



- Argument order is correct.
- Conceptual argument names match code generator naming conventions.

- Implementation argument names are correct.
- Algorithm properties (for example, saturation and rounding mode) are set correctly.
- Header or source file specification is not missing.
- I/O types are correct.
- Relative priority of entries is correct.

Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the line of MATLAB code that triggered the replacement. The Code Replacements report is not available for generated MEX functions.

The following example illustrates two complementary approaches for reviewing code replacements:

- Check the Code Replacements Report section of the code generation report for expected replacements.
- Trace code replacements.

1. Identify the MATLAB function where you anticipate that a function or operator replacement occurs. This example uses the function *`matlabroot`*`/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`.

   ```
   function [y1, y2] = addsub_two_int16(u1, u2)

   y1 = int16(u1 + u2);
   y2 = int16(u1 - u2);
   ```

2. Identify or create code or a script to exercise the function. For example, consider test file `addsub_to_int16_test.m`, which includes the following code:

   ```
   disp('Input')
   u1 = int16(10)
   u2 = int16(10)

   [y1, y2] = addsub_two_int16(u1, u2);
   ```

```
disp('Output')
disp('y1 =')
disp(y1);
disp('y2 =')
disp(y2);
```

3. Open the MATLAB Coder app.
4. On the **Select Source Files** page, add your function to the project. For this example, add function `addsub_two_int16`. Click **Next**.
5. On the **Define Input Types** page, use the test file `addsub_to_int16_test` to automatically define the input types. Click **Next**.
6. On the **Check for Run-Time Issues** page, specify the test file `addsub_to_int16_test`. The app runs the test file, replacing calls to `addsub_to_int16_test` with calls to a MEX version of `addsub_to_int16_test`. Click **Next**.
7. To open the **Generate** dialog box, on the **Generate Code** page, click the **Generate** arrow  .
8. Set **Build type** to generate source code. Before you build an executable, you want to review your code replacements in the generated code.
9. In the Generate dialog box, click **More Settings**.
10. Configure the code generator to use your code replacement library. On the **Custom Code** tab, set the **Code replacement library** parameter to the name of your library. For this example, set the library to `Addition & Subtraction Examples`.
11. Configure the code generation report to include the Code Replacements Report. On the **Debugging** tab, select:
    - **Always create a code generation report**
    - **Code replacements**
    - **Automatically launch a report if one is generated**
12. To generate code and a report, set **Build type** to `Source Code`. Then, click **Generate**.
13. Open the **Code Replacements Report** section of the code generation report.

    That report lists the replacement functions that the code generator used. The report provides a mapping between each replacement instance and the MATLAB code that triggered the replacement.

Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each code link to see the source that triggered the reported code replacement.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the **Code Replacement Viewer** provides. See “Troubleshoot Code Replacement Misses” on page 66-75.

- “Develop a Code Replacement Library” on page 66-15
- “What Is Code Replacement Customization?” on page 66-3

Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the **Code Replacement Viewer** to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

```
1. Mismatched data types (argument name, CSO value, table entry value)
```

The parenthetical information represents placeholders for actual values that appear in the report details.

In the **Miss Source Locations** table that lists the miss details, the **Reason** column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following **Reason** details indicate a data type mismatch because the call site object specifies data type `int8` for arguments `y1`, `u1`, and `u2`, while the code replacement table entry specifies `uint32`.

```
1. y1, int8, uint32
   u1, int8, uint32
   u2, int8, uint32
```

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.

- Information missing from the code replacement table entry or a source parameter setting.
- Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
- Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
- Failed algorithm classification for an addition or subtraction operation due to:
  - An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  - Input or output casts with a floating-point cast type.
  - Input or output casts with cast types that have different slope adjustment factors or biases.
  - Output casts not being convertible to a single output cast.
  - Input casts resulting in loss of bits.

Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your MATLAB code.

1 Review the code generated for a specific code element, looking for expected code replacement. Regenerate or reopen the code generation report for your MATLAB code. If you already generated the code generation report that includes the Code Replacements Report for *`matlabroot`*`/toolbox/rtw/rtwdemos/crl_demo/addsub_two_int16.m`, open the file `codegen/lib/addsub_two_int16/html/mldatx.html`. For information on how to regenerate the report, see “Verify Code Replacements” on page 66-66.

To examine the code generated for the function, from the code generation report, open the generated file `addsub_two_int16.h`.

```
extern void addsub_two_int16(double u1, double u2, short *b_y1, short *y2);
```

The code generator replaced code, but the replacement is for the signed version of the 16-bit addition and subtraction operations. You expected code replacements for operations on unsigned data.

2. Open the Code Replacements Report for the MATLAB code.
3. Click the link to open the Code Replacement Viewer.
4. In the viewer left pane, select your code replacement table. For this example, select code replacement table `crl_table_addsub`.
5. In the middle pane, select table entry `RTW_OP_ADD` with implementation function `u16_add_u16_u16`.
6. In the right pane, select the **Trace Information** tab.

   The **Trace Information** is a table that lists the following information for each miss:

   - Call site object preview. The call site object is the conceptual representation of addition operator. The code generator uses this object to query the code replacement library for a match.
   - A link to the source location in the MATLAB function where the code generator considered replacing code.
   - The reasons that the miss occurred. See “Miss Reason Messages” on page 66-75.

   For this example, the report shows misses for function `addsub_two_int16.m`.
7. Find the source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or a source parameter setting. For a list of conditions to consider, see“Miss Reason Messages” on page 66-75.

   For this example, determine why code for function `addsub_two_int16` is not replaced with code for an unsigned 16-bit addition operation. The miss reasons for the function indicate data type and algorithm mismatches:

   - The data type in the call site object is a signed 16-bit integer. The code replacement entry specifies an unsigned 16-bit integer.
   - The algorithm property in the call site object is `RTW_CAST_AFTER_OP` while the code replacement entry specifies `RTW_CAST_BEFORE_OP`.
8. Fix the specified MATLAB code and relevant specifications or code replacement table entry. If the issue concerns the MATLAB code, use the source location in the trace information to find the code to fix. For this example, you expected an unsigned addition operation to occur for the `addsub_two_int16` function.

   To fix the mismatches, in the test file `addsub_to_int16_test`, change the data types definitions for `u1` and `u2` as follows:

```
u1 = uint16(10)
u2 = uint16(10)
```

In the MATLAB Coder app:

- Open the project that contains the `addsub_to_int16` function.
- Use the updated test file `addsub_to_int16_test` to automatically redefine the input types.
- Change the addition and subtraction algorithm setting. Open the code replacement library `crl_table_addsub`. Change the entry **Algorithm** parameter setting from `Cast before operation` (`RTW_CAST_BEFORE_OP`) to `Cast after operation` (`RTW_CAST_AFTER_OP`).
- Regenerate code and a report.

9 From the Code Replacements Report, open the Code Replacement Viewer. Use the Code Replacement Viewer trace information to verify that your MATLAB code or code replacement table entry corrects the code replacement issue. The trace information shows a hit for function `addsub_two_int16`.

- “Verify Code Replacements” on page 66-66

Deploy Code Replacement Library

After you verify code replacements and are ready to package and deploy a code replacement library for others to use:

1. Move your code replacement table files to an area that is on the MATLAB search path and that is accessible to and shared by other users.
2. Move the `rtwTargetInfo.m` registration file, to an area that is on the MATLAB search path and that is accessible to and shared by other users. If you are deploying a library to a folder in a development environment that already contains a `rtwTargetInfo.m` file, copy the registration code from your code replacement library version of `rtwTargetInfo.m` and paste it into the shared version of that file.
3. Register the library customizations or restart MATLAB.
4. Verify that the libraries are available for configuring the code generator and that code replacements occur as expected.
5. Inform users that the libraries are available and provide direction on when and how to apply them.

Math Function Code Replacement

This example shows how to define a code replacement mapping for a math function. The example defines a mapping for the `sin` function programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_sinfcn2()
%CRL_TABLE_SINFCN2 - Define function entry for code replacement table.
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```
% Create entry for sin function replacement
fcn_entry = RTW.TflCFunctionEntry;
```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(fcn_entry, ...
                               'Key',                    'sin', ...
                               'Priority',               30, ...
                               'ImplementationName',     'mySin', ...
                               'ImplementationHeaderFile', 'basicMath.h',...
                               'ImplementationSourceFile', 'basicMath.c');
```

5. Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call.

```
createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
                          'Name',         'y1',...
                          'IOType',       'RTW_IO_OUTPUT',...
                          'DataTypeMode', 'double');

createAndAddConceptualArg(fcn_entry, 'RTW.TflArgNumeric', ...
                          'Name',         'u1', ...
                          'IOType',       'RTW_IO_INPUT',...
                          'DataTypeMode', 'double');
```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the `copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Memory Function Code Replacement

This example shows how to define a code replacement mapping for a memory function. The example defines a mapping for the `memcpy` function programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_memcpy()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   % Create entry for void* memcpy(void*, void*, size_t)
   fcn_entry = RTW.TflCFunctionEntry;
   ```

4. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   % Set SideEffects to 'true' for function returning void to prevent it from
   % being optimized away.
   setTflCFunctionEntryParameters(fcn_entry, ...
                                  'Key',                    'memcpy', ...
                                  'Priority',               90, ...
                                  'ImplementationName',     'memcpy_int', ...
                                  'ImplementationHeaderFile', 'memcpy_int.h',...
                                  'SideEffects',            true);
   ```

5. Create conceptual arguments `y1`, `u1`, `u2`, and `u3`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'void*');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u2', 'void*');
   addConceptualArg(fcn_entry, arg);

   arg = getTflArgFromString(hTable, 'u3', 'size_t');
   addConceptualArg(fcn_entry, arg);
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the

`copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(fcn_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, fcn_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Specify In-Place Code Replacement

In-place code replacement is an optimization technique that uses a single buffer, that is, the same memory, to store function input and output data, as in `x=foo(x)`.

When you generate C or C++ code from MATLAB code, the code generator supports in-place function argument code replacement. When you interactively create a code replacement table entry with the Code Replacement Tool, you can specify in-place function argument replacement. You can also specify in-place function argument replacement programmatically with the Code Replacement Library API.

Argument Specification Requirements

- The argument must be a pointer.
- An argument can be in-place with only one other argument.
- Specify an input argument as in-place (shares memory) with an output argument or an output argument as in-place with an input argument.

Interactive Argument Replacement Specification with Code Replacement Tool

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function with the Code Replacement Tool. The tool enforces in-place argument specification requirements as you add arguments and modify argument properties.

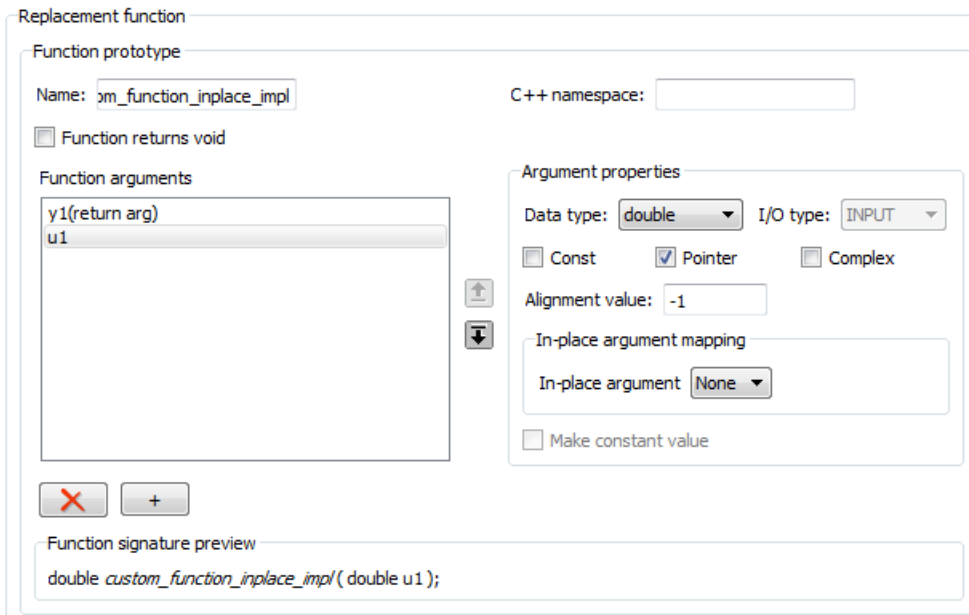
1. Create the following MATLAB function, `customFunction.m`.

   ```
   function x = customFunction(x)
   % Function that updates the input and returns it as an output

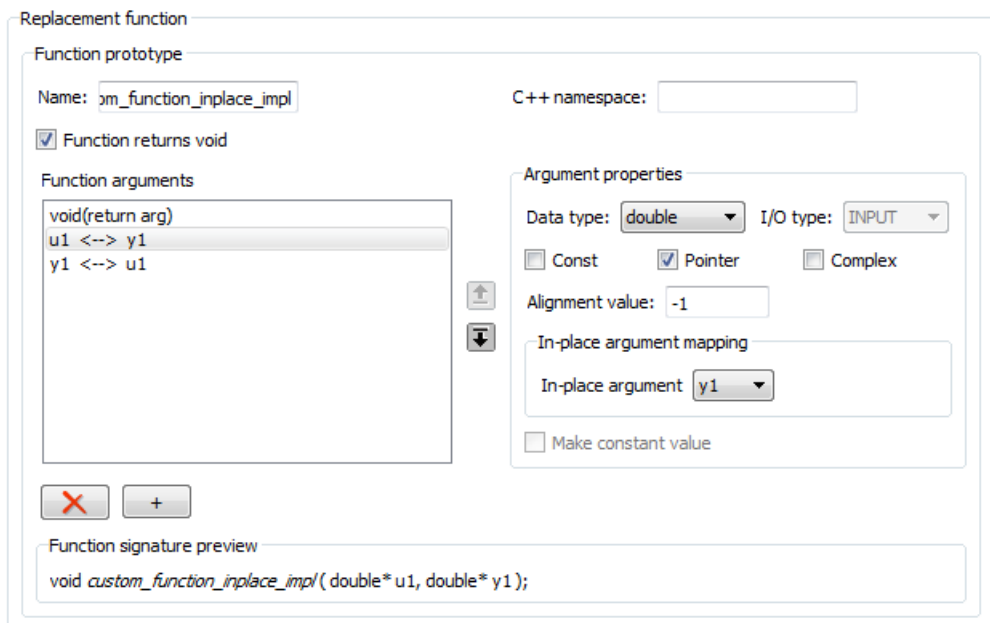
   coder.replace('-errorifnoreplacement');
   x = sin(x);
   ```

2. In the Code Replacement Tool, add a new table, select that table, and add a new function entry. For more information, see “Define Code Replacement Mappings” on page 66-30.
3. On the **Mapping Information** tab, select `Custom` for the **Function** parameter.
4. In the **function-name** text box, name the custom function. For this example, type the name `customFunction`.

5. Under the **Conceptual arguments** list box, click **+** to add two arguments. By default, the tool creates an output argument *y1* and an input argument *u1*, both of type `double`.
6. In the **Replacement function** > **Function prototype** section, type the name `custom_function_inplace_impl` in the **Name** text box.
7. Under the **Function arguments** list box, click **+** to add two function implementation arguments. By default, the tool creates an output argument *y1* and an input argument *u1*, both of type `double`.
8. For each input argument that you want to specify as in-place with a corresponding output argument, in the **Argument properties** box, select the **Pointer** check box. The **Argument properties** section of the dialog box expands to include an **In-place argument** drop-down list. For this example, in the **Function arguments** list, select input argument *u1*, and then select the **Pointer** check box.



9. From the **In-place argument** list, select *y1*, the output argument for the code replacement mapping. The **Function arguments** list box is updated to show possible in-place argument mappings.



10 Select and delete one of the two possible argument mappings. For this example, delete the mapping `y1<-->u1`.

11 In the **Function signature preview** box, if the function signature appears as expected, click **Apply**. Otherwise, make adjustments, and then click **Apply**. The function signature for this example, appears as

```
void custom_function_inplace_impl(double* u1);
```

12 Click **Validate entry**.

13 Save the code replacement table in the same folder as `customFunction.m`. Name the file `htfl_inplace_table.m`.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate the replacement code and a code generation report.

4 Review the code replacements.

Programmatic Argument Replacement Specification

This example shows how to specify in-place function argument replacement when replacing code for a MATLAB function programmatically. For the input implementation argument that shares the memory buffer, the example:

- Sets the name of the implementation argument to the same name as the corresponding conceptual argument.
- Associates the corresponding implementation argument with the argument property `ArgumentForInPlaceUse`.

1. Create the following MATLAB function, `customFunction.m`.

```
function y = customFunction(x)
% Function that updates the input and returns it as an output

coder.replace('-errorifnoreplacement');
x = sin(x);
```

2. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_inplace()
```

3. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

```
hEnt = RTW.TflCFunctionEntry;
```

5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

```
setTflCFunctionEntryParameters(hEnt, ...
    'Key', 'customFunction', ...
    'Priority', 100, ...
    'ImplementationName', 'custom_function_inplace_impl', ...
    'SideEffects', true);
```

6. Create conceptual arguments `y1` and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);
```

```
arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

7 Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments that map to arguments in the replacement function prototype: output argument *y1* and input argument *u1*. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

```
arg = getTflArgFromString(hEnt, 'y2','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = getTflArgFromString(hEnt, 'u1','double*');
arg.ArgumentForInPlaceUse = 'y1';
hEnt.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1 Register the table that contains the entry in a code replacement library.

2 Configure the code generator to use a code replacement library and to include the Code Replacements Report in the code generation report.

3 Generate the replacement code and a code generation report.

4 Review the code replacements.

Data Alignment for Code Replacement

Code replacement libraries can align data objects passed into a replacement function to a specified boundary.

Code Replacement Data Alignment

You can take advantage of function implementations that require aligned data to optimize application performance when using MATLAB Coder. To configure data alignment for a function implementation:

1. Specify the data alignment requirements in a code replacement entry. Specify alignment separately for each implementation function argument or collectively for all function arguments. See “Specify Data Alignment Requirements for Function Arguments” on page 65-137.
2. Specify the data alignment capabilities and syntax for one or more compilers. Include the alignment specifications in a library registration entry in the `rtwTargetInfo.m` file. See “Provide Data Alignment Specifications for Compilers” on page 65-139.
3. Register the library containing the table entry and alignment specification object.
4. Configure the code generator to use the code replacement library and generate code. Observe the results.

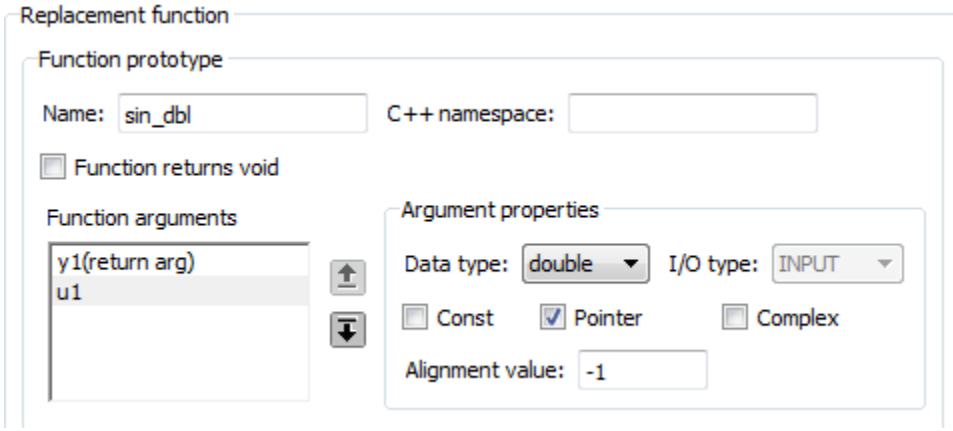
For examples, see “Basic Example of Code Replacement Data Alignment” on page 65-144 and the “Data Alignment for Function Implementations” section of the “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®” example page.

Note If replacement that requires alignment uses imported data (for example, I/O of an entry-point function or exported function), specify the data alignment with `coder.dataAlignment` statements in the MATLAB code. Specify alignment separately for each instance of imported data. See “Specify Data Alignment in MATLAB Code for Imported Data” on page 66-96.

Specify Data Alignment Requirements for Function Arguments

To specify the data alignment requirement for an argument in a code replacement entry:

- If you are defining a replacement function in a code replacement table registration file, create an argument descriptor object (`RTW.ArgumentDescriptor`). Use its `AlignmentBoundary` property to specify the required alignment boundary and assign the object to the argument `Descriptor` property.
- If you are defining a replacement function using the **Code Replacement Tool**, on the **Mapping Information** tab, in the **Argument properties** section for the replacement function, enter a value for the **Alignment value** parameter.



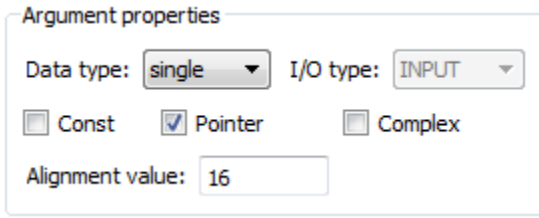
The `AlignmentBoundary` property (or **Alignment value** parameter) specifies the alignment boundary for data passed to a function argument, in number of bytes. The `AlignmentBoundary` property is valid only for addressable objects, including matrix and pointer arguments. It is not applicable for value arguments. Valid values are:

- `-1` (default) — If the data is a `Simulink.Bus`, `Simulink.Signal`, or `Simulink.Parameter` object, specifies that the code generator determines an optimal alignment based on usage. Otherwise, specifies that there is not an alignment requirement for this argument.
- Positive integer that is a power of 2, not exceeding 128 — Specifies number of bytes in the boundary. The starting memory address for the data allocated for the function argument is a multiple of the specified value. If you specify an alignment boundary that is less than the natural alignment of the argument data type, the alignment directive is emitted in the generated code. However, the target compiler ignores the directive.

The following code specifies the `AlignmentBoundary` for an argument as 16 bytes.

```
hLib = RTW.TflTable;
entry = RTW.TflCOperationEntry;
arg = getTflArgFromString(hLib, 'u1','single*');
desc = RTW.ArgumentDescriptor;
desc.AlignmentBoundary = 16;
arg.Descriptor = desc;
entry.Implementation.addArgument(arg);
```

The equivalent alignment boundary specification in the Code Replacement Tool dialog box is in this figure.



Note If your model imports `Simulink.Bus`, `Simulink.Parameter`, or `Simulink.Signal` objects, specify an alignment boundary in the object properties, using the **Alignment** property. For more information, see `Simulink.Bus`, `Simulink.Parameter`, and `Simulink.Signal`.

Provide Data Alignment Specifications for Compilers

To support data alignment in generated code, describe the data alignment capabilities and syntax for your compilers in the code replacement library registration. Provide one or more alignment specifications for each compiler in a library registry entry.

To describe the data alignment capabilities and syntax for a compiler:

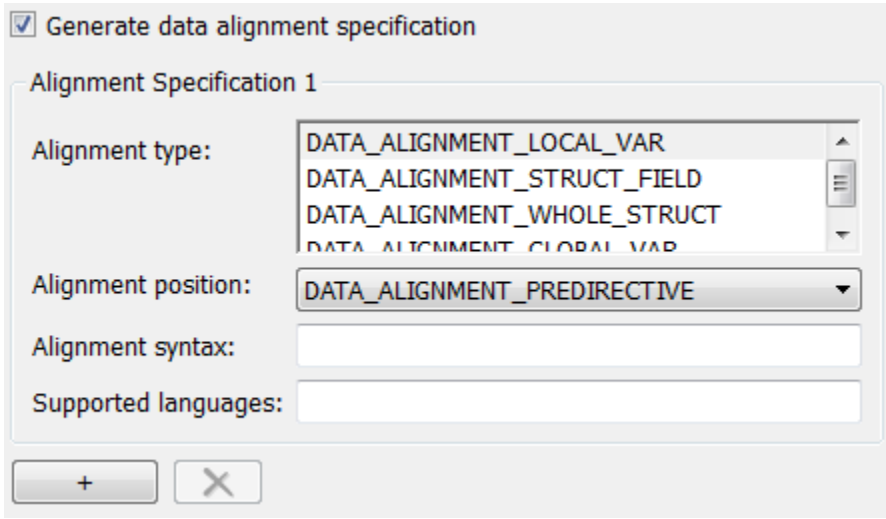
- If you are defining a code replacement library registration entry in a `rtwTargetInfo.m` customization file, add one or more `AlignmentSpecification` objects to an `RTW.DataAlignment` object. Attach the `RTW.DataAlignment` object to the `TargetCharacteristics` object of the registry entry.

  The `RTW.DataAlignment` object also has the property `DefaultMallocAlignment`, which specifies the default alignment boundary, in bytes, that the compiler uses for dynamically allocated memory. If the code generator uses dynamic memory allocation

for a data object involved in a code replacement, this value determines if the memory satisfies the alignment requirement of the replacement. If not, the code generator does not use the replacement. The default value for `DefaultMallocAlignment` is `-1`, indicating that the default alignment boundary used for dynamically allocated memory is unknown. In this case, the code generator uses the natural alignment of the data type to determine whether to allow a replacement.

Additionally, you can specify the alignment boundary for complex types by using the `addComplexTypeAlignment` function.

- If you are generating a customization file function using the Code Replacement Tool, fill out the following fields for each compiler.



Click the plus (+) symbol to add additional compiler specifications.

For each data alignment specification, provide the following information.

Alignment-Specification Property	Dialog Box Parameter	Description
`AlignmentType`	**Alignment type**	Cell array of predefined enumerated strings, specifying which types of alignment this specification supports. • `DATA_ALIGNMENT_LOCAL_VAR` — Local variables. • `DATA_ALIGNMENT_GLOBAL_VAR` — Global variables. • `DATA_ALIGNMENT_STRUCT_FIELD` — Individual structure fields. • `DATA_ALIGNMENT_WHOLE_STRUCT` — Whole structure, with padding (individual structure field alignment, if specified, is favored and takes precedence over whole structure alignment). Each alignment specification must specify at least `DATA_ALIGNMENT_GLOBAL_VAR` and `DATA_ALIGNMENT_STRUCT_FIELD`.

Alignment-Specification Property	Dialog Box Parameter	Description
AlignmentPosition	**Alignment position**	Predefined enumerated string specifying the position in which you must place the compiler alignment directive for alignment type DATA_ALIGNMENT_WHOLE_STRUCT: • DATA_ALIGNMENT_PREDIRECTIVE — The alignment directive is emitted before `struct st_tag{…}`, as part of the type definition statement (for example, MSVC). • DATA_ALIGNMENT_POSTDIRECTIVE — The alignment directive is emitted after `struct st_tag{…}`, as part of the type definition statement (for example, gcc). • DATA_ALIGNMENT_PRECEDING_STATEMENT — The alignment directive is emitted as a standalone statement immediately preceding the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. • DATA_ALIGNMENT_FOLLOWING_STATEMENT — The alignment directive is emitted as a standalone statement immediately following the definition of the structure type. A semicolon (;) must terminate the registered alignment syntax. For alignment types other than DATA_ALIGNMENT_WHOLE_STRUCT, code generation uses alignment position DATA_ALIGNMENT_PREDIRECTIVE.

Alignment-Specification Property	Dialog Box Parameter	Description
`AlignmentSyntax-Template`	**Alignment syntax**	Specifies the alignment directive string that the compiler supports. The string is registered as a syntax template that has placeholders in it. These placeholders are supported: • `%n` — Replaced by the alignment boundary for the replacement function argument. • `%s` — Replaced by the aligned symbol, usually the identifier of a variable. For example, for the gcc compiler, you can specify `__attribute__((aligned(%n)))`, or for the MSVC compiler, `__declspec(align(%n))`.
`SupportedLanguages`	**Supported languages**	Cell array specifying the languages to which this alignment specification applies, among `c` and `c++`. Sometimes alignment syntax and position differ between languages for a compiler.

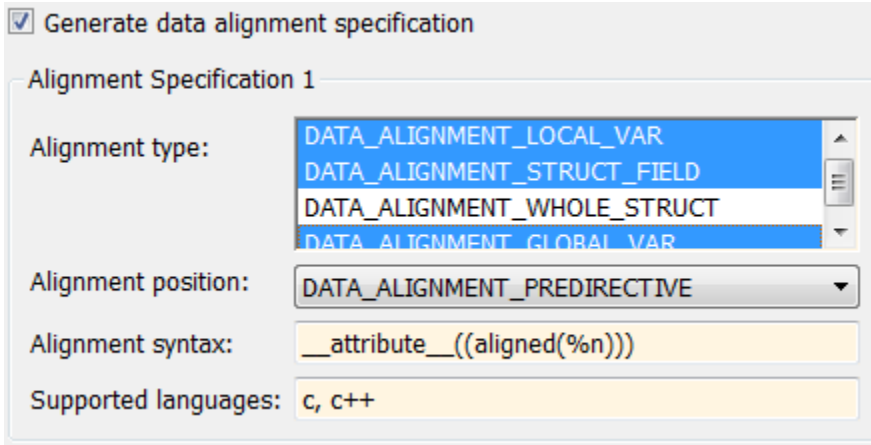
Here is a data alignment specification for the GCC compiler:

```
da = RTW.DataAlignment;

as = RTW.AlignmentSpecification;
as.AlignmentType = {'DATA_ALIGNMENT_LOCAL_VAR', ...
                    'DATA_ALIGNMENT_STRUCT_FIELD', ...
                    'DATA_ALIGNMENT_GLOBAL_VAR'};
as.AlignmentSyntaxTemplate = '__attribute__((aligned(%n)))';
as.AlignmentPosition = 'DATA_ALIGNMENT_PREDIRECTIVE';
as.SupportedLanguages = {'c', 'c++'};
da.addAlignmentSpecification(as);

tc = RTW.TargetCharacteristics;
tc.DataAlignment = da;
```

Here is the corresponding specification in the **Generate customization** dialog box of the Code Replacement Tool.



Specify Data Alignment in MATLAB Code for Imported Data

If MATLAB Coder code replacements that require data alignment use imported data, such as an entry-point or exported function I/O, specify data alignment to external code with `coder.dataAlignment` statements in the MATLAB code.

If MATLAB Coder code replacements occur that require data alignment (uses imported data), such as an entry-point or exported function with I/O, specify code replacement data alignment with `coder.DataAlignment` statements in the MATLAB code.

To specify the data alignment requirements for imported data in a MATLAB code:

- For each instance of imported data that requires data alignment, specify the alignment in the function with a `coder.dataAlignment` statement of the form:

  `coder.dataAlignment('varName', align_value)`
- The *`varName`* is a character array of the variable name that requires alignment information specification. The *`align_value`* is an integer number which should be a power of 2, from 2 through 128. This number specifies the power-of-2 byte alignment boundary.
- An example function that specifies data alignment is:

```
function y = testFunction(x1,x2)

coder.dataAlignment('x1',16);      % Specifies information
```

```
coder.dataAlignment('x2',16);    % Specifies information
coder.dataAlignment('y',16);     % Specifies information

y = x1 + x2;

end
```

If `testFunction` is an entry-point or exported function, imported data `x1`, `x2`, and `y` are not aligned automatically by the code generator. The `coder.DataAlignment` statements for these variables are only meant as information for the code generator. The call sites allocating memory for the data need to ensure that the data is aligned as specified.

You also can specify code replacement data alignment for exported data, such as a `global` variable or an `ExportedGlobal` custom storage class. For more information, see “Built-In Storage Classes You Can Choose” on page 32-85 and “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69.

Replacing Math Functions and Operators with Implementations that require Data Alignment - MATLAB®

This example shows how to develop and use code replacement library entries for target-specific function implementations that require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.
- Specify the data alignment capabilities and syntax for your compiler. Attach an AlignmentSpecification object to the TargetCharacteristics object of the registry entry specified in your rtwTargetInfo.m file.

If externally allocated data (e.g. entry-point function arguments) are used in an operation that can be replaced with an implementation that requires alignment, use the coder.dataAlignment directive to specify alignment so that replacement occurs.

This example is configured to use the GCC, Clang, or MSVC compiler.

Create a New Folder and Copy Relevant Files

The following code creates a folder in your current working folder (pwd). The new folder will contain the files that are relevant for this example. If you do not want to affect the

current folder (or if you cannot generate files in this folder), you should change your working folder.

Run Command: Create a New Folder and Copy Relevant Files

```
coderdemo_setup('coderdemo_crlalign');
cleanupObj = {};
mlpath = addpath(fullfile(...
    matlabroot,'toolbox','coder','codegendemos','coderdemo_crlalign'));
cleanupObj{end+1} = onCleanup(@()path(mlpath));
```

Check selected compiler

This example is configured to use either GCC, Clang, or MSVC to compile the generated code.

```
cc = rtwprivate('getMexCompilerInfo');
isDaDemoSupported = strcmpi(cc.comp.Manufacturer,'GNU') || ...
                    strcmpi(cc.comp.Manufacturer,'Apple') || ...
                    strcmpi(cc.comp.Manufacturer,'Microsoft');
if ~isDaDemoSupported
  recMsg = ['Use "mex -setup" to select either GCC, Clang,'...
      'or MSVC and restart this example'];
  warning(['Example %s is configured to use either GCC, Clang,'
      'or MSVC to compile the generated code. %s.'], mfilename,recMsg);
end
```

Set MATLAB Coder options

Set up the configuration object and define the function input types.

```
cfg = coder.config('lib','ecoder',true);
cfg.GenerateReport = false;
cfg.LaunchReport = false;
cfg.VerificationMode = 'SIL';
cfg.CodeExecutionProfiling = true;

len = 400000;
args = {coder.typeof(single(0),[len,1]), ...
        coder.typeof(single(0))};
global g1;
g1 = single(zeros([len,1]));
```

Generate code using the SIMD Examples Code Replacement Library

To see the code replacement table definition file, look here.

```
RTW.TargetRegistry.getInstance('reset');

mcode_da16 = 'biased_sum_of_square_differences_da16';
cfg.CodeReplacementLibrary = 'SIMD Examples';
codegen('-config',cfg, mcode_da16,'-args',args,'-global',{'g1',g1});
```

Inspect the MATLAB Coder Generated Code

After compiling, explore the generated source code.

Performance Gain from Data Alignment

Compare performance of normal ANSI code against the earlier generated code that used SIMD intrinsics.

```
% Generate ansi code
mcode_noda = 'biased_sum_of_square_differences';
cfg.CodeReplacementLibrary = 'None';
codegen('-config',cfg, mcode_noda,'-args',args,'-global',{'g1',g1});

% Run SIMD executable and collect execution profile information
coder.runTest('run_biased_ssd_da16',[mcode_da16,'_sil.',mexext])
pause(120);
clear([mcode_da16,'_sil']); % stop simulation
executionProfile_simd = getCoderExecutionProfile(mcode_da16);
idx_section = find(strcmp(mcode_da16,{executionProfile_simd.Sections.Name}),1);
avg_selftime_simd = executionProfile_simd.Sections(idx_section)...
    .TotalSelfTimeInTicks/executionProfile_simd.Sections(idx_section).NumCalls;

% Run ANSI executable and collect execution profile information
coder.runTest('run_biased_ssd',[mcode_noda,'_sil.',mexext])
pause(120);
clear([mcode_noda,'_sil']); % stop simulation
executionProfile_ansi = getCoderExecutionProfile(mcode_noda);
idx_section = find(strcmp(mcode_noda,{executionProfile_ansi.Sections.Name}),1);
avg_selftime_ansi = executionProfile_ansi.Sections(idx_section)...
    .TotalSelfTimeInTicks/executionProfile_ansi.Sections(idx_section).NumCalls;

% Compare execution profile results
barObj = bar([avg_selftime_ansi; ...
    avg_selftime_simd]);
axesObj = barObj.Parent;
figObj = axesObj.Parent;
axesObj.XTickLabel = {'ANSI SSD', 'SIMD SSD'};
axesObj.YLabel.String = 'Average Execution Time (Timer Ticks)';
```

```
axesObj.YLim = [min([0,avg_selftime_ansi,avg_selftime_simd]), ...
                max(avg_selftime_ansi,avg_selftime_simd)*1.3];

percent_perf_gain = ...
    100 * (avg_selftime_ansi-avg_selftime_simd)/avg_selftime_ansi;
annotation(figObj, 'textbox',axesObj.Position, ...

Array Layout and Code Replacement

To improve execution speed of algorithms or simplify integration with external code or data, you can define code replacement mappings that apply a specific layout for storing array elements in memory. By default, the code generator stores array elements in a column-major layout. To change the layout to row-major, change the value of the entry parameter `ArrayLayout` to `ROW_MAJOR`.

The following table definition file for a sum operation uses the row-major array layout.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_rowmajor_matrix
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   hEnt = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the parameter `ArrayLayout` to `ROW_MAJOR`

   ```
   setTflCOperationEntryParameters(hEnt, ...
                       'Key',                      'RTW_OP_ADD', ...
                       'Priority',                 100, ...
                       'ArrayLayout',              'ROW_MAJOR', ...
                       'ImplementationName',        'MyMul_ROW', ...
                       'ImplementationHeaderFile', 'MyMul_ROW.h', ...
                       'ImplementationSourceFile', 'MyMul_ROW.c');
   ```

5. Create conceptual arguments y1, u1, and u2. There are multiple ways to set up the conceptual arguments. This example uses calls to the `RTW.TflArgMatrix` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT',  'double');
   arg.DimRange = [2 2; 50 50];
   hEnt.addConceptualArg(arg);

   arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT',  'double');
   arg.DimRange = [2 3; 2 3];
   ```

```
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT',  'double');
arg.DimRange = [3 4; 3 4];
hEnt.addConceptualArg(arg);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a `void` output argument. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Implementation Args
arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','double*');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u3','uint32',2);
arg.Type.ReadOnly = true;
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u4','uint32',3);
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u5','uint32',3);
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u6','uint32',4);
hEnt.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, hEnt);
```

8 Save the table definition file. To name the file, use the name of the table definition function . Then, generate code and a code generation report and review the code replacements.

Allow Shape Agnostic Match

Code replacement shape-agnostic match allows matrix inputs for certain operations to be matched based on the number of elements as opposed to matrix shape. For example, a `6x1` matrix matches a `2x3` matrix in shape-agnostic match because both have a total of 6 elements. Such matches can only be made if the output and inputs are contiguously allocated in memory and if the replacement function can be performed element-wise. Shape-agnostic matrix match increases replacement rate so it is advantageous for replacement that does not require matrix shape to be considered.

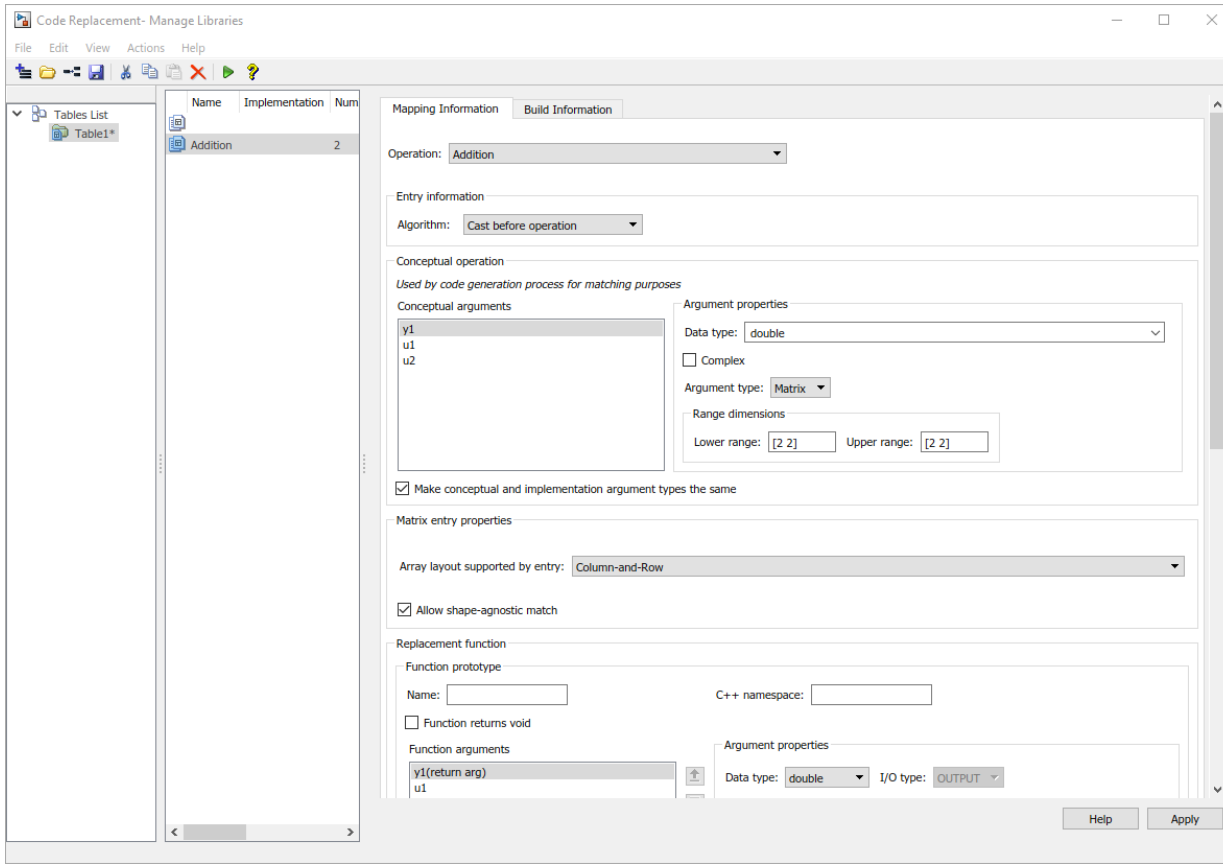
Shape-agnostic code replacement entries can be created either with the user interface of the **Code Replacement Tool** or programmatically.

User Interface Method- Code Replacement Tool

This example shows how to set up shape-agnostic matrix replacement for an addition code replacement table entry.

1. Open the Code Replacement Tool. From the MATLAB command line, enter `crtool`.
2. Create a code replacement table. Go to `File > New Table`.
3. Create a table entry. Shape-agnostic matrix replacement only supports **Math Operation** table entries. Either `right-click` on your table or go to `File > New Entry` and select **Math Operation**. Mapping information appears. From the `Operation` drop down menu, select `addition`.
4. Create conceptual arguments. The `Conceptual operation` section defines each of your conceptual arguments. To enable shape-agnostic replacement set the `Argument type:` to `matrix` to open the `Matrix entry properties` menu.
5. Set entry parameters. In the `Matrix entry properties` menu, select the `Allow shape-agnostic match` checkbox to enable shape-agnostic replacement.
6. Validate your table entry. Either click the `validate entry` button or right-click the entry and select `Validate entries`.
7. Click `save`.

   This display shows the **Code Replacement Tool** settings for this example.



Programmatic Method

This example shows how to set up a shape-agnostic matrix replacement for an addition code replacement table entry.

1. Create the code replacement table. Create a function definition with the table name `'ShapeAgnosticTable'`. Call `RTW.TflTable` to create the table.

   ```
   function hLib = ShapeAgnosticTable
   hLib = RTW.TflTable;
   ```

2. Create a table entry for code replacement. Shape-agnostic replacement only supports operation entries, as specified with a call to `RTW.TflCOperationEntry`.

```
hEnt = RTW.TflCOperationEntry;
```

3. Set entry parameters to customize input processing. You can enable shape-agostic matrix replacement by setting the entry parameter `'AllowShapeAgnosticMatch'` to `true`.

```
hEnt.setTflCOperationEntryParameters( ...
          'Key', 'RTW_OP_ADD', ...
          'Priority', 100, ...
          'AllowShapeAgnosticMatch', true, ...
          'ImplementationName', 'MyAdd_Matrix', ...
          'SideEffects', true);
```

4. Create conceptual arguments. For this example, create conceptual arguments y1, u1, and u2 with calls to the create function, `RTW.TflArgMatrix`, and add function, `addConceptualArg`.

```
arg = RTW.TflArgMatrix('y1', 'RTW_IO_OUTPUT',  'double');
arg.DimRange = [2 2; 50 50];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u1', 'RTW_IO_INPUT',  'double');
arg.DimRange = [2 3; 2 3];
hEnt.addConceptualArg(arg);

arg = RTW.TflArgMatrix('u2', 'RTW_IO_INPUT',  'double');
arg.DimRange = [2 3; 2 3];
hEnt.addConceptualArg(arg);
```

5. Create implementation arguments. For this example, call the function `getTflArgFromString` to create the arguments. Define the implementation return argument as a `void` output argument. Define the conceptual output argument, y1, as a pointer with the IOType as `output`.

```
arg = hEnt.getTflArgFromString('unused','void');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('u2','double*');
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('y1','double*');
arg.IOType = 'RTW_IO_OUTPUT';
```

```
hEnt.Implementation.addArgument(arg);

arg = hEnt.getTflArgFromString('numElements','uint32',6);
hEnt.Implementation.addArgument(arg);
```

6 Add this entry to a code replacement table with the function `addEntry`.

```
hLib.addEntry( hEnt );
```

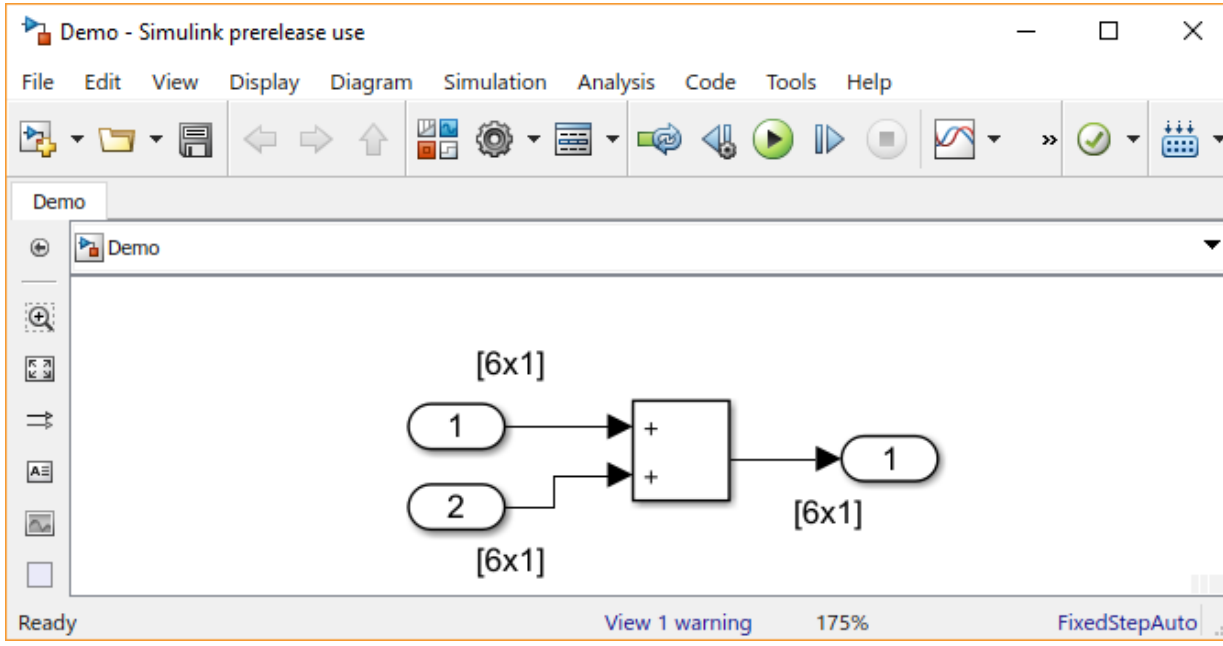
7 Save the table as its function name. For this example, `ShapeAgnosticTable`.

8 Validate your entry at the MATLAB command line. Invoke the table definition file with the following command.

```
hTbl = ShapeAgnosticTable
```

Example Model

An example of this code replacement table entry is demonstrated through the following model. Even though the matrix shape in this model does not match the entry, the operation can be performed element-wise and the entry enables shape-agnostic match, so code replacement is observed in the generated code.



```
/* Outport: '<Root>/Out1' incorporates:
  *  Inport: '<Root>/In1'
  *  Inport: '<Root>/In2'
  *  Sum: '<Root>/Add'
  */
 MyAdd_Matrix(Demo_U.In1, Demo_U.In2, Demo_Y.Out1, 6U);
```

Limitations

- If you enable shape-agnostic match for an operation that is inherently not computed element-wise, a regular match is performed.
- When shape-agnostic match is enabled, code replacement does not honor the setting for `'DimRange'`. Instead, it computes the number of elements and uses that value to match.
- If you are working with customized code replacement entries, adjust the `'do_match'` function to accept the total number of elements as opposed to matrix dimensions. For more information, see “Customize Match and Replacement Process” on page 65-160.

Replace MATLAB Functions with Custom Code Using coder.replace

The `coder.replace` function provides the ability to replace a specified MATLAB function with a code replacement function in generated code. Use `coder.replace` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

You can replace MATLAB functions that have:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

Supported types include:

- `single`, `double` (complex and noncomplex)
- `int8`, `uint8` (complex and noncomplex)
- `int16`, `uint16` (complex and noncomplex)
- `int32`, `uint32` (complex and noncomplex)
- Fixed-point integers
- Mixed types (different type on each input)

Replace coder.ceval Calls to External Functions

The `coder.ceval` function calls external C/C++ functions from code generated from MATLAB code. The code replacement software supports replacement of the function that you specify in a call to `coder.ceval`. An application of this code replacement scenario is to write generic MATLAB code that you can customize for different platforms with code replacements. A code replacement library can define hardware-specific code replacements for the function call. Use `coder.ceval` in MATLAB code from which you want to generate C code using:

- MATLAB Coder
- MATLAB code in a Simulink MATLAB Function block

Example Files

For the examples in "Interactive External Function Call Replacement Specification with Code Replacement Tool" on page 66-113 and "Programmatic External Function Call Replacement Specification" on page 66-115 you must have set up the following:

- Custom C function `my_add.c`.

```
/* my_add.c */

#include "my_add.h"

double my_add(double in1, double in2)
{
  return in1 + in2;
}
```

- Custom C header file `my_add.h`.

```
/* my_add.h */

double my_add(double in1, double in2);
```

- MATLAB function `call_my_add.m`, which uses `coder.ceval` to invoke `my_add.c`.

```
function y = call_my_add(in1, in2)  %#codegen

y=0.0;

if ~coder.target('Rtw')
```

```
% Executing in MATLAB, call MATLAB equivalent of C function my_add
  y= in1+in2;
else
% Executing in generated code, call C function my_add
  y = coder.ceval('my_add', in1, in2);
end
```

- MATLAB test function `call_my_add_test.m`, which calls `call_my_add.m`.

```
in1=10;
in2=20;

y = call_my_add(in1, in2);

disp('Output')
disp('y =')
disp(y);
```

- Replacement C function `my_add_replacement.c`.

```
/* my_add_replacement.c */

#include "my_add_replacement.h"

double my_add_replacement(double in1, double in2)
{
  return in1 + in2;
}
```

- Replacement C header file `my_add_replacement.h`.

```
/* my_add_replacement.h */

double my_add_replacement(double in1, double in2);
```

Interactive External Function Call Replacement Specification with Code Replacement Tool

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry interactively with the Code Replacement Tool.

1 Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval`, a MATLAB test function, and the source and header files for

your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 66-112.

2. In the Code Replacement Tool, add a table, select that table, and add a function entry. For more information, see “Define Code Replacement Mappings” on page 66-30.
3. On the **Mapping Information** tab, select `Custom` for the **Function** parameter.
4. In the **function-name** text box, type the custom function name. For this example, type the name `my_add`.
5. Under the **Conceptual arguments** list box, click **+** to add three arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type `double`.
6. In the **Replacement function** > **Function prototype** section, type the name `my_add_replacement` in the **Name** text box.
7. Under the **Function arguments** list box, click **+** to add three function implementation arguments. By default, the tool creates an output argument `y1` and input arguments `u1` and `u2` of type double. Use the default settings.
8. In the **Function signature preview** box, if you see the expected function signature, click **Apply**. The function signature for this example, appears as:

   ```
   double my_add_replacement(double u1, double u2);
   ```
9. On the **Build Information** tab, specify `my_add_replacement.h` for the **Implementation header file** parameter and `my_add_replacement.c` for the **Implementation source file**.
10. Click **Validate entry**.
11. Save the code replacement table in the same folder as `my_add_replacement.c`. Name the file `crl_table_my_add.m`.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Programmatic External Function Call Replacement Specification

This example shows how to define a code replacement table entry for a MATLAB function that calls `coder.ceval` to invoke an external C function. The example shows how to define the entry programmatically.

1. Identify or create the C/C++ code and relevant header files, the MATLAB function that calls `coder.ceval` to invoke the C/C++ function, a MATLAB test function, and the source and header files for your replacement code. To follow along with this example, set up the files identified in “Example Files” on page 66-112.
2. Create a table definition file that contains a function definition. For example:

   ```
   function hLib = crl_table_my_add
   ```
3. Within the function body, create the table by calling the function `RTW.TflTable`.
4. Create an entry for the function mapping with a call to the `RTW.TflCFunctionEntry` function.

   ```
   hEnt = RTW.TflCFunctionEntry;
   ```
5. Set function entry parameters with a call to the `setTflCFunctionEntryParameters` function.

   ```
   hEnt.setTflCFunctionEntryParameters( ...
             'Key', 'my_add', ...
             'Priority', 100, ...
             'ImplementationName', 'my_add_replacement', ...
             'ImplementationHeaderFile', 'my_add_replacement.h', ...
             'ImplementationSourceFile', 'my_add_replacement.c');
   ```
6. Create conceptual arguments `y1`, `u1`, and `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.addConceptualArg(arg);

   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.addConceptualArg(arg);
   ```

7. Create the implementation arguments and add them to the entry. This example uses calls to the `getTflArgFromString` function to create implementation arguments. These functions map to arguments in the replacement function prototype: output argument `y1` and input arguments `u1` and `u2`. For each argument, the example uses the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument. For each argument, this example adds the argument to the entry array of implementation arguments.

   ```
   arg = hEnt.getTflArgFromString('y1','double');
   arg.IOType = 'RTW_IO_OUTPUT';
   hEnt.Implementation.setReturn(arg);

   arg = hEnt.getTflArgFromString('u1','double');
   hEnt.Implementation.addArgument(arg);

   arg = hEnt.getTflArgFromString('u2','double');
   hEnt.Implementation.addArgument(arg);
   ```

8. Add the entry to a code replacement table with a call to the `addEntry` function.

   ```
   hLib.addEntry(hEnt);
   ```

9. Save the table definition file. Use the name of the table definition function to name the file.

To test the example:

1. Register the table that contains the entry in a code replacement library.
2. Configure the code generator to use the code replacement library and to include the Code Replacements Report in the code generation report.
3. Generate code and the report.
4. Review the code replacements.

Reserved Identifiers and Code Replacement

The code generator and C programming language use, internally, reserved keywords for code generation. Do not use reserved keywords as identifiers or function names. Reserved keywords for code generation include many code replacement library identifiers, the majority of which are function names, such as `acos`.

To view a list of reserved identifiers for the code replacement library that you use to generate code, specify the name of the library in a call to the function `RTW.TargetRegistry.getInstance.getTflReservedIdentifiers`. For example:

```
crl_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU99 (GNU)')
```

In a code replacement table, the code generator registers each function implementation name defined by a table entry as a reserved identifier. You can register additional reserved identifiers for the table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier-related compile and link issues.

To register additional code replacement reserved identifiers, use the `setReservedIdentifiers` function. This function registers specified reserved identifiers to be associated with a code replacement table.

You can register up to four reserved identifier structures in a code replacement table. You can associate one set of reserved identifiers with a code replacement library, while the other three (if present) must be associated with ANSI C. The following example shows a reserved identifier structure that specifies two identifiers and the associated header file.

```
d{1}.LibraryName = 'ANSI_C';
d{1}.HeaderInfos{1}.HeaderName = 'math.h';
d{1}.HeaderInfos{1}.ReservedIds = {'y0', 'y1'};
```

The code generator adds the identifiers to the list of reserved identifiers and honors them during the build procedure.

More About

- “Code You Can Replace from MATLAB Code” on page 66-5

- “Customize Match and Replacement Process” on page 66-119
- “Define Code Replacement Mappings” on page 66-30
- “Develop a Code Replacement Library” on page 66-15

Customize Match and Replacement Process

During the build process, the code generator uses:

- Preset match criteria to identify functions and operators for which application-specific implementations replace default implementations.
- Preset replacement function signatures.

It is possible that preset match criteria and preset replacement function signatures do not completely meet your function and operator replacement needs. For example:

- You want to replace an operator with a particular fixed-point implementation function only when fraction lengths are within a particular range.
- When a match occurs, you want to modify your replacement function signature based on compile-time information, such as passing fraction-length values into the function.

To add extra logic into the code replacement match and replacement process, create custom code replacement table entries. With custom entries, you can specify additional match criteria and modify the replacement function signature to meet application needs.

To create a custom code replacement entry:

1. Create a custom code replacement entry class, derived from `RTW.TflCFunctionEntryML (for function replacement) or RTW.TflCOperationEntryML` (for operator replacement).
2. In your derived class, implement a `do_match` method with a fixed preset signature as a MATLAB function. In your `do_match` method, provide either or both of the following customizations that instantiate the class:

    - Add match criteria that the base class does not provide. The base class provides a match based on:

        - Argument number
        - Argument name
        - Signedness
        - Word size
        - Slope (if not specified with wildcards)
        - Bias (if not specified with wildcards)

    - Math modes, such as saturation and rounding
    - Operator or function key
  - Modify the implementation signature by adding additional arguments or setting constant input argument values. You can inject a constant value, such as an input scaling value, as an additional argument to the replacement function.
3. Create code replacement entries that instantiate the custom entry class.
4. Register a library containing the code replacement table that includes your entries.

During code generation, the code replacement match process tries to match function or operator call sites with the base class of your derived entry class. If the process finds a match, the software calls your `do_match` method to execute your additional match logic (if any) and your replacement function customizations (if any).

Customize Match and Replacement Process for Operators

This example shows how to create custom code replacement entries that add logic to the code match and replacement process for a scalar operation. Custom entries specify additional match criteria or modify the replacement function signature to meet application needs.

For example:

- When fraction lengths are within a specific range, replace an operator with a fixed-point implementation function.
- When a match occurs, modify the replacement function signature based on compile-time information, such as passing fraction-length values into the function.

This example modifies a fixed-point addition replacement such that the implementation function passes in the fraction lengths of the input and output data types as arguments.

To create custom code replacement entries that add logic to the code replacement match and replacement process:

1. Create a class, for example `TflCustomOperationEntry`, that is derived from the base class `RTW.TflCOperationEntryML`. The derived class defines a `do_match` method with the following signature:

```
function ent = do_match(hThis, ...
        hCSO, ...
        targetBitPerChar, ...
```

```
        targetBitPerShort, ...
        targetBitPerInt, ...
        targetBitPerLong, ...
        targetBitPerLongLong)
```

In the `do_match` signature:

- `ent` is the return handle, which is returned as empty (indicating that the match failed) or as a `TflCOperationEntry` handle.
- `hThis` is the handle to the class instance.
- `hCSO` is a handle to an object that the code generator creates for querying the library for a replacement.
- Remaining arguments are the number of bits for various data types of the current target.

The `do_match` method adds match criteria that the base class does not provide. The method makes modifications to the implementation signature. In this case, the `do_match` method relies on the base class for checking word size and signedness. `do_match` must match only the number of conceptual arguments to the value 3 (two inputs and one output) and the bias for each argument to value 0. If the code generator finds a match, `do_match`:

- Sets the return handle.
- Removes slope and bias wild cards from the conceptual arguments (the match is for specific slope and bias values).
- Writes fraction-length values for the inputs and output into replacement function arguments 3, 4, and 5.

You can create and add three additional implementation function arguments for passing fraction lengths in the class definition or in each code replacement entry definition that instantiates this class. This example creates the arguments, adds them to a code replacement table definition file, and sets them to specific values in the class definition code.

```
classdef TflCustomOperationEntry < RTW.TflCOperationEntryML
  methods
    function ent = do_match(hThis, ...
        hCSO, ... %#ok
        targetBitPerChar, ... %#ok
        targetBitPerShort, ... %#ok
        targetBitPerInt, ... %#ok
        targetBitPerLong, ... %#ok
        targetBitPerLongLong) %#ok
```

```
        % DO_MATCH - Create a custom match function. The base class
        % checks the types of the arguments prior to calling this
        % method. This class will check additional data and can
        % modify the implementation function.

        % The base class checks word size and signedness. Slopes and biases
        % have been wildcarded, so the only additional checking to do is
        % to check that the biases are zero and that there are only three
        % conceptual arguments (one output, two inputs)

        ent = []; % default the return to empty, indicating the match failed

        if length(hCSO.ConceptualArgs) == 3 && ...
            hCSO.ConceptualArgs(1).Type.Bias == 0 && ...
            hCSO.ConceptualArgs(2).Type.Bias == 0 && ...
            hCSO.ConceptualArgs(3).Type.Bias == 0

          % Modify the default implementation. Since this is a
          % generator entry, a concrete entry is created using this entry
          % as a template. The type of entry being created is a standard
          % TflCOperationEntry. Using the standard operation entry
          % provides required information, and you do not need
          % a custom match function.
          ent = RTW.TflCOperationEntry(hThis);

          % Since this entry is modifying the implementation for specific
          % fraction-length values (arguments 3, 4, and 5), the conceptual argument
          % wild cards must be removed (the wildcards were inherited from the
          % generator when it was used as a template for the concrete entry).
          % This concrete entry is now for a specific slope and bias.
          % hCSO holds the slope and bias values (created by the code generator).
          for idx=1:3
            ent.ConceptualArgs(idx).CheckSlope = true;
            ent.ConceptualArgs(idx).CheckBias = true;

            % Set the specific Slope and Biases
            ent.ConceptualArgs(idx).Type.Slope = hCSO.ConceptualArgs(idx).Type.Slope;
            ent.ConceptualArgs(idx).Type.Bias = 0;
          end

          % Set the fraction-length values in the implementation function.
          ent.Implementation.Arguments(3).Value = ...
             -1.0*hCSO.ConceptualArgs(2).Type.FixedExponent;
          ent.Implementation.Arguments(4).Value = ...
             -1.0*hCSO.ConceptualArgs(3).Type.FixedExponent;
          ent.Implementation.Arguments(5).Value = ...
             -1.0*hCSO.ConceptualArgs(1).Type.FixedExponent;
        end
      end
    end
  end
```

Exit the class folder and return to the previous working folder.

2 Create and save the following code replacement table definition file, `crl_table_custom_add_ufix32.m`. This file defines a code replacement table that contains a single operator entry, an entry generator for unsigned 32-bit fixed-point addition operations, with arbitrary fraction-length values on the inputs and the output. The table entry:

- Instantiates the derived class `TflCustomOperationEntry` from the previous step. If you want to replace word sizes and signedness attributes, you can use the same derived class, but not the same entry, because you cannot use a wild card with the `WordLength` and `IsSigned` arguments. For example, to support `uint8`, `int8`, `uint16`, `int16`, and `int32`, add five other distinct entries. To use different implementation functions for saturation and rounding modes other than overflow and round to floor, add entries for those match permutations.
- Sets operator entry parameters with the call to the `setTflCOperationEntryParameters` function.
- Calls the `createAndAddConceptualArg` function to create conceptual arguments `y1`, `u1`, and `u2`.
- Calls `createAndSetCImplementationReturn` and `createAndAddImplementationArg` to define the signature for the replacement function. Three of the calls to `createAndAddImplementationArg` create implementation arguments to hold the fraction-length values for the inputs and output. Alternatively, the entry can omit those argument definitions. Instead, the `do_match` method of the derived class `TflCustomOperationEntry` can create and add the three implementation arguments. When the number of additional implementation arguments required can vary based on compile-time information, use the alternative approach.
- Calls `addEntry` to add the entry to a code replacement table.

```
function hTable = crl_table_custom_add_ufix32

hTable = RTW.TflTable;

% Add TflCustomOperationEntry
op_entry = TflCustomOperationEntry;

setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_ADD', ...
    'Priority',                 30, ...
    'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
    'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
    'ImplementationName',       'myFixptAdd', ...
```

```
    'ImplementationHeaderFile', 'myFixptAdd.h', ...
    'ImplementationSourceFile', 'myFixptAdd.c');

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',       'y1', ...
     'IOType',     'RTW_IO_OUTPUT', ...
     'CheckSlope', false, ...
     'CheckBias',  false, ...
     'DataType',   'Fixed', ...

     'IsSigned',   false, ...
     'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
      'Name',       'u1', ...
      'IOType',     'RTW_IO_INPUT', ...
      'CheckSlope', false, ...
      'CheckBias',  false, ...
      'DataType',   'Fixed', ...
      'Scaling',    'BinaryPoint', ...
      'IsSigned',   false, ...
      'WordLength', 32);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
       'Name',       'u2', ...
       'IOType',     'RTW_IO_INPUT', ...
       'CheckSlope', false, ...
       'CheckBias',  false, ...
       'DataType',   'Fixed', ...
       'Scaling',    'BinaryPoint', ...
       'IsSigned',   false, ...
       'WordLength', 32);

% Specify replacement function signature
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'y1', ...
    'IOType',     'RTW_IO_OUTPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'u1', ...
    'IOType',     'RTW_IO_INPUT', ...
```

```
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',       'u2', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0);

% Add 3 fraction-length args. Actual values are set during code generation.
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',       'fl_in1', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',       0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',       'fl_in2', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',       0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumericConstant', ...
    'Name',       'fl_out', ...
    'IOType',     'RTW_IO_INPUT', ...
    'IsSigned',   false, ...
    'WordLength', 32, ...
    'FractionLength', 0, ...
    'Value',       0);

addEntry(hTable, op_entry);
```

3 Check the validity of the operator entry.

- At the command prompt, invoke the table definition file.

  ```
  tbl = crl_table_custom_add_ufix32
  ```

- In the Code Replacement Viewer, view the table definition file.

```
crviewer(crl_table_custom_add_ufix32)
```

Scalar Operator Code Replacement

This example shows how to define a code replacement mapping for a scalar operator. The example defines a mapping for the + (addition) operator programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set function entry parameters with a call to the `setTflCOperationEntryParameters` function.

   ```
   % Define addition operation of built-in uint8 data type
   % Saturation on, Rounding unspecified
   setTflCOperationEntryParameters(op_entry, ...
                       'Key',                    'RTW_OP_ADD', ...
                       'Priority',               90, ...
                       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
                       'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
                       'ImplementationName',     'u8_add_u8_u8', ...
                       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
                       'ImplementationSourceFile', 'u8_add_u8_u8.c' );
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'uint8');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);

   arg = getTflArgFromString(hTable, 'u1', 'uint8');
   addConceptualArg(op_entry, arg );

   arg = getTflArgFromString(hTable, 'u2', 'uint8');
   addConceptualArg(op_entry, arg );
   ```

6. Copy the conceptual arguments to the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses a call to the

`copyConceptualArgsToImplementation` function to create and add implementation arguments to the entry by copying matching conceptual arguments.

```
copyConceptualArgsToImplementation(op_entry);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

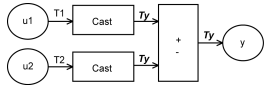
Addition and Subtraction Operator Code Replacement

Consider the following when defining mappings for addition and subtraction operator code replacements.

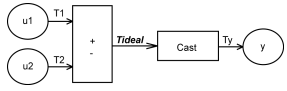
Algorithm Options

When creating a code replacement table entry for an addition or subtraction operator, first determine the type of algorithm that your library function implements.

- Cast-before-operation (CBO), default — Prior to performing the addition or subtraction operation, the algorithm type casts input values to the output type. If the output data type cannot exactly represent the input values, losses can occur as a result of the cast to the output type. Additional loss can occur when the result of the operation is cast to the final output type.



- Cast-after-operation (CAO) — The algorithm computes the ideal result of the addition or subtraction operation of the two inputs. The algorithm then type casts the result to the output data type. Loss occurs during the type cast. This algorithm behaves similarly to the C language except when the signedness of the operands does not match. For example, when you add a signed long operand to an unsigned long operand, standard C language rules convert the signed long operand to an unsigned long operand. The result is a value that is not ideal.



Interactive Specification with Code Replacement Tool

When you use the Code Replacement Tool to create a code replacement table entry for an addition or subtraction operation, the tool displays an **Algorithm** menu. Use that menu to specify the `Cast before operation` or `Cast after operation` algorithm for that entry.

Programmatic Specification

Create a code replacement table file, as a MATLAB function, that describes the addition or subtraction code replacement table entry. In the call to `setTflCOperationEntryParameters`, set at least these parameters:

- `Key` to `RTW_OP_ADD` or `RTW_OP_MINUS`
- `ImplementationName` to the name of your replacement function
- `EntryInfoAlgorithm` to `RTW_CAST_BFORE_OP` (cast-before-operation) or `RTW_CAST_AFTER_OP` (cast-after-operation)

This example sets parameters for a code replacement operator entry for a cast-after-operation implementation of a `uint8` addition.

```
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                  'Key',                      'RTW_OP_ADD', ...
                  'EntryInfoAlgorithm',       'RTW_CAST_AFTER_OP', ...
                  'ImplementationName',       'u8_add_u8_u8');
```

For more information, see `setTflCOperationEntryParameters`.

Algorithm Classification

During code generation, the code generator examines addition and subtraction operations, including adjacent type cast operations, to determine the type of algorithm to compute the expression result. Based on the data types in the expression and the type of the accumulator (type used to hold the result of the addition or subtraction operation), the code generator uses these rules.

- Floating-point types only

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
`double`	`double`	`double`	`double`	CBO, CAO
`double`	`double`	`double`	`single`	—
`double`	`double`	`single`	`double`	—
`double`	`double`	`single`	`single`	CBO
`double`	`single`	`double`	`double`	CBO, CAO

Input 1 Data Type	Input 2 Data Type	Accumulator Data Type	Output Data Type	Classification
`double`	`single`	`double`	`single`	—
`double`	`single`	`single`	`double`	—
`double`	`single`	`single`	`single`	CBO
`single`	`single`	`single`	`single`	CBO, CAO
`single`	`single`	`single`	`double`	—
`single`	`single`	`double`	`single`	—
`single`	`single`	`double`	`double`	CBO, CAO

- Floating-point and fixed-point types on the immediate addition or subtraction operation

Algorithm	Conditions
CBO	One of the following is true: • Operation type is `double`. • Operation type is `single` and input types are `single` or fixed-point.
CAO	Operation type is a superset of input types—that is, output type can represent values of input types without loss of data.

- Fixed-point types only

Algorithm	Conditions
CBO	At least one of the following is true: • Accumulator type equals output type (`Tacc == Tout`). • Output type is a superset of input types (`Tacc >= {Tin1, Tin2}`) and accumulator type is a superset of output type (`Tacc >= Tout`). • Operation does not incur range or precision loss.

Algorithm	Conditions
CAO	Net bias is zero and the data types in the expression have equal slope adjustment factors. For more information on net bias, see “Addition” or “Subtraction” in “Fixed-Point Operator Code Replacement” on page 66-155 (for MATLAB code) or “Fixed-Point Operator Code Replacement” on page 65-205 (for Simulink models).

In many cases, the numerical result of a CBO operation is equal to that of a CAO operation. For example, if the input and output types are such that the operation produces the ideal result, as in the case of `int8 + int8 –> int16`. To maximize the probability of code replacement occurring in such cases, set the algorithm to cast-after-operation.

Limitations

- The code generator does not replace operations with nonzero net bias.
- When classifying an operation as a CAO operation, the code generator includes the adjacent casts in the expression when the expression involves only fixed-point types. Otherwise, the code generator classifies and replaces only the immediate addition or subtraction operation. Casts that the code generator excludes from the classification appear in the generated code.
- To enable the code generator to include multiple cast operations, which follow an addition or subtraction of fixed-point data, in the classification of an expression, the rounding mode must be `simplest` or `floor`. Consider the expression `y=(cast A)(cast B)(u1+u2)`. If the rounding mode of `(cast A)`, `(cast B)`, and the addition operator (+) are set to `simplest` or `floor`, the code generator takes into account `(cast A)` and `(cast B)` when classifying the expression and performing the replacement only.

Small Matrix Operation to Processor Code Replacement

This example shows how to define code replacement mappings that replace nonscalar small matrix operations with processor-specific intrinsic functions. The example defines a table containing two matrix operator replacement entries for the + (addition) operator and the `double` data type. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_matrix_add_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the first operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create table entry for matrix_sum_2x2_double
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction. For code replacement entries for nonscalar addition and subtraction operations that do not involve fixed-point data, in the call to `setTflCOperationEntryParameters`, specify `'RTW_SATURATE_UNSPECIFIED'` for the `SaturationMode` property and `{'RTW_ROUND_UNSPECIFIED'}` for `RoundingModes`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_ADD', ...
       'Priority',               30, ...
       'SaturationMode',         'RTW_WRAP_ON_OVERFLOW', ...
       'ImplementationName',     'matrix_sum_2x2_double', ...
       'ImplementationHeaderFile', 'MatrixMath.h', ...
       'ImplementationSourceFile', 'MatrixMath.c', ...
       'ImplementationHeaderPath', LibPath, ...
       'ImplementationSourcePath', LibPath, ...
       'AdditionalIncludePaths',   {LibPath}, ...
       'GenCallback',            'RTW.copyFileToBuildDir', ...
       'SideEffects',            true);
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix`. Specify the base type and the dimensions for which the

argument is valid. The first table entry specifies `[2 2]` and the second table entry specifies `[3 3]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2]);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` to create the arguments. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Create the entry for the second operator mapping.

```
% Create table entry for matrix_sum_3x3_double
op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                    'RTW_OP_ADD', ...
    'Priority',               30, ...
    'SaturationMode',         'RTW_WRAP_ON_OVERFLOW', ...
    'ImplementationName',     'matrix_sum_3x3_double', ...
    'ImplementationHeaderFile', 'MatrixMath.h', ...
```

```
    'ImplementationSourceFile', 'MatrixMath.c', ...
    'ImplementationHeaderPath', LibPath, ...
    'ImplementationSourcePath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [3 3]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [3 3]);

% Specify replacement function signature
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);
arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);
arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Matrix Multiplication Operation to MathWorks BLAS Code Replacement

This example shows how to replace floating-point matrix/matrix and matrix/vector multiplication operations with the multiplication functions `dgemm` and `dgemv` defined in the MathWorks BLAS library. If you use a third-party BLAS library for replacement, you will need to change the build requirements in this example to point to your library. This example defines the function mappings programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mappings.

Code replacement libraries only support limited cases from BLAS libraries. BLAS libraries support matrix/matrix multiplication in the form C = a(op(A) * op(B)) + bC. Where the expression op(X) represents either the transposition or Hermitian transposition of X. However, code replacement libraries only support the limited case of C = op(A) * op(B) (a = 1.0, b = 0.0). Additionally, BLAS libraries support matrix/vector multiplication in the form of y = a(op(A) * x) + by, while code replacement libraries only support the limited case of y = op(A) * x (a = 1.0, b = 0.0).

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_tmwblas_mmult_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the BLAS function library. If your replacement functions are on the MATLAB search path or are in your working folder, you can skip this step.

   ```
   % Define library path for Windows or UNIX
   arch = computer('arch');
   if ~ispc
       LibPath = fullfile('$(MATLAB_ROOT)', 'bin', arch);
   else
       % Use Stateflow to get the compiler info
       compilerInfo = sf('Private','compilerman','get_compiler_info');
       compilerName = compilerInfo.compilerName;
       if strcmp(compilerName, 'msvc90') || ...
               strcmp(compilerName, 'msvc80') || ...
               strcmp(compilerName, 'msvc71') || ...
               strcmp(compilerName, 'msvc60'), ...
               compilerName = 'microsoft';
       end
       LibPath = fullfile('$(MATLAB_ROOT)', 'extern', 'lib', arch, compilerName);
   end
   ```

4. Create an entry for the first mapping with a call to the `RTW.TflBlasEntryGenerator` function.

```
% Create table entry for dgemm32
op_entry = RTW.TflBlasEntryGenerator;
```

5 Call `setTflCFunctionEntryParameters` to set operator entry parameters. For floating-point nonscalar addition and subtraction, the code generator ignores saturation and rounding modes. For nonscalar addition and subtraction operations that do not involve fixed-point data, specify `SaturationMode` as `'RTW_SATURATE_UNSPECIFIED'` and `RoundingModes` as `{'RTW_ROUND_UNSPECIFIED'}`.

```
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                    'RTW_OP_MUL', ...
    'Priority',               100, ...
    'ImplementationName',     'dgemm32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',     {['libmwblascompat32.' libExt]}, ...
    'AdditionalLinkObjsPaths', {LibPath}, ...
    'SideEffects',            true);
```

6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`, while the conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
```

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf inf]);
```

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` and `RTW.TflArgCharConstant` functions to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Using RTW.TflBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(char* TRANSA, char* TRANSB, int* M, int* N, int* K,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* LDB,
%        type* BETA, type* y, int* LDC)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and inserts them into the
% generated code. TRANSA and TRANSB are set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANSA');
% Possible values for PassByType property are
%  RTW_PASSBY_AUTO, RTW_PASSBY_POINTER,
%  RTW_PASSBY_VOID_POINTER, RTW_PASSBY_BASE_POINTER
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = RTW.TflArgCharConstant('TRANSB');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
```

```
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Create the entry for the second mapping.

```
% Create table entry for dgemv32
op_entry = RTW.TflBlasEntryGenerator;
if ispc
    libExt = 'lib';
elseif ismac
    libExt = 'dylib';
else
    libExt = 'so';
```

```
end
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...
    'ImplementationName',       'dgemv32', ...
    'ImplementationHeaderFile', 'blascompat32_crl.h', ...
    'ImplementationHeaderPath', fullfile('$(MATLAB_ROOT)','extern','include'), ...
    'AdditionalLinkObjs',       {['libmwblascompat32.' libExt]}, ...
    'AdditionalLinkObjsPaths',  {LibPath},...
    'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf 1]);

% Using RTW.TflBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(char* TRANS, int* M, int* N,
%        type* ALPHA, type* u1, int* LDA, type* u2, int* INCX,
%        type* BETA, type* y, int* INCY)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY, and insert them into the
% generated code. TRANS will be set to 'N'.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = RTW.TflArgCharConstant('TRANS');
arg.PassByType = 'RTW_PASSBY_POINTER';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
arg.PassByType = 'RTW_PASSBY_POINTER';
arg.Type.ReadOnly = true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);

Matrix Multiplication Operation to ANSI/ISO C BLAS Code Replacement

This example shows how to define code replacement mappings that replace nonscalar multiplication operations with ANSI/ISO C BLAS multiplication functions *x*`gemm` and *x*`gemv`. The example defines code replacement entries that map floating-point matrix/matrix and matrix/vector multiplication operations to ANSI/ISO C BLAS library multiplication functions `dgemm` and `dgemv`. The example defines the function mappings programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mappings.

BLAS libraries support matrix/matrix multiplication in the form of C = a(op(A) * op(B)) + bC. op(X) means X, transposition of X, or Hermitian transposition of X. However, code replacement libraries support only the limited case of C = op(A) * op(B) (a = 1.0, b = 0.0). Correspondingly, although BLAS libraries support matrix/vector multiplication in the form of y = a(op(A) * x) + by, code replacement libraries support only the limited case of y = op(A) * x (a = 1.0, b = 0.0).

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cblas_mmult_double
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Define the path for the CBLAS function library. For example:

   ```
   LibPath = fullfile(matlabroot, 'toolbox', 'rtw', 'rtwdemos', 'crl_demo');
   ```

4. Create an entry for the first mapping with a call to the `RTW.TflBlasEntryGenerator` function.

   ```
   % Create table entry for cblas_dgemm
   op_entry = RTW.TflCBlasEntryGenerator;
   ```

5. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The function call sets matrix multiplication operator entry properties. The code generator ignores saturation and rounding modes for floating-point nonscalar addition and subtraction.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                      'RTW_OP_MUL', ...
       'Priority',                 100, ...
       'ImplementationName',       'cblas_dgemm', ...
       'ImplementationHeaderFile', 'cblas.h', ...
   ```

```
    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);
```

6 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. To specify a matrix argument in the function call, use the argument class `RTW.TflArgMatrix` and specify the base type and the dimensions for which the argument is valid. This type of table entry supports a range of dimensions specified in the format `[Dim1Min Dim2Min ... DimNMin; Dim1Max Dim2Max ... DimNMax]`. For example, `[2 2; inf inf]` means a two-dimensional matrix of size 2x2 or larger. The conceptual output argument for the `dgemm32` entry for matrix/matrix multiplication replacement specifies dimensions `[2 2; inf inf]`. The conceptual output argument for the `dgemv32` entry for matrix/vector multiplication replacement specifies dimensions `[2 1; inf 1]`.

```
% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf inf]);
```

7 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. The example code configures special implementation arguments that are required for `dgemm` and `dgemv` function replacements. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Using RTW.TflCBlasEntryGenerator for xgemm requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, enum TRANSB, int M, int N, int K,
%        type ALPHA, type* u1, int LDA, type* u2, int LDB,
%        type BETA, type* y, int LDC)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
```

```
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% When a match occurs, the code generator computes the
% values for M, N, K, LDA, LDB, and LDC and insert them into the
% generated code.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSB', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'K', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDB', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);
```

```
arg = getTflArgFromString(hTable, 'LDC', 'integer', 0);
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Create the entry for the second mapping.

```
% Create table entry for cblas_dgemv
op_entry = RTW.TflCBlasEntryGenerator;
setTflCOperationEntryParameters(op_entry, ...
    'Key',                      'RTW_OP_MUL', ...
    'Priority',                 100, ...

    'ImplementationHeaderPath', LibPath, ...
    'AdditionalIncludePaths',   {LibPath}, ...
    'GenCallback',              'RTW.copyFileToBuildDir', ...
    'SideEffects',              true);

% Specify operands and result
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'y1', ...
                          'IOType',       'RTW_IO_OUTPUT', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 1; inf 1]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix', ...
                          'Name',         'u1', ...
                          'BaseType',     'double', ...
                          'DimRange',     [2 2; inf inf]);
createAndAddConceptualArg(op_entry, 'RTW.TflArgMatrix',...
                          'Name',         'u2', ...
                          'BaseType',     'double', ...
                          'DimRange',     [1 1; inf 1]);

% Using RTW.TflCBlasEntryGenerator for xgemv requires the following
% implementation signature:
%
% void f(enum ORDER, enum TRANSA, int M, int N,
%        type ALPHA, type* u1, int LDA, type* u2, int INCX,
%        type BETA, type* y, int INCY)
%
% Since CRLs do not have the ability to specify enums, you must
% use integer.  (This will cause problems with C++ code generation,
% so for C++, use a wrapper function to cast each int to the
% corresponding enumeration type.)
%
% Upon a match, the CRL entry will compute the
% values for M, N, LDA, INCX, and INCY and insert them into the
% generated code.

% Specify replacement function signature

arg = getTflArgFromString(hTable, 'y2', 'void');
```

```
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'ORDER', 'integer', 102);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'TRANSA', 'integer', 111);
% arg.Type.ReadOnly=true;
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'M','integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'N', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'ALPHA', 'double', 1);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u1', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'LDA', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2', ['double' '*']);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCX', 'integer', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'BETA', 'double', 0);
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'y1', ['double' '*']);
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'INCY', 'integer', 0);
op_entry.Implementation.addArgument(arg);

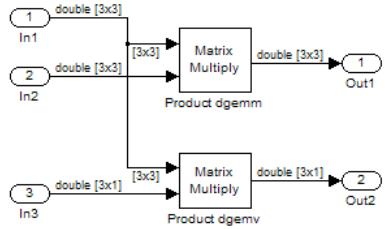
addEntry(hTable, op_entry);
```

10 Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses two Product blocks. For example:

1 Create a model that includes two Product blocks, such as the following:



2 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step, discrete solver with a fixed-step size such as `0.1`.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.

3 For each Product block, set the block parameter **Multiplication** to the value `Matrix(*)`.

4 In the Model Explorer, configure the **Signal Attributes** for the `In1`, `In2`, and `In3` source blocks. For `In1` and `In2`, set **Port dimensions** to `[3 3]` and set the **Data type** to `double`. For `In3`, set **Port dimensions** to `[3 1]` and set the **Data type** to `double`.

5 Generate code and a code generation report.

6 Review the code replacements.

Remap Operator Output to Function Input

If your generated code must meet a specific coding pattern or you want more flexibility, for example, to further improve performance, you can remap operator outputs to input positions in an implementation function argument list.

Note Remapping outputs to implementation function inputs is supported only for operator replacement.

For example, for a sum operation, the code generator produces code similar to:

```
add8_Y.Out1 = u8_add_u8_u8(add8_U.In1, add8_U.In2);
```

If you remap the output to the first input, the code generator produces code similar to:

```
u8_add_u8_u8(&add8_Y.Out1;, add8_U.In1, add8_U.In2);
```

The following table definition file for a sum operation remaps operator output `y1` as the first function input argument.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_add_uint8
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create an entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   % Create operation entry
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. In the function call, set the property `SideEffects` to `true`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
                       'Key',                      'RTW_OP_ADD', ...
                       'Priority',                 90, ...
                       'ImplementationName',       'u8_add_u8_u8', ...
                       'ImplementationHeaderFile', 'u8_add_u8_u8.h', ...
                       'ImplementationSourceFile', 'u8_add_u8_u8.c', ...
                       'SideEffects',              true );
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create and add the arguments.

```
arg = getTflArgFromString(hTable, 'y1', 'uint8');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);

arg = getTflArgFromString(hTable, 'u1', 'uint8');
addConceptualArg(op_entry, arg );

arg = getTflArgFromString(hTable, 'u2', 'uint8');
addConceptualArg(op_entry, arg );
```

6. Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. When defining the implementation function return argument, create a new `void` output argument, for example, `y2`. When defining the implementation function argument for the conceptual output argument (`y1`), set the operator output argument as an additional input argument. Mark its `IOType` as output. Make its type a pointer type. The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument and adds the argument to the entry's array of implementation arguments.

```
% Create new void output y2
arg = getTflArgFromString(hTable, 'y2', 'void');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.setReturn(arg);

% Set y1 as first input arg, mark IOType as output, and use pointer type
arg=getTflArgFromString(hTable, 'y1', 'uint8*');
arg.IOType = 'RTW_IO_OUTPUT';
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u1', 'uint8');
op_entry.Implementation.addArgument(arg);

arg=getTflArgFromString(hTable, 'u2', 'uint8');
op_entry.Implementation.addArgument(arg);
```

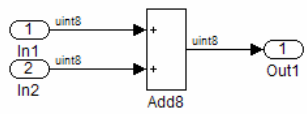
7. Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8. Save the table definition file. Use the name of the table definition function to name the file.

To test this example, create a model that uses an Add block. For example:

1. Create a model that includes an Add block, such as the following:



2 Configure the model with the following settings:

- On the **Solver** pane, select a fixed-step solver.
- On the **Code Generation** pane, select an ERT-based system target file.
- On the **Code Generation** > **Interface** pane, select the code replacement library that contains your addition operation entry.
- Set the **Optimize global data access** parameter to `Use global to hold temporary results`. This reduces data copies in the generated code.

3 Generate code and a code generation report.

4 Review the code replacements.

Fixed-Point Operator Code Replacement

If you have a Fixed-Point Designer license, you can define fixed-point operator code replacement entries to match:

- A binary-point-only scaling combination on the operator inputs and output.
- A slope bias scaling combination on the operator inputs and output.
- Relative scaling or net slope between multiplication or division operator inputs and output. Use one of these methods to map a range of slope and bias values to a replacement function for multiplication or division.
- Equal slope and zero net bias across addition or subtraction operator inputs and output. Use this method to disregard specific slope and bias values and map relative slope and bias values to a replacement function for addition or subtraction.

Common Ways to Match Fixed-Point Operator Entries

The following table maps common ways to match fixed-point operator code replacement entries with the associated fixed-point parameters that you specify in a code replacement table definition file.

Match	Create entry	Minimally specify parameters
A specific binary-point-only scaling combination on the operator inputs and output.	`RTW.TflCOperationEntry`	`createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `true`. • `CheckBias`: Specify the value `true`. • `DataTypeMode` (or `DataType/Scaling` equivalent): Specify fixed-point binary-point-only scaling. • `FractionLength`: Specify a fraction length (for example, 3).

Match	Create entry	Minimally specify parameters
A specific slope bias scaling combination on the operator inputs and output.	`RTW.TflCOperationEntry`	`createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `true`. • `CheckBias`: Specify the value `true`. • `DataTypeMode` (or `DataType/Scaling` equivalent): Specify fixed-point [slope bias] scaling. • `Slope` (or `SlopeAdjustmentFactor/-FixedExponent` equivalent): Specify a slope value (for example, `15`). • `Bias`: Specify a bias value (for example, `2`).
Net slope between operator inputs and output (multiplication and division).	`RTW.TflCOperationEntry-Generator_NetSlope`	`setTflCOperationEntryParameters` function: • `NetSlopeAdjustmentFactor`: Specify the slope adjustment factor (`F`) part of the net slope, $F2^E$ (for example, `1.0`). • `NetFixedExponent`: Specify the fixed exponent (`E`) part of the net slope, $F2^E$ (for example, `-3.0`). `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`. • `DataType`: Specify the value `'Fixed'`.

Match	Create entry	Minimally specify parameters
Relative scaling between operator inputs and output (multiplication and division).	`RTW.TflCOperationEntry-Generator`	`setTflCOperationEntryParameters` function: • `RelativeScalingFactorF`: Specify the slope adjustment factor (`F`) part of the relative scaling factor, $F2^E$ (for example, `1.0`). • `RelativeScalingFactorE`: Specify the fixed exponent (`E`) part of the relative scaling factor, $F2^E$ (for example, `-3.0`). `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`. • `DataType`: Specify the value `'Fixed'`.
Equal slope and zero net bias across operator inputs and output (addition and subtraction).	`RTW.TflCOperationEntry-Generator`	`setTflCOperationEntryParameters` function: • `SlopesMustBeTheSame`: Specify the value `true`. • `MustHaveZeroNetBias`: Specify the value `true`. `createAndAddConceptualArg` function: • `CheckSlope`: Specify the value `false`. • `CheckBias`: Specify the value `false`.

Fixed-Point Numbers and Arithmetic

Fixed-point numbers use integers and integer arithmetic to represent real numbers and arithmetic with the following encoding scheme:

$$V = \tilde{V} = SQ + B$$

- V is an arbitrarily precise real-world value.
- $\tilde{V}$ is the approximate real-world value that results from fixed-point representation.
- Q is an integer that encodes $\tilde{V}$, referred to as the quantized integer.
- S is a coefficient of Q, referred to as the slope.
- B is an additive correction, referred to as the bias.

The general equation for an operation between fixed-point operands is:

$$(S_O Q_O + B_O) = (S_1 Q_1 + B_1) < op > (S_2 Q_2 + B_2)$$

The objective of fixed-point operator replacement is to replace an operator that accepts and returns fixed-point or integer inputs and output with a function that accepts and returns built-in C numeric data types. The following sections provide additional programming information for each supported operator.

Addition

The operation $V_0 = V_1 + V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1 + \left(\frac{S_2}{S_0}\right)Q_2 + \left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

If an addition replacement function is defined such that the scaling on the operands and sum are equal and the net bias

$$\left(\frac{B_1 + B_2 - B_0}{S_0}\right)$$

is zero (for example, a function `s8_add_s8_s8` that adds two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all addition conceptual arguments. (For

parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Subtraction

The operation $V_0 = V_1 - V_2$ implies that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1 - \left(\frac{S_2}{S_0}\right)Q_2 + \left(\frac{B_1 - B_2 - B_0}{S_0}\right)$$

If a subtraction replacement function is defined such that the scaling on the operands and difference are equal and the net bias

$$\left(\frac{B_1 - B_2 - B_0}{S_0}\right)$$

is zero (for example, a function `s8_sub_s8_s8` that subtracts two signed 8-bit values and produces a signed 8-bit result), then the operator entry must set the operator entry parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` to `true`. To match for replacement, the slopes must be the same for all subtraction conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Multiplication

There are different ways to specify multiplication replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry.

The operation $V_0 = V_1 * V_2$ implies, for binary-point-only scaling, that

$$S_0Q_0 = (S_1Q_1)(S_2Q_2)$$

$$Q_0 = \left(\frac{S_1S_2}{S_0}\right)Q_1Q_2$$

$$Q_0 = S_nQ_1Q_2$$

where S_n is the net slope.

It is common to replace all multiplication operations that have a net slope of 1.0 with a function that performs C-style multiplication. For example, to replace all signed 8-bit multiplications that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the `s8_mul_s8_u8` function, set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all multiplication conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Note When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Division

There are different ways to specify division replacements. The most direct way is to specify an exact match of the input and output types. This is feasible if a model contains only a few known slope and bias combinations. Use the `TflCOperationEntry` class and specify the exact values of slope and bias on each argument. For scenarios where there are numerous slope/bias combinations, it is not feasible to specify each value with a different entry. Use a net slope entry or create a custom entry (see “Customize Match and Replacement Process” on page 65-160).

The operation $V_0 = (V_1 / V_2)$ implies, for binary-point-only scaling, that

$$S_0Q_0 = \left(\frac{S_1Q_1}{S_2Q_2}\right)$$

$$Q_0 = S_n\left(\frac{Q_1}{Q_2}\right)$$

where S_n is the net slope.

It is common to replace all division operations that have a net slope of 1.0 with a function that performs C-style division. For example, to replace all signed 8-bit divisions that have a net scaling of 1.0 with the `s8_mul_s8_u8_` replacement function, the operator entry must define a net slope factor, $F2^E$. You specify the values for F and E using operator entry parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`. For the

`s16_netslope0p5_div_s16_s16` function, you would set `NetSlopeAdjustmentFactor` to 1 and `NetFixedExponent` to 0.0. Also, set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all division conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Note When an operator entry specifies `NetSlopeAdjustmentFactor` and `NetFixedExponent`, matching entries must have arguments with zero bias.

Data Type Conversion (Cast)

The data type conversion operation $V_0 = V_1$ implies, for binary-point-only scaling, that

$$Q_0 = \left(\frac{S_1}{S_0}\right)Q_1$$
$$Q_0 = S_n Q_1$$

where S_n is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement, the biases must be zero for all cast conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Shift

The shift left or shift right operation $V_0 = (V_1 / 2^n)$ implies, for binary-point-only scaling, that

$$S_0 Q_0 = \left(\frac{S_1 Q_1}{2^n}\right)$$
$$Q_0 = \left(\frac{S_1}{S_0}\right)\left(\frac{Q_1}{2^n}\right)$$
$$Q_0 = S_n\left(\frac{Q_1}{2^n}\right)$$

where S_n is the net slope. Set the operator entry parameter `SlopesMustBeTheSame` to `false` and the parameter `MustHaveZeroNetBias` to `true`. To match for replacement,

the biases must be zero for all shift conceptual arguments. (For parameter descriptions, see the reference page for the function `setTflCOperationEntryParameters`.)

Binary-Point-Only Scaling Code Replacement

You can define code replacement entries for operations on fixed-point data types such that they match a binary-point-only scaling combination on operator inputs and output. These binary-point-only scaling entries can map the specified binary-point-scaling combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for multiplication of fixed-point data types. You specify arguments using binary-point-only scaling. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_binptscale
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as multiplication, the saturation mode as saturate on integer overflow, rounding modes as unspecified, and the name of the replacement function as `s32_mul_s16_s16_binarypoint`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_MUL', ...
       'Priority',               90, ...
       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_UNSPECIFIED'}, ...
       'ImplementationName',     's32_mul_s16_s16_binarypoint', ...
       'ImplementationHeaderFile', 's32_mul_s16_s16_binarypoint.h', ...
       'ImplementationSourceFile', 's32_mul_s16_s16_binarypoint.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is binary-point-only scaling, and its derived slope and bias values must exactly match the call-site slope and bias values. The output argument is 32 bits, signed, with a

fraction length of 28. The input arguments are 16 bits, signed, with fraction lengths of 15 and 13.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     32, ...
    'FractionLength', 28);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 15);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     true, ...
    'CheckBias',      true, ...
    'DataTypeMode',   'Fixed-point: binary point scaling', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 13);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output argument is 32 bits and signed (`int32`). The input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'IsSigned',       true, ...
   'WordLength',     32, ...
   'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
```

```
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       true, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Slope Bias Scaling Code Replacement

You can define code replacement for operations on fixed-point data types as matching a slope bias scaling combination on the operator inputs and output. The slope bias scaling entries can map the specified slope bias combination to a replacement function for addition, subtraction, multiplication, or division.

This example creates a code replacement entry for division of fixed-point data types. You specify arguments using slope bias scaling. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_s16divslopebias
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturate on integer overflow, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16_slopebias`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
      'Key',                    'RTW_OP_DIV', ...
      'Priority',               90, ...
      'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
      'RoundingModes',          {'RTW_ROUND_CEILING'}, ...
      'ImplementationName',     's16_div_s16_s16_slopebias', ...
      'ImplementationHeaderFile', 's16_div_s16_s16_slopebias.h', ...
      'ImplementationSourceFile', 's16_div_s16_s16_slopebias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument specifies that the data type is fixed-point, the mode is slope bias scaling, and its specified slope and bias values must exactly match the call-site slope and bias values. The output argument and input arguments are 16 bits, signed, each with specific slope bias specifications.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          15, ...
   'Bias',           2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          15, ...
   'Bias',           2);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'u2', ...
   'IOType',         'RTW_IO_INPUT', ...
   'CheckSlope',     true, ...
   'CheckBias',      true, ...
   'DataTypeMode',   'Fixed-point: slope and bias scaling', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'Slope',          13, ...
   'Bias',           5);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
   'Name',           'y1', ...
   'IOType',         'RTW_IO_OUTPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u1', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'FractionLength', 0);
```

```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
   'Name',           'u2', ...
   'IOType',         'RTW_IO_INPUT', ...
   'IsSigned',       true, ...
   'WordLength',     16, ...
   'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Net Slope Scaling Code Replacement

Multiplication and Division with Saturation

You can define code replacement entries for operations on fixed-point data types as matching net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using wrap on overflow saturation mode and a net slope. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_netslopesaturate
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

   ```
   wv = [16,32];
   for iy = 1:2
     for inum = 1:2
       for iden = 1:2
         hTable = getDivOpEntry(hTable, ...
            fixdt(1,wv(iy)),fixdt(1,wv(inum)),fixdt(1,wv(iden)));
       end
     end
   end

   %------------------------------------------------------------
   function hTable = getDivOpEntry(hTable,dty,dtnum,dtden)
   %------------------------------------------------------------
   % Create an entry for division of fixed-point data types where
   % arguments are specified using Slope and Bias scaling
   % Saturation on, Rounding unspecified

   funcStr = sprintf('user_div_%s_%s_%s',...
           typeStrFunc(dty),...
           typeStrFunc(dtnum),...
           typeStrFunc(dtden));
   ```

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as wrap on overflow, rounding modes as unspecified, and the name of the replacement function as `user_div_*`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
setTflCOperationEntryParameters(op_entry, ...
   'Key',                     'RTW_OP_DIV', ...
   'Priority',                90, ...
   'SaturationMode',          'RTW_WRAP_ON_OVERFLOW',...
   'RoundingModes',           {'RTW_ROUND_UNSPECIFIED'},...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',        0.0, ...
   'ImplementationName',      funcStr, ...
   'ImplementationHeaderFile', [funcStr,'.h'], ...
   'ImplementationSourceFile', [funcStr,'.c']);
```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name',            'y1',...
   'IOType',          'RTW_IO_OUTPUT',...
   'CheckSlope',      false,...
   'CheckBias',       false,...
   'DataTypeMode',    'Fixed-point: slope and bias scaling',...
   'IsSigned',        dty.Signed,...
   'WordLength',      dty.WordLength,...
   'Bias',            0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric',...
   'Name',            'u1', ...
   'IOType',          'RTW_IO_INPUT',...
   'CheckSlope',      false,...
   'CheckBias',       false,...
   'DataTypeMode',    'Fixed-point: slope and bias scaling',...
   'IsSigned',        dtnum.Signed,...
   'WordLength',      dtnum.WordLength,...
   'Bias',            0);

createAndAddConceptualArg(op_entry, ...
   'RTW.TflArgNumeric', ...
   'Name',            'u2', ...
```

```
    'IOType',          'RTW_IO_INPUT',...
    'CheckSlope',      false,...
    'CheckBias',       false,...
    'DataTypeMode',    'Fixed-point: slope and bias scaling',...
    'IsSigned',        dtden.Signed,...
    'WordLength',      dtden.WordLength,...
    'Bias',            0);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `getTflArgFromString` function to create the arguments. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). The convenience methods `setReturn` and `addArgument` specify whether an argument is a return value or argument. These methods add the argument to the entry array of implementation arguments.

```
arg = getTflArgFromString(hTable, 'y1', typeStrBase(dty));
op_entry.Implementation.setReturn(arg);

arg = getTflArgFromString(hTable, 'u1', typeStrBase(dtnum));
op_entry.Implementation.addArgument(arg);

arg = getTflArgFromString(hTable, 'u2',typeStrBase(dtden));
op_entry.Implementation.addArgument(arg);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Define functions that determine the data type word length.

```
%------------------------------------------------------------------
function str = typeStrFunc(dt)
%------------------------------------------------------------------

if dt.Signed
    sstr = 's';
else
    sstr = 'u';
end
str = sprintf('%s%d',sstr,dt.WordLength);

%------------------------------------------------------------------
function str = typeStrBase(dt)
%------------------------------------------------------------------

if dt.Signed
    sstr = ;
else
    sstr = 'u';
end
str = sprintf('%sint%d',sstr,dt.WordLength);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Multiplication and Division with Rounding Mode and Additional Implementation Arguments

You can define code replacement entries for multiplication and division operations on fixed-point data types such that they match the net slope between operator inputs and output. The net slope entries can map a range of slope and bias values to a replacement function for multiplication or division.

This example creates a code replacement entry for division of fixed-point data types, using the ceiling rounding mode and a net slope scaling factor. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_fixed_netsloperound
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as division, the saturation mode as saturation off, rounding modes as round to ceiling, and the name of the replacement function as `s16_div_s16_s16`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the relative scaling factor $F2^E$.

```
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_DIV', ...
   'Priority',                 90, ...
   'SaturationMode',           'RTW_WRAP_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_CEILING'}, ...
   'NetSlopeAdjustmentFactor',   1.0, ...
   'NetFixedExponent',           0.0, ...
```

```
    'ImplementationName',       's16_div_s16_s16', ...
    'ImplementationHeaderFile', 's16_div_s16_s16.h', ...
    'ImplementationSourceFile', 's16_div_s16_s16.c');
```

5 Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Specify each argument as fixed-point, 16 bits, and signed. Also, for each argument, specify that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'DataType',       'Fixed', ...
    'IsSigned',       true, ...
    'WordLength',     16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and signed (`int16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
                                  'Name',           'y1', ...
                                  'IOType',         'RTW_IO_OUTPUT', ...
                                  'IsSigned',       true, ...
                                  'WordLength',     16, ...
                                  'FractionLength', 0);
```

```
createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
                               'Name',           'u1', ...
                               'IOType',         'RTW_IO_INPUT', ...
                               'IsSigned',       true, ...
                               'WordLength',     16, ...
                               'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
                               'Name',           'u2', ...
                               'IOType',         'RTW_IO_INPUT', ...
                               'IsSigned',       true, ...
                               'WordLength',     16, ...
                               'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Equal Slope and Zero Net Bias Code Replacement

You can define code replacement entries for addition or subtraction of fixed-point data types such that they match the relative slope and bias values (equal slope and zero net bias) across operator inputs and output. These entries allow you to disregard slope and bias values when mapping relative slope and bias values to a replacement function for addition or subtraction.

This example creates a code replacement entry for the addition of fixed-point data types. Slopes must be equal and net bias must be zero across the operator inputs and output. The example defines the function mapping programmatically. Alternatively, you can also use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_fixed_slopeseq_netbiaszero
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator` function, which provides access to the fixed-point parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias`.

   ```
   op_entry = RTW.TflCOperationEntryGenerator;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as addition, the saturation mode as saturation off, rounding modes as unspecified, and the name of the replacement function as `u16_add_SameSlopeZeroBias`. The parameters `SlopesMustBeTheSame` and `MustHaveZeroNetBias` must be set to `true` to indicate that slopes must be equal and net bias must be zero across the addition (or subtraction) of inputs and output.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_ADD', ...
       'Priority',                90, ...
       'SaturationMode',          'RTW_WRAP_ON_OVERFLOW', ...
       'RoundingModes',           {'RTW_ROUND_UNSPECIFIED'}, ...
       'SlopesMustBeTheSame',     true, ...
       'MustHaveZeroNetBias',     true, ...
       'ImplementationName',      'u16_add_SameSlopeZeroBias', ...
       'ImplementationHeaderFile', 'u16_add_SameSlopeZeroBias.h', ...
       'ImplementationSourceFile', 'u16_add_SameSlopeZeroBias.c');
   ```

5. Create conceptual arguments `y1`, `u1`, and `u2`. There are multiple ways to set up the conceptual arguments. This example uses calls to the

`createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as 16 bits and unsigned. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'CheckSlope',     false, ...
    'CheckBias',      false, ...
    'IsSigned',       false, ...
    'WordLength',     16);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types). In this case, the output and input arguments are 16 bits and unsigned (`uint16`).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
```

```
    'Name',           'u2', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       false, ...
    'WordLength',     16, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Data Type Conversions (Casts) and Operator Code Replacement

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry that replaces `int32` to `int16` data type conversion (cast) operations. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_cast_int32_to_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_sat_cast`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_CAST', ...
       'Priority',               50, ...
       'ImplementationName',     'my_sat_cast', ...
       'SaturationMode',         'RTW_SATURATE_ON_OVERFLOW', ...
       'RoundingModes',          {'RTW_ROUND_FLOOR'}, ...
       'ImplementationHeaderFile', 'some_hdr.h', ...
       'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

```
arg = getTflArgFromString(hTable, 'y1', 'int16');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(op_entry, arg);
op_entry.Implementation.setReturn(arg);
```

6. Create the `int32` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int32');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7. Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hLib, hEnt);
```

8. Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for data type conversion (cast) operations.

This example creates a code replacement entry to replace data type conversions (casts) of fixed-point data types by using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_cast_fixpt_net_slope
```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function, which provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as cast, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as

`my_fxp_cast`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_CAST', ...
   'Priority',                 50, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',         (OutFL - InFL), ...
   'ImplementationName',       'my_fxp_cast', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
```

5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',         'u1', ...
     'IOType',       'RTW_IO_INPUT', ...
     'CheckSlope',   false, ...
     'CheckBias',    false, ...
     'DataTypeMode', 'Fixed-point: binary point scaling', ...
     'IsSigned',     InSgn, ...
     'WordLength',   InWL, ...
     'FractionLength',InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation

arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric',...
    'Name',           'u1', ...
    'IOType',         'RTW_IO_INPUT', ...
    'IsSigned',       InSgn, ...
    'WordLength',     InWL, ...
    'FractionLength', 0);
```

7 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

8 Save the table definition file. Use the name of the table definition function to name the file.

Shift Left Operations and Code Replacement

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for `int16` data. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_shift_left_int16
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

3. Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntry` function.

   ```
   op_entry = RTW.TflCOperationEntry;
   ```

4. Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left and the name of the replacement function as `my_shift_left`.

   ```
   setTflCOperationEntryParameters(op_entry, ...
       'Key',                    'RTW_OP_SL', ...
       'Priority',               50, ...
       'ImplementationName',     'my_shift_left', ...
       'ImplementationHeaderFile', 'some_hdr.h', ...
       'ImplementationSourceFile', 'some_hdr.c');
   ```

5. Create the `int16` argument as conceptual argument `y1` and the implementation return value. There are multiple ways to set up the conceptual and implementation arguments. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `setReturn` specifies the argument as the implementation return value.

   ```
   arg = getTflArgFromString(hTable, 'y1', 'int16');
   arg.IOType = 'RTW_IO_OUTPUT';
   addConceptualArg(op_entry, arg);
   op_entry.Implementation.setReturn(arg);
   ```

6. Create the `int16` argument as conceptual and implementation argument `u1`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. Convenience method `addArgument` specifies the argument as an implementation input argument.

```
arg = getTflArgFromString(hTable, 'u1', 'int16');
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, the example disables type checking by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'int8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

- The function `getTflArgFromString` is called to create an `int8` input argument. This argument is added to the operator entry both as the third conceptual argument and the second implementation input argument.
- Add the entry to a code replacement table with a call to the `addEntry` function.

  ```
  addEntry(hTable, op_entry);
  ```

- Save the table definition file. Use the name of the table definition function to name the file.

You can use code replacement entries to replace code that the code generator produces for shift (<<) operations.

This example creates a code replacement entry to replace shift left operations for fixed-point data using a net slope. The example defines the function mapping programmatically. Alternatively, you can use the **Code Replacement Tool** to define the same mapping.

1 Create a table definition file that contains a function definition. For example:

```
function hTable = crl_table_shift_left_fixpt_net_slope
```

2 Within the function body, create the table by calling the function `RTW.TflTable`.

```
hTable = RTW.TflTable;
```

3 Create the entry for the operator mapping with a call to the `RTW.TflCOperationEntryGenerator_Netslope` function. This function provides access to the fixed-point parameters `NetSlopeAdjustmentFactor` and `NetFixedExponent`.

```
op_entry = RTW.TflCOperationEntryGenerator_NetSlope;
```

4 Set operator entry parameters with a call to the `setTflCOperationEntryParameters` function. The parameters specify the type of operation as shift left, the saturation mode as saturate on integer overflow, rounding modes as toward negative infinity, and the name of the replacement function as `my_fxp_shift_left`. `NetSlopeAdjustmentFactor` and `NetFixedExponent` specify the `F` and `E` parts of the net slope $F2^E$.

```
InFL = 2;
InWL = 16;
InSgn = true;
OutFL = 4;
OutWL = 32;
OutSgn = true;
setTflCOperationEntryParameters(op_entry, ...
   'Key',                      'RTW_OP_SL', ...
   'Priority',                 50, ...
   'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
   'RoundingModes',            {'RTW_ROUND_FLOOR'}, ...
   'NetSlopeAdjustmentFactor', 1.0, ...
   'NetFixedExponent',         (OutFL - InFL),...
   'ImplementationName',       'my_fxp_shift_left', ...
   'ImplementationHeaderFile', 'some_hdr.h', ...
   'ImplementationSourceFile', 'some_hdr.c');
```

5 Create conceptual arguments `y1` and `u1`. There are multiple ways to set up the conceptual arguments. This example uses calls to the `createAndAddConceptualArg` function to create and add an argument with one function call. Each argument is specified as fixed-point and signed. Each argument specifies that code replacement request processing does *not* check for an exact match to the call-site slope and bias values.

```
createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'y1', ...
    'IOType',       'RTW_IO_OUTPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     OutSgn, ...
    'WordLength',   OutWL, ...
    'FractionLength',OutFL);

createAndAddConceptualArg(op_entry, 'RTW.TflArgNumeric', ...
    'Name',         'u1', ...
    'IOType',       'RTW_IO_INPUT', ...
    'CheckSlope',   false, ...
    'CheckBias',    false, ...
    'DataTypeMode', 'Fixed-point: binary point scaling', ...
    'IsSigned',     InSgn, ...
    'WordLength',   InWL, ...
    'FractionLength',InFL);
```

6 Create the implementation arguments. There are multiple ways to set up the implementation arguments. This example uses calls to the `createAndSetCImplementationReturn` and `createAndAddImplementationArg` functions to create and add implementation arguments to the entry. Implementation arguments must describe fundamental numeric data types (not fixed-point data types).

```
createAndSetCImplementationReturn(op_entry, 'RTW.TflArgNumeric', ...
    'Name',           'y1', ...
    'IOType',         'RTW_IO_OUTPUT', ...
    'IsSigned',       OutSgn, ...
    'WordLength',     OutWL, ...
    'FractionLength', 0);

createAndAddImplementationArg(op_entry, 'RTW.TflArgNumeric', ...
     'Name',           'u1', ...
     'IOType',         'RTW_IO_INPUT', ...
     'IsSigned',       InSgn, ...
     'WordLength',     InWL, ...
     'FractionLength', 0);
```

7 Create the `int8` argument as conceptual and implementation argument `u2`. This example uses calls to the `getTflArgFromString` and `addConceptualArg` functions to create the conceptual argument and add it to the entry. This argument specifies the number of bits to shift the previous input argument. Because the argument type is not relevant, type checking is disabled by setting the `CheckType` property to `false`. Convenience method `addArgument` specifies the argument as implementation input argument.

```
arg = getTflArgFromString(hTable, 'u2', 'uint8');
arg.CheckType = false;
addConceptualArg(op_entry, arg);
op_entry.Implementation.addArgument(arg);
```

8 Add the entry to a code replacement table with a call to the `addEntry` function.

```
addEntry(hTable, op_entry);
```

9 Save the table definition file. Use the name of the table definition function to name the file.

Optimize Generated Code By Developing and Using Code Replacement Libraries - MATLAB®

Develop and use code replacement libraries to replace function and operators in generated code. Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware
- Integration with existing application code
- Compliance with a standard, such as AUTOSAR
- Modification of code behavior, such as enabling or disabling nonfinite or inline support
- Application- or project-specific code requirements, such as use of BLAS or elimination of `math.h`, system header files, or calls to `memcpy` or `memset`.

You can configure the code generator to use a code replacement library that MathWorks® provides. If you have an Embedded Coder® license, you can develop your own code replacement library interactively with the Code Replacement Tool or programmatically.

This example provides MATLAB® code that shows a variety of ways you can define code replacement mappings. With each example MATLAB® function, the example provides MATLAB® files that illustrate how to develop function and operator code replacements programmatically.

Additional Requirements:

- MATLAB Coder
- Embedded Coder
- Fixed-Point Designer

For more information, see “What Is Code Replacement Customization?” on page 66-3 and “Develop a Code Replacement Library” on page 66-15.

Create a New Folder and Copy Relevant Files

The following code creates a folder in your current working folder (pwd). The new folder contains files that are relevant for this example. If you do not want to affect the current folder (or if you cannot generate files in this folder), change your working folder.

```
coderdemo_setup('coderdemo_crl');
```

Steps for Developing a Code Replacement Library

1. Identify your code replacement requirements with respect to function or operating mappings, build information, and registration information.
2. Prepare for code replacement library development (for example, identify or develop models to test your library).
3. Define code replacement mappings.
4. Specify build information for replacement code.
5. Register code replacement mappings.
6. Verify code replacements.
7. Deploy the library.

For more information, see “Develop a Code Replacement Library” on page 66-15.

Math Function Replacement

This example defines and registers code replacement mappings for math functions. You can define code replacement mappings for a variety of functions. For details, see “Code You Can Replace from MATLAB Code” on page 66-5.

1. Open and explore the MATLAB® file for this example.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','replace_mat
```

2. Configure the code generator to use the code replacement library **Function Replacement Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'Function Replacement Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the function input type.

```
t = single(2);
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_fu
```

5. Compile the MATLAB® program into a C source file by using the configuration parameters that point to the code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```
codegen('replace_math_fcns', '-config', cfg, '-args', {t, t});
```

6. Open the file `replace_math_fcns.c` and explore the generated source code.

```
open(fullfile('codegen','lib','replace_math_fcns','replace_math_fcns.c'))
```

7. Close `replace_math_fcns.m`.

For more information on math function replacement, see “Math Function Code Replacement” on page 66-80. For more information on embeddable C code generation using MATLAB® Coder™, see “Register Code Replacement Mappings” on page 66-57 and “C/C++ Code Generation” (MATLAB Coder).

Addition and Subtraction Operator Replacement

This example shows how to define and register code replacement mappings for addition (+) and subtraction (-) operations. When defining entries for addition and subtraction operations, you can specify which of the following algorithms (`EntryInfoAlgorithm`) your library functions implement:

- Cast-before-operation (CBO) (`RTW_CAST_BEFORE_OP`), the default
- Cast-after-operation (CAO) (`RTW_CAST_AFTER_OP`)

1. Open and explore the MATLAB® file for this example.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','addsub_two_
%
% CBO, the default algorithm, is assumed.
```

2. Configure the code generator to use a code replacement library **Addition & Subtraction Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'Addition & Subtraction Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the operation input type.

```
t = int16(2);
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_ad
```

5. Compile the MATLAB® program into a C source file by using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```
codegen('addsub_two_int16','-config', cfg, '-args', {t, t});
```

6. Open the file `addsub_two_int16.c` and explore the generated source code.

```
open(fullfile('codegen','lib','addsub_two_int16','addsub_two_int16.c'))
```

7. Close `addsub_two_int16.m`.

For more information on addition and subtraction operator replacement, see “Scalar Operator Code Replacement” on page 66-127 and “Addition and Subtraction Operator Code Replacement” on page 66-129. For more information on embeddable C code generation using MATLAB® Coder™, see “Register Code Replacement Mappings” on page 66-57 and “C/C++ Code Generation” (MATLAB Coder).

Matrix Operator Replacement

This example defines and registers code replacement mappings for matrix operations: addition, subtraction, multiplication, transposition, conjugate, and Hermitian.

Supported types include:

- `single`, `double`
- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`
- `csingle`, `cdouble`
- `cint8`, `cuint8`
- `cint16`, `cuint16`
- `cint32`, `cuint32`
- fixed-point integers

- mixed types (different type on each input)

1. Open and explore the MATLAB® file for this example:

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','replace_mat
```

2. Configure the code generator to use a code replacement library **Matrix Op Replacement Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'Matrix Op Replacement Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the operation input type.

```
t = [1.0 2.0; 3.0, 4.0];
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_ma
```

5. Compile the MATLAB® program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```
codegen('replace_matrix_ops', '-config', cfg, '-args', {t, t});
```

6. Open the file `replace_matrix_ops.c` and explore the generated source code.

```
open(fullfile('codegen','lib','replace_matrix_ops','replace_matrix_ops.c'))
```

7. Close `replace_matrix_ops.m`.

For more information on matrix operator replacement, see “Small Matrix Operation to Processor Code Replacement” on page 66-134.

Matrix Multiplication Replacement for BLAS

This example defines and registers code replacement mappings for Basic Linear Algebra Subroutines (BLAS) subroutines `xGEMM` and `xGEMV`. You can map the following operations to a BLAS subroutine:

- Matrix multiplication
- Matrix multiplication with transpose on single or both inputs
- Matrix multiplication with Hermitian operation on single or both inputs

1. Open and explore the MATLAB® file for this example.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','replace_matr
```

2. Configure the code generator to use a code replacement library **BLAS Replacement Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'BLAS Replacement Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the function input type.

```
t = [1.0 2.0 3.0; 4.0 5.0 6.0; 7.0 8.0 9.0];
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_bl
```

5. Compile the MATLAB® program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```
codegen('replace_matrix_ops_blas', '-config', cfg, '-args', {t, t});
```

6. Open the file `replace_matrix_ops_blas.c` and explore the generated source code.

```
open(fullfile('codegen','lib','replace_matrix_ops_blas','replace_matrix_ops_blas.c'))
```

7. Close `replace_matrix_ops_blas.m`.

For more information on matrix multiplication replacement for BLAS, see “Matrix Multiplication Operation to MathWorks BLAS Code Replacement” on page 66-138.

MATLAB Function Replacement Using Coder.Replace

Code replacement libraries support the replacement of MATLAB® functions with scalar and matrix inputs and outputs for built-in, complex, and fixed-point data types.

1. Open and explore the MATLAB® file for this example.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','coder_replac
```

2. Configure the code generator to use a code replacement library **Coder Replace Examples**.

```
RTW.TargetRegistry.getInstance('reset');
cfg = coder.config('lib','ecoder',true);
cfg.CodeReplacementLibrary = 'Coder Replace Examples';
cfg.GenerateReport = false;
cfg.LaunchReport = false;
```

3. Set up the configuration parameters to build and define the function input type.

```
t = [1 2; 3 4];
```

4. Explore the code replacement table definition file.

```
edit(fullfile(matlabroot,'toolbox','coder','codegendemos','coderdemo_crl','crl_table_co
```

5. Compile the MATLAB® program using the configuration parameters that point to the desired code replacement library and the example input class defined in step 3 as input parameters to the `codegen` command.

```
codegen('coder_replace_fcn', '-config', cfg, '-args', {t, t});
```

6. Open the file `coder_replace_fcn.c` and explore the generated source code.

```
open(fullfile('codegen','lib','coder_replace_fcn','coder_replace_fcn.c'))
```

7. Close `coder_replace_fcn.m`.

For more information, see “Replace MATLAB Functions with Custom Code Using coder.replace” on page 66-111.

Build Information

For each entry in a code replacement table, you can specify build information such as the following, for replacement functions:

- Header file dependencies
- Source file dependencies

- Additional include paths
- Additional source paths
- Additional link flags

Additionally, you can specify `RTW.copyFileToBuildDir` to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. You can specify `RTW.copyFileToBuildDir` by setting it as the value of:

- Property `GenCallback` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`.
- Argument `genCallback` in a call to `registerCFunctionEntry`, `registerCOperationEntry`, or `registerCSemaphoreEntry`.

Note: Models in this example are configured for code generation only because the implementations for the replacement functions are not provided.

For more information on specifying build information for replacement code, see “Specify Build Information for Replacement Code” on page 66-48.

Cleanup

Remove files and return to original folder

```
RTW.TargetRegistry.getInstance('reset');
clear coderdemo_crl
cd ../
```

Performance

Optimizations for Generated Code in Simulink Coder

Increase Code Generation Speed

In this section...

The amount of time it takes to generate code for a model depends on the size and configuration settings of the model. For instance, if you are working with a large model, it can take awhile to generate code. To decrease the amount of time for code generation of a model, try one or more of the following methods:

- Build a model in increments
- Build large model reference hierarchies in parallel
- Minimize memory requirements during code generation
- Generate only code
- Disable the creation of a code generation report

Build a Model in Increments

You can use the `rtwbuild` command to build a model and generate code. By default, when rebuilding a model, `rtwbuild` provides an incremental model build, which only rebuilds a model or submodels that have changed since the most recent model build. Incremental model build saves code generation time. Use the **Rebuild** parameter on the **Model Referencing** pane to change the method that Simulink uses to determine when to rebuild code for referenced models. For more information on the **Rebuild** parameter, see “Rebuild” (Simulink).

Build Large Model Reference Hierarchies in Parallel

In a parallel computing environment, whenever conditions allow, you can increase the speed of code generation and compilation by building models containing large model reference hierarchies in parallel. For example, if you have Parallel Computing Toolbox software, you can distribute code generation and compilation for each referenced model

across the cores of a multicore host computer. If you have MATLAB Parallel Server software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Parallel Server configuration.

The execution speed improvement realized by using parallel builds for referenced models depends on several factors, including:

- How many models can be built in parallel for a given model referencing hierarchy
- The size of the referenced models
- Parallel computing resources such as the number of local and remote workers available
- The hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on)

For more information, see “Reduce Build Time for Referenced Models” (Simulink Coder).

Minimize Memory Requirements During Code Generation

Models that have large amounts of parameter and constant data (such as lookup tables) can tax memory resources and slow code generation. The code generator copies this data to the *`model`*`.rtw` file. The *`model`*`.rtw` file is a partial representation of the model that the Target Language Compiler parses to transform block computations, parameters, signals, and constant data into a high-level language (for example, C). The Target Language Compiler (TLC) is an integral part of the code generator. The code generator copies parameters and data into *`model`*`.rtw`, whether they originate in the model or come from variables or objects in a workspace.

You can improve code generation speed by specifying the maximum number of elements that data vectors can have for the code generator to copy this data to *`model`*`.rtw`. When a data vector exceeds the specified size, the code generator places a reference key in *`model`*`.rtw`. The TLC uses this key to access the data from Simulink and format it into the generated code. Reference keys result in maintaining only one copy of large data vectors in memory.

The default value above which the code generator uses reference keys in place of actual data values is 10 elements. You can verify this value. In the Command Window, type the following command:

```
get_param(0, 'RTWDataReferencesMinSize')
```

To set the threshold to a different value, in the Command Window, type the following `set_param` function:

```
set_param(0, 'RTWDataReferencesMinSize', <size>)
```

Provide an integer value for `size` that specifies the number of data elements above which the code generator uses reference keys in place of actual data values.

Generate Only Code

You can increase code generation speed by specifying that the build process generate code and a makefile, but not invoke the make command. When the code generator invokes the make command, the build process takes longer because the code generator generates code, compiles code, and creates an executable file.

On the **Code Generation** pane in the Model Configuration Parameters dialog box, you can specify that the build process generate only code by selecting the **Generate code only** parameter. You can specify that the code generation process build a makefile by selecting the **Configuration Parameters > Code Generation > Build process > Makefile configuration > Generate makefile** parameter.

Suppress Creation of a Code Generation Report

You can speed up code generation by not generating a code generation report as a part of the build process. To disable the creation of a code generation report, on the **Code Generation > Report** pane, clear the **Create code generation report** parameter. After the build process, you can generate a code generation report by doing this procedure, “Generate Code Generation Report After Build Process” (Simulink Coder).

Control Compiler Optimizations

To control compiler optimizations for a makefile build at the GUI level, use the **Compiler optimization level** parameter. The **Compiler optimization level** parameter provides

- Target-independent values `Optimizations on (faster runs)` and `Optimizations off (faster builds)`, which allow you to easily toggle compiler optimizations on and off during code development
- The value `Custom` for entering custom compiler optimization flags at the Simulink GUI level, rather than editing compiler flags into template makefiles (TMFs) or supplying compiler flags to build process make commands

The default setting is `Optimizations off (faster builds)`. Selecting the value `Custom` enables the **Custom compiler optimization flags** field, in which you can enter custom compiler optimization flags (for example, `-O2`).

If you specify compiler options for your makefile build using `OPT_OPTS`, `MEX_OPTS` (except `MEX_OPTS="-v"`), or `MEX_OPT_FILE`, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

For a rapid simulation (Simulink Coder) that uses the MinGW® compiler:

- If `RTWCompilerOptimization (Simulink Coder)` is set to `'on'`, the build process customizes compiler optimization to minimize run time. The build process ignores the `BuildConfiguration (Simulink Coder)` and `CustomToolchainOptions (Simulink Coder)` settings.
- If `RTWCompilerOptimization` is set to `'custom'` or `'off'`, the build process uses `BuildConfiguration` and `CustomToolchainOptions` settings. The build process ignores the `RTWCompilerOptimization` setting.

Optimization Tools and Techniques

Use the Model Advisor to Optimize a Model for Code Generation

You can use the Model Advisor to analyze a model for code generation and identify aspects of your model that impede production deployment or limit code efficiency. You can select from a set of checks to run on a model's current configuration. The Model Advisor analyzes the model and generates check results providing suggestions for improvements in each area. Most Model Advisor diagnostics do not require the model to be in a compiled state; those that do are noted.

Before running the Model Advisor, select the target you plan to use for code generation. The Model Advisor works most effectively with ERT and ERT-based system target files.

Use the following examples to investigate optimizing models for code generation using the Model Advisor:

- `rtwdemo_advisor1`
- `rtwdemo_advisor2`
- `rtwdemo_advisor3`

Note Example models `rtwdemo_advisor2` and `rtwdemo_advisor3` require Stateflow and Fixed-Point Designer software.

For more information on using the Model Advisor, see “Run Model Checks” (Simulink). For more information about the checks, see “Simulink Coder Checks” (Simulink Coder).

Design Tips for Optimizing Generated Code for Stateflow Objects

Do Not Access Machine-Parented Data In a Graphical Function

This restriction prevents long parameter lists from appearing in the code generated for a graphical function. You can access local data that resides in the same chart as the graphical function. For more information, see “Reuse Logic Patterns by Defining Graphical Functions” (Stateflow).

Be Explicit About the Inline Option of a Graphical Function

When you use a graphical function in a Stateflow chart, select `Inline` or `Function` for the property **Function Inline Option**. Otherwise, the code generated for a graphical function may not appear as you want. For more information, see “Specify Graphical Function Properties” (Stateflow).

Avoid Using Multiple Edge-Triggered Events in Stateflow Charts

If you use more than one trigger, you generate multiple code statements to handle rising or falling edge detections. If multiple triggers are required, use function-call events instead. For more information, see “Activate a Stateflow Chart by Sending Input Events” (Stateflow).

Combine Input Signals of a Chart Into a Single Bus Object

When you use a bus object, you reduce the number of parameters in the parameter list of a generated function. This guideline also applies to output signals of a chart. For more information, see “Define Stateflow Structures” (Stateflow).

Use Charts with Discrete Sample Times

The code generated for discrete charts that are not inside a triggered or enabled subsystem uses integer counters to track time instead of Simulink provided time. This allows for more efficient code generation in terms of overhead and memory, as well as enabling this code for use in Software-in-the-Loop(SIL) and Processor-in-the-Loop(PIL) simulation modes.

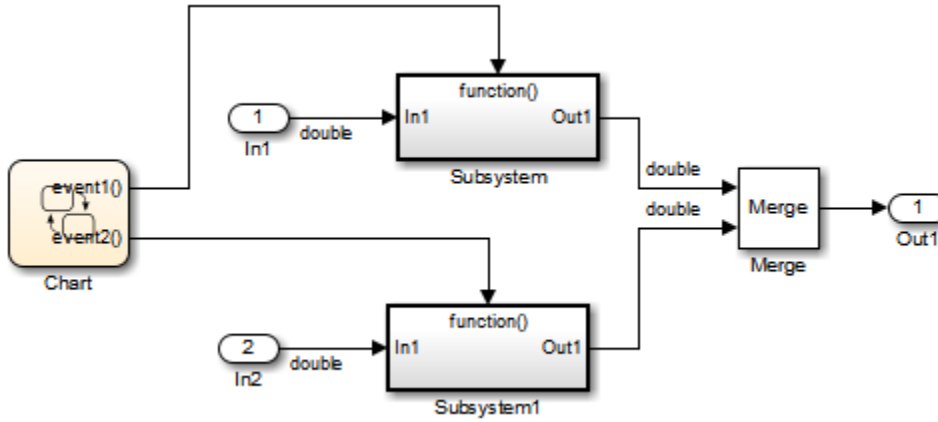
Additional Optimization Techniques

You can apply the following techniques to optimize a model for code generation:

- For Embedded Coder users, if your application uses only integer arithmetic, clear the **Support floating-point numbers** parameter in the **Software environment** section of the **Interface** pane so that the generated code does not contain floating-point data or operations. When this parameter is cleared, an error is raised if noninteger data or expressions are encountered during code generation. The error message reports the offending blocks and parameters.
- Disable the **Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file logging**parameter. Deselecting this parameter eliminates extra code and memory usage for initializing, updating, and cleaning-up

logging variables. In addition, the code generated to support MAT-file logging invokes `malloc`, which can be undesirable for your application.

- Use the Upgrade Advisor to upgrade older models (saved by prior versions or the current version) to use current features. For details, see "Model Upgrades" (Simulink).
- Before building, set optimization flags for the compiler (for example, `-O2` for `gcc`, `-Ot` for the Microsoft Visual C++ compiler).
- Directly inline C/C++ S-functions into the generated code by writing a TLC file for the S-function. For more information, see "Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target" (Simulink Coder) and see "Inline C MEX S-Functions" (Simulink Coder).
- Use a Simulink data type other than `double` when possible. The available data types are `Boolean`, signed and unsigned 8-, 16-, and 32-bit integers, and 32- and 64-bit floats (a `double` is a 64-bit float). For more information, see "About Data Types in Simulink" (Simulink). For a block-by-block summary, click `showblockdatatypetable` or type the command in the Command Window.
- For tunable block parameters that you configure to store in memory in the generated code, you can match parameter data types with signal data types to eliminate unnecessary typecasts and C shifts. Where possible, store parameter values in small integer data types. See "Parameter Data Types in the Generated Code" on page 32-161.
- Remove repeated values in lookup table data.
- Use the Merge block to merge the output of signals wherever possible. This block is particularly helpful when you need to control the execution of function-call subsystems with a Stateflow chart. The following model shows an example of how to use the Merge block.



When more than one signal connected to a Merge block has a non-`Auto` storage class, all non-`Auto` signals connected to that block must *be identically labeled* and *have the same storage class*. When Merge blocks connect directly to one another, these rules apply to the signals connected to any of the Merge blocks in the group.

Control Memory Allocation for Time Counters

The **Application lifespan (days)** parameter lets you control the allocation of memory for absolute and elapsed time counters. Such counters exist in the code for blocks that use absolute or elapsed time. For a list of such blocks, see “Absolute Time Limitations” (Simulink Coder).

The size of the time counters in generated code is 8, 16, 32, or 64 bits. The size is set automatically to the minimum that can accommodate the duration value specified by **Application lifespan (days)** given the step size specified in the Configuration Parameters **Solver** pane. To minimize the amount of RAM used by time counters, specify the smallest lifespan possible and the largest step size possible.

An application runs to its specified lifespan. It may be able to run longer. For example, running a model with a step size of one millisecond (0.001 seconds) for one day requires a 32-bit timer, which could continue running without overflow for 49 days more.

To maximize application lifespan, specify **Application lifespan (days)** as `inf`. This value allocates 64 bits (two `uint32` words) for each timer. Using 64 bits to store timing data would allow a model with a step size of 0.001 microsecond (10E-09 seconds) to run for more than 500 years, which would rarely be required. 64-bit counters do not violate the usual code generator length limitation of 32 bits because the value of a time counter does not provide the value of a signal, state, or parameter.

Execution Profiling for Generated Code

Use code execution profiling to:

- Determine whether the generated code meets execution time requirements for real-time deployment on your target hardware.
- Identify code sections that require execution speed improvements.

The following tasks represent a general workflow that uses code execution profiling:

1. With the Simulink model, design and optimize your algorithm.
2. Configure the model for code execution profiling, and generate code.
3. Execute generated code on target. For example, you can:
   - Run a software-in-the-loop (SIL) simulation on your development computer.
   - Run a processor-in-the-loop (PIL) simulation using a target support package or custom PIL target.
   - Perform real-time execution with Simulink Real-Time or a target support package.
4. Analyze execution speed through code execution profiling plots and reports. For example, check that the algorithm code satisfies execution time requirements for real-time deployment:
   - If the algorithm code easily meets the requirements, consider enhancing your algorithm to exploit available processing power.
   - If the code cannot be executed in real time, look for ways to reduce execution time.

     Identify the tasks that require the most time. For these tasks, investigate whether trade-offs between functionality and speed are possible.

     If your target is a multicore processor, distribute the execution of algorithm code across available cores.
5. If required, refine the model and return to step 2.

To find information about code execution profiling with Simulink products, use the following table.

Target	Execution Feature	Type of Profiling	Relevant Products	See
Development computer	Model configured for concurrent execution	Execution time	Simulink Coder	• “Optimize and Deploy on a Multicore Target” (Simulink) • “Concurrent Execution Models” (Simulink)

Optimize Generated Code by Combining Multiple for Constructs

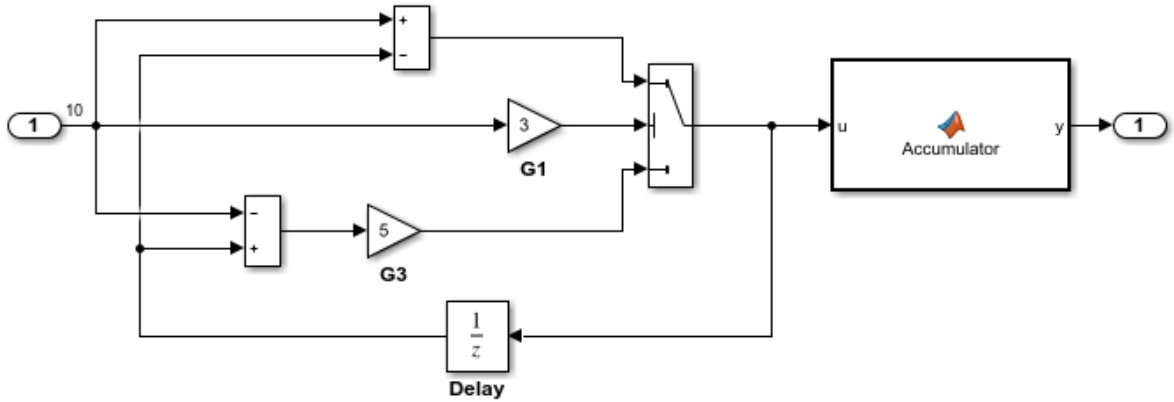
This example shows how the code generator combines `for` loops. The generated code uses `for` constructs to represent a variety of modeling patterns, such as a matrix signal or Iterator blocks. Using data dependency analysis, the code generator combines `for` constructs to reduce static code size and runtime branching.

The benefits of optimizing `for` loops are:

- Reducing ROM and RAM consumption.
- Increasing execution speed.

`for` Loop Modeling Patterns

In the model, rtwdemo_forloop, the Switch block and MATLAB Function block represent `for` constructs. In the `In1` Block Parameters dialog box, the **Port dimensions** parameter is set to `10` .



Generate Code

The model does not contain data dependencies across the `for` loop iterations. Therefore, the code generator combines `for` loops into one loop. Build the model and view the generated code.

```
### Starting build procedure for model: rtwdemo_forloop
### Successful completion of build procedure for model: rtwdemo_forloop
```

The generated file, `rtwdemo_forloop.c`, contains the code for the single `for` loop.

```
/* Model step function */
void rtwdemo_forloop_step(void)
{
  int32_T k;

  /* MATLAB Function: '<Root>/Accum' */
```

```
  /* MATLAB Function 'Accum': '<S1>:1' */
  /* '<S1>:1:3' */
  /* '<S1>:1:4' */
  rtwdemo_forloop_Y.Out1 = 0.0;

  /* '<S1>:1:5' */
  for (k = 0; k < 10; k++) {
    /* Switch: '<Root>/Switch' incorporates:
     *  Gain: '<Root>/G1'
     *  Gain: '<Root>/G3'
     *  Inport: '<Root>/In1'
     *  Sum: '<Root>/Sum1'
     *  Sum: '<Root>/Sum2'
     *  UnitDelay: '<Root>/Delay'
     */
    if (3.0 * rtwdemo_forloop_U.In1[k] >= 0.0) {
      rtwdemo_forloop_DW.Delay_DSTATE[k] = rtwdemo_forloop_U.In1[k] -
        rtwdemo_forloop_DW.Delay_DSTATE[k];
    } else {
      rtwdemo_forloop_DW.Delay_DSTATE[k] = (rtwdemo_forloop_DW.Delay_DSTATE[k] -
        rtwdemo_forloop_U.In1[k]) * 5.0;
    }

    /* End of Switch: '<Root>/Switch' */

    /* MATLAB Function: '<Root>/Accum' */
    /* '<S1>:1:5' */
    /* '<S1>:1:6' */
    rtwdemo_forloop_Y.Out1 += (1.0 + (real_T)k) +
      rtwdemo_forloop_DW.Delay_DSTATE[k];
  }
}
```

Close the model.

Subnormal Number Execution Speed

Subnormal numbers, formerly known as denormal numbers in floating-point literature, fill the underflow gap around zero in floating-point arithmetic. Subnormal values are a special category of floating-point values that are too close to `0.0` to be represented as a normalized value. The leading significand (mantissa) of a subnormal number is zero. When adding and subtracting floating-point numbers, subnormal numbers prevent underflow.

Using subnormal numbers provides precision beyond the normal representation by using leading zeros in the significand to represent smaller values after the representation reaches the minimum exponent. As the value approaches `0.0`, you trade off precision for extended range. Subnormal numbers are useful if your application requires extra range.

However, in a real-time system, using subnormal numbers can dramatically increase execution latency, resulting in excessive design margins and real-time overruns. If the simulation or generated code performs calculations that produce or consume subnormal numbers, the execution of these calculations can be up to 50 times slower than similar calculations on normal numbers. The actual simulation or code execution time for subnormal number calculations depends on your computer operating environment. Typically, for desktop processors, the execution time for subnormal number calculations is five times slower than similar calculations on normal numbers.

To minimize the possibility of execution slowdowns or overruns due to subnormal number calculation latency, do one of the following:

- In your model, manually flush to zero any incoming or computed subnormal values at inputs and key operations, such as washouts and filters. For an example, see “Flush Subnormal Numbers to Zero” on page 67-20.

  To detect a subnormal value for a single precision, 32-bit floating-point number:

  1. Find the smallest normalized number on a MATLAB host. In the Command Window, type:

     ```
     >> SmallestNormalSingle = realmin('single')
     ```

     In the C language, `FLT_MIN` , defined in `float.h`, is equivalent to `realmin('single')`.

  2. Look for values in range:

     ```
     0 < fabsf(x) < SmallestNormalSingle
     ```

To detect a subnormal value for a double precision, 64-bit floating-point number:

1. Find the smallest normalized number on a MATLAB host. In the Command Window, type:

   ```
   >> SmallestNormalDouble = realmin('double')
   ```

   In the C language, `DBL_MIN` , defined in `float.h`, is equivalent to `realmin('double')`.

2. To detect a subnormal value, look for values in this range:

   ```
   0 < fabs(x) < SmallestNormalDouble
   ```

- On your processor, set flush-to-zero mode or, with your compiler, specify an option to disable subnormal numbers. Flush-to-zero modes treat a subnormal number as 0 when it is an input to a floating-point operation. Underflow exceptions do not occur in flush-to-zero mode.

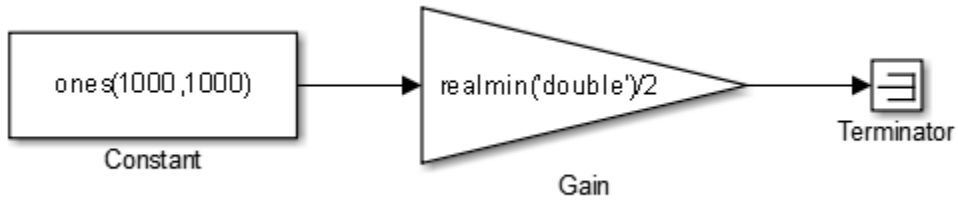
  For example, in Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register control floating-point calculations. For the gcc compiler on Linux, `-ffast-math` sets abrupt underflow (FTZ), flush-to-zero, while `-O3 -ffast-math` reverts to gradual underflow, using subnormal numbers.

For more information, see the IEEE Standard 754, *IEEE Standard for Floating-Point Arithmetic*.

Simulation Time With and Without Subnormal Numbers

This model shows how using subnormal numbers increases simulation time by ~5 times.

Open the model ex_subnormal. The Gain is set to subnormal value `realmin('double')/2`.



To run a simulation, in the Command Window, type `for k=1:5, tic; sim('ex_subnormal'); toc,end`. Observe the elapsed times for simulation using subnormals, similar to the following:

```
>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 9.909326 seconds.
Elapsed time is 9.617966 seconds.
Elapsed time is 9.797183 seconds.
Elapsed time is 9.702397 seconds.
Elapsed time is 9.893946 seconds.
```

Set the Gain to a number, 2, that is not a subnormal value:

```
>> set_param('ex_subnormal/Gain', 'Gain', '2');
```

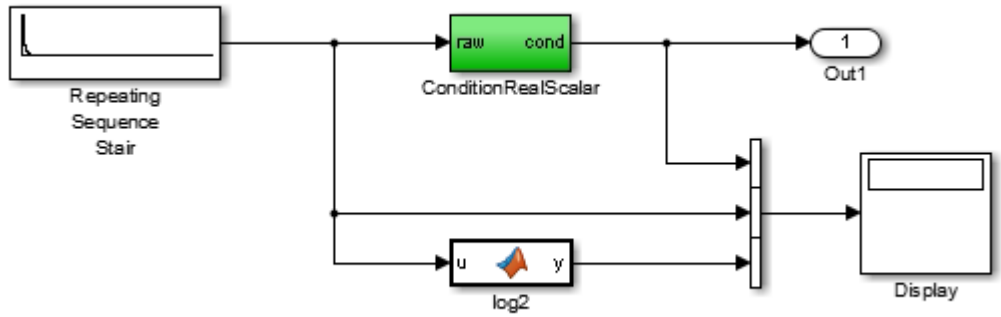
To run a simulation, in the Command Window, type `for k=1:5, tic; sim('ex_subnormal'); toc,end`. Observe elapsed times for simulations that do not use subnormal values, similar to the following:

```
>> for k=1:5, tic; sim('ex_subnormal'); toc,end
Elapsed time is 2.045123 seconds.
Elapsed time is 1.796598 seconds.
Elapsed time is 1.758458 seconds.
Elapsed time is 1.721721 seconds.
Elapsed time is 1.780569 seconds.
```

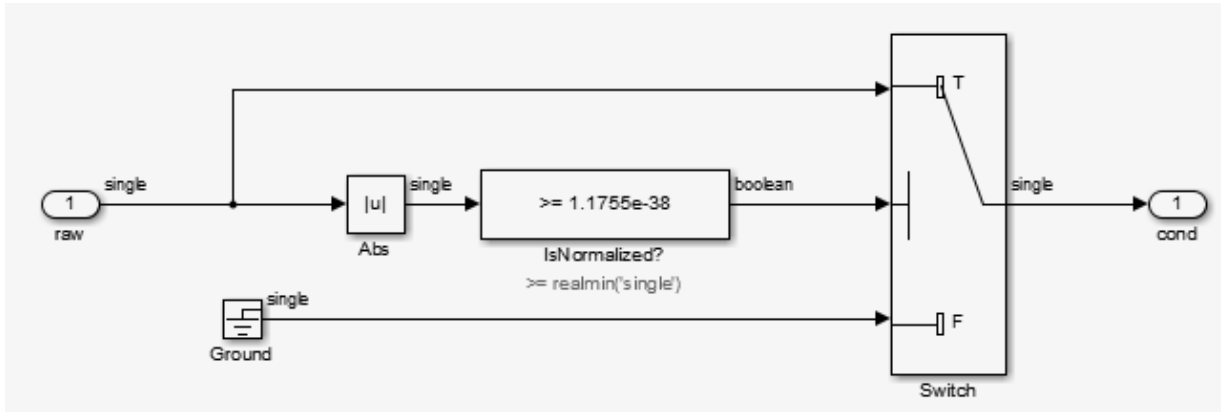
Flush Subnormal Numbers to Zero

This example shows how to flush single precision subnormal numbers to zero.

1 Open the model ex_flush_to_zero:



- `Repeating Sequence Stair` generates a sequence of numbers from two raised to the power of 0 through two raised to the power of -165. The sequence approaches zero.
- `ConditionRealScalar` flushes subnormal single precision values that are less than `realmin('single')` to zero.



- MATLAB function block `log2` generates the base 2 logarithm of the `Repeating Sequence Stair` output. Specifically, `log2` generates the numbers 0 through -165.

2 On the **Simulation** > **Stepping Options** pane:

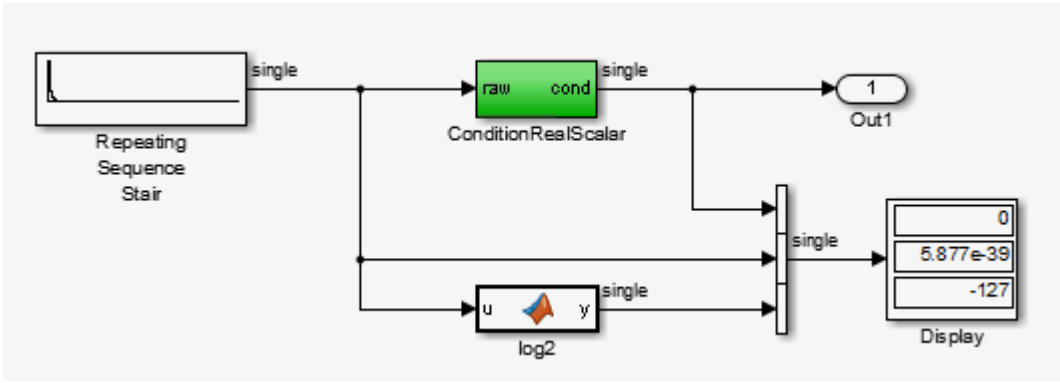
- Select **Enable stepping back**.

- Select **Pause simulation when time reaches** and enter `121`.

3 In the model window, run the simulation. The simulation pauses at `T=121`. The displayed values:

- `ConditionRealScalar` output approaches zero.
- `Repeating Sequence Stair output` approaches zero.

4 Step the simulation forward to `T=127`. `ConditionRealScalar` flushes the subnormal value output from `Repeating Sequence Stair` to zero.



5 Continue stepping the simulation forward. `ConditionRealScalar` flushes the subnormal single precision values output from `Repeating Sequence Stair` to zero. When `T=150`, the output of `Repeating Squence Stair` is itself zero.

Remove Code From Floating-Point to Integer Conversions That Wraps Out-of-Range Values

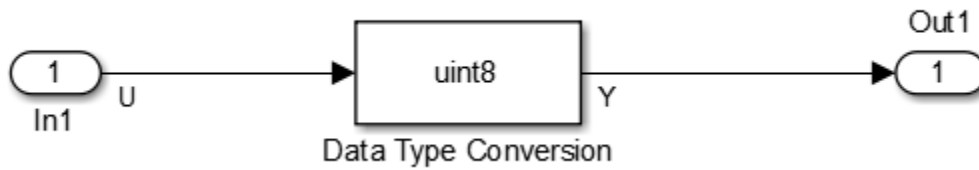
In this section...

This example shows how to remove code for out-of-range floating-point to integer conversions. Without this code, there might be a mismatch between simulation and code generation results. Standard C does not define the behavior of out-of-range floating-point to integer conversions, while these conversions are well-defined during simulation. In Standard C and during simulation, floating-point to integer conversions are well-defined for input values in the range of the output type.

If the input values in your application are in the range of the output type, remove code for out-of-range floating-point to integer conversions. Removing this code reduces the size and increases the speed of the generated code.

Example Model

In this model, a Data Type Conversion block converts an input signal from a `double` to a `uint8`. A `uint8` can support values from 0 to 255. If the input signal has a value outside of this range, an out-of-range conversion occurs. In this example, the model is named `conversion_ex`.



1. Use Inport, Outport, and Data Type Conversion blocks to create the example model.
2. Open the Inport Block Parameters dialog box and select the **Signal Attributes** tab. For the **Data Type** parameter, select `double`.

3. Open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`.
4. For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter the name `U`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.
5. For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter the name `Y`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.

