```
initStruct = struct(...
    'thermocpl',15.23,...
    'magFlow',79,...
    'posSwitch',false ...
    );

initStruct = Simulink.Parameter(initStruct);
```

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the Unit Delay block. The Model Data Editor highlights the row that corresponds to the **Initial condition** parameter of the block.

In the Model Data Editor, set the parameter value (**Value** column) to `initStruct`.

Click the **Show/refresh additional information** button. The parameter object, `initStruct`, appears in the data table as a row.

Use the **Data Type** column to set the data type of `initStruct` to `Bus: ComponentData`.

```
initStruct.DataType = 'Bus: ComponentData';
```

Set the **Change View** drop-down list to `Code`.

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to `initStruct`.

```
initStruct.StorageClass = 'ExportedGlobal';
```

Generate code from the example model.

```
### Starting build procedure for model: rtwdemo_init_struct_busobj
### Successful completion of build procedure for model: rtwdemo_init_struct_busobj
```

In the code generation report, view the file `rtwdemo_init_struct_busobj_types.h`. The code creates a structure type `ComponentData` whose fields use the data types in the bus object.

```
#ifndef DEFINED_TYPEDEF_FOR_ComponentData_
#define DEFINED_TYPEDEF_FOR_ComponentData_

typedef struct {
  real_T thermocpl;
  uint32_T magFlow;
  boolean_T posSwitch;
} ComponentData;
```

View the file `rtwdemo_init_struct_busobj.c`. The code creates a global variable to represent the tunable parameter object `initStruct`.

```
/* Exported block parameters */
ComponentData initStruct = {
  15.23,
  79U,
  0
} ;                                    /* Variable: initStruct
```

The model initialization function uses the structure fields to initialize the block states.

```
/* InitializeConditions for UnitDelay: '<Root>/Unit Delay' */
rtwdemo_init_struct_busobj_DW.UnitDelay_1_DSTATE = initStruct.thermocpl;
rtwdemo_init_struct_busobj_DW.UnitDelay_2_DSTATE = initStruct.magFlow;
rtwdemo_init_struct_busobj_DW.UnitDelay_3_DSTATE = initStruct.posSwitch;
```

To change the data type of a signal element, specify the new type in the bus object. The signal element in the model uses the new type. Before simulation and code generation, the parameter object `initStruct` casts the corresponding structure field to the new type.

Initialization of Signal, State, and Parameter Data in the Generated Code

Signal lines, block parameters, and block states in a model can appear in the generated code as data, for example, as global variables. By default, the code initializes this data before execution of the primary algorithm. To match the numerics of simulation in Simulink, the code generator chooses the initial values based on specifications that you make in the model.

By understanding how the generated code initializes data, you can:

- Model a system that reinitializes states during execution, which means that the application can restart the entire system.
- Store initial values in memory as variables, which can persist between execution runs. You can then overwrite these values before starting or restarting a system.
- Generate efficient code by eliminating storage for invariant initial values and by preventing the generation of code that unnecessarily or redundantly initializes data.

For basic information about initializing signals and states in a model, see “Initialize Signals and Discrete States” (Simulink) and “Load State Information” (Simulink).

Static Initialization and Dynamic Initialization

To initialize a data item such as a global variable, an application can use static or dynamic initialization.

- Static initialization occurs in the same statement that defines (allocates memory for) the variable. The initialization does not occur inside a function definition.

  The code can be more efficient because none of the generated model functions execute initialization statements.
- Dynamic initialization occurs inside a function. For each model or nonvirtual subsystem, the code generator typically creates one or more functions that are dedicated to initialization.

  The generated code or your code can restart a system by calling an initialization function during execution.

Real-World Ground Initialization Requiring Nonzero Bit Pattern

Each data item has a real-world ground value. This value can depend on the data type of the item. For example, for a signal whose data type is `double` or `int8`, the real-world ground value is zero. For an enumeration, the ground value is the default enumeration member.

For some kinds of data, to represent a real-world ground value, a computer stores zero in memory (all bits zero). However, for some other data, a computer stores a nonzero value in memory. This data includes, for example:

- Fixed-point data with bias. The code initializes such a data item to the stored integer value that, given the scaling and bias, represents real-world zero.
- An enumeration whose default member maps to an integer value other than zero. For example, if the default member is `High` with an underlying integer value of 3, the code initializes such a data item to `High`.

Initialization of Signal and State Data

In a model, you can control signal and state initial values through block parameters. For example, to set the initial value of a Unit Delay block, you use the **Initial condition** parameter. In some cases, you can also use the `InitialValue` property of a `Simulink.Signal` object. For most of these block parameters, the default value is `0`.

You can also initialize states by using State Writer blocks in Initialize Function subsystems and the **Initial states** model configuration parameter.

By default, the generated code dynamically initializes signal and state data (and other data, such as the model error status) in the generated initialization function. The function, named *`model`*`_initialize` by default, performs signal and state initialization operations in this order:

1. Initializes the signal and state data in the default generated structures, such as the DWork structure, to a stored value of zero.
2. Initializes additional signal and state data that are not in the default generated structures to the relevant real-world ground value.

   This initialization applies only to data that meet both of these criteria:

- The generated code defines (allocates memory for) the data.
- The data use a storage class other than `Auto` (the default storage class) or `Model default` (when the Code Mapping Editor specifies the `Default` storage class, the default setting).

For example, the code applies this operation to data items that use the storage class `ExportedGlobal`.

3. Initializes each signal and state to the real-world value that the model specifies, for example, through the **Initial condition** parameter of a Unit Delay block.
4. Initializes each state to the real-world value that you assign by using a State Writer block. The function performs this initialization only if you use an Initialize Function subsystem in the model.
5. Initializes each state to the real-world value that you specify with the configuration parameter **Initial states**.

After this initialization function executes, each data item has the last real-world value that the function assigned. For example, if you use a State Writer block to initialize a block state to `5` while also using the **Initial states** configuration parameter to initialize the same state to `10`, the state ultimately uses `10` as an initial value.

memset for Bulk Initialization

To initialize signal or state data items that have contiguous storage to a stored value of zero, the generated code can call `memset` in an initialization function. Data items that have contiguous storage include the DWork structure, arrays, or data items that use a multiword data type.

If your application requires it, you can prevent the generated code from using `memset` for initializing floating-point data to stored zero. See “Use memset to initialize floats and doubles to 0.0” (Simulink Coder).

Tunable Initial Values

You can configure the way that tunable block parameters, such as the **Gain** parameter of a Gain block, appear in the generated code. Most block parameters that set initial values (for example, **Initial condition**) are tunable. For example, the configuration parameter **Default parameter behavior** can determine whether the initial values appear in the generated code as inlined constants or as tunable global data. You can also use parameter objects and storage classes to control the representation of these initial values.

For tunable initial values, in the model initialization function, the right-hand side of the assignment statement is a global variable, structure field, or other data whose value you can change in memory.

To make initial values tunable in the generated code, see “Control Signal and State Initialization in the Generated Code” on page 32-220.

Initialization of Parameter Data

The generated code statically initializes parameter data to the values that you specify in Simulink.

To express the initial value of a tunable parameter (a global variable) as a mathematical expression involving system constants or other macros, which requires Embedded Coder, see “Initialization by Mathematical Expression (Embedded Coder)” (Simulink Coder).

Kinds of Parameter Data

These model elements appear in the generated code as parameter data:

- Tunable block parameters, such as the **Gain** parameter of a Gain block, when you set **Default parameter behavior** to `Tunable`. Each parameter appears as a field of a dedicated global structure.
- Some tunable block parameters when you set **Default parameter behavior** to `Inlined`. When the code generator cannot inline the value of a parameter as a literal number, the parameter appears as a field of a dedicated global `const` structure.
- `Simulink.Parameter` objects to which you apply a storage class or custom storage class that has an exported data scope. For example, the built-in storage class `ExportedGlobal` has an exported data scope, but the storage class `ImportedExtern` does not.

Initialization by Mathematical Expression (Embedded Coder)

You can set the value of a parameter object (such as `Simulink.Parameter`) to a mathematical expression involving numbers, MATLAB variables, and other parameter objects. See “Set Variable Value by Using a Mathematical Expression” (Simulink).

If you use this technique with Embedded Coder, you can generate code that initializes the corresponding parameter data (global variable) by using the specified expression. For an example, see “Initialize Parameter Value From System Constant or Other Macro

(Embedded Coder)” on page 32-129. For general information, including limitations, see “Code Generation of Parameter Objects With Expression Values” (Simulink Coder).

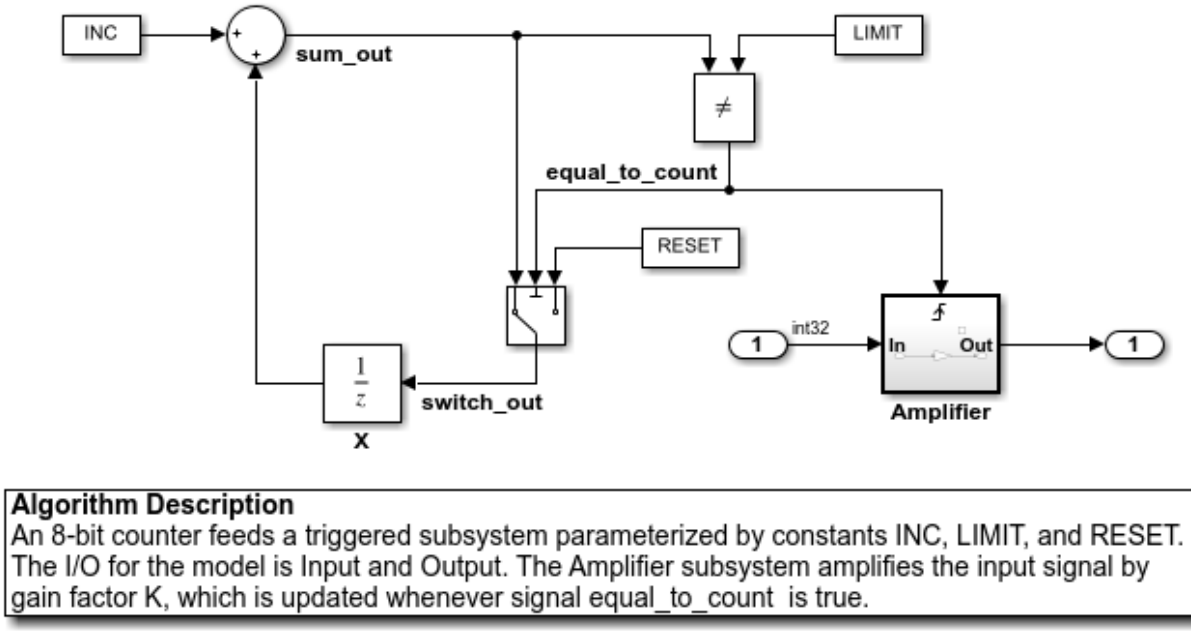
Data Initialization in the Generated Code

This example shows how the generated code initializes signal, state, and parameter data.

Explore Example Model

Open the example model, `rtwdemo_rtwintro`.

```
open_system('rtwdemo_rtwintro')
```



In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **States** tab. For the Unit Delay block state, the **Initial Value** is set to `0`, the default, which means the initial value of the state is zero. The state is named `X`.

Set **Initial Value** to a nonzero number, for example, `5`.

```
set_param('rtwdemo_rtwintro/X','InitialCondition','5')
```

Set the **Change view** drop-down list to `Code`.

In the data table, set **Storage Class** to `ExportedGlobal`. With this setting, the block state appears in the generated code as a separate global variable.

```
set_param('rtwdemo_rtwintro/X','StateStorageClass','ExportedGlobal')
```

In the model, open the `Amplifier` subsystem, which is a triggered subsystem.

In the Model Data Editor, inspect the **Parameters** tab and set the **Change view** drop-down list to `Design`. To set and inspect initial values of signals and states, you can use the **Parameters** tab instead of the **States** tab.

The Model Data Editor shows that for the Outport block, the **Initial output** (`InitialOutput`) parameter is set to `0`, the default. This subsystem output requires an initial value because the subsystem executes conditionally. Leave the initial value at the default.

In the model, clear **Configuration Parameters > Signal storage reuse**. When you clear this setting, signal lines appear in the generated code as fields of a generated structure whose purpose is to store signal data. This representation of the signals makes it easier to see how the code generator initializes data.

```
set_param('rtwdemo_rtwintro','OptimizeBlockIOStorage','off')
```

In the model, inspect the configuration parameter **Configuration Parameters > Optimization > Default parameter behavior**. The configuration parameter is set to `Inlined`, which means block parameters, including initial values, appear in the generated code as inlined literals or as `const` data.

Navigate to the root level of the model.

In the Model Data Editor, click the **Show/refresh additional information** button.

Near the **Filter contents** box, click the **Filter using selection** button.

In the model, click the Constant block labeled `INC`. The Model Data Editor shows that the **Constant value** (`Value`) parameter of the block is set to `INC`. `INC` is a MATLAB variable in the base workspace.

For `INC`, set the value in the **Value** column to `Simulink.Parameter(uint8(1))`. MATLAB converts `INC` to a `Simulink.Parameter` object.

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to `INC`. With this setting, the generated code defines `INC` as a global variable. Concerning initialization, `INC` is an item of parameter data.

```
INC = Simulink.Parameter(INC);
INC.StorageClass = 'ExportedGlobal';
```

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_rtwintro');
```

```
### Starting build procedure for model: rtwdemo_rtwintro
### Successful completion of build procedure for model: rtwdemo_rtwintro
```

In the generated file `rtwdemo_rtwintro.c`, outside the definition of a function, the code statically initializes the parameter data `INC`. The value of `INC` is `1`.

```
file = fullfile('rtwdemo_rtwintro_grt_rtw','rtwdemo_rtwintro.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T INC = 1U;',1,1)
```

```
/* Exported block parameters */
uint8_T INC = 1U;                      /* Variable: INC
```

In the same file, inspect the definition of the `rtwdemo_rtwintro_initialize` function. First, the function uses `memset` to initialize the internal signals in the model to a stored value of `0`.

```
rtwdemodbtype(file,'/* block I/O */','sizeof(B_rtwdemo_rtwintro_T));',1,1)
```

```
  /* block I/O */
  (void) memset(((void *) &rtwdemo_rtwintro_B), 0,
                sizeof(B_rtwdemo_rtwintro_T));
```

The function then initializes the Unit Delay state, `X`, to a ground value. In this case, the ground value is zero.

```
rtwdemodbtype(file,'/* exported global states */','X = 0U;',1,1)
```

```
  /* exported global states */
  X = 0U;
```

The function also initializes other data, including the root-level inputs and outputs (Inport and Outport blocks), to ground values.

```
rtwdemodbtype(file,'/* external inputs */','Amplifier_Trig_ZCE = POS_ZCSIG;',1,1)
```

```
  /* external inputs */
  rtwdemo_rtwintro_U.Input = 0;

  /* external outputs */
  rtwdemo_rtwintro_Y.Output = 0;
  rtwdemo_rtwintro_PrevZCX.Amplifier_Trig_ZCE = POS_ZCSIG;
```

The function then initializes `X` to the value that you specified in the **Initial condition** block parameter.

```
rtwdemodbtype(file,'/* InitializeConditions for UnitDelay: ''<Root>/X'' */',...
    'X = 5U;',1,1)
```

```
  /* InitializeConditions for UnitDelay: '<Root>/X' */
  X = 5U;
```

Finally, the function initializes the output of the `Amplifier` subsystem.

```
rtwdemodbtype(file,'SystemInitialize for Triggered SubSystem',...
    'End of SystemInitialize for SubSystem',1,1)
```

```
  /* SystemInitialize for Triggered SubSystem: '<Root>/Amplifier' */
  /* SystemInitialize for Outport: '<Root>/Output' incorporates:
   *  Outport: '<S1>/Out'
   */
  rtwdemo_rtwintro_Y.Output = 0;
```

Inspect Difference Between Stored Value and Real-World Value

For some data, even if the real-world initial value is zero, a computer stores a nonzero value in memory. To observe this difference, apply a slope-bias fixed-point data type to the block state, X. To run this example, you must have Fixed-Point Designer™.

In the Model Data Editor, inspect the **Signals** tab.

In the model, click the output signal of the Switch block, `switch_out`.

Use the **Data Type** column of the Model Data Editor to set the signal data type to `fixdt(1,16,1,3)`. This expression represents a fixed-point data type with a slope of 1 and a bias of 3.

```
set_param('rtwdemo_rtwintro/Switch','OutDataTypeStr',...
    'fixdt(1,16,1,3)')
```

In the model, select **View > Property Inspector** and click the Sum block.

In the Property Inspector, under **Signal Attributes**, clear **Require all inputs to have the same data type**.

```
set_param('rtwdemo_rtwintro/Sum','InputSameDT','off')
```

To prevent compilation errors on different platforms, select the model configuration parameter **Generate code only**. This setting causes the model to generate only code.

```
set_param('rtwdemo_rtwintro','GenCodeOnly','on')
```

Generate code from the model.

```
rtwbuild('rtwdemo_rtwintro')
```

```
### Starting build procedure for model: rtwdemo_rtwintro
### Successful completion of code generation for model: rtwdemo_rtwintro
```

The model initialization function first initializes X to a real-world ground value, `0`. Due to the slope-bias data type, which has bias 3, this real-world value corresponds to a stored value of `-3`.

```
rtwdemodbtype(file,'/* exported global states */','X = -3;',1,1)
```

```
  /* exported global states */
  X = -3;
```

The function then initializes X to the real-world initial value that you specified in the **Initial condition** block parameter, 5. This real-world value corresponds to a stored value of 2.

```
rtwdemodbtype(file,'/* InitializeConditions for UnitDelay: ''<Root>/X'' */',...
    'X = 2;',1,1)
```

```
  /* InitializeConditions for UnitDelay: '<Root>/X' */
  X = 2;
```

Modeling Goals

Goal	More Information
Explicitly model initialization behavior by using blocks	You can explicitly model initialization and reset behavior by using Initialize Function and Reset Function subsystems. In the subsystems, use State Writer blocks to calculate and assign an initial value for a state dynamically. The corresponding code appears in the model initialization function. For more information, see “Generate Code That Responds to Initialize, Reset, and Terminate Events” on page 10-2.
Prevent generation of code that explicitly initializes data to zero	If your application environment already initializes global variables to zero, for more efficient code, you can prevent the generation of statements that explicitly initialize global variables to zero. This optimization applies only to signals and states whose initial values are stored in memory as zero. For example, the code generator does not apply the optimization to: • Data for which you specify a nonzero initial value by using a block parameter. • Data whose real-world initial value is zero but whose corresponding stored value is not zero. • Enumerated data whose default member maps to a nonzero integer. The optimization requires Embedded Coder. For more information, see “Remove Initialization Code” on page 70-4.

Goal	More Information
Generate code that imports data from your external code	You can generate code that reuses (imports) data that your external code defines. For example, you can apply the storage class `ImportedExtern` to a signal line, block state, or parameter object. For imported data: • The generated code does not initialize parameter data. Your code must initialize imported parameter data. • The generated initialization functions dynamically initialize some signal and state data. Unlike data that the generated code allocates, the code does not initialize imported signal or state data to a stored value of zero. Instead, the code immediately initializes the data to the real-world value that you specify in Simulink. For more information, including how to prevent the generated code from initializing imported data, see “Exchange Data Between External Calling Code and Generated Code” (Simulink Coder).

Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box

You can use the Model Parameter Configuration dialog box to declare numeric MATLAB variables in the base workspace as tunable parameters. You can select code generation options, such as storage class, for each tunable parameter.

However, it is a best practice to instead use parameter objects to declare tunable parameters. Do not use the Model Parameter Configuration dialog box to select parameter objects in the base workspace. To use parameter objects, instead of the Model Parameter Configuration dialog box, to declare tunable parameters, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.

Note You cannot use the Model Parameter Configuration dialog box to declare tunable parameters for a referenced model. Use `Simulink.Parameter` objects instead.

Declare Existing Workspace Variables as Tunable Parameters

Use the Model Parameter Configuration dialog box to declare existing workspace variables as tunable parameters for a model.

1. In the Configuration Parameters dialog box, on the **Optimization** pane, click **Configure**.
2. In the Model Parameter Configuration dialog box, under **Source list**, select a method to populate the list of available workspace variables.
   - Select `MATLAB workspace` to view numeric variables that are defined in the base workspace.
   - Select `Referenced workspace variables` to view only the numeric variables in the base workspace that the model uses. Selecting this option begins a diagram update and a search for used variables, which can take time for a large model.
3. In the Model Parameter Configuration dialog box, under **Source list**, select one or more workspace variables.
4. Click **Add to table**. The variables appear as tunable parameters under **Global (tunable) parameters**, and appear in italic font under **Source list**.
5. Optionally, select a parameter under **Global (tunable) parameters**, and adjust the code generation settings for the parameter. For more information about adjusting the

code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 32-248

6 Click **OK** to apply your selection of tunable parameters and close the dialog box.

Declare New Tunable Parameters

Use the Model Parameter Configuration dialog box to declare new tunable parameters. You can use this technique to declare the names of tunable parameters, and to adjust their code generation settings, before you create the corresponding workspace variables.

1 In the Configuration Parameters dialog box, on the **Optimization > Signals and Parameters** pane, click **Configure**.

2 In the Model Parameter Configuration dialog box, under **Global (tunable) parameters**, click **New**.

3 Under the **Name** column, specify a name for the new tunable parameter.

4 Optionally, adjust the code generation settings for the new parameter. For more information about adjusting the code generation options for tunable parameters, see “Set Tunable Parameter Code Generation Options” on page 32-248

5 Click **OK** to apply your changes and close the dialog box.

Set Tunable Parameter Code Generation Options

To set the properties of tunable parameters listed under **Global (tunable) parameters** in the Model Parameter Configuration dialog box, select a parameter and specify a storage class and, optionally, a storage type qualifier.

Property	Description
Storage class	Select one of the following to use for code generation: • `Model default` • `ExportedGlobal` • `ImportedExtern` • `ImportedExternPointer` For more information about tunable parameter storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.
Storage type qualifier	For variables with a storage class other than `Auto`, you can add a qualifier (such as `const` or `volatile`) to the generated storage declaration. To do so, you can select a predefined qualifier from the list, or add qualifiers not in the list by typing them in. The code generator does not check the storage type qualifier for validity, and includes the qualifier text in the generated code without checking syntax .

Programmatically Declare Workspace Variables as Tunable Parameters

Tune Parameters from the Command Line

When parameters are MATLAB workspace variables, the Model Parameter Configuration dialog box is the recommended way to see or set the properties of tunable parameters. In addition to that dialog box, you can also use MATLAB `get_param` and `set_param` commands.

Note You can also use `Simulink.Parameter` objects for tunable parameters. See “Create Tunable Calibration Parameter in the Generated Code” on page 32-121 for details.

The following commands return the tunable parameters and corresponding properties:

- `get_param(gcs,'TunableVars')`
- `get_param(gcs,'TunableVarsStorageClass')`
- `get_param(gcs,'TunableVarsTypeQualifier')`

The following commands declare tunable parameters or set corresponding properties:

- `set_param(gcs,'TunableVars',str)`

  The argument `str` (character vector) is a comma-separated list of variable names.
- `set_param(gcs,'TunableVarsStorageClass',str)`

  The argument `str` (character vector) is a comma-separated list of storage class settings.

  The valid storage class settings are

  - `Auto`
  - `ExportedGlobal`
  - `ImportedExtern`
  - `ImportedExternPointer`
- `set_param(gcs,'TunableVarsTypeQualifier',str)`

  The argument `str` (character vector) is a comma-separated list of storage type qualifiers.

The following example declares the variable `k1` to be tunable, with storage class `ExportedGlobal` and type qualifier `const`. The number of variables and number of specified storage class settings must match. If you specify multiple variables and storage class settings, separate them with a comma.