Generate Code Without Optimization

1. Open the Model Configuration Parameters dialog box. On the **Solver** pane, for the **Type** parameter, select `Fixed-step`.
2. On the **Code Generation > Report** pane, select **Create code generation report**.
3. On the **Code Generation** pane, select **Generate code only**, and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report opens.
4. In the Code Generation report, select the `conversion_ex.c` file and view the model step function. The code generator applies the `fmod` function to handle out-of range-results.

```
/* Model step function */
void conversion_ex_step(void)
{
  real_T tmp;

  /* DataTypeConversion:
       '<Root>/Data Type Conversion' incorporates:
         Inport: '<>/In1'
   */
  tmp = floor(U);
  if (rtIsNaN(tmp) || rtIsInf(tmp)) {
    tmp = 0.0;
  } else {
    tmp = fmod(tmp, 256.0);
  }

  Y = (uint8_T)
      (tmp < 0.0 ?
         (int32_T)
```

```
(uint8_T)-(int8_T)
(uint8_T)-tmp :
(int32_T)
(uint8_T) tmp);
```

Generate Code with Optimization

1. Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove code from floating-point to integer conversions that wraps out-of-range values**. Generate code.
2. In the code generation report, select the `conversion_ex.c` file and view the model step function. The generated code does not contain code that protects against out-of-range values.

```
/* Model step function */
void conversion_ex_step(void)
{
  /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
   *  Inport: '<Root>/In1'
   */
  Y = (uint8_T)U;
```

The generated code is more efficient without this protective code, but it is possible that the execution of generated code does not produce the same results as simulation for values not in the range of 0 to 255.

Remove Code That Maps NaN to Integer Zero

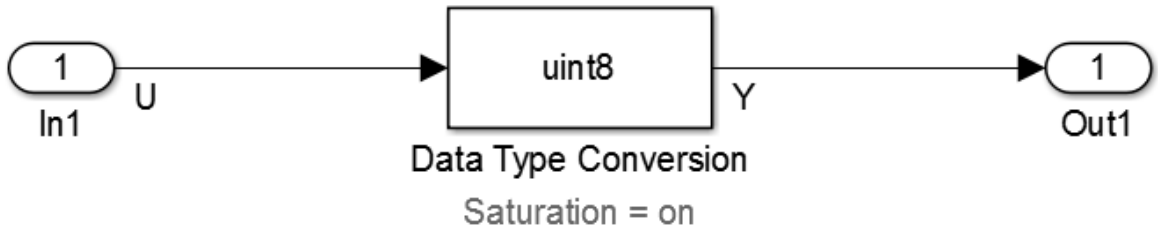
In this section...

This example shows how to remove code that maps `NaN` to integer zero. For floating-point to integer conversions involving saturation, Simulink converts `NaN` to integer zero during simulation. If your model contains an input value of `NaN`, you can specify that the code generator produce code that maps `NaN` to zero. Without this code, there is a mismatch between simulation and code generation results because in Standard C, every condition involving `NaN` evaluates to false.

If input values of `NaN` doe not exist in your application, you can remove code that maps `NaN` to integer zero. Removing this code reduces the size and increases the speed of the generated code.

Example Model

In this model, a Data Type Conversion block converts an input signal from a `double` to a `uint8`. In this example, the model is named `conversion_ex`.



1. Use Inport, Outport, and Data Type Conversion blocks to create the example model.
2. Open the Inport Block Parameters dialog box and click the **Signal Attributes** tab. For the **Data Type** parameter, select `double`.
3. Open the Data Type Conversion dialog box. For the **Output data type** parameter, select `uint8`.

4. Select **Saturate on integer overflow**. Selecting this parameter specifies that an out-of-range signal value equals either the minimum or maximum value that the data type can represent.
5. For the signal feeding into the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of `U`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.
6. For the signal leaving the Data Type Conversion block, open the Signal Properties dialog box. Enter a name of `Y`. On the **Code Generation** tab, for the **Storage Class** parameter, select `ImportedExtern`.

Generate Code

1. Set the **Configuration Parameters > Solver > Solver options > Type** parameter to `Fixed-step` .
2. Disable the **Configuration Parameters > Optimization > Advanced parameters > Remove code from floating-point to integer conversions with saturation that maps NaN to zero** parameter.
3. Enable the **Configuration Parameters > Code Generation > Report > Create code generation report** parameter.
4. Enable the **Configuration Parameters > Code Generation > Build process > Generate code only** parameter. Then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report opens.
5. In the Code Generation report, select the `nan_int_ex.c` file and view the model step function. For an input value of `NaN`, there is agreement between the generated code and simulation because `NaN` maps to integer zero.

```
/* Model step function */
void nan_int_ex_step(void)
{
  /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (U < 256.0) {
    if (U >= 0.0) {
      Y = (uint8_T)U;
    } else {
      Y = 0U;
    }
  } else if (U >= 256.0) {
```

```
    Y = MAX_uint8_T;
  } else {
    Y = 0U;
  }
```

Generate Code with Optimization

1. Enable the **Configuration Parameters > Optimization > Code generation > Integer and fixed-point > Remove code from floating-point to integer conversions that wraps out-of-range values** parameter. Generate code.
2. In the Code Generation report, select the `nan_int_ex.c` section and view the model step function. The generated code maps `NaN` to 255 and not integer zero. The generated code is more efficient without the extra code that maps `NaN` to integer zero, but the execution of the generated code does not produce the same results as simulation for `NaN` values.

```
/* Model step function */
void nan_int_ex_step(void)
{
  /* DataTypeConversion: '<Root>/Data Type Conversion' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (U < 256.0) {
    if (U >= 0.0) {
      Y = (uint8_T)U;
    } else {
      Y = 0U;
    }
  } else {
    Y = MAX_uint8_T;
  }

  /* End of DataTypeConversion: '<Root>/Data Type Conversion' */
```

Disable Nonfinite Checks or Inlining for Math Functions

When the code generator produces code for math functions:

- If the model option **Support non-finite numbers** is selected, nonfinite number checking is generated uniformly for math functions, without the ability to specify that nonfinite number checking should be generated for some functions, but not for others.
- By default, inlining is applied uniformly for math functions, without the ability to specify that inlining should be generated for some functions, while invocations should be generated for others.

You can use code replacement library (CRL) customization entries to:

- Selectively disable nonfinite checks for math functions. This can improve the execution speed of the generated code.
- Selectively disable inlining of math functions. This can increase code readability and decrease code size.

The functions for which these customizations are supported include the following:

- Floating-point only: `atan2`, `copysign`, `fix`, `hypot`, `log`, `log10`, `round`, `sincos`, and `sqrt`
- Floating-point and integer: `abs`, `max`, `min`, `mod`, `rem`, `saturate`, and `sign`

The general workflow for disabling nonfinite number checking and/or inlining is as follows:

1 If you can disable nonfinite number checking for a particular math function, or if you want to disable inlining for a particular math function and instead generate a function invocation, you can copy the following MATLAB function code into a MATLAB file with an `.m` file name extension, for example, `crl_table_customization.m`.

```
function hTable = crl_table_customization

% Create an instance of the Code Replacement Library table for controlling
% function intrinsic inlining and nonfinite support

hTable = RTW.TflTable;

% Inline - true (if function needs to be inline)
%          false (if function should not be inlined)
% SNF (support nonfinite) - ENABLE (if non-finite checking should be performed)
%                           DISABLE (if non-finite checking should NOT be performed)
```

```
%                           UNSPECIFIED (Default behavior)

% registerCustomizationEntry(hTable, ...
%       Priority, numInputs, key, inType, outType, Inline, SNF);

```

```
registerCustomizationEntry(hTable, ...
        100, 1, 'sqrt', 'double', 'double', true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'sqrt', 'single', 'single', true, 'UNSPECIFIED');

registerCustomizationEntry(hTable, ...
        100, 1, 'fix', 'double', 'double', false, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'fix', 'single', 'single', false, 'UNSPECIFIED');

registerCustomizationEntry(hTable, ...
        100, 1, 'copysign', 'double', 'double', true, 'UNSPECIFIED');
registerCustomizationEntry(hTable, ...
        100, 1, 'copysign', 'single', 'single', true, 'UNSPECIFIED');
```

2. To reduce the size of the file, you can delete the `registerCustomizationEntry` lines for functions for which the default nonfinite number checking and inlining behavior is acceptable.
3. For each remaining entry,

   - Set the `Inline` argument to `true` if the function should be inlined or `false` if it should not be inlined.
   - Set the `SNF` argument to `ENABLE` if nonfinite checking should be generated, `DISABLE` if nonfinite checking should not be generated, or `UNSPECIFIED` to accept the default behavior based on the model option settings.

   Save the file.
4. Optionally, perform a quick check of the syntactic validity of the customization table entries by invoking the table definition file at the MATLAB command line (`>> tbl = crl_table_customization`). Fix syntax errors that are flagged.
5. Optionally, view the customization table entries in the **Code Replacement Viewer** (`>> crviewer(crl_table_customization)`). For more information about viewing code replacement tables, see “Choose a Code Replacement Library” (Simulink Coder).
6. To register these changes and make them appear in the **Code replacement library** drop-down list located on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box, first copy the following MATLAB function code into an instance of the file `rtwTargetInfo.m`.

Note For the example below, specify the argument `'RTW'` if a GRT target is selected for your model, otherwise omit the argument.

```
function rtwTargetInfo(cm)
% rtwTargetInfo function to register a code replacement library (CRL)

  % Register the CRL defined in local function locCrlRegFcn
  cm.registerTargetInfo(@locCrlRegFcn);

end % End of RTWTARGETINFO

% Local function to define a CRL containing crl_table_customization
function thisCrl = locCrlRegFcn

  % Instantiate a CRL registry entry - specify 'RTW' for GRT
  thisCrl = RTW.TflRegistry('RTW');

  % Define the CRL properties
  thisCrl.Name = 'CRL Customization Example';
  thisCrl.Description = 'Example  of CRL Customization';
  thisCrl.TableList = {'crl_table_customization'};
  thisCrl.TargetHWDeviceType = {'*'};

end % End of LOCCRLREGFCN
```

You can edit the `Name` field to specify the library name that appears in the **Code replacement library** drop-down list. Also, the file name in the `TableList` field must match the name of the file you created in step 1.

To register your changes, with both of the MATLAB files you created present in the MATLAB path, enter the following command at the MATLAB command line:

```
sl_refresh_customizations
```

7. Create or open a model that generates function code corresponding to one of the math functions for which you specified a change in nonfinite number checking or inlining behavior.
8. Open the Configuration Parameters dialog box, go to the **Code Generation** > **Interface** pane, and use the **Code replacement library** drop-down list to select the code replacement entry you registered in step 6, for example, `CRL Customization Example`.
9. Generate code for the model and examine the generated code to verify that the math functions are generated as expected.

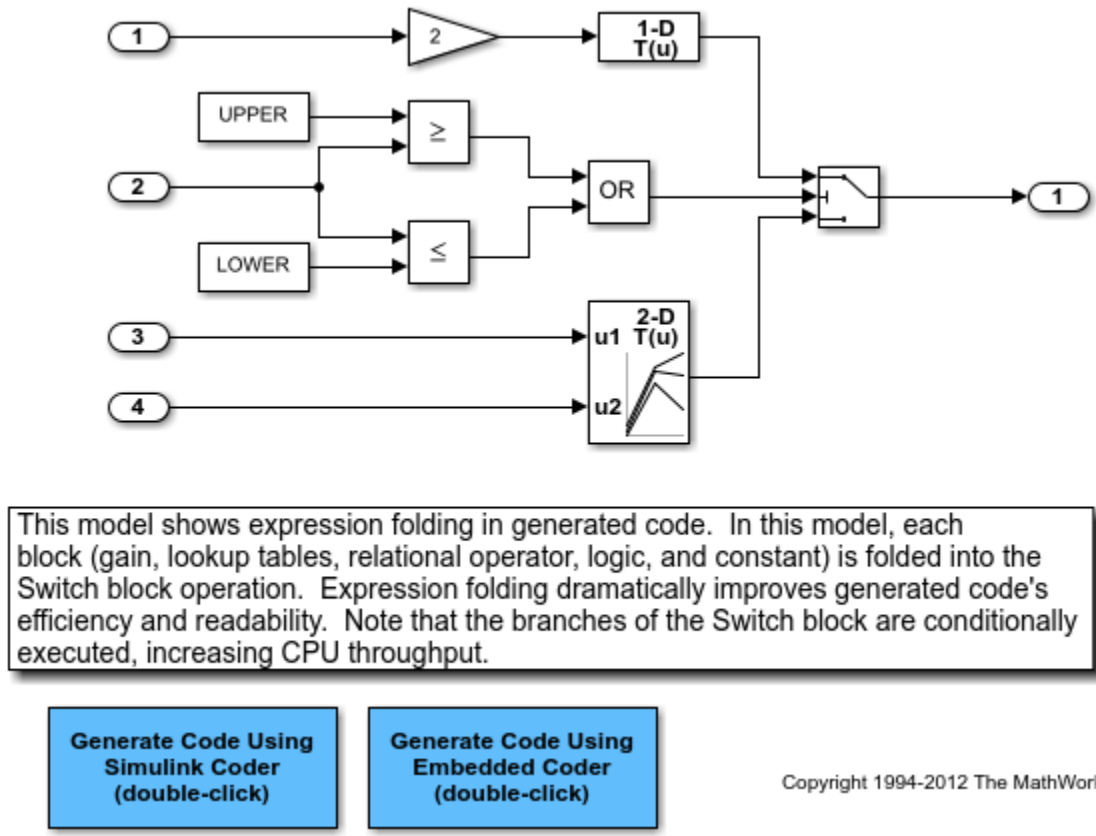
Fold Expressions

Expression folding optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in a model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

Example Model

```
model = 'rtwdemo_slexprfold';
open_system(model);
```



Generate Code

Expression folding is available only when the **Signal storage reuse** parameter is set to on because expression folding operates only on expressions involving local variables. The **Signal storage reuse** and **Eliminate superfluous local variables (expression folding)** parameters are on by default. Clear the **Eliminate superfluous local variables (expression folding)** parameter or enter the following command in the MATLAB Command Window to turn the parameter off:

```
set_param(model, 'ExpressionFolding','off');
```

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_slexprfold
### Successful completion of build procedure for model: rtwdemo_slexprfold
```

With expression folding off, in the `rtwdemo_slexprfold.c` file, there are separate code statements before and in the Switch block operation.

```
cfile = fullfile(cgDir,'rtwdemo_slexprfold_grt_rtw','rtwdemo_slexprfold.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_slexprfold_step(void)
{
  boolean_T rtb_LogicalOperator;
  boolean_T rtb_RelationalOperator;
  real_T rtb_Gain;

  /* RelationalOperator: '<Root>/Relational Operator1' incorporates:
   *  Constant: '<Root>/Constant'
   *  Inport: '<Root>/In2'
   */
  rtb_LogicalOperator = (rtwdemo_slexprfold_P.UPPER >= rtwdemo_slexprfold_U.In2);

  /* RelationalOperator: '<Root>/Relational Operator' incorporates:
   *  Constant: '<Root>/Constant1'
   *  Inport: '<Root>/In2'
   */
  rtb_RelationalOperator = (rtwdemo_slexprfold_U.In2 <=
    rtwdemo_slexprfold_P.LOWER);

  /* Logic: '<Root>/Logical Operator' */
  rtb_LogicalOperator = (rtb_LogicalOperator || rtb_RelationalOperator);

  /* Switch: '<Root>/Switch' */
  if (rtb_LogicalOperator) {
    /* Gain: '<Root>/Gain' incorporates:
     *  Inport: '<Root>/In1'
     */
```

```
    rtb_Gain = 2.0 * rtwdemo_slexprfold_U.In1;

    /* Lookup_n-D: '<Root>/Look-Up Table' */
    rtwdemo_slexprfold_Y.Out1 = look1_binlx(rtb_Gain,
      rtwdemo_slexprfold_P.T1Break, rtwdemo_slexprfold_P.T1Data, 10U);
  } else {
    /* Lookup_n-D: '<Root>/Look-Up Table (2-D)' incorporates:
     *  Inport: '<Root>/In3'
     *  Inport: '<Root>/In4'
     */
    rtwdemo_slexprfold_Y.Out1 = look2_binlx(rtwdemo_slexprfold_U.In3,
      rtwdemo_slexprfold_U.In4, rtwdemo_slexprfold_P.T2Break,
      rtwdemo_slexprfold_P.T2Break, rtwdemo_slexprfold_P.T2Data,
      rtCP_LookUpTable2D_maxIndex, 3U);
  }

  /* End of Switch: '<Root>/Switch' */
}
```

Generate Code with Optimization

Enter the following command to turn expression folding on:

```
set_param(model, 'ExpressionFolding','on');
```

Build the model.

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_slexprfold
### Successful completion of build procedure for model: rtwdemo_slexprfold
```

The following is a portion of rtwdemo_slexprfold.c. In the optimized code, the code generator folds all computations into the Switch block operation.

```
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_slexprfold_step(void)
{
  /* Switch: '<Root>/Switch' incorporates:
   *  Constant: '<Root>/Constant'
   *  Constant: '<Root>/Constant1'
   *  Inport: '<Root>/In2'
```

```
   *  Logic: '<Root>/Logical Operator'
   *  RelationalOperator: '<Root>/Relational Operator'
   *  RelationalOperator: '<Root>/Relational Operator1'
   */
  if ((rtwdemo_slexprfold_P.UPPER >= rtwdemo_slexprfold_U.In2) ||
      (rtwdemo_slexprfold_U.In2 <= rtwdemo_slexprfold_P.LOWER)) {
    /* Outport: '<Root>/Out1' incorporates:
     *  Gain: '<Root>/Gain'
     *  Inport: '<Root>/In1'
     *  Lookup_n-D: '<Root>/Look-Up Table'
     */
    rtwdemo_slexprfold_Y.Out1 = look1_binlx(2.0 * rtwdemo_slexprfold_U.In1,
      rtwdemo_slexprfold_P.T1Break, rtwdemo_slexprfold_P.T1Data, 10U);
  } else {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In3'
     *  Inport: '<Root>/In4'
     *  Lookup_n-D: '<Root>/Look-Up Table (2-D)'
     */
    rtwdemo_slexprfold_Y.Out1 = look2_binlx(rtwdemo_slexprfold_U.In3,
      rtwdemo_slexprfold_U.In4, rtwdemo_slexprfold_P.T2Break,
      rtwdemo_slexprfold_P.T2Break, rtwdemo_slexprfold_P.T2Data,
      rtCP_LookUpTable2D_maxIndex, 3U);
  }

  /* End of Switch: '<Root>/Switch' */
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

For an example in which code expressions are expression folded between Simulink and Stateflow, open this model `rtwdemo_sfexprfold`.

Minimize Computations and Storage for Intermediate Results at Block Outputs

In this section...

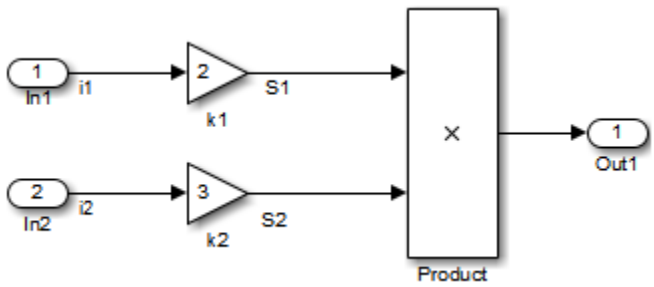
Expression Folding

Expression folding optimizes code to minimize the computation of intermediate results at block outputs and the storage of such results in temporary buffers or variables. When expression folding is on, the code generator collapses (folds) block computations into a single expression, instead of generating separate code statements and storage declarations for each block in the model. Most Simulink blocks support expression folding.

Expression folding improves the efficiency of generated code, frequently achieving results that compare favorably to hand-optimized code. In many cases, entire groups of model computations fold into a single, highly optimized line of code.

You can use expression folding in your own inlined S-function blocks. For more information, see “S-Functions That Support Expression Folding” (Simulink Coder).

Example Model



Generate Code

With expression folding off, in the `explfld.c` file, the code generator generates this code.

```
/* Model step function */
void exprfld_step(void)
{
  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   */
  exprfld_B.S1 = exprfld_P.Gain_Gain * exprfld_U.i1;

  /* Gain: '<Root>/Gain1' incorporates:
   *  Inport: '<Root>/In2'
   */
  exprfld_B.S2 = exprfld_P.Gain1_Gain * exprfld_U.i2;

  /* Outport: '<Root>/Out1' incorporates:
   *  Product: '<Root>/Product'
   */
  exprfld_Y.Out1 = exprfld_B.S1 * exprfld_B.S2;
}
```

There are separate code statements for both Gain blocks. Before final output, these code statements compute temporary results for the Gain blocks.

Enable Optimization

Expression folding is on by default. To see if expression folding is on for an existing model:

1. Expression folding is available only when the **Configuration Parameters > Signal storage reuse** parameter is selected because expression folding operates only on expressions involving local variables. Enable the **Signal storage reuse** parameter.
2. When you select **Signal storage reuse**, the **Enable local block outputs**, **Reuse local block outputs**, and **Eliminate superfluous local variables (expression folding)** parameters are all on by default.

Generate Code with Optimization

With expression folding, the code generator generates a single-line output computation, as shown in the `expfld.c` file. The generated comments document the block parameters that appear in the expression.

```
/* Model step function */
void exprfld_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   *  Gain: '<Root>/Gain1'
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   *  Product: '<Root>/Product'
   */
  exprfld_Y.Out1 =
     exprfld_P.Gain_Gain *
     exprfld_U.i1 *
     (exprfld_P.Gain1_Gain * exprfld_U.i2);
}
```

For an example of expression folding in the context of a more complex model, click `rtwdemo_slexprfold` , or at the command prompt, type:

```
rtwdemo_slexprfold
```

For more information, see “Enable and Reuse Local Block Outputs in Generated Code” (Simulink Coder)

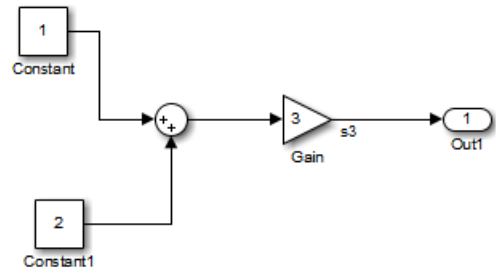
Inline Invariant Signals

You can optimize the generated code by selecting **Inline invariant signals** on the **Optimization** pane. The generated code uses the numerical values of the invariant signals instead of their symbolic names.

An invariant signal is a block output signal that does not change during Simulink simulation. For example, the signal `S3` is an invariant signal. An *invariant signal* is not the same as an *invariant constant*. The two constants (1 and 2) and the gain value of 3 are invariant constants. To inline invariant constants, set **Default parameter behavior** to `Inlined`.



Optimize Generated Code Using Inline Invariant Signals

This example shows how to use inline invariant signals to optimize the generated code. This optimization transforms symbolic names of invariant signals into constant values.

The `InlineInvariantSignals` optimization:

- Reduces ROM and RAM consumption.
- Improves execution speed.

Example Model

Consider the model matlab:rtwdemo_inline_invariant_signals.

```
model = 'rtwdemo_inline_invariant_signals';
open_system(model);
```

Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model using Simulink Coder.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_inline_invariant_signals
### Successful completion of build procedure for model: rtwdemo_inline_invariant_signal
```

View the generated code without the optimization. These lines of code are in `rtwdemo_inline_invariant_signals.c`.

```
cfile = fullfile(cgDir,'rtwdemo_inline_invariant_signals_grt_rtw',...
    'rtwdemo_inline_invariant_signals.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
    '/* Model output', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline__InlinedConstFcn(int32_T rtu_In1,
  B_InlinedConstFcn_rtwdemo_inl_T *localB, const ConstB_InlinedConstFcn_rtwdem_T
  *localC)
{
  /* Product: '<S1>/Product' */
  localB->Product = rtu_In1 * localC->Sum_p;
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Inline Invariant Signals**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'InlineInvariantSignals', 'on');
```

Generate Code with Optimization

The generated code uses the numerical values of the folded constants instead of creating an additional structure (rtwdemo_inline_invariant_ConstB).

Build the model using Simulink Coder.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_inline_invariant_signals
### Successful completion of build procedure for model: rtwdemo_inline_invariant_signal
```

View the generated code with the optimization. These lines of code are in `rtwdemo_minmax.c`.

```
rtwdemodbtype(cfile,...
    '/* Output and update for atomic system', '/* Model output', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/InlinedConstFcn' */
void rtwdemo_inline__InlinedConstFcn(int32_T rtu_In1,
  B_InlinedConstFcn_rtwdemo_inl_T *localB)
{
  /* Product: '<S1>/Product' */
  localB->Product = rtu_In1 << 5;
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

- “Inline Numeric Values of Block Parameters” on page 67-48

Inline Numeric Values of Block Parameters

This example shows how to optimize the generated code by inlining the numeric values of block parameters. *Block parameters* include the **Gain** parameter of a Gain block and the table data and breakpoint sets of an n-D Lookup Table block.

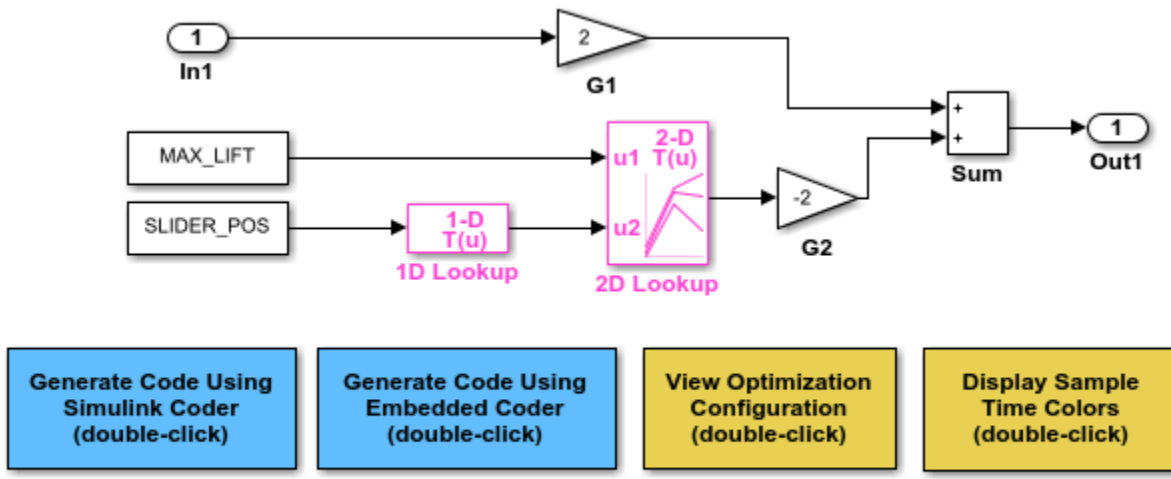
This optimization determines whether numeric block parameters occupy global memory in the generated code. The optimization can:

- Improve execution speed.
- Reduce RAM and ROM consumption.

Explore Example Model

Open the example model `rtwdemo_paraminline` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```



The model contains blocks that have these numeric parameters:

- The **Gain** parameters of the Gain blocks
- The **Constant value** parameters of the Constant blocks
- The table data and breakpoint sets of the n-D Lookup Table blocks

The output of the block G2, and the outputs of blocks upstream of G2, change only if you tune the values of the block parameters during simulation or during code execution. When you update the model diagram, these blocks and signal lines appear magenta in color.

Several blocks use `Simulink.Parameter` objects in the base workspace to set the values of their parameters. The parameter objects all use the storage class `Auto`, which means that you can configure the generated code to inline the parameter values.

Generate Code Without Optimization

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Disable the optimization by setting **Configuration Parameters > Default parameter behavior** to `Tunable`.

```
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

In the code generation report, view the source file `rtwdemo_paraminline_data.c`. The code defines a global structure that contains the block parameter values. Each block parameter in the model, such as a lookup table array, breakpoint set, or gain, appears as a field of the structure.

```
cfile = fullfile(...
    cgDir,'rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline_data.c');
rtwdemodbtype(cfile,'/* Block parameters (default storage) */', '};', 1, 1);
```

```
/* Block parameters (default storage) */
P_rtwdemo_paraminline_T rtwdemo_paraminline_P = {
  /* Variable: MAX_LIFT
   * Referenced by: '<Root>/Constant'
   */
  10.0,

  /* Variable: SLIDER_POS
   * Referenced by: '<Root>/Constant1'
   */
  0.0,

  /* Variable: T1Break
   * Referenced by: '<Root>/1D Lookup'
   */
  { -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 },

  /* Variable: T1Data
   * Referenced by: '<Root>/1D Lookup'
   */
  { -1.0, -0.99, -0.98, -0.96, -0.76, 0.0, 0.76, 0.96, 0.98, 0.99, 1.0 },

  /* Variable: T2Break
   * Referenced by: '<Root>/2D Lookup'
   */
  { 1.0, 2.0, 3.0 },

  /* Variable: T2Data
   * Referenced by: '<Root>/2D Lookup'
   */
  { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 },

  /* Expression: 2
   * Referenced by: '<Root>/G1'
   */
  2.0,

  /* Expression: -2
   * Referenced by: '<Root>/G2'
   */
  -2.0,

  /* Computed Parameter: uDLookup_maxIndex
```

```
   * Referenced by: '<Root>/2D Lookup'
   */
  { 2U, 2U }
};
```

You can tune the structure fields during code execution because they occupy global memory. However, at each step of the generated algorithm, the code must calculate the output of each block, including the outputs of the block G2 and the upstream blocks. View the algorithm in the model `step` function in the file `rtwdemo_paraminline.c`.

```
cfile = fullfile(cgDir,'rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(...
    cfile,'/* Model step function */','/* Model initialize function */',1,0);
```

```
/* Model step function */
void rtwdemo_paraminline_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Constant: '<Root>/Constant'
   *  Constant: '<Root>/Constant1'
   *  Gain: '<Root>/G1'
   *  Gain: '<Root>/G2'
   *  Inport: '<Root>/In1'
   *  Lookup_n-D: '<Root>/1D Lookup'
   *  Lookup_n-D: '<Root>/2D Lookup'
   *  Sum: '<Root>/Sum'
   */
  rtwdemo_paraminline_Y.Out1 = rtwdemo_paraminline_P.G1_Gain *
    rtwdemo_paraminline_U.In1 + rtwdemo_paraminline_P.G2_Gain * look2_binlx
    (rtwdemo_paraminline_P.MAX_LIFT, look1_binlx
     (rtwdemo_paraminline_P.SLIDER_POS, rtwdemo_paraminline_P.T1Break,
      rtwdemo_paraminline_P.T1Data, 10U), rtwdemo_paraminline_P.T2Break,
     rtwdemo_paraminline_P.T2Break, rtwdemo_paraminline_P.T2Data,
     rtwdemo_paraminline_P.uDLookup_maxIndex, 3U);
}
```

Generate Code with Optimization

Set **Default parameter behavior** to `Inlined`.

```
set_param('rtwdemo_paraminline','DefaultParameterBehavior','Inlined')
```

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')

### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

In the code generation report, view the algorithm in the file `rtwdemo_paraminline.c`.

```
rtwdemodbtype(...
    cfile,'/* Model step function */','/* Model initialize function */',1,0);

/* Model step function */
void rtwdemo_paraminline_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/G1'
   *  Inport: '<Root>/In1'
   *  Sum: '<Root>/Sum'
   */
  rtwdemo_paraminline_Y.Out1 = 2.0 * rtwdemo_paraminline_U.In1 + 150.0;
}
```

The code does not allocate memory for block parameters or for parameter objects that use the storage class `Auto`. Instead, the code generator uses the parameter values from the model, and from the parameter objects, to calculate and inline the constant output of the block G2, `150.0`. The generator also inlines the value of the **Gain** parameter of the Gain block G1, `2.0`.

With the optimization, the generated code leaves out computationally expensive algorithmic code for blocks such as the lookup tables. The optimized code calculates the output of a block only if the output can change during execution. For this model, only the outputs of the Inport block In1, the Gain block G1, and the Sum block can change.

Close the model and the code generation report.

```
bdclose('rtwdemo_paraminline')
rtwdemoclean;
cd(currentDir)
```

Preserve Block Parameter Tunability

When you set **Default parameter behavior** to `Inlined`, you can preserve block parameter tunability by creating `Simulink.Parameter` objects for individual parameters. You can configure each object to appear in the code as a tunable field of the

global parameter structure or as an individual global variable. You can change parameter values during code execution and interface the generated code with your own handwritten code. For more information, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

Inline Invariant Signals

You can select the **Inline invariant signals** code generation option (which also places constant values in the generated code) only when you set **Default parameter behavior** to `Inlined`. See “Inline Invariant Signals” (Simulink Coder).

See Also

“Default parameter behavior” (Simulink Coder)

Related Examples

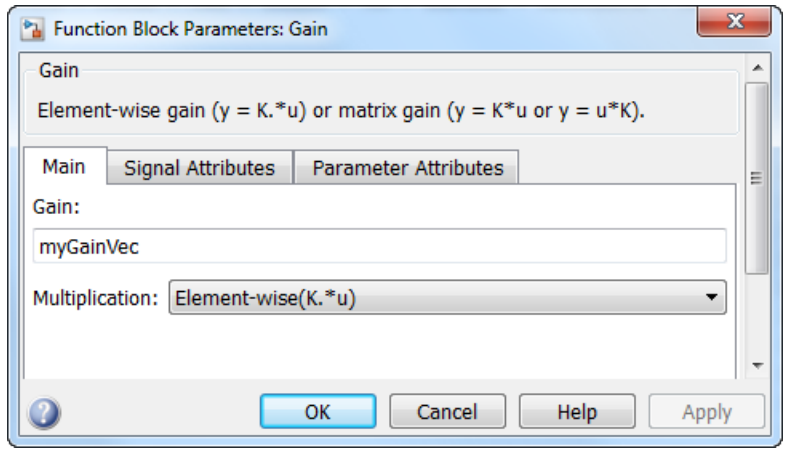
- “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50

Configure Loop Unrolling Threshold

The **Loop unrolling threshold** parameter on the **Optimization** pane determines when a wide signal or parameter should be wrapped into a `for` loop and when it should be generated as a separate statement for each element of the signal. The default threshold value is 5.

For example, consider the model below:

The gain parameter of the Gain block is the vector `myGainVec`.



Assume that the loop unrolling threshold value is set to the default, 5.

If `myGainVec` is declared as

```
myGainVec = [1:10];
```

an array of 10 elements, `myGainVec_P.Gain_Gain[]`, is declared within the `Parameters_model` data structure. The size of the gain array exceeds the loop unrolling threshold. Therefore, the code generated for the Gain block iterates over the array in a `for` loop, as shown in the following code:

```
{
    int32_T i1;

    /* Gain: '<Root>/Gain' */
    for(i1=0; i1<10; i1++) {
      myGainVec_B.Gain_f[i1] = rtb_foo *
        myGainVec_P.Gain_Gain[i1];
    }
  }
```

If `myGainVec` is declared as

```
myGainVec = [1:3];
```

an array of three elements, `myGainVec_P.Gain_Gain[]`, is declared within the `Parameters` data structure. The size of the gain array is below the loop unrolling threshold. The generated code consists of inline references to each element of the array, as in the code below.

```
/* Gain: '<Root>/Gain' */
  myGainVec_B.Gain_f[0] = rtb_foo * myGainVec_P.Gain_Gain[0];
  myGainVec_B.Gain_f[1] = rtb_foo * myGainVec_P.Gain_Gain[1];
  myGainVec_B.Gain_f[2] = rtb_foo * myGainVec_P.Gain_Gain[2];
```

See “Explore Variable Names and Loop Rolling” (Simulink Coder) for more information on loop rolling.

Note When a model includes Stateflow charts or MATLAB Function blocks, you can apply a set of Stateflow optimizations on the **Optimization** pane. The settings you select for the Stateflow options also apply to MATLAB Function blocks in the model. This is because the MATLAB Function blocks and Stateflow charts are built on top of the same technology and share a code base. You do not need a Stateflow license to use MATLAB Function blocks.

Use memcpy Function to Optimize Generated Code for Vector Assignments

In this section...

You can use the **Use memcpy for vector assignment** parameter to optimize generated code for vector assignments by replacing `for` loops with `memcpy` function calls. The `memcpy` function is more efficient than `for`-loop controlled element assignment for large data sets. This optimization improves execution speed.

Selecting the **Use memcpy for vector assignment** parameter enables the associated parameter **Memcpy threshold (bytes)**, which allows you to specify the minimum array size in bytes for which `memcpy` function calls should replace `for` loops in the generated code. For more information, see “Use memcpy for vector assignment” (Simulink Coder) and “Memcpy threshold (bytes)” (Simulink Coder). In considering whether to use this optimization,

- Verify that your target supports the `memcpy` function.
- Determine whether your model uses signal vector assignments (such as `Y=expression`) to move large amounts of data, for example, using the Selector block.

To apply this optimization,

1. Consider first generating code without this optimization and measuring its execution speed, to establish a baseline for evaluating the optimized assignment.
2. Select **Use memcpy for vector assignment** and examine the setting of **Memcpy threshold (bytes)**, which by default specifies 64 bytes as the minimum array size for which `memcpy` function calls replace `for` loops. Based on the array sizes used in your application's signal vector assignments, and target environment considerations that might bear on the threshold selection, accept the default or specify another array size.
3. Generate code, and measure its execution speed against your baseline or previous iterations. Iterate on steps 2 and 3 until you achieve an optimal result.

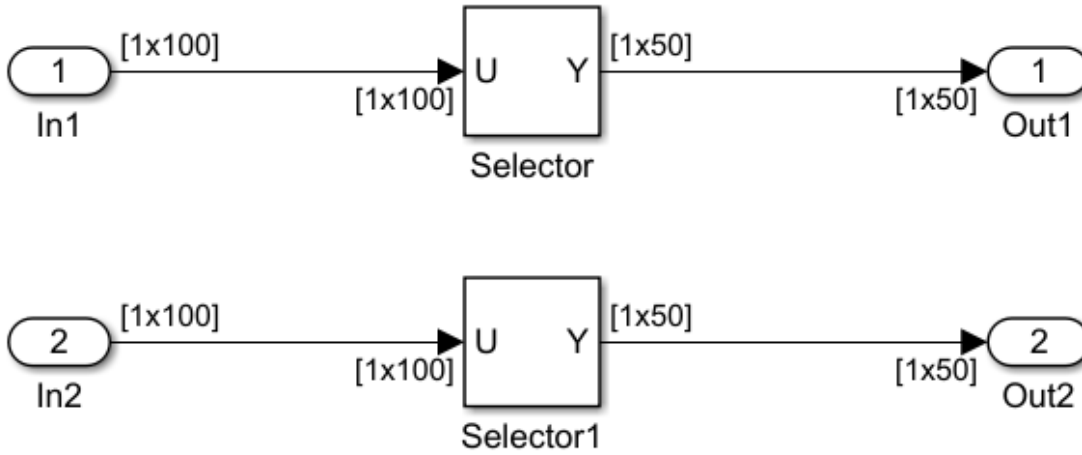
Note The `memcpy` optimization may not occur under certain conditions, including when other optimizations have a higher precedence than the `memcpy` optimization, or when the generated code is originating from Target Language Compiler (TLC) code, such as a TLC file associated with an S-function block.

Note If you are licensed for Embedded Coder software, you can use a code replacement library (CRL) to provide your own custom implementation of the `memcpy` function to be used in generated model code. For more information, see “Memory Function Code Replacement” on page 65-100.

Example Model

To examine the result of using the **Use memcpy for vector assignment** parameter on the generated vector assignment code, create a model that generates signal vector assignments. For example,

1. Use In, Out, and Selector blocks to create the following model.



2. Open Model Explorer and configure the **Signal Attributes** for the `In1` and `In2` source blocks. For each, set **Port dimensions** to `[1,100]`, and set **Data type** to `int32`. Apply the changes and save the model. In this example, the model has the name `vectorassign`.

3 For each Selector block, set the **Index** parameter to `1:50`. Set the **Input port size** parameter to `100`.

Generate Code

1 The **Use memcpy for vector assignment** parameter is on by default. To turn off the parameter, go to the **Optimization** pane and clear the **Use memcpy for vector assignment** parameter.

2 Go to the **Code Generation > Report** pane of the Configuration Parameters dialog box and select the **Create code generation report**. Then go to the **Code Generation** pane, select the **Generate code only** option, and generate code for the model. When code generation completes, the HTML code generation report is displayed.

3 In the HTML code generation report, click the `vectorassign.c` section and inspect the model step function. Notice that the vector assignments are implemented using `for` loops.

```
/* Model step function */
void vectorassign_step(void)
{
  int32_T i;
  for (i = 0; i < 50; i++) {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In1'
     */
    vectorassign_Y.Out1[i] = vectorassign_U.In1[i];

    /* Outport: '<Root>/Out2' incorporates:
     *  Inport: '<Root>/In2'
     */
    vectorassign_Y.Out2[i] = vectorassign_U.In2[i];
  }
}
```

Generate Code with Optimization

1 Go to the **Optimization** pane of the Configuration Parameters dialog box and select the **Use memcpy for vector assignment** option. Leave the **Memcpy threshold (bytes)** option at its default setting of `64`. Apply the changes and regenerate code for the model. When code generation completes, the HTML code generation report again is displayed.

2 In the HTML code generation report, click the `vectorassign.c` section and inspect the model output function. Notice that the vector assignments now are implemented using `memcpy` function calls.

```
/* Model step function */
void vectorassign_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
   */
  memcpy(&vectorassign_Y.Out1[0], &vectorassign_U.In1[0], 50U * sizeof(real_T));

  /* Outport: '<Root>/Out2' incorporates:
   *  Inport: '<Root>/In2'
   */
  memcpy(&vectorassign_Y.Out2[0], &vectorassign_U.In2[0], 50U * sizeof(real_T));
}
```

Generate Target Optimizations Within Algorithm Code

Some application components are hardware-specific and cannot simulate on a host system. For example, consider a component that includes `pragmas` and assembly code for enabling hardware instructions for saturate on add operations or a Fast Fourier Transform (FFT) function.

The following table lists integration options to customize generated algorithm code with target-specific optimizations.

Note Solutions marked with *EC only* require an Embedded Coder license.

If...	Then...	For More Information, See
You want to optimize the execution speed and memory of the model code by replacing default math functions and operators with target-specific code	*EC only*—Implement function and operator replacements by using the **Code Replacement Tool**, code replacement library (CRL) API, and **Code Replacement Viewer** to create, examine, validate, and register hardware-specific replacement tables	"Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®"
You want to control how code generation technology declares, stores, and represents signals, tunable parameters, block states, and data objects in generated code	*EC only*—Design (create) and apply custom storage classes	• `rtwdemo_cscpredef` • `rtwdemo_importstruct` • `rtwdemo_advsc` • "Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements" on page 36-28

Note To simulate an algorithm that includes target-specific elements in a host environment, you must create code that is equivalent to the target code and can run in the host environment.

Remove Code for Blocks That Have No Effect on Computational Results

This example shows how the code generator optimizes generated code by removing code that has no effect on computational results. This optimization:

- Increases execution speed.
- Reduces ROM consumption.

Example

In the model rtwdemo_blockreduction, a Gain block of value `1.0` is in between Inport and Outport blocks.

```
model = 'rtwdemo_blockreduction';
open_system(model);
```

Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
set_param(model,'BlockReduction','off');
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_blockreduction
### Successful completion of build procedure for model: rtwdemo_blockreduction
```

Here is the code from `rtwdemo_blockreduction.c`.

```
cfile = fullfile(cgDir,'rtwdemo_blockreduction_ert_rtw','rtwdemo_blockreduction.c');
rtwdemodbtype(cfile, '/* Model step function */',...
    '/* Model initialize function */', 1, 0);
```

```
/* Model step function */
void rtwdemo_blockreduction_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/In1'
   */
  rtwdemo_blockreduction_Y.Out1 = 1.0 * rtwdemo_blockreduction_U.In1;
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. Select **Block reduction**. This optimization is on by default.

Alternately, use the command-line API to enable the optimization.

```
set_param(model,'BlockReduction','on');
```

Generate Code with Optimization

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_blockreduction
### Successful completion of build procedure for model: rtwdemo_blockreduction
```

Here is the optimized code from `rtwdemo_blockreduction.c`.

```
cfile = fullfile(cgDir,'rtwdemo_blockreduction_ert_rtw','rtwdemo_blockreduction.c');
rtwdemodbtype(cfile, '/* Model step function */',...
    '/* Model initialize function */', 1, 0);
```

```
/* Model step function */
void rtwdemo_blockreduction_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
```

```
   */
  rtwdemo_blockreduction_Y.Out1 = rtwdemo_blockreduction_U.In1;
}
```

Because multiplying the input signal by a value of `1.0` does not impact computational results, the code generator excludes the Gain block from the generated code. Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

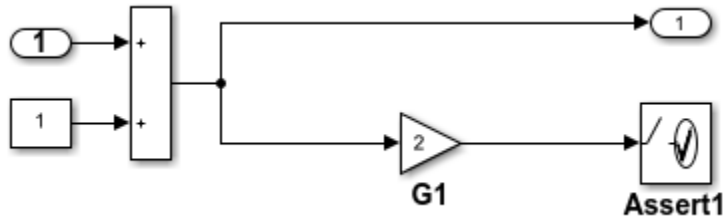
Eliminate Dead Code Paths in Generated Code

This example shows how the code generator eliminates dead (that is, unused) code paths from generated code. This optimization increases execution speed and conserves ROM and RAM consumption.

Example

In the model rtwdemo_deadpathElim, the signal leaving the Sum block divides into two separate code paths. The top path is not a dead code path. If the user disables the Assertion block, the bottom path becomes a dead code path.

```
model = 'rtwdemo_deadpathElim';
open_system(model);
```



Generate Code with an Enabled Assertion Block

1. For the Assertion block, open the block parameters dialog box.
2. Select the **Enable assertion** box. Alternatively, use the command-line API to enable the Assertion block.

```
set_param([model '/Assert1'], 'Enabled', 'on');
```

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_deadpathElim
### Successful completion of build procedure for model: rtwdemo_deadpathElim
```

Because the Assertion block is enabled, these lines of `rtwdemo_deadpathElim.c` include code for the Gain and Assertion blocks.

```
cfile = fullfile(cgDir,'rtwdemo_deadpathElim_grt_rtw','rtwdemo_deadpathElim.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize function */', 0, 1);
```

```
void rtwdemo_deadpathElim_step(void)
{
  /* Sum: '<Root>/Sum1' incorporates:
   *  Constant: '<Root>/Constant1'
   *  Inport: '<Root>/In1'
   */
  rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;

  /* Assertion: '<Root>/Assert1' incorporates:
   *  Gain: '<Root>/G1'
   */
  utAssert(2.0 * rtwdemo_deadpathElim_Y.Out1 != 0.0);
}
```

Generate Code with a Disabled Assertion Block

Disable the Assertion block to generate a dead code path. The code generator detects the dead code path and eliminates it from the generated code.

1. For the Assertion block, open the Block Parameters dialog box.
2. Deselect the **Enable assertion** box.

Alternatively, use the command-line API to disable the Assertion block.

```
set_param([model '/Assert1'], 'Enabled', 'off');
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_deadpathElim
### Successful completion of build procedure for model: rtwdemo_deadpathElim
```

Because the Assertion block is disabled, these lines of `rtwdemo_deadpathElim.c` do not include code for the Gain and Assertion blocks.

```
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize function */', 0, 1);
```

```
void rtwdemo_deadpathElim_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Constant: '<Root>/Constant1'
   *  Inport: '<Root>/In1'
   *  Sum: '<Root>/Sum1'
   */
  rtwdemo_deadpathElim_Y.Out1 = rtwdemo_deadpathElim_U.In1 + 1.0;
}
```

Close the model and clean-up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

For another example of how the code generator eliminates dead code paths in the generated code, see rtwdemo_deadpath.

Floating-Point Multiplication to Handle a Net Slope Correction

This example shows how to use floating-point multiplication to handle a net slope correction. When converting floating-point data types to fixed-point data types in the generated code, a net slope correction is one method of scaling fixed-point data types. Scaling the fixed-point data types avoids overflow conditions and minimizes quantization errors.

For processors that support efficient multiplication, using floating-point multiplication to handle a net slope correction improves code efficiency. If the net slope correction has a value that is not a power of two, using division improves precision.

Note: This example requires a Fixed-Point Designer™ license.

Example

In the model rtwdemo_float_mul_for_net_slope_correction, a Convert block converts an input signal from a floating-point data type to a fixed-point data type. The net slope correction has a value of 3.

```
model = 'rtwdemo_float_mul_for_net_slope_correction';
open_system(model);
```

Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)

### Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
### Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope
```

In these lines of `rtwdemo_float_mul_for_net_slope_correction.c` code, the code generator divides the input signal by `3.0F` .

```
cfile = fullfile(cgDir,'rtwdemo_float_mul_for_net_slope_correction_ert_rtw',...
    'rtwdemo_float_mul_for_net_slope_correction.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
  /* Outport: '<Root>/Output' incorporates:
   *  DataTypeConversion: '<Root>/Data Type Conversion'
   *  Inport: '<Root>/Input'
   */
  rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input / 3.0F));
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Math and Data Types** pane, select **Use floating-point multiplication to handle net slope corrections**. This optimization is on by default.

Alternatively, you can use the command-line API to enable the optimization.

```
set_param(model, 'UseFloatMulNetSlope', 'on');
```

Generate Code with Optimization

```
rtwbuild(model)

### Starting build procedure for model: rtwdemo_float_mul_for_net_slope_correction
### Successful completion of build procedure for model: rtwdemo_float_mul_for_net_slope
```

In the optimized code, the code generator multiplies the input signal by the reciprocal of `3.0F` , that is `0.333333343F` .

```
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_float_mul_for_net_slope_correction_step(void)
{
  /* Outport: '<Root>/Output' incorporates:
   *  DataTypeConversion: '<Root>/Data Type Conversion'
   *  Inport: '<Root>/Input'
   */
  rtY.Output = (int16_T)(real32_T)floor((real_T)(rtU.Input * 0.333333343F));
}
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

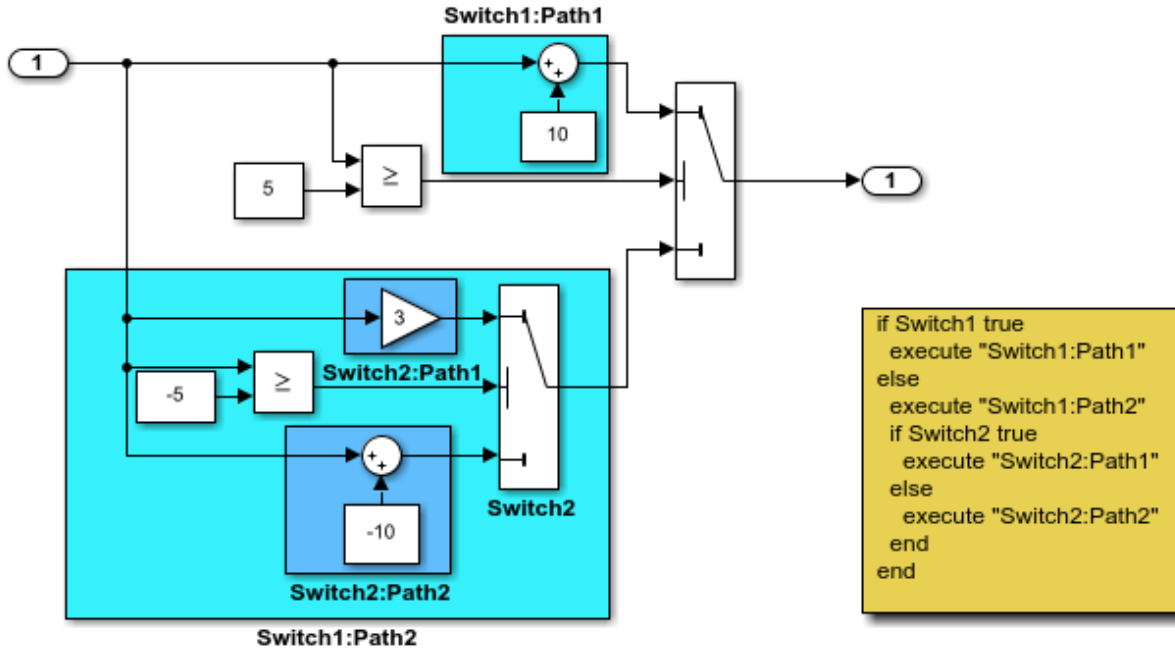
Use Conditional Input Branch Execution

This example shows how to optimize the generated code for a model that contains Switch and Multiport Switch blocks. When you select the model configuration parameter **Conditional input branch execution**, Simulink executes only blocks that compute the control input and data input that the control input selects. This optimization improves execution speed.

Example Model

In this example, switch paths are conditionally executed. If `Switch1` control input is true, `Switch1` executes blocks grouped in the `Switch1:Path1` branch. If `Switch1` control input is false, `Switch1` executes blocks grouped in the `Switch1:Path2` branch. If `Switch1` executes blocks in the `Switch1:Path2` branch and `Switch2` control input is true, `Switch2` executes blocks in the `Switch2:Path1` branch. If `Switch2` control input is false, `Switch2` executes blocks in the `Switch2:Path2` branch. The pseudo code shows this logic.

```
model='rtwdemo_condinput';
open_system(model);
```



This model shows conditional input branch execution performed by Simulink and Simulink Coder. Conditional input branch execution improves simulation and code generation execution performance. In this example, switch paths are conditionally executed. That is, if Switch1's control input is true, Switch1 executes blocks grouped in the "Switch1:Path1" branch. Otherwise, it executes blocks grouped in the "Switch1:Path2" branch. If blocks in "Switch1:Path2" are executed, Switch2 executes the "Switch2:Path1" branch if its control input is true. Otherwise, it executes the "Switch2:Path2" branch. This logic is illustrated by the pseudo code above.

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

Generate Code

The **Conditional input branch execution** parameter is on by default. Enter the following command-line API to turn off the parameter.

```
set_param(model, 'ConditionallyExecuteInputs', 'off');
```

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_condinput
### Successful completion of build procedure for model: rtwdemo_condinput
```

View the generated code without the optimization. These lines of code are in the `rtwdemo_condinput.c` file.

```
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_condinput_step(void)
{
  /* Switch: '<Root>/ Switch2' incorporates:
   *  Constant: '<Root>/ C_10'
   *  Constant: '<Root>/C_5'
   *  Gain: '<Root>/  G3'
   *  Inport: '<Root>/input'
   *  RelationalOperator: '<Root>/Relational Operator'
   *  Sum: '<Root>/ Sum'
   */
  if (rtwdemo_condinput_U.input >= -5.0) {
    rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
  } else {
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
  }

  /* End of Switch: '<Root>/ Switch2' */
```

```
  /* Switch: '<Root>/Switch1' incorporates:
   *  Constant: '<Root>/C5'
   *  Inport: '<Root>/input'
   *  RelationalOperator: '<Root>/Relational Operator1'
   */
  if (rtwdemo_condinput_U.input >= 5.0) {
    /* Outport: '<Root>/output' incorporates:
     *  Constant: '<Root>/  C10'
     *  Sum: '<Root>/ Sum1'
     */
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
  }

  /* End of Switch: '<Root>/Switch1' */
}
```

The generated code contains an `if-else` statement for the `Switch1` block and an `if` statement for the `Switch2` block. Therefore, the generated code for `Switch1:Path2` executes even if the `if` statement for `Switch1:Path1` evaluates to true.

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. Select the **Conditional input branch execution** parameter. Alternatively, you can use the command-line API to enable the optimization.

```
set_param(model, 'ConditionallyExecuteInputs','on');
```

Generate Code with Optimization

```
rtwbuild(model)
cfile = fullfile(cgDir,'rtwdemo_condinput_grt_rtw','rtwdemo_condinput.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);

### Starting build procedure for model: rtwdemo_condinput
### Successful completion of build procedure for model: rtwdemo_condinput

/* Model step function */
void rtwdemo_condinput_step(void)
{
  /* Switch: '<Root>/Switch1' incorporates:
   *  Constant: '<Root>/C5'
   *  Constant: '<Root>/C_5'
   *  Inport: '<Root>/input'
```

```
   *  RelationalOperator: '<Root>/Relational Operator'
   *  RelationalOperator: '<Root>/Relational Operator1'
   *  Switch: '<Root>/ Switch2'
   */
  if (rtwdemo_condinput_U.input >= 5.0) {
    /* Outport: '<Root>/output' incorporates:
     *  Constant: '<Root>/  C10'
     *  Sum: '<Root>/ Sum1'
     */
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + 10.0;
  } else if (rtwdemo_condinput_U.input >= -5.0) {
    /* Switch: '<Root>/ Switch2' incorporates:
     *  Gain: '<Root>/  G3'
     *  Outport: '<Root>/output'
     */
    rtwdemo_condinput_Y.output = 3.0 * rtwdemo_condinput_U.input;
  } else {
    /* Outport: '<Root>/output' incorporates:
     *  Constant: '<Root>/ C_10'
     *  Sum: '<Root>/ Sum'
     *  Switch: '<Root>/ Switch2'
     */
    rtwdemo_condinput_Y.output = rtwdemo_condinput_U.input + -10.0;
  }

  /* End of Switch: '<Root>/Switch1' */
}
```

The generated code contains one `if` statement. The generated code for `Switch1:Path2` only executes if the `if` statement evaluates to false.

Close Model and Code Generation Report

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Optimize Generated Code for Complex Signals

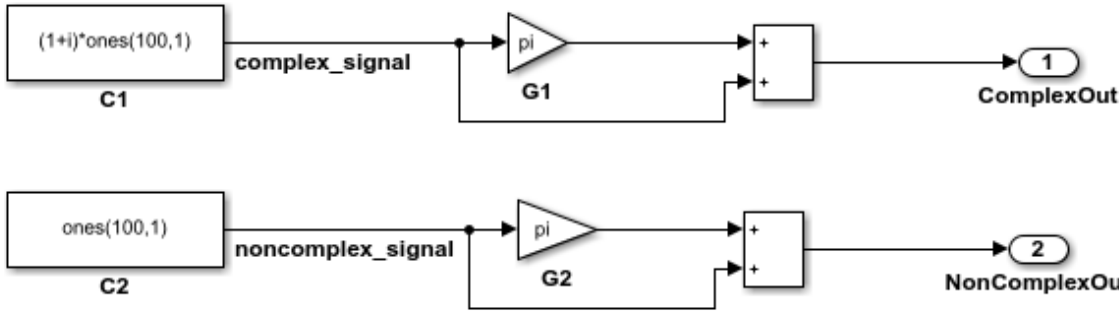
This example shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using **Simulation > Update Diagram**. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example:

- Expression Folding: Gain and Sum operations on the complex signal are folded into a single expression.
- For-loop fusion: Two separate for-loops, one for the complex signal and one for noncomplex signal, are combined into a single for-loop.
- Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

Example Model

```
model='rtwdemo_complex';
open_system(model);
```



This model shows how Simulink Coder handles complex signals efficiently. To view the data types of the signals, update the model using Simulation > Update Diagram. Complex signals are represented as structures in generated code. Simulink Coder performs various optimizations on these structures. For example,

- o Expression folding: Gain and Sum operations on the complex signal are folded into a single expression.
- o For-loop fusion: Two separate for-loops, one for the complex signal and one for the noncomplex signal, are combined into a single for-loop.
- o Inlined block parameters: The value of Gain block "pi" is inlined in the expression of the complex Gain-Sum.

Because of optimizations such as these, the code generated for complex and noncomplex signals is equally efficient.

Speed Up Linear Algebra in Code Generated from a MATLAB Function Block

To improve the execution speed of code generated for certain linear algebra functions in a MATLAB Function block, specify that the code generator produce LAPACK calls. LAPACK is a software library for numerical linear algebra. The code generator uses the LAPACKE C interface to LAPACK. If you specify that you want to generate LAPACK calls, and the input arrays for the linear algebra functions meet certain criteria, the code generator produces the LAPACK calls. Otherwise, the code generator produces code for the linear algebra functions.

The code generator uses the LAPACK library that you specify. Specify a LAPACK library that is optimized for your execution environment. See www.netlib.org/lapack/faq.html#_what_and_where_are_the_lapack_vendors_implementations.

Specify LAPACK Library

To generate LAPACK calls, you must have access to a LAPACK callback class. A LAPACK callback class specifies the LAPACK library and LAPACKE header file for the LAPACK calls. To indicate that you want to generate LAPACK calls and that you want to use a specific LAPACK library, specify the name of the LAPACK callback class. In the Configuration Parameters dialog box, set **Custom LAPACK library callback** to the name of the callback class, for example, `useMyLAPACK`.

Write LAPACK Callback Class

To specify the locations of a particular LAPACK library and LAPACKE header file, write a LAPACK callback class. Share the callback class with others who want to use this LAPACK library for LAPACK calls in generated code.

The callback class must derive from the abstract class `coder.LAPACKCallback`. Use this example callback class as a template.

```
classdef useMyLAPACK < coder.LAPACKCallback
    methods (Static)
        function hn = getHeaderFilename()
            hn = 'mylapacke_custom.h';
        end
        function updateBuildInfo(buildInfo, buildctx)
```

```
            buildInfo.addIncludePaths(fullfile(pwd,'include'));
            libName = 'mylapack';
            libPath = fullfile(pwd,'lib');
            [~,linkLibExt] = buildctx.getStdLibInfo();
            buildInfo.addLinkObjects([libName linkLibExt], libPath, ...
                '', true, true);
            buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
            buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
        end
    end
end
```

You must provide the `getHeaderFilename` and `updateBuildInfo` methods. The `getHeaderFilename` method returns the LAPACKE header file name. In the example callback class, replace `mylapacke_custom.h` with the name of your LAPACKE header file. The `updateBuildInfo` method provides the information required for the build process to link to the LAPACK library. Use code like the code in the template to specify the location of header files and the full path name of the LAPACK library. In the example callback class, replace `mylapack` with the name of your LAPACK library.

If your compiler supports only complex data types that are represented as structures, include these lines in the `updateBuildInfo` method.

```
buildInfo.addDefines('HAVE_LAPACK_CONFIG_H');
buildInfo.addDefines('LAPACK_COMPLEX_STRUCTURE');
```

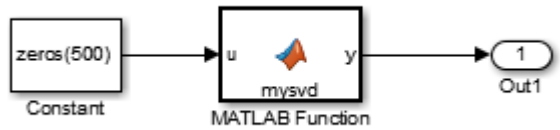
Generate LAPACK Calls by Specifying a LAPACK Callback Class

This example shows how to generate code that calls LAPACK functions in a specific LAPACK library. For this example, assume that the LAPACK callback class `useMyLAPACK` specifies the LAPACK library that you want.

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.
3. In the MATLAB Function block, add code that calls a linear algebra function. For example, add the function `mysvd` that calls the MATLAB function `svd`.

   ```
   function s = mysvd(A)
       %#codegen
       s = svd(A);
   end
   ```
4. Add a Constant block to the left of the MATLAB Function block. Set the value to `zeros(500)`.

5 Add an Outport block to the right of the MATLAB Function block.
6 Connect the blocks.



7 Set the **Configuration Parameters** > **Code Generation** > **Advanced parameters** > **Custom LAPACK library callback** parameter to `useMyLAPACK`.

   The callback class must be on the MATLAB path.
8 Build the model.

If the input to `mysvd` is large enough, the code generator produces a LAPACK call for `svd`. An example of a call to the LAPACK library function for `svd` is:

```
info_t = LAPACKE_dgesvd( ...
     LAPACK_COL_MAJOR, 'N', 'N', (lapack_int)500, ...
     (lapack_int)500, &A[0], (lapack_int)500, &S[0], ...
     NULL, (lapack_int)1, NULL,(lapack_int)1, &superb[0]);
```

Locate LAPACK Library in Execution Environment

The LAPACK library must be available in your execution environment. If your LAPACK library is shared, use environment variables or linker options to specify the location of the LAPACK library.

- On a Windows platform, modify the PATH environment variable.
- On a Linux platform, modify the LD_LIBRARY_PATH environment variable or use the `rpath` linker option.
- On a macOS platform, modify the DYLD_LIBRARY_PATH environment variable or use the `rpath` linker option.

To specify the `rpath` linker option, you can use the build information `addLinkFlags` method in the `updateBuildInfo` method of your `coder.LAPACKCallback` class. For example, for a GCC compiler:

```
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"',libPath));
```

Speed Up Matrix Operations in Code Generated from a MATLAB Function Block

To improve the execution speed of code generated for certain low-level vector and matrix operations (such as matrix multiplication) in a MATLAB Function block, specify that you want the code generator to produce BLAS calls. BLAS is a software library for low-level vector and matrix computations that has several highly optimized machine-specific implementations. The code generator uses the CBLAS C interface to BLAS. If you specify that you want to generate BLAS calls, and the input arrays for the matrix functions meet certain criteria, the code generator produces the BLAS calls. Otherwise, the code generator produces code for the matrix functions.

The code generator uses the BLAS library that you specify. Specify a BLAS library that is optimized for your execution environment.

Specify BLAS Library

To produce BLAS calls in generated code, you must have access to a BLAS callback class. A BLAS callback class specifies the BLAS library, the CBLAS header file, certain C data types the particular CBLAS interface uses and the compiler and linker options for the build process.

To indicate that you want to generate BLAS calls and use a specific BLAS library, specify the name of the BLAS callback class. In the Configuration Parameters dialog box, set **Custom BLAS library callback** to the name of the callback class.

Write BLAS Callback Class

To generate calls to a specific BLAS library in the generated code, write a BLAS callback class. Share the callback class with others who want to use this BLAS library for BLAS calls in standalone code.

The callback class must derive from the abstract class `coder.BLASCallback`. This example is an implementation of the callback class `mklcallback` for integration with the Intel MKL BLAS library on a Windows platform.

```
classdef mklcallback < coder.BLASCallback
    methods (Static)
        function updateBuildInfo(buildInfo, ~)
```

```
            libPath = fullfile(pwd,'mkl','WIN','lib','intel64');
            libPriority = '';
            libPreCompiled = true;
            libLinkOnly = true;
            libs = {'mkl_intel_ilp64.lib' 'mkl_intel_thread.lib' 'mkl_core.lib'};
            buildInfo.addLinkObjects(libs, libPath, libPriority, libPreCompiled, libLi
            buildInfo.addLinkObjects('libiomp5md.lib',fullfile(matlabroot,'bin','win64
                libPriority, libPreCompiled, libLinkOnly);
            buildInfo.addIncludePaths(fullfile(pwd,'mkl','WIN','include'));
            buildInfo.addDefines('-DMKL_ILP64');
        end
        function headerName = getHeaderFilename()
            headerName = 'mkl_cblas.h';
        end
        function intTypeName = getBLASIntTypeName()
            intTypeName = 'MKL_INT';
        end
    end
end
```

You must provide the `getHeaderFilename`, `getBLASIntTypeName`, and `updateBuildInfo` methods. The `getHeaderFilename` method returns the CBLAS header file name. If you are using a different BLAS library, replace `mkl_cblas.h` with the name of your CBLAS header file. The `getBLASIntTypeName` method returns the name of the integer data type that your CBLAS interface uses. If you are using a different BLAS library, replace `MKL_INT` with the name of the integer data type specific to your CBLAS interface. The `updateBuildInfo` method provides the information required for the build process to link to the BLAS library. Use code that is like the code in the example callback class to specify the location of header file, the full path name of the BLAS library, and the compiler and linker options. If you use the Intel MKL BLAS library, use the link line advisor to see which libraries and compiler options are recommended for your use case.

There are three other methods that are already implemented in `coder.BLASCallback`. These methods are `getBLASDoubleComplexTypeName`, `getBLASSingleComplexTypeName`, and `useEnumNameRatherThanTypedef`. By default, your callback class inherits these implementations from `coder.BLASCallback`. In certain situations, you must override these methods with your own definitions when you define your callback class.

The `getBLASDoubleComplexTypeName` method returns the type used for double-precision complex variables in the generated code. If your BLAS library takes a type other than `double*` and `void*` for double-precision complex array arguments, include this method in your callback class definition.

```
function doubleComplexTypeName = getBLASDoubleComplexTypeName()
doubleComplexTypeName = 'my_double_complex_type';
end
```

Replace `my_double_complex_type` with the type that your BLAS library takes for double-precision complex array arguments.

The `getBLASSingleComplexTypeName` method returns the type used for single-precision complex variables in the generated code. If your BLAS library takes a type other than `float*` and `void*` for single-precision complex array arguments, include this method in your callback class definition.

```
function singleComplexTypeName = getBLASSingleComplexTypeName()
doubleComplexTypeName = 'my_single_complex_type';
end
```

Replace `my_single_complex_type` with the type that your BLAS library takes for single-precision complex array arguments.

The `useEnumNameRatherThanTypedef` method returns `false` by default. If types for enumerations in your BLAS library include the `enum` keyword, redefine this method to return `true` in your callback class definition.

```
function p = useEnumNameRatherThanTypedef()
p = true;
end
```

An excerpt from generated C source code that includes the `enum` keyword is:

```
enum CBLAS_SIDE t;
enum CBLAS_UPLO b_t;
double temp;
enum CBLAS_TRANSPOSE c_t;
enum CBLAS_DIAG d_t;
```

Generate BLAS Calls by Specifying a BLAS Callback Class

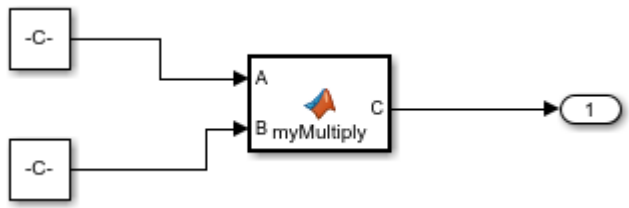
This example shows how to generate code that calls BLAS functions in a specific BLAS library. The BLAS callback class `useMyBLAS` specifies the BLAS library that you want to use in this example.

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.

3. In the MATLAB Function block, add code that calls a function for a basic matrix operation. For example, add the function `myMultiply` that multiplies two matrices `A` and `B`.

   ```
   function C = myMultiply(A,B) %#codegen
   C = A*B;
   end
   ```

4. Add two Constant blocks to the left of the MATLAB Function block. Set their values to `zeros(1000)`.
5. Add an Outport block to the right of the MATLAB Function block.
6. Connect the blocks.



7. In the Configuration Parameters dialog box, set **Custom BLAS library callback** to the name of the callback class `useMyBLAS`.

   The callback class must be on the MATLAB path.
8. Build the model.

   If `A` and `B` are large enough, the code generator produces a BLAS call for the matrix multiplication function.

Locate BLAS Library in Execution Environment

The BLAS library must be available in your execution environment. If your BLAS library is shared, use environment variables or linker options to specify the location of the BLAS library.

- On a Windows platform, modify the PATH environment variable.
- On a Linux platform, modify the LD_LIBRARY_PATH environment variable or use the `rpath` linker option.
- On a macOS platform, modify the DYLD_LIBRARY_PATH environment variable or use the `rpath` linker option.

To specify the `rpath` linker option, use the build information `addLinkFlags` method in the `updateBuildInfo` method of your BLAS callback class. For example, for a GCC compiler:

```
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"',libPath));
```

Usage Notes and Limitations for OpenBLAS Library

If you generate code that includes calls to the OpenBLAS library functions, follow these guidelines and restrictions:

- If you generate C++ code that includes calls to OpenBLAS library functions, compiling it with the `-pedantic` option produces warnings. To disable the `-pedantic` compiler option, include these lines in the `updateBuildInfo` method:

  ```
  if ctx.getTargetLang() == 'C++'
      buildInfo.addCompileFlags('-Wno-pedantic');
  end
  ```

- OpenBLAS does not support the C89/C90 standard.

Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block

This example shows how to generate calls to a specific installed FFTW library. For more information about FFTW, see www.fftw.org.

When you simulate a model that includes a MATLAB Function block that calls MATLAB fast Fourier transform (FFT) functions, the simulation software uses the library that MATLAB uses for FFT algorithms. If you generate C/C++ code for this model, by default, the code generator produces code for the FFT algorithms instead of producing FFT library calls. To increase the speed of fast Fourier transforms in generated code, specify that the code generator produce calls to a specific installed FFTW library.

The code generator produces FFTW library calls when all of these conditions are true:

- A MATLAB Function block calls one of these MATLAB functions:`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`.
- You generate C/C++ code from a model that includes the MATLAB Function block.
- You have access to an FFTW library installation, version 3.2 or later.
- You specify the FFTW library installation in an FFT library callback class that derives from `coder.fftw.StandaloneFFTW3Interface`.
- You set the **Custom FFT library callback** configuration parameter to the name of the callback class.

Install an FFTW Library

If you do not have access to an installed FFTW library, version 3.2 or later, then you must install one.

For a Linux platform or a Mac platform, consider using a package manager to install the FFTW library.

For a Windows platform, in addition to `.dll` files, you must have `.lib` import libraries, as described in the Windows installation notes on the FFTW website.

See the installation instructions for your platform on the FFTW website.

Write FFT Callback Class

To specify your installation of the FFTW library, write an FFT callback class. Share the callback class with others who want to use this FFTW library for FFTW calls.

The callback class must derive from the abstract class `coder.fftw.StandaloneFFTW3Interface`. Use this example callback class as a template.

```
% copyright 2017 The MathWorks, Inc.

classdef useMyFFTW < coder.fftw.StandaloneFFTW3Interface

    methods (Static)
        function th = getNumThreads
            coder.inline('always');
            th = int32(coder.const(1));
        end

        function updateBuildInfo(buildInfo, ctx)
            fftwLocation = '/usr/lib/fftw';
            includePath = fullfile(fftwLocation, 'include');
            buildInfo.addIncludePaths(includePath);
            libPath = fullfile(fftwLocation, 'lib');

            %Double
            libName1 = 'libfftw3-3';
            [~, libExt] = ctx.getStdLibInfo();
            libName1 = [libName1 libExt];
            addLinkObjects(buildInfo, libName1, libPath, 1000, true, true);

            %Single
             libName2 = 'libfftw3f-3';
            [~, libExt] = ctx.getStdLibInfo();
            libName2 = [libName2 libExt];
            addLinkObjects(buildInfo, libName2, libPath, 1000, true, true);
        end
    end
end
```

Implement the `updateBuildInfo` and `getNumThreads` methods. In the `updateBuildInfo` method, set `fftwLocation` to the full path for your installation of the library. Set `includePath` to the full path of the folder that contains `fftw3.h`. Set `libPath` to the full path of the folder that contains the library files. If your FFTW installation uses multiple threads, modify the `getNumThreads` method to return the number of threads that you want to use.

Optionally, you can implement these methods:

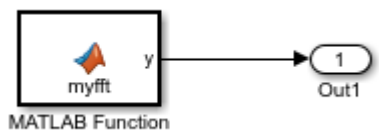
- `getPlanMethod` to specify the FFTW planning method. See `coder.fftw.StandaloneFFTW3Interface`.
- `lock` and `unlock` to synchronize multithreaded access to the FFTW planning process. See “Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block” (Simulink Coder).

Generate FFTW Calls by Specifying an FFT Callback Class

1. Create a Simulink model.
2. Add a MATLAB Function block to the model.
3. In the MATLAB Function block, add code that calls a MATLAB FFT function. For example, add the function `myfft` that calls the MATLAB function `fft`.

```
function y = myfft()
t = 0:1/50:10-1/50;
x = sin(2*pi*15*t) + sin(2*pi*20*t);
y = fft(x);
end
```

4. Connect the blocks.



5. Indicate that the code generator produce calls to the FFTW library specified in the FFT library callback class `useMyFFTW`. In the Configuration Parameters dialog box, set **Custom FFT library callback** to `useMyFFTW`.

   The callback class must be on the MATLAB path.
6. Build the model.

Locate FFTW Library in Execution Environment

The FFTW library must be available in your execution environment. If the FFTW library is shared, use environment variables or linker options to specify the location of the library.

- On a Windows platform, modify the PATH environment variable.
- On a Linux platform, modify the LD_LIBRARY_PATH environment variable or use the `rpath` linker option.

- On a macOS platform, modify the DYLD_LIBRARY_PATH environment variable or use the `rpath` linker option.

To specify the `rpath` linker option, you can use the build information `addLinkFlags` method in the `updateBuildInfo` method of your `coder.fftw.StandaloneFFTW3Interface` class. For example, for a GCC compiler:

```
buildInfo.addLinkFlags(sprintf('-Wl,-rpath,"%s"',libPath));
```

Synchronize Multithreaded FFTW Planning in Code Generated from a MATLAB Function Block

This example shows how to generate code that synchronizes multithreaded access to the FFTW planning process for FFTW library calls in code generated from a MATLAB Function block.

The code generator produces FFTW library calls when all of these conditions are true:

- A MATLAB Function block calls one of these functions:`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, or `ifftn`.
- You generate C/C++ code for a model that includes the MATLAB Function block.
- You have access to an FFTW library installation, version 3.2 or later.
- You specify the FFTW library installation in an FFT library callback class that derives from `coder.fftw.StandaloneFFTW3Interface`.
- You set the **Custom FFT library callback** configuration parameter to the name of the callback class.

If you integrate the code that contains the FFTW calls with external code that runs on multiple threads, then you must prevent concurrent access to the FFTW planning process. In your FFT library callback class, implement the `lock` and `unlock` methods. You must also provide C code that manages a lock or mutex. Many libraries, such as OpenMP, pthreads, and the C++ standard library (C++ 11 and later), provide locks. This example shows how to implement the `lock` and `unlock` methods and provide supporting C code. To manage a lock, this example uses the OpenMP library.

Prerequisites

Before you start, for the basic workflow for generating FFTW library calls for fast Fourier transforms in a MATLAB Function block, see “Speed Up Fast Fourier Transforms in Code Generated from a MATLAB Function Block” (Simulink Coder).

You must have:

- Access to an installed FFTW library.
- A compiler that supports the OpenMP library. To use a different library, such as pthreads, modify the supporting C code accordingly.

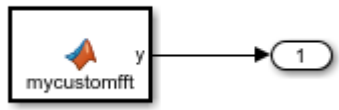
Create a Model with a MATLAB Function Block That Calls an FFT Function

1. Create a Simulink model and add a MATLAB Functon block to it.
2. Add this code to the MATLAB Function block.

```
function y  = mycustomfft()

t = 0:1/50:10-1/50;
x = sin(2*pi*15*t) + sin(2*pi*20*t);
y = fft(x);
for k = 1:100
    y = y + ifft(x+k);
end
```

3. Add an `outport` block and connect it to the MATLAB Function block.



Write Supporting C Code

Write C functions that initialize, set, and unset a lock. This example uses the OpenMP library to manage the lock. For a different library, modify the code accordingly.

- Create a file `mylock.c` that contains this C code:

```
#include "mylock.h"
#include "omp.h"

static omp_nest_lock_t lockVar;

void mylock_initialize(void)
{
    omp_init_nest_lock(&lockVar);
}

void mylock(void)
```

```
{
    omp_set_nest_lock(&lockVar);
}

void myunlock(void)
{
    omp_unset_nest_lock(&lockVar);
}
```

- Create a header file `mylock.h` that contains:

```
#ifndef MYLOCK_H
#define MYLOCK_H

 void mylock_initialize(void);
 void mylock(void);
 void myunlock(void);

#endif
```

Create an FFT Library Callback Class

Write an FFT callback class `myfftcb` that:

- Specifies the FFTW library.
- Implements `lock` and `unlock` methods that call the supporting C code to control access to the FFTW planning.

Use this class as a template. Replace `fftwLocation` with the location of your FFTW library installation.

```
classdef myfftcb < coder.fftw.StandaloneFFTW3Interface

    methods (Static)
        function th = getNumThreads
            coder.inline('always');
            th = int32(coder.const(1));
        end

        function lock()
            coder.cinclude('mylock.h', 'InAllSourceFiles', true);
            coder.inline('always');
            coder.ceval('mylock');
        end
```

```
        function unlock()
            coder.cinclude('mylock.h', 'InAllSourceFiles', true);
            coder.inline('always');
            coder.ceval('myunlock');
        end

        function updateBuildInfo(buildInfo, ctx)
            fftwLocation = '\usr\lib\fftw';
            includePath = fullfile(fftwLocation, 'include');
            buildInfo.addIncludePaths(includePath);
            libPath = fullfile(fftwLocation, 'lib');

            %Double
            libName1 = 'libfftw3-3';
            [~, libExt] = ctx.getStdLibInfo();
            libName1 = [libName1 libExt];
            addLinkObjects(buildInfo, libName1, libPath, 1000, true, true);

            %Single
            libName2 = 'libfftw3f-3';
            [~, libExt] = ctx.getStdLibInfo();
            libName2 = [libName2 libExt];
            addLinkObjects(buildInfo, libName2, libPath, 1000, true, true);

        end
    end
end
```

Configure Code Generation Parameters and Build the Model

1 Configure code generation to use the FFTW callback class and the C code called by the `lock` and `unlock` methods. Configure code generation to generate a call to `mylock_initialize` in the initialization code.

   In the Configuration Parameters dialog box:

   - Set **Custom FFT library callback** to `myfftcb`.
   - In **Code Generation > Custom Code**, under **Additional build information**, set **Source files** to `mylock.c`.
   - In **Code Generation > Custom Code**, under **Insert custom C code in generated**, set **Initialize function** to `mylock_initialize();`.

2 Build the model.

Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays on page 67-99.
- Disable dynamic memory allocation for MATLAB Function blocks on page 67-100.
- Modify the dynamic memory allocation threshold on page 67-100.

Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays” (Simulink).

Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, clear or select **Dynamic memory allocation in MATLAB functions**.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, set the **Dynamic memory allocation threshold in MATLAB functions** parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to `0`.

Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter **Application lifespan (days)**, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

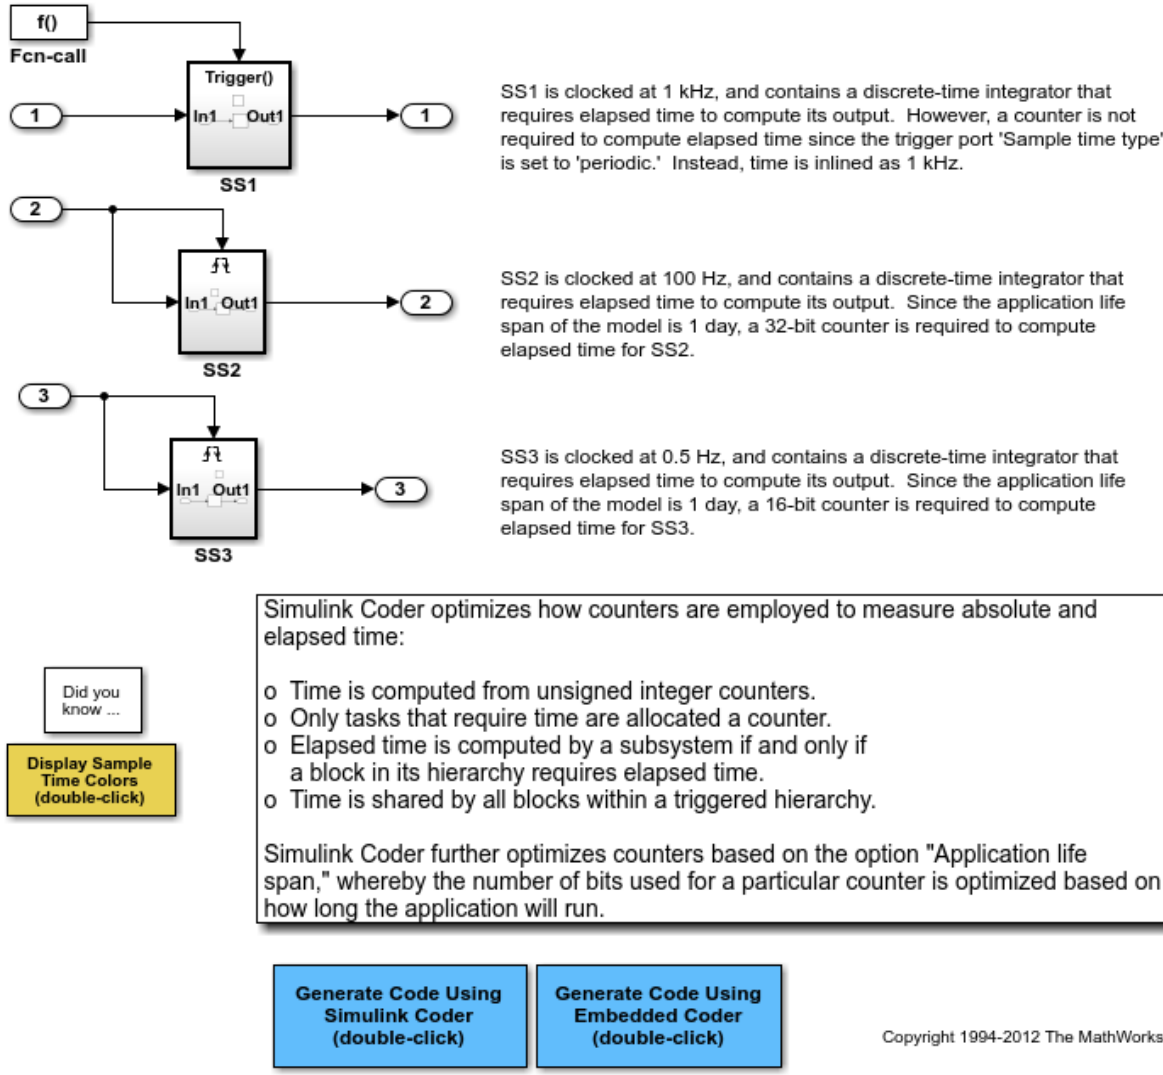
The number of bits that a time counter uses depends on the setting of the **Application lifespan (days)** parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

Open Example Model

Open the example model `rtwdemo_abstime`.



The model consists of three subsystems `SS1`, `SS2`, and `SS3`. On the **Math and Data Types** pane, the **Application lifespan (days)** parameter is set to the default, which is `inf`.

The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to `periodic`. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

Generate Code and Report

1. Create a temporary folder for the build and inspection process.

2. Configure the model for the code generator to use the GRT system target file and a lifespan of `inf` days.

3. Build the model.

```
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

Review Generated Code

Open the generated source file `rtwdemo_abstime.c`.

```
struct tag_RTM_rtwdemo_abstime_T {
  const char_T *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
```

```
    uint32_T clockTickH1;
    uint32_T clockTick2;
    uint32_T clockTickH2;
    struct {
      uint16_T TID[3];
      uint16_T cLimit[3];
    } TaskCounters;
  } Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model.  The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model.  For example,
 *
 * hilite_system('<S3>')    - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtwdemo_abstime'
 * '<S1>'   : 'rtwdemo_abstime/SS1'
 * '<S2>'   : 'rtwdemo_abstime/SS2'
```

```
 * '<S3>'   : 'rtwdemo_abstime/SS3'
 */
#endif                                 /* RTW_HEADER_rtwdemo_abstime_h_ */
```

Four 32-bit unsigned integers, `clockTick1` , `clockTickH1` , `clockTick2` , and `clockTickH2` are counters for storing the elapsed time of subsystems `SS2` and `SS3`.

Enable Optimization and Regenerate Code

1. Reconfigure the model to set the lifespan to 1 day.

2. Build the model.

```
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

Review the Regenerated Code

```
struct tag_RTM_rtwdemo_abstime_T {
  const char_T *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
    uint16_T clockTick2;
    struct {
      uint16_T TID[3];
      uint16_T cLimit[3];
    } TaskCounters;
  } Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;
```

```
/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model.  The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model.  For example,
 *
 * hilite_system('<S3>')    - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtwdemo_abstime'
 * '<S1>'   : 'rtwdemo_abstime/SS1'
 * '<S2>'   : 'rtwdemo_abstime/SS2'
 * '<S3>'   : 'rtwdemo_abstime/SS3'
 */
#endif                                 /* RTW_HEADER_rtwdemo_abstime_h_ */
```

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for `SS2`
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for `SS3`

Optimize Generated Code Using Boolean Data for Logical Signals

Optimize generated code by storing logical signals as Boolean data. When you select the model configuration parameter **Implement logic signals as Boolean data (vs. double)**, blocks that generate logic signals output Boolean signals.

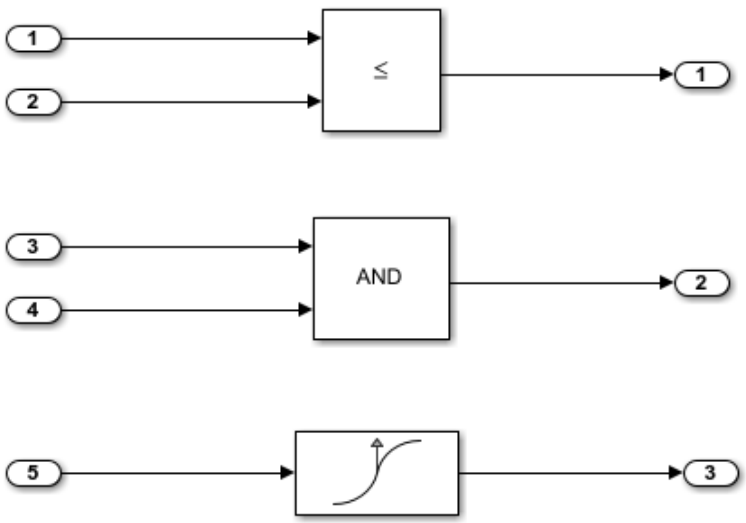
The optimization:

- Reduces the ROM and RAM consumption.
- Improves execution speed.

Example Model

Consider the model rtwdemo_logicalAsBoolean. The outputs of the `Relational Operator`, `Logical Operator` and `HitCrossing` blocks are `double`, even though they represent logical data.

```
model = 'rtwdemo_logicalAsBoolean';
open_system(model);
```



Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_logicalAsBoolean
### Successful completion of build procedure for model: rtwdemo_logicalAsBoolean
```

View the generated code without the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_logicalAsBoolean_ert_rtw',...
    'rtwdemo_logicalAsBoolean.h');
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (default storage) */',1,0);
```

```
/* External outputs (root outports fed by signals with default storage) */
typedef struct {
  real_T Out1;                         /* '<Root>/Out1' */
  real_T Out2;                         /* '<Root>/Out2' */
  real_T Out3;                         /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. Select the **Implement logic signals as Boolean data (vs. double)** parameter.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'BooleanDataType','on');
```

Generate Code with Optimization

The generated code stores the logical signal output as Boolean data.

Build the model.

```
rtwbuild(model)

### Starting build procedure for model: rtwdemo_logicalAsBoolean
### Successful completion of build procedure for model: rtwdemo_logicalAsBoolean
```

View the generated code with the optimization. These lines of code are in `rtwdemo_logicalAsBoolean.h`.

```
rtwdemodbtype(hfile,'/* External outputs','/* Parameters (default storage) */',1,0);

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
  boolean_T Out1;                      /* '<Root>/Out1' */
  boolean_T Out2;                      /* '<Root>/Out2' */
  boolean_T Out3;                      /* '<Root>/Out3' */
} ExtY_rtwdemo_logicalAsBoolean_T;
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Reduce Memory Usage for Boolean and State Configuration Variables

1. Open the Model Configuration Parameters dialog box.
2. In the Model Configuration Parameters dialog box, select the **Optimization** pane.
3. Choose from these options:

   - **Use bitsets for storing state configuration** — Reduces the amount of memory that stores state configuration variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.
   - **Use bitsets for storing Boolean data** — Reduces the amount of memory that stores Boolean variables. However, it can increase the amount of memory that stores target code if the target processor does not include instructions for manipulating bitsets.

   Note You cannot use bitsets when you generate code for these cases:

   - An external mode simulation
   - A target that specifies an explicit structure alignment

Customize Stack Space Allocation

Your application might be constrained by limited memory. Controlling the maximum allowable size for the stack is one way to modify whether data is defined as local or global in the generated code. You can limit the use of stack space by specifying a positive integer value for the “Maximum stack size (bytes)” (Simulink Coder) parameter, on the **Optimization** pane of the Configuration parameter dialog box. Specifying the maximum allowable stack size provides control over the number of local and global variables in the generated code. Specifically, lowering the maximum stack size might generate more variables into global structures. The number of local and global variables help determine the required amount of stack space for execution of the generated code.

The default setting for “Maximum stack size (bytes)” (Simulink Coder) is `Inherit from target`. In this case, the value of the maximum stack size is the smaller value of the following: the default value set by the code generator (200,000 bytes) or the value of the TLC variable `MaxStackSize` found in the system target file (`ert.tlc`).

To specify a smaller stack size for your application, select the `Specify a value` option of the **Maximum stack size (bytes)** parameter and enter a positive integer value. To specify a smaller stack size at the command line, use:

```
set_param(model_name, 'MaxStackSize', 65000);
```

Note For overall executable stack usage metrics, you might want to do a target-specific measurement, such as using runtime (empirical) analysis or static (code path) analysis with object code.

It is recommended that you use the **Maximum stack size (bytes)** parameter to control stack space allocation instead of modifying the TLC variable, `MaxStackSize`, in the system target file. However, a target author might want to set the TLC variable, `MaxStackSize`, for a target. To set `MaxStackSize`, use `assign` statements in the system target file (`ert.tlc`), as in the following example.

```
%assign MaxStackSize = 4096
```

Write your `%assign` statements in the `Configure RTW code generation settings` section of the system target file. The `%assign` statement is described in “Target Language Compiler” (Simulink Coder).

Optimize Generated Code Using memset Function

This example shows how to optimize the generated code by using the `memset` function to clear the internal storage. When you select the model configuration parameter **Use memset to initialize floats and doubles to 0.0**, the `memset` function clears internal storage, regardless of type, to the integer bit pattern `0` (that is, all bits are off).

If your compiler and target CPU both represent floating-point zero with the integer bit pattern `0`, consider setting this parameter to gain execution and ROM efficiency.

NOTE: The command-line values are the reverse of the settings values. 'on' in the command line corresponds to clearing the setting. `'off'` in the command line corresponds to selecting the setting.

This optimization:

- Reduces ROM consumption.
- Improves execution speed.

Example Model

Consider the model matlab:rtwdemo_memset.

```
model = 'rtwdemo_memset';
open_system(model);
```

Generate Code

The code generator uses a loop to initialize the `Constant` block values.

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_memset
### Successful completion of build procedure for model: rtwdemo_memset
```

View the generated code without the optimization. These lines of code are in `rtwdemo_memset.c`.

```
cfile = fullfile(cgDir,'rtwdemo_memset_grt_rtw','rtwdemo_memset.c');
rtwdemodbtype(cfile,'/* Model initialize function */',...
    '/* Model terminate function */',1,0);
```

```
/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

  /* external outputs */
  {
    int32_T i;
    for (i = 0; i < 50; i++) {
      rtwdemo_memset_Y.Out1[i] = 0.0;
    }
  }

  {
    int32_T i;

    /* ConstCode for Outport: '<Root>/Out1' */
    for (i = 0; i < 50; i++) {
      rtwdemo_memset_Y.Out1[i] = 56.0;
    }

    /* End of ConstCode for Outport: '<Root>/Out1' */
  }
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. In the Configuration Parameter dialog box select the the **Use memset to initialize floats and doubles to 0.0** parameter. Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'InitFltsAndDblsToZero','off');
```

```
% # Open the Configuration Parameters dialog box.
```

Generate Code with Optimization

The code generator uses the `memset` function to initialize the `Constant` block values.

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_memset
### Successful completion of build procedure for model: rtwdemo_memset
```

View the generated code with the optimization. These lines of code are in `rtwdemo_memset.c`.

```
rtwdemodbtype(cfile,'/* Model initialize function */',...
    '/* Model terminate function */',1,0);
```

```
/* Model initialize function */
void rtwdemo_memset_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtwdemo_memset_M, (NULL));

  /* external outputs */
  (void) memset(&rtwdemo_memset_Y.Out1[0], 0,
                50U*sizeof(real_T));

  {
    int32_T i;

    /* ConstCode for Outport: '<Root>/Out1' */
```

```
    for (i = 0; i < 50; i++) {
      rtwdemo_memset_Y.Out1[i] = 56.0;
    }

    /* End of ConstCode for Outport: '<Root>/Out1' */
  }
}
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

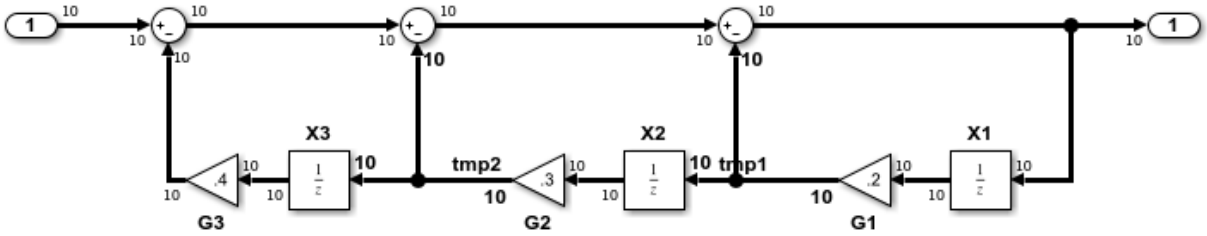
Vector Operation Optimization

This example shows how Simulink® Coder™ optimizes generated code by setting block output that generates vectors to scalars, for blocks such as the Mux, Sum, Gain, and Bus. This optimization reduces stack memory by replacing temporary local arrays with local variables.

Example Model

In the model, rtwdemo_VectorOptimization, the output of Gain blocks `G1` and `G2` are the vector signals `tmp1` and `tmp2`. These vectors have a width of 10.

```
model = 'rtwdemo_VectorOptimization';
open_system(model);
set_param(model, 'SimulationCommand', 'update')
```



Generate Code

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_VectorOptimization
### Successful completion of build procedure for model: rtwdemo_VectorOptimization
```

The optimized code is in `rtwdemo_VectorOptimization.c`. The signals `tmp1` and `tmp2` are the local variables `rtb_tmp1` and `rtb_tmp2`.

```
cfile = fullfile(cgDir,'rtwdemo_VectorOptimization_grt_rtw',...
    'rtwdemo_VectorOptimization.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_VectorOptimization_step(void)
{
  int32_T i;
  real_T rtb_tmp2;
  real_T rtb_tmp1;
  real_T rtb_Sum3;
  for (i = 0; i < 10; i++) {
    /* Gain: '<Root>/G2' incorporates:
     *  UnitDelay: '<Root>/X2'
     */
    rtb_tmp2 = 0.3 * rtwdemo_VectorOptimization_DW.X2_DSTATE[i];

    /* Gain: '<Root>/G1' incorporates:
     *  UnitDelay: '<Root>/X1'
     */
    rtb_tmp1 = 0.2 * rtwdemo_VectorOptimization_DW.X1_DSTATE[i];

    /* Sum: '<Root>/Sum3' incorporates:
     *  Gain: '<Root>/G3'
     *  Inport: '<Root>/In2'
     *  Sum: '<Root>/Sum1'
     *  Sum: '<Root>/Sum2'
     *  UnitDelay: '<Root>/X3'
     */
    rtb_Sum3 = ((rtwdemo_VectorOptimization_U.In2[i] - 0.4 *
                 rtwdemo_VectorOptimization_DW.X3_DSTATE[i]) - rtb_tmp2) -
      rtb_tmp1;

    /* Outport: '<Root>/Out2' */
    rtwdemo_VectorOptimization_Y.Out2[i] = rtb_Sum3;

    /* Update for UnitDelay: '<Root>/X3' */
    rtwdemo_VectorOptimization_DW.X3_DSTATE[i] = rtb_tmp2;
```

```
    /* Update for UnitDelay: '<Root>/X2' */
    rtwdemo_VectorOptimization_DW.X2_DSTATE[i] = rtb_tmp1;

    /* Update for UnitDelay: '<Root>/X1' */
    rtwdemo_VectorOptimization_DW.X1_DSTATE[i] = rtb_Sum3;
  }
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

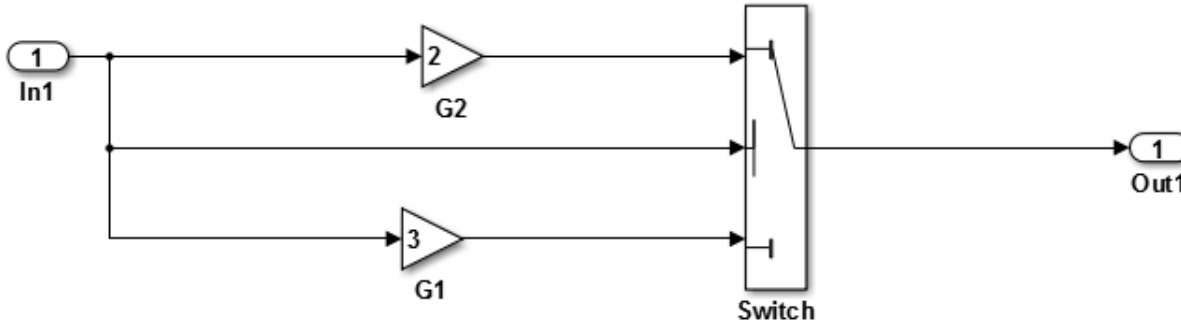
Enable and Reuse Local Block Outputs in Generated Code

In this section...

This example shows how to specify block output as local variables. The code generator can potentially reuse these local variables in the generated code. Declaring block output as local variables conserves ROM consumption. Reusing local variables conserves RAM consumption, reduces data copies, and increases execution speed.

Example Model

1. Use Inport, Outport, Gain, and Switch blocks to create the following model. In this example, the model is named `local_variable_ex`.



2. For `G2`, open the Gain Block Parameters dialog box. Enter a value of `2`.
3. For `G1`, enter a value of `3`.
4. For the Switch block, open the Block Parameters dialog box. For the **Criteria for passing first input** parameter, select `u2>=Threshold`.

Generate Code Without Optimization

1. Open the Model Configuration Parameters dialog box. Select the **Solver** pane. For the **Type** parameter, select `Fixed-step`.
2. Clear the **Configuration Parameters > Signal storage reuse** parameter.
3. Select the **Code Generation > Report** pane and select **Create code generation report**.
4. Select the **Code Generation** pane. Select **Generate code only**, and then, in the model window, press **Ctrl+B**. When code generation is complete, an HTML code generation report appears.
5. In the code generation report, select the `local_variable_ex.c` section and view the model step function. The Gain block outputs are the global variables `local_variable_ex_B.G2` and `local_variable_ex_B.G1`.

```
/* Model step function */
void local_variable_ex_step(void)
{
  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (local_variable_ex_U.In1 >= 0.0) {
    /* Gain: '<Root>/G2' */
    local_variable_ex_B.G2 = 2.0 * local_variable_ex_U.In1;

    /* Outport: '<Root>/Out1' */
    local_variable_ex_Y.Out1 = local_variable_ex_B.G2;
  } else {
    /* Gain: '<Root>/G1' */
    local_variable_ex_B.G1 = 3.0 * local_variable_ex_U.In1;

    /* Outport: '<Root>/Out1' */
    local_variable_ex_Y.Out1 = local_variable_ex_B.G1;
  }

  /* End of Switch: '<Root>/Switch' */
```

Enable Local Block Outputs and Generate Code

1. Select the **Configuration Parameters > Signal Storage Reuse** parameter. The **Signal Storage Reuse** enables the following optimization parameters:

- **Enable local block outputs**
- **Reuse local block outputs**
- **Eliminate superfluous local variables (expression folding)**

2. Clear **Reuse local block outputs** and **Eliminate superfluous local variables (expression folding)**.
3. Generate code and view the model step function. There are three local variables in the model step function because you selected the optimization parameter **Enable Local Block Outputs**. The local variables `rtb_G2` and `rtb_G1` hold the outputs of the Gain blocks. The local variable `rtb_Switch` holds the output of the Switch block.

```
/* Model step function */
void local_variable_ex_step(void)
{
  real_T rtb_Switch;
  real_T rtb_G2;
  real_T rtb_G1;

  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (local_variable_ex_U.In1 >= 0.0) {
    /* Gain: '<Root>/G2' */
    rtb_G2 = 2.0 * local_variable_ex_U.In1;
    rtb_Switch = rtb_G2;
  } else {
    /* Gain: '<Root>/G1' */
    rtb_G1 = 3.0 * local_variable_ex_U.In1;
    rtb_Switch = rtb_G1;
  }

  /* End of Switch: '<Root>/Switch' */

  /* Outport: '<Root>/Out1' */
  local_variable_ex_Y.Out1 = rtb_Switch;
```

Reuse Local Block Outputs and Generate Code

1. Select the **Configuration Parameters** > **Reuse local block outputs** parameter.
2. Generate code. In the `local_variable_ex.c` section, view the model step function. There is one local variable, `rtb_G2`, that the code generator uses three times.

```
/* Model step function */
void local_variable_ex_step(void)
{
  real_T rtb_G2;

  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  if (local_variable_ex_U.In1 >= 0.0) {
    /* Gain: '<Root>/G2' */
    rtb_G2 = 2.0 * local_variable_ex_U.In1;
  } else {
    /* Gain: '<Root>/G1' */
    rtb_G2 = 3.0 * local_variable_ex_U.In1;
  }

  /* End of Switch: '<Root>/Switch' */

  /* Outport: '<Root>/Out1' */
  local_variable_ex_Y.Out1 = rtb_G2;
```

The extra temporary variable `rtb_Switch` and the associated data copy is not in the generated code.

Configuration in Embedded Coder

Set Hardware Implementation Parameters

Specification of target hardware device characteristics (such as word sizes for `char`, `short`, `int`, and `long` data types, or desired rounding behaviors in integer operations) for generated code can be critical in embedded systems development. The **Hardware Implementation** category of parameters in a configuration set provides a way to control such characteristics in simulation and code generation.

By configuring the **Hardware Implementation** parameters of the active configuration set for a model to match the behaviors of your compiler and hardware, you can generate more efficient code. For example, if you specify the **Byte ordering** parameter, you can avoid generation of extra code that tests the byte ordering of the target CPU.

Before generating and deploying code, get familiar with the **Hardware Implementation** pane of the Configuration Parameters dialog box. By default, target hardware microprocessor device details are hidden. To view the details, click the **Device details** arrow. See “Hardware Implementation Pane” (Simulink) and “Configure Run-Time Environment Options” (Simulink Coder) for more information.

You can use the example “Configure Target Hardware Characteristics” on page 53-13 to determine characteristics of your C or C++ compiler and target hardware. By using the example model with your target development system and debugger, you can observe the behavior of the code as it executes on the target hardware. You can then use the information to refine hardware target device parameters for your model.

Data Copy Reduction in Embedded Coder

Optimize Global Variable Usage

In this section...

To tune your application and choose tradeoffs for execution speed and memory usage, you can choose a global variable reference optimization for the generated code.

On the Configuration Parameters dialog box, in the **Optimize global data access** drop-down list, three parameter options control global variable usage optimizations.

- `None`. Use default optimizations. This choice works well for most models. The code generator balances the use of local and global variables. It generates code which balances RAM and ROM consumption and execution speed.
- `Use global to hold temporary results`. Reusing global variables improves code efficiency and readability. This optimization reuses global variables, which results in the code generator defining fewer variables. It reduces RAM and ROM consumption and data copies.
- `Minimize global data access`. Using local variables to cache global data reduces ROM consumption by reducing code size. This optimization improves execution speed because the code uses fewer instructions for local variable references than for global variable references.

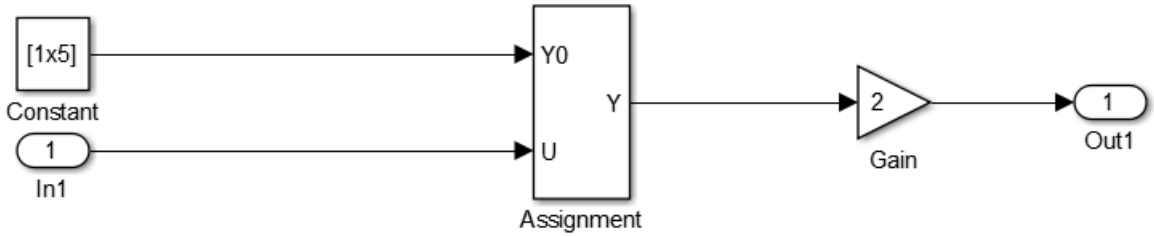
  Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation” (Simulink Coder).

Use Global to Hold Temporary Results

The code generator uses global and local variables when you select `None` versus when you select `Use global to hold temporary results`.

Example Model

In the model matlab:rtwdemo_optimize_global_ebf, an Assignment block assigns values coming from the Inport and Constant blocks to an output signal. The output signal feeds into a Gain block.



```
model = 'rtwdemo_optimize_global_ebf';
load_system('rtwdemo_optimize_global_ebf')
```

Generate Code without Optimization

1. In the Configuration Parameters dialog box, verify that the **Signal storage reuse** parameter is selected.
2. In the Configuration Parameters dialog box, for the **Optimize global access parameter**, select `None` or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global_ebf','GlobalVariableUsage','None');
```

In your system's temporary folder, create a folder for the build and inspection process:

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_optimize_global_ebf
### Successful completion of build procedure for model: rtwdemo_optimize_global_ebf
```

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ebf_ert_rtw',...
    'rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);
```

```
/* Model step function */
void rtwdemo_optimize_global_ebf_step(void)
{
```

```
  real_T rtb_Assignment[5];
  int32_T i;

  /* SignalConversion: '<Root>/TmpHiddenBufferAtAssignmentInport1' incorporates:
   *  Constant: '<Root>/Constant'
   */
  for (i = 0; i < 5; i++) {
    rtb_Assignment[i] = rtCP_Constant_Value[i];
  }

  /* End of SignalConversion: '<Root>/TmpHiddenBufferAtAssignmentInport1' */

  /* Assignment: '<Root>/Assignment' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtb_Assignment[1] = rtU.In1;

  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   */
  for (i = 0; i < 5; i++) {
    rtY.Out1[i] = 2.0 * rtb_Assignment[i];
  }

  /* End of Outport: '<Root>/Out1' */
}
```

The code assigns values to the local vector `rtb_Assignment`. The last statement copies the values in the local vector `rtb_Assignment` to the global vector `rtY.Out1`. Fewer global variable references result in improved execution speed. The code uses more instructions for global variable references than for local variable references.

In the Static Code Metrics Report, examine the Global Variables section.

1. In the Code Generation Report window, select **Static Code Metrics Report**.
2. Scroll down to the `Global Variables` section.
3. Select the **[+]** sign before each variable to expand it.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[-] rtY	40	1	1
Out1	40	1	1
[-] rtU	8	1	1
In1	8	1	1
[-] rtM_	4	0*	0*
errorStatus	4	0	0
Total	**52**	**2**	

* The global variable is not directly used in any function.

The total number of reads and writes for global variables is 2.

Generate Code with Optimization

In the Configuration Parameters dialog box, for the **Optimize global access parameter**, select `Use global to hold temporary results`, or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global_ebf',...
    'GlobalVariableUsage','Use global to hold temporary results');
```

Build the model.

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_optimize_global_ebf
### Successful completion of build procedure for model: rtwdemo_optimize_global_ebf
```

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global_ebf.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ebf_ert_rtw',...
    'rtwdemo_optimize_global_ebf.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);
```

```
/* Model step function */
void rtwdemo_optimize_global_ebf_step(void)
{
  int32_T i;
```

```
  /* SignalConversion: '<Root>/TmpHiddenBufferAtAssignmentInport1' incorporates:
   *  Constant: '<Root>/Constant'
   */
  for (i = 0; i < 5; i++) {
    rtY.Out1[i] = rtCP_Constant_Value[i];
  }

  /* End of SignalConversion: '<Root>/TmpHiddenBufferAtAssignmentInport1' */

  /* Assignment: '<Root>/Assignment' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtY.Out1[1] = rtU.In1;

  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   */
  for (i = 0; i < 5; i++) {
    rtY.Out1[i] *= 2.0;
  }

  /* End of Outport: '<Root>/Out1' */
}
```

The code assigns values to the global vector `rtY.Out1` without using a local variable. This assignment improves ROM and RAM consumption and reduces data copies. The code places the value in the destination variable for each assignment instead of copying the value at the end. In the Static Code Metrics Report, examine the Global Variables section.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[-] rtY	40	4	4
Out1	40	4	4
[-] rtU	8	1	1
In1	8	1	1
[-] rtM_	4	0*	0*
errorStatus	4	0	0
Total	**52**	**5**	

* The global variable is not directly used in any function.

As a result of using global variables to hold local results, the total number of reads and writes for global variables has increased from 2 to 5. This optimization reduces data copies by reusing global variables.

Close the code generation report.

```
rtwdemoclean;
cd(currentDir)
```

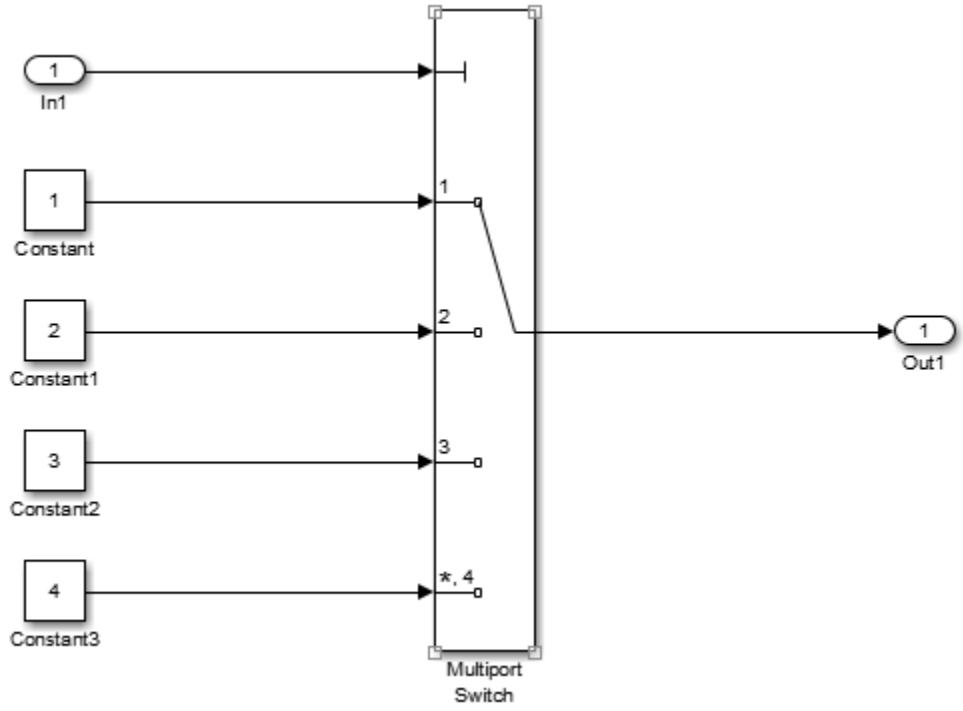
Minimize Global Data Access

Generate optimized code that reads from and writes to global variables less frequently.

Example Model

In the model matlab:rtwdemo_optimize_global, five signals feed into a Multiport Switch block.

```
model = 'rtwdemo_optimize_global';
load_system('rtwdemo_optimize_global')
```



Generate Code without Optimization

1. In the Configuration Parameters dialog box, verify that the **Signal storage reuse** parameter is selected.
2. In the Configuration Parameters dialog box, for the **Optimize global access** parameter, select `None` or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global','GlobalVariableUsage','None');
```

In your system's temporary folder, create a folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model);

### Starting build procedure for model: rtwdemo_optimize_global
### Successful completion of build procedure for model: rtwdemo_optimize_global
```

View the generated code without the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
    'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);

/* Model step function */
void rtwdemo_optimize_global_step(void)
{
  /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  switch ((int32_T)rtU.In1) {
   case 1:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant'
     */
    rtY.Out1 = 1.0;
    break;

   case 2:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant1'
     */
    rtY.Out1 = 2.0;
    break;

   case 3:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant2'
     */
    rtY.Out1 = 3.0;
    break;

   default:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant3'
     */
    rtY.Out1 = 4.0;
```

```
    break;
  }

  /* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}
```

In the Static Code Metrics Report, examine the `Global Variables` section.

1. In the Code Generation Report window, select **Static Code Metrics Report**.
2. Scroll down to the `Global Variables` section.
3. Select the **[+]** sign before each variable to expand it.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[−] rtU	8	1	1
In1	8	1	1
[−] rtY	8	4	4
Out1	8	4	4
[−] rtM	4	0*	0*
errorStatus	4	0	0
Total	**20**	**5**	

* The global variable is not directly used in any function.

The total number of reads and writes for global variables is 5.

Enable Optimization and Generate Code

In the Configuration Parameters dialog box, for the **Optimize global data access** parameter, select `Minimize global data access` or enter the following command in the MATLAB Command Window:

```
set_param('rtwdemo_optimize_global',...
    'GlobalVariableUsage','Minimize global data access');
```

Build the model.

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_optimize_global
### Successful completion of build procedure for model: rtwdemo_optimize_global
```

View the generated code with the optimization. Here is a portion of `rtwdemo_optimize_global.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimize_global_ert_rtw',...
    'rtwdemo_optimize_global.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize',1, 0);
```

```
/* Model step function */
void rtwdemo_optimize_global_step(void)
{
  real_T tmp_Out1;

  /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
   *  Inport: '<Root>/In1'
   */
  switch ((int32_T)rtU.In1) {
   case 1:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant'
     */
    tmp_Out1 = 1.0;
    break;

   case 2:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant1'
     */
    tmp_Out1 = 2.0;
    break;

   case 3:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant2'
     */
    tmp_Out1 = 3.0;
    break;

   default:
    /* Outport: '<Root>/Out1' incorporates:
     *  Constant: '<Root>/Constant3'
     */
    tmp_Out1 = 4.0;
```

```
    break;
  }

  /* End of MultiPortSwitch: '<Root>/Multiport Switch' */

  /* Outport: '<Root>/Out1' */
  rtY.Out1 = tmp_Out1;
}
```

In `rtwdemo_optimize_global.c`, the code assigns a constant value to the local variable `tmp_Out1` in each case statement. The last statement in the code copies the value of `tmp_Out1` to the global variable `rtY.Out1`. Fewer global variable references result in fewer instructions and improved execution speed.

In the **Static Code Metrics Report**, examine the `Global Variables` section. As a result of minimizing global data accesses, the total number of reads and writes for global variables has decreased from 5 to 2.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[−] rtU	8	1	1
In1	8	1	1
[−] rtY	8	1	1
Out1	8	1	1
[−] rtM	4	0*	0*
errorStatus	4	0	0
Total	20	2	

* The global variable is not directly used in any function.

Close the code generation report.

```
rtwdemoclean;
cd(currentDir)
```

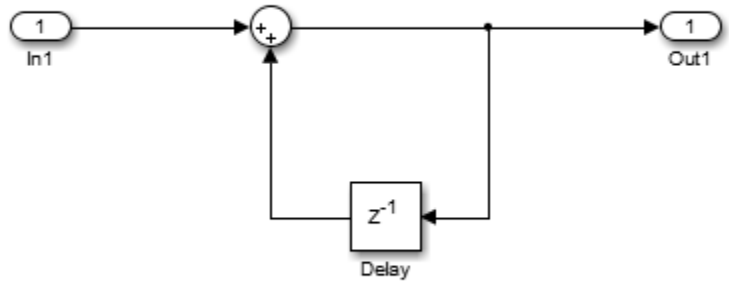
- “Reuse Global Block Outputs in the Generated Code” on page 69-14

Reuse Global Block Outputs in the Generated Code

Reduce ROM and RAM consumption and data copies and increase execution speed of generated code. Configure the code generator to reuse global variables by selecting the model configuration parameter **Reuse global block outputs**.

Example

In the Command Window, type rtwdemo_reuse_global.



Generate Code without Optimization

1. On the Configuration Parameters dialog box, verify that **Signal storage reuse** is selected.
2. Clear **Reuse global block outputs** and click **Apply**.
3. On the **Code Generation > Report** pane, select **Static code metrics**.
4. In your system's temporary folder, create a folder for the build and inspection process.

Press **Ctrl+B** to generate code.

```
### Starting build procedure for model: rtwdemo_reuse_global
### Successful completion of build procedure for model: rtwdemo_reuse_global
```

View the generated code without the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```
/* Model step function */
void rtwdemo_reuse_global_step(void)
{
  /* Sum: '<Root>/Sum' incorporates:
   *  Delay: '<Root>/Delay'
   *  Inport: '<Root>/In1'
   */
  rtDW.Delay_DSTATE += rtU.In1;

  /* Outport: '<Root>/Out1' incorporates:
   *  Delay: '<Root>/Delay'
   */
  rtY.Out1 = rtDW.Delay_DSTATE;
}
```

The generated code contains a data copy to the global variable `rtDW.Delay_DSTATE`. Open the Static Code Metrics Report. The total number of reads and writes for global variables is 8. The total size is 32 bytes.

Enable Optimization and Generate Code

1. On the Configuration Parameters dialog box, select **Reuse global block outputs** and click **Apply**.
2. Generate code.
3. View the generated code with the optimization. Here is a portion of `rtwdemo_reuse_global.c`.

```
### Starting build procedure for model: rtwdemo_reuse_global
### Successful completion of build procedure for model: rtwdemo_reuse_global

/* Model step function */
void rtwdemo_reuse_global_step(void)
{
  /* Sum: '<Root>/Sum' incorporates:
   *  Delay: '<Root>/Delay'
   *  Inport: '<Root>/In1'
   */
  rtY.Out1 += rtU.In1;
}
```

The code generator eliminates a data copy, reduces two statements to one statement and three global variables to two global variables.

Open the Static Code Metrics Report. For global variables, this optimization reduces the total number of reads and writes for global variables from 8 to 5 and the total size from 32 bytes to 24 bytes.

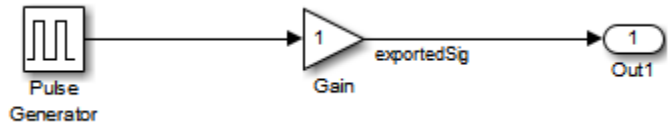
Virtualized Output Ports Optimization

The *virtualized output ports* optimization lets you store the signal entering the root output port as a global variable. Clearing the **MAT-file logging** option and setting the TLC variable `FullRootOutputVector` to `0`, both defaults for Embedded Coder, eliminate code and data storage associated with root output ports.

Consider the model in the following block diagram. The signal `exportedSig` has `exportedGlobal` storage class.



In the default case, the output of the Gain block is written to the signal storage location, `exportedSig`. The code generator does not generate code or data for the `Out1` block, which has become a virtual block.

```
/* Gain Block: <Root>/Gain */
  exportedSig = rtb_PulseGen * VirtOutPortLogOFF_P.Gain_Gain;
```

In cases where you enable **MAT-file logging** or set `FullRootOutputVector = 1`, the generated code represents root output ports as members of an external outputs vector.

The following code fragment was generated with **MAT-file logging** enabled. The output port is represented as a member of the external outputs vector `VirtOutPortLogON_Y`. The Gain block output value is copied to `exportedSig` and to the external outputs vector.

```
/* Gain Block: <Root>/Gain */
  exportedSig = rtb_PulseGen * VirtOutPortLogON_P.Gain_Gain;

/* Outport Block: <Root>/Out1 */
  VirtOutPortLogON_Y.Out1 = exportedSig;
```

Data maintenance in the external outputs vector can be significant for smaller models that perform benchmarks.

You can force root output ports to be stored in the external outputs vector (regardless of the setting of **MAT-file logging**) by setting the TLC variable `FullRootOutputVector` to `1`. Add the statement

```
%assign FullRootOutputVector = 1
```

to the Embedded Coder system target file. Alternatively, you can enter the assignment from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For more information, see “Specify TLC for Code Generation” (Simulink Coder) and “Configure TLC” (Simulink Coder).

For more information on how to control signal storage in generated code, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50 and “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.

- “Optimize Global Variable Usage” on page 69-2

Specify Buffer Reuse by Using Simulink.Signal Objects

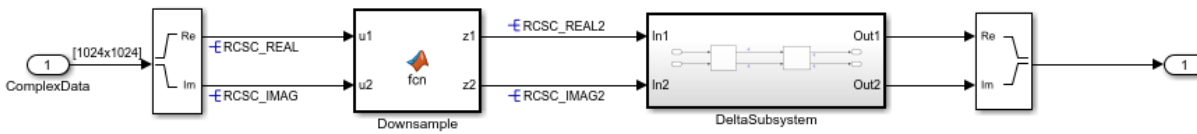
If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using `Simulink.Signal` objects to specify buffer reuse. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you specify signal objects on signal lines.

You can specify buffer reuse on signals that include a pair of root inport and outport signals. You can also specify buffer reuse on just a pair of root inport and outport signals. This optimization reduces ROM and RAM consumption because there are less global variables and data copies in the generated code. Code execution speed also increases.

Example Model

The model rtwdemo_reusable_csc contains the nonreusable subsystem `DeltaSubsystem` and the MATLAB Function block `Downsample`. `DeltaSubsystem` contains the MATLAB Function blocks `DeltaX` and `DeltaY`.

```
model ='rtwdemo_reusable_csc';
open_system(model);
```



Specify a Simulink Signal Object for Reuse

1. In the model, open the Model Data Editor (**View > Model Data Editor**).
2. In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select `Code`.
3. Click the **Show/refresh additional information** button. Now, the Model Data Editor shows information about variables and objects in workspaces such as the base workspace.
4. Next to the **Filter contents** box, activate the **Filter using selection** button.

5. In the model, select the RCSC_REAL signal line. The Model Data Editor shows two rows: One that represents the signal line and one that represents a `Simulink.Signal` object in the base workspace.
6. For the row that represents the signal line, inspect the **Resolve** column. The check box is selected, which means the signal line resolves to the `Simulink.Signal` object, acquiring code generation settings from that object.
7. For the row that represents the signal object, inspect the **Storage Class** column. The signal object uses the storage class `Reusable`, which means the object appears in the generated code as a global variable named RCSC_REAL.
8. In the model, navigate into the `DeltaSubsystem` subsystem.
9. Select the RCSC_REAL signal line in this subsystem. This signal also resolves to the signal object in the base workspace.

With the `Reusable` storage class, the generated code can store the output of the `Complex to Real-Imag` block (at the root level of the model) and the output of the `DeltaX` block (in the subsystem) in the RCSC_REAL global variable.

Generate Code

Build the model.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_reusable_csc
### Successful completion of build procedure for model: rtwdemo_reusable_csc
```

For buffer reuse, the `rtwdemo_reusable_csc.c` file contains these global variables:

- `static real_T RCSC_IMAG[1048576];`
- `static real_T RCSC_IMAG2[262144];`
- `static real_T RCSC_REAL[1048576];`
- `static real_T RCSC_REAL2[262144];`

The `rtwdemo_reusable_csc.c` file contains this code:

```
cfile = fullfile(cgDir,...
    'rtwdemo_reusable_csc_ert_rtw','rtwdemo_reusable_csc.c');
rtwdemodbtype(cfile,...
    '/* Output and update for atomic system: ''<Root>/DeltaSubsystem'' */',...
```

```
    '/* Output and update for atomic system: ''<Root>/Downsample'' */',1,0);
rtwdemodbtype(cfile,...
    '/* Model step function */','/* Model initialize function */',1,0);
```

```
/* Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
  /* MATLAB Function: '<S1>/DeltaX' */
  DeltaX((&(RCSC_REAL2[0])), (&(RCSC_IMAG2[0])), (&(RCSC_REAL[0])),
         (&(RCSC_IMAG[0])));

  /* MATLAB Function: '<S1>/DeltaY' */
  DeltaY((&(RCSC_REAL[0])), (&(RCSC_IMAG[0])), (&(RCSC_REAL2[0])),
         (&(RCSC_IMAG2[0])));
}

/* Model step function */
void rtwdemo_reusable_csc_step(void)
{
  int32_T i;

  /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
   *  Inport: '<Root>/ComplexData'
   */
  for (i = 0; i < 1048576; i++) {
    RCSC_REAL[i] = rtU.ComplexData[i].re;
    RCSC_IMAG[i] = rtU.ComplexData[i].im;
  }

  /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

  /* MATLAB Function: '<Root>/Downsample' */
  Downsample((&(RCSC_REAL[0])), (&(RCSC_IMAG[0])), (&(RCSC_REAL2[0])),
             (&(RCSC_IMAG2[0])));

  /* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
  DeltaSubsystem();

  /* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

  /* Outport: '<Root>/Out1' incorporates:
   *  RealImagToComplex: '<Root>/Real-Imag to Complex'
   */
  for (i = 0; i < 261121; i++) {
```

```
    rtY.Out1[i].re = RCSC_REAL2[i];
    rtY.Out1[i].im = RCSC_IMAG2[i];
  }

  /* End of Outport: '<Root>/Out1' */
}
```

The variables `RCSC_REAL` and `RCSC_IMAG` hold the outputs of the Complex to Real-Image block and `DeltaX`. These variables hold the inputs to the `DeltaY` block. The variables `RCSC_REAL2` and `RCSC_IMAG2` hold the outputs of `Downsample` and `DeltaY`. These variables hold the inputs to the `DeltaX` block. By interleaving buffers in this way, you eliminate global variables in the generated code.

To remove the signal objects from the signal lines and regenerate code, in the MATLAB Command Window, enter these commands:

```
portHandles = get_param(...
    'rtwdemo_reusable_csc/Complex to Real-Imag','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

portHandles = get_param(...
    'rtwdemo_reusable_csc/Downsample','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

portHandles = get_param(...
    'rtwdemo_reusable_csc/DeltaSubsystem/DeltaX','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

portHandles = get_param(...
    'rtwdemo_reusable_csc/DeltaSubsystem/DeltaY','portHandles');
set_param(portHandles.Outport(1),'MustResolveToSignalObject','off');
set_param(portHandles.Outport(2),'MustResolveToSignalObject','off');

rtwbuild(model);

### Starting build procedure for model: rtwdemo_reusable_csc
### Successful completion of build procedure for model: rtwdemo_reusable_csc
```

The `rtwdemo_reusable_csc.c` file now contains this code.

```
cfile = fullfile(cgDir,...
    'rtwdemo_reusable_csc_ert_rtw','rtwdemo_reusable_csc.c');
```

```
rtwdemodbtype(cfile,...
    '/* Output and update for atomic system: ''<Root>/DeltaSubsystem'' */',...
    '/* Output and update for atomic system: ''<Root>/Downsample'' */',1,0);
rtwdemodbtype(cfile,...
    '/* Model step function */','/* Model initialize function */',1,0);

/* Output and update for atomic system: '<Root>/DeltaSubsystem' */
static void DeltaSubsystem(void)
{
  /* MATLAB Function: '<S1>/DeltaX' */
  DeltaX(rtDWork.z2, rtDWork.z1, rtDWork.z1_m, rtDWork.z2_c);

  /* MATLAB Function: '<S1>/DeltaY' */
  DeltaY(rtDWork.z1_m, rtDWork.z2_c, &rtDWork.z1[0], &rtDWork.z2[0]);
}

/* Model step function */
void rtwdemo_reusable_csc_step(void)
{
  int32_T i;

  /* ComplexToRealImag: '<Root>/Complex to Real-Imag' incorporates:
   *  Inport: '<Root>/ComplexData'
   */
  for (i = 0; i < 1048576; i++) {
    rtDWork.RCSC_REAL[i] = rtU.ComplexData[i].re;
    rtDWork.RCSC_IMAG[i] = rtU.ComplexData[i].im;
  }

  /* End of ComplexToRealImag: '<Root>/Complex to Real-Imag' */

  /* MATLAB Function: '<Root>/Downsample' */
  Downsample(rtDWork.RCSC_REAL, rtDWork.RCSC_IMAG, rtDWork.z2, rtDWork.z1);

  /* Outputs for Atomic SubSystem: '<Root>/DeltaSubsystem' */
  DeltaSubsystem();

  /* End of Outputs for SubSystem: '<Root>/DeltaSubsystem' */

  /* Outport: '<Root>/Out1' incorporates:
   *  RealImagToComplex: '<Root>/Real-Imag to Complex'
   */
  for (i = 0; i < 261121; i++) {
    rtY.Out1[i].re = rtDWork.z1[i];
```

```
    rtY.Out1[i].im = rtDWork.z2[i];
  }

  /* End of Outport: '<Root>/Out1' */
}
```

The generated code contains two additional global variables for holding block inputs and outputs.

Note: You can specify buffer reuse on signals that the code generator cannot implement. For those cases, use two new diagnostics to specify the message type that the model displays. In the Configuration Parameters dialog box, these diagnostics are **Detect non-reused custom storage classes** and **Detect ambiguous custom storage class final values**.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Buffer Reuse for Unit Delay and Delay Blocks

To reuse the signal of a Unit Delay or Delay block:

1. Use the same reusable custom storage class specification for a pair of input and state arguments or a pair of output and state arguments of a Unit Delay block or a Delay block.
2. In the Model Data Editor, select the **States** tab and from the **Change view** drop-down list, select `Code`.
3. Use the **Name** column to set the name of the target Unit Delay or Delay block states. Specify the name of the signal object that you want to reuse.
4. For each state, check the box in the **Resolve** column.

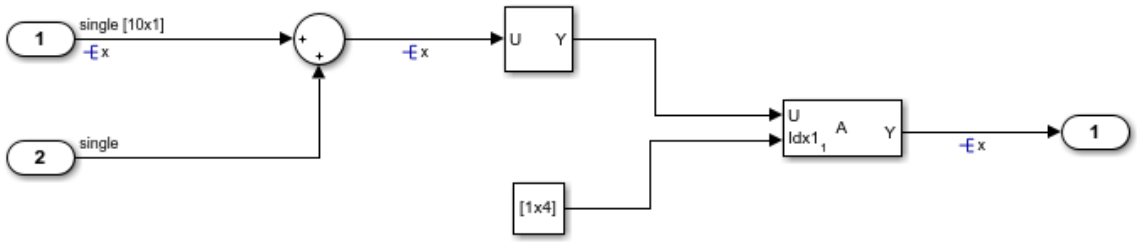
For Delay blocks, you must set the **Delay length** parameter to `1` and **Initial condition > Source** to `Dialog`. To access these parameters, in the model, open the Property Inspector (**View > Property Inspector**) and click the block in the model.

Limitations for Root Inport and Outport Signals

These limitations apply to a model in which you specify buffer reuse for a pair of root inport and outport signals:

- The output ports cannot be conditional.

- If the code generator cannot reuse the same buffer in a top model, the generated code contains additional buffers. If the top model is a reference model, the code generator reports an error. To resolve the error, remove the Simulink.signal specification from the signal that connects to the outport port.
- When you run the executable that the code generator produces, and you reuse a pair of root inport and outport signals, when the root input value is zero, the root output value must also be zero. If the output value is nonzero and you reuse the signals, then the results from the simulation can differ from the results that the executable produces.
- There might be a simulation versus code generation mismatch when you assign the same Reusable custom storage class to pair of root inport and root outport signals. This mismatch occurs when an Assignment block drives the Root Outport block, and the Assignment block does not assign a value to every element of the output signal because the Y0 port of the Assignment block is not active. This image shows a model in which the mismatch occurs:



During simulation, the unwritten Assignment block output values are zero. During code generation, the unwritten output values are the same as the input.

Limitations for the Model

These limitations apply to a model in which you specify buffer reuse for signals:

- Signals that you specify for reuse must have the same data types and sampling rates.
- For user-specified buffer reuse, blocks that modify a signal specified for reuse must execute before blocks that use the original signal value. Sometimes the code generator has to change the block operation order so that buffer reuse can occur. For models in

which the code generator is unable to reorder block operations, buffer reuse does not occur.

- For models in which the code generator reorders block operations so that `Simulink.Signal` reuse can occur, you can observe the difference in the sorted order. In the model window, select **Display > Blocks > Sorted Execution Order**. To display the sorted execution order during simulation, select **Simulation > Update Diagram**. To display the execution order in the generated code, select **Code > C/C++ Code > Build Model**.

- “Design Data Interface by Configuring Inport and Outport Blocks” on page 32-210

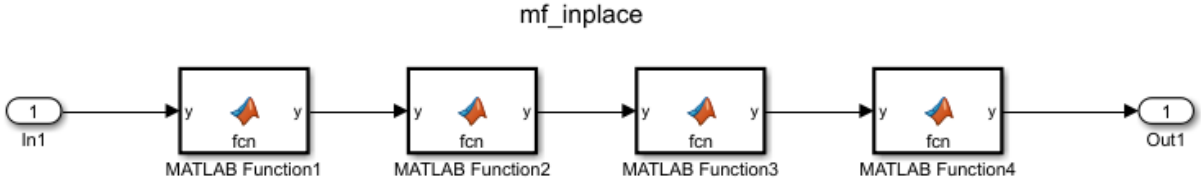
Specify Buffer Reuse for MATLAB Function Blocks in a Path

In this section...

You can specify buffer reuse across MATLAB Function blocks by using the same variable name for the input and output arguments. The code generator tries to reuse the output of one MATLAB Function block as the input to the next MATLAB Function block. This optimization conserves RAM and ROM consumption and reduces data copies.

Example Model

1. Use Inport, Outport, and MATLAB Function blocks to create the model `mf_inplace`.



2. Open each MATLAB Function block and copy the following code:

```
function y = fcn(y)
%#codegen

y=y+4;
```

3. Open the Configuration Parameters dialog box. On the **Code Generation** tab, change the **System target file** to `ert.tlc`.
4. On the **Solver** tab, change the **Type** parameter to `Fixed-step`.

Generate Code with Optimization

Generate code for the model. The `mf_inplace.c` file contains this code:

```
void mf_inplace_MATLABFunction(real_T *rty_y)
{
  *rty_y += 4.0;
}

void mf_inplace_step(void)
{
  real_T rtb_y_p5;
  rtb_y_p5 = mf_inplace_U.In1;
  mf_inplace_MATLABFunction(&rtb_y_p5);
  mf_inplace_MATLABFunction(&rtb_y_p5);
  mf_inplace_MATLABFunction(&rtb_y_p5);
  mf_inplace_Y.Out1 = rtb_y_p5;
  mf_inplace_MATLABFunction(&mf_inplace_Y.Out1);
}
```

The code generator reuses the variable `rtb_y_p5` for the input and output arguments of each MATLAB Function block.

Note On the **Code Generation** tab in the Subsystem Block Parameters dialog box, if the **Function packaging** parameter is set to `Nonreusable function` and the **Function interface** parameter is set to `Allow arguments`, the code generator cannot reuse the input and output arguments.

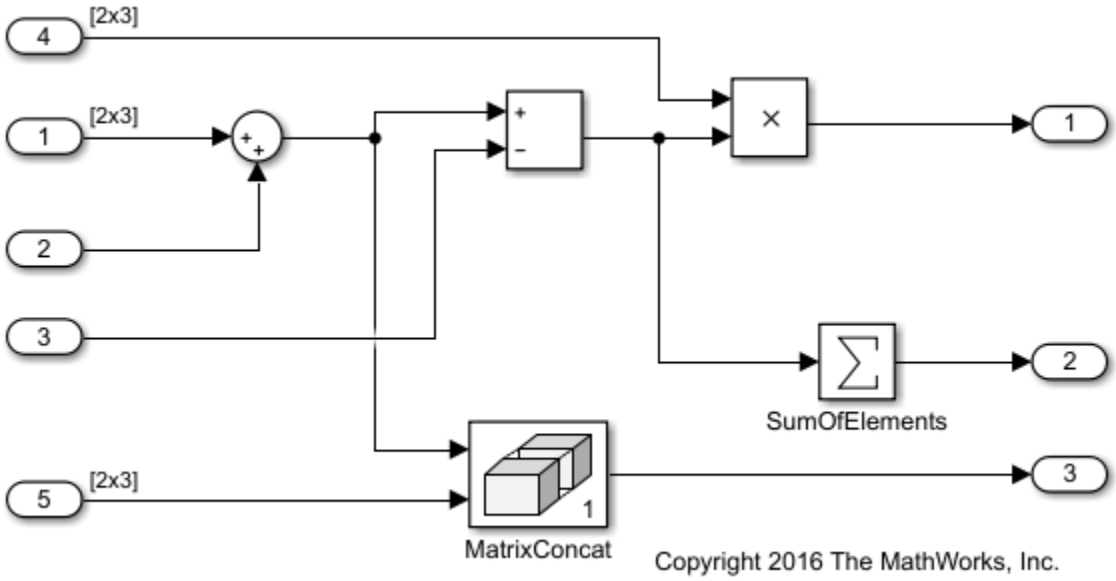
Remove Data Copies by Reordering Block Operations in the Generated Code

This example show how to remove data copies by changing the **Optimize block order in the generated code** parameter from `off` to `Improved Execution Speed`. Changing this setting indicates to the code generator to reorder block operations where possible to remove data copies. This parameter is in the Configuration Parameters dialog box. This optimization conserves RAM and ROM consumption.

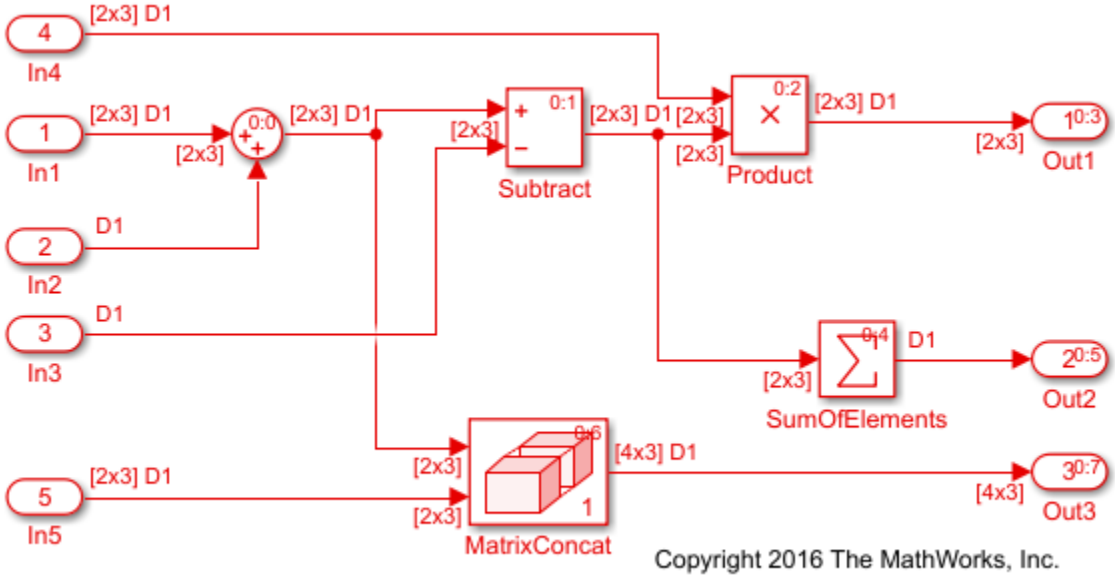
Example Model

In the model `ex_optimizeblockorder`, the signal that leaves the Sum block enters a Subtract block and a Concatenate block. The signal that leaves the Subtract block enters a Product block and a Sum of Elements block.



Generate Code without Optimization

The image shows the model `ex_optimizeblockorder` after a model build. The red numbers indicate the default block order in the generated code. The Subtract block executes before the Concatenate block. The Product block executes before the Sum of Elements block.



View the generated code without the optimization. Here is the `ex_optimizeblockorder_step` function.

```
/* Model step function */
void ex_optimizeblockorder_step(void)
{
  real_T rtb_Sum2x3[6];
  int32_T i;
  real_T rtb_Sum2x3_d;
  real_T rtb_Subtract;

  /* Sum: '<Root>/SumOfElements' */
  rtY.Out2 = -0.0;
```

```
  for (i = 0; i < 6; i++) {
    /* Sum: '<Root>/Sum2x3' incorporates:
     *  Inport: '<Root>/In1'
     *  Inport: '<Root>/In2'
     */
    rtb_Sum2x3_d = rtU.In1[i] + rtU.In2;

    /* Sum: '<Root>/Subtract' incorporates:
     *  Inport: '<Root>/In3'
     */
    rtb_Subtract = rtb_Sum2x3_d - rtU.In3;

    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In4'
     *  Product: '<Root>/Product'
     */
    rtY.Out1[i] = rtU.In4[i] * rtb_Subtract;

    /* Sum: '<Root>/Sum2x3' */
    rtb_Sum2x3[i] = rtb_Sum2x3_d;

    /* Sum: '<Root>/SumOfElements' */
    rtY.Out2 += rtb_Subtract;
  }

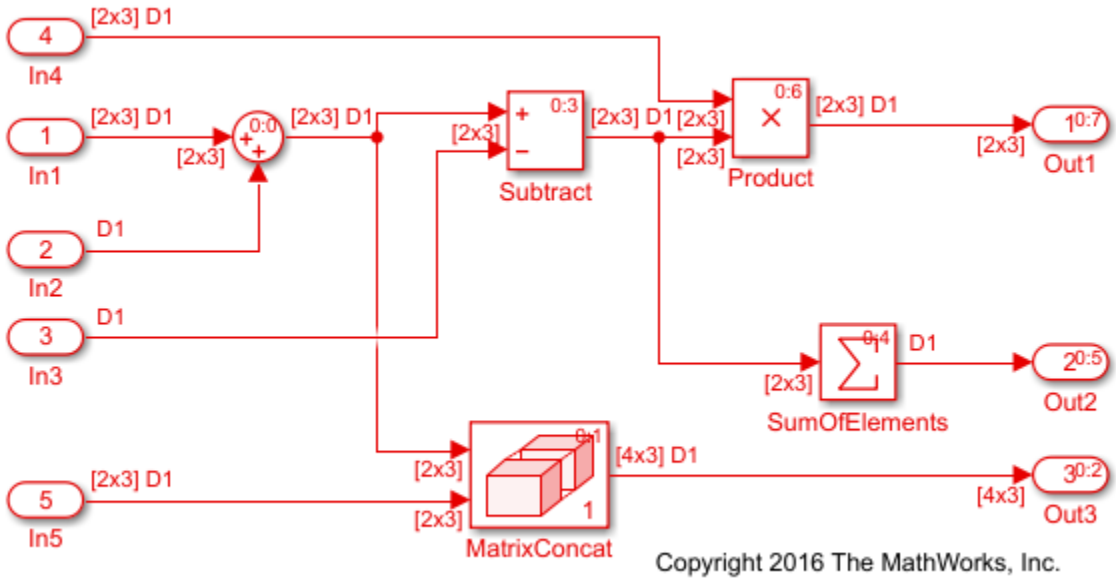
  /* Concatenate: '<Root>/MatrixConcat ' */
  for (i = 0; i < 3; i++) {
    /* Outport: '<Root>/Out3' incorporates:
     *  Inport: '<Root>/In5'
     */
    rtY.Out3[i << 2] = rtb_Sum2x3[i << 1];
    rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
    rtY.Out3[1 + (i << 2)] = rtb_Sum2x3[(i << 1) + 1];
    rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
  }

  /* End of Concatenate: '<Root>/MatrixConcat ' */
}
```

With the default order, the generated code contains three buffers, `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract`. The generated code contains these temporary variables and associated data copies because the Matrix Concatenate block must use the output from the Sum block and the Sum of Elements block must use the output from the Subtract block.

Generate Code with Optimization

The image shows the `ex_optimizeblockorder` model after setting the **Optimize block order in the generated code** parameter to `Improved Execution Speed` and building the model. The Subtract block executes after the Concatenate block. The Product block executes after the Sum of Elements block.



In the optimized code, the three buffers `rtb_Sum2x3[6]`, `rtb_Sum2x3_d`, and `rtb_Subtract` and their associated data copies are gone. The generated code does not require these temporary variables to hold the outputs of the Sum and Subtract blocks because the Subtract block executes after the Concatenate block and the Product block executes after the Sum of Elements block.

```
/* Model step function */
void ex_optimizeblockorder_step(void)
{
  int32_T i;

  /* Sum: '<Root>/Sum2x3' incorporates:
```

```
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   */
  for (i = 0; i < 6; i++) {
    rtY.Out1[i] = rtU.In1[i] + rtU.In2;
  }

  /* End of Sum: '<Root>/Sum2x3' */

  /* Concatenate: '<Root>/MatrixConcat ' */
  for (i = 0; i < 3; i++) {
    /* Outport: '<Root>/Out3' incorporates:
     *  Inport: '<Root>/In5'
     */
    rtY.Out3[i << 2] = rtY.Out1[i << 1];
    rtY.Out3[2 + (i << 2)] = rtU.In5[i << 1];
    rtY.Out3[1 + (i << 2)] = rtY.Out1[(i << 1) + 1];
    rtY.Out3[3 + (i << 2)] = rtU.In5[(i << 1) + 1];
  }

  /* End of Concatenate: '<Root>/MatrixConcat ' */

  /* Sum: '<Root>/SumOfElements' */
  rtY.Out2 = -0.0;
  for (i = 0; i < 6; i++) {
    /* Sum: '<Root>/Subtract' incorporates:
     *  Inport: '<Root>/In3'
     */
    rtY.Out1[i] -= rtU.In3;

    /* Sum: '<Root>/SumOfElements' */
    rtY.Out2 += rtY.Out1[i];

    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In4'
     *  Product: '<Root>/Product'
     */
    rtY.Out1[i] *= rtU.In4[i];
  }
}
```

To implement buffer reuse, the code generator does not violate user-specified block priorities.

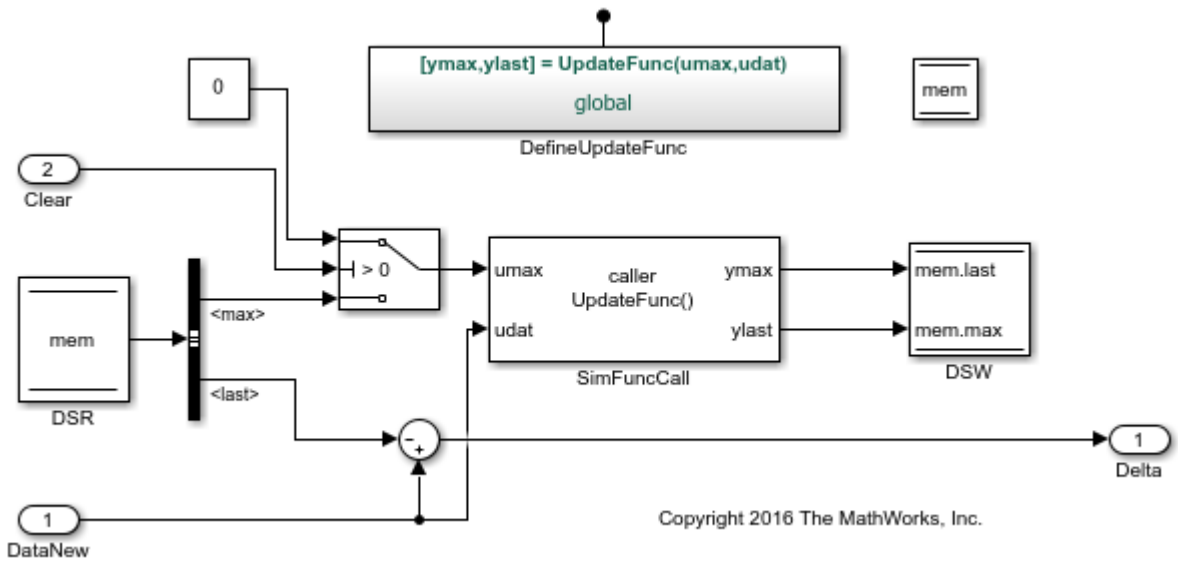
Data Copy Reduction for Data Store Read and Data Store Write Blocks

This example shows how the code generator removes temporary buffers for Data Store Read and Data Store Write blocks. This optimization improves execution speed and reduces RAM consumption.