```
set_param(gcs,'TunableVars','k1')
set_param(gcs,'TunableVarsStorageClass','ExportedGlobal')
set_param(gcs,'TunableVarsTypeQualifier','const')
```

Share Data Between Code Generated from Simulink, Stateflow, and MATLAB

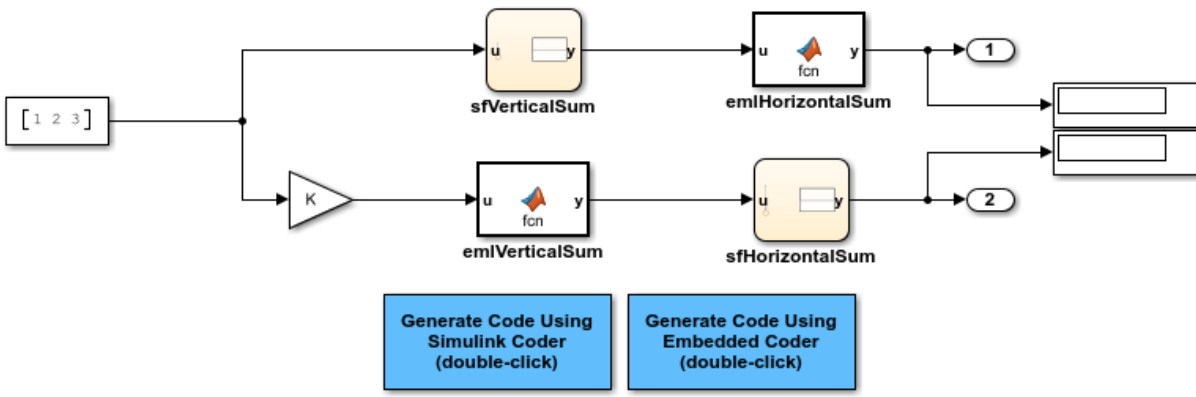
Stateflow and MATLAB Coder can fully define their data definitions, or they can inherit them from Simulink. Data definition capabilities include:

- Inheriting input/output data types and sizes from Simulink.
- Parameterized data types and sizes. That is, data type and size may be specified as a function of another data's type and size, e.g., `type(y)=type(u)` and `size(y)=size(u)`.
- Inferred output size and type from Simulink via signal attribute back propagation.
- Parameter scoped data, which allows referencing Simulink parameters in Stateflow and MATLAB.

Open Example Model

Open the example model `rtwdemo_dynamicio`.

```
open_system('rtwdemo_dynamicio')
```



Instructions

1. Compile the model (**Simulation > Update Diagram**) and note the displayed signal types and sizes.
2. Change the data type and/or size of the Constant block and recompile the model. Note that the attributes of the signals automatically adapt to the Constant block specification.
3. Generate and inspect code using the blue buttons in the model. Note that K is shared by the Gain and sfVerticalSum block.

Notes

- The data type and size of Stateflow and MATLAB data is inherited from Simulink.
- The Gain block and the Stateflow chart sfVerticalSum share the Simulink parameter K, which is defined in the MATLAB workspace as a Simulink.Parameter with `Model default` storage class (i.e., `rtP.K` in the generated code).

Data Definition and Declaration Management in Embedded Coder

Control Placement of Global Data Definitions and Declarations in Generated Files

The generated code can create standard, global structure variables whose fields represent the signal, state, and parameter data in a model. With storage classes, you can configure data to appear in the code as separate global variables or custom global structures. For information about the standard data structures, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50 and “How Generated Code Exchanges Data with an Environment” on page 32-33. For information about storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69.

You can control the file placement of the variable definitions and declarations. Use the information in the table.

Goal	Details and Techniques
Generate a variable that external code can use	Apply a storage class with exported data scope, such as `ExportToFile`. The generated code declares the variable in a file that your code can include (`#include`). To generate an `extern` declaration in *`model`*`.h`, consider using the storage class `ExportedGlobal`. Alternatively, to place the declaration in a file whose name you can specify, choose one of these techniques: • To aggregate multiple variable declarations into one or more specific header files by default, apply a storage class such as `ExportToFile` to a category of data by using the Code Mapping Editor. As you add blocks and signals to the model, new data items are declared in the files that you specify. • To explicitly specify the placement for an individual data item, directly apply a storage class such as `ExportToFile` and specify a header file name by using the **Header file** custom attribute. To configure multiple data items in a list that you can search, sort, and filter, use the Model Data Editor (see “Configure Data Properties by Using the Model Data Editor” (Simulink)). See “Exchange Data Between External Calling Code and Generated Code” on page 53-114.

Goal	Details and Techniques
Generate code that uses a variable defined by external code	Apply a storage class with imported data scope, such as `ImportFromFile`, to a data element in a model that represents the variable. Then, the generated code does not define the variable, but instead includes (`#include`) an external header file whose name you can specify. The generated algorithm (for example, the model `step` function) reads and writes to the variable. Alternatively, if you do not have an external declaration header file or do not want the generated code to include a header file, apply the storage class `ImportedExtern`. Then, the generated code declares the variable in *`model`*`_private.h`. See “Exchange Data Between External Calling Code and Generated Code” on page 53-114.

Goal	Details and Techniques
• Reduce the size of a generated file by creating multiple smaller files • Organize data into different files to make generated code easier to understand	Depending on the setting of **Configuration Parameters > File packaging format**, generated files such as *`model`*`.c` and *`model`*`_data.c` can contain many definitions of global variables. Corresponding header files can contain many declarations. • To make *`model`*`.c` smaller, consider setting **File packaging format** to `Modular` or `Compact (with separate data file)`. Then, the generated code defines the standard structures that represent tunable and constant parameter data in *`model`*`_data.c` instead of *`model`*`.c`. • To place different categories of data (for example, global parameters, block states, and internal signals) in specific files by default, use the Code Mapping Editor. For each category of data, use a storage class such as `ExportToFile` and specify the custom attribute **Header file**. See “Configure Default Code Generation for Data” on page 31-8. • For precise control over the file placement of data, apply storage classes such as `ExportToFile` to individual data items. Use the custom attributes of the storage class, such as **Definition file** and **Header file**, to specify file placement for each data item. To configure multiple data elements at once, you can use the Model Data Editor. For an example, see “Definition and Declaration of Signal Data” on page 24-9.

Goal	Details and Techniques
Combine multiple files into a single file	• Consider setting the model configuration parameter **File packaging format** to `Compact`. Then, the code generator does not create the *`model`*`_data.c` file. Instead, the definitions of the standard structures that store tunable and constant parameter data appear in *`model`*`.c`. • When you apply a custom storage class such as `ExportToFile` to data elements, leave the custom attributes **Definition file** and **Header file** blank, the default value. Also, set the model configuration parameter **Data definition** to `Data defined in source file`. Then, the data definitions appear in *`model`*`.c` with the definitions of other global data.

Goal	Details and Techniques
Separate data definitions from function definitions	By default, the generated file that defines the entry-point functions for a model or subsystem also defines the data for that model or subsystem. When you frequently make changes to data, especially initial values for tunable parameters, the changing source code files can impede verification and make change management more difficult. To separate the data from the functions: • Consider setting the model configuration parameter **File packaging format** to a value that results in the generation of the separate data file *`model`*`_data.c`. Then, the definitions of the standard structures that store tunable and constant parameter data appear in this file instead of in *`model`*`.c`. • Apply storage classes such as `ExportToFile` to data elements by using the Code Mapping Editor and the Model Data Editor. Use the custom attributes of the custom storage class, such as **Definition file** and **Header file**, to specify file placement. For more information, see “Configure Default Code Generation for Data” on page 31-8 and “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28.
Isolate data definitions in separate files for component-based, team-oriented model development	See “Organize Data to Support Component-Based, Team-Oriented Model Development” on page 33-9.

Goal	Details and Techniques
Aggregate definitions of variant control parameters (`#define` macros) into a single header file	As described in “Generate Preprocessor Conditionals for Variant Systems” on page 25-35, a variant control parameter is a parameter object such as `Simulink.Parameter`. You apply a storage class that makes the object appear in the generated code as a macro. To control the file placement, choose one of these techniques: • For each variant control parameter that uses the storage class `Define`, set the **Header file** property to the same value. To configure these objects in a list that you can search, sort, and filter, you can use the Model Data Editor **Parameters** tab. For an example, see “Generate Variant Control Macros in Same Header File” on page 25-37. • Create one or more storage classes that represent variant control parameters. In the Custom Storage Class Designer, you can set **Header file** to a value that applies to all of the variant control parameters that use the storage class. With this technique, you do not need to manually specify a header file for each variant control parameter. For more information, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 36-35.

Organize Data to Support Component-Based, Team-Oriented Model Development

Depending on your model configuration, data definitions can appear aggregated in large generated files. In a system of components (subsystems or referenced models), you can separate and organize the data definitions into manageable, meaningful files based on the component hierarchy.

Goal	Technique
Establish ownership of global data by placing the data definitions with the code generated for specific components	When you divide a system into components by using referenced models and atomic subsystems, by default, global data is typically defined by the code generated for the top component in the hierarchy. Global data includes parameters, signals, and states to which you apply storage classes (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81). Instead, you can place global data definitions with other components in the hierarchy. For an example involving referenced models, see “Establish Data Ownership in a System of Components” on page 33-15. • To place a data definition with the code generated for a referenced model, use a built-in storage class such as `ExportToFile`, or a storage class that you create in a package, and set the **Owner** property to the name of the referenced model. To use **Owner** in a model, you must select the model configuration parameter **Use owner from data object for data definition placement**. The default setting for this parameter, cleared, means the code generator ignores the setting that you specify for **Owner**. If only one referenced model uses a parameter object, consider storing the object in the model workspace of that model. Then, the code generated for

Goal	Technique
	that model defines the data. You do not need to specify an owner (**Owner**) for the object. • In an atomic subsystem, use a storage class such as `ExportToFile` and explicitly specify the name of the definition file by using the **Definition file** custom attribute. However, you cannot place the definition file with the source files that belong to the subsystem. Instead, the definition file that you specify appears in the folder generated for the model.
For an atomic subsystem, place the standard data structures for the subsystem with the subsystem code	By default, the standard data structures for an atomic subsystem appear as substructures of the data structures for the entire model. To generate separate data structures for a subsystem, select the **Function with separate data** parameter in the subsystem block. Then, the subsystem data appear in separate structure variables that the subsystem code defines. See “Generate Modular Function Code for Nonvirtual Subsystems” on page 39-64.

Specify Default Placement

When you create data in a model by adding blocks and signal lines, by default, the data definitions appear in *`model`*`.c`. To specify a different default placement, use these tools and parameters:

- The model configuration parameter **File packaging format**. The setting that you choose determines whether the code generator places the standard structures that store tunable and constant parameter data in *`model`*`_data.c` instead of *`model`*`.c`. See “File packaging format”.

- The Code Mapping Editor. For each category of model data, you can specify a default storage class, which controls file placement. For example, apply the storage class `ExportToFile` to a data category and, in the Property Inspector, use the **DefinitionFile**,**HeaderFile**, and **Owner** custom attributes to control file placement.
- The model configuration parameters **Data definition** and **Data declaration**. These configuration parameters specify the default file placement for data items to which you apply storage classes.

  - These configuration parameters do not affect data items to which you apply the storage classes `ExportedGlobal`, `ImportedExtern`, and `ImportedExternPointer`.
  - If you apply a storage class that explicitly specifies definition and declaration files for a data element, those specifications override the **Data definition** and **Data declaration** configuration parameters.

  For more information, see “Data definition” and “Data declaration”.
- The subsystem block parameter **Function with separate data**. When you select this parameter, the standard structures that store the subsystem data, such as the DWork structure, appear as separate structure variables. By default, the variable definitions appear in the source file that defines the subsystem execution function. See “Generate Modular Function Code for Nonvirtual Subsystems” on page 39-64.

Override Default Placement for Individual Data Items

For an individual data item, to override the default file placement, use the Model Data Editor to apply a storage class directly. For example, to make a data item appear in the generated code as a global variable, apply the custom storage class `ExportToFile`. Then, use the **Definition file**, **Header file** custom attributes to control file placement. To apply storage classes directly, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28.

Prevent Name Clashes by Configuring Data Item as static

To apply the C keyword `static` to a global variable, which can help you avoid name clashes by limiting the scope of the variable name to the file that defines the variable, choose one of these techniques:

- Apply the built-in storage class `FileScope`. For more information, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69.

- If `FileScope` does not satisfy your requirements, create your own custom storage class by using the Custom Storage Class Designer. In the Designer, set **Data scope** to `File` or `Auto`.
  - With `File`, the data element appears in the code as a `static` global variable.
  - With `Auto`, the code generator first attempts to represent the data element with a local variable in a function. If this attempt fails, the code generator uses a `static` global variable.

  For an example that shows how to create your own custom storage class by using the Designer, see “Create and Apply a Custom Storage Class” on page 36-35.

You cannot apply `static` to the standard data structures such as the DWork structure.

To access `static` data, you can configure the generated code to include an interface such as an `a2l` (ASAP2) file. For more information, see “Export ASAP2 File for Data Measurement and Calibration” on page 58-2. To place the data in a specific memory location by including pragmas or other decorations in the generated code, create your own memory section and custom storage class. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2.

Code Generation Impact of Storage Location for Parameter Objects

You can create a parameter object (such as `Simulink.Parameter`) in the base workspace, a model workspace, or a data dictionary. However, when you apply a storage class or custom storage class to the object, the location of the object can impact the file placement of the corresponding data definition in the generated code. See “Code Generation Impact of Storage Location for Parameter Objects” on page 32-130.

Specify Default #include Syntax for Data Header Files

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28). You then use the **Header file** custom attribute to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify **Header file**, you can omit delimiters (" or <>) and use only the file name. You can then control the default delimiters

that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters** > **Code Generation** > **Code Placement** > **#include file delimiters** to `#include <header.h>`.

Establish Data Ownership in a System of Components

This example shows how to establish ownership of global data in the code generated from a system of components (referenced models).

When you create a global variable in the generated code by applying a storage class to a data element in a referenced model (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81), under certain conditions, the code generator places the variable definition with the code generated from the top model in the hierarchy. This default placement can make it more difficult to determine which component is responsible for the data and to manage code changes in a team-based development environment.

To establish ownership of a global variable by placing the definition with the code generated from the relevant component, apply a storage class such as `ExportToFile` and specify the **Owner** custom attribute. Alternatively, for parameter objects such as `Simulink.Parameter` that you use in only one component, you can establish ownership by storing the object in a model workspace instead of the base workspace or a data dictionary.

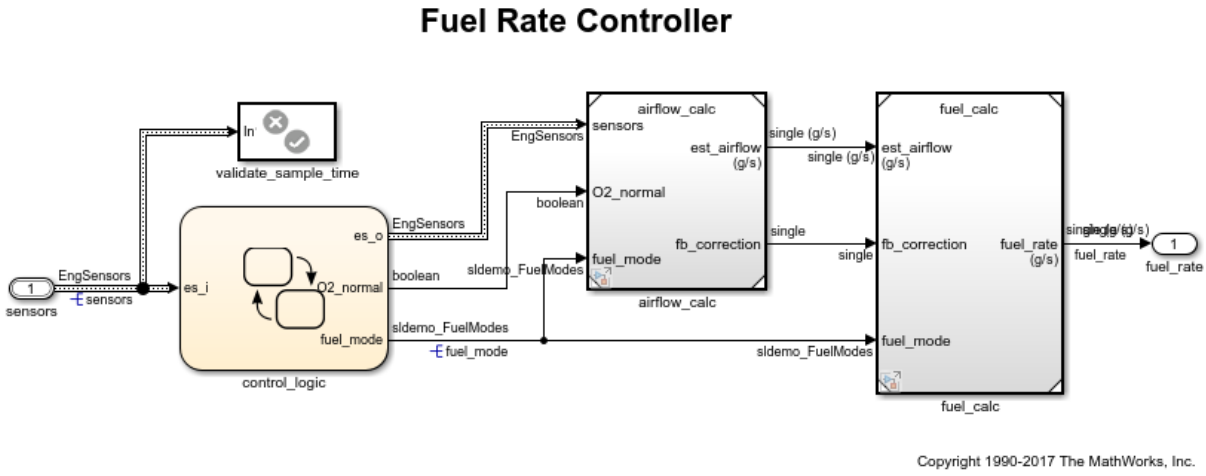
Explore Example Model

Copy the script file `prepare_sldemo_fuelsys_dd_ctrl.m` to your current folder.

```
[~, ~] = copyfile(fullfile(matlabroot,'examples','ecoder','main','prepare_sldemo_fuelsy
    'prepare_sldemo_fuelsys_dd_ctrl.m','f');
```

Run the copy of the script in your current folder. The script opens the model `sldemo_fuelsys_dd_controller` and prepares it for this example.

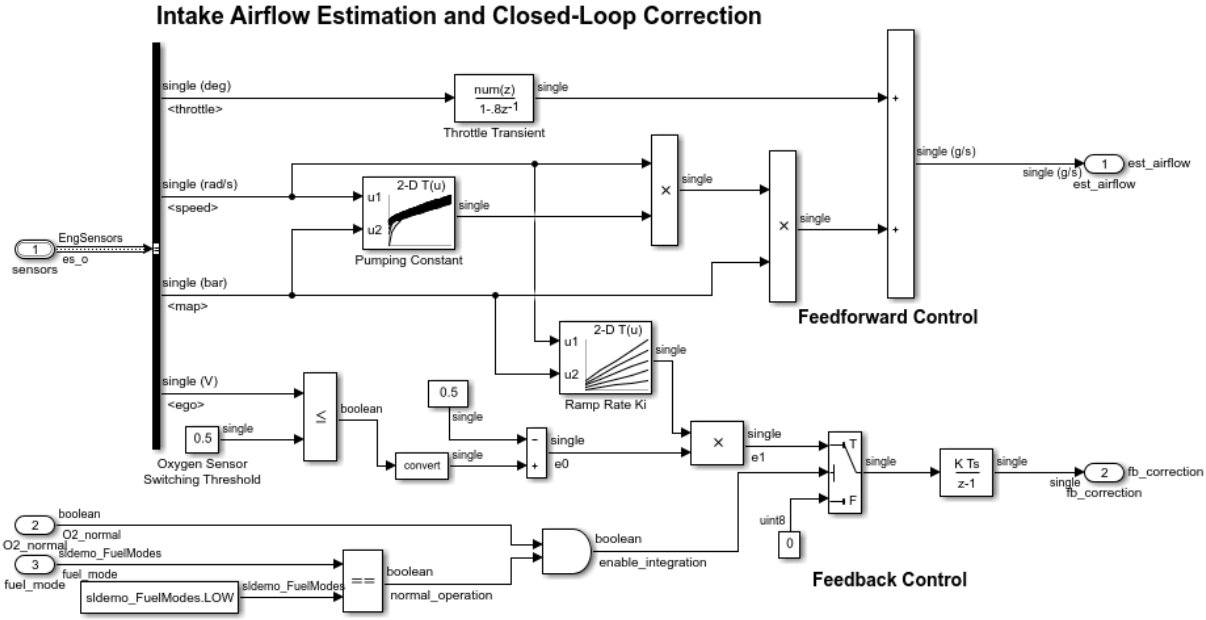
```
prepare_sldemo_fuelsys_dd_ctrl
open_system('sldemo_fuelsys_dd_controller')
```



This controller model contains two component models, `airflow_calc` and `fuel_calc`. The two outputs of `airflow_calc`, `est_airflow` and `fb_correction`, are inputs of `fuel_calc`.

Open the `airflow_calc` model.

```
open_system('airflow_calc')
```



In this model, select **View > Model Data Editor**.

In the Model Data Editor, set the **Change view** drop-down list to `Code`.

In the model, select the upper Outport block.

In the Model Data Editor, inspect the value in the **Storage Class** column. The signal that this block represents, `est_airflow`, uses the storage class `ExportToFile`. With this setting, the signal appears in the generated code as a global variable. The Outport block labeled `fb_correction` also uses this setting.

In the Model Data Editor, select the **Parameters** tab and click the **Show/refresh additional information** button. The Model Data Editor now shows information about workspace variables and objects, such as `Simulink.Parameter` objects, that the model uses to set block parameter values.

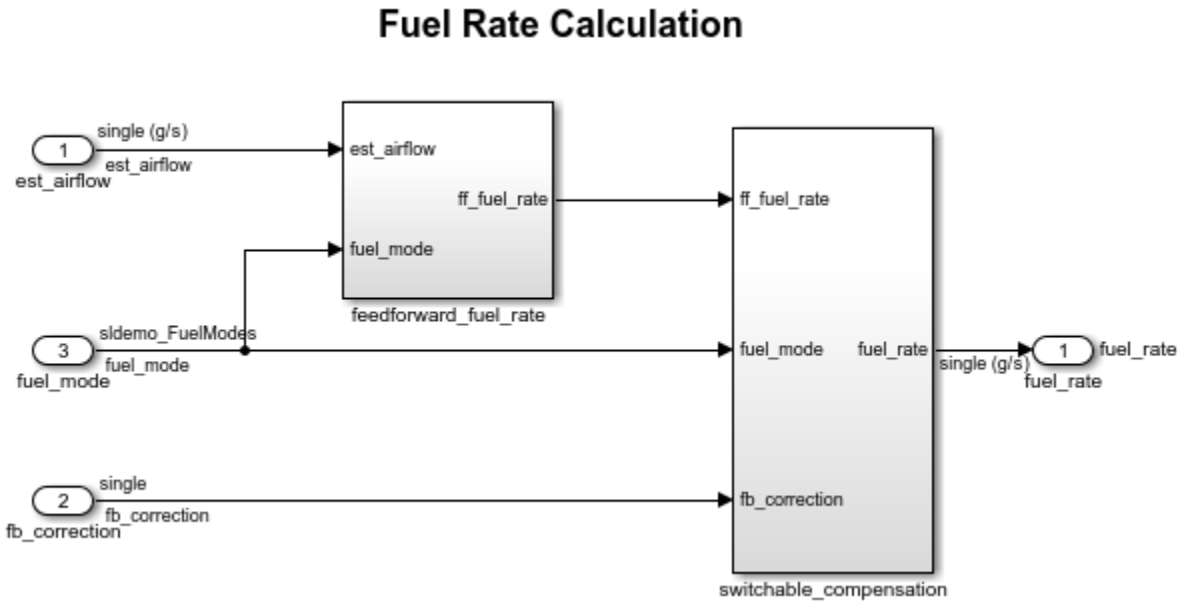
In the **Filter contents** box, enter `numerator`. The `Simulink.Parameter` object `numerator_param`, which is in the base workspace, sets the value of the **Numerator** parameter in the Discrete Filter block labeled `Throttle Transient`. The object uses the storage class `ExportToFile`.

Select the **Signals** tab.

In the **Filter contents** box, enter `e0`. The signal `e0`, which is internal to the `airflow_calc` component, also uses `ExportToFile`. The signal is internal because it is not a root-level input or output of the model.

Open the `fuel_calc` model.

```
open_system('fuel_calc')
```



In the Model Data Editor for this model, on the **Inports/Outports** tab, set **Change view** to `Code`. The Inport blocks `est_airflow` and `fb_correction` use the same storage class, `ExportToFile`, as the corresponding Outport blocks in `airflow_calc`. The Outport block labeled `fuel_rate` also uses `ExportToFile`.

Generate and Inspect Code

Generate code from the controller model, `sldemo_fuelsys_dd_controller`.

```
rtwbuild('sldemo_fuelsys_dd_controller')
```

```
### Starting build procedure for model: airflow_calc
### Successful completion of build procedure for model: airflow_calc
### Starting build procedure for model: fuel_calc
### Successful completion of build procedure for model: fuel_calc
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

In the code generation report, under **Referenced Models**, click the hyperlink to inspect the code generated for `airflow_calc`.

The file `airflow_calc.c` defines the global variable that represents the signal `e0`. Because the blocks that write to and read from `e0` exist only in `airflow_calc`, the code generator assumes that this component owns the signal.

```
file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
    'real32_T e0;',1,1)
```

```
/* Definition for custom storage class: ExportToFile */
real32_T e0;
```

In the code generation report, return to the code generated for `sldemo_fuelsys_dd_controller`.

The file `sldemo_fuelsys_dd_controller.c` defines the other global variables.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,...
    '/* Definition for custom storage class: ExportToFile */',...
    'real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1);
```

```
/* Definition for custom storage class: ExportToFile */
real32_T est_airflow;
real32_T fb_correction;
real32_T fuel_rate;
real32_T numerator_param[2] = { 0.01F, -0.01F } ;
```

Because the signals `est_airflow` and `fb_correction` pass between the two components and through the top-level controller model, the code generator assumes that `sldemo_fuelsys_dd_controller` owns the signals. The code generator makes a similar assumption about `fuel_rate`. Because the parameter object `numerator_param`

exists in the base workspace, any model in the hierarchy can use the object. Therefore, the code generator assumes that `sldemo_fuelsys_dd_controller` owns the parameter.

You can configure each shared signal and the parameter object so that the corresponding variable definition appears in the code generated for the relevant component.

Configure Data Ownership

In this example, you configure code generation settings so that:

- The code generated for the `airflow_calc` model defines the signals that pass between the two components, `est_airflow` and `fb_correction`.
- The code generated for `airflow_calc` defines the parameter data, `numerator_param`.
- The code generated for `fuel_calc` defines the output signal that it calculates, `fuel_rate`.

In the `airflow_calc` model, select **View > Property Inspector**.

In the Model Data Editor, select the **Inports/Outports** tab.

Find the row that corresponds to the Outport block `est_airflow`.

In the row, click the icon in the left column. The Property Inspector shows the properties of the Outport block.

In the Property Inspector, under **Code**, set **CoderInfo.CustomAttributes.Owner** to `airflow_calc`. The code generator places the definition of the global variable with the code generated for `airflow_calc`.

For `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`.

Select the **Parameters** tab.

Find the row that corresponds to the parameter object, `numerator_param`.

In the row, double-click the icon in the left column. The Model Explorer opens and displays the properties of `numerator_param`.

In the **Model Hierarchy** pane, expand the **airflow_calc** node so that you can see the subordinate **Model Workspace** node.

Use the Model Explorer to move `numerator_param` from the base workspace to the `airflow_calc` model workspace. For example, in the **Model Hierarchy** pane, select **Base Workspace**. Then, drag `numerator_param` from the **Contents** pane to the **Model Workspace** node in the **Model Hierarchy** pane. With this change, the code generator assumes that `airflow_calc` owns `numerator_param`, and places the variable definition in the code generated for `airflow_calc`.

In the `fuel_calc` model, select **View > Property Inspector**.

For the Inport blocks `est_airflow` and `fb_correction`, use the Model Data Editor and the Property Inspector to set **Owner** to `airflow_calc`. With this configuration, the `fuel_calc` code does not define the variables.

For the Outport block, use the Model Data Editor and the Property Inspector to set **Owner** to `fuel_calc`.

Alternatively, to configure the data in the models, use these commands at the command prompt:

```
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow','SignalName','est_airflow')
set_param('airflow_calc/est_airflow','SignalObject',copy(temp))

set_param('airflow_calc/fb_correction','SignalName','fb_correction')
set_param('airflow_calc/fb_correction','SignalObject',copy(temp))

mdlwks = get_param('airflow_calc','ModelWorkspace');
assignin(mdlwks,'numerator_param',copy(numerator_param));

portHandles = get_param('fuel_calc/est_airflow','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'Name','est_airflow')
set_param(outportHandle,'SignalObject',copy(temp))

portHandles = get_param('fuel_calc/fb_correction','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'Name','fb_correction')
set_param(outportHandle,'SignalObject',copy(temp))

temp.CoderInfo.CustomAttributes.Owner = 'fuel_calc';
```

```
set_param('fuel_calc/fuel_rate','SignalName','fuel_rate')
set_param('fuel_calc/fuel_rate','SignalObject',copy(temp))

clear temp portHandles outportHandle numerator_param
```

In each of the three models, select **Configuration Parameters > Use owner from data object for data definition placement**. With this setting cleared (the default), the code generator ignores the values that you specify for **Owner**.

```
set_param('fuel_calc','EnableDataOwnership','on')
set_param('airflow_calc','EnableDataOwnership','on')
set_param('sldemo_fuelsys_dd_controller','EnableDataOwnership','on')
```

Save the component models.

```
save_system('fuel_calc')
save_system('airflow_calc')
```

Generate Improved Code

Generate code from the controller model, `sldemo_fuelsys_dd_controller`.

```
rtwbuild('sldemo_fuelsys_dd_controller')
```

```
### Starting build procedure for model: airflow_calc
### Successful completion of build procedure for model: airflow_calc
### Starting build procedure for model: fuel_calc
### Successful completion of build procedure for model: fuel_calc
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

Now, the file `sldemo_fuelsys_dd_controller.c` does not define any of the global variables.

In the code generation report, inspect the code generated for `airflow_calc`.

The file `airflow_calc.c` now defines the global variables that belong to `airflow_calc`.

```
file = fullfile('slprj','ert','airflow_calc','airflow_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
    'real32_T numerator_param[2] = { 0.01F, -0.01F } ;',1,1)
```

```
/* Definition for custom storage class: ExportToFile */
```

```
real32_T e0;
real32_T est_airflow;
real32_T fb_correction;
real32_T numerator_param[2] = { 0.01F, -0.01F } ;
```

Inspect the code generated for `fuel_calc`. The file `fuel_calc.c` defines the global variable `fuel_rate`.

```
file = fullfile('slprj','ert','fuel_calc','fuel_calc.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ExportToFile */',...
    'real32_T fuel_rate;',1,1)
```

```
/* Definition for custom storage class: ExportToFile */
real32_T fuel_rate;
```

Create Single Point of Specification for Signals That Pass Between Components

The signal data elements `est_airflow` and `fb_correction` are represented by Outport blocks in `airflow_calc` and by Inport blocks in `fuel_calc`. If you want to change the configuration of one of these signals, you must make the change in both models. For example, if you want to change the storage class of `est_airflow` from `ExportToFile` to `Volatile`, you must change the storage class twice: once for the Outport block in `airflow_calc` and again for the Inport block in `fuel_calc`.

To make maintenance of each signal easier, store the code generation settings in a `Simulink.Signal` object, which can exist in the base workspace or a data dictionary.

In the Model Data Editor for `airflow_calc`, on the **Inports/Outports** tab, find the row that corresponds to `est_airflow`.

For that row, in the **Signal Name** column, click the cell.

In the cell, next to the `est_airflow` text, click the action button (with three vertical dots). Select **Create and Resolve**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Signal` and click **Create**. A `Simulink.Signal` object named `est_airflow` appears in the base workspace. In the Model Data Editor, for `est_airflow`, the check box in the **Resolve** check box is selected, which means the Outport block acquires code generation settings from the signal object in the base workspace.

In the `est_airflow` property dialog box, set **Storage class** to `ExportToFile`.

Set **Owner** to `airflow_calc`.

Use the Model Data Editor to create a similar signal object for `fb_correction`.

In the Model Data Editor for `fuel_calc`, on the **Inports/Outports** tab, in the **Resolve** column, select the check boxes for `est_airflow` and `fb_correction`. Now, each Inport block acquires code generation settings from the corresponding signal object.

Alternatively, to create the signal object and configure the blocks and lines in the model, at the command prompt, use these commands:

```
est_airflow = Simulink.Signal;
est_airflow.CoderInfo.StorageClass = 'Custom';
est_airflow.CoderInfo.CustomStorageClass = 'ExportToFile';
est_airflow.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

fb_correction = Simulink.Signal;
fb_correction.CoderInfo.StorageClass = 'Custom';
fb_correction.CoderInfo.CustomStorageClass = 'ExportToFile';
fb_correction.CoderInfo.CustomAttributes.Owner = 'airflow_calc';

set_param('airflow_calc/est_airflow','MustResolveToSignalObject','on')

set_param('airflow_calc/fb_correction','MustResolveToSignalObject','on')

portHandles = get_param('fuel_calc/est_airflow','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'MustResolveToSignalObject','on')

portHandles = get_param('fuel_calc/fb_correction','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'MustResolveToSignalObject','on')

clear portHandles outportHandle
```

Save the component models and generate code from `sldemo_fuelsys_dd_controller`. The code is the same as it was before you created the `Simulink.Signal` objects. Now, you can make changes to the signal objects instead of the corresponding blocks and lines in the models.

```
save_system('airflow_calc')
save_system('fuel_calc')
rtwbuild('sldemo_fuelsys_dd_controller')
```

```
### Starting build procedure for model: airflow_calc
### Successful completion of build procedure for model: airflow_calc
### Starting build procedure for model: fuel_calc
### Successful completion of build procedure for model: fuel_calc
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

Data Types in Embedded Coder

Control Data Type Names in Generated Code

By default, the generated code uses Simulink Coder data type aliases to define scalar and array variables. For example, the Simulink Coder type `real32_T` corresponds to the Simulink type `single`. The code defines these types through `typedef` statements that build on C primitive types such as `float` and `short`. You can configure the code to use custom type names instead.

The code also aggregates signal, block parameter, and state data into structures (see "How Generated Code Exchanges Data with an Environment" on page 32-33 and "How Generated Code Stores Internal Signal, State, and Parameter Data" on page 32-50) by default. You can specify a naming rule for these structure types. You can also place data items into separate custom structures whose type names you can control.

Control these type names to help you to:

- Conform to coding standards. For an example, see "Replace and Rename Data Types to Conform to Coding Standards" on page 34-27.
- Integrate the generated code with your external code. For an example, see "Exchange Structured and Enumerated Data Between Generated and External Code" on page 34-34.
- Make the generated code more readable and meaningful.

For custom types, you can also specify that the generated code reuse type definitions, for example, `typedef` statements, from your external code.

For information about data type names that you cannot control and about custom data types that the generated code does not support, see "Limitations" on page 34-21.

To inform the code generator about the bit length of generic C types such as `int` and `short` for your target hardware, use **Hardware Implementation** configuration parameters. See "Configure Run-Time Environment Options" on page 8-2.

Control Names of Primitive Data Types

To rename a Simulink Coder primitive data type such as `int8_T`, create a `Simulink.AliasType` object whose name matches the type name that you want the generated code to use. For example, to create a type named `myType`, at the command prompt, enter:

```
myType = Simulink.AliasType;
```

Set the `BaseType` property to the name of the Simulink data type that corresponds to the target Simulink Coder data type. For example, if the target type is `int8_T`, specify `int8`. To identify the Simulink data type, use the information in the table.

Simulink Coder Type Name	Corresponding Simulink Type Name
`real_T`	`double`
`real32_T`	`single`
`int32_T`	`int32`
`int16_T`	`int16`
`int8_T`	`int8`
`uint32_T`	`uint32`
`uint16_T`	`uint16`
`uint8_T`	`uint8`
`boolean_T`	`boolean` For configuring data type replacement throughout an entire model (**Configuration Parameters > Code Generation > Data Type Replacement**), you can alternatively use one of these types: • `uint8` • `int8` • `int`*n**
`int_T`	`int`*n**
`uint_T`	`uint`*n**
`char_T`	`int`*n**

* Replace *n* with the number of bits displayed in **Configuration Parameters > Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to rename.

Note The `boolean_T` `BaseType` must promote to a signed `int`.

For example, to replace the type name `uint8_T` with `myType`, set the `BaseType` property of the `Simulink.AliasType` object to `'int8'`.

```
myType.BaseType = 'int8';
```

Then, use one or both of these techniques to apply the type to data items in a model:

- Configure data type replacements. Throughout the code that you generate from a model, you can replace a Simulink Coder data type name with the name of the `Simulink.AliasType` object. You configure data type replacements through model configuration parameters (**Configuration Parameters** > **Code Generation** > **Data Type Replacement**.

  For an example that shows how to use data type replacement, see “Replace and Rename Data Types to Conform to Coding Standards” on page 34-27.
- Use the name of the `Simulink.AliasType` object to specify the data type of an individual signal, that is, a block output, or block parameter. By default, due to data type propagation and inheritance (see “Data Type Inheritance Rules” (Simulink)), the signals, states, and parameters of other downstream blocks typically inherit the same data type. Optionally, you can configure data items in upstream blocks to inherit the type (`Inherit: Inherit via back propagation`) or stop the propagation at an arbitrary block by specifying a noninherited data type setting.

  To specify a data type for an individual data item, use the Model Data Editor (**View** > **Model Data Editor**). You can use the name of the same `Simulink.AliasType` object to specify the data types of multiple data items.

  For an example that shows how to use a `Simulink.AliasType` object directly in a model, see “Create Data Type Alias in the Generated Code” on page 34-12.

Control Names of Primitive Types	Technique
Change the name of a primitive type that the generated code uses to define variables by default (for example, `int8_T`).	Configure a data type replacement for an entire model. To replace a default Simulink Coder data type name with the corresponding Simulink type name, for example, to replace `int8_T` with `int8`, you do not need to create a `Simulink.AliasType` object. See “Use Simulink Data Type Names Instead of Simulink Coder Data Type Names” on page 34-7. To share data type replacements throughout a model reference hierarchy, use referenced configuration sets (see “Share a Configuration Across Referenced Models” (Simulink)).
Configure the generated code to define a particular data item, such as a variable, by using a specific, meaningful type name.	In the model, locate the data item that corresponds to the variable. For example, trace from the code generation report to the model. Use the name of the `Simulink.AliasType` object to set the data type of the item. If necessary, to prevent other data items in upstream and downstream blocks from using the same type name, configure those items to use a data type setting that is not inherited. By default, most signals use the inherited type `Inherit: Inherit via internal rule`.

Control Names of Primitive Types	Technique
Use the same type name for multiple signals and other data items in a data path, which is a series of connected blocks.	In the model, use the name of a `Simulink.AliasType` object to set the data type of one of the signals in the path, for example, a root-level Inport block or a Constant block. For example, if the path begins with an Inport block at the root level of the model, you can specify the type in that block. By default, due to data type propagation, the data items in the other blocks typically inherit the same type. Usually, no matter where on the data path you specify the type, downstream data items inherit the type. You can configure upstream data items to inherit the type, too. Consider specifying the type in a block that you do not expect to remove or change frequently.
Configure the generated code to replace an implementation-dependent type, such as `char_T` or `boolean_T`, and another type of equivalent bit length with a single type name that you specify.	Use the name of the `Simulink.AliasType` object to configure multiple data type replacements simultaneously. See “Replace Implementation-Dependent Types with the Same Type Name” on page 34-8.

Control Names of 64-Bit Integers

To rename a Simulink Coder data type such as `uint64` and `int64`, create a `Simulink.NumericType` object. The name of the object must match the type name that you want the generated code to use. For example, to create a type named `myType`, at the command prompt, enter:

```
myType = Simulink.NumericType;
```

Set these properties:

- `DataTypeMode` - `Fixed-point: binary point scaling`
- `WordLength` - `64`

- `IsAlias` - `true`

The value for `Signedness` can be `Signed` or `Unsigned` depending on whether the integer is signed or unsigned respectively.

Use Simulink Data Type Names Instead of Simulink Coder Data Type Names

For consistency between the data type names that you see in a model and in the generated code, you can configure data type replacements so the code uses Simulink type names instead of Simulink Coder names. For each Simulink Coder type that you want to rename, use the Simulink data type name to specify the replacement name. You do not need to create `Simulink.AliasType` objects.

Simulink Name	Code Generation Name	Replacement Name
double	real_T	<empty>
single	real32_T	<empty>
int32	int32_T	<empty>
int16	int16_T	<empty>
int8	int8_T	int8
uint32	uint32_T	<empty>
uint16	uint16_T	<empty>
uint8	uint8_T	<empty>
boolean	boolean_T	<empty>
int	int_T	<empty>
uint	uint_T	<empty>
char	char_T	<empty>
uint64	uint64_T	<empty>
int64	int64_T	<empty>

To replace `boolean_T`, `int_T`, or `uint_T`, use the information in the table.

Simulink Coder Type Name	Replacement Names to Use
`boolean_T`	One of these names: • `boolean` • `uint8` • `int8` • `intn`*
`int_T`	`intn`*
`uint_T`	`uintn`*
`char_T`	`intn`*

* Replace *n* with the number of bits displayed in **Configuration Parameters** > **Hardware Implementation** for either **Number of bits: int** or **Number of bits: char**. Use the appropriate number of bits for the data type that you want to replace.

You cannot use this technique to replace `real_T` with `double` or `real32_T` with `single`.

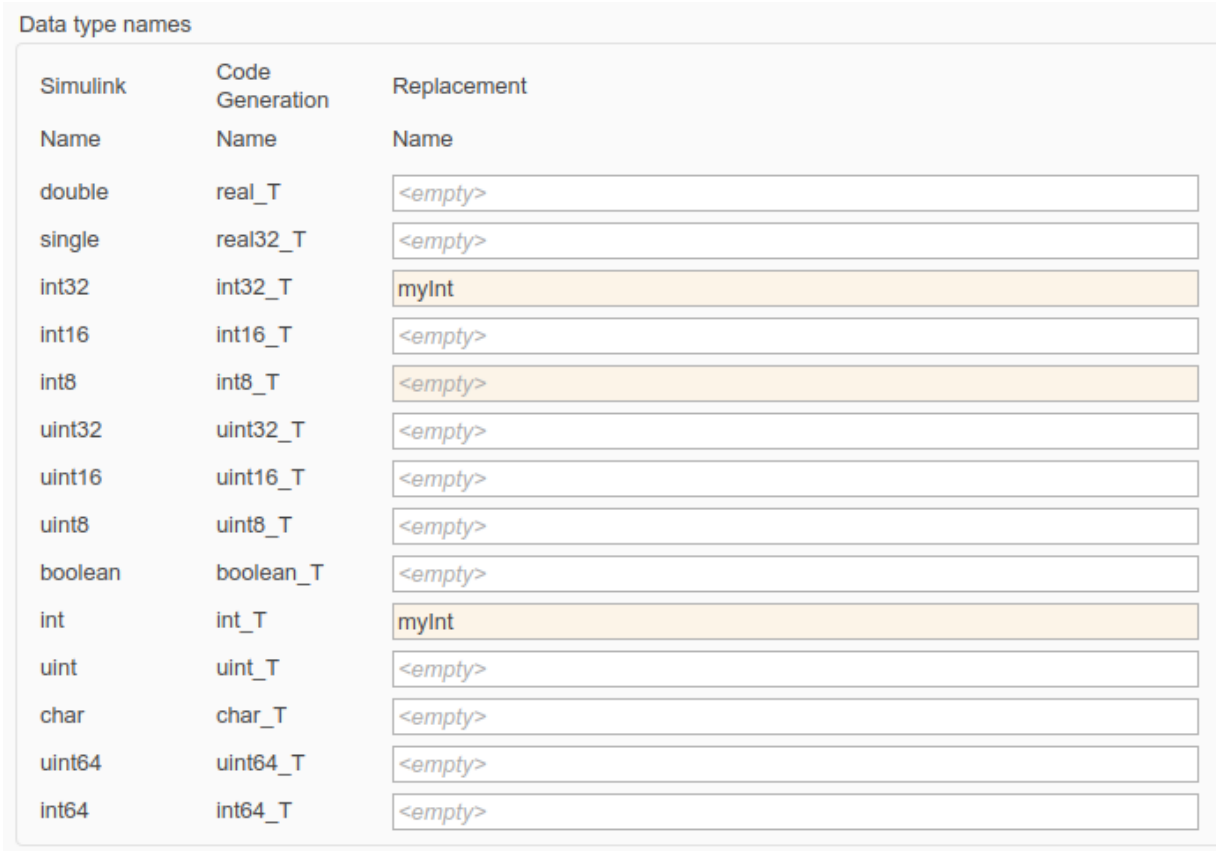
Replace Implementation-Dependent Types with the Same Type Name

Some Simulink Coder type names map to C primitives that are implementation-dependent. For example, the Simulink Coder type `int_T` maps to the C type `int`, whose bit length depends on the native integer size of your target hardware. Other implementation-dependent types include `boolean_T`, `char_T`, and `uint_T`.

For more readable, simpler code, you can use the same type name to replace multiple Simulink Coder types of the same size. For example, if the native integer size of your hardware is 32 bits, you can replace `int_T` and `int32_T` with the same type name, say, `myInt`.

1. Configure your target hardware settings in **Configuration Parameters** > **Hardware Implementation**.
2. Create a `Simulink.AliasType` object named `myInt`. In this case, because `int_T` and `int32_T` represent a 32-bit signed integer, set `BaseType` to `int32`.

   ```
   myInt = Simulink.AliasType('int32')
   ```
3. Configure the same data type replacement for `int32_T` and `int_T`.



Note Many-to-one data type replacement does not support the `char` (`char_T`) built-in data type. Use `char` only in one-to-one data type replacements.

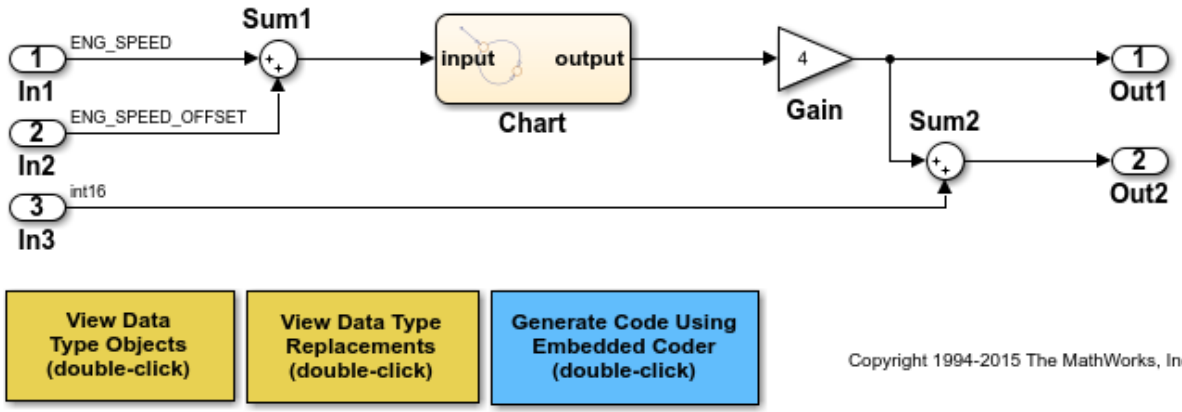
Define Abstract Numeric Types and Rename Types

This model shows user-defined types, consisting of numeric and alias types. Numeric types allow you to define abstract numeric types, which is particularly useful for fixed-point types. Alias types allow you to rename types, which allows you create a relationship for types.

Explore Example Model

Open the example model and configure it to show the generated names of blocks.

```
load_system('rtwdemo_udt')
set_param('rtwdemo_udt','HideAutomaticNames','off')
open_system('rtwdemo_udt')
```



Key Features of User-Defined Types

- Displayed and propagated on signal lines
- Used to parameterize a model by type (e.g., In1 specifies its **Output data type** as `ENG_SPEED`)
- Types with a common ancestor can be mixed, whereby the common ancestor is propagated (e.g., output of Sum1)
- Intrinsically supported by the Simulink Model Explorer
- Include an optional header file attribute that is ideal for importing legacy types (ignored for GRT targets)
- Types used in the generated code (ignored for GRT targets)

Instructions

1. Inspect the user-defined types in the Model Explorer by double-clicking the first yellow button below.
2. Inspect the replacement data type mapping by double-clicking the second yellow button below.

3. Compile the diagram to display the types in this model (Simulation > Update Diagram or **Ctrl+D**).
4. Generate code with the blue button below and inspect model files to see how user-defined types appear in the generated code.
5. Modify the attributes of `ENG_SPEED` and `ENG_SPEED_OFFSET` and repeat steps 1-4.

Notes

- User-defined types are a feature of Simulink that facilitate parameterization of the data types in a model. Embedded Coder preserves alias data type names (e.g., `ENG_SPEED`) in the generated code, whereas Simulink Coder implements user-define types as their base type (e.g., `real32_T`).
- Embedded Coder also enables you to replace the built-in data types with user-defined data types in the generated code.

Control Names of Structure Types

To control the names of the standard structures that Simulink Coder creates by default to store data (*`model`*`_P` for parameter data, for example), use **Configuration Parameters > Code Generation > Symbols > Global types** to specify a naming rule. For more information, see “Customize Generated Identifiers” on page 88-21.

When you use nonvirtual buses and parameter structures to aggregate signals and block parameters into a custom structure in the generated code, control the name of the structure type by creating a `Simulink.Bus` object. For more information, see “Organize Data into Structures in Generated Code” on page 32-181.

Generate Code That Reuses Data Types From External Code

To generate code that reuses a data type definition from your external C code, specify the data scope of the corresponding data type object or enumeration in Simulink as `Imported`. With this setting, the generated code includes (`#include`) the definition from your code. For more information about controlling the file placement of a custom data type, see “Control File Placement of Custom Data Types” on page 34-23.

Instead of creating individual data type objects and enumerated types, and then configuring them, consider creating the objects and types by using the `Simulink.importExternalCTypes` function. By default, the function configures the new objects and types so that the generated code imports (reuses) the type definitions

from your code. You can then use the objects and types to set data types in a model and to configure data type replacements. For more information, see `Simulink.importExternalCTypes` and “Exchange Structured and Enumerated Data Between Generated and External Code” on page 34-34.

Create Data Type Alias in the Generated Code

This example shows how to configure the generated code to use a data type name (`typedef`) that you specify.

Export Type Definition

When you integrate code generated from a model with code from other sources, your model code can create an exported `typedef` statement. Therefore, all of the integrated code can use the type. This example shows how to export the definition of a data type to a generated header file.

Create a `Simulink.AliasType` object named `mySingleAlias` that acts as an alias for the built-in data type `single`.

```
mySingleAlias = Simulink.AliasType('single')
```

```
mySingleAlias =

  AliasType with properties:

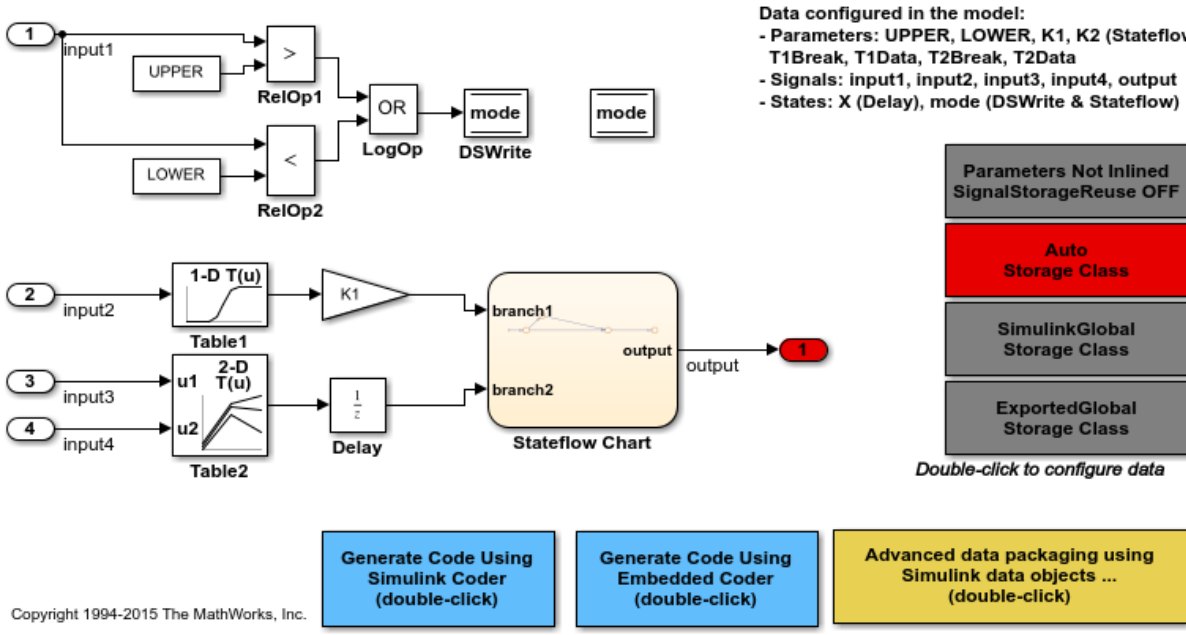
    Description: ''
      DataScope: 'Auto'
     HeaderFile: ''
       BaseType: 'single'
```

Configure the object to export its definition to a header file called `myHdrFile.h`.

```
mySingleAlias.DataScope = 'Exported';
mySingleAlias.HeaderFile = 'myHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```



Configure the model to show the generated names of blocks.

```
set_param('rtwdemo_basicsc','HideAutomaticNames','off')
```

In the model, select **View > Model Data Editor**.

In the model, select the Inport block labeled `In1`.

Use the **Data Type** column to set the data type to `mySingleAlias`.

```
set_param('rtwdemo_basicsc/In1','OutDataTypeStr','mySingleAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. The code generator honors data type aliases such as `mySingleAlias` only if you select an ERT-based system target file.

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for the generated file `myHdrFile.h`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwdemodbtype(file,'#include "myHdrFile.h"',...
    '#include "myHdrFile.h"',1,1)
```

```
#include "myHdrFile.h"
```

View the file `myHdrFile.h`. The code uses the identifier `mySingleAlias` as an alias for the data type `real32_T`. By default, generated code represents the Simulink data type `single` by using the identifier `real32_T`.

The code also provides a macro guard of the form `RTW_HEADER_filename_h_`. When you export a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','myHdrFile.h');
rtwdemodbtype(file,'#ifndef RTW_HEADER_myHdrFile_h_',...
    ' * File trailer for generated code.',1,0)
```

```
#ifndef RTW_HEADER_myHdrFile_h_
#define RTW_HEADER_myHdrFile_h_
#include "rtwtypes.h"

typedef real32_T mySingleAlias;
typedef creal32_T cmySingleAlias;

#endif                                 /* RTW_HEADER_myHdrFile_h_ */

/*
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `mySingleAlias` to define the structure field `input1`, which corresponds to the Inport block labeled `In1`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,...
    '/* External inputs (root inport signals with default storage) */',...
    '} ExtU_rtwdemo_basicsc_T;',1,1)
```

```
/* External inputs (root inport signals with default storage) */
typedef struct {
  mySingleAlias input1;                /* '<Root>/In1' */
  real32_T input2;                     /* '<Root>/In2' */
  real32_T input3;                     /* '<Root>/In3' */
  real32_T input4;                     /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;
```

Import Type Definition

When you integrate code generated from a model with code from other sources, to avoid redundant `typedef` statements, you can import a data type definition from the external code. This example shows how to import your own definition of a data type from a header file that you create.

Use a text editor to create a header file to import. Name the file `ex_myImportedHdrFile.h`. Place it in your working folder. Copy the following code into the file.

```
#ifndef HEADER_myImportedHdrFile_h_
#define HEADER_myImportedHdrFile_h_

typedef float myTypeAlias;

#endif
```

The code uses the identifier `myTypeAlias` to create an alias for the data type `float`. The code also uses a macro guard of the form `HEADER_filename_h`. When you import a data type definition to integrate generated code with code from other sources, you can use macro guards of this form to prevent unintentional identifier clashes.

At the command prompt, create a `Simulink.AliasType` object named `myTypeAlias` that creates an alias for the built-in type `single`. The Simulink data type `single` corresponds to the C data type `float`.

```
myTypeAlias = Simulink.AliasType('single')

myTypeAlias =

  AliasType with properties:
```

```
    Description: ''
      DataScope: 'Auto'
     HeaderFile: ''
       BaseType: 'single'
```

Configure the object so that generated code imports the type definition from the header file `ex_myImportedHdrFile.h`.

```
myTypeAlias.DataScope = 'Imported';
myTypeAlias.HeaderFile = 'ex_myImportedHdrFile.h';
```

Open the model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```

In the model, select **View > Model Data Editor**.

In the model, select the Inport block labeled `In1`.

Use the **Data Type** column to set the data type to `myTypeAlias`.

```
set_param('rtwdemo_basicsc/In1','OutDataTypeStr','myTypeAlias')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. The code generator honors data type aliases such as `mySingleAlias` only if you select an ERT-based system target file.

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc_types.h`. The code creates a `#include` directive for your header file `ex_myImportedHdrFile.h`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc_types.h');
rtwdemodbtype(file,'#include "ex_myImportedHdrFile.h',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#include "ex_myImportedHdrFile.h"
```

View the file `rtwdemo_basicsc.h`. The code uses the data type alias `myTypeAlias` to define the structure field `input1`, which corresponds to the Inport block labeled `In1`.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,...
    '/* External inputs (root inport signals with default storage) */',...
    '} ExtU_rtwdemo_basicsc_T;',1,1)
```

```
/* External inputs (root inport signals with default storage) */
typedef struct {
  myTypeAlias input1;                  /* '<Root>/In1' */
  real32_T input2;                     /* '<Root>/In2' */
  real32_T input3;                     /* '<Root>/In3' */
  real32_T input4;                     /* '<Root>/In4' */
} ExtU_rtwdemo_basicsc_T;
```

Display Base Data Types and Aliases on Model Diagram

When you display signal data types on the model diagram by selecting **Display > Signals and Ports > Port Data Types**, by default, the diagram displays aliases (such as `myTypeAlias`) instead of base data types (such as `int16`). To display the base types, choose an option for **Display > Signals and Ports > Port Data Type Display Format**. For more information, see “Port Data Types” (Simulink).

Create a Named Fixed-Point Data Type in the Generated Code

This example shows how to create and name a fixed-point data type in generated code. You can use the name of the type to specify parameter and signal data types throughout a model and in generated code.

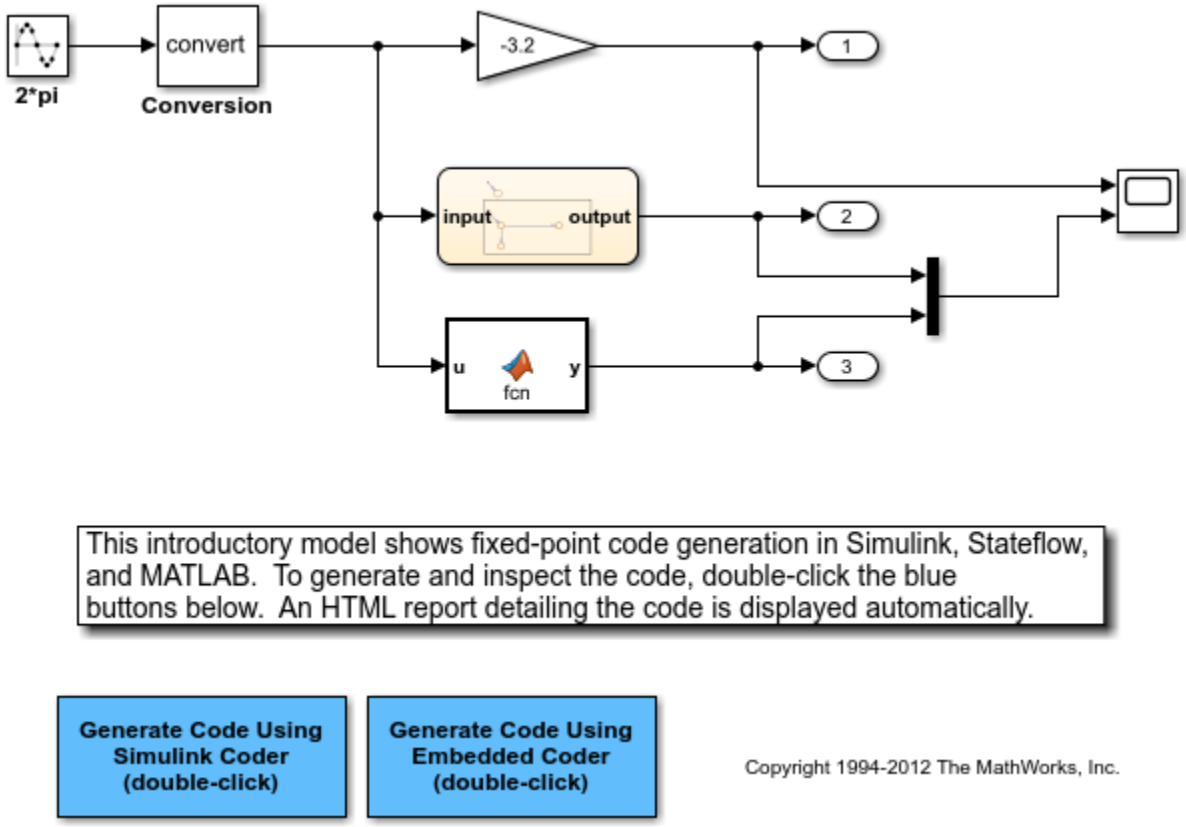
The example model `rtwdemo_fixpt1` uses fixed-point data types. So that you can more easily see the fixed-point data type in the generated code, in this example, you create a `Simulink.Parameter` object that appears in the code as a global variable.

Create a `Simulink.AliasType` object that defines a fixed-point data type. Name the object `myFixType`. The generated code uses the name of the object as a data type.

```
myFixType = Simulink.AliasType('fixdt(1,16,4)');
```

Open the model `rtwdemo_fixpt1`.

```
open_system('rtwdemo_fixpt1')
```



Configure the model to show the generated names of the blocks.

```
set_param('rtwdemo_fixpt1','HideAutomaticNames','off')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, for the row that represents the **Gain** parameter of the Gain block, in the **Value** column, specify `myParam`.

Click the action button (with three vertical dots) next to the parameter value. Select **Create**.

In the **Create New Data** dialog box, set `Value` to `Simulink.Parameter(8)`. In this example, for more easily readable code, you set the parameter value to 8 instead of -3.2. Click **Create**. A `Simulink.Parameter` object named `myParam` appears in the base workspace. The object stores the real-world value `8`, which the Gain block uses for the value of the **Gain** parameter.

In the **Simulink.Parameter** property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**. With this setting, `myParam` appears in the generated code as a separate global variable.

In the Model Data Editor, use the **Data Type** column to set the data type of the **Gain** parameter of the Gain block to `myFixType`.

On the **Signals** tab, use the **Data Type** column to set the data type of the Gain block output to `myFixType`.

Use the **Data Type** column to set the data type of the `Conversion` block output to `myFixType`.

Alternatively, you can use these commands at the command prompt to configure the blocks and create the object:

```
set_param('rtwdemo_fixpt1/Gain','Gain','myParam','OutDataTypeStr','myFixType',...
    'ParamDataTypeStr','myFixType')
myParam = Simulink.Parameter(8);
myParam.StorageClass = 'ExportedGlobal';
set_param('rtwdemo_fixpt1/Conversion','OutDataTypeStr','myFixType')
```

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors data type aliases such as `myFixType`.