Example Model

The model `rtwdemo_optimizedatastorebuffers` contains the Function caller `UpdateFunc`, which calls the Simulink Function `DefineUpdateFunc`. The Data Store Read block `DSR` reads from `mem`. The Data Store Write block `DSW` writes to `mem`.

```
model='rtwdemo_optimizedatastorebuffers';
open_system(model);
```



Generate Code without Optimization

In the Configuration Parameters dialog box, deselect the **Reuse buffers for Data Store Read and Data Store Write blocks parameter** or at the MATLAB command prompt, enter this command:

```
set_param(model,'OptimizeDataStoreBuffers','off');
```

Build the model.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_optimizedatastorebuffers
### Successful completion of build procedure for model: rtwdemo_optimizedatastorebuffe
```

View the generated code without the optimization. This code is in `rtwdemo_optimizedatastorebuffers.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimizedatastorebuffers_ert_rtw',...
    'rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_optimizedatastorebuffers_step(void)
{
  real_T rtb_DSR_last;
  real_T rtb_SimFuncCall_o1;
  real_T rtb_Sum_p;

  /* DataStoreRead: '<Root>/DSR' */
  rtb_DSR_last = mem.last;

  /* Switch: '<Root>/Switch' incorporates:
   *  Constant: '<Root>/Constant'
   *  DataStoreRead: '<Root>/DSR'
   *  Inport: '<Root>/Clear'
   */
  if (rtU.Clear) {
    rtb_SimFuncCall_o1 = 0.0;
  } else {
    rtb_SimFuncCall_o1 = mem.max;
  }

  /* End of Switch: '<Root>/Switch' */

  /* FunctionCaller: '<Root>/SimFuncCall' incorporates:
   *  Inport: '<Root>/DataNew'
   */
```

```
  UpdateFunc(rtb_SimFuncCall_o1, rtU.DataNew, &rtb_SimFuncCall_o1, &rtb_Sum_p);

  /* DataStoreWrite: '<Root>/DSW' */
  mem.last = rtb_SimFuncCall_o1;
  mem.max = rtb_Sum_p;

  /* Outport: '<Root>/Delta' incorporates:
   *  Inport: '<Root>/DataNew'
   *  Sum: '<Root>/Sum'
   */
  rtY.Delta = rtU.DataNew - rtb_DSR_last;
}
```

The generated code contains data copies for the Data Store Read and Data Store Write blocks, respectively.

Generate Code with Optimization

In the Configuration Parameters dialog box, clear the **Reuse buffers for Data Store Read and Data Store Write blocks** parameter or at the MATLAB command prompt, enter this command:

```
set_param(model,'OptimizeDataStoreBuffers','on');
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_optimizedatastorebuffers
### Successful completion of build procedure for model: rtwdemo_optimizedatastorebuffe
```

View the generated code with the optimization. This code is in `rtwdemo_optimizedatastorebuffers.c`.

```
cfile = fullfile(cgDir,'rtwdemo_optimizedatastorebuffers_ert_rtw',...
    'rtwdemo_optimizedatastorebuffers.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_optimizedatastorebuffers_step(void)
{
  real_T rtb_DSR_last;
  real_T tmp;
```

```
  /* DataStoreRead: '<Root>/DSR' */
  rtb_DSR_last = mem.last;

  /* Switch: '<Root>/Switch' incorporates:
   *  Constant: '<Root>/Constant'
   *  DataStoreRead: '<Root>/DSR'
   *  Inport: '<Root>/Clear'
   */
  if (rtU.Clear) {
    tmp = 0.0;
  } else {
    tmp = mem.max;
  }

  /* End of Switch: '<Root>/Switch' */

  /* FunctionCaller: '<Root>/SimFuncCall' incorporates:
   *  DataStoreWrite: '<Root>/DSW'
   *  Inport: '<Root>/DataNew'
   */
  UpdateFunc(tmp, rtU.DataNew, &mem.last, &mem.max);

  /* Outport: '<Root>/Delta' incorporates:
   *  Inport: '<Root>/DataNew'
   *  Sum: '<Root>/Sum'
   */
  rtY.Delta = rtU.DataNew - rtb_DSR_last;
}
```

The data copy for the Data Store Write block is not in the generated code. The code contains the data copy for the Data Store Read block because the Sum block executes after the Data Store Write block. The generated code contains the variable `rtb_DSR_last` to hold the output of the Sum block. Therefore, the Sum block gets the values that `SimFuncCall` calculates at the start of the time step rather than those values at the next time step. If the priority of the Sum block is lower than `SimFuncCall`, the code generator can remove the data copy for the Data Store Read block. Some other cases in which the code generator might not eliminate data copies are:

- A Simulink Function internally writes to the Data Store Memory block.
- The Data Store Read or Data Store Write blocks select elements of an array from the Data Store Memory block.
- The Data Store Memory block has a custom storage class.

- The Data Store Read and Data Store Write blocks occur on the same block unless that block is a Bus Assignment block or an Assignment block.

Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

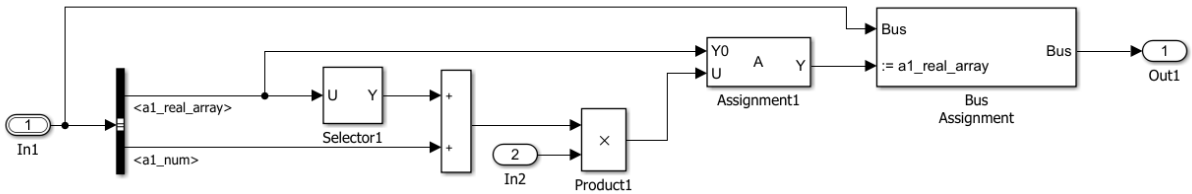
Reduce Data Copies for Bus Assignment Blocks

For models containing a Bus Assignment block, if possible, the code generator uses the same variable for the block input and output. Reusing these variables reduces data copies, conserves RAM consumption and increases code execution speed.

Example Model

For example, in `bus_assignoptim`, a bus signal containing six elements feeds into a Bus Assignment block and a Bus Selector block. The Bus Assignment block assigns new values to the bus element `a1_real_array`. This bus signal feeds into `Out1`.



Generate Code Without Optimization

Generate code without the optimization by setting the **Perform inplace updates for Bus Assignment blocks** parameter to `on`. Without the optimization the `bus_assignoptim_step` function contains this code:

```
void bus_assignoptim_step(void)
{
  real_T rtb_Assignment[36];
  int32_T i;

  /* Assignment: '<Root>/Assignment' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   *  Product: '<Root>/Product'
   *  Selector: '<Root>/Selector'
   *  Sum: '<Root>/Sum1'
   */
  for (i = 0; i < 36; i++) {
    rtb_Assignment[i] = bus_assignoptim_U.In1.a1_real_array[i];
```

```
  }

  for (i = 0; i < 2; i++) {
    rtb_Assignment[(int32_T)(i + 22)] = (bus_assignoptim_U.In1.a1_real_array
      [(int32_T)(i + 22)] + bus_assignoptim_U.In1.a1_num) *
      bus_assignoptim_U.In2;
  }

  /* End of Assignment: '<Root>/Assignment' */

  /* Outport: '<Root>/Out' incorporates:
   *  BusAssignment: '<Root>/Bus Assignment'
   *  Inport: '<Root>/In1'
   */
  bus_assignoptim_Y.Out = bus_assignoptim_U.In1;

  /* BusAssignment: '<Root>/Bus Assignment' incorporates:
   *  Outport: '<Root>/Out'
   */
  for (i = 0; i < 36; i++) {
    bus_assignoptim_Y.Out.a1_real_array[i] = rtb_Assignment[i];
  }
}
```

The generated code contains the temporary array `rtb_Assignment` for holding data before this data is assigned to `bus_assignoptim_Y.Out.a1_real_array`.

Generate Code with Optimization

Generate code with the optimization by setting the **Perform inplace updates for Bus Assignment blocks** parameter to `off`. With the optimization, the `bus_assignoptim_step` function contains this code:

```
/* Model step function */
void bus_assignoptim_step(void)
{
  int32_T i;

  /* Outport: '<Root>/Out' incorporates:
   *  Inport: '<Root>/In1'
   *  SignalConversion: '<Root>/TmpBusAssignmentBufferAtBus AssignmentInport1'
   */
  bus_assignoptim_Y.Out = bus_assignoptim_U.In1;
```

```
  /* Assignment: '<Root>/Assignment' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   *  Outport: '<Root>/Out'
   *  Product: '<Root>/Product'
   *  Selector: '<Root>/Selector'
   *  Sum: '<Root>/Sum1'
   */
  for (i = 0; i < 36; i++) {
    bus_assignoptim_Y.Out.a1_real_array[i] =
      bus_assignoptim_U.In1.a1_real_array[i];
  }

  for (i = 0; i < 2; i++) {
    bus_assignoptim_Y.Out.a1_real_array[(int32_T)(i + 22)] =
      (bus_assignoptim_U.In1.a1_real_array[(int32_T)(i + 22)] +
       bus_assignoptim_U.In1.a1_num) * bus_assignoptim_U.In2;
  }

  /* End of Assignment: '<Root>/Assignment' */
}
```

The generated code does not contain the temporary array `rtb_Assignment1` for holding data. The generated code directly assigns this data to `bus_assignoptim_Y.Out.a1_real_array`.

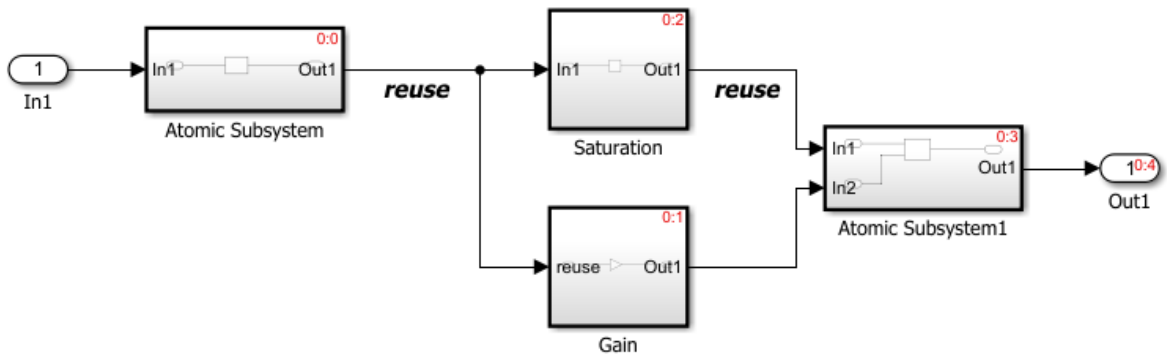
Optimize Generated Code by Using Signal Labels to Guide Buffer Reuse

If your model has the optimal parameter settings for removing data copies, you might be able to remove additional data copies by using signal labels. After studying the generated code and the Static Code Metrics Report and identifying areas where you think buffer reuse is possible, you can add labels to signal lines. If possible, the code generator reorders block operations to implement the reuse specification.

Specifying buffer reuse improves execution speed and may reduce RAM consumption.

Example Model

The model `rtwdemo_label_guided_reuse` demonstrates how you can use signal labels to request buffer reuse for block input and output signals. For this model, the code generator can use the same variable for the Atomic Subsystem and either the Gain or Saturation block outputs. The generated code uses the same variable for the Saturation and Atomic Subsystem block outputs because those signals contain the same label and the **Use Signal Labels to Guide Buffer Reuse** parameter is selected.



Generate Code Without Optimization

1 Open the model.

```
model='rtwdemo_label_guided_reuse';
open_system(model);
```

2. In the Configuration Parameters dialog box, clear the **Use Signal Labels to Guide Buffer Reuse** parameter.
3. Build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```
void rtwdemo_label_guided_reuse_step(void)
{
  real_T rtb_Saturation[4];
  real_T rtb_Bias[4];
  int32_T i;
  AtomicSubsystem(rtU.In1, rtb_Bias);
  for (i = 0; i < 4; i++) {
    if (rtb_Bias[i] > 10.0) {
      rtb_Saturation[i] = 10.0;
    } else if (rtb_Bias[i] < -10.0) {
      rtb_Saturation[i] = -10.0;
    } else {
      rtb_Saturation[i] = rtb_Bias[i];
    }

    rtb_Bias[i] *= 3.0;
  }

  AtomicSubsystem1(rtb_Saturation, rtb_Bias, rtY.Out1);
}
```

   By default, within the `for` loop, the Gain block executes after the Saturation block. The generated code uses the same variable for the output of the Atomic Subsystem and the Gain blocks. As a result, the generated code contains two local variables `rtb_Saturation` and `rtb_Bias` for holding intermediate results.

Generate Code with Optimization

In the Configuration Parameters dialog box, select the **Use Signal Labels to Guide Buffer Reuse** parameter and build the model. The `rtwdemo_label_guided_reuse_step` function contains this code:

```
void rtwdemo_label_guided_reuse_step(void)
{
  real_T rtb_Gain1[4];
  int32_T i;
  AtomicSubsystem(rtU.In1, rtY.Out1);
  for (i = 0; i < 4; i++) {
```

```
    rtb_Gain1[i] = 3.0 * rtY.Out1[i];
    if (rtY.Out1[i] > 10.0) {
      rtY.Out1[i] = 10.0;
    } else {
      if (rtY.Out1[i] < -10.0) {
        rtY.Out1[i] = -10.0;
      }
    }
  }

  AtomicSubsystem1(rtY.Out1, rtb_Gain1, rtY.Out1);
}
```

The code generator changed the block execution order so that within the `for` loop, the Saturation block executes after the Gain block. The generated code contains one local variable `rtb_Gain1` for holding intermediate results.

In addition to requesting which buffers to reuse, another possible use case is to request buffer reuse for block input and output signals that are complex.

Using Label-Based Reuse Versus Reusable Custom Storage Classes

You can also use the same `Reusable` custom storage class specification on different signal lines to specify which buffers to reuse. As compared to using `Reusable` custom storage classes, using signal labels to specify reuse has these benefits:

- Signal labels are not observation points in the generated code, so using them does not block other optimizations such as dead code elimination and expression folding.
- The code generator does not force a signal with a label to be a global variable in the generated code. The signal can be a local or global variable.
- Signals with labels can reuse buffers with signals that do not have labels, so reuse among local and global variables is possible.

Using signal labels is a more conservative method of specifying reuse than using `Reusable` custom storage classes. The code generator does not implement label-based reuse when it can implement reuse by using `Reusable` custom storage classes in these cases:

- Reuse that can potentially prevent other optimizations from occurring in the generated code.

- Reuse on root inport and outport ports.
- Reuse across model reference or subsystem boundaries.
- Within a subsystem, buffer reuse on an intermediary signal and an input or output port.

Execution Speed in Embedded Coder

Reduce Memory Usage for Signals

The configuration parameter **Signal storage reuse** reduces the memory requirements of your real-time program by enabling parameters that reuse the memory allocated for signals with an `auto` storage class. These parameters are the following:

- **Enable local block outputs**
- **Reuse local block outputs**
- **Reuse global block outputs**
- **Optimize global data access**

When the **Enable local block outputs** parameter is on, where possible the code generator declares block outputs as local variables instead of global variables. Replacing global variables with local variables improves execution speed and reduces RAM/ROM consumption. Creating more local variables can increase stack usage. Some of the global variables that the code generator can localize include:

- Global signals that cross subsystem boundaries
- Global signals across Simulink and Stateflow domains
- Unused global state variables
- Redundant local Data Store Memory block signals

When the **Reuse local block outputs** parameter is on, wherever possible the code generator reuses local (function) variables for block outputs. When you select **Reuse global block outputs**, the code generator reuses global (function) variables wherever possible.

The **Optimize global data access** parameter has these settings:

- `None`
- `Use global to hold temporary results`
- `Minimize global data access`

When you select `None`, the code generator uses the default optimizations. The setting `Use global to hold temporary results` maximizes the use of global variables. The setting `Minimize global data access` minimizes the use of global variables by using local variables to hold intermediate values.

Clearing **Signal storage reuse** makes all block outputs global and unique, which often significantly increases RAM and ROM usage.

The code generator does not localize global variables for MATLAB system objects or AUTOSAR.

Remove Initialization Code

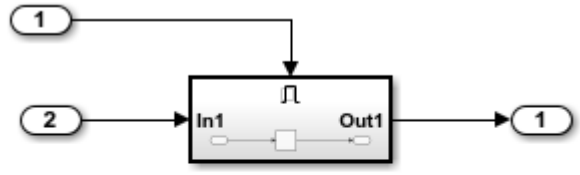
The “Remove root level I/O zero initialization” (Simulink Coder) and “Remove internal data zero initialization” (Simulink Coder) parameters control whether the generated code contains initialization code for internal data (block states and block outputs) and external data (root inports and outports) whose value is zero. If your embedded application initializes RAM to zero at startup, you might not need initialization code. Eliminating this code accelerates model initialization, reduces ROM consumption and increases the execution speed of the generated code.

Remove Zero Initialization Code for Internal Data

This example shows how to eliminate code that initializes internal data to zero. If your embedded application does not require generating initialization code for internal data whose value is zero, you can enable this optimization.

Example Model

Open the model rtwdemo_internal_init. The model contains an enabled subsystem whose initial output is zero. The subsystem contains a Unit Delay block whose initial condition is `0`.



Generate Code Without Optimization

Build the model using Embedded Coder.

```
### Starting build procedure for model: rtwdemo_internal_init
### Successful completion of build procedure for model: rtwdemo_internal_init
```

This code is in the `rtwdemo_internal_init.c` file.

```
/* Model initialize function */
void rtwdemo_internal_init_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtM, (NULL));

  /* states (dwork) */
  (void) memset((void *)&rtDWork, 0,
                sizeof(D_Work));

  /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem' */
  /* InitializeConditions for UnitDelay: '<S1>/Unit Delay' */
  rtDWork.UnitDelay_DSTATE = 0.0;

  /* End of SystemInitialize for SubSystem: '<Root>/Enabled Subsystem' */
}

/*
```

Enable Optimization

Open the Configuration Parameters dialog box. On the **Optimization** pane, select **Remove internal data zero initialization**.

Alternatively, you can use the command prompt to enable the optimization. To enable the optimization, set the model parameter `ZeroInternalMemoryAtStartup` to `'off'`.

```
set_param(model, 'ZeroInternalMemoryAtStartup', 'off');
```

Generate Code with Optimization

Build the model using Embedded Coder.

```
### Starting build procedure for model: rtwdemo_internal_init
### Successful completion of build procedure for model: rtwdemo_internal_init
```

This code is in the `rtwdemo_internal_init.c` file. The generated code does not initialize internal data by assignment to zero.

```
/* Model initialize function */
```

```
void rtwdemo_internal_init_initialize(void)
{
  /* (no initialization code required) */
}

/*
```

If you select the **Remove internal data zero initialization** parameter, be aware that memory might not be in a known state each time the generated code executes. This means that running a model (or a generated S-function) multiple times can result in different answers for each run. This behavior is sometimes desirable. For example, you can select the **Remove internal data zero initialization** parameter if you want to test the behavior of your design during a warm boot (that is, a restart without full system reinitialization). For models in which you select the **Remove internal data zero initialization** parameter but still want to get the same answer on every run from an S-function, you can use either of the following commands before each run:

```
clear SFcnName
```

where *SFcnName* is the name of the S-function, or

```
clear mex
```

Remove Initialization Code for Root-Level Inports and Outports Set to Zero

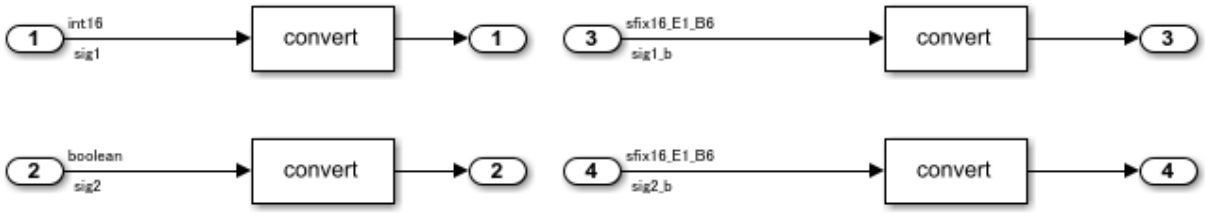
This example shows how to remove initialization code for root-level inports and outports set to zero. If your embedded application does not require generating initialization code for external data whose value is zero, you can enable this optimization.

Note: This example requires an Embedded Coder® license.

Example Model

In the model rtwdemo_rootlevel_zero_initialization, all of the input and output signals have a numeric value of zero. Because signals `sig1` and `sig2` have data types `int16` and `Boolean`, respectively, and all of the output signals have data type `double`, these signals also have initial values of bitwise zero. The signals have an integer bit pattern of `0`, meaning that all bits are off. Signals `sig1_b` and `sig2_b` have a fixed-point data type with bias, so their initial value is not bitwise zero.

```
model = 'rtwdemo_rootlevel_zero_initialization';
open_system(model);
```



Generate Code

In your system temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'ZeroExternalMemoryAtStartup','on');
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
### Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initiali
```

These lines of `rtwdemo_rootlevel_zero_initialization.c` code show the initialization of root-level inports and outports without the optimization. The four input signals are individually initialized as global variables. The four output signals are members of a global structure that the `memset` function initializes to bitwise zero.

```
cfile = fullfile(cgDir,'rtwdemo_rootlevel_zero_initialization_ert_rtw',...
    'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize',...
    'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
  /* Registration code */

  /* external inputs */
```

```
  sig1 = 0;
  sig1_b = -3;
  sig2 = false;
  sig2_b = -3;

  /* external outputs */
  (void) memset((void *)&rtY, 0,
                sizeof(ExternalOutputs));
}

/*
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Remove root level I/O zero initialization**.

Alternatively, use the command-line API to enable the optimization:

```
set_param(model, 'ZeroExternalMemoryAtStartup','off');
```

Generate Code with Optimization

The optimized code does not contain initialization code for the input signals `sig1`, `sig2`, and the four output signals, because their initial values are bitwise zero.

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_rootlevel_zero_initialization
### Successful completion of build procedure for model: rtwdemo_rootlevel_zero_initial
```

Here is the `rtwdemo_rootlevel_zero_initialization.c` optimized code in the initialization function.

```
cfile = fullfile(cgDir,'rtwdemo_rootlevel_zero_initialization_ert_rtw',...
    'rtwdemo_rootlevel_zero_initialization.c');
rtwdemodbtype(cfile, 'rtwdemo_rootlevel_zero_initialization_initialize',...
    'trailer for generated code', 1, 0);
```

```
void rtwdemo_rootlevel_zero_initialization_initialize(void)
{
  /* Registration code */
```

```
  /* external inputs */
  sig1_b = -3;
  sig2_b = -3;
}

/*
```

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Additional Information

- You can use the **Use memset to initialize floats and doubles** parameter to control the representation of zero during initialization. See “Use memset to initialize floats and doubles to 0.0” (Simulink Coder).
- The code still initializes data structures whose value is not zero when you select **Remove internal data zero initialization** and **Remove root level I/O zero initialization**.
- The data of `ImportedExtern` or `ImportedExternPointer` storage classes are not initialized, regardless of the settings of the **Remove internal data zero initialization** and **Remove root level I/O zero initialization** parameters.

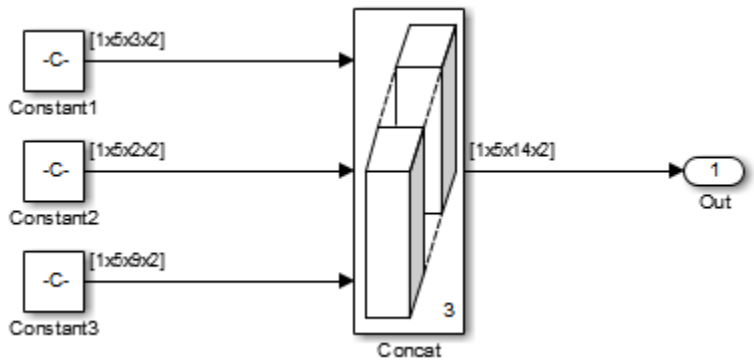
Simplify Multiply Operations in Array Indexing

In this section...

The generated code might have multiply operations when indexing an element of an array. You can select the optimization parameter “Simplify array indexing” (Simulink Coder) to replace multiply operations in the array index with a temporary variable. This optimization can improve execution speed by reducing the number of times the multiply operation executes.

Example Model

If you have the following model:



The Constant blocks have the following **Constant value**:

- `Const1`: `reshape(1:30,[1 5 3 2])`
- `Const2`: `reshape(1:20,[1 5 2 2])`
- `Const3`: `reshape(1:90,[1 5 9 2])`

The Concatenate block parameter **Mode** is set to `Multidimensional array`. The Constant blocks **Sample time** parameter is set to `-1`.

Generate Code

Building the model with the **Simplify array indexing** parameter turned off generates the following code:

```
int32_T i;
int32_T i_0;
int32_T i_1;

for (i = 0; i < 2; i++) {
  for (i_1 = 0; i_1 < 3; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[(i_0 + 5 * i_1) + 70 * i] =
        ex_arrayindex_P.Constant1_Value[(5 * i_1 + i_0) + 15 * i];
    }
  }
}

for (i = 0; i < 2; i++) {
  for (i_1 = 0; i_1 < 2; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 3)) + 70 * i] =
        ex_arrayindex_P.Constant2_Value[(5 * i_1 + i_0) + 10 * i];
    }
  }
}

for (i = 0; i < 2; i++) {
  for (i_1 = 0; i_1 < 9; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[(i_0 + 5 * (i_1 + 5)) + 70 * i] =
        ex_arrayindex_P.Constant3_Value[(5 * i_1 + i_0) + 45 * i];
    }
  }
}
```

Generate Code with Optimization

Open the Configuration Parameters dialog box and select the **Simplify array indexing** parameter. Build the model again. In the generated code, `[(i_0 + tmp_1) + tmp]` replaces a multiply operation in the array index, `[(i_0 + 5 * i_1) + 70 * i]`. The generated code is now:

```
int32_T i;
int32_T i_0;
int32_T i_1;
int32_T tmp;
int32_T tmp_0;
int32_T tmp_1;

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
  tmp_1 = 0;
  for (i_1 = 0; i_1 < 3; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[(i_0 + tmp_1) + tmp] =
        ex_arrayindex_P.Constant1_Value[(i_0 + tmp_1) + tmp_0];
    }

    tmp_1 += 5;
  }

  tmp += 70;
  tmp_0 += 15;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
  tmp_1 = 0;
  for (i_1 = 0; i_1 < 2; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 15] =
        ex_arrayindex_P.Constant2_Value[(i_0 + tmp_1) + tmp_0];
    }

    tmp_1 += 5;
  }

  tmp += 70;
  tmp_0 += 10;
}

tmp = 0;
tmp_0 = 0;
for (i = 0; i < 2; i++) {
```

```
  tmp_1 = 0;
  for (i_1 = 0; i_1 < 9; i_1++) {
    for (i_0 = 0; i_0 < 5; i_0++) {
      ex_arrayindex_Y.Out[((i_0 + tmp_1) + tmp) + 25] =
        ex_arrayindex_P.Constant3_Value[(i_0 + tmp_1) + tmp_0];
    }

    tmp_1 += 5;
  }

  tmp += 70;
  tmp_0 += 45;
}
```

Replace boolean with Specific Integer Data Type

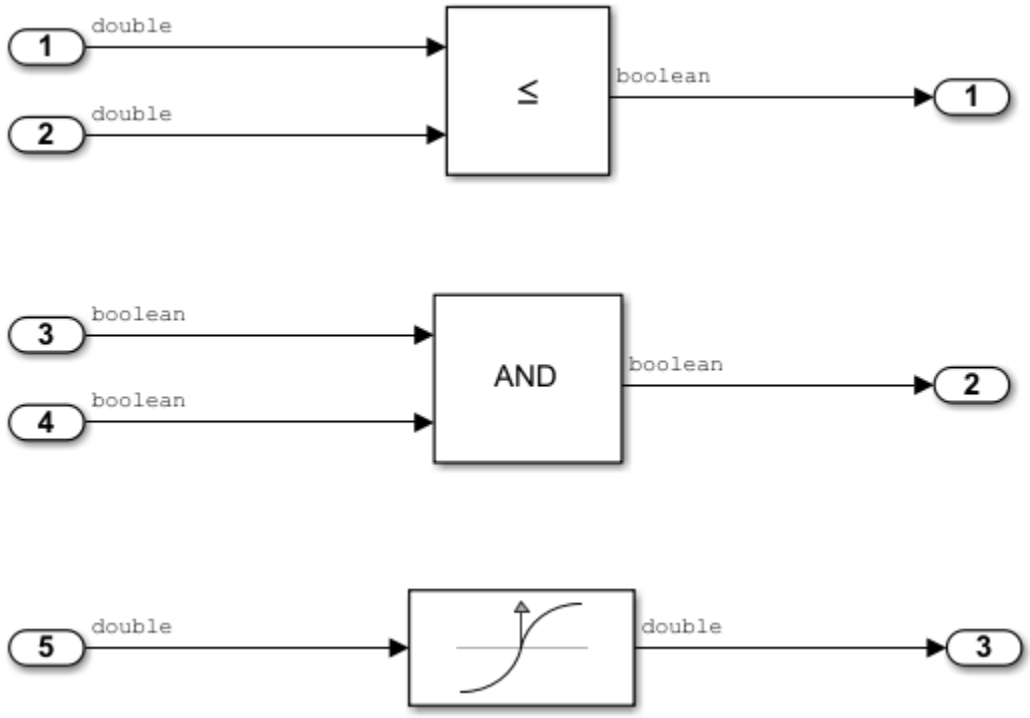
Depending on the architecture of the processor that your production hardware uses, you can improve the execution speed of the generated code. Select a specific integer data type for the built-in type `boolean`. Using data type replacement, in the generated code you can replace the `boolean` built-in data type with one of these integer types:

- `int8`
- `uint8`
- `int`*n*

To match the integer word size for the production hardware, replace *n* with 8, 16, or 32 .

Example Model

The model `ex_bool` contains two blocks that output `boolean` values and two blocks that take `boolean` values as inputs. This example shows how to replace the data type `boolean` with the integer data type `int32` in the code generated for a 32-bit hardware target.



Generate Code That Contains the Default boolean Data Type

View the generated file `rtwtypes.h`. The `typdef` statements contain the generic type definition of `boolean_T`, which is the code generation name for `boolean`.

```
/*=======================================================================*
 * Generic type definitions: boolean_T, char_T, byte_T, int_T, uint_T,   *
 *                           real_T, time_T, ulong_T.                    *
 *=======================================================================*/
typedef double real_T;
typedef double time_T;
typedef unsigned char boolean_T;
typedef int int_T;
typedef unsigned int uint_T;
typedef unsigned long ulong_T;
```

```
typedef char char_T;
typedef unsigned char uchar_T;
typedef char_T byte_T;
```

View the generated file `ex_bool.c`. The code declares `boolean` variables by using the type `boolean_T`.

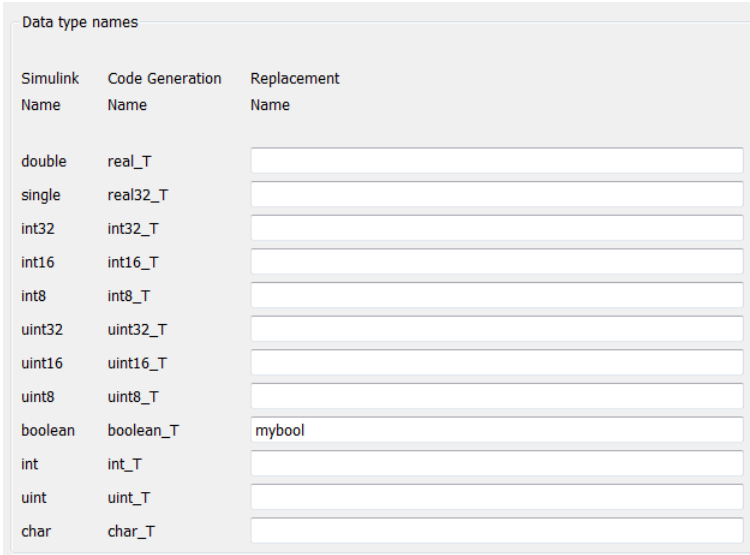
```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  real_T In1;                          /* '<Root>/In1' */
  real_T In2;                          /* '<Root>/In2' */
  boolean_T In3;                       /* '<Root>/In3' */
  boolean_T In4;                       /* '<Root>/In4' */
  real_T In5;                          /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
  boolean_T Out1;                      /* '<Root>/Out1' */
  boolean_T Out2;                      /* '<Root>/Out2' */
  real_T Out3;                         /* '<Root>/Out3' */
} ExtY_ex_bool_T;
```

Generate Code That Contains the Target boolean Data Type

1. Define a `Simulink.AliasType` object with a base type of `int32`. Name the object using the replacement name that you want to appear in the generated code.

   ```
   mybool = Simulink.AliasType;
   mybool.BaseType = 'int32';
   ```
2. In the Configuration Parameters dialog box, specify the **Replacement Name** field for the data type `boolean` as `mybool`.



View the generated file `rtwtypes.h`. The code maps the identifier `mybool` to the native integer type of the target hardware by creating `typedef` statements.

```
/* Generic type definitions ... */
...
typedef int boolean_T;
 ...
/* Define Simulink Coder replacement data types. */
typedef boolean_T mybool;    /* User defined replacement datatype for boolean_T */
```

View the generated file *`ex_bool`*`.c`. The code declares `boolean` variables that use the type `mybool`.

```
  /* External inputs (root inport signals with auto storage) */
typedef struct {
  real_T In1;                          /* '<Root>/In1' */
  real_T In2;                          /* '<Root>/In2' */
  mybool In3;                          /* '<Root>/In3' */
  mybool In4;                          /* '<Root>/In4' */
  real_T In5;                          /* '<Root>/In5' */
} ExtU_ex_bool_T;

/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
  mybool Out1;                         /* '<Root>/Out1' */
  mybool Out2;                         /* '<Root>/Out2' */
  real_T Out3;                         /* '<Root>/Out3' */
} ExtY_ex_bool_T;
```

Remove Code That Guards Against Division Exceptions for Integers and Fixed-Point Data

Optimize generated code by removing code that protects against division by zero and overflows in division `INT_MIN/-1` operations for integers and fixed-point data. If you are sure that these arithmetic exceptions do not occur during program execution, enable this optimization but it may lead to a quotient that cannot be represented.

This optimization:

- Increases execution speed.
- Results in smaller code thereby reducing ROM consumption.

Risks

When you select the `NoFixptDivByZeroProtection` parameter, the code generator removes code that protects against the following errors:

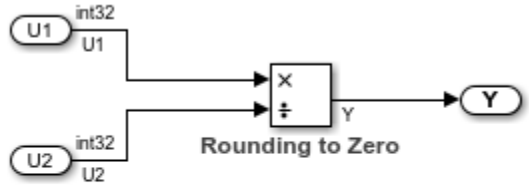
- When you divide by zero it is undefined and results in a runtime error in the generated code.
- When you divide the minimum representable value of a signed integer by negative one, the ideal result is equal to the maximum representable value plus one (INT_MAX + 1), which is not representable. This exception may cause the application to unexpectedly halt or crash at run-time.

NOTE: If you enable this optimization, it is possible that simulation results and results from generated code are not in bit-for-bit agreement. This example requires an Embedded Coder® license.

Example Model

In the model rtwdemo_nzcheck, two signals of type `int8` feed into a divide block.

```
model = 'rtwdemo_nzcheck';
open_system(model);
```



Generate Code

In your system's temporary folder, create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model, 'NoFixptDivByZeroProtection', 'off');
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_nzcheck
### Successful completion of code generation for model: rtwdemo_nzcheck
```

View the generated code without the optimization. Here is a portion of `rtwdemo_nzcheck.c`.

```
cfile = fullfile(cgDir,'rtwdemo_nzcheck_ert_rtw','rtwdemo_nzcheck.c');
rtwdemodbtype(cfile,'/* Real-time model','/* Model initialize function',1, 1);
```

```
/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_;
int32_T div_s32(int32_T numerator, int32_T denominator)
{
  int32_T quotient;
  uint32_T tempAbsQuotient;
  if (denominator == 0) {
```

```
    quotient = numerator >= 0 ? MAX_int32_T : MIN_int32_T;

    /* Divide by zero handler */
  } else {
    tempAbsQuotient = (numerator < 0 ? ~(uint32_T)numerator + 1U : (uint32_T)
                       numerator) / (denominator < 0 ? ~(uint32_T)denominator +
      1U : (uint32_T)denominator);
    quotient = (numerator < 0) != (denominator < 0) ? -(int32_T)tempAbsQuotient :
      (int32_T)tempAbsQuotient;
  }

  return quotient;
}

/* Model step function */
void rtwdemo_nzcheck_step(void)
{
  /* Product: '<Root>/Divide' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   */
  Y = div_s32(U1, U2);
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Remove code that protects against division arithmetic exceptions**.

Alternatively, you may use the command-line API to enable the optimization:

```
set_param(model, 'NoFixptDivByZeroProtection', 'on');
```

Generate Code with Optimization

The optimized code does not contain code that checks for whether or not the divisor has a value of zero.

Build the model.

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_nzcheck
### Successful completion of code generation for model: rtwdemo_nzcheck
```

The following is a portion of `rtwdemo_nzcheck.c`. The code that protects against division arithmetic exceptions is not in the generated code.

```
rtwdemodbtype(cfile,'/* Real-time model','/* Model initialize function',1, 1);
```

```
/* Real-time model */
RT_MODEL_rtwdemo_nzcheck rtwdemo_nzcheck_M_;
RT_MODEL_rtwdemo_nzcheck *const rtwdemo_nzcheck_M = &rtwdemo_nzcheck_M_;

/* Model step function */
void rtwdemo_nzcheck_step(void)
{
  /* Product: '<Root>/Divide' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   */
  Y = U1 / U2;
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Additional Information

There are several other factors that can affect the appearance of the generated code for division operations. The generated code for blocks containing MATLAB® code with integer or fixed-point division operations differs from the built-in Divide block in Simulink®. To balance the efficiency and semantics of fixed-point and integer divisions in these blocks, use `fi` objects and set the `fimath` properties to fit your needs and requires a Fixed-Point Designer™ license. Rounding and overflow modes also affect the size and efficiency of the generated code.

Optimize Generated Code by Consolidating Redundant If-Else Statements

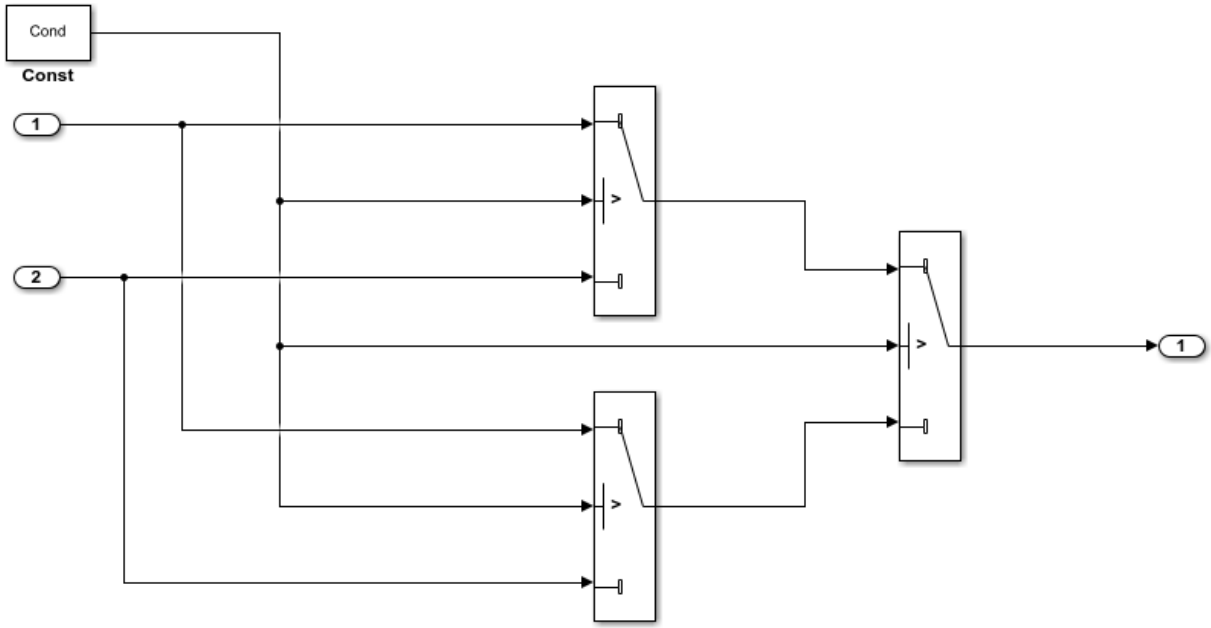
This example shows how to optimize generated code by combining `if-else` statements that share the same condition. This optimization:

- Improves control flow.
- Reduces code size.
- Reduces RAM consumption.
- Increases execution speed.

Example

The model rtwdemo_controlflow_opt contains three Switch blocks. The Constant block provides the control input to the Switch blocks. The variable named `Cond` determines the value of the Constant block.

```
model = 'rtwdemo_controlflow_opt';
open_system(model);
```



Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_controlflow_opt
### Successful completion of build procedure for model: rtwdemo_controlflow_opt
```

These lines of `rtwdemo_controlflow_opt.c` code show that in the generated code, two `if-else` statements and one `else-if` statement represent the three Switch blocks.

```
cfile = fullfile(cgDir,'rtwdemo_controlflow_opt_ert_rtw',...
    'rtwdemo_controlflow_opt.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
  /* Switch: '<Root>/Switch3' incorporates:
   *  Constant: '<Root>/Const'
   *  Switch: '<Root>/Switch2'
   */
  if (Cond) {
    /* Switch: '<Root>/Switch1' */
    if (Cond) {
      /* Outport: '<Root>/Out1' incorporates:
       *  Inport: '<Root>/In1'
       */
      rtY.Out1 = rtU.In1;
    } else {
      /* Outport: '<Root>/Out1' incorporates:
       *  Inport: '<Root>/In2'
       */
      rtY.Out1 = rtU.In2;
    }

    /* End of Switch: '<Root>/Switch1' */
  } else if (Cond) {
    /* Switch: '<Root>/Switch2' incorporates:
     *  Inport: '<Root>/In1'
     *  Outport: '<Root>/Out1'
     */
    rtY.Out1 = rtU.In1;
  } else {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In2'
     */
    rtY.Out1 = rtU.In2;
  }

  /* End of Switch: '<Root>/Switch3' */
}
```

Enable Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Code generation**-> **Code Style** pane, clear **Preserve condition expression in if statement**. This parameter is on by default.

Alternatively, use the command-line API to turn off the parameter:

```
set_param(model, 'PreserveIfCondition', 'off');
```

Generate Code with Optimization

In the optimized code, the code generator consolidates the two `if-else` statements and one `else-if` statement into one `if-else` statement. The code generator consolidates these statements because they all share the same condition. There is no intervening code that affects the outcomes of these statements.

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_controlflow_opt
### Successful completion of build procedure for model: rtwdemo_controlflow_opt
```

Here is the `rtwdemo_controlflow_opt.c` optimized code.

```
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_controlflow_opt_step(void)
{
  /* Switch: '<Root>/Switch1' incorporates:
   *  Constant: '<Root>/Const'
   *  Switch: '<Root>/Switch3'
   */
  if (Cond) {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In1'
     */
    rtY.Out1 = rtU.In1;
  } else {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/In2'
```

```
     */
    rtY.Out1 = rtU.In2;
  }

  /* End of Switch: '<Root>/Switch1' */
}
```

Close the model and clean up.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

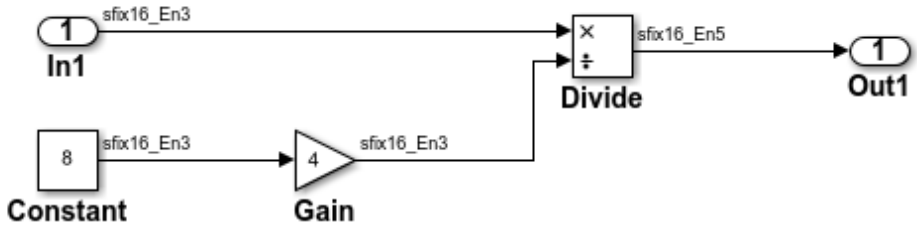
Optimize Generated Code for Fixed-Point Data Operations

This example shows how the code generator optimizes fixed-point operations by replacing expensive division operations with highly efficient product operations. This optimization improves execution speed.

Example Model

In the model rtwdemo_fixptdiv, two fixed point signals connect to a Divide block. The **Number of inputs** parameter has the value `/*`.

```
model='rtwdemo_fixptdiv';
load_system(model)
set_param(model,'HideAutomaticNames','off','SimulationCommand','Update')
open_system(model);
```



Description
This model shows optimized fixed-point operations. An expensive division operation is avoided by precomputing the constant input of the Divide block and transforming the division to a highly efficient product operation. The entire computation is realized with a single shift-right operation. Note that the resulting operation also includes the adjustment in signal scaling from 2^{-3} to 2^{-5}.

Instructions
1. Double-click the yellow button below to view the signal data types.
2. Generate and inspect the code by double-clicking the blue button below.
   An HTML report detailing the code is displayed automatically.

This example requires a Fixed-Point Designer license

Generate Code Using Embedded Coder (double-click)

Display Signal Data Types (double-click)

Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
set_param(model,'GenCodeOnly','on');
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_fixptdiv
### Successful completion of code generation for model: rtwdemo_fixptdiv
```

View the generated code. Here is a portion of `rtwdemo_fixptdiv.c`.

```
cfile = fullfile(cgDir,'rtwdemo_fixptdiv_ert_rtw','rtwdemo_fixptdiv.c');
rtwdemodbtype(cfile,'/* Model step','/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_fixptdiv_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
   *  Product: '<Root>/Divide'
   */
  rtY.Out1 = (int16_T)(rtU.In1 >> 3);
}
```

The generated code contains a highly efficient right shift operation instead of an expensive division operation. The generated code also contains the precomputed value for the constant input to the Product block.

Note that the resulting operation also includes the adjustment in signal scaling from 2^-3 to 2^-5.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®

Develop and use code replacement libraries to replace function and operators in generated code. Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware
- Integration with existing application code
- Compliance with a standard, such as AUTOSAR
- Modification of code behavior, such as enabling or disabling nonfinite or inline support
- Application- or project-specific code requirements, such as use of BLAS or elimination of `math.h`, system header files, or calls to `memcpy` or `memset`.

You can configure a model such that the code generator uses a code replacement library that MathWorks® provides. If you have an Embedded Coder® license, you can develop your own code replacement library interactively with the Code Replacement Tool or programmatically.

This example uses models to show a variety of ways you can define code replacement mappings programmatically. Each model includes buttons that you can use to

- View the code replacement library table definitions from the Code Replacement Viewer
- Open the library table definition file in the editor
- Open the library registration file in the editor
- View the model configuration
- Generate code

For more information, see “Define Code Replacement Mappings” on page 65-44 and “Register Code Replacement Mappings” on page 65-71.

Steps for Developing a Code Replacement Library

1. Identify your code replacement requirements with respect to function or operating mappings, build information, and registration information.

2. Prepare for code replacement library development (for example, identify or develop models to test your library).
3. Define code replacement mappings.
4. Specify build information for replacement code.
5. Register code replacement mappings.
6. Verify code replacements.
7. Deploy the library.

For more information, see “Quick Start Code Replacement Library Development - Simulink®” on page 65-28.

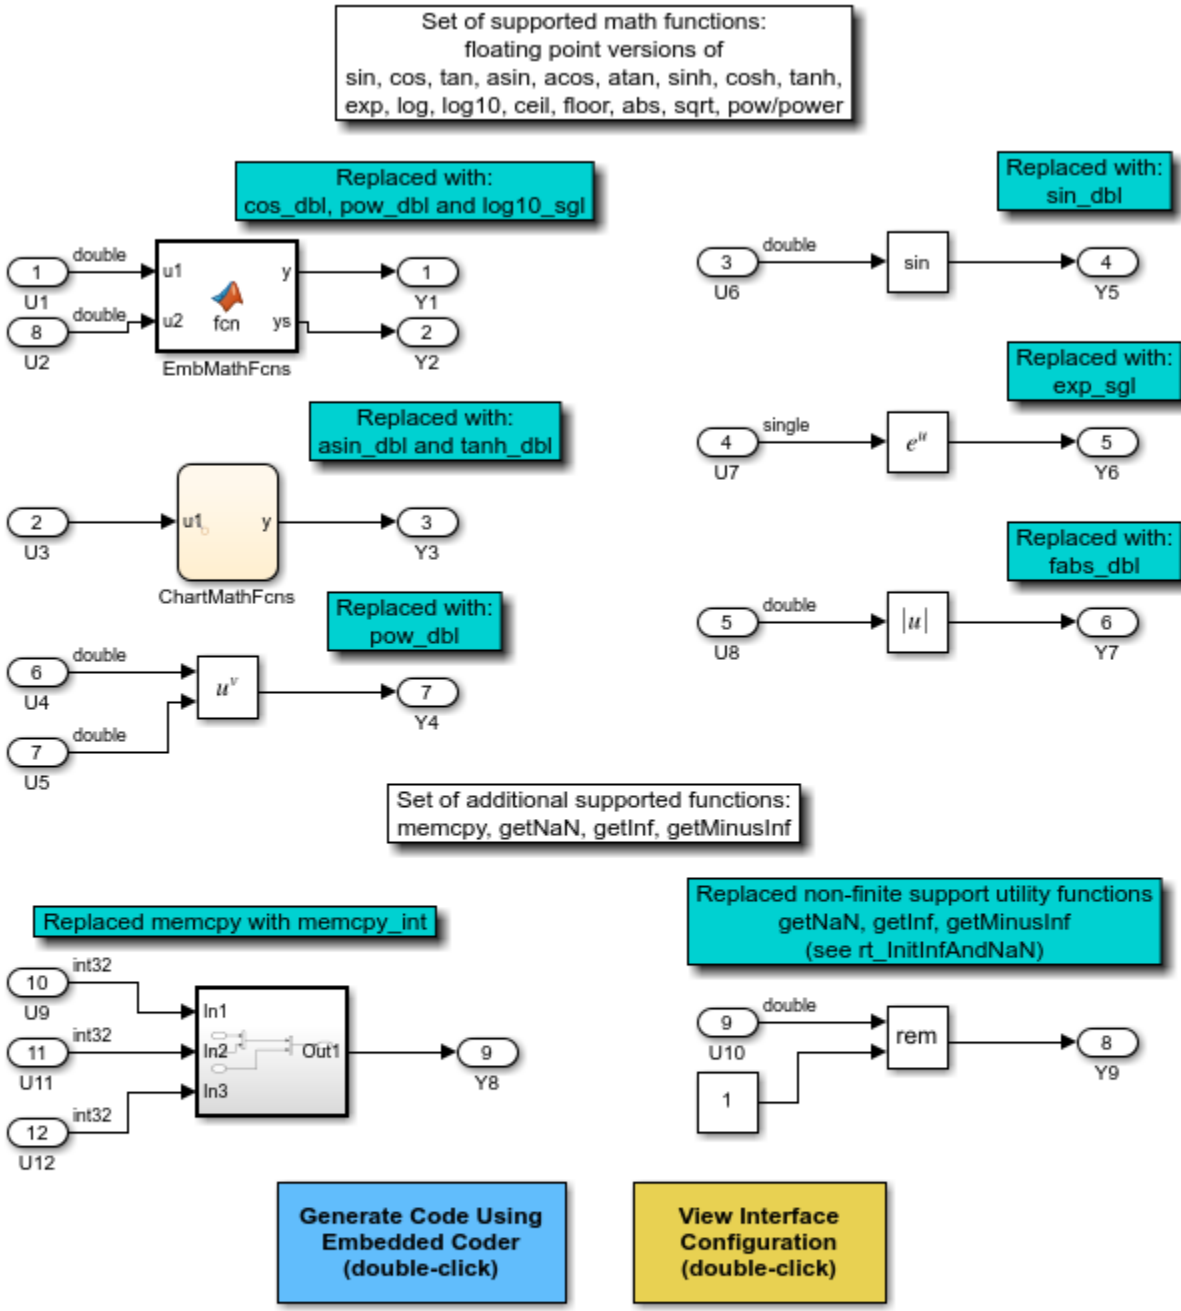
Math Function Replacement

This example defines and registers code replacement mappings for math functions. You can define code replacement mappings for a variety of functions (see “Code You Can Replace From Simulink Models” on page 65-7).

Open the model `rtwdemo_crlmath` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information, see “Math Function Code Replacement” on page 65-98.

```
open_system('rtwdemo_crlmath')
```



Set of supported math functions:
floating point versions of
sin, cos, tan, asin, acos, atan, sinh, cosh, tanh,
exp, log, log10, ceil, floor, abs, sqrt, pow/power
Replaced with:
cos_dbl, pow_dbl and log10_sgl
Replaced with:
sin_dbl
Replaced with:
asin_dbl and tanh_dbl
Replaced with:
exp_sgl
Replaced with:
fabs_dbl
Replaced with:
pow_dbl
Set of additional supported functions:
memcpy, getNaN, getInf, getMinusInf
Replaced memcpy with memcpy_int
Replaced non-finite support utility functions
getNaN, getInf, getMinusInf
(see rt_InitInfAndNaN)

Addition and Subtraction Operator Replacement

This example shows how to define and register code replacement mappings for addition (+) and subtraction (-) operations. When defining entries for addition and subtraction operations, you can specify which of the following algorithms (`EntryInfoAlgorithm`) your library functions implement:

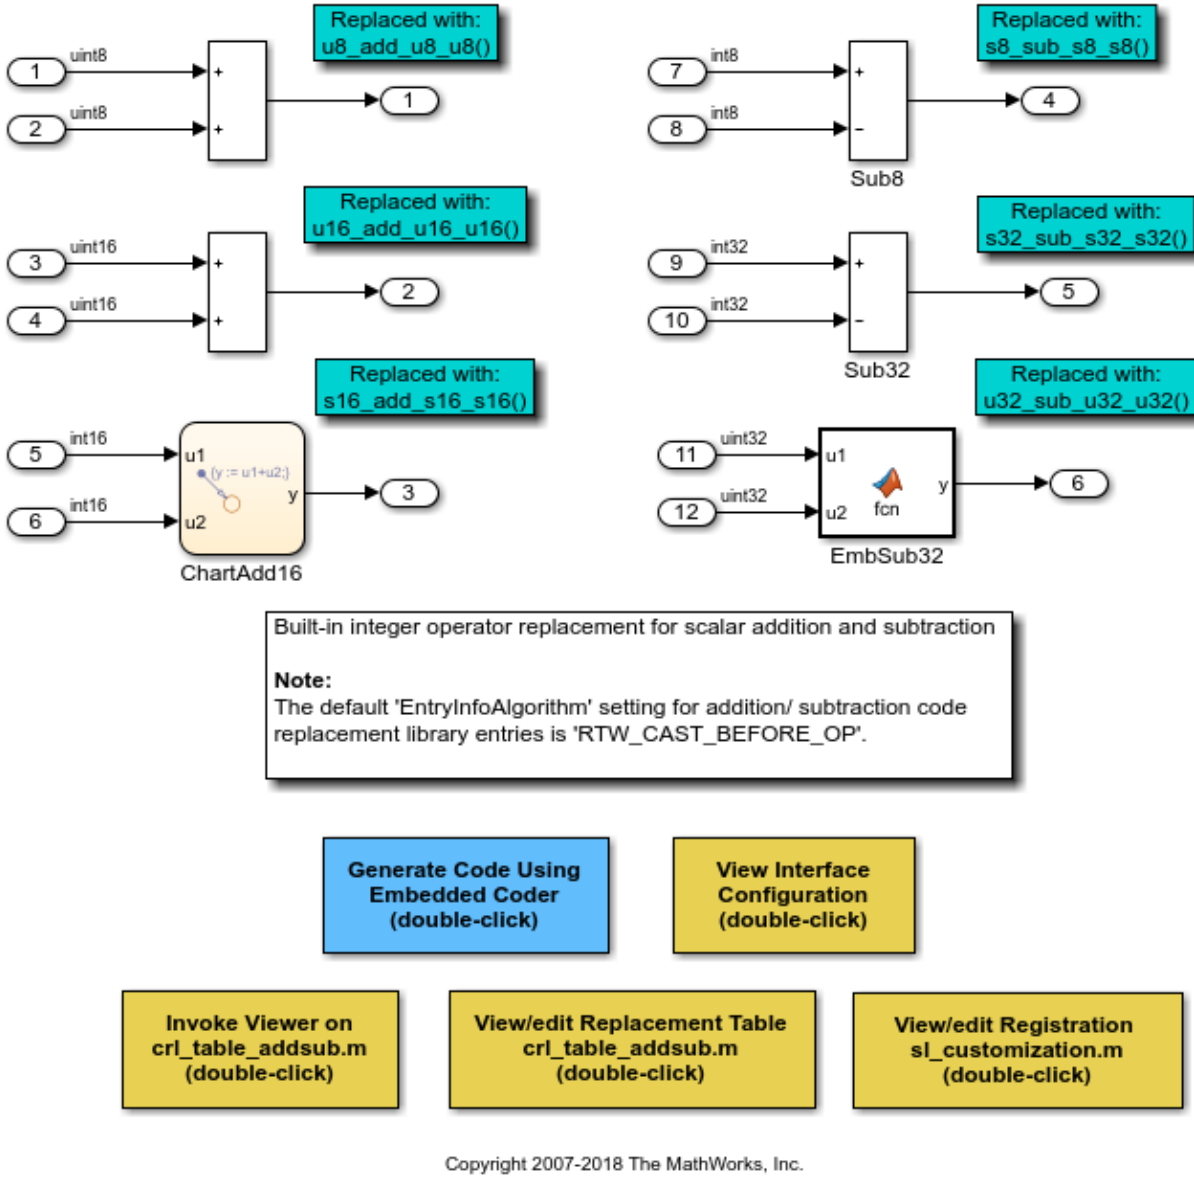
- Cast-before-operation (CBO) (`RTW_CAST_BEFORE_OP`), the default
- Cast-after-operation (CAO) (`RTW_CAST_AFTER_OP`)

1. Open the model `rtwdemo_crladdsub`. The model shows how to define and register code replacement mappings for scalar addition subtraction (-) operations on two operands with the following pairings of built-in integer data types:

- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`

CBO, the default algorithm, is assumed.

```
open_system('rtwdemo_crladdsub')
```

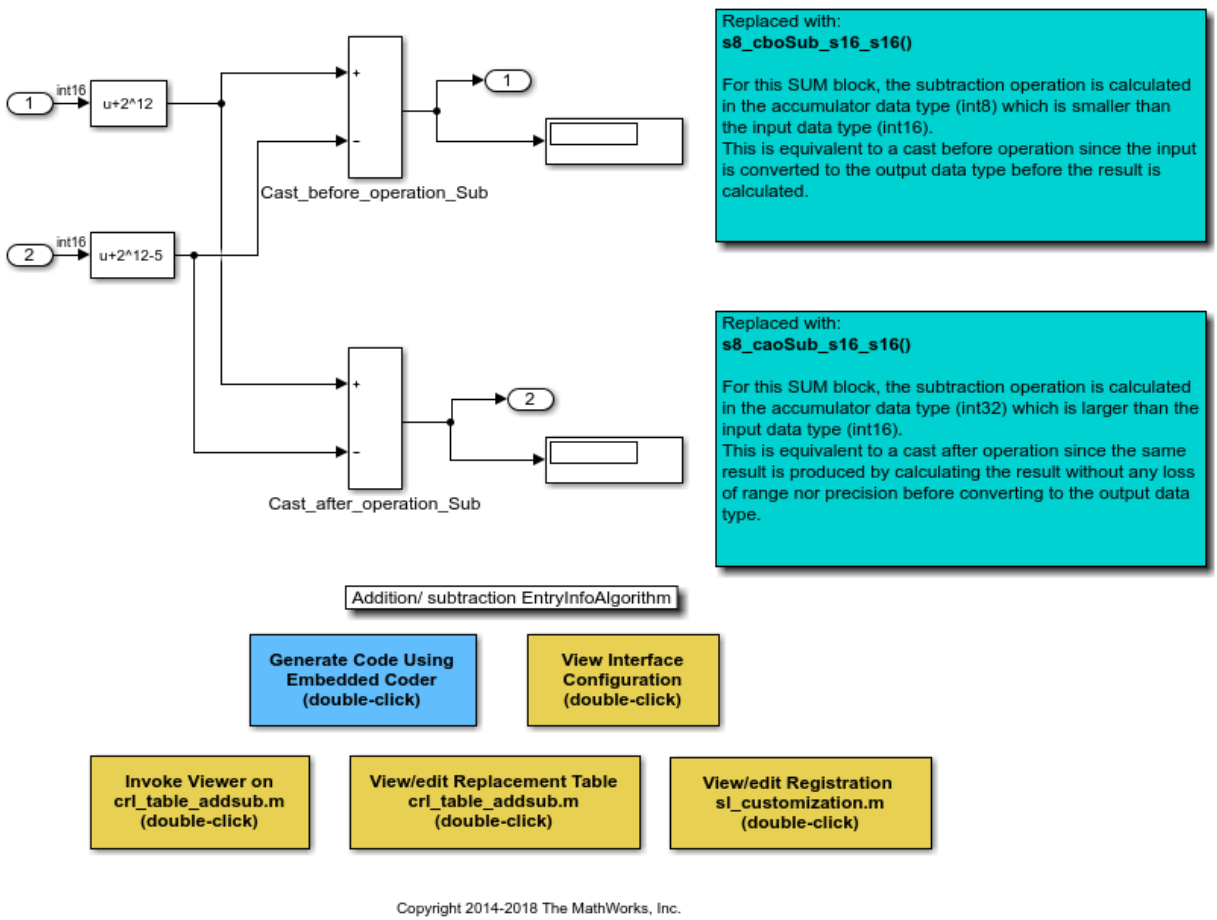


2. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

3. Explore the differences between the CBO and CAO algorithms by opening the model `rtwdemo_crl_cbo_cao`. The model shows two SUM blocks, each demonstrating one of the algorithm settings to match a corresponding code replacement entry.

- For the `Cast_before_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int8`), which is smaller than the input data type (`int16`). This is equivalent to a CBO because the code generator converts the input to the output data type before calculating the result.
- For the `Cast_after_operation_Sub` block, the code generator calculates the subtraction operation in the accumulator data type (`int32`), which is larger than the input data type (`int16`). This is equivalent to a CAO because the code generator produces the same result by calculating the result without loss of range or precision before converting to the output data type.

```
open_system('rtwdemo_crl_cbo_cao')
```



4. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on addition and subtraction operator replacement, see “Addition and Subtraction Operator Code Replacement” on page 65-178. For more information on the addition and subtraction algorithm (`EntryInfoAlgorithm`) options, see `setTflCOperationEntryParameters`.

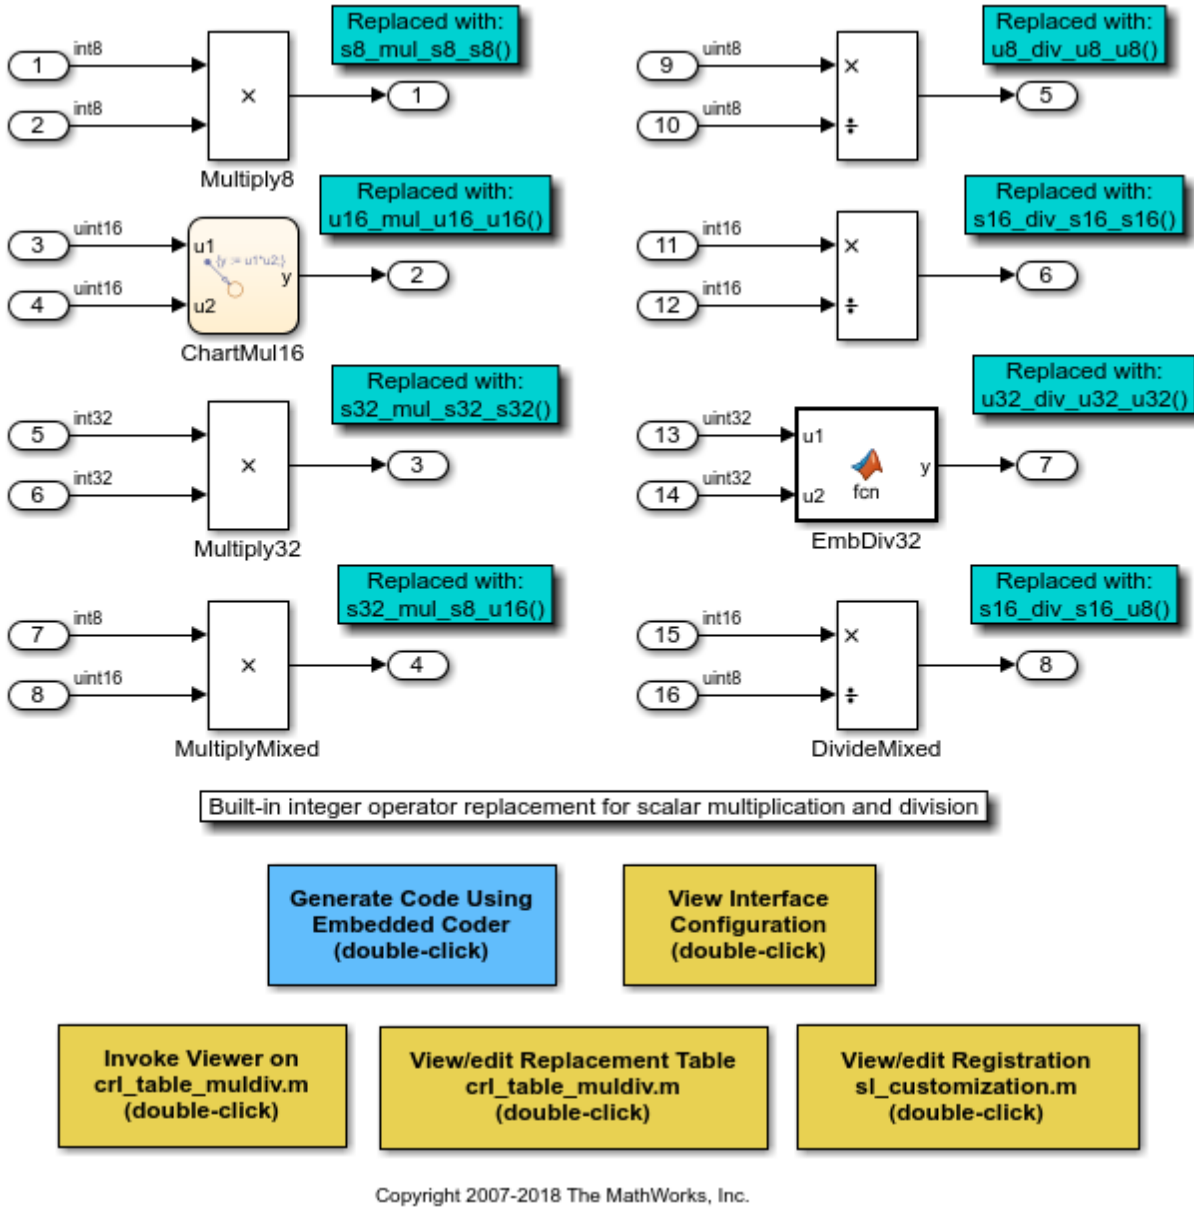
Multiplication and Division Operator Replacement for Built-In Integers

This example defines and registers code replacement mappings for scalar multiplication (*) and division (/) operations. The operations take two operands with the following pairings of built-in integer data types:

- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`

Open the model `rtwdemo_crlmuldiv` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

```
open_system('rtwdemo_crlmuldiv')
```



Scalar Operator Replacement

This example defines and registers code replacement mappings for scalar operations: addition, subtraction, multiplication, complex conjugate, cast, arithmetic shift right, and arithmetic shift left.

Supported types include:

- single, double
- int8, uint8
- int16, uint16
- int32, uint32
- csingle, cdouble
- cint8, cuint8
- cint16, cuint16
- cint32, cuint32
- fixed-point integers
- mixed types (different type on each input)

Open the model `rtwdemo_crlscalarops` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on scalar operator replacement, “Scalar Operator Code Replacement” on page 65-175.

CBO, the default algorithm for addition and subtraction operations, is assumed.

```
open_system('rtwdemo_crlscalarops')

Matrix Operator Replacement

This example defines and registers code replacement mappings for matrix operations: addition, subtraction, multiplication, transposition, conjugate, and Hermitian.

Supported types include:

- `single`, `double`
- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`
- `csingle`, `cdouble`
- `cint8`, `cuint8`
- `cint16`, `cuint16`
- `cint32`, `cuint32`
- fixed-point integers
- mixed types (different type on each input)

Open the model `rtwdemo_crlmatops`, which shows some of these replacements. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix operator replacement, see “Small Matrix Operation to Processor Code Replacement” on page 65-183.

CBO, the default algorithm for addition and subtraction operations, is assumed.

Matrix Multiplication Replacement for BLAS

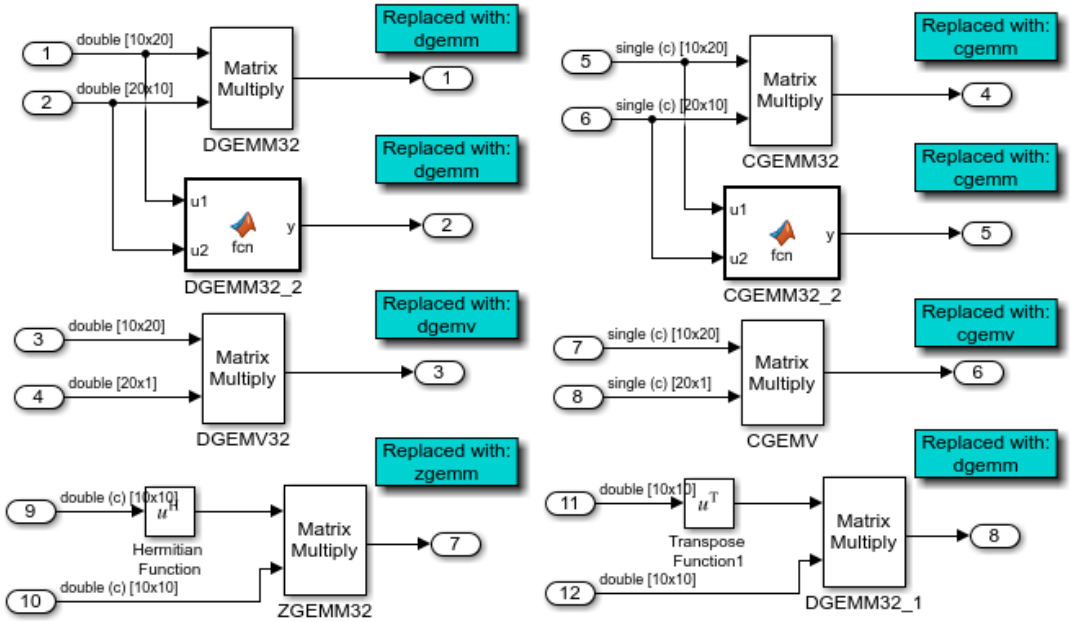
This example defines and registers code replacement mappings for Basic Linear Algebra Subroutines (BLAS) subroutines `xGEMM` and `xGEMV`. You can map the following operations to a BLAS subroutine:

- Matrix multiplication
- Matrix multiplication with transpose on single or both inputs
- Matrix multiplication with Hermitian operation on single or both inputs

Open the model `rtwdemo_crlblas` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

For more information on matrix multiplication replacement for BLAS, see “Matrix Multiplication Operation to MathWorks BLAS Code Replacement” on page 65-187.

```
open_system('rtwdemo_crlblas')
```



This example replaces floating point matrix multiplication with either MathWorksBLAS library calls or with ANSI/ISO C BLAS library calls.
Double-click the 'Current CRL'button to switch between the BLAS and ANSI/ISO C BLAS code replacement libraries.

Although BLAS supports matrix/matrix multiplication in the form of C = a .* op(A) * op(B) + bC,
code replacement only supports the limited case of C = op(A) * op(B) (a = 1.0, b = 0.0).
Likewise, although BLAS supports matrix/vector multiplication in the form of y=a op(A)x + by,
code replacement only supports the limited case of y = op(A) x (a = 1.0, b = 0.0)
Here, op(X) = X (no Transpose), XT (Transpose), XH(Conjugate Transpose)

The BLAS library used by this example is supported on Windows and UNIX platforms.

The C BLAS example does not include BLAS implementations and
therefore does not create an executable.

Fixed-Point Operator Replacement for Basic Operators

This example defines and registers code replacement mappings for scalar addition (+), subtraction (-), multiplication (*), and division (/) operations. The operations take two operands with fixed-point data types.

You can define code replacements as matching:

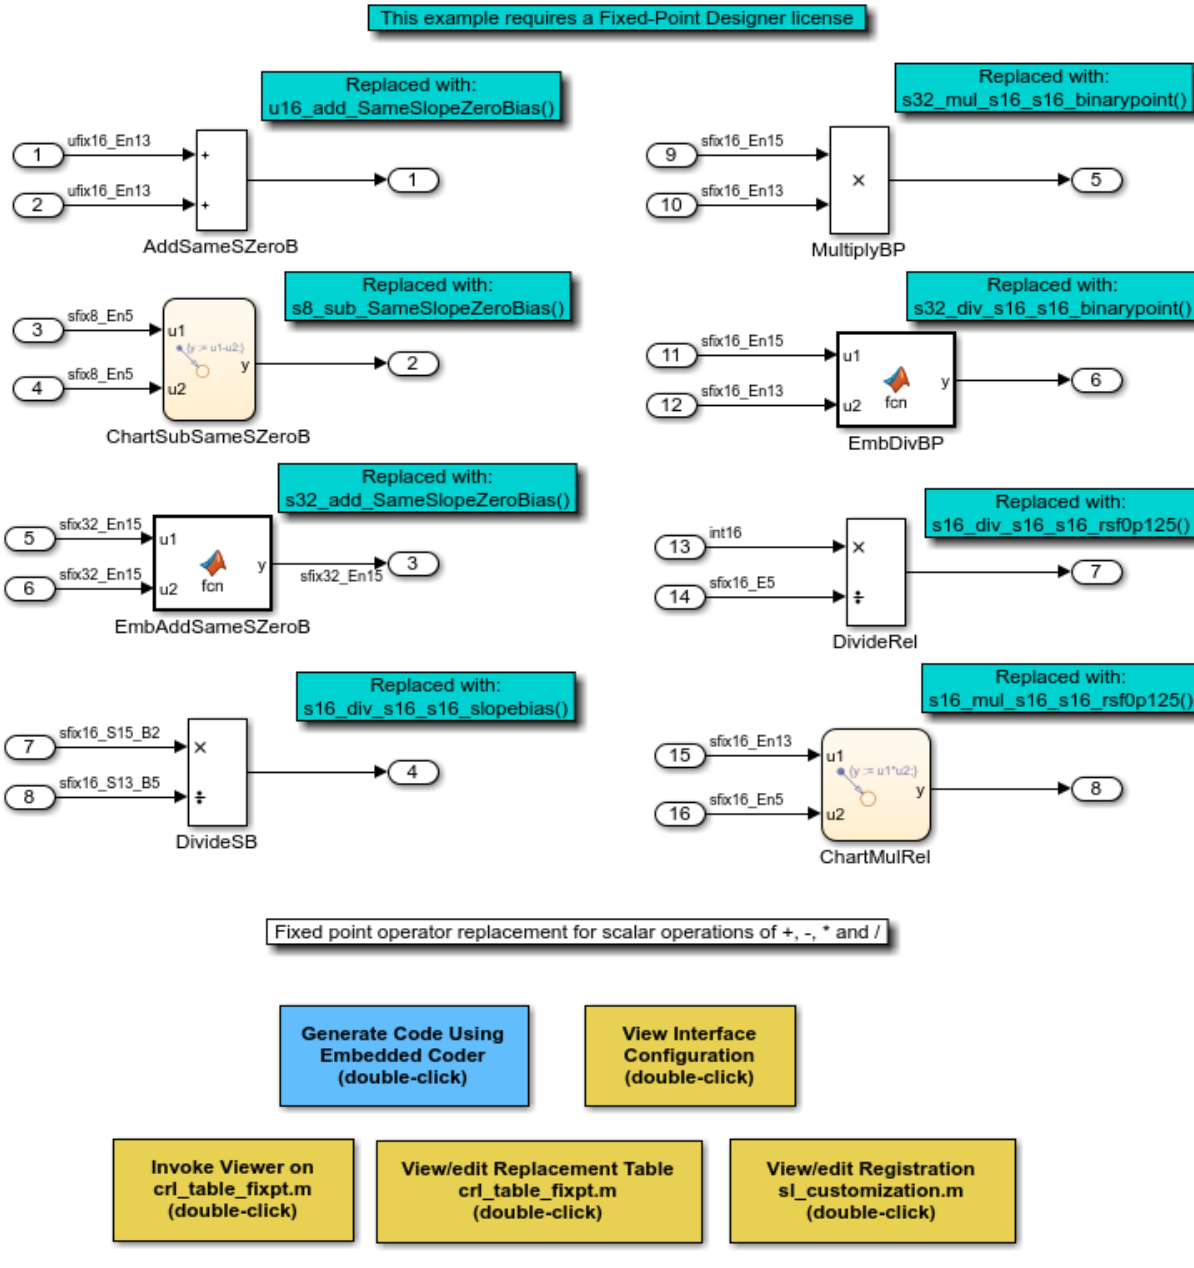
- Slope/bias scaling combination on the inputs and output
- Binary-point scaling combination on the inputs and output
- Relative scaling between the inputs and output
- Same slope value and a zero net bias across the inputs and output.

Open the model `rtwdemo_crlfixpt` and use the buttons at the bottom of the model window to explore the files that define and register the code replacement library mappings.

- By default, for addition and subtraction operator code replacements, the code generator assumes that replacement code implements a cast-before-operation (CBO) algorithm.
- Using fixed-point data types in a model requires a Fixed-Point Designer™ license.

For more information about fixed-point operator code replacement, see “Fixed-Point Operator Code Replacement” on page 65-205.

```
open_system('rtwdemo_crlfixpt')
```



Match and Replacement Process Customization for Functions

This example defines and registers code replacement mappings for custom entries. You can create your own entry by subclassing from `RTW.TflCFunctionEntryML` or `RTW.TflCOperationEntryML`. Your entry class must implement a `do_match` method that customizes your matching logic or modifies the matched entry. The `do_match` method must have a fixed preset signature.

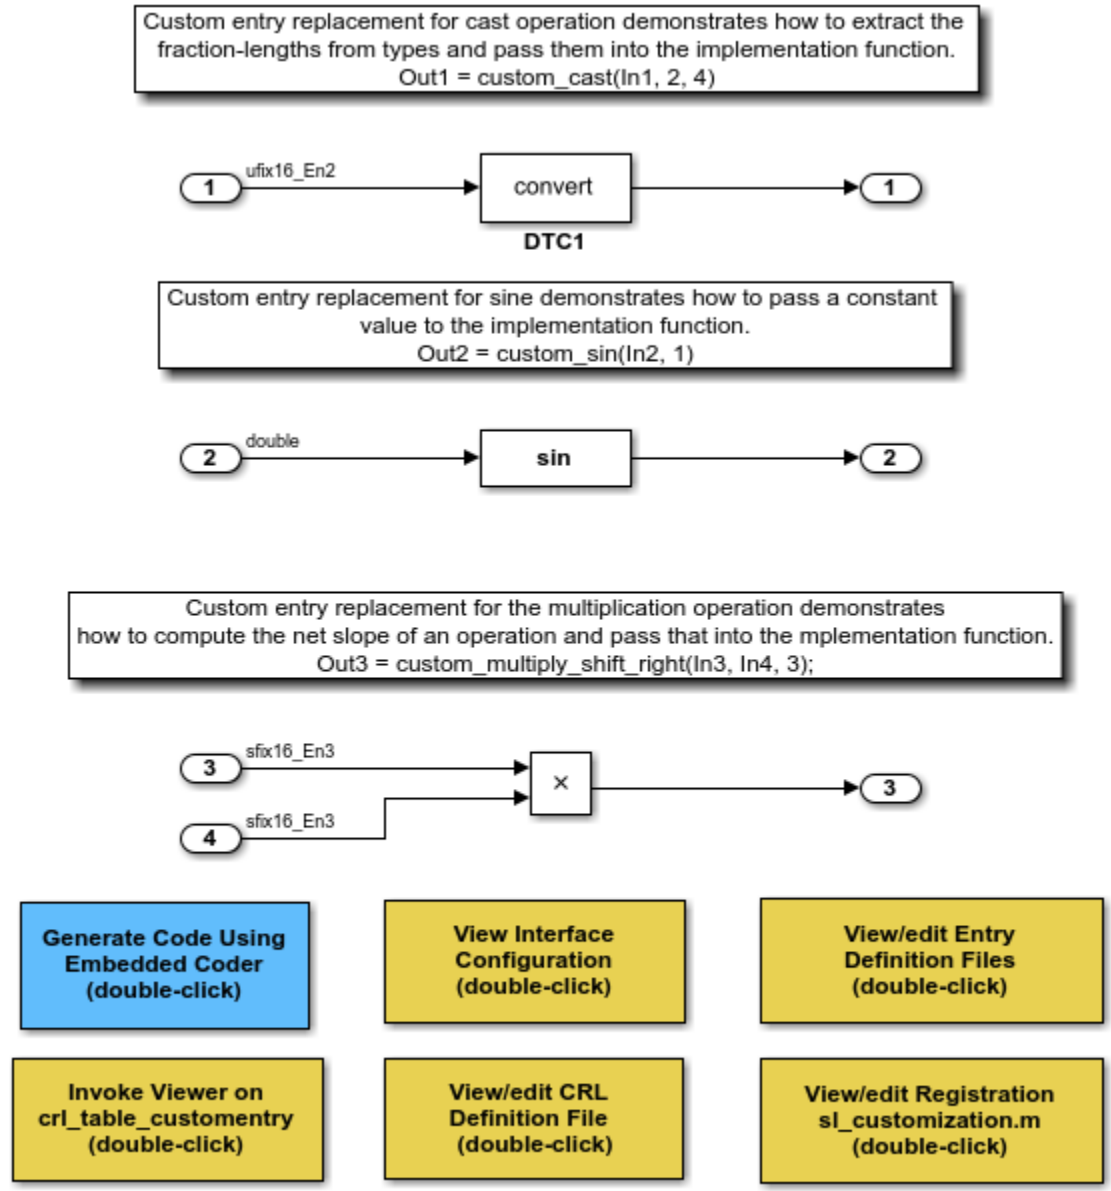
Open the model `rtwdemo_crlcustomentry`. The model shows how to modify the matched entry by injecting constants as additional implementation function arguments. `DTC1`, `Trigonometric Function`, and `Product` show custom entry code replacement for:

- Cast operation that demonstrates how to extract the fraction lengths from types and pass them into the implementation function - `Out1 = custom_cast(In1, 2, 4)`.
- Sine that demonstrates how to pass a constant value to the implementation function - `Out2=custom_sin(In2, 1)`.
- Multiplication operation that demonstrates how to compute the net slope of an operation and pass that into the implementation function - `Out3=custom_multiply_shift_right(In3,In4,3)`.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on custom entries, see “Customize Match and Replacement Process” on page 65-160.

```
open_system('rtwdemo_crlcustomentry')
```



MATLAB Function Replacement

This example defines and registers code replacement mappings for MATLAB® functions specified in the MATLAB Function block. The function can be opted for replacement by specifying `coder.replace` within it. This feature supports replacement of MATLAB® functions with the following:

- Single or multiple inputs
- Single or multiple outputs
- Scalar and matrix inputs and outputs

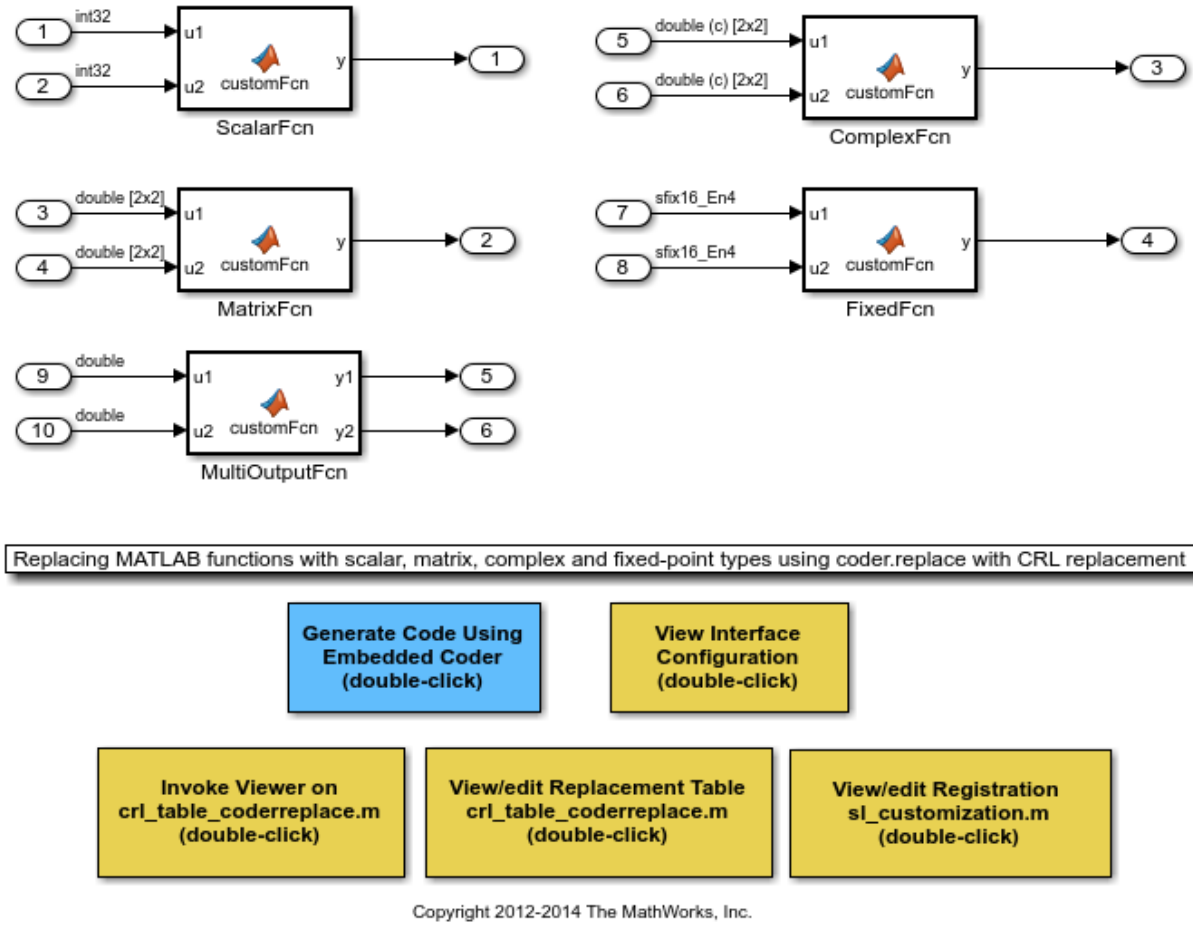
Open the model `rtwdemo_crlcoderreplace`. The model shows some of these requirements. Supported types include:

- `single`, `double`
- `int8`, `uint8`
- `int16`, `uint16`
- `int32`, `uint32`
- `csingle`, `cdouble`
- `cint8`, `cuint8`
- `cint16`, `cuint16`
- `cint32`, `cuint32`
- Fixed-point integers
- Mixed types (different type on each input)

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

For more information on MATLAB® function replacement, see `coder.replace`.

```
open_system('rtwdemo_crlcoderreplace')
```



Data Alignment for Function Implementations

This example shows how to specify the alignment of matrix operands passed into a replacement function. Some target-specific function implementations require data to be aligned to optimize application performance. To configure data alignment for a function implementation:

- Specify the data alignment requirements in a table entry. You can specify alignment for implementation function arguments individually or collectively.

- Specify the data alignment capabilities and syntax for your compiler. Attach an `AlignmentSpecification` object to the `TargetCharacteristics` object of the registry entry specified in your `rtwTargetInfo.m` file.

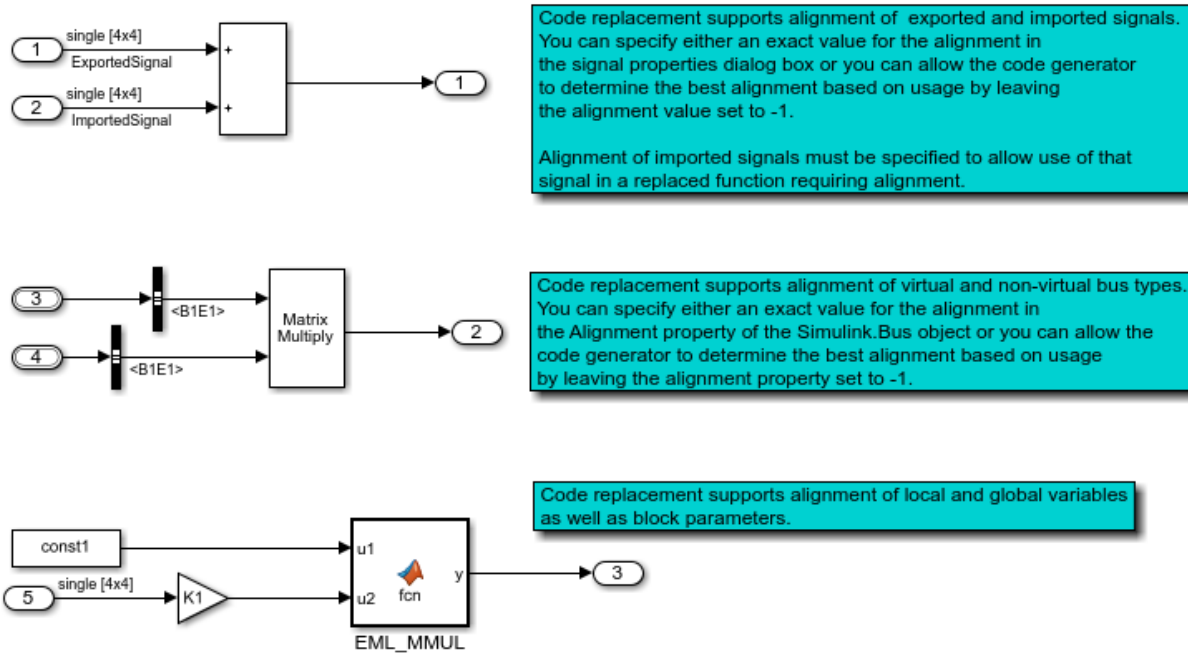
Open the model `rtwdemo_crlalign`. The model shows three data alignment code replacement scenarios:

- `Add` - Alignment of exported and imported signals. You can specify an exact value for the alignment in the Signal Properties dialog box or allow the code generator to determine the best alignment based on usage by leaving the alignment value set to -1.
- `Product` - Alignment of virtual and nonvirtual bus types. You can specify an exact value for the alignment for the **Alignment** property of the Simulink.Bus object or allow the code generator to determine the best alignment based on usage by leaving the **Alignment** property set to -1.
- `EML_MMUL` - Alignment of local variables, global variables, and block parameters.

Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings. Note that the model is configured to use a GCC, Clang, MSVC, or MinGW compiler.

For more information on specifying data alignment for code replacement, see “Data Alignment for Code Replacement” on page 65-137.

```
open_system('rtwdemo_crlalign')
```



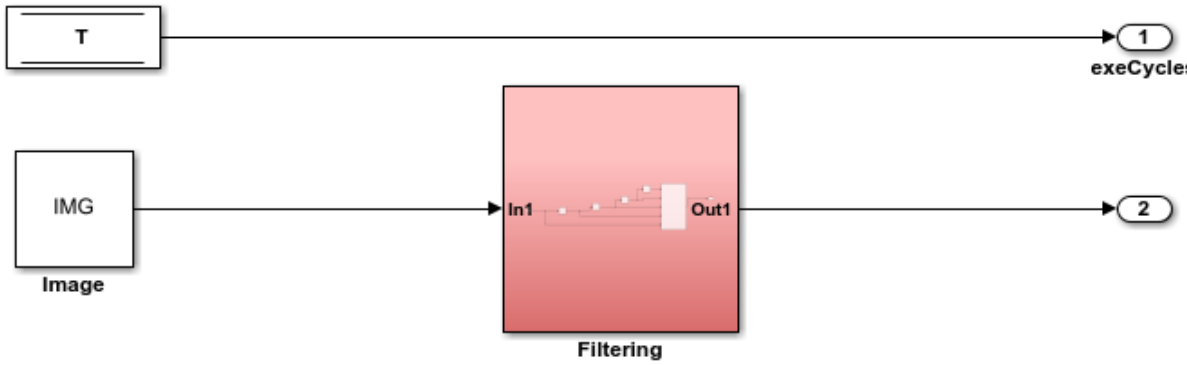
Performance Gain from Data Alignment

This example shows how code replacement data alignment can accelerate execution of a generated executable by enabling deployment of SIMD operations in generated code.

1. Open model `rtwdemo_crlalignperf`. This model illustrates a basic image processing algorithm, represented by subsystem `Root/Filtering/Process/ALGORITHM`. The algorithm slides a 5x5 template across the image one pixel at a time. The image area covered by the template forms another 5x5 matrix. This matrix is element-wise multiplied by the template matrix. The twenty-five elements in the resultant matrix are summed together to form the new value for that pixel. This element-wise matrix multiplication is performed for all pixels in an image, so its efficiency has a significant impact on the overall algorithm performance.

```
perf = 'rtwdemo_crlalignperf';
open_system(perf)

cc = rtwprivate('getCompilerForModel',perf);
isDaDemoSupported = strcmpi(cc.comp.Manufacturer,'GNU') || ...
                    strcmpi(cc.comp.Manufacturer,'Apple') || ...
                    strcmpi(cc.comp.Manufacturer,'Microsoft');
if ~isDaDemoSupported
  recMsg = ['Use "mex -setup" to select either GCC, Clang,'...
      'MSVC, or MinGW and restart this example'];
  warning(['The model "%s" is configured to use GCC, Clang,'...
      'MSVC, or MinGW to create a Data Aligned Executable. %s.'],...
      perf,recMsg); %#ok<CTPCT>
end
```



This example shows how the code replacement data alignment capability can accelerate the execution of the generated program by enabling the deployment of SIMD operations in generated code.

This model example illustrates a basic image processing algorithm, represented by subsystem <Root/Filtering/Process/
ALGORITHM>. The algorithm slides a 5x5 template across the image one pixel at a time. The image area covered by the template forms another 5x5 matrix. This matrix is element-wise multiplied by the template matrix. The twenty-five elements in the resultant matrix are summed together to form the new value for that pixel. This element-wise matrix multiply is performed for all of the pixels in an image, so its efficiency has a significant impact on the overall algorithm performance.

In this example, the model is compiled twice. First, the model is compiled to generate portable, ANSI-C code without data alignment. Next, the model is compiled using a SIMD CRL that does the element-wise matrix multiply using SIMD instructions. The data that the SIMD instructions operate on need to be aligned on a 16-byte boundary.

Double-click the blue button below to execute the example. For both compilations, the generated code is profiled by a profiling hook. After the compilations complete, a figure is displayed that compares the execution time of the subsystem <Root/Filtering/Process/ALGORITHM> with and without data alignment.

For details about how a profile hook works, please refer to example: rtwdemo_profile.

Note:
Select "SIMD Single 5x5 Element-wise Mul for Non-MinGW" CRL for GCC, Clang, and MSVC.
Select " SIMD Single 5x5 Element-wise Mul for MinGW" CRL for MinGW.

Start the Example (double-click)

View/edit Registration sl_customization.m (double-click)

View Replacement Table crl_simd_mul.m (double-click)

View Replacement Function DataAlignment.c (double-click)

View Profiling Hook da_profile_hook.tlc (double-click)

2. Use the buttons at the bottom of the model window to explore the files that define and register the code replacement mappings.

3. Execute the example by double-clicking **Start the Example**. Note that the model is configured to use a GCC, Clang, MSVC, or MinGW compiler. This example compiles the model twice. The first compilation produces portable, ANSI-C code without data alignment. The second compilation uses a SIMD code replacement library that does the element-wise matrix multiply using SIMD instructions. The data on which the SIMD instructions operate needs to be aligned on a 16-byte boundary. For both compilations, the generated code is profiled by a profiling hook. After the compilations complete, a figure appears to show a comparison of the execution time of the subsystem `Root/Filtering/Process/ALGORITHM` with and without data alignment.

4. Generate a baseline by selecting the ANSI® library, building the model, and then running the generated executable ten times. This model uses an element-wise matrix multiplication operation as part of an image processing algorithm. The matrix multiplication is executed numerous times as each pixel in the image is processed. Profiling hooks time the execution of the executable.

```
if (isDaDemoSupported)
  % Create a temporary folder (in your system's temporary folder) for the
  % build and inspection process.
  currentDir = pwd;
  [~,cgDir] = rtwdemodir();

  set_param(perf, 'CodeReplacementLibrary','None'...
      , 'TargetLangStandard','C89/C90 (ANSI)');
  rtwbuild(perf);
  iterations = 10;
  T1 = zeros(iterations, 1);
  for idx = 1:iterations
      evalc(['!', fullfile('.', perf)]);
      evalc(['load ', fullfile('.','rtwdemo_crlalignperf.mat')]);
      T1(idx) = rt_yout.signals(1).values;
  end
  if exist('rtwdemo_crlalignperf_ANSI', 'dir')
      rmdir('rtwdemo_crlalignperf_ANSI', 's');
  end
  movefile('rtwdemo_crlalignperf_ert_rtw', 'rtwdemo_crlalignperf_ANSI');
else
  warning('Unable to build model "%s". %s.', perf,recMsg);
end
```

```
### Starting build procedure for model: rtwdemo_crlalignperf
### Successful completion of build procedure for model: rtwdemo_crlalignperf
```

5. Generate an optimized, data-aligned executable by selecting a library that maps element-wise matrix multiplication operations to SIMD intrinsic calls, and then building the model. The SIMD intrinsic calls impose an alignment requirement on data passed to the intrinsic. The optimized executable is run ten times. Profiling hooks again capture timing data.

```
if (isDaDemoSupported)
  crl=getCorrectCrlForSelectedCompiler(perf);
  set_param(perf,'CodeReplacementLibrary',crl);
  rtwbuild(perf);
  T2 = zeros(iterations, 1);
  for idx=1:iterations
      evalc(['!', fullfile('.', perf)]);
      evalc(['load ', fullfile('.','rtwdemo_crlalignperf.mat')]);
      T2(idx) = rt_yout.signals(1).values;
  end
  if exist('rtwdemo_crlalignperf_SIMD', 'dir')
      rmdir('rtwdemo_crlalignperf_SIMD','s');
  end
  movefile('rtwdemo_crlalignperf_ert_rtw', 'rtwdemo_crlalignperf_SIMD');
else
  warning(...
      'The Data Aligned Executable for the model "%s" could not be generated. %s.'...
          ,perf,recMsg);
end

### Starting build procedure for model: rtwdemo_crlalignperf
### Successful completion of build procedure for model: rtwdemo_crlalignperf
```

6. Compare timing results of the baseline and data-aligned executables. The timing data captured from running the baseline and data-aligned executables is displayed in a graph. The graph illustrates that using SIMD operations with data alignment can effectively speed up execution of data-parallel operations.

```
if (isDaDemoSupported)

      ' could not be executed. %s.'], recMsg);
end
```

Code Replacement Library Exploration and Verification

This example shows Code Replacement Viewer. You can use the Code Replacement Viewer to:

- Explore which code replacement library to use
- Verify the list of tables in a library and the entries in each table
- Review table entry specifications
- Troubleshoot code replacement misses

The following commands open the Code Replacement Viewer for code replacement table `crl_tablemuldiv`:

```
crl = crl_table_muldiv;
crviewer(crl);
daRoot = DAStudio.Root;
me = daRoot.find('-isa', 'DAStudio.Explorer');
```

For more information on the Code Replacement Viewer, see “Verify Code Replacements” on page 65-80.

Build Information

For each entry in a code replacement table, you can specify build information such as the following, for replacement functions:

- Header file dependencies
- Source file dependencies
- Additional include paths
- Additional source paths
- Additional link flags

Additionally, you can specify `RTW.copyFileToBuildDir` to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. You can specify `RTW.copyFileToBuildDir` by setting it as the value of:

- Property `GenCallback` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`.
- Argument `genCallback` in a call to `registerCFunctionEntry`, `registerCOperationEntry`, or `registerCSemaphoreEntry`.

Note: Models in this example are configured for code generation only because the implementations for the replacement functions are not provided.

For more information on specifying build information, see “Specify Build Information for Replacement Code” on page 65-62.

Reserved Identifiers

Each function implementation name defined by a code replacement table entry is reserved as a unique identifier. You can specify other identifiers with a table on a per-header-file basis. Providing additional reserved identifiers can help prevent duplicate symbols and other identifier related compile and link issues.

For more information on specifying reserved identifiers, see “Reserved Identifiers and Code Replacement” on page 65-158.

Remove Example Code Replacement Libraries

When you finish using the example models, remove the example code replacement libraries and close the example models with these commands:

```

```

Improve Execution Efficiency by Reordering Block Operations in the Generated Code

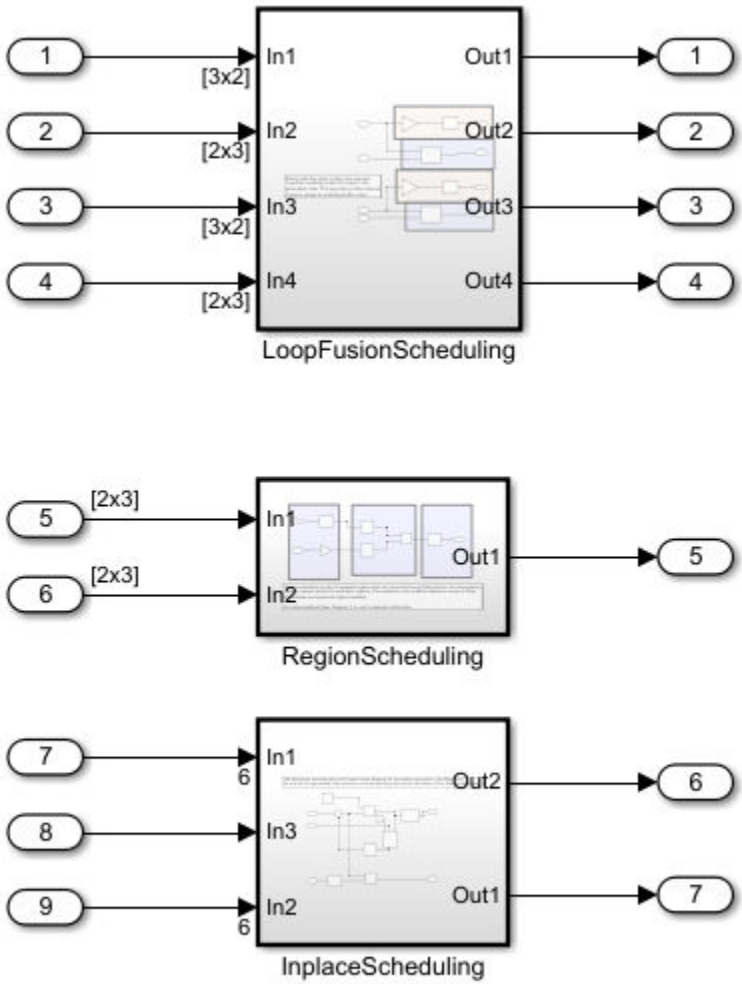
To improve execution efficiency, the code generator can change the block execution order. In the Configuration Parameters dialog box, when you set the **Optimize Block Order** parameter to `Improved Execution Speed`, the code generator can change the block operation order to implement these optimizations:

- Eliminate data copies for blocks that perform inplace operations (that is, use the same input and output variable) and contain algorithm code with unnecessary data copies.
- Combine more `for` loops by executing blocks together that have the same size.
- Reuse the same variable for the input, output, and state of a Unit Delay block by executing the Unit Delay block before upstream blocks.

These optimizations improve execution speed and conserve RAM and ROM consumption.

Example Model

Open the model matlab:rtwdemo_optimizeblockorder. This model contains three subsystems for demonstrating how reordering block operations improves execution efficiency.



`for` Loop Fusion

The subsystem `LoopFusionScheduling` shows how the code generator reorders block operations so that blocks that have the same output size execute together. This

reordering enables `for` loop fusion. Set the **Optimize block order in the generated code** parameter to `Off`.

In your system's temporary folder, create a folder for the build and inspection process and build the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code without the optimization. Code for the `LoopFusionScheduling` subsystem:

```
/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
  const real_T rtu_In3[6], const real_T rtu_In4[6], real_T rty_Out1[6], real_T
  rty_Out2[9], real_T rty_Out3[6], real_T rty_Out4[9])
{
  int32_T i;
  int32_T i_0;
  int32_T tmp;
  int32_T tmp_0;

  /* Bias: '<S2>/Bias' incorporates:
   *  Gain: '<S2>/Gain'
   */
  for (i = 0; i < 6; i++) {
    rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;
  }

  /* End of Bias: '<S2>/Bias' */

  /* Product: '<S2>/Product' */
  for (i = 0; i < 3; i++) {
    for (i_0 = 0; i_0 < 3; i_0++) {
      tmp = i_0 + 3 * i;
      rty_Out2[tmp] = 0.0;
      tmp_0 = i << 1;
      rty_Out2[tmp] += rtu_In2[tmp_0] * rtu_In1[i_0];
      rty_Out2[tmp] += rtu_In2[tmp_0 + 1] * rtu_In1[i_0 + 3];
    }
  }

  /* End of Product: '<S2>/Product' */
```

```
  /* Bias: '<S2>/Bias1' incorporates:
   *  Gain: '<S2>/Gain1'
   */
  for (i = 0; i < 6; i++) {
    rty_Out3[i] = -0.3 * rtu_In3[i] + 0.5;
  }

  /* End of Bias: '<S2>/Bias1' */

  /* Product: '<S2>/Product1' */
  for (i = 0; i < 3; i++) {
    for (i_0 = 0; i_0 < 3; i_0++) {
      tmp = i_0 + 3 * i;
      rty_Out4[tmp] = 0.0;
      tmp_0 = i << 1;
      rty_Out4[tmp] += rtu_In4[tmp_0] * rtu_In3[i_0];
      rty_Out4[tmp] += rtu_In4[tmp_0 + 1] * rtu_In3[i_0 + 3];
    }
  }

  /* End of Product: '<S2>/Product1' */
}
```

With the default execution order, the blocks execute from left to right and from top to bottom. As a result, there are separate `for` loops for the two combinations of Gain and Bias blocks and the Product blocks.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to `Improved Execution Speed` and build the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code with the optimization.

```
/* Output and update for atomic system: '<Root>/LoopFusionScheduling' */
static void LoopFusionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
  const real_T rtu_In3[6], const real_T rtu_In4[6], real_T rty_Out1[6], real_T
  rty_Out2[9], real_T rty_Out3[6], real_T rty_Out4[9])
{
  int32_T i;
  int32_T i_0;
  int32_T tmp;
```

```
  int32_T tmp_0;
  for (i = 0; i < 3; i++) {
    for (i_0 = 0; i_0 < 3; i_0++) {
      /* Product: '<S2>/Product' incorporates:
       *  Product: '<S2>/Product1'
       */
      tmp = i_0 + 3 * i;
      rty_Out2[tmp] = 0.0;

      /* Product: '<S2>/Product1' */
      rty_Out4[tmp] = 0.0;

      /* Product: '<S2>/Product' incorporates:
       *  Product: '<S2>/Product1'
       */
      tmp_0 = i << 1;
      rty_Out2[tmp] += rtu_In2[tmp_0] * rtu_In1[i_0];

      /* Product: '<S2>/Product1' */
      rty_Out4[tmp] = rty_Out4[3 * i + i_0] + rtu_In4[tmp_0] * rtu_In3[i_0];

      /* Product: '<S2>/Product' incorporates:
       *  Product: '<S2>/Product1'
       */
      tmp_0++;
      rty_Out2[tmp] += rtu_In2[tmp_0] * rtu_In1[i_0 + 3];

      /* Product: '<S2>/Product1' */
      rty_Out4[tmp] += rtu_In4[tmp_0] * rtu_In3[i_0 + 3];
    }
  }

  for (i = 0; i < 6; i++) {
    /* Bias: '<S2>/Bias' incorporates:
     *  Gain: '<S2>/Gain'
     */
    rty_Out1[i] = -0.3 * rtu_In1[i] + 0.5;

    /* Bias: '<S2>/Bias1' incorporates:
     *  Gain: '<S2>/Gain1'
     */
    rty_Out3[i] = -0.3 * rtu_In3[i] + 0.5;
  }
}
```

In the optimized code, blocks with the same output size execute together. The two sets of Gain and Bias blocks have an output dimension size of `6`, so they execute together. The Product blocks have an output dimension size of `9`, so they execute together. The fusion of `for` loops enables the code generator to set the value of the expression `3 * i + i_0` equal to the temporary variable `tmp_0`. This optimization also improves execution efficiency.

Buffer Reuse for the Input, Output, and State of Unit Delay Blocks

The subsystem `RegionScheduling` shows how the code generator reorders block operations to enable buffer reuse for the input, output, and state of Unit Delay blocks. When computation is part of separate regions that connect only through Delay blocks, the code generator can change the block execution order so that the downstream regions execute before the upstream regions. This execution order enables maximum reuse of Delay block states and input and output variables. Set the **Optimize block order in the generated code** parameter to `Off` and build the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code without the optimization. Code for the `RegionScheduling` subsystem:

```
/* Output and update for atomic system: '<Root>/RegionScheduling' */
static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
  real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
  int32_T i;
  real_T rtb_Sum;
  for (i = 0; i < 6; i++) {
    /* Sum: '<S3>/Sum' incorporates:
     *  UnitDelay: '<S3>/Delay'
     *  UnitDelay: '<S3>/UnitDelay'
     */
    rtb_Sum = localDW->Delay_DSTATE[i] + localDW->UnitDelay_DSTATE[i];

    /* UnitDelay: '<S3>/UnitDelay2' */
    rty_Out1[i] = localDW->UnitDelay2_DSTATE[i];

    /* Update for UnitDelay: '<S3>/Delay' incorporates:
     *  Bias: '<S3>/Bias'
     */
    localDW->Delay_DSTATE[i] = rtu_In1[i] + 3.0;
```

```
    /* Update for UnitDelay: '<S3>/UnitDelay' incorporates:
     *  Gain: '<S3>/Gain'
     */
    localDW->UnitDelay_DSTATE[i] = 2.0 * rtu_In2[i];

    /* Update for UnitDelay: '<S3>/UnitDelay2' */
    localDW->UnitDelay2_DSTATE[i] = rtb_Sum;
  }
}
```

With the default execution order, the generated code contains the extra, temporary variable `rtb_Sum` and a data copy.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to `Improved Execution Speed` and build the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code with the optimization.

```
/* Output and update for atomic system: '<Root>/RegionScheduling' */
static void RegionScheduling(const real_T rtu_In1[6], const real_T rtu_In2[6],
  real_T rty_Out1[6], rtDW_RegionScheduling *localDW)
{
  int32_T i;
  for (i = 0; i < 6; i++) {
    /* UnitDelay: '<S3>/UnitDelay2' */
    rty_Out1[i] = localDW->UnitDelay2_DSTATE[i];

    /* Sum: '<S3>/Sum' incorporates:
     *  UnitDelay: '<S3>/Delay'
     *  UnitDelay: '<S3>/UnitDelay'
     *  UnitDelay: '<S3>/UnitDelay2'
     */
    localDW->UnitDelay2_DSTATE[i] = localDW->Delay_DSTATE[i] +
      localDW->UnitDelay_DSTATE[i];

    /* Bias: '<S3>/Bias' incorporates:
     *  UnitDelay: '<S3>/Delay'
     */
    localDW->Delay_DSTATE[i] = rtu_In1[i] + 3.0;
```

```
    /* Gain: '<S3>/Gain' incorporates:
     *  UnitDelay: '<S3>/UnitDelay'
     */
    localDW->UnitDelay_DSTATE[i] = 2.0 * rtu_In2[i];
  }
}
```

In the optimized code, the blocks in Regions 3, 2, and 1 execute in that order. With that execution order, the generated code does not contain the temporary variable `rtb_Sum` and the corresponding data copy.

Eliminate Data Copies for Blocks That Perform Inplace Operations

The subsystem `InplaceScheduling` shows how the code generator reorders block operations to eliminate data copies for blocks that perform inplace operations. In the Configuration Parameters dialog box, set the **Optimize block order in the generated code** parameter to `Off` and build the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code without the optimization. Code for the `InplaceScheduling` subsystem:

```
/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(void)
{
  int32_T idx1;
  int32_T idx2;
  real_T acc;
  int32_T k;
  real_T rtb_Max[6];
  for (idx1 = 0; idx1 < 6; idx1++) {
    /* Sum: '<S1>/Sum2x3' incorporates:
     *  Inport: '<Root>/In7'
     *  UnitDelay: '<S1>/Unit Delay'
     */
    rtDWork.UnitDelay_DSTATE[idx1] += rtU.In7[idx1];

    /* MinMax: '<S1>/Max' */
    if (2.0 > rtDWork.UnitDelay_DSTATE[idx1]) {
      rtb_Max[idx1] = 2.0;
    } else {
```

```
    rtb_Max[idx1] = rtDWork.UnitDelay_DSTATE[idx1];
  }

  /* End of MinMax: '<S1>/Max' */
}

/* S-Function (sdsp2norm2): '<S1>/Normalization' incorporates:
 *  Outport: '<Root>/Out7'
 */
idx1 = 0;
idx2 = 0;
acc = 0.0;
for (k = 0; k < 6; k++) {
  acc += rtb_Max[idx1] * rtb_Max[idx1];
  idx1++;
}

acc = 1.0 / (sqrt(acc) + 1.0E-10);
for (k = 0; k < 6; k++) {
  rtY.Out7[idx2] = rtb_Max[idx2] * acc;
  idx2++;

  /* Outport: '<Root>/Out6' incorporates:
   *  Bias: '<S1>/Bias'
   *  Inport: '<Root>/In8'
   *  Outport: '<Root>/Out7'
   *  Product: '<S1>/Product'
   */
  rtY.Out6[k] = (rtU.In8 + 1.0) * rtDWork.UnitDelay_DSTATE[k];

  /* Switch: '<S1>/Switch' incorporates:
   *  Inport: '<Root>/In9'
   *  UnitDelay: '<S1>/Unit Delay'
   */
  if (rtU.In9[k] > 0.0) {
    rtDWork.UnitDelay_DSTATE[k] = 0.0;
  } else {
    rtDWork.UnitDelay_DSTATE[k] = rtb_Max[k];
  }

  /* End of Switch: '<S1>/Switch' */
}
```

```
  /* End of S-Function (sdsp2norm2): '<S1>/Normalization' */
}
```

With the default execution order, the Max block executes before the Product block. To hold the Sum block output, the generated code contains two variables, `UnitDelay_DSTATE` and `rtb_Max`.

Generate code with the optimization. Set the **Optimize block order in the generated code** parameter to `Improved Execution Speed` and build the model.

```
### Starting build procedure for model: rtwdemo_optimizeblockorder
### Successful completion of build procedure for model: rtwdemo_optimizeblockorder
```

View the generated code with the optimization.

```
/* Output and update for atomic system: '<Root>/InplaceScheduling' */
static void InplaceScheduling(void)
{
  real_T rtb_Max[6];
  int32_T idx2;
  real_T acc;
  int32_T k;
  int32_T i;
  for (i = 0; i < 6; i++) {
    /* Sum: '<S1>/Sum2x3' incorporates:
     *  Inport: '<Root>/In7'
     *  UnitDelay: '<S1>/Unit Delay'
     */
    acc = rtU.In7[i] + rtDWork.UnitDelay_DSTATE[i];

    /* Outport: '<Root>/Out6' incorporates:
     *  Bias: '<S1>/Bias'
     *  Inport: '<Root>/In8'
     *  Product: '<S1>/Product'
     */
    rtY.Out6[i] = (rtU.In8 + 1.0) * acc;

    /* MinMax: '<S1>/Max' */
    if (2.0 > acc) {
      acc = 2.0;
    }

    /* End of MinMax: '<S1>/Max' */
```

```
    /* Switch: '<S1>/Switch' incorporates:
     *  Inport: '<Root>/In9'
     *  UnitDelay: '<S1>/Unit Delay'
     */
    if (rtU.In9[i] > 0.0) {
      rtDWork.UnitDelay_DSTATE[i] = 0.0;
    } else {
      rtDWork.UnitDelay_DSTATE[i] = acc;
    }

    /* End of Switch: '<S1>/Switch' */

    /* Sum: '<S1>/Sum2x3' */
    rtb_Max[i] = acc;
  }

  /* S-Function (sdsp2norm2): '<S1>/Normalization' incorporates:
   *  Outport: '<Root>/Out7'
   */
  i = 0;
  idx2 = 0;
  acc = 0.0;
  for (k = 0; k < 6; k++) {
    acc += rtb_Max[i] * rtb_Max[i];
    i++;
  }

  acc = 1.0 / (sqrt(acc) + 1.0E-10);
  for (k = 0; k < 6; k++) {
    rtY.Out7[idx2] = rtb_Max[idx2] * acc;
    idx2++;
  }

  /* End of S-Function (sdsp2norm2): '<S1>/Normalization' */
}
```

The optimized code does not contain the variable `rtb_Max` or the data copy. The generated code contains one variable, `UnitDelay_DSTATE`, for holding the Sum block output. The Product block reads from `UnitDelay_DSTATE` and the Max block reads from and writes to `UnitDelay_DSTATE`.

To implement buffer reuse, the code generator does not violate user-specified block priorities.

Speed Up for-Loop Implementation in Code Generated by Using parfor

When you generate C/C++ code for a model by using a MATLAB Function, a MATLAB System, and For Each subsystem block, by default, the code generator produces code that implements `for`-loops in a single thread. This `for`-loop can be optimized for MATLAB Function and MATLAB System blocks. The iterations of the `parfor`-loop can run in parallel on multiple cores on the target hardware.

Running the iterations in parallel might significantly improve execution speed of generated code. For more information, see “How parfor-Loops Improve Execution Speed” on page 70-76.

The code generator implements the `for`-loops in parallel by using OpenMP.

Embedded Coder software uses the Open Multiprocessing (OpenMP) application interface to support shared-memory, multicore code generation. By default, Embedded Coder uses as many threads as it finds available. If you specify the number of threads to use, Embedded Coder uses at most that number of threads, even if additional threads are available. For more information, see `parfor`.

How parfor-Loops Improve Execution Speed

A `parfor`-loop might provide better execution speed than its analogous `for`-loop because several threads can compute concurrently on the same loop.

Each execution of the body of a `parfor`-loop is called an iteration. The threads evaluate iterations in an arbitrary order and independently of each other. Because each iteration is independent, the threads do not have to be synchronized. If the number of threads is equal to the number of loop iterations, each thread performs one iteration of the loop. If the number of iterations is greater than the number of threads, some threads perform more than one loop iteration.

For example, when a loop of 100 iterations runs on 20 threads, each thread simultaneously executes five iterations of the loop. If your loop takes a long time to run because of the large number of iterations or lengthy individual iterations, you can reduce the run time significantly by using multiple threads. In this example, you might not get 20 times improvement in speed because of parallelization overheads, such as thread creation and deletion.

When to Use parfor-Loops

Use `parfor` when you have:

- Many iterations of a simple calculation. `parfor` divides the loop iterations into groups so that each thread executes one group of iterations.
- A loop iteration that takes a long time to execute. `parfor` executes the iterations simultaneously on different threads. Although this simultaneous execution does not reduce the time spent on an individual iteration, it might significantly reduce overall time spent on the loop.

When Not to Use parfor-Loops

Do not use `parfor` when:

- An iteration of your loop depends on other iterations. Running the iterations in parallel can lead to erroneous results.

  To help you avoid using `parfor` when an iteration of your loop depends on other iterations,Embedded Coder specifies a rigid classification of variables. For more information, see “Classification of Variables in parfor-Loops” (MATLAB Coder). If Embedded Coderdetects loops that do not conform to the `parfor` specifications, it does not generate code and produces an error.

  Reductions are an exception to the rule that loop iterations must be independent. A reduction variable accumulates a value that depends on all the iterations together, but is independent of the iteration order. For more information, see “Reduction Variables” (MATLAB Coder).
- There are only a few iterations that perform some simple calculations.

  Note For small number of loop iterations, you might not accelerate execution due to parallelization overheads. Such overheads include time taken for thread creation, data synchronization between threads, and thread deletion.

Write Code by Using parfor-Loops

To run for-loops in parallel in the generated code, write the code within a MATLAB Function, or a MATLAB System, block using `parfor`.

1. Create a Simulink model.
2. Add the MATLAB Function or the MATLAB System block to the model.
3. Add the code to the MATLAB Function or the MATLAB System block.

```
function y = access3a(u) %#codegen

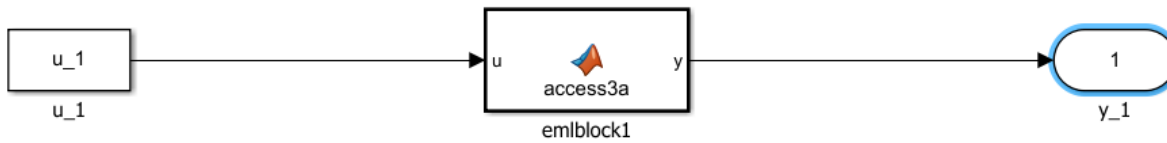
%   Copyright 2010 The MathWorks, Inc.

persistent pA;
if isempty(pA)
    pA = 0;
end
A = ones(20,50);
t = 0;

parfor (i = 1:10,4)
    A(i,1) = A(i,1) + 1;
end

y = A(1,4) + u + t + pA;
```

4. In the **Optimization** pane select the `Maximize execution speed` option from the "Priority" (Simulink Coder) drop-down list. The parameter "Generate parallel for-loops" (Simulink Coder) is automatically selected. The parameter enables the compiler to compute loops in parallel.
5. Connect the blocks.



6. Build the model and generate code.

   In the generated code, the pragma instructs the compiler to execute the looping in OpenMP parallel for-loops through multithreading :

```
#pragma omp parallel for num_threads(4 >
                omp_get_max_threads() ? omp_get_max_threads() : 4)
```

   The number 4 indicates the number of processing threads.

Because the loop body can execute in parallel on multiple threads, it must conform to certain restrictions. If the Embedded Coder software detects loops that do not conform to `parfor` specifications, it produces an error. For more information, see "parfor Restrictions" (MATLAB Coder).

Memory Usage in Embedded Coder

Optimize Generated Code Using Minimum and Maximum Values

To optimize the generated code for your model, you can choose an option to use input range information, also known as design minimum and maximum, that you specify on signals and parameters. These minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

In the Configuration Parameters dialog box, when you select the **Optimize using specified minimum and maximum values** check box, the software uses the minimum and maximum values to derive range information for downstream signals in the model. It then uses this derived range information to determine if it is possible to streamline the generated code by:

- Reducing expressions to constants
- Removing dead branches of conditional statements
- Eliminating unnecessary mathematical operations

This optimization results in:

- Reduced ROM and RAM consumption
- Improved execution speed

Configure Your Model

To make optimization more likely:

- Provide as much design minimum and maximum information as possible. Specify minimum and maximum values for signals and parameters in the model for:
  - Inport and Outport blocks
  - Block outputs
  - Block inputs, for example, for the MATLAB Function and Stateflow Chart blocks
  - `Simulink.Signal` objects
- Before generating code, test the minimum and maximum values for signals and parameters. Otherwise, optimization might result in numerical mismatch with

simulation. You can simulate your model with simulation range checking enabled. If errors or warnings occur, fix these issues before generating code.

Enable Simulation Range Checking

1. In your model, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. In the Configuration Parameters dialog box, select **Diagnostics > Data Validity**.
3. On the **Data Validity** pane, under **Signals**, set **Simulation range checking** to `warning` or `error`.

- Provide design minimum and maximum information upstream of blocks as close to the inputs of the blocks as possible. If you specify minimum and maximum values for a block output, these values are most likely to affect the outputs of the blocks immediately downstream.

Optimize Generated Code Using Specified Minimum and Maximum Values

This example shows how the minimum and maximum values specified on signals and parameters in a model are used to optimize the generated code.

Overview

The specified minimum and maximum values usually represent environmental limits, such as temperature, or mechanical and electrical limits, such as output ranges of sensors.

This optimization uses these values to streamline the generated code. For example, it reduces expressions to constants or removes dead branches of conditional statements.

NOTE: Make sure the minimum and maximum values that you specify are valid limits. Otherwise, this optimization might result in numerical mismatch with simulation.

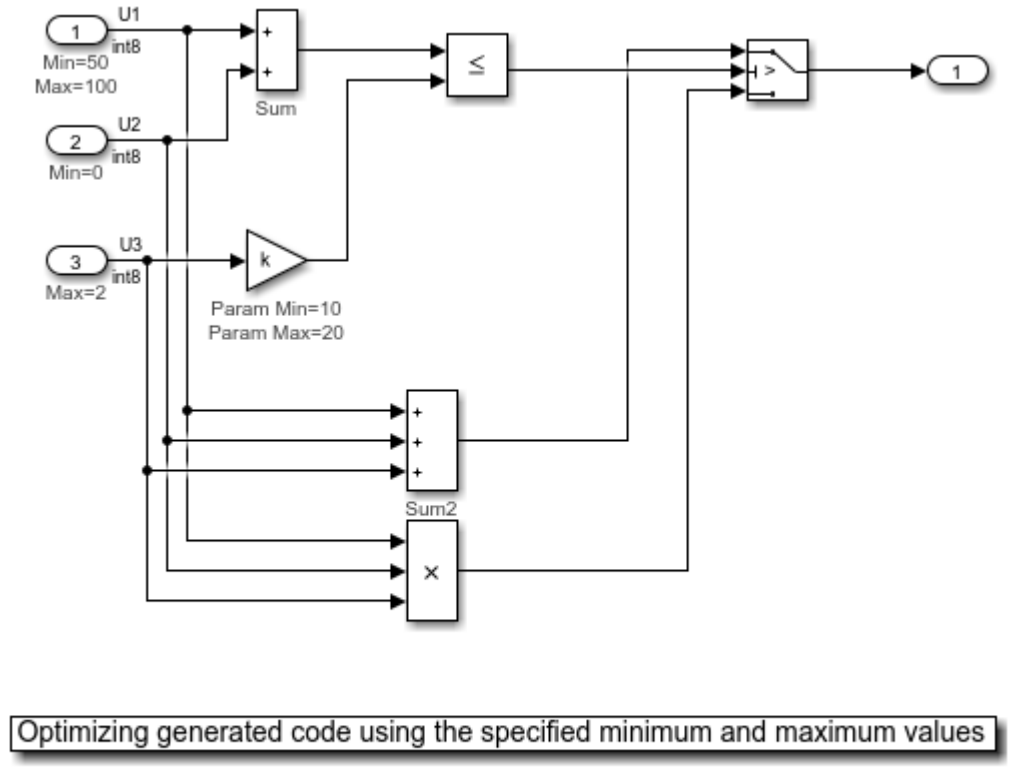
The benefits of optimizing the generated code are:

- Reducing the ROM and RAM consumption.
- Improving the execution speed.

Review Minimum and Maximum Information

Consider the model rtwdemo_minmax. In this model, there are minimum and maximum values specified on Inports and on the gain parameter of the Gain block.

```
model = 'rtwdemo_minmax';
open_system(model);
```



Generate Code Without This Optimization

First, generate code for this model without considering the min and max values.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_minmax
### Successful completion of build procedure for model: rtwdemo_minmax
```

A portion of `rtwdemo_minmax.c` is listed below.

```
cfile = fullfile(cgDir,'rtwdemo_minmax_ert_rtw','rtwdemo_minmax.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_minmax_step(void)
{
  int32_T tmp;

  /* Sum: '<Root>/Sum' incorporates:
   *  Inport: '<Root>/U1'
   *  Inport: '<Root>/U2'
   *  Sum: '<Root>/Sum2'
   *  Switch: '<Root>/Switch'
   */
  tmp = U1 + U2;

  /* Switch: '<Root>/Switch' incorporates:
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/U3'
   *  RelationalOperator: '<Root>/Relational Operator'
   *  Sum: '<Root>/Sum'
   */
  if (tmp <= k * U3) {
    /* Outport: '<Root>/Out1' incorporates:
     *  Sum: '<Root>/Sum2'
     */
    rtY.Out1 = tmp + U3;
  } else {
    /* Outport: '<Root>/Out1' incorporates:
     *  Inport: '<Root>/U1'
     *  Inport: '<Root>/U2'
     *  Product: '<Root>/Product'
     */
    rtY.Out1 = U1 * U2 * U3;
  }
}
```

Enable This Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, select **Optimize using the specified minimum and maximum values**.

Alternatively, you can enable this optimization by setting the command-line parameter.

```
set_param(model, 'UseSpecifiedMinMax', 'on');
```

Generate Code With This Optimization

In the model, with the specified minimum and maximum values for `U1` and `U2`, the sum of `U1` and `U2` has a minimum value of 50. Considering the range of `U3` and the specified minimum and maximum values for the Gain block parameter, the maximum value of the Gain block's output is 40.

The output of the Relational Operator block remains false, and the output of the Switch block remains the product of the three inputs.

Configure and build the model using Embedded Coder.

```
rtwconfiguredemo(model,'ERT')
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_minmax
### Successful completion of build procedure for model: rtwdemo_minmax
```

View the optimized code from `rtwdemo_minmax.c`.

```
cfile = fullfile(cgDir,'rtwdemo_minmax_ert_rtw','rtwdemo_minmax.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_minmax_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/U1'
   *  Inport: '<Root>/U2'
   *  Inport: '<Root>/U3'
   *  Product: '<Root>/Product'
   *  Switch: '<Root>/Switch'
   */
```

```
  rtY.Out1 = U1 * U2 * U3;
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Limitations

- This optimization does not take into account minimum and maximum values for:
  - Merge block inputs. To work around this issue, use a `Simulink.Signal` object on the Merge block output and specify the range on this object.
  - Bus elements.
  - Conditionally-executed subsystem (such as a triggered subsystem) block outputs that are directly connected to an Outport block.

    Outport blocks in conditionally-executed subsystems can have an initial value specified for use only when the system is not triggered. In this case, the optimization cannot use the range of the block output because the range might not cover the initial value of the block.
- If you use Polyspace software to verify code generated using this optimization, it might mark code that was previously green as orange. For example, if your model contains a division where the range of the denominator does not include zero, the generated code does not include protection against division by zero. Polyspace might mark this code orange because it does not have information about the minimum and maximum values for the inputs to the division.

  Polyspace Code Prover automatically captures some minimum and maximum values specified in the MATLAB workspace, for example, for `Simulink.Signal` and `Simulink.Parameter` objects. In this example, to provide range information to the Polyspace software, use a `Simulink.Signal` object on the input of the division and specify a range that does not include zero.

  Polyspace Code Prover stores these values in a Data Range Specification (DRS) file. However, they do not capture all minimum and maximum values in your Simulink model. To provide additional minimum and maximum information to Polyspace, you can manually define a DRS file.

- If you are using double-precision data types and the **Support non-finite numbers** configuration parameter is selected, this optimization does not occur.
- If your model contains multiple instances of a reusable subsystem and each instance uses input signals with different minimum and maximum values, this optimization might result in different generated code for each subsystem so code reuse does not occur. Without this optimization, code is generated once for the subsystem and shares this code among the multiple instances of the subsystem.
- The Model Advisor check Check safety-related optimization settings generates a warning if this option is selected. For many safety-critical applications, removing dead code automatically is unacceptable because doing so might make code untraceable.

Reduce Global Variables in Nonreusable Subsystem Functions

In this section...

Global variables can increase memory requirements and reduce execution speed. To reduce global RAM for a nonreusable subsystem, you can generate a function interface that passes data through arguments instead of global variables. The Subsystem block parameter “Function interface” (Simulink) provides this option. To compare the outputs for the **Function interface** options, first generate a function for a subsystem with a `void-void` interface, and then generate a function with arguments.

Generate void-void Function

By default, when you configure a Subsystem block as a nonreusable function, it generates a `void-void` interface.

1. Open the example model `rtwdemo_roll`.
2. Right-click the subsystem `RollAngleReference`. From the list select `Block Parameter (Subsystem)`.
3. In the Block Parameters dialog box, confirm that the **Treat as atomic unit** check box is selected.
4. Click the **Code Generation** tab and set the **Function packaging** parameter to `Nonreusable function`.
5. The **Function interface** parameter is already set to `void_void`.
6. Click **Apply** and **OK**.
7. Repeat steps 2–6, for the other subsystems `HeadingMode` and `BasicRollMode`.
8. Generate code and the static code metrics report for `rtwdemo_roll`. This model is configured to generate a code generation report and to open the report automatically. For more information, see “Generate Static Code Metrics Report for Simulink Model” on page 49-39.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` contains a `void-void` function definition:

```
void rtwdemo_roll_RollAngleReference(void)
{
 ...
}
```

In the static code metrics report, navigate to **Global Variables**. With the `void_void` option, the number of bytes for global variables is 55.

2. Global Variables [hide]

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] rtwdemo_roll_U	26	14	6
[+] rtwdemo_roll_DW	9	17	14
[+] rtwdemo_roll_B	8	17	10
[+] rtwdemo_roll_M_	8	0*	0*
[+] rtwdemo_roll_Y	4	1	1
Total	**55**	**49**	

* The global variable is not directly used in any function.

Next, generate the same function with the `Allow arguments` option to compare the results.

Generate Function with Arguments

To reduce global RAM, improve ROM usage and execution speed, generate a function that allows arguments:

1. Open the Subsystem Block Parameter dialog box for `RollAngleReference`.
2. Click the **Code Generation** tab. Set the **Function interface** parameter to `Allow arguments`.
3. Click **Apply** and **OK**.
4. Repeat steps 2 and 3, for the other subsystems `HeadingMode` and `BasicRollMode`.
5. Generate code and the static code metrics report for `rtwdemo_roll`.

In the code generation report, in `rtwdemo_roll.c`, the generated code for subsystem `RollAngleReference` now has arguments:

```
real32_T rtwdemo_roll_RollAngleReference(real32_T rtu_Phi,...
                                         boolean_T rtu_AP_Eng,...
                                         real32_T rtu_Turn_Knob)
 {
 ...
 }
```

In the static code metrics report, navigate to **Global Variables**. With the `Allow arguments` option set, the total number of bytes for global variables is now 47 bytes.

2. Global Variables [hide]

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] rtwdemo_roll_U	26	11	11
[+] rtwdemo_roll_DW	9	17	14
[+] rtwdemo_roll_M_	8	0*	0*
[+] rtwdemo_roll_Y	4	2	2
Total	**47**	**30**	

* The global variable is not directly used in any function.

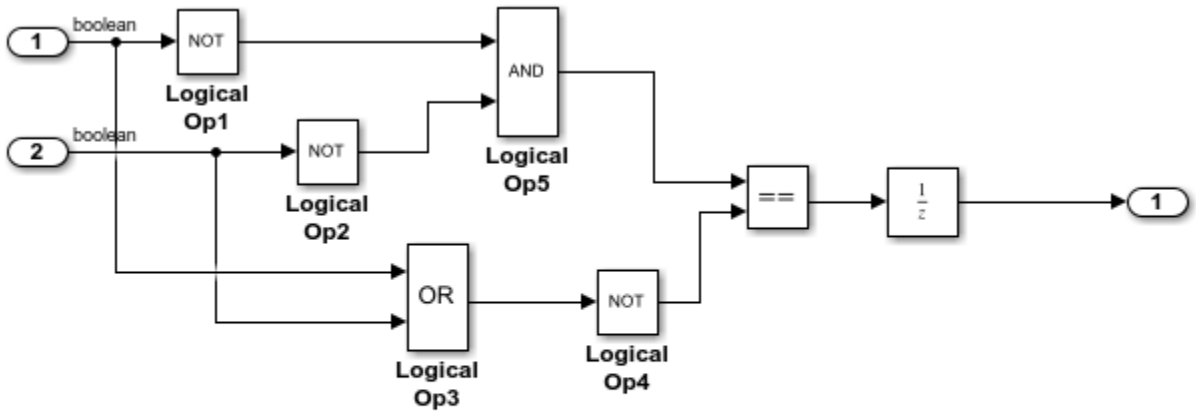
Optimize Generated Code By Packing Boolean Data Into Bitfields

This example shows how to optimize the generated code by packing Boolean data into bitfields. When you select the model configuration parameter **Pack Boolean data into bitfields**, Embedded Coder® packs the Boolean signals into 1-bit bitfields, reducing RAM consumption. By default, the optimization is enabled. This optimization reduces the RAM consumption. Be aware that this optimization can potentially increase code size and execution speed.

Example Model

Consider the model rtwdemo_pack_boolean.

```
model = 'rtwdemo_pack_boolean';
open_system(model);
```



Disable Optimization

1 Open the Configuration Parameters dialog box.

2 On the **Optimization > Signals and Parameters** pane, clear **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to disable the optimization:

```
set_param(model,'BooleansAsBitfields','off');
```

Create a temporary folder (in your system temporary folder) for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Generate Code Without Optimization

Build the model using Embedded Coder®.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_pack_boolean
### Successful completion of build procedure for model: rtwdemo_pack_boolean
```

View the generated code without the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
  boolean_T LogicalOp1;                /* '<Root>/Logical Op1' */
  boolean_T LogicalOp2;                /* '<Root>/Logical Op2' */
  boolean_T LogicalOp5;                /* '<Root>/Logical Op5' */
  boolean_T LogicalOp3;                /* '<Root>/Logical Op3' */
  boolean_T LogicalOp4;                /* '<Root>/Logical Op4' */
  boolean_T RelationalOperator;        /* '<Root>/Relational Operator' */
  boolean_T UnitDelay_DSTATE;          /* '<Root>/Unit Delay' */
} DW;
```

Enable Optimization

1 Open the Configuration Parameters dialog box.

2 On the **Optimization > Signals and Parameters** pane, select **Pack Boolean data into bitfields**.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model,'BooleansAsBitfields','on');
```

Generate Code with Optimization

Build the model using Embedded Coder®.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_pack_boolean
### Successful completion of build procedure for model: rtwdemo_pack_boolean
```

View the generated code with the optimization. These lines of code are in `rtwdemo_pack_boolean.h`.

```
hfile = fullfile(cgDir,'rtwdemo_pack_boolean_ert_rtw','rtwdemo_pack_boolean.h');
rtwdemodbtype(hfile,'/* Block signals and states','/* External inputs',1,0);
```

```
/* Block signals and states (default storage) for system '<Root>' */
typedef struct {
  struct {
    uint_T LogicalOp1:1;               /* '<Root>/Logical Op1' */
    uint_T LogicalOp2:1;               /* '<Root>/Logical Op2' */
    uint_T LogicalOp5:1;               /* '<Root>/Logical Op5' */
    uint_T LogicalOp3:1;               /* '<Root>/Logical Op3' */
    uint_T LogicalOp4:1;               /* '<Root>/Logical Op4' */
    uint_T RelationalOperator:1;       /* '<Root>/Relational Operator' */
    uint_T UnitDelay_DSTATE:1;         /* '<Root>/Unit Delay' */
  } bitsForTID0;
} DW;
```

Selecting **Pack Boolean data into bitfields** enables model configuration parameter **Bitfield declarator type specifier**. To optimize your code further, select `uchar_t`. However, the optimization benefit of the **Bitfield declarator type specifier** setting depends on your choice of target.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

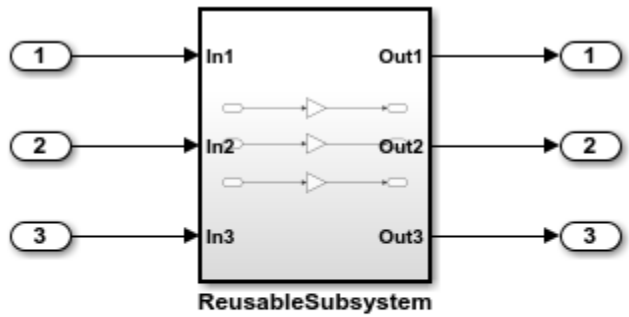
Optimize Generated Code By Passing Reusable Subsystem Outputs as Individual Arguments

This example shows how passing reusable subsystem outputs as individual arguments instead of as a pointer to a structure stored in global memory optimizes the generated code. This optimization conserves RAM consumption and increases code execution speed by reducing global memory usage and eliminating data copies from local variables back to global block I/O structures.

Example Model

Consider the model rtwdemo_reusable_sys_outputs. In this model, the reusable subsystem outputs feed the root outputs of the model.

```
model = 'rtwdemo_reusable_sys_outputs';
open_system(model);
```



Generate Code Without This Optimization

Generate code for this model while passing subsystem outputs as a structure reference. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_reusable_sys_outputs
### Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs
```

The code snippet shows portions of `rtwdemo_reusable_sys_outputs.c`. Notice the global block I/O structure and in the model step function a data copy from this structure.

```
cfile = fullfile(cgDir,'rtwdemo_reusable_sys_outputs_ert_rtw',...
'rtwdemo_reusable_sys_outputs.c');
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
'/* Model initialize', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
  DW_ReusableSubsystem *localDW)
{
  /* Gain: '<S1>/Gain' */
  localDW->Gain = 5.0 * rtu_In1;

  /* Gain: '<S1>/Gain1' */
  localDW->Gain1 = 6.0 * rtu_In2;

  /* Gain: '<S1>/Gain2' */
  localDW->Gain2 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

  /* Inport: '<Root>/In1' incorporates:
   *  Inport: '<Root>/In2'
   *  Inport: '<Root>/In3'
   */
  ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtDW.ReusableSubsystem_d);

  /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */

  /* Outport: '<Root>/Out1' */
  rtY.Out1 = rtDW.ReusableSubsystem_d.Gain;
```

```
  /* Outport: '<Root>/Out2' */
  rtY.Out2 = rtDW.ReusableSubsystem_d.Gain1;

  /* Outport: '<Root>/Out3' */
  rtY.Out3 = rtDW.ReusableSubsystem_d.Gain2;
}
```

Enable This Optimization

1. Open the Configuration Parameters dialog box.
2. On the **Optimization** pane, set **Pass reusable subsystem outputs as** to `Individual arguments`.

Alternatively, you can use the command-line API to enable the optimization:

```
set_param(model, 'PassReuseOutputArgsAs', 'Individual arguments');
```

Generate Code With This Optimization

With this optimization, the `ReusableSubsystem` function has three output arguments, which are direct references to the external outputs. The `rtDW` global structure no longer exists, and the data copies from this structure to the `rtY` (external outputs) structure are not in the generated code.

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_reusable_sys_outputs
### Successful completion of build procedure for model: rtwdemo_reusable_sys_outputs
```

The code snippet below is a portion of `rtwdemo_reusable_sys_outputs.c`. Observe the optimized code.

```
rtwdemodbtype(cfile,'/* Output and update for atomic system',...
'/* Model initialize', 1, 0);
```

```
/* Output and update for atomic system: '<Root>/ReusableSubsystem' */
static void ReusableSubsystem(real_T rtu_In1, real_T rtu_In2, real_T rtu_In3,
  real_T *rty_Out1, real_T *rty_Out2, real_T *rty_Out3)
{
  /* Gain: '<S1>/Gain' */
```

```
  *rty_Out1 = 5.0 * rtu_In1;

  /* Gain: '<S1>/Gain1' */
  *rty_Out2 = 6.0 * rtu_In2;

  /* Gain: '<S1>/Gain2' */
  *rty_Out3 = 7.0 * rtu_In3;
}

/* Model step function */
void rtwdemo_reusable_sys_outputs_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/ReusableSubsystem' */

  /* Inport: '<Root>/In1' incorporates:
   *  Inport: '<Root>/In2'
   *  Inport: '<Root>/In3'
   *  Outport: '<Root>/Out1'
   *  Outport: '<Root>/Out2'
   *  Outport: '<Root>/Out3'
   */
  ReusableSubsystem(rtU.In1, rtU.In2, rtU.In3, &rtY.Out1, &rtY.Out2, &rtY.Out3);

  /* End of Outputs for SubSystem: '<Root>/ReusableSubsystem' */
}
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Convert Data Copies to Pointer Assignments

The code generator optimizes generated code for vector signal assignments by trying to replace `for` loop controlled element assignments and `memcpy` function calls with pointer assignments. Pointer assignments avoid expensive data copies. Therefore, they use less stack space and offer faster execution speed than `for` loop controlled element assignments and `memcpy` function calls. If you assign large data sets to vector signals, this optimization can result in significant improvements to code efficiency.

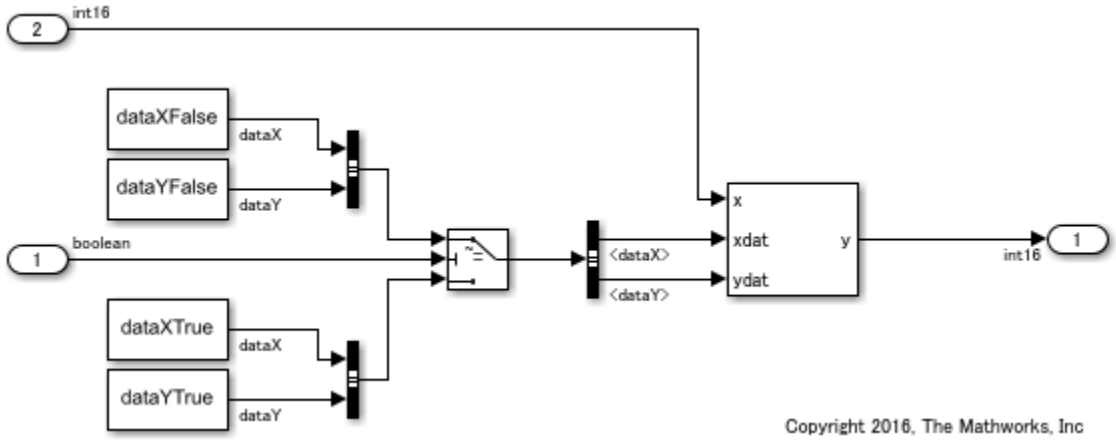
Configure Model to Optimize Generated Code for Vector Signal Assignments

To apply this optimization:

1. Verify that your target supports the `memcpy` function.
2. Determine whether your model uses vector signal assignments (such as `Y=expression`) to move large amounts of data. For example, your model could use a Selector block to select input elements from a vector, matrix, or multidimension signal.
3. On the **Optimization** pane, the **Use memcpy for vector assignment parameter**, which is on by default, enables the associated **Memcpy threshold (bytes)** parameter.
4. Examine the setting of **Memcpy threshold (bytes)**. By default, it specifies 64 bytes as the minimum array size for which `memcpy` function calls or pointer assignments can replace `for` loops in the generated code. Based on the array sizes in your application's vector signal assignments, and target environment considerations on the threshold selection, accept the default value or specify another array size.

Example Model

Consider the following model named rtwdemo_pointer_conversion. This model uses a Switch block to assign data to a vector signal. This signal then feeds into a Bus Selector block.



Generate Code without Optimization

1. In the Configuration Parameters dialog box, clear the **Use memcpy for vector assignment** parameter.
2. Create a temporary folder for the build and inspection process.
3. Press **Ctrl+B** to generate code.

```
### Starting build procedure for model: rtwdemo_pointer_conversion
### Successful completion of build procedure for model: rtwdemo_pointer_conversion
```

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c` .

```
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
  int16_T rtb_dataX[100];
  int16_T rtb_dataY[100];
  int32_T i;

  /* Switch: '<Root>/Switch' incorporates:
   *  Constant: '<Root>/Constant'
   *  Constant: '<Root>/Constant1'
   *  Constant: '<Root>/Constant2'
   *  Constant: '<Root>/Constant3'
```

```
   *  Inport: '<Root>/In1'
   */
  for (i = 0; i < 100; i++) {
    if (rtU.In1) {
      rtb_dataX[i] = rtCP_Constant_Value[i];
      rtb_dataY[i] = rtCP_Constant1_Value[i];
    } else {
      rtb_dataX[i] = rtCP_Constant2_Value[i];
      rtb_dataY[i] = rtCP_Constant3_Value[i];
    }
  }

  /* End of Switch: '<Root>/Switch' */

  /* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
   *  Inport: '<Root>/In2'
   *  Outport: '<Root>/Out1'
   */
  /* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
   * Input0  Data Type:  Integer        S16
   * Input1  Data Type:  Integer        S16
   * Input2  Data Type:  Integer        S16
   * Output0 Data Type:  Integer        S16
   * Lookup Method: Linear_Endpoint
   *
   */
  LookUp_S16_S16( &(rtY.Out1), &rtb_dataY[0], rtU.In2, &rtb_dataX[0], 99U);
}
```

Without the optimization, the generated code contains `for` loop controlled element assignments.

Enable Optimization and Generate Code

1. In the Configuration Parameter dialog box, select the **Use memcpy for vector assignment** parameter.
2. Generate code.

```
### Starting build procedure for model: rtwdemo_pointer_conversion
### Successful completion of build procedure for model: rtwdemo_pointer_conversion
```

View the generated code without the optimization. Here is a portion of `rtwdemo_pointer_conversion.c`.

```
/* Model step function */
void rtwdemo_pointer_conversion_step(void)
{
  const int16_T *rtb_dataX_0;
  const int16_T *rtb_dataY_0;

  /* Inport: '<Root>/In1' */
  if (rtU.In1) {
    /* Switch: '<Root>/Switch' incorporates:
     *  Constant: '<Root>/Constant'
     *  Constant: '<Root>/Constant1'
     */
    rtb_dataX_0 = &rtCP_Constant_Value[0];
    rtb_dataY_0 = &rtCP_Constant1_Value[0];
  } else {
    /* Switch: '<Root>/Switch' incorporates:
     *  Constant: '<Root>/Constant2'
     *  Constant: '<Root>/Constant3'
     */
    rtb_dataX_0 = &rtCP_Constant2_Value[0];
    rtb_dataY_0 = &rtCP_Constant3_Value[0];
  }

  /* End of Inport: '<Root>/In1' */

  /* S-Function (sfix_look1_dyn): '<Root>/Lookup Table Dynamic' incorporates:
   *  Inport: '<Root>/In2'
   *  Outport: '<Root>/Out1'
   */
  /* Dynamic Look-Up Table Block: '<Root>/Lookup Table Dynamic'
   * Input0  Data Type:  Integer        S16
   * Input1  Data Type:  Integer        S16
   * Input2  Data Type:  Integer        S16
   * Output0 Data Type:  Integer        S16
   * Lookup Method: Linear_Endpoint
   *
   */
  LookUp_S16_S16( &(rtY.Out1), &rtb_dataY_0[0], rtU.In2, &rtb_dataX_0[0], 99U);
}
```

Because the setting of the **Memcpy threshold (bytes)** parameter is below the array sizes in the generated code, the optimized code contains pointer assignments for the vector signal assignments.

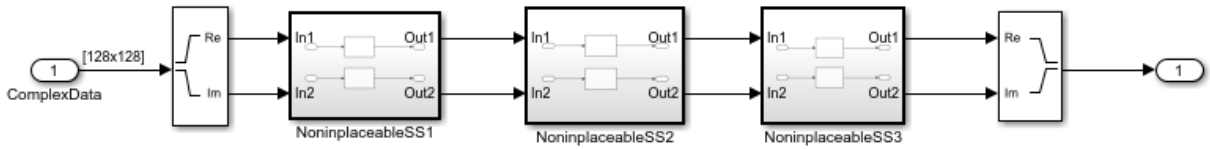
Reuse Buffers of Different Sizes and Dimensions

You can reuse buffers for matrices that have different sizes and shapes. In the Configuration Parameters dialog box, you enable this optimization by selecting **Reuse buffers of different sizes and dimensions**. This optimization conserves RAM and ROM usage and improves code execution speed.

Example Model

The model rtwdemo_differentsizereuse contains signals of different sizes and dimensions.