```
set_param('rtwdemo_fixpt1','SystemTargetFile','ert.tlc')
```

Select the configuration parameter **Generate code only**.

```
set_param('rtwdemo_fixpt1','GenCodeOnly','on')
```

Generate code from the model.

```
rtwbuild('rtwdemo_fixpt1')
```

```
### Starting build procedure for model: rtwdemo_fixpt1
### Successful completion of code generation for model: rtwdemo_fixpt1
```

In the code generation report, view the file `rtwdemo_fixpt1_types.h`. The code defines the type `myFixType` based on an integer type of the specified word length (16).

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_myFixType_',...
    '/* Forward declaration for rtModel */',1,0)
```

```
#ifndef DEFINED_TYPEDEF_FOR_myFixType_
#define DEFINED_TYPEDEF_FOR_myFixType_

typedef int16_T myFixType;
typedef cint16_T cmyFixType;

#endif
```

View the file `rtwdemo_fixpt1.c`. The code uses the type `myFixType`, which is an alias of the integer type `int16`, to define the variable `myParam`.

```
file = fullfile('rtwdemo_fixpt1_ert_rtw','rtwdemo_fixpt1.c');
rtwdemodbtype(file,'myFixType myParam = 128;','myFixType myParam = 128;',1,1)
```

```
myFixType myParam = 128;               /* Variable: myParam
```

The stored integer value `128` of `myParam` is not the same as the real-world value `8` because of the scaling that the fixed-point data type `myFixType` specifies. For more information, see “Scaling” (Fixed-Point Designer) in the Fixed-Point Designer documentation.

The line of code that represents the Gain block applies a right bit shift corresponding to the fraction length specified by `myFixType`.

```
rtwdemodbtype(file,...
    'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',...
    'rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);',1,1)
```

```
rtwdemo_fixpt1_Y.Out1 = (myFixType)((myParam * rtb_Conversion) >> 4);
```

Rename Data Type Object

To rename a data type object such as `Simulink.AliasType` or `Simulink.Bus` after you create it (for example, to rename an alias when coding standards change or when you encounter a naming conflict), you can allow Simulink to rename the object and correct all of the references to the object that appear in a model or models. In the Model Explorer, right-click the variable and select **Rename All**. For more information, see “Rename Variables” (Simulink).

Display Signal Data Types on Block Diagram

For readability, you can display signal data types directly on a block diagram. When you use custom names for primitive data types, you can choose to display the custom name (the alias), the underlying primitive, or both. See “Port Data Types” (Simulink).

Limitations

- You cannot configure the generated code to use these custom C data types:
  - Array types
  - Pointer types
  - `const` or `volatile` types
- You cannot configure the generated code to use generic C primitive types such as `int` and `short`.

Data Type Replacement Limitations

When you select the model configuration parameter **Replace data type names in the generated code** on the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box, these limitations apply:

- Data type replacement does not support multiple levels of mapping. Each replacement data type name maps directly to one or more built-in data types.
- Data type replacement is not supported for simulation target code generation for referenced models.

- If you select the **Classic call interface** configuration parameter for your model, data type replacement is not supported.
- Code generation performs data type replacements while generating `.c`, `.cpp`, and `.h` files. Code generation places these files in build folders (including top and referenced model build folders) and in the `_sharedutils` folder. *Exceptions* are as follows:
  `rtwtypes.h`
  `multiword_types.h`
  `model_reference_types.h`
  `builtin_typeid_types.h`
  `model_sf.c` or `.cpp` (ERT S-function wrapper)
  `model_dt.h` (C header file supporting external mode)
  `model_capi.c` or `.cpp`
  `model_capi.h`
- Data type replacement is not supported for complex data types.
- Many-to-one data type replacement is not supported for the `char` data type. Attempting to use `char` as part of a many-to-one mapping to a custom data type represents a violation of the MISRA C specification. For example, if you map `char` (`char_T`) and either `int8` (`int8_T`) or `uint8` (`uint8_T`) to the same replacement type, the result is a MISRA C violation. If you try to generate C++ code, the code generator makes invalid implicit type casts, resulting in compile-time errors. Use `char` only in one-to-one data type replacements.
- For ERT S-functions, replace the `boolean` data type with only an 8-bit integer, `int8`, or `uint8`.
- Set the `DataScope` property of a `Simulink.AliasType` object to `Auto` (default) or `Imported`.

Control File Placement of Custom Data Types

By default, when you use data type objects, such as `Simulink.AliasType` and `Simulink.Bus`, and custom enumerations to specify data types for signals and block parameters, the code generated from the model defines the types (for example, with `typedef` statements). To ease integration of the generated code with other existing code and to modularize the generated code, you can control the file placement of the type definitions by adjusting the properties of the objects and the enumerations.

Data Scope and Header File

To control the file placement of a custom type definition in generated code, set the `DataScope` and `HeaderFile` properties of the data type object according to the table. Similarly, for an enumeration that you define in a MATLAB file, set the return arguments of the `getDataScope` and `getHeaderFile` methods.

- *`typename`* is the name of the custom data type.
- *`filename`* is the name of a header file.
- *`model`* is the name of the model.

Goal	Specify `DataScope` as	Specify `HeaderFile` as
Export type definition to *`model`*`_types.h`	`Auto`	Empty
Import type definition from a header file that you create, *`filename`*	`Auto` or `Imported`	*`filename`* (if necessary, include a `.h` extension)
Export type definition to a generated header file, *`filename`*`.h`	`Exported`	*`filename`* or *`filename`*`.h`
Export type definition to a generated header file, *`typename`*`.h`	`Exported`	Empty

When you import a data type definition (for example, by setting `DataScope` to `Imported`), the generated model code creates an `#include` directive for your header file in place of a type definition. You supply the header file that contains the definition.

Considerations for Data Type Replacement

- If you use data type replacement to replace a built-in Simulink data type with your own data type in generated code (see "Model Configuration Parameters: Code Generation Data Type Replacement"), `typedef` statements and `#include` directives appear in `rtwtypes.h` instead of *`model`*`_types.h`.
- When a `Simulink.AliasType` or `Simulink.NumericType` object participates in data type replacements, you cannot set the `DataScope` property of the object to `Exported`. Therefore, if you want the code generator to generate the corresponding `typedef` statement, you cannot control the file placement of the statement. However, you can set `DataScope` to `Imported`, which means that you can configure the code to reuse the `typedef` statement that your external code provides.

  As a workaround, instead of using the data type object as a data type replacement, use the object to set the data types of individual data items in a model. To configure many data items, you can use the Model Data Editor and take advantage of data type propagation and inheritance. For more information, see "Control Names of Primitive Data Types" on page 34-2.

Import Definition of Numerically Complex Data Type

You can use a `Simulink.AliasType` object with numerically complex data (`i`). In this case, if you configure the generated code to import the type definition from your external code (for example, by setting the `DataScope` property to `Imported`), your code must provide two complementary `typedef` statements.

Suppose your external header file `myAliasTypes.h` defines the data type `IAT_int32` as an alias of a 32-bit integer. The file must define two types: `IAT_int32` and `cIAT_int32`:

```
#ifndef myAliasTypes_H_
#define myAliasTypes_H_

#include "rtwtypes.h"

typedef int32_T IAT_int32;
typedef cint32_T cIAT_int32;

#endif
```

You do not need to create two `Simulink.AliasType` objects. In this example, you create one object, `IAT_int32`. The generated code then creates complex data (variables) by using both `IAT_int32` and `cIAT_int32`.

Macro Guards

When you export one or more data type definitions to a generated header file, the file contains a file-level macro guard of the form `RTW_HEADER_`*`filename`*`_h`.

Suppose that you use several `Simulink.AliasType` objects: `mySingleAlias`, `myDoubleAlias`, and `myIntAlias` with these properties:

- `DataScope` set to `Exported`
- `HeaderFile` set to `myTypes.h`

When you generate code, the guarded file `myTypes.h` contains the `typedef` statements:

```
#ifndef RTW_HEADER_myTypes_h_
#define RTW_HEADER_myTypes_h_
#include "rtwtypes.h"

typedef real_T myDoubleAlias;
typedef real32_T mySingleAlias;
typedef int16_T myIntAlias;

#endif
```

When you export data type definitions to *`model`*`_types.h`, the file contains a macro guard of the form `_DEFINED_TYPEDEF_FOR_`*`typename`*`_` for each `typedef` statement. Suppose that you use a `Simulink.AliasType` object `mySingleAlias` with these properties:

- `DataScope` set to `Auto`
- `HeaderFile` not specified

When you generate code, the file *`model`*`_types.h` contains the guarded `typedef` statement:

```
#ifndef _DEFINED_TYPEDEF_FOR_mySingleAlias_
#define _DEFINED_TYPEDEF_FOR_mySingleAlias_

typedef real32_T mySingleAlias;

#endif
```

Related Examples

- “Control Data Type Names in Generated Code” on page 34-2

Replace and Rename Data Types to Conform to Coding Standards

By default, the generated code uses data type aliases such as `real_T` and `int32_T`. The code uses these aliases to define global and local variables. If your coding standards require that you use other data type aliases, including aliases that your existing code defines, you can:

- Configure data type replacement for the entire model.
- Configure individual data items (such as signals, parameters, and states) to use specific data type aliases.

For information about controlling data types in a model, see “Control Signal Data Types” (Simulink).

Inspect External C Code

Save this C code into a file named `my_types.h` in your current folder. This file represents a header file in your existing code that defines custom data type aliases by using `typedef` statements.

```
#include <stdbool.h>

typedef double my_dblPrecision;
typedef short my_int16;
typedef bool my_bool;
```

Explore Example Model and Default Generated Code

1. Open the example model ex_data_type_replacement.

   ```
   open_system(fullfile(docroot,'toolbox','ecoder','examples',...
   'ex_data_type_replacement'))
   ```

2. In the model, select **View** > **Model Data Editor**.
3. In the Model Data Editor, inspect the **Signals** tab.
4. Set the **Change view** drop-down list to `Code`. In the data table, the **Storage Class** column shows that named signal lines such as `temp` use the storage class `ExportedGlobal`. With this setting, the signal lines appear in the generated code as separate global variables.

5. Set the **Change view** drop-down list to `Design`.
6. Update the block diagram.

   Simulink assigns a specific data type to each signal that uses an inherited data type setting such as `Inherit: Inherit via internal rule`.
7. In the data table, expand the width of the **Data Type** column. The column shows that the signals in the model use a mix of the data types `int16`, `double`, and `boolean`. You can also see these data types in the model.
8. Generate code from the model.
9. In the code generation report, inspect the shared utility file `rtwtypes.h`. The code uses `typedef` statements to rename the primitive C data types by using standard Simulink Coder aliases. For example, the code renames the primitive type `double` by using the alias `real_T`.

   ```
   typedef double real_T;
   ```
10. Inspect the file `ex_data_type_replacement.c`. The code uses the default data type aliases to declare and define variables. For example, the code uses the data types `real_T`, `int16_T`, and `boolean_T` to define the global variables `flowIn`, `temp`, and `intlk`.

    ```
    real_T flowIn;                          /* '<Root>/In3' */
    int16_T temp;                           /* '<Root>/Add2' */
    boolean_T intlk;                        /* '<S1>/Compare' */
    ```

    The model `step` function defines local variables by using the same data type aliases.

    ```
    real_T rtb_Add;
    real_T rtb_FilterCoefficient;
    ```

Reuse External Data Type Definitions

Configure the generated code to define variables by using the custom data types defined in `my_types.h` instead of the default type names.

1. At the command prompt, create a `Simulink.AliasType` object for each data type alias that your external code defines.

   ```
   Simulink.importExternalCTypes('my_types.h');
   ```

   In the base workspace, the `Simulink.importExternalCTypes` function creates the objects `my_dblPrecision`, `my_int16`, and `my_bool`.

For each object, the function sets the `DataScope` property to `'Imported'` and the `HeaderFile` property to `'my_types.h'`. With these settings, the code generator does not create a `typedef` statement for each object, but instead the generated code reuses the statements from `my_types.h` by including (`#include`) the file.

2. In the model, in the Configuration Parameters dialog box, on the **Code Generation** > **Data Type Replacement** pane, select **Replace data type names in the generated code**.
3. Specify the options in the **Replacement Name** column according to the table.

Simulink Name	Replacement Name
`double`	`my_dblPrecision`
`int16`	`my_int16`
`boolean`	`my_bool`

4. Generate code from the model.
5. In the code generation report, inspect the file `rtwtypes.h`. Now, the code uses an `#include` directive to import the contents of the external header file `my_types.h`, which contains the custom data type aliases.

```
#include "my_types.h"     /* User defined replacement datatype for int16_T real_T boolean_T  */
```

6. Inspect the file `ex_data_type_replacement.c`. The code uses the custom data type aliases `my_dblPrecision`, `my_int16`, and `my_bool` to define the global variables such as `flowIn`, `temp`, and `intlk`.

```
my_dblPrecision flowIn;                /* '<Root>/In3' */
my_int16 temp;                         /* '<Root>/Add2' */
my_bool intlk;                         /* '<S1>/Compare' */
```

The model `step` function defines local variables by using the custom data type aliases.

```
my_dblPrecision rtb_Add;
my_dblPrecision rtb_FilterCoefficient;
```

Create Meaningful Data Type Aliases for Individual Data Items

Suppose that your coding standards require that important data items use a data type whose name indicates the real-world significance. You can create more `Simulink.AliasType` objects to represent these custom data type aliases. Use the objects to set the data types of data items in the model.

1. In the Model Data Editor **Data Type** column, use the `Simulink.AliasType` objects to set the data types of these block outputs. You can select a signal line in the model, which highlights the corresponding row in the Model Data Editor, or search for the signals in the Model Data Editor by using the **Filter contents** box.

Block	Output Data Type
Flow Setpoint	`flow_T`
Add2 (which feeds the Compare block)	`diffTemp_T`

2. Use the Model Data Editor **Inports/Outports** tab to set the data type of the third Inport block to `flow_T`.
3. In the model, select **View** > **Property Inspector**.
4. Select the block labeled Flow Controller. In the Property Inspector, click **Open** to open the block dialog box.
5. On the **Data Types** tab, set **Sum output** to `ctrl_T`. Click **OK**.

   With these data type settings, some of the named signals, such as `temp` and `flowIn`, use data types that evoke real-world quantities, such as liquid flow rate and temperature.
6. At the command prompt, create `Simulink.AliasType` objects to represent these new custom data type aliases.

   ```
   flow_T = Simulink.AliasType('double');
   diffTemp_T = Simulink.AliasType('int16');
   ctrl_T = Simulink.AliasType('double');
   ```

   In the model, the signals `flowIn` and `flowSetPt` use the primitive data type `double`, so the data type alias `flow_T` maps to `double`.
7. Update the block diagram.

   Due to data type inheritance, other signals also use the custom data type aliases. For example, the output data type of the Add block fed by the third Inport block is set to `Inherit: Inherit via internal rule`. The internal rule chooses the same data type that the block inputs use, `flow_T`.
8. Generate code from the model.
9. The file `ex_data_type_replacement_types.h` defines the new data types `flow_T`, `diffTemp_T`, and `ctrl_T` as aliases of `my_dblPrecision` and `my_int16`.

```
typedef my_dblPrecision flow_T;
typedef my_int16 diffTemp_T;
typedef my_dblPrecision ctrl_T;
```

10 In the file `ex_data_type_replacement.c`, the code defines global variables by using the new type names.

```
flow_T flowIn;                          /* '<Root>/In3' */
flow_T flowSetPt;                       /* '<Root>/Flow Setpoint' */
ctrl_T flowCtrl;                        /* '<Root>/Interlock' */
diffTemp_T temp;                            /* '<Root>/Add2' */
```

11 For blocks that do not use the new data types, the corresponding generated code continues to use the replacement types that you specified earlier. For example, in the file `ex_data_type_replacement.h`, the outputs of the blocks In1 and In2 appear as structure fields that use the replacement type `my_int16`.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
  my_int16 In1;                         /* '<Root>/In1' */
  my_int16 In2;                         /* '<Root>/In2' */
} ExtU_ex_data_type_replacement_T;
```

Create Single Point of Definition for Primitive Types

The custom data type aliases `flow_T` and `ctrl_T` map to the primitive data type `double`. If you want to change this underlying data type from `double` to `single` (`float`), you must remember to modify the `BaseType` property of both `Simulink.AliasType` objects.

To more easily make this change, you can create a `Simulink.NumericType` object and configure both `Simulink.AliasType` objects to refer to it. Then, you need to modify only the `Simulink.NumericType` object. A `Simulink.NumericType` object enables you to share a data type without creating a data type alias.

1 At the command prompt, create a `Simulink.NumericType` object to represent the primitive data type `single`.

```
sharedType = Simulink.NumericType;
sharedType.DataTypeMode = 'Single';
```

2 Configure the `Simulink.AliasType` objects `flow_T` and `ctrl_T` to acquire an underlying data type from this new object.

```
flow_T.BaseType = 'sharedType';
ctrl_T.BaseType = 'sharedType';
```

3. In the model, select **Display > Signals and Ports > Port Data Type Display Format > Base and Alias Types** (see “Port Data Types” (Simulink)). Update the block diagram.

   The data type indicators in the model show that the aliases `flow_T` and `ctrl_T` map to the primitive type `single`. To change this underlying primitive type, you can modify the `DataTypeMode` property of the `Simulink.NumericType` object, `sharedType`.

By default, the `Simulink.NumericType` object does not cause another `typedef` statement to appear in the generated code.

If you generate code from the model while the `Simulink.NumericType` object represents the data type `single`, the generated code maps `flow_T` and `ctrl_T` to the default Simulink Coder data type alias `real32_T`, which maps to the C data type `float`. You can replace `real32_T` in the same way that you replaced `real_T`, `int16_T`, and `boolean_T` (**Configuration Parameters > Code Generation > Data Type Replacement**).

Permanently Store Data Type Objects

The `Simulink.NumericType` and `Simulink.AliasType` objects in the base workspace do not persist if you end your current MATLAB session. To permanently store these objects, consider migrating your model to a data dictionary. See “Migrate Models to Use Simulink Data Dictionary” (Simulink).

Create and Maintain Objects Corresponding to Multiple C typedef Statements

To create `Simulink.AliasType` objects for a large number of `typedef` statements in your external C code, consider using the `Simulink.importExternalCTypes` function.

Exchange Structured and Enumerated Data Between Generated and External Code

This example shows how to generate code that exchanges data with external, existing code. Construct and configure a model to match data types with the external code and to avoid duplicating type definitions and memory allocation (definition of global variables). Then, compile the generated code together with the external code into a single application.

Inspect External Code

Create the file `ex_cc_algorithm.c` in your current folder.

```
#include "ex_cc_algorithm.h"

inSigs_T inSigs;

float_32 my_alg(void)
{
    if (inSigs.err == TMP_HI) {
        return 27.5;
    }
    else if (inSigs.err == TMP_LO) {
        return inSigs.sig1 * calPrms.cal3;
    }
    else {
        return inSigs.sig2 * calPrms.cal3;
    }
}
```

The C code defines a global structure variable named `inSigs`. The code also defines a function, `my_alg`, that uses `inSigs` and another structure variable named `calPrms`.

Create the file `ex_cc_algorithm.h` in your current folder.

```
#ifndef ex_cc_algorithm_h
#define ex_cc_algorithm_h

typedef float float_32;

typedef enum {
```

```
    TMP_HI = 0,
    TMP_LO,
    NORM,
} err_T;

typedef struct inSigs_tag {
    err_T err;
    float_32 sig1;
    float_32 sig2;
} inSigs_T;

typedef struct calPrms_tag {
    float_32 cal1;
    float_32 cal2;
    float_32 cal3;
} calPrms_T;

extern calPrms_T calPrms;
extern inSigs_T inSigs;

float_32 my_alg(void);

#endif
```

The file defines `float_32` as an alias of the C data type `float`. The file also defines an enumerated data type, `err_T`, and two structure types, `inSigs_T` and `calPrms_T`.

The function `my_alg` is designed to calculate a return value by using the fields of `inSigs` and `calPrms`, which are global structure variables of the types `inSigs_T` and `calPrms_T`. The function requires another algorithm to supply the signal data that `inSigs` stores.

This code allocates memory for `inSigs`, but not for `calPrms`. Create a model whose generated code:

- Defines and initializes `calPrms`.
- Calculates values for the fields of `inSigs`.
- Reuses the type definitions (such as `err_T` and `float_32`) that the external code defines.

Create Simulink Model

1. So that you can create enumerated and structured data in the Simulink model, first create Simulink representations of the data types that the external code defines. Store the Simulink types in a new data dictionary named `ex_cc_integ.sldd`.

   ```
   Simulink.importExternalCTypes('ex_cc_algorithm.h',...
       'DataDictionary','ex_cc_integ.sldd');
   ```

   The data dictionary appears in your current folder.

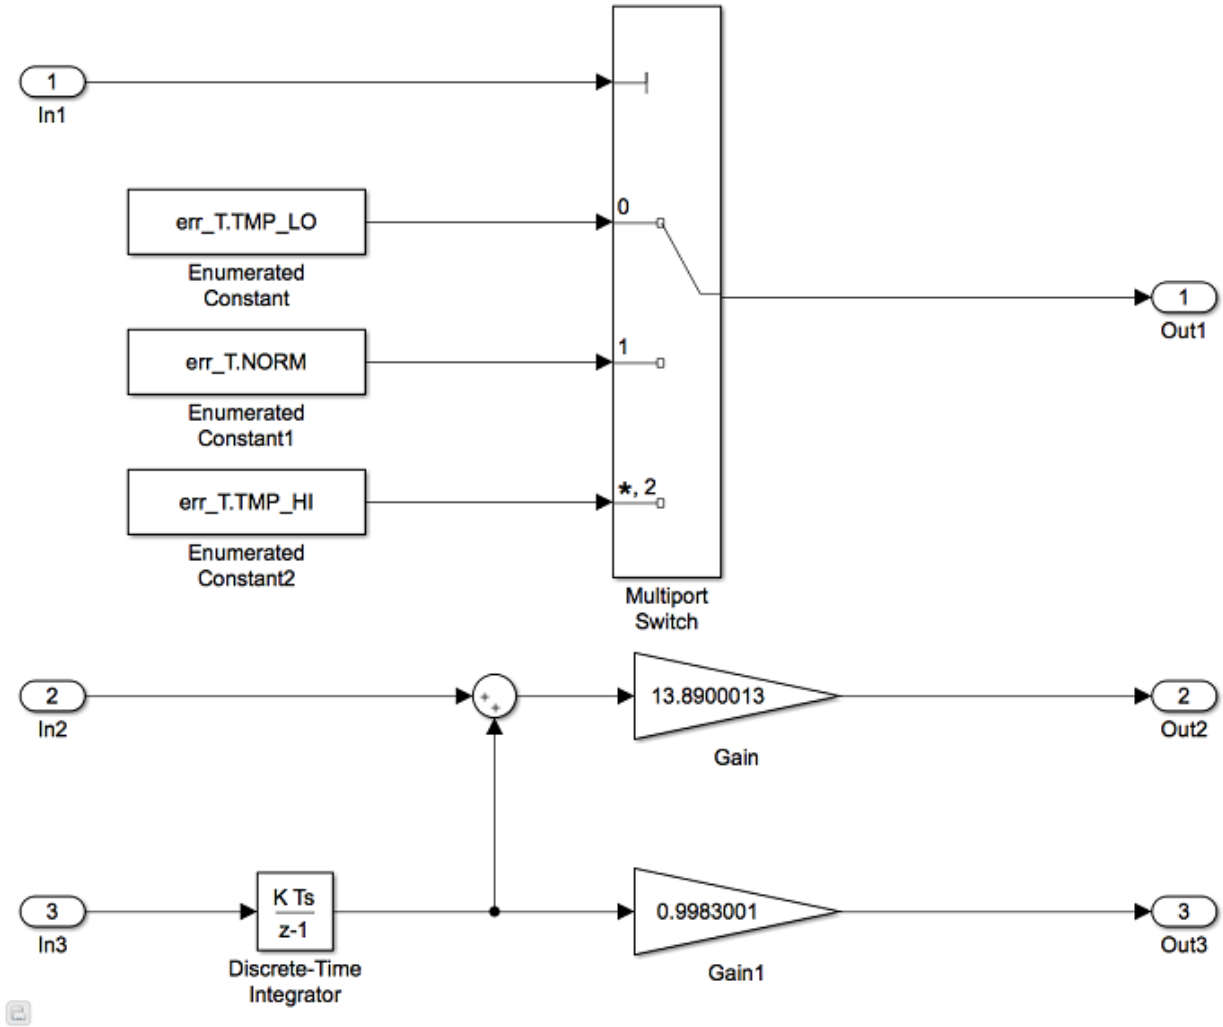
2. To inspect the dictionary contents in the Model Explorer, in your current folder, double-click the file, `ex_cc_integ.sldd`.

   The `Simulink.importExternalCTypes` function creates `Simulink.Bus`, `Simulink.AliasType`, and `Simulink.data.dictionary.EnumTypeDefinition` objects that correspond to the custom C data types from `ex_cc_algorithm.h`.

3. Create a new model and save it in your current folder as `ex_struct_enum_integ`.

4. Link the model to the data dictionary. In the model, select **File** > **Model Properties** > **Link to Data Dictionary**.

5. Add algorithmic blocks that calculate the fields of `inSigs`.



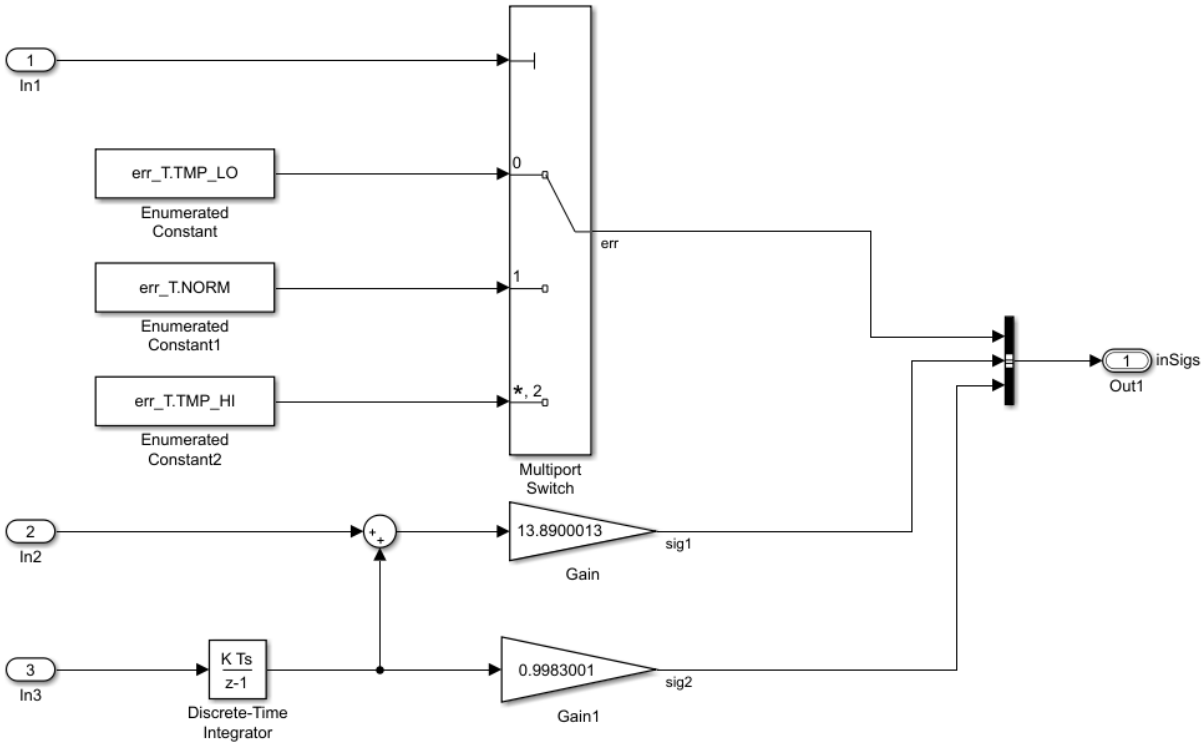
Now that you have the algorithm model, you must:

- Organize the output signals into a structure variable named `inSigs`.
- Create the structure variable `calPrms`.
- Include `ex_cc_algorithm.c` in the build process that compiles the code after code generation.

Configure Generated Code to Write Output Data to Existing Structure Variable

1. Add a Bus Creator block near the existing Outport blocks. The output of a Bus Creator block is a bus signal, which you can configure to appear in the generated code as a structure.
2. In the Bus Creator block, set these parameters:
   - **Number of inputs** to 3
   - **Output data type** to `Bus: inSigs_T`
   - **Output as nonvirtual bus** to selected
3. Delete the three existing Outport blocks (but not the signals that enter the blocks).
4. Connect the three remaining signal lines to the inputs of the Bus Creator block.
5. Add an Outport block after the Bus Creator block. Connect the output of the Bus Creator to the Outport.
6. In the Outport block, set the **Data type** parameter to `Bus: inSigs_T`.
7. In the model, select **View** > **Model Data Editor**.
8. On the **Inports/Outports** tab, for the Inport blocks labeled `In2` and `In3`, change **Data Type** from `Inherit: auto` to `float_32`.
9. Change the **Change View** drop-down list from `Design` to `Code`.
10. For the Outport block, set **Signal Name** to `inSigs`.
11. Set **Storage Class** to `ImportFromFile`.
12. Set **Header File** to `ex_cc_algorithm.h`.
13. Inspect the **Signals** tab.
14. In the model, select the output signal of the Multiport Switch block.
15. In the Model Data Editor, for the selected signal, set **Name** to `err`.
16. Set the name of the output signal of the Gain block to `sig1`.
17. Set the name of the output signal of the Gain1 block to `sig2`.

When you finish, the model stores output signal data (such as the signals `err` and `sig1`) in the fields of a structure variable named `inSigs`.



Because you set **Storage Class** to `ImportFromFile`, the generated code does not allocate memory for `inSigs`.

Configure Generated Code to Define Parameter Data

Configure the generated code to define the global structure variable, `calPrms`, that the external code needs.

1. In the Model Explorer **Model Hierarchy** pane, under the dictionary node **ex_cc_integ**, select the **Design Data** node.
2. In the **Contents** pane, select the `Simulink.Bus` object `calPrms_T`.
3. In the Dialog pane (the right pane), click **Launch Bus Editor**.
4. In the Bus Editor, in the left pane, select `calPrms_T`.

5. On the Bus Editor toolbar, click the **Create/Edit a Simulink.Parameter Object from a Bus Object** button.
6. In the MATLAB Editor, copy the generated MATLAB code and run the code at the command prompt. The code creates a `Simulink.Parameter` object in the base workspace.
7. In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
8. Use the Model Explorer to move the parameter object, `calPrms_T_Param`, from the base workspace to the Design Data section of the data dictionary.
9. With the data dictionary selected, in the **Contents** pane, rename the parameter object as `calPrms`.
10. In the Model Data Editor, select the **Parameters** tab.
11. Set the **Change view** drop-down list to `Design`.
12. For the Gain block, replace the value `13.8900013` with `calPrms.cal1`.
13. In the other Gain block, use `calPrms.cal2`.
14. While editing the value of the other Gain block, next to `calPrms.cal2`, click the action button ⋮ and select **calPrms** > **Open**.
15. In the `calPrms` property dialog box, next to the **Value** box, click the action button ⋮ and select **Open Variable Editor**.
16. Use the Variable Editor to set the field values in the parameter object.

    - For the fields `cal1` and `cal2`, use the numeric values that the Gain blocks in the model previously used.
    - For `cal3`, use a nonzero number such as `15.2299995`.

    When you finish, close the Variable Editor.
17. In the property dialog box, set **Storage class** to `ExportedGlobal`. Click **OK**.
18. Use the Model Explorer to save the changes that you made to the dictionary.

Generate, Compile, and Inspect Code

1. Configure the model to include `ex_cc_algorithm.c` in the build process. Set **Configuration Parameters** > **Code Generation** > **Custom Code** > **Additional build information** > **Source files** to `ex_cc_algorithm.c`.
2. Generate code from the model.

3 Inspect the generated file `ex_struct_enum_integ.c`. The file defines and initializes `calPrms`.

```
/* Exported block parameters */
calPrms_T calPrms = {
  13.8900013F,
  0.998300076F,
  15.23F
} ;                                    /* Variable: calPrms
```

The generated algorithm in the model `step` function defines a local variable for buffering the value of the signal `err`.

```
err_T rtb_err;
```

The algorithm then calculates and stores data in the fields of `inSig`.

```
inSigs.err = rtb_err;
inSigs.sig1 = (rtU.In2 + rtDW.DiscreteTimeIntegrator_DSTATE) * calPrms.cal1;
inSigs.sig2 = (real32_T)(calPrms.cal2 * rtDW.DiscreteTimeIntegrator_DSTATE);
```

Replace Data Type Names Throughout Model

To generate code that uses `float_32` instead of the default, `real32_T`, instead of manually specifying the data types of block output signals and bus elements, you can use data type replacement (**Configuration Parameters > Code Generation > Data Type Replacement**). For more information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 34-27.

- “Organize Data into Structures in Generated Code” on page 32-181

Specify Boolean and Data Type Limit Identifiers

You can use command-line parameters to replace the default Boolean and data type limit identifiers. If you want to associate the data type limit identifiers with the data type names, consider replacing the default identifiers. You can also use command-line parameters to import a header file with the Boolean and data type limit identifier definitions.

Data Type Limit Identifiers

You can control the data type limit identifiers in the generated code by using the command-line parameters in this table.

Data Type Limit	Default Identifier	Command-Line Parameter
64-bit integer maximum	`MAX_int64_T`	`MaxIdInt64`
16-bit integer maximum	`MAX_int16_T`	`MaxIdInt16`
32-bit integer maximum	`MAX_int32_T`	`MaxIdInt32`
8-bit integer maximum	`MAX_int8_T`	`MaxIdInt8`
64-bit unsigned integer maximum	`MAX_uint64_T`	`MaxIdUint64`
16-bit unsigned integer maximum	`MAX_uint16_T`	`MaxIdUint16`
32-bit unsigned integer maximum	`MAX_uint32_T`	`MaxIdUint32`
8-bit unsigned integer maximum	`MAX_uint8_T`	`MaxIdUint8`
64-bit integer minimum identifier	`MIN_int64_T`	`MinIdInt64`
16-bit integer minimum	`MIN_int16_T`	`MinIdInt16`
32-bit integer minimum	`MIN_int32_T`	`MinIdInt32`
8-bit integer minimum	`MIN_int8_T`	`MinIdInt8`

For example, to change the default identifiers for the 8-bit integer data limit minimum and maximum to `s4g_S4MIN` and `s4g_S4MAX`, respectively:

```
set_param(gcs,'MinIdInt8','s4g_S4MIN');
set_param(gcs,'MaxIdInt8','s4g_S4MAX')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the 8-bit integer data minimum and maximum identifiers:

```
#define s4g_S4MAX                      ((int8_T)(127))
#define s4g_S4MIN                      ((int8_T)(-128))
```

If you do import a header file defining the data type limit identifiers, the header file is included in `rtwtypes.h`.

Boolean Identifiers

You can control the Boolean identifiers in the generated code by using the command-line parameters in this table. When changing boolean identifiers, you must define `false` to be numerically equivalent to `0`, and `true` to be numerically equivalent to `1`.

Boolean	Default Identifier	Command-Line Parameter
True	`true`	`BooleanTrueId`
False	`false`	`BooleanFalseId`

For example, to change the default Boolean true and false identifiers:

```
set_param(gcs,'BooleanTrueId','bTrue');
set_param(gcs,'BooleanFalseId','bFalse')
```

If you do not import a header file, the generated file `rtwtypes.h` defines the Boolean identifiers:

```
#define bFalse                         (0U)
#define bTrue                          (1U)
```

If you do import a header file defining the Boolean identifiers, the header file is included in `rtwtypes.h`.

Note When changing boolean identifiers, you must define `false` to be numerically equivalent to `0`, and `true` to be numerically equivalent to `1`.

Boolean and Data Type Limit Identifier Header Files

You can import a header file that defines Boolean and data type limit identifiers by using the configuration parameter **Type limit identifier replacement header file** or command-line parameter `TypeLimitIdReplacementHeaderFile`. The header file is included in `rtwtypes.h`. You must use the command-line parameters to specify the Boolean and data type limit identifiers that are included in the imported header file.

For example, if you have a header file `myfile.h` with data type limit definitions, use `TypeLimitIdReplacementHeaderFile` to include the definitions in the generated code:

```
set_param(gcs,'TypeLimitIdReplacementHeaderFile','myfile.h');
```

The generated file `rtwtypes.h` includes `myfile.h`.

```
/* Import type limit identifier replacement definitions. */
#include "myfile.h"
```

Air-Fuel Ratio Control System with Fixed-Point Data

This example shows how to generate and optimize the code for a fixed-point air-fuel ratio control system designed with Simulink® and Stateflow®. For a detailed explanation of the model, see sldemo_fuelsys and fxpdemo_fuelsys. The example uses the Embedded Coder® (ERT target). The concepts also apply for Simulink® Coder™.

Relevant Portions of the Model

Figures 1-4 show relevant portions of the `sldemo_fuelsys` model, which is a closed-loop system containing a plant subsystem and a controller subsystem. The plant allows engineers to validate the controller through simulation early in the design cycle. In this example, generate code for the relevant controller subsystem, `fuel_rate_control`. Figure 1 shows the top-level simulation model.

```
% Open |sldemo_fuelsys| via |rtwdemo_fuelsys_fxp| and update the model diagram
% to view the signal data types.
rtwdemo_fuelsys_fxp;

sldemo_fuelsys([],[],[],'compile');
sldemo_fuelsys([],[],[],'term');
```

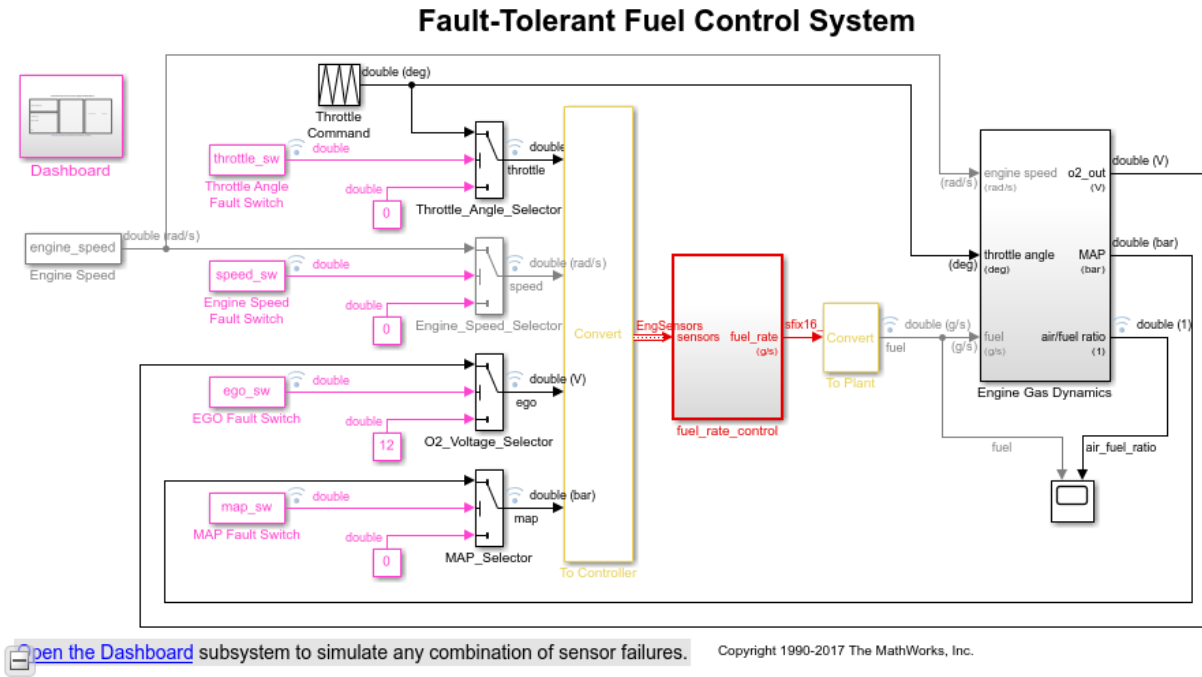

Figure 1: Top-level model of the plant and controller

The air-fuel ratio control system is composed of Simulink® and Stateflow® blocks. It is the portion of the model for which to generate code.

```
open_system('sldemo_fuelsys/fuel_rate_control');
```

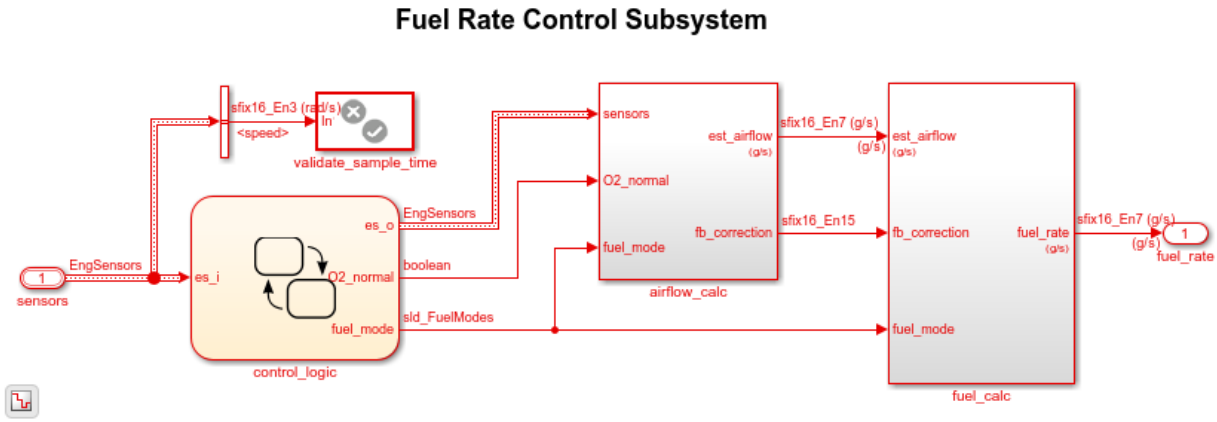

Figure 2: The air-fuel ratio controller subsystem

The intake airflow estimation and closed loop correction system contains two lookup tables, Pumping Constant and Ramp Rate Ki.

```
open_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
```