```
model='rtwdemo_differentsizereuse';
open_system(model);
```



Generate Code Without Optimization

In the Configuration Parameters dialog box, set **Reuse buffers of different sizes and dimension** parameter to `off` or in the MATLAB Command Window, enter:

```
set_param('rtwdemo_differentsizereuse','DifferentSizesBufferReuse','off');
```

Create a folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Turn off comments and build the model.

```
set_param('rtwdemo_differentsizereuse','GenerateComments','off');
rtwbuild('rtwdemo_differentsizereuse');
```

```
### Starting build procedure for model: rtwdemo_differentsizereuse
### Successful completion of build procedure for model: rtwdemo_differentsizereuse
```

View the generated code without the optimization. The `D_Work` structure is:

```
/* Block signals and states (auto storage) for system '<Root>' */
typedef struct {
  real_T ComplextoRealImag_o1[16384];  /* '<Root>/Complex to Real-Imag' */
  real_T ComplextoRealImag_o2[16384];  /* '<Root>/Complex to Real-Imag' */
  real_T z[3969];                      /* '<S3>/DeltaY1' */
  real_T z_i[3969];                    /* '<S3>/DeltaY' */
  real_T z_d[4032];                    /* '<S2>/DeltaX1' */
  real_T z_g[4032];                    /* '<S2>/DeltaX' */
  real_T z_it[4096];                   /* '<S1>/Downsample1' */
  real_T z_m[4096];                    /* '<S1>/Downsample' */
} D_Work;
```

The portion of `rtwdemo_differentsizereuse.c` is:

```
cfile = fullfile(cgDir,'rtwdemo_differentsizereuse_ert_rtw',...
    'rtwdemo_differentsizereuse.c');
rtwdemodbtype(cfile,'#include "rtwdemo_differentsizereuse.h"',...
    'void rtwdemo_differentsizereuse_initialize(void)',1,0);
```

```
#include "rtwdemo_differentsizereuse.h"

  for (i = 0; i < 3969; i++) {
    rtY.Out1[i].re = rtDWork.z_i[i];
    rtY.Out1[i].im = rtDWork.z[i];
  }
}
```

The `D_work` structure contains eight global variables for holding the inputs and outputs of `Downsample`, `DeltaX`, and `DeltaY`. These variables have different sizes.

Generate Code with Optimization

1. In the Configuration Parameters dialog box, verify that **Signal storage reuse** is selected.
2. Set the **Reuse buffers of different sizes and dimensions** parameter to `on` or in the MATLAB Command Window, enter:

```
set_param('rtwdemo_differentsizereuse','DifferentSizesBufferReuse','on');
```

Build the model.

```
set_param('rtwdemo_differentsizereuse','GenerateComments','off');
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_differentsizereuse
### Successful completion of build procedure for model: rtwdemo_differentsizereuse
```

View the generated code without the optimization. The `D_Work` structure is:

```
/* Block signals and states (auto storage) for system '<Root>' */
typedef struct {
  real_T z[4096];                      /* '<S2>/DeltaX1' */
  real_T z_i[16384];                   /* '<S3>/DeltaY' */
  real_T z_if[16384];                  /* '<S3>/DeltaY1' */
} D_Work;
```

The portion of `rtwdemo_differentsizereuse.c` is:

```
cfile = fullfile(cgDir,'rtwdemo_differentsizereuse_ert_rtw',...
    'rtwdemo_differentsizereuse.c');
rtwdemodbtype(cfile,'#include "rtwdemo_differentsizereuse.h"',...
    'void rtwdemo_differentsizereuse_initialize(void)',1,0);
```

```
#include "rtwdemo_differentsizereuse.h"

D_Work rtDWork;
ExternalInputs rtU;
ExternalOutputs rtY;
RT_MODEL rtM_;
RT_MODEL *const rtM = &rtM_;
static void Downsample(const real_T rtu_u[16384], real_T rty_z[4096]);

{
  int32_T x;
  int32_T y;
  int32_T tmp;
  int32_T tmp_0;
  int32_T tmp_1;
  for (x = 0; x < 64; x++) {
    for (y = 0; y < 64; y++) {
```

```
      tmp_0 = (1 + y) << 1;
      tmp_1 = (1 + x) << 1;
      tmp = ((tmp_0 - 2) << 7) + tmp_1;
      tmp_0 = ((tmp_0 - 1) << 7) + tmp_1;
      rty_z[x + (y << 6)] = (((rtu_u[tmp - 2] + rtu_u[tmp - 1]) + rtu_u[tmp_0 -
        2]) + rtu_u[tmp_0 - 1]) / 4.0;
    }
  }
}

static void NoninplaceableSS1(void)
{
  Downsample(rtDWork.z_i, rtDWork.z);
  Downsample(rtDWork.z_e, &rtDWork.z_i[0]);
}

static void DeltaX(const real_T rtu_u[4096], real_T rty_z[4032])
{
  int32_T x;
  int32_T y;
  int32_T tmp;
  for (x = 0; x < 63; x++) {
    for (y = 0; y < 64; y++) {
      tmp = (y << 6) + x;
      rty_z[x + 63 * y] = fabs(rtu_u[tmp] - rtu_u[tmp + 1]);
    }
  }
}

static void NoninplaceableSS2(void)
{
  DeltaX(rtDWork.z, &rtDWork.z_e[0]);
  DeltaX(&rtDWork.z_i[0], &rtDWork.z[0]);
}

static void DeltaY(const real_T rtu_u[4032], real_T rty_z[3969])
{
  int32_T x;
  int32_T y;
  int32_T tmp;
  for (x = 0; x < 63; x++) {
    for (y = 0; y < 63; y++) {
      tmp = 63 * y + x;
      rty_z[tmp] = fabs(rtu_u[tmp] - rtu_u[(1 + y) * 63 + x]);
```

```
    }
  }
}

static void NoninplaceableSS3(void)
{
  DeltaY(&rtDWork.z_e[0], &rtDWork.z_i[0]);
  DeltaY(&rtDWork.z[0], &rtDWork.z_e[0]);
}

void rtwdemo_differentsizereuse_step(void)
{
  int32_T i;
  for (i = 0; i < 16384; i++) {
    rtDWork.z_i[i] = rtU.ComplexData[i].re;
    rtDWork.z_e[i] = rtU.ComplexData[i].im;
  }

  NoninplaceableSS1();
  NoninplaceableSS2();
  NoninplaceableSS3();
  for (i = 0; i < 3969; i++) {
    rtY.Out1[i].re = rtDWork.z_i[i];
    rtY.Out1[i].im = rtDWork.z_e[i];
  }
}
```

The `D_work` structure now contains three global variables instead of eight global variables for holding the inputs and outputs of `Downsample`, `DeltaX`, and `DeltaY`. The generated code uses these variables to hold the differently-sized inputs and outputs.

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Limitations

- If you use a `Reusable` custom storage class to specify reuse on signals that have different sizes and shapes, you must select the **Reuse buffers of different sizes and dimensions** parameter. Otherwise, the model does not build.
- The code generator does not replace a buffer with a lower priority buffer that has a smaller size.

- The code generator does not reuse buffers that have different sizes and symbolic dimensions.

Remove Reset and Disable Functions from the Generated Code

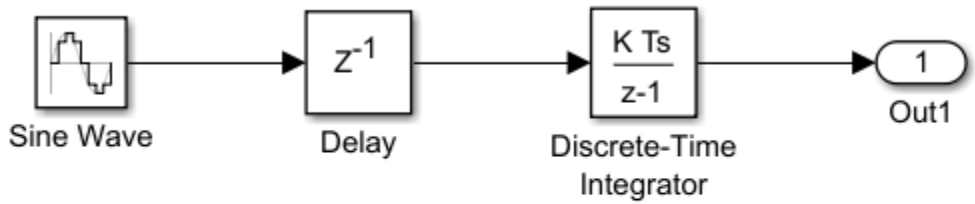
In this section...

This example shows how the code generator removes unreachable (dead code) instances of the reset and disable functions from the generated code for ERT-based systems that include model referencing hierarchies. Optimizing the generated code to remove unreachable code is a requirement for safety-critical systems. This optimization also improves execution speed and reduces ROM consumption.

If a model contains blocks with states, the generated code contains reset and disable functions. If the model is not part of a conditionally executed system, such as an enabled subsystem, the code generator can remove the disable function because the generated code does not call it. If the model is not part of a conditionally executed system that can reset states when a control input enables it, the code generator can remove the reset function because the generated code does not call it.

Example Model

A referenced model, `rtwdemo_optionalDisableResetFunc_bot`, is in `rtwdemo_optionalDisableResetFunc_top`. The referenced model contains two blocks with states, a Delay block and a Discrete-Time Integrator block.



Generate Code

1. Open the models. In the Command Window, type `rtwdemo_optionalDisableResetFunc_bot` and `rtwdemo_optionalDisableResetFunc_top`.
2. In your system temporary folder, create a temporary folder for the build and inspection process.
3. Build the model.
4. Open the `rtwdemo_optionalDisableResetFunc_top.c` and `rtwdemo_optionalDisableResetFunc_bot.c` files.

The `rtwdemo_optionalDisableResetFunc_bot.c` file contains these reset and disable functions.

```
/* System reset for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Reset
  (DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
  /* InitializeConditions for Delay: '<Root>/Delay' */
  localDW->Delay_DSTATE = 0.0;

  /* InitializeConditions for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
  localDW->DiscreteTimeIntegrator_DSTATE = 3.0;
}

/* Disable for referenced model: 'rtwdemo_optionalDisableResetFunc_bot' */
void rtwdemo_optionalDisableResetFunc_bot_Disable(real_T *rty_Out1,
  DW_rtwdemo_optionalDisableResetFunc_bot_f_T *localDW)
{
  /* Disable for DiscreteIntegrator: '<Root>/Discrete-Time Integrator' */
  localDW->DiscreteTimeIntegrator_DSTATE = *rty_Out1;
}
```

The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Disable` function because the model is not part of a conditionally executed system. The `rtwdemo_optionalDisableResetFunc_top_step` function does not call the `rtwdemo_optionalDisableResetFunc_bot_Reset` function because the model is not part of a conditionally executed system that can reset states when a control input enables it.

Enable Optimization

1. Open the Model Configuration Parameters dialog box for `rtwdemo_optionalDisableResetFunc_bot`.
2. Select **Remove Disable Function** and **Remove Reset Function**.

Open the `rtwdemo_optionalDisableResetFunc_bot.c` file. The code does not contain the `rtwdemo_optionalDisableResetFunc_bot_Reset` function or the `rtwdemo_optionalDisableResetFunc_bot_Disable` function.

Code Execution Profiling in Embedded Coder

Code Execution Profiling with SIL and PIL

You can configure a software-in-the-loop (SIL) or processor-in-the-loop (PIL) on page 78-2 simulation to produce execution-time metrics for tasks and functions in your generated code. The software calculates execution times from data that is obtained through code instrumentation added to the SIL or PIL application or the generated code under test. You can use the execution-time metrics to determine whether the generated code meets the requirements for real-time deployment on your target hardware.

For example, you can perform the following analysis:

1. Identify tasks that require the most time. Tasks are main entry points into the generated code. For example, the step function for a sample rate or the *model*`_initialize` function.
2. In these tasks, investigate code sections that require the most time.
3. Identify variations in execution time over time steps.

If you are trying to reduce execution times, the analysis results help you to focus on the most critical code sections. To observe performance changes for an updated model, rerun the SIL or PIL simulation and compare the new metrics against previous metrics.

Note Execution-time measurements depend greatly on the hardware that you use. For reliable results, collect execution-time metrics using hardware on which you plan to deploy the generated code, that is, run PIL simulations that execute code on your target hardware. SIL simulations, which execute code on your host computer, might not produce representative metrics.

When the SIL or PIL simulation is complete, you can:

- View execution-time metrics through a display window or report.
- Use the Simulation Data Inspector to view and compare the variation of execution times over a simulation.
- Analyze the measurements within the MATLAB environment.

Configure Code Execution Profiling

To configure code execution profiling for a SIL or PIL simulation:

1. In your top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
2. Select the **Measure task execution time** check box.
3. For function execution times, from the **Measure function execution times** drop-down list, select one of these options:
   - `Coarse (referenced models and subsystems only)` –– if you want to analyse generated function code for the main model components.
   - `Detailed (all function call sites)` –– if you want to analyse generated function code for all blocks in the model.
4. In the **Workspace variable** field, specify a name. When you run the simulation, the software generates a variable with this name in the MATLAB base workspace. The variable contains the execution-time measurements, and is an object of type `coder.profile.ExecutionTime`.

   If you select the **Data Import/Export > Single simulation output** check box, the software creates the variable in the `Simulink.SimulationOutput` object that you specify.
5. From the **Save options** drop-down list, select one of the following:
   - `Summary data only` — If you want to generate only a report and reduce memory usage, for example, during a long simulation.
   - `All data` — Allows you to generate a report and store execution-time profiles in the base workspace. After the simulation, you can use methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes to retrieve execution-time measurements for every call to each profiled section of code that occurs during the simulation.
6. Click **OK**.

For a PIL simulation, you must configure a hardware-specific timer. When you set up the connectivity configuration for your target, create a timer object. This action is not required for a SIL simulation.

If you select `All data` from the **Save options** drop-down list, the metrics display window and generated report display Simulation Data Inspector icons  . When you click one of the icons, the software imports simulation results into the Simulation Data Inspector. You can then plot execution times and manage and compare plots from various simulations.

Control Profiling Granularity

You can control the granularity of execution-time profiling, that is, prevent the addition of code instrumentation to specific function-call sites. Through the control of profiling granularity, you can:

- Focus on the performance of model components that require improvement. For example, after an initial run, disable profiling for blocks that require little processing time. This action reduces the number of items displayed by the profiling report.
- Reduce the code instrumentation overhead. For example, for simple functions, the code instrumentation overhead can be greater than the execution time of the function code.

To generate execution-time metrics for tasks only, on the **Code Generation** > **Verification** pane of the Configuration Parameters dialog box, select the **Measure task execution time** check box and set **Measure function execution times** to `Off`.

To generate function execution data for referenced models and atomic subsystems in the top model, on the **Code Generation** > **Verification** pane, select the **Measure task execution time** check box and set **Measure function execution times** to `Coarse (referenced models and subsystems only)`.

The generation of function execution data requires the insertion of measurement probes into the generated code. The software inserts measurement probes for an atomic subsystem only if you set the **Function packaging** field (on the **Code Generation** tab of the Function Block Parameters dialog box) to either `Nonreusable function` or `Reusable function`. If the field is set to `Auto`, then the insertion of probes depends on the packaging choice that results from the `Auto` setting. If the field is set to `Inline`, the software does not insert probes.

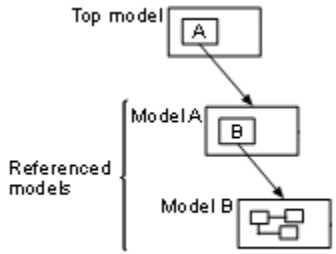
Note In the generated code, the software wraps each function call with measurement probes except when:

- The call site cannot be wrapped because of expression folding (see “Minimize Computations and Storage for Intermediate Results at Block Outputs” (Simulink Coder)).
- The call site is located in the shared utility code (see “Sharing Utility Code” (Simulink Coder)).

To generate function execution times for model reference hierarchies:

1. In the top model, open the Configuration Parameters dialog box, and select the **Code Generation > Verification** pane.
2. Select the **Measure task execution time** check box
3. For each Model block that you want to profile, specify **Measure function execution times** only at the reference level for which you require function execution times.

For example, consider a top model that has Model block A, which in turn contains Model block B.



If you want to generate execution times for functions from model B, select **Measure task execution time** for the top model and specify **Measure function execution times** for model B.

These parameters of the top model override the corresponding parameters of referenced models:

- **Measure task execution time**. If you disable this parameter for the top model, you also disable function profiling for referenced models.
- **Workspace variable**
- **Save options**

To control code execution profiling for a block in a model, for example, a subsystem block, use the `CodeProfilingOverride` block parameter:

1. In the Simulink Editor, select the block.
2. In the Command Window, run:

```
set_param(gcb, 'CodeProfilingOverride', blockParameterValue)
```

Use one of these values for *`blockParameterValue`*:

- `'off'` –– Disables profiling for the block.
- `'on'` –– Enables profiling for the block if profiling is enabled for the parent model.
- `'inherit'` (default) –– Applies profiling settings of parent block.

Changing the block profiling configuration does not cause the regeneration of production code.

If your top model has a PIL block, the execution profiling settings that apply to the PIL block are the settings from the original model that you used to create the PIL block. See “Simulation with Blocks From Subsystems” on page 78-21. You cannot use `CodeProfilingOverride` to control profiling for a PIL block.

- “Analyze Code Execution Data” on page 72-16
- “Specify Hardware Timer” on page 78-56
- “View and Analyze Simulation Results” (Simulink)

View and Compare Code Execution Times

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, you can use the Simulation Data Inspector to observe streamed execution times. At the end of the simulation, you can:

- View execution-time metrics for a profiled model component.
- Open a report of execution-time metrics for all profiled components.
- Use the Simulation Data Inspector to plot and compare execution times from various simulations.

Consider the `rtwdemo_sil_topmodel` model, which has two subsystems `CounterTypeA` and `CounterTypeB`. To measure code execution times for the subsystems, on the **Configuration Parameters** > **Code Generation** > **Verification** pane:

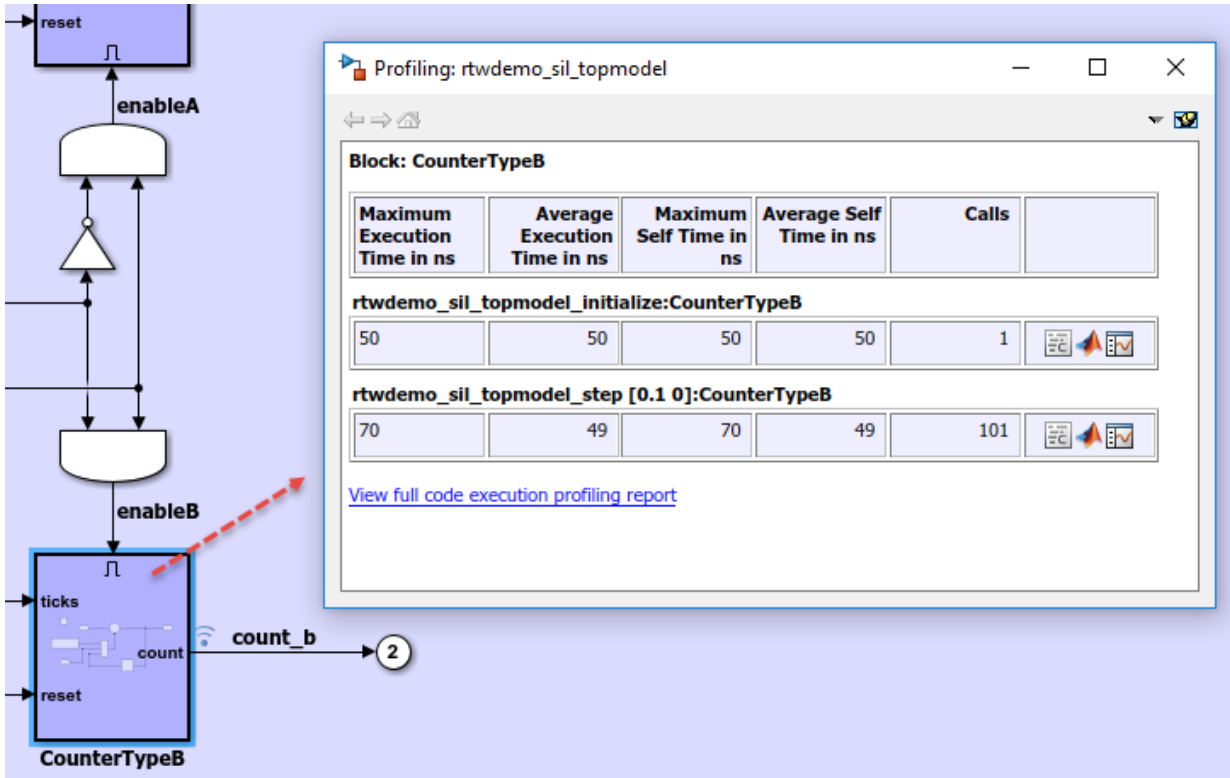
1. Select **Measure task execution time**, which provides execution-time metrics for the task generated from the top model `rtwdemo_sil_topmodel`.
2. Set **Measure function execution times** to `Coarse (referenced models and subsystems only)`, which provides execution-time metrics for the functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.
3. Specify a **Workspace variable**, for example, `executionProfile`.
4. From the **Save options** drop-down list, select `All data`.

Running a simulation generates the variable `executionProfile` in the MATLAB base workspace.

Note If you select the **Data Import/Export** > **Single simulation output** check box, the simulation creates the variable in your specified `Simulink.SimulationOutput` object.

To view streamed execution times during the simulation, open the Simulation Data Inspector. On the Simulink Editor toolbar, click the Simulation Data Inspector button.

When the simulation is complete, the profiled model components are colored blue. To view execution-time metrics for a profiled component, click the component. For example, subsystem `CounterTypeB`.



The display window also has links to:

- The complete profiling report, which provides execution-time metrics for all profiled code sections.
- The profiled code section in the code generation report.
- The Simulation Data Inspector, which allows you to plot and compare execution-time measurements for the profiled code section.

For top-model SIL or PIL simulations, the Simulink Editor background is also colored blue. When you click the background, the display window shows execution-time metrics for top-model tasks.

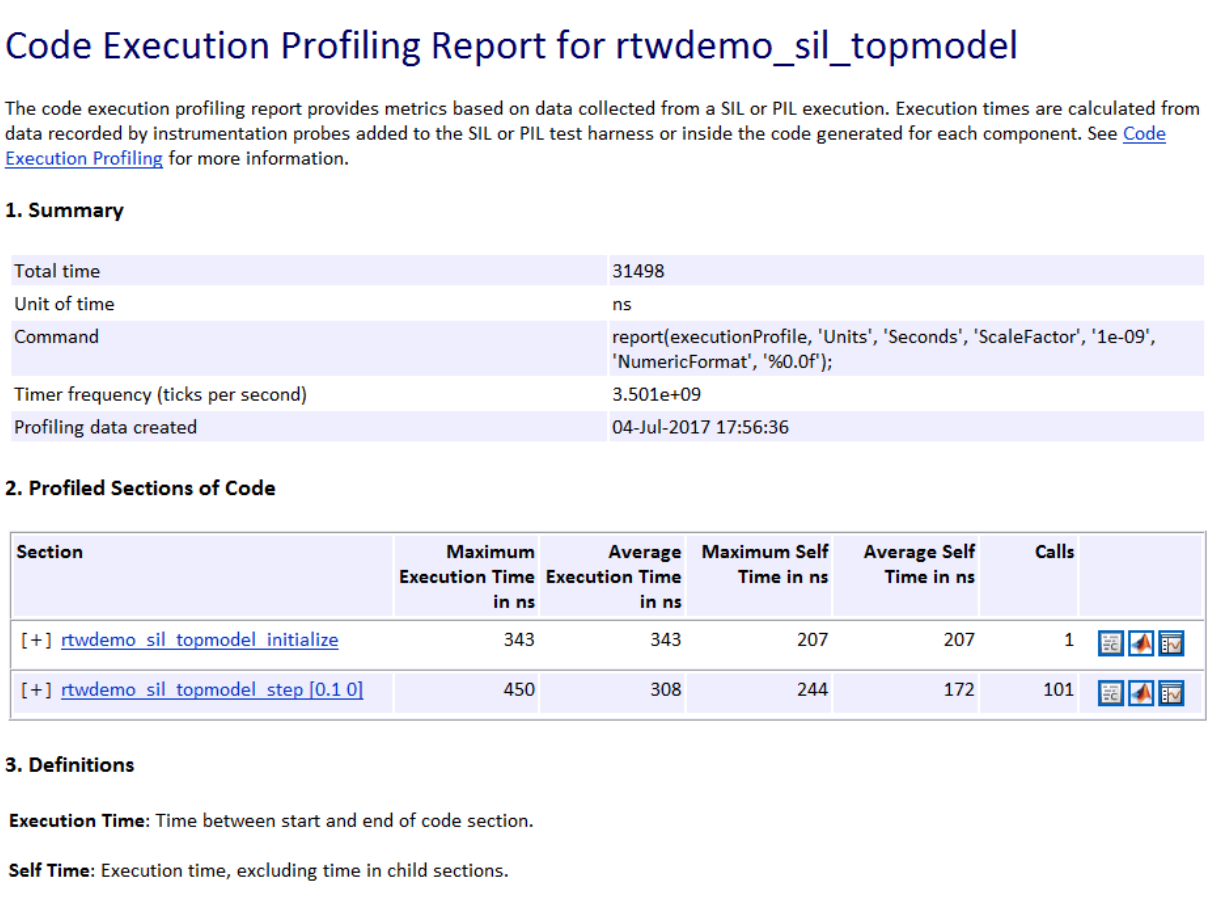
If you close the model or display window, you can reopen the colored model and display window with this line command:

```
>> annotate(executionProfile)
```

Code Execution Profiling Report

At the end of the simulation, you can open this report through the metrics display window or with this line command:

```
>> report(executionProfile)
```



Code Execution Profiling Report for rtwdemo_sil_topmodel

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See Code Execution Profiling for more information.

1. Summary

Total time	31498
Unit of time	ns
Command	report(executionProfile, 'Units', 'Seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f');
Timer frequency (ticks per second)	3.501e+09
Profiling data created	04-Jul-2017 17:56:36

2. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls	
[+] rtwdemo_sil_topmodel_initialize	343	343	207	207	1	
[+] rtwdemo_sil_topmodel_step [0.1 0]	450	308	244	172	101	

3. Definitions

Execution Time: Time between start and end of code section.

Self Time: Execution time, excluding time in child sections.

Part 1 provides a summary. Part 2 contains information about profiled code sections.

Expand and collapse profiled sections in Part 2 by clicking [+] and [–] respectively. This graphic shows fully expanded sections.

2. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls	
[–] rtwdemo_sil_topmodel_initialize	343	343	207	207	1	
CounterTypeA	86	86	86	86	1	
CounterTypeB	50	50	50	50	1	
[–] rtwdemo_sil_topmodel_step [0.1 0]	450	308	244	172	101	
CounterTypeA	136	88	136	88	101	
CounterTypeB	70	49	70	49	101	

The report contains time measurements for:

- The model initialization function `rtwdemo_sil_topmodel_initialize`.
- A task represented by the step function `rtwdemo_sil_topmodel_step [0.1 0]`.
- Functions generated from the subsystems `CounterTypeA` and `CounterTypeB`.

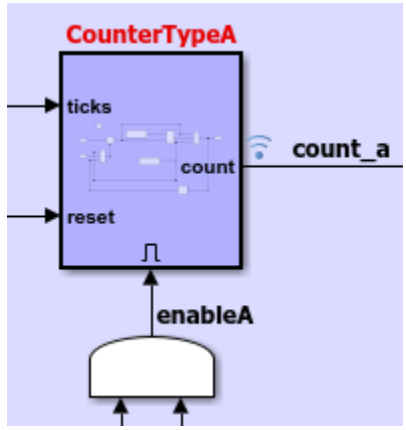
You can go to a profiled code section in the Generated Code view of the Code Generation Report. In the Code Execution Profiling Report, on a code section row, click the icon  . For example, if you click the icon for the `rtwdemo_sil_topmodel_initialize` task, you see the measurement probes around the call site in the SIL application.

```
66 XIL_INTERFACE_ERROR_CODE xilInitialize(uint32_T xilFcnId)
67 {
68   XIL_INTERFACE_ERROR_CODE errorCode = XIL_INTERFACE_SUCCESS;
69
70   /* initialize output storage owned by In-the-Loop */
71   /* Single In-the-Loop Component */
72   if (xilFcnId == 0) {
73     taskTimeStart_51c545e6ce8b10bf(1U);
74     rtwdemo_sil_topmodel_initialize();
75     taskTimeEnd_rt_38248ea98502ec29(1U);
76   } else {
77     errorCode = XIL_INTERFACE_UNKNOWN_FCNID;
78   }
79
80   return errorCode;
81 }
```

If you click the icon for a function, the call site is highlighted.

```
147  /* Model step function */
148  void rtwdemo_sil_topmodel_step(void)
149  {
150    /* Logic: '<Root>/Logical Operator2' incorporates:
151     *  Inport: '<Root>/count_enable'
152     *  Inport: '<Root>/counter_mode'
153     *  Logic: '<Root>/Logical Operator'
154     */
155    enableA = ((!rtU.counter_mode) && rtU.count_enable);
156
157    /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
158    CounterTypeA();
159
160    /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */
```

From the Code Execution Profiling Report, you can trace the model component that produces a set of metrics. For example, in the **Section** column, if you click the `CounterTypeA` hyperlink, the Simulink Editor identifies the subsystem.



By default, the report displays time in nanoseconds (10^{-9} seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds (10^{-6} seconds), use the following command:

```
>>report(executionProfile,...
         'Units', 'Seconds', ...
         'ScaleFactor', '1e-06', ...
         'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is known. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, calibrate the timer manually. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
>>executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a task or function, click the Simulation Data Inspector icon  on the corresponding row. Use the Simulation Data Inspector to manage and compare plots from various simulations.

Note To observe how code sections are invoked over the execution timeline, use the `timeline` function.

The following table describes the information provided in the code section profiles.

Column	Description
Section	Name of task, top model, subsystem, or Model block. Click the link to go to the model. With a task, the sample period and sample offset are listed next to the task name. For example, *`rtwdemo_sil_topmodel_step [0.1 0]`* indicates that the sample period is 0.1 seconds and the sample offset is 0.
Maximum Turnaround Time (Simulink Real-Time and support packages in real-time mode)	Longest time between start and end of code section. Includes preemption time.

Column	Description
Average Turnaround Time (Simulink Real-Time and support packages in real-time mode)	Average time between start and end of code section. Includes preemption time.
Maximum Execution Time	Longest time between start and end of code section.
Average Execution Time	Average time between start and end of code section.
Maximum Self Time	Maximum execution time, excluding time in child sections.
Average Self Time	Average execution time, excluding time in child sections.
Calls	Number of calls to the code section.
	Icon that you click to see the profiled code section in the Generated Code view of the Code Generation Report. The code section can be a task or a function. The specified workspace variable, for example, `executionProfile`, must be present in the base workspace.
	Icon that you click to display the profiled code section in the Command Window. Equivalent to executing the command `executionProfile.Sections(`*`i`*`)`. The specified workspace variable, for example, `executionProfile`, must be present in the base workspace.
	Icon that you click to display measured execution times with Simulation Data Inspector. The specified workspace variable, for example, `executionProfile`, must be present in the base workspace.

More About

- “Tips and Limitations” on page 72-24

Analyze Code Execution Data

After a SIL or PIL simulation, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

1. Open `rtwdemo_sil_topmodel`.
2. On the **Configuration Parameters** > **Code Generation** > **Verification** pane, specify profiling options:
   - Select the **Measure task execution time** check box.
   - Specify a **Workspace variable**, for example, `myExecutionProfile`.
   - From the **Save options** drop-down list, select `All data`.
3. Run a SIL simulation.

The software generates the workspace variable `myExecutionProfile`, an `coder.profile.ExecutionTime` object.

To get the total number of code sections that have profiling data, use the `Sections` method.

```
>> no_of_Sections = myExecutionProfile.Sections

no_of_Sections =

  1×2 ExecutionTimeTaskSection array with properties:

    Name
    Number
    ExecutionTimeInTicks
    SelfTimeInTicks
    TurnaroundTimeInTicks
    TotalExecutionTimeInTicks
    TotalSelfTimeInTicks
    TotalTurnaroundTimeInTicks
    MaximumExecutionTimeInTicks
    MaximumExecutionTimeCallNum
    MaximumSelfTimeInTicks
    MaximumSelfTimeCallNum
    MaximumTurnaroundTimeInTicks
    MaximumTurnaroundTimeCallNum
    NumCalls
    ExecutionTimeInSeconds
    Time
```

To get the `coder.profile.ExecutionTimeSection` object for a profiled code section, use the method `Sections`.

```
>> FirstSectionProfile = myExecutionProfile.Sections(1)
SecondSectionProfile = myExecutionProfile.Sections(2)

FirstSectionProfile =

  ExecutionTimeTaskSection with properties:

                            Name: 'rtwdemo_sil_topmodel_initialize'
                          Number: 1
              ExecutionTimeInTicks: 1188
                   SelfTimeInTicks: 1188
               TurnaroundTimeInTicks: 1188
         TotalExecutionTimeInTicks: 1188
              TotalSelfTimeInTicks: 1188
        TotalTurnaroundTimeInTicks: 1188
       MaximumExecutionTimeInTicks: 1188
       MaximumExecutionTimeCallNum: 1
            MaximumSelfTimeInTicks: 1188
            MaximumSelfTimeCallNum: 1
      MaximumTurnaroundTimeInTicks: 1188
      MaximumTurnaroundTimeCallNum: 1
                        NumCalls: 1
            ExecutionTimeInSeconds: 5.4000e-07
                            Time: 0

SecondSectionProfile =

  ExecutionTimeTaskSection with properties:

                            Name: 'rtwdemo_sil_topmodel_step [0.1 0]'
                          Number: 2
              ExecutionTimeInTicks: [1×101 uint64]
                   SelfTimeInTicks: [1×101 uint64]
               TurnaroundTimeInTicks: [1×101 uint64]
         TotalExecutionTimeInTicks: 70316
              TotalSelfTimeInTicks: 70316
        TotalTurnaroundTimeInTicks: 70316
       MaximumExecutionTimeInTicks: 2448
       MaximumExecutionTimeCallNum: 2
            MaximumSelfTimeInTicks: 2448
            MaximumSelfTimeCallNum: 2
      MaximumTurnaroundTimeInTicks: 2448
      MaximumTurnaroundTimeCallNum: 2
                        NumCalls: 101
            ExecutionTimeInSeconds: [1×101 double]
                            Time: [101×1 double]
```

Use `coder.profile.ExecutionTimeSection` methods to extract profiling information for a particular code section. For example, use `Name` to obtain the name of a profiled task.

```
>> name_of_section = SecondSectionProfile.Name

name_of_section =
```

```
rtwdemo_sil_topmodel_step [0.1 0]
```

If the timer is uncalibrated and you know the timer rate, for example 2.2 GHz, you can use the `coder.profile.ExecutionTime` method `TimerTicksPerSecond` to calibrate the timer:

```
>> myExecutionProfile.TimerTicksPerSecond = 2.2e9;
>> SecondSectionProfile = myExecutionProfile.Sections(2);
```

Remove Instrumentation Overheads from Execution Time Measurements

To improve execution-time profiling of generated code that runs on deterministic hardware, you can run processor-in-the-loop (PIL) simulations that automatically filter the overheads associated with code instrumentation. You can use the target hardware to estimate the average overhead value or you can specify the value manually.

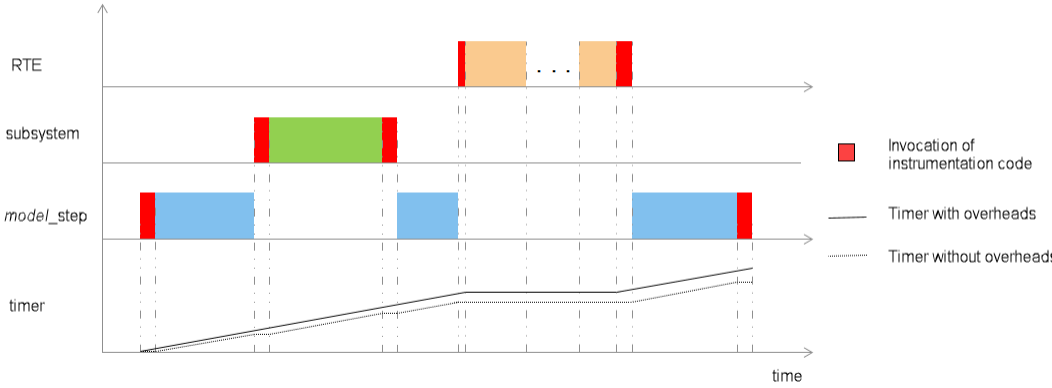
Note By default, the software filters the execution times of AUTOSAR Runtime Environment (RTE) code and functions that run within Simulink, for example, Function Caller blocks.

Approach for Estimating and Removing Instrumentation Overhead

When you create a target connectivity configuration for PIL simulations, through an `rtw.connectivity.Config` subclass, you can specify functions that estimate and remove instrumentation overheads from execution-time measurements. At the start of a processor-in-the-loop (PIL) simulation, the software runs a benchmark program a specified number of times and obtains an average value for the instrumentation overheads. The benchmark program estimates the overheads for the timer API and for timer freezing and unfreezing, task, and function instrumentation code.

During the simulation, the software subtracts the average value of instrumentation overheads from the execution-time measurements. The Simulation Data Inspector and the code execution profiling report display the corrected measurement values.

This figure shows how the uncorrected and corrected timer values correspond to invocations of code sections.



The corrected timer value excludes execution time associated with instrumentation code, RTE code, and function code that runs within Simulink.

To estimate and remove instrumentation overheads from execution-time measurements, the `rtw.connectivity.Config` class provides these functions.

Function	Description
`activateOverheadFiltering`	`obj.activateOverheadFiltering (value);` activates filtering of instrumentation overheads if value is `true`. Deactivates overhead filtering if value is `false`.
`isOverheadFilteringActive`	`obj.isOverheadFilteringActive` returns `true` if instrumentation overhead filtering is activated. Otherwise, returns `false`.
`runOverheadBenchmark`	`obj.runOverheadBenchmark(value);` runs a benchmark program if value is `true`. Does not run the benchmark program if value is `false`.

Function	Description
`isOverheadBenchmarkExecuted`	`obj.isOverheadBenchmarkExecuted;` returns `true` if execution of benchmark program is complete. Otherwise, returns `false`.
`setOverheadBenchmarkSteps`	`obj.setOverheadBenchmarkSteps(`*`steps`*`);` specifies number of steps for benchmark program.
`getOverheadBenchmarkSteps`	*`steps`* `= obj.getOverheadBenchmarkSteps` returns the number of specified steps for the benchmark program.
`setOverheads`	`obj.setOverheads(`*`taskInstrumentationOverhead`*`, `*`functionInstrumentationOverhead`*`, `*`freezingInstrumentation`*`);` specifies the overhead values for task, function, and freezing instrumentation respectively.
`getOverheads`	`[`*`taskInstrumentationOverhead`*`, `*`functionInstrumentationOverhead`*`, `*`freezingInstrumentation`*`] = obj.getOverheads;` returns overhead values for task, function, and freezing instrumentation respectively.

Configure Removal of Instrumentation Overhead

When you set up target connectivity for processor-in-the-loop (PIL) simulations, configure the removal of the instrumentation overheads through an `rtw.connectivity.Config` subclass. For example, this code shows how you can run the benchmark program.

```
classdef overheadConnectivityConfig < rtw.connectivity.Config
  methods
    function this = customConnectivityConfig(componentArgs)

      % Create builder
      targetApplicationFramework = ...
        mypil.TargetApplicationFramework(componentArgs);
```

```
        builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
          targetApplicationFramework, '');

        % Create launcher
        launcher = mypil.Launcher(componentArgs, builder);

        % Set up communication
        hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
                           componentArgs, ...
                           launcher, ...
                           rtiostreamLibTCPIP);

        % Call super class constructor to register components
          this@rtw.connectivity.Config(componentArgs,...
                                       builder,...
                                       launcher,...
                                       hostCommunicator);

        % Register hardware-specific timer, which enables
        % code execution profiling. This example uses a
        % timer for the host platform.
        timer = coder.profile.crlHostTimer();
        this.setTimer(timer);

        % Specify removal of profiling instrumentation overheads
        this.activateOverheadFiltering(true);
        this.runOverheadBenchmark(true);
        this.setOverheadBenchmarkSteps(50);

    end
  end
end
```

Instead of running the benchmark program, you can use `setOverheads` to provide your values for instrumentation overheads.

```
    ...

    % Remove instrumentation overhead using manually specified values
    this.activateOverheadFiltering(true);
    this.setOverheads (taskInstrumentationOverhead, ...
      functionInstrumentationOverhead, freezingInstrumentation);

    ...
```

Retrieve Benchmark Results

When a PIL simulation is complete, you can retrieve benchmark results from the variable that you specify in the **Code Generation** > **Verification** > **Workspace variable** field (`CodeExecutionProfileVariable`), for example, `myExecutionProfile`.

```
benchmarkResults = myExecutionProfile.getOverheadBenchmarkData();
```

`benchmarkResults` is a structure that contains code instrumentation overhead values.

```
>> benchmarkResults
 ans =
 struct with fields:
 TimestampOverhead: [1×1 struct]
 TaskOverhead: [1×1 struct]
 FunctionOverhead: [1×1 struct]
 FreezingOverhead: [1×1 struct]

>> benchmarkResults.TaskOverhead
 ans =
 struct with fields:
 Data: [1×100 uint64]
 NumSamples: 100
 Average: 45.2800
```

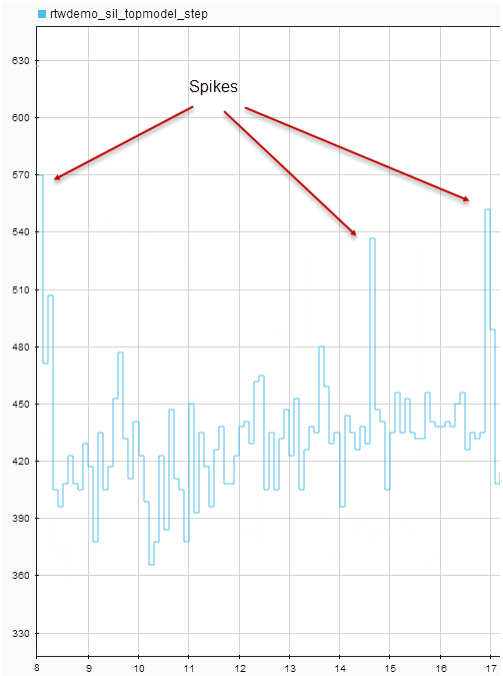
Tips and Limitations

Triggered Model Block

Consider the case where a triggered Model block is configured to run in the SIL or PIL simulation mode. The software generates one execution-time measurement each time the referenced model is triggered to run. If there are multiple triggers in a single time step, the software generates multiple measurements for the triggered Model block. Conversely, if there is no trigger in a given time step, the software generates no time measurements.

Outliers in Execution-Time Profiles

When you run a SIL simulation with execution time profiling enabled, you might see spikes in execution-time measurements.



The spikes are due to process preemption that occurs with a multitasking host operating system. If the operating system preempts the SIL process and runs another process, the

measured execution time includes the time during which the SIL process is suspended. With a PIL simulation, you do not see spikes because code execution on the target is not preempted.

Counter wrapping produces execution-time measurements that are smaller than expected. For SIL, the counter wraps when an execution-time period is greater than 2^{64} ticks (2^{32} ticks if the MEX compiler is LCC). For PIL, the wrapping point depends on the timer you specify and can be 2^8, 2^{16}, 2^{32}, or 2^{64} ticks.

Consider a PIL example where the timer frequency is 20 MHz. For a 32-bit timer, wrapping occurs when the execution-time period is greater than `1/(20e6)*(2^32-1)`, that is, 214.7 s. However, for a 16-bit timer, the point at which wrapping occurs is 0.0033 s.

For a real-time, multi-core application, the software accommodates synchronization discrepancies when recording timer values for different cores, which effectively reduces the timer measurement range.

Hardware-Specific Timer

If your target configuration does not already specify a timer, create a timer object that provides details of the hardware-specific timer and associated source files:

- For SIL simulation, the timer word length is 64 bits.
- For PIL simulation, you can specify an 8-, 16-, 32-, or 64-bit timer.

Task Context Switching Due to Preemption

Profiling instrumentation is intrusive and affects the quantity that it is meant to measure. Therefore, the design goal is to maximize code understanding with a minimum of instrumentation. For example, with a real-time system, there can be task context switches due to preemption. These context switches are not explicitly instrumented. To record the start and end of each task, the software must infer context switches from instrumentation. As a result, the software reports behavior that is an estimate. The estimate is subject to error because of incomplete instrumentation within the kernel.

In some cases, when the software cannot accurately determine behavior, the software generates a warning:

```
Warning: Analysis unsuccessful for one or more profiling data points. ...
```

For example, the software might generate this warning when not all mutex take system calls (associated with rate transitions) are instrumented. In the case of Simulink Real-Time, this situation might arise if you generate code for a model reference hierarchy without enabling function profiling for all referenced models (`set_param(model, 'CodeProfilingInstrumentation', 'on')`). If a mutex take system call is not instrumented, a task context switch might occur that is not visible to the execution profiling analysis.

In other cases, although the software cannot accurately determine behavior, the software does *not* generate a warning.

Subsystem Code Reuse

You cannot generate execution-time profiles for function call sites within subsystem code that is reused across a model or multiple models. For information about subsystem code reuse, see “Generate Reusable Code from Library Subsystems Shared Across Models” (Simulink Coder).

Cannot Load Execution-Time Measurements from Previous Release

You cannot load execution-time measurements saved with a previous release. For example, using R2014a, you save workspace variables to a MAT-file. One of the workspace variables contains execution-time measurements. In R2015b, if you try to load the MAT-file, you see this error:

```
Format of execution profiling data is invalid. This error can occur if
you load data from a previous release. Loading data from a previous
release is not supported.
```

Code Execution Profiling for MATLAB Coder

Execution Time Profiling for SIL and PIL

During a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can produce a profile of execution times for code generated from entry-point functions. The software calculates execution times from data that is obtained through instrumentation probes added to the SIL or PIL application.

Use the execution time profile to check whether your code runs within the required time on your target hardware:

- If code execution overruns, look for ways to reduce execution time.
- If your code easily meets time requirements, consider enhancing functionality to exploit the unused processing power.

At the end of the SIL or PIL execution, you can:

- View a report of code execution times.
- Use the Simulation Data Inspector to view and compare plots of function execution times.
- Access and analyze execution time profiling data.

Note SIL and PIL execution supports multiple entry-point functions. An entry-point function can call another entry-point function as a subfunction. However, the software generates execution time profiles only for functions that are called at the entry-point level. The software does not generate execution time profiles for entry-point functions that are called as subfunctions by other entry-point functions.

Generate Execution Time Profile

Before running a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, enable execution time profiling:

1. To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
2. To open your project, click  and then click `Open existing project`. Select the project.
3. On the **Generate Code** page, click **Verify Code**.
4. Select the **Enable entry point execution profiling for SIL/PIL** check box.

Or, from the Command Window, specify the `CodeExecutionProfiling` property of your `coder.EmbeddedCodeConfig` object. For example:

```
config.CodeExecutionProfiling = true;
```

More About

- “Execution Time Profiling for SIL and PIL” on page 73-2

View Execution Times

When you run a SIL or PIL execution with execution time profiling enabled, the software generates a message in the **Test Output** tab. For example:

```
Current plot held
### Starting SIL execution for 'kalman01'
    To terminate execution: clear kalman01_sil
    Execution profiling data is available for viewing. Open Simulation Data Inspector.
    Execution profiling report available after termination.
Current plot released
```

To observe streamed execution times while the execution runs, click the `Simulation Data Inspector` link.

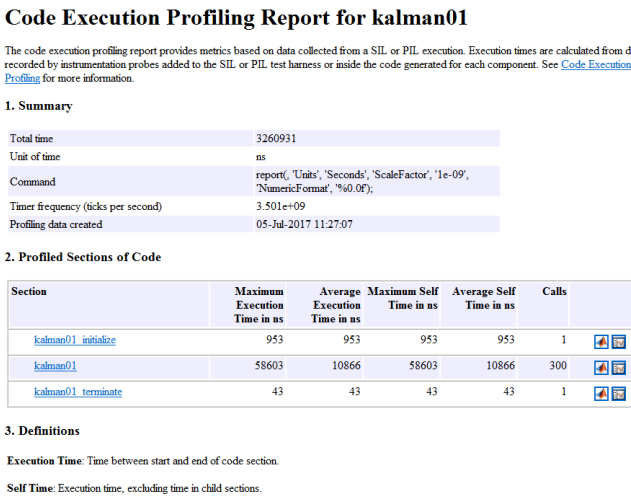
To open the code execution profiling report:

1. Click the `Stop SIL Verification` link.

   The software terminates the execution process and displays a new link.

   ```
   ### Stopping SIL execution for 'kalman01'
       Execution profiling report: report(getCoderExecutionProfile('kalman01'))
   ```

2. Click the new link.



Code Execution Profiling Report for kalman01

The code execution profiling report provides metrics based on data collected from a SIL or PIL execution. Execution times are calculated from data recorded by instrumentation probes added to the SIL or PIL test harness or inside the code generated for each component. See Code Execution Profiling for more information.

1. Summary

Total time	3260931
Unit of time	ns
Command	report(, 'Units', 'Seconds', 'ScaleFactor', '1e-09', 'NumericFormat', '%0.0f');
Timer frequency (ticks per second)	3.501e+09
Profiling data created	05-Jul-2017 11:27:07

2. Profiled Sections of Code

Section	Maximum Execution Time in ns	Average Execution Time in ns	Maximum Self Time in ns	Average Self Time in ns	Calls	
kalman01_initialize	953	953	953	953	1	
kalman01	58603	10866	58603	10866	300	
kalman01_terminate	43	43	43	43	1	

3. Definitions

Execution Time: Time between start and end of code section.

Self Time: Execution time, excluding time in child sections.

The report provides:

- A summary.
- Information about profiled code sections, which includes time measurements for:
  - The *`entry_point_fn`*`_initialize` function, for example, `kalman01_initialize`.
  - The entry-point function, for example, `kalman01`.
  - The *`entry_point_fn`*`_terminate` function, for example, `kalman01_terminate`.
- Definitions for metrics.

By default, the report displays time in nanoseconds (10^{-9} seconds). You can specify the time unit and numeric display format. For example, to display time in microseconds (10^{-6} seconds), use the `report` command:

```
executionProfile=getCoderExecutionProfile('kalman01'); % Create workspace var
report(executionProfile, ...
       'Units', 'Seconds', ...
       'ScaleFactor', '1e-06', ...
       'NumericFormat', '%0.3f')
```

The report displays time in seconds only if the timer is calibrated, that is, the number of timer ticks per second is established. On a Windows machine, the software determines this value for a SIL simulation. On a Linux machine, you must manually calibrate the timer. For example, if your processor speed is 1 GHz, specify the number of timer ticks per second:

```
executionProfile.TimerTicksPerSecond = 1e9;
```

To display measured execution times for a code section, click the Simulation Data Inspector icon  on the corresponding row. You can use the Simulation Data Inspector to manage and compare plots from various executions.

The following table lists the information provided in the code section profiles.

Column	Description
Section	Name of function from which code is generated.
Maximum Execution Time	Longest time between start and end of code section.
Average Execution Time	Average time between start and end of code section.

Column	Description
Maximum Self Time	Maximum execution time, excluding time in child sections.
Average Self Time	Average execution time, excluding time in child sections.
Calls	Number of calls to the code section.
	Icon that you click to display the profiled code section.
	Icon that you click to display measured execution times with Simulation Data Inspector.

Analyze Execution Time Data

After a software-in-the-loop (SIL) or processor-in-the-loop (PIL) execution, you can analyze execution-time data using methods from the `coder.profile.ExecutionTime` and `coder.profile.ExecutionTimeSection` classes.

In the following example, you run a SIL execution and apply supplied methods to execution-time data.

Extract Execution Time Data for Kalman Estimator Code

1 Run SIL execution to generate execution time data

Copy MATLAB code to your working folder.

```
src_dir = ...
    fullfile(docroot,'toolbox','coder','examples','kalman');

copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
```

For a description of the Kalman estimator, see “Generate C Code at the Command Line” (MATLAB Coder).

Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
config.GenerateReport = true; % HTML report
```

Configure the object for SIL and enable execution time profiling.

```
config.VerificationMode = 'SIL';
config.CodeExecutionProfiling = true;
```

Generate library code for the `kalman01` MATLAB function and the SIL interface.

```
codegen('-config', config, '-args', {zeros(2,1)}, 'kalman01');
```

Run the MATLAB test file `test01_ui` with `kalman01_sil`. `kalman01_sil` is the SIL interface for `kalman01`.

```
coder.runTest('test01_ui', ['kalman01_sil.' mexext]);
```

You see the following message.

```
### Starting SIL execution for 'kalman01'
    To terminate execution: clear kalman01_sil
    Execution profiling data is available for viewing. Go to Simulation Data Inspector.
    Execution profiling report available after termination.
Current plot released
```

Terminate the SIL execution process. Click the link `clear kalman01_sil`.

```
 ### Stopping SIL execution for 'kalman01'
    Execution profiling report: report(getCoderExecutionProfile('kalman01'))
```

2 Create workspace variable that holds execution time data

Use the `getCoderExecutionProfile` function to create a workspace variable that holds execution time profiling data.

```
executionProfile=getCoderExecutionProfile('kalman01');
```

3 Extract code sections

Use the `Sections` method.

```
allSections = executionProfile.Sections
```

The software displays the number of code sections and a list of properties.

```
allSections =

  1x3 ExecutionTimeTaskSection array with properties:

    Name
    Number
    ExecutionTimeInTicks
    SelfTimeInTicks
    TurnaroundTimeInTicks
    TotalExecutionTimeInTicks
    TotalSelfTimeInTicks
    TotalTurnaroundTimeInTicks
    MaximumExecutionTimeInTicks
    MaximumExecutionTimeCallNum
    MaximumSelfTimeInTicks
    MaximumSelfTimeCallNum
    MaximumTurnaroundTimeInTicks
    MaximumTurnaroundTimeCallNum
    NumCalls
    ExecutionTimeInSeconds
    Time
```

4 Extract execution time data from specific code section

Specify the code section that you want to examine.

```
secondSectionProfile = executionProfile.Sections(2)
```

The software displays profile data for the code section.

```
secondSectionProfile =

  ExecutionTimeTaskSection with properties:

                          Name: 'kalman01'
                        Number: 2
            ExecutionTimeInTicks: [1x300 uint64]
                 SelfTimeInTicks: [1x300 uint64]
           TurnaroundTimeInTicks: [1x300 uint64]
       TotalExecutionTimeInTicks: 6641016
            TotalSelfTimeInTicks: 6641016
      TotalTurnaroundTimeInTicks: 6641016
     MaximumExecutionTimeInTicks: 48864
     MaximumExecutionTimeCallNum: 158
          MaximumSelfTimeInTicks: 48864
          MaximumSelfTimeCallNum: 158
    MaximumTurnaroundTimeInTicks: 48864
    MaximumTurnaroundTimeCallNum: 158
                       NumCalls: 300
          ExecutionTimeInSeconds: [1x300 double]
                         Time: [300x1 double]
```

You can extract specific properties, for example, the name of a profiled function.

```
nameOfSection = secondSectionProfile.Name
```

The software displays the name.

```
nameOfSection =

kalman01
```

The following table lists the information that you can extract from each code section.

Property	Description
`Name`	Name of entry-point function
`Number`	Code section number
`ExecutionTimeInTicks`	Vector of execution times, measured in timer ticks. Each element contains the difference between the timer reading at the start and at the end of the code section. The data type is the same data type as the data type of the timer used on the target, which allows you to infer the maximum range of the timer measurements.

Property	Description
`SelfTimeInTicks`	Vector of timer tick numbers. Each element contains the number of ticks recorded for the code section, excluding the time spent in calls to child functions.
`TurnaroundTimeInTicks`	Vector of timer tick numbers. Each element contains the number of ticks recorded between the start and the finish of the code section. Unless the code is preempted, this number is the same number as the execution time.
`TotalExecutionTimeInTicks`	Total number of timer ticks recorded for the code section over the entire execution.
`TotalSelfTimeInTicks`	Total number of timer ticks recorded for the profiled code section over the entire execution. However, this number excludes the time spent in calls to child functions.
`TotalTurnaroundTimeInTicks`	Total number of timer ticks recorded between the start and the finish of the profiled code section over the entire execution. Unless the code is preempted, this number is the same as the total execution time.
`MaximumExecutionTimeInTicks`	Maximum number of timer ticks recorded for a single invocation of the code section over the execution.
`MaximumExecutionTimeCallNum`	Number of call in which `MaximumExecutionTimeInTicks` occurs.
`MaximumSelfTimeInTicks`	Maximum number of timer ticks recorded for a single code section invocation, but excluding the time spent in calls to child functions.
`MaximumSelfTimeCallNum`	Number of call in which `MaximumSelfTimeInTicks` occurs.
`MaximumTurnaroundTimeInTicks`	Maximum number of timer ticks recorded between the start and the finish of a single invocation of the profiled code section over the execution. Unless the code is preempted, this time is the same as the maximum execution time.
`MaximumTurnaroundTimeCallNum`	Number of call in which `MaximumTurnaroundTimeInTicks` occurs.
`NumCalls`	Total number of calls to the code section over the entire execution.

Property	Description
`ExecutionTimeInSeconds`	Vector of execution times, measured in seconds. Each element contains the difference between the timer reading at the start and at the end of the code section. Produced only if `TimerTicksPerSecond` is set.
`Time`	Vector of execution time measurements for the code section.

Verification

Simulation and Code Comparison in Simulink Coder

Simulation and Code Comparison

In this section...

This example shows how to verify the answers computed by code generated from the `slexAircraftExample` model. It shows how to capture and compare two sets of output data. Simulating the model produces one set of output data. Executing the generated code produces a second set of output data.

Note To obtain a valid comparison between model output and the generated code, use the same **Solver selection** and **Step size** for the simulation run and the build process.

Configure Signal Data for Logging

Configure the model for logging and recording signal data.

1. Make sure that `slexAircraftExample` is closed. Clear the base workspace to eliminate the results of previous simulation runs. In the Command Window, type:

   ```
   clear
   ```

   The clear operation clears variables created during previous simulations and all workspace variables, some of which are standard variables that the `slexAircraftExample` model requires.
2. In the Command Window, enter `slexAircraftExample` to open the model.
3. In the model window, choose **File > Save As**, navigate to the working folder, and save a copy of the `slexAircraftExample` model as `myAircraftExample`.
4. Set up your model to log signal data for signals: `Stick`, `alpha,rad`, and `q, rad/sec`. For each signal:

   a. Right-click the signal. From the context menu, select **Properties**.

b In the Signal Properties dialog box, select **Log signal data**.

c In the **Logging name** section, from the drop-down list, select `Custom`.

d In the text field, enter the logging name for the corresponding signal.

Signal Name	Logging Name
`Stick`	`Stick_input`
`alpha,rad`	`Alpha`
`q, rad/sec`	`Pitch_rate`

e Click **Apply** and **OK**.

For more information, see “Export Signal Data Using Signal Logging” (Simulink).

5 Select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.

6 Select the **Solver** pane and in the **Solver selection** section, specify the **Type** parameter as `Fixed-step`.

7 On the **Data Import/Export** pane:

- Specify the **Format** parameter as `Structure with time`.
- Clear the **States** parameter check box.
- Select the **Signal logging** parameter.
- Select the **Record logged workspace data in Simulation Data Inspector** parameter to enable logged signal data to send to the Simulation Data Inspector after the simulation is finished.

8 Save the model.

Proceed to “Log Simulation Data” on page 74-3.

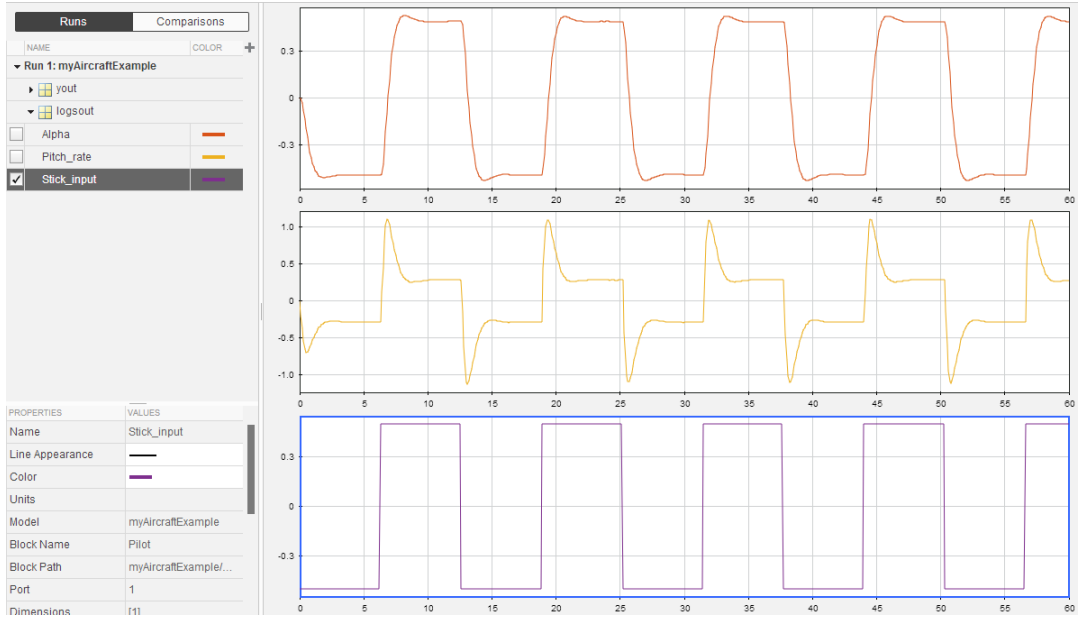
Log Simulation Data

Run the simulation, log the signal data, and view the data in the Simulation Data Inspector.

1 Run the model. When the simulation is done, on the Simulink Editor toolbar, the **Simulation Data Inspector** button is highlighted to indicate that new simulation output is available in the Simulation Data Inspector.

2. Click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
3. Group the signals:
   a. On the **Visualize** tab, click **Group Signals**.
   b. In the Group Signals dialog box, select `Data Hierarchy` from the **Then By** list.

   c. Click **OK**.
4. Click the `logsout` expander to view the logged signals.
5. Click the **Format** tab.
6. Click the **Subplots** button and select `3x1` to show three subplots.
7. For each signal:
   a. Click the top subplot. A blue border indicates the plot selection.
   b. Select the check box next to the `Alpha` signal name. The signal data appears in the subplot.
   c. Plot the `Pitch_rate` signal in the middle subplot.
   d. Plot the `Stick_input` signal in the bottom subplot.



Proceed to “Run Executable and Load Data” on page 74-5.

Run Executable and Load Data

You must rebuild and run the `myAircraftExample` executable to obtain a valid data file because you have modified the model.

1. Select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. Select the **Code Generation > Interface** pane.
3. Set the **MAT-file variable name modifier** parameter to `rt_`. `rt_` is prefixed to each variable that you selected for logging in the first part of this example.
4. Click **Apply** and **OK**.
5. Save the model.
6. On the Simulink Editor toolbar, click the **Build Model** button to generate code.
7. When the build is finished, run the standalone program from the Command Window.

```
!myAircraftExample
```

The executing program writes the following messages to the Command Window.

```
** starting the model **
** created myAircraftExample.mat **
```

8 Load the data file `myAircraftExample.mat`.

```
load myAircraftExample
```

Tip For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see "Run External Commands, Scripts, and Programs" (MATLAB).

Proceed to "Visualize and Compare Results" on page 74-6.

Visualize and Compare Results

When you follow the example sequence that began in "Configure Signal Data for Logging" on page 74-2, you obtain data from a Simulink run of the model and from a run of the program generated from the model.

1 To view the execution output for `alpha,rad`, import the data into the Simulation Data Inspector.

   a On the Simulation Data Inspector **Visualize** tab, click the **Import** button to open the Import dialog.

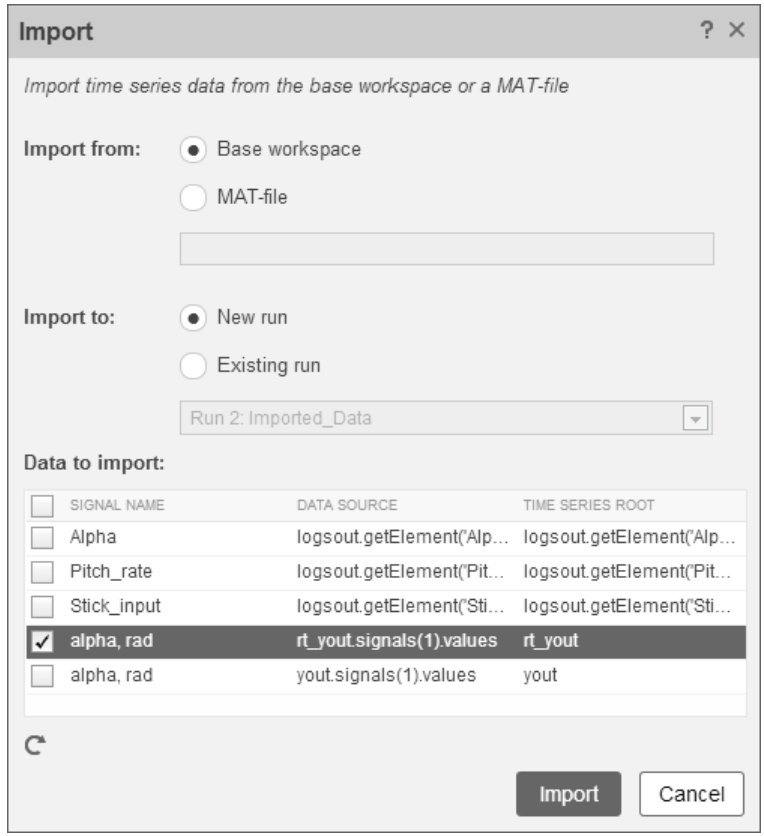
   b Specify **Import from** as **Base workspace**.

   c Specify **Import to** as **New run**.

   d To the left of **Signal Name**, click the check mark to clear the check boxes.

   e Select the check box for the `alpha,rad` data where the **Time Series Root** is `rt_yout`.

   f Click **Import**.



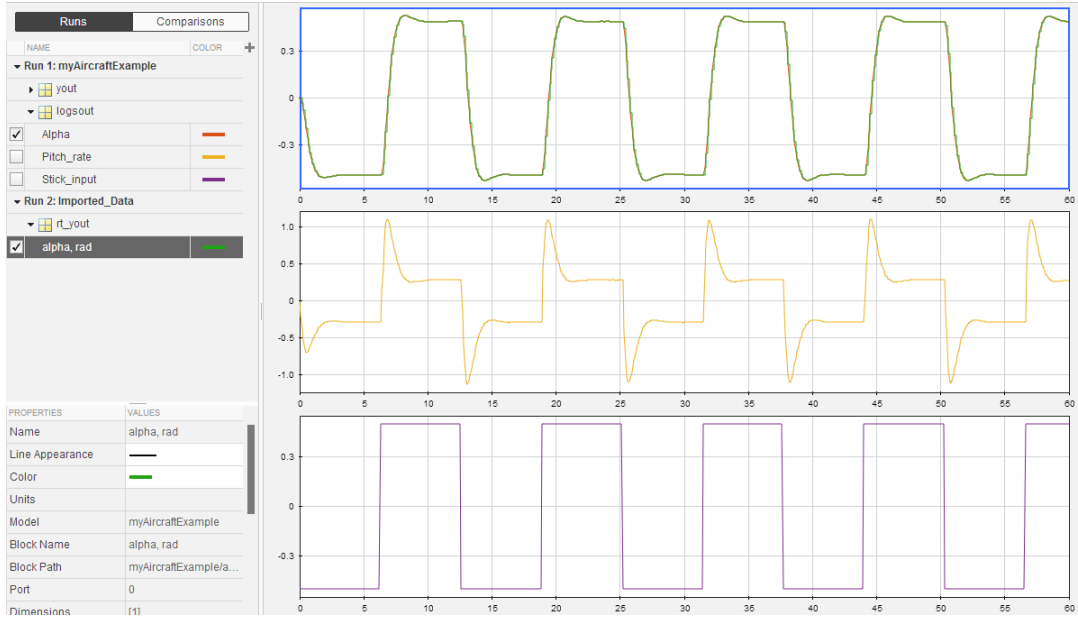
The selected data is now under **Run 2: Imported_Data**.

2 View a plot of the executed data.

   a Click the `rt_yout` expander.

   b Click the top subplot and select the check box next to the `alpha, rad` signal name. The signal data appears in the top subplot.

      The `alpha, rad` signal from Run 1 and Run 2 overlap in the subplot because the signals are equivalent.



It is possible to see a very small difference between simulation and code generation results. A slight difference can be caused by many factors, including:

- Different compiler optimizations
- Statement ordering
- Run-time libraries

For example, a function call such as `sin(2.0)` can return a slightly different value depending on which C library you use. Such variations can also cause differences between your results and these results.

Compare States for Simulation and Code Generation

The order in which Simulink logs states during simulation is different than the order in which Simulink Coder logs states during code generation. If you want to compare states between simulation and code generation, sort the states by block name.

For example, by default, Simulink exports state data to the MATLAB variable, `xout`. Simulink Coder exports state data to the variable `rt_xout`. To sort the state data for these variables, enter the following commands in the MATLAB Command Window:

```
[~,idx1]=sort({xout.signals.blockName});
xout_sorted=[xout.signals(idx1).values];
[~,idx2]=sort({rt_xout.signals.blockName});
rt_xout_sorted=[rt_xout.signals(idx2).values];
```

You can confirm that the logging order is the same between code generation and simulation by entering the following command in the MATLAB Command Window:

```
isequal(xout_sorted, rt_xout_sorted)
```

Code Tracing in Embedded Coder

Verify Generated Code by Using Code Tracing

In this section...

Code tracing (traceability) uses hyperlinks to navigate between a line of generated code and its corresponding elements in a model. To find the lines of code and their corresponding elements, you can also right-click an element or elements in a model. This two-way navigation is *bidirectional* traceability.

Using code tracing, you can:

- Verify that generated code is as you expect. You can identify which model elements correspond to a line of code. You can track code from different elements that you have or have not reviewed.
- Verify that generated code meets the design requirements. You can link requirements to the model element and use code tracing to verify that the generated code for a model element meets the assigned requirements.

The HTML code generation report includes resources that support code tracing:

- Code element hyperlinks (indicated by underlining when you hover over the code) to trace variables or types in the generated code to their declarations or definitions in the header files.
- Tags in code comments that identify elements in a model from which lines of code are generated.
- Line number hyperlinks that link to the model component from which the line of code was generated.

Traceable Elements

Bidirectional traceability is supported for Simulink blocks and these Stateflow elements:

- States
- Transitions
- State transition tables
- MATLAB functions. Traceability is not supported for external code that you call from a MATLAB function.
- Truth table blocks
- Graphical functions
- Simulink functions

Traceability in one direction is supported for these Stateflow elements:

- Events (code-to-model)

  Code-to-model traceability works for explicit events, but not implicit events. Clicking a hyperlink for an explicit event in the generated code highlights that item in the **Contents** pane of the Model Explorer.
- Junctions (model-to-code)

  Model-to-code traceability works for junctions with at least one outgoing transition. Right-clicking such a junction in the Stateflow Editor highlights the line of code that corresponds to the first outgoing transition for that junction.

For more information, see “Trace Stateflow Elements in Generated Code” on page 75-13.

MATLAB Function blocks that you insert directly into a Simulink model are also traceable. For more information, see “Use Traceability in MATLAB Function Blocks” on page 75-42.

Traceability in Code Generation Report

This example shows how to create an HTML code generation report that includes links for tracing between the source code and the Simulink model.

1. Open the model and make sure that it is configured for an ERT target.
2. Select **Create code generation report** if it is not already selected. By default, **Open report automatically**, **Code-to-model**, and **Model-to-code** are selected.
3. If your model contains referenced models and you want to enable traceability for the referenced model's code generation report, repeat step 2 for each referenced model.

4. Press **Ctrl+B** to generate code for your model. The build process opens the code generation report in a MATLAB web browser.
5. In the left navigation pane, select a source code file. The source code and line numbers in the right pane contain hyperlinks to blocks in the model.
6. Click a comment or line number hyperlink. The Simulink Editor displays and highlights the corresponding block or blocks in the model.
7. To highlight the generated code for a block in your Simulink model, right-click the block and select **C/C++ Code** > **Navigate to C/C++ Code**. The generated code for the block is then highlighted in the HTML code generation report. To highlight the generated code for multiple blocks that you select, hold the **SHIFT** key, select multiple blocks, and then right-click any one block to select **C/C++ Code** > **Navigate to C/C++ Code**. The generated code for the blocks is then highlighted in the HTML code generation report.
8. If you have a referenced model in your model, in the left navigation pane, under **Reference Models**, click the link to a referenced model. The code generation report for the referenced model is now displayed in theMATLABweb browser.
9. In the left navigation pane, you can click the **Back** button to go back to the previous code generation report.

Traceability Tags

A traceability tag appears in a comment above the corresponding line of generated code. The format of the tag is `<system>/block_name`.

- *system* is one of the following:
  - The text `Root`
  - A unique system number assigned by the Simulink engine
- *block_name* is the name of the source block.

The code generator documents the tags for a model in the comments section of the generated header file *model*`.h`. For example, this comment appears in the header file for a model, `foo`, that has a subsystem `Outer` and a nested subsystem `Inner`:

```
/* Here is the system hierarchy for this model.
 *
 * <Root> : foo
 * <S1>   : foo/Outer
```

```
 * <S2>   : foo/Outer/Inner
 */
```

This code shows a tag comment above the generated line of code. A Gain block at the root level of a source model generates this code:

```
/* Gain: '<Root>/UnDeadGain1' */
rtb_UnDeadGain1_h = dead_gain_U.In1 *  dead_gain_P.UnDeadGain1_Gain;
```

This code shows a tag comment above the generated line of code. A Gain block within a subsystem one level below the root level of the source model generates this code:

```
/* Gain: '<S1>/Gain' */
dead_gain_B.temp0 *= (dead_gain_P.s1_Gain_Gain);
```

Operator Traceability

The HTML code generation report provides traceability between operators in the generated code and Simulink blocks, Stateflow elements, or MATLAB Function blocks.

To verify the generated code by using operator traceability, in the HTML report window, click an operator hyperlink to highlight the source block in the model.

These operators are supported.

Operator Type	Operators
Arithmetic	+, -, *, /, %
	+=, -=, *=, /=, %=
	++, - - (prefix and postfix)
Logical	!, &&, ||
Relational	==, !=, <, >, <=, >=
Bit	~, |, ^, &, >>, <<
	&=, ^=, |=, <<=, >>=
Conditional	?:

These operators are not supported.

Operator Type	Operator Examples
Assignment operator	`=`
Member of and pointer operators	Array subscript: `a[b]`
	Address of and pointer dereference: `&a`, `*a`
	Member of: `a.b`, `a->b`
Other operators	Parenthesis in function call: `foo(a,b)`
	Comma: `a`, `b`
	Scope resolution: `a::b`
	Cast: `type(a)`
	`new`, `new[]`
	`delete`, `delete[]`

Traceability Limitations

These limitations apply to reports generated by Embedded Coder software:

- Under the following conditions, model-to-code traceability is disabled for a block if the block name contains:
  - A single quote (`'`).
  - An asterisk (*) that causes a name-mangling ambiguity relative to other names in the model. This name-mangling ambiguity occurs if in a block name or at the end of a block name, an asterisk precedes or follows a slash (`/`).
  - The character ÿ (`char(255)`).
- If a block name contains a newline character (`\n`), the generated code comment for the block path hyperlink replaces the newline character with a space for readability.
- You cannot trace blocks representing these types of subsystems to generated code:
  - Virtual subsystems
  - Masked subsystems
  - Nonvirtual subsystems for which code has been removed due to optimization

  If you cannot trace a subsystem at subsystem level, you can trace individual blocks within the subsystem.

- If you open a model on a platform that is different from the platform used to generate code, you cannot use model-to-code and code-to-model traceability.

Related Examples

- “Trace Simulink Model Elements in Generated Code” on page 75-8

Trace Simulink Model Elements in Generated Code

To verify the generated code, Embedded Coder provides bidirectional traceability between the Simulink model and the code generation report. You can use either method for traceability:

- Code-to-model: The code generation report displays these hyperlinks in comment lines in the generated code:
  - Block/subsystems names
  - Line numbers
  - Operators

  To highlight the corresponding block or subsystem in the Simulink Editor, click the hyperlinks.
- Model-to-code: You can select single or multiple blocks of a model in the Simulink Editor and navigate to the corresponding generated code in the code generation report.

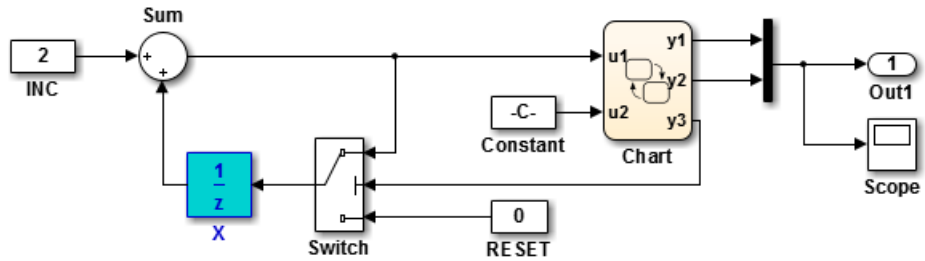
Code-to-Model Traceability

To use hyperlinks for tracing code-to-model elements:

1. Open the model and make sure that it is configured for an ERT target.
2. On the **Code Generation** > **Report** pane, verify that you have selected these parameters:
   - **Create code generation report** (Simulink Coder)
   - **Open report automatically** (Simulink Coder)
   - **Code-to-model** (Simulink Coder)
   - **Model-to-code** (Simulink Coder)
3. Build or generate code for the model. An HTML code generation report is displayed in the MATLAB web browser.
4. In the HTML report window, click hyperlinks to highlight source blocks. For example, generate an HTML report for the model `rtwdemo_hyperlinks`. In the generated code for the model step function in `rtwdemo_hyperlinks.c`, click the first `UnitDelay: '<Root>/X'` block hyperlink.

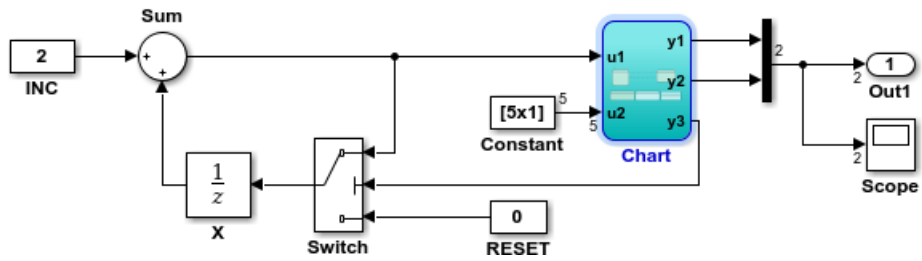
```
138 void rtwdemo_hyperlinks_step(void)
139 {
140   /* Chart: '<Root>/Chart' incorporates:
141    *  Constant: '<Root>/Constant'
142    *  Constant: '<Root>/INC'
143    *  Sum: '<Root>/Sum'
144    *  UnitDelay: '<Root>/X'
145    */
146   /* Gateway: Chart */
147   if (rtDWork.temporalCounter_i1 < 7U) {
148     rtDWork.temporalCounter_i1++;
149   }
```

In the model window, the corresponding `UnitDelay` block is highlighted.



To use line numbers for tracing code-to-model elements:

1. In the previous model, `rtwdemo_hyperlinks`, click the hyperlink at line number 147. The line numbers can differ from the numbers that appear in your code generation report.
2. In the model window, the Chart subsystem is highlighted and contains the functionality on line 147.



Model-to-Code Traceability

To trace model elements to their corresponding generated code:

1. Complete steps 1 and 2 as in “Code-to-Model Traceability” on page 75-8
2. Verify that you have selected the **Model-to-code** parameter. This parameter enables the **Configure** (Simulink Coder) button, which opens a dialog box for loading existing traceability information. For more information, see “Reload Existing Traceability Information” on page 75-34.
3. Build or generate code for the model. An HTML code generation report is displayed in the MATLAB web browser.
4. In the model window, right-click a model element. To select multiple blocks, hold the **SHIFT** key and select additional blocks.
5. From the context menu, select **C/C++ Code > Navigate to C/C++ Code**. In the HTML code generation report, you see the first instance of highlighted code that is generated for the model element. In the left pane of the report, numbers that appear to the right of generated file names indicate the total number of highlighted lines in each file. This figure shows the result of tracing the Unit Delay block in model `rtwdemo_hyperlinks`.

At the top of the code window, use the navigation bar to move forward and backward through multiple instances of highlighted lines. Use the navigation sidebar to go directly to a line of code.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. Do one of the following:

- Reset the current working folder to the parent folder of the existing build folder.
- Select **Model-to-code** and rebuild the model. Rebuilding the model regenerates the build folder into the current working folder.
- Click **Configure**. In the Model-to-code navigation dialog box, reload the existing traceability information by specifying the original build folder.

- “Trace Stateflow Elements in Generated Code” on page 75-13

Trace Stateflow Elements in Generated Code

In this section...

To verify the generated code for your Stateflow elements, you can trace Stateflow elements in your model to the code generation report by using these types of navigation:

- Code-to-model: Trace generated code from the code generation report back to the model by clicking hyperlinks in the comments or the hyperlinked line numbers, which highlights the corresponding model element in the Simulink Editor.
- Model-to-code: Trace the model elements in the Simulink Editor to corresponding lines in generated code by right-clicking the model element and navigating to the generated code.

These examples illustrate how to trace different Stateflow elements.

Inline Traceability for Stateflow Elements

Inline traceability refers to the line-level traceability available in the code generation report. You can click the hyper-linked line numbers to trace single or multiple Stateflow elements at the same time.

1. At the command prompt, type `old_sf_car`.
2. Select **Simulation** > **Model Configuration Parameters**.
3. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Click **Apply**.
4. On the **Code Generation** > **Report** pane, verify that you have selected these parameters:

- **Create code generation report** (Simulink Coder)
- **Open report automatically** (Simulink Coder)
- **Code-to-model** (Simulink Coder)
- **Model-to-code** (Simulink Coder)

5 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.

6 Press **Ctrl+B**.

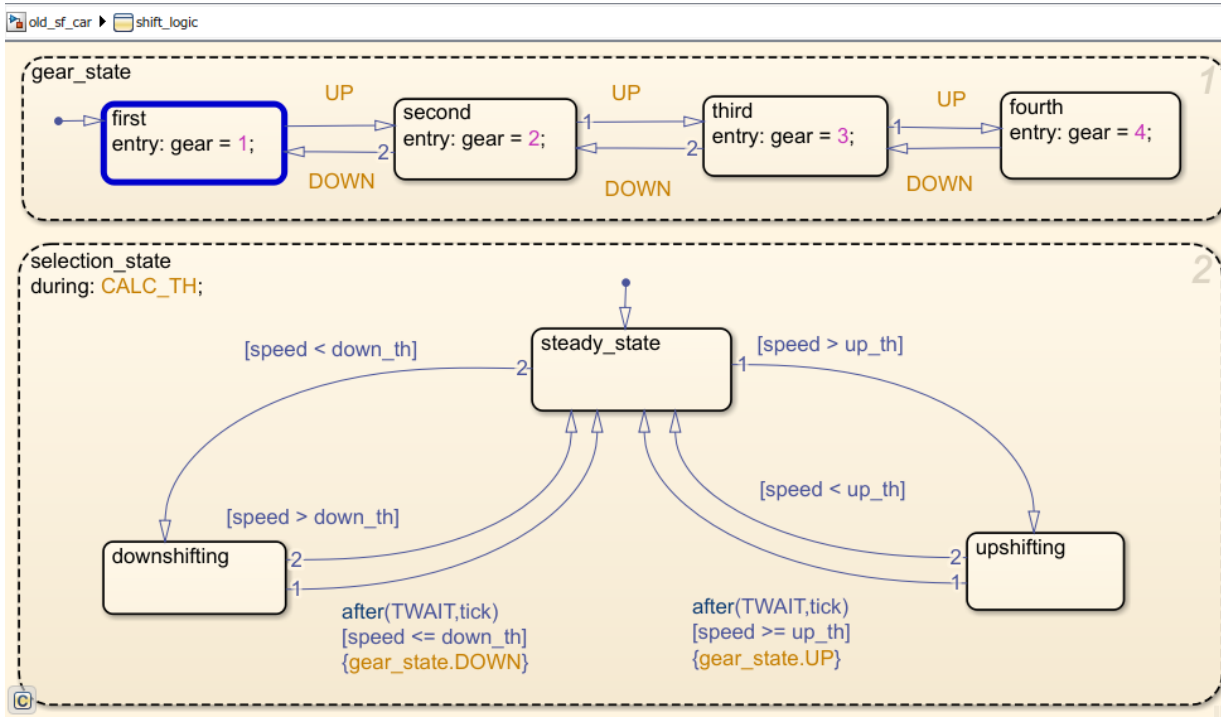
After the code generation process is complete, the code generation report appears.

7 In the report, on the left navigation pane, click the `old_sf_car.c` hyperlink.

8 To the view the inline traceability hyperlinks, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```
185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188   switch (old_sf_car_DW.is_gear_state) {
189    case old_sf_car_IN_first:
190     old_sf_car_B.gear = 1.0;
191     if (*sfEvent == old_sf_car_event_UP) {
192       old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
193       old_sf_car_B.gear = 2.0;
194     }
195     break;
```

9 Click the hyperlink on line number `190`. The corresponding element is highlighted.



Bidirectional Traceability for States and Transitions

1. At the command prompt, type `old_sf_car`.
2. Select **Simulation** > **Model Configuration Parameters**.
3. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Click **Apply**. Traceability comments appear in generated code only for embedded real-time targets.
4. Verify that you have selected these parameters on the **Code Generation** > **Report** pane:
   - **Create code generation report**
   - **Open report automatically**
   - **Code-to-model**
   - **Model-to-code**

5 Go to the **Code Generation** > **Comments** pane and select **Stateflow object comments**. This parameter enables the traceability comments for Stateflow elements.

6 Go to the **Code Generation** > **Interface** pane. In the **Software environment** section, select **continuous time**. Click **Apply**. Before generating code, you must perform this step because this model contains a block with a continuous sample time.

7 Press **Ctrl+B** to generate source code and header files for the `old_sf_car` model that contains the `shift_logic` chart. After the code generation process is complete, the code generation report appears.

8 In the report, click the `old_sf_car.c` hyperlink.

View Results

1 To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```
185 /* Function for Chart: '<Root>/shift_logic' */
186 static void old_sf_car_gear_state(const int32_T *sfEvent)
187 {
188   /* During 'gear_state': '<S5>:2' */
189   switch (old_sf_car_DW.is_gear_state) {
190    case old_sf_car_IN_first:
191     /* During 'first': '<S5>:6' */
192     if (*sfEvent == old_sf_car_event_UP) {
193       /* Transition: '<S5>:12' */
194       old_sf_car_DW.is_gear_state = old_sf_car_IN_second;
195
196       /* Entry 'second': '<S5>:4' */
197       old_sf_car_B.gear = 2.0;
```

2 Click the <S5>:2 hyperlink in this traceability comment:

```
/* During 'gear_state': '<S5>:2' */
```

The corresponding state appears highlighted in the chart.

3 Click the <S5>:12 hyperlink in this traceability comment:

```
/* Transition: '<S5>:12' */
```

The corresponding transition appears highlighted in the chart. To remove highlighting from an element in the chart, select **Display** > **Remove Highlighting**.

4 You can also trace elements in the model to lines of generated code. In the chart, right-click the element `gear_state` and select **C/C++ Code** > **Navigate to C/C++ Code**.

The code for that state appears highlighted in `old_sf_car.c`.

```
188  /* Function for Stateflow: '<Root>/shift_logic' */
189  static void old_sf_car_gear_state(void)
190  {
191    /* During 'gear_state': '<S5>:2' */
192    if (old_sf_car_DWork.is_active_gear_state != 0) {
193      switch (old_sf_car_DWork.is_gear_state) {
194       case old_sf_car_IN_first:
195        /* During 'first': '<S5>:6' */
```

Highlighted line of code

5 In the chart, right-click the transition with the condition `[speed > up_th]` and select **C/C++ Code** > **Navigate to C/C++ Code**.

The code for that transition appears highlighted in `old_sf_car.c`.

```
446            case old_sf_car_IN_steady_state:
447             /* During 'steady_state': '<S5>:9' */
448             if (old_sf_car_B.mph > old_sf_car_B.interp_up) {
449               /* Transition: '<S5>:18' */
450               /* Exit 'steady_state': '<S5>:9' */
```

Highlighted line of code

Note For a list of the Stateflow elements in your model that are traceable, click the `Traceability Report` hyperlink in the code generation report.

Bidirectional Traceability for State Transition Tables

This example shows how to navigate bidirectionally between elements in a state transition table and the generated C/C++ and HDL code for traceability.

1 At the command prompt, type `sf_cdplayer_STT`. This model is already configured for traceability. For more information on these configurations, see “Traceability of Stateflow Objects in Generated Code” (Stateflow).

2 Press **Ctrl+B** to generate source code and header files for the `sf_cdplayer_STT` model. After the code generation process is complete, the code generation report appears.

3 Click the `sf_cdplayer_STT.c` hyperlink in the report.

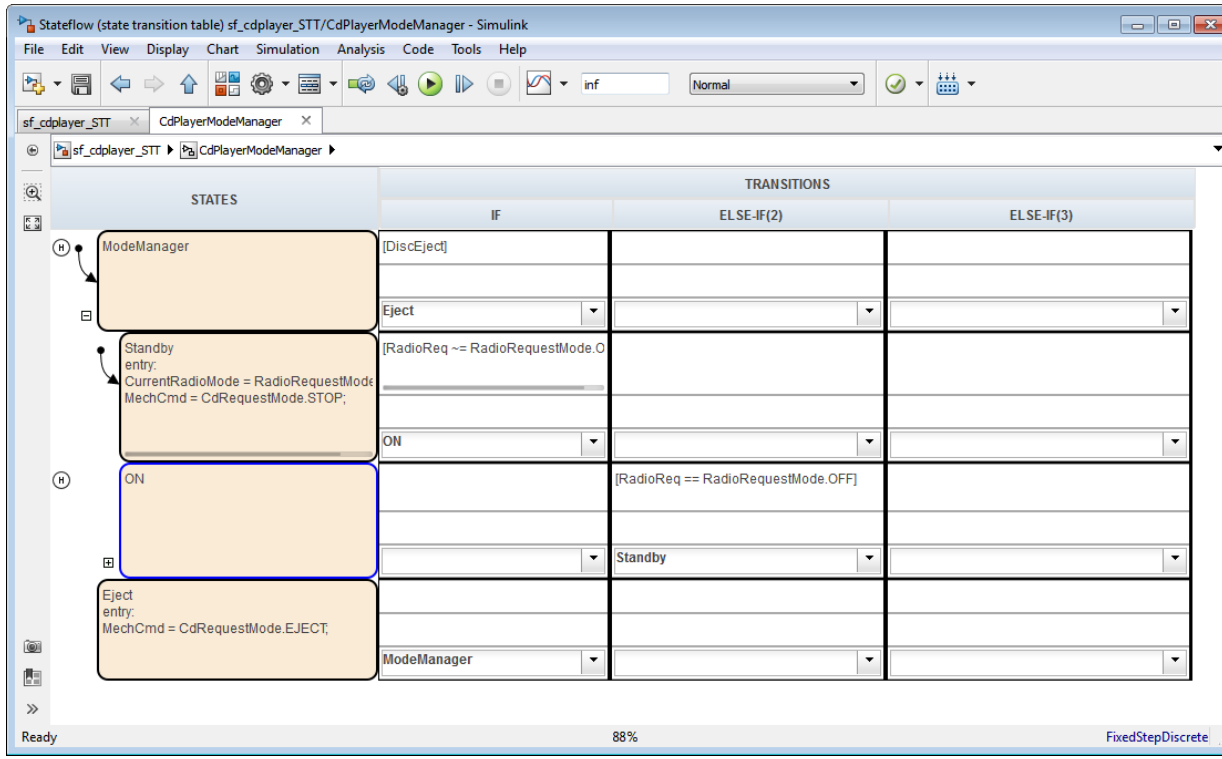
4 To see the traceability comments, scroll through the code. The line numbers shown can differ from the numbers that appear in your code generation report.

```
60  /* Function for State Transition Table: '<Root>/CdPlayerModeManager' */
61  static void sf_cdplayer_S_enter_internal_ON(void)
62  {
63    /* Entry Internal 'ON': '<S2>:58' */
64    switch (sf_cdplayer_STT_DWork.bitsForTID1.was_ON) {
65     case sf_cdplayer_STT_IN_AMMode:
66      sf_cdplayer_STT_DWork.bitsForTID1.is_ON = sf_cdplayer_STT_IN_AMMode;
67      sf_cdplayer_STT_DWork.bitsForTID1.was_ON = sf_cdplayer_STT_IN_AMMode;
68
69      /* Entry 'AMMode': '<S2>:61' */
70      sf_cdplayer_STT_B.CurrentRadioMode = AM;
71      sf_cdplayer_STT_B.MechCmd = STOP;
72      break;
73
```

5 Click the <S2>:58 hyperlink in this traceability comment:

```
/* Entry Internal 'ON': '<S2>:58' */
```

The corresponding state 'ON' appears highlighted in the state transition table.



6 Right-click the highlighted state and select **View state element**. The state `'ON'` also appears highlighted in the underlying state transition diagram.

7 You can trace a state or transition from the state transition table to the generated code. Right-click the state `Standby` and select **C/C++ Code > Navigate to C/C++ Code**.

The entry code for the state `Standby` is highlighted in the generated code.

```
222       } else {
223         sf_cdplayer_STT_DWork.bitsForTID1.is_ON =
224           sf_cdplayer_IN_NO_ACTIVE_CHILD;
225       }
226
227       sf_cdplayer_STT_DWork.bitsForTID1.is_ModeManager =
228         sf_cdplayer_STT_IN_Standby;
229       sf_cdplayer_STT_DWork.bitsForTID1.was_ModeManager =
230         sf_cdplayer_STT_IN_Standby;
231
232       /* Entry 'Standby': '<S2>:57' */
233       sf_cdplayer_STT_B.MechCmd = STOP;
234     } else if (*RadioReq_prev != sf_cdplayer_STT_DWork.RadioReq_start) {
235       /* Transition: '<S2>:75' */
236       if (sf_cdplayer_STT_P.RR_Value == CD) {
```

Bidirectional Traceability for Truth Table Blocks

1. At the command prompt, type `sf_climate_control`
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 75-15.
3. To build the model, press **Ctrl+B**.
4. In the code generation report, click the `sf_climate_control.c` hyperlink.
5. To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code.

```
77        /*  Turn On Humidifier */
78        /* Action '3': '<S1>:1:47' */
79        rtb_humidifier = 1;
80      } else if (eml_aVarTruthTableCondition) {
81        /* Decision 'D2': '<S1>:1:18' */
```

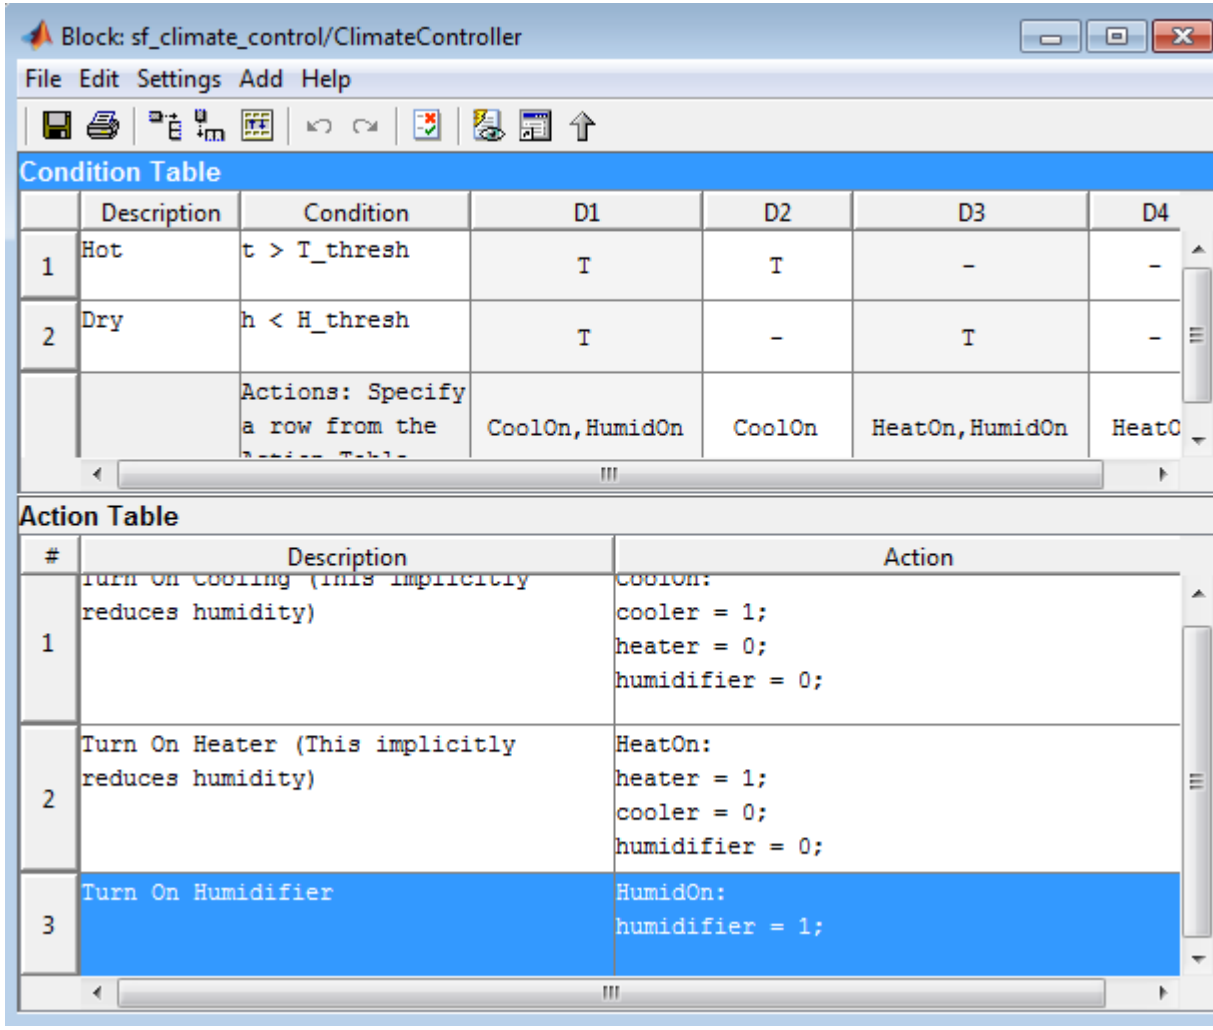
Traceability comment for a truth table action

Traceability comment for a truth table decision

6. Click the `<S1>:1:47` hyperlink in this traceability comment:

   ```
   /* Action '3': '<S1>:1:47' */
   ```

   In the Truth Table Editor, row 3 of the Action Table appears highlighted.



7 You can also trace a condition, decision, or action in the table to a line of generated code. For example, right-click a cell in the column `D2` and select **C/C++ Code** > **Navigate to C/C++ Code**.

The code for that decision appears highlighted in `sf_climate_control.c`.

```
77        /*  Turn On Humidifier */
78        /* Action '3': '<S1>:1:47' */
79        rtb_humidifier = 1;
80      } else if (eml_aVarTruthTableCondition) {
81        /* Decision 'D2': '<S1>:1:18' */
```

Highlighted line of code

Tip To select **C/C++ Code** > **Navigate to C/C++ Code** for a condition, decision, or action, right-click a cell in the row or column that corresponds to that truth table element.

Bidirectional Traceability for Graphical Functions

1. At the command prompt, type `sf_clutch_enabled_subsystems`.
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 75-15.
3. In the Model Configuration Parameters dialog box, go to the **Solver** pane. In the **Solver selection** section, select `Fixed-step` in the **Type** field. Click **Apply**. Before generating code, you must perform this step because the model does not work with variable-step solvers.
4. To build the model, press **Ctrl+B**.
5. In the code generation report, click the `sf_clutch_enabled_subsystems.c` hyperlink.
6. To see the traceability comments, scroll through the code. These line numbers can differ from the numbers that appear in your code generation report.

```
235           case sf_clutch_IN_Slipping:
236            /* Graphical Function 'detectLockup': '<S1>:10' */
237            /* Transition: '<S1>:28' */
238            /* Graphical Function 'getSlipTorque': '<S1>:3' */
```

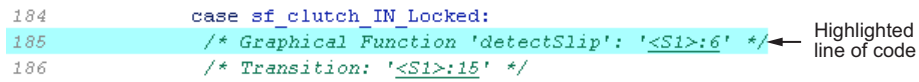
Traceability comment for a graphical function

7. Click the `<S1>:3` hyperlink in this traceability comment:

   ```
   /* Graphical Function 'getSlipTorque': '<S1>:3' */
   ```

   In the chart, the graphical function `getSlipTorque` appears highlighted.
8. You can trace a graphical function in the chart to a line of generated code. For example, right-click the graphical function `detectSlip` and select **C/C++ Code** > **Navigate to C/C++ Code**.

The code for that graphical function appears highlighted in `sf_clutch_enabled_subsystems.c`.



Code-to-Model Traceability for Events

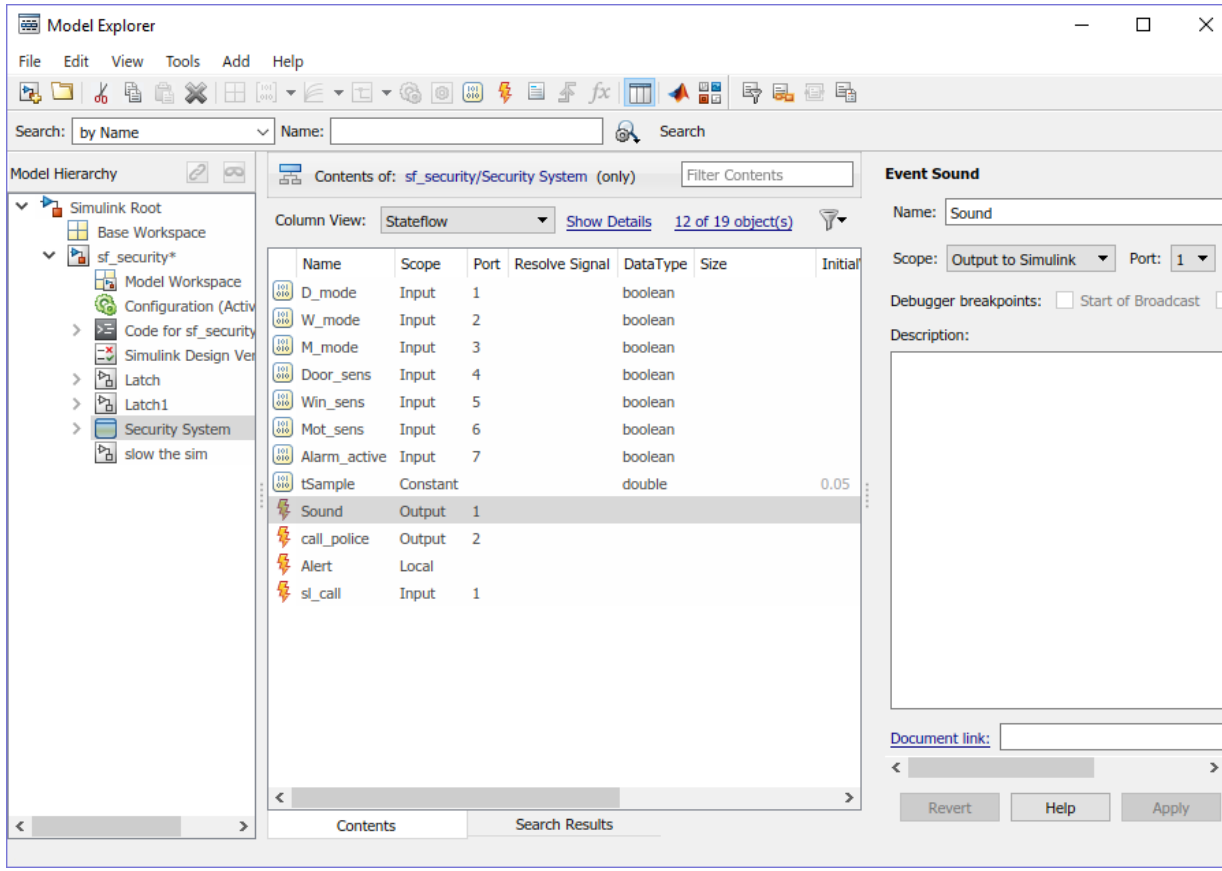
1. At the command prompt, type `sf_security`.
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 75-15.
3. To build the model, press **Ctrl+B**.
4. In the code generation report, click the `sf_security.c` hyperlink.
5. To see this traceability comment, scroll through the code. These numbers can differ from the numbers that appear in your code generation report.

```
236         /* Entry 'Pending': '<S3>:5' */
237         /* Event: '<S3>:56' */
238         sf_security_DW.SoundEventCounter++;
239       }
240       break;
```

6. Click the `<S3>:56` hyperlink in this traceability comment:

   ```
   /* Event: '<S3>:56' */
   ```

   In the **Contents** pane of the Model Explorer, the event `Sound` appears highlighted.



Model-to-Code Traceability for Junctions

1. At the command prompt, type `sf_abs`.
2. Complete steps 2 through 6 in “Bidirectional Traceability for States and Transitions” on page 75-15.
3. In the Model Configuration Parameters dialog box, go to the **Solver** pane. In the **Solver selection** section, select `Fixed-step` in the **Type** field. Click **Apply**. Before generating code, you must perform this step because the model does not work with variable-step solvers.
4. To build the model, press **Ctrl+B**.

5 In the code generation report, open the `AbsoluteValue` chart.

6 Right-click the left junction and select **C/C++ Code** > **Navigate to C/C++ Code**.

The code for the first outgoing transition of that junction appears highlighted in `sf_abs.c`.

```
58        /* Entry Internal: AbsoluteValue */
59        /* Transition: '<S1>:5' */
60        if (SineWave1 >= 0.0) {
61          /* Transition: '<S1>:6' */
62          stateChanged = true;
63          sf_abs_DW.is_c1_sf_abs = sf_abs_IN_P;
64        } else {
65          /* Transition: '<S1>:7' */
66          /* Transition: '<S1>:8' */
67          stateChanged = true;
68          sf_abs_DW.is_c1_sf_abs = sf_abs_IN_N;
69        }
```

Format of Traceability Comments for Stateflow Elements

The format of a traceability comment depends on the Stateflow element type.

State

Syntax

```
/* <ActionType> '<StateName>': '<elementHyperlink>' */
```

Example

```
/* During 'gear_state': '<S5>:2' */
```

This comment refers to the `during` action of the state `gear_state`, which has the hyperlink `<S5>:2`.

Transition

Syntax

```
/* Transition: '<elementHyperlink>' */
```

Example

```
/* Transition: '<S5>:12' */
```

This comment refers to a transition, which has the hyperlink `<S5>:12`.

MATLAB Function

Syntax

```
/* MATLAB Function '<Name>': '<elementHyperlink>' */
```

Within the inlined code for a MATLAB function, comments that link to individual lines of the function have this syntax:

```
/* '<elementHyperlink>' */
```

Examples

```
/* MATLAB Function 'test_function': '<S50>:99' */

/* '<S50>:99:20' */
```

The first comment refers to the MATLAB function named `test_function`, which has the hyperlink `<S50>:99`.

The second comment refers to line 20 of the MATLAB function in your chart.

Truth Table Block

Syntax

```
/* Truth Table Function '<Name>': '<elementHyperlink>' */
```

Within the inlined code for a Truth Table block, comments for conditions, decisions, and actions have this syntax:

```
/* Condition '#<Num>': '<elementHyperlink>' */
/* Decision 'D<Num>': '<elementHyperlink>' */
/* Action '<Num>': '<elementHyperlink>' */
```

`<Num>` is the row or column number that appears in the Truth Table Editor.

Examples

```
/* Truth Table Function 'truth_table_default': '<S10>:100' */

/* Condition '#1': '<S10>:100:8' */
/* Decision 'D1': '<S10>:100:16' */
/* Action '1': '<S10>:100:31' */
```

The first comment refers to a Truth Table block named `truth_table_default`, which has the hyperlink `<S10>:100`.

The other three comments refer to elements of that Truth Table block. Each condition, decision, and action in the Truth Table block has a unique hyperlink.

Truth Table Function

For syntax and examples, see “Truth Table Block” on page 75-26.

Graphical Function

Syntax

```
/* Graphical Function '<Name>': '<elementHyperlink>' */
```

Example

```
/* Graphical Function 'hello': '<S1>:123' */
```

This comment refers to a graphical function named `hello`, which has the hyperlink `<S1>:123`.

Simulink Function

Syntax

```
/* Simulink Function '<Name>': '<elementHyperlink>' */
```

Example

```
/* Simulink Function 'simfcn': '<S4>:10' */
```

This comment refers to a Simulink function named `simfcn`, which has the hyperlink `<S4>:10`.

Event

Syntax

```
/* Event: '<elementHyperlink>' */
```

Example

```
/* Event: '<S3>:33' */
```

This comment refers to an event, which has the hyperlink `<S3>:33`.

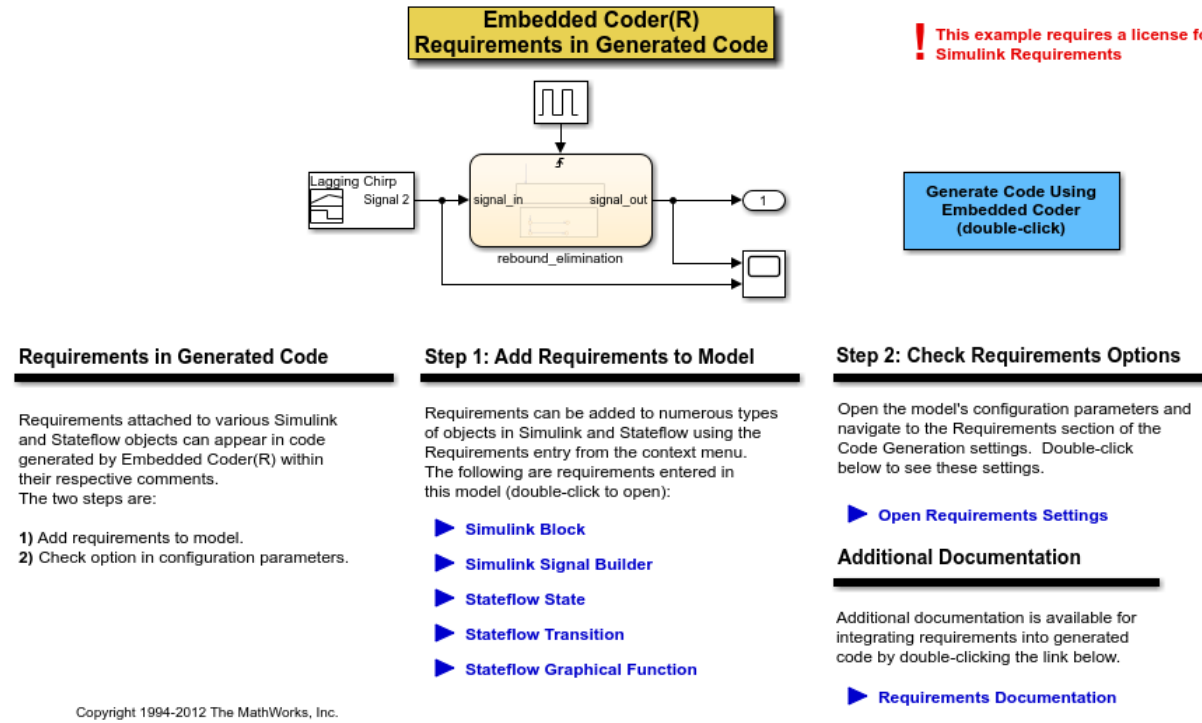
Link Generated Code to Requirements

Link generated code to model element requirements. Using configuration parameters, you can specify whether to include requirement descriptions as comments in the generated code.

Open Model

Open the rtwdemo_requirements model. The model contains Simulink® and Stateflow® elements with associated requirements.

```
model='rtwdemo_requirements';
open_system(model);
```



View Requirements

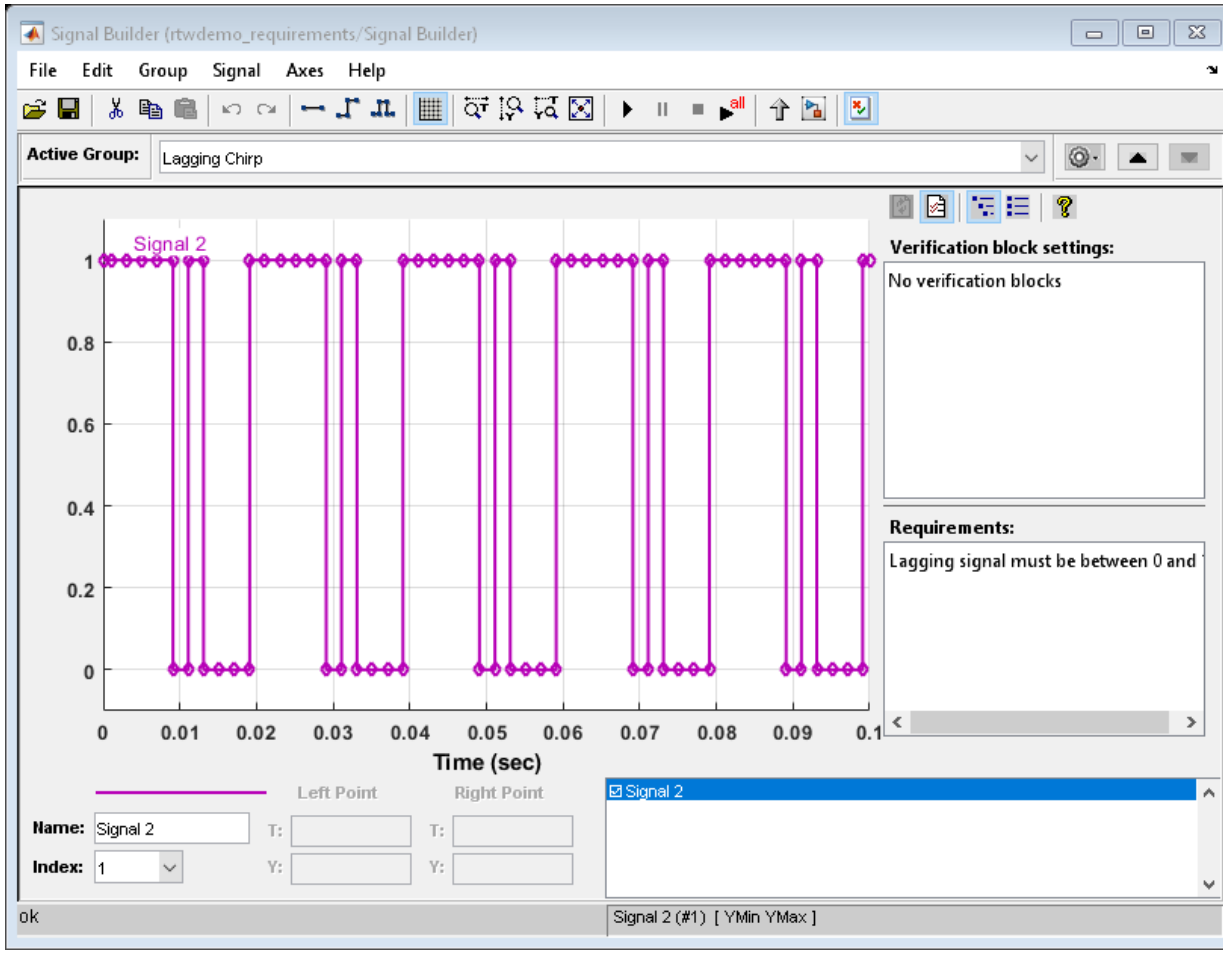
You can view requirements linked to the model by using the Requirements Editor. In the Simulink Editor, select **Analysis > Requirements > Requirements Editor**. You can view requirements specific to model objects by using the object context menu. Right-click an element and select **Requirements > Open Outgoing Links dialog ...**. To view the requirements, use these commands:

1. To view the requirements for the `DiscretePulseGenerator` block, right click on the `DiscretePulseGenerator` block and select **Requirements > Open Outgoing Links dialog ...** to open Outgoing Links Editor. Using Outgoing Links Editor, you can create, edit, and delete requirements traceability links.

```
clockblock='rtwdemo_requirements/clock';
clockblockh=get_param(clockblock,'handle');
rmi('edit',clockblockh);
```

2. To view the requirements, open the **Signal Builder** block by double clicking on it.

```
sigbblock='rtwdemo_requirements/Signal Builder';
open_system(sigbblock)
```



3. To view the requirements for the Stateflow® state, open the Outgoing Links Editor.

```
state=find(sfroot,'-isa','Stateflow.State','-and','Tag','req_state');
rmi('edit',state.id);
```

4. To view the requirements for the Stateflow transition, open the Outgoing Links Editor.

```
trans=find(sfroot,'-isa','Stateflow.Transition','-and','Tag','req_trans');
rmi('edit',trans.id);
```

5. To view the requirements for the Stateflow function, open the Outgoing Links Editor.

```
func=find(sfroot,'-isa','Stateflow.Function','-and','Tag','req_function');
rmi('edit',func.id);
```

Close the open windows.

```
close_system(sigbblock);
```

Set Configuration Parameters

Open the Configuration Parameters dialog box **Code Generation > Comments** pane. View the configuration parameter settings.

```
model = bdroot;
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Comments');
```

Generate Code

Generate code for the model.

```
rtwbuild('rtwdemo_requirements')
```

```
### Starting build procedure for model: rtwdemo_requirements
### Successful completion of build procedure for model: rtwdemo_requirements
```

In the generated code, view the comments containing the requirements. To view all the requirements, click the hyperlinked requirement comment.

```
rtwdemodbtype('rtwdemo_requirements_ert_rtw/rtwdemo_requirements.c',...
    '/* Function for Chart:','return result;',1,0);
```

```
/* Function for Chart: '<Root>/rebound_elimination' */
static real_T rebound_fcn(real_T prev_in, real_T prev_out, real_T curr_in)
{
  real_T result;

  /* Graphical Function 'rebound_fcn': '<S2>:2':
   *  1. Result Computation
   */
  /* Transition: '<S2>:4' */
  if (prev_in == curr_in) {
    /* Transition: '<S2>:5' */
    result = curr_in;
  } else {
```

```
    /* Transition: '<S2>:6' */
    /* Transition: '<S2>:7' */
    result = prev_out;
  }
```

Close Model

```
rtwdemoclean;
close_system('rtwdemo_requirements',0);
```

Reload Existing Traceability Information

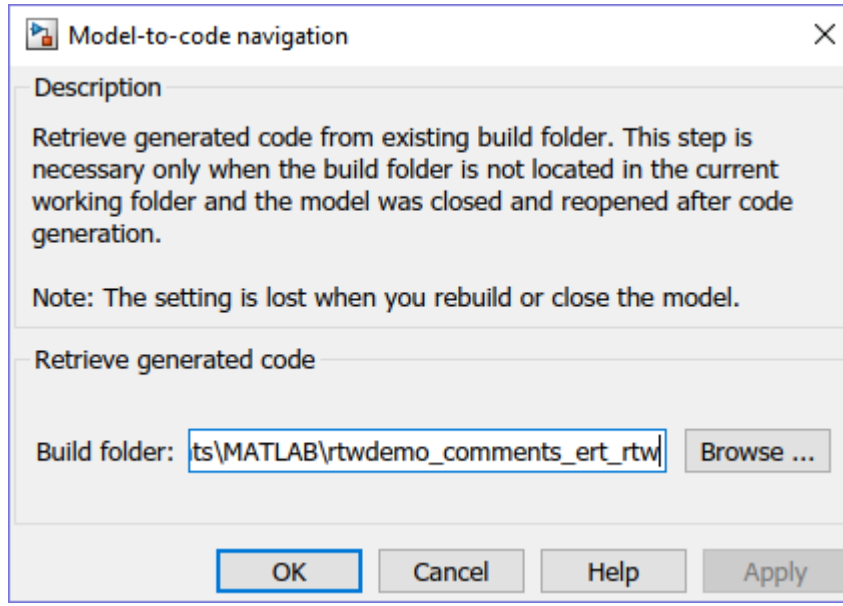
When you build a model, the traceability information is stored in the build folder. The format of the build folder for an ERT-based target is *model*_ert_rtw.

Model-to-code (Simulink Coder) parameter should be selected in the original build to be able to reload the traceability information in a new Simulink session. To reload existing traceability information for a model:

1. Reset the current working folder to the parent folder of the existing build folder.
2. In the Configuration Parameters dialog box, next to **Model-to-code**, click **Configure** (Simulink Coder).
3. In the Model-to-code navigation dialog box, in the **Build folder** field, type or browse to the build folder that contains the existing traceability information.

If you close and reopen a model, the **Navigate to Code** context menu option might not be available because Embedded Coder cannot find a build folder for your model in the current working folder. In that case, perform these steps:

1. To open the Model-to-code navigation dialog box, click **Configure**.
2. In the Model-to-code navigation dialog box, click **Browse**.
3. Browse to the build folder for your model and select the folder. The build folder path is displayed in the **Build folder** field.



4 If you selected **Model-to-code** for the build, clicking **Apply** or **OK** loads traceability information from the earlier build into your Simulink session.

5 To open the context menu and trace a model element to corresponding code, right-click a model element and select **C/C++ Code** > **Navigate to C/C++ Code**.

Customize Traceability Reports

Even a relatively small model can generate hundreds of lines of C/C++ code. To help you navigate more easily between the generated code and your source model, Embedded Coder provides the traceability report section. When you enable traceability, Embedded Coder creates and displays an HTML code generation report. You can generate reports in the Configuration Parameters dialog box or at the command line.

In the Configuration Parameters dialog box, the **Code Generation > Report** pane lists parameters that you can select and clear to customize the content of your traceability reports.

Select or clear any combination of these parameters. These parameters are on by default.

- **Eliminated / virtual blocks** (Simulink Coder) (account for blocks that are untraceable)
- **Traceable Simulink blocks** (Simulink Coder)
- **Traceable Stateflow elements** (Simulink Coder)
- **Traceable MATLAB functions** (Simulink Coder)

If you select all parameters, you get a complete mapping between model elements and the generated code.

This figure shows the top section of the traceability report, which is generated when you select all traceability content parameters for model `rtwdemo_hyperlinks`.

Traceability Report for rtwdemo_hyperlinks

Generate Traceability Matrix

Table of Contents

Eliminated / Virtual Blocks

<Root>/Constant	rtwdemo_hyperlinks.c:141, 176, 189, 214 rtwdemo_hyperlinks_private.h:26

Generate a Traceability Matrix

The traceability matrix provides traceability among model elements, generated code, and model requirements in a Microsoft Excel® file format.

If you have DO Qualification Kit software or IEC Certification Kit software and are using a Windows host, you can generate a traceability matrix into Microsoft Excel format directly from the traceability report.

Go to the **Traceability Report** section of the HTML code generation report and click **Generate Traceability Matrix**.

To select an existing matrix file to update or specify a matrix file to create, use the options in the Generate Traceability Matrix dialog box. Optionally, you can select and create an order to the columns that appear in the generated matrix. After specifying the location where you want the matrix file, click the **Generate** button.

For more information, see "Generating a Traceability Matrix" in either the DO Qualification Kit documentation (DO Qualification Kit) or the IEC Certification Kit documentation (IEC Certification Kit).

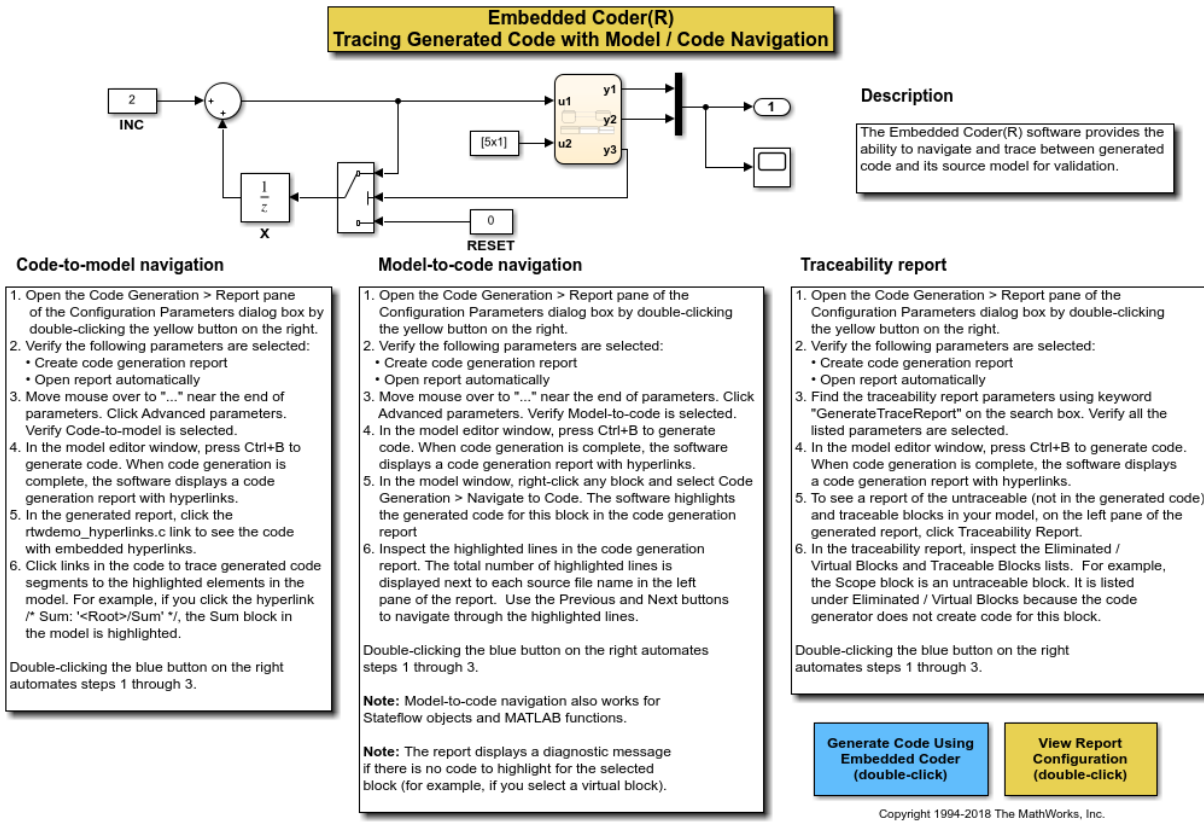
Trace Generated Code to Blocks

Navigate and trace between generated code and its source model for verification.

Open Example Model

Open the example model `rtwdemo_hyperlinks`.

```
model='rtwdemo_hyperlinks';
open_system(model)
```



Code to Model Navigation

Navigate from the generated code to the model.

1. In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.
2. Verify that the following parameters are selected: **Create code generation report**, **Open report automatically** and **Code-to-model**.
3. In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
4. In the generated report, click the `rtwdemo_hyperlinks.c` link to see the code with embedded hyperlinks.
5. Click links in the code to trace generated code segments to the highlighted elements in the model. For example, if you click the hyperlink `<Root>/Sum`, the Sum block in the model is highlighted.

Model to Code Navigation

Navigate from the model to the generated code.

1. In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.
2. Verify that the following parameters are selected: **Create code generation report**, **Open report automatically** and **Model-to-code**.
3. In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
4. In the model window, right-click any block and select **Code Generation > Navigate to Code**. The software highlights the generated code for this block in the code generation report.
5. Inspect the highlighted lines in the code generation report. The total number of highlighted lines is displayed next to each source file name in the left pane of the report. Use the **Previous** and **Next** buttons to navigate through the highlighted lines.

Note: **Model-to-code** navigation also works for Stateflow objects and **MATLAB** functions.

Note: The report displays a diagnostic message if there is no code to highlight for the selected block (for example, if you select a virtual block).

Traceability Report

Generate and inspect the **Traceability Report**.

1. In the Configuration Parameters dialog box, open the **Code Generation > Report** pane.
2. Verify that the following parameters are selected: **Create code generation report**, **Open report automatically**
3. Search for the traceability report parameters using keyword `GenerateTraceReport`. Verify all the listed parameters are selected.
4. In the model editor window, press **Ctrl+B** to generate code. After the code generation process is complete, the code generation report appears.
5. To see a report of the untraceable (not in the generated code) and traceable blocks in your model, on the left pane of the generated report click **Traceability Report**.
6. In the **Traceability Report**, inspect the **Eliminated / Virtual Blocks** and **Traceable Blocks** lists. For example, the **Scope** block is an untraceable block. It is listed under **Eliminated / Virtual Blocks** because the code generator does not generate code for this block.

Use Traceability in MATLAB Function Blocks

In this section...

Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, MATLAB Function blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select **MATLAB source code as comments** parameter, the MATLAB source code appears immediately after the associated traceability tag. For more information, see “Include MATLAB Code as Comments in Generated Code” on page 42-29.

For information about how traceability works in Simulink blocks, see “Verify Generated Code by Using Code Tracing” on page 75-2.

Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (ERT) target.

Note Traceability is not supported for MATLAB files that you call from a MATLAB Function block.

Tutorial: Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a MATLAB Function block in the `eml_fire` model. Follow these steps:

1. Type `eml_fire` at the MATLAB prompt.
2. In the Simulink model window, select **Simulation** > **Model Configuration Parameters**.
3. In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Then click **Apply**.Traceability comments appear hyperlinked in generated code only for embedded real-time (`ert`) targets.
4. In the **Code Generation > Report** pane, select the **Create code generation report** (Simulink Coder) parameter, if not already selected.

   This action automatically selects the “Open report automatically” (Simulink Coder), “Code-to-model” (Simulink Coder), and “Model-to-code” (Simulink Coder) parameters.
5. Verify that **Code-to-model** and **Model-to-code** parameters are enabled.
6. In the **Code Generation > Comments** pane, select the “MATLAB source code as comments” (Simulink Coder) and “Stateflow object comments” (Simulink Coder) parameters. These parameters control different parts of the traceability comment.
7. Go to the **Code Generation > Interface** pane. In the **Software environment** section, select the **continuous time** parameter. Then click **Apply**. Because this example model contains a block with a continuous sample time, you must perform this step before generating code.
8. In the model window, press **Ctrl+B**.

   This action generates source code and header files for the `eml_fire` model that contains the `flame` block. After the code generation process is complete, the code generation report appears automatically.
9. Click the `eml_fire.c` hyperlink in the report.
10. Scroll down through the code to see the traceability comments, which appear as links inside `/*...*/` brackets, as in this example.

```
/* '<S2>:1:19' for x = 1 : WIDTH */
for (x = 0; x < 256; x++) {
  /* '<S2>:1:21' yb = y+2; */
  yb = iU;

  /* '<S2>:1:22' xb1 = x-1; */
  xb1 = x;
```

11 Click the <S2>:1:19 hyperlink in this traceability comment:

```
/* '<S2>:1:19' */
```

Line 19 of the function in the source code appears highlighted in the MATLAB Function Block Editor.

12 You can trace a line in a MATLAB function to lines of generated code. For example, right-click on line 21 of your function and select **Code Generation** > **Navigate to Code** from the context menu.

The code location for line 21 appears highlighted in `eml_fire.c`.

13 You can trace a line of generated code to a line of source code in a MATLAB function using the line number hyperlinks in the generated code.

Component Verification in Embedded Coder

Component Verification in Target Environment

After you generate production code for a component design, you need to integrate, compile, link, and deploy the code as a complete application on the embedded system. One approach is to manually integrate the code into an existing software framework that consists of an operating system, device drivers, and support utilities. The algorithm can include externally written legacy or custom code.

An easier approach to verifying a component in a target environment is to use processor-in-the-loop (PIL) simulation. For information about PIL simulations, see “SIL and PIL Simulations” on page 78-2.

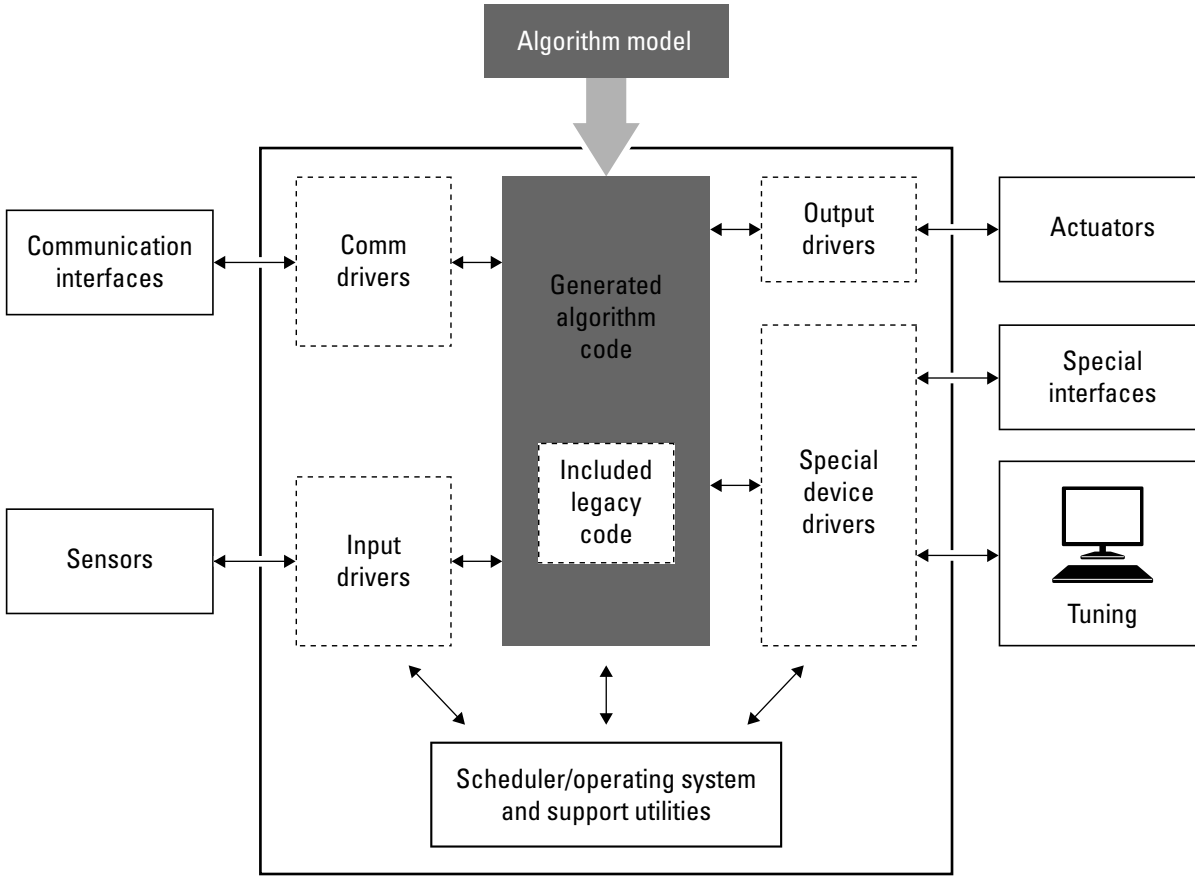
Goals of Component Verification

Assuming that you have generated production source code and integrated required externally written code, such as drivers and a scheduler, you can verify that the integrated software operates as expected by testing it in the target environment. During testing, you can achieve either of the following goals, depending on whether you export code that is strictly ANSI C/C++ or mixes ANSI C/C++ with code optimized for a target environment.

Goal	Type of Code Export
Maximize code portability and configurability	ANSI C/C++
Simplify integration and maximize use of processor resources and code efficiency	Mixed code

Regardless of your goal, you must integrate required external drivers and scheduling software. To achieve real-time execution, you must integrate the real-time scheduling software.

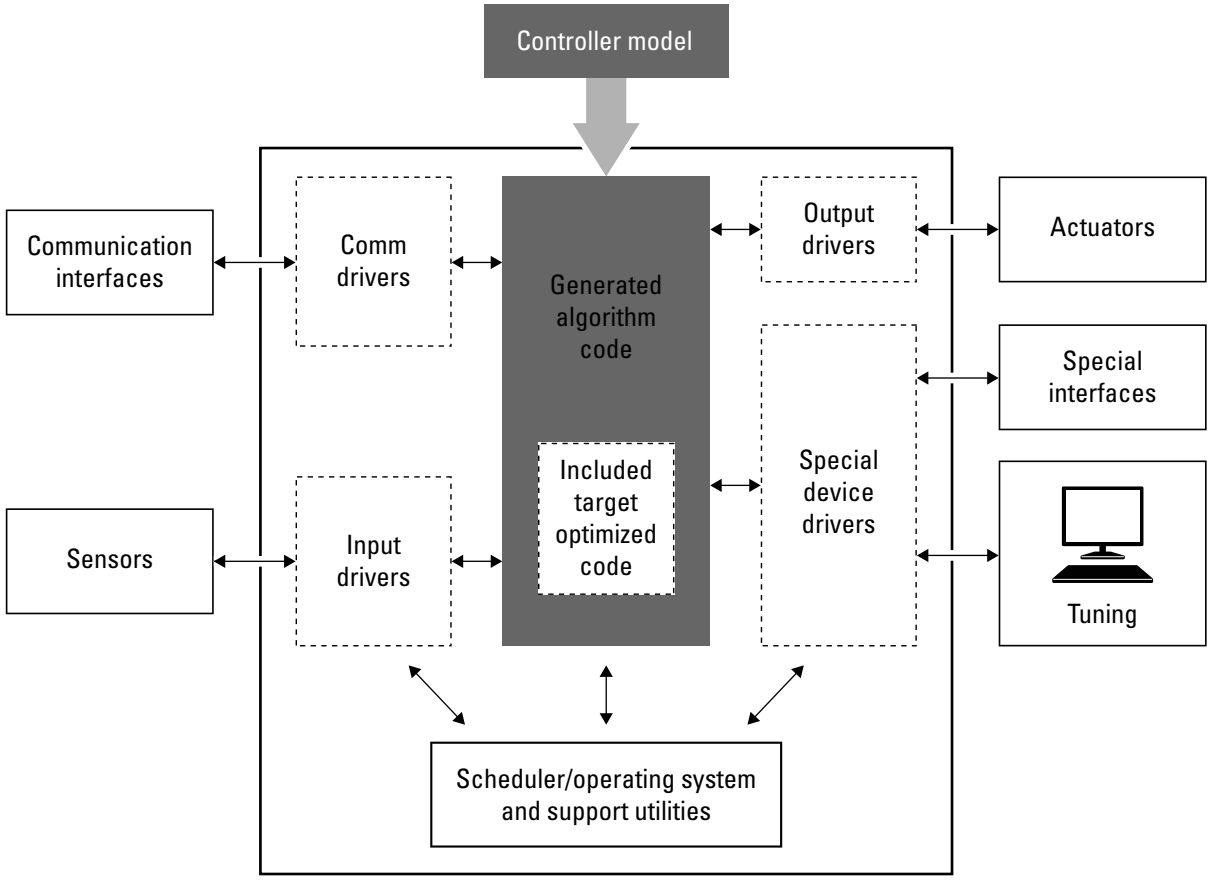
To maximize code portability and configurability, limit the application code to ANSI/ISO C or C++ code only, as the following figure shows.



To simplify code integration and maximize code efficiency for a target environment, use Embedded Coder features for:

- Controlling code interfaces
- Exporting subsystems
- Including target-specific code, including compiler optimizations

The following figure shows a mix of ANSI C/C++ code with code that is optimized for a target environment.



Run Component Tests

The workflow for running software component tests in the target environment is:

1 Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation” (Simulink Coder). For more specific references that depend on your verification goals, see the following table.

For	See
ANSI C/C++ code integration	“Integrate C Functions Using Legacy Code Tool” (Simulink). Also, open `rtwdemos` and navigate to the **Custom Code** folder.
Mixed code integration	• “Generate Component Source Code for Export to External Code Base” on page 53-64 and example `rtwdemo_exporting_functions` • “Customize Generated C Function Interfaces” on page 39-2, “Customize Generated C++ Class Interfaces” on page 39-35, and example rtwdemo_fcnprotoctrl • “What Is Code Replacement?” on page 52-2, “What Is Code Replacement Customization?” on page 65-3, and example `rtwdemo_crl_script`

2. Simulate the integrated component model.
3. Generate code for the integrated component model.
4. Connect to data interfaces for the generated C code data structures. See “Exchange Data Between Generated and External Code Using C API” (Simulink Coder) and “Export ASAP2 File for Data Measurement and Calibration” (Simulink Coder). Also see examples `rtwdemo_capi` and `rtwdemo_asap2`.
5. Customize and control the build process, if required. See “Customize Post-Code-Generation Build Processing” (Simulink Coder), and example `rtwdemo_buildinfo` .
6. Create a zip file that contains generated code files, static files, and dependent data to build the generated code in an environment other than your host computer. See “Relocate Code to Another Development Environment” (Simulink Coder), and example `rtwdemo_buildinfo`.

Component Verification With a Real-Time Target Environment in Embedded Coder

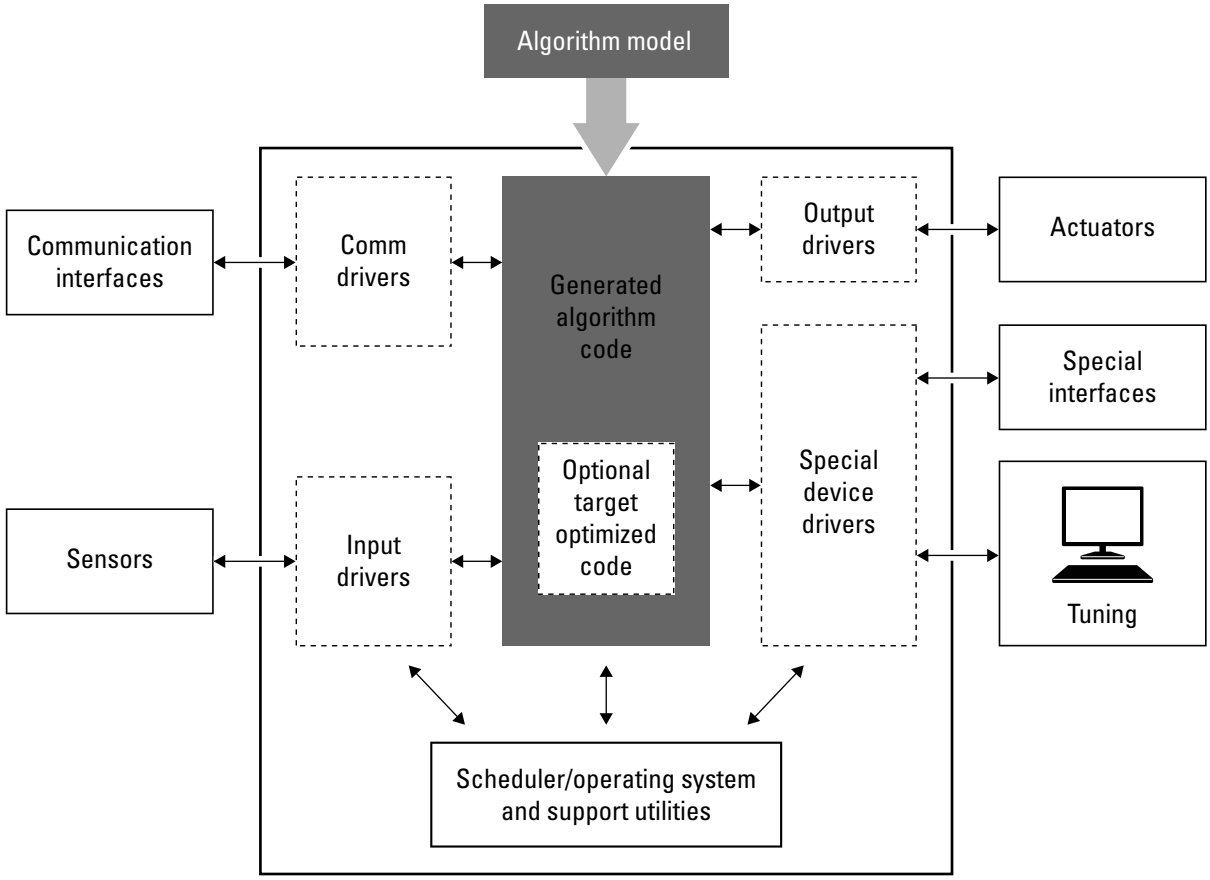
Real-Time Software Component Verification

One approach to verifying a software component is to build the component into a complete software system that can execute in real time in the target environment. A complete software system includes:

- Algorithm for the software component
- Scheduling algorithms
- Calls to drivers for board-specific devices

This single build approach is more time consuming to set up, but makes it easier to get the complete application running in the target environment.

The following figure shows code generated for an algorithm being built into a complete system executable for the target environment.



The workflow for testing component software as part of a complete real-time target environment is:

1 Develop a component model and generate source code for production.

For information on building in scheduling and real-time system support, see:

- “Time-Based Scheduling and Code Generation” (Simulink Coder) and “Modeling for Multitasking Execution” (Simulink Coder). For an example, open `rtwdemos` and navigate to the **Multirate Support** folder.
- “Asynchronous Events” (Simulink Coder) and example `rtwdemo_async`

- “Deploy Generated Standalone Executable Programs To Target Hardware” on page 63-2
- “Workflows for AUTOSAR” (AUTOSAR Blockset) and example “Develop a Model that Complies with the AUTOSAR Standard” on page 22-24.

2 Optimize generated code for a specific run-time environment, using specialized function libraries. For more information, see “What Is Code Replacement?” on page 52-2, “What Is Code Replacement Customization?” on page 65-3, and “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®”.

3 Customize post code generation build processing to accommodate third-party tools and processes, as required. See “Customize Post-Code-Generation Build Processing” (Simulink Coder) and example `rtwdemo_buildinfo`.

4 Integrate external code, for example, for device drivers and a scheduler, with the generated C or C++ code for your component model. For more information, see “S-Functions and Code Generation” (Simulink Coder). For more specific references depending on your verification goals, see the following table.

For...	See...
ANSI C/C++ code integration	“Integrate C Functions Using Legacy Code Tool” (Simulink). Also, open `rtwdemos` and navigate to the **Custom Code** folder.
Mixed code integration	• “Generate Component Source Code for Export to External Code Base” on page 53-64 and example `rtwdemo_exporting_functions` • “Customize Generated C Function Interfaces” on page 39-2, “Customize Generated C++ Class Interfaces” on page 39-35, and example rtwdemo_fcnprotoctrl • “What Is Code Replacement?” on page 52-2, “What Is Code Replacement Customization?” on page 65-3, and example “Optimize Generated Code By Developing and Using Code Replacement Libraries - Simulink®”

5 Simulate the integrated model.

6 Generate code for the integrated model.

7. Connect to data interfaces for the generated C code data structures. See “Exchange Data Between Generated and External Code Using C API” (Simulink Coder) and “Export ASAP2 File for Data Measurement and Calibration” (Simulink Coder). Also see examples `rtwdemo_capi` and `rtwdemo_asap2`.
8. Customize and control the build process, as required. See “Customize Post-Code-Generation Build Processing” (Simulink Coder), and example `rtwdemo_buildinfo` .
9. Create a zip file that contains generated code files, static files, and dependent data to build the generated code in an environment other than your host computer. See “Relocate Code to Another Development Environment” (Simulink Coder), and example `rtwdemo_buildinfo`.

Real-Time Software Component Testing

Numerical Equivalence Checking in Embedded Coder

SIL and PIL Simulations

In this section...

What Are SIL and PIL Simulations?

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations of your model. These simulations generate source code for either the top model or part of the model. A SIL simulation compiles and runs the generated code on your development computer. A PIL simulation cross-compiles source code on your development computer, and then downloads and runs the object code on a target processor or an equivalent instruction set simulator.

With SIL and PIL simulations, you can:

- Test whether your model and generated code are numerically equivalent.
- Observe code coverage.
- Perform code execution profiling.

Why Use SIL and PIL

Through SIL and PIL, you can early on test and fix defects. For example, you can model and test a system component in normal mode. Then, you can reuse your test suites in a SIL or PIL simulation that runs compiled generated code. To check numerical equivalence, you compare normal and SIL or PIL simulation results. You thereby avoid leaving the Simulink environment to test generated code on a separate infrastructure.

This table describes situations where you can use SIL and PIL.

Situation	Use
Test numerical equivalence between model and generated code. See “Test Generated Code with SIL and PIL Simulations” on page 78-85.	SIL and PIL
Reuse test vectors developed for normal mode simulation to verify numerical output of generated (or legacy) code. For example: • Reuse test cases generated by Simulink Design Verifier. See “What Is Test Case Generation?” (Simulink Design Verifier). • Perform equivalence testing with Simulink Test. See “Test Two Simulations for Equivalence” (Simulink Test).	SIL and PIL
Collect metrics for generated code: • Code coverage. See “Code Coverage”. • Execution profiling. See “Code Execution Profiling with SIL and PIL” on page 72-2	SIL and PIL
Achieve IEC 61508, IEC 62304, ISO 26262, or DO-178 certification. See “IEC Certification Kit Reference Workflow Overview” (IEC Certification Kit) and Testing of Outputs of Integration Process (DO Qualification Kit).	SIL and PIL
Without target hardware, get a convenient alternative to PIL.	SIL

Situation	Use
With target hardware, for example, an evaluation board or instruction set simulator: • Verify behavior of target-specific code, for example, code replacement optimizations, and legacy code. See “What Is Code Replacement?” on page 52-2 and “What Is Code Replacement Customization?” on page 65-3. • Optimize the execution speed and memory footprint of your code. In this table, see the information about collecting execution profiling and stack profiling metrics. • Investigate effects of compiler settings and optimizations, for example, deviation from ANSI C overflow behavior. Normal simulation techniques do not account for restrictions and requirements that the hardware imposes, such as limited memory resources or behavior of target-specific optimized code. For information about running PIL simulations on specific targets, see “Sample Custom Targets” (Simulink Coder) in the Simulink Coder documentation.	PIL

Note The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

How SIL and PIL Simulations Work

In a SIL or PIL simulation, code is generated for either the top model or part of the model. With SIL, this code is compiled for and executed on your development computer. With PIL, the code is cross-compiled for the target hardware and runs on the target processor.

Through a communication channel, Simulink sends stimulus signals to the code on your computer or target processor for each sample interval of the simulation.

- For a top model, Simulink uses stimulus signals from the base or model workspace.
- If you have designated only part of the model to simulate in SIL or PIL mode, then a part of the model remains in Simulink and code is not generated for this part of the

model. Typically, you configure this part of the model to provide test vectors for the software executing on the hardware. This part of the model can represent other parts of the algorithm or the environment in which the algorithm operates.

When your computer or target processor receives signals from Simulink, the processor executes the SIL or PIL algorithm for one sample step. The SIL or PIL algorithm returns output signals calculated during this step to Simulink through a communication channel. One sample cycle of the simulation is complete, and Simulink proceeds to the next sample interval. The process keeps repeating itself and the simulation progresses. SIL and PIL simulations do not run in real time. In each sample period, Simulink and the object code exchange I/O data.

Comparison of SIL and PIL Simulations

Type of SIL or PIL Simulation	What Happens in SIL Simulation	What Happens in PIL Simulation
Specify through: • Top-model simulation mode • Model block **Simulation mode** parameter	• Test behavior of generated source code on development computer. Simulation does not test code compiled for target hardware because code is compiled for the development computer (different compiler and different processor architecture than the target). • Generated production code compiled and executed on development computer as separate process, independent of MATLAB process. • Execution is host/host and nonreal time.	• Test object code that you intend to deploy in production on either real target hardware or an instruction set simulator. • On development computer, generated production code cross-compiled for target. Object code downloaded and executed on target processor or instruction set simulator. • Execution is host/target and nonreal time.

Type of SIL or PIL Simulation	What Happens in SIL Simulation	What Happens in PIL Simulation
Use SIL or PIL block created from subsystem.	• Simulation runs compiled object code through S-function. S-function communicates with object code executing as standalone application on development computer. SIL block execution is independent of the MATLAB process. • Execution is host/host and nonreal time.	• Simulation runs cross-compiled object code through S-function on development computer. S-function communicates with object code executing as standalone application on target processor or instruction set simulator. • Execution is host/target and nonreal time.

Code Interfaces for SIL and PIL

You generate standalone code when you perform, for example, a top-model or right-click subsystem build for a single deployable component. You can compile and link standalone code into a standalone executable or integrate it with other code. For more information on the standalone code interface, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

When you generate code for a referenced model hierarchy, the software generates standalone executable code for the top model and a library module called a *model reference target* for each referenced model. When the code executes, the standalone executable invokes the applicable model reference targets to compute the referenced model outputs. For more information, see “Build Model Reference Targets” (Simulink Coder).

To integrate generated code with legacy code, use standalone code because the standalone code interface is documented.

Note SIL and PIL simulations do not provide direct support for custom code interfaces. You can incorporate these interfaces into Simulink as an S-function, for example, using the Legacy Code Tool, S-Function Builder, or handwritten code. Then, you can verify the custom code by using SIL and PIL simulations.

This table provides the interfaces that SIL and PIL simulations generate.

SIL/PIL Simulation	Code Interface
Top-model	SIL/PIL simulation generates the standalone code interface. If code exists, simulation calls standalone code for the model . If code does not exist, simulation generates standalone code.
Model block	If you set **Code interface** block parameter to `Top model`, SIL/PIL simulation generates standalone code interface. Simulation calls standalone code for the model if it exists. Otherwise, simulation generates standalone code by using `slbuild('model')` command. If you set **Code interface** block parameter to `Model reference`, SIL/PIL simulation generates model reference code interface. Simulation calls model reference target for Model block if it exists. Otherwise, simulation generates model reference target by using `slbuild('model', 'ModelReferenceCoderTargetOnly')` command.
SIL or PIL block	Block uses standalone code interface.

Scheduling Considerations

Item	Information
Algebraic loops	There are algebraic loops that occur in SIL and PIL simulations but not in normal mode simulations: • **Single output/update function** in code generation optimization can introduce algebraic loops because the option introduces direct feedthrough via a combined output and update function. **Single output/update function** is not compatible with **Minimize algebraic loop occurrences** (in the Subsystem Parameters dialog box and **Configuration Parameters > Model Referencing** pane). **Minimize algebraic loop occurrences** allows code generation to remove algebraic loops by partitioning generated code between output and update functions to avoid direct feedthrough. • If you generate code for a virtual subsystem, code generation treats the subsystem as atomic and generates the code accordingly. The resulting code can change the execution behavior of your model, for example, by applying algebraic loops, and introduce inconsistencies to the simulation behavior. To enable consistent simulation and execution behavior for your model, declare virtual subsystems as atomic subsystems. For more information, see: • “Algebraic Loop Concepts” (Simulink) • “Algebraic Loops” (Simulink Coder) • “Control Generation of Functions for Subsystems” (Simulink Coder)

Item	Information
Exported functions in feedback loops	If your model has function-call subsystems and you export a subsystem that has context-dependent inputs (for example, feedback signals), the results of a SIL/PIL simulation with the generated code and the results of the normal mode simulation of your model can differ. One approach to make SIL/PIL and normal mode simulations yield identical results is to use Function-Call Feedback Latch blocks in your model. You can make context-dependent inputs become context-independent. Embedded Coder generates a warning identifying context-dependent inputs of exported function-call subsystems if you set **Configuration Parameters > Diagnostics > Connectivity > Context-dependent inputs** to one of the following: • `Enable all as warnings` • `Use local settings` • `Disable all` For more information, see: • “Control Generation of Functions for Subsystems” (Simulink Coder) • Function-Call Feedback Latch • “Context-dependent inputs” (Simulink)

Imported Data and Function Definitions

Imported Data

In SIL and PIL simulations, you can use signals, parameters, and data stores that specify storage classes with imported data definitions. The simulations define storage for imported data associated with:

- Signals at the root level of the component (on the I/O boundary).

- Parameters in the base workspace or a data dictionary. For parameters in the model workspace:
  - Top-model SIL/PIL and SIL/PIL block simulations define storage.
  - Model block SIL/PIL simulations do not define storage. You must define storage and specify initial values that match MATLAB values.
- Global data stores.

SIL and PIL simulations do not define storage for other imported data. For example, the simulations do not define storage for imported data associated with:

- Internal signals (not on the I/O boundary)
- Local data stores

In these cases, define the storage through custom code included by the component under test or through the PIL `rtw.pil.RtIOStreamApplicationFramework` API.

See also “Tunable Parameters and SIL/PIL” on page 78-70.

GetSet Custom Storage Class

SIL and PIL simulations support the `GetSet` custom storage class. The SIL/PIL test harness provides C definitions of the `Get` and `Set` functions that are used during simulations. For more information, see “Access Data Through Functions with Custom Storage Class GetSet” on page 36-51.

Custom Storage Class of Type Other

To enable SIL and PIL support for the custom storage class where **Type** is set to `Other` , create a custom attributes class for the custom storage class and associate the custom attributes class with a Boolean property, `SupportSILPIL`, set to `true`.