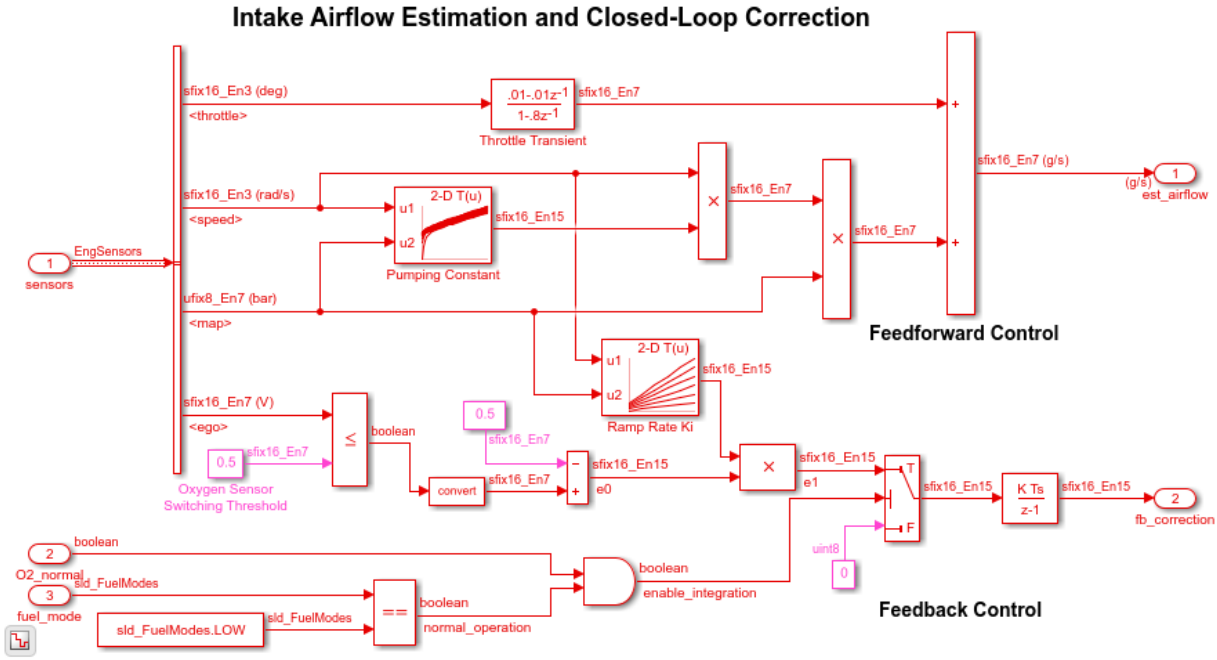

Figure 3: The airflow_calc subsystem

The control logic is a Stateflow® chart that specifies the different modes of operation.

```
open_system('sldemo_fuelsys/fuel_rate_control/control_logic');
```

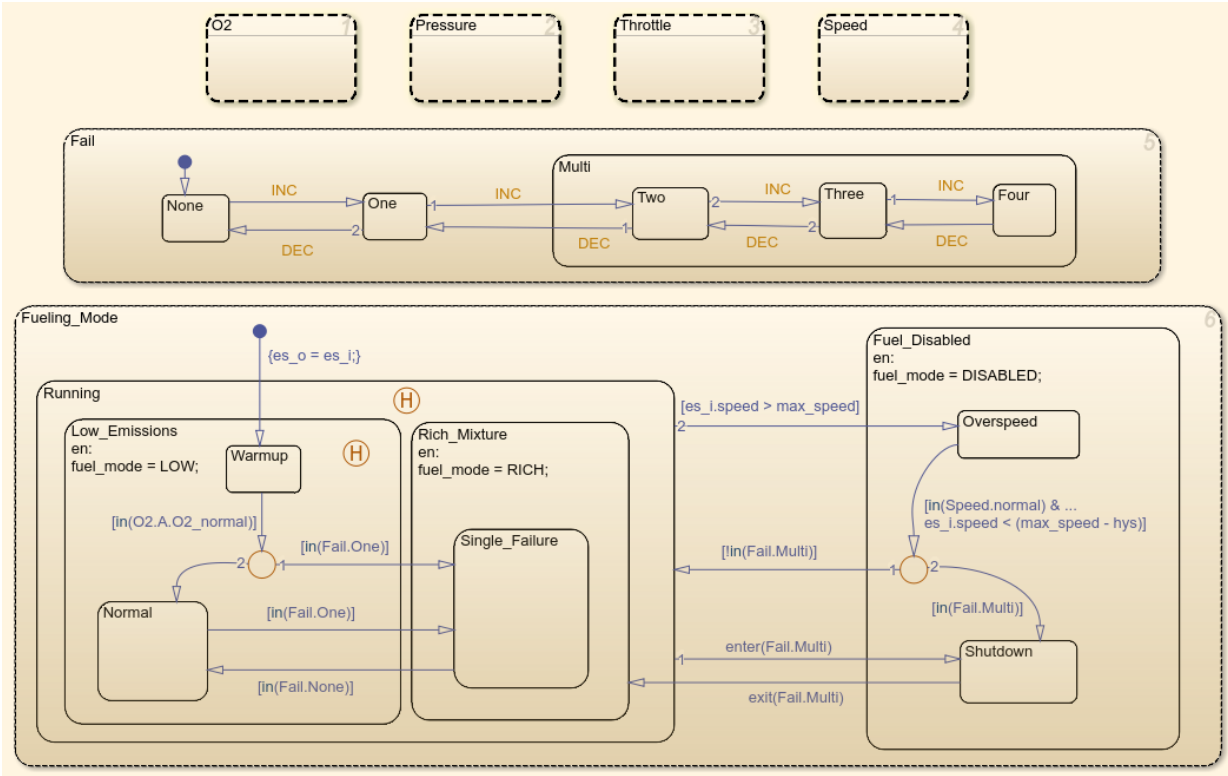

Figure 4: Fuel ratio controller logic

Remove the window clutter.

```
close_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
close_system('sldemo_fuelsys/fuel_rate_control/fuel_calc');
close_system('sldemo_fuelsys/fuel_rate_control/control_logic');
hDemo.rt=sfroot;hDemo.m=hDemo.rt.find('-isa','Simulink.BlockDiagram');
hDemo.c=hDemo.m.find('-isa','Stateflow.Chart','-and','Name','control_logic');
hDemo.c.visible=false;
close_system('sldemo_fuelsys/fuel_rate_control');
```

Build the air-fuel ratio control system only. Once the code generation process is complete, an HTML report detailing the generated code is displayed. The main body of the code is located in `fuel_rate_control.c`.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
```

```
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

Figure 5 shows snippets of the generated code for the lookup table Pumping Constant.

To see the code for Pumping Constant, right-click the block and select **Code Generation > Navigate to code**.

```
rtwtrace('sldemo_fuelsys/fuel_rate_control/airflow_calc/Pumping Constant');
```

The code for the pumping constant contains two breakpoint searches and a 2D interpolation. The `SpeedVect` breakpoint is unevenly spaced, and while the `PressVect` breakpoint is evenly spaced, neither have power of two spacing. The current spacing leads to extra code (ROM), including a division, and requires all breakpoints to be in memory (RAM).

```
/* Lookup_n-D: '<S2>/Pumping Constant' */

Figure 5: Generated code for Pumping Constant lookup (contains unevenly spaced breakpoints)

Optimize Code with Evenly Spaced Power of Two Breakpoints

You can optimize the generated code performance by using evenly spaced power of two breakpoints. In this example, remap the lookup table data in the air-fuel ratio control system based on the existing measured data.

When you loaded the model, the model `PostLoadFcn` created the lookup table data in the model workspace. Retrieve the original table data via `sldemo_fuelsys_data`, modify it for evenly spaced power of two, and reassign it in the model workspace.

```
td = sldemo_fuelsys_data('sldemo_fuelsys', 'get_table_data');
```

Compute new table data for evenly spaced power of two breakpoints.

```
ntd.SpeedVect   = 64 : 2^5 : 640;             % 32 rad/sec
ntd.PressVect   = 2*2^-5 : 2^-5 : 1-(2*2^-5); % 0.03 bar
ntd.ThrotVect   = 0:2^1:88;                   % 2 deg
ntd.RampRateKiX = 128:2^7:640;                % 128 rad/sec
ntd.RampRateKiY = 0:2^-2:1;                   % 0.25 bar
```

Remap table data.

```
ntd.PumpCon  = interp2(td.PressVect,td.SpeedVect,td.PumpCon, ntd.PressVect',ntd.SpeedVe
ntd.PressEst = interp2(td.ThrotVect,td.SpeedVect,td.PressEst,ntd.ThrotVect',ntd.SpeedVe
ntd.SpeedEst = interp2(td.PressVect,td.ThrotVect,td.SpeedEst,ntd.PressVect',ntd.ThrotVe
ntd.ThrotEst = interp2(td.PressVect,td.SpeedVect,td.ThrotEst,ntd.PressVect',ntd.SpeedVe
```

Recompute Ramp Rate table data.

```
ntd.RampRateKiZ = (1:length(ntd.RampRateKiX))' * (1:length(ntd.RampRateKiY)) * td.Ki;
```

Pumping Constant Power Of Two Spacing

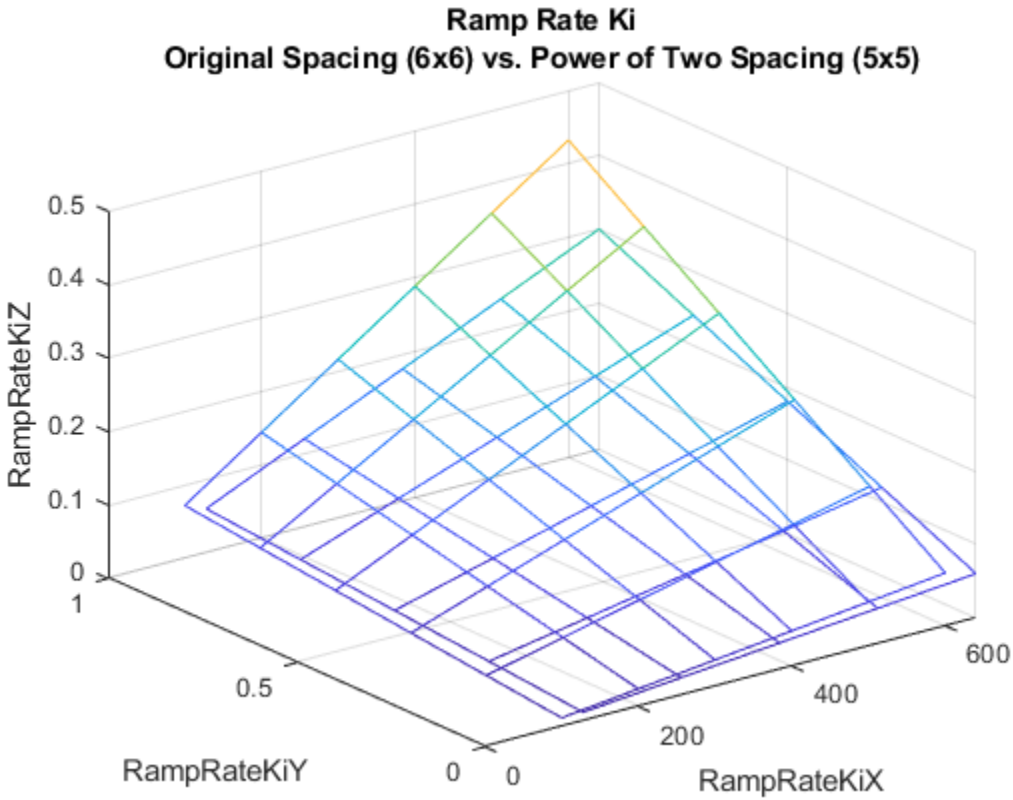
    size(td.RampRateKiZ,1),size(td.RampRateKiZ,2),size(ntd.RampRateKiZ,1),size(ntd.Ramp
```



The default configuration causes the model to log simulation data for the top-level signals. These simulation results are stored in the workspace variable `sldemo_fuelsys_output`. Before updating the model workspace with the new data, save the result of the simulation in `hDemo.orig_data` for later comparison with the evenly spaced power of two table simulation.

```
set_param('sldemo_fuelsys','StopTime','8')
sim('sldemo_fuelsys')
hDemo.orig_data = sldemo_fuelsys_output;
```

Reassign the new table data in the model workspace.

```
hDemo.hWS = get_param('sldemo_fuelsys', 'ModelWorkspace');
hDemo.hWS.assignin('PressEst',   ntd.PressEst);
```

```
hDemo.hWS.assignin('PressVect',  ntd.PressVect);
hDemo.hWS.assignin('PumpCon',    ntd.PumpCon);
hDemo.hWS.assignin('SpeedEst',   ntd.SpeedEst);
hDemo.hWS.assignin('SpeedVect',  ntd.SpeedVect);
hDemo.hWS.assignin('ThrotEst',   ntd.ThrotEst);
hDemo.hWS.assignin('ThrotVect',  ntd.ThrotVect);
hDemo.hWS.assignin('RampRateKiX',ntd.RampRateKiX);
hDemo.hWS.assignin('RampRateKiY',ntd.RampRateKiY);
hDemo.hWS.assignin('RampRateKiZ',ntd.RampRateKiZ);
```

Reconfigure lookup tables for evenly spaced data.

```
hDemo.lookupTables = find_system(get_param('sldemo_fuelsys','Handle'),...
    'BlockType','Lookup_n-D');

for hDemo_blkIdx = 1 : length(hDemo.lookupTables)
    hDemo.blkH = hDemo.lookupTables(hDemo_blkIdx);
    set_param(hDemo.blkH,'IndexSearchMethod','Evenly spaced points')
    set_param(hDemo.blkH,'InterpMethod','None - Flat')
    set_param(hDemo.blkH,'ProcessOutOfRangeInput','None')
end
```

Rerun the simulation for the evenly spaced power of two implementation, and store the result of the simulation in `hDemo.pow2_data`.

```
sim('sldemo_fuelsys')
hDemo.pow2_data = sldemo_fuelsys_output;
```

Compare the result of the simulation for the fuel flow rate and the air fuel ratio. The simulation exercised the Pumping Constant and Ramp Rate Ki lookup tables, and shows an excellent match for the evenly spaced power of two breakpoints relative to the original table data.

```
figure('Tag','CloseMe');
subplot(2,1,1);
plot(hDemo.orig_data.get('fuel').Values.Time, ...
     hDemo.orig_data.get('fuel').Values.Data,'r-');

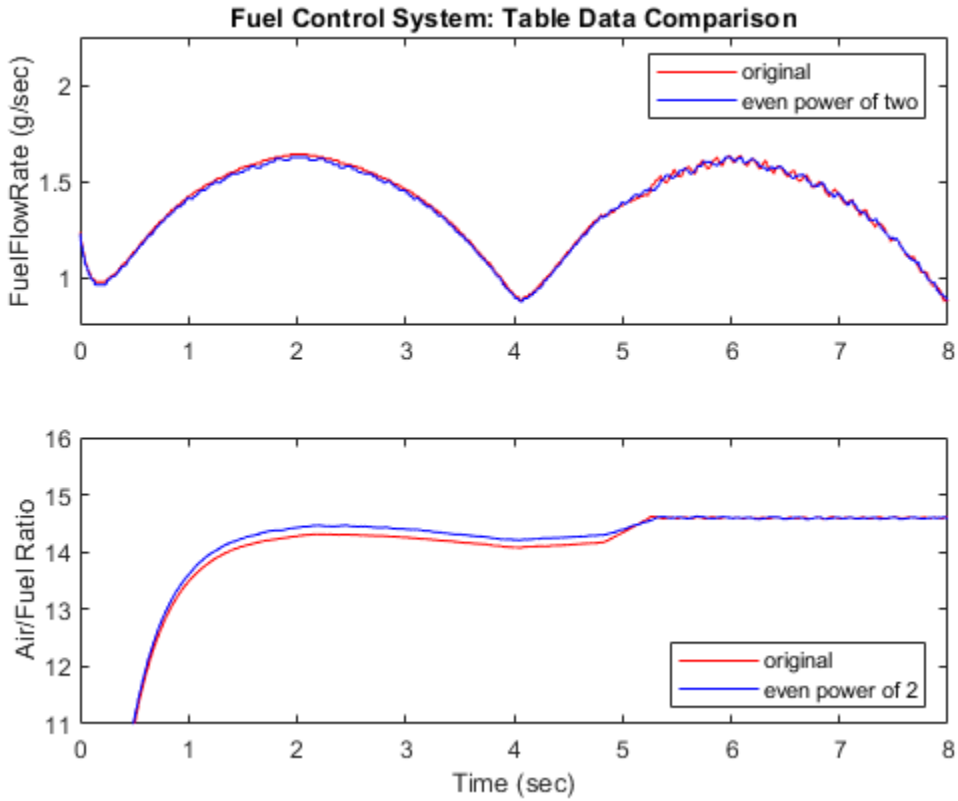
legend('original','even power of 2','Location','SouthEast');
axis([0 8 11 16]);

Current plot held
Current plot held
```



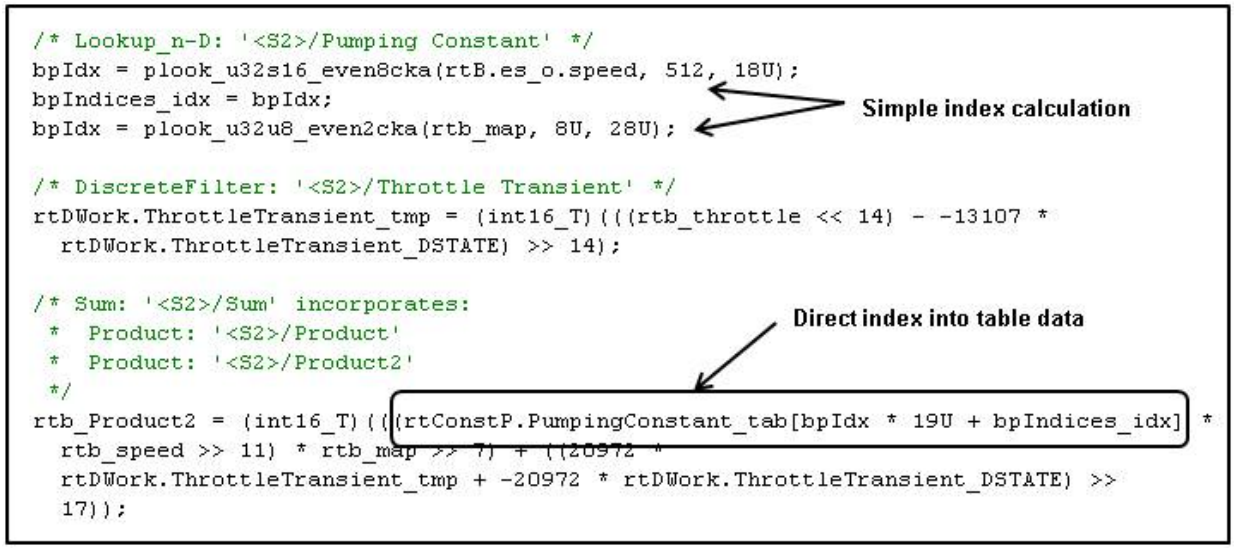
Rebuild the air-fuel ratio control system and compare the difference in the generated lookup table code.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
```

```
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

Figure 6 shows the same snippets of the generated code for the 'Pumping Constant' lookup table. The generated code for evenly spaced power of two breakpoints is significantly more efficient than the unevenly spaced breakpoint case. The code consists of two simple breakpoint calculations and a direct index into the 2D lookup table data. The expensive division is avoided and the breakpoint data is not required in memory.

```
rtwtrace('sldemo_fuelsys/fuel_rate_control/airflow_calc/Pumping Constant');
```



```
uint32_T plook_u32s16_even8cka(int16_T u, int16_T bp0, uint32_T maxIndex)
{
  uint32_T bpIndex;
  uint16_T fbpIndex;

  /* Prelookup - Index only
     Index Search method: 'even'
     Process out of range input: 'Clip to range'
     Use previous index: 'off'
     Use last breakpoint for index at or above upper limit: 'on'
   */
  if (u < bp0) {
    bpIndex = 0U;
  } else {
    fbpIndex = (uint16_T)((uint32_T)u - (uint32_T)bp0) >> 8U;
    if ((uint32_T)fbpIndex >= maxIndex) {
      bpIndex = maxIndex;
    } else {
      bpIndex = (uint32_T)fbpIndex;
    }
  }

  return bpIndex;
}
```

Figure 6: Generated code for Pumping Constant lookup (evenly spaced power of two breakpoints)

Close the example.

```
close(findobj(0,'Tag','CloseMe'));
clear hDemo* td ntd
close_system('sldemo_fuelsys',0);
```

Model Advisor for Code Efficiency

Improving code efficiency by using evenly spaced power of two breakpoints is one of several important optimizations for fixed-point code generation. The Simulink® Model Advisor is a great tool for identifying other methods of improving code efficiency for a

Simulink® and Stateflow® model. Make sure to run the checks under the Embedded Coder® folder.

Module Packaging Tool (MPT) Data Objects in Embedded Coder

MPT Data Object Properties

In this section...

The following table describes the properties and property values for `mpt.Parameter` and `mpt.Signal` data objects that appear in the Model Explorer.

Note You can create `mpt.Signal` and `mpt.Parameter` objects in the base MATLAB or model workspace. However, if you create a signal object in a model workspace, the object's storage class must be set to `Auto`.

The figure below shows an example of the Model Explorer. When you select an `mpt.Parameter` or `mpt.Signal` data object in the middle pane, its properties and property values display in the rightmost pane.

In the Properties column, the table lists the properties in the order in which they appear on the Model Explorer.

Parameter and Signal Property Values

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Both	User object type	`*auto`	Prenamed and predefined property sets that are registered in the `sl_customization.m` file. (See “Register mpt User Object Types” on page 35-19.) This field is active when a user object type is registered. Select `auto` if this field is available but you do not want to apply the properties of a user object type to a selected data object. The fields on the Model Explorer are populated with default values.
		Listed user object type name	Select a user object type name to apply the properties and values that you associated with this name in the `sl_customization.m` file. The fields on the Model Explorer are automatically populated with those values.
Parameter	`Value`	`*0`	The data type and numeric value of the data object. For example, `int8(5)`. The numeric value is used as an initial parameter value in the generated code.
Both	Data type		Used to specify the data type for an `mpt.Signal` data object, but not for an `mpt.Parameter` data object. The data type for an `mpt.Parameter` data object is specified in the **Value** field above. See “About Data Types in Simulink” (Simulink).
Both	Unit	`*null`	Units of measurement of the signal or parameter. (Enter text in this field.)