```
classdef CSCOtherAttributes < Simulink.CustomStorageClassAttributes
  properties(PropertyType = 'logical scalar')
    SupportSILPIL = true;
  end
end
```

For more information about custom attributes, see “Further Customize Generated Code by Writing TLC Code” on page 36-46 and “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 36-48.

To build the SIL or PIL application interface, the code generator calls the `DataAccess` and `ClassAccess` functions in the associated custom TLC file to get required information. The code generator stores the extracted information in build artifacts in the build folder.

For a custom storage class that is not grouped:

- The code generator calls `DataAccess` with the request argument taking values of `define`, `declare`, `layout`, `contents`, `address`, or `set`.
- The code generator uses the string returned by `DataAccess(record, "define", "", "")` to define the variable in the SIL or PIL application if one of these is true:
  - The signal or parameter has an `Imported` data scope.
  - The model uses a model reference code interface.
  - The model uses a top model code interface, `EnableDataOwnership` is `on`, and the `Owner` attribute for the custom storage class is not empty and not equal to the name of the current model
- The code generator uses the string returned by `DataAccess(record, "declare", "", "")` to declare the variable in the SIL or PIL application if the following are true:
  - The model uses a top model code interface.
  - The signal or parameter uses an `Exported` storage class.
  - `EnableDataOwnership` is `off`, or `EnableDataOwnership` is `on` and the `Owner` attribute for the custom storage class is empty or equal to the model name.
  - Code packaging is configured so that the variable is not declared in *`model`*`.h` or a header file that is included by *`model`*`.h`

For a custom storage class that is grouped:

- The code generator calls `DataAccess` with the `request` argument taking values of `layout`, `address`, or `set`.
- The code generator calls `ClassAccess` with the `request` argument taking the value of `groupTypeDeclDefn`.
- You must provide the grouped type (`struct`) definition and the `extern` declaration of the grouped variable if one of these is true:
  - The signal or parameter has an `Imported` data scope.
  - The model uses a model reference code interface.

  - The model uses a top model code interface, `EnableDataOwnership` is `on`, and the `Owner` attribute for the custom storage class is not empty and not equal to the name of the current model

  Provide the definition and declaration in a header file associated with the custom storage class by using the `HeaderFile` attribute or custom code that you include through the *`model`*`.h` file. To define the variable in the SIL or PIL application, the code generator uses the string returned by `ClassAccess(record, "groupTypeDeclDefn")`.

- Static initialization can assume an order of `struct` elements that is different from the order that is generated if the data scope is `Exported`. When the code generator queries `ClassAccess(record, "groupTypeDeclDefn")`, it temporarily overrides the data initialization attribute of the custom storage class with the value `None`.

To determine whether the SIL or PIL application can access the variable in the code by address, the code generator uses the elements returned by `DataAccess(record, "layout", "", "")`. To create the functionality in the application that transfers input or output port, tunable parameter, or global data store memory values between the development computer and target hardware, the code generator uses the output from:

- `DataAccess(record, "address", idx, reim)` if the first returned element is `scalar`, `vector`, `row-mat`, or `col-mat`.
- `DataAccess(record, "contents", idx, reim)` (or `DataAccess(record, "set", idx, reim)`) if the first returned element is `other`.

The code generator assumes that for `row-mat` and `col-mat`, matrices are stored in row-major format respectively. The assumption is independent of the array layout for the rest of the model. The code generator assumes that if the array layout of the storage implemented by the custom storage class differs from the rest of the model, the TLC file associated with the custom storage file performs the required transformations.

You can construct the custom TLC file associated with a custom storage class of type `Other` to perform other functions (in addition to returning the requested code fragments). For example, write directly to a custom file or call MATLAB functions that change the state of the base workspace. If you do not always want to execute these functions when `DataAccess` or `ClassAccess` are called, use the `LibIsAccessingCustomDataForSILPIL(record)` TLC function to distinguish between target code generation and requests for code fragments for the construction of the SIL or PIL application. For example:

```
...
%case "contents"
  %if !LibIsAccessingCustomDataForSILPIL(record)
    %matlab functionWithSideEffects()
  %endif
%return LibDefaultCustomStorageContents(record, idx, reim)
...
```

See also Other custom storage class limitations on page 78-76.

AUTOSAR Runtime Environment (RTE)

You can use top-model and Model block SIL/PIL and SIL/PIL block simulations to perform model-based testing of an AUTOSAR software component. The generated code for the AUTOSAR software component is linked with a basic component-specific AUTOSAR Runtime Environment (RTE) to create a test application. This application tests AUTOSAR API calls made by the AUTOSAR software component.

Note For Model block SIL/PIL, to test the AUTOSAR interface, set the **Code interface** block parameter to `Top model`.

For more information, see “Verify AUTOSAR C or C++ Code with SIL and PIL” (AUTOSAR Blockset).

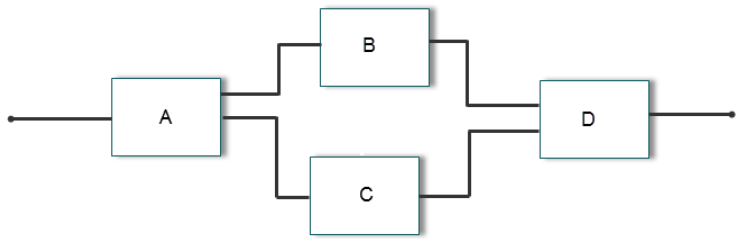
Choose a SIL or PIL Approach

In this section...

Consider a top model that consists of components `A`, `B`, `C`, and `D`:

- `A` and `B` are existing components for which code has previously been generated and tested.
- `C`, a referenced model, and `D`, a subsystem, are new components.



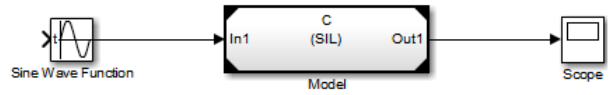
With software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations, you can use the following approaches to numerical equivalence testing:

- Test code from all components together. See “Test Top-Model Code” on page 78-15.
- Test new components separately (before testing code from all components). See “Test Referenced Model Code” on page 78-16 and “Test Subsystem Code” on page 78-16.

For some forms of testing, you require a test harness model. The test harness model:

- Generates test vectors or stimulus inputs that feed the block under test.
- Makes it possible for you to observe or capture output from the block.

The following example shows a simple test harness model.



The block under test is a Model block. The Sine Wave block generates the input for the Model block. Through the Scope block, you can observe the output from the Model block.

Test Top-Model Code

To test code generated from the top-model components together (`A`, `B`, `C`, and `D`), you can use top-model SIL/PIL or Model block SIL/PIL.

- Top-model SIL/PIL:

  1. Create test vectors or stimulus inputs in the MATLAB workspace (Simulink).
  2. Run the top model in normal, SIL, and PIL simulation modes. The software loads the test vectors or stimulus inputs from the MATLAB workspace.
  3. For each simulation mode, observe or capture outputs.
  4. Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

- Model block SIL/PIL:

  1. Create a Model block that contains the top-model components.
  2. Insert the Model block in a simulation model, for example, your test harness model.
  3. Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Top model`.
  4. Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

Test Referenced Model Code

To test code generated from the component `C` as part of a model reference hierarchy, use the Model block SIL/PIL approach:

- Insert the Model block `C` in a simulation model, for example, your test harness model.
- Run simulations, switching the Model block between normal, SIL, and PIL modes. For the SIL and PIL simulation modes, set the **Code interface** Model block parameter to `Model reference`.
- Verify numerical equivalence by comparing normal outputs against SIL and PIL outputs.

Test Subsystem Code

To test code generated from the subsystem `D`, use the SIL or PIL block approach:

1. Insert the subsystem in a simulation model, for example, your test harness model.
2. Run a normal mode simulation, capturing the outputs.
3. Create a SIL or PIL block from the subsystem.
4. In the model, replace the subsystem with the SIL or PIL block.
5. Run a simulation of the model, capturing the outputs.
6. Verify numerical equivalence by comparing normal mode subsystem outputs against SIL or PIL block outputs.

Summary

Simulation Type	Component From Which Code Is Generated	Mode Selection Method	Generated Code Interface	Test Signal Source
Top-model SIL/PIL	Top model	Menu item on Simulink Editor toolbar	Standalone	MATLAB workspace (Simulink)

Simulation Type	Component From Which Code Is Generated	Mode Selection Method	Generated Code Interface	Test Signal Source
Model block SIL/PIL	Model referenced by Model block	Model block parameter **Simulation mode**	Determined by Model block parameter **Code interface**: standalone or model reference.	Simulation model, for example, test harness model
SIL or PIL block	Subsystem	Manual block substitution	Standalone	Simulation model, for example, test harness model.

Configure and Run SIL Simulation

In this section...

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

1. Open your model.
2. Select either **Simulation > Mode > Software-in-the-Loop (SIL)** or **Simulation > Mode > Processor-in-the-Loop (PIL)**. This option is available only if the model is configured for an ERT, GRT, or AUTOSAR target. See “Model Configuration Parameters: Code Generation” (Simulink Coder) and “Configure AUTOSAR Code Generation” (AUTOSAR Blockset) for configuration information.
3. If you have not already done so, in the Configuration Parameters dialog box, on the **Data Import/Export** pane:

   - In the **Input** check box and field, specify stimulus signals (or test vectors) for your top model.
   - Configure logging for model outputs, with either *output logging* or *signal logging*:

    - In the **Output** check box and field, specify *output logging*.
    - In the **Signal logging** check box and field, specify *signal logging*.
  - Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.

4. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
5. If required, configure:
   - Code coverage.
   - Code execution profiling.
   - Creation of code generation report and static code metrics.
6. Start the simulation.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(`*`model`*`)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

With a top-model SIL or PIL simulation, Simulink creates a hidden model, *`modelName`*`_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:

```
Warning: The model 'modelName_wrapper' has the 'Configuration Parameters' ...
```

Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

1. Open your model, for example, `rtwdemo_sil_modelblock`.
2. Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
3. From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
4. From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model reference`.
5. Click **OK**. The software displays the simulation mode as a block label.

   If you select `Top model`, the software displays the block label `(SIL: Top)`.
6. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
7. If required, configure:
   - Code coverage.
   - Code execution profiling for your Model block, by configuring execution profiling for the top model.
   - Creation of code generation report and static code metrics.

8 Start the simulation.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Simulation with Blocks From Subsystems

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

1 From the **Configuration Parameters > Code Generation > Verification > Advanced Parameters > Create block** drop-down list, select either `SIL` or `PIL`.

2 If required, configure code execution profiling.

3 Click **OK**.

4 In your model window, right-click the subsystem that you want to simulate.

5 Select **C/C++ Code > Build This Subsystem**.

6 Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.

7 Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.

8 Run simulations with the environment or test harness model.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot create a SIL or PIL block if you do one of the following:

- Disable the `CreateSILPILBlock` property.
- Select a code coverage tool.

Create block appears dimmed.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Configure Hardware Implementation Settings

For a SIL simulation, you must configure hardware implementation settings, which enables generated code compilation for your development computer. These settings can differ from the hardware implementation settings that you use when building the model for your production hardware. Use one of these approaches.

Approach	Details
Portable word sizes	Switch between SIL and PIL modes without regenerating code. You use the same generated source code files for the SIL simulation on your development computer and for production deployment on the target platform. To configure a model to use portable word sizes, set: • `ProdEqTarget` to `'on'`. • `PortableWordSizes` to `'on'`.

Approach	Details

	When you generate code for a model with portable word sizes specified, the code generator conditionalizes data type definitions in `rtwtypes.h`:
	
	`#ifdef PORTABLE_WORDSIZES /* PORTABLE_WORDSIZES defined */`
	
	…
	
	`#else /* PORTABLE_WORDSIZES not defined */`
	
	…
	
	`#endif /* PORTABLE_WORDSIZES */`
	
	The template makefile that you use to build code for your target must not contain the `PORTABLE_WORDSIZES` definition.
	
	For the template makefile and toolchain approaches to building code, the software specifies `-DPORTABLE_WORDSIZES` for the compiler only for host-based builds.
	
	For information about the template makefile and toolchain approaches to building code, see “Choose Build Approach and Configure Build Process” (Simulink Coder).

	Consider the case where your target uses code that your development computer cannot compile. When you switch from the PIL mode to the SIL mode and try to simulate the model, you see compilation errors. You can try to work around this problem by adding the source code files to the `SkipForSil` group in the build information object `RTW.BuildInfo`. The SIL build on the host platform does not compile source files present in the `SkipForSil` group. For information about how you add source code files to a group in the build information object, see: • `addSourceFiles` in the Simulink Coder documentation • “Customize Post-Code-Generation Build Processing” (Simulink Coder) in the Simulink Coder documentation

Approach	Details
	Numerical results can differ between generated code executing in a SIL simulation and generated code executing on the production hardware under one of these conditions: • Your model contains blocks implemented in TLC, for which C integral promotion in expressions can behave differently between the MATLAB host and the production hardware target. Normal and PIL simulation results match, but SIL simulation results can differ. • Your production hardware implements rounding to `Floor` for signed integer division, and divisions in your model use rounding mode `Ceiling`, `Floor`, `Simplest`, or `Zero`. Normal and PIL simulation results match, but SIL simulation results can differ. • The byte ordering for your production hardware is `Big Endian`. Normal and PIL simulation results match, but SIL simulation results can differ. For example, when generated code depends on byte order *and* generated production code is implemented with the aim that its behavior matches normal simulation behavior. • You use custom code with the Stateflow product. In this case, type conversion statements are not inserted into the custom code, which target overflow behavior on the host can require. Normal and PIL simulation results match, but SIL simulation results can differ.
Test hardware	Use this approach only when you want to work around a limitation of portable word sizes. Set: • `PortableWordSizes` to `'off'`. • `ProdEqTarget` to `'off'`. • `TargetHWDeviceType` to `'Custom Processor->MATLAB Host Processor'`.

Approach	Details
Production hardware	Use this approach only when the production hardware settings match your development computer architecture. Set: • `PortableWordSizes` to `'off'`. • `ProdEqTarget` to `'on'`. • `ProdHWDeviceType` to match your development computer architecture.

For information about test and production targets, see “Configure Run-Time Environment Options” (Simulink Coder) in the Simulink Coder documentation.

Log Internal Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logsout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters** > **Data Import/Export** > **Format** to `Dataset`.
- Select the **Configuration Parameters** > **Code Generation** > **Interface** > **Generate C API for: signals** check box.

  The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  1. Inside the component, connect a Data Store Write block to the required signal.
  2. Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logsout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.

For more information, see:

- “Test Points” (Simulink)
- “Export Signal Data Using Signal Logging” (Simulink)
- “Local and Global Data Stores” (Simulink)
- “Global Data Store Example” (Simulink)
- “Log Program Execution Results” (Simulink Coder)

Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, set **Configuration Parameters** > **Model Referencing** > **Rebuild** to `Never`. If the Model block **Code interface** parameter is `Model reference`, the software does not rebuild the referenced model code. (If the **Code interface** parameter is `Top model`, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	**Configuration Parameters** > **Model Referencing** > **Rebuild** of test harness model set to `Never`.	**1** Component (algorithm) code from initial build is not regenerated. **2** Component code makefile is not called. **3** SIL/PIL application files from initial build are not regenerated. **4** SIL/PIL application makefile is called.
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1–4.

For more information, see:

- “Model Configuration Parameters: Model Referencing” (Simulink)
- “Protect Models to Conceal Contents” (Simulink Coder)

Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode (Simulink). This mode accelerates the simulation of model components that are not in SIL or PIL mode.

- Turning on fast restart (Simulink) with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.

Note The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

Simulation with Function Calls

Use the Simulink Function block and Function Caller block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” (AUTOSAR Blockset) shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation” (Simulink Coder).

Configure and Run PIL Simulation

In this section...

There are three ways of running SIL and PIL simulations. You can use:

- The top model.
- Model blocks.
- SIL and PIL blocks that you create from subsystems.

Simulation with Top Model

To configure and run a top-model SIL or PIL simulation:

1. Open your model.
2. Select either **Simulation > Mode > Software-in-the-Loop (SIL)** or **Simulation > Mode > Processor-in-the-Loop (PIL)**. This option is available only if the model is configured for an ERT, GRT, or AUTOSAR target. See “Model Configuration Parameters: Code Generation” (Simulink Coder) and “Configure AUTOSAR Code Generation” (AUTOSAR Blockset) for configuration information.
3. If you have not already done so, in the Configuration Parameters dialog box, on the **Data Import/Export** pane:

   - In the **Input** check box and field, specify stimulus signals (or test vectors) for your top model.
   - Configure logging for model outputs, with either *output logging* or *signal logging*:

     - In the **Output** check box and field, specify *output logging*.

    - In the **Signal logging** check box and field, specify *signal logging*.
  - Disable logging of Data Store Memory variables. The software does not support this option for this simulation mode. If you do not clear the **Data stores** check box, the software produces a warning when you run the simulation.

4. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
5. If required, configure:
   - Code coverage.
   - Code execution profiling.
   - Creation of code generation report and static code metrics.
6. Start the simulation.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot:

- Close the model while the simulation is running. To interrupt the simulation, in the Command Window, press **Ctrl+C**.
- Alter the model during the simulation. You can move blocks and lines as long as it does not alter the behavior of the model.

You can run a top-model SIL or PIL simulation with the command `sim(`*`model`*`)`. The software supports the `sim` command option `SrcWorkspace` for the value `'base'`.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

With a top-model SIL or PIL simulation, Simulink creates a hidden model, *`modelName`*`_wrapper`. The simulation generates code for the model and uses the hidden model to call this code at each time step. As a result, in some circumstances, logged signals can have a `_wrapper` suffix. The simulation can also generate warnings that refer to the hidden model. For example:

```
Warning: The model 'modelName_wrapper' has the 'Configuration Parameters' ...
```

Simulation with Model Blocks

To configure a Model block for a SIL or PIL simulation:

1. Open your model, for example, `rtwdemo_sil_modelblock`.
2. Right-click your Model block, for example, `Counter A`. In the context menu, select **Block Parameters (ModelReference)**, which opens the Function Block Parameters dialog box.
3. From the **Simulation Mode** drop-down list, select the required mode, for example, `Software-in-the-loop (SIL)`.
4. From the **Code interface** drop-down list, specify the code that you want to test, for example, `Model reference`.
5. Click **OK**. The software displays the simulation mode as a block label.

   If you select `Top model`, the software displays the block label `(SIL: Top)`.
6. If you are configuring a SIL simulation, specify the portable word sizes option. You can then switch seamlessly between the SIL and PIL modes. Select **Code Generation > Verification > Enable portable word sizes**.
7. If required, configure:
   - Code coverage.
   - Code execution profiling for your Model block, by configuring execution profiling for the top model.
   - Creation of code generation report and static code metrics.
8. Start the simulation.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Simulation with Blocks From Subsystems

To create a SIL or PIL block from a subsystem and use this block to test the code generated from the subsystem:

1. From the **Configuration Parameters** > **Code Generation** > **Verification** > **Advanced Parameters** > **Create block** drop-down list, select either `SIL` or `PIL`.
2. If required, configure code execution profiling.
3. Click **OK**.
4. In your model window, right-click the subsystem that you want to simulate.
5. Select **C/C++ Code** > **Build This Subsystem**.
6. Click **Build**, which starts the subsystem build process that creates a SIL or PIL block for the generated subsystem code.
7. Add the generated block to an environment or test harness model that supplies test vectors or stimulus input.
8. Run simulations with the environment or test harness model.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL simulation. To allow the simulation, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

You cannot create a SIL or PIL block if you do one of the following:

- Disable the `CreateSILPILBlock` property.
- Select a code coverage tool.

Create block appears dimmed.

For a PIL simulation, you control the way code compiles and executes in the target environment through connectivity configurations.

Log Internal Signals of a Component

SIL and PIL component outputs are available for observation and comparison with other simulation mode outputs. If you want to examine an internal signal, you can enable internal signal logging for top-model or Model block SIL or PIL. With signal logging, you can:

- Collect signal logging outputs during SIL/PIL simulations, for example, `logsout`.
- Log the internal signals and the root-level outputs of a SIL/PIL component.
- Manage the SIL/PIL signal logging settings with the Simulink Signal Logging Selector.
- Use the Simulation Data Inspector to:
  - Observe streamed signals during normal, SIL, and PIL simulations.
  - Compare logged signals from normal, SIL, and PIL simulations.

For SIL and PIL signal logging:

- Set **Configuration Parameters** > **Data Import/Export** > **Format** to `Dataset`.
- Select the **Configuration Parameters** > **Code Generation** > **Interface** > **Generate C API for: signals** check box.

  The C API determines the addresses of the internal signals that require logging.

You can use other methods to examine internal signals of the SIL or PIL component:

- Manually route the signal to the top level.
- Use global data stores to access internal signals:
  1. Inside the component, connect a Data Store Write block to the required signal.
  2. Outside the component, use a Data Store Read block to access the signal value.
- Use MAT-file logging. Note that:
  - MAT-file logging does not support signal logging. If signal logging is enabled, `logsout` is generated but not stored in the MAT-file.
  - For PIL, the target environment must support MAT-file logging.

For more information, see:

- “Test Points” (Simulink)
- “Export Signal Data Using Signal Logging” (Simulink)
- “Local and Global Data Stores” (Simulink)
- “Global Data Store Example” (Simulink)
- “Log Program Execution Results” (Simulink Coder)

Prevent Code Changes in Multiple Simulations

Use Model block SIL/PIL or the SIL/PIL block with fast restart when you want to run multiple SIL or PIL simulations with:

- Varying test vectors (parameter sets and input data).
- Unchanged generated code, that is, none of the simulations regenerate or rebuild code after the initial build. For example, you want to avoid the incremental code generation that an initial value change can trigger.

For Model block SIL/PIL, you can also use one of these methods:

- In your test harness model, set **Configuration Parameters > Model Referencing > Rebuild** to `Never`. If the Model block **Code interface** parameter is `Model reference`, the software does not rebuild the referenced model code. (If the **Code interface** parameter is `Top model`, the software ignores the **Rebuild** setting.)
- Create a protected model and generate source or binary code. Then, insert the protected model in your test harness model. With this method, you can verify top-model code (with the standalone code interface) or model reference code.

For the alternative methods of running Model block SIL/PIL, the following table summarizes code generation behavior after the initial build.

SIL and PIL Approach		Code Generation Behavior After Initial Build
Model block	**Configuration Parameters** > **Model Referencing** > **Rebuild** of test harness model set to `Never`.	**1** Component (algorithm) code from initial build is not regenerated. **2** Component code makefile is not called. **3** SIL/PIL application files from initial build are not regenerated. **4** SIL/PIL application makefile is called.
Model block (protected model)	Source code from protected model.	You observe the same behavior except for feature 2. In this case, the component code makefile is run. The component code is recompiled and linked to produce new object code.
	Binary code from protected model.	You observe features 1–4.

For more information, see:

- “Model Configuration Parameters: Model Referencing” (Simulink)
- “Protect Models to Conceal Contents” (Simulink Coder)

Speed Up Testing

If your model has SIL/PIL blocks or Model blocks in SIL/PIL mode, you can speed up SIL/PIL testing by:

- Running the top-model simulation in accelerator mode (Simulink). This mode accelerates the simulation of model components that are not in SIL or PIL mode.
- Turning on fast restart (Simulink) with the **Fast restart** button on the Simulink Editor toolbar. After the first simulation, you can tune parameters and rerun simulations without model recompilation.

Note The SIL and PIL simulation modes are not designed for the reduction of model simulation times. If you want to speed up the simulation of your model, use the rapid accelerator mode. For more information, see “What Is Acceleration?” (Simulink).

Simulation with Function Calls

Use the Simulink Function block and Function Caller block when you want to:

- Generate code that makes a function-call to external code, for example, driver or legacy code.
- Provide a subsystem that behaves like the external code in normal, SIL, or PIL simulations.

The example in “Configure Calls to AUTOSAR NVRAM Manager Service” (AUTOSAR Blockset) shows how you can configure client calls to Basic Software (BSW) NVRAM Manager (NvM) service interfaces from your AUTOSAR software component. In a simulation, Simulink implements the BSW NvM calls through Simulink Function and preconfigured Function Caller blocks. For the final system, you link function-call stubs with external BSW function code that runs in the AUTOSAR Runtime Environment (RTE).

For more information, see “Simulink Function Blocks and Code Generation” (Simulink Coder).

- “Simulation Mode Override Behavior in Model Reference Hierarchy” on page 78-39
- “SIL and PIL Limitations” on page 78-70

Simulation Mode Override Behavior in Model Reference Hierarchy

When the top model contains a Model block, the simulation mode of the top model can override the simulation mode of the Model block. The Model block itself can be a parent block containing child Model blocks at lower levels of its reference hierarchy. The simulation mode of the parent block can override the simulation mode of the child block.

You can specify the simulation mode of a top model to be normal, accelerator, rapid accelerator, SIL, or PIL. With a Model block, you can specify all modes *except* rapid accelerator. This table shows how the software determines the effective simulation mode of a Model block in a reference hierarchy.

Mode of Top Model or Parent Block	**Mode of Parent or Child Block in Reference Hierarchy**			
	Normal	**Accelerator**	**SIL**	**PIL**
Normal	Equivalent	Compatible	Compatible	Compatible
Accelerator	Override	Equivalent	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.	Compatible if top model mode is accelerator. Error if parent block mode is accelerator.
Rapid accelerator	Override	Override	Error	Error
SIL	Override	Override	Equivalent	Error
PIL	Override	Override	Error	Equivalent

The different types of behavior are:

- Equivalent — Both parent and child Model block run in the same simulation mode.
- Compatible — The software simulates the child block in the mode specified for the child block, for example, when the simulation mode of the top model is normal or accelerator.
- Error — The simulation produces an error. For example, if a top model has simulation mode rapid accelerator but contains a child block in SIL or PIL mode, then running a simulation produces an error: the rapid accelerator mode cannot override the SIL and

PIL mode of child blocks. This behavior avoids the risk of “false positives”, that is, the simulation of a model in rapid accelerator mode does not lead to the conclusion that generated source or object code of child Model blocks is tested or verified.

- Override — The simulation mode of the top model or parent Model block overrides the simulation mode of the child block. For example, if a top model or parent Model block that you configured for a SIL simulation contains a child Model block with normal or accelerator simulation mode, then the software simulates the child block in SIL mode. The override behavior:
  - Allows a Model block in the reference hierarchy to have the SIL or PIL mode.
  - Makes lower-level referenced models execute in SIL or PIL mode if you simulate the top model or parent Model block in SIL or PIL mode. You do not have to switch the simulation mode of every model component in the hierarchy.

Note You can view your model hierarchy in the Model Dependency Viewer. In the Referenced Model Instances view, the software displays Model blocks differently to indicate their simulation modes, for example, normal, accelerator, SIL, and PIL. In this view, the software does not indicate the simulation mode of the top model.

Debug Generated Code During SIL Simulation

If a software-in-the-loop (SIL) simulation fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL simulation with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which can help you to understand the cause of the issue.

For a SIL simulation failure, you can also view information from the standard output and standard error streams in the Diagnostic Viewer. For example:

- Output from `printf` statements in your code.
- Error messages sent to `stderr`.
- Some low-level system messages.

During a SIL simulation, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the Diagnostic Viewer displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX® signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

A SIL simulation supports these debuggers;

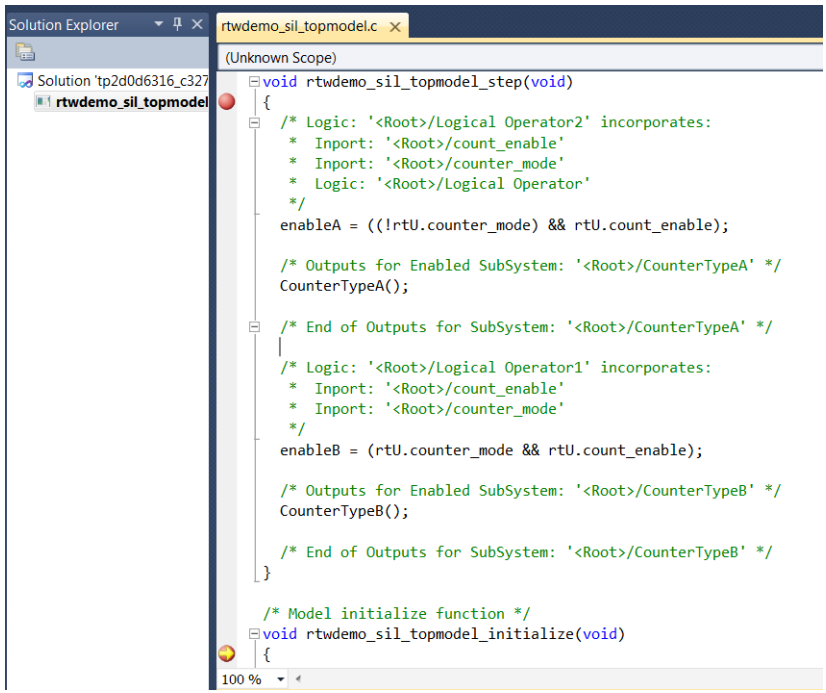
- On Windows, Microsoft Visual Studio debugger.
- On Linux, GNU Data Display Debugger (DDD).

Note You can perform SIL debugging only if the Simulink product family supports your Microsoft Visual C++ or GNU GCC compiler. For more information, see supported compilers.

To enable your debugger for a SIL simulation, on the **Configuration Parameters > Code Generation > Verification** pane, select the **Enable source-level debugging for SIL** check box.

If your top model has Model blocks, the **Enable source-level debugging for SIL** parameter for the top model overrides the corresponding parameter for referenced models.

When you run the SIL simulation, for example on a Windows computer, your *model*.c or *model*.cpp file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the *model*_initialize and *model*_step functions.



You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

1. Remove all breakpoints.
2. Click the `Continue` button (**F5**).

   The SIL simulation runs to completion and the Microsoft Visual Studio IDE closes.

Note In the Microsoft Visual Studio IDE, if you select **Debug > Stop Debugging**, the SIL simulation times out with the following error message:

```
The timeout of 1 seconds for receiving data from the rtiostream
interface has been exceeded. There are multiple possible causes
for this failure.
...
...
```

Create PIL Target Connectivity Configuration for Simulink

In this section...

Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) simulation for your target environments.

Through a target connectivity configuration, you specify:

- A configuration name for a target connectivity API implementation.
- Settings that define the set of compatible Simulink models. For example, the set of models that have a particular system target file, template makefile, and hardware implementation.

A PIL simulation requires a target connectivity API implementation that integrates third-party tools for:

- Cross-compiling generated code, creating the PIL application that runs on the target hardware.
- Downloading, starting, and stopping the application on the target.
- Communicating between Simulink and the target.

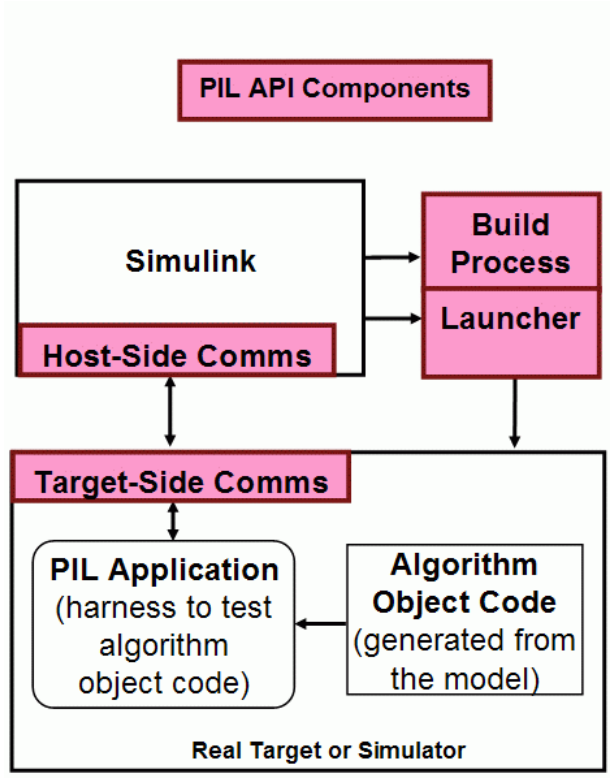
You can have many different target connectivity configurations for PIL simulation. Register a connectivity configuration with Simulink by creating an `sl_customization.m` file and placing it on the MATLAB search path.

When you run a PIL simulation, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the model under test. If the software finds multiple or no

compatible connectivity configurations, the software generates an error message with information about resolving the problem.

Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.



You must provide implementations of the three API components:

- Build API — Specify the Simulink Coder toolchain or template makefile approach for building generated code.
- Launcher API — Control how Simulink starts and stops the PIL executable.
- Communications API — Customize connectivity between Simulink and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from `ConnectivityConfig.m` in "Configure Processor-In-The-Loop (PIL) for a Custom Target" on page 78-108.

1. Create a subclass of `rtw.connectivity.Config`.

   ```
   ConnectivityConfig < rtw.connectivity.Config
   ```

2. In the subclass:

   - Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

     ```
     builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
                                                targetApplicationFramework, ...
                                                exeExtension);
     ```

   - Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

     ```
     launcher = mypil.Launcher(componentArgs, builder);
     ```

3. Configure your `rtiostream` API implementation of the host-target communications on page 78-50 channel.

   - For the target side, you must provide the driver code for communications, for example, TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
   - For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

     ```
     hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(componentArgs, ...
                                                                    launcher, ...
                                                                    rtiostreamLib);
     ```

4. If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See "Specify Hardware Timer" on page 78-56.

Note Each time you modify a connectivity implementation, close and reopen the models to refresh them.

Register a Connectivity API Implementation

To register a target connectivity API implementation as a target connectivity configuration in Simulink:

1. Create or update an `sl_customization.m` file. In this file:
   - Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible models.
   - Invoke `registerTargetInfo`.
2. Add the folder containing `sl_customization.m` to the search path and refresh your customizations.

   ```
   addpath(sl_customization_path);
   sl_refresh_customizations;
   ```

For more information, see `rtw.connectivity.ConfigRegistry`.

Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your model development and code generation, use the supplied `piltest` function. With the function, you can run a suite of tests. In the tests, the function runs various normal, SIL, and PIL simulations. The function compares results and produces errors if it detects differences between simulation modes.

Target Connectivity API Examples

For step-by-step examples, see:

- “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 78-108

  This example shows you how to create a custom PIL implementation using the target connectivity APIs. You can examine the code that configures the build process to support PIL, a downloading and execution tool, and a communication channel between host and target. To activate a full host-based PIL configuration, follow the steps in the example.
- “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation” on page 78-101

This example shows you how to implement a communication channel for use with the Embedded Coder product and your embedded target. This communication channel enables exchange of data between different processes. PIL simulation requires exchange of data between the Simulink software running on your development computer and deployed code executing on target hardware.

The `rtiostream` interface provides a generic communication channel that you can implement in the form of target connectivity drivers for a range of connection types. The example shows how to configure your own target-side driver for TCP/IP, to operate with the default host-side TCP/IP driver. The default TCP/IP communications allow high-bandwidth communication between host and target, which you can use for transferring data such as video.

Note If you customize the `rtiostream` TCP/IP implementation for your PIL simulations, you must turn off Nagle's algorithm for the server side of the connection. If Nagle's algorithm is not turned off, your PIL simulations can run at a significantly slower speed. The *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c` file shows how you can turn off Nagle's algorithm:

```
/* Disable Nagle's Algorithm*/
option = 1;
sockStatus = setsockopt(lFd,IPPROTO_TCP,TCP_NODELAY,(char*)&option,sizeof(option));
```

The code for your custom TCP/IP implementation can require modification.

The example also shows how to implement custom target connectivity drivers, for example, using serial, CAN, or USB for both host and target sides of the communication channel.

Host-Target Communication for PIL

In this section...

Communications rtiostream API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL simulation requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that this driver code must implement.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation and a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`

- `rtIOStreamSend`
- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 78-45.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see “Test an rtiostream Driver” on page 78-52.

Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents Simulink from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP rtiostream implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because Simulink automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the Simulink side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher` / `rtiostream` implementation that confirms completion of target initialization.

Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduces time for testing custom `rtiostream` drivers.
- Helps analyze the performance of custom `rtiostream` drivers.

The test suite has two parts. One part of the test suite runs on the target.

Note After building the target application, download it to the target and run it.

To start this part, compile and link the following files, which are in the folder *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtest` (open).

- `rtiostreamtest.c`
- `rtiostreamtest.h`
- `rtiostream.h`, located in the folder *`matlabroot`*`/toolbox/coder/rtiostream/src` (open)
- `rtiostream` implementation under investigation (for example, `rtiostream_tcpip.c`)
- `main.c`

To run the MATLAB part of the test suite, invoke `rtiostreamtest`. The syntax is as follows:

```
rtiostreamtest(connection,param1,param2)
```

- `connection` is a character vector indicating the communication method. It can have values `'tcp'` or `'serial'`.
- `param1` and `param2` have different values depending on the value of `connection`.
  - If `connection` is `'tcp'`, then `param1` and `param2` are hostname and port, respectively. For example, `rtiostreamtest('tcp', 'localhost', 2345)`.

- If `connection` is `'serial'`, then `param1` and `param2` are COM port and baud rate, respectively. For example, `rtiostreamtest('serial', 'COM1', 9600)`.

You can run the MATLAB part of the test suite as follows:

```
rtiostreamtest('tcp','localhost','2345')
```

An output in the following format appears in the MATLAB window:

```
### Test suite for rtiostream ###
Initializing connection with target...

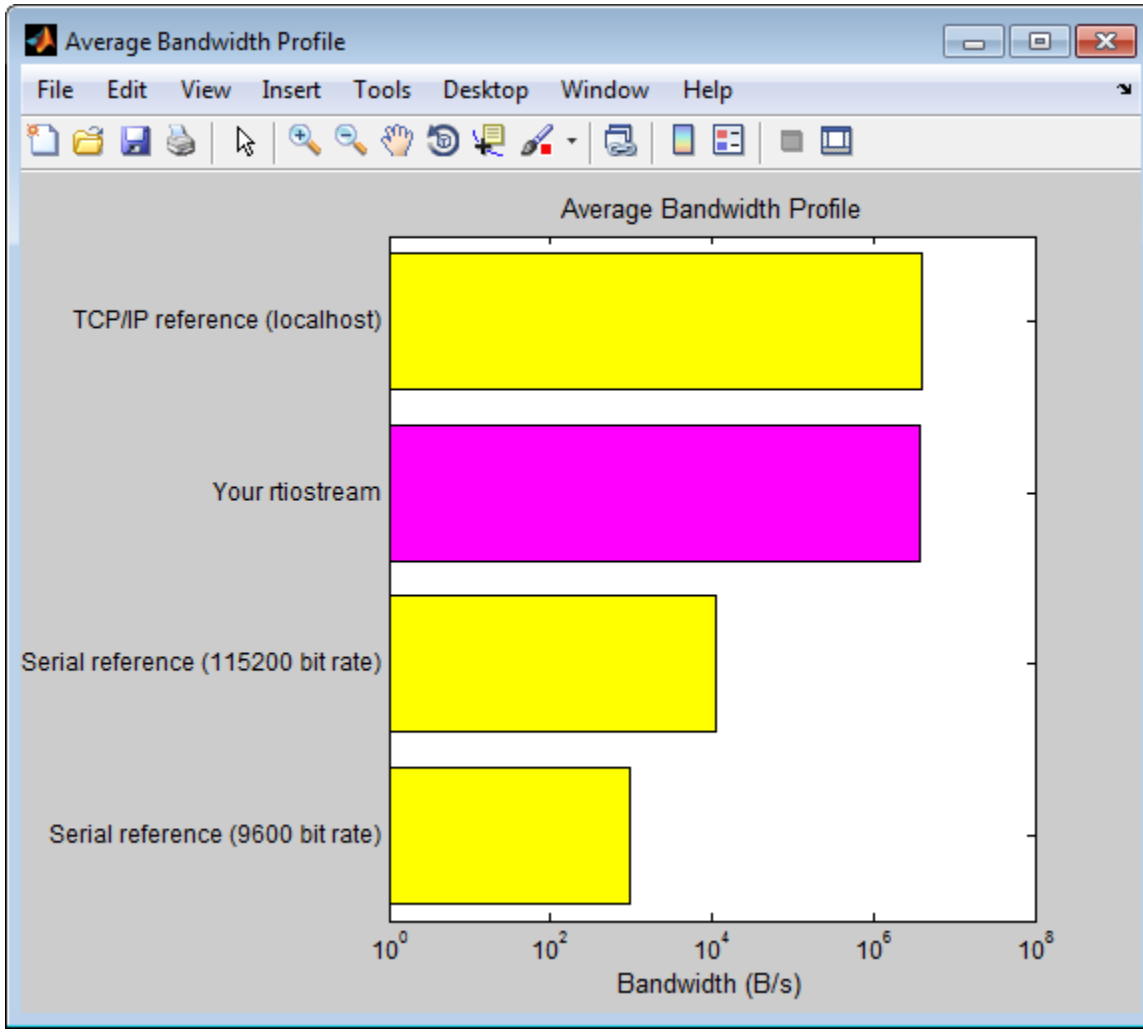
### Hardware characteristics discovered
Size of char    : 8 bit
Size of short   : 16 bit
Size of int     : 32 bit
Size of long    : 32 bit
Size of float   : 32 bit
Size of double  : 64 bit
Size of pointer : 64 bit
Byte ordering   : Little Endian

### rtiostream characteristics discovered
Round trip time : 0.96689 ms
rtIOStreamRecv behavior : non-blocking

### Test results
Test 1 (fixed size data exchange): ......... PASS
Test 2 (varying size data exchange): ......... PASS

### Test suite for rtiostream finished successfully ###
```

Furthermore, the following profile appears.



Word Addressable Target Hardware

On the **Hardware Implementation** pane, when you specify **Device vendor** and **Device type** settings, you provide PIL simulations with memory addressing information about the target hardware.

For example, consider the case when **Device vendor** is set to `Texas Instruments` and **Device type** is set to `C5000`.

The settings specify that the target hardware uses 16-bit word addresses and big-endian word order. The rtiostream implementation operates with 16-bit words.

On the target hardware, if an `rtIOStream` function specifies a size of 1, then the target hardware must send or receive one 16-bit word (2 bytes). `sizeof(char)` and `sizeof(short)` return 1, which corresponds to one 16-bit word. The `rtIOStream` function expects the byte order within the word to be little-endian, that is, less significant bytes are transmitted before more significant bytes.

`rtiostreamtest` identifies the target hardware and handles data in terms of 16-bit words, for example, a byte value is transferred as a 16-bit word value.

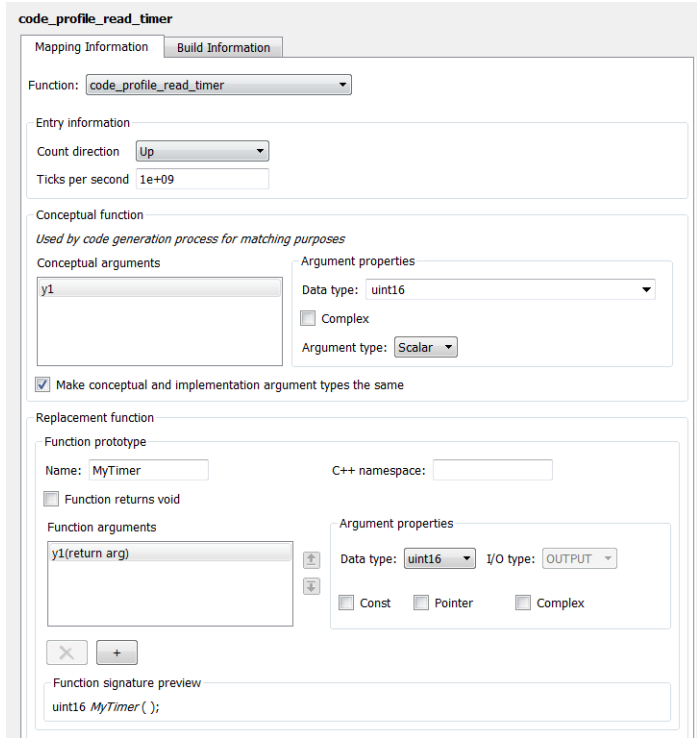
Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the **Code Replacement Tool** or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

1. Open the Code Replacement Tool. In the Command Window, enter `crtool`.
2. Create a new code replacement table. Select **File** > **New table**.
3. Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry** > **Function**.
4. In the middle view, select the new unnamed function.
5. On the **Mapping Information** pane:
   a. From the **Function** drop-down list, select `code_profile_read_timer`.
   b. Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select `Up`.
   c. In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

      The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.
   d. In the **Name** field, specify a replacement function name, for example, `MyTimer`.
   e. Click **Apply**.



f To validate the function entry, click **Validate entry**.

6 On the **Build Information** pane, specify the required build information. See “Specify Build Information for Replacement Code” on page 65-62.

7 Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

8 Assuming you save the table as *`MyCrlTable`*`.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCrlTable)
```

PIL Simulation Sequence

A processor-in-the-loop (PIL) simulation cross-compiles production source code, and then downloads and runs object code on your target hardware. The connectivity configuration that you create controls the way code is compiled and executed on the target. This table describes the sequence of stages in a PIL simulation.

Stage		Description
1	Start	For top-model PIL, on the Simulink Editor toolbar, you select the `Processor-in-the-Loop (PIL)` mode, and then click the Run button. For Model block PIL, you set the **Simulation mode** parameter of the Model block to `Processor-in-the-loop (PIL)`, and then run a simulation of the harness model that contains the Model block. For the PIL block, you run a simulation of the harness model that contains the PIL block.
2	Validate target connectivity	The software verifies that a target connectivity configuration is registered for PIL. Otherwise, the software produces an error.
3	Generate production source code and build object code for target	The generated source code is identical to the code that is produced when you run the `slbuild` command. • For top-model PIL or Model block PIL with block parameter **Code interface** set to `Top model`, the generated code is identical to the code produced when you run `slbuild('model')`. • For Model block PIL with block parameter **Code interface** set to `Model reference`, the generated code is identical to the code produced when you run `slbuild('model', 'ModelReferenceCoderTargetOnly')`. The software builds object code for the target by using the template makefile or toolchain that you specify.

Stage		Description
4	Create instances of PIL API components	The software instantiates your `rtw.connectivity.Config` class, which creates instances of `rtw.connectivity.MakefileBuilder`, `rtw.connectivity.Launcher`, `rtw.pil.RtIOStreamApplicationFramework`, and `rtw.connectivity.RtIOStreamHostCommunicator`.
5	Generate PIL files	The generated PIL files are in the `pil` folder. At the end of the simulation, use the code generation report to view the files.
6	Build target application	The software: • Uses your instance of `rtw.connectivity.MakefileBuilder` to build the target application. • Compiles the PIL interface file, `xil_interface.c`, and other PIL files into the target executable file. On a Windows system, for example, this file is called *`modelName`*`.exe`. The object code, including the executable file, is in the `pil` folder. • If configured, produces the code generation report.
7	Start target application	The software uses `rtw.connectivity.Launcher` to start the application on the target.
8	Simulink engine interacts with PIL S-function	The Simulink engine interacts with the PIL S-function in the same way that it interacts with a C S-function. From the host-side, the PIL S-function communicates with the target executable code through `rtIOStream` commands. On the target side, `xil_interface` executes generated code.
9	Stop target application	The software uses `rtw.connectivity.Launcher` to stop the application on the target.

Stage		Description
10	End PIL simulation	For top-model PIL, at the end of the simulation, the software destroys the `rtw.connectivity.Config` instance. For Model block PIL and PIL block, the block creates and owns the `rtw.connectivity.Config` instance, which is not destroyed at the end of the simulation. You can rerun the simulation, which now does not require the creation of another `rtw.connectivity.Config` instance. If you want to destroy the instance, close the parent model.

Verification of Code Generation Assumptions

At the start of a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation, the software verifies some configuration parameter settings with reference to the target hardware.

For example, the settings on the **Configuration Parameters > Hardware Implementation** pane specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

The software checks:

- The correctness of settings. For example, the integer bit length in the **Number of bits: int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

The simulation generates a Coder Assumptions page on page 53-17 for the code generation report, which provides a list of:

- Code generation assumptions that are checked
- Expected results for the assumption checks

This table shows when checks occur and outcomes when code generation assumptions are incorrect.

Stage	What is Checked	Outcome
Preprocessor	**Number of bits** per: • **char** (`ProdBitPerChar`) • **short** (`ProdBitPerShort`) • **int** (`ProdBitPerInt`) • **long** (`ProdBitPerLong`) If **Support long long** (`ProdLongLongMode`) is selected, number of bits per `long long` For each data type, the preprocessor check is not performed if the number of bits exceeds these settings for the target C preprocessor: • For signed integer math, `TargetPreprocMaxBitsSint`. • For unsigned integer math, `TargetPreprocMaxBitsUint`.	Error if data type sizes for model and target hardware do not match.
Run-time	**Number of bits** per: • **char** (`ProdBitPerChar`) • **short** (`ProdBitPerShort`) • **int** (`ProdBitPerInt`) • **long** (`ProdBitPerLong`)	Error if data type sizes for model and target hardware do not match.

Stage	What is Checked	Outcome
	If **Support long long** (`ProdLongLongMode`) is selected, number of bits per `long long`	Error if: • Target hardware does not support `long long`. • Data type sizes for model and target hardware do not match.
	Size of: • `float` • `double` You cannot configure these data type sizes through the **Hardware Implementation** pane. The check is performed only if **Support: floating-point numbers** is selected.	Warning if data type sizes for model and target hardware do not match. For `double`, warning is generated if size of target hardware data type is not 32 or 64 bits.
	Number of bits per: • **pointer** (`ProdBitPerPointer`) • **size_t** (`ProdBitPerSizeT`) • **ptrdiff_t** (`ProdBitPerPtrDiffT`)	Error if data type sizes for model and target hardware do not match.

Stage	What is Checked	Outcome
	Signed integer division rounds to (`ProdIntDivRoundTo`) setting	Warning if model parameter setting is `Undefined`. Error if target hardware behavior is undefined and model parameter setting is not `Undefined`. Error if target hardware behavior is defined but settings for model and target hardware do not match.
	Byte ordering (`ProdEndianess`) setting	Warning if setting is `Unspecified`. Otherwise, error if settings for model and target hardware do not match.
	Shift right on a signed integer as arithmetic shift (`ProdShiftRightIntArith`) setting	Error if settings for model and target hardware do not match.
	Remove root level I/O zero initialization (`ZeroExternalMemoryAtStartup`) setting	Warning if `ZeroExternalMemoryAtStartup` is `'off'` and initial values of global variables in the target application are not zero.
	Remove internal data zero initialization (`ZeroInternalMemoryAtStartup`) setting	Warning if `ZeroInternalMemoryAtStartup` is `'off'` and initial values of global variables in the target application are not zero.

View SIL and PIL Files in Code Generation Report

With top-model and Model block SIL and PIL simulations, you can produce a code generation report and static code metrics that cover SIL and PIL files. The information helps you to:

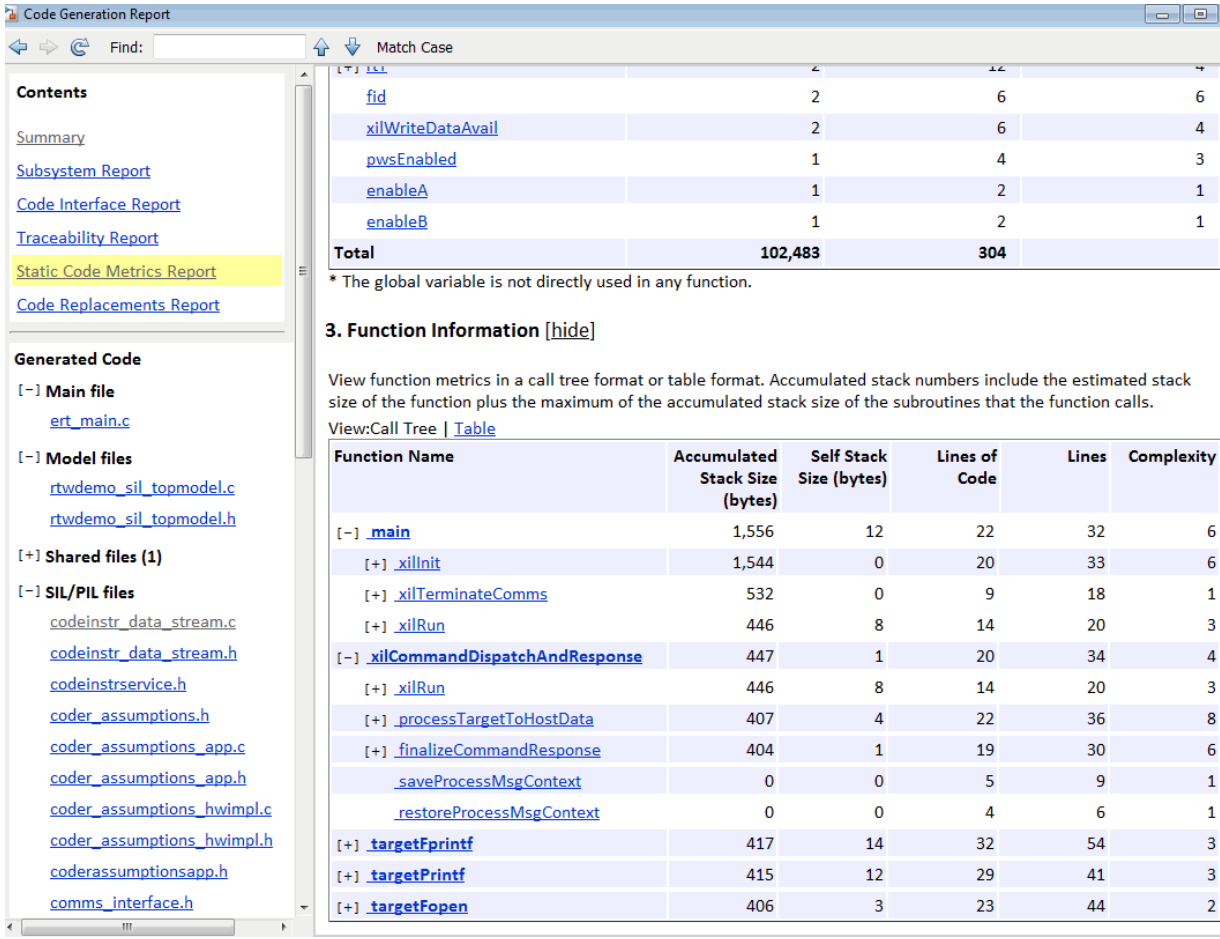
- Understand and review the SIL and PIL testing process.
- See how your registered custom target connectivity files fit into the target application that runs during a SIL or PIL simulation.

This capability is not supported for simulations that you run with the PIL block.

To configure the creation of a code generation report and static code metrics, on the **Configuration Parameters > Code Generation > Report** pane, select the **Create code generation report**, **Open report automatically**, and **Static code metrics** check boxes. Then click **OK**.

At the end of the simulation, in the Code Generation Report window:

- To review code metrics, in the **Contents** view, click **Static Code Metrics Report**.
- To review SIL and PIL files, in the **Generated Code** view, expand the **SIL/PIL files** node. For example:
  - To review the S-function that runs on the host, click *`modelName`*`_sbs.c` or *`modelName`*`_pbs.c`.
  - To view the SIL or PIL interface that runs on the target, click `xil_interface.c`.



Note Do not use the SIL or PIL files in code development as these files can change over releases. Use supplied APIs for code development.

SIL and PIL Limitations

In this section...

About SIL and PIL Limitations

With Embedded Coder, you can run software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations in three ways:

- Top-model SIL/PIL — Set the top-model simulation mode to `Software-in-the-Loop (SIL)` or `Processor-in-the-Loop (PIL)`.
- Model block SIL/PIL — Set the Model block parameter **Simulation mode** to `Software-in-the-loop (SIL)` or `Processor-in-the-loop (PIL)`.
- SIL/PIL block — Use SIL or PIL blocks in the model.

The following sections describe modeling and code generation features that are either unsupported or partially supported by SIL and PIL simulations.

General SIL and PIL Limitations

Tunable Parameters and SIL/PIL

For Model block SIL/PIL and SIL/PIL block simulations, you can tune tunable *workspace* parameters but not tunable *dialog box* parameters. For information about tuning parameters, see “Tune and Experiment with Block Parameter Values” (Simulink).

For a top model with tunable parameters, you can run a SIL/PIL simulation but you cannot tune the parameters during the simulation.

The software cannot define, initialize, or tune the following types of tunable workspace parameters.

Parameter description	Software response		
	Top-Model SIL/PIL	Model Block SIL/PIL	SIL/PIL Block
Parameters with storage class that applies `"static"` scope or `"const"` keyword. For example, `Custom`, `Const`, or `ConstVolatile`	Warning	Warning	Warning
Parameters with multiword, fixed-point data types	Warning	Error	Warning
Parameters with data types that have different sizes on host and target	Warning	Error	Warning

For C++ class code, SIL/PIL you can tune tunable workspace parameters when **Parameter visibility** is `public`. If **Parameter visibility** is `private` or `protected`, tuning is supported only if **Parameter access** is `Method` or `Inlined method`.

For top-model SIL/PIL and the SIL/PIL block, consider the case where all of the following conditions apply:

- **Code Generation > Interface > Code interface packaging** is `Reusable function`.
- **Code Generation > Interface > Use dynamic memory allocation for model initialization** is not selected.
- **Optimization > Default parameter behavior** is `Tunable`.
- In the Code Mapping Editor for the model, the default storage class for the **Global parameters** or **Local parameters** category is set to `Default`, and the model contains corresponding parameters that use the storage classes `Auto` or `Model default`.

If the SIL/PIL component cannot dynamically initialize tunable parameters in the `rtP` model parameter structure, you see an error message like the following:

```
Parameter Dialog:InitialOutput in 'rtwdemo_sil_topmodel/CounterTypeA/count'
is part of the imported "rtP" structure in the generated code but cannot be
initialized by SIL or PIL. To avoid this error, make sure the parameter
corresponds to a tunable workspace variable. Alternatively, set
"Configuration Parameters > Code Generation > Interface > Code interface packaging"
to ''Nonreusable function'', or search for ''Use dynamic memory allocation
```

```
for model initialization'' in the Configuration Parameters dialog box
and select the checkbox.
```

If you select **Code Generation > Interface > Use dynamic memory allocation for model initialization**, this limitation does not apply.

For Model block SIL/PIL, if you specify **Code interface** to be `Top model`, you can tune parameters while a simulation runs. If you tune parameters between successive runs of the simulation, the software generates new code for the later run. The new code uses your latest settings as initial parameter values.

For top model or Model block SIL/PIL, if you change the value of a MATLAB variable or parameter object (such as `Simulink.Parameter`) that you store in a workspace, Simulink Coder regenerates the C code.

Model block SIL/PIL does not support test harness data definition, dynamic initialization, or tuning of model workspace parameters.

Global and Local Data Stores

SIL/PIL supports global data stores. For components that are not export-function models, top-model SIL/PIL and SIL/PIL block simulations that access global data stores must be single rate. Otherwise, the software produces an error.

SIL/PIL does not support local data stores.

Model block SIL/PIL does not support local Data Store Memory blocks that have these parameter settings:

- **Share across model instances** – Selected.
- **Storage class** – `Auto` or `Model default`.

You cannot create SIL/PIL blocks from models that use local Data Store Memory blocks with the **Share across model instances** parameter selected.

SIL/PIL Does Not Check Simulink Coder Error Status

SIL/PIL does not check the Simulink Coder error status of the generated code under test. This error status flags exceptional conditions during execution of the generated code.

Blocks in the model can also set the Simulink Coder error status, for example, custom blocks that you create. SIL/PIL does not check this error status and report errors.

Missing Code Interface Description File Errors

SIL/PIL requires a code interface description file, which is created during code generation for the component under test. If the code interface description file is missing, the SIL/PIL simulation cannot proceed. You see an error reporting that the file does not exist. If you select the unsupported option **Classic call interface**, this error can occur. Therefore, do not select the option.

To Workspace Block

If you enable MAT-file logging, top-model SIL/PIL and SIL/PIL blocks support To Workspace blocks.

Model block SIL/PIL does not support To Workspace blocks.

Cannot Connect SIL/PIL Outputs to Merge Block

If you connect Model block SIL/PIL or SIL/PIL block outputs to a Merge block, you see an error because S-function memory is not reusable.

Variant Condition Propagation with Variant Source and Variant Sink Blocks

Top-model SIL/PIL and SIL/PIL block simulations do not support the propagation of variant conditions across component boundaries.

Unsupported Blocks

SIL/PIL does not support the following blocks:

- Scope blocks, and all types of run-time display. For example, display of port values and signal values.
- Stop blocks. SIL/PIL ignores the Stop Simulation block and continues simulating.

Multiword Fixed-Point I/O

You cannot run SIL and PIL simulations of models that have multiword, fixed-point signals across component boundaries.

Fixed-Point Data Types Wider Than 32 Bits

SIL/PIL supports fixed-point data types that are wider than 32 bits. For example:

- 64-bit `long` and `long long`
- 64-bit execution profiling timer data type
- `int64` and `uint64` in MATLAB Coder SIL execution.

The following constraints apply:

- For 64-bit data type support, the data type must be representable as `long` or `long long` on the MATLAB host *and* the target. Otherwise, the software uses the multiword, fixed-point approach, which SIL/PIL does not support.
- The software does not support the 40-bit `long` data type of the TI's C6000™ target.

  Through the **Configuration > Hardware Implementation** pane, you can enable support for the 64-bit `long long` data type. For data types with widths between 33 and 40 bits (inclusive), the software implements the data types using the 40-bit `long` data type, which SIL/PIL does not support.

Data Type Replacement

The software does not support replacement data type names that you define for the built-in data type `boolean` if these names map to the `int` or `uint` built-in data type.

Continuous Sample Times

Top-model SIL/PIL and SIL/PIL block do not support continuous sample times at the SIL or PIL component boundary. However, they support continuous sample times within the component.

Model block SIL/PIL does not support continuous sample times.

Variable-Size Signals

Model block SIL/PIL simulations support variable-size signals only if **Diagnostics > Model Referencing > Propagate sizes of variable-size signals** is `During execution`.

Top-model SIL/PIL and SIL/PIL block simulations treat variable-size signals at the I/O boundary of the SIL/PIL component as fixed-size signals, which can lead to errors during propagation of signal sizes. To avoid such errors, use only fixed-size signals at the I/O boundary of the SIL/PIL component.

There can be cases where no error occurs during propagation of signal sizes. In these cases, the software treats variable-size input signals as zero-size signals.

Internal Signal Logging

SIL/PIL blocks do not support signal logging. For a workaround, see “Log Internal Signals of a Component” on page 78-25.

The following internal signal logging limitations apply to top-model and Model block SIL/PIL simulations.

Limitation	Applies To	
	Top-Model SIL/PIL	Model Block SIL/PIL
Only signals that are included in the C API are logged during SIL/PIL simulation. To observe the signals in the generated code, you can configure the signals as test points. For each signal, select the **Signal Properties > Test point** check box.	Yes	Yes
Signals feeding merge blocks are not supported for logging in normal simulation but are logged in SIL/PIL mode. The logged values during SIL/PIL are the same as the logged values for the output of the merge block.	Yes	No
Top-model normal simulation logs data at a periodic rate but top-model SIL/PIL simulation logs data at a constant rate under these circumstances: • **Default parameter behavior** is `Tunable`. • A constant sample time signal from a Model block is logged in the top model. • The logged signal is not directly connected to a root-level output port. To avoid this behavior and log at the constant rate in all simulation modes, set **Default parameter behavior** to `Inlined`.	Yes	No

Limitation	Applies To	
	Top-Model SIL/PIL	Model Block SIL/PIL
Features not supported: • Signal logging in models referenced by the SIL/PIL component. • Signal logging in Simulink Function block. • Virtual signals, for example, mux. • Buses. • Custom storage classes. • Continuous, asynchronous, and triggered sample times. At the top-level of export-function models, you can log signals with triggered sample times. • Logging of Stateflow states and local data. • Units.	Yes	Yes
Variable-size, function-call, and Action signals are not supported. A normal simulation produces an error. A SIL/PIL simulation produces a warning.	Yes	No
State port signals are not supported. A normal simulation produces an error. A SIL/PIL simulation does not produce a warning.	Yes	No

Custom Storage Class of Type Other

SIL/PIL simulations support the custom storage class where **Type** is set to `Other` on page 78-10. These limitations apply:

- If the code fragments returned by the TLC file associated with the custom storage class are incomplete, the SIL/PIL application might fail to compile, or produce incorrect results.
- Custom storage classes with `Imported` scope and `Pointer` access are supported, but you must provide code to initialize the pointer. For example, you can modify the response to `DataAccess(record, "define", "", "")` to provide a definition of the storage implementation, and initialize the pointer to the address of the implementation variable.

- To determine whether a variable is `const` and therefore not tunable, the build process for the SIL/PIL application uses the memory section definition in the custom storage class. If the custom storage class defines a variable as `const` and is not associated with a `const` memory section, the target application might fail to compile, or produce an error during the simulation. In this case, associate the custom storage class with a memory section for which `Is const` is specified, for example, `MemConst`. Alternatively, if `SupportSILPIL` is an instance-specific parameter in the custom attributes class, for the associated signal or parameter, set `CoderInfo.CustomAttributes.SupportSILPIL` to `false`.

Unsupported Implementation Errors

If you use a data store, signal, or parameter implementation that SIL/PIL does not support, you can see errors like the following:

```
The following data interfaces have
implementations that are not supported by SIL or PIL.
```

`data interfaces` can be global data stores, `inports`, `outports`, or `parameters`.

The model output port has been optimized through virtual output port optimization. See “Virtualized Output Ports Optimization” on page 69-17. The error occurs because the properties (for example, data type, dimensions) of the signal or signals entering the virtual root output port have been modified by routing the signals in one of the following ways:

- Through a Mux block.
- Through a block that changes the signal data type. To check the consistency of data types in the model, display Port Data Types by selecting **Display > Signals & Ports > Port Data Types** (see “Port Data Types” (Simulink)).
- Through a block that changes the signal dimensions. To check the consistency of data types in the model, display dimensions by selecting **Display > Signal & Ports > Signal Dimensions**.

Hardware Implementation

PIL does not support multiword data types where the word order differs from the target byte order. The PIL simulation fails, displaying undefined behavior.

PIL requires that you configure the correct **Hardware Implementation** settings for the target environment, including byte ordering for targets. If you do not specify the correct byte ordering, the PIL simulation fails, displaying undefined behavior.

Non-ASCII Characters in Folder Name

If the name of the current working folder contains non-ASCII characters, you cannot run a SIL simulation.

State Logging

SIL/PIL does not support state logging (Simulink).

Bus Elements Mapped to Imported Bit-Field Definitions

If you map Simulink bus elements to bit fields through an imported header file, a SIL or PIL simulation produces a build error. For example, if your model has an Inport block connected to a bus that is a `Simulink.Bus` object with these properties:

- **Name** — `myBus`
- **Bus elements** — An array of `Simulink.BusElement` objects with these properties.

Name	DataType	Complexity	Dimensions
bitField0	boolean	real	1
bitField1	boolean	real	1
bitField2	boolean	real	1
bitField3	boolean	real	1
bitField4	boolean	real	1
bitField5	boolean	real	1

- **Data scope** — `Imported`
- **Header file** — `busSpecification.h`. This file contains `myBus`, which defines C bit-field data types for the bus elements.

```
typedef struct myBus
{
   unsigned int bitField0 : 1;
   unsigned int bitField1 : 1;
   unsigned int bitField2 : 1;
   unsigned int bitField3 : 1;
   unsigned int bitField4 : 1;
   unsigned int bitField5 : 1;
} myBus;
```

Size Mismatch Between Simulink and Target Hardware Data Types

When a Simulink data type and the corresponding target hardware data type differ in size, a SIL or PIL simulation produces an error. This size mismatch can occur if you map a Simulink data type to the target hardware data type through definitions in an imported header file. For example, if you create a data type alias, `T_BOOL`, which is a `Simulink.AliasType` object with these properties:

- **Base type** — `boolean`.
- **Mode** — `Built in`, `boolean`.
- **Data scope** — `Imported`.
- **Header file** — `myDefinitions.h`. This file defines `T_BOOL` as an enumerated data type:

  ```
  typedef enum _BOOL_TYPE
  {
    FALSE           = 0,
    TRUE            = 1
  } BOOL_TYPE;

  typedef BOOL_TYPE T_BOOL;
  ```

  In this case, the compiler for the target hardware determines the size of `T_BOOL`, which can differ from the size of the Simulink data type, `boolean`.

SIL Simulations with Target-Specific Custom Code

Target-specific custom code that is not portable for execution on your development computer can produce compilation or run-time failures during a SIL simulation.

For example, SIL does not support the use of custom code that explicitly casts pointers to integer-type variables that are smaller than the length of a pointer variable on your development computer. Consider using one of these alternatives:

- Run a PIL simulation.
- If you have custom code that casts pointers to a 32-bit integer type, for your development computer, set up a PIL target connectivity configuration that uses a toolchain that is configured to build a 32-bit binary application.

Top-Model SIL/PIL Limitations

Top-Model Root-Level Logging

Top-model SIL/PIL supports signal logging for signals connected to root-level inports and outports. The C API is not required. Root-level logging has the following limitations:

- The characteristics of the logged data such as data type, sample time, and dimensions must match the characteristics of the root-level inports and outports (rather than the characteristics of the connected signal).

  In some cases, there can be differences in data type and dimensions between the signal being logged and the root inport or outport that the signal is connected to. Consider the following examples.

  - If a signal being logged has matrix dimensions `[1x5]` but the outport connected to the signal has vector dimensions (`5`), then the data logged during a SIL or PIL simulation has vector dimensions (`5`).
  - If a signal being logged has scalar dimensions but the outport connected to the signal has matrix dimensions `[1x1]`, then the data logged during a SIL or PIL simulation has matrix dimensions `[1x1]`.
- Signals connected to duplicated inports are not logged during SIL/PIL simulation. No warning is issued.

  During normal simulation, signals connected directly to duplicated inports are logged.
- The Signal Logging Selector / `DataLoggingOverride` override mechanism is not supported.
- Normal and SIL/PIL simulations log bus signals with names that are different when all of the following conditions apply:

  - The `SaveOutput` or `SignalLogging` configuration parameter is `on`.
  - The names of the elements in the bus signal are different from the corresponding names in the bus object. For example, when the `InheritFromInputs` parameter for a Bus Creator block is set to `'on'`.
- The software inserts the suffix, `_wrapper` for *output logging*, if the save format is `Structure`, `Structure with time`, or `Dataset` and you run the `sim` command without specifying the single-output format. The software adds `_wrapper` to the block name for signals in `yout`. If the save format is `Array`, the software does not add the suffix. For example:

```
>> yout.signals

ans =
        values: [11x1 double]
    dimensions: 1
         label: 'SignalLogging'
     blockName: 'sillogging_wrapper/OutputLogging'
```

To avoid this behavior, run command-line simulations with the `sim` command specifying the single-output format. See “Run Simulations Programmatically” (Simulink).

Model in Compiled State During Top-Model SIL/PIL

During a top-model SIL/PIL simulation, the software places the model in a compiled state – see `model`. This action can result in a conflict over global resources between the model and the generated SIL/PIL code. In this case, differences between normal mode and SIL/PIL simulation outputs can result.

For example, consider a model that uses UDP blocks from the DSP System Toolbox. These blocks open UDP sockets, which can lead to resource contention between the model and the generated SIL/PIL code.

Callback Support

SIL/PIL does not support the callbacks (model or block) `StartFcn` and `StopFcn`.

Note Top-model SIL/PIL supports the callback `InitFcn`.

Incremental Build

When you start a top-model SIL/PIL simulation, the software regenerates code if it detects changes to your model. The software detects changes by using a checksum for the model. The software does not detect changes that you make to:

- The `HeaderFile` property of a `Simulink.AliasType` object
- Legacy S-functions

If you make these changes, build (**Ctrl-B**) your model again before starting the next PIL simulation.

Model Block SIL/PIL Limitations

Top-Model Code Testing

The following limitations apply:

- Because model arguments do not apply to a top model, when the **Code interface** block parameter is set to `Top model`, the software does not support the **Model arguments** block parameter.
- Conditional execution does not apply to a top model. If a Model block is set up to execute conditionally and the **Code interface** block parameter is set to `'Top model'`, the software produces an error when you run a SIL or PIL simulation.
- For sample time independent models, you must set **Configuration Parameters** > **Solver** > **Periodic sample time constraint** to `Ensure sample time independent`.

Conditionally Executed Subsystem

You see an error if:

- You place your Model block, in either SIL or PIL simulation mode, in a conditionally executed subsystem and the referenced model is multirate (that is, has multiple sample times). Single-rate, referenced models (with only a single sample time) are not affected.
- Your Model block, in either SIL or PIL simulation mode, has blocks that depend on absolute time **and** is conditionally executed.

Outputs with Constant Sample Time

If the block parameter **Code interface** is `Top model`, Model block SIL/PIL supports outputs with constant sample time.

Noninlined S-Functions

Model-block SIL/PIL simulations do not support noninlined S-functions.

Referenced Models That Use Same Target Connectivity Configuration

Consider a top model with two or more Model blocks that reference models that use the same target connectivity configuration. If the Model blocks are in PIL mode simultaneously, you cannot run a simulation of the top model. An error occurs.

SIL and PIL Instances of a Referenced Model

Consider a top model that contains two instances of a Model block that reference the same model. If one instance is in SIL mode and the other instance is in PIL mode, you cannot run a simulation of the top model. An error occurs.

SIL/PIL Block Limitations

PIL Block Mux

The PIL block supports mux signals, except mixed data-type mux signals that expand into individual signals during a right-click subsystem build.

Code Coverage

SIL block simulations do not support the generation of code coverage results. PIL block support for code coverage depends on your target connectivity configuration and third-party product support.

Subsystem with Inherited Sample Time Blocks

When you create a SIL/PIL block from a subsystem that has blocks with inherited sample times, the generated code and SIL/PIL wrapper acquire the sample time of the original parent model. If you use the SIL/PIL block in a context that does not allow explicit sample times, for example, within a triggered subsystem, you see an error.

Try one of these workarounds:

- Before you create the SIL/PIL block, in the parent model, set **Configuration Parameters** > **Solver** > **Periodic sample time constraint** to `Ensure sample time independent`.
- Using the subsystem, create a Model block that is independent of sample time. With this block, run Model block SIL/PIL simulations.

Test Generated Code with SIL and PIL Simulations

Test numerical equivalence between model components and production code that you generate from the components by using software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations.

With a SIL simulation, you test source code on your development computer. With a PIL simulation, you test the compiled object code that you intend to deploy in production by running the object code on real target hardware or an instruction set simulator. To determine whether model components and generated code are numerically equivalent, compare SIL and PIL results against normal mode results.

There are three ways of running SIL and PIL simulations. You can use the top model, Model blocks, or SIL and PIL blocks that you create from a subsystem. See “Choose a SIL or PIL Approach” on page 78-14.

Target Connectivity Configuration for PIL

Before you can run PIL simulations, you must configure target connectivity. The target connectivity configuration enables the PIL simulation to:

- Build the target application.
- Download, start, and stop the application on the target.
- Support communication between Simulink and the target.

To produce a target connectivity configuration, you can use the supplied target connectivity API. For details, see “Create PIL Target Connectivity Configuration for Simulink” on page 78-44.

For supported hardware, you can use target support packages. For details, see “Embedded Coder Supported Hardware” on page 82-2.

SIL or PIL Simulation with a Top Model

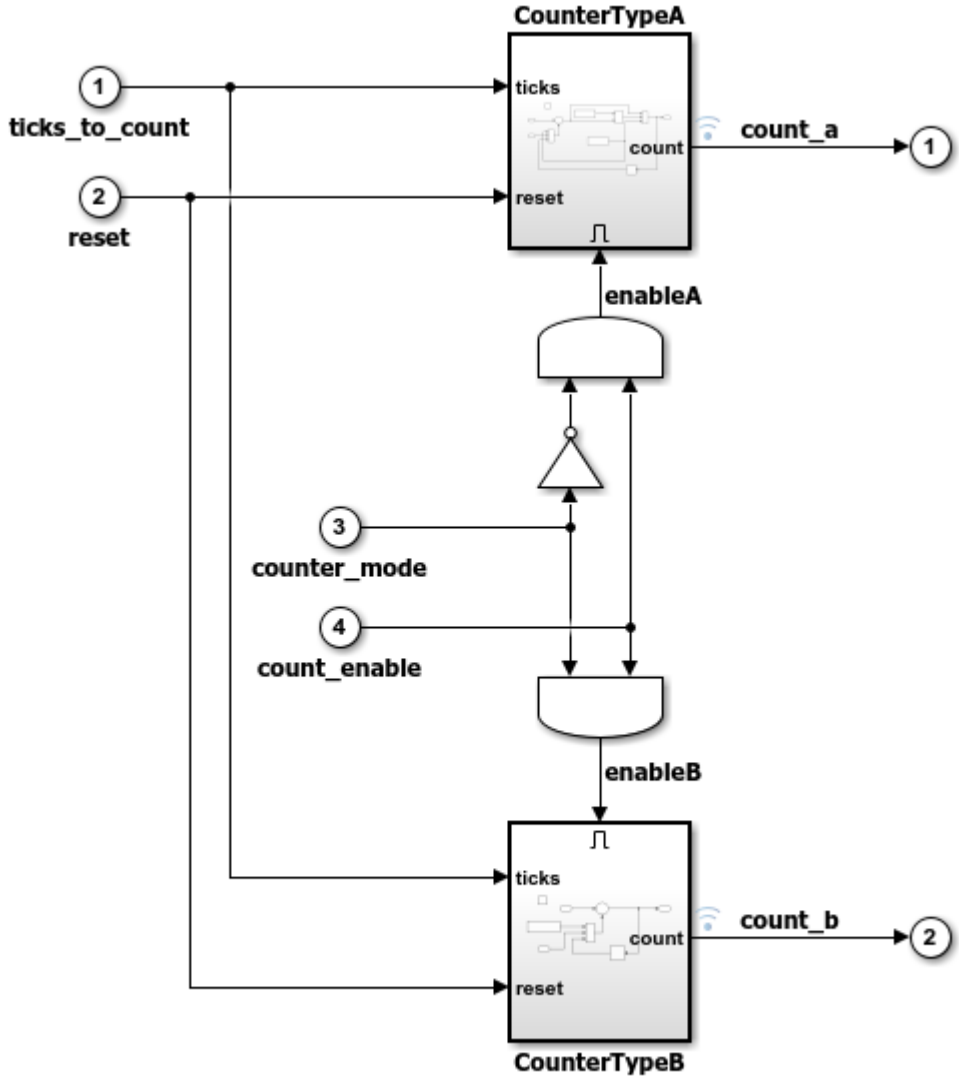
Test generated model code by running a top-model SIL or PIL simulation. With this approach:

- You test code generated from the top model, which uses the standalone code interface.
- You configure the model to load test vectors or stimulus inputs from the MATLAB workspace.

- You can easily switch the top model between the normal, SIL, and PIL simulation modes.

Open a simple counter top model.

```
model='rtwdemo_sil_topmodel';
close_system(model,0)
open_system(model)
```



To focus on numerical equivalence testing, turn off:

- Model coverage
- Code coverage
- Execution time profiling

```
set_param(gcs, 'RecordCoverage','off');
coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.CoverageTool='None';
set_param(model, 'CodeCoverageSettings',coverageSettings);
set_param(model, 'CodeExecutionProfiling','off');
```

Configure the input stimulus data.

```
[ticks_to_count, reset, counter_mode, count_enable] = ...
    rtwdemo_sil_topmodel_data(T);
```

Configure logging options in the model.

```
set_param(model, 'LoadExternalInput','on');
set_param(model, 'ExternalInput','ticks_to_count, reset, counter_mode, count_enable');
set_param(model, 'SignalLogging', 'on');
set_param(model, 'SignalLoggingName', 'logsOut');
```

Run a normal mode simulation.

```
set_param(model,'SimulationMode','normal')
[~, ~, yout_normal] = sim(model,10);
```

Run a top-model SIL simulation.

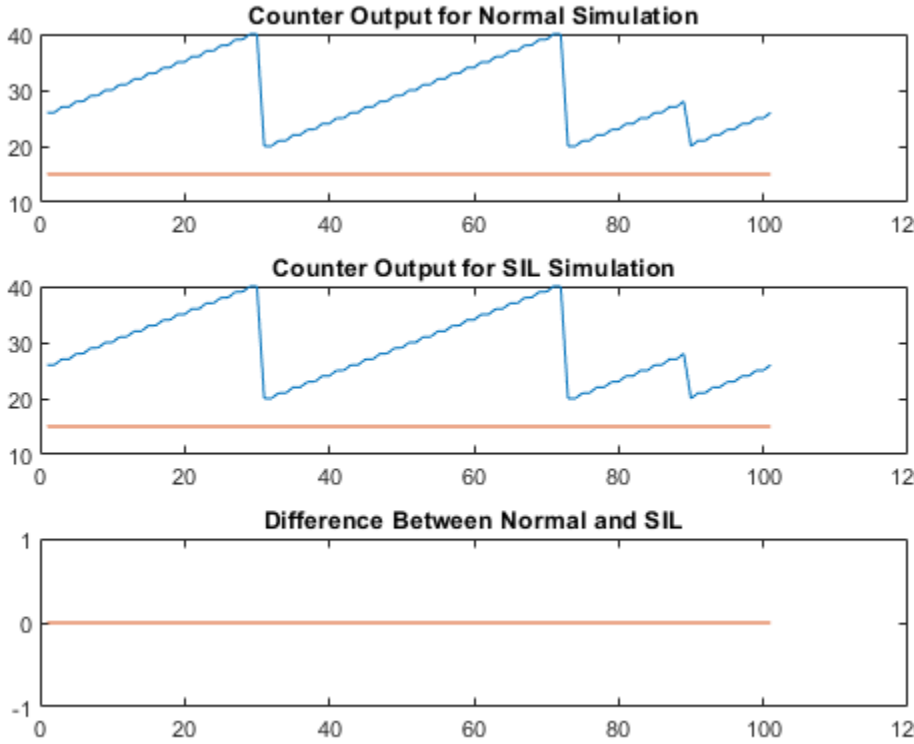
```
set_param(model,'SimulationMode','Software-in-the-Loop (SIL)')
[~, ~, yout_sil] = sim(model,10);
```

```
### Starting build procedure for model: rtwdemo_sil_topmodel
### Successful completion of build procedure for model: rtwdemo_sil_topmodel
### Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Updating code generation report with SIL files ...
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
```

Unless up-to-date code for this model exists, new code is generated and compiled. The generated code runs as a separate process on your computer.

Plot and compare the results of the normal and SIL simulations. Observe that the results match.

```
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), plot(yout_sil), title('Counter Output for SIL Simulation')
subplot(3,1,3), plot(yout_normal-yout_sil), ...
    title('Difference Between Normal and SIL');
```



Clean up.

```
close_system(model,0);
if ishandle(fig1), close(fig1), end
clear fig1
```

```
simResults = {'yout_sil','yout_normal','model','T',...
              'ticks_to_count','reset'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

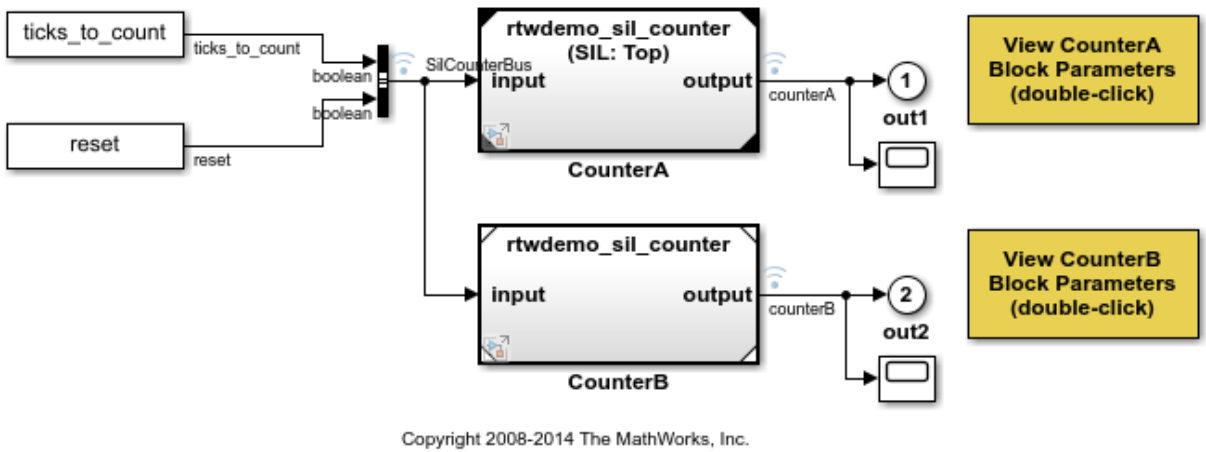
SIL or PIL Simulation with a Model Block

Test generated model code by using a test harness model that runs a Model block in SIL mode. With this approach:

- You can test code that is generated from a top model or a referenced model. The code from the top model uses the standalone code interface. The code from the referenced model uses the model reference code interface. For more information, see “Code Interfaces for SIL and PIL” on page 78-6.
- You use a test harness model or a system model to provide test vector or stimulus inputs.
- You can easily switch a Model block between the normal, SIL, and PIL simulation modes.

Open an example model that has two Model blocks which reference the same model. In a simulation, you run one Model block in SIL mode and the other Model block in normal mode.

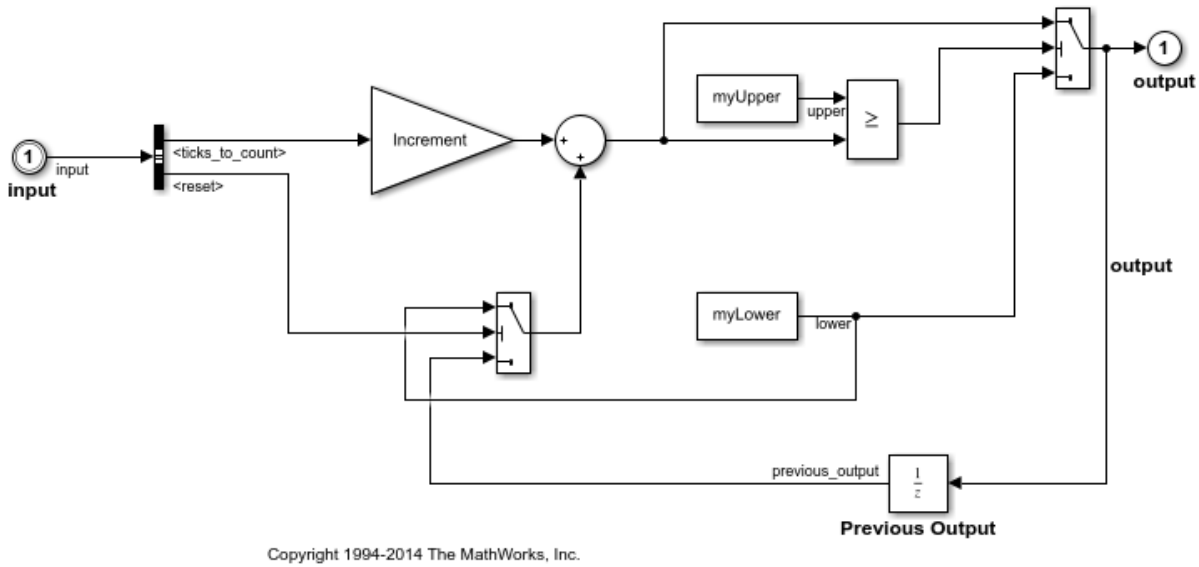
```
model='rtwdemo_sil_modelblock';
open_system(model);
```



Turn off:

- Code coverage
- Execution time profiling

```
coverageSettings = get_param(model, 'CodeCoverageSettings');
coverageSettings.CoverageTool='None';
set_param(model, 'CodeCoverageSettings',coverageSettings);
open_system('rtwdemo_sil_modelblock')
set_param('rtwdemo_sil_modelblock', 'CodeExecutionProfiling','off');
open_system('rtwdemo_sil_counter')
set_param('rtwdemo_sil_counter', 'CodeExecutionProfiling','off');
currentFolder=pwd;
save_system('rtwdemo_sil_counter', fullfile(currentFolder,'rtwdemo_sil_counter.slx'))
```



Test Top-Model Code

For the Model block in SIL mode, specify generation of top-model code, which uses the standalone code interface.

```
set_param([model '/CounterA'], 'CodeInterface', 'Top model');
```

Run a simulation of the test harness model.

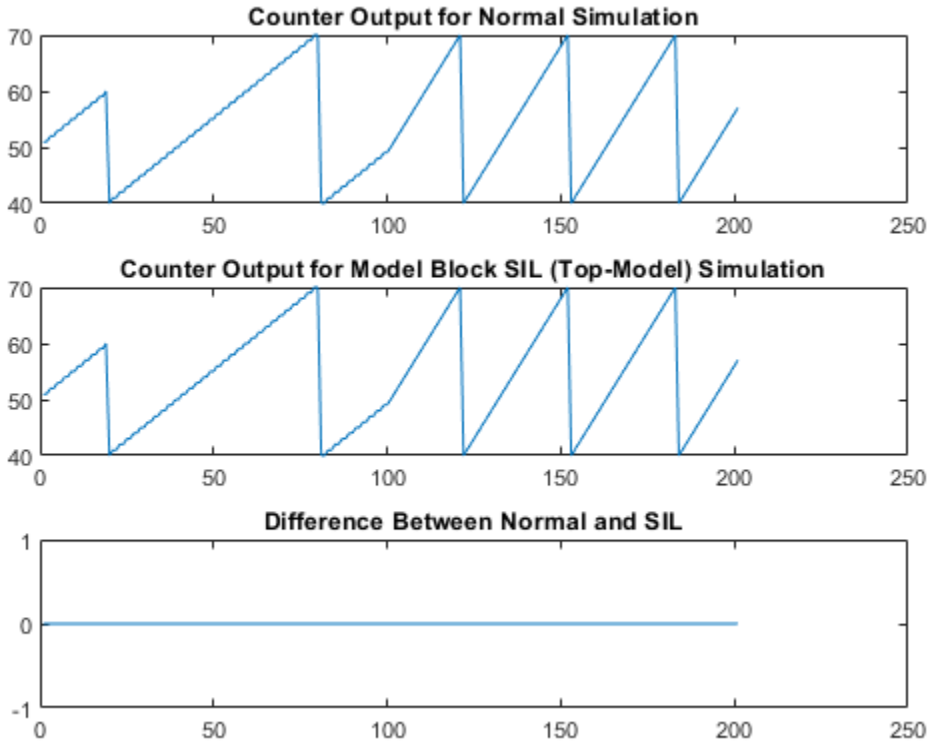
```
out = sim(model,20);

### Starting build procedure for model: rtwdemo_sil_counter
### Successful completion of build procedure for model: rtwdemo_sil_counter
### Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Updating code generation report with SIL files ...
### Starting SIL simulation for component: rtwdemo_sil_counter
### Stopping SIL simulation for component: rtwdemo_sil_counter
```

The model block in SIL mode runs as a separate process on your computer. In the working folder, you see that standalone code is generated for the referenced model unless generated code from a previous build exists.

Compare the behavior of Model blocks in normal and SIL modes. The results match.

```
yout = find(out,'logsOut');
yout_sil = yout.get('counterA').Values.Data;
yout_normal = yout.get('counterB').Values.Data;
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), ...
    plot(yout_sil), title('Counter Output for Model Block SIL (Top-Model) Simulation')
subplot(3,1,3), plot(yout_normal-yout_sil), ...
    title('Difference Between Normal and SIL');
```



Test Model Reference Code

For the Model block in SIL mode, specify generation of referenced model code, which uses the model reference code interface.

```
set_param([model '/CounterA'], 'CodeInterface', 'Model reference');
```

Run a simulation of the test harness model.

```
out2 = sim(model,20);
```

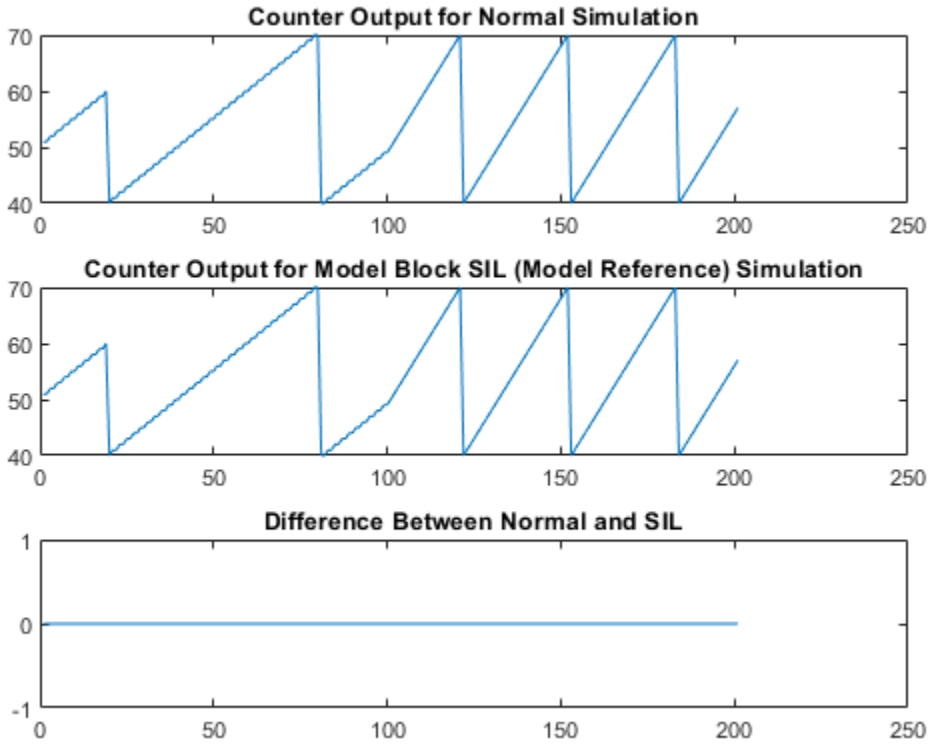
```
### Starting build procedure for model: rtwdemo_sil_counter
### Successful completion of build procedure for model: rtwdemo_sil_counter
Building with 'Microsoft Visual C++ 2017 (C)'.
```

```
MEX completed successfully.
### Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Updating code generation report with SIL files ...
### Starting SIL simulation for component: rtwdemo_sil_counter
### Stopping SIL simulation for component: rtwdemo_sil_counter
```

The model block in SIL mode runs as a separate process on your computer. In the working folder, you see that model reference code is generated unless code from a previous build exists.

Compare the behavior of Model blocks in normal and SIL modes. The results match.

```
yout2 = find(out2,'logsOut');
yout2_sil = yout2.get('counterA').Values.Data;
yout2_normal = yout2.get('counterB').Values.Data;
fig1 = figure;
subplot(3,1,1), plot(yout2_normal), title('Counter Output for Normal Simulation')
subplot(3,1,2), ...
    plot(yout2_sil), title('Counter Output for Model Block SIL (Model Reference) Simula
subplot(3,1,3), plot(yout2_normal-yout2_sil), ...
    title('Difference Between Normal and SIL');
```



Clean up.

```
close_system(model,0);
if ishandle(fig1), close(fig1), end, clear fig1
simResults={'out','yout','yout_sil','yout_normal', ...
            'out2','yout2','yout2_sil','yout2_normal', ...
            'SilCounterBus','T','reset','ticks_to_count','Increment'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

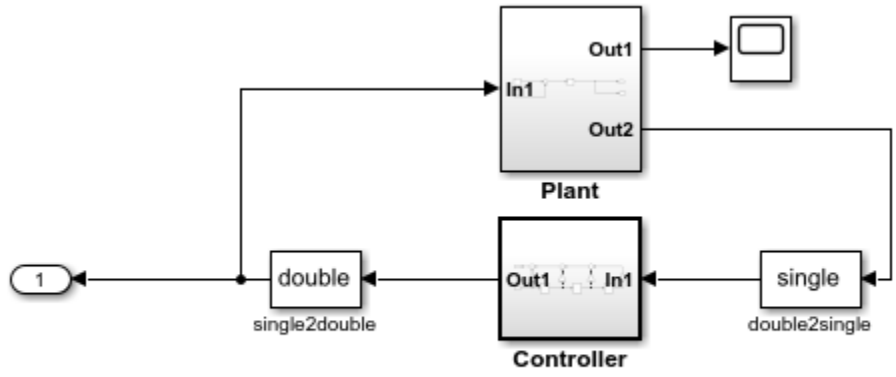
SIL or PIL Block Simulation

Test generated subsystem code by using a SIL or PIL block in a simulation. With this approach:

- You test code generated from subsystems, which uses the standalone code interface.
- You provide a test harness or a system model to supply test vector or stimulus inputs.
- You replace your original subsystem with the generated SIL or PIL block.

Open a simple model, which consists of a control algorithm and a plant model in a closed loop. The control algorithm regulates the output from the plant.

```
model='rtwdemo_sil_block';
close_system(model,0)
open_system(model)
```



Run a normal mode simulation

```
out = sim(model,10);
yout_normal = find(out,'yout');
clear out
```

Configure the build process to create the SIL block for testing.

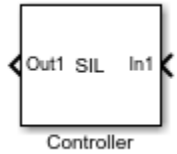
```
set_param(model,'CreateSILPILBlock','SIL');
```

To test the behavior on production hardware, specify a PIL block.

To create the SIL block, generate code for the control algorithm subsystem. You see the SIL block at the end of the build process. Its input and output ports match those of the control algorithm subsystem.

```
close_system('untitled',0);
rtwbuild([model '/Controller'])

### Starting build procedure for model: Controller
### Successful completion of build procedure for model: Controller
### Creating SIL block ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
```



Alternatively, you can right-click the subsystem and select C/C++ Code > Build This Subsystem. In the dialog box that opens, click Build.

To perform a SIL simulation of the controller and plant model in a closed loop, replace the original control algorithm with the new SIL block. To avoid losing your original subsystem, do not save your model in this state.

```
controllerBlock = [model '/Controller'];
blockPosition = get_param(controllerBlock,'Position');
delete_block(controllerBlock);
add_block('untitled/Controller',[controllerBlock '(SIL)'],...
          'Position', blockPosition);
close_system('untitled',0);
clear controllerBlock blockPosition
```

Run the SIL simulation.

```
out = sim(model,10);

### Preparing to start SIL block simulation: rtwdemo_sil_block/Controller(SIL) ...
### Starting SIL simulation for component: rtwdemo_sil_block/Controller
### Stopping SIL simulation for component: rtwdemo_sil_block/Controller
```

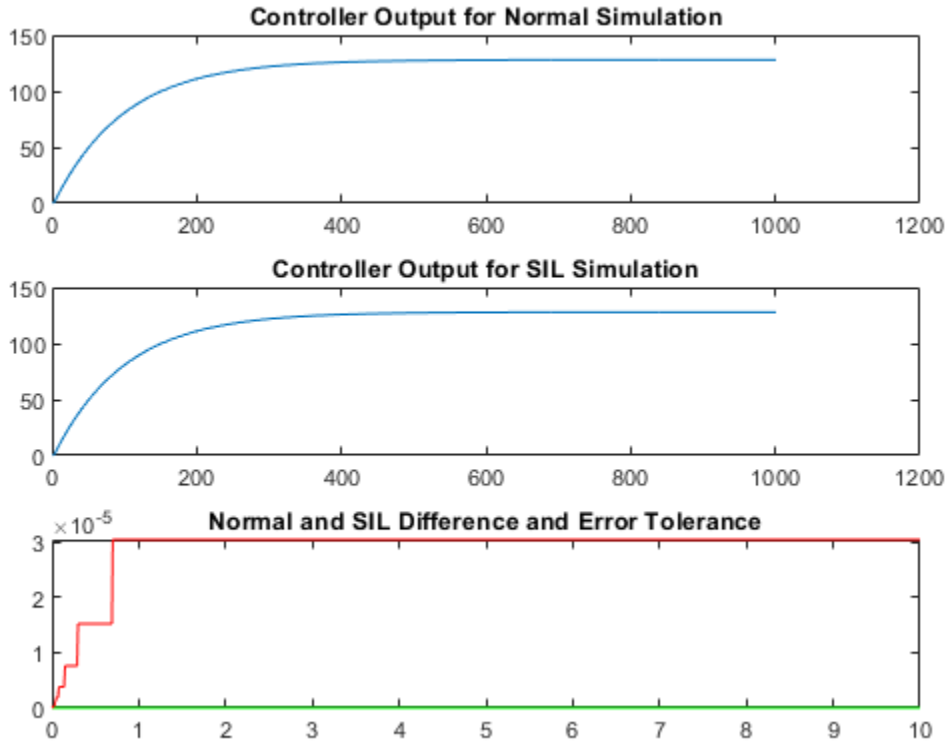
The control algorithm uses single-precision, floating-point arithmetic. You can expect the order of magnitude for differences between SIL and normal simulations to be close to the machine precision for single-precision data.

Define an error tolerance for SIL simulation results that is based on the machine precision for the single-precision, normal simulation results.

```
machine_precision = eps(single(yout_normal));
tolerance = 4 * machine_precision;
```

Compare normal and SIL simulation results. In the third plot, the differences between the simulations lie well within the defined error tolerance.

```
yout_sil = find(out,'yout');
tout = find(out,'tout');
fig1 = figure;
subplot(3,1,1), plot(yout_normal), title('Controller Output for Normal Simulation')
subplot(3,1,2), plot(yout_sil), title('Controller Output for SIL Simulation')
subplot(3,1,3), plot(tout,abs(yout_normal-yout_sil),'g-', tout,tolerance,'r-'), ...
    title('Normal and SIL Difference and Error Tolerance');
```



Clean up.

```
close_system(model,0);
if ishandle(fig1), close(fig1), end
clear fig1
simResults={'out','yout_sil','yout_normal','tout','machine_precision'};
save([model '_results'],simResults{:});
clear(simResults{:},'simResults')
```

Hardware Implementation Settings

When you run a SIL simulation, you must configure your hardware implementation settings (characteristics such as native word sizes) to allow compilation for your development computer. These settings can differ from the hardware implementation

settings that you use when building the model for your production hardware. To avoid the need to change hardware implementation settings between SIL and PIL simulations, enable portable word sizes. For more information, see “Configure Hardware Implementation Settings” on page 78-22.

Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation

Implement a communication channel for processor-in-the-loop (PIL) simulation.

The communication channel enables exchange of data between different processes. The communication channel supports capabilities that require the exchange of data between the Simulink® software environment that runs on your development computer (host) and deployed code that runs on target hardware. For example, a PIL simulation.

You learn about the rtiostream interface and how it provides a generic communication channel that you can implement in the form of target connectivity drivers for different connection types. This example describes how to use the default TCP/IP implementation.

Two entities, Station A and Station B, use the rtiostream interface to set up a communication channel and exchange data. For this example, Station A and Station B are configured within the same process on your desktop computer.

The target connectivity drivers support an on-target PIL simulation. In the simulation, Station A and Station B represent the target and host computers that exchange data via the communication channel. On the host side, the target connectivity driver is implemented as a shared library that is loaded and called from within the MATLAB® product. On the target side, the driver is source code or a library that is linked to the application that runs on the target.

Additionally, you can:

- Configure your own target-side driver for TCP/IP to operate with the default host-side TCP/IP driver.
- Configure the supplied host-side driver for serial communications.
- Implement custom target connectivity drivers, for example, by using CAN or USB for host and target sides of the communication channel.

See also “Test Generated Code with SIL and PIL Simulations” on page 78-85 and “Configure Processor-In-The-Loop (PIL) for a Custom Target” on page 78-108.

View Source Code for the Default TCP/IP Implementation

The file rtiostream_tcpip.c implements client-side and server-side TCP/IP communication. A startup parameter configures the driver to operate in either client or server mode. You

can use this source file as a starting point for a custom implementation. Each side of the communication channel requires only one or the other of the server or client implementations. If the client and server drivers run on different architectures, consider placing the driver code for each architecture in a separate source file.

The header file rtiostream.h contains prototypes for the functions rtIOStreamOpen/Send/Recv/Close. Include it (using #include) for custom implementations.

Extract the location of TCP/IP driver source code.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src',...
                             'rtiostreamtcpip');
```

View rtiostream_tcpip.c.

```
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'));
```

View rtiostream.h.

```
edit(fullfile(matlabroot,'rtw','c','src','rtiostream.h'));
```

Location of Shared Library Files

To access the target connectivity drivers from the MATLAB product, you must compile them to a shared library. The shared library must be located on your system path. A shared library for the default TCP/IP drivers is located in matlabroot/bin/$ARCH ($ARCH is your system architecture, for example, win64).

The shared library filename extension and location depends on your operating system.

```
[~, ~, sharedLibExt] = coder.BuildConfig.getStdLibInfo;
```

Identify the shared library for Station A and Station B.

```
libTcpip = ['libmwrtiostreamtcpip' sharedLibExt];
disp(libTcpip)
```

Test the Target Connectivity Drivers

If you are implementing a custom target connectivity driver, it is helpful to test it from within the MATLAB product. The following example shows how to load the default TCP/IP target connectivity drivers and use them for data exchange between Station A and Station B.

To access the drivers, you can use the MEX-file rtiostream_wrapper. With this MEX-file, you can load the shared library and access the rtiostream functions to open and close an rtiostream channel, and send and receive data.

Station A and Station B run on the host computer. Station A is configured as a TCP/IP server and Station B as a TCP/IP client. For host to target communication, you typically configure the host as a TCP/IP client and the target as a TCP/IP server.

Choose a port number for TCP.

```
if usejava('jvm')
    % Find a free port
    tempSocket = java.net.ServerSocket(0);
    port = num2str(tempSocket.getLocalPort);
    tempSocket.close;
else
    % Use a hard-coded port
    port = '14646';
end
```

Open the Station A rtiostream as a TCP/IP server.

```
stationA = rtiostream_wrapper(libTcpip,'open',...
                                    '-client', '0',...
                                    '-blocking', '0',...
                                    '-port',port);
```

If the communication channel opens, the return value is a handle to the connection. A return value of -1 indicates an error.

Check the return value.

```
assert(stationA~=(-1))
```

Open the Station B rtiostream as a TCP/IP client.

```
stationB = rtiostream_wrapper(libTcpip,'open',...
                                    '-client','1',...
                                    '-blocking', '0',...
                                    '-port',port,...
                                    '-hostname','localhost');
```

If the communication channel opens, the return value is a handle to the connection. A return value of -1 indicates an error.

Check the return value.

```
assert(stationB~=(-1))
```

Send Data from Station B to Station A

The target connectivity drivers send a stream of data in 8-bit bytes. For processors that are not byte-addressable, the data is sent in the smallest addressable word size.

Send message data from Station B to Station A.

```
msgOut = uint8('Station A, this is Station B. Are you there? OVER');

[retVal, sizeSent] = rtiostream_wrapper(libTcpip,...
                                        'send',...
                                        stationB,...
                                        msgOut,...
                                        length(msgOut));
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Make sure that bytes in the message were sent.

```
assert(sizeSent==length(msgOut));
```

Allow time for data transmission to be completed.

```
pause(0.2)
```

Receive data in Station A.

```
[retVal, msgRecvd, sizeRecvd] = rtiostream_wrapper(libTcpip,...
                                                   'recv',...
                                                   stationA,...
                                                   100);
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Make sure that bytes in the message were received.

```
assert(sizeRecvd==sizeSent);
```

Display the received data.

```
disp(char(msgRecvd))
```

Send a Response from Station A to Station B

Send response data from Station A to Station B.

```
msgOut = uint8('Station B, this is Station A. Yes, I''m here! OVER.');
[~, sizeSent] = rtiostream_wrapper(libTcpip,... %#ok
                                   'send',...
                                   stationA,...
                                   msgOut,...
                                   length(msgOut));
```

Allow time for data transmission to be completed.

```
pause(0.2)
```

Receive data in Station B.

```
[~, msgRecvd, sizeRecvd] = rtiostream_wrapper(libTcpip,... %#ok
                                              'recv',...
                                              stationB,...
                                              100);
```

Display the received data.

```
disp(char(msgRecvd))
```

Close Connection and Unload Shared Libraries

Close rtiostream on Station B.

```
retVal = rtiostream_wrapper(libTcpip,'close',stationB);
```

A return value of zero indicates success.

```
assert(retVal==0);
```

Close rtiostream on Station A.

```
retVal = rtiostream_wrapper(libTcpip,'close',stationA);
```

A return value of zero indicates success.

```
assert(retVal==0)
```

Unload the shared library.

```
rtiostream_wrapper(libTcpip, 'unloadlibrary');
```

Host-Side Driver for Serial Communications

You can use the supplied host-side driver for serial communications as an alternative to the drivers for TCP/IP. To configure the serial driver, see rtiostream_wrapper in the Embedded Coder® reference documentation.

Configure Your Own Target-Side Driver

If your target has an Ethernet connection and you have a TCP/IP stack available, follow these steps:

1. Write a wrapper for your TCP/IP stack that makes it available via the rtiostream interface defined in rtiostream.h.
2. Write a test application for your target that sends and receives some data.
3. Use the rtiostream_wrapper MEX-file and host-side TCP/IP driver to test your driver software that is running on the target.
4. When you have a working target-side driver, include the driver source files in the build for your automatically generated code.

You can configure your target-side driver to operate only as a TCP/IP server because the default host-side driver for PIL is configured as a TCP/IP client.

If you need to use a communications channel that is not already supported on the host-side, write drivers for host and target. In this case, you can still use the rtiostream_wrapper MEX-file for testing your rtiostream drivers.

Configure Your Own Host-Side Driver

You can implement the target connectivity drivers by using different communication channels. For example, you can implement host-target communications via a special serial connection, which requires that you provide drivers for the host and target.

On the host side, you can test the drivers by using the rtiostream_wrapper MEX-file. If your driver includes diagnostic output from printf statements and rtiostream_wrapper loads the shared library, you must replace the printf statements with mexPrintf statements.

When you have a working host-side device driver, you must make it available within the Simulink software environment. For PIL simulation, register the shared host-side shared library via sl_customization.

Configure Processor-In-The-Loop (PIL) for a Custom Target

Create a target connectivity configuration by using target connectivity APIs. With a target connectivity configuration, you can run processor-in-the-loop (PIL) simulations on custom embedded hardware.

You learn how to:

- Adapt the build process to support PIL simulations.
- Configure a tool for downloading and starting execution of a PIL executable on your target hardware.
- Configure a communication channel between host and target to support PIL simulation on the target hardware.

Start with a model configured for software-in-the-loop (SIL) simulation. This example guides you through the process of creating a target connectivity configuration so that you can simulate the model in PIL mode. The example runs entirely on your host computer. You can follow the same steps to create a connectivity configuration for your own embedded target hardware.

See also “Test Generated Code with SIL and PIL Simulations” on page 78-85 and “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation” on page 78-101.

Preliminaries

Later in this example, you will add a folder to the search path. Create the folder path.

```
sl_customization_path = fullfile(matlabroot,...
    'toolbox',...
    'rtw',...
    'rtwdemos',...
    'pil_demo');
```

If this folder is already on the search path, remove it.

```
if strfind(path,sl_customization_path)
    rmpath(sl_customization_path)
end
```

Reset customizations.

```
sl_refresh_customizations
```

Create a temporary folder (in your system's temporary folder) for the build and inspection process.

```
currentDir = pwd;
rtwdemodir();
```

Test Generated Code with SIL Simulation

Simulate a model configured for SIL. Verify the generated code compiled for your host computer by comparing the SIL simulation behavior with the normal simulation behavior.

Make sure that the example model is newly opened.

```
close_system('rtwdemo_sil_modelblock',0);
close_system('rtwdemo_sil_counter',0)
open_system('rtwdemo_sil_modelblock')
```

The CounterA Model block displays the text (SIL), which indicates that its referenced model is configured for SIL simulation.

Run a simulation of the system.

```
set_param('rtwdemo_sil_modelblock','StopTime','10');
sim('rtwdemo_sil_modelblock');
```

```
### Starting build procedure for model: rtwdemo_sil_counter
### Successful completion of build procedure for model: rtwdemo_sil_counter
### Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Updating code generation report with SIL files ...
### Starting SIL simulation for component: rtwdemo_sil_counter
### Stopping SIL simulation for component: rtwdemo_sil_counter
```

Target Connectivity Configuration

Start work on a target connectivity configuration for PIL.

Make a local copy of the target connectivity configuration classes.

```
src_dir = ...
    fullfile(matlabroot,'toolbox','coder','simulinkcoder','+coder','+mypil');
if exist(fullfile('.','+mypil'),'dir')
```

```
    rmdir('+mypil','s')
end
mkdir +mypil
copyfile(fullfile(src_dir,'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir,'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir,'ConnectivityConfig.m'), '+mypil');
```

Make the copied files writable.

```
fileattrib(fullfile('+mypil', '*'),'+w');
```

Update the package name to reflect the new location of the files.

```
coder.mypil.Utils.UpdateClassName(...
    './+mypil/ConnectivityConfig.m',...
    'coder.mypil',...
    'mypil');
```

Verify that you now have a folder +mypil in the current folder, which has the files Launcher.m, TargetApplicationFramework.m, and ConnectivityConfig.m.

```
dir './+mypil'
```

```
.                               Launcher.m
..                              TargetApplicationFramework.m
ConnectivityConfig.m
```

Review Code to Launch the PIL Executable

The class that configures a tool for launching the PIL executable is mypil.Launcher. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. The method setArgString supplies additional command-line parameters to the executable. These parameters can include a TCP/IP port number. For an embedded processor implementation, you can choose to hard-code these settings.

Configure the Overall Target Connectivity Configuration

View the class mypil.ConnectivityConfig.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. You should be able to identify:

- The creation of an instance of rtw.connectivity.RtIOStreamHostCommunicator that configures the host side of the TCP/IP communications channel.
- A call to the setArgString method of Launcher that configures the target side of the TCP/IP communications channel.
- A call to setTimer that configures a timer for execution time measurement

To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function code_profile_read_timer. Use a command-line API or the crtool user interface.

Review the Target-Side Communications Drivers

View the file rtiostream_tcpip.c.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src',...
    'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. See that this file contains a TCP/IP implementation of the functions rtIOStreamOpen, rtIOStreamSend, and rtIOStreamRecv. These functions are required for the target hardware to communicate with your host computer. You must provide an implementation for each of these functions that is specific to your target hardware and communication channel.

Add Target-Side Communications Drivers to the Connectivity Configuration

The class that configures additional files to include in the build is mypil.TargetApplicationFramework. Open this class in the editor.

```
edit(which('mypil.TargetApplicationFramework'))
```

Use sl_customization to Register the Target Connectivity Configuration

To use the new target connectivity configuration, you must provide an sl_customization file. The sl_customization file registers your new target connectivity configuration and specifies the required conditions for its use. The conditions specified in this file can include the name of your system target file and your hardware implementation settings.

You can view the sl_customization file. For this example, you do not have to make changes to the file.

```
edit(fullfile(sl_customization_path,'sl_customization.m'))
```

Add the sl_customization folder to the search path and refresh the customizations.

```
addpath(sl_customization_path);
sl_refresh_customizations;
```

Test Generated Code with PIL Simulation

Run the PIL simulation.

```
close_system('rtwdemo_sil_modelblock',0)
open_system('rtwdemo_sil_modelblock')
set_param('rtwdemo_sil_modelblock/CounterA','SimulationMode','processor-in-the-loop (pi
set_param('rtwdemo_sil_modelblock','StopTime','10');
sim('rtwdemo_sil_modelblock');

### Starting build procedure for model: rtwdemo_sil_counter
### Generated code for 'rtwdemo_sil_counter' is up to date because no structural, paran
### Successful completion of build procedure for model: rtwdemo_sil_counter
### Connectivity configuration for referenced model "rtwdemo_sil_counter": My PIL Examp
EXECUTING METHOD SETARGSTRING
SETARGSTRING called from line 71 of ConnectivityConfig.m
### Preparing to start PIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Updating code generation report with PIL files ...
### Starting application: 'rtwdemo_sil_counter_ert_rtw\pil\rtwdemo_sil_counter.exe'
Starting PIL simulation
Started new process, pid = 14132
Stopping PIL simulation
Terminated process, pid = 14132
```

Review the preceding messages. Confirm that the simulation ran without errors. You have now implemented a target connectivity configuration for PIL. You can use the same APIs to implement a connectivity configuration for your own combination of embedded processor, download tool, and communications channel.

Cleanup

Remove the search path for this example.

```
rmpath(sl_customization_path)
```

Reset customizations.

```
sl_refresh_customizations
```

Close the models.

```
close_system('rtwdemo_sil_modelblock',0)
close_system('rtwdemo_sil_counter',0)

rtwdemoclean;
cd(currentDir)
```

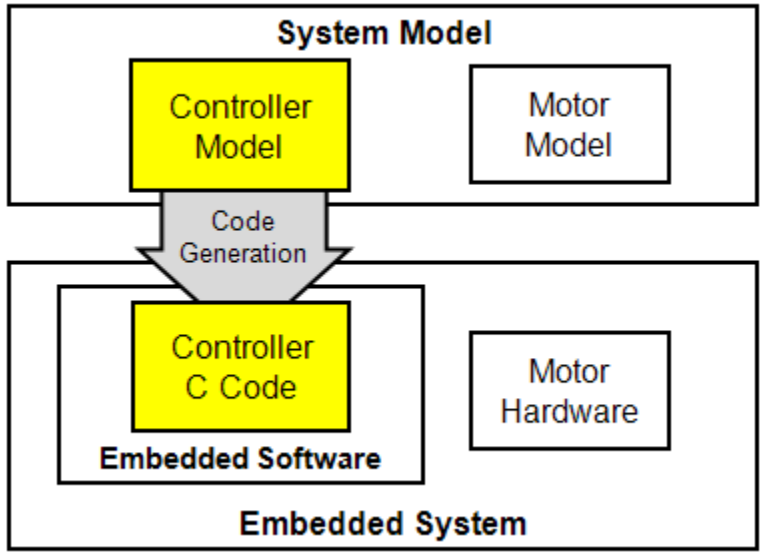
Field-Oriented Control of Permanent Magnet Synchronous Machine

This example shows the basic workflow and key APIs for generating C code from a motor control algorithm, and for verifying its compiled behavior and execution time. You will use Processor-in-the-loop (PIL) simulation to gain confidence that the C code will perform as expected when you integrate it with embedded software that interfaces with the motor hardware. Although this workflow uses a motor control application for a specific processor, you can apply this workflow to virtually any application or processor.

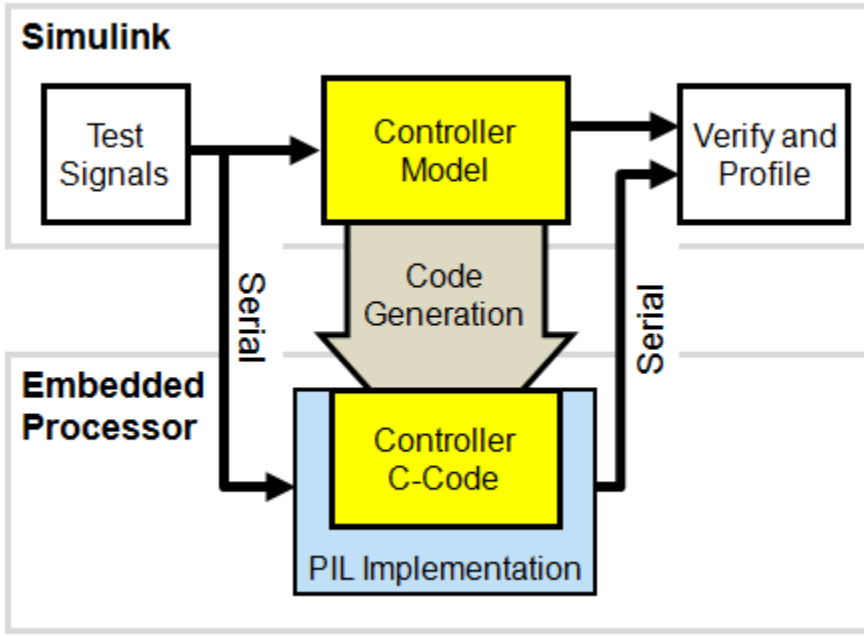


We use a Field-Oriented Control algorithm for a Permanent Magnet Synchronous Machine to show this workflow. This control technique is common in motor drive systems for hybrid electric vehicles, manufacturing machinery, and industrial automation.

Overview

In this example, generate and verify C code from a control algorithm model, which you can integrate with additional embedded software required to interface to motor hardware.

You will use a simulation environment to model and verify the behavior of a closed-loop motor control system. Once the control system behavior is within specification, you will generate C code from the controller model. After inspecting the code, you will assess its functional behavior and execution time using processor-in-the-loop (PIL) testing.



To facilitate PIL testing, you will select test signals to exercise the controller model and establish reference outputs. You will review an example PIL implementation for a Texas Instruments™ F28335 processor that communicates with Simulink® on the host computer over a serial connection. You can use this example as a starting point to create a PIL implementation for your own processor. You will run the controller model in PIL mode to measure execution time and verify execution behavior of the code running on the embedded processor against the simulation reference outputs.

In the final implementation on the embedded processor, you would integrate the generated controller C code with additional embedded software, such as peripherals and interrupts, required to interface with the motor hardware.

Notes

- Simscape™ Electrical is required for system simulation in the section "Verify Behavior through System Simulation." It is not required for other tasks.
- The Texas Instruments™ F28335 PIL implementation is a reference approach that you can apply to virtually any processor. However, if you wish to use this implementation directly, you will need additional support files, compilers, and tools from Texas Instruments™. You can find more information about those in "Create PIL Implementation and Register with Simulink®" section of this example. This reference PIL implementation does not require the Texas Instrument C2000™ Embedded Target feature of Embedded Coder®, but C2000™ users are encouraged to install Texas Instruments C2000 Support Package using Add-On Explorer.

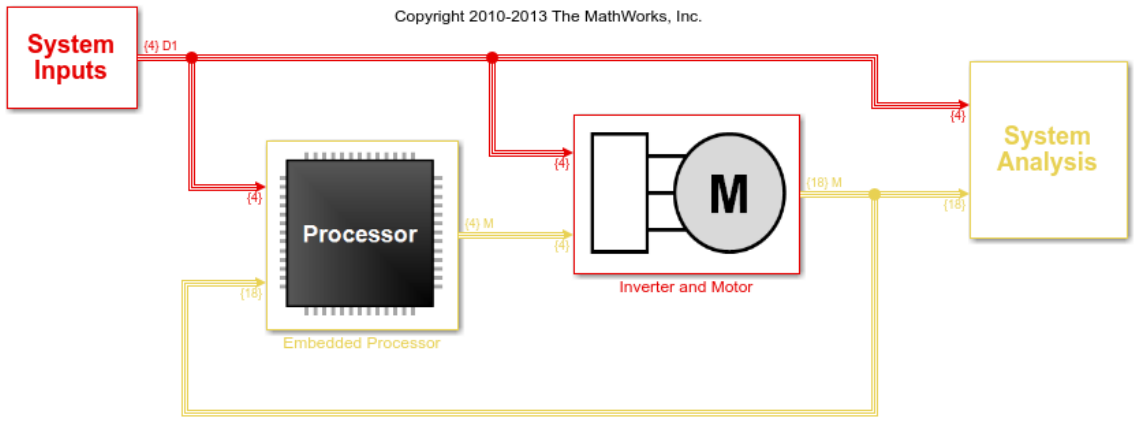
Verify Behavior through System Simulation

In this section, you will verify the controller in a closed loop system simulation.

The system model test bench consists of test inputs, the embedded processor, the power electronics and motor hardware, and visualizations. You can use the system model to exercise the controller and explore its expected behavior. You can use the following commands to execute the model and plot logged signals.

```
open_system('rtwdemo_pmsmfoc_system')
sim('rtwdemo_pmsmfoc_system')
rtwdemo_pmsmfoc_plotsignals(logsout)
```

Field-Oriented Control of Permanent Magnet Synchronous Machine System Test Bench



Model Description: Field-Oriented Control of Permanent Magnet Synchronous Machine

Demonstrates a Field-Oriented Control algorithm with Space Vector Modulation for a Permanent Magnet Synchronous Machine (PMSM).
The test bench can be used to evaluate the system performance. Examples include turning the motor on, searching for a valid rotor position, transitioning to closed loop operation, and changing speed and torque during closed loop control.
The Embedded Processor subsystem contains the controller algorithm (which supports C code generation) as well as simulation models of peripherals.

The plots show that the motor is stationary until the `motor_on` signal is true. The motor then spins in an open loop until a known position is detected, which is indicated by the encoder index pulse. The controller then transitions to closed loop operation and the motor reaches a steady state speed.

Explore Model Architecture

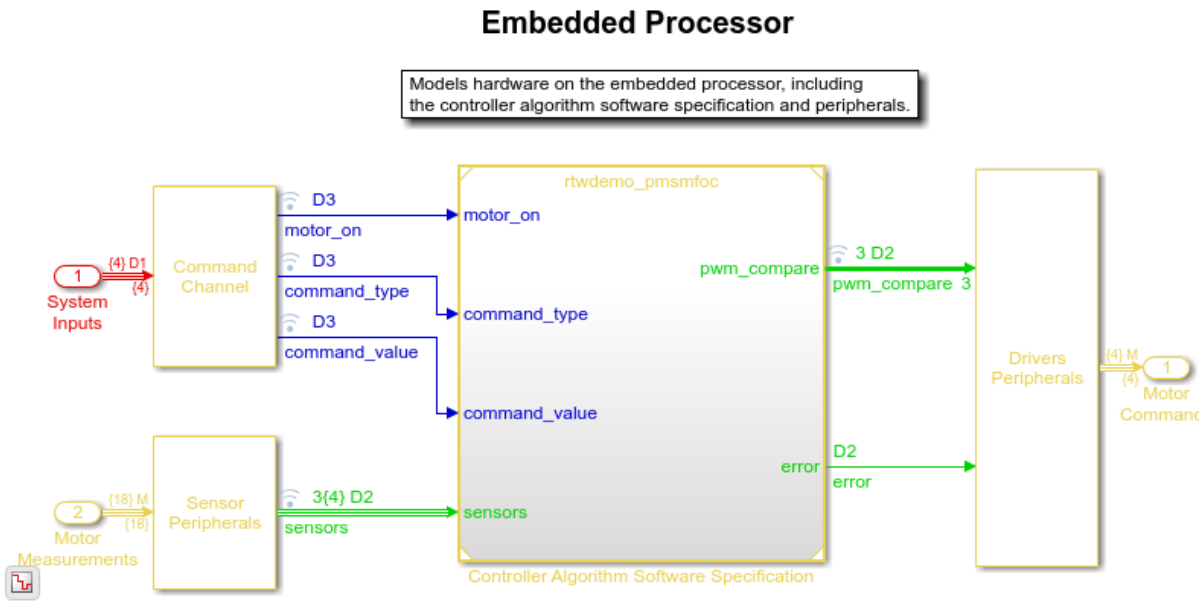
In this section, you will explore the model architecture including how data is specified, how the controller is partitioned from the test bench, and how controller is scheduled. This architecture facilitates system simulation, algorithmic code generation, and PIL testing.

A data definition file creates the MATLAB® data required for simulation and code generation. This data file is automatically run within the `PreLoadFcn` callback of the system test bench model.

```
edit('rtwdemo_pmsmfoc_data.m')
```

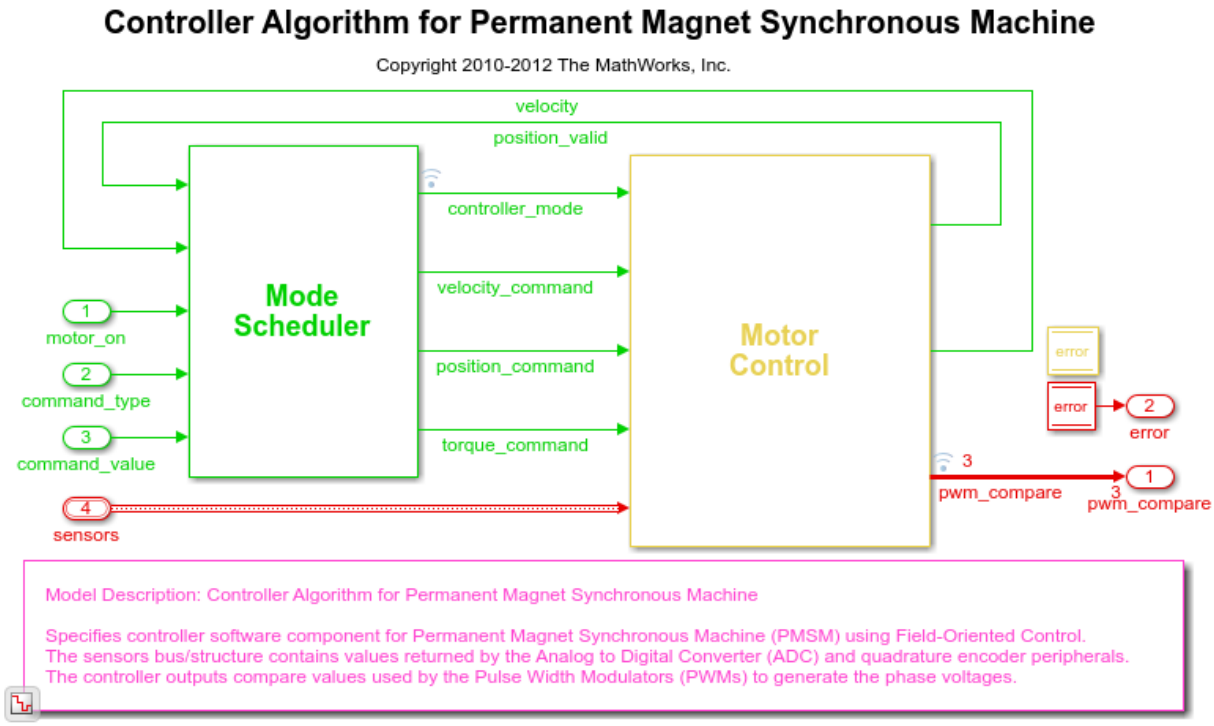
Within the system test bench model, the embedded processor is modeled as a combination of the peripherals and the controller software.

```
open_system('rtwdemo_pmsmfoc_system/Embedded Processor')
```



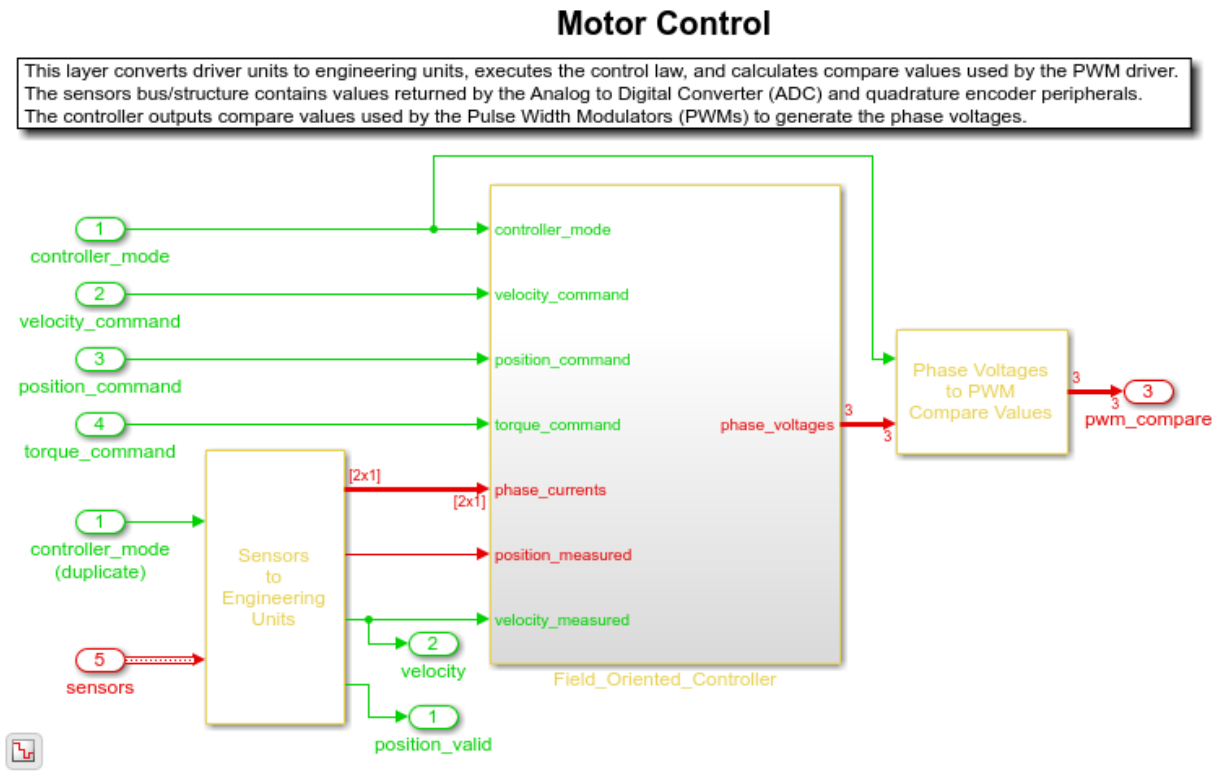
The controller software is specified in a separate model. Within this model, the Mode_Scheduler subsystem uses Stateflow® to schedule different modes of operation of the Motor_Control algorithm.

```
open_system('rtwdemo_pmsmfoc')
```



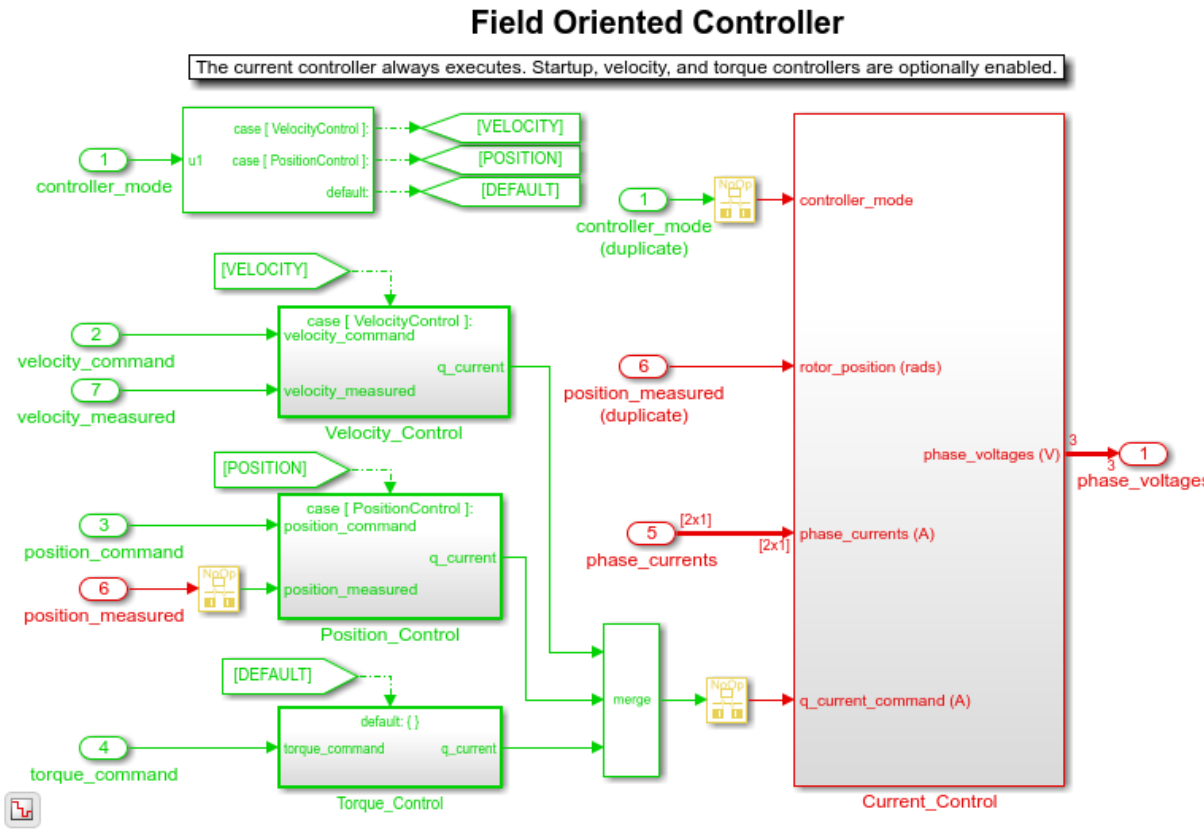
Within the Motor_Control subsystem, sensor signals are converted to engineering units and passed to the core controller algorithm. The controller algorithm calculates voltages. The voltages are then converted to a driver signal.

```
open_system('rtwdemo_pmsmfoc/Motor_Control')
```



The primary control law is a field-oriented controller. The controller has a low rate outer loop that controls the speed, and a higher rate inner loop that controls the current.

```
open_system('rtwdemo_pmsmfoc/Motor_Control/Field_Oriented_Controller')
```



The Velocity Controller outer loop is executed as a multiple of the Current Control loop time. You can view the MATLAB® variables, which specify these sample times:

```
fprintf('High rate sample time = %f seconds\n', ctrlConst.TsHi)
fprintf('Low rate sample time  = %f seconds\n', ctrlConst.TsLo)
```

```
High rate sample time = 0.000040 seconds
Low rate sample time  = 0.005000 seconds
```

Notice that the highest rate in the controller algorithm is 25 kHz.

```
fprintf('High rate frequency = %5.0f Hz\n', 1/ctrlConst.TsHi)
```

```
High rate frequency = 25000 Hz
```

Generate Controller C Code for Integration into Embedded Application

In this section, you will generate and visually inspect the C code function for the controller.

To ease integration, the controller model is configured in single-tasking mode so that the generated code can be invoked using one function call. This function handles the lower and higher rates. The generated controller function must be executed at the high rate sample time.

The function prototype is specified in the model configuration parameters and the input and output ports are passed as arguments. You can view the function specification for the controller algorithm.

```
mdlFcn = RTW.getFunctionSpecification('rtwdemo_pmsmfoc');
disp(mdlFcn.getPreview('init'))
disp(mdlFcn.getPreview('step'))
```

```
Controller_Init ( )
error = Controller ( motor_on, command_type, current_request, * sensors, * pwm_compare
```

Through use of a global structure in the generated code, you can access the field-oriented controller proportional and integral gains. This global structure is specified in the data definition file.

```
disp(ctrlParams.Value)
disp(ctrlParams.CoderInfo)
```

```
                          Current_P: 10
                          Current_I: 10000
                         Velocity_P: 0.0050
                         Velocity_I: 0.0150
                         Position_P: 0.1000
                         Position_I: 0.6000
                StartupAcceleration: 1
                     StartupCurrent: 0.2000
                RampToStopVelocity: 20
            AdcZeroOffsetDriverUnits: 2.2523e+03
               AdcDriverUnitsToAmps: 0.0049
    EncoderToMechanicalZeroOffsetRads: 0
                      PmsmPolePairs: 4

Simulink.CoderInfo
    StorageClass: 'ExportedGlobal'
```

```
          Alias: ''
      Alignment: -1
```

You generate C code from the model as follows.

```
rtwbuild('rtwdemo_pmsmfoc')
```

```
### Starting build procedure for model: rtwdemo_pmsmfoc
### Generated code for 'rtwdemo_pmsmfoc' is up to date because no structural, parameter
### Successful completion of build procedure for model: rtwdemo_pmsmfoc
```

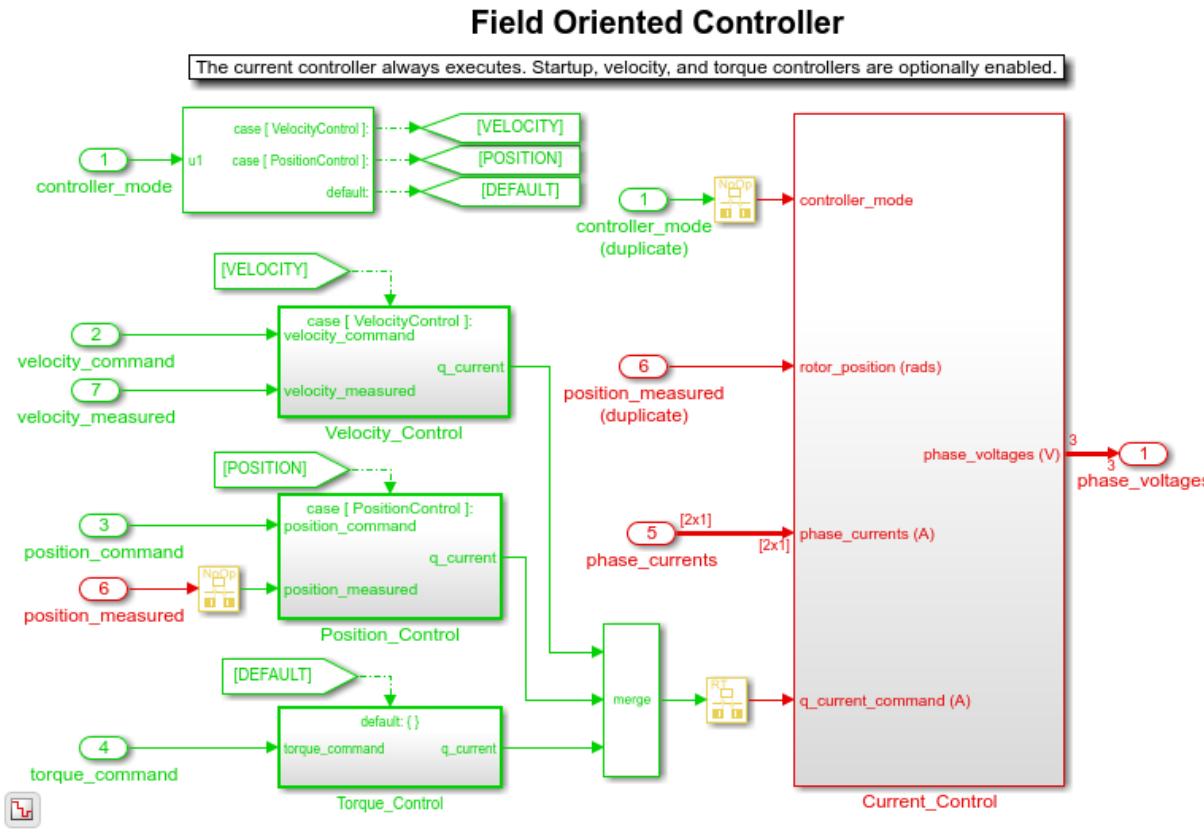
Use the generated report to inspect the generated C code file and verify that the correct step and initialization functions were generated. Also verify that the parameter structure was created as a global variable.

Establish Reference Behavior for Controller Model

In this section, you will establish test inputs and a reference output to help verify behavior and profile execution time during PIL testing. You will make a local copy of the controller model then load a set of test input signals that exercise the different modes within the controller. You will then configure the controller model to attach these logged signals to input ports, execute the controller model, and log the output port signal to the workspace.

Configuration parameters of the controller model used to establish the reference behavior and test environment will change as described below. Blocks and parameters used to specify the controller model's design and generate production code will not change. However, to avoid modifying any part of the installed controller model, save the model and change its name to `rtwdemo_pmsmfoc_local.slx`.

```
save_system('rtwdemo_pmsmfoc','rtwdemo_pmsmfoc_local.slx')
close_system('rtwdemo_pmsmfoc_system',0);
close_system('rtwdemo_pmsmfoc',0);
```



To profile execution times, select a set of test inputs that will execute the paths of interest within the controller. One way to acquire these test inputs and reference output is to log them from the system simulation model.

```
in.motor_on      = logsout.getElement('motor_on').Values;
in.command_type  = logsout.getElement('command_type').Values;
in.command_value = logsout.getElement('command_value').Values;
in.sensors       = logsout.getElement('sensors').Values;
display(in)
```

```
in =

  struct with fields:
```

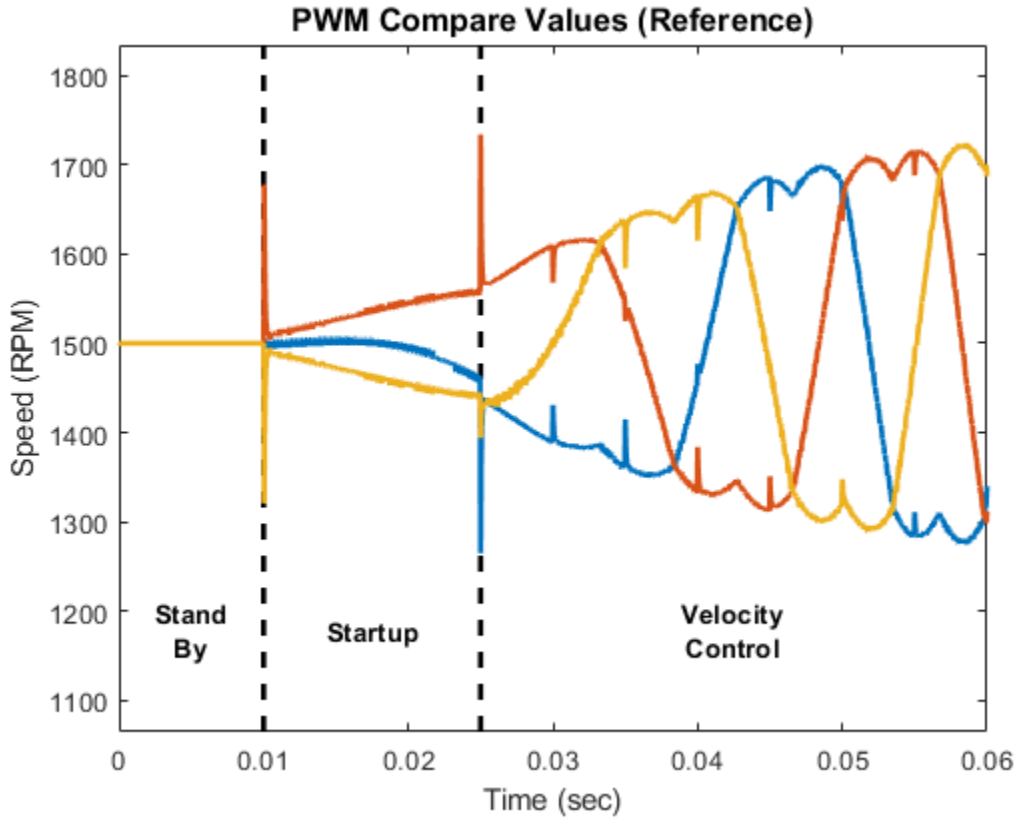
```
        motor_on: [1×1 timeseries]
    command_type: [1×1 timeseries]
   command_value: [1×1 timeseries]
         sensors: [1×1 struct]
```

These signals can now be attached to the input ports and imported into the controller model such that it can execute directly and independently from the system model. An advantage of this approach is that the controller model can be tested and verified as a standalone component, facilitating reuse and integration with other system models or closed-loop test benches. To elaborate, or prepare, the controller model for testing, change its Configuration Parameters to attach input signals and log signals in the MATLAB® workspace. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```
set_param('rtwdemo_pmsmfoc_local',...
    'LoadExternalInput', 'on',...
    'ExternalInput', 'in.motor_on, in.command_type, in.command_value, in.sensors',...
    'StopTime','0.06',...
    'ZeroInternalMemoryAtStartup','on',...
    'SimulationMode', 'normal')
save_system('rtwdemo_pmsmfoc_local.slx')
```

You can now execute the controller model and plot the signal associated with the PWM Compare output port.

```
sim('rtwdemo_pmsmfoc_local')
controller_mode = logsout.getElement('controller_mode').Values;
pwm_compare_ref = logsout.getElement('pwm_compare').Values;
rtwdemo_pmsmfoc_plotpwmcompare(controller_mode, pwm_compare_ref)
```



The logged output will be used as the reference behavior for PIL testing.

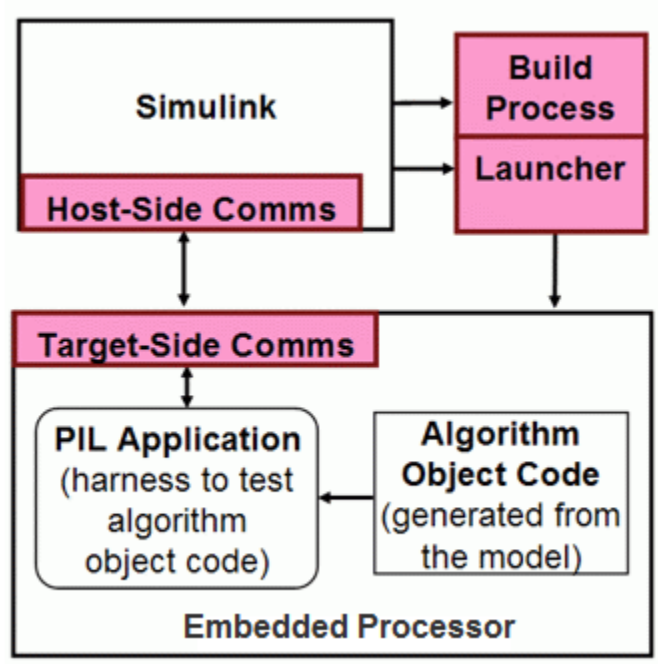
Notice that the plot is annotated with information about the mode of the controller at each time step. This mode information will be useful when interpreting execution profiling information.

Create PIL Implementation

In this section, you will study and use an example PIL implementation. You will begin by reviewing prerequisite help documentation from Embedded Coder®. You will then copy the example PIL implementation into your local directory and register it with Simulink®. You will review the approach used to develop the PIL implementation and can explore the associated files to gain additional insight. If you are using a Spectrum Digital Inc. eZdsp

F28335 board with Code Composer v4 and a serial connection, you will be able to configure this PIL implementation to directly work with the controller model. If you are using a different processor, you can use this PIL implementation as a starting point to create your own implementation.

The fundamentals of creating a custom PIL implementation are described in Creating a Connectivity Configuration for a Target . You should familiarize yourself with the basic concept of using the rtiostream API to facilitate communication between Simulink® (host-side) and the embedded processor (target-side) during PIL testing. Note that Embedded Coder® provides host-side drivers for the default TCP/IP implementation (for all platforms supported by Simulink®) as well as a Windows® only version for serial communication. Building the generated code is accomplished using a makefile as described in Customizing Template Makefiles . To create a PIL implementation you will need to perform several tasks in the embedded environment including writing a target-side communications driver, writing a makefile to build the generated code, and automating download and execution of the built executable.



Using the above approach, a PIL implementation was created for a Spectrum Digital Inc. eZdsp F28335 board. Below is a summary of the target connectivity API components used in this implementation.

- **Host-Side Communication** - The host-side connectivity driver is configured to use serial communication.
- **Target-Side Communication** - The target-side communication is achieved using a handwritten serial implementation of the rtiostream functions as well as timer access functions.
- **Build Process** - A makefile based approach is used to build the executable application.
- **Launcher** - Downloading and running the executable is accomplished using the Debug Server Scripting (DSS) utility of Code Composer Studio™ v4 (CCSv4).

The PIL implementation was iteratively developed in three stages. Below is a description of these stages and the tasks performed in these stages. You may find it helpful to follow a similar approach when developing your own PIL implementation

Stage 1: Create serial communication application with CCSv4

- Install CCSv4 and verify that it can connect with the F28335 eZdsp board.
- Write an embedded application that sends and receives serial data.
- Test the serial communication between the host computer and the embedded application.
- Identify the commands and options for the compiler, linker, and archiver to build the application using a makefile.
- Download and run the application from a Windows® Command Prompt using the DSS utility.

Stage 2: Implement and test embedded serial rtiostream and launch automation with MATLAB®

- Extend the serial application to implement the rtiostream API functions for echoing data. Write the rtIOStreamOpen to perform general board initialization, including configuring the serial port.
- Verify sending and receiving serial data with the embedded processor from MATLAB® using the rtiostream_wrapper function.
- Download and run the application from MATLAB® using the system command to call the DSS utility.

Stage 3: Implement and test connectivity configuration with Simulink®

- Create a connectivity configuration class to configure the host-side serial communication, specify which target-side code files from the rtiostream application should be included in the build process, specify how to access a timer that will be used to collect profiling data, and integrate calling the DSS utility to launch the embedded application.
- Create a tool specification makefile (`target_tools.mk`) which specifies the commands and options for the compiler, linker, and archiver. This makefile is included by the template makefile (`target_tools.mk`).
- Create a template makefile (`ec_target.tmf`) that includes `target_tools.mk`.
- Identify parameters which may be installation dependent and store them as MATLAB® preferences.
- Create a Simulink® customization file which specifies when the PIL implementation is valid

The files associated with this PIL implementation are included with Embedded Coder®, but are not on the MATLAB® path. To explore these files, you can copy them into a local directory. You can register this PIL implementation by adding this directory to the MATLAB® path and refreshing the Simulink® customizations.

```
%copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335'),'examplePi
addpath(genpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335')))
sl_refresh_customizations
```

MATLAB® preferences are used to specify path information and the host serial COM port number. If you are using this PIL implementation directly, you must specify these preferences as appropriate for your configuration.

Note that the `TI_F28xxx_SysSWDir` preference points to a directory provided by Texas Instruments™ in their **C2000™ Experimenter Kit Application Software** (`sprc675.zip`). These files are not included with Embedded Coder®.

```
setpref('examplePilF28335','examplePilF28335Dir', fullfile(matlabroot,'toolbox','rtw',
setpref('examplePilF28335','CCSRootDir',          'C:\Program Files\Texas Instruments\c
setpref('examplePilF28335','TI_F28xxx_SysSWDir',  'C:\Program Files\Texas Instruments\T

```

The PIL implementation is now ready to be used.

Prepare Controller Model for PIL Testing

In this section you will configure the controller model to use the PIL implementation. You will review the customization file used to register the PIL implementation, set the configuration parameters of the model to use the PIL implementation, and enable logging controller outputs and execution profiling data.

When you begin a simulation in PIL mode, Simulink® will check if any of the registered PIL implementations are valid. A customization file specifies which configuration parameters correspond to a valid PIL implementation. You can explore the customization file for this implementation by invoking the following command.

```
edit(fullfile(matlabroot,'toolbox','rtw','rtwdemos','examplePilF28335','sl_customizatio
```

Notice that this file specifies setting for the hardware device and the template makefile which are required to use this PIL implementation. You can modify the configuration parameters in the controller model to match these settings. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```
set_param('rtwdemo_pmsmfoc_local',...
       'ProdHWDeviceType', 'Texas Instruments->C2000',...
       'TemplateMakefile', 'ec_target.tmf',...
       'GenCodeOnly', 'off',...
       'SimulationMode', 'processor-in-the-loop (pil)')
```

You can specify collecting execution profiling information during PIL testing by logging the simulation output values as the variable `pilOut` and logging the execution profiling information as the variable `executionProfile`. These changes can be made graphically in the model's Configuration Parameters dialog, or programmatically as shown below.

```
set_param('rtwdemo_pmsmfoc_local',...
    'CodeExecutionProfiling', 'on',...
    'CodeExecutionProfileVariable','executionProfile',...
    'CodeProfilingSaveOptions','AllData');
save_system('rtwdemo_pmsmfoc_local.slx')
```

The controller model is now ready to be run in PIL mode.

Test Behavior and Execution Time of Generated Code

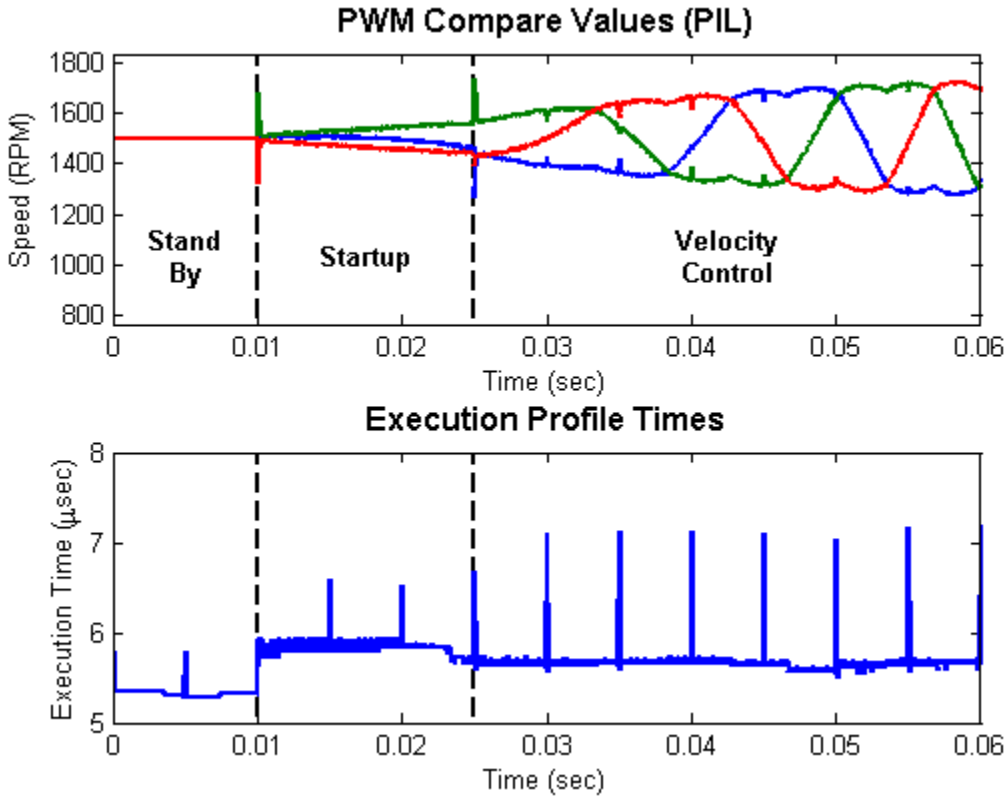
In this section you will run the controller model in PIL mode and explore the behavioral and execution profiling results. You will verify that the behavior of the compiled controller

code matches the reference simulation behavior, and then verify that the execution of the code meets timing requirements.

You can run the model and plot the PIL simulation results. When you start the model for the first time, Embedded Coder® will generate code for the algorithm, link the algorithm code with the serial communication interface code, build the embedded application, download the application to the board, and begin the on-target simulation. Note that during subsequent PIL simulations, code is only regenerated if the model changes. Due to the overhead associated with the serial communication interface, the PIL simulation may run slower than the model in normal mode.

The MATLAB® commands below are intentionally commented out as they require connection to hardware and use of embedded development tools described previously. If you have the hardware connected and embedded development tools installed, uncomment and execute these lines to run the model, plot the results, and verify the behavior is numerically equivalent to the simulation running in normal mode. Otherwise, continue reviewing this section to learn about PIL execution analysis options.

```
% UNCOMMENT THE BELOW LINES TO RUN THE SIMULATION AND PLOT THE RESULTS
% if exist('slprj','dir'), rmdir('slprj','s'); end
% sim('rtwdemo_pmsmfoc_local')
% pwm_compare_pil = logsout.getElement('pwm_compare').Values;
% rtwdemo_pmsmfoc_plotpwmcompare_pil(controller_mode, pwm_compare_pil, executionProfile
```



The upper plot is the output of the controller, PWM Compare. Note that the outputs in PIL mode look the same as the outputs of the simulation in normal mode shown in the section "Establish Reference Behavior for Controller Model". You can subtract the outputs of normal mode simulation from the PIL mode simulation output to verify that they are numerically equivalent:

```
% UNCOMMENT THE BELOW LINE TO VERIFY NUMERICAL EQUIVALENCE OF THE OUTPUTS
% pilErrorWithRespectToReference = sum(abs(pwm_compare_pil.Data - pwm_compare_pil.Data)
```

```
pilErrorWithRespectToReference =

   0     0     0
```

The lower plot is the amount of time spent executing the controller model at each simulation time step. The "Stand By" state requires the least time. Small periodic spikes in execution time occur because the controller is multi-rate and single tasking. The periodic spikes correspond to the time required to run both the base rate and 5 millisecond rate code in the same task.

Since the controller must be executed at 25 kHz on the embedded processor, the algorithm must complete its execution within 40 microseconds (minus additional headroom requirements by other code, which may also be executing on the final application.) The profiling results indicate that the algorithm will execute within the time allotted for this configuration of the embedded environment.

The generated code is now verified to provide numerically equivalent results and meets the execution timing requirements for this test case.

```
close_system('rtwdemo_pmsmfoc_local',0);
close_system('power_utile',0);
```

The MATLAB® preferences used in this PIL implementation are persistent between MATLAB® sessions. If you want to remove these preferences, run the following commands.

```
rmpref('examplePilF28335');
rmexamplePilF28335hooks();
```

Conclusion

This example showed system level simulation and algorithmic code generation using a Field-Oriented Control algorithm for a Permanent Magnet Synchronous Machine to explore functional behavior of the controller algorithm. It also showed a general approach for target integration, functional testing, and execution profiling for any embedded processor. Once the algorithm was behaviorally correct, code was generated from the controller model, tested on the target processor and profiled. The algorithm code is now

verified and can be integrated with embedded software that interfaces with the motor hardware for further testing.

Check Configuration

Use the `cgv.Config` class to check model settings for a SIL or PIL simulation. You can review your model configuration and determine the settings that you must change. By default, `cgv.Config` changes configuration parameter values to the value that it recommends, but does not save the model. Alternatively, you can:

- Change configuration parameter values to the values that `cgv.Config` recommends, and save the model. Specify this approach using the `SaveModel` property.
- List the values that `cgv.Config` recommends for the configuration parameters, but not change the configuration parameters or the model. Specify this approach using the `ReportOnly` property.

Note

- Execution in the target environment can require additional modifications to configuration parameter values or the model.
- Do not use referenced configuration sets in models that you are changing using `cgv.Config`. If the model uses a referenced configuration set, update the model with a copy of the configuration set. Use the `getRefConfigSet` method of the `Simulink.ConfigSetRef` class.
- If you use `cgv.Config` on a model that executes a callback function, the callback function can change configuration parameter values each time the model loads. The callback function can revert changes that `cgv.Config`. For more information, see “Callbacks for Customized Model Behavior” (Simulink).

To verify that your model is configured for SIL or PIL:

1. Construct a `cgv.Config` object that changes the configuration parameter values without saving the model. For example, to configure your model for SIL:

   ```
   c = cgv.Config('vdp', 'connectivity', 'sil');
   ```

   Tip

   - You can obtain a list of changes without changing the configuration parameter values. When you construct the object, include the `'ReportOnly', 'on'` property name and value pair.

- You can change the configuration parameter values and save the model. When you construct the object, include the `'SaveModel', 'on'` property name and value pair.

---

2. Determine and change the configuration parameter values that the object recommends using the `configModel` method. For example:

   ```
   c.configModel();
   ```

3. Display a report of the changes that `configModel` makes. For example:

   ```
   c.displayReport();
   ```

4. Review the changes.
5. To apply the changes to your model, save the model.

- “Verify Numerical Equivalence Between Two Modes of Execution of a Model” on page 78-141

Verify Numerical Equivalence with CGV

Before verifying numerical equivalence:

- Configure your model for SIL or PIL simulation.
- Use the `cgv.Config` class of the CGV API to verify the model configuration for SIL or PIL simulation.
- Configure your model for code generation. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 43-2.
- Save your model. If you modify a model without saving it, CGV can issue an error.

To verify numerical equivalence:

- Set up the tests for the first execution environment. For example, simulation.
- Use `run` to run the tests for the first execution environment.
- Set up the tests for the second execution environment. For example, top-model PIL.
- Use `cgv.CGV.run` to run the tests for the second execution environment.
- Use `getOutputData` to get the output data for each execution environment.
- Use `getSavedSignals` to display the signal names in the output data. (optional)
- Build a list of signal names for input to other `cgv.CGV` methods. (optional)
- Use `createToleranceFile` to create a file correlating tolerance information with output signal names. (optional)
- Use `compare` to compare the output signals of the first and second execution environments for numerical equivalence.

Note Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

Verify Numerical Equivalence Between Two Modes of Execution of a Model

In this section...

The following example describes configuring, executing, and comparing the results of the rtwdemo_cgv model in normal and software-in-the-loop (SIL) simulation modes.

Configure the Model

The first task for verifying numerical equivalence is to check the configuration of your model.

1. Open the `rtwdemo_cgv` model.

   ```
   cgvModel = 'rtwdemo_cgv';
   load_system(cgvModel);
   ```

2. Save the model to a working directory.

   ```
   save_system(cgvModel, fullfile(pwd, cgvModel));
   close_system(cgvModel); % avoid original model shadowing saved model
   ```

3. Use the `cgv.Config` to create a `cgv.Config` object. Specify parameters that check and modify configuration parameter values and save the model for top-model SIL mode of execution.

   ```
   cgvCfg = cgv.Config('rtwdemo_cgv', 'connectivity', 'sil', 'SaveModel', 'on');
   ```

4. Use the `configModel` method to review your model configuration and to change the settings to configure your model for SIL. When `'connectivity'` is set to `'sil'`, the system target file is automatically set to `'ert.tlc'`. If you specified the parameter/value pair, (`'SaveModel', 'on'`) when you created the `cgvCfg` object, the `cgv.Config.configModel` method saves the model.

Note CGV runs on models that are open. If you modify a model without saving it, CGV can issue an error.

```
cgvCfg.configModel(); % Evaluate, change, and save your model for SIL
```

5 Display a report of the changes that `cgv.Config.configModel` makes to the model.

```
cgvCfg.displayReport(); % In this example, this reports no changes
```

Execute the Model

Use the CGV API to execute the model in two modes. The two modes in this example are normal mode simulation and SIL mode. In each execution of the model, the CGV object for each mode captures the output data and writes the data to a file.

1 If you have not already done so, follow the steps described in “Configure the Model” on page 78-141.

2 Create a `cgv.CGV` object that specifies the `rtwdemo_cgv` model in normal mode simulation.

```
cgvSim = cgv.CGV(cgvModel, 'connectivity', 'sim');
```

Note When the top model is set to normal simulation mode, the CGV API sets referenced models in PIL mode to accelerator mode.

3 Provide the input file to the `cgvSim` object.

```
cgvSim.addInputData(1, [cgvModel '_data']);
```

4 Before execution of the model, specify the MATLAB files to execute or MAT-files to load. This step is optional.

```
cgvSim.addPostLoadFiles({[cgvModel '_init.m']});
```

5 Specify a location where the object writes all output data and metadata files for execution. This step is optional.

```
cgvSim.setOutputDir('cgv_output');
```

6 Execute the model.

```
result1 = cgvSim.run();
```

7 Get the output data associated with the input data.

```
outputDataSim = cgvSim.getOutputData(1);
```

8 For the next mode of execution, SIL, repeat steps 2–7.

```
cgvSil = cgv.CGV( cgvModel, 'Connectivity', 'sil');
cgvSil.addInputData(1, [cgvModel '_data']);
cgvSil.addPostLoadFiles({[cgvModel '_init.m']});
cgvSil.setOutputDir('cgv_output');
result2 = cgvSil.run();
```

Compare All Output Signals

After setting up and running the test, compare the outputs by doing the following:

1 If you have not already done so, configure and test the model, as described in “Configure the Model” on page 78-141 and “Execute the Model” on page 78-142.

2 Test that the execution result of the model:

```
if ~result1 || ~result2
    error('Execution of model failed.');
end
```

3 Use the `getOutputData` method to get the output data from the cgv.CGV objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

4 Display a list of signals by name using the `getSavedSignals` method.

```
cgvSim.getSavedSignals(simData);
```

5 Using the list of signals, build a list of signals in a cell array of character vectors. The signal list can contain a number of signals.

```
signalList = {'simData.getElement(4).Values.Data'};
```

6 Use the `createToleranceFile` method to create a file, in this example, `'localtol'`, correlating tolerance information with output signal names.

```
toleranceList = {{'absolute', 0.5}};
cgv.CGV.createToleranceFile('localtol', signalList, toleranceList);
```

7 Compare the output data signals. By default, the `compare` method looks at all signals which have a common name between both executions. If a tolerance file is present, `cgv.CGV.compare` uses the associated tolerance for a specific signal during comparison; otherwise the tolerance is zero. In this example, the `'Plot'` parameter is set to `'mismatch'`. Therefore, only mismatched signals produce a plot.

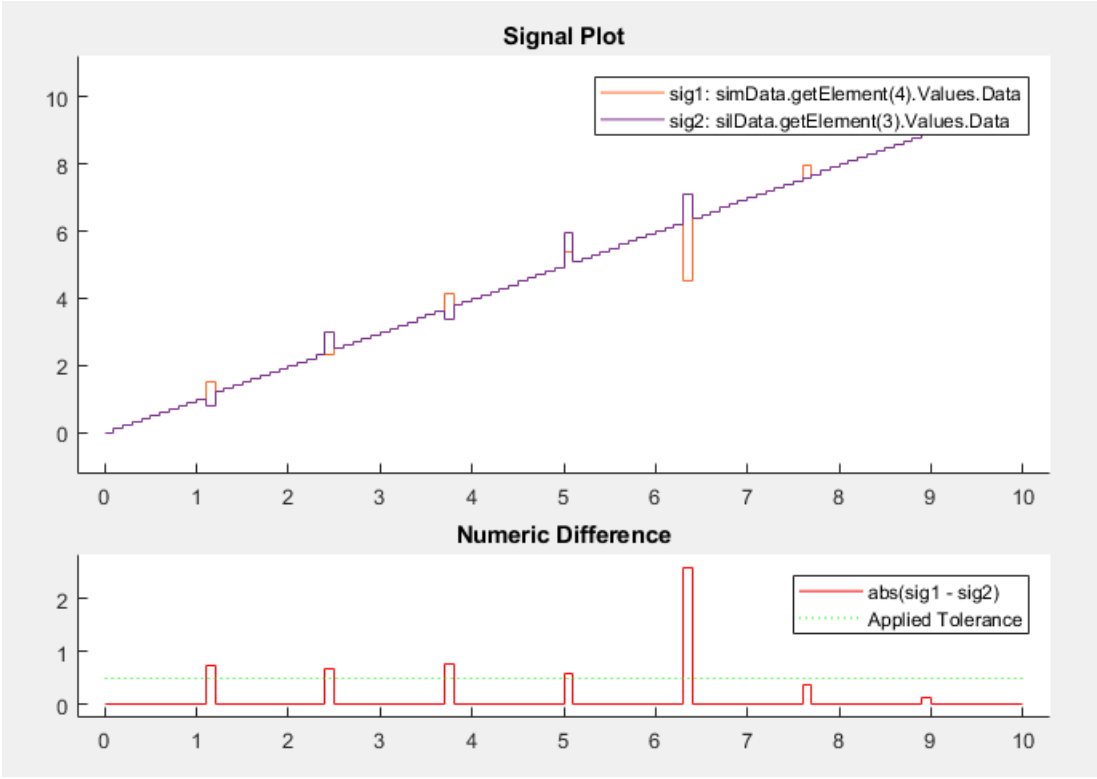
```
[matchNames, ~, mismatchNames, ~] = ...
    cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
    'Tolerancefile', 'localtol');
fprintf( '%d Signals match, %d Signals mismatch\n', ...
    length(matchNames), length(mismatchNames));
```

```
disp('Mismatched Signal Names:');
disp(mismatchNames);
```

At the MATLAB command line, you see:

```
14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
    'simData.getElement(4).Values.Data'
```

A plot results from the signal mismatch.



The lower plot displays the numeric difference between the results.

Compare Individual Output Signals

After setting up and running the test, compare the outputs of individual signals by doing the following:

1. If you have not already done so, configure and test the model, as described in "Configure the Model" on page 78-141 and "Execute the Model" on page 78-142.
2. Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
silData = cgvSil.getOutputData(1);
```

3. Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.

```
cgv.CGV.getSavedSignals(simData);

signalList = {'simData.getElement(3).Values.hi1.mid0.lo1.Data', ...
'simData.getElement(3).Values.hi1.mid0.lo2.Data', ...
'simData.getElement(2).Values.Data(:,3)'};
```

4. Use the specified signals as input to the `compare` method to compare the signals from separate runs.

```
[matchNames, ~, mismatchNames, ~] = ...
    cgv.CGV.compare(simData, silData, 'Plot', 'mismatch', ...
    'signals', signalList);
fprintf( '%d Signals match, %d Signals mismatch\n', ...
    length(matchNames), length(mismatchNames));
if ~isempty(mismatchNames)
    disp( 'Mismatched Signal Names:');
    disp(mismatchNames);
end
```

   At the MATLAB command line, the result is:

```
3 Signals match, 0 Signals mismatch
```

Plot Output Signals

After setting up and running the test, use the `plot` method to plot output signals.

1. If you have not already done so, configure and test the model, as described in "Configure the Model" on page 78-141 and "Execute the Model" on page 78-142.
2. Use the `getOutputData` method to get the output data from the `cgv.CGV` objects.

```
simData = cgvSim.getOutputData(1);
```

3. Use the `getSavedSignals` method to display the output data signal names. Build a list of specific signal names in a cell array of character vectors. The signal list can contain a number of signals.

```
cgv.CGV.getSavedSignals(simData);
signalList = {'simData.getElement(2).Values.Data(:,1)'};
```

4 Use the specified signal list as input to the `plot` method to compare the signals from separate runs.

```
[signalNames, signalFigures] = cgv.CGV.plot(simData, ...
     'Signals', signalList);
```

Related Examples

- “Verify Numerical Equivalence with CGV” on page 78-139
- “Check Configuration” on page 78-137

Using Code Generation Verification API

Configure and run normal, software-in-the-loop (SIL), and processor-in-the-loop (PIL) simulations, and compare results.

Note: Simulink Test is a separate product that provides additional capabilities for SIL and PIL testing, for example, test sequence construction and test management.

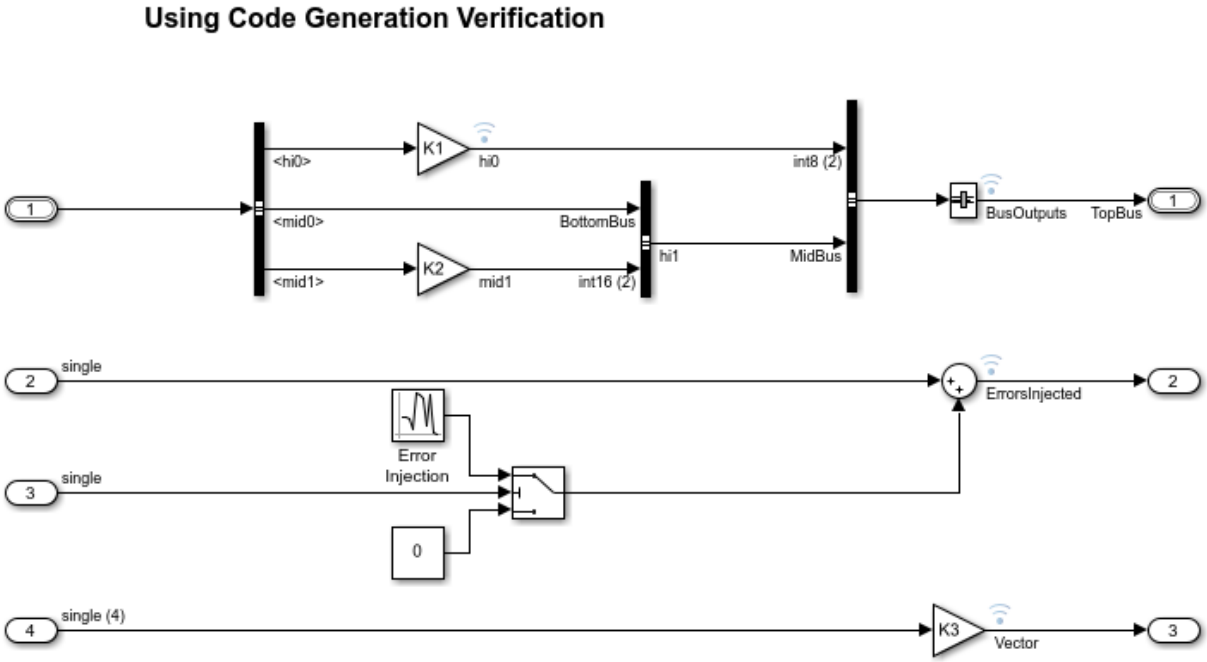
Review the Model

The `rtwdemo_cgv` model uses buses, scalars, and vectorized data, plus error injection to create differences between test executions.

Note: Before executing the code in this example, change to a writable folder. If you are not working in a writable folder, code generation errors occur.

To open rtwdemo_cgv, in the MATLAB® Command Window, enter the following commands.

```
baseVars = who;  % For future cleanup.
cgvModel = 'rtwdemo_cgv';
close_system(cgvModel,0);
open_system( cgvModel);
```



The model contains a hierarchical bus with three nested buses. This arrangement of buses produces complex hierarchical data at the first logged outport. At the second outport, the model injects errors in the signal at fixed intervals. These errors produce different results between two runs. The signal at the third outport is a vector of four values per sample to help show the comparison support.

Verify the Model Configuration

CGV provides a class, cgv.Config, to check whether models have a configuration that is compatible with execution in a SIL or PIL environment using an ert target. This model has already been modified using the cgv.Config class.

Execute Under CGV

Run in Normal and SIL Modes

The model executes in three modes under CGV: normal, SIL, and PIL. In each case, the CGV object captures the output data and writes it to a file. For more information, see `CGV Documentation`. To execute the model in normal and SIL simulation modes, enter:

```
cgvSim = cgv.CGV( cgvModel, 'Connectivity', 'Normal');
cgvSim.addInputData(1, [cgvModel '_data']);
% This next CGV function, addPostLoadFiles(), allows you to specify MATLAB(R)
% programs to execute, or mat-files to load, before execution of the model.
cgvSim.addPostLoadFiles({[cgvModel '_init.m']});
cgvSim.setOutputDir('cgv_output');
cgvSim.activateConfigSet( 'CS1_default');
result1 = cgvSim.run();

% CGV provides methods to simplify numerical equivalence checking.
% The copySetup method creates an exact duplicate of an existing CGV object without
% results data.  You can change the SimulationMode using setMode() and then
% execute again.
cgvSil = cgvSim.copySetup();
cgvSil.setMode( 'SIL');
% You can provide a baseline file to CGV for comparing the simulation
% output. In this example, the comparison results set the status to
% 'failed', because the ErrorsInjected signal differs between simulations.
cgvSil.addBaseline( 1, 'rtwdemo_cgv_results');
result2 = cgvSil.run();

% To see the name(s) of the signal(s) that did match, use getMismatches.
% Mismatched signal names are only available if a baseline was added and
% the comparison failed.
if strcmp( cgvSil.getStatus( 1), 'failed')
    disp( 'Mismatched Signal Names:');
    [signalNames, plotFiles] = cgvSil.getMismatches( 1);
    fprintf( 1, 'Signal Names: %s\n', signalNames{:} );
    fprintf( 1, 'Path to plot files: %s\n', plotFiles{:});
    assert(numel(signalNames)==1,'Expected exactly one mismatch');
end
```

```

Run in PIL Mode

Next, the model runs a PIL simulation, using your embedded processor. A universal embedded processor does not exist. Therefore, PIL support is provided by using the host computer where MATLAB® is running. The host processor is treated as an embedded target.

A customization file is executed that maps this model's PIL execution onto the SIL infrastructure. After the customization file is executed, CGV execution displays PIL messages for the mode. SIL messages display the connectivity target.

The configuration set for the model is already configured with: **Hardware Implementation > Test hardware > Test hardware is the same as production hardware** is checked. **Code Generation > Verification > Enable portable word sizes** is checked. These settings work in SIL and in PIL when PIL is mapped onto the SIL connectivity target.

```
copyfile( which( 'rtwdemo_cgv_sl_customization.m'),...
    fullfile( pwd, 'sl_customization.m'),'f');
```

```
sl_refresh_customizations();

cgvPil = cgvSim.copySetup();
cgvPil.setMode( 'PIL');
result3 = cgvPil.run();

Applying PostLoad file:
  B:\matlab\toolbox\rtw\rtwdemos\rtwdemo_cgv_init.m
Starting execution:
  ComponentType: topmodel
  Connectivity: pil
  InputData:
  B:\matlab\toolbox\rtw\rtwdemos\rtwdemo_cgv_data.mat
### Starting build procedure for model: rtwdemo_cgv
### Successful completion of build procedure for model: rtwdemo_cgv
### Preparing to start PIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Connectivity configuration for "C:\TEMP\Bdoc19a_1067994_6688\ib99EA80\28\tp19e605e4
### Updating code generation report with PIL files ...
### Starting application: 'rtwdemo_cgv_ert_rtw\pil\rtwdemo_cgv.exe'
End CGV execution: status completed.
```

Remove Customization

To prevent problems with other models, immediately remove the customization used to show PIL mode.

```
delete( 'sl_customization.m');
sl_refresh_customizations();
```

Check that execution did not terminate with an error

The run() function returns a Boolean value, which is true if the execution completes without model compilation or simulation error. Before accessing the data, check the result returned from each execution.

```
if ~result1 || ~result2 || ~result3
    disp('Execution of model failed.');
end

simData   = cgvSim.getOutputData(1);
silData   = cgvSil.getOutputData(1);
pilData   = cgvPil.getOutputData(1);
```

Compare Results

The executions are now complete. Compare the results. The comparison code supports a plot with filters. Plots display both the data and the difference.

CGV functions display signals names (as used in the command window) and create a file correlating tolerance information with signal names.

Show Signal Names from Normal Simulation

Display a list of signal names from the saved data.

Note: cgv.CGV.compare ignores signals that appear in only one data set. For example, the compare function ignores a logged internal signal hi0 that appears in the output of a normal simulation, but does not appear in the output of a SIL simulation.

```
cgv.CGV.getSavedSignals( simData);
```

```
simData.getElement(1).Values.Data(:,1)
simData.getElement(1).Values.Data(:,2)
simData.getElement(2).Values.Data(:,1)
simData.getElement(2).Values.Data(:,2)
simData.getElement(2).Values.Data(:,3)
simData.getElement(2).Values.Data(:,4)
simData.getElement(3).Values.hi0.Data(:,1)
simData.getElement(3).Values.hi0.Data(:,2)
simData.getElement(3).Values.hi1.mid0.lo0.Data(1,1,:)
simData.getElement(3).Values.hi1.mid0.lo0.Data(2,1,:)
simData.getElement(3).Values.hi1.mid0.lo0.Data(1,2,:)
simData.getElement(3).Values.hi1.mid0.lo0.Data(2,2,:)
simData.getElement(3).Values.hi1.mid0.lo1.Data
simData.getElement(3).Values.hi1.mid0.lo2.Data
simData.getElement(3).Values.hi1.mid1.Data(:,1)
simData.getElement(3).Values.hi1.mid1.Data(:,2)
simData.getElement(4).Values.Data
```

Create a Tolerance File

The CGV createToleranceFile function creates a file correlating tolerance information with signal names. For the options available to configure tolerances, see cgv.CGV.createToleranceFile. By default, tolerances are zero. Therefore the signals must match exactly. This example allows a delta of 0.5 on the ErrorsInjected signal.

```
signalList = {'simData.ErrorsInjected.Data' };
toleranceList = { { 'absolute', 0.5}};
cgv.CGV.createToleranceFile( 'localtol', signalList, toleranceList );
```

Compare Signals

By default, the cgv.CGV.compare function looks at signals that have a common name between both executions. In the following code, the simData.hi0.Data signals are not compared, because the signals do not appear in silData.

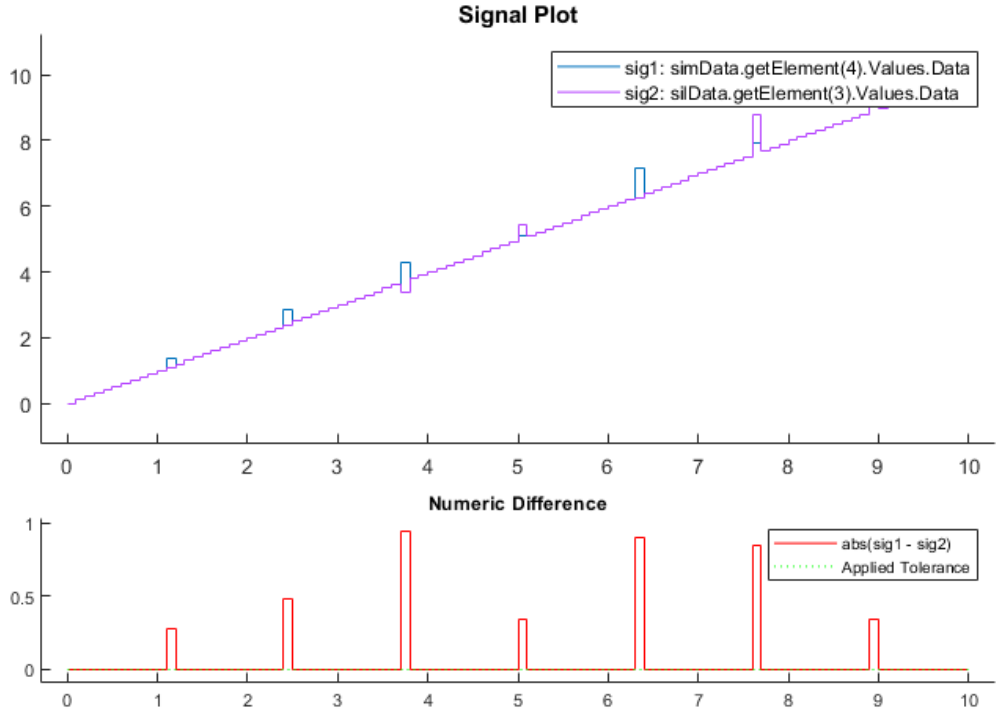
The second and fourth return parameters of the compare function are for matched figures and mismatched figures. Tildes (~) represent these parameters because this example does not use the return values.

A plot results from the mismatch on signal simData.ErrorsInjected.Data.

```
[matchNames, ~, mismatchNames, ~] = ...
    cgv.CGV.compare( simData, silData, 'Plot', 'mismatch', ...
    'Tolerancefile', 'localtol');
fprintf( '%d Signals match, %d Signals mismatch\n', ...
    length(matchNames), length(mismatchNames));
assert(length(mismatchNames) == 1,'Expected exactly one mismatch');
assert(length(matchNames) == 14, 'Expected exactly 14 matches');

disp( 'Mismatched Signal Names:');
disp(mismatchNames');
```

```
14 Signals match, 1 Signals mismatch
Mismatched Signal Names:
    'simData.getElement(4).Values.Data'
```



Compare Individual Signals

The cgv.CGV.compare function also compares only the specified signals. In this example, the function compares only three signals.

```
[matchNames, ~, mismatchNames, ~ ] = ...
    cgv.CGV.compare( simData, silData, 'Plot', 'mismatch', ...
    'Signals', {'simData.getElement(3).Values.hi1.mid0.lo1.Data',...
    'simData.getElement(3).Values.hi1.mid0.lo2.Data', ...
    'simData.getElement(2).Values.Data(:,3)'});
fprintf( '%d Signals match, %d Signals mismatch\n', ...
    length(matchNames), length(mismatchNames));
assert(isempty(mismatchNames),'Expected no mismatches');
if ~isempty(mismatchNames)
    disp( 'Mismatched Signal Names:');
    disp(mismatchNames');
```

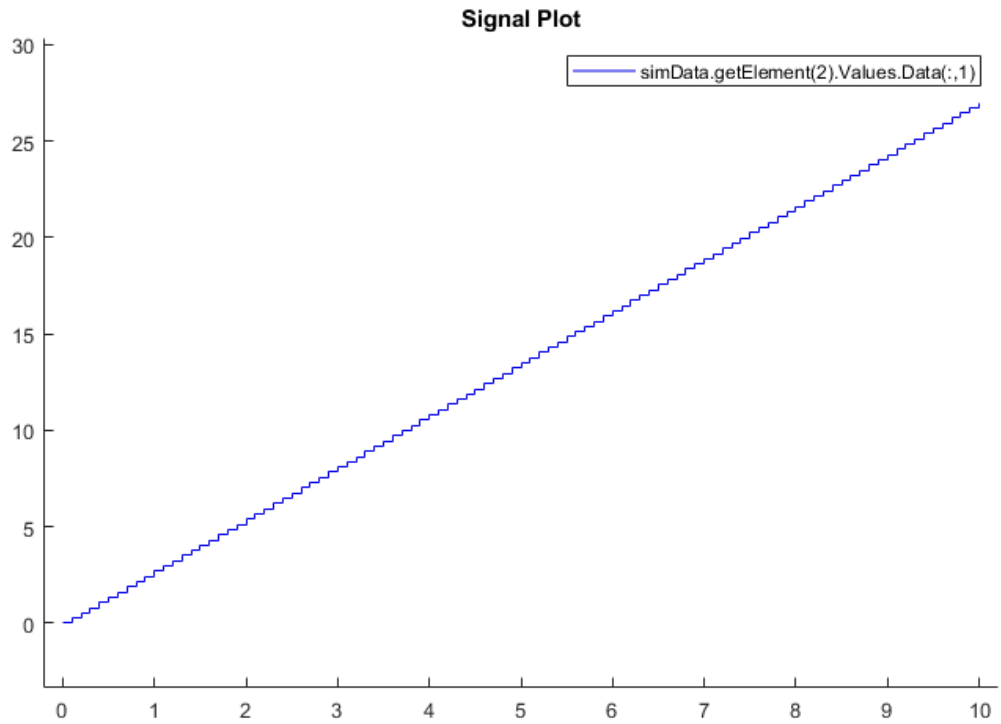
```
end

% Since a mismatch does not occur for these signals, a plot is not generated.
3 Signals match, 0 Signals mismatch
```

Additional Plotting Support

To create a plot of a list of signals, call cgv.CGV.plot. For example,

```
[signalNames, signalFigures] = cgv.CGV.plot( simData, ...
    'Signals', {'simData.getElement(2).Values.Data(:,1)'});
```



View Signal Data in the Simulation Data Inspector Tool

To open the Simulation Data Inspector tool, at the MATLAB® command line, enter Simulink.sdi.view. To import the signal data, in the Simulation Data Inspector tool, select

File > Import Data, which opens the Data Import tool. Select **Import from > Base workspace**, to view and select the signals saved in simData and silData.

Clear Your Workspace

Clear the variables from the workspace:

```
newBaseVars = who;
addedVars = setdiff( newBaseVars, baseVars);
clearCmd = ['clear ' sprintf( '%s ', addedVars{:})];
eval( clearCmd);
clear newBaseVars addedVars clearCmd
rtwdemoclean;
```

Numerical Consistency between Model and Generated Code

Numerical Consistency of Model and Generated Code Simulation Results

In this section...

Numerical Consistency

In the Model-Based Design workflow, you use MathWorks products to generate code for numerical applications that employ fixed-point and floating-point arithmetic.

- To develop models, you use MATLAB, Simulink, and Stateflow.
- To generate source code, you use Simulink Coder and Embedded Coder.
- To test numerical equivalence between your model and generated code, you compare model and generated code simulation results. For example, normal mode simulation results compared with software-in-the-loop (SIL) simulation results.

The results from the model and generated code simulations are numerically consistent if:

- In fixed-point applications, the results agree in a bit-wise comparison.
- In floating-point applications, the results agree with an error tolerance that you specify.

Use the Simulation Data Inspector to compare results. To determine whether discrepancies exist or are significant, you can specify absolute and relative tolerance values:

- For fixed-point applications, you can specify an absolute tolerance of zero.
- For floating-point applications, you can specify tolerance with respect to a reference value or signal. The choice of reference depends on your application. Consider these examples:
  - An algorithm that solves a linear algebraic equation by iterative, feed-forward error calculations. You can specify tolerance with respect to `eps`.

- A Proportional-Integral-Derivative (PID) controller for a closed-loop system. For transient behavior, you can specify tolerance with criteria from a standard. For steady-state behavior, you can specify tolerance with reference to the PID controller characteristics.

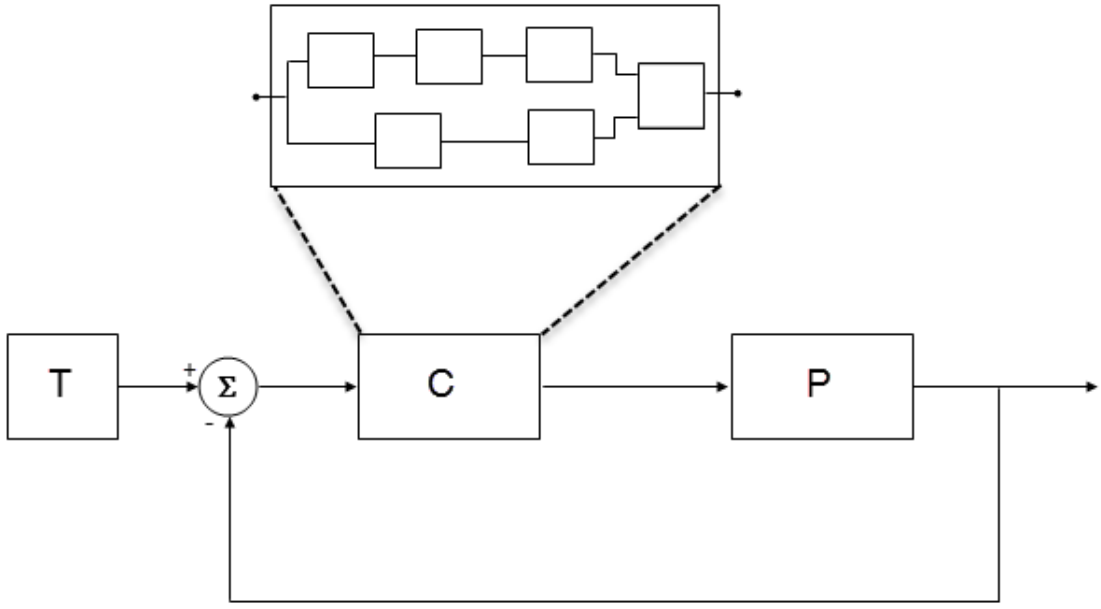
Programmatically, you can specify absolute and relative tolerance values through the `absTol` and `relTol` properties of the `Simulink.sdi.Signal` object.

Numerical Consistency in Complex Systems

For complex systems, numerical differences between model and generated code simulations can be a result of block-level differences propagating through the system. If you observe numerical differences at the system level:

1. Identify blocks for which block-level numerical differences exceed the error tolerance.
2. Investigate each identified block.

Consider the following plant-controller model.



- T produces reference or test signals.
- C is the controller component. The controller output is the plant input. C can be a Model block that comprises multiple Model blocks.
- P is the plant component. The plant output is subtracted from the reference signal to produce the controller input.

To test numerical equivalence between the model controller and the generated code version:

1. Run the model in normal mode, and, using the Simulation Data Inspector, record the output of C.
2. Specify SIL mode for C. Rerun the simulation, recording the output of C.
3. Using the Simulation Data Inspector, compare normal and SIL mode outputs with reference to your specified error tolerance.

If the Simulation Data Inspector comparison indicates a match, the model and generated code results are numerically consistent.

If the normal and SIL mode outputs do not match:

1. Within C, enable signal logging for block outputs.
2. Run the model in normal mode.
3. Rerun the simulation with C in SIL mode.
4. Using the Simulation Data Inspector, compare the logged output signals with reference to your specified error tolerance. See “Compare Simulation Data” (Simulink).
5. Identify blocks for which normal and SIL mode output differences exceed the error tolerance.
6. Analyze each identified block and look for the cause. For example, the generated code might use a different math library than MATLAB.

Note If the comparison of a large number of signals is required, you can automate the workflow with Simulink Test. See “Code Generation Verification Workflow” (Simulink Test).

Reasons for Block-Level Numerical Differences

In fixed-point and floating-point application development, there are factors that can affect numerical agreement between block-level results from model and generated code simulations.

Some factors can affect both fixed-point and floating-point applications. For example, the use of:

- Code generation optimization.
- Custom code.
- Code replacement library entries whose results differ from MATLAB results.
- Code replacement libraries that implement different algorithms.

Other factors affect only floating-point applications. For example:

- Numerical soundness of algorithm.

- Algorithm sensitivity to input.
- Closed loop and open loop behavior.

Software-in-the-Loop Execution for MATLAB Coder

Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution

MATLAB Coder supports software-in-the-loop (SIL) and processor-in-the-loop (PIL) execution, which enables you to verify production-ready source code and compiled object code. With these execution modes, you can reuse test vectors developed for your MATLAB functions to verify the numerical behavior of library code.

In SIL execution, through a MATLAB SIL interface, the software compiles and runs library code on your development computer. In PIL execution, through a MATLAB PIL interface, the software cross-compiles and runs production object code on a target processor or an equivalent instruction set simulator. Before you run a PIL execution, you must set up a PIL connectivity configuration for your target.

The workflow for generating and verifying code is:

1. Set up MATLAB Coder.
2. Fix errors detected at design time.
3. Generate MEX function.
4. Test MEX function.
5. Generate C/C++ library code.
6. Verify generated C/C++ code through SIL or PIL execution — requires Embedded Coder license.

In step 4, you verify code that is generated for execution within MATLAB. However, this code is different from the standalone code generated for libraries. In step 6, with an Embedded Coder license, you use SIL or PIL execution to verify the standalone code.

For more information, use the following table.

Software-in-the-Loop Execution with the MATLAB Coder App

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

1. To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
2. To open your project, click  , and then click `Open existing project`. Select the project. For example, `kalman_filter01.prj`.
3. On the **Generate Code** page, click the **Generate** arrow  .
4. In the **Generate** dialog box:
   a. Set **Build type** to `Static Library` or `Dynamic Library`.
   b. In the **Output file name** field, use the default value. For example, `kalman01`.
   c. Specify **Language**.
   d. Clear the **Generate code only** check box.
   e. In the **Hardware Board** field, use the default value (`MATLAB Host Computer`).

   You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.
5. To generate the C or C++ code, click **Generate**.
6. Click **Verify Code**.
7. In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
8. If required, select the **Enable source-level debugging for SIL** check box.
9. To start the SIL execution, click **Run Generated Code**.

   The MATLAB Coder app:

   - Generates a standalone library, for example, `codegen\lib\kalman01`.
   - Generates SIL interface code, for example, `codegen\lib\kalman01\sil`.
   - Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.

- Displays messages from the SIL execution in the **Test Output** tab.

10 Verify that the results from the SIL execution match the results from the original MATLAB functions.

11 To terminate the SIL execution process, click **Stop SIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows `To terminate execution`.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

Software-in-the-Loop Execution From Command Line

Use software-in-the-loop (SIL) execution to verify the numerical behavior of the generated C/C++ code with reference to your original MATLAB functions.

To set up and start a SIL execution from the command line:

1. Create a `coder.EmbeddedCodeConfig` object.
2. Configure the object for SIL.
3. Use the `codegen` function to generate library code for your MATLAB function and the SIL interface.
4. Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the SIL execution, use the `clear` *`function`*`_sil` or `clear mex` command.

The following example shows how you can set up and run a SIL execution from the command line.

SIL Execution of Code Generated for a Kalman Estimator

1 Copy MATLAB code for Kalman estimator

From *`docroot`*`\toolbox\coder\examples\kalman`, copy the following files to your working folder:

- `kalman01.m` — MATLAB function for the Kalman estimator
- `test01_ui.m` — MATLAB file to test `kalman01.m`
- `plot_trajectory.m` — File that plots actual target trajectory and Kalman estimator output
- `position.mat` — Input data

```
src_dir = ...
    fullfile(docroot,'toolbox','coder','examples','kalman');

copyfile(fullfile(src_dir,'kalman01.m'), '.')
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
```

For a description of the Kalman estimator in this example, see “Generate C Code at the Command Line” (MATLAB Coder).

2 Configure SIL execution

a From your working folder, create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
config.GenerateReport = true; % Optional, documents code in HTML report
```

b Configure the object for SIL.

```
config.VerificationMode = 'SIL';

% Check that production hardware setting is the default
% i.e. 'Generic->MATLAB Host Computer'
disp(config.HardwareImplementation.ProdHWDeviceType);
```

c If required, enable the Microsoft Visual Studio debugger for SIL execution:

```
config.SILDebugging = true;
```

3 Generate code and run SIL execution

Generate library code for the `kalman01` MATLAB function and the SIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_sil`, the generated SIL interface for `kalman01`.

```
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\sil` — SIL interface code for `kalman01`.

Verify that the output of this run matches the output from the original `kalman01.m` function.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

---

4 **Debug code during SIL execution**

If you enable the Microsoft Visual Studio debugger, then running the test file opens the Microsoft Visual Studio IDE with debugger breakpoints at the start of the `kalman01_initialize` and `kalman01` functions.

You can use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

a Remove all breakpoints.

b Click the **Continue** button (**F5**).

The SIL execution runs to completion.

5 **Terminate SIL execution**

Terminate the SIL execution process.

```
clear kalman01_sil;
```

You can also use the command `clear mex`, which clears MEX functions from memory.

More About

- “Code Verification Through Software-in-the-Loop and Processor-in-the-Loop Execution” on page 80-2

Debug Generated Code During SIL Execution

If a SIL execution fails or you notice differences between the outputs of your original functions and the generated code, you can rerun the SIL execution with a debugger enabled. By inserting breakpoints, you can observe the behavior of code sections, which might help you to understand the cause of the problem.

For a SIL execution failure, you can also view information from the standard output and standard error streams in the MATLAB Command Window. For example:

- Output from `printf` statements in your code.
- If you enable run-time error detection, messages sent to `stderr`.
- Some low-level system messages.

Note During a SIL execution, the SIL application redirects the `stdout` and `stderr` streams. When the application terminates, the MATLAB Command Window displays the information from the redirected streams. The SIL application also provides a basic signal handler, which captures the POSIX signals `SIGFPE`, `SIGILL`, `SIGABRT`, and `SIGSEV`. For this signal handler, the SIL application includes the file `signal.h`.

A SIL execution supports the following debuggers:

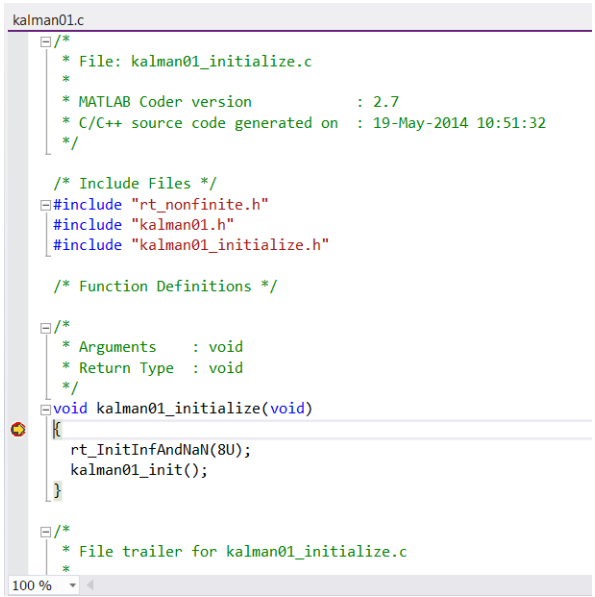
- On Windows, Microsoft Visual Studio debugger.
- On Linux, GNU Data Display Debugger (DDD).

Note You can perform SIL debugging only if your Microsoft Visual C++ or GNU GCC compiler is supported by the MATLAB product family. For more information, see supported compilers.

To run a SIL execution with debugging enabled:

1. On the **Generate Code** page, click **Verify Code**.
2. Select the **Enable source-level debugging for SIL** check box.
3. Click **Run Generated Code**.

On a Windows computer, your *user_fn*.c or *user_fn*.cpp file opens in the Microsoft Visual Studio IDE with debugger breakpoints at the start of the *user_fn*_initialize and *user_fn* functions.



You can now use the debugger features to observe code behavior. For example, you can step through code and examine variables.

To end the debugging session:

1. Remove all breakpoints.
2. Click the **Continue** button (**F5**).

   The SIL execution runs to completion.
3. To terminate the SIL execution process, on the **Test Output** tab, click the link that follows `To terminate execution`, for example, `clear kalman01_sil`.

   The Microsoft Visual Studio IDE closes automatically.

Note If you select **Debug** > **Stop Debugging**, the SIL execution times out with the following error message:

```
Communications error: failed to send data to the target. There might be
multiple reasons for this failure.

...
...
```

Create PIL Target Connectivity Configuration for MATLAB

In this section...

Target Connectivity Configurations for PIL

Use target connectivity configurations and the target connectivity API to customize processor-in-the-loop (PIL) execution for your target environments.

Through a target connectivity configuration, you specify:

- A target connectivity configuration name for a target connectivity API implementation.
- Settings that define compatible MATLAB code. For example, the code that is generated for a particular hardware implementation.

A PIL execution requires a target connectivity PIL API implementation that integrates third-party tools for:

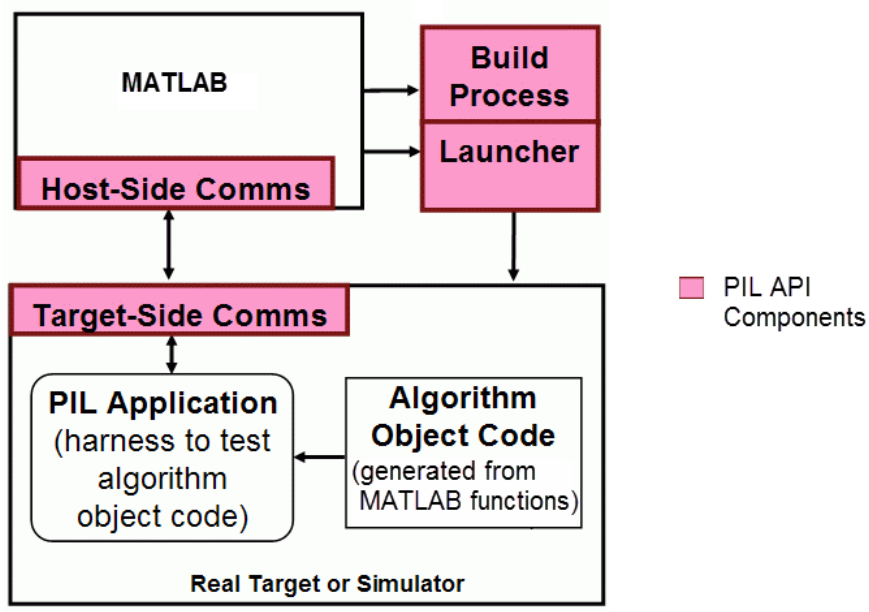
- Building the PIL application that runs on the target hardware
- Downloading, starting, and stopping the application on the target
- Communicating between MATLAB and the target

You can have many different connectivity configurations for PIL execution. Register a connectivity configuration with MATLAB by creating an `rtwTargetInfo.m` file and placing it on the MATLAB search path.

In a PIL execution, the software determines which of the available connectivity configurations to use. The software looks for a connectivity configuration that is compatible with the MATLAB code under test. If the software finds multiple or no compatible connectivity configurations, the software generates an error message with information about resolving the problem.

Create a Target Connectivity API Implementation

This diagram shows the components of the PIL target connectivity API.



You must provide implementations of the three API components:

- Build API — Specify a toolchain approach for building generated code.
- Launcher API — Control how MATLAB starts and stops the PIL executable.
- Communications API — Customize connectivity between MATLAB and the PIL target. Embedded Coder provides host-side support for TCP/IP and serial communications, which you can adapt for other protocols.

These steps outline how you create a target connectivity API implementation. The example code shown in the steps is taken from the `ConnectivityConfig.m` file used in “Processor-in-the-Loop Execution From Command Line” on page 80-28.

1. Create a subclass of `rtw.connectivity.Config`.

   ```
   ConnectivityConfig < rtw.connectivity.Config
   ```

2. In the subclass:

- Instantiate `rtw.connectivity.MakefileBuilder`, which configures the build process.

  ```
  builder = rtw.connectivity.MakefileBuilder(componentArgs, ...
                  targetApplicationFramework, ...
                  exeExtension);
  ```

- Create a subclass of `rtw.connectivity.Launcher`, which downloads and executes the application using a third-party tool.

  ```
  launcher = mypil.Launcher(componentArgs, builder);
  ```

3 Configure your `rtiostream` API implementation of the host-target communications on page 80-16 channel.

- For the target side, you must provide the driver code for communications, for example, code for TCP/IP or serial communications. To integrate this code into the build process, create a subclass of `rtw.pil.RtIOStreamApplicationFramework`.
- For the host side, you can use a supplied library for TCP/IP or serial communications. Instantiate `rtw.connectivity.RtIOStreamHostCommunicator`, which loads and initializes the library that you specify.

  ```
  hostCommunicator = rtw.connectivity.RtIOStreamHostCommunicator(...
                          componentArgs, ...
                          launcher, ...
                          rtiostreamLib);
  ```

4 If you require execution-time profiling of generated code, create a timer object that provides details of the hardware-specific timer and associated source files. See “Specify Hardware Timer” on page 80-22.

Register Target Connectivity Configuration

To register a target connectivity API implementation as a target connectivity configuration in MATLAB:

1 Create or update an `rtwTargetInfo.m` file. In this file:

- Create a target connectivity configuration object that specifies, for example, the configuration name for a target connectivity API implementation and compatible MATLAB code.
- Invoke `registerTargetInfo`.

2 Add the folder containing `rtwTargetInfo.m` to the search path and refresh the MATLAB Coder library registration information.

For more information, see `rtw.connectivity.ConfigRegistry`.

Verify Target Connectivity Configuration

To verify your target connectivity configuration early on and independently of your algorithm development and code generation, use the `piltest` function. With the function, you can run a suite of tests. The function:

- Runs the MATLAB function and performs PIL executions.
- Compares results and produces errors if it detects differences.

For an example, see “PIL Execution of Code Generated for a Kalman Estimator” on page 80-28.

Host-Target Communication for PIL

In this section...

Communications rtiostream API

The `rtiostream` API supports communications for the target connectivity API. Use the `rtiostream` API to implement a communication channel that enables data exchange between different processes.

PIL verification requires a host-target communications channel. This communications channel comprises driver code that runs on the host and target. The `rtiostream` API defines the signature of target-side and host-side functions that must be implemented by this driver code.

The API is independent of the physical layer that sends the data. Possible physical layers include RS232, Ethernet, or Controller Area Network (CAN).

A full `rtiostream` implementation requires both host-side and target-side drivers. Code generation software includes host-side drivers for the default TCP/IP implementation as well as a version for serial communications. To use:

- The TCP/IP `rtiostream` communications channel, you must provide, or obtain from a third party, target-specific TCP/IP device drivers.
- The serial communications channel, you must provide, or obtain from a third party, target-specific serial device drivers.

For other communication channels and platforms, the code generation software does not provide default implementations. You must provide both the host-side and the target-side drivers.

The `rtiostream` API comprises the following functions:

- `rtIOStreamOpen`
- `rtIOStreamSend`

- `rtIOStreamRecv`
- `rtIOStreamClose`

For information about:

- Using `rtiostream` functions in a connectivity implementation, see “Create a Target Connectivity API Implementation” on page 80-13.
- Testing the `rtiostream` shared library methods from MATLAB code, see `rtiostream_wrapper`.
- Debugging and verifying the behavior of custom `rtiostream` interface implementations, see “Test an rtiostream Driver” on page 80-18.

Synchronize Host and Target

If you use the `rtiostream` API to implement the communications channel, the host and target must be synchronized, which prevents MATLAB from transmitting and receiving data before the target application is fully initialized.

To synchronize the host and target for TCP/IP rtiostream implementations, use the `setInitCommsTimeout` method from `rtw.connectivity.RtIOStreamHostCommunicator`. This approach works well for connection-oriented TCP/IP `rtiostream` implementations because MATLAB automatically waits until the target server is running.

With other `rtiostream` implementations, for example, serial, the MATLAB side of the `rtiostream` connection opens without waiting for the target to be fully initialized. In this case, you must make your `Launcher` implementation wait until the target application is fully initialized. Use one of the following approaches to synchronize your host and target:

- Add a pause at the end of the `Launcher` implementation that makes the `Launcher` wait until target initialization is complete.
- In the `Launcher` implementation, use third-party downloader or debugger APIs that wait until target initialization is complete.
- Implement a handshaking mechanism in the `Launcher` / `rtiostream` implementation that confirms completion of target initialization.

Test an rtiostream Driver

Use a test suite to debug and verify the behavior of custom `rtiostream` interface implementations.

The test suite has the following advantages:

- Reduces time for integrating custom hardware that does not have built-in `rtiostream` support.
- Reduces time for testing custom `rtiostream` drivers.
- Helps analyze the performance of custom `rtiostream` drivers.

The test suite has two parts. One part of the test suite runs on the target.

Note After building the target application, download it to the target and run it.

To start this part, compile and link the following files, which are in the folder *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtest` (open).

- `rtiostreamtest.c`
- `rtiostreamtest.h`
- `rtiostream.h`, located in the folder *`matlabroot`*`/toolbox/coder/rtiostream/src` (open)
- `rtiostream` implementation under investigation (for example, `rtiostream_tcpip.c`)
- `main.c`

To run the MATLAB part of the test suite, invoke `rtiostreamtest`. The syntax is as follows:

```
rtiostreamtest(connection,param1,param2)
```

- `connection` is a character vector indicating the communication method. It can have values `'tcp'` or `'serial'`.
- `param1` and `param2` have different values depending on the value of `connection`.
  - If `connection` is `'tcp'`, then `param1` and `param2` are hostname and port, respectively. For example, `rtiostreamtest('tcp', 'localhost', 2345)`.

- If `connection` is `'serial'`, then `param1` and `param2` are COM port and baud rate, respectively. For example, `rtiostreamtest('serial', 'COM1', 9600)`.

You can run the MATLAB part of the test suite as follows:

```
rtiostreamtest('tcp','localhost','2345')
```

An output in the following format appears in the MATLAB window:

```
### Test suite for rtiostream ###
Initializing connection with target...

### Hardware characteristics discovered
Size of char    : 8 bit
Size of short   : 16 bit
Size of int     : 32 bit
Size of long    : 32 bit
Size of float   : 32 bit
Size of double  : 64 bit
Size of pointer : 64 bit
Byte ordering   : Little Endian

### rtiostream characteristics discovered
Round trip time : 0.96689 ms
rtIOStreamRecv behavior : non-blocking

### Test results
Test 1 (fixed size data exchange): ......... PASS
Test 2 (varying size data exchange): ......... PASS

### Test suite for rtiostream finished successfully ###
```

Furthermore, the following profile appears.

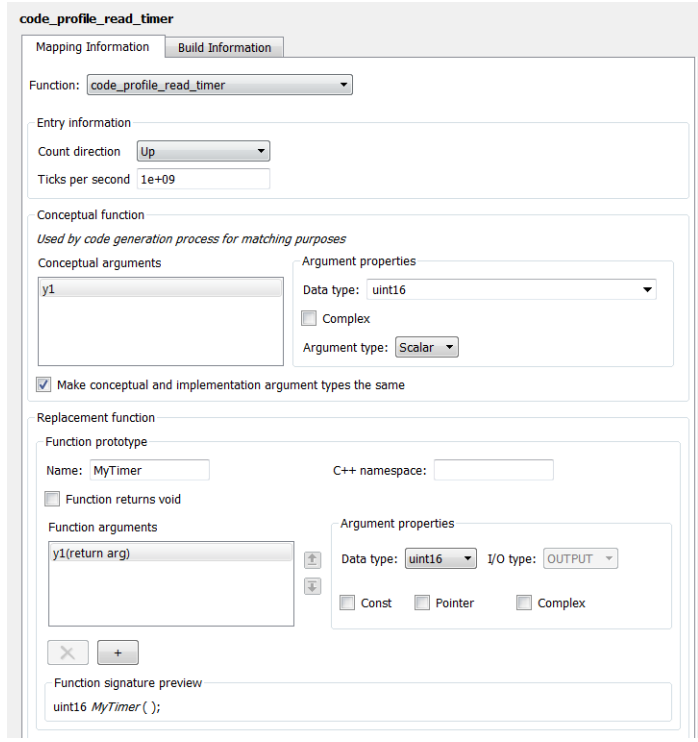
Specify Hardware Timer

For processor-in-the-loop (PIL) code execution profiling, you must create a timer object that provides details of the hardware-specific timer and associated source files. You can use the **Code Replacement Tool** or the code replacement library API to specify this hardware-specific timer.

To specify the timer with the Code Replacement Tool:

1. Open the Code Replacement Tool. In the Command Window, enter `crtool`.
2. Create a new code replacement table. Select **File** > **New table**.
3. Create a new function entry. Under **Tables List**, right-click the new table. Then, from the context-menu, select **New entry** > **Function**.
4. In the middle view, select the new unnamed function.
5. On the **Mapping Information** pane:
   a. From the **Function** drop-down list, select `code_profile_read_timer`.
   b. Specify the count direction for your timer. For example, from the **Count direction** drop-down list, select `Up`.
   c. In the **Ticks per second** field, specify the number of ticks per second for your timer, for example, `1e+09`.

      The default value is 0. In this case, the software reports time measurements in terms of ticks, not seconds.
   d. In the **Name** field, specify a replacement function name, for example, `MyTimer`.
   e. Click **Apply**.



f To validate the function entry, click **Validate entry**.

6 On the **Build Information** pane, specify the required build information. See “Specify Build Information for Replacement Code” on page 65-62.

7 Save the table (**Ctrl+S**). When you save the table for the first time, use the Save As dialog box to specify the file name and location.

You must save the table in a location that is on the MATLAB search path. For example, you can save this file in the folder for your subclass of `rtw.connectivity.Config`.

The software stores your timer information as a code replacement library table.

8 Assuming you save the table as *`MyCrlTable`*`.m`, in your subclass of `rtw.connectivity.Config`, add the following line:

```
setTimer(this, MyCrlTable)
```

- “What Is Code Replacement Customization?” on page 65-3

Processor-in-the-Loop Execution with the MATLAB Coder App

Use processor-in-the-loop (PIL) execution to verify the numerical behavior of cross-compiled object code with reference to your original MATLAB functions.

Before you run a PIL execution, you must define a target connectivity configuration. In “Processor-in-the-Loop Execution From Command Line” on page 80-28, steps 1 and 2 of the example PIL Execution of Code Generated for a Kalman Estimator show how you can set up and register a connectivity configuration for PIL execution on your development computer.

1. To open the MATLAB Coder app, on the MATLAB Toolstrip **Apps** tab, under **Code Generation**, click the app icon.
2. To open your project, click  , and then click `Open existing project`. Select the project. For example, `kalman_filter.prj`.
3. On the **Generate Code** page, click the **Generate** arrow  .
4. In the **Generate** dialog box:
   a. Set **Build type** to `Static Library` or `Dynamic Library`.
   b. In the **Output file name** field, use the default value. For example, `kalman01`.
   c. Clear the **Generate code only** check box.
   d. From the **Hardware Board** drop-down list, select `None - Select device below`.
   e. In the **Device** fields, specify vendor and type. These settings must match the target hardware settings in the `rtwTargetInfo.m` file of your target connectivity configuration. For host-based PIL, select settings that match your host computer. For example:
      - For a Windows 64-bit system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Windows64)`. In addition, set **Enable long long** to `Yes`.
      - For a Linux 64-bit system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Linux 64)`.
      - For a Mac OS X system, set **Device vendor** to `Intel` and **Device type** to `x86-64 (Mac OS X)`.

You do not have to specify the **Toolchain** setting. By default, the MATLAB Coder app locates an installed toolchain.

5. To generate the C or C++ code, click **Generate**.
6. Click **Verify Code**.
7. In the command field, specify the test file that calls the original MATLAB functions, for example, `test01_ui.m`.
8. To start the PIL execution, click **Run Generated Code**.

   The MATLAB Coder app:

   - Generates a standalone library, for example, `codegen\lib\kalman01`.
   - Generates PIL interface code, for example, `codegen\lib\kalman01\pil`.
   - Runs the test file, replacing calls to the MATLAB function with calls to the generated code in the library.
   - Displays messages from the PIL execution in the **Test Output** tab.
9. Verify that the results from the PIL execution match the results from the original MATLAB functions.
10. To terminate the PIL execution process, click **Stop PIL Verification**. Alternatively, on the **Test Output** tab, click the link that follows `To terminate execution`.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

Processor-in-the-Loop Execution From Command Line

Use processor-in-the-loop (PIL) execution to verify code that you intend to deploy in production.

To set up and start a PIL execution from the command line:

1. Create, register, and verify your target connectivity configuration.
2. Create a `coder.EmbeddedCodeConfig` object.
3. Configure the object for PIL.
4. Use the `codegen` function to generate library code for your MATLAB function and the PIL interface.
5. Use the `coder.runTest` function to run the test file for your original MATLAB function.

To terminate the PIL execution, use the `clear` *`function`*`_pil` or `clear mex` command.

The following example shows how you can use line commands to set up and run a PIL execution on your development computer.

PIL Execution of Code Generated for a Kalman Estimator

1 Create a target connectivity API implementation

a In your current working folder, make a local copy of the connectivity classes.

```
src_dir = ...
    fullfile(matlabroot,'toolbox','coder','simulinkcoder','+coder','+mypil');
if exist(fullfile('.','+mypil'),'dir')
    rmdir('+mypil','s')
end
mkdir +mypil
copyfile(fullfile(src_dir,'Launcher.m'), '+mypil');
copyfile(fullfile(src_dir,'TargetApplicationFramework.m'), '+mypil');
copyfile(fullfile(src_dir,'ConnectivityConfig.m'), '+mypil');
```

b Make the copied files writable.

```
fileattrib(fullfile('+mypil', '*'),'+w');
```

c Update the package name to reflect the new location of the files.

```
coder.mypil.Utils.UpdateClassName(...
    './+mypil/ConnectivityConfig.m',...
    'coder.mypil',...
    'mypil');
```

d Check that you now have a folder `+mypil` in the current folder, which includes three files, `Launcher.m`, `TargetApplicationFramework.m`, and `ConnectivityConfig.m`.

```
dir './+mypil'
```

e Review the code that starts the PIL application. The `mypil.Launcher` class configures a tool for starting the PIL executable. Open this class in the editor.

```
edit(which('mypil.Launcher'))
```

Review the content of this file. For example, consider the `setArgString` method. This method allows additional command line parameters to be supplied to the application. These parameters can include a TCP/IP port number. For an embedded processor implementation, you might have to hard code these settings.

f The class `mypil.ConnectivityConfig` configures target connectivity.

```
edit(which('mypil.ConnectivityConfig'))
```

Review the content of this file. For example:

- The creation of an instance of `rtw.connectivity.RtIOStreamHostCommunicator` that configures the host side of the TCP/IP communications channel.
- A call to the `setArgString` method of `Launcher` that configures the target side of the TCP/IP communications channel.
- A call to `setTimer` that configures a timer for execution time measurement. To define your own target-specific timer for execution time profiling, you must use the Code Replacement Library to specify a replacement for the function `code_profile_read_timer`.

g Review the target-side communication drivers.

```
rtiostreamtcpip_dir=fullfile(matlabroot,'toolbox','coder','rtiostream','src',...
    'rtiostreamtcpip');
edit(fullfile(rtiostreamtcpip_dir,'rtiostream_tcpip.c'))
```

Scroll down to the end of this file. The file contains a TCP/IP implementation of the functions `rtIOStreamOpen`, `rtIOStreamSend`, and`rtIOStreamRecv`.

These functions are required for target communication with the host. For each of these functions, you must provide an implementation that is specific to your target hardware and communication channel.

The `mypil.TargetApplicationFramework` class adds target-side communication drivers to the connectivity configuration.

```
edit(which('mypil.TargetApplicationFramework'))
```

The file specifies additional files to include in the build.

2 Register a target connectivity configuration

Use an `rtwTargetInfo.m` file to:

- Create a target connectivity configuration object.
- Invoke `registerTargetInfo`, which registers the target connectivity configuration.

The target connectivity configuration object specifies, for example:

- The configuration name and associated API implementation. See `rtw.connectivity.ConfigRegistry`.
- A toolchain for your target hardware. This example assumes that the target hardware is your host computer, and uses the toolchain supplied for host-based PIL verification. For information about toolchains, see “Custom Toolchain Registration” (MATLAB Coder).

a Insert the following code into your `rtwTargetInfo.m` file, and save the file in the current working folder or in a folder that is on the MATLAB search path:

```
function rtwTargetInfo(tr)
% Register PIL connectivity config: mypil.ConnectivityConfig

tr.registerTargetInfo(@loc_createConfig);

% local function
function config = loc_createConfig

% Create object for connectivity configuration
config = rtw.connectivity.ConfigRegistry;
% Assign connectivity configuration name
config.ConfigName = 'My PIL Example';
% Associate the connectivity configuration with the connectivity
```

```
% API implementation
config.ConfigClass = 'mypil.ConnectivityConfig';

% Specify toolchains for host-based PIL
config.Toolchain =  rtw.connectivity.Utils.getHostToolchainNames;

% Through the HardwareBoard and TargetHWDeviceType properties,
% define compatible code for the target connectivity configuration
config.HardwareBoard = {};  % Any hardware board
config.TargetHWDeviceType = {'Generic->32-bit x86 compatible' ...
                             'Generic->Custom' ...
                             'Intel->x86-64 (Windows64)', ...
                             'Intel->x86-64 (Mac OS X)', ...
                             'Intel->x86-64 (Linux 64)'};
```

b Refresh the MATLAB Coder library registration information.

```
RTW.TargetRegistry.getInstance('reset');
```

3 Verify target connectivity configuration

Use the supplied `piltest` function to verify your target connectivity configuration.

a Create a `coder.EmbeddedCodeConfig` object for verifying the target connectivity configuration.

```
configVerify = coder.config('lib');
```

b Specify the manufacturer and test hardware type. For example, PIL execution on a 64-bit Windows development computer requires:

```
configVerify.HardwareImplementation.TargetHWDeviceType =...
   'Intel->x86-64 (Windows64)';
configVerify.HardwareImplementation.ProdLongLongMode = true;
```

c Run `piltest`.

```
piltest(configVerify, 'ConfigParam', {'ProdLongLongMode'} )
```

4 Copy MATLAB code for Kalman estimator

Copy the MATLAB code to your working folder.

```
src_dir = ...
    fullfile(docroot,'toolbox','coder','examples','kalman');

copyfile(fullfile(src_dir,'kalman01.m'), '.')
```

```
copyfile(fullfile(src_dir,'test01_ui.m'), '.')
copyfile(fullfile(src_dir,'plot_trajectory.m'), '.')
copyfile(fullfile(src_dir,'position.mat'), '.')
```

For a description of the Kalman estimator in this example, see “Generate C Code at the Command Line” (MATLAB Coder).

5 Configure the PIL execution

a Create a `coder.EmbeddedCodeConfig` object.

```
config = coder.config('lib');
```

b Configure the object for PIL.

```
config.VerificationMode = 'PIL';
```

c Specify production hardware, which must match one of the test hardware settings in `rtwTargetInfo.m`. For PIL execution on your development computer, specify settings that match the computer. For example, if your computer is a Windows 64-bit system, specify:

```
config.HardwareImplementation.ProdHWDeviceType =...
   'Intel->x86-64 (Windows64)';
config.HardwareImplementation.ProdLongLongMode = true;
```

For a Linux 64-bit system, set `ProdHWDeviceType` to `'Intel->x86-64 (Linux 64)'`.

For a Mac OS X system, set `ProdHWDeviceType` to `'Intel->x86-64 (Mac OS X)'`.

6 Generate code and run PIL execution

Generate library code for the `kalman01` MATLAB function and the PIL interface, and run the MATLAB test file, `test01_ui`. The test file uses `kalman01_pil`, the generated PIL interface for `kalman01`.

```
codegen -config config -args {zeros(2,1)} kalman01 -test test01_ui
```

The software creates the following output folders:

- `codegen\lib\kalman01` — Standalone code for `kalman01`.
- `codegen\lib\kalman01\pil` — PIL interface code for `kalman01`.

Verify that the output of this run matches the output from the original `kalman01.m` function.

Note On a Windows operating system, the Windows Firewall can potentially block a SIL or PIL execution. To allow the execution, use the Windows Security Alert dialog box. For example, in Windows 7, click **Allow access**.

7 Terminate PIL execution

Terminate the PIL execution process.

```
clear kalman01_pil;
```

Verification of Code Generation Assumptions

The settings on the **More Settings** > **Hardware** tab specify target behavior, which result in the implementation of implicit assumptions in the generated code. Incorrect settings can lead to:

- Suboptimal code
- Code execution failure, incorrect code output, and nondeterministic code behavior

At the start of a processor-in-the-loop (PIL) execution, the software verifies the **Hardware** tab settings with reference to the target hardware. The software checks:

- The correctness of settings. For example, the integer bit length in the **Sizes** > **int** field.
- Whether the settings are optimized. For example, the rounding of signed integer division in the **Signed integer division rounds to** field.

If required, the software generates warnings and errors.

SIL/PIL Execution Support and Limitations

Feature		Supported
Output types	Static library	Yes
	Dynamic library	Yes
	Executable	No
Languages	C	Yes
	C++	Yes
Interface types	Inputs	Yes
	Outputs	Yes
	Constant inputs	Yes

Feature		Supported
	Global data	Yes. SIL and PIL execution supports four types of storage classes on page 90-2 for MATLAB Coder global variables. The synchronization (MATLAB Coder) of global data between MATLAB and the SIL or PIL application depends on the type of storage class that you specify: • `ExportedGlobal` (default) — The synchronization of global data between MATLAB and a SIL or PIL application is identical to the synchronization between MATLAB and a MEX function. • `ExportedDefine` — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses the values of the global variables in MATLAB at the time of code generation. • `ImportedExtern` and `ImportedExternPointer` — There is no synchronization of global data between MATLAB and the SIL or PIL application. The application uses initial values of global variables, which you specify in the external code. If the global variables are not initialized in the external code, the SIL or PIL execution results are undefined.
	Constant global data	Yes
	Reentrant code	Yes

Feature		Supported
	Multiple entry points	Yes
Data types	Basic types	Yes
	Enumerated types	Yes
	Structures	Yes
	Complex data	Yes
	Fixed-point data	Yes
	Multiword fixed-point data	SIL only
	`char` arrays	Yes
	Empty values	Yes
	Cell arrays	Yes
Size	Scalars	Yes
	Fixed-size arrays	Yes
	Static variable-size arrays	Yes
	Dynamic variable-size size arrays	Yes

Speed Up SIL/PIL Execution by Disabling Constant Input Checking and Global Data Synchronization

By default, a SIL or PIL execution performs constant input checking and global data synchronization. Constant input checking compares the value that a test file provides for a constant input argument with the value specified at code generation time. If the values do not match, an error occurs. Global data synchronization makes the values of global variables in the SIL or PIL execution environment consistent with the values in the MATLAB workspace. If a global variable is constant and its value in the SIL or PIL execution environment differs from its value in the MATLAB workspace, an error occurs.

It is possible to speed up a SIL or PIL execution by disabling constant input checking or global data synchronization. However, if you disable these features, the SIL or PIL execution results might differ from the results in MATLAB.

Disable Constant Input Checking or Global Data Synchronization at the Command Line

In a `coder.EmbeddedCodeConfig` object that you configured for SIL or PIL execution:

- To disable constant input checking, set the `SILPILCheckConstantInputs` property to `false`. For example, for an object `cfg`, use this code:

  ```
  cfg.SILPILCheckConstantInputs = false;
  ```

- To disable global data synchronization, set the `SILPILSyncGlobalData` property to `false`. For example, for an object `cfg`, use this code:

  ```
  cfg.SILPILSyncGlobalData = false;
  ```

Disable Constant Input Checking or Global Data Synchronization in the MATLAB Coder App

In the settings for a project that you set up for SIL or PIL execution, on the **Debugging** tab:

- To disable constant input checking, set **Check constant inputs in SIL/PIL** to `No`.
- To disable global data synchronization, set **Synchronize global data in SIL/PIL** to `No`.

Code Coverage in Embedded Coder

Simulink Code Coverage Metrics

In this section...

If you have a Simulink Coverage license, you can run a SIL or PIL simulation that produces code coverage metrics for generated model code. The simulation performs several types of code coverage analysis.

Statement Coverage for Code Coverage

Statement coverage determines the number of source code statements that execute when the code runs. Use this type of coverage to determine whether every statement in the program has been invoked at least once.

Statement coverage = (Number of executed statements / Total number of statements) *100

Statement Coverage Example

This code snippet contains five statements. To achieve 100% statement coverage, you need at least three test cases. Specifically, tests with positive *x* values, negative *x* values, and *x* values of zero.

```
if (x > 0)
  printf( "x is positive" );
else if (x < 0)
  printf( "x is negative" );
else
  printf( "x is 0" );
```

Condition Coverage for Code Coverage

Condition coverage analyzes statements that include conditions in source code. Conditions are C/C++ Boolean expressions that contain relation operators (<, >, <=, or >=), equation operators (!= or ==), or logical negation operators (!), but that do not contain logical operators (&& or ||). This type of coverage determines whether every condition has been evaluated to all possible outcomes at least once.

Condition coverage = (Number of executed condition outcomes / Total number of condition outcomes) *100

Condition Coverage Example

In this expression:

```
y = x<=5 && x!=7;
```

there are these conditions:

```
x<=5
x!=7
```

Decision Coverage for Code Coverage

Decision coverage analyzes statements that represent decisions in source code. Decisions are Boolean expressions composed of conditions and one or more of the logical C/C++ operators && or ||. Conditions within branching constructs (if/else, while, do-while) are decisions. Decision coverage determines the percentage of the total number of decision outcomes the code exercises during execution. Use this type of coverage to determine whether all decisions, including branches, in your code are tested.

Note The decision coverage definition for DO-178C compliance differs from the Simulink Coverage definition. For decision coverage compliance with DO-178C, select the `Condition Decision` structural coverage level for Boolean expressions not containing && or || operators.

Decision coverage = (Number of executed decision outcomes / Total number of decision outcomes) *100

Decision Coverage Example

This code snippet contains three decisions:

```
y = x<=5 && x!=7;                // decision #1

if( x > 0 )                     // decision #2
  printf( "decision #2 is true" );
else if( x < 0 && y )                // decision #3
  printf( "decision #3 is true" );
else
  printf( "decisions #2 and #3 are false" );
```

Modified Condition/Decision Coverage (MCDC) for Code Coverage

Modified condition/decision coverage (MCDC) is the extent to which the conditions within decisions are independently exercised during code execution.

- All conditions within decisions have been evaluated to all possible outcomes at least once.
- Every condition within a decision independently affects the outcome of the decision.

MCDC coverage = (Number of conditions evaluated to all possible outcomes affecting the outcome of the decision / Total number of conditions within the decisions) *100

Modified Condition/Decision Coverage Example

For this decision:

```
X || ( Y && Z )
```

the following set of test cases delivers 100% MCDC coverage.

	X	Y	Z
Test case #1	0	0	1
Test case #2	0	1	0
Test case #3	0	1	1
Test case #4	1	0	1

Cyclomatic Complexity for Code Coverage

Cyclomatic complexity is a measure of the structural complexity of code that uses the McCabe complexity measure. To compute the cyclomatic complexity of code, code coverage uses this formula:

$$c = \sum_{1}^{N} (o_n - 1)$$

N is the number of decisions in the code. o_n is the number of outcomes for the n^{th} decision point. Code coverage adds 1 to the complexity number for each C/C++ function.

Coverage Example

For this code snippet:

```
void evalNum( int x ){

    if (x > 0)
      printf( "x is positive" );
    else if (x < 0)
      printf( "x is negative" );
    else
  printf( "x is 0" );
}
```

the cyclomatic complexity is 3.

Relational Boundary for Code Coverage

Relational boundary code coverage examines code that has relational operations. Relational boundary code coverage metrics align with those for model coverage, as described in “Relational Boundary Coverage” (Simulink Coverage). Fixed-point values in your model are integers during code coverage.

See Also

Related Examples

- “Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode” on page 81-7

Code Coverage for Models in Software-in-the-Loop (SIL) Mode and Processor-in-the-Loop (PIL) Mode

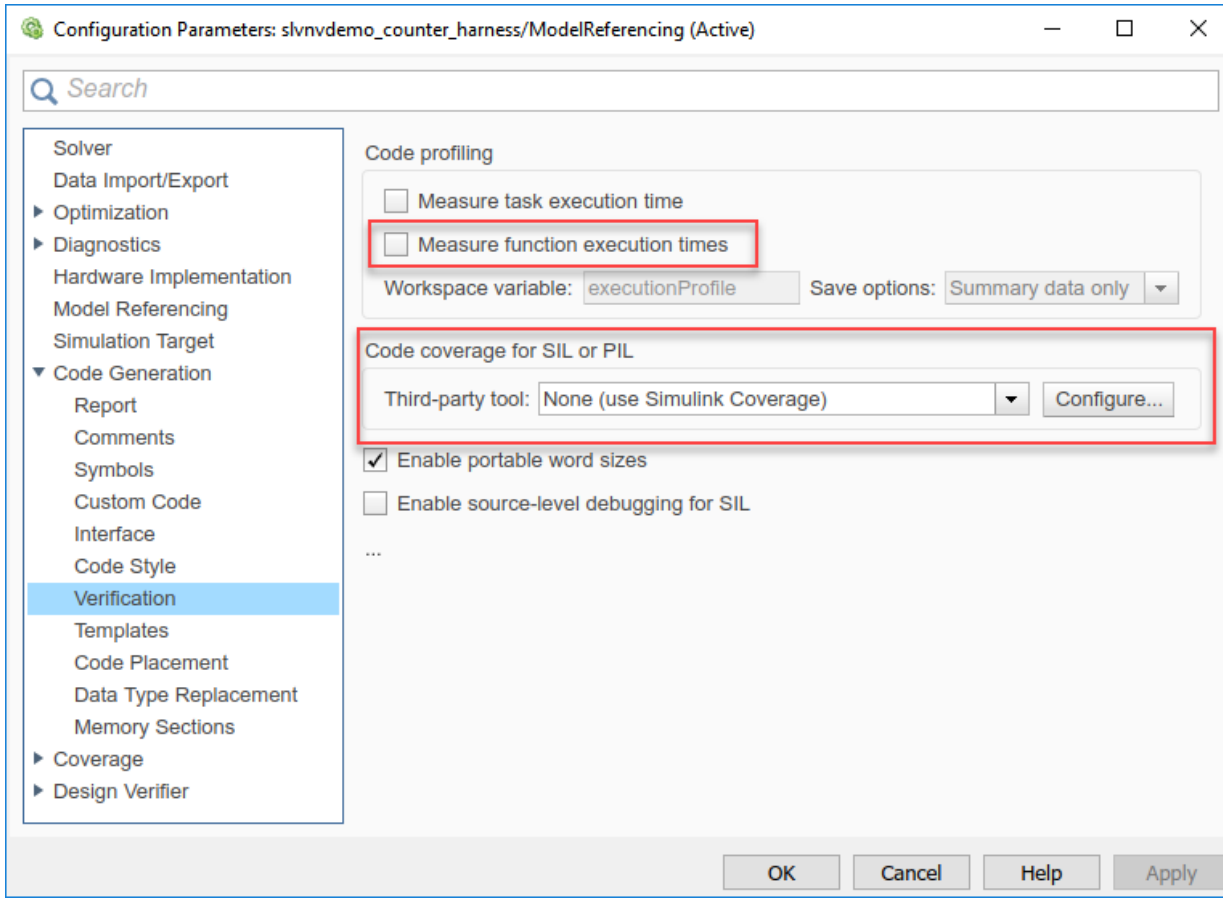
If you have Embedded Coder and Simulink Coverage, you can analyze coverage for generated code during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation.

In this section...

Enable SIL or PIL Code Coverage for a Model

To record SIL or PIL code coverage for a model:

1. In the Configuration Parameters dialog box, on the left pane, click **Code Generation**. From the list, select **Verification**.
2. Under **Code profiling**, clear **Measure function execution times**.
3. Under **Code coverage for SIL or PIL**, for the **Third-party tool** select `None (use Simulink Coverage)`.



Simulink Coverage Code Coverage Measurement Workflows

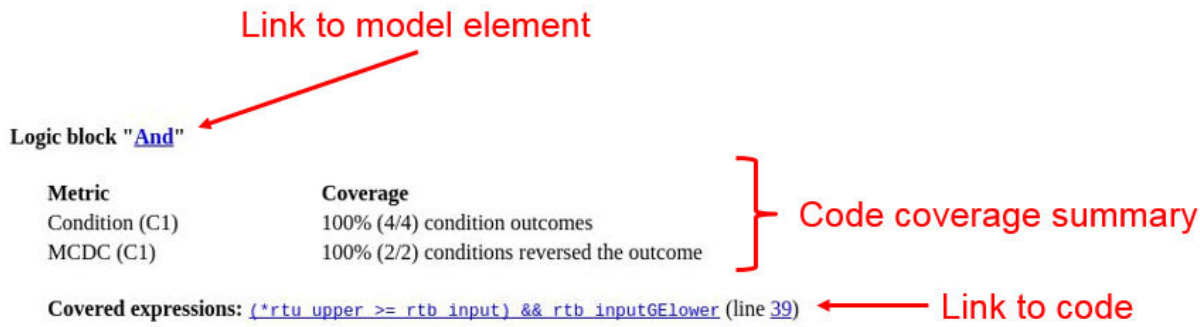
To measure code coverage, use either of these workflows:

- The top model is in SIL mode or PIL mode. Simulink Coverage measures code coverage for the top model, depending `RecordCoverage`. Simulink Coverage also measures code coverage for referenced models, depending on `CovModelRefEnable`.
- The top model is in Normal mode and contains at least one reference model in SIL or PIL mode. Simulink Coverage measures code coverage for the referenced model if

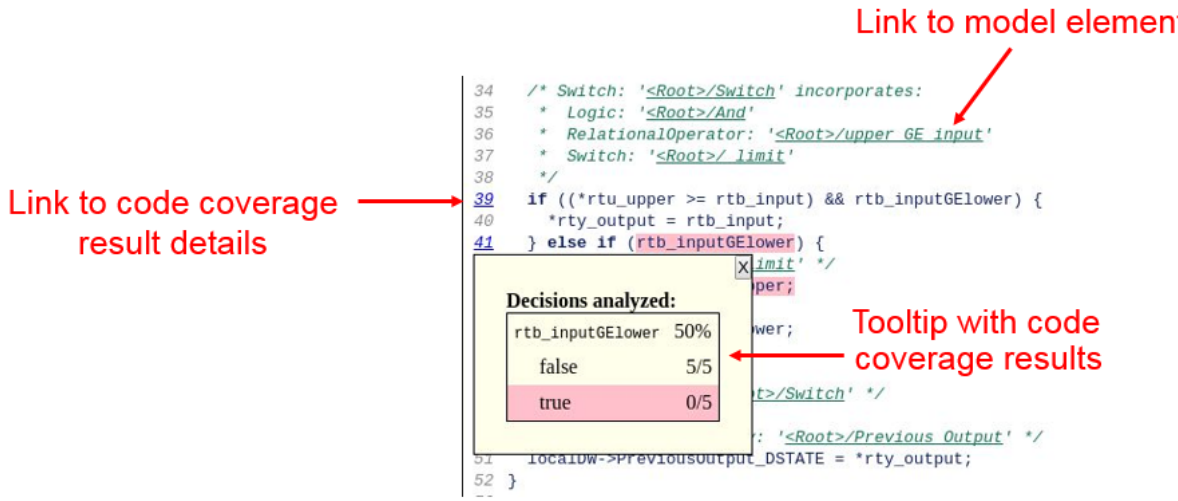
`CovModelRefEnable` is `'on'`, `'all'`, or `'filtered'` and `RecordCoverage` is `'off'`.

Review the Coverage Results for Models in SIL or PIL Mode

In the code coverage report, each hyperlink opens a report with more details on the coverage analysis for the model. The code coverage results in these reports are similar to the coverage results for C/C++ code in S-function blocks, as described in “View Coverage Results for Custom C/C++ Code in S-Function Blocks” (Simulink Coverage). You can navigate from code coverage results to the associated model blocks by using the links within the detailed code coverage reports.



Each detailed code coverage report also contains syntax highlighted code with coverage information.



Limitations

Coverage for models in SIL and PIL mode has these limitations:

- The model must meet the requirements listed in “Enable SIL or PIL Code Coverage for a Model” on page 81-7.
- Code coverage results must not include external C/C++ files in read-only folders.

See Also

Related Examples

- “Software-in-the-Loop Code Coverage” (Simulink Coverage)

Configure Code Coverage with Third-Party Tools

During a top-model or Model block SIL or PIL simulation, you can collect code coverage metrics for generated code using a third-party tool. Embedded Coder supports the following tools:

- LDRA Testbed from LDRA Software Technology. For information about installing and using this tool, go to www.ldra.com.

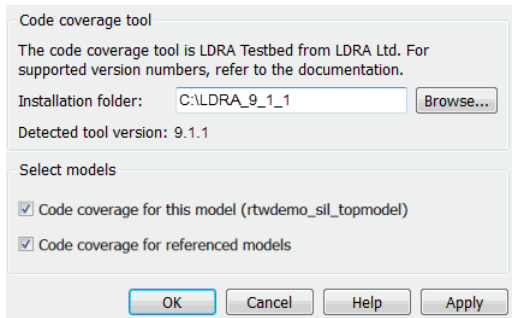
  The software supports LDRA Testbed code coverage for SIL and PIL.

- BullseyeCoverage from Bullseye Testing Technology. For information about installing and using this tool, go to www.bullseye.com.

  The software supports BullseyeCoverage code coverage for SIL and, in certain cases, PIL.

To configure a code coverage tool for a top-model or Model block SIL or PIL simulation:

1. Select **Simulation > Model Configuration Parameters > Code Generation > Verification**.
2. From the **Third-party tool** drop-down list, select a tool, for example, `BullseyeCoverage` or `LDRA Testbed`.
3. Click **Configure** to open the Code Coverage Settings dialog box.
4. In the **Installation folder** field, specify the location where your coverage tool is installed. If you click **Browse**, the Select Installation Folder dialog box opens, which allows you to navigate to the folder where your coverage tool is installed. The software detects and displays the tool version.



By default, the following parameters are enabled:

- **Code coverage for this model** — Generate coverage data for the current (top) model.
- **Code coverage for referenced models** — Generate data for models referenced by the current (top) model.

If your top model has Model blocks, these parameters of the top model override the corresponding parameters of referenced models.

5 Click **OK**. You return to the **Verification** pane.

6 To view cumulative code coverage results within a code generation report, in the **Configuration Parameters > Code Generation > Report** pane, select the following check boxes:

- **Create code generation report**
- **Open report automatically**

7 Click **OK**. You return to the model window.

With LDRA Testbed:

- The evaluation of cumulative code coverage begins from the point when you last added a new file to the existing set of source files. For example, existing code coverage results are deleted when you:
  - Run a simulation with a new model using the existing code generation folder.
  - Run a simulation that results in additional source code files being instrumented.
- If you switch between SIL and PIL simulations of a model, the software generates separate cumulative code coverage results for the SIL and PIL simulations.

For a model in a reference hierarchy, the software does not support simultaneous function execution time measurement and code coverage.

View Code Coverage Information at the End of SIL or PIL Simulations

In this section...

If you configure third-party code coverage for a SIL or PIL simulation, when the simulation is complete, the code generation report opens automatically and you see hyperlinks in the Command Window.

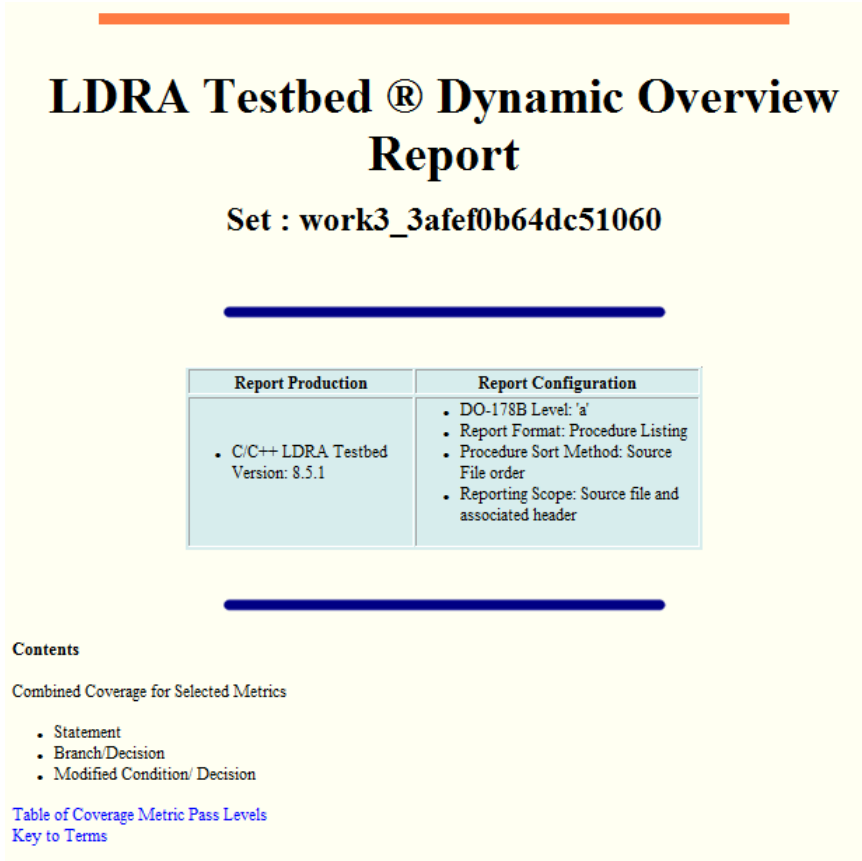
View LDRA Testbed Results

If you specified the LDRA Testbed, you see three links in the Command Window:

```
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Starting analysis of coverage data
### Use the following links to view code coverage results:
    LDRA Testbed GUI
    LDRA Testbed Code Coverage Overview Report
    HTML code generation report with code coverage annotations
### Completed code coverage analysis
>>
```

To go to the LDRA Testbed GUI, click the `LDRA Testbed GUI` link.

To open the LDRA Testbed Report with your Web browser, click the `LDRA Testbed Code Coverage Overview Report` link.



LDRA Testbed ® Dynamic Overview Report

Set : work3_3afef0b64dc51060

Report Production	Report Configuration
• C/C++ LDRA Testbed Version: 8.5.1	• DO-178B Level: 'a' • Report Format: Procedure Listing • Procedure Sort Method: Source File order • Reporting Scope: Source file and associated header

Contents

Combined Coverage for Selected Metrics

- Statement
- Branch/Decision
- Modified Condition/ Decision

Table of Coverage Metric Pass Levels
Key to Terms

For information about using this report, refer to the LDRA Testbed documentation.

LDRA Testbed analysis results for all code in the current code generation folder belong to a set. In this set, you can find analysis results for models that share the same code generation folder. The `LDRA Testbed Code Coverage Overview Report` link identifies the location of the LDRA Testbed analysis results, which is determined by:

- The LDRA Testbed configuration.
- The name of the LDRA Testbed set associated with the current code generation folder.

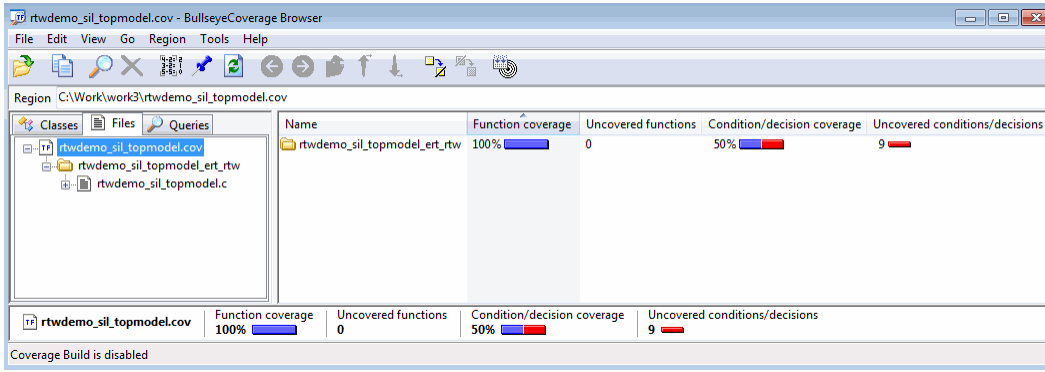
To view summary data and code annotations with coverage information in the code generation report, click the `HTML code generation report with code coverage annotations` link.

View BullseyeCoverage Results

If you specified the BullseyeCoverage tool, you see two links in the Command Window:

```
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Processing code coverage data
### Use the following links to view code coverage results:
    BullseyeCoverage browser (coverage for last run)
    HTML code generation report (cumulative coverage)
### Completed code coverage analysis
>>
```

To view the coverage report using the BullseyeCoverage Browser, click the `BullseyeCoverage browser (coverage for last run)` link.



The BullseyeCoverage Browser shows coverage data for instrumented files associated with your latest top-model simulation. The coverage data shown in the browser is not cumulative and pertains only to the most recent simulation. For information about the BullseyeCoverage Browser, go to www.bullseye.com.

To view summary data and code annotations with coverage information in the code generation report, click the `HTML code generation report (cumulative coverage)` link.

Configure Code Coverage Programmatically

You can configure code coverage for your model using command-line APIs. A typical workflow with BullseyeCoverage is:

1. Using `get_param`, retrieve the object containing coverage settings for the current model, for example, `gcs`.

   ```
   >> covSettings = get_param(gcs, 'CodeCoverageSettings')

   covSettings =

     CodeCoverageSettings with properties:

             TopModelCoverage: 'on'
       ReferencedModelCoverage: 'off'
                  CoverageTool: 'BullseyeCoverage'
   ```

   The property `TopModelCoverage` determines whether the software generates code coverage data for just the top model, while `ReferencedModelCoverage` determines whether the software generates coverage data for models referenced by the top model. If neither property is `'on'`, the code generator does not produce code coverage data during a SIL simulation.

   If LDRA Testbed is the specified code coverage tool, then the property `CoverageTool` is `'LDRA Testbed'`.

   When you save your model, the properties `TopModelCoverage`, `ReferencedModelCoverage`, and `CoverageTool` are also saved.

2. Check the class of `covSettings`.

   ```
   >> class(covSettings)

   ans =

   coder.coverage.CodeCoverageSettings
   ```

3. Turn on coverage for referenced models.

   ```
   >> covSettings.ReferencedModelCoverage='on';
   ```

4. Using `set_param`, apply the new coverage settings to the model.

   ```
    >>set_param(gcs,'CodeCoverageSettings', covSettings);
   ```

5. Assuming you have installed the BullseyeCoverage tool, specify the installation path.

   ```
   >>coder.coverage.BullseyeCoverage.setPath('C:\Program Files\BullseyeCoverage')
   ```

For LDRA Testbed, use `coder.coverage.LDRA.setPath('C:\...)`.

6 Check that the path is saved as a preference.

```
>> coder.coverage.BullseyeCoverage.getPath
```

For LDRA Testbed, use `coder.coverage.LDRA.getPath`.

Code Coverage Summary and Annotations

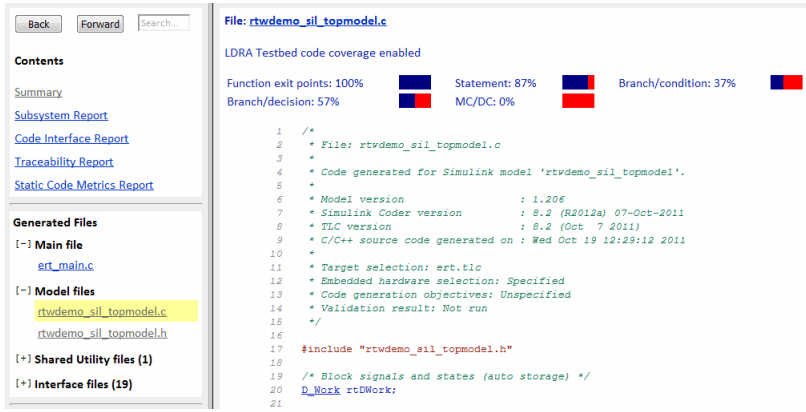
In this section...

If you specify a code coverage tool for a SIL or PIL simulation, the software produces a code generation report that provides summary data and code annotations with coverage information. Each code annotation is associated with a code feature and indicates the nature of the feature coverage during code execution.

The code generation report also allows you to navigate easily between blocks in your model and the corresponding sections in the source code.

LDRA Testbed Coverage

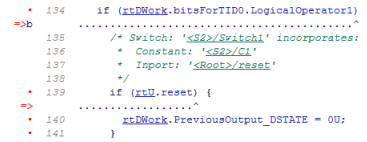
The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from simulations with other top models that share referenced models with your current top model.



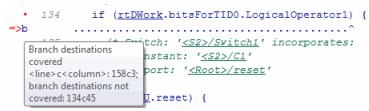
The software provides LDRA Testbed annotations in the code generation report to help you to review code coverage.

Note Do not use the code generation report alone to verify that you have achieved your coverage goals. You must refer to the LDRA Testbed Report.

This example shows three kinds of annotations. On lines 134, 139, 140, and 141, the annotation • indicates that statement coverage for each of these lines of code is not complete.



Placing the cursor over the annotation =>b produces a tooltip.



This tooltip indicates that only one branch destination is covered. The code within the curly brackets, which starts at column 45 of line 134, is not executed. As the `if` statement on line 139 lies within this code, the corresponding annotation => states that the branch is not covered.

This table describes the LDRA Testbed code annotations that you might see in a code generation report produced by a SIL and PIL simulations.

Code feature	Annotation symbol	What happened during simulation
Function	Fcn	Function *name* returned through this exit point.
	=>	Function *name* never returned through this exit point.
Branch/condition	=>	Condition not encountered.
	=>t	Condition evaluated true only.

Code feature	Annotation symbol	What happened during simulation
	=>f	Condition evaluated false only.
	tf	Condition evaluated both true and false.
Branch/decision	=>	Branch never encountered.
	=>b	Branch to at least one destination covered and branch to at least one other destination not covered.
	b	Branch fully exercised.
Modified Condition/Decision Coverage (MC/DC)	=>mc	Condition did not independently affect outcome of decision.
	mc	Condition independently affected outcome of decision.
Statement	.	Statements associated with line covered.
	.	Not all statements associated with line covered.
Code that is reformatted by LDRA Testbed and does not match the original source code. For example, source code with `#include` statements to include other files, and source code with `#define` statements for macros. For detailed coverage information, refer to the LDRA Testbed report.	=>Σ	Zero coverage — probes within source code line or files included by source code line not exercised.
	=>Σ	Coverage probes within source code line or any included file partially exercised.
	Σ	Coverage probes within source code line or included files fully exercised.

BullseyeCoverage Information

The cumulative coverage data in a code generation report is derived from instrumented files associated with your latest top-model simulation **and** coverage data collected from simulations with other top models that share referenced models with your current top model.

The software provides BullseyeCoverage annotations in the code generation report to help you to review code coverage.

This example shows two kinds of annotations. At line 41, TF indicates that the `if` decision had both true and false outcomes during the simulation. At line 52, =>F indicates that the `if` decision was false only during the simulation.

```
TF      41    if (rtU.reset) {
        42      rtDWork.PreviousOutput_DSTATE = 20U;
        43    }
        44
        45    /* Switch: '<Root>/Switch' incorporates:
        46     *  Constant: '<Root>/C1'
        47     *  Constant: '<Root>/C5'
        48     *  Inport: '<Root>/ ticks_to_count'
        49     *  RelationalOperator: '<Root>/upper GE input'
        50     *  Sum: '<Root>/Add'
        51     */
 =>F    52    if ((uint8_T)((uint32_T)rtU.ticks_to_count + (uint32
        53                  rtDWork.PreviousOutput_DSTATE) == 40)
```

This table describes the BullseyeCoverage code annotations that you might see in a code generation report produced by a SIL simulation.

Code feature	Annotation symbol	What happened during simulation
Decision	=>	Decision not executed.
	TF	Decision evaluated both true and false.
	=>T	Decision evaluated true only.
	=>F	Decision evaluated false only.
Function	=>	Function not called.
	Fcn	Function called.
Switch label	=>	Switch command not used.
	Sw	Switch command used.
Constant	k	Decision or condition was constant, which did not allow any variation in coverage.
Condition	=>	Condition not encountered.
	tf	Condition evaluated both true and false.
	=>t	Condition evaluated true only.
	=>f	Condition evaluated false only.
Try	=>	Try block never completed.
	Try	Try block covered.
Catch	=>	Catch block not covered.
	Cat	Catch block covered.

Code Coverage Tool Support

Embedded Coder code coverage provides the following support for the BullseyeCoverage and LDRA Testbed tools.

Operating system	BullseyeCoverage		LDRA Testbed	
	Version supported	Compiler supported	Version supported	Compiler supported
Windows	8.9.37	Microsoft Visual C++ (MSVC)	9.4.6	• Microsoft Visual C++ (MSVC) • LCC • MinGW
Linux	8.9.37	`gcc`	9.4.6	`gcc`
Mac	Not supported		Not supported

Tips and Limitations

Model Build and SIL/PIL Blocks Not Supported

Code coverage does not support:

- The model build process, for example, the `Ctrl+B` command.
- SIL or PIL blocks.

Code coverage settings are ignored by the `Ctrl+B` command and SIL or PIL blocks.

BullseyeCoverage License Wait

When you build your model, you might have to wait for a BullseyeCoverage license. If you want to see information about the wait, before you build your model, select **Configuration Parameters** > **Verbose build**.

Current Working Folder Cannot be UNC Path

If your MATLAB current working folder is a Universal Naming Convention (UNC) path, code coverage fails.

Characters in matlabroot and File Path

If `matlabroot` or the path to your generated files contains a space or the `.` (period) character, code coverage might fail.

Header Files with Identical Names

Consider a model that is configured for LDRA Testbed code coverage. During the build process, if the software detects two header files with the same name in the folder for generated code, the software generates an error.

Code Coverage for Source Files in Shared Utility Folders

The software supports code coverage for source files generated in shared utility folders. If you configure code coverage for a model that uses shared utility code generation, when

you build the model, you also build all source files in the shared utilities folder with code coverage enabled.

Whenever you build a model, the code coverage settings of the model must be consistent with source files that you previously built in the shared utilities folder. Otherwise, the software reports that code in the shared utilities folder is inconsistent with the current model configuration and must be rebuilt. For example, if you run a SIL simulation for a model with code coverage enabled and then run a SIL simulation for another model with code coverage disabled, the software must rebuild all source files in the shared utilities folder.

BullseyeCoverage Behavior with Inline Macros

The BullseyeCoverage tool, by default, does not provide code coverage data for inline macros.

For example, if a model generates a file `slprj/ert/_sharedutils/rt_SATURATE.h` that contains the macro

```
#define rt_SATURATE(sig,ll,ul) (((sig) >= (ul)) ? (ul) : (((sig) <=
(ll)) ? (ll) : (sig)) )
```

and the macro is in `sat_ert_rtw/sat.c`, then the coverage report provides a measurement for `sat.c`, but no coverage data for the conditions within the macro `rt_SATURATE`.

To configure the BullseyeCoverage tool to provide code coverage data for inline macros:

1. Open the BullseyeCoverage Browser.
2. Select **Tools** > **Options** to open the Options dialog box.
3. On the **Build** tab, select the **Instrument macro expansions** check box.
4. Click **OK**.
5. Rerun your simulation.

Alternatively, you can add the text `-macro` to the `BullseyeCoverage` configuration file. For more information, go to www.bullseye.com/help.

SIL and PIL Simulations with Open LDRA Testbed

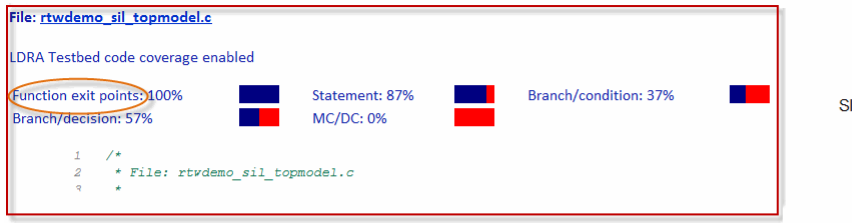
If you enable code coverage with the LDRA Testbed tool, you must verify that the LDRA Testbed GUI is not open when you run your SIL or PIL simulation. If the set name in the

LDRA Testbed GUI differs from the set name used by the SIL or PIL simulation, the SIL or PIL simulation fails.

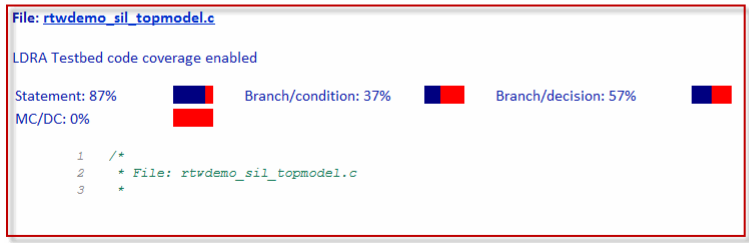
Minor SIL and PIL Differences for LDRA Testbed

The target connectivity API supports code coverage with LDRA Testbed for top-model and Model block PIL.

There are minor differences in the code coverage information collected during SIL and PIL simulations. In particular, with PIL, the software does not explicitly show function exit point coverage. However, you can infer the coverage of function exit points by examining statement coverage.



SIL



PIL

PIL Zero Coverage LDRA Testbed Annotations

For a PIL simulation with LDRA Testbed code coverage specified, there might be some source files where the recorded coverage is zero. In this case, the software provides summary information indicating that:

- There is coverage to measure.
- The coverage is zero.

You do not see information for individual probes on each line. The displayed summary information has an associated annotation tooltip:

```
0 out of N coverage probes were exercised (detailed breakdown unavailable)
```

PIL Support for BullseyeCoverage

Code coverage with BullseyeCoverage is available for top-model and Model block PIL provided your PIL application can write directly to the host file system. Your target for the PIL application must provide `fopen` and `fread` access to the host file system.

If code coverage is not available when you run the PIL application on your target hardware, you might be able to collect code coverage measurements by running the PIL application on an instruction set simulator that supports direct file I/O with the host file system.

Modify Legacy Code

If you modify legacy code and rerun a SIL or PIL simulation, the legacy code is recompiled. However, the code from the model may be up-to-date. In this case, the code generation report is not updated and does not show the modified legacy code. Instead, the code coverage information for the modified legacy code is displayed with reference to the original legacy code. You must regenerate the report. For more information, see “Limitation” (Simulink Coder).

IDE Link Does Not Support LDRA Testbed

When you generate code for IDE Link, you cannot use LDRA Testbed for SIL or PIL code coverage. Specifically, this limitation applies when you use the following settings together:

- **Configuration Parameters > Code Generation > System target file**: `idelink_ert.tlc`
- **Configuration Parameters > Code Generation > Verification > Third-party tool**: `LDRA Testbed`.

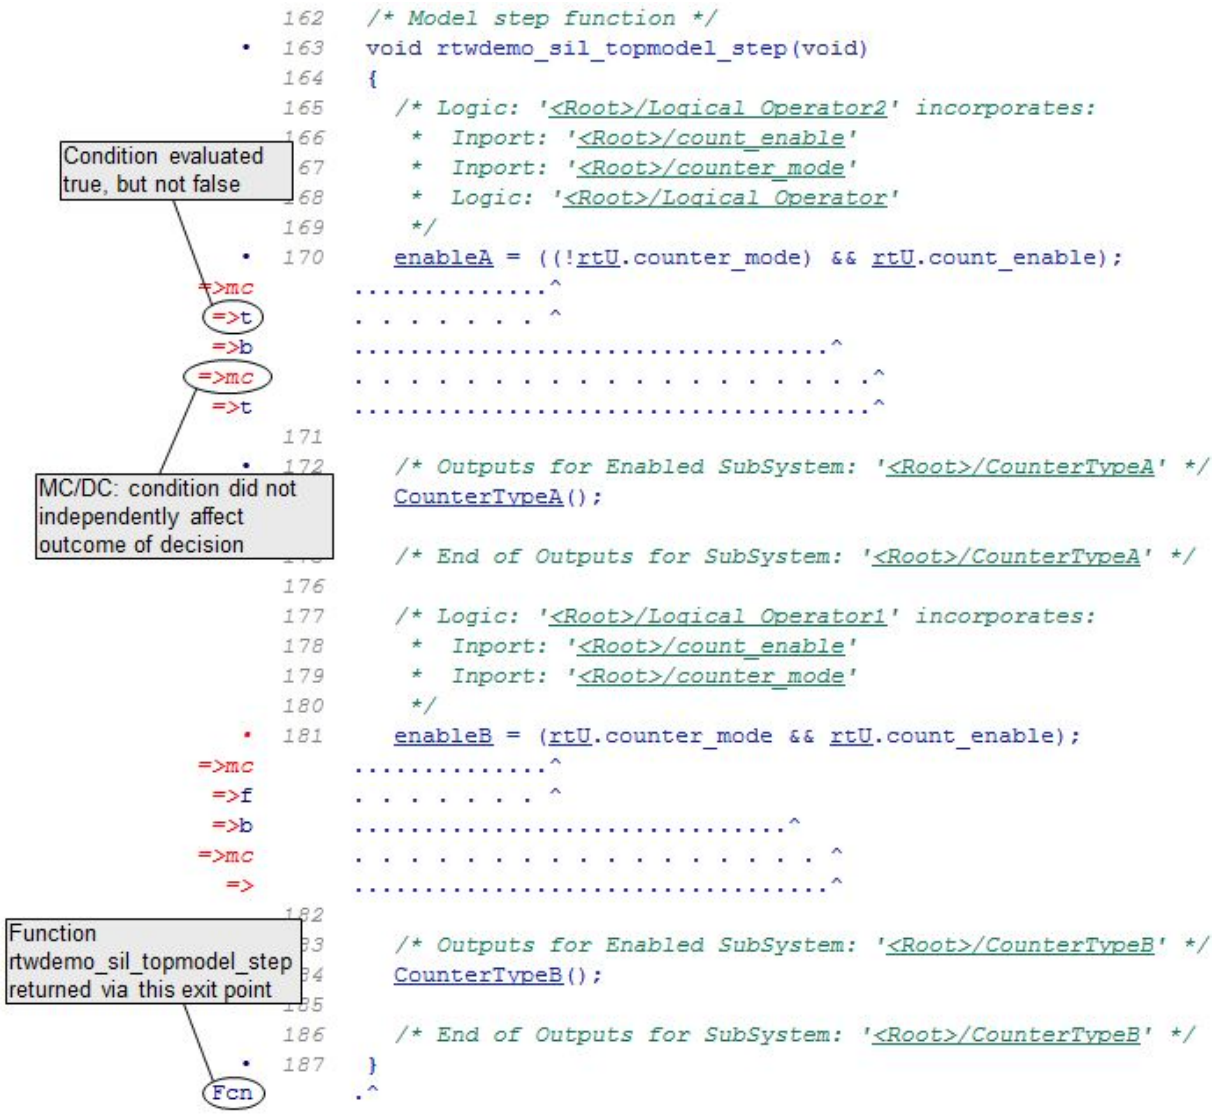
Collect Code Coverage Metrics with a Third-Party Tool

If Simulink® Coverage™ is installed, you can collect code coverage metrics during a software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation - see “Collect Code Coverage Data” (Simulink Coverage). In this example, you can collect code coverage metrics with a third-party tool, i.e., BullseyeCoverage or LDRA Testbed. You must install the third-party tool - see “Code Coverage Tool Support” on page 81-26.

This screen shot shows a code coverage report obtained by running a SIL simulation with a code coverage tool enabled. The annotations depend on the code coverage tool that you specify.



```
162   /* Model step function */
163   void rtwdemo_sil_topmodel_step(void)
164   {
165     /* Logic: '<Root>/Logical Operator2' incorporates:
166      *  Inport: '<Root>/count_enable'
167      *  Inport: '<Root>/counter_mode'
168      *  Logic: '<Root>/Logical Operator'
169      */
170     enableA = ((!rtU.counter_mode) && rtU.count_enable);
              ..............^
              . . . . . . . ^
              ..................................^
              . . . . . . . . . . . . . . . . . .^
              ..................................^
171
172     /* Outputs for Enabled SubSystem: '<Root>/CounterTypeA' */
        CounterTypeA();

        /* End of Outputs for SubSystem: '<Root>/CounterTypeA' */
176
177     /* Logic: '<Root>/Logical Operator1' incorporates:
178      *  Inport: '<Root>/count_enable'
179      *  Inport: '<Root>/counter_mode'
180      */
181     enableB = (rtU.counter_mode && rtU.count_enable);
              ..............^
              . . . . . . . ^
              ..................................^
              . . . . . . . . . . . . . . . . . ^
              ..................................^
182
183     /* Outputs for Enabled SubSystem: '<Root>/CounterTypeB' */
184     CounterTypeB();
185
186     /* End of Outputs for SubSystem: '<Root>/CounterTypeB' */
187   }
      .^
```

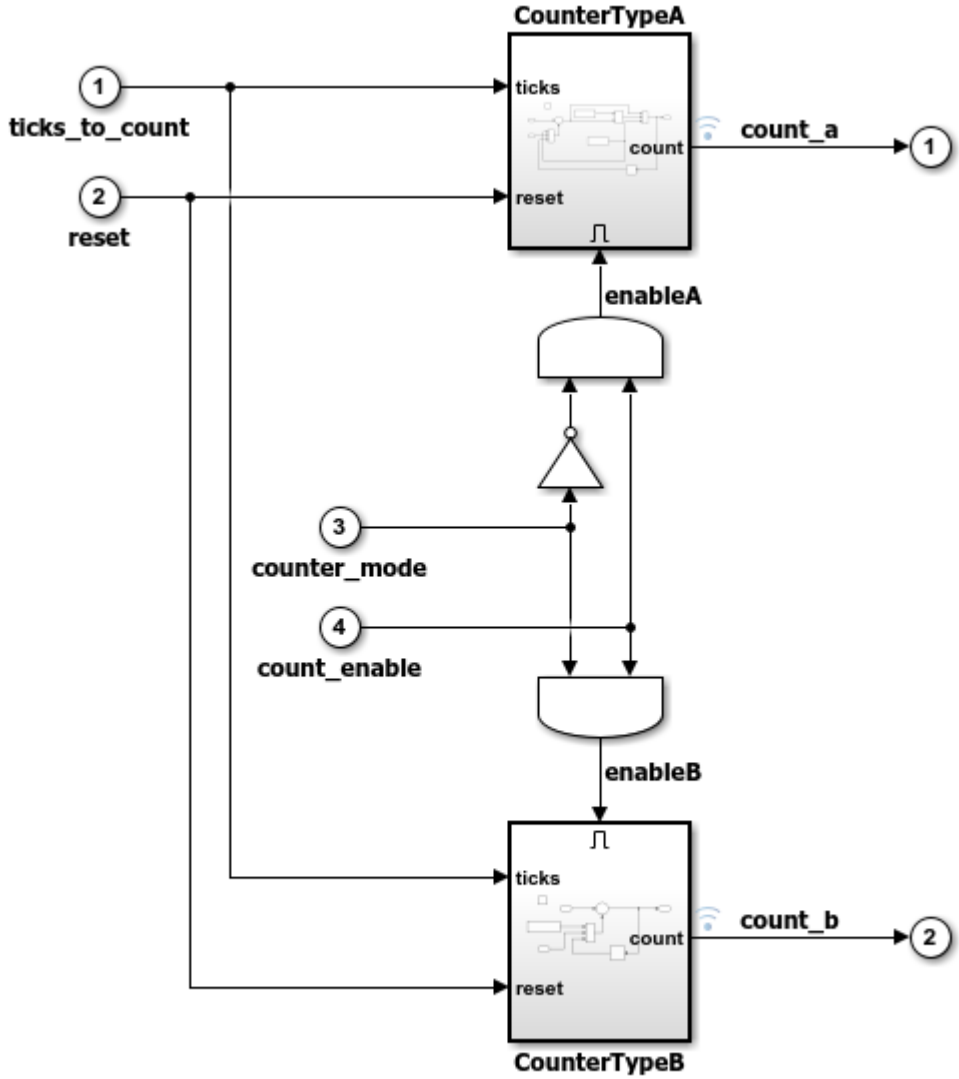
In this example, you measure model coverage during normal mode simulation and repeat the same simulation in SIL mode to measure code coverage. By using the hyperlinks in the model coverage and code coverage reports, you can compare model coverage and code coverage results.

For SIL and PIL simulation examples, see “Test Generated Code with SIL and PIL Simulations” on page 78-85.

Initial Setup

Make sure the model is newly opened.

```
model='rtwdemo_sil_topmodel';
close_system(model,0)
open_system(model)
```



Remove existing build folders.

```
buildFolder=RTW.getBuildDir(model);
if exist(buildFolder.BuildDirectory,'dir')
    rmdir(buildFolder.BuildDirectory,'s');
end
```

Configure generation of model coverage report.

```
set_param(model, 'RecordCoverage','on')
clear covCumulativeData
```

Set up the stimulus data.

```
T=0.1; % sample time
[ticks_to_count, reset, counter_mode, count_enable, ...
 counter_mode_values_run1, counter_mode_values_run2, ...
 count_enable_values_run1, count_enable_values_run2] = ...
    rtwdemo_sil_topmodel_data(T);
```

Run a Simulation in Normal Mode

The model is configured to collect model coverage metrics. When a simulation is complete, the model coverage report opens. Use the coverage display window to navigate from blocks in the model to the corresponding sections of the coverage report.

```
counter_mode.signals.values = counter_mode_values_run1;
count_enable.signals.values = count_enable_values_run1;
set_param(model,'SimulationMode','normal');
```

Set up Simulation Data Inspector for interactive viewing and comparison of simulation results.

```
Simulink.sdi.view;
Simulink.sdi.clear;
```

Run the simulation.

```
simout_normal_run1 = sim(model, 'ReturnWorkspaceOutputs', 'on');
```

Capture the results.

```
Simulink.sdi.createRun('Run 1 (normal mode)', 'namevalue',...
                       {'simout_normal_run1'}, {simout_normal_run1});
```

Run a Second Simulation in Normal Mode

For the first simulation, the report shows that the achieved coverage is less than 100%. Run a second simulation with different input signals that increase the level of MC/DC

coverage to 100%. Note that the model coverage report is configured to show cumulative coverage across both simulation runs.

```
counter_mode.signals.values = counter_mode_values_run2;
count_enable.signals.values = count_enable_values_run2;
set_param(model,'SimulationMode','normal');

simout_normal_run2 = sim(model, 'ReturnWorkspaceOutputs', 'on');

Simulink.sdi.createRun('Run 2 (normal mode)', 'namevalue',...
                       {'simout_normal_run2'}, {simout_normal_run2});
```

Configure the Model to Measure Code Coverage

Before running a SIL simulation, check the availability of third-party tools, and configure the model to collect code coverage metrics. If a third-party tool is not available, the model uses Simulink® Verification and Validation™.

```
covToolPath = '';
ldraPath = coder.coverage.LDRA.getPath;
bullseyePath = coder.coverage.BullseyeCoverage.getPath;

coverageSettings = get_param(model,'CodeCoverageSettings');
coverageSettings.TopModelCoverage='on';
if ~isempty(ldraPath)
    coverageSettings.CoverageTool='LDRA Testbed';
elseif ~isempty(bullseyePath)
    coverageSettings.CoverageTool='BullseyeCoverage';
else
    coverageSettings.CoverageTool='None';
end
set_param(model,'CodeCoverageSettings',coverageSettings);
```

Run Simulations in SIL Mode

The normal mode simulations produce coverage metrics for the model. With a SIL simulation, you can apply the same input stimulus signals to the generated code and measure code coverage.

Run the first simulation in SIL mode.

```
counter_mode.signals.values = counter_mode_values_run1;
count_enable.signals.values = count_enable_values_run1;
set_param(model,'SimulationMode','software-in-the-loop');
set_param(model,'CodeExecutionProfiling','off');
```

```
set_param(model,'CodeProfilingInstrumentation','off');
simout_sil_run1 = sim(model, 'ReturnWorkspaceOutputs', 'on');
Simulink.sdi.createRun('Run 1 (SIL mode)', 'namevalue',...
                       {'simout_sil_run1'}, {simout_sil_run1});

### Starting build procedure for model: rtwdemo_sil_topmodel
### Successful completion of build procedure for model: rtwdemo_sil_topmodel
### Preparing to start SIL simulation ...
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Updating code generation report with SIL files ...
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Completed code coverage analysis
```

Run the second simulation in SIL mode.

```
counter_mode.signals.values = counter_mode_values_run2;
count_enable.signals.values = count_enable_values_run2;
set_param(model,'SimulationMode','software-in-the-loop');
set_param(model,'CodeExecutionProfiling','off');
set_param(model,'CodeProfilingInstrumentation','off');
simout_sil_run2 = sim(model, 'ReturnWorkspaceOutputs', 'on');
Simulink.sdi.createRun('Run 2 (SIL mode)', 'namevalue',...
                       {'simout_sil_run2'}, {simout_sil_run2});

### Starting build procedure for model: rtwdemo_sil_topmodel
### Generated code for 'rtwdemo_sil_topmodel' is up to date because no structural, para
### Successful completion of build procedure for model: rtwdemo_sil_topmodel
### Preparing to start SIL simulation ...
### Starting SIL simulation for component: rtwdemo_sil_topmodel
### Stopping SIL simulation for component: rtwdemo_sil_topmodel
### Completed code coverage analysis
```

When a simulation is complete, click the link in the Command Window to open the code coverage report and view the cumulative code coverage results. The link is available only if you have a third-party tool installed.

Use hyperlinks in the code coverage report to go to corresponding locations in the block diagram. Then, by using the coverage display window, you can open corresponding sections of the model coverage report. Compare model coverage and code coverage results.

The Simulation Data Inspector opens automatically, allowing interactive viewing and analysis of the results. Use the Compare and Inspect panes to confirm that the SIL and normal mode logged signals are identical for both runs.

Concluding Remarks

In this example, you:

- Collected model coverage metrics during a normal mode simulation.
- Collected code coverage metrics during a SIL simulation.
- Navigated between the code coverage and model coverage reports.
- Cross-checked metrics from both reports.

Embedded IDEs and Embedded Targets

Getting Started with Embedded Targets in Embedded Coder

Embedded Coder Supported Hardware

Embedded Coder generates ANSI/ISO C and C++ code that can be compiled and executed on any processor by manually integrating the generated code with the RTOS, I/O devices, and build tools for your processor.

Embedded Coder provides support packages that help to automate integration, execution, and verification of generated code for the processors and devices in this table.

Support Package	Vendor	Earliest Release Available	Last Release Available
Analog Devices DSPs	Analog Devices®	R2013a	R2015b
ARM Cortex-A Processors	ARM®	R2014a	Current
ARM Cortex-M Processors	ARM	R2013b	Current
ARM Cortex-R Processors	ARM	R2016b	Current
AUTOSAR Standard	AUTOSAR (AUTomotive Open System ARchitecture) development partnership	R2014b	R2018b
BeagleBone Black Hardware	BeagleBoard	R2014b	Current
Green Hills MULTI	Green Hills® Software	R2012b	R2014a
Intel SoC Devices	Intel	R2014b	Current
PX4 Autopilots	Dronecode	R2019a	Current
STMicroelectronics Discovery Boards	STMicroelectronics®	R2013b	Current
Texas Instruments C2000 Processors	Texas Instruments	R2013b	Current
Texas Instruments C2000 F28M3x Concerto Processors	Texas Instruments	R2014b	Current

Support Package	Vendor	Earliest Release Available	Last Release Available
Texas Instruments C6000 DSPs	Texas Instruments	R2014a	R2016a
Wind River VxWorks RTOS	Wind River	R2013b	R2017a
Xilinx Zynq Platform	Xilinx®	R2013a	Current

For a complete list of hardware support packages, see Hardware Support.

Run-Time Data Interface Extensions in Simulink Coder

Customize Generated ASAP2 File

In this section...

About ASAP2 File Customization

The Embedded Coder product provides a number of Target Language Compiler (TLC) files to enable you to customize the ASAP2 file generated from a Simulink model.

ASAP2 File Structure on the MATLAB Path

The ASAP2 related files are organized within the folders identified below:

- TLC files for generating ASAP2 file

  The *matlabroot*`/rtw/c/tlc/mw` (open) folder contains TLC files that generate ASAP2 files, `asamlib.tlc`, `asap2lib.tlc`, `asap2main.tlc`, and `asap2grouplib.tlc`. These files are included by the selected **System target file**. (See “Targets Supporting ASAP2” on page 58-3.)
- ASAP2 target files

  The *matlabroot*`/toolbox/rtw/targets/asap2/asap2` (open) folder contains the ASAP2 system target file and other control files.
- Customizable TLC files

  The *matlabroot*`/toolbox/rtw/targets/asap2/asap2/user` (open) folder contains files that you can modify to customize the content of your ASAP2 files.
- ASAP2 templates

  The *matlabroot*`/toolbox/rtw/targets/asap2/asap2/user/templates` (open) folder contains templates that define each type of `CHARACTERISTIC` in the ASAP2 file.

Customize the Contents of the ASAP2 File

The ASAP2 related TLC files enable you to customize the appearance of the ASAP2 file generated from a Simulink model. Most customization is done by modifying or adding to the files contained in the *matlabroot*/toolbox/rtw/targets/asap2/asap2/user (open) folder. This section refers to this folder as the asap2/user folder.

The user-customizable files provided are divided into two groups:

- The *static* files define the parts of the ASAP2 file that are related to the environment in which the generated code is used. They describe information specific to the user or project. The static files are not model dependent.
- The *dynamic* files define the parts of the ASAP2 file that are generated based on the structure of the source model.

The procedure for customizing the ASAP2 file is as follows:

1. Make a copy of the asap2/user folder before making modifications.
2. Remove the old asap2/user folder from the MATLAB path, or add the new asap2/user folder to the MATLAB path above the old folder. The MATLAB session uses the ASAP2 setup file, asap2setup.tlc, in the new folder.

   asap2setup.tlc specifies the folders and files to include in the TLC path during the ASAP2 file generation process. Modify asap2setup.tlc to control the folders and folders included in the TLC path.
3. Modify the static parts of the ASAP2 file. These include

   - Project and header symbols, which are specified in asap2setup.tlc
   - Static sections of the file, such as file header and tail, A2ML, MOD_COMMON, and so on These are specified in asap2userlib.tlc.
   - Specify the appearance of the dynamic contents of the ASAP2 file by modifying the existing ASAP2 templates or by defining new ASAP2 templates. Sections of the ASAP2 file affected include

     RECORD_LAYOUT: modify parts of the ASAP2 template files.

     CHARACTERISTIC: modify parts of the ASAP2 template files. For more information on modifying the appearance of CHARACTERISTIC records, see “ASAP2 Templates” on page 83-4.

- MEASUREMENT: These are specified in asap2userlib.tlc.
- COMPU_METHOD: These are specified in asap2userlib.tlc.

ASAP2 Templates

The appearance of CHARACTERISTIC records in the ASAP2 file is controlled using a different template for each type of CHARACTERISTIC. The asap2/user folder contains template definition files for scalars, 1-D Lookup Table blocks and 2-D Lookup Table blocks. You can modify these template definition files, or you can create additional templates as required.

The procedure for creating a new ASAP2 template is as follows:

1. Create a template definition file. See “Create Template Definition Files” on page 83-4.
2. Include the template definition file in the TLC path. The path is specified in the ASAP2 setup file, asap2setup.tlc.

Create Template Definition Files

This section describes the components that make up an ASAP2 template definition file. This description is in the form of code examples from asap2lookup1d.tlc, the template definition file for the Lookup1D template. This template corresponds to the Lookup1D parameter group.

Note When creating a new template, use the corresponding parameter group name in place of Lookup1D in the code shown.

Template Registration Function

The input argument is the name of the parameter group associated with this template:

```
%<LibASAP2RegisterTemplate("Lookup1D")>
```

RECORD_LAYOUT Name Definition Function

Record layout names (aliases) can be arbitrarily specified for each data type. This function is used by the other components of this file.

```
%function ASAP2UserFcnRecordLayoutAlias_Lookup1D(dtId) void
  %switch dtId
```

```
  %case tSS_UINT8
    %return "Lookup1D_UBYTE"
  ...
  %endswitch
%endfunction
```

Function to Write RECORD_LAYOUT Definitions

This function writes `RECORD_LAYOUT` definitions associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore:

```
%function ASAP2UserFcnWriteRecordLayout_Lookup1D() Output
  /begin RECORD_LAYOUT
%<ASAP2UserFcnRecordLayoutAlias_Lookup1D(tSS_UINT8)>
    ...
  /end   RECORD_LAYOUT
%endfunction
```

Function to Write the CHARACTERISTIC

This function writes the `CHARACTERISTIC` associated with this template. The function is called by the built-in functions involved in the ASAP2 file generation process. The function name must be defined as shown, with the template name after the underscore.

The input argument to this function is a pointer to a parameter group record. The example shown is for a `Lookup1D` parameter group that has two members. The references to the associated `x` and `y` data records are obtained from the parameter group record as shown.

This function calls a number of built-in functions to obtain the required information. For example, `LibASAP2GetSymbol` returns the symbol (name) for the specified data record:

```
%function ASAP2UserFcnWriteCharacteristic_Lookup1D(paramGroup)
Output
  %assign xParam = paramGroup.Member[0].Reference
  %assign yParam = paramGroup.Member[1].Reference
  %assign dtId = LibASAP2GetDataTypeId(xParam)
    /begin CHARACTERISTIC
     /* Name */              %<LibASAP2GetSymbol(xParam)>
     /* Long identifier */   "%<LibASAP2GetLongID(xParam)>"
     ...
```

```
    /end CHARACTERISTIC
%endfunction
```

Customize Computation Method Names

In generated ASAP2 files, computation methods translate the electronic control unit (ECU) internal representation of measurement and calibration quantities into a physical model oriented representation. Simulink Coder software provides the ability to customize the names of computation methods. You can provide names that are more intuitive, enhancing ASAP2 file readability, or names that meet organizational requirements.

To customize computation method names, use the MATLAB function `getCompuMethodName`, which is defined in *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.

The `getCompuMethodName` function constructs a computation method name. The function prototype is

```
cmName = getCompuMethodName(dataTypeName, cmUnits)
```

where *`dataTypeName`* is the name of the data type associated with the computation method, *`cmUnits`* is the units as specified in the `Unit` property of a `Simulink.Parameter` or `Simulink.Signal` object (for example, `rpm` or `m/s`), and *`cmName`* returns the constructed computation method name.

The default constructed name returned by the function has the format

```
<localPrefix><datatype>_<cmUnits>
```

where

- `<local_Prefix>` is a local prefix, `CM_`, defined in *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/user/getCompuMethodName.m`.
- `<datatype>` and `<cmUnits>` are the arguments you specified to the `getCompuMethodName` function.

Additionally, in the generated ASAP2 file, the constructed name is prefixed with `<ASAP2CompuMethodName_Prefix>`, a model prefix defined in *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

For example, if you call the `getCompuMethodName` function with the *`dataTypeName`* argument `'int16'` and the *`cmUnits`* argument `'m/s'`, and generate an ASAP2 file for a

model named `myModel`, the computation method name would appear in the generated file as follows:

```
/begin COMPU_METHOD
   /* Name of CompuMethod */ myModel_CM_int16_m_s
   /* Units */ "m/s"
   ...
/end COMPU_METHOD
```

Suppress Computation Methods for FIX_AXIS

Versions 1.51 and later of the ASAP2 specification state that for certain cases of lookup table axis descriptions (integer data type and no doc units), a computation method is not required and the Conversion Method parameter must be set to the value `NO_COMPU_METHOD`. You can control whether or not computation methods are suppressed when not required using the Target Language Compiler (TLC) option `ASAP2GenNoCompuMethod`. This TLC option is disabled by default. If you enable the option, ASAP2 file generation does not generate computation methods for lookup table axis descriptions when not required, and instead generates the value `NO_COMPU_METHOD`. For example:

```
/begin CHARACTERISTIC
/* Name            */
lu1d_fix_axisTable_data
...
/begin AXIS_DESCR
    ...
    /* Conversion Method    */
NO_COMPU_METHOD
    ...
/end CHARACTERISTIC
```

The `ASAP2GenNoCompuMethod` option is defined in *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/user/asap2setup.tlc`.

Build Process Integration in Simulink Coder

Control Build Process Compiling and Linking

After generating code for a model, the build process determines whether to compile and link an executable program. Various factors guide this determination:

- **Generate code only** option

  When you select this option, the code generator produces code for the model, including a makefile.

- **Generate makefile** option

  When you clear this option, the code generator does not produce a makefile for the model. You must specify post code generation processing, including compilation and linking, as a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” on page 84-14.

- Makefile-only target

  The Microsoft Visual C++ Project Makefile versions of the `grt` and Embedded Coder target configurations generate a Visual C++ project makefile (*`model`*`.mak`). To build an executable, you must open *`model`*`.mak` in the Visual C++ IDE and compile and link the model code.

- `HOST` template makefile variable

  The template makefile variable `HOST` identifies the type of system upon which your executable is intended to run. The variable can be set to one of three possible values: `PC`, `UNIX`, or `ANY`.

  By default, `HOST` is set to `UNIX` in template makefiles designed for use with The Open Group UNIX platforms (such as `grt_unix.tmf`), and to `PC` in the template makefiles designed for use with development systems for the PC (such as `grt_vc.tmf`).

  If the Simulink software is running on the same type of system as the system specified by the `HOST` variable, then the executable is built. Otherwise,

  - If `HOST = ANY`, an executable is still built. This option is useful when you want to cross-compile a program for a system other than the one that the Simulink software is running on.
  - Otherwise, processing stops after generating the model code and the makefile; the following message is displayed on the MATLAB command line.

    ```
    ### Make will not be invoked - template makefile is for a different host
    ```

- `TGT_FCN_LIB` template makefile variable

  The template makefile variable `TGT_FCN_LIB` specifies compiler command-line options. The line in the makefile is `TGT_FCN_LIB = |>TGT_FCN_LIB<|`. Use this token in a makefile conditional statement to specify a standard math library as a compiler option. Possible |>TGT_FCN_LIB<| token values are:

Value	Generates Calls To
Name of custom CRL	ISO®/IEC 9899:1990 C (`ANSI_C`) standard math library
`ISO_C`	ISO/IEC 9899:1999 C standard math library
`ISO_C++`	ISO/IEC 14882:2003 C++ standard math library
`GNU`	GNU extensions to the ISO/IEC 9899:1999 C standard math library

Cross-Compile Code Generated on Microsoft Windows

To generate code with the code generator on a Microsoft Windows system but compile the generated code on a different supported platform, you can do so by modifying your TMF and model configuration parameters. For example, you would need to follow this process if you develop applications with the MATLAB and Simulink products on a Windows system, but you run your generated code on a Linux system.

To set up a cross-compilation development environment, do the following (here a Linux system is the destination platform):

1. On your Windows system, copy the UNIX TMF for your target to a local folder. This folder is your working folder for initiating code generation. For example, you could copy the file *matlabroot*`/rtw/c/grt/grt_unix.tmf` to `D:/work/my_grt_unix.tmf`.
2. Make the following changes to your copy of the TMF:
   - Add the following line near the `SYS_TARGET_FILE =` line:

     ```
     MAKEFILE_FILESEP = /
     ```
   - Search for the line `'ifeq ($(OPT_OPTS),$(DEFAULT_OPT_OPTS))'` and, for each occurrence, remove the conditional logic and retain only the `'else'` code. That is, remove everything from the `'if'` to the `'else'`, inclusive, and the closing `'endif'`. Only the lines from the `'else'` portion remain. This logic forces the run-time libraries to build for a Linux system.
3. Open your model and make the following changes in the **Code Generation** pane of the Configuration Parameters dialog box:
   - Specify the name of your new TMF in the “Template makefile” (Simulink Coder) text box (for example, `my_grt_unix.tmf`).
   - Select **Generate code only** and click **Apply**.
4. Generate the code.
5. If the build folder (folder from which the model was built) is not already Linux accessible, copy it to a Linux accessible path. For example, if your build folder for the generated code was `D:\work\mymodel_grt_rtw`, copy that entire folder tree to a path such as `/home/user/mymodel_grt_rtw`.
6. If the MATLAB folder tree on the Windows system is Linux accessible, skip this step. Otherwise, copy the include and source folders to a Linux accessible drive partition, for example, `/home/user/myinstall`. These folders appear in the makefile after

`ADD_INCLUDES =` and can be found by searching for `$(MATLAB_ROOT)`. Paths that contain `$(MATLAB_ROOT)` must be copied. Here is an example list (your list varies depending on your model):

```
$(MATLAB_ROOT)/rtw/c/grt
$(MATLAB_ROOT)/extern/include
$(MATLAB_ROOT)/simulink/include
$(MATLAB_ROOT)/rtw/c/src
$(MATLAB_ROOT)/rtw/c/tools
```

Also, paths containing `$(MATLAB_ROOT)` in the build rules (lines with `%.o :`) must be copied. For example, based on the build rule

```
%.o : $(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip/%.c
```

copy the following folder:

```
$(MATLAB_ROOT)/rtw/c/src/ext_mode/tcpip
```

Note The path hierarchy relative to the MATLAB root must be maintained. For example, `c:\MATLAB\rtw\c\tools\*` would be copied to `/home/user/mlroot/rtw/c/tools/*`.

For some blocksets, it is easiest to copy a higher-level folder that includes the subfolders listed in the makefile. For example, the DSP System Toolbox product requires the following folders to be copied:

```
$(MATLAB_ROOT)/toolbox/dspblks
$(MATLAB_ROOT)/toolbox/rtw/dspblks
```

---

7 Make the following changes to the generated makefile:

- Set both `MATLAB_ROOT` and `ALT_MATLAB_ROOT` equal to the Linux accessible path to *`matlabroot`* (for example, `home/user/myinstall`).
- Set `COMPUTER` to the computer value for your platform, such as `GLNX86`. Enter `help computer` in the MATLAB Command Window for a list of computer values.
- In the `ADD_INCLUDES` list, change the build folder (designating the location of the generated code on the Windows system) and parent folders to Linux accessible include folders. For example, change `D:\work\mymodel_grt_rtw\` to `/home/user/mymodel_grt_rtw`.

  Also, if *`matlabroot`* is a UNC path, such as `\\my-server\myapps\matlab`, replace the hard-coded MATLAB root with `$(MATLAB_ROOT)`.

8 From a Linux shell, compile the code you generated on the Windows system. You can compile by running the generated *model*`.bat` file or by typing the make command line as it appears in the `.bat` file.

Note If errors occur during makefile execution, you can run the `dos2unix` utility on the makefile (for example, `dos2unix mymodel.mk`).

Control Library Location and Naming During Build

When you generate precompiled, non-precompiled, and model reference libraries, you can control the library location and library name by using configuration parameters. These parameters control values in generated makefiles during model builds:

- For build processes that use the toolchain approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter.
- For build processes that use the template makefile approach, control the generated library location by using the `TargetPreCompLibLocation` configuration parameter and control the generated library name by using the `TargetLibSuffix` configuration parameter.

Library Control Parameters

Use the library control parameters to:

- Specify the location of precompiled libraries, such as blockset libraries or the Simulink Coder block library. Typically, a target has cross-compiled versions of these libraries and places them in a target-specific folder.
- Control the suffix applied to library file names (for example, `_target.a` or `_target.lib`).

Targets can set the parameters inside the system target file (STF) select callback. For example:

```
function mytarget_select_callback_handler(varargin)
    hDig=varargin{1};
    hSrc=varargin{2};
    slConfigUISetVal(hDig, hSrc, 'TargetPreCompLibLocation',...
    'c:\mytarget\precomplibs');
    slConfigUISetVal(hDig, hSrc, 'TargetLibSuffix',...
    '_target.library');
```

The TMF has corresponding expansion tokens:

```
    |>EXPAND_LIBRARY_LOCATION<|
    |>EXPAND_LIBRARY_SUFFIX<|
```

Alternatively, you can use a call to the `set_param` function. For example:

```
set_param(model,'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

Note If your model contains referenced models, you can use the make option `USE_MDLREF_LIBPATHS` to control whether libraries used by the referenced models are copied to the build folder of the parent model. For more information, see “Control the Location of Model Reference Libraries” on page 84-10.

Identify Library File Type for Toolchain Approach

The toolchain approach for model builds does not use the value of the `TargetLibSuffix` configuration parameter to select the library file name *`suffix`* and *`extension`*.

With the toolchain approach, the final binary name is composed of the *`modelname`*, the *`compilername`*, and the *`extension`* provided by the build tool description in the toolchain definition:

`model_compilername.extension`

You can identify the static library file name extension from the build tool description in the toolchain definition. To get this information for the default toolchain, use this procedure:

1. Get the default toolchain name. For example, enter:

   ```
   tc_name = coder.make.getDefaultToolchain()
   ```
2. Get the default toolchain handle. For example, enter:

   ```
   tc = coder.make.getToolchainInfoFromRegistry(tc_name)
   ```
3. Get the handle to the toolchain object. For example, enter:

   ```
   tool_archiver = tc.getBuildTool('Archiver');
   ```
4. Get the extension. For example, enter:

   ```
   ext_archiver = tool_archiver.getFileExtension('Static Library');
   ```

Note If you do not set the `TargetLibSuffix` parameter, template makefile and toolchain approaches produce the same static library file name *`extension`*. See “Customize Library File Suffix and File Type” (Simulink Coder).

Specify the Location of Precompiled Libraries

Use the `TargetPreCompLibLocation` configuration parameter to:

- Override the precompiled library location specified in the `rtwmakecfg.m` file (see “Use rtwmakecfg.m API to Customize Generated Makefiles” on page 84-26 for details)
- Precompile and distribute target-specific versions of product libraries (for example, the DSP System Toolbox product)

For a precompiled library, such as a blockset library or the Simulink Coder block library, the location specified in `rtwmakecfg.m` is typically a location specific to the blockset or the Simulink Coder product. The code generator expects that the library exists in this location and links against the library during builds.

For some applications, such as custom targets, it is preferable to locate the precompiled libraries in a target-specific or other alternate location rather than in the location specified in `rtwmakecfg.m`. For a custom target, the code generator expects that the target-specific cross-compiler creates the library, and you place the library in the target-specific location. Compile and place libraries supported by the target in the target-specific location, so they can be used during the build process.

You can set up the `TargetPreCompLibLocation` parameter in its select callback. The path that you specify for the parameter must be a fully qualified, absolute path to the library location. Relative paths are not supported. For example:

```
slConfigUISetVal(hDlg, hSrc, 'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

Alternatively, you set the parameter with a call to the `set_param` function. For example:

```
set_param(model,'TargetPreCompLibLocation',...
'c:\mytarget\precomplibs');
```

During makefile generation, the build process replaces the tokens with the location from the `rtwmakecfg.m` file. For example, if the library name in the `rtwmakecfg.m` file is `'rtwlib'`, the template makefile build approach expands the token from:

```
LIBS += |>EXPAND_LIBRARY_LOCATION<|\|>EXPAND_LIBRARY_NAME<|\
_target.library
```

to:

```
LIBS += c:\mytarget\precomplibs\rtwlib_target.library
```

By default, `TargetPreCompLibLocation` is an empty character vector. The build process uses the location in `rtwmakecfg.m` for the token replacement.

Control the Location of Model Reference Libraries

On platforms other than the Apple Macintosh platform, when building a model that uses referenced models, the default build process includes:

- Copy libraries that the referenced models use to the build folder of the parent model.
- Assign the file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

For example, if a model includes a referenced model `sub`, the build process assigns the library name `sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process copies the library file to the build folder of the parent model. This definition is then used in the final link line, which links the library into the final product (usually an executable). This technique minimizes the length of the link line.

On the Macintosh platform, and optionally on other platforms, the build process includes:

- No copying of libraries that the referenced models use to the build folder of the parent model.
- Assign the relative paths and file names of the libraries to `MODELREF_LINK_LIBS` in the generated makefile.

When using this technique, the build process assigns a relative path such as `../slprj/grt/sub/sub_rtwlib.lib` to `MODELREF_LINK_LIBS`. The build process uses the path to gain access to the library file at link time.

To change to the nondefault behavior on platforms other than the Macintosh platform, select the **Configuration Parameters** > **Code Generation** > **Make command** field. Enter:

```
make_rtw USE_MDLREF_LIBPATHS=1
```

If you specify other Make command arguments, such as `OPTS="-g"`, the order in which you specify the multiple arguments does not matter.

To return to the default behavior, set `USE_MDLREF_LIBPATHS` to 0, or remove it.

Control the Suffix Applied to Library File Names

With the template makefile approach for model builds, use the `TargetLibSuffix` configuration parameter to control the suffix applied to library names (for example,

`_target.lib` or `_target.a`). The specified suffix scheme must include a period (.). You can apply `TargetLibSuffix` to the following libraries:

- Libraries on which a target depends, as specified in the `rtwmakecfg.m` API. You can use `TargetLibSuffix` to change the suffix of both precompiled and non-precompiled libraries configured from the `rtwmakecfg` API. For details, see “Use rtwmakecfg.m API to Customize Generated Makefiles” on page 84-26.

  In this case, a target can set the parameter in its select callback. For example:

  ```
  slConfigUISetVal(hDlg, hSrc, 'TargetLibSuffix',...
  '_target.library');
  ```

  Alternatively, you can use a call to the `set_param` function. For example:

  ```
  set_param(model,'TargetLibSuffix','_target.library');
  ```

  During the TMF-to-makefile conversion, the build process replaces the token `|>EXPAND_LIBRARY_SUFFIX<|` with the specified suffix. For example, if the library name specified in the `rtwmakecfg.m` file is `'rtwlib'`, the TMF expands from:

  ```
  LIBS += |>EXPAND_LIBRARY_LOCATION<|\|>EXPAND_LIBRARY_NAME<|\
  |>EXPAND_LIBRARY_SUFFIX<|
  ```

  to:

  ```
  LIBS += c:\mytarget\precomplibs\rtwlib_target.library
  ```

  By default, `TargetLibSuffix` is set to an empty character vector. In this case, the build process replaces the token `|>EXPAND_LIBRARY_SUFFIX<|` with an empty character vector.
- Model libraries created with model reference. For these cases, associated makefile variables do not require the `|>EXPAND_LIBRARY_SUFFIX<|` token. Instead, the build process includes `TargetLibSuffix` implicitly. For example, for a top model named `topmodel` with referenced models named `refmodel1` and `refmodel2`, the TMF of the top model is expanded from:

  ```
  MODELLIB           = |>MODELLIB<|
  MODELREF_LINK_LIBS = |>MODELREF_LINK_LIBS<|
  ```

  to:

  ```
  MODELLIB           = topmodellib_target.library
  MODELREF_LINK_LIBS = \
  refmodel1_rtwlib_target.library refmodel2_rtwlib_target.library
  ```

  By default, the `TargetLibSuffix` parameter is an empty character vector. In this case, the build process chooses a default suffix for these three tokens using a file

extension of `.lib` on Windows hosts and `.a` on UNIX hosts. For model reference libraries, the default suffix also includes `_rtwlib`. For example, on a Windows host, the expanded makefile values are:

```
MODELLIB           = topmodellib.lib
MODELREF_LINK_LIBS = refmodel1_rtwlib.lib refmodel2_rtwlib.lib
```

Recompile Precompiled Libraries

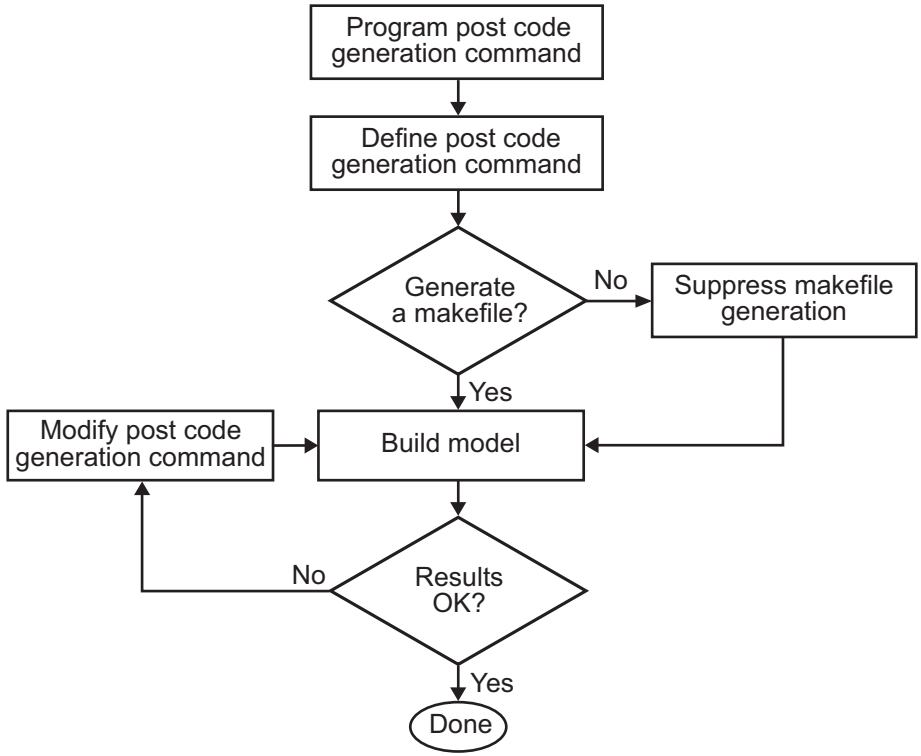
You can recompile precompiled libraries included as part of the code generator, such as `rtwlib` or `dsplib`, by using a supplied MATLAB function, `rtw_precompile_libs`. You can consider recompiling precompiled libraries to customize compiler settings for various platforms or environments. For details on using `rtw_precompile_libs`, see “Precompile S-Function Libraries” on page 53-60.

Customize Post-Code-Generation Build Processing

The code generator provides a set of tools, including a build information object, you can use to customize build processing that occurs after code generation. You can use such customizations for target development or the integration of third-party tools into your application development environment.

Workflow for Setting Up Customizations

The following figure and the steps that follow show the general workflow for setting up post-code-generation customizations.



1. Program the post code generation command on page 84-15.
2. Define the post code generation command on page 84-16.

3. Suppress makefile generation on page 84-20, if applicable.
4. Build the model.
5. Modify the command and rebuild the model until the build results are acceptable.

Build Information Object

At the start of a model build, the build process logs the following build option and dependency information to a temporary build information object:

- Compiler options
- Preprocessor identifier definitions
- Linker options
- Source files and paths
- Include files and paths
- Precompiled external libraries

You can retrieve information from and add information to this object by using an extensive set of functions. For a list of available functions and detailed function descriptions, see “Build Process Customization” (Simulink Coder). “Program a Post Code Generation Command” on page 84-15 explains how to use the functions to control post code generation build processing.

Program a Post Code Generation Command

For certain applications, you could want to control aspects of the build process after the code generation. For example, you can use this approach if you develop your own target, or you want to apply an analysis tool to the generated code before continuing with the build process. You can apply this level of control to the build process by programming and then defining a post code generation command.

A post code generation command is a MATLAB language file that typically calls functions that get data from or add data to the build information object of the model. You can program the command as a script or function.

If you program the command as a:	Then the:
Script	Script can gain access to the model name and the build information directly
Function	Function can pass the model name and the build information as arguments

If your post code generation command calls user-defined functions, make sure that the functions are on the MATLAB path. If the build process cannot find a function you use in your command, the build process errors out.

You can then call a combination of build information functions, as listed in “Build Process Customization” (Simulink Coder), to customize the post code generation build processing of the model.

The following example shows a fragment of a post code generation command that gets the file names and paths of the source and include files generated for a model for analysis.

```
function analyzegencode(buildInfo)
% Get the names and paths of source and include files
% generated for the model and then analyze them.

% buildInfo - build information for my model.

% Define cell array to hold data.
MyBuildInfo={};

% Get source file information.
MyBuildInfo.srcfiles=getSourceFiles(buildInfo, true, true);
MyBuildInfo.srcpaths=getSourcePaths(buildInfo, true);

% Get include (header) file information.
MyBuildInfo.incfiles=getIncludeFiles(buildInfo, true, true);
MyBuildInfo.incpaths=getIncludePaths(buildInfo, true);

% Analyze generated code.
.
.
.
```

Define a Post Code Generation Command

After you program a post code generation command, inform the build process that the command exists and to add it to the build processing of the model. Define the command with the `PostCodeGenCommand` model configuration parameter. When you define a post

code generation command, the build process evaluates the command after generating and writing the generated code to disk and before generating a makefile.

As the following syntax lines show, the arguments that you specify when setting the configuration parameter varies depending on whether you program the command as a script, function, or set of functions.

Note When defining the command as a function, you can specify an arbitrary number of input arguments. To pass the name and build information of the model to the function, specify identifiers `modelName` and `buildInfo` as arguments.

Script

```
set_param(model, 'PostCodeGenCommand',...
'pcgScriptName');
```

Function

```
set_param(model, 'PostCodeGenCommand',...
 'pcgFunctionName(modelName)');
```

Multiple Functions

```
pcgFunctions=...
'pcgFunction1Name(modelName);...
pcgFunction2Name(buildInfo)';
set_param(model, 'PostCodeGenCommand',...
 pcgFunctions);
```

The following call to `set_param` defines `PostCodGenCommand` to evaluate the function `analyzegencode`.

```
set_param(model, 'PostCodeGenCommand',...
'analyzegencode(buildInfo)');
```

Customize Build Process with PostCodeGenCommand and Relocate Generated Code to an External Environment

This example shows how to use the Build Information API and the **Post Code Generation Command** parameter, `PostCodeGenCommand`.

The `PostCodeGenCommand` parameter value is `rtwdemo_buildinfo_data`. This value directs the build process to invoke the function after code generation.

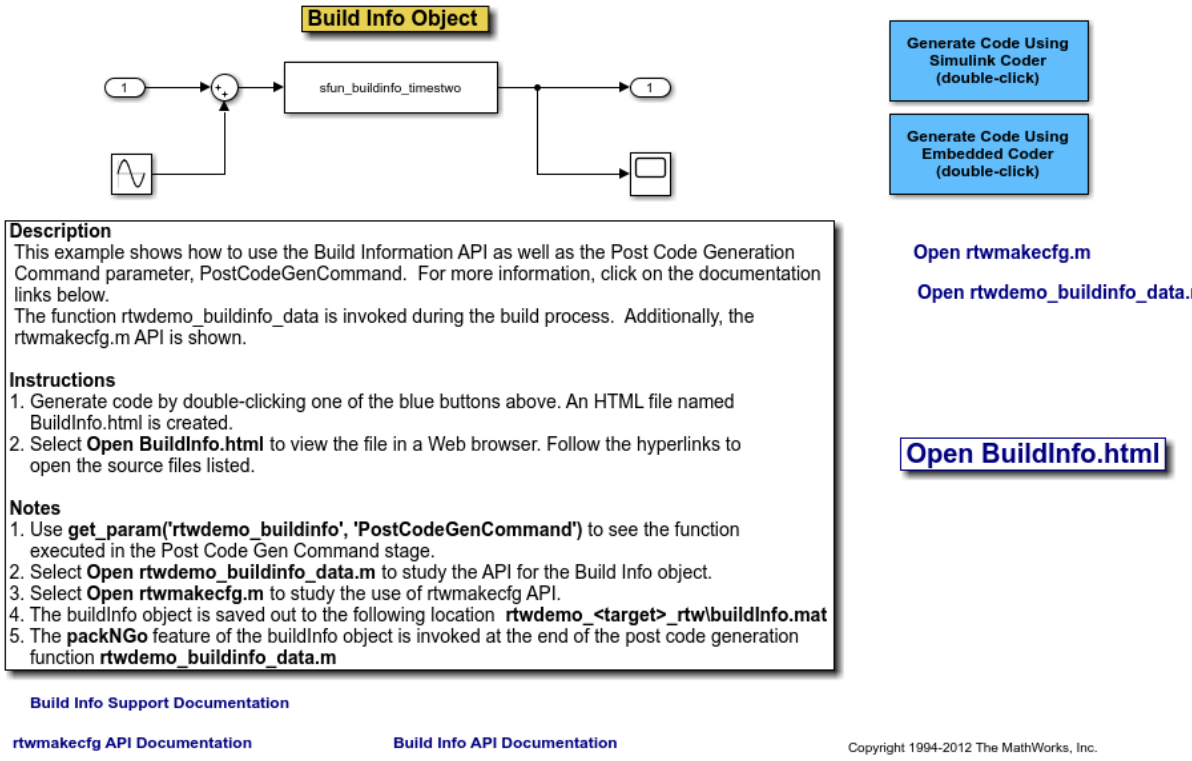
The example also demonstrates how to use the `rtwmakecfg.m` API.

For more information, click on the documentation links in the model.

Open Example Model

Open the example model `rtwdemo_buildinfo`.

```
open_system('rtwdemo_buildinfo');
```



Generate Code from Model

Double-click on the **Generate Code Using Simulink Coder** button to generate code for the GRT target.

Or, if Embedded Coder is installed, double-click on the **Generate Code Using Embedded Coder** button to generate code for the ERT target.

The build process generates a `BuildInfo.html` file to document the build information object.

Examine the Build Process Customizations and Output

Use the links in the model to examine the build process customizations and the post code generation query of the build information object.

To view the `BuildInfo.html` file in a Web browser, click on **Open BuildInfo.html**.

The example uses the `PostCodeGenCommand` parameter of the model to generate the html file from the build information object. The file provides hyperlinks to open the source files (generated code) from the model. To view the `PostCodeGenCommand` parameter value, type:

```
get_param('rtwdemo_buildinfo','PostCodeGenCommand');
```

This value indicates a function to execute in the **Post Code Gen Command** stage.

```
rtwdemo_buildinfo_data(buildInfo);
```

To study how the example uses the `rtwmakecfg` API, click on **Open rtwmakecfg.m** or type:

```
edit rtwmakecfg.m;
```

To study the API for the `buildInfo.mat` object, click on **Open rtwdemo_buildinfo_data.m** or type:

```
edit rtwdemo_buildinfo_data.m;
```

The `buildInfo.mat` object is available at:

```
rtwdemo_<target>_rtw\buildInfo.mat
```

At the end of the `rtwdemo_buildinfo_data.m` post code generation function, the function invokes `packNGo` to package the source and objects identified in the `buildInfo` object for relocation.

Further Study Topics

- “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder)
- “Relocate Code to Another Development Environment” (Simulink Coder)

Suppress Makefile Generation

The code generator lets you suppress makefile generation during the build process. For example, you can use this support when you integrate tools into the build process that do not use makefiles.

To instruct the code generator not to produce a makefile, do one of the following:

- Clear the **Generate makefile** option on the **Code Generation** pane of the Configuration Parameters dialog box.
- Set the value of the configuration parameter `GenerateMakefile` to `off`.

When you suppress makefile generation,

- You cannot explicitly specify a make command or template makefile.
- Specify your own instructions for a post code generation processing, including compilation and linking, in a post code generation command as explained in “Program a Post Code Generation Command” on page 84-15 and “Define a Post Code Generation Command” on page 84-16.

Configure Generated Code with TLC

You can use the Target Language Compiler (TLC) to fine-tune your generated code. TLC supports extended code generation variables and options in addition to parameters available on the **Code Generation** pane on the Configuration Parameters dialog box. There are two ways to set TLC variables and options, as described in this section.

Note Do not customize TLC files in the folder *`matlabroot`*`/rtw/c/tlc` even though the capability exists to do so. It is possible that such TLC customizations are not applied during the code generation process. Such customizations can lead to unpredictable results.

Assigning Target Language Compiler Variables

The `%assign` statement lets you assign a value to a TLC variable, as in:

```
%assign MaxStackSize = 4096
```

This assignment is also known as creating a *parameter name/parameter value pair*.

For a description of the `%assign` statement, see “Target Language Compiler Directives” (Simulink Coder). Write your `%assign` statements in the `Configure RTW code generation settings` section of the system target file.

The following table lists the code generation variables you can set with the `%assign` statement.

Target Language Compiler Optional Variables

Variable	Description
`MaxStackSize=`*`N`*	When the **Enable local block outputs** (Simulink Coder) check box is selected, the total allocation size of local variables that are declared by block outputs in the model cannot exceed `MaxStackSize` (in bytes). `MaxStackSize` can be a positive integer. If the total size of local block output variables exceeds this maximum, the remaining block output variables are allocated in global, rather than local, memory. The default value for `MaxStackSize` is `rtInf`, that is, unlimited stack size. **Note:** Local variables in the generated code from sources other than local block outputs, such as from a Stateflow diagram or MATLAB Function block, and stack usage from sources such as function calls and context switching are not included in the `MaxStackSize` calculation. For overall executable stack usage metrics, do a target-specific measurement by using run-time (empirical) analysis or static (code path) analysis with object code.
`MaxStackVariableSize=`*`N`*	When the **Enable local block outputs** check box is selected, this selection limits the size of a local block output variable declared in the code to `N` bytes, where `N>0`. A variable whose size exceeds `MaxStackVariableSize` is allocated in global, rather than local, memory. The default is 4096.
`WarnNonSaturatedBlocks=`*`value`*	Flag to control display of overflow warnings for blocks that have saturation capability, but have it turned off (not selected) in their dialog box. Options include: • `0` — Warning is not displayed. • `1` — Displays one warning for the model during code generation • `2` — Displays one warning that contains a list of offending blocks

Set Target Language Compiler Options

You can specify TLC command-line options for code generation using the model parameter `TLCOptions` in a `set_param` function call. For information about these options, see “Specify TLC for Code Generation” (Simulink Coder) and “Configure TLC” (Simulink Coder).

Use makecfg to Customize Generated Makefiles for S-Functions

With the toolchain and template makefile approach for building code, you can customize generated makefiles for S-functions. Through the customization, you can specify additional items for the S-function build process:

- Source files and folders
- Include files and folders
- Library names
- Preprocessor macro definitions
- Compiler flags
- Link objects

1. To customize the generated makefile:
   - For all S-functions in the build folder (Simulink Coder), create a `makecfg.m` file.
   - For a specific S-function in the build folder, create a *`specificSFunction`*`_makecfg.m` file.
2. In the file that you create, use `RTW.BuildInfo (Simulink Coder)` functions to specify additional items for the S-function build process. For example, you can use:
   - `addCompileFlags` to specify compiler options.
   - `addDefines` to specify preprocessor macro definitions.
3. Save the created file in the build folder.

After code generation, in the build folder, the code generator searches for `makecfg.m` and *`specificSFunction`*`_makecfg.m` files. If the files are present in the build folder, the code generator uses these files to customize the generated makefile, *`model`*`.mk`.

For example, consider a build folder that contains `signalConvert.mexa64` (S-function binary file) and `signalConvert.tlc` (inlined S-function implementation) after the TLC phase (Simulink Coder) of the build process. The S-function requires an additional source code file, `filterV1.c`, which is located in `anotherFolder`. You can create a file, `signalConvert_makecfg.m`, that uses `RTW.BuildInfo` functions to specify `filterV1.c` for the build process.

```
function signalConvert_makecfg(objBuildInfo)
```

```
absolute = fullfile('$(START_DIR)', 'anotherFolder');

addIncludePaths(objBuildInfo, absolute);
addSourcePaths(objBuildInfo, absolute);
addSourceFiles(objBuildInfo,'filterV1.c');
```

Use rtwmakecfg.m API to Customize Generated Makefiles

Both the toolchain approach and the template makefile approach for builds let you add the following items to generated makefiles:

- Source folders
- Include folders
- Library names
- Module objects

About the rtwmakecfg Function

Using an `rtwmakecfg` function, you add this information to the makefile during the build operation for S-functions. The `rtwmakecfg` function is useful when specifying added sources and libraries to build a model that contains one or more of your S-function blocks.

To add information pertaining to an S-function to the makefile:

1. Create the MATLAB language `rtwmakecfg` function in the `rtwmakecfg.m` file. The code generator associates this file with your S-function based on its folder location. “Create the rtwmakecfg Function” on page 84-26 describes the requirements for the `rtwmakecfg` function and the data it returns.
2. If you are using the template makefile approach, modify the TMF of your target such that it supports macro expansion for the information that the `rtwmakecfg` function returns. “Modify the Template Makefile for rtwmakecfg” on page 84-29 describes the required modifications. If you are using the toolchain approach, the information that the rtwmakecfg function returns is used by the generated makefile; no further configuration is required.

After the TLC phase of the build process, when generating a makefile, the code generator searches for an `rtwmakecfg.m` file in the folder that contains the S-function MEX file. If it finds the file, the build process calls the `rtwmakecfg` function.

Create the rtwmakecfg Function

Create the `rtwmakecfg.m` file containing the `rtwmakecfg` function in the same folder as your S-function component (a MEX-file with a platform-dependent extension, such

as `.mexext` on Microsoft Windows systems). The function must return a structured array that contains these fields.

Field	Description
`makeInfo.includePath`	A cell array that specifies additional include folder names, organized as a row vector. The build process expands the folder names into include instructions in the generated makefile.
`makeInfo.sourcePath`	A cell array that specifies additional source folder names, organized as a row vector. Include the folder names of files entered into the **S-function modules** field on the S-Function Block Parameters dialog box or into the `SFunctionModules` parameter of the block if they are not in the same folder as the S-function. The build process expands the folder names into make rules in the generated makefile.
`makeInfo.sources`	A cell array that specifies additional source file names (C or C++), organized as a row vector. Do not include the name of the S-function or files entered into the **S-function modules** field on the S-Function Block Parameters dialog box or into the `SFunctionModules` parameter of the block. The build process expands the file names into make variables that contain the source files. Specify only file names (with extension). Specify path information with the `sourcePath` field.
`makeInfo.linkLibsObjs`	A cell array that specifies additional, fully qualified paths to object or library files against which the generated code links. The build process does not compile the specified objects and libraries. However, it includes them when linking the final executable. This inclusion can be useful for incorporating libraries that you do not want the build process to recompile or for which the source files are not available. You can also use this element to integrate source files from languages other than C and C++. This integration is possible if you first create a C compatible object file or library outside of the build process.

Field	Description
`makeInfo.precompile`	A Boolean flag that indicates whether the libraries specified in the `rtwmakecfg.m` file exist in a specified location (`precompile==1`) or if you must create the libraries in the build folder during the build process (`precompile==0`).
`makeInfo.library`	A structure array that specifies additional run-time libraries and module objects, organized as a row vector. The build process expands the information into make rules in the generated makefile. For a list of the library fields, see the next table.

The `makeInfo.library` field consists of the following elements.

Element	Description
`makeInfo.library(n).Name`	A character array that specifies the name of the library (without an extension).
`makeInfo.library(n).Location`	A character array that specifies the folder in which the library is located when precompiled. For more information, see the description of `makeInfo.precompile` in the preceding table. A target can use the `TargetPreCompLibLocation` parameter to override this value. See “Specify the Location of Precompiled Libraries” (Simulink Coder).
`makeInfo.library(n).Modules`	A cell array that specifies the C or C++ source file base names (without an extension) that comprise the library. Do not include the file extension. The makefile appends the object extension.

Note The `makeInfo.library` field must fully specify each library and how to build it. The modules list in the `makeInfo.library(n).Modules` element cannot be empty. To specify a link-only library, use the `makeInfo.linkLibsObjs` field instead.

Example:

```
disp(['Running rtwmakecfg from folder: ',pwd]);
   makeInfo.includePath = { fullfile(pwd, 'somedir2') };
   makeInfo.sourcePath = {fullfile(pwd, 'somedir2'), fullfile(pwd, 'somedir3')};
   makeInfo.sources  = { 'src1.c', 'src2.cpp'};
```

```
makeInfo.linkLibsObjs = { fullfile(pwd, 'somedir3', 'src3.object'),...
                          fullfile(pwd, 'somedir4', 'mylib.library')};
makeInfo.precompile = 1;
makeInfo.library(1).Name     = 'myprecompiledlib';
makeInfo.library(1).Location = fullfile(pwd,'somdir2','lib');
makeInfo.library(1).Modules  = {'srcfile1' 'srcfile2' 'srcfile3' };
```

Note If a path that you specify in the `rtwmakecfg.m` API contains spaces, the build process does not convert the path to its nonspace equivalent. If the build environments you intend to support do not support spaces in paths, refer to “Build Process Support for Folder Names with Spaces or Special Characters” (Simulink Coder).

Modify the Template Makefile for rtwmakecfg

To expand the information that an `rtwmakecfg` function generates, modify the following sections in the TMF of your target:

- `Include Path`
- `C Flags` and/or `Additional Libraries`
- `Rules`

It is possible that these TMF code examples do not apply to your make utility. For additional examples, see the GRT or ERT TMFs located in *`matlabroot`*`/rtw/c/grt` (open) or *`matlabroot`*`/rtw/c/ert` (open).

Add Folder Names to the Makefile Include Path

The following TMF code example adds folder names to the include path in the generated makefile:

```
ADD_INCLUDES = \
|>START_EXPAND_INCLUDES<|   -I|>EXPAND_DIR_NAME<| \
|>END_EXPAND_INCLUDES<|
```

Also, the `ADD_INCLUDES` macro must be added to the `INCLUDES` line.

```
INCLUDES = -I. -I.. $(ADD_INCLUDES) $(USER_INCLUDES)
```

Add Library Names to the Makefile

The following TMF code example adds library names to the generated makefile.

```
LIBS =
|>START_PRECOMP_LIBRARIES<|
```

```
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_PRECOMP_LIBRARIES<|
|>START_EXPAND_LIBRARIES<|
LIBS += |>EXPAND_LIBRARY_NAME<|.a |>END_EXPAND_LIBRARIES<|
```

For more information, see “Control Library Location and Naming During Build” on page 84-7.

Add Rules to the Makefile

The TMF code example adds rules to the generated makefile.

```
|>START_EXPAND_RULES<|
$(BLD)/%.o: |>EXPAND_DIR_NAME<|/%.c $(SRC)/$(MAKEFILE) rtw_proj.tmw
    @$(BLANK)
    @echo ### "|>EXPAND_DIR_NAME<|\$*.c"
    $(CC) $(CFLAGS) $(APP_CFLAGS) -o $(BLD)$(DIRCHAR)$*.o \
    |>EXPAND_DIR_NAME<|$(DIRCHAR)$*.c > $(BLD)$(DIRCHAR)$*.lst
|>END_EXPAND_RULES<|

|>START_EXPAND_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<|    |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
    @$(BLANK)
    @echo ### Creating $@
    $(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_EXPAND_LIBRARIES<|

|>START_PRECOMP_LIBRARIES<|MODULES_|>EXPAND_LIBRARY_NAME<| = \
|>START_EXPAND_MODULES<|    |>EXPAND_MODULE_NAME<|.o \
|>END_EXPAND_MODULES<|

|>EXPAND_LIBRARY_NAME<|.a : $(MAKEFILE) rtw_proj.tmw
$(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
    @$(BLANK)
    @echo ### Creating $@
    $(AR) -r $@ $(MODULES_|>EXPAND_LIBRARY_NAME<|:%.o=$(BLD)/%.o)
|>END_PRECOMP_LIBRARIES<|
```

Register Custom Toolchain and Build Executable

This example shows how to register and use a toolchain to build an executable. This example uses the Intel® compiler. However, the concepts and programming interface apply for other toolchains. Once you register a toolchain, you can configure a model such that the code generator uses that toolchain to build an executable for the model.

Toolchain

A toolchain is a collection of tools required to compile, link, download, and run code on a specified platform. A toolchain consists of multiple tools, such as a compiler, linker, and archiver. You can configure the tools in a toolchain with multiple options and group tool specifications into types of configurations.

Create a New Folder and Copy Relevant Files

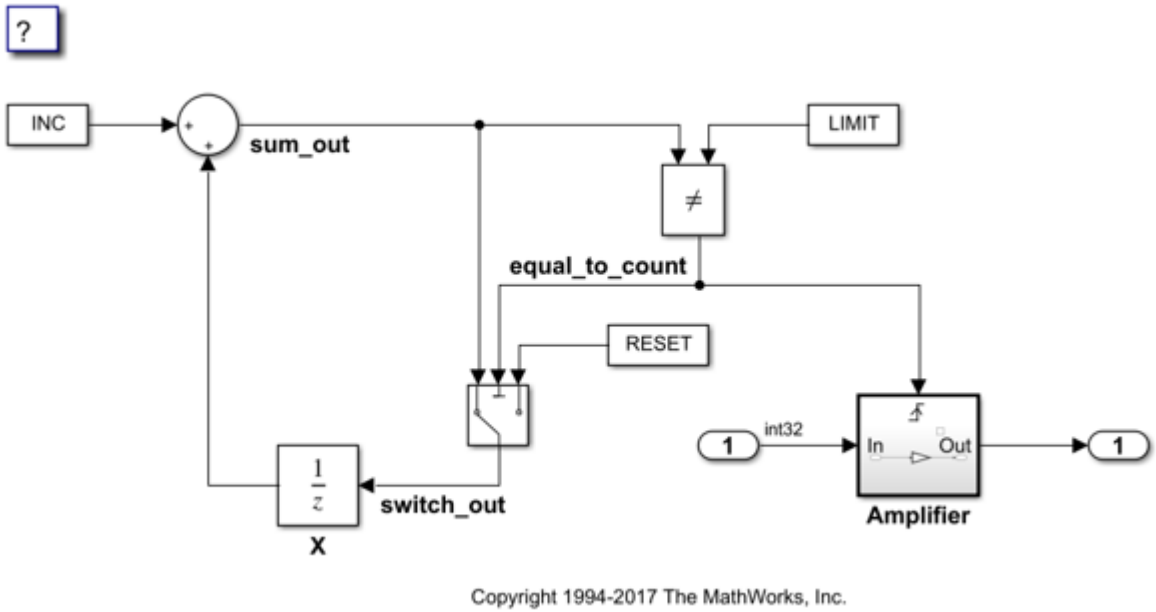
The following code creates a folder in your current working folder (pwd). The new folder contains files for this example. If you do not want to affect the current folder, or cannot generate files in this folder, change your working folder before invoking the command.

```
copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos','toolchain_demo'),'toolchain_de
cd toolchain_demo
```

Open a Model

Open the `rtwdemo_counter` model. By default, this model is configured to use the Generic Real-Time Target (GRT) configuration and the toolchain approach for building an executable. The capability demonstrated in this example is available for models configured to use the Toolchain approach.

```
model = 'rtwdemo_counter';
open_system(model)
```



Choose a Toolchain

In the model window, click **Simulation > Model Configuration Parameters** to open the **Configuration Parameters** dialog box. Select **Code Generation**. The **Toolchain settings** section contains parameters for configuring a toolchain. From the **Toolchain** drop-down list, select the toolchain installed on your development system for building an executable from the code generated from your model.

By default, the **Faster Runs** build configuration is selected. Click **Show settings** to see the toolchain flags specified for building the generated code. Choose a build configuration based on your current application development goal.

Close the **Configuration Parameters** dialog box.

Create a ToolchainInfo Object

This example shows how you can register a custom toolchain and add it as a selectable **Toolchain** option.

The first step to registering a custom toolchain is to create a `ToolchainInfo` object that contains information about the toolchain. Methods are available to set toolchain specifications. You can share a `ToolchainInfo` object across installations.

Open the toolchain definition file for an Intel compiler. This file creates a `ToolchainInfo` object that contains information about the Intel toolchain on a 64-bit Windows® platform.

```
edit intel_tc
type intel_tc
```

```
function tc = intel_tc
%INTEL_TC Creates an Intel v14 ToolchainInfo object.
% This file can be used as a template to define other toolchains on Windows.

% Copyright 2012-2016 The MathWorks, Inc.

tc = coder.make.ToolchainInfo('BuildArtifact', 'nmake makefile');
tc.Name             = 'Intel v14 | nmake makefile (64-bit Windows)';
tc.Platform         = 'win64';
tc.SupportedVersion = '14';

tc.addAttribute('TransformPathsWithSpaces');
tc.addAttribute('RequiresCommandFile');
tc.addAttribute('RequiresBatchFile');

tc.setBuildConfigurationOption('all', 'Download',      '');
tc.setBuildConfigurationOption('all', 'Execute',       '');
tc.setBuildConfigurationOption('all', 'Make Tool',     '-f $(MAKEFILE)');
```

You can display the errors and warnings in the diagnostics messages pane from builds generated by custom compilers. For more information, see “Diagnostic Message Pane” (Simulink).

Run the toolchain definition file to generate the `ToolchainInfo` object.

```
tc = intel_tc;
```

Save the `ToolchainInfo` object `tc` to a MAT file.

```
save intel_tc tc
```

Register the Custom Toolchain

After you create the `ToolchainInfo` object for the new toolchain, register it. Register a toolchain in `RTW.TargetRegistry`. To register the toolchain, write an `rtwTargetInfo.m` file. Then, add that file to the MATLAB path so the system loads it automatically.

```
type rtwTargetInfo
```

```
function rtwTargetInfo(tr)
%RTWTARGETINFO Registration file for custom toolchains.

% Copyright 2012-2016 The MathWorks, Inc.

tr.registerTargetInfo(@loc_createToolchain);

end

% ----------------------------------------------------------------------
% Create the ToolchainInfoRegistry entries
% ----------------------------------------------------------------------
function config = loc_createToolchain

config(1)                       = coder.make.ToolchainInfoRegistry;
config(1).Name                  = 'Intel v14 | nmake makefile (64-bit Windows)';
config(1).FileName              = fullfile(fileparts(mfilename('fullpath')), 'intel_tc
config(1).TargetHWDeviceType    = {'*'};
config(1).Platform              =  {computer('arch')};

end
```

Reset the `TargetRegistry` to use the new `rtwTargetInfo.m` file.

```
RTW.TargetRegistry.getInstance('reset');
```

Choose the Custom Toolchain

Reopen the **Configuration Parameters** dialog box. Click **Toolchain**. You should see the new toolchain in the list. Select the `Intel v14` toolchain.

Programmatically, you can accomplish the same task with the following commands:

```
cs = getActiveConfigSet(model);
set_param(cs, 'Toolchain', tc.Name)
```

Verify your selection.

```
toolchain = get_param(cs, 'Toolchain')
```

```
toolchain =

    'Intel v14 | nmake makefile (64-bit Windows)'
```

Build the Model Using the Custom Toolchain

You can now build the model with the new custom toolchain.

Note: If you do not have the Intel toolchain installed, you can use the following command to generate the code and makefile only.

```
set_param(cs, 'GenCodeOnly', 'on')
```

Build the model to generate the code and makefile that uses the new toolchain.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_counter
### Successful completion of code generation for model: rtwdemo_counter
```

Obtain the build directory information.

```
dirInfo = RTW.getBuildDir(model);
```

Examine the generated makefile.

```
type(fullfile(dirInfo.BuildDirectory, [model '.mk']))
```

```

```

Once the build process is finished, and you had Intel compilers installed, you can run the generated executable.

```
if ispc
   system([model '.exe'])
else
```

```
   system(model)
end
```

Restore

You can optionally remove the folder you created earlier.

```
cd ..
```

rmdir('toolchain_demo', 's')

Reset the `TargetRegistry` to remove the toolchain that you registered above.

```
RTW.TargetRegistry.getInstance('reset');
```

Close the model.

```
close_system(model, 0)
```

Clear the variables introduced in the workspace.

```
clear INC K LIMIT RESET model tc cs toolchain
```

Customize Build Process with STF_make_rtw_hook File

The build process lets you supply optional custom code in hook methods that are executed at specified points in the code generation and make process. You can use hook methods to add target-specific actions to the build process.

STF_make_rtw_hook File

You can modify hook methods in a file generically referred to as *STF*_make_rtw_hook.m, where *STF* is the name of a system target file, such as `ert` or `mytarget`. This file implements a function, *STF*_make_rtw_hook, that dispatches to a specific action, depending on the `hookMethod` argument passed in.

The build process calls *STF*_make_rtw_hook, passing in the`hookMethod` argument and other arguments. You implement only those hook methods that your build process requires.

If your model contains reference models, you can implement an *STF*_make_rtw_hook.m for each reference model as required. The build process calls each *STF*_make_rtw_hook for reference models, processing these files recursively (in dependency order).

Conventions for Using the STF_make_rtw_hook File

For the build process to call the *STF*_make_rtw_hook, check that the following conditions are met:

- The *STF*_make_rtw_hook.m file is on the MATLAB path.
- The file name is the name of your system target file (STF), appended to the text _make_rtw_hook.m. For example, if you generate code with a custom system target file `mytarget.tlc`, name your hook file `mytarget_make_rtw_hook.m`, and name the hook function implemented within the file `mytarget_make_rtw_hook`.
- The hook function implemented in the file uses the function prototype described in “STF_make_rtw_hook.m Function Prototype and Arguments” on page 84-50.

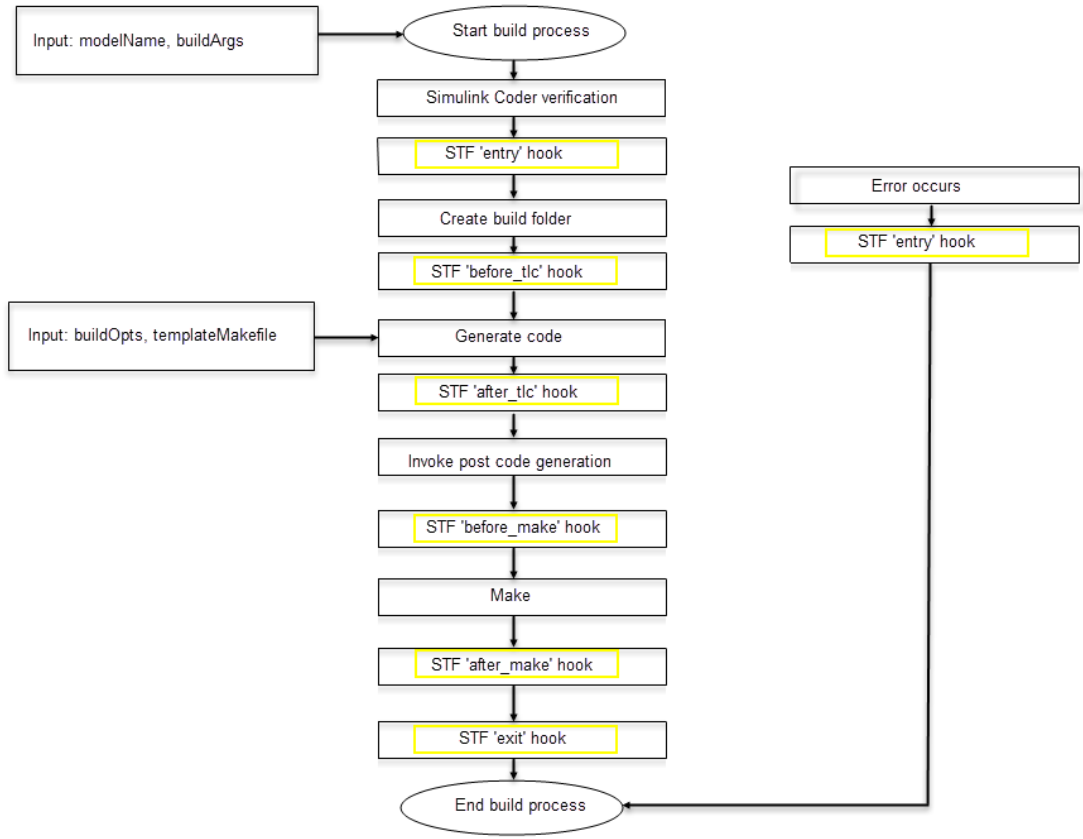
STF_make_rtw_hook.m Function Prototype and Arguments

The function prototype for *STF*_make_rtw_hook is:

```
function STF_make_rtw_hook(hookMethod, modelName, rtwRoot, templateMakefile,
buildOpts, buildArgs, buildInfo)
```

The arguments are defined as:

- `hookMethod`: Character vector specifying the stage of build process from which the *STF*`_make_rtw_hook` function is called. The following flow chart summarizes the build process, highlighting the hook points. Valid values for `hookMethod` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, `'exit'`, and `'error'`. The *STF*`_make_rtw_hook` function dispatches to the relevant code with a `switch` statement.



- `modelName`: Character vector specifying the name of the model. Valid at all stages of the build process.
- `rtwRoot`: Reserved.
- `templateMakefile`: Name of template makefile.
- `buildOpts`: A MATLAB structure containing the fields described in the following list. Valid for the `'before_make'`, `'after_make'`, and `'exit'` stages only. The `buildOpts` fields include:
  - `modules`: Character vector specifying a list of additional files to compile.
  - `codeFormat`: Character vector specifying the value of the `CodeFormat` TLC variable for the target. (ERT-based targets must use the `'Embedded-C'` value for the `CodeFormat` TLC variable and use the corresponding `'ert.tlc'` value in the `rtwgensettings.DerivedFrom` field.)
  - `noninlinedSFcns`: Cell array specifying a list of noninlined S-functions in the model.
- `buildArgs`: Character vector containing the argument to `make_rtw`. When you invoke the build process, `buildArgs` is copied from the argument following `"make_rtw"` in the **Configuration Parameters** + **Code Generation** + **Make command** field.

  For example, the following make arguments from the **Make command** field

  ```
  make_rtw VAR1=0 VAR2=4
  ```

  generate the following:

  ```
  % make -f untitled.mk VAR1=0 VAR2=4
  ```

  The `buildArgs` argument does not apply for toolchain approach builds because these builds do not allow adding make arguments to the `make_rtw` call. On the compiler command line, to provide custom definitions (for example, `VAR1=0 VAR2=4`) that apply for both TMF approach and toolchain approach builds, use the **Configuration Parameters** > **Code Generation** > **Custom Code** > **Defines** field.
- `buildInfo`: The MATLAB structure that contains the model build information fields. Valid for the `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'` stages only. For information about these fields and functions to access them, see “Build Process Customization” (Simulink Coder).

Applications for STF_make_rtw_hook.m

Here are some examples of how to apply the *STF*_make_rtw_hook.m hook methods.

In general, you can use the 'entry' hook to initialize the build process, for example, to change or validate settings before code is generated. One application for the 'entry' hook is to rerun the auto-configuration script that initially ran at target selection time to compare model parameters before and after the script executes, for validation purposes.

The other hook points, 'before_tlc', 'after_tlc', 'before_make', 'after_make', 'exit', and 'error' are useful for interfacing with external tool chains, source control tools, and other environment tools.

For example, you could use the *STF*_make_rtw_hook.m file at a stage after 'entry' to obtain the path to the build folder. At the 'exit' stage, you could then locate generated code files within the build folder and check them into your version control system. You can use 'error' to clean up static or global data used by the hook function when an error occurs during code generation or the build process.

Note The build process temporarily changes the MATLAB working folder to the build folder for stages 'before_make', 'after_make', 'exit', and 'error'. Your *STF*_make_rtw_hook.m file must not make incorrect assumptions about the location of the build folder. At a point after the 'entry' stage, you can obtain the path to the build folder. In the following MATLAB code example, the build folder path is returned as a character vector to the variable buildDirPath.

```
buildDirPath = rtwprivate('get_makertwsettings',gcs,'BuildDirectory');
```

Note A change to model configuration within *STF*_make_rtw_hook.m file (including switching Variants) might lead to unexpected results in code generation.

Control Code Regeneration Using STF_make_rtw_hook.m

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. (For details on the criteria, see “Control Regeneration of Top Model Code” on page 54-46.) If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. If the checks indicate that the top

model generated code is current with respect to the model, and model settings do not require full regeneration, the build process omits regeneration of the top model code.

Regardless of whether the top model code is regenerated, the build process subsequently calls the build process hooks, including *STF*_make_rtw_hook functions and the post code generation command. The following mechanisms allow you to perform actions related to code regeneration in the *STF*_make_rtw_hook functions:

- To force code regeneration, use the following function call from the `'entry'` hook:

  ```
  rtw.targetNeedsCodeGen('set', true);
  ```

- In hooks from `'before_tlc'` through `'exit'`, the `buildOpts` structure passed to the hook has a Boolean field `codeWasUpToDate`. The field is set to `true` if model code was up to date and code was not regenerated, or `false` if code was not up to date and code was regenerated. You can customize hook actions based on the value of this field. For example:

  ```
  ...
  case 'before_tlc'
      if buildOpts.codeWasUpToDate
          %Perform hook actions for up to date model
      else
          %Perform hook actions for full code generation
      end
  ...
  ```

Use STF_make_rtw_hook.m for Your Build Procedure

To create a custom *STF*_make_rtw_hook hook file for your build procedure, copy and edit the example `ert_make_rtw_hook.m` file, which is located in the folder*matlabroot*`/toolbox/coder/embeddedcoder` (open), as follows:

1. Copy `ert_make_rtw_hook.m` to a folder in the MATLAB path. Rename it in accordance with the naming conventions described in “Conventions for Using the STF_make_rtw_hook File” on page 84-50. For example, to use it with the GRT target `grt.tlc`, rename it to `grt_make_rtw_hook.m`.
2. Rename the `ert_make_rtw_hook` function within the file to match the file name.
3. Implement the hooks that you require by adding code to case statements within the `switch hookMethod` statement.

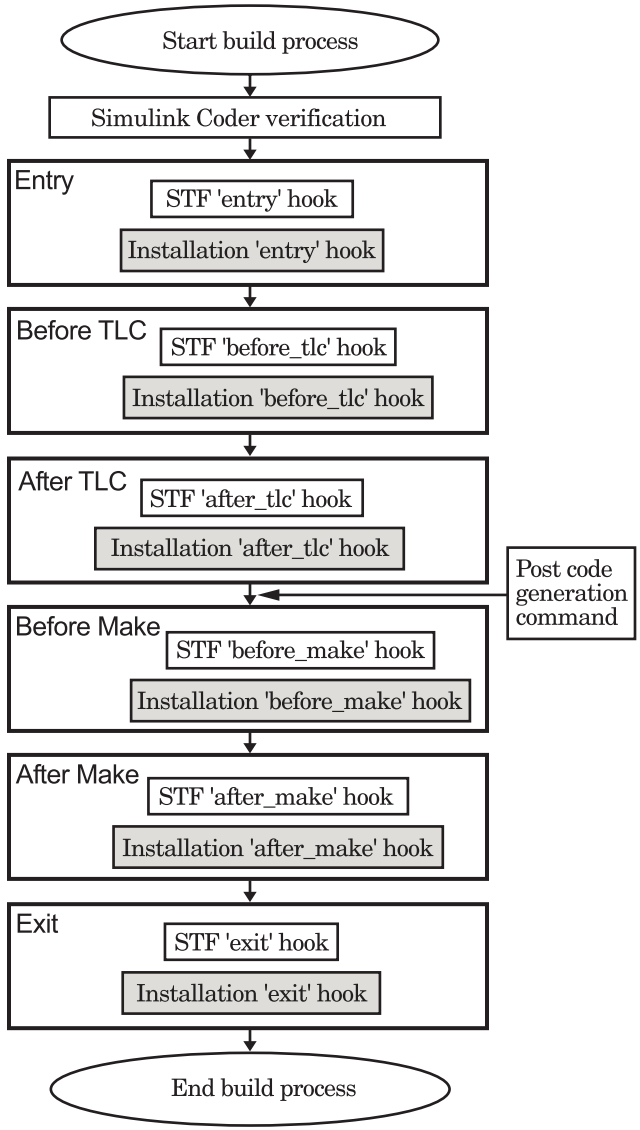
Customize Build Process with sl_customization.m

The Simulink customization file `sl_customization.m` is a mechanism that allows you to use MATLAB to customize the build process interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see “Registering Customizations” (Simulink).

The sl_customization.m File

The `sl_customization.m` file can be used to register installation-specific hook functions to be invoked during the build process. The hook functions that you register through `sl_customization.m` complement System Target File (STF) hooks (described in “Customize Build Process with STF_make_rtw_hook File” on page 84-50) and post-code generation commands (described in “Customize Post-Code-Generation Build Processing” on page 84-14).

The following figure shows the relationship between installation-level hooks and the other available mechanisms for customizing the build process.



Start build process
Simulink Coder verification
Entry
STF 'entry' hook
Installation 'entry' hook
Before TLC
STF 'before_tlc' hook
Installation 'before_tlc' hook
After TLC
STF 'after_tlc' hook
Installation 'after_tlc' hook
Post code generation command
Before Make
STF 'before_make' hook
Installation 'before_make' hook
After Make
STF 'after_make' hook
Installation 'after_make' hook
Exit
STF 'exit' hook
Installation 'exit' hook
End build process

Register Build Process Hook Functions Using sl_customization.m

To register installation-level hook functions that are invoked during the build process, you create a MATLAB function called `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.RTWBuildCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following method for registering build process hook customizations:

- `addUserHook(hObj, hookType, hook)`

  Registers the MATLAB hook script or function specified by `hook` for the build process stage represented by `hookType`. The valid values for `hookType` are `'entry'`, `'before_tlc'`, `'after_tlc'`, `'before_make'`, `'after_make'`, and `'exit'`.

Use this method to register installation-specific hook functions in your instance of the `sl_customization` function.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, you must restart the Simulink session or enter the following command in the Command Window to enable the changes:

```
sl_refresh_customizations
```

Variables Available for sl_customization.m Hook Functions

The following variables are available for `sl_customization.m` hook functions to use:

- `modelName` — The name of the Simulink model (valid for all stages)
- `dependencyObject` — An object containing the dependencies of the generated code (valid only for the `'after_make'` stage)

A hook script can directly access the valid variables. A hook function can pass the valid variables as arguments to the function. For example:

```
hObj.addUserHook('after_make', 'afterMakeFunction(modelName,dependencyObject);');
```

Example of Build Process Customization with sl_customization.m

The `sl_customization.m` file shown in the example, **sl_customization.m for Build Process Customizations**, uses the `addUserHook` method to specify installation-specific build process hooks to be invoked at the `'entry'` and `'after_tlc'` stages of the build process. For the hook function source code, see the **CustomRTWEntryHook.m** and **CustomRTWPostProcessHook.m** examples.

Example 84.1. sl_customization.m for Build Process Customizations

```
function sl_customization(cm)
% Register user customizations

% Get default (factory) customizations
hObj = cm.RTWBuildCustomizer;

% Register build process hooks
hObj.addUserHook('entry', 'CustomRTWEntryHook(modelName);');
hObj.addUserHook('after_tlc', 'CustomRTWPostProcessHook(modelName);');

end
```

Example 84.2. CustomRTWEntryHook.m

```
function [str, status] = CustomRTWEntryHook(modelName)
str =sprintf('Custom entry hook for model ''%s.''',modelName);
disp(str)
status =1;
```

Example 84.3. CustomRTWPostProcessHook.m

```
function [str, status] = CustomRTWPostProcessHook(modelName)
str =sprintf('Custom post process hook for model ''%s.''',modelName);
disp(str)
status =1;
```

If you include the above three files on the MATLAB path of the Simulink installation that you want to customize, the coded hook function messages appear in the displayed output for builds. For example, if you open the ERT-based model `rtwdemo_udt`, open the **Code Generation** pane of the Configuration Parameters dialog box, and press **Ctrl+B** to initiate a build, the following messages are displayed:

```
>> rtwdemo_udt

### Starting build procedure for model: rtwdemo_udt
```

```
Custom entry hook for model 'rtwdemo_udt.'
Custom post process hook for model 'rtwdemo_udt.'
### Successful completion of build procedure for model: rtwdemo_udt
>>
```

Replace STF_rtw_info_hook Supplied Target Data

Prior to MATLAB Release 14, custom targets supplied target-specific information with a hook file (referred to as *STF*_rtw_info_hook.m). The *STF*_rtw_info_hook specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The *STF*_rtw_info_hook mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify properties that were formerly specified in your *STF*_rtw_info_hook file.

For backward compatibility, existing *STF*_rtw_info_hook files are available. However, you should convert your target and models to use of the **Hardware Implementation** pane. See “Configure Production and Test Hardware” (Simulink Coder).

Custom Target Development in Simulink Coder

About Embedded Target Development

Target files bundled with the code generator are suitable for many different applications and development environments. Third-party targets provide additional versatility. In addition, you have the option of implementing a custom target.

To implement a target based on the ARM Cortex®-A or ARM Cortex-M processor, install the corresponding support package and see the Target SDK: Embedded Coder Support Package for ARM Cortex-A Processors, “Develop a Target” (Embedded Coder Support Package for ARM Cortex-A Processors) or Embedded Coder Support Package for ARM Cortex-M Processors, “Develop a Target” (Embedded Coder Support Package for ARM Cortex-M Processors). Otherwise, use these functions and topics.

Custom Targets

You might want to implement a custom target for one of the following reasons:

- To enable end users to generate executable production code for a specific CPU or development board, using a specific development environment (compiler/linker/debugger).
- To support I/O devices on the target hardware by incorporating custom device driver blocks into your models.
- To configure the build process for a special compiler (such as a cross-compiler for an embedded microcontroller or DSP board) or development/debugging environment.

The code generator provides a point of departure for the creation of custom embedded targets, for the basic purposes above. This manual covers the tasks and techniques you need to implement a custom embedded target.

Types of Targets

The following sections describe several types of targets intended for different use cases

• “HIL Simulation” on page 85-4

About Target Types

There is a progression of capabilities from baseline or rapid prototyping targets to production targets. Initially, you might want to implement a rapid prototyping target. Later, you can enhance the target to be more full-featured. For example, you might want to add support for software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation at some point for verifying your embedded target. The target types are not mutually exclusive. An embedded target can support more than one of these use cases, or additional uses not outlined here.

The discussion of target types is followed by “Recommended Features for Embedded Targets” on page 85-4, which contains a suggested list of features and general guidelines for embedded target development.

Rapid Prototyping Targets

A *rapid prototyping target* or baseline target offers a starting point for targeting a production processor. A rapid prototyping target integrates coded generator software with one or more popular cross-development environments (compiler/linker/debugger tool chains). A rapid prototyping target provides a starting point from which you can customize the target for application needs.

Target files provided for this type of target should be readable, easy to understand, and fully commented and documented. Specific attention should be paid to the interface to the intended cross-development environment. This interface should be implemented using the preferred approach for that particular development system. For example, some development environments use traditional make utilities, while others are based on project-file builds that can be automated under control of the code generator.

When you use a rapid prototyping target, you need to include your own device driver and legacy code and modify linker memory maps to suit your needs. You should be familiar with the targeted development system.

Production Targets

A *production target* supports embedded application development for a production processor. It includes the capability to create program executables that interact immediately with the external world. In general, ease of use is more important than simplicity or readability of generated code files, because it is assumed that you do not want or need to modify the files.

Desirable features for a production target include:

- Significant I/O driver support, provided out of the box
- Easy downloading of generated standalone executable programs with third-party debuggers
- User-controlled placement of an executable in FLASH or RAM memory
- Support for code visibility and tuning on target hardware

Verifying Targets With SIL and PIL Simulation

You can use software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulation to verify generated code and validate the target compiler/processor environment.

You can use SIL and PIL simulation modes to verify automatically generated code by comparing the results with a normal mode simulation. With SIL, you can easily verify the behavior of production-intent source code on your host computer; however, it is generally not possible to verify exactly the same code that will subsequently be compiled for your target hardware because the code must be compiled for your host platform (i.e. a different compiler and different processor architecture than the target). With PIL simulation, you can verify exactly the same code that you intend to deploy in production, and you can run the code either on real target hardware or on an instruction set simulator.

For examples describing how to run processor-in-the-loop testing to verify a custom target, see “Sample Custom Targets” on page 85-9.

For more information on SIL and PIL simulation, see “SIL and PIL Simulations” on page 78-2.

HIL Simulation

A specialized use case is the generation of executables intended for use in *hardware-in-the-loop* (HIL) simulations. In a HIL simulation, parts of a pure simulation are gradually replaced with hardware components as components are refined and fabricated. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

Recommended Features for Embedded Targets

- “Basic Target Features” on page 85-5

Basic Target Features

- You can base targets on the generic real-time (GRT) target or the Embedded Real-Time (ERT) target that is included in the Embedded Coder product.

  If your target is based on the ERT target, it should use `'Embedded-C'` value for the `CodeFormat` TLC variable, and it should inherit the options defined in the ERT target's system target file with the following lines in the TLC file:

  ```
  %% Assign code format
  %assign CodeFormat = "Embedded-C"
  %%-----------------------------
  /%
    BEGIN_RTW_OPTIONS
    rtwgensettings.DerivedFrom = 'ert.tlc';
    END_RTW_OPTIONS
  %/
  %%-----------------------------
  ```

  By following these recommendations, your target has the production code generation capabilities of the ERT target.

  See “Customize System Target Files” on page 85-28 for further details on the inheritance mechanism, setting the `CodeFormat`, and other details.

- The most fundamental requirement for an embedded target is that it generate a real-time executable from a model or subsystem. Typically, an embedded target generates a timer interrupt-based, bareboard executable (although targets can be developed for an operating system environment as well).

  Your target should support code generator concepts of single-tasking and multitasking solver modes for model execution. Tasking support is available with the ERT target, but you should thoroughly understand how it works before implementing an ERT-based target.

  For information on timer interrupt-based execution, see “Absolute and Elapsed Time Computation” (Simulink Coder) and “Asynchronous Events” (Simulink Coder).

- You should generate the target executable's main program module, rather than using a static main module (such as the static `rt_main.c` or `rt_cppclass_main.cpp` module provided with the software). A generated `main.c` or `.cpp` can be made much

more readable and more efficient, since it omits preprocessor checks and other extra code.

For information on generated and static main program modules, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 63-2.

- Follow the guidelines in “Folder and File Naming Conventions” on page 85-11.

Integration with Target Development Environments

- Most cross-development systems run under a Microsoft Windows PC host. Your target should support the Windows operating system as the host environment.

  Some cross-development systems support one or more versions of The Open Group UNIX platforms, allowing for UNIX host support as well.
- Your embedded target must support at least one embedded development environment. The interface to a development environment can take one of several forms. The toolchain approach and template makefile approach generate standard makefiles to work with your development environment. For general information about these build approaches, see “Choose Build Approach and Configure Build Process” (Simulink Coder). For detailed information about the structure of template makefiles, see “Customize Template Makefiles” on page 85-62.

  It is important to consider the license requirements and restrictions of the development environment vendor. You may need to modify files provided by the vendor and ship them as part of the embedded target.

  See “Interface to Development Tools” on page 85-98 for further information.

Observing Execution of Target Code

- Your target should support a mechanism you can use to observe the target code as it runs in real time (outside of a debugger).

  You can use the `rtiostream` API to implement a communication channel to enable exchange of data between different processes. For an example of creating a communication channel for target connectivity, see “Create a Target Communication Channel for Processor-In-The-Loop (PIL) Simulation” on page 78-101. This `rtiostream` communication channel is required to enable processor-in-the-loop (PIL) on a new target. See “Communications rtiostream API” on page 78-50.

  One industry-standard approach is to use the CAN bus, with an ASAP2 file and CAN Calibration Protocol (CCP). There are several host-based graphical front-end tools

available that connect to a CCP-enabled target and provide data viewing and parameter tuning. Supporting these tools requires implementation of CAN hardware drivers and CCP protocol for the target, as well as ASAP2 file generation. Your target can leverage the ASAP2 support provided with the code generator.

Another option is to support Simulink external mode simulation. For more information, see the “Host-Target Communication with External Mode Simulation” (Simulink Coder).

Deployment and Hardware Issues

- Device driver support is an important issue in the design of an embedded target. Device drivers are Simulink blocks that support either hardware I/O capabilities of the target CPU, or I/O features of the development board.

  If you are developing a rapid prototyping target, consider providing minimal driver support, on the assumption that end users develop their own drivers. If you are developing a production target, you should provide full driver support.

  See “Device Drivers” (Simulink Coder).
- Automatic download of generated code to the target hardware makes a target easier to use. Typically a debugger utility is used; if the chosen debugger supports command script files, this can be straightforward to implement. “STF_make_rtw_hook.m” on page 85-20 describes a mechanism to execute code from the build process. You can use this mechanism to make `system()` calls to invoke utilities such as a debugger. You can invoke other simple downloading utilities in a similar fashion.

  If your development system supports COM automation, you can control the download process by that mechanism. Using COM automation is discussed in “Interface to Development Tools” on page 85-98.
- Executables that are mapped to RAM memory are typical. You can provide optional support for FLASH or RAM placement of the executable by using your target's code generation options. To support this capability, you might need multiple linker command files, multiple debugger scripts, and possibly multiple makefiles or project files. Also include the ability to automatically switch between these files, depending on the RAM/FLASH option value.
- Select a popular, widely available evaluation or prototype board for your target processor. Consider enclosed and ruggedized versions of the target board. Also consider board level support for the various on-chip I/O capabilities of the target CPU, and the availability of development systems that support the selected board.

Sample Custom Targets

There are technical solutions on the MathWorks Web site that you can use as a starting point to create your own target solution. The solutions provide guides to the following tasks for creating custom targets:

- Methods of embedding code onto a custom processor
- Creating a system target file
- Customizing the makefile and main file
- Adding compiler, chip, and board specific information
- Integrating legacy code and device drivers
- Creating blocks and libraries
- Implementing processor-in-the-loop (PIL) testing.

1 Start by downloading the embedded targets development guide `zip` file from this web page:

Is there an example guide on developing an embedded target...?

The `zip` file provides example files and a guide to developing a custom embedded target. The guide is divided into two parts, one on creating a generic custom target and another on creating a target for the Freescale™ S12X processor using the Cosmic Compiler.

Read the example guide along with this document to understand the tasks for developing embedded targets.

2 For more detailed example files for specific processors, see:

- Is there an example Freescale S12X target... using the Cosmic Compiler?
- Is there an example Freescale S12X target... using the CodeWarrior Compiler?

These example kits contain example models, code generation files, and instruction guides on generating and testing code for the processor. The Cosmic example illustrates the use of the target connectivity API for processor-in-the-loop (PIL) testing. The CodeWarrior example does not have PIL but shows CAN Calibration Protocol (CCP) and Simulink external mode.

The intent of the example kits is to provide working examples that you can use as a base to create your own target solution. The intent is not to provide a full featured

and maintained Embedded Target product like those provided by MathWorks or third-party products, as listed on the Embedded Coder Hardware Support Web page.

3 You can watch videos showing overviews of both the example kits at the following links:

- `www.mathworks.com/videos/programming-the-freescale-s12x-target-68811.html`
- `www.mathworks.com/videos/programming-arm9-using-the-hitex-str9-comstick-68812.html`

For another example target for the ARM9 (STR9) processor, see Is there an example ARM9 (STR9) target... using the GNU ARM Compiler and Hitex STR9-comStick?.

If you have questions on specific targets, please email mytarget@mathworks.com.

The example kits and this document describe Embedded Coder features such as customized `ert` system target files and processor-in-the-loop testing, but you can study the examples as a starting point for use with Simulink Coder targets.

Target Development Folders, Files, and Builds

Target development mechanics work with a number of folder and file types. The following topics provide the information to develop custom targets, configure folder usage, and use custom targets in the build process.

Folder and File Naming Conventions

You can use a single folder for your custom target files, or if desired you can use subfolders, for example containing files associated with specific development environments or tools.

For a custom target implementation, the recommended folder and file naming conventions are

- Use *only* lowercase in folder names, filenames, and extensions.
- Do not embed spaces in folder names. Spaces in folder names cause errors with many third-party development environments.
- Include desired folders in the MATLAB path
- Do *not* place your custom target folder anywhere in the MATLAB folder tree (that is, in or under the `matlabroot` folder). If you place your folder under `matlabroot` you risk losing your work if you install a new MATLAB version (or reinstall the current version).

The following sections explain how to organize your target folders and files and add them to your MATLAB path. They also provide high-level descriptions of the files.

In this document, `mytarget` is a placeholder name that represents folders and files that use the target's name. The names `dev_tool1`, `dev_tool2`, and so on represent subfolders containing files associated with development environments or tools. This document describes an example structure where the folder `mytarget` contains subfolders for `mytarget`, `blocks`, `dev_tool1`, `dev_tool2`. The top level folder `mytarget` is the *target root folder*.

Components of a Custom Target

Overview

The components of a custom target are files located in a hierarchy of folders. The top-level folder in this structure is called the *target root folder*. The target root folder and its contents are named, organized, and located on the MATLAB path according to conventions described in “Folder and File Naming Conventions” on page 85-11.

The components of a custom target include

- Code components: C source code that supervises and supports execution of generated model code.
- Control files:
  - A system target file (STF) to control the code generation process.
  - File(s) to control the building of an executable from the generated code. In a traditional make-based environment, a template makefile (TMF) generates a makefile for this purpose. Another approach is to generate project files in support of a modern integrated development environment (IDE) such as the Freescale Semiconductor CodeWarrior IDE.
  - Hook files: Optional TLC and MATLAB program files that can be invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.
- Other target files: Files that let you integrate your target into the MATLAB environment. For example, you can provide an `info.xml` file to make your target block libraries and examples available from a MATLAB session.

The next sections introduce key concepts and terminology you need to know to develop each component. References to more detailed information sources are provided.

Code Components

An executable program containing code generated from a Simulink model consists of a number of code modules and data structures. These fall into two categories: application components and execution support files.

Application Components

Application components are those which are specific to a particular model; they implement the functions represented by the blocks in the model. Application components are not specific to the target. Application components include

- Modules generated from the model
- User-written blocks (S-functions)
- Parameters of the model that are visible, and can be interfaced to, external code

Execution Support Files

A number of code modules and data structures, referred to collectively as the *execution support files*, are responsible for managing and supporting the execution of the generated program. The execution support files modules are not automatically generated. Depending on the requirements of your target, you must implement certain parts of the execution support files. Execution Support Files summarizes the execution support files.

Execution Support Files

You Provide...	The Code Generator Provides...
Customized main program	Generic main program
Timer interrupt handler to run model	Execution engine and integration solver (called by timer interrupt handler)
Other interrupt handlers	Example interrupt handlers (Asynchronous Interrupt blocks)
Device drivers	Example device drivers
Data logging, parameter tuning, signal monitoring, and external mode support	Data logging, parameter tuning, signal monitoring, and external mode APIs

User-Written Execution Support Files

The code generator provides most of the execution support files. Depending on the requirements of your target, you must implement some or all of the following elements:

- A timer *interrupt service routine* (ISR). The timer runs at the program's base sample rate. The timer ISR is responsible for operations that must be completed within a single clock period, such as computing the current output sample. The timer ISR usually calls the `rt_OneStep` function.

  If you are targeting a real-time operating system (RTOS), your generated code usually executes under control of the timing and task management mechanisms provided by the RTOS. In this case, you may not have to implement a timer ISR.
- The *main program*. Your main program initializes the blocks in the model, installs the timer ISR, and executes a background task or loop. The timer periodically interrupts

the main loop. If the main program is designed to run for a finite amount of time, it is also responsible for cleanup operations — such as memory deallocation and masking the timer interrupt — before terminating the program.

If you are targeting a real-time operating system (RTOS), your main program most likely spawns tasks (corresponding to the sample rates used in the model) whose execution is timed and controlled by the RTOS.

Your main program typically is based on a generated or static main program. For details on the structure of the execution support files, code execution, and guidelines for customizing main programs, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 63-2.

- *Device drivers*. Drivers communicate with I/O devices on your target hardware. In production code, device drivers are normally implemented as inlined S-functions.
- *Other interrupt handlers*. If your models need to support asynchronous events, such as hardware generated interrupts and asynchronous read and write operations, you must supply interrupt handlers. The Interrupt Templates library provides examples.
- *Data logging, parameter tuning, signal monitoring, and external mode support*. It is atypical to implement rapid prototyping features such as external mode support in an embedded target. However, it is possible to support these features by using standard code generator APIs. See “Data Exchange Interfaces” (Simulink Coder) for details.

Control Files

The code generation and build process is directed by a number of TLC and MATLAB files collectively called *control files*. This section introduces and summarizes the main control files.

Top-Level Control File (make_rtw)

The build process is initiated when you press **Ctrl+B**. At this point, the build process parses the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box, expecting to find the name of a MATLAB command that controls the build process (as well as optional arguments to that command). The default command is `make_rtw`, and the default top-level control file for the build process is `make_rtw.m`.

Note `make_rtw` is an internal MATLAB command used by the build process. Normally, target developers do not need detailed knowledge of how `make_rtw` works. (The details for target developers are described in “Target Development and the Build Process” on

page 85-23.) You should not invoke `make_rtw` directly from MATLAB code, and you should not customize `make_rtw.m`.

The `make_rtw.m` file contains the logic required to execute your target-specific control files, including a number of hook points for execution of your custom code. `make_rtw` does the following:

- Passes optional arguments in to the build process
- Performs required preprocessing before code generation
- Executes the STF to perform code generation (and optional HTML report generation)
- Processes the TMF to generate a makefile
- Invokes a make utility to execute the makefile and build an executable
- Performs required post-processing (such as generating calibration data files or downloading the generated executable to the target)

System Target File (STF)

The Target Language Compiler (TLC) generates target-specific C or C++ code from a partial description of your Simulink block diagram (*`model`*`.rtw`). The Target Language Compiler reads *`model`*`.rtw` and executes a program consisting of several target files (`.tlc` files.) The STF, at the top level of this program, controls the code generation process. The output of this process is a number of source files, which are fed to your development system's make utility.

You need to create a customized STF to set code generation parameters for your target. You should copy, rename, and modify the standard ERT system target file (*`matlabroot`*`/rtw/c/ert/ert.tlc`).

The detailed structure of the STF is described in “Customize System Target Files” on page 85-28.

Note The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See “Customize System Target Files” on page 85-28.

Template Makefile (TMF)

A TMF provides information about your model and your development system. The build process uses this information to create a makefile (`.mk` file) that builds an executable program.

Some targets implement more than one TMF, in order to support multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

The Embedded Coder software provides a large number of TMFs suitable for different types of development computer systems. These TMFs are located in *`matlabroot`*`/rtw/c/ert` (open). The standard TMFs are described in "Template Makefiles and Make Options" (Simulink Coder).

The detailed structure of the TMF is described in "Customize Template Makefiles" on page 85-62.

Note The STF selects whether the target supports the toolchain approach or template makefile approach for code generation. See "Customize System Target Files" on page 85-28.

Hook Files

The build process allows you to supply optional *hook files* that are executed at specified points in the code generation and make process. You can use hook files to add target-specific actions to the build process.

The hook files must follow well-defined naming and location requirements. "Folder and File Naming Conventions" on page 85-11 describes these requirements.

Key Folders Under Target Root (mytarget)

- “Target Source Code Folder (mytarget/src)” on page 85-19

Target Root Folder (mytarget)

This folder contains the key subfolders for the target (see “Folder and File Naming Conventions” on page 85-11). You can also locate miscellaneous files (such as a `readme` file) in the target root folder. The following sections describe required and optional subfolders and their contents.

Target Folder (mytarget/mytarget)

This folder contains files that are central to the target, such as the system target file (STF) and template makefile (TMF). “Key Files in Target Folder (mytarget/mytarget)” on page 85-19 summarizes the files that should be stored in `mytarget/mytarget`, and provides pointers to detailed information about these files.

Note `mytarget/mytarget` should be on the MATLAB path.

Target Block Folder (mytarget/blocks)

If your target includes device drivers or other blocks, locate the block implementation files in this folder. `mytarget/blocks` contains

- Compiled block MEX-files
- Source code for the blocks
- TLC inlining files for the blocks
- Library models for the blocks (if you provide your blocks in one or more libraries)

Note `mytarget/blocks` should be on the MATLAB path.

You can also store example models and supporting files in `mytarget/blocks`. Alternatively, you can create a `mytarget/mytargetdemos` folder, which should also be on the MATLAB path.

To display your blocks in the standard Simulink Library Browser and/or integrate your example models into the MATLAB session environment , you can create the files described below and store them in `mytarget/blocks`.

mytarget/blocks/slblocks.m

This file allows a group of blocks to be integrated into the Simulink Library and Simulink Library Browser.

Example 85.1. Example slblocks.m File

```
function blkStruct = slblocks
% Information for "Blocksets and Toolboxes" subsystem
blkStruct.Name = sprintf('Embedded Target\n for MYTARGET');
blkStruct.OpenFcn = 'mytargetlib';
blkStruct.MaskDisplay = 'disp(''MYTARGET'')';

% Information for Simulink Library Browser
Browser(1).Library = 'mytargetlib';
Browser(1).Name    = 'Embedded Target for MYTARGET';
Browser(1).IsFlat  = 1;% Is this library "flat" (i.e. no subsystems)?

blkStruct.Browser = Browser;
```

mytarget/blocks/demos.xml

This file provides information about the components, organization, and location of example models. MATLAB software uses this information to place the example in the MATLAB session environment.

Example 85.2. Example demos.xml File

```
<?xml version="1.0" encoding="utf-8"?>
<demos>
   <name>Embedded Target for MYTARGET</name>
   <type>simulink</type>
   <icon>$toolbox/matlab/icons/boardicon.gif</icon>
   <description source = "file">mytarget_overview.html</description>

   <demosection>
      <label>Multirate model</label>
      <demoitem>
         <label>MYTARGET demo</label>
         <file>mytarget_overview.html</file>
         <callback>mytarget_model</callback>
      </demoitem>
   </demosection>

</demos>
```

Development Tools Folder (mytarget/dev_tool1, mytarget/dev_tool2)

These folders contain files associated with specific development environments or tools (`dev_tool1`, `dev_tool2`, etc.). Normally, your target supports at least one such development environment and invokes its compiler, linker, and other utilities during the

build process. `mytarget/dev_tool1` includes linker command files, startup code, hook functions, and other files required to support this process.

For each development environment, you should provide a separate folder.

Target Source Code Folder (mytarget/src)

This folder is optional. If the complexity of your target requires it, you can use `mytarget/src` to store common source code and configuration code (such as boot and startup code).

Key Files in Target Folder (mytarget/mytarget)

Introduction

The target folder `mytarget/mytarget` contains key files in your target implementation. These include the system target file, template makefile, main program module, and optional M and TLC hook files that let you add target-specific actions to the build process. The following sections describe the key target folder files.

mytarget.tlc

`mytarget.tlc` is the system target file (STF). Functions of the STF include

- Making the target visible in the System Target File Browser
- Definition of code generation options for the target (inherited and target-specific)
- Providing an entry point for the top-level control of the TLC code generation process

You should base your STF on `ert.tlc`, the STF provided by Embedded Coder software.

"Customize System Target Files" on page 85-28 gives detailed information on the structure of the STF, and also gives instructions on how to customize an STF to

- Display your target in the System Target File Browser
- Add your own target options to the Configuration Parameters dialog box
- Tailor the code generation and build process to the requirements of your target

mytarget.tmf

`mytarget.tmf` is the template makefile for building an executable for your target.

For basic information on the structure and operation of template makefiles, see "Customize Template Makefiles" on page 85-62.

If your target development environment requires automation of a modern integrated development environment (IDE) rather than use of a traditional make utility, see "Interface to Development Tools" on page 85-98.

mytarget_genfiles.tlc

This file is optional. `mytarget_genfiles.tlc` is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads. See "Using mytarget_genfiles.tlc" on page 85-45 for details.

mytarget_main.c

A main program module is required for your target. To provide a main module, you can either

- Modify the `rt_main.c` or `rt_cppclass_main.cpp` module provided by the software
- Generate `mytarget_main.c` or `.cpp` during the build process

For a description of the operation of main programs, see "Deploy Generated Standalone Executable Programs To Target Hardware" on page 63-2. The section also contains guidelines for generating and modifying a main program module.

STF_make_rtw_hook.m

STF`_make_rtw_hook.m` is an optional hook file that you can use to invoke target-specific functions or executables at specified points in the build process. *STF*`_make_rtw_hook.m`

implements a function that dispatches to a specific action depending on the `method` argument that is passed into it.

"Customize Build Process with STF_make_rtw_hook File" (Simulink Coder) describes the operation of the *STF*`_make_rtw_hook.m` hook file in detail.

STF_rtw_info_hook.m (obsolete)

Prior to Release 14, custom targets supplied target-specific information with a hook file (referred to as *STF*`_rtw_info_hook.m`). The *STF*`_rtw_info_hook` specified properties such as word sizes for integer data types (for example, `char`, `short`, `int`, and `long`), and C implementation-specific properties of the custom target.

The *STF*`_rtw_info_hook` mechanism has been replaced by the **Hardware Implementation** pane of the Configuration Parameters dialog box. Using this dialog box, you can specify the properties that were formerly specified in your *STF*`_rtw_info_hook` file.

For backward compatibility, existing *STF*`_rtw_info_hook` files are still available. However, you should convert your target and models to use the **Hardware Implementation** pane. See "Configure Run-Time Environment Options" (Simulink Coder).

info.xml

This file provides information to MATLAB software that specifies where to display the target toolbox in the MATLAB session environment. For more information, see "Display Custom Documentation" (MATLAB).

mytarget_overview.html

By convention, this file serves as home page for the target examples.

The `<description>` field in `demos.xml` should point to `mytarget_overview.html` (see "mytarget/blocks/demos.xml" on page 85-18).

Example mytarget_overview.html File

```
<html>
<head><title>Embedded Target for MYTARGET</title></head><body>
<p style="color:#990000; font-weight:bold; font-size:x-large">Embedded Target
for MYTARGET Example Model</p>

<p>This example provides a simple model that allows you to generate an executable
for a supported target board. You can then download and run the executable and
```

```
set breakpoints to study and monitor the execution behavior.</p>

</body>
</html>
```

Additional Files for Externally Developed Targets

Introduction

If you are developing an embedded target that is not installed into the MATLAB tree, you should provide a target setup script and target documentation within `mytarget/mytarget`, for the convenience of your users. The following sections describe the required materials and where to place them.

mytarget/mytarget/mytarget_setup.m

This file script adds paths for your target to the MATLAB path. Your documentation should instruct users to run the script when installing the target.

You should include a call to the MATLAB function `savepath` in your `mytarget_setup.m` script. This function saves the added paths, so users need to run `mytarget_setup.m` only once.

The following code is an example `mytarget_setup.m` file.

```
function mytarget_setup()
curpath = pwd;
tgtpath = curpath(1:end-length('\mytarget'));
addpath(fullfile(tgtpath, 'mytarget'));
addpath(fullfile(tgtpath, 'dev_tool1'));
addpath(fullfile(tgtpath, 'blocks'));
addpath(fullfile(tgtpath, 'mytargetdemos'));
savepath;
disp('MYTARGET Target Path Setup Complete.');
```

mytarget/mytarget/doc

You should put the documentation related to your target in the folder `mytarget/mytarget/doc`.

Target Development and the Build Process

About the Build Process

To develop an embedded target, you need a thorough understanding of the build process. Your embedded target uses the build process and may require you to modify or customize the process. A general overview of code generation and the build process is given in “Code Generation” (Simulink Coder) and “Build Process” (Simulink Coder).

This section supplements that overview with a description of the build process as customized by the Embedded Coder software. The emphasis is on points in the process where customization hooks are available and on passing information between different phases of the process.

This section concludes with “Additional Information Passing Techniques” on page 85-24, describing assorted tips and tricks for passing information during the build process.

Build Process Phases and Information Passing

It is important to understand where (and when) the build process obtains required information. Sources of information include

- The *`model`*`.rtw` file, which provides information about the generating model. The information in *`model`*`.rtw` is available to target TLC files.
- The code generation panes of the Configuration Parameters dialog box. Options (both general and target-specific) are provided through check boxes, menus, and edit fields. You can associate options with TLC variables in the `rtwoptions` data structure. Use the **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** field to define makefile tokens .
- The selected toolchain (for toolchain approach builds) or selected template makefile `.tmf` (for template makefile approach builds); these generate the model-specific makefile.
- Environment variables on the host computer. Environment variables provide additional information about installed development tools.
- Other target-specific files such as target-related TLC files, linker command files, or project files.

It is also important to understand the several phases of the build process and how to pass information between the phases. The build process comprises several high-level phases:

- Execution of the top-level file (`slbuild.m` or `rtwbuild.m`) to sequence through the build process for a target
- Conversion of the model into the TLC input file (*`model`*`.rtw`)
- Generation of the target code by the TLC compiler
- Compilation of the generated code with `make` or other utilities
- Transmission of the final generated executable to the target hardware with a debugger or download utility

It is helpful to think of each phase of the process as a different “environment” that maintains its own data. These environments include

- MATLAB code execution environment (MATLAB)
- Simulink
- Target Language Compiler execution environment
- makefile
- Development environments such as and IDE or debugger

In each environment, you might get information from the various sources mentioned above. For example, during the TLC phase, execute MATLAB file might execute to obtain information from the MATLAB environment. Also, a given phase may generate information for a subsequent phase.

See “Key Files in Target Folder (mytarget/mytarget)” on page 85-19 for details on the available MATLAB file and TLC hooks for information passing, with code examples.

Additional Information Passing Techniques

This section describes a number of useful techniques for passing information among different phases of the build process.

tlcvariable Field in rtwoptions Structure

Parameters on the code generation panes of the Configuration Parameters dialog box can be associated with a TLC variable, and specified in the `tlcvariable` field of the option's entry in the `rtwoptions` structure. The variable value is passed on the command line when TLC is invoked. This provides a way to make code generation parameters and their values available in the TLC phase.

See “System Target File Structure” on page 85-29 for further information.

makevariable Field in rtwoptions Structure

You can associate code generation parameters with a template makefile token, that you specify in the `makevariable` field of the option's entry in the `rtwoptions` structure. If a token of the same name as the `makevariable` name exists in the TMF, the token is updated with the option value when the final makefile is created. If the token does not exist in the TMF, the `makevariable` is passed in on the command line when make is invoked. Thus, in either case, the `makevariable` is available to the makefile.

See “System Target File Structure” on page 85-29 for further information.

Accessing Host Environment Variables

You can access host shell environment variables at the MATLAB command line by entering the `getenv` command. For example:

```
getenv ('MSDEVDIR')

ans =

D:\Applications\Microsoft Visual Studio\Common\MSDev98
```

To access the same information from TLC, use the `FEVAL` directive to invoke `getenv`.

```
%assign eVar = FEVAL("getenv","<varname>")
```

Supplying Development Environment Information to Your Template Makefile

An embedded target must tie the build process to target-specific development tools installed on a host computer. For the make process to run these tools, the TMF must be able to determine the name of the tools, the path to the compiler, linker, and other utilities, and possibly the host operating system environment variable settings.

Require the end user to modify the target TMF. The user enters path information (such as the location of a compiler executable), and possibly host operating system environment variables, as make variables. This allows the TMF to be tailored to specific needs.

Using MATLAB Application Data

Application data provides a way for applications to save and retrieve data stored with the GUI. This technique enables you to create what is essentially a user-defined property for an object, and use this property to store data for use in the build process. If you are

unfamiliar with this technique for creating graphical user interfaces, see “Store Data as Application Data” (MATLAB).

The following code examples illustrates the use of application data to pass information to TLC.

This file, `tlc2appdata.m`, stores the `data` passed in as application data under the name passed in (`appDataName`).

```
function k = tlc2appdata(appDataName,data)
  disp([mfilename,': ',appDataName,' ', data]);
  setappdata(0,appDataName,data);
  k = 0;  % TLC expects a return value for FEVAL.
```

The following sample TLC file uses the `FEVAL` directive to invoke `tlc2appdata.m` to store arbitrary application data, under the name `z80`.

```
%% test.tlc
%%
%assign myApp = "z80"
%assign myData = "314159"
%assign dummy = FEVAL("tlc2appdata",myApp,myData)
```

To test this technique:

1. Create the `tlc2appdata.m` file as shown. Check that `tlc2appdata.m` is stored in a folder on the MATLAB path.
2. Create the TLC file as shown. Save it as `test.tlc`.
3. Enter the following command at the MATLAB prompt to execute the TLC file:

   ```
   tlc test.tlc
   ```
4. Get the application data at the MATLAB prompt:

   ```
   k = getappdata(0,'z80')
   ```

   The function returns the value 314159.
5. Enter the following command.

   ```
   who
   ```

   Note that application data is not stored in the MATLAB workspace. Also observe that the z80 data is not visible. Using application data in this way has the advantage that

it does not clutter the MATLAB workspace. Also, it helps prevent you from accidentally deleting your data, since it is not stored directly in your workspace.

A real-world use of application data might be to collect information from the *`model`*`.rtw` file and store it for use later in the build process.

Adding Block-Specific Information to the Makefile

The `rtwmakecfg` mechanism provides a method for inlined S-functions such as driver blocks to add information to the makefile. This mechanism is described in “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder).

Customize System Target Files

This section provides information on the structure of the system target file (STF), guidelines for customizing an STF, and a basic tutorial that helps you to produce a skeletal STF.

Control Code Generation With the System Target File

The system target file (STF) controls the code generation stage of the build process. The STF also lets you control the presentation of your target to the end user. The STF provides

- Definitions of variables that are fundamental to the build process, such as the value for the `CodeFormat` TLC variable
- The main entry point to the top-level TLC program that generates code
- Target information for display in the System Target File Browser
- A mechanism for defining target-specific code generation options (and other parameters related to the build process) and for displaying them in the Configuration Parameters dialog box
- A mechanism for inheriting options from another target (such as the Embedded Real-Time (ERT) target)

Note that, although the STF is a Target Language Compiler (TLC) file, it contains embedded MATLAB code. Before creating or modifying an STF, you should acquire a working knowledge of TLC and of the MATLAB language. “Target Language Compiler” (Simulink Coder) and “Scripts vs. Functions” (MATLAB) describe the features and syntax of both the TLC and MATLAB languages.

While reading this section, you may want to refer to the STFs provided with the code generator. Most of these files are stored in the target-specific folders under *`matlabroot`*`/rtw/c` (open). Additional STFs are stored under *`matlabroot`*`/toolbox/rtw/targets` (open).

System Target File Naming and Location Conventions

An STF must be located in a folder on the MATLAB path for the target to be displayed in the System Target File Browser and invoked in the build process. Follow the location and naming conventions for STFs and related target files given in “Folder and File Naming Conventions” on page 85-11.

System Target File Structure

Overview

This section is a guide to the structure and contents of an STF. The following listing shows the general structure of an STF. Note that this is not a complete code listing of an STF. The listing consists of excerpts from each of the sections that make up an STF.

```
%%----------------------------
%% Header Comments Section
%%----------------------------
%% SYSTLC: Example Real-Time Target
%%    TMF: my_target.tmf MAKE: make_rtw
%% Initial comments contain directives for STF Browser.
%% Documentation, date, copyright, and other info may follow.
          ...
%selectfile NULL_FILE
         ...
%%----------------------------
%% TLC Configuration Variables Section
%%----------------------------
%% Assign code format, language, target type.
%%
%assign CodeFormat = "Embedded-C"
%assign TargetType = "RT"
%assign Language   = "C"
%%
%%----------------------------
%% TLC Program Entry Point
%%----------------------------
%% Call entry point function.
%include "codegenentry.tlc"
%%
%%----------------------------
%% (OPTIONAL) Generate Files for Build Process
%%----------------------------
%include "mytarget_genfiles.tlc"
%%----------------------------
```

```
%% RTW_OPTIONS Section
%%----------------------------
/%
  BEGIN_RTW_OPTIONS
  %% Define rtwoptions structure array. This array defines target-specific
  %% code generation variables, and controls how they are displayed.
  rtwoptions(1).prompt = 'example code generation options';
        ...
  rtwoptions(6).prompt = 'Show eliminated blocks';
  rtwoptions(6).type = 'Checkbox';
         ...
  %---------------------------------------%
  % Configure RTW code generation settings %
  %---------------------------------------%
         ...
  %%----------------------------
  %% rtwgensettings Structure
  %%----------------------------
  %% Define suffix text for naming build folder here.
  rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
  %% Callback compatibility declaration
  rtwgensettings.Version = '1';

  %% (OPTIONAL) target inheritance declaration
  rtwgensettings.DerivedFrom = 'ert.tlc';
  %% (OPTIONAL) other rtwGenSettings fields...
         ...
  END_RTW_OPTIONS
%/
%%----------------------------
%% targetComponentClass - MATHWORKS INTERNAL USE ONLY
%% REMOVE NEXT SECTION FROM USER_DEFINED CUSTOM TARGETS
%%----------------------------
/%
  BEGIN_CONFIGSET_TARGET_COMPONENT
  targetComponentClass = 'Simulink.ERTTargetCC';
  END_CONFIGSET_TARGET_COMPONENT
%/
```

If you are creating a custom target based on an existing STF, you must remove the `targetComponentClass` section (bounded by the directives `BEGIN_CONFIGSET_TARGET_COMPONENT` and `END_CONFIGSET_TARGET_COMPONENT`). This section is reserved for the use of targets developed internally by MathWorks.

Header Comments

These lines at the head of the file are formatted as TLC comments. They provide required information to the System Target File Browser and to the build process. Note that you must place the browser comments at the head of the file, before other comments or TLC statements.

The presence of the comments enables the code generator to detect STFs. When the System Target File Browser is opened, the code generator scans the MATLAB path for TLC files that have formatted header comments. The comments contain the following directives:

- SYSTLC: The descriptor that appears in the browser.
- TMF: Name of the template makefile (TMF) to use during build process. When the target is selected, this filename is displayed in the “Template makefile” (Simulink Coder) field of the **Code Generation** pane of the Configuration Parameters dialog box.
- MAKE: `make` command to use during build process. When the target is selected, this command is displayed in the **Make command** field of the **Code Generation** pane of the Configuration Parameters dialog box.

The following header comments are from *`matlabroot`*`/rtw/c/ert/ert.tlc`.

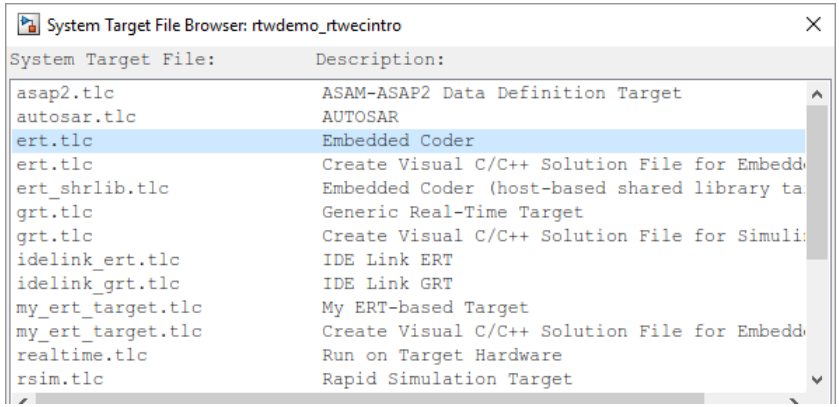
```
%% SYSTLC: Embedded Coder TMF: ert_default_tmf MAKE: make_rtw
%% SYSTLC: Create Visual C/C++ Solution File for Embedded Coder\
%%    TMF: RTW.MSVCBuild MAKE: make_rtw
.
.
.
```

Each comment can only contain a maximum of two lines.

If you do not specify the `TMF` field in the system target file, the file is still valid. To change the value for the`TemplateMakefile` parameter, you can instead use the callback function specified by `rtwgensettings.SelectCallback`.

You can also use the callback function specified by `rtwgensettings.SelectCallback` to change the value for external mode parameters, `ExtMode`, `ExtModeTransport`, `ExtModeMexFile`, or `ExtModeIntrfLevel`.

You can specify more than one group of directives in the header comments. Each such group is displayed as a different target configuration in the System Target File Browser. In the above example, the first two lines of code specify the default configuration of the ERT target. The next two lines specify a configuration that creates and builds a Microsoft Visual C++ Solution (`.sln`) file. The figure below shows how these configurations appear in the System Target File Browser.



See “Create a Custom Target Configuration” on page 85-48 for an example of customized header comments.

TLC Configuration Variables

This section of the STF assigns global TLC variables that relate to the overall code generation process.

For an embedded target, in most cases you should simply use the global TLC variable settings used by the ERT target (`ert.tlc`). It is especially important that your STF use the `'Embedded-C'` value for the `CodeFormat` TLC variable and uses the corresponding `rtwgensettings.DerivedFrom = 'ert.tlc'` in the `RTW_OPTIONS` section of the TLC file. Verify that values are assigned to the following variables:

- `CodeFormat`: The `CodeFormat` TLC variable selects generated code features. The `'Embedded-C'` value for this variable is used by the ERT target. Your ERT-based target should specify `'Embedded-C'` as the value for `CodeFormat`. This selection is designed for production code, minimal memory usage, static memory allocation, and a simplified interface to generated code.

  For information on other values for the `CodeFormat` TLC variable, see “Compare System Target File Support Across Products” (Simulink Coder).
- `Language`: The only valid value is `C`, which enables support for `C` or `C++` code generation as specified by the configuration parameter `TargetLang`.
- `TargetType`: The code generator defines the preprocessor symbols `RT` and `NRT` to distinguish simulation code from real-time code. These symbols are used in conditional compilation. The `TargetType` variable determines whether `RT` or `NRT` is defined.

Most targets are intended to generate real-time code. They assign `TargetType` as follows.

```
%assign TargetType = "RT"
```

Some targets, such as the model reference simulation target, accelerated simulation target, RSim target, and S-function target, generate code for use in nonreal time only. Such targets assign `TargetType` as follows.

```
%assign TargetType = "NRT"
```

TLC Program Entry Point and Related %includes

The code generation process normally begins with `codegenentry.tlc`. The STF invokes `codegenentry.tlc` as follows.

```
%include "codegenentry.tlc"
```

Note `codegenentry.tlc` and the lower-level TLC files assume that `CodeFormat`, `TargetType`, and `Language` have been assigned. Set these variables before including `codegenentry.tlc`.

If you need to implement target-specific code generation features, you should include the TLC file `mytarget_genfiles.tlc` in your STF. This file provides a mechanism for executing custom TLC code before and after invoking `codegenentry.tlc`. For information on this mechanism, see

- “Using mytarget_genfiles.tlc” on page 85-45 for an example of custom TLC code for execution after the main code generation entry point.
- “Target Development and the Build Process” on page 85-23 for general information on the build process, and for information on other build process customization hooks.

Another way to customize the code generation process is to call lower-level functions (normally invoked by `codegenentry.tlc`) directly, and include your own TLC functions at each stage of the process. This approach should be taken with caution. See “TLC Files” (Simulink Coder) for more information.

The lower-level functions called by `codegenentry.tlc` are

- `genmap.tlc`: maps block names to corresponding language-specific block target files.

- `commonsetup.tlc`: sets up global variables.
- `commonentry.tlc`: starts the process of generating code.

RTW_OPTIONS Section

The `RTW_OPTIONS` section is bounded by the directives:

```
/%
  BEGIN_RTW_OPTIONS
.
.
.
  END_RTW_OPTIONS
%/
```

The first part of the `RTW_OPTIONS` section defines an array of `rtwoptions` structures. This structure is discussed in “Using rtwoptions to Display Custom Target Options” on page 85-37.

The second part of the `RTW_OPTIONS` section defines `rtwgensettings`, a structure defining the build folder name and other settings for the code generation process. See “rtwgensettings Structure” on page 85-34 for information about `rtwgensettings`.

rtwgensettings Structure

The final part of the STF defines the `rtwgensettings` structure. This structure stores information that is written to the *`model`*`.rtw` file and used by the build process. The `rtwgensettings` fields of most interest to target developers are

- `rtwgensettings.Version`: Use this property to enable `rtwoptions` callbacks and to use the Callback API in `rtwgensettings.SelectCallback`.

  Note To use callbacks, you *must* set:

  ```
  rtwgensettings.Version = '1';
  ```

  Add the statement above to the **Configure RTW code generation settings** section of the system target file.

- `rtwgensettings.DerivedFrom`: This structure field defines the system target file from which options are to be inherited. See “Inheriting Target Options” on page 85-44.
- `rtwgensettings.SelectCallback`: This structure field specifies a `SelectCallback` function. You must set `rtwgensettings.Version = '1';` or your callback will be ignored. `SelectCallback` is associated with the target rather than with any of its individual options. The `SelectCallback` function is triggered when you:

  - Load the model.
  - Update any configuration settings in the Configuration Parameters dialog box.
  - Build the model.

  The `SelectCallback` function is useful for setting up (or disabling) configuration parameters specific to the target.

  The following code installs a `SelectCallback` function:

  ```
  rtwgensettings.SelectCallback = 'my_select_callback_handler(hDlg,hSrc)';
  ```

  The arguments to the `SelectCallback` function `(hDlg, hSrc)` are handles to private data used by the callback API functions.

  Note If you have developed a custom target and you want it to be compatible with model referencing, you must implement a `SelectCallback` function to declare model reference compatibility. See “Support Model Referencing” on page 85-82.

- `rtwgensettings.ActivateCallback`: this property specifies an `ActivateCallback` function. The `ActivateCallback` function is triggered when the active configuration set of the model changes. This could happen during model loading, and also when the user changes the active configuration set.

  The following code installs an `ActivateCallback` function:

  ```
  rtwgensettings.ActivateCallback = 'my_activate_callback_handler(hDlg,hSrc)';
  ```

  The arguments to the `ActivateCallback` function `(hDlg,hSrc)` are handles to private data used by the callback API functions.
- `rtwgensettings.PostApplyCallback`: this property specifies a `PostApplyCallback` function. The `PostApplyCallback` function is triggered when the user clicks the **Apply** or **OK** button after editing options in the Configuration

Parameters dialog box. The `PostApplyCallback` function is called after the changes have been applied to the configuration set.

The following code installs an `PostApplyCallback` function:

```
rtwgensettings.PostApplyCallback = 'my_postapply_callback_handler(hDlg,hSrc)';
```

The arguments to the `PostApplyCallback` function `(hDlg, hSrc)` are handles to private data used by the callback API functions.

- `rtwgensettings.BuildDirSuffix`: Most targets define a folder name suffix that identifies build folders created by the target. The build process appends the suffix defined in the `rtwgensettings.BuildDirSuffix` field to the model name to form the name of the build folder. For example, if you define `rtwgensettings.BuildDirSuffix` as follows

  ```
  rtwgensettings.BuildDirSuffix = '_mytarget_rtw'
  ```

  the build folders are named *`model`*`_mytarget_rtw`.

Additional Code Generation Options

"Configure Generated Code with TLC" (Simulink Coder) describes additional TLC code generation variables. End users of a target can assign these variables by entering a MATLAB command of the form

```
set_param(modelName,'TLCOptions','-aVariable=val');
```

(For more information, see "Specify TLC for Code Generation" (Simulink Coder).)

However, the preferred approach is to assign these variables in the STF using statements of the form:

```
%assign Variable = val
```

For readability, we recommend that you add such assignments in the section of the STF after the comment **Configure RTW code generation settings**.

Model Reference Considerations

See "Support Model Referencing" on page 85-82 for important information on STF and other modifications you may need to make to support the code generator model referencing features.

Define and Display Custom Target Options

Using rtwoptions to Display Custom Target Options

You control the options to display in the **Code Generation** pane in the Configuration Parameters dialog box by customizing the `rtwoptions` structure in your system target file.

The fields of the `rtwoptions` structure define variables and associated user interface elements to be displayed in the Configuration Parameters dialog box. Using the `rtwoptions` structure array, you can define target-specific options displayed in the dialog box and organize options into categories. You can also write callback functions to specify how these options are processed.

When the **Code Generation** pane opens, the `rtwoptions` structure array is scanned and the listed options are displayed. Each option is represented by an assigned user interface element (check box, edit field, menu, or push button), which displays the current option value.

The user interface elements can be in an enabled or disabled (appears dimmed) state. If an option is enabled, the user can change the option value. If an option is disabled, the option uses the default value and the user cannot change the option value.

You can also use the `rtwoptions` structure array to define special NonUI elements that cause callback functions to be executed, but that are not displayed in the **Code Generation** pane. See “NonUI Elements” on page 85-42.

The elements of the `rtwoptions` structure array are organized into groups. Each group of items begins with a header element of type `Category`. The default field of a `Category` header must contain a count of the remaining elements in the category.

The `Category` header is followed by options to be displayed on the **Code Generation** pane. The header in each category is followed by one or more option definition elements.

Each category of target options corresponds to options listed under **Code Generation** in the Configuration Parameters dialog box.

The table rtwoptions Structure Fields Summary summarizes the fields of the `rtwoptions` structure.

Example rtwoptions Structure

The following `rtwoptions` structure is excerpted from an example system target file, *`matlabroot`*`/toolbox/rtw/rtwdemos/rtwoptions_demo/usertarget.tlc`. The code defines an `rtwoptions` structure array. The default field of the first (header) element is set to `4`, indicating the number of elements that follow the header.

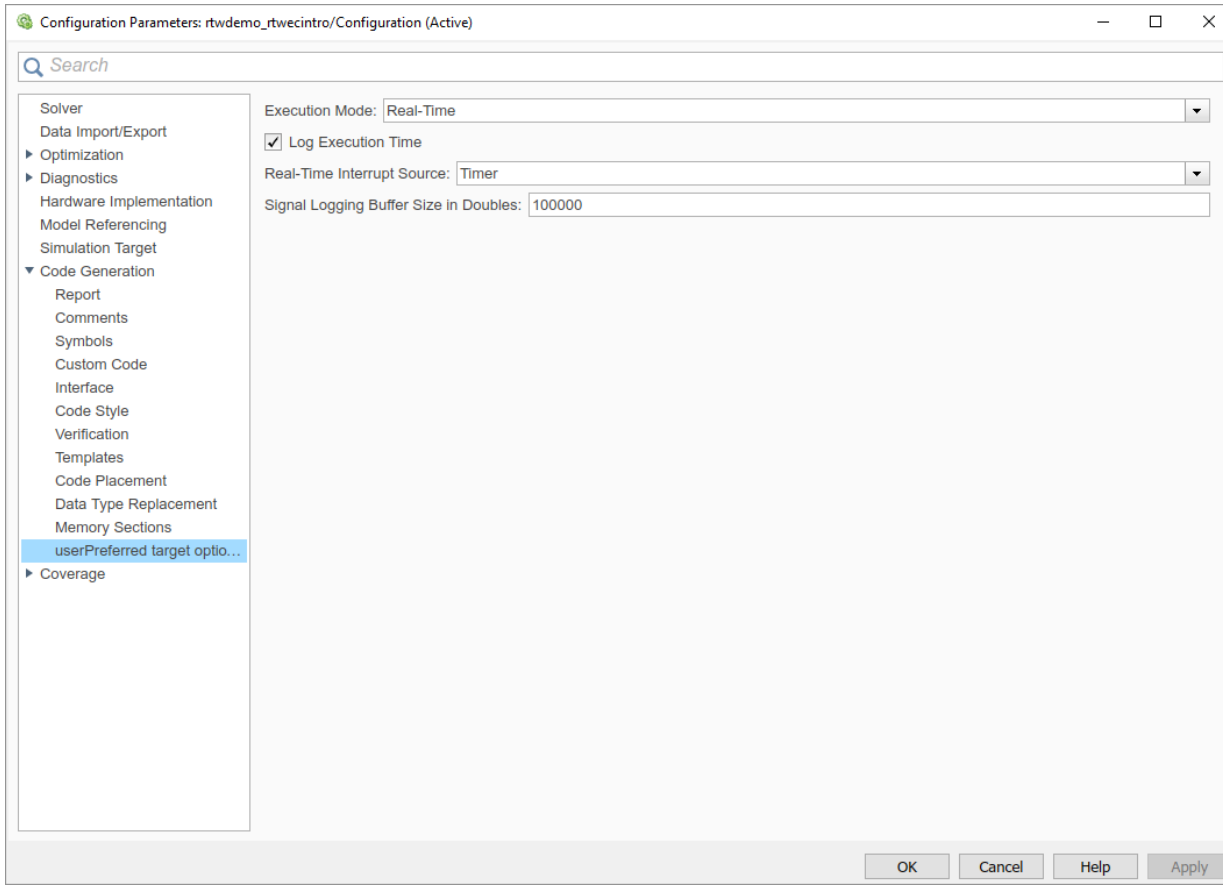
```
  rtwoptions(1).prompt        = 'userPreferred target options (I)';
  rtwoptions(1).type          = 'Category';
  rtwoptions(1).enable        = 'on';
  rtwoptions(1).default       = 4;   % number of items under this category
                                     % excluding this one.
  rtwoptions(1).popupstrings  = '';  % At the first item, user has to
  rtwoptions(1).tlcvariable   = '';  % initialize all supported fields
  rtwoptions(1).tooltip       = '';
  rtwoptions(1).callback      = '';
  rtwoptions(1).makevariable  = '';

  rtwoptions(2).prompt        = 'Execution Mode';
  rtwoptions(2).type          = 'Popup';
  rtwoptions(2).default       = 'Real-Time';
  rtwoptions(2).popupstrings  = 'Real-Time|UserDefined';
  rtwoptions(2).tlcvariable   = 'tlcvariable1';
  rtwoptions(2).tooltip       = ['See this text as tooltip'];

  rtwoptions(3).prompt        = 'Log Execution Time';
  rtwoptions(3).type          = 'Checkbox';
  rtwoptions(3).default       = 'on';
  rtwoptions(3).tlcvariable   = 'RL32LogTETModifier';
  rtwoptions(3).tooltip       = ['']; % no tooltip

  rtwoptions(4).prompt        = 'Real-Time Interrupt Source';
  rtwoptions(4).type          = 'Popup';
  rtwoptions(4).default       = 'Timer';
  rtwoptions(4).popupstrings  = 'Timer|5|6|7|8|9|10|11|12|13|14|15';
  rtwoptions(4).tlcvariable   = 'tlcvariable3';
  rtwoptions(4).callback      = 'usertargetcallback(hDlg, hSrc, ''tlcvariable3'')';
  rtwoptions(4).tooltip       = [''];
  rtwoptions(4).tooltip       = ['See TLC file for how to use reserved '...
    ' keyword ''hDlg'', and ''hSrc''.'];
...
  rtwoptions(5).prompt        = 'Signal Logging Buffer Size in Doubles';
  rtwoptions(5).type          = 'Edit';
  rtwoptions(5).default       = '100000';
  rtwoptions(5).tlcvariable   = 'tlcvariable2';
  rtwoptions(5).tooltip       = [''];
```

The first element adds a **userPreferred target options (I)** pane under **Code Generation** in the Configuration Parameters dialog box. The pane displays the options defined in `rtwoptions(2)`, `rtwoptions(3)`, `rtwoptions(4)`, and `rtwoptions(5)`.



If you want to define a large number of options, you can define multiple `Category` groups within a single system target file.

Note the `rtwoptions` structure and callbacks are written in MATLAB code, although they are embedded in a TLC file. To verify the syntax of your `rtwoptions` structure definitions and code, you can execute the commands at the MATLAB prompt by copying and pasting them to the MATLAB Command Window.

To learn more about `usertarget.tlc` and the example callback files provided with it, see “Example System Target File With Customized rtwoptions” on page 85-42. For more examples of target-specific `rtwoptions` definitions, see the *`target`*`.tlc` files under *`matlabroot`*`/rtw/c` (open).

rtwoptions Structure Fields Summary lists the fields of the `rtwoptions` structure.

rtwoptions Structure Fields Summary

Field Name	Description
`callback`	For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 85-42.
`closecallback` (obsolete)	Do not use `closecallback`. Use `rtwgensettings.PostApplyCallback` instead (see “rtwgensettings Structure” on page 85-34). `closecallback` is ignored. For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 85-42.
`default`	Default value of the option (empty if the `type` is `Pushbutton`).
`enable`	Must be `'on'` or `'off'`. If `'on'`, the option is displayed as an enabled item; otherwise, as a disabled item.
`makevariable`	Template makefile token (if any) associated with the option. The `makevariable` is expanded during processing of the template makefile. See “Template Makefile Tokens” on page 85-62.
`modelReferenceParameterCheck`	Specifies whether the option must have the same value in a referenced model and its parent model. If this field is unspecified or has the value `'on'` the option values must be same. If the field is specified and has the value `'off'` the option values can differ. See “Controlling Configuration Option Value Agreement” on page 85-86.
`NonUI`	Element that is not displayed, but is used to invoke a close or open callback. See “NonUI Elements” on page 85-42.
`opencallback` (obsolete)	Do not use `opencallback`. Use `rtwgensettings.SelectCallback` instead (see “rtwgensettings Structure” on page 85-34). For examples of callback usage, see “Example System Target File With Customized rtwoptions” on page 85-42.

Field Name	Description
`popupstrings`	If `type` is `Popup`, `popupstrings` defines the items in the menu. Items are delimited by the "|" (vertical bar) character. The following example defines the items of the **MAT-file variable name modifier** menu used by the GRT target. `'rt_|_rt|none'`
`prompt`	Label for the option.
`tlcvariable`	Name of TLC variable associated with the option.
`tooltip`	Help text displayed when mouse is over the item.
`type`	Type of element: `Checkbox`, `Edit`, `NonUI`, `Popup`, `Pushbutton`, or `Category`.

NonUI Elements

Elements of the `rtwoptions` array that have type `NonUI` exist solely to invoke callbacks. A `NonUI` element is not displayed in the Configuration Parameters dialog box. You can use a `NonUI` element if you want to execute a callback that is not associated with a user interface element, when the dialog box opens or closes. See the next section, “Example System Target File With Customized rtwoptions” on page 85-42 for an example.

Note The default value of an element of type `NonUI` or `Edit` determines the set of values allowed for that element.

- If the default value is `'0'` or `'1'`:
  - For type `NonUI`, the element stores a Boolean value.
  - For type `Edit`, the element stores a value of type `int32`.
- If the default value contains an integer other than `'0'` or `'1'`, the element stores a value of type `int32`.
- If the default value does not contain an integer, the element is evaluated as a character vector.

Example System Target File With Customized rtwoptions

A working system target file, with MATLAB file callback functions, has been provided as an example of how to use the `rtwoptions` structure to display and process custom

options on the **Code Generation** pane. The examples are compatible with the callback API.

The example target files are in the folder (open):

matlabroot/toolbox/rtw/rtwdemos/rtwoptions_demo

The example target files include:

- `usertarget.tlc`: The example system target file. This file illustrates how to define custom menus, check boxes, and edit fields. The file also illustrates the use of callbacks.
- `usertargetcallback.m`: A MATLAB file callback invoked by a menu.

Refer to the example files while reading this section. The example system target file, `usertarget.tlc`: illustrates the use of `rtwoptions` to display the following custom target options:

- The **Execution Mode** menu.
- The **Log Execution Time** check box.
- The **Real-Time Interrupt Source** menu. The menu executes a callback defined in an external file, `usertargetcallback.m`. The TLC variable associated with the menu is passed in to the callback, which displays the menu's current value.
- The edit field **Signal Logging Buffer Size in Doubles**.

Try studying the example code while interacting with the example target options in the Configuration Parameters dialog box. To interact with the example target file,

1. Make *matlabroot*/toolbox/rtw/rtwdemos/rtwoptions_demo (open) your working folder.
2. Open a model of your choice.
3. Open the Configuration Parameters dialog box and select the **Code Generation** pane.
4. Click **Browse**. The System Target File Browser opens. Select `usertarget.tlc`. Then click **OK**.
5. Observe that the **Code Generation** pane contains a custom sub-tab: **userPreferred target options (I)**.
6. As you interact with the options in this category and open and close the Configuration Parameters dialog box, observe the messages displayed in the MATLAB

Command Window. These messages are printed from code in the STF, or from callbacks invoked from the STF.

Inheriting Target Options

`ert.tlc` provides a basic set of Embedded Coder code generation options. If your target is based on `ert.tlc`, your STF should normally inherit the options defined in ERT.

Use the `rtwgensettings.DerivedFrom` field in the `rtwgensettings` structure to define the system target file from which options are to be inherited. You should convert your custom target to use this mechanism as follows.

Set the `rtwgensettings.DerivedFrom` field value as in the following example:

```
rtwgensettings.DerivedFrom = 'stf.tlc';
```

where `stf` is the name of the system target file from which options are to be inherited. For example:

```
rtwgensettings.DerivedFrom = 'ert.tlc';
```

When the Configuration Parameters dialog box executes this line of code, it includes the options from `stf.tlc` automatically. If `stf.tlc` is a MathWorks internal system target file that has been converted to a new layout, the dialog box displays the inherited options using the new layout.

Handling Unsupported Options

If your target does not support all of the options inherited from `ert.tlc`, you should detect unsupported option settings and display a warning or error message. In some cases, if a user has selected an option your target does not support, you may need to abort the build process. For example, if your target does not support the **Generate an example main program** option, the build process should not be allowed to proceed if that option is selected.

Even though your target may not support all inherited ERT options, it is required that the ERT options are retained in the **Code Generation** pane of the Configuration Parameters dialog box. Do not simply remove unsupported options from the `rtwoptions` structure in the STF. Options must be in the dialog box to be scanned by the code generator when it performs optimizations.

For example, you may want to prevent users from turning off the **Single output/update function** option. It may seem reasonable to remove this option from the dialog box and

simply assign the TLC variable `CombineOutputUpdateFcns` to `on`. However, if the option is not included in the dialog box, the code generator assumes that output and update functions are *not* to be combined. Less efficient code is generated as a result.

Tips and Techniques for Customizing Your STF

Introduction

The following sections include information on techniques for customizing your STF, including:

- How to invoke custom TLC code from your STF
- Approaches to supporting multiple development environments
- Considerations for when you update your STF

Required and Recommended %includes

If you need to implement target-specific code generation features, we recommend that your STF include the TLC file `mytarget_genfiles.tlc`.

Once your STF has set up the required TLC environment, you must include `codegenentry.tlc` to start the standard code generation process.

`mytarget_genfiles.tlc` provides a mechanism for executing custom TLC code after the main code generation entry point. See "Using mytarget_genfiles.tlc" on page 85-45.

Using mytarget_genfiles.tlc

`mytarget_genfiles.tlc` (optional) is useful as a central file from which to invoke target-specific TLC files that generate additional files as part of your target build process. For example, your target may create sub-makefiles or project files for a development environment, or command scripts for a debugger to do automatic downloads.

The build process can then invoke these generated files either directly from the make process or after the executable is created. This is done with the *STF*`_make_rtw_hook.m`

mechanism, as described in “Customize Build Process with STF_make_rtw_hook File” (Simulink Coder).

The following TLC code shows an example `mytarget_genfiles.tlc` file.

```
%selectfile NULL_FILE

%assign ModelName = CompiledModel.Name

%% Create Debugger script
%assign model_script_file = "%<ModelName>.cfg"
%assign script_file = "debugger_script_template.tlc"

%if RTWVerbose
   %selectfile STDOUT
   ### Creating %<model_script_file>
   %selectfile NULL_FILE
%endif

%include "%<script_file>"
%openfile bld_file = "%<model_script_file>"
%<CreateDebuggerScript()>
%closefile bld_file
```

Handling Aliases for Target Option Values

This section describes utility functions that can be used to detect and resolve alias values or legacy values when testing user-specified values for the target device type (`ProdHWDeviceType`) and the code replacement library (`CodeReplacementLibrary`).

RTW.isHWDeviceTypeEq

To test if two target device type values represent the same hardware device, invoke the following function:

```
result = RTW.isHWDeviceTypeEq(type1,type2)
```

where *`type1`* and *`type2`* are character vectors containing target device type values or aliases.

The `RTW.isHWDeviceTypeEq` function returns true if *`type1`* and *`type2`* are character vectors representing the same hardware device. For example, the following call returns true:

```
RTW.isHWDeviceTypeEq('Specified','Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” (Simulink) and “Device type” (Simulink).

RTW.resolveHWDeviceType

To return the device type value for a hardware device, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveHWDeviceType(type)
```

where *`type`* is a character vector containing a target device type value or alias.

The `RTW.resolveHWDeviceType` function returns the device type value of the device. For example, the following calls both return `'Generic->Custom'`:

```
RTW.resolveHWDeviceType('Specified')
RTW.resolveHWDeviceType('Generic->Custom')
```

For a description of the target device type option `ProdHWDeviceType`, see the command-line information for the **Hardware Implementation** pane parameters “Device vendor” (Simulink) and “Device type” (Simulink).

RTW.isTflEq

To test if two code replacement library (CRL) names represent the same CRL, invoke the following function:

```
result = RTW.isTflEq(name1,name2)
```

where *`name1`* and *`name2`* are character vectors containing CRL values or aliases.

The `RTW.isTflEq` function returns true if *`name1`* and *`name2`* are character vectors representing the same code replacement library. For example, the following call returns true:

```
RTW.isTflEq('GNU','GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see “Code replacement library” (Simulink Coder).

RTW.resolveTflName

To return the CRL value for a code replacement library, given a value that might be an alias or legacy value, invoke the following function:

```
result = RTW.resolveTflName(name)
```

where *name* is a character vector containing a CRL value or alias.

The `RTW.resolveTflName` function returns the value of the referenced code replacement library. For example, the following calls both return `'GNU C99 extensions'`:

```
RTW.resolveTflName('GNU')
RTW.resolveTflName('GNU C99 extensions')
```

For a description of the `CodeReplacementLibrary` parameter, see "Code replacement library" (Simulink Coder).

Supporting Multiple Development Environments

Your target may require support for multiple development environments (for example, two or more cross-compilers) or multiple modes of code generation (for example, generating a binary executable versus generating a project file for your compiler).

One approach to this requirement is to implement multiple STFs. Each STF invokes a template makefile for the development environment. This amounts to providing two separate targets.

Updating Your Custom STF

Updating your custom STF can impact the option values of a model that you load that uses the updated STF. If you disable an option, the updated STF uses the default value for that option. If a model has a different value for that option, when you load the model with the updated STF, the value from the model is discarded and the STF uses the default value instead.

Create a Custom Target Configuration

Introduction

This tutorial can supplement the example target guides described in “Sample Custom Targets” on page 85-9. For an introduction and example files, try the example targets first.

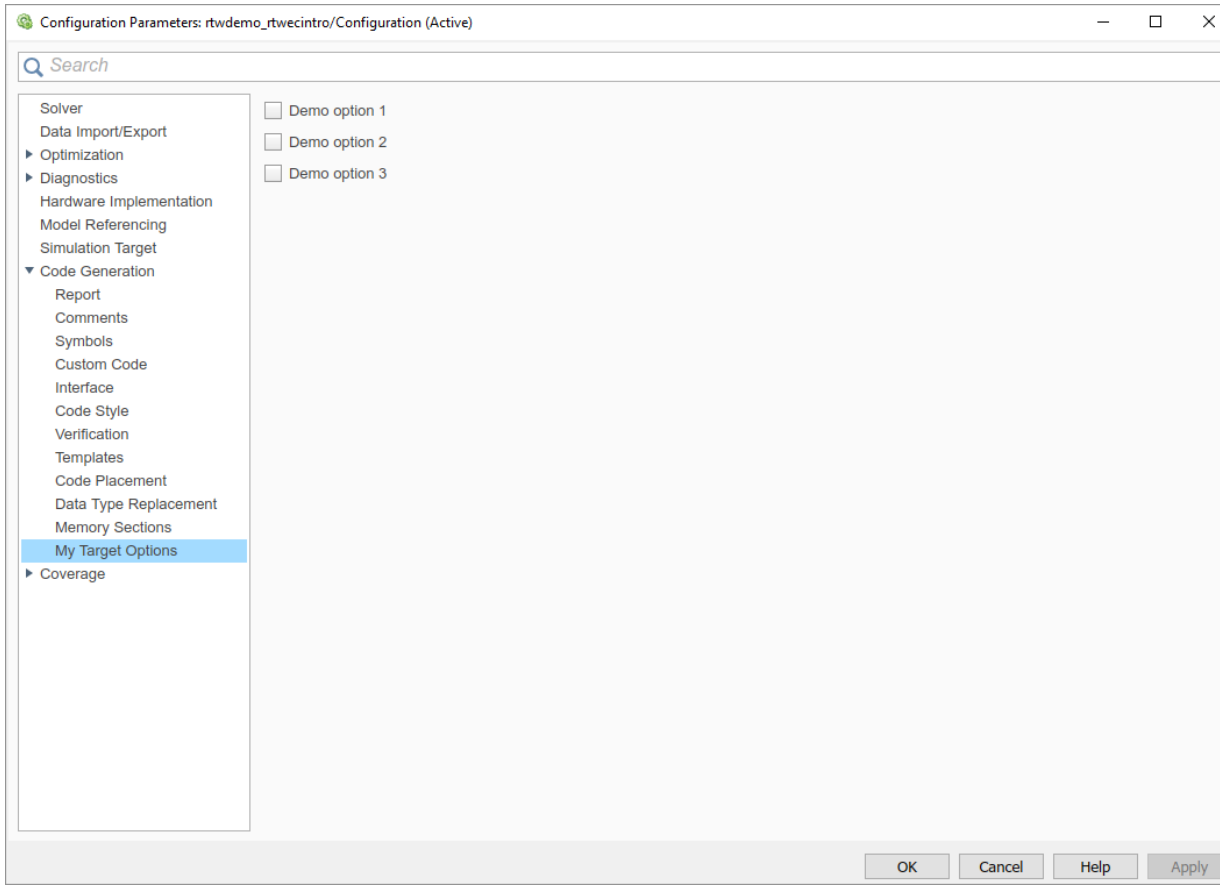
This tutorial guided you through the process of creating an ERT-based target, `my_ert_target`. This exercise illustrates several tasks, which are typical for creating a custom target:

- Setting up target folders and modifying the MATLAB path.
- Making modifications to a standard STF and TMF such that the custom target is visible in the System Target File Browser, inherits ERT options, displays target-specific options, and generates code with the default host-based compiler.
- Testing the build process with the custom target, using a simple model that incorporates an inlined S-function.

During this exercise, you implement an operational, but skeletal, ERT-based target. This target can be useful as a starting point in a complete implementation of a custom embedded target.

my_ert_target Overview

In the following sections, you create a skeletal target, `my_ert_target`. The target inherits and supports the standard options of the ERT target and displays additional target-specific options in the Configuration Parameters dialog box (see “Target-Specific Options for my_ert_target” on page 85-50).



Target-Specific Options for my_ert_target

`my_ert_target` supports a toolchain-based build, generating code and executables that run on the host system. `my_ert_target` uses the `lcc` compiler on a Microsoft Windows platform. The chosen compiler is readily available and is distributed with the code generator. On a Microsoft Windows platform, if you use a different compiler, you can set up `lcc` temporarily as your default compiler through the following MATLAB command:

```
mex -setup
```

The software displays links for supported compilers that are installed on your computer. Click the `lcc` link.

Note On Linux systems, make sure that you have an installed C compiler. If so, you can use Linux folder syntax to complete this exercise.

`my_ert_target` can also support template makefile-based builds. For more information about using this target with the template makefile approach, see “Create ERT-Based TMF” on page 85-58.

You can test `my_ert_target` with a model that is compatible with the ERT target (see “Configure a System Target File” on page 44-2). Generated programs operate identically to ERT generated programs.

To simplify the testing of your target, test with `targetmodel`, a very simple fixed-step model (see “Create Test Model and S-Function” on page 85-58). The S-Function block in `targetmodel` uses the source code from the `timestwo` example, and generates fully inlined code. See “S-Function Examples” (Simulink) and “Inline S-Functions with TLC” (Simulink Coder) for further discussion of the `timestwo` example S-function.

Creating Target Folders

Create folders to store the target files and add them to the MATLAB path, following the recommended conventions (see “Folder and File Naming Conventions” on page 85-11). You also create a folder to store the test model, S-function, and generated code.

This example assumes that your target and model folders are located within the folder `c:/work`. Do not place your target and model folders within the MATLAB folder tree (that is, in or under the *`matlabroot`* folder).

To create the folders and make them accessible:

1. Create a target root folder, `my_ert_target`. From the MATLAB Command Window on a Windows platform, enter:

   ```
   cd c:/work
   mkdir my_ert_target
   ```

2. Within the target root folder, create a subfolder to store your target files.

   ```
   mkdir my_ert_target/my_ert_target
   ```

3. Add these folders to your MATLAB path.

   ```
   addpath c:/work/my_ert_target
   addpath c:/work/my_ert_target/my_ert_target
   ```

4. Create a folder, `my_targetmodel`, to store the test model, S-function, and generated code.

```
mkdir my_targetmodel
```

Create ERT-Based, Toolchain Compliant STF

Create an STF for your target by copying and modifying the standard STF for the ERT target. Then, validate the STF by viewing the new target in the System Target File Browser and in the Configuration Parameters dialog box.

Editing the STF

To edit the STF, use these steps:

1. Change your working folder to the folder you created in “Creating Target Folders” on page 85-51.

   ```
   cd c:/work/my_ert_target/my_ert_target
   ```

2. Place a copy of *matlabroot*`/rtw/c/ert/ert.tlc` in `c:/work/my_ert_target/my_ert_target` and rename it to `my_ert_target.tlc`. The file `ert.tlc` is the STF for the ERT target.
3. Open `my_ert_target.tlc` in a text editor of your choice.
4. Customize the STF, replacing the header comment lines with directives that make your STF visible in the System Target File Browser and define the associated TMF, `make` command, and external mode interface file (if any). For more information about these directives, see “Header Comments” on page 85-30 .

   Replace the header comments in `my_ert_target.tlc` with the following header comments.

   ```
   %% SYSTLC: My ERT-based Target TMF: my_ert_target_lcc.tmf MAKE: make_rtw
   ```

5. The file `my_ert_target.tlc` inherits the standard ERT options, using the mechanism described in “Inheriting Target Options” on page 85-44. Therefore, the existing `rtwoptions` structure definition is superfluous. Edit the RTW_OPTIONS section such that it includes only the following code.

   ```
   /%
     BEGIN_RTW_OPTIONS

     %----------------------------------------%
     % Configure RTW code generation settings %
     %----------------------------------------%

     rtwgensettings.BuildDirSuffix = '_ert_rtw';

     END_RTW_OPTIONS
    %/
   ```

6. Delete the code after the end of the `RTW_OPTIONS` section, which is delimited by the directives `BEGIN_CONFIGSET_TARGET_COMPONENT and END_CONFIGSET_TARGET_COMPONENT`. This code is for use only by internal MathWorks developers.

7. Modify the build folder suffix in the `rtwgenSettings` structure in accordance with the conventions described in “rtwgensettings Structure” on page 85-34.

   To set the suffix to a character vector for the `_my_ert_target` custom target, change the line

   ```
   rtwgensettings.BuildDirSuffix = '_ert_rtw'
   ```

   to

   ```
   rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw'
   ```

8. Modify the `rtwgenSettings` structure to inherit options from the ERT target and declare Release 14 or later compatibility as described in “rtwgensettings Structure” on page 85-34. Add the following code to the `rtwgenSettings` definition:

   ```
   rtwgensettings.DerivedFrom = 'ert.tlc';
   rtwgensettings.Version = '1';
   ```

9. Add an `rtwoptions` structure that defines a target-specific options category with three check boxes just after the `BEGIN_RTW_OPTIONS` directive. The following code shows the complete `RTW_OPTIONS` section, including the previous `rtwgenSettings` changes.

   ```
   /%
     BEGIN_RTW_OPTIONS

     rtwoptions(1).prompt         = 'My Target Options';
     rtwoptions(1).type           = 'Category';
     rtwoptions(1).enable         = 'on';
     rtwoptions(1).default        = 3;   % number of items under this category
                                         % excluding this one.
     rtwoptions(1).popupstrings  = '';
     rtwoptions(1).tlcvariable   = '';
     rtwoptions(1).tooltip       = '';
     rtwoptions(1).callback      = '';
     rtwoptions(1).makevariable  = '';

     rtwoptions(2).prompt         = 'Demo option 1';
     rtwoptions(2).type           = 'Checkbox';
     rtwoptions(2).default        = 'off';
     rtwoptions(2).tlcvariable    = 'DummyOpt1';
     rtwoptions(2).makevariable   = '';
     rtwoptions(2).tooltip        = ['Demo option1 (non-functional)'];
     rtwoptions(2).callback       = '';
   ```

```
      rtwoptions(3).prompt         = 'Demo option 2';
      rtwoptions(3).type           = 'Checkbox';
      rtwoptions(3).default        = 'off';
      rtwoptions(3).tlcvariable    = 'DummyOpt2';
      rtwoptions(3).makevariable   = '';
      rtwoptions(3).tooltip        = ['Demo option2 (non-functional)'];
      rtwoptions(3).callback       = '';

      rtwoptions(4).prompt         = 'Demo option 3';
      rtwoptions(4).type           = 'Checkbox';
      rtwoptions(4).default        = 'off';
      rtwoptions(4).tlcvariable    = 'DummyOpt3';
      rtwoptions(4).makevariable   = '';
      rtwoptions(4).tooltip        = ['Demo option3 (non-functional)'];
      rtwoptions(4).callback       = '';

      %---------------------------------------%
      % Configure RTW code generation settings %
      %---------------------------------------%

      rtwgensettings.BuildDirSuffix = '_my_ert_target_rtw';
      rtwgensettings.DerivedFrom = 'ert.tlc';
      rtwgensettings.Version = '1';
      rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
      %SelectCallback provides toolchain approach support, but requires custom function
      %Omit this SelectCallback if using the template makefile approach

      END_RTW_OPTIONS
    %/
```

10 Save your changes to `my_ert_target.tlc` and close the file.

Create ToolchainCompliant Function

To enable builds using the toolchain approach, you create a function that corresponds to the `SelectCallback` near the end of the custom STF. This function sets properties for toolchain compliance.

```
function enableToolchainCompliant(hSrc, hDlg)
  % The following parameters enable toolchain compliance.
  slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
  slConfigUISetVal(hDlg, hSrc, 'GenerateMakefile','on');

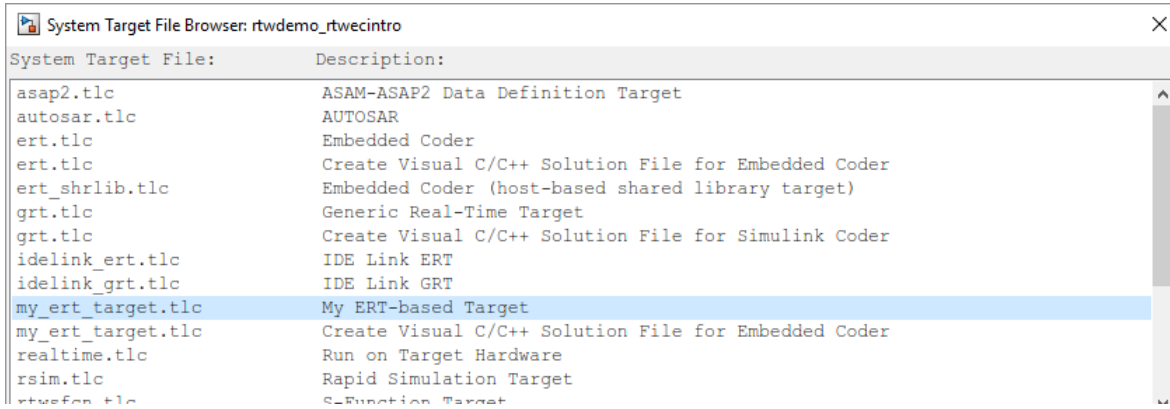
  % The following parameters are not required for toolchain compliance.
  % But, it is recommended practice to set these default values and
  % disable the parameters (as shown).
  slConfigUISetVal(hDlg, hSrc, 'RTWCompilerOptimization','off');
  slConfigUISetVal(hDlg, hSrc, 'MakeCommand','make_rtw');
  slConfigUISetEnabled(hDlg, hSrc, 'RTWCompilerOptimization',false);
  slConfigUISetEnabled(hDlg, hSrc, 'MakeCommand',false);
end
```

Note If you are using the template makefile approach, omit calling the function enabling toolchain-compliance from your STF file. Instead, use the information in “Create ERT-Based TMF” on page 85-58.

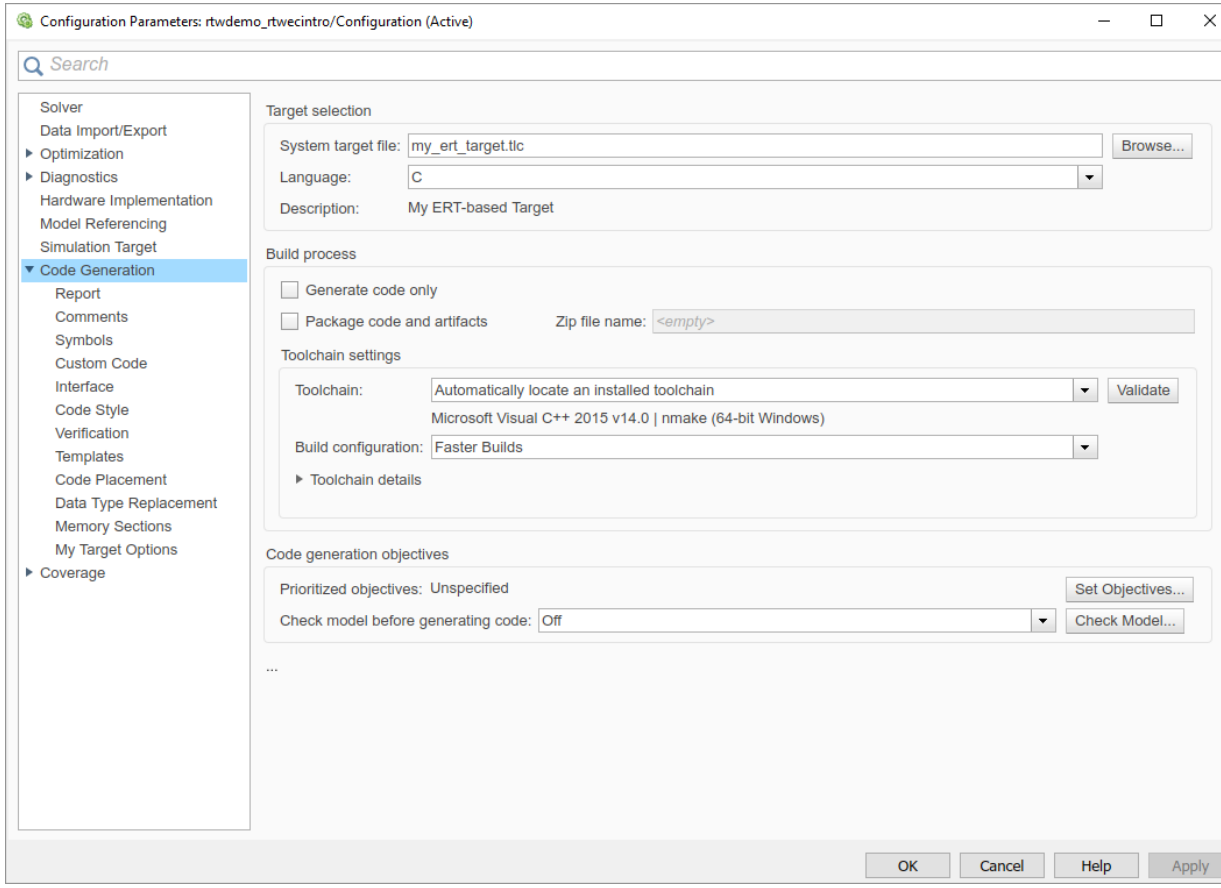
Viewing the STF

At this point, you can verify that the target inherits and displays ERT options as follows:

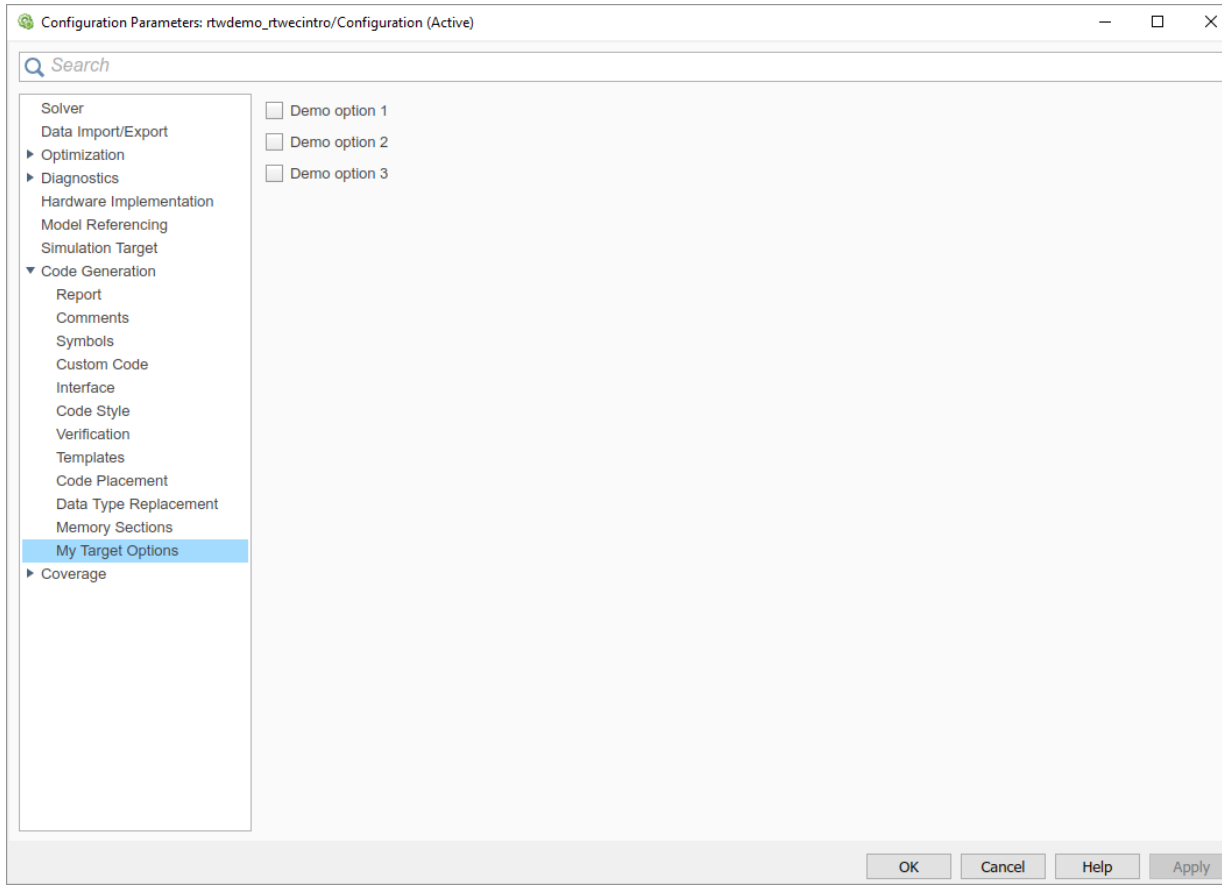
1. Create a new model.
2. Open the Model Explorer or the Configuration Parameters dialog box.
3. Select the **Code Generation** pane.
4. Click **Browse** to open the System Target File browser.
5. In the file browser, scroll through the list of targets to find the new target, `my_ert_target.tlc`. (This step assumes that your MATLAB path contains `c:/work/my_ert_target/my_ert_target`, as previously set in “Creating Target Folders” on page 85-51.)
6. Select `My ERT-based Target` and click **OK.**



7. The **Code Generation** pane now shows that the model is configured for the `my_ert_target.tlc` target. The **System target file**, **Language**, **Toolchain**, and **Build configuration** fields should appear:



8 Select the **My Target Options** pane. The target displays the three check box options defined in the `rtwoptions` structure.



9 Select the **Code Generation** pane and reopen the System Target File Browser.

10 Select the Embedded Coder target (`ert.tlc`). The target displays the standard ERT options.

11 Close the model. You do not need to save it.

The STF for the skeletal target is complete. If you are using the toolchain approach, you are ready to invoke the build process for your target.

If you prefer to use the template makefile approach, the reference to a TMF, `my_ert_target_lcc.tmf`, in the STF header comments prevents you from invoking the build process for your target until the TMF file is in place. First, you must create a `my_ert_target_lcc.tmf` file.

Create ERT-Based TMF

If you are using the toolchain makefile approach with a toolchain compliant custom target, omit the steps that apply to the template makefile approach. (Skip this section.)

If you are using the templated makefile approach, follow the steps applying to TMF and omit calling the function enabling toolchain-compliance from your STF file, which is described in “Create ERT-Based, Toolchain Compliant STF” on page 85-52.

Create a TMF for your target by copying and modifying the standard ERT TMF for the LCC compiler:

1. Make sure that your working folder is still set to the target file folder you created previously in “Creating Target Folders” on page 85-51.

   ```
   c:/work/my_ert_target/my_ert_target
   ```

2. Place a copy of *`matlabroot`*`/rtw/c/ert/ert_lcc.tmf` in `c:/work/my_ert_target/my_ert_target` and rename it `my_ert_target_lcc.tmf`. The file `ert_lcc.tmf` is the ERT compiler-specific template makefile for the LCC compiler.
3. Open `my_ert_target_lcc.tmf` in a text editor.
4. Change the `SYS_TARGET_FILE` parameter so that the file reference for your `.tlc` file is generated in the `make` file. Change the line

   ```
   SYS_TARGET_FILE = any
   ```

   to

   ```
   SYS_TARGET_FILE = my_ert_target.tlc
   ```

5. Save changes to `my_ert_target_lcc.tmf` and close the file.

Your target can now generate code and build a host-based executable. In the next sections, you create a test model and test the build process using `my_ert_target`.

Create Test Model and S-Function

In this section, you build a simple test model for later use in code generation:

1. Set your working folder to `c:/work/my_targetmodel`.

   ```
   cd c:/work/my_targetmodel
   ```

   For the remainder of this tutorial, `my_targetmodel` is assumed to be the working folder. Your target writes the output files of the code generation process into a build

folder within the working folder. When inlined code is generated for the `timestwo` S-function, the build process looks for the TLC implementation of the S-function in the working folder.

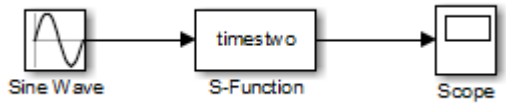
2. Copy the following C and TLC files for the `timestwo` S-function to your working folder:

   - *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/src/timestwo.c`
   - *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc`

3. Build the `timestwo` MEX-file in `c:/work/my_targetmodel`.

   ```
   mex timestwo.c
   ```

4. Create the following model, using an S-Function block from the Simulink User-Defined Functions library. Save the model in your working folder as `targetmodel`.



5. Double-click the S-Function block to open the Block Parameters dialog box. Enter the S-function name `timestwo`. Click **OK**. The block is now bound to the `timestwo` MEX-file.
6. Open Model Explorer or the Configuration Parameters dialog box and select the **Solver** pane.
7. Set the solver **Type** to `fixed-step` and click **Apply**.
8. Save the model.
9. Open the scope and run a simulation. Verify that the `timestwo` S-function multiplies its input by 2.0.

Keep the `targetmodel` model open for use in the next section, in which you generate code using the test model.

Verify Target Operation

In this section you configure `targetmodel` for the `my_ert_target` custom target, and use the target to generate code and build an executable:

1. Open the Configuration Parameters dialog box and select the **Code Generation** pane.
2. Click **Browse** to open the System Target File Browser.
3. In the Browser, select `My ERT-based Target` and click **OK**.
4. The Configuration Parameters dialog box now displays the **Code Generation** pane for `my_ert_target`.
5. Select the **Code Generation** > **Report** pane and select the **Create code generation report** option.
6. Click **Apply** and save the model. The model is configured for `my_ert_target`.
7. Build the model. If the build succeeds, the MATLAB Command Window displays the message below.

   ```
   ### Created executable: ../targetmodel.exe
   ### Successful completion of build procedure for model:
   targetmodel
   ```

   Your working folder contains the `targetmodel.exe` file and the build folder, `targetmodel_my_ert_target_rtw`, which contains generated code and other files. The working folder also contains an `slprj` folder, used internally by the build process.

   The code generator also creates and displays a code generation report.
8. To view the generated model code, go to the code generation report window. In the **Contents** pane, click the `targetmodel.c` link.
9. In `targetmodel.c`, locate the model step function, `targetmodel_step`. Observe the following code.

   ```
   /* S-Function Block: <Root>/S-Function */
   /* Multiply input by two */
   targetmodel_B.SFunction = targetmodel_B.SineWave * 2.0;
   ```

   The presence of this code confirms that the `my_ert_target` custom target has generated an inlined output computation for the S-Function block in the model.

Customize Template Makefiles

To configure or customize a template makefile (TMF), you should be familiar with how the `make` command works and how it processes a makefile (`.mk` file). You should also understand makefile build rules. For information on these topics, refer to the documentation provided with the make utility that you use.

Template Makefiles and Tokens

A template makefile contains tokens. The build process expands the tokens and creates makefiles:

- *`model`*`.mk` –– Compiles and links code generated from model components.
- `rtwshared.mk` –– Compiles generated shared utility code.

The makefiles (*`model_or_sharedutils`*`.mk`) use commands that are specific to your development computer.

Template Makefile Tokens

The `make_rtw` command (or a different command provided with some targets) directs the process of generating *`model_or_sharedutils`*`.mk`. The `make_rtw` command processes the TMF specified on the **Code Generation** pane of the Configuration Parameters dialog box. `make_rtw` copies the TMF, line by line, expanding each token encountered. Template Makefile Tokens Expanded by make_rtw lists the tokens and their expansions.

These tokens are used in several ways by the expanded makefile:

- To control the conditional behavior in the makefile. The conditionals are used to control the source file lists, library names, target to be built, and other build-related information.
- To provide the macro definitions for compiling the files, for example, `-DINTEGER_CODE=1`.

Template Makefile Tokens Expanded by make_rtw

Token	Expansion
General purpose	
`|>ADDITIONAL_LDFLAGS<|`	Linker flags automatically added by blocks.
`|>ALT_MATLAB_BIN<|`	Alternate full pathname for the MATLAB executable; value is different than value for `MATLAB_BIN` token when the full pathname contains spaces.
`|>ALT_MATLAB_ROOT<|`	Alternate full pathname for the MATLAB installation; value is different than value for `MATLAB_ROOT` token when the full pathname contains spaces.
`|>BUILDARGS<|`	Options passed to `make_rtw`. This token is provided so that the contents of your *`model_or_sharedutils`*`.mk` file change when you change the build arguments, thus forcing an update of modules when your build options change.
`|>COMBINE_OUTPUT_UPDATE_FCNS<|`	True (1) when **Single output/update function** is selected, otherwise False (0). Used for the macro definition `-DONESTEPFCN=1`.
`|>COMPUTER<|`	Computer type. See the MATLAB `computer` command.
`|>EXPAND_LIBRARY_LOCATION<|`	Location of precompiled library file. The `TargetPreCompLibLocation` configuration parameter can override this setting. For examples, see “Control Library Location and Naming During Build” (Simulink Coder).
`|>EXPAND_LIBRARY_NAME<|`	Library name. For examples, see “Control Library Location and Naming During Build” (Simulink Coder) and “Modify the Template Makefile for rtwmakecfg” (Simulink Coder).
`|>EXPAND_LIBRARY_SUFFIX<|`	Library suffix. The `TargetLibSuffix` configuration parameter can override this setting. For examples, see “Control Library Location and Naming During Build” (Simulink Coder).

Token	Expansion
`|>EXT_MODE<|` (Not required for R2018a and later provided template makefile specifies `TOOLCHAIN_NAME (Simulink Coder)`)	True (1) to enable generation of external mode support code, otherwise False (0).
`|>EXTMODE_TRANSPORT<|` (Not required for R2018a and later provided template makefile specifies `TOOLCHAIN_NAME (Simulink Coder)`)	Index of transport mechanism (for example, `tcpip`, `serial`) for external mode.
`|>EXTMODE_STATIC<|` (Not required for R2018a and later provided template makefile specifies `TOOLCHAIN_NAME (Simulink Coder)`)	True (1) if static memory allocation is selected for external mode. False (0) if dynamic memory allocation is selected.
`|>EXTMODE_STATIC_SIZE<|` (Not required for R2018a and later provided template makefile specifies `TOOLCHAIN_NAME (Simulink Coder)`)	Size of static memory allocation buffer (if any) for external mode.
`|>GENERATE_ERT_S_FUNCTION<|`	True (1) when **Create SIL block** is selected, otherwise False (0). Used for control of the makefile target of the build.
`|>INCLUDE_MDL_TERMINATE_FCN<|`	True (1) when **Terminate function required** is selected, otherwise False (0). Used for the macro definition `-DTERMFCN==1`.
`|>INTEGER_CODE<|`	True (1) when **Support floating-point numbers** is not selected, otherwise False (0). `INTEGER_CODE` is a required macro definition when compiling the source code and is used when selecting precompiled libraries to link against.
`|>MAKEFILE_NAME<|`	*`model_or_sharedutils`*`.mk` — The name of the makefile that was created from the TMF.
`|>MAT_FILE<|`	True (1) when **MAT-file logging** is selected, otherwise False (0). `MAT_FILE` is a required macro definition when compiling the source code and also is used to include logging code in the build process.
`|>MATLAB_BIN<|`	Location of the MATLAB executable.

Token	Expansion
`|>MATLAB_ROOT<|`	Path to where MATLAB is installed.
`|>MEM_ALLOC<|`	Either `RT_MALLOC` or `RT_STATIC`. Indicates how memory is to be allocated.
`|>MEXEXT<|`	MEX-file extension. See the MATLAB `mexext` command.
`|>MODEL_MODULES<|`	Additional generated source modules. For example, you can split a large model into two files, *`model`*`.c` and *`model`*`1.c`. In this case, this token expands to *`model`*`1.c`.
`|>MODEL_MODULES_OBJ<|`	Object filenames (`.obj`) corresponding to additional generated source modules.
`|>MODEL_NAME<|`	Name of the Simulink block diagram currently being built.
`|>MULTITASKING<|`	True (1) if solver mode is multitasking, otherwise False (0).
`|>NCSTATES<|`	Number of continuous states.
`|>NUMST<|`	Number of sample times in the model.
`|>RELEASE_VERSION<|`	The MATLAB release version.
`|>S_FUNCTIONS_LIB<|`	List of S-function libraries available for linking.
`|>SOLVER<|`	Solver source filename, for example, `ode3.c`.
`|>SOLVER_OBJ<|`	Solver object (`.obj`) filename, for example, `ode3.obj`.
`|>TARGET_LANG_EXT<|`	`c` when the **Language** selection is C, `cpp` when the **Language** selection is C++. Used in the makefile to control the extension on generated source files.

<table>
<tr><th>Token</th><th>Expansion</th></tr>
<tr><td>|>TGT_FCN_LIB<|</td><td>Specifies compiler command line options. The line in the makefile is TGT_FCN_LIB = |>TGT_FCN_LIB<|. Use this token in a makefile conditional statement to specify a standard math library as a compiler option. Possible |>TGT_FCN_LIB<| token values are:
<table>
<tr><th>Value</th><th>Generates Calls To</th></tr>
<tr><td>Name of custom CRL</td><td>ISO®/IEC 9899:1990 C (ANSI_C) standard math library</td></tr>
<tr><td>ISO_C</td><td>ISO/IEC 9899:1999 C standard math library</td></tr>
<tr><td>ISO_C++</td><td>ISO/IEC 14882:2003 C++ standard math library</td></tr>
<tr><td>GNU</td><td>GNU extensions to the ISO/IEC 9899:1999 C standard math library</td></tr>
</table></td></tr>
<tr><td>|>TID01EQ<|</td><td>True (1) if sampling rates of the continuous task and the first discrete task are equal, otherwise False (0).</td></tr>
<tr><td colspan="2">S-function and build information support

Note For examples of the tokens in this section, see “Modify the Template Makefile for rtwmakecfg” (Simulink Coder).</td></tr>
<tr><td>|>START_EXPAND_INCLUDES<|
|>EXPAND_DIR_NAME<|
|>END_EXPAND_INCLUDES<|</td><td>List of folder names to add to the include path. Additionally, the ADD_INCLUDES macro must be added to the INCLUDES line.</td></tr>
<tr><td>|>START_EXPAND_LIBRARIES<|
|>EXPAND_LIBRARY_NAME<|
|>END_EXPAND_LIBRARIES<|</td><td>List of library names.</td></tr>
<tr><td>|>START_EXPAND_MODULES<|
|>EXPAND_MODULE_NAME<|
|>END_EXPAND_MODULES<|</td><td>Library module names within |>START_EXPAND_LIBRARIES<| and |>START_PRECOMP_LIBRARIES<| library lists.</td></tr>
</table>

Token	Expansion

`|>START_EXPAND_RULES<|`
`|>EXPAND_DIR_NAME<|`
`|>END_EXPAND_RULES<|`
	Makefile rules.

`|>START_PRECOMP_LIBRARIES<|`
`|>EXPAND_LIBRARY_NAME<|`
`|>END_PRECOMP_LIBRARIES<|`
	List of precompiled library names.

Model reference support **Note** For examples of the tokens in this section, see "Providing Model Referencing Support in the TMF" on page 85-83.	
`|>MASTER_ANCHOR_DIR<|`	For parallel builds, current work folder (`pwd`) at the time the build started.
`|>MODELLIB<|`	Name of the library file generated for the current model.
`|>MODELREFS<|`	List of models referenced by the top model.
`|>MODELREF_LINK_LIBS<|`	List of referenced model libraries against which the top model links.
`|>MODELREF_LINK_RSPFILE_NAME<|`	Name of a response file against which the top model links. This token is valid only for build environments that support linker response files. For an example of its use, see *`matlabroot`*`/rtw/c/grt/grt_vc.tmf`.
`|>MODELREF_TARGET_TYPE<|`	Type of target being built. Possible values are • `NONE`: Standalone model or top model referencing other models • `RTW`: Model reference target build • `SIM`: Model reference simulation target build
`|>RELATIVE_PATH_TO_ANCHOR<|`	Relative path, from the location of the generated makefile, to the MATLAB working folder.
`|>START_DIR<|`	Current work folder (`pwd`) at the time the build started. This token is required for parallel builds.

These tokens are expanded by substitution of parameter values known to the build process. For example, if the source model contains blocks with two different sample times, the TMF statement

```
NUMST = |>NUMST<|
```

expands to:

```
NUMST = 2
```

In addition to the above, `make_rtw` expands tokens from other sources:

- Target-specific tokens defined in the target options of the Configuration Parameters dialog box
- Structures in the `rtwoptions` section of the system target file. Structures in the `rtwoptions` structure array that contain the field `makevariable` are expanded.

The following example is extracted from *`matlabroot`*`/rtw/c/grt/grt.tlc`. The section starting with `BEGIN_RTW_OPTIONS` contains MATLAB code that sets up `rtwoptions`. The following directive causes the `|>EXT_MODE<|` token to be expanded to `1` (on) or `0` (off), depending on how you set the external mode options.

```
rtwoptions(2).makevariable = 'EXT_MODE'
```

Invoke the make Utility

make Command

After creating *`model_or_sharedutils`*`.mk` from your TMF, the build process invokes a `make` command. To invoke `make`, the build process issues this command.

```
makecommand -f model_or_sharedutils.mk
```

`makecommand` is defined by the `MAKECMD` macro in your target's TMF (see “Structure of the Template Makefile” on page 85-69). You can specify additional options to `make` in the **Make command** field of the **Code Generation** pane. (See the sections “Specify a Make Command” (Simulink Coder) and “Template Makefiles and Make Options” (Simulink Coder).)

For example, specifying `OPT_OPTS=-O2` in the **Make command** field causes `make_rtw` to generate the following `make` command.

```
makecommand -f model_or_sharedutils.mk OPT_OPTS=-O2
```

A comment at the top of the TMF specifies the available `make` command options. If these options do not provide you with enough flexibility, you can configure your own TMF.

make Utility Versions

The make utility lets you control nearly every aspect of building your real-time program. There are several different versions of `make` available. The code generator provides the Free Software Foundation GNU `make` for both UNIX[9] and PC platforms in platform-specific subfolders under

```
matlabroot/bin
```

It is possible to use other versions of `make` with the code generator, although GNU Make is recommended. To be compatible with the code generator, verify that your version of `make` supports the following command format.

```
makecommand -f model_or_sharedutils.mk
```

Structure of the Template Makefile

A TMF has multiple sections, including the following:

- `Abstract` — Describes what the makefile targets. Here is a representative abstract from the GRT TMFs in *`matlabroot`*`/rtw/c/grt` (open):

```
# File    : grt_lcc64.tmf
#
# Abstract:
#    Template makefile for building a PC-based stand-alone generic real-time
#       version of Simulink model using    generated C code and LCC compiler
#       Version 2.4
#
#     This makefile attempts to conform to the guidelines specified in the
#     IEEE Std 1003.2-1992 (POSIX) standard. It is designed to be used
#       with GNU Make (gmake) which is located in matlabroot/bin/win64.
#
#     Note that this template is automatically customized by the build
#       procedure to create "<model>.mk"
#
```

9. UNIX is a registered trademark of The Open Group in the United States and other countries.

```
#       The following defines can be used to modify the behavior of the
#    build:
#      OPT_OPTS       - Optimization options. Default is none. To enable
#                           debugging specify as OPT_OPTS=-g4.
#      OPTS           - User specific compile options.
#      USER_SRCS      - Additional user sources, such as files needed by
#               S-functions.
#      USER_INCLUDES  - Additional include paths
#               (i.e. USER_INCLUDES="-Iwhere-ever -Iwhere-ever2")
#               (For Lcc, have a '/'as file separator before the
#               file name instead of a '\' .
#               i.e.,  d:\work\proj1/myfile.c - required for 'gmake')
#
#       This template makefile is designed to be used with a system target
#       file that contains 'rtwgensettings.BuildDirSuffix' see grt.tlc
```

- `Macros read by make_rtw` section — Defines macros that tell `make_rtw` how to process the TMF. Here is a representative `Macros read by make_rtw` section from the GRT TMFs in *`matlabroot`*`/rtw/c/grt` (open):

```
#------------------------ Macros read by make_rtw -----------------------------
#
# The following macros are read by the build procedure:
#
#  MAKECMD         - This is the command used to invoke the make utility
#  HOST            - What platform this template makefile is targeted for
#                    (i.e. PC or UNIX)
#  BUILD           - Invoke make from the build procedure (yes/no)?
#  SYS_TARGET_FILE - Name of system target file.

MAKECMD         = "%MATLAB%\bin\win64\gmake"
SHELL           = cmd
HOST            = PC
BUILD           = yes
SYS_TARGET_FILE = grt.tlc
BUILD_SUCCESS    = *** Created

# Opt in to simplified format by specifying compatible Toolchain
TOOLCHAIN_NAME = "LCC-win64 v2.4.1 | gmake (64-bit Windows)"

MAKEFILE_FILESEP = /
```

  The macros in this section might include:

  - `MAKECMD` — Specifies the command used to invoke the make utility. For example, if `MAKECMD = mymake`, then the `make` command invoked is

    `mymake -f` *`model_or_sharedutils`*`.mk`
  - `HOST` — Specifies the platform targeted by this TMF. This can be `PC`, `UNIX`, *`computer_name`* (see the MATLAB `computer` command), or `ANY`.
  - `SHELL` — Specifies an operating system shell command for the platform. For Windows, this can be `cmd`.

- `BUILD` — Instructs `make_rtw` whether or not it should invoke `make` from the build procedure. Specify `yes` or `no`.
- `SYS_TARGET_FILE` — Specifies the name of the system target file or the value `any`. This is used for consistency checking by `make_rtw` to verify the system target file specified in the **Target selection** panel of the **Code Generation** pane of the Configuration Parameters dialog box. If you specify `any`, you can use the TMF with any system target file.
- `BUILD_SUCCESS` — Optional macro that specifies the build success message to be displayed for `make` completion on the PC. For example,

  ```
  BUILD_SUCCESS = ### Successful creation of
  ```

  The `BUILD_SUCCESS` macro, if used, replaces the standard build success message found in the TMFs distributed with the bundled code generator targets (such as GRT):

  ```
  @echo ### Created executable $(MODEL).exe
  ```

  Your TMF must include either the standard build success message, or use the `BUILD_SUCCESS` macro. For an example of the use of `BUILD_SUCCESS`, see *`matlabroot`*`/rtw/c/grt/grt_lcc.tmf` or the code example above this list of macros.
- `BUILD_ERROR` — Optional macro that specifies the build error message to be displayed when an error is encountered during the `make` procedure. For example,

  ```
  BUILD_ERROR = ['Error while building ', modelName]
  ```
- `VERBOSE_BUILD_OFF_TREATMENT = PRINT_OUTPUT_ALWAYS` — Optional macro to include if you want the makefile output to be displayed regardless of the setting of the **Verbose build** option in the **Code Generation** > **Debug** pane.
- `DOWNLOAD` — An optional macro that you can specify as yes or no. If specified as yes (and `BUILD=yes`), then `make` is invoked a second time with the download target.

  ```
  make -f model_or_sharedutils.mk download
  ```
- `DOWNLOAD_SUCCESS` — An optional macro that you can use to specify the download success message to be used when looking for a completed download. For example,

  ```
  DOWNLOAD_SUCCESS = ### Downloaded
  ```

  - DOWNLOAD_ERROR — An optional macro that you can use to specify the download error message to be displayed when an error is encountered during the download. For example,

    ```
    DOWNLOAD_ERROR = ['Error while downloading ', modelName]
    ```

- Tokens expanded by make_rtw section — Defines the tokens that make_rtw expands. Here is a brief excerpt from a representative Tokens expanded by make_rtw section from the GRT TMFs in *matlabroot*/rtw/c/grt (open):

  ```
  #---------------------- Tokens expanded by make_rtw ----------------------------
  #
  # The following tokens, when wrapped with "|>" and "<|" are expanded by the
  # build procedure.
  #
  #  MODEL_NAME          - Name of the Simulink block diagram
  #  MODEL_MODULES       - Any additional generated source modules
  #  MAKEFILE_NAME       - Name of makefile created from template makefile <model>.mk
  #  MATLAB_ROOT         - Path to where MATLAB is installed.
  ...

  MODEL                = |>MODEL_NAME<|
  MODULES              = |>MODEL_MODULES<|
  MAKEFILE             = |>MAKEFILE_NAME<|
  MATLAB_ROOT          = |>MATLAB_ROOT<|
  ...
  ```

  For more information about TMF tokens, see Template Makefile Tokens Expanded by make_rtw.

- Subsequent sections vary based on compiler, host, and target. Some common sections include Model and reference models, External mode, Tool Specifications or Tool Definitions, Include Path, C Flags, Additional Libraries, and Source Files.
- Rules section — Contains the make rules used in building an executable from the generated source code. The build rules are typically specific to your version of make. The Rules section might be followed by related sections such as Dependencies.

Customize and Create Template Makefiles

Introduction

This section describes the mechanics of setting up a custom template makefile (TMF) and incorporating it into the build process. It also discusses techniques for modifying a TMF and MATLAB file mechanisms associated with the TMF.

Before creating a custom TMF, you should read “Folder and File Naming Conventions” on page 85-11 to understand the folder structure and MATLAB path requirements for custom targets.

Setting Up a Template Makefile

To customize or create a new TMF, you should copy an existing GRT or ERT TMF from one of the following locations:

```
matlabroot/rtw/c/grt (open)
matlabroot/rtw/c/ert (open)
```

Place the copy in the same folder as the associated system target file (STF). Usually, this is the `mytarget/mytarget` folder within the target folder structure. Then, rename your TMF (for example, `mytarget.tmf`) and modify it.

To allow the build process to locate and select your TMF, you must provide information in the STF file header (see “System Target File Structure” on page 85-29). For a target that implements a single TMF, the standard way to specify the TMF to be used in the build process is to use the TMF directive of the STF file header.

```
TMF: mytarget.tmf
```

Using Macros and Pattern Matching Expressions in a Template Makefile

This section shows, through an example, how to use macros and file-pattern-matching expressions in a TMF to generate commands in *`model_or_sharedutils`*`.mk`.

The make utility processes *`model_or_sharedutils`*`.mk` and generates a set of commands based upon dependency rules defined in *`model_or_sharedutils`*`.mk`. After `make` generates the set of commands for building or rebuilding `test`, `make` executes them.

For example, to build a program called `test`, `make` must link the object files. However, if the object files don't exist or are out of date, `make` must compile the source code. Thus there is a dependency between source and object files.

Each version of `make` differs slightly in its features and how rules are defined. For example, consider a program called `test` that gets created from two sources, `file1.c` and `file2.c`. Using most versions of `make`, the dependency rules would be

```
test: file1.o file2.o
        cc -o test file1.o file2.o

file1.o: file1.c
        cc -c file1.c

file2.o: file2.c
        cc -c file2.c
```

In this example, a UNIX[10] environment is assumed. In a PC environment the file extensions and compile and link commands are different.

In processing the first rule

```
test: file1.o file2.o
```

`make` sees that to build `test`, it needs to build `file1.o` and `file2.o`. To build `file1.o`, `make` processes the rule

```
file1.o: file1.c
```

If `file1.o` doesn't exist, or if `file1.o` is older than `file1.c`, `make` compiles `file1.c`.

The format of TMFs follows the above example. Our TMFs use additional features of `make` such as macros and file-pattern-matching expressions. In most versions of `make`, a macro is defined with

```
MACRO_NAME = value
```

References to macros are made with `$(MACRO_NAME)`. When `make` sees this form of expression, it substitutes *`value`* for `$(MACRO_NAME)`.

10. UNIX is a registered trademark of The Open Group in the United States and other countries.

You can use pattern matching expressions to make the dependency rules more general. For example, using GNU[11] Make, you could replace the two "`file1.o: file1.c`" and "`file2.o: file2.c`" rules with the single rule

```
%.o : %.c
        cc -c $<
```

Note that `$<` in the previous example is a special macro that equates to the dependency file (that is, `file1.c` or `file2.c`). Thus, using macros and the "%" pattern matching character, the previous example can be reduced to

```
SRCS = file1.c file2.c
OBJS = $(SRCS:.c=.o)

test: $(OBJS)
        cc -o $@ $(OBJS)

%.o : %.c
        cc -c $<
```

Note that the `$@` macro above is another special macro that equates to the name of the current dependency target, in this case `test`.

This example generates the list of objects (`OBJS`) from the list of sources (`SRCS`) by using the text substitution feature for macro expansion. It replaces the source file extension (for example, `.c`) with the object file extension (`.o`). This example also generalized the build rule for the program, `test`, to use the special "`$@`" macro.

Customizing Generated Makefiles with rtwmakecfg

TMFs provide tokens that let you add the following items to generated makefiles:

- Source folders
- Include folders
- Run-time library names
- Run-time module objects

S-functions can add this information to the makefile by using an `rtwmakecfg.m` file function. This function is particularly useful when building a model that contains one or more of your S-Function blocks, such as device driver blocks.

11. GNU is a registered trademark of the Free Software Foundation.

To add information pertaining to an S-function to the makefile,

1. Create the function `rtwmakecfg` in file `rtwmakecfg.m`. The code generator associates this file with your S-function based on its folder location.
2. Modify your target's TMF such that it supports macro expansion for the information returned by `rtwmakecfg` functions.

After the TLC phase of the build process, when generating a makefile from the TMF, the build process searches for an `rtwmakecfg.m` file in the folder that contains the S-function component. If it finds the file, the build process calls the `rtwmakecfg` function. For more information, see “Use rtwmakecfg.m API to Customize Generated Makefiles” (Simulink Coder).

Supporting Continuous Time in Custom Targets

If you want your custom ERT-based target to support continuous time, you must update your template makefile (TMF) and the static main program module (for example, `mytarget_main.c`) for your target.

Template Makefile Modifications

Add the `NCSTATES` token expansion after the `NUMST` token expansion, as follows:

```
NUMST = |>NUMST<|
NCSTATES = |>NCSTATES<|
```

In addition, add `NCSTATES` to the `CPP_REQ_DEFINES` macro, as in the following example:

```
CPP_REQ_DEFINES = -DMODEL=$(MODEL) -DNUMST=$(NUMST) -DNCSTATES=$(NCSTATES) \
-DMAT_FILE=$(MAT_FILE)
-DINTEGER_CODE=$(INTEGER_CODE) \
-DONESTEPFCN=$(ONESTEPFCN) -DTERMFCN=$(TERMFCN) \
-DHAVESTDIO
-DMULTI_INSTANCE_CODE=$(MULTI_INSTANCE_CODE) \
```

Modifications to Main Program Module

The main program module defines a static main function that manages task scheduling for the supported tasking modes of single- and multiple-rate models. `NUMST` (the number of sample times in the model) determines whether the main function calls multirate or single-rate code. However, when a model uses continuous time, do not rely on `NUMST` directly.

When the model has continuous time and the flag `TID01EQ` is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code

associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and `TID01EQ` is true, the generated code has a single-rate call interface.

To support models that have continuous time, update the static main module to take `TID01EQ` into account, as follows:

1. Before `NUMST` is referenced in the file, add the following code:

```
#if defined(TID01EQ) && TID01EQ == 1 && NCSTATES == 0
#define DISC_NUMST (NUMST - 1)
#else
#define DISC_NUMST NUMST
#endif
```

2. Replace instances of `NUMST` in the file by `DISC_NUMST`.

Model Reference Considerations

See “Support Model Referencing” on page 85-82 for important information on TMF modifications you may need to make to support the code generator model referencing features.

Note If you are using a TMF without the variable `MODELREFS`, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add `MODELREFS` to the make file.

- “Support Toolchain Approach with Custom Target” (Simulink Coder)

Custom Target Optional Features

This section describes how to configure a custom embedded target to support these optional features.

To ...	Use Target Configuration Parameters ...	For more information, see ...
Indicate a custom target is toolchain-compliant	`UseToolchainInfoCompliant` `GenerateMakefile`	"Support Toolchain Approach with Custom Target" (Simulink Coder)
Build a model that includes referenced models and uses a custom target	`ModelReferenceCompliant` `ParMdlRefBuildCompliant` (parallel build support)	"Support Model Referencing" (Simulink Coder)
Control the compiler optimization level building generated code for a custom target	`CompOptLevelCompliant`	"Support Compiler Optimization Level Control" (Simulink Coder)
Control C function prototypes of initialize and step functions that are generated for a model that uses a custom target	`ModelStepFunctionPrototypeControlCompliant` (ERT only)	"Support C Function Prototype Control" (Simulink Coder)
Control C++ class interfaces that are generated for a model that uses a custom target	`CPPClassGenCompliant` (ERT only)	"Support C++ Class Interface Control" (Simulink Coder)
Enable concurrent execution of multiple tasks on a multicore platform for a model that uses a custom target	`ConcurrentExecutionCompliant`	"Support Concurrent Execution of Multiple Tasks" (Simulink Coder)

The required configuration changes are modifications to your system target file (STF), and in some cases also modifications to your template makefile (TMF) or your custom static main program.

The API for STF callbacks provides a function `SelectCallback` for use in STFs. `SelectCallback` is associated with the target rather than with its individual options. If you implement a `SelectCallback` function for a target, it is triggered whenever the user selects the target in the System Target File Browser.

The API provides the functions `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` for controlling custom target configuration options from a user-written `SelectCallback` function. (For function descriptions and examples, see the function reference pages.)

The general requirements for supporting one of the optional features include:

- To support model referencing or compiler optimization level control, the target must be derived from the GRT or the ERT target. To support C function prototype control or C++ class interface control, the target must be derived from the ERT target.
- The system target file (STF) must declare feature compliance by including one of the target configuration parameters listed above in a `SelectCallback` function call.
- Additional changes such as TMF modifications or static main program modifications may be required, depending on the feature. See the detailed steps in the subsections for individual features.

For an example that shows how to configure custom target optional features, see "Customize System Target Files" (Simulink Coder).

Support Toolchain Approach with Custom Target

This section describes how to configure a custom system target file to support builds with the toolchain approach.

In the Configuration Parameters dialog box, on the Code Generation pane of, you can present either the build controls for the toolchain approach or the template makefile approach. The model parameters that contribute to determining which build controls appear include these parameters.

Model Parameter	Value	Notes
`UseToolchainInfoCompliant`	`on`	For toolchain approach, set this parameter to `'on'`. For TMF approach, set this parameter to `'off'`.
`GenerateMakefile`	`on`	For toolchain approach, set this parameter to `'on'`.

When the dialog box detects that the selected target has these properties, the dialog box recognizes the target as toolchain-compliant and displays the build controls for the toolchain approach.

Because the custom target file cannot set these properties directly, use a `SelectCallback` function in the custom target file to set the properties. The `SelectCallback` function call in the RTW_OPTION section of the TLC file can take the form:

```
rtwgensettings.SelectCallback = 'enableToolchainCompliant(hSrc, hDlg)';
```

A corresponding callback function can contain:

```
function enableToolchainCompliant(hSrc, hDlg)
  % The following parameters enable toolchain compliance.
  slConfigUISetVal(hDlg, hSrc, 'UseToolchainInfoCompliant', 'on');
  slConfigUISetVal(hDlg, hSrc, 'GenerateMakefile','on');

  % The following parameters are not required for toolchain compliance.
  % But, it is recommended practice to set these default values and
  % disable the parameters (as shown).
  slConfigUISetVal(hDlg, hSrc, 'RTWCompilerOptimization','off');
  slConfigUISetVal(hDlg, hSrc, 'MakeCommand','make_rtw');
  slConfigUISetEnabled(hDlg, hSrc, 'RTWCompilerOptimization',false);
  slConfigUISetEnabled(hDlg, hSrc, 'MakeCommand',false);
end
```

When you select your custom target, the configuration parameters dialog box displays the toolchain approach build controls. For an example, see “Create a Custom Target Configuration” on page 85-48.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Support Model Referencing

If you want to use a custom system target file for building a model that has referenced models, you must configure the custom system target file to support model referencing.

Requirements for Model Referencing with a Custom System Target File

To build a model that references other models:

- Use a custom system target file that is derived from a GRT or ERT system target file.
- The custom system target file must declare model reference compliance –– see “Declaring Model Referencing Compliance” on page 85-82.
- The template makefile must define some entities that support model referencing –– see “Providing Model Referencing Support in the TMF” on page 85-83.

Declaring Model Referencing Compliance

To declare model reference compliance for your target, you must implement a callback function that sets the `ModelReferenceCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ModelReferenceCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelReferenceCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelReferenceCompliant',false);
```

If you might use the target to build models containing large model reference hierarchies, consider configuring the target to support parallel builds, as discussed in “Reduce Build Time for Referenced Models” (Simulink Coder).

To configure a target for parallel builds, your callback function must also set the `ParMdlRefBuildCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ParMdlRefBuildCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ParMdlRefBuildCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

Providing Model Referencing Support in the TMF

To configure the template makefile (TMF) for model referencing:

1 Add the following make variables and tokens to be expanded when the makefile is generated:

```
MODELREFS                 = |>MODELREFS<|
MODELLIB                  = |>MODELLIB<|
MODELREF_LINK_LIBS        = |>MODELREF_LINK_LIBS<|
MODELREF_LINK_RSPFILE     = |>MODELREF_LINK_RSPFILE_NAME<|
RELATIVE_PATH_TO_ANCHOR   = |>RELATIVE_PATH_TO_ANCHOR<|
MODELREF_TARGET_TYPE      = |>MODELREF_TARGET_TYPE<|
```

The following code excerpt shows how makefile tokens are expanded for a referenced model.

```
MODELREFS                 =
MODELLIB                  = engine3200cc_rtwlib.a
MODELREF_LINK_LIBS        =
MODELREF_LINK_RSPFILE     =
RELATIVE_PATH_TO_ANCHOR   = ../../..
MODELREF_TARGET_TYPE      = RTW
```

The following code excerpt shows how makefile tokens are expanded for the top model that references the referenced model.

```
MODELREFS                 = engine3200cc transmission
MODELLIB                  = archlib.a
MODELREF_LINK_LIBS        = engine3200cc_rtwlib.a transmission_rtwlib.a
MODELREF_LINK_RSPFILE     =
RELATIVE_PATH_TO_ANCHOR   = ..
MODELREF_TARGET_TYPE      = NONE
```

Token	Expands to
`MODELREFS` for the top model	List of referenced model names.
`MODELLIB`	Name of the library generated for the model.

Token	Expands to
MODELREF_LINK_LIBS token for the top model	List of referenced model libraries that the top model links against.
MODELREF_LINK_RSPFILE token for the top model	Name of a response file that the top model links against. This token is valid only for build environments that support linker response files. For an example of its use, see *matlabroot*/rtw/c/grt/grt_vc.tmf.
RELATIVE_PATH_TO_ANCHOR	Relative path, from the location of the generated makefile, to the MATLAB working folder.
MODELREF_TARGET_TYPE	Signifies the type of target being built. Possible values are • NONE: Standalone model or top model referencing other models • RTW: Model reference target build • SIM: Model reference simulation target build

If you are configuring your target to support parallel builds, as discussed in "Reduce Build Time for Referenced Models" (Simulink Coder), you must also add the following token definitions to your TMF:

```
START_DIR = |>START_DIR<|
MASTER_ANCHOR_DIR = |>MASTER_ANCHOR_DIR<|
```

Token	Expands to
START_DIR	Current work folder (pwd) at the time the build started.
MASTER_ANCHOR_DIR	Current work folder (pwd) at the time the build started.

2 Add the RELATIVE_PATH_TO_ANCHOR include path to the overall INCLUDES variable.

```
INCLUDES = -I. -I$(RELATIVE_PATH_TO_ANCHOR) $(ADD_INCLUDES) \
       $(USER_INCLUDES) $(SHARED_INCLUDES)
```

3. Change the SRCS variable in your TMF so that it initially lists only common modules. Additional modules are then appended conditionally, as described in the next step. For example, change

```
SRCS  = $(MODEL).c $(MODULES) ert_main.c $(ADD_SRCS) $(EXT_SRC)
```

to

```
SRCS = $(MODULES)
```

4. Create variables to define the final target of the makefile. You can remove variables that may have existed for defining the final target. For example, remove

```
PROGRAM   = ../$(MODEL)
```

and replace it with

```
ifeq ($(MODELREF_TARGET_TYPE), NONE)
  # Top model for RTW
  PRODUCT            = $(RELATIVE_PATH_TO_ANCHOR)/$(MODEL)
  BIN_SETTING        = $(LD) $(LDFLAGS) -o $(PRODUCT) $(SYSLIBS)
  BUILD_PRODUCT_TYPE = "executable"
  # ERT based targets
  SRCS               += $(MODEL).c ert_main.c $(EXT_SRC)
  # GRT based targets
  # SRCS             += $(MODEL).c grt_main.c rt_sim.c $(EXT_SRC) $(SOLVER)

else
  # sub-model for RTW
  PRODUCT            = $(MODELLIB)
  BUILD_PRODUCT_TYPE = "library"
endif
```

Note If the template makefile is associated with a toolchain, remove `$(MODEL).c` or `$(MODEL).$(TARGET_LANG_EXT)` from the SRCS list.

5. Create rules for the final target of the makefile (replace existing final target rules). For example:

```
ifeq ($(MODELREF_TARGET_TYPE),NONE)
  # Top model for RTW
  $(PRODUCT) : $(OBJS) $(LIBS) $(MODELREF_LINK_LIBS)
               $(BIN_SETTING) $(LINK_OBJS) $(MODELREF_LINK_LIBS)
               $(LIBS)
               @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
else
  # sub-model for RTW
  $(PRODUCT) : $(OBJS) $(LIBS)
               @rm -f $(MODELLIB)
               $(ar) ruvs $(MODELLIB) $(LINK_OBJS)
               @echo "### Created $(MODELLIB)"
```

```
                @echo "### Created $(BUILD_PRODUCT_TYPE): $@"
endif
```

6 Create a rule to allow referenced models to compile files that reside in the MATLAB working folder (pwd).

```
%.o : $(RELATIVE_PATH_TO_ANCHOR)/%.c
    $(CC) -c $(CFLAGS) $<
```

Note If you are using a TMF without the variable MODELREFS, the file might have been used with a previous release of Simulink software. If you want your TMF to support model referencing, add either variable MODELREFS to the make file.

Controlling Configuration Option Value Agreement

By default, the value of a configuration option defined in the system target file for a TLC-based custom target must be the same in a referenced model and its parent model. To relax this requirement, include the `modelReferenceParameterCheck` field in the `rtwoptions` structure element that defines the configuration option, and set the value of the field to `'off'`. For example:

```
rtwoptions(2).prompt         = 'My Custom Parameter';
rtwoptions(2).type           = 'Checkbox';
rtwoptions(2).default        = 'on';
rtwoptions(2).modelReferenceParameterCheck  = 'on';
rtwoptions(2).tlcvariable    = 'mytlcvariable';
...
```

The configuration option **My Custom Parameter** can differ in a referenced model and its parent model. See “Customize System Target Files” on page 85-28 for information about TLC-based system target files, and rtwoptions Structure Fields Summary for a list of `rtwoptions` fields.

Verifying Worker Configuration for Parallel Builds of Model Reference Hierarchies (Optional)

If your target supports parallel builds for large model reference hierarchies, you can additionally set up automatic verification of MATLAB Parallel Server workers. This addresses the possibility that parallel workers might have different configurations, some of which might not be compatible with a specific target build. For example, the required compiler might not be installed on a worker system.

The code generator provides a programming interface that you can use to automatically check the configuration of parallel workers. If parallel workers are not set up as expected, take action, such as reverting to sequential builds or throwing an error.

To set up automatic verification of workers, you must define a parallel configuration check function named *STF*`_par_cfg_chk`, where *STF* designates your system target file name. For example, the parallel configuration check function for `ert.tlc` is `ert_par_cfg_chk`.

The general syntax for the function is:

```
function varargout = STF_par_cfg_chk(action,varargin)
```

The number of output and input arguments vary according to the *`action`* specified, and according to the types of information you choose to coordinate between the client and the workers. The function should support the following general sequence of parallel configuration setup calls, differentiated by the first argument passed in:

Call Syntax	Called on:	Action
`cfg` `= STF_par_cfg_chk ('getPreferredCfg');`	Client	Return a structure representing the preferred configuration for MATLAB Parallel Server workers.
`[`*`tf`*`, `*`cfg`*`] = STF_par_cfg_chk ('getWorkerCfg', `*`cfg`*`);`	Workers	Each worker is passed the MATLAB Parallel Server client's preferred configuration. Return true if the worker can support the preferred configuration; otherwise return false along with a structure representing a configuration the worker can support. Information returned by each worker is added to a cell array of configurations.
`[`*`tf`*`, `*`cfg`*`] = STF_par_cfg_chk ('getCommonCfg', `*`cfgs`*`);`	Client	The client is passed the cell array of worker configurations. If a usable common configuration exists, return true, and return the common configuration to set for all systems. If a common configuration cannot be established, return false or take some action, such as reverting to sequential builds or throwing an error.

Call Syntax	Called on:	Action
tf = *STF*_par_cfg_chk ('setCommonCfg', *cfg*);	Workers and client	Each system is passed the common configuration to use. Set up the common configuration and, if successful, return true. If errors or issues occur, return false or take some action, such as reverting to sequential builds or throwing an error.
*STF*_par_cfg_chk ('clearCfg');	Workers and client	Clean up after completion of the parallel build.

The parallel configuration check functions for MathWorks provided targets are implemented as wrapper functions that call a function named `parallelMdlRefHostConfigCheckFcn`. For example, see the ERT parallel configuration check function in the file *`matlabroot`*`/toolbox/rtw/rtw/ert_par_cfg_chk.m`, and the function it calls in the file *`matlabroot`*`/toolbox/simulink/simulink/+Simulink/parallelMdlRefHostConfigCheckFcn.m`. The `parallelMdlRefHostConfigCheckFcn` function tries to establish a common compiler across the MATLAB Parallel Server client and workers.

For more information about parallel builds, see “Reduce Build Time for Referenced Models” (Simulink Coder).

Preventing Resource Conflicts (Optional)

Hook files are optional TLC and MATLAB program files that are invoked at well-defined stages of the build process. Hook files let you customize the build process and communicate information between various phases of the process.

If you are adapting your custom target for code generation compatibility with model reference features, consider adding checks to your hook files for handling referenced models differently than top models to prevent resource conflicts.

For example, consider adding the following check to your *STF*`_make_rtw_hook.m file`:

```
% Check if this is a referenced model
mdlRefTargetType = get_param(codeGenModelName,`ModelReferenceTargetType');
isNotModelRefTarget = strcmp(mdlRefTargetType, `NONE'); % NONE, SIM, or RTW
if isNotModelRefTarget
  % code that is specific to the top model
else
  % code that is specific to the referenced model
end
```

You may need to do a similar check in your TLC code.

```
%if !IsModelReferenceTarget()
  %% code that is specific to the top model
%else
  %% code that is specific to the referenced model
%endif
```

Support Compiler Optimization Level Control

This section describes how to configure a custom embedded target to support compiler optimization level control. Without the described modifications, you cannot use the **Configuration Parameters > Code Generation > Build process > Compiler optimization level** parameter to control the compiler optimization level for building generated code. For more information about compiler optimization level control, see "Compiler optimization level" (Simulink Coder).

About Compiler Optimization Level Control and Custom Targets

The requirements for supporting compiler optimization level control are as follows:

- The target must be derived from the GRT target or the ERT target.
- The system target file (STF) must declare compiler optimization level control compliance, as described in "Declaring Compiler Optimization Level Control Compliance" on page 85-90.
- The target makefile must honor the setting for **Compiler optimization level**, as described in "Providing Compiler Optimization Level Control Support in the Target Makefile" on page 85-91.

For an example that shows how to configure custom target optional features, see "Customize System Target Files" (Simulink Coder).

Declaring Compiler Optimization Level Control Compliance

To declare compiler optimization level control compliance for your target, you must implement a callback function that sets the `CompOptLevelCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `CompOptLevelCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CompOptLevelCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CompOptLevelCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CompOptLevelCompliant` target configuration parameter is set to `on`, the **Compiler optimization level** parameter is displayed in the **Code Generation** pane of the Configuration Parameters dialog box for your model.

Providing Compiler Optimization Level Control Support in the Target Makefile

As part of supporting compiler optimization level control for your target, you must modify the target makefile to honor the setting for **Compiler optimization level**. Use a GRT or ERT target provided by MathWorks as a model for making the modifications.

More About

- “About Embedded Target Development” (Simulink Coder)
- “Sample Custom Targets” (Simulink Coder)
- “Customize System Target Files” (Simulink Coder)

Support C Function Prototype Control

This section describes how to configure a custom embedded target to support function prototype control. Without the described modifications, you will not be able to use available interfaces for customizing entry-point function interfaces. For more information, see “Customize Generated C Function Interfaces” on page 39-2.

About C Function Prototype Control and Custom Targets

The requirements for supporting C function prototype control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C function prototype control compliance, as described in “Declaring C Function Prototype Control Compliance” on page 85-92.
- If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, the static main program must call the function prototype controlled initialize and step functions, as described in “Providing C Function Prototype Control Support in the Custom Static Main Program” on page 85-93.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Declaring C Function Prototype Control Compliance

To declare C function prototype control compliance for your target, you must implement a callback function that sets the `ModelStepFunctionPrototypeControlCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `ModelStepFunctionPrototypeControlCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'ModelStepFunctionPrototypeControlCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ModelStepFunctionPrototypeControlCompliant` target configuration parameter is set to `on`, you can use the Configure C Step Function Interface dialog box to control the function prototype of the base-rate step function generated for a rate-based model.

Providing C Function Prototype Control Support in the Custom Static Main Program

If your target uses a custom static main program, and if a nondefault function prototype control configuration is associated with a model, you must update the static main program to call the function prototype controlled initialize and step functions. You can do this in either of the following ways:

1. Manually adapt your static main program to declare model data and call the function prototype controlled initialize and step functions.
2. Generate your main program using **Generate an example main program** on the **Templates** pane of the Configuration Parameters dialog box. The generated main program declares model data and calls the function prototype controlled initialize and step function.

- “Customize System Target Files” (Simulink Coder)

Support C++ Class Interface Control

This section describes how to configure a custom embedded target to support C++ class interface control. Without the described modifications, you will not be able to use `C++ class` code interface packaging and the **Configure C++ Class Interface** button on the **Interface** pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code. For more information about C++ class interface control, see “Customize Generated C++ Class Interfaces” on page 39-35.

About C++ Class Interface Control and Custom Targets

The requirements for supporting C++ class interface control are as follows:

- The target must be derived from the ERT target.
- The system target file (STF) must declare C++ class interface control compliance, as described in “Declaring C++ Class Interface Control Compliance” on page 85-94.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Declaring C++ Class Interface Control Compliance

To declare C++ class interface control compliance for your target, you must implement a callback function that sets the `CPPClassGenCompliant` flag, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

```
rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
```

The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

Your callback function should set the `CPPClassGenCompliant` flag as follows:

```
slConfigUISetVal(hDlg,hSrc,'CPPClassGenCompliant','on');
slConfigUISetEnabled(hDlg,hSrc,'CPPClassGenCompliant',false);
```

For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `CPPClassGenCompliant` target configuration parameter is set to `on`, you can use the `C++ class` code interface packaging and the **Configure C++ Class Interface** button on the **Interface** pane of the Configuration Parameters dialog box to generate and configure C++ class interfaces to model code.

Providing C++ Class Interface Control Support in the Custom Static Main Program

Selecting `C++ class` code interface packaging for your model turns on the model option **Generate an example main program**. With this option on, code generation generates an example main program, `ert_main.cpp`. The generated example main program declares model data and calls the C++ class interface configured model step method, and illustrates how the generated code can be deployed.

To customize the build process and disable generation and inclusion of an example main program, see the `setTargetProvidesMain` function. Disabling example main generation permits including a custom main program.

Support Concurrent Execution of Multiple Tasks

If a custom embedded target must support concurrent execution of multiple tasks on a multicore platform, the target must declare support for concurrent execution by setting the target configuration option `ConcurrentExecutionCompliant`. Otherwise, you will not be able to configure a multicore target model for concurrent execution.

If `ConcurrentExecutionCompliant` is not already configured for your custom target, you can set the option in the following ways:

- Include the following code directly in your system target file (*`mytarget`*`.tlc`):

  ```
  rtwgensettings.SelectCallback = 'slConfigUISetVal(hDlg,hSrc,...
       ''ConcurrentExecutionCompliant'',''on'');';
  rtwgensettings.ActivateCallback = 'slConfigUISetVal(hDlg,hSrc,...
       ''ConcurrentExecutionCompliant'',''on'');';
  ```

- Implement a callback function that sets the `ConcurrentExecutionCompliant` option, and then install the callback function in the `SelectCallback` field of the `rtwgensettings` structure in your STF. The callback function is triggered whenever the user selects the target in the System Target File Browser. For example, the following STF code installs a `SelectCallback` function named `custom_select_callback_handler`:

  ```
  rtwgensettings.SelectCallback = 'custom_select_callback_handler(hDlg,hSrc)';
  ```

  The arguments to the `SelectCallback` function (`hDlg`, `hSrc`) are handles to private data used by the callback API functions. These handles are restricted to use in STF callback functions. They should be passed in without alteration.

  Your callback function should set the `ConcurrentExecutionCompliant` option as follows:

  ```
  slConfigUISetVal(hDlg,hSrc,'ConcurrentExecutionCompliant','on');
  slConfigUISetEnabled(hDlg,hSrc,'ConcurrentExecutionCompliant',false);
  ```

  For more information about the STF callback API, see the `slConfigUIGetVal`, `slConfigUISetEnabled`, and `slConfigUISetVal` function reference pages.

When the `ConcurrentExecutionCompliant` target configuration option is set to `'on'`, you can select the custom target and configure your multicore target model for concurrent execution.

For an example that shows how to configure custom target optional features, see “Customize System Target Files” (Simulink Coder).

Interface to Development Tools

Unless you are developing a target purely for code generation purposes, you will want your embedded target to support a complete build process. A full post-code generation build process includes

- Compilation of generated code
- Linking of compiled code and runtime libraries into an executable program module (or some intermediate representation of the executable code, such as S-Rec format)
- Downloading the executable to target hardware with a debugger or other utility
- Initiating execution of the downloaded program

Supporting a complete build process is inherently a complex task, because it involves interfacing to cross-development tools and utilities that are external to the code generator.

If your development tools can be controlled with traditional makefiles and a make utility such as `gmake`, it may be relatively simple for you to adapt existing target files (such as the `ert.tlc` and `ert.tmf` files provided by the Embedded Coder software) to your requirements. This approach is discussed in “Template Makefile Approach” on page 85-98.

About Interfacing to Development Tools

Automating your build process through a modern integrated development environment (IDE) presents a different set of challenges. Each IDE has its own way of representing the set of source files and libraries for a project and for specifying build arguments. Interfacing to an IDE may require generation of specialized file formats required by the IDE (for example, project files) and, and also may require the use of inter-application communication (IAC) techniques to run the IDE. One such approach to build automation is discussed in “Interface to an Integrated Development Environment” on page 85-99.

Template Makefile Approach

A template makefile provides information about your model and your development system. The build process uses this information to create makefiles for building an executable program. The code generator provides a number of template makefiles suitable for development computer compilers, such as LCC (`ert_lcc.tmf`) and Microsoft Visual C++ (`ert_vcx64.tmf`).

Adapting one of the existing template makefiles to your cross-compiler's make utility may require little more than copying and renaming the template makefile in accordance with the conventions of your project.

If you need to make more extensive modifications, you need to understand template makefiles in detail. For a detailed description of the structure of template makefiles and of the tokens used in template makefiles, see “Customize Template Makefiles” on page 85-62.

The following topics supplement the basic template makefile information:

- “Supporting Multiple Development Environments” on page 85-48
- “Supplying Development Environment Information to Your Template Makefile” on page 85-25

Interface to an Integrated Development Environment

This section describes techniques that have been used to integrate embedded targets with integrated development environment (IDEs), including

- How to generate a header file containing directives to define variables (and their values) required by a non-makefile based build.
- Some problems and solutions specific to interfacing embedded targets with the Freescale Semiconductor CodeWarrior IDE. The examples provided should help you to deal with similar interfacing problems with your particular IDE.

- “Generating a CPP_REQ_DEFINES Header File” on page 85-99
- “Interfacing to the Freescale CodeWarrior IDE” on page 85-100

Generating a CPP_REQ_DEFINES Header File

In template makefiles, the token `CPP_REQ_DEFINES` is expanded and replaced with a list of parameter settings entered with various dialog boxes. This variable often contains information such as `MODEL` (name of generating model), `NUMST` (number of sample times in the model), `MT` (model is multitasking or not), and numerous other parameters (see “Template Makefiles and Tokens” on page 85-62).

The makefile mechanism handles the `CPP_REQ_DEFINES` token automatically. If your target requires use of a project file, rather than the traditional makefile approach, you can generate a header file containing directives to define these variables and provide their values.

The following TLC file, `gen_rtw_req_defines_h.tlc`, provides an example. The code generates a C header file, `cpp_req_defines.h`. The information required to generate each `#define` directive is derived either from information in the *`model`*`.rtw` file (e.g., `CompiledModel.NumSynchronousSampleTimes`), or from make variables from the `rtwoptions` structure (for example, `PurelyIntegerCode`).

```
%% File: gen_rtw_req_defines_h.tlc
%openfile CPP_DEFINES = "cpp_req_defines.h"
#ifndef _CPP_REQ_DEFINES_
#define _CPP_REQ_DEFINES_
#define MODEL %<CompiledModel.Name>
#define ERT  1
#define NUMST %<CompiledModel.NumSynchronousSampleTimes>
#define TID01EQ %<CompiledModel.FixedStepOpts.TID01EQ>
%%
%if CompiledModel.FixedStepOpts.SolverMode == "MultiTasking"
#define MT  1
#define MULTITASKING  1
%else
#define MT  0
#define MULTITASKING  0
%endif
%%
#define MAT_FILE  0
#define INTEGER_CODE %<PurelyIntegerCode>
#define ONESTEPFCN %<CombineOutputUpdateFcns>
#define TERMFCN %<IncludeMdlTerminateFcn>
%%
#define MULTI_INSTANCE_CODE  0
#define HAVESTDIO  0
#endif
%closefile CPP_DEFINES
```

Interfacing to the Freescale CodeWarrior IDE

Interfacing an embedded target's build process to the CodeWarrior IDE requires that two problems must be dealt with:

- The build process must generate a CodeWarrior compatible project file. This problem, and a solution, is discussed in “XML Project Import” on page 85-101. The solution described is applicable to ASCII project file formats.
- During code generation, the target must automate a CodeWarrior session that opens a project file and builds an executable. This task is described in “Build Process

Automation” on page 85-104. The solution described is applicable to IDEs that can be controlled with Microsoft Component Object Model (COM) automation.

XML Project Import

This section illustrates how to use the Target Language Compiler (TLC) to generate an eXtensible Markup Language (XML) file, suitable for import into the CodeWarrior IDE, that contains information about the source code generated by an embedded target.

The choice of XML format is dictated by the fact that the CodeWarrior IDE supports project export and import with XML files. As of this writing, native CodeWarrior project files are in a proprietary binary format.

Note that if your target needs to support some other compiler's project file format, you can apply the techniques shown here to other ASCII file formats (see “Generating a CPP_REQ_DEFINES Header File” on page 85-99).

To illustrate the basic concept, consider a hypothetical XML file exported from a CodeWarrior stationery project. The following is a partial listing:

```
<target>
   <settings>
    ...
   <\settings>
   <file><name>foo.c<\name>
   <\file>
   ...
   <file><name>foobar.c<\name>
   <\file>
   <fileref><name>foo.c<\name>
   <\fileref>
   ...
   <fileref><name>foobar.c<\name>
   <\fileref>
<\target>
```

Insert this XML code into an `%openfile/%closefile` block within a TLC file, `test.tlc`, as shown below.

```
%% test.tlc
%% This code will generate a file model_project.xml,
%% where model is the generating model name specified in
%% the CompiledModel.Name field of the model.rtw file.
%openfile XMLFileContents = %<CompiledModel.Name>_project.xml
```

```
<target>
   <settings>
    ...
   <\settings>
   <file><name>%<CompiledModel.Name>.c<\name>
   <\file>
   ...
   <file><name>foobar.c<\name>
   <\file>
   <fileref><name>%<CompiledModel.Name>.c<\name>
   <\fileref>
   ...
   <fileref><name>foobar.c<\name>
   <\fileref>
<\target>
%closefile XMLFileContents
%selectfile NULL_FILE
```

Note the use of the TLC token `CompiledModel.Name`. The token is resolved and the resulting filename is included in the output stream. You can specify other information, such as paths and libraries, in the output stream by specifying other tokens defined in *`model`*`.rtw`. For example, `System.Name` may be defined as `<Root>/Subsystem1`.

Now suppose that `test.tlc` is invoked during a target's build process, where the generating model is `mymodel`. This should be done after the `codegenentry` statement. For example, `test.tlc` could be included directly in the system target file:

```
%include "codegenentry.tlc"
%include "test.tlc"
```

Alternatively, the `%include "test.tlc"` directive could be inserted into the `mytarget_genfiles.tlc` hook file, if present.

TLC tokens such as

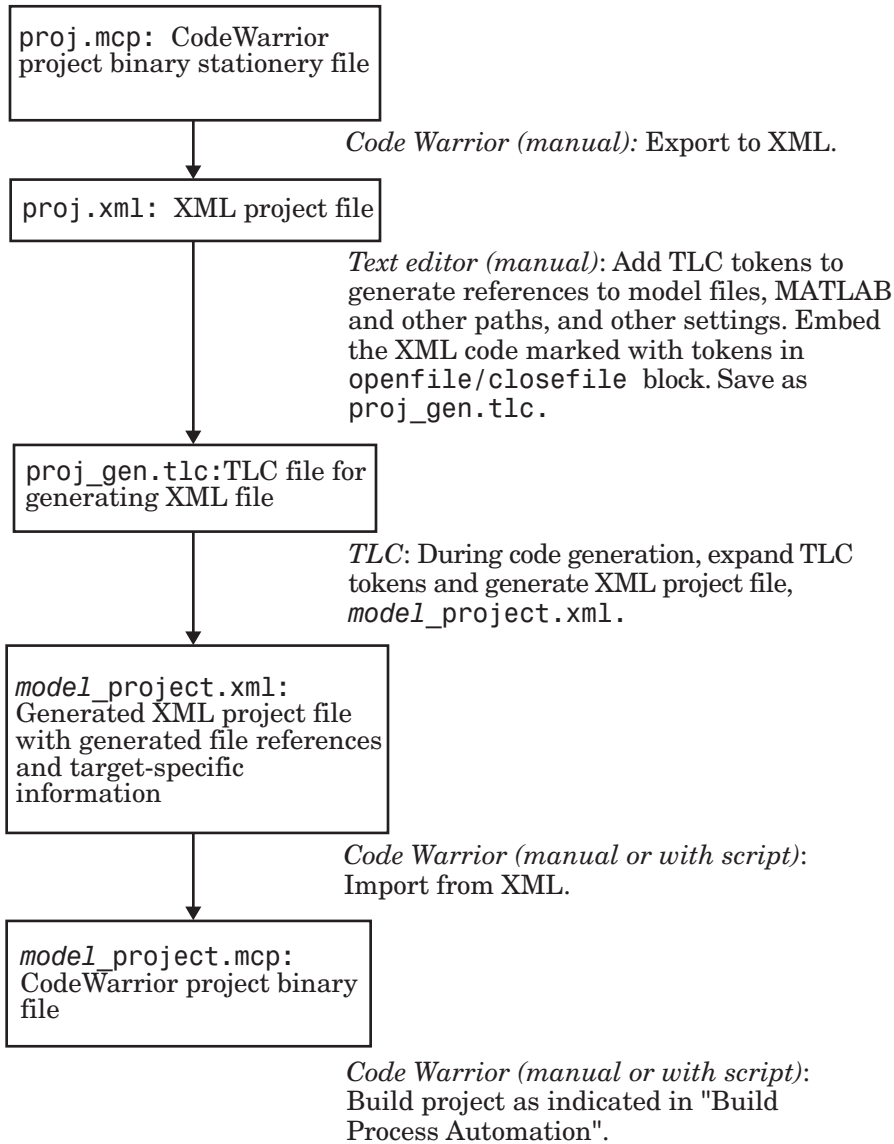
```
<file><name>%<CompiledModel.Name>.c<\name>
```

are expanded, with the `CompiledModel` record in the `mymodel.rtw` file, as in

```
<file><name>mymodel.c<\name>
```

`test.tlc` generates an XML file, file *`model`*`_project.xml`, from a model. *`model`*`_project.xml` contains references to generated code files. *`model`*`_project.xml` can be imported into the CodeWarrior IDE as a project.

The following flowchart summarizes this process.



Note This process has drawbacks. First, manually editing an XML file exported from a CodeWarrior stationery project can be a laborious task, involving modification of a few dozen lines embedded within several thousand lines of XML code. Second, if you make changes to the CodeWarrior project after importing the generated XML file, the XML file must be exported and manually edited once again.

Build Process Automation

An application that supports COM automation can control other applications that include a COM interface. Using MATLAB COM automation functions, a MATLAB file can command a COM-compatible development system to execute tasks required by the build process.

The MATLAB COM automation functions described in this section are documented in "COM Objects" (MATLAB).

For information about automation commands supported by the CodeWarrior IDE, see your CodeWarrior documentation.

COM automation is used by some embedded targets to automate the CodeWarrior IDE to execute tasks such as:

- Opening a new CodeWarrior session
- Configure a project
- Loading a CodeWarrior project file
- Removing object code from the project
- Building or rebuilding the project
- Debug an application

COM technology automates certain repetitive tasks and allows the user to interact directly with the external application. For example, when the end user of the embedded targets capability initiates a build, the target quickly invokes CodeWarrior actions and leaves a project built and ready to run with the IDE.

Example COM Automation Functions

The functions below use the MATLAB `actxserver` command to invoke COM functions for controlling the CodeWarrior IDE from a MATLAB file:

- `CreateCWComObject`: Create a COM connection to the CodeWarrior IDE.
- `OpenCW`: Open the CodeWarrior IDE without opening a project.
- `OpenMCP`: Open the CodeWarrior project file (`.mcp` file) specified by the input argument.
- `BuildCW`: Open the specified `.mcp` file, remove object code, and build project.

These functions are examples; they do not constitute a full implementation of a COM automation interface. If your target creates the project file during code generation, the top-level `BuildCW` function should be called after the code generation process is completed. Normally `BuildCW` would be called from the `exit` method of your *`STF`*`_make_rtw_hook.m` file (see “STF_make_rtw_hook.m” on page 85-20).

In the code examples, the variable `in_qualifiedMCP` is assumed to store a fully qualified path to a CodeWarrior project file (for example, path, filename, and extension). For example:

```
in_qualifiedMCP = 'd:\work\myproject.mcp';
```

In actual practice, your code is responsible for determining the conventions used for the project filename and location. One simple convention would be to default to a project file *`model`*`.mcp`, located in your target's build folder.

```
%=============================================================================
% Function: CreateCWComObject
% Abstract: Creates the COM connection to CodeWarrior
%
function ICodeWarriorApp = CreateCWComObject
  vprint([mfilename ': creating CW com object']);
  try
    ICodeWarriorApp = actxserver('CodeWarrior.CodeWarriorApp');
  catch
    error(['Error creating COM connection to ' ComObj ...
       '. Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
  end
  return;

%=============================================================================
% Function: OpenCW
% Abstract: Opens CodeWarrior. Returns the
%           handle ICodeWarriorApp.
%
function ICodeWarriorApp = OpenCW()
  ICodeWarriorApp = CreateCWComObject;
  CloseAll;
  OpenMCP(in_qualifiedMCP);
```

```
%=====================================================================
% Function: OpenMCP
% Abstract: open an MCP project file
%
function OpenMCP(in_qualifiedMCP)
  % Argument checking. This method requires valid project file.
  if ~exist(in_qualifiedMCP)
      error([mfilename ': Missing or empty project file argument']);
  end
  if isempty(in_qualifiedMCP)
      error([mfilename ': Missing or empty project file argument']);
  end
  ICodeWarriorApp = CreateCWComObject;
  vprint([mfilename ': Importing']);
  try
    ICodeWarriorProject = ...
      invoke(ICodeWarriorApp.Application,...
      'OpenProject', in_qualifiedMCP,...
      1,0,0);
  catch
    error(['Error using COM connection to import project. ' ...
       ' Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
  end

%=====================================================================
% Function: BuildCW
% Abstract: Opens CodeWarrior.
%           Opens the specified CodeWarrior project.
%           Deletes objects.
%           Builds.
%
function ICodeWarriorApp = BuildCW(in_qualifiedMCP)
    % ICodeWarriorApp = BuildCW;
    ICodeWarriorApp = CreateCWComObject;
    CloseAll;
    OpenMCP(in_qualifiedMCP);
    try
      invoke(ICodeWarriorApp.DefaultProject,'RemoveObjectCode', 0, 1);
    catch
      error(['Error using COM connection to remove objects of current project. ' ...
       'Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
    end
    try
      invoke(ICodeWarriorApp.DefaultProject,'BuildAndWaitToComplete');
    catch
      error(['Error using COM connection to build current project. ' ...
       'Verify that CodeWarrior is installed. Verify COM access to
CodeWarrior outside of MATLAB.']);
    end
```

Device Drivers

Device drivers that communicate with target hardware are essential to many real-time development projects.

You can integrate existing C (or C++) device driver functions into Simulink models by using the Legacy Code Tool. When you use the code generator to generate code from a model, the Legacy Code Tool can insert a call to your C function into the generated code. For details, see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder) and “Integrate C Functions into Simulink Models with Legacy Code Tool” (Simulink).

Build Configurations for Embedded Targets in Embedded Coder

Model Setup

In this section...

Block Selection

You can create models for targeting the same way you create other Simulink models—by combining standard blocks and C-MEX S-functions.

You can use blocks from the following sources:

- The Embedded Coder Support Packages.
- The Embedded Targets library (`embeddedtargetslib`) in the Embedded Coder product.
- Blocks from the System Toolboxes products
- Custom blocks

Avoid using blocks that do not generate code, including the following blocks.

Block Name/Category	Library	Description
Scope	Simulink, DSP System Toolbox software	Provides oscilloscope view of your output. Do not use the **Save data to workspace** option on the **Data history** pane in the Scope Parameters dialog.
To Workspace	Simulink	Return data to your MATLAB workspace.
From Workspace	Simulink	Send data to your model from your MATLAB workspace.

Block Name/Category	Library	Description
Spectrum Scope	DSP System Toolbox	Compute and display the short-time FFT of a signal. It has internal buffering that can slow your process without adding value.
To File	Simulink	Send data to a file on your host machine.
From File	Simulink	Get data from a file on your host machine.
Triggered to Workspace	DSP System Toolbox	Send data to your MATLAB workspace.
Signal To Workspace	DSP System Toolbox	Send a signal to your MATLAB workspace.
Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
Triggered Signal From Workspace	DSP System Toolbox	Get a signal from your MATLAB workspace.
To Wave device	DSP System Toolbox	Send data to a `.wav` device.
From Wave device	DSP System Toolbox	Get data from a `.wav` device.

Configure Target Hardware Resources

Configure Parameters Under the Hardware Implementation Tab

Configure the parameters under the **Hardware Implementation** tab of your Simulink model for a specific target hardware and tool chain. Doing so updates other parameters in the Configuration Parameters dialog to the default values for the software build tool chain and target hardware you are using.

Note The Target Preferences (Removed) block has been removed from the Simulink block libraries for the Embedded Coder and Simulink Coder products.

Parameters in the Target Preferences block have been moved to the Target Hardware Resources tab.

To configure your Simulink model for a specific target hardware and tool chain:

1. In a Simulink model, open the model Configuration Parameters by:
   - Clicking the gear icon,

     
   - Pressing **Ctrl+E** on your keyboard
   - Selecting the **Simulation > Model Configuration Parameters** menu items
2. In the Configuration Parameters dialog, click **Hardware Implementation**, and then select the **Hardware board** you are using.

   Note Selecting a **Hardware board** automatically populates many parameters in the **Code Generation** appropriate for the hardware.
3. Review the other parameters under the **Target Hardware Resources** tab.
4. (Optional) In the Configuration Parameters dialog, click **Code Generation** to review and modify other code generation features for your model.
5. Click **Apply**, and save the changes to your model.

Configuration Parameters

What are Configuration Parameters?

To see the model Configuration Parameters, open the **Configuration Parameters** dialog. You can do this in the model editor by selecting **Simulation > Model Configuration Parameters**, or by pressing **Ctrl+E** on your keyboard.

The **Configuration Parameters** dialog specifies the values for a model's active configuration set. These parameters determine the type of solver used, the import and export settings, and other values that determine how the model runs.

Setting Model Configuration Parameters

To set the Configuration Parameters to the right values for you to generate code from your model, see "Configure Parameters Under the Hardware Implementation Tab" on

page 86-3. This action initializes the model Configuration Parameters to the right default values for you to generate code. You can then use the Configuration Parameters dialog to make further modifications to the values. You can generate buildable code using these default values.
“Supported Hardware”

Processor-Specific Optimizations for Embedded Targets in Embedded Coder

Replace Code for Embedded Targets

In this section...

Using a Processor-Specific Code Replacement Library to Optimize Code

You can optimize the code the code generator produces for a specific processor by configuring the code generator to use a code replacement library (CRL) during code generation. If you have an Embedded Coder license, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 52-2 and “Replace Code Generated from Simulink Models” on page 52-10. For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 65-3 and “Develop a Code Replacement Library” on page 65-27.

Process of Determining Optimization Effects Using Real-Time Profiling Capability

You can use the real-time profiling capability to examine the results of applying the processor-specific library functions and operators to your generated code. After you select a processor-specific code replacement library, use the real-time execution profiling capability to examine the change in program execution time.

Use the following process to evaluate the effects of applying a processor-specific code replacement library when you generate code:

1. Enable real-time profiling in your model. Refer to “Code Execution Profiling”.
2. Generate code for your project without specifying a code replacement library (the default **Code replacement library** setting is `None`).
3. Profile the code, and save the report.

4. Rebuild your project using a processor-specific code replacement library.
5. Profile the code, and save the second report.
6. Compare the profile report from running your application with the processor-specific library selected to the profile results in the first report with no code replacement library selected.

For an example of verifying the code optimization, search help for "Optimizing Embedded Code via Code Replacement Library" and select the example that matches your IDE.

Code Generation from MATLAB Code

Build Configuration for Code Generation from MATLAB Code

Specify Comment Style for C/C++ Code

In this section...

If you have an Embedded Coder, you can specify the comment style for C/C++ code generated from MATLAB code. Specify single-line style to generate single-line comments preceded by `//`. Specify multiline style to generate single-line or multiline comments delimited by `/*` and `*/`. Single-line style is the default for C++ code generation. Multiline style is the default for C code generation. For C code generation, select single-line comment style only if your compiler supports it.

Specify Comment Style Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **Code Appearance** tab, select the **Include comments** check box if it is not already selected. By default, the **Include comments** check box is selected.
5. Set **Comment Style** to one of the following options.

Value	Description
`Auto(Use standard comment style of the target language)`	For C, generate multiline comments. For C++, generate single-line comments. (default)
`Single-line (Use C++-style comments)`	Generate single-line comments preceded by `//`.
`Multi-line (Use C-style comments)`	Generate single-line or multiline comments delimited by `/*` and `*/`.

Specify Comment Style Using the Command-Line Interface

1. Create a code configuration object for C/C++ code generation. For example, create a configuration object for C/C++ static library generation:

   ```
   cfg = coder.config('lib','ecoder',true);
   ```

2. Set the `CommentStyle` property to one of the following values:

Value	Description
`'Auto'`	For C, generate multiline comments. For C++, generate single-line comments. (default)
`'Single-line'`	Generate single-line comments preceded by `//`.
`'Multi-line'`	Generate single-line or multiline comments delimited by `/*` and `*/`.

   For example, this code sets the comment style to single-line style:

   ```
   cfg.CommentStyle='Single-line';
   ```

More About

- “Configure Build Settings” (MATLAB Coder)

Specify Indent Style for C/C++ Code

In this section...

If you have an Embedded Coder license, you can control the indent style and indent size in C/C++ code generated from MATLAB code. Indent style controls the placement of braces. Indent size controls the number of characters per indentation level.

You can specify the K&R indent style or the Allman indent style. Both styles:

- Place the function opening and closing braces on their own lines at the same indentation level as the function header.
- Indent code within the function according to the indent size.
- For blocks within a function, place closing braces on a new line at the same indentation level as the control statement.
- Indent code within a block according to the indent size.

The K&R style and the Allman style differ in their placement of the opening brace for a control statement. If you want the opening brace on the same line as its control statement, select the K&R style. Here is code that has the K&R indent style:

```
void addone(const double x[6], double z[6])
{
  int i0;
  for (i0 = 0; i0 < 6; i0++) {
    z[i0] = x[i0] + 1.0;
  }
}
```

If you want the opening brace on its own line, select the Allman style. Here is code that has the Allman indent style:

```
void addone(const double x[6], double z[6])
{
  int i0;
  for (i0 = 0; i0 < 6; i0++)
  {
    z[i0] = x[i0] + 1.0;
```

```
  }
}
```

Specify Indent Style Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **All Settings** tab, under **Advanced**, set **Indent style** to K&R or `Allman`.
5. On the **All Settings** tab, under **Advanced**, set **Indent size** to an integer from 2 to 8.

Specify Indent Style Using the Command-Line Interface

1. Create a code configuration object for `'lib'`, `'dll'`, or `'exe'`. For example:

   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```
2. Set the `IndentStyle` property to `'K&R'` or `'Allman'`. For example:

   ```
   cfg.IndentStyle = 'Allman';
   ```
3. Set the `IndentSize` property to an integer from 2 to 8. For example:

   ```
   cfg.IndentSize = 4;
   ```

- “Configure Build Settings” (MATLAB Coder)

Generate Custom File and Function Banners for C/C++ Code

When you generate C and C++ code from MATLAB code, you can use a code generation template (CGT) file to specify custom:

- File banners
- Function Banners
- File trailers
- Comments before code sections

This example shows how you can create your own CGT file and customize it to generate your own file and function banners.

1. Create a local copy of the default CGT file for MATLAB Coder and rename it. The default CGT file is `matlabcoder_default_template.cgt` in the *`matlabroot`*`/toolbox/coder/matlabcoder/templates/` folder.
2. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If necessary, add the folder to the MATLAB path. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder. If the file is not on the MATLAB path, specify a full path to the file when adding the file to your configuration.
3. View the default template and generated output. For example, here is the default File Banner section:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version           : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

   When you generate code using this default, the file banner looks similar to this file banner:

```
/*
 * File: coderand.c
 *
 * MATLAB Coder version            : 2.7
 * C/C++ source code generated on  : 06-Apr-2014 14:34:15
 */
```

4 Edit your local copy of the CGT file. You can change the default values and add your own custom tokens. For example, here is the File Banner section with the style changed to `box` and a custom token `myCustomToken`:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="box">
File: %<FileName>

My custom token                : %<myCustomToken>

MATLAB Coder version           : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

For more information, see “Code Generation Template Files for MATLAB Code” on page 88-9.

5 Create a configuration object for generation of a C static library for an embedded target.

```
% Create configuration object for an embedded target
cfgObj = coder.config('lib','ecoder',true);
```

6 Create a `MATLABCodeTemplate` object from your CGT file and add it to the configuration object.

```
% Specify the custom CGT file
CGTFile = 'myCGTFile.cgt';
% Use custom template
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);
```

7 Assign values for custom tokens that you added to the template. For example, assign the value `'myValue'` to the `myCustomToken` token that you added in a previous step.

```
cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
```

8 Make sure that generation of comments is enabled. Otherwise, the code generator does not produce file or function banners.

```
cfgObj.GenerateComments=true;
```

9 Generate code using the configuration object that you created.

```
codegen -config cfgObj coderand
```

10 View the changes to the generated file banner. For example, here is the file banner for `coderand.c` using the customized CGT file:

```
/*************************************************************************/
/* File: coderand.c                                                      */
/*                                                                       */
/* My custom token               : myValue                               */
/*                                                                       */
/* MATLAB Coder version          : 2.7                                   */
/* C/C++ source code generated on : 06-Apr-2014 14:42:55                 */
/*************************************************************************/
```

Changes to a CGT file do not affect the generated code unless you create a `MATLABCodeTemplate` object from the modified CGT file, and then add it to the configuration object. If you modify the CGT File, `myCGTFile.cgt`, used in the previous example, you must repeat these steps:

1 Create a `MATLABCodeTemplate` object from `myCGTFile.cgt` and add it to the configuration object.

```
CGTFile = 'myCGTFile.cgt';
cfgObj.CodeTemplate = coder.MATLABCodeTemplate(CGTFile);
```

2 Assign the value `'myValue'` to the `myCustomToken` token.

```
cfgObj.CodeTemplate.setTokenValue('myCustomToken','myValue');
```

3 Generate code.

```
codegen -config cfgObj coderand
```

More About

- “Code Generation Template Files for MATLAB Code” on page 88-9

Code Generation Template Files for MATLAB Code

In this section...

A code generation template (CGT) file defines the sections in generated code that you can customize using comments and tokens. Using a code generation template (CGT) file for the generation of C and C++ code from MATLAB code, you can specify custom file banners and function banners for generated code. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. You can also customize comments before code sections. Use these banners to:

- Add a company copyright statement.
- Specify a special version symbol for your configuration management system.
- Remove timestamps.
- Add other custom information to your generated files.

For information on creating, customizing, and using a CGT file, see “Generate Custom File and Function Banners for C/C++ Code” on page 88-6.

Default CGT File

You can base your custom template on the default CGT file, `matlabcoder_default_template.cgt`, in the *`matlabroot`*`/toolbox/coder/matlabcoder/templates/` folder.

Note If you choose not to customize banners for your generated code, the default template is used for code generation.

CGT File Structure

A CGT file consists of 13 optional sections.

File Banner Section

Contains comments and tokens for use in generating a custom file banner.

Function Banner Section

Contains comments and tokens for use in generating a custom function banner.

Shared Utility Function Banner

Contains comments and tokens for use in generating custom banners for shared utility functions.

File Trailer Section

Contains comments for use in generating a custom trailer banner.

Include Files Banner

Contains comments for use in generating a custom banner for the include files section.

Type Definitions

Contains comments for use in generating a custom banner for the type definitions section.

Named Constants

Contains comments for use in generating a custom banner for the named constants section.

Variable Declarations

Contains comments for use in generating a custom banner for the variable declarations section.

Variable Definitions

Contains comments for use in generating a custom banner for the variable definitions section.

Function Declarations

Contains comments for use in generating a custom banner for the function declarations section.

Function Definitions

Contains comments for use in generating a custom banner for the function definitions section.

Custom Source Code

Contains comments for use in generating a custom banner for the custom source code section.

Custom Header Code

Contains comments for use in generating a custom banner for the custom header code section.

Components of the CGT File Sections

Each CGT file section is defined by open and close tags.

CGT File Section	Open Tag	Close Tag
"File Banner" on page 88-14	`<FileBanner>`	`</FileBanner>`
"Function Banner Section" on page 88-10	`<FunctionBanner>`	`</FunctionBanner>`
"Shared Utility Function Banner" on page 88-10	`<SharedUtilityBanner>`	`</SharedUtilityBanner>`
"File Trailer Section" on page 88-10	`<FileTrailer>`	`</FileTrailer>`
"Include Files Banner" on page 88-10	`<IncludeFilesBanner>`	`</IncludeFilesBanner>`
"Type Definitions" on page 88-10	`<TypeDefinitionsBanner>`	`</TypeDefinitionsBanner>`
"Named Constants" on page 88-10	`<NamedConstantsBanner>`	`</NamedConstantsBanner>`
"Variable Declarations" on page 88-10	`<VariableDeclarationsBanner>`	`</VariableDeclarationsBanner>`

CGT File Section	Open Tag	Close Tag
“Variable Definitions” on page 88-10	`<VariableDefinitionsBanner>`	`</VariableDefinitionsBanner>`
“Function Declarations” on page 88-10	`<FunctionDeclarationsBanner>`	`</FunctionDeclarationsBanner>`
“Function Definitions” on page 88-11	`<FunctionDefinitionsBanner>`	`</FunctionDefinitionsBanner>`
“Custom Source Code” on page 88-11	`<CustomSourceCodeBanner>`	`</CustomSourceCodeBanner>`
“Custom Header Code” on page 88-11	`<CustomHeaderCodeBanner>`	`</CustomHeaderCodeBanner>`

You can customize your banners by including tokens and comments between the open and close tags for each section. Tokens are replaced with values in the generated code. The following rules apply to tokens in your CGT file:

- You can have only one token per line.
- Token values must not contain a ‘\t’ for formatting.

Note In the contents of your banner, C comment indicators, '/*' or '*/', can introduce an error in the generated code.

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- `width`: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- `style`: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is:

`<`*`OpenTag`* `style = “`*`style_value`*`” width = “`*`num_width`*`”>`

There are five options for the banner style. The `CommentStyle` and `TargetLang` configuration object properties determine the use of C or C++ comment style. The built-in style options for the `style` attribute are:

- `classic`

  Using C style comments

  ```
  /* single line comments */

  /*
   * multiple line comments
   * second line
   */
  ```

  Using C++ style comments

  ```
  // single line comments

  //
  // multiple line comments
  // second line
  //
  ```

- `box`

  Using C style comments

  ```
  /*********************************************************/
  /* banner contents                                       */
  /*********************************************************/
  ```

  Using C++ style comments

  ```
  ///////////////////////////////////////////////////////////
  // banner contents                                       //
  ///////////////////////////////////////////////////////////
  ```

- `open_box`

  Using C style comments

  ```
  /*********************************************************
   * banner contents
   *********************************************************/
  ```

  Using C++ style comments

  ```
  ///////////////////////////////////////////////////////////
  // banner contents
  ///////////////////////////////////////////////////////////
  ```

- `doxygen`

  Using C style comments

  ```
  /** single line comments */

  /**
   * multiple line comments
   * second line
   */
  ```

  Using C++ style comments

  ```
  ///single line comments

  ///
  /// multiple line comments
  ///second line
  ///
  ```

- `doxygen_qt`

  Using C style comments

  ```
  /*! single line comments */

  /*!
   * multiple line comments
   * second line
   */
  ```

  Using C++ style comments

  ```
  //!single line comments

  //!
  //! multiple line comments
  //!second line
  //!
  ```

File Banner

This section contains comments and tokens for use in generating a custom file banner that precedes the generated C and C++ code. If you omit the file banner section from the CGT file, the code generator does not generate a file banner in the generated code. The file banner section provided in the default CGT file is:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom File Banner section (optional)
%% Customize File banners by using either custom tokens or the following
%% predefined tokens:
%% %<FileName>, %<MATLABCoderVersion>, %<EmbeddedCoderVersion>
%% %<SourceGeneratedOn>, %<HardwareSelection>, %<OutputType>
%%
%% You can also use "custom tokens" in all of the sections below. See the
%% documentation center for more details.
%%
<FileBanner style="classic">
File: %<FileName>

MATLAB Coder version           : %<MATLABCoderVersion>
C/C++ source code generated on : %<SourceGeneratedOn>
</FileBanner>
```

Summary of Tokens for File Banner Generation

`FileName`	Name of the generated file (for example, `"kalman.c"`)
`SourceGeneratedOn`	Timestamp of generated file
`MATLABCoderVersion`	Version of MATLAB Coder
`EmbeddedCoderVersion`	Version of Embedded Coder
`HardwareSelection`	Selected target
`OutputType`	Type of output (for example, lib, exe, or dll)

Function Banner

This section contains comments and tokens for use in generating a custom function banner that precedes a generated C or C++ function. If you omit the function banner section from the CGT file, the code generator does not generate function banners. The function banner section provided in the default CGT file is:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom Function Banner section (optional)
%% Customize function banners by using the following predefined tokens:
%% %<FunctionName>, %<FunctionDescription>, %<FunctionPrototype>
%% %<Arguments>, %<ReturnType>
%%
<FunctionBanner style="classic">
%<FunctionPrototype>
%<FunctionDescription>
Arguments    : %<Arguments>
Return Type  : %<ReturnType>
</FunctionBanner>
```

Summary of Tokens for Function Banner Generation

`FunctionName`	Name of function
`FunctionDescription`	Short abstract about the function If the configuration parameter `MATLABFcnDesc` is `true`, the function description appears in the function banner. Otherwise, the code generator treats the function description as user comments.
`FunctionPrototype`	MATLAB function prototype The function prototype appears in the function banner only if the `MATLABSourceComments` configuration parameter is `true`.
`Arguments`	List of function arguments
`ReturnType`	Return type of function

Shared Utility Banner

This section contains comments and tokens for use in generating a custom shared utility function banner that precedes a generated C or C++ shared utility function. If you omit the shared utility function banner section from the CGT file, the code generator does not generate shared utility function banners. The shared utility function banner section provided in the default CGT file is:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom Shared Utility Function Banner section (optional)
%% Customize shared utility function banners by using the following
%% predefined tokens:
%% %<FunctionName>, %<FunctionDescription>
%% %<Arguments>, %<ReturnType>
%%
<SharedUtilityBanner style="classic">
Arguments    : %<Arguments>
Return Type  : %<ReturnType>
</SharedUtilityBanner>
```

Summary of Tokens for Shared Utility Function Banner Generation

FunctionName	Name of function
FunctionDescription	Short abstract about the function
Arguments	List of function arguments
ReturnType	Return type of function

File Trailer

The file trailer section contains comments for generating a custom file trailer that follows the generated C or C++ code. If you omit the file trailer section from the CGT file, the code generator does not generate a file trailer. The file trailer section provided in the default CGT file is:

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file trailer section (optional)
%% You can use any of the predefined tokens used for File Banner
%%
<FileTrailer style="classic">
File trailer for %<FileName>

[EOF]
</FileTrailer>
```

Tokens for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

Include Files Banner

The include files banner section contains comments for generating a custom banner that precedes the include files section in the generated code. If you omit the include files banner section from the CGT file, the code generator does not generate a banner for this section. The include files banner section provided in the default CGT file is:

```
<IncludeFilesBanner  style="classic">
Include Files
</IncludeFilesBanner>
```

Type Definitions Banner

The type definitions banner section contains comments for generating a custom banner that precedes the type definitions section in the generated code. If you omit the type definitions banner section from the CGT file, the code generator does not generate a

banner for this section. The type definitions banner section provided in the default CGT file is:

```
<TypeDefinitionsBanner  style="classic">
Type Definitions
</TypeDefinitionsBanner>
```

Named Constants Banner

The named constants banner section contains comments for generating a custom banner that precedes the named constants section in the generated code. If you omit the named constants banner section from the CGT file, the code generator does not generate a banner for this section. The named constants banner section provided in the default CGT file is:

```
<NamedConstantsBanner  style="classic">
Named Constants
</NamedConstantsBanner>
```

Variable Declarations

The variable declarations banner section contains comments for generating a custom banner that precedes the variable declarations section in the generated code. If you omit the variable declarations banner section from the CGT file, the code generator does not generate a banner for this section. The variable declarations banner section provided in the default CGT file is:

```
<VariableDeclarationsBanner  style="classic">
Variable Declarations
</VariableDeclarationsBanner>
```

Variable Definitions

The variable definitions banner section contains comments for generating a custom banner that precedes the variable definitions section in the generated code. If you omit the variable definitions banner section from the CGT file, the code generator does not generate a banner for this section. The variable definitions banner section provided in the default CGT file is:

```
<VariableDefinitionsBanner  style="classic">
Variable Definitions
</VariableDefinitionsBanner>
```

Function Declarations

The function declarations banner section contains comments for generating a custom banner that precedes the function declarations section in the generated code. If you omit the function declarations banner section from the CGT file, the code generator does not generate a banner for this section. The function declarations banner section provided in the default CGT file is:

```
<functionDeclarationsBanner  style="classic">
Function Declarations
</FunctionDeclarationsBanner>
```

Function Definitions

The function definitions banner section contains comments for generating a custom banner that precedes the function definitions section in the generated code. If you omit the function definitions banner section from the CGT file, the code generator does not generate a banner for this section. The function definitions banner section provided in the default CGT file is:

```
<FunctionDefinitionsBanner  style="classic">
Function Definitions
</FunctionDefinitionsBanner>
```

Custom Source Code

The custom source code banner section contains comments for generating a custom banner that precedes the custom source code section in the generated code. If you omit the custom source code banner section from the CGT file, the code generator does not generate a banner for this section. The custom source code banner section provided in the default CGT file is:

```
<CustomSourceCodeBanner  style="classic">
Custom Source Code
</CustomSourceCodeBanner>
```

Custom Header Code

The custom header code banner section contains comments for generating a custom banner that precedes the custom header code section in the generated code. If you omit the custom header code banner section from the CGT file, the code generator does not generate a banner for this section. The custom header code banner section provided in the default CGT file is:

```
<CustomHeaderCodeBanner  style="classic">
Custom Header Code
</CustomHeaderCodeBanner>
```

Customize Generated Identifiers

In this section...

If you have Embedded Coder, you can customize the identifiers in C/C++ code generated from MATLAB code. For each kind of identifier that you want to customize, set the appropriate identifier format parameter to a macro that specifies the format of the generated identifiers. The macro can include:

- Valid C or C++ language identifiers (a-z, A-Z, _, 0–9).
- The tokens listed in the following table. `$M` is required.

Token	Description
`$M`	Code generator inserts name mangling text to avoid naming collisions. Required.
`$N`	Code generator inserts the name of the object (global variable, global type, local function, local temporary variable, or constant macro) for which the identifier is generated. Improves readability of generated code.
`$R`	Code generator inserts the root project name into identifier, replacing unsupported characters with the underscore (_) character.

Customize Identifiers by Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library`

- `Dynamic Library`
- `Executable`

3 Click **More Settings**.

4 On the **Code Appearance** tab, under **Identifier Format**, for each kind of identifier that you want to customize, enter the macro.

Parameter	Default Macro
Global variables	`$M$N`
Global types	`$M$N`
Field name of global types	`$M$N`
Local functions	`$M$N`
Local temporary variables	`$M$N`
Constant macros	`$M$N`
EMX Array Types	`emxArray_$M$N`
EMX Array Utility Functions	`emx$M$N`

For example, suppose that **Global variables** has the value `glob_$M$N`. For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

Customize Generated Identifiers by Using the Command-Line Interface

1 Create a code configuration object for a library or executable program. For example:

```
cfg = coder.config('lib','ecoder',true);
```

2 For each kind of identifier that you want to customize, specify the macro as a character vector.

Parameter	Description	Default Macro
`CustomSymbolStrGlobalVar`	Global variables	`'$M$N'`
`CustomSymbolStrType`	Global types	`'$M$N'`
`CustomSymbolStrField`	Field name of global types	`'$M$N'`

Parameter	Description	Default Macro
`CustomSymbolStrFcn`	Local functions	`'$M$N'`
`CustomSymbolStrTmpVar`	Local temporary variables	`'$M$N'`
`CustomSymbolStrMacro`	Constant macros	`'$M$N'`
`CustomSymbolStrEMXArray`	EMX Array Types	`'emxArray_$M$N'`
`CustomSymbolStrEMXArrayFcn`	EMX Array Utility Functions	`'emx$M$N'`

For example:

```
cfg.CustomSymbolStrGlobalVar = 'glob_$M$N';
```

For a global variable named `g`, when name mangling is not required, the generated identifier is `glob_g`. If name mangling is required, the generated identifier includes the name mangling text.

Control Signed Left Shifts in Generated Code

In this section...

If you have an Embedded Coder license, you can control whether MATLAB Coder replaces multiplications by powers of two with signed left bitwise shifts. Some coding standards, such as MISRA, do not allow bitwise operations on signed integers.

By default, MATLAB Coder replaces multiplication by powers of two with signed left shifts. Here is an example of generated C code that uses a signed left shift for multiplication by eight.

```
i <<= 3;
```

To increase the likelihood of generating MISRA C:2012 compliant code, disable the replacement of multiplication by powers of two with signed left shifts. Here is an example of generated C code that does not use a signed left shift for multiplication by eight:

```
i = i * 8;
```

Control Signed Left Shifts Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **Code Appearance** tab, select or clear the **Use signed shift left for fixed-point operations and multiplication by powers of 2** check box.

Control Signed Left Shifts Using the Command-Line Interface

1. Create a code configuration object for `'lib'`, `'dll'`, or `'exe'`. For example:

   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```

2. Set the `EnableSignedLeftShifts` property to `true` or `false`. For example:

   ```
   cfg.EnableSignedLeftShifts = false;
   ```

More About

- “Configure Build Settings” (MATLAB Coder)

Control Data Type Casts in Generated Code

In this section...

If you have an Embedded Coder license, you can control data type casts in C/C++ code generated from MATLAB code. You can specify one of the following casting modes.

Casting Mode	Description

Nominal	Nominal casting mode is the default casting mode. Generated C/C++ code uses the default C compiler data type casting. When you do not have special data type information requirements, choose this option. Here is an example of code generated using nominal casting mode:
	`short addone(short x)`
	`{`
	`  int i0;`
	`  i0 = x + 1;`
	`  if (i0 > 32767) {`
	`  i0 = 32767;`
	`  }`
	
	`  return (short)i0;`
	`}`

Casting Mode	Description

Standards Compliant	Generated C/C++ code has data type casts that conform to MISRA standards. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations. Here is an example of code generated using standards-compliant casting mode:
	`short addone(short x)`
	`{`
	`  int i0;`
	`  i0 = (int)x + (int)1;`
	`  if (i0 > (int)32767) {`
	`  i0 = (int)32767;`
	`  }`
	`  return (short)i0;`
	`}`

Explicit	Generated C/C++ code has explicit data type casts. Explicit data type casts provide information about the amount of memory that the variable uses and the level of precision for calculations using the variable. Here is an example of code generated using explicit casting mode:
	`short addone(short x)`
	`{`
	`  int i0;`
	`  i0 = (int)x + 1;`
	`  if (i0 > 32767) {`
	`  i0 = 32767;`
	`  }`
	`  return (short)i0;`
	`}`

Specify Casting Mode Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **All Settings** tab, under **Advanced**, set **Casting mode** to one of the following values:
   - `Nominal`
   - `Standards Compliant`
   - `Explicit`

Specify Casting Mode Using the Command-Line Interface

1. Create a code configuration object for `'lib'`, `'dll'`, or `'exe'`. For example:

   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```
2. Set the `CastingMode` property to one of the following values:
   - `'Nominal'`
   - `'Standards'`
   - `'Explicit'`

   For example:

   ```
   cfg.CastingMode = 'Standards';
   ```

- “Configure Build Settings” (MATLAB Coder)

Simplify Multiply Operations for Array Indexing in Loops

If you use Embedded Coder to generate C/C++ code from MATLAB code, you can enable an optimization that simplifies array indexing in loops in the generated code. When possible, for array indices in loops, this optimization replaces multiply operations with add operations. Multiply operations can be expensive. This optimization, referred to as strength reduction, is useful when the C/C++ compiler on the target platform does not optimize the array indexing.

Here is code generated without the optimization:

```
for (i = 0; i < 10; i++) {
    z[5 * (1 + i) - 1] = x[5 * (1 + i)];
  }
```

Here is code generated with the optimization:

```
for (b_i = 0; b_i < 10; b_i++) {
    z[i + 4] = x[i + 5];
    i += 5;
  }
```

By default, the strength reduction optimization is disabled. To enable it:

- At the command line, set the configuration object parameter `EnableStrengthReduction` to `true`.
- In the MATLAB Coder app, project build settings, on the **All Settings** tab, set **Simplify array indexing** to `Yes`.

Even when the optimization replaces the multiply operations in the generated code, it is possible that the C/C++ compiler can generate multiply instructions.

- “Configure Build Settings” (MATLAB Coder)

Increase Likelihood of Generating MISRA C Compliant Code from MATLAB Code

The Motor Industry Software Reliability Association (MISRA)[12] has established "Guidelines for the Use of the C Language in Critical Systems" (MISRA C). When you generate code from MATLAB code, if you have Embedded Coder, you can configure certain code generation parameters to increase the likelihood of generating code that complies with the MISRA C:2012 guidelines.

Configure Code Generation Configuration Object Properties to Increase Likelihood of MISRA C Compliant Code

1. Create an Embedded Coder code generation configuration object.

```
cfg = coder.config('lib', 'ecoder', true);
```

2. Set the properties listed in the table to the values for increased MISRA C compliance.

Property	Value for Increased MISRA C Compliance
`CastingMode`	`'Standards'`
`DataTypeReplacement`	`'CoderTypedefs'`
`DynamicMemoryAllocation`	'Off'
`EnableRuntimeRecursion`	`false`
`EnableSignedLeftShifts`	`false`
`EnableSignedRightShifts`	`false`
`GenerateDefaultInSwitch`	`true`
`ParenthesesLevel`	`'Maximum'`
`TargetLangStandard`	`'C99 (ISO)'` for C, `'C++03 (ISO)'` for C++

To set these properties in one step, use `coder.setupMISRAConfig`.

```
coder.setupMISRAConfig(cfg);
```

12. MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.

Alternatively, set properties individually. For example:

```
cfg.CastingMode = 'Standards';
```

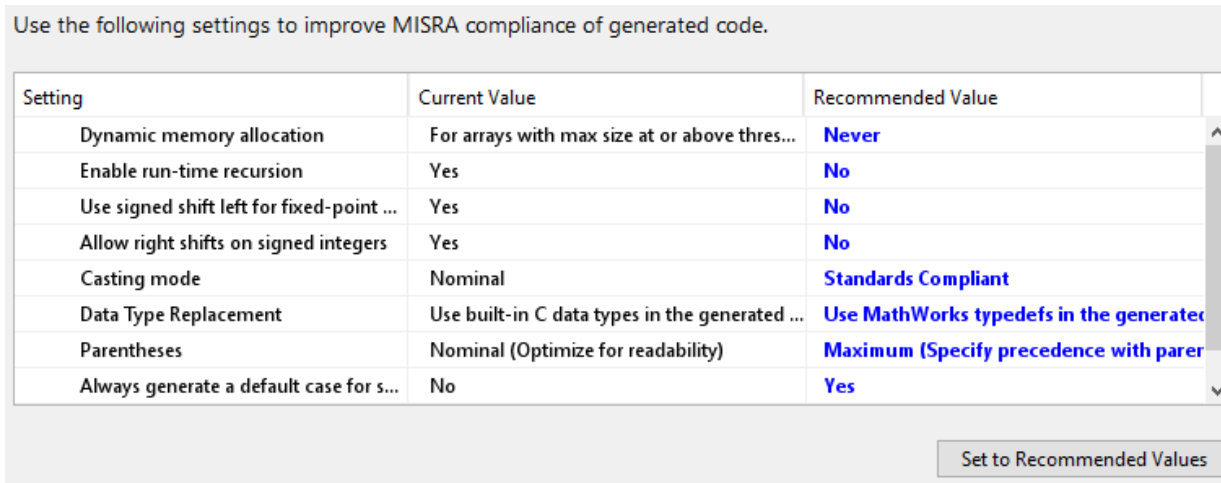
3 Pass the configuration object to `codegen` by using the `-config` option.

```
codegen myFunction -config cfg ...
```

Configure MATLAB Coder App Settings to Increase Likelihood of MISRA C Compliant Code

1 On the **Generate Code** page, set **Build type** to `Source Code`, `Static Library`, `Dynamic Library`, or `Executable`.
2 Click **More Settings**.
3 Click **MISRA Compliance**.

The app displays the settings that might impact MISRA C compliance.



4 To set all of these settings to the recommended values, click **Set to Recommended Values**.

To modify an individual setting, click **All Settings**, and then search for the setting.

Additional Settings for MISRA C++ Compliance

By default, the C++ code that you generate uses a custom type definition for `bool` to maximize compatibility with certain precompiled libraries. This custom type definition can cause violations for MISRA C++:2008 Rule 5-0-13 and Rule 5-3-1.

To use the built-in `bool` type in generated C++ code, and avoid these violations, change the **Hardware Board** setting in the configuration object from `MATLAB Host Computer`. To see how to change this setting in the App, see "Access Hardware Implementation Properties with a Dialog Box" (MATLAB Coder). For example, for code generation and build on a 64-bit Windows platform, change the **Hardware Board** to `None - Select device below`, and then set **Device vendor** to `Intel` and **Device type** to `x86-64 (Windows64)`.

Customize Data Type Replacement

While generating C/C++ code from MATLAB code, the **Data Type Replacement** option enables you to use built-in C data types or MathWorks typedefs in the generated code. The code generation supports these data types:

- `double`
- `single`
- `uint8`
- `uint16`
- `uint32`
- `uint64`
- `int8`
- `int16`
- `int32`
- `int64`
- `char`
- `logical`

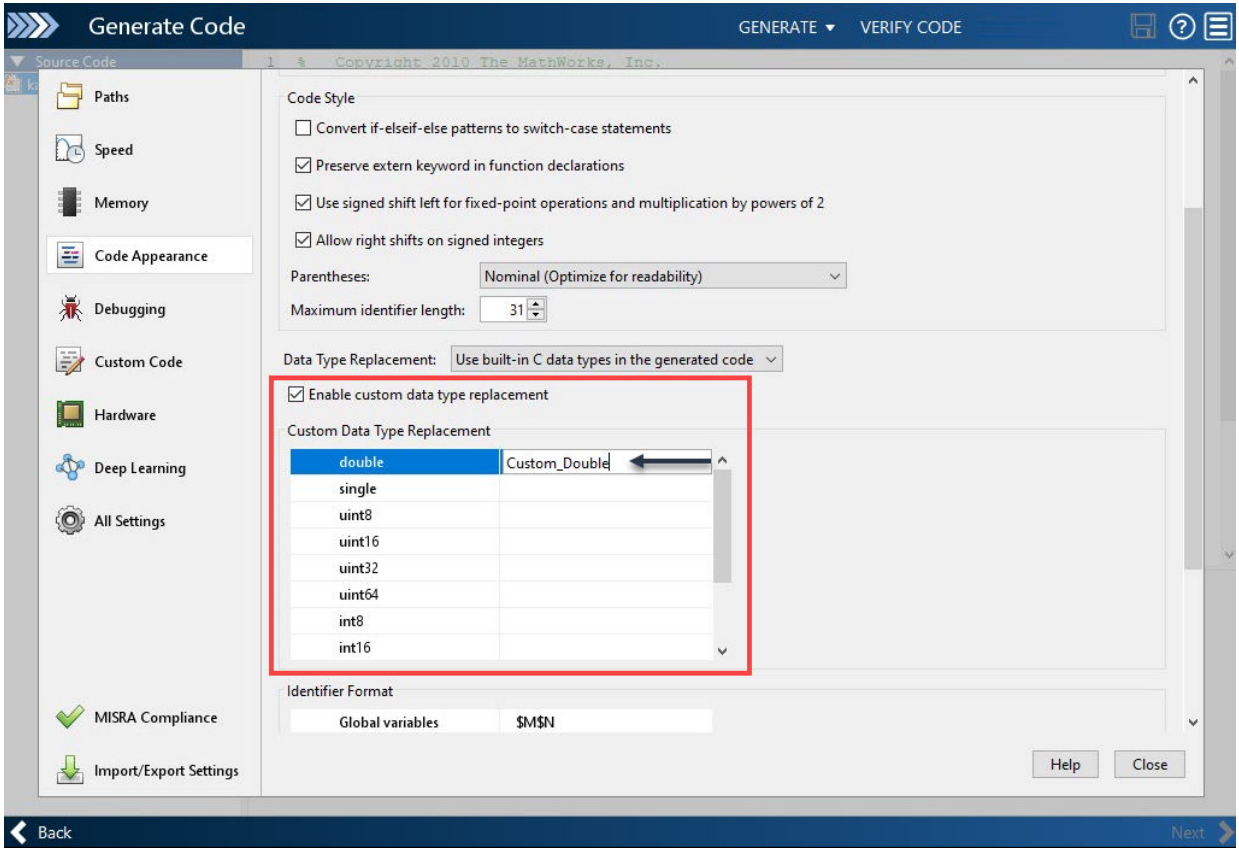
If you have Embedded Coder installed, you can specify custom names for MATLAB built-in data types in the generated C/C++ code. For example, `double` can be customized as `Custom_Double`.

Specify Custom Data Type Names by Using the MATLAB Coder App

To specify custom names for the MATLAB data types:

1. Open the MATLAB Coder app.
2. Navigate to the **Generate Code** step.
3. Click **More Settings**.
4. Select **Enable custom data type replacement** in the **Code Appearance** tab.
5. The **Custom Data Type Replacement** table lists the name of the supported data types. You can specify your custom names for these data types. The specified custom

names replace the built-in data type names in the generated code. If you do not specify a custom name, the code generator uses a default name.



Specify Custom Data Type Names by Using the Command-Line Interface

To specify custom names at the command line, use the `EnableCustomReplacementTypes` and `ReplacementTypes` properties in an Embedded Coder configuration object when you generate code by using `codegen`.

1. Create a code configuration object for `'lib'`, `'dll'`, or `'exe'`.

```
cfg = coder.config('lib','ecoder',true);
```

2. Set the `EnableCustomReplacementTypes` property to `true`.

   ```
   cfg.EnableCustomReplacementTypes = true;
   ```

3. Specify custom name for the data types. Here, the built-in data type name `uint8` is customized to `Custom_Uint8`.

   ```
   cfg.ReplacementTypes.uint8 = "Custom_Uint8";
   ```

4. Generate code by using `codegen` and `-config` option.

   ```
   codegen -c inputfile.m -config cfg
   ```

Code Replacement for MATLAB Code

What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for

a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

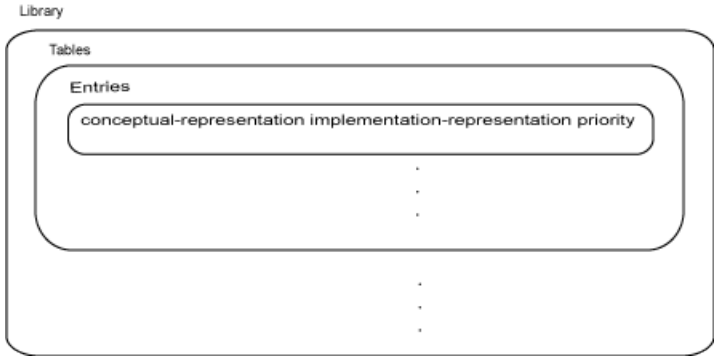

Table Entry Component	Description
Conceptual representation	Identifies the table entry and contains match criteria for the code generator. Consists of: • Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name `'cos'` and operator key `'RTW_OP_ADD'`. • Conceptual arguments that observe code generator naming (`'y1'`, `'u1'`, `'u2'`, ...), with corresponding I/O types (output or input) and data types. • Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.

Table Entry Component	Description
Implementation representation	Specifies replacement code. Consists of: • Function name. For example, `'cos_dbl'` or `'u8_add_u8_u8'`. • Implementation arguments, with corresponding I/O types (output or input) and data types. • Parameters that provide additional implementation details, such as header and source file names and paths of build resources.
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.

Term	Definition
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.

Term	Definition
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: • Function or operator name or key • Conceptual arguments with type, dimension, and complexity specification for inputs and output • Attributes, such as an algorithm and fixed-point saturation and rounding modes
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.
Implementation representation	Specifies C or C++ replacement function prototype. Consists of: • Function name (for example, `'cos_dbl'` or `'u8_add_u8_u8'`) • Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output • Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags
Key	Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key `RTW_OP_ADD` identifies the addition operator.

Term	Definition
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

Choose a Code Replacement Library

In this section...

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 89-2.
   - See “Explore Available Code Replacement Libraries” on page 89-8.
2. Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 89-8.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

You can select the code replacement library to use for code generation in a project, on the **Custom Code** tab, by setting the **Code replacement library** parameter. Alternatively, in a code configuration object, set the `CodeReplacementLibrary` parameter.

Explore Code Replacement Library Contents

Use the **Code Replacement Viewer** to explore the content of a code replacement library.

1. At the command prompt, type `crviewer`.

   ```
   >> crviewer
   ```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

2. In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
3. In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
4. In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

   If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

Replace Code Generated from MATLAB Code

This example shows how to replace generated code using a code replacement library. Code replacement is a technique for changing the code that the code generator produces for functions and operators to meet application code requirements.

Prepare for Code Replacement

1. Make sure that you have installed required software. Required software is:

   - MATLAB
   - MATLAB Coder
   - C compiler

   Some code replacement libraries available in your development environment require Embedded Coder.

   For instructions on installing MathWorks products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the MATLAB Command Window, enter `ver`.
2. Identify an existing MATLAB function or create a new MATLAB function for which you want the code generator to replace code.

Choose a Code Replacement Library

If you are not sure which library to use, explore available libraries.

Configure Code Generator To Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the MATLAB function. Do one of the following:

   - In a project, on the **Custom Code** tab, set the **Code replacement library** parameter.
   - In a code configuration object, set the `CodeReplacementLibrary` parameter.
2. Configure the code generator to produce only code. Before you build an executable, verify your code replacements. Do one of the following:

   - In a project, in the **Generate** dialog box, select the **Generate code only** check box.

- In a code configuration object, set the `GenCodeOnly` parameter.

Include Code Replacement Information In Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information helps you verify code replacements.

1. Configure the code generator to generate a report.
   - In a project, on the **Debugging** tab, set the **Always create a code generation report** parameter.
   - In a code configuration object, set the `GenerateReport` parameter.
2. Include the code replacement section in the report.
   - In a project, on the **Debugging** tab, select the **Code replacements** check box.
   - In a code configuration object, set the `GenerateCodeReplacementReport` parameter.

Generate Replacement Code

Generate C/C++ code from the MATLAB code. If you configured the code generator to produce a report, generate a code generation report. For example, in the MATLAB Coder app, on the **Generate Code** page, click **Generate**. Or, at the command prompt, enter:

```
codegen -report myFunction -args {5} -config cfg
```

The code generator produces the code and displays the report.

Verify Code Replacements

Verify code replacements by examining the generated code. Code replacement can sometimes behave differently than you expect. For example, data types that you observe

in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Storage Classes for Code Generation from MATLAB Code

Storage Classes for Code Generation from MATLAB Code

If you have an Embedded Coder license, you can use storage classes to control the declaration and definition of a global variable in the generated C/C++ code.

In the context of code generation, a storage class is a specification that determines the declaration and definition of a variable in the generated code. For code generation, the term storage class is not the same as the C language term storage class specifier.

Storage classes help you to integrate generated code with external code. You can make a generated variable visible to external code. You can also make variables declared in the external code visible to the generated code. For code generation from MATLAB code, you can use storage classes with global variables only. The storage class determines:

- The file placement of a global variable declaration and definition.
- Whether the global variable is imported from external code or exported for use by external code.

To assign a storage class to a global variable, in your MATLAB code, use the `coder.storageClass` function. Only when you use an Embedded Coder project or configuration object for generation of C/C++ libraries or executables does the code generator recognize `coder.storageClass` calls.

The syntax for `coder.storageClass` is:

```
coder.storageClass(global_name, storage_class)
```

`global_name` is the name of a global variable, specified as a character vector. `global_name` must be a compile-time constant.

`storage_class` can be one of the following values.

Storage Class	Description
`'ExportedGlobal'`	• Defines the variable in the `Variable Definitions` section of the C file *`entry_point_name`*`.c`. • Declares the variable as an `extern` in the `Variable Declarations` section of the header file *`entry_point_name`*`.h` • Initializes the variable in the function *`entry_point_name`*`_initialize.h`.
`'ExportedDefine'`	Declares the variable with a `#define` directive in the `Exported data define` section of the header file *`entry_point_name`*`.h`.
`'ImportedExtern'`	Declares the variable as an `extern` in the `Variable Declarations` section of the header file *`entry_point_name`*`_data.h`. The external code must supply the variable definition.
`'ImportedExternPointer'`	Declares the variable as an `extern` pointer in the `Variable Declarations` section of the header file *`entry_point_name`*`_data.h`. The external code must define a valid pointer variable.

Storage classes have these requirements and limitations:

- Assign the storage class to a global variable in a function that declares the global variable. You do not have to assign the storage class in more than one function.
- After you assign a storage class to a global variable, you cannot assign a different storage class to that global variable.
- You cannot assign a storage class to a constant global variable.
- A global variable with an `ExportedDefine` storage class must be a scalar but not a complex or multi-word scalar. The global variable must only be read and not written to in the code.

If you do not assign a storage class to a global variable, except for the declaration location, the variable behaves like it has an `'ExportedGlobal'` storage class. For an `'ExportedGlobal'` storage class, the global variable is declared in the file *`entry_point_name`*`.h`. When the global variable does not have a storage class, the variable is declared in the file *`entry_point_name`*`_data.h`.

`coder.storageClass`

Related Examples

- “Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code” on page 90-5
- “Generate Code for Global Data” (MATLAB Coder)

Control Declarations and Definitions of Global Variables in Code Generated from MATLAB Code

This example uses storage classes to control the declarations and definitions of global variables in C/C++ code generated from MATLAB code. Using storage classes helps you to interface generated code with external code.

This example requires an Embedded Coder license.

Write a function `addglobals` that adds four global variables. Declare the global variables in the function.

```
function y = addglobals

% Define the global variables.

global u;
global v;
global x;
global z;

% Assign the storage classes.

coder.storageClass('u','ExportedGlobal');
coder.storageClass('v','ImportedExtern');
coder.storageClass('x','ImportedExternPointer');
coder.storageClass('z','ExportedDefine');
y = u + v + x + z;
end
```

Create a file `c:\myfiles\myfile.c` that defines and initializes the imported global variables `u` and `v`.

```
#include <stdio.h>

/* Variable definitions for imported variables */
double v = 1.0;
double *x = &v;
```

Create a code configuration object. Configure the code generation parameters to include `myfile.c`. For output type `'lib'`, or if you generate source code only, you can generate code without providing this file. Otherwise, you must provide this file.

```
cfg = coder.config('dll','ecoder', true);
cfg.CustomSource = 'myfile.c';
cfg.CustomInclude = 'c:\myfiles';
```

Generate the code. This example uses the `-globals` argument to specify the types and initial values of the global variables `u`, `v`, `x`, and `z`. Alternatively, you can define global variables in the MATLAB global workspace. For the imported global variables `v` and `x`, the code generator uses the initial values only to determine the type.

```
codegen -config cfg -globals {'u', 1, 'v', 2, 'x', 3, 'z', 4} addglobals -report
```

From the initial values `1`, `2`, `3`, and `4` `codegen` determines that `u`, `v`, `x` and `z` have type `double`. `codegen` defines and declares the exported global variables `u` and `z`. It generates code that initializes `u` to `1.0` and `z` to `4.0`. `codegen` declares the imported global variables `v` and `x`. It does not define these variables or generate code that initializes them. `myfile.c` provides the code that defines and initializes `v` and `x`.

To view the code generated for the global variables, open the report. Click the **View report** link.

View the definition for the exported global `z` in the `Exported data define` section in `addglobals.h`.

```
/* Definition for custom storage class: ExportedDefine */
#define z                              4.0
```

View the definition and declaration for the exported global `u`.

- `u` is defined in the `Variable Definitions` section in `addglobals.c`.

  ```
  /* Variable Definitions */
  /* Definition for custom storage class: ExportedGlobal */
  double u;
  ```

- `u` is declared as `extern` in the `Variable Declarations` section in `addglobals.h`.

  ```
  /* Variable Declarations */
  /* Declaration for custom storage class: ExportedGlobal */
  extern double u;
  ```

- `u` is initialized in `addglobals_initialize.c`.

  ```
  /* Include Files */
  #include "rt_nonfinite.h"
  #include "addglobals.h"
  ```

```
#include "addglobals_initialize.h"

/* Named Constants */
#define b_u                            (1.0)

/* Function Definitions */

/*
 * Arguments    : void
 * Return Type  : void
 */
void addglobals_initialize(void)
{
  rt_InitInfAndNaN(8U);
  u = b_u;
}
```

View the definition and declaration for the imported external global `v` and the imported external global pointer `x`.

`v` and `x` are declared as `extern` in the `Variable Declarations` section in `addglobals_data.h`.

```
/* Variable Declarations */
/* Declaration for custom storage class: ImportedExtern */
extern double v;

/* Declaration for custom storage class: ImportedExternPointer */
extern double *x;
```

Verification of Code Generated from MATLAB Code

Highlight Potential Data Type Issues in a Report

In this section...

If you have Embedded Coder, you have the option to highlight potential data types issues in the code generation report for standalone code generated from MATLAB code. If you enable this option, on the **Code Insights** tab, the report identifies single-precision and double-precision operations in the generated C/C++ code. If you have Fixed-Point Designer, the report also identifies expensive fixed-point operations.

To view potential data type issues in a code generation report:

1. Click the **Code Insights** tab.
2. Expand the **Potential data type issues** section.
3. Expand the data type issues section that you want to see.

   For example, this report identifies MATLAB code that results in double-precision operations in the generated code.

The option to highlight potential data type issues is disabled by default.

Enable Highlight Option Using the MATLAB Coder App

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow .
2. Set **Build type** to one of the following:

   - `Source Code`
   - `Static Library (.lib)`

- `Dynamic Library (.dll)`
- `Executable (.exe)`

3. Click **More Settings**.
4. On the **Debugging** tab, select the **Always create a code generation report** and **Highlight potential data type issues** check boxes.

Enable Highlight Option Using the Command Line Interface

1. Create an embedded code configuration object for `'lib'`, `'dll'`, or `'exe'`:

   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```

2. Set the `GenerateReport` and `HighlightPotentialDataTypeIssues` configuration object properties to `true`:

   ```
   cfg.GenerateReport = true;
   cfg.HighlightPotentialDataTypeIssues = true;
   ```

Find Potential Data Type Issues in Generated Code

In this section...

Data Type Issues Overview

When you generate C code from MATLAB code, you can highlight potential data type issues in the C code generation report. The report highlights MATLAB code that requires single-precision, double-precision, or expensive fixed-point operations. The expensive fixed-point operations checks require a Fixed-Point Designer.

- The double-precision check highlights expressions that result in a double-precision operation. When trying to achieve a strict-single or fixed-point design, manual inspection of code can be time-consuming and error prone.

  For a strict-single precision design, specify a standard math library that supports single-precision implementations. To change the library for a project, during the Generate Code step, in the project settings dialog box, on the **Custom Code** tab, set the **Standard math library** to `C99 (ISO)`.
- The single-precision check highlights expressions that result in a single operation.
- The expensive fixed-point operations check identifies optimization opportunities for fixed-point code. It highlights expressions in the MATLAB code that require cumbersome multiplication or division, expensive rounding, expensive comparison, or multiword operations. For more information on optimizing generated fixed-point code, see “Tips for Making Generated Code More Efficient” (Fixed-Point Designer).

Enable Highlighting of Potential Data Type Issues

Enable the highlight option using the MATLAB Coder app

1. On the **Generate Code** page, to open the **Generate** dialog box, click the **Generate** arrow  .
2. Set **Build type** to one of the following:
   - `Source Code`
   - `Static Library (.lib)`
   - `Dynamic Library (.dll)`
   - `Executable (.exe)`
3. Click **More Settings**.
4. On the **Debugging** tab, select the **Always create a code generation report** and **Highlight potential data type issues** check boxes.

Enable the highlight option using the command-line interface

1. Create an embedded code configuration object for `'lib'`, `'dll'`, or `'exe'`:

   ```
   cfg = coder.config('lib','ecoder',true); % or dll or exe
   ```
2. Set the `GenerateReport` and `HighlightPotentialDataTypeIssues` configuration object properties to `true`:

   ```
   cfg.GenerateReport = true;
   cfg.HighlightPotentialDataTypeIssues = true;
   ```

Find and Address Cumbersome Operations

Cumbersome operations usually occur due to an insufficient range of output. Avoid inputs to a multiply or divide operation that have word lengths larger than the base integer type of your processor. Software can process operations with larger word lengths, but this approach requires more code and runs slower.

This example requires Embedded Coder and Fixed-Point Designer. The target word length for the processor in this example is 64.

1. Create the function `myMul`.

```
function out = myMul(in1, in2)
    out = fi(in1*in2, 1, 64, 0);
end
```

2 Generate code for `myMul`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
fm = fimath('ProductMode', 'SpecifyPrecision', 'ProductWordLength', 64);
codegen -config cfg myMul -args {fi(1, 1, 64, 4, fm), fi(1, 1, 64, 4, fm)}
```

3 Click **View report**.

4 In the code generation report, click the **Code Insights** tab.

5 Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

The report flags the expression `in1 * in2`. To resolve the issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length of 64.

Find and Address Expensive Rounding

Traditional handwritten code, especially for control applications, almost always uses "no effort" rounding. For example, for unsigned integers and two's complement signed integers, shifting right and dropping the bits is equivalent to rounding to floor. To get results comparable to, or better than, what you expect from traditional handwritten code, use the `floor` rounding method.

This example requires Embedded Coder and Fixed-Point Designer.

1 Create the function `myRounding`.

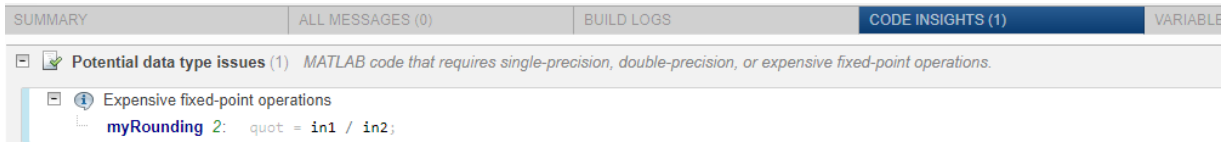
```
function [quot] = myRounding(in1, in2)
   quot = in1 / in2;
end
```

2 Generate code for `myRounding`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
```

```
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRounding -args {fi(1, 1, 16, 2), fi(1, 1, 16, 4)}
```

3. Click **View report**.
4. In the code generation report, click the **Code Insights** tab.
5. Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.



The division operation `in1/in2` uses the default rounding method, `nearest`. Changing the rounding method to `Floor` provides a more efficient implementation.

Find and Address Expensive Comparison Operations

Comparison operations generate extra code when a casting operation is required to do the comparison. For example, before comparing an unsigned integer to a signed integer, one of the inputs must be cast to the signedness of the other. Consider optimizing the data types of the input arguments so that a cast is not required in the generated code.

This example requires Embedded Coder and Fixed-Point Designer.

1. Create the function `myRelop`.

```
function out = myRelop(in1, in2)
    out = in1 > in2;
end
```

2. Generate code for `myRelop`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myRelop -args {fi(1, 1, 14, 3, 1), fi(1, 0, 14, 3, 1)}
```

3. Click **View report**.
4. In the code generation report, click the **Code Insights** tab.
5. Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

The first input argument, `in1`, is signed, while `in2` is unsigned. Extra code is generated because a cast must occur before the two inputs can be compared.

Change the signedness and scaling of one of the inputs to generate more efficient code.

Find and Address Multiword Operations

Multiword operations can be inefficient on hardware. When an operation has an input or output data type larger than the largest word size of your processor, the generated code contains multiword operations. You can avoid multiword operations in the generated code by specifying local `fimath` properties for variables. You can also manually specify input and output word lengths of operations that generate multiword code.

This example requires Embedded Coder and Fixed-Point Designer. In this example, the target word length is 64.

1. Create the function `myMul`.

```
function out = myMul(in1, in2)
    out = in1 * in2;
end
```

2. Generate code for `myMul`.

```
cfg = coder.config('lib');
cfg.GenerateReport = true;
cfg.HighlightPotentialDataTypeIssues = true;
codegen -config cfg myMul -args {fi(1, 1, 33, 4), fi(1, 1, 32, 4)}
```

3. Click **View report**.
4. In the code generation report, click the **Code Insights** tab.
5. Expand the **Potential data type issues** section. Then, expand the **Expensive fixed-point operations** section.

The report flags the `in1 * in2` operation in line 2 of `myMul`.

6 In the code pane, pause over `in1`, `in2`, and the expression `in1 * in2`. You see that:

- The word length of `in1` is 33 bits and the word length of `in2` is 32 bits.
- The word length of the expression `in1 * in2` is 65 bits.

The software detects a multiword operation because the word length 65 is larger than the target word length of 64.

7 To resolve this issue, modify the data types of `in1` and `in2` so that the word length of the product does not exceed the target word length. Alternatively, specify the `ProductMode` property of the local `fimath` object.

PIL Execution with ARM Cortex-A at the Command Line

This example shows how to set up a PIL execution to verify generated code at the command line.

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone® Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

In the Command Window, select the hardware for PIL execution.

```
hw = coder.hardware('ARM Cortex-A9 (QEMU)')
```

```
hw =

  Hardware with properties:

            Name: 'ARM Cortex-A9 (QEMU)'
    CPUClockRate: 1000
```

When using the BeagleBone hardware, more hardware properties are supported (`Username`, `Password`, and `DeviceAddress`). Set these properties based on your specific hardware or application.

```
hw = coder.hardware('BeagleBone Black')
```

```
hw =

  Hardware with properties:

             Name: 'BeagleBone Black'
     CPUClockRate: 1000
         Password: 'root'
         Username: 'admin'
    DeviceAddress: '192.168.1.10'
```

Add the hardware to the MATLAB Coder configuration object.

```
cfg = coder.config('lib','ecoder',true);
cfg.VerificationMode = 'PIL';
cfg.Hardware = hw;
```

Generate PIL code for a function, `averaging_filter`.

```
codegen -config cfg averaging_filter -args {zeros(1,16)}
```

For more information on the `averaging_filter` function, see “Averaging Filter” (MATLAB Coder).

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. To install the Embedded Coder Support Package for ARM Cortex-A Processors, see “Supported Hardware”.

PIL Execution with ARM Cortex-A by Using the MATLAB Coder App

You can use processor-in-the-loop (PIL) executions to verify generated code that you deploy to target hardware by using a MATLAB Coder procedure. You can profile algorithm performance and speed for your generated code. To verify generated code with the MATLAB Coder app, you must have an Embedded Coder license.

This PIL execution is available with these hardware support packages. To use the PIL execution, install one of these support packages.

- Embedded Coder Support Package for BeagleBone Black Hardware
- Embedded Coder Support Package for ARM Cortex-A Processors

You can set up PIL execution with the MATLAB Coder app.

To configure the build type and hardware board:

1. On the **Generate Code** page, in the **Generate** dialog box:
   - Set the **Build type** to `Static Library`.
   - Clear the **Generate code only** check box.
   - Set the **Hardware Board** to `BeagleBone Black` or `ARM Cortex-A9 (QEMU)`.
2. If necessary, modify the settings for your board. To modify the settings, click **More Settings**, and then click **Hardware**.
3. To generate the library, click **Generate**.
4. Set up your PIL execution. Click **Verify Code** to open the **Verify Code** dialog box.

   Because the hardware board is not `MATLAB Host Computer`, the **Verify Code** dialog box is configured for PIL execution.

   In the **Verify Code** dialog box:
   - Enter the name of the test file to use for PIL execution.
   - Select **Generated code**.
5. To start the PIL execution, click **Run Generated Code**.
6. To stop the PIL execution, click **Stop**.

For another example of PIL verification, see the "Processor-in-the-Loop Verification of MATLAB Functions" page in the documentation of the Embedded Coder Support Package for ARM Cortex-A Processors. Install the support package to view the documentation.

Interactively Trace Between MATLAB Code and Generated C/C++ Code

This example shows how to trace between MATLAB source code and the generated C/C++ code. Tracing between source code and generated code helps you to:

- Understand how the code generator implemented your algorithm.
- Debug issues in the generated code.
- Evaluate the quality of the generated code.

If you have Embedded Coder and enable production of a code generation report with traceability, you can view MATLAB source code and generated C/C++ code next to each other. As you move your pointer over code, you can follow highlighted traces to the corresponding generated code or source MATLAB code.

Create the MATLAB Source Code

To illustrate interactive traceability, this example produces a report for generation of a C static library for a MATLAB function `lpsolve` that solves the linear program:

- maximize y = c*x
- subject to A*x <= b
- where x >= 0 and b >= 0

lpsolve

```
%Attempts to solve the linear program:
%
%   maximize y = c*x
%   subject to: A*x <= b,
%   where x >= 0 and b >= 0
%
%   using the dictionary form of the simplex algorithm.
%
%   c must be a double, real row vector.
%   b must be a double, real column vector.
%   A must be a double, real, non-empty matrix with
%     size(A) = [length(b),length(c)].
%
%   Compare to
```

```
%   x = linprog(-c(:),A,b,[],[],zeros(length(c),1))
%   y = c*x
%
%   Copyright 2011-2018 The MathWorks, Inc.

function [x,y] = lpsolve(c,A,b)
%#codegen
narginchk(3,3);
m = int32(size(A,1));
n = int32(size(A,2));
if ~validInputs(c,A,b)
    % Something is wrong with the inputs. Return NaNs.
    x = nan(n,1);
    y = nan;
    return
end
cn = c;
nIdx = 1:n; % indices of non-basic variables
bIdx = n + (1:m); % indices of basic variables
% Perform iterations.
j = findPivotColumn(cn,nIdx);
unbounded = false;
while j > 0 && ~unbounded
    [i,r] = findPivotRow(j,A,b);
    if i == 0 || isinf(r)
        unbounded = true;
    else
        b(i) = r;
        % Take account of the variables entering and leaving the basis.
        entering = nIdx(j);
        leaving = bIdx(i);
        bIdx(i) = entering;
        nIdx(j) = leaving;
        [cn,A,b] = pivot(cn,A,b,i,j);
        j = findPivotColumn(cn,nIdx);
    end
end
% Construct the solution.
if unbounded
    x = nan(n,1);
    y = inf;
else
    x = zeros(n,1);
    y = 0;
```

```
    for k = 1:m
        j = bIdx(k);
        if j <= n
            x(j) = b(k);
            y = y + c(j)*x(j);
        end
    end
end

%--------------------------------------------------------------------------

function p = validInputs(c,A,b)
coder.inline('never');
% All inputs must be double.
p = isa(c,'double') && isa(A,'double') && isa(b,'double');
% All inputs must be real.
p = p && isreal(c) && isreal(A) && isreal(b);
% A must be a non-empty matrix.
p = p && ismatrix(A) && ~isempty(A);
% c must be a row-vector with length = size(A,2).
p = p && isrow(c) && size(c,2) == size(A,2);
% b must be a column-vector with length = size(A,1).
p = p && iscolumn(b) && size(b,1) == size(A,1);
% The elements of b must be non-negative.
p = p && all(b(:) >= 0);

%--------------------------------------------------------------------------

function [c,A,b] = pivot(c,A,b,i,j)
% Pivot on element i,j.
coder.inline('never');
m = int32(size(A,1));
aij = A(i,j);
A(i,j) = 1;
A(i,:) = A(i,:)/aij;
for k = 1:m
    if k ~= i
        akj = A(k,j);
        A(k,j) = 0;
        A(k,:) = A(k,:) - akj*A(i,:);
        b(k) = b(k) - akj*b(i);
    end
end
cj = c(j);
```

```
c(j) = 0;
c = c - cj*A(i,:);

%--------------------------------------------------------------------------

function j = findPivotColumn(c,idx)
% Find a suitable variable to enter the basis using the smallest
% subscript rule to prevent cycling.
coder.inline('never');
j = int32(0);
nc = int32(numel(c));
lastidx = int32(0);
for k = 1:nc
    if c(k) > 0 && (lastidx < 1 || idx(k) < lastidx)
        j = k;
        lastidx = idx(k);
    end
end

%--------------------------------------------------------------------------

function [i,r] = findPivotRow(j,A,b)
% Find the pivot row in column j of A and also return r = b(i)/A(i,j).
coder.inline('never');
r = inf;
i = int32(0);
nb = int32(numel(b));
for k = 1:nb
    if A(k,j) > 0
        rtmp = b(k)/A(k,j);
        if rtmp < r
            r = rtmp;
            i = k;
        end
    end
end

%--------------------------------------------------------------------------
```

The example also uses a test function `lpsolve_test` that calls `lpsolve` with representative input values.

lpsolve_test

```
% Test function for lpsolve
%
%   Copyright 2011-2018 The MathWorks, Inc.

function lpsolve_test()
c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
[x,y] = lpsolve(c,A,b);
x % display x
y % display y
```

Copy `lpsolve.m` and `lpsolve_test.m` to a writable folder.

```
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsolve.m'))
copyfile(fullfile(docroot, 'toolbox', 'ecoder', 'examples', 'lpsolve_test.m'))
```

Prepare for Code Generation

Before you generate C/C++ code, it is a best practice to screen your MATLAB code for code generation readiness.

```
coder.screener('lpsolve')
```

The code generation readiness report indicates that `lpsolve` is suitable for code generation.

It is also a best practice to check for run-time issues by generating and testing a MEX function.

- To specify the types of the inputs arguments, pass representative input values to the `codegen -args` option. Alternatively, because you have a test function, you can use `coder.getArgTypes` to determine the types.
- To generate and test a MEX function, use the `-test` option.

```
c = [2 3 1 1];
A = [2 3 1 -1;1 0 2 1;0 2 1 1];
b = [27;9;18];
codegen lpsolve -args {c A b} -test lpsolve_test
```

```
Running test file: 'lpsolve_test' with MEX function 'lpsolve_mex'.
```

```
x =

     5
     7
     0
     4

y =

    35
```

`codegen` successfully generates and runs the MEX function.

Produce a Code Generation Report with Traceability

To generate a report that has interactive traceability:

- Create a `coder.EmbeddedCodeConfig` object. The `EnableTraceability` property controls traceability. By default, the `EnableTraceability` property is `true`.
- Specify the types of the input arguments by passing representative input values to the `-args` option.
- Enable production of a code generation report by using the `-report` option.

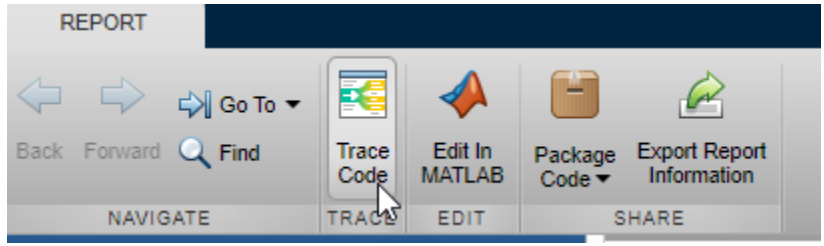
```
cfg = coder.config('lib', 'ecoder', true);
codegen -config cfg lpsolve -args {c A b} -report
```

Access Trace Mode in the Report

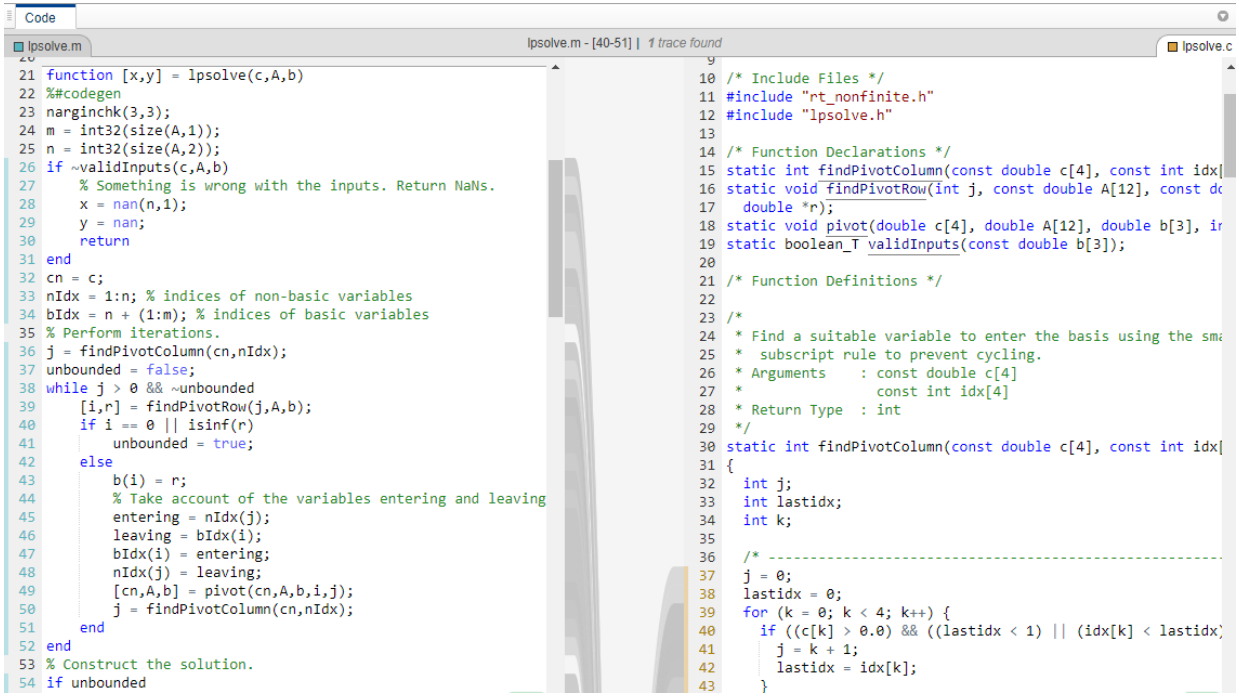
To open the code generation report, click **View report**.

In the code pane, you see `lpsolve.m`.

To enable tracing, on the **Report** tab, click **Trace Code**.



You see the MATLAB source code and the generated C code next to each other.

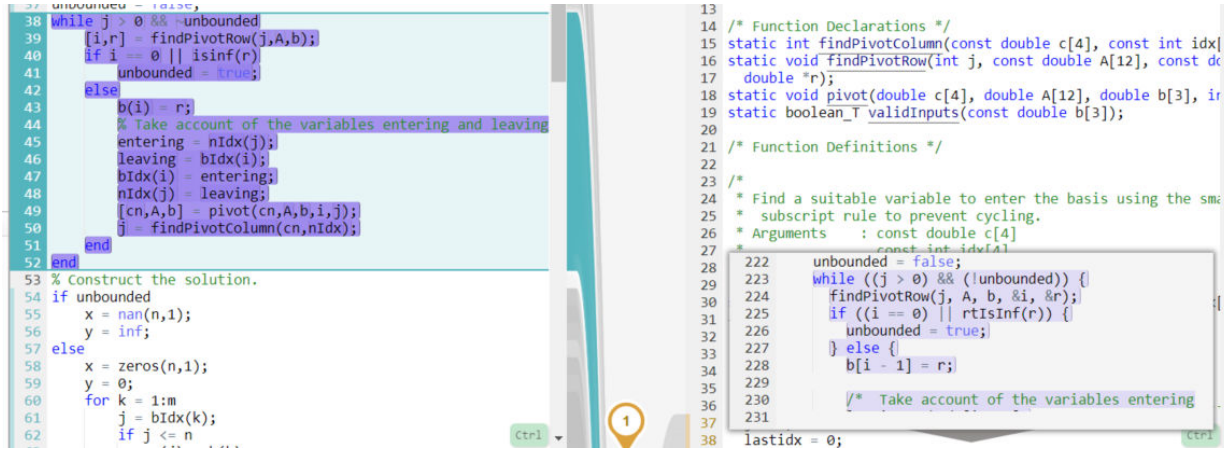


Trace Code

You can trace from the MATLAB code to the C code or from the C code to the MATLAB code. Traceable code is marked with blue on the side that you are tracing from and with orange on the side that you are tracing to. As you move your pointer over traceable code, the code is highlighted in purple and you see the traces to the corresponding code on the other side. When you select highlighted code by clicking it, the code becomes yellow and you can see the traces even when you move your pointer away from the selection. The code remains selected until you press **Esc** or select different code. To change the side that you are tracing from, select code on the other side.

Explore tracing in the example report.

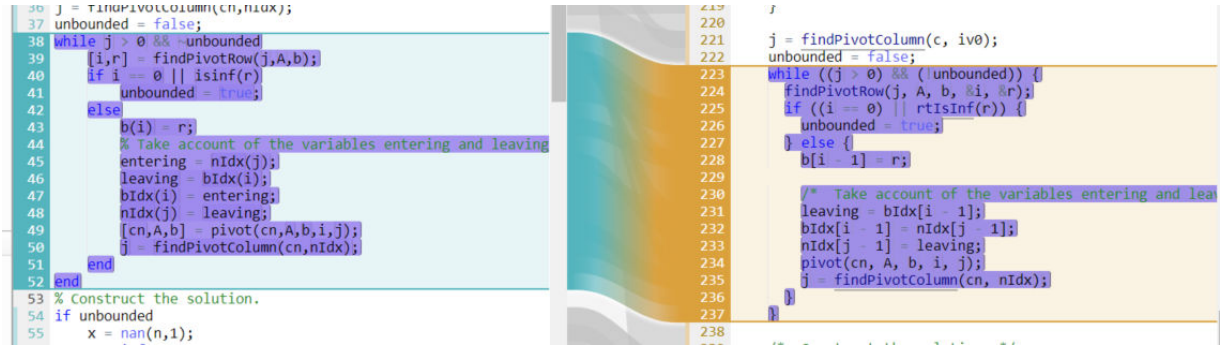
1. In the MATLAB code, point to the `while`-loop that starts at line 38 and scroll down until the entire `while`-loop is in view.



You see this symbol that tells you that the highlighted MATLAB code has one trace that is not in view.

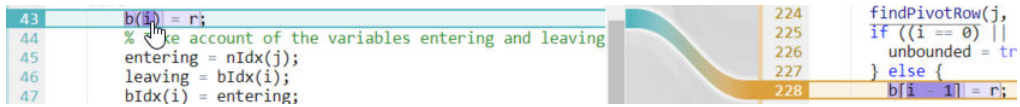
You see the corresponding C code in a separate window in the C code pane.

2 In the C code pane, scroll down until you see the C code that corresponds to the `while` loop.

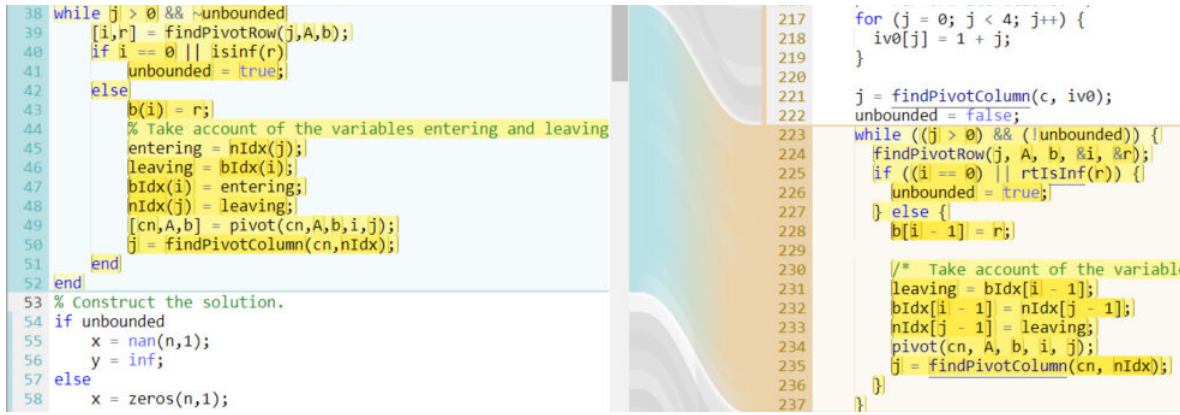


3 In the MATLAB code, move your pointer over different syntax elements in the `while` loop. Highlight variables, expressions, and code blocks.

When you move your pointer over expressions that are part of larger expressions, different shades of purple help you to find the relevant expression in the corresponding C code. For example, at line 43, pause over `i`.



4 In the MATLAB code, move your pointer back to the `while`-loop that starts at line 38. When the entire loop is highlighted in purple, select it by clicking. When you move your pointer outside of the trace, the yellow highlighting identifies the selected trace.



To clear the selection, press **Esc** or select different code.

View Multiple Traces

When code traces to more than one place in the corresponding source or generated code:

- If you pause over the code that you are tracing, at the top of the code pane, you see the number of traces.
- If some traces are not in view, you see a symbol that tells you how many traces are out of view.

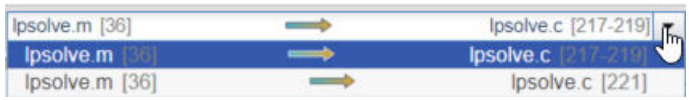
- In the code pane, if you select the code that you want to trace, at the top of the code pane, you can select the trace that you want to see.

In the report for `lpsolve`, view multiple traces.

1. Pause over line 36.

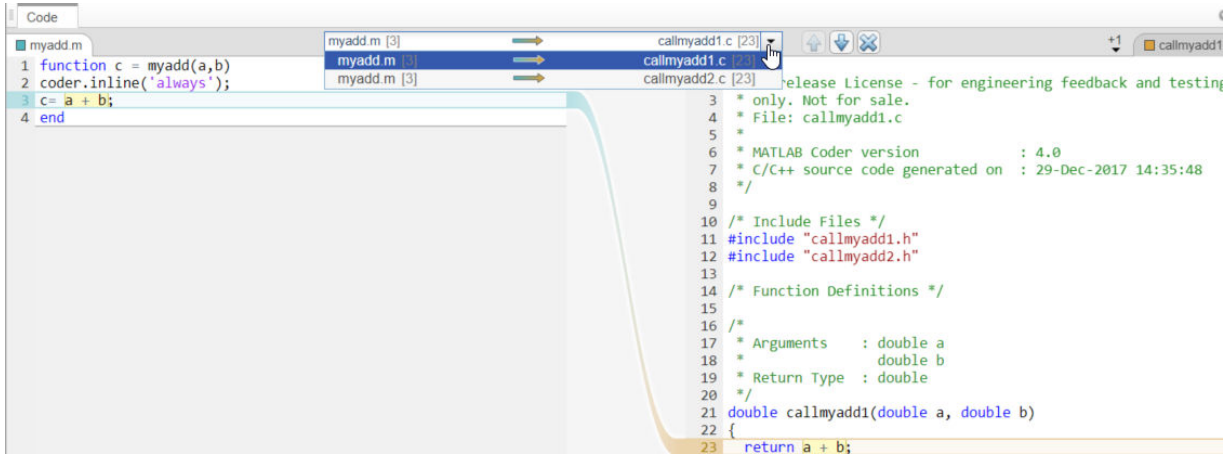
   At the top of the code pane, you see that line 36 has two traces.
2. Select line 36.

   At the top of the code pane, you see the location of the first trace.
3. To list all traces, click the arrow to the right of the traces.



View Traces to Different Files

In the code generation report for `lpsolve`, all traces from the MATLAB code go to one C file `lpsolve.c`. If MATLAB code traces to multiple C files, above the C code, you see a symbol such as  that provides the number of additional files in which you can find a trace. If you click the symbol, you can select the file that you want to see. If you select the MATLAB code, then you can select the trace that you want to see.



Likewise, above the MATLAB source code, a symbol such as  indicates that the highlighted C code traces to multiple MATLAB files.

Switch the Locations of the Source and Generated Code

1. To view `lpsolve.c` on the left side of the code pane, in the list of generated files, click `lpsolve.c`.
2. To view the MATLAB code on the left side of the code pane, click a MATLAB function, for example, `lpsolve`.

Enable Code Tooltips and Links

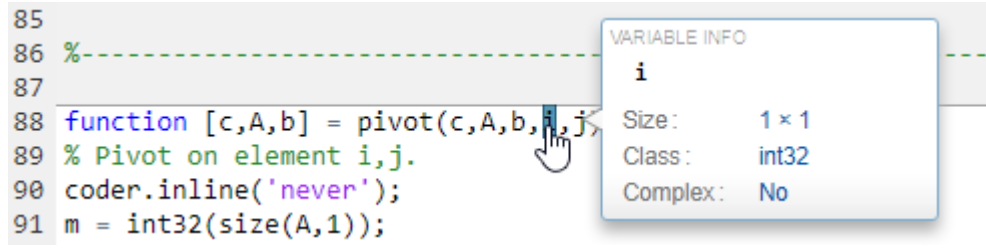
When you are not in trace mode:

- In the MATLAB code, if you point to a variable or expression, a tooltip provides information such as the type.
- In the C code, links go to other parts of the code such as type or function definitions.

When you are in trace mode, to enable MATLAB code tooltips and C code links, hold down **Ctrl**. MATLAB code tooltips are available only for a selected MATLAB function.

In the report for `lpsolve`, view type information for a variable.

1. In the **MATLAB Source** pane, select `pivot`.
2. In the code pane, hold down **Ctrl** and pause over the input argument `i`.



Note On a Macintosh platform, use the **Command** key instead of **Ctrl**.

Disable Traceability

To produce a code generation report that does not include traceability:

- In a `coder.EmbeddedCodeConfig` object, set the `EnableTraceability` property to `false`.
- In the MATLAB Coder app, set **Enable code traceability** to `No`.

Polyspace Verification of C/C++ Code Generated by MATLAB Coder

To check for run-time errors in C/C++ code generated from MATLAB code, you can use Polyspace Code Prover. To check for defects, you can use Polyspace Bug Finder. If you have Polyspace and Embedded Coder, Polyspace is integrated into the MATLAB Coder workflow.

- In the MATLAB Coder app, you can run Polyspace analysis without additional setup.
- At the command line, after code generation with `codegen`, you can run Polyspace analysis on the generated code by providing the code generation output folder to `pslinkrun`.

Run Polyspace Analysis in the MATLAB Coder App

1. Generate standalone C/C++ code (a static library, dynamically linked library, or executable program).
2. On the **Generate Code** page, click **Polyspace**.
3. Select the options. See “Configure Advanced Polyspace Options in MATLAB Coder App” (Polyspace Code Prover).
4. Click **Run**.

   The app logs the analysis output on the **Polyspace Log** tab and opens the Polyspace user interface.

Run Polyspace Analysis on Code Generated by codegen

1. Create a `pslinkoptions` object for verification of code generated by MATLAB Coder.
2. As needed, change object properties:

   - In the `ResultDir` property, specify the name of the folder for the Polyspace results.
   - In the `VerificationMode` property, specify the Polyspace verification product.
3. Run the verification by using `pslinkrun`. Provide the `pslinkoptions` object and the folder that contains the generated code.
4. To view verification results, open the Polyspace user interface.

For example, suppose that you generated a static library for the MATLAB function `myFunction` and that the code generation output folder is `codegen/lib/myFunction`. To run Polyspace Code Prover on the generated code, use this code:

```
opts = pslinkoptions('codegen');
opts.ResultDir = 'polyspace';
opts.VerificationMode = 'CodeProver';
pslinkrun('-codegenfolder', 'codegen/lib/myFunction', opts);
polyspaceCodeProver('polyspace/myFunction.psprj');
```

You can also set the `VerificationMode` property to `'BugFinder'` and view verification results by using `polyspaceBugFinder`.

Review Analysis Results

In the **Results List** pane of the Polyspace user interface, review the run-time checks. See whether you can trace the issues back to the original MATLAB code. See “Interactively Trace Between MATLAB Code and Generated C/C++ Code” on page 91-14.

For example, an operation in the C code might overflow because Polyspace assumes an unbounded range for a function input. Consider specifying a constraint on the input and reanalyzing the code with Polyspace. See “Run Polyspace on C/C++ Code Generated from MATLAB Code” (Polyspace Code Prover).