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Both	Dimensions	`*-1`	The dimension of the signal or parameter. For a parameter, the dimension is derived from its value.

Both	Complexity	`*auto`
		
		`real`
		
		`complex`
			Complexity specifies whether the signal or parameter is a real or complex number. Select `auto` for the code generator to decide. For a parameter, the complexity is derived from its value.

Signal	Sample time	`*-1`	Model or block execution rate.
Signal	Sample mode	`*auto`	Determines how the signal propagates through the model. Select `auto` for the code generator to decide.
		`Sample based`	The signal propagates through the model one sample at a time.
		`Frame based`	The signal propagates through the model in batches of samples.
Both	Minimum	`*0.0`	The minimum value to which the parameter or signal is expected to be bound.
		Number within the minimum range of the parameter or signal. (Based on the data type and resolution of the parameter or signal.)	
Both	Maximum	`*0.0`	Maximum value to which the parameter or signal is expected to be bound. (Enter information using a dialog box.)
	Code generation options		

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
	Storage class		Note that an `auto` selection for a storage class tells the build process to decide how to declare and store the selected parameter or signal.
Both	Global (Custom)	`Global (Custom)` is the default storage class for `mpt` data objects.	Specifies that a code generator not place a qualifier in the data object's declaration.
Both	Memory section	*`Default`	**Memory section** allows you to specify storage directives for the data object. `Default` specifies that the code generator not place a type qualifier and `pragma` statement with the data object's declaration.
Parameter		`MemConst`	Places the `const` type qualifier in the declaration.
Both		`MemVolatile`	Places the `volatile` type qualifier in the declaration.
Parameter		`MemConstVolatile`	Places the `const volatile` type qualifier in the declaration.

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Both	Header file		Name of the file used to import or export the data object. This file contains the declaration (`extern`) to the data object. Also, you can specify this header filename between the double-quotation or angle-bracket delimiter. You can specify the delimiter with or without the `.h` extension. For example, specify `"object.h"` or `"object"`. For the selected data object, this overrides the general delimiter selection in the **#include file delimiter** field on the Configuration Parameters dialog box.
Both	Owner	*Blank	The name of the module that owns this signal or parameter. This is used to help determine the ownership of a definition. For details, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 33-2.
Both	Definition file	*Blank	Name of the file that defines the data object.
		Valid character vector	

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Both	Persistence level		The number you specify is relative to **Signal display level** or **Parameter tune level** on the **Code Placement** pane of the Configuration Parameters dialog box. For a signal, allows you to specify whether or not the code generator declares the data object as global data. For a parameter, allows you to specify whether or not the code generator declares the data object as tunable global data. See **Signal display level** and **Parameter tune level** in “Model Configuration Parameters: Code Generation Code Placement”.
Both	Bitfield (Custom)		Embeds Boolean data in a named bit field.
	Struct name		Name of the `struct` into which the object's data will be packed.
Parameter	Const (Custom)		Places the `const` type qualifier in the declaration.
Parameter	Header file		See above.
Parameter	Owner		See above.
Parameter	Definition file		See above.
Parameter	Persistence level		See above.
Both	Volatile (Custom)		Places the `volatile` type qualifier in the declaration.
Both	Header file		See above.
Both	Owner		See above.
Both	Definition file		See above.
Both	Persistence level		See above.

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Parameter	ConstVolatile (Custom)		Places the `const volatile` type qualifier in declaration.
Parameter	Header file		See above.
Parameter	Owner		See above.
Parameter	Definition file		See above.
Parameter	Persistence level		See above.
Parameter	Define (Custom)		Represents parameters with a `#define` macro.
Parameter	Header file		See above.
Both	ExportToFile (Custom)		Generates global variable definition, and generates a user-specified header (`.h`) file that contains the declaration (`extern`) to that variable.
Both	Memory section		See above.
Both	Header file		See above.
Both	Definition file		See above.
Both	ImportFromFile (Custom)		Includes predefined header files containing global variable declarations, and places the `#include` in a corresponding file. Assumes external code defines (allocates memory) for the global variable.
Both	Data access	`*Direct`	Allows you to specify whether the identifier that corresponds to the selected data object stores data of a data type (`Direct`) or stores the address of the data (a pointer).

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Both		`Pointer`	If you select `Pointer`, the code generator places * before the identifier in the generated code.
	Header file		See above.
Both	Struct (Custom)		Embeds data in a named `struct` to encapsulate sets of data.
Both	Struct name		See above.
Signal	GetSet (Custom)		Reads (gets) and writes (sets) data using functions.
Signal	Header file		See above.
Signal	Get function		Specify the Get function.
Signal	Set function		Specify the Set function.
Both	Alias	`*null`	As explained in detail in “Override Data Object Naming Rules” on page 50-20, for a Simulink or `mpt` data object (identifier), specifying a name in the **Alias** field overrides the global naming rule selection you make on the Configuration Parameters dialog box.
		Valid ANSI[a] C/C++ variable name	
Both	`Description`	`*null`	Text description of the parameter or signal. Appears as a comment beside the signal or parameter's identifier in the generated code.
		Character vector	

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Signal	Reusable (Custom)		Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same custom storage class for both. The custom storage class is either `Reusable (Custom)` or derived from `Reusable (Custom)`.
Signal	Data Scope	`*Auto`	You can specify the scope of symbols code generation generates for a data object of this class by selecting a value for **DataScope**. When you take the default of `Auto`, code generation determines the symbol scope internally. If possible, symbols have `File` scope. Otherwise, they have `Exported` scope.
		`File`	Code generation defines the scope of each symbol as the file that defines it. File scope requires each symbol to be used in a single file. If the same symbol is referenced in multiple files, code generation reports an error.
		`Exported`	Code generation exports symbols to external code in the header file specified by the **HeaderFile** field. If a **HeaderFile** is not specified, symbols are exported to external code in *`model`*`.h`.
		`Imported`	Code generation imports symbols from external code in the header file specified by the **HeaderFile** field. If you do not specify a header file, code generation generates an `extern` directive in *`model`*_private.h.
Signal	Header file		See above.
Signal	Owner		See above.

Class: Parameter, Signal, or Both	Property	Available Property Values (* Indicates Default)	Description
Signal	Definition file		See above.

a. ANSI is a registered trademark of the American National Standards Institute, Inc.

`mpt` Package Custom Storage Classes

CSC Name	Purpose	Signals?	Parameters?
`BitField`	Generate a `struct` declaration that embeds Boolean data in named bit fields.	Y	Y
`CompilerFlag`	Supports preprocessor conditionals defined via compiler flag. See “Generate Preprocessor Conditionals for Variant Systems” on page 25-35.	N	Y
`Const`	Generate a constant declaration with the `const` type qualifier.	N	Y
`ConstVolatile`	Generate declaration of volatile constant with the `const volatile` type qualifier.	N	Y
`Define`	Generate `#define` directive.	Y	Y
`ExportToFile`	Generate header (`.h`) file, with user-specified name, containing global variable declarations.	Y	Y
`FileScope`	Generate a static qualifier suffix for a variable declaration so that the scope of the variable is limited to the current file.	Y	Y
`GetSet`	Supports specialized function calls to read and write the memory associated with a Data Store Memory block. See “Access Data Through Functions with Custom Storage Class GetSet” on page 36-51.	Y	Y
`Global`	The default custom storage class for the `mpt` package. Generate the declaration and definition of a data object in specified files, and use the specified memory section.	Y	Y

CSC Name	Purpose	Signals?	Parameters?
`ImportedDefine`	Supports preprocessor conditionals defined via legacy header file. See “Generate Preprocessor Conditionals for Variant Systems” on page 25-35.	N	Y
`ImportFromFile`	Generate directives to include predefined header files containing global variable declarations.	Y	Y
`Reusable`	Allows the code generator to reuse a pair of root I/O signals when you specify the same name and the same custom storage class for both. The custom storage class is either `Reusable (Custom)` or derived from `Reusable (Custom)`.	Y	N
`Struct`	Generate a `struct` declaration encapsulating parameter or signal object data.	Y	Y
`StructConst`	Generate a `struct` declaration, with a `const` type qualifier, encapsulating parameter object data.	N	Y
`StructVolatile`	Generate a `struct` declaration, with a `volatile` type qualifier, encapsulating parameter or signal object data.	Y	Y
`Volatile`	Use `volatile` type qualifier in declaration.	Y	Y

Examples of Property Value Changes on Generated Code

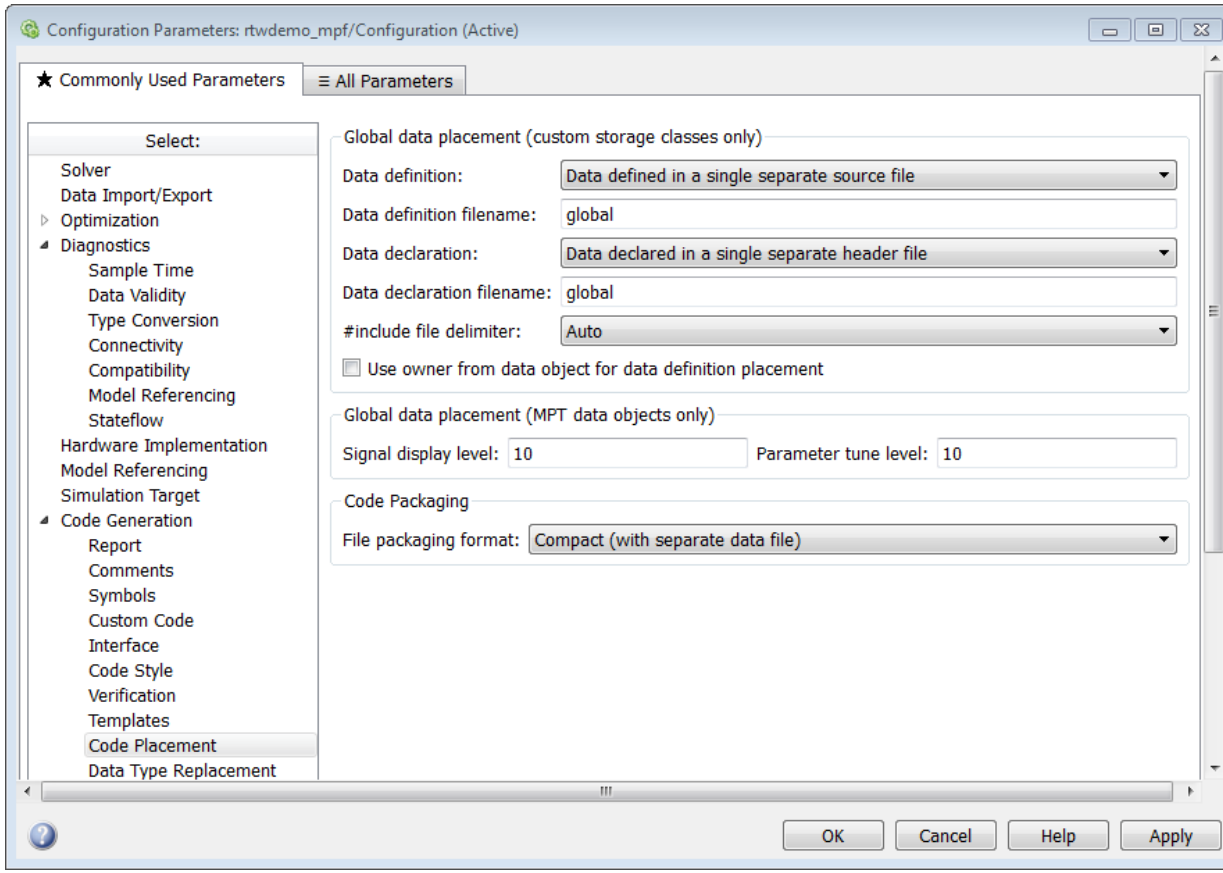
What I noticed when inspecting the .c/.cpp file	Change I made to property value settings	What I noticed after regenerating and reinspecting the file
Example 1: Parameter data objects can be declared or defined as constants. I know that the data object `GAIN` is a parameter. I want this to be declared or defined in the `.c` file as a variable. But I notice that `GAIN` is declared as a constant by the statement `const real_T GAIN = 5.0;`. Also, this statement is in the constant section of the file.	In the Model Explorer, I clicked the data object `GAIN`. I noticed that the property value for its **Memory section** property is set at `MemConst`. I changed this to `Default`.	I notice two differences. One is that now `GAIN` is declared as a variable with the statement `real_T GAIN = 5.0;`. The second difference is that the declaration now is located in the `MemConst` memory section in the `.c` or `.cpp` file.
Example 2: I notice again the declaration of `GAIN` in the `.c` file mentioned in Example 1. It appears as `real_T GAIN = 5.0;`. But I have changed my mind. I want data object `GAIN` to be `#define`.	I changed the **Storage class** selection to `Define (Custom)`.	`GAIN` is not declared in the `.c` file as a `MemConst` parameter. Rather, it is defined as a `#define` macro by the code `#define GAIN 5.0`, and this is located near the top of the `.c` file with the other preprocessor directives.
Example 3: I changed my mind again after doing Example 2. I do want `GAIN` defined using the `#define` preprocessor directive. But I do not want to include the `#define` in this file. I know it exists in another file and I want to reference that file.	On the Model Explorer, I notice that the property value for the **Header file** property is blank. I changed this to `filename.h`. (I chose the ANSI C/C++ double quote mechanism for the `#include`, but could have chosen the angle bracket mechanism.) Also, I must make the user-defined `filename.h` available to the compiler, placing it either in the system path or local directory.	`#define GAIN 5.0` is not present in this `.c` file. Instead, the `#include filename.h` code appears as a preprocessor directive at the top of the file.

What I noticed when inspecting the .c/.cpp file	Change I made to property value settings	What I noticed after regenerating and reinspecting the file
Example 4: I have one more change I want to make. Let us say that we have declared the data object `data_in`, and that its declaration statement in the `.c` file reads `real_T data_in = 0.0;`. I want to replace this statement with an alias in the `.c` file.	In the Model Explorer, I selected the data object `data_in`. I noticed that the **Alias** field is blank. I changed this to `data_in_alias`, which I know is a valid ANSI C/C++ variable name.	The identifier `data_in_alias` now appears in the `.c` file everywhere `data_in` appeared.

Specify Persistence Level for Signals and Parameters

With this procedure, you can control the persistence level of signal and parameter objects associated with a model. Persistence level allows you to make intermediate variables or parameters global during initial development. At the later stages of development, you can use this procedure to remove these signals and parameters for efficiency. Use the **Persistence Level** property of `mpt.Signal` and `mpt.Parameter` data objects. For descriptions of the properties on the Model Explorer, see “MPT Data Object Properties” on page 35-2.

Notice also the **Signal display level** and **Parameter tune level** fields on the **Code Placement** pane of the Configuration Parameters dialog box, as illustrated in the next figure.



The **Signal display level** field allows you to specify whether or not the code generator defines a signal data object as global data in the generated code. The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Signal display level** number is for `mpt` (module packaging tool) signal data objects in the model. The **Persistence level** number is for a *particular* `mpt` signal data object. If the data object's **Persistence level** is equal to or less than the **Signal display level**, the signal appears in the generated code as global data with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Signal display level** is 5.

Otherwise, the code generator automatically determines how the particular signal data object appears in the generated code. Depending on the settings on the **Optimization**

pane of the Configuration Parameters dialog box, the signal data object could appear in the code as local data without the custom attributes you specified for that data object. Or, based on expression folding, the code generator could remove the data object so that it does not appear in the code.

The **Parameter tune level** field allows you to specify whether or not the code generator declares a parameter data object as tunable global data in the generated code.

The number you specify in this field is relative to the number you specify in the **Persistence level** field. The **Parameter tune level** number is for `mpt` parameter data objects in the model. The **Persistence level** number is for a *particular* `mpt` parameter data object. If the data object's **Persistence level** is equal to or less than the **Parameter tune level**, the parameter appears tunable in the generated code with the custom attributes that you specified. For example, this would occur if **Persistence level** is 2 and **Parameter tune level** is 5.

Otherwise, the parameter is inlined in the generated code, and the code generation settings determine its exact form.

Note that, in the initial stages of development, you might be more concerned about debugging than code size. Or, you might want one or more particular data objects to appear in the code so that you can analyze intermediate calculations of an equation. In this case, you might want to specify the **Parameter tune level** (**Signal display level** for signals) to be higher than **Persistence level** for some `mpt` parameter (or signal) data objects. This results in larger code size, because the code generator defines the parameter (or signal) data objects as global data, which have the custom properties you specified. As you approach production code generation, however, you might have more concern about reducing the size of the code and less need for debugging or intermediate analyses. In this stage of the tradeoff, you could make the **Parameter tune level** (**Signal display level** for signals) greater than **Persistence level** for one or more data objects, generate code and observe the results. Repeat until satisfied.

1. With the model open, in the Configuration Parameters dialog box, select **Code Generation > Code Placement**.
2. Type the desired number in the **Signal display level** or **Parameter tune level** field, and click **Apply**.
3. In the Model Explorer, type the desired number in the **Persistence** field for the selected signal or parameter, and click **Apply**.
4. Save the model and generate code.

Register mpt User Object Types

Introduction

Embedded Coder allows you to create custom `mpt` object types and specify properties and property values to be associated with them. Once created, a user object type can be applied to data objects displayed in Model Explorer. When you apply a user object type to a data object, by selecting a type name in the **User object type** pull-down list in Model Explorer, the data object is automatically populated with the properties and property values that you specified for the user object type.

To register `mpt` user object type customizations, use the Simulink customization file `sl_customization.m`. This file is a mechanism that allows you to use MATLAB code to perform customizations of the standard Simulink user interface. The Simulink software reads the `sl_customization.m` file, if present on the MATLAB path, when it starts and the customizations specified in the file are applied to the Simulink session. For more information on the `sl_customization.m` customization file, see "Registering Customizations" (Simulink).

Register mpt User Object Types Using sl_customization.m

To register `mpt` user object type customizations, you create an instance of `sl_customization.m` and include it on the MATLAB path of the Simulink installation that you want to customize. The `sl_customization` function accepts one argument: a handle to a customization manager object. For example,

```
function sl_customization(cm)
```

As a starting point for your customizations, the `sl_customization` function must first get the default (factory) customizations, using the following assignment statement:

```
hObj = cm.slDataObjectCustomizer;
```

You then invoke methods to register your customizations. The customization manager object includes the following methods for registering `mpt` user object type customizations:

- `addMPTObjectType(hObj, objectTypeName, classtype, propName1, propValue1, propName2, propValue2, ...)`

`addMPTObjectType(hObj, objectTypeName, classtype, {propName1, propName2, ...}, {propValue1, propValue2, ...})`

Registers the specified user object type, along with specified values for object properties, and adds the object type to the top of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `objectTypeName` — Name of the user object type
- `classType` — Class to which the user object type applies: `'Signal'`, `'Parameter'`, or `'Both'`
- `propName` — Name of a property of an `mpt` or `mpt`-derived data object to be populated with a corresponding `propValue` when the registered user object type is selected
- `propValue` — Specifies the value for a corresponding `propName`

- `moveMPTObjectTypeToTop(hObj, objectTypeName)`

  Moves the specified user object type to the top of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `moveMPTObjectTypeToEnd(hObj, objectTypeName)`

  Moves the specified user object type to the end of the user object type list, as displayed in the **User object type** pull-down list in the Model Explorer.

- `removeMPTObjectType(hObj, objectTypeName)`

  Removes the specified user object type from the user object type list.

Your instance of the `sl_customization` function should use these methods to register `mpt` object type customizations for your Simulink installation.

The Simulink software reads the `sl_customization.m` file when it starts. If you subsequently change the file, to use the changes, you must restart your MATLAB session.

mpt User Object Type Customization Using sl_customization.m

The `sl_customization.m` file shown in “mpt User Object Type Customization Using sl_customization.m” on page 35-20 uses the `addMPTObjectType` method to register the user signal types `EngineType` and `FuelType` for `mpt` objects.

Example 35.1. sl_customization.m for mpt Object Type Customizations

```
function sl_customization(cm)
% Register user customizations
```

```
% Get default (factory) customizations
hObj = cm.slDataObjectCustomizer;

% Add commonly used signal types
hObj.addMPTObjectType(...
    'EngineType','Signal',...
    'DataType', 'uint8',...
    'Min', 0,...
    'Max', 255,...
    'Unit','m/s');

hObj.addMPTObjectType(...
    'FuelType','Signal',...
    'DataType', 'int16',...
    'Min', -12,...
    'Max', 3000,...
    'Unit','mg/hr');

end
```

If you include the above file on the MATLAB path of the Simulink installation that you want to customize, the specified customizations will appear in Model Explorer. For example, you could view the customizations as follows:

1. Start a MATLAB session.
2. Open Model Explorer, for example, by entering the MATLAB command `daexplr`.
3. Select **Base Workspace**.
4. Add an `mpt` signal, for example, by selecting **Add** > **Add Custom**.
5. In the right-hand pane display for the added `mpt` signal, examine the **User object type** drop-down list, noting the impact of the changes specified in “mpt User Object Type Customization Using sl_customization.m” on page 35-20.
6. From the **User object type** drop-down list, select one of the registered user signal types, for example, `FuelType`, and verify that the displayed settings are consistent with the arguments specified to the `addMPTObjectType` method in `sl_customization.m`.

Custom Storage Classes in Embedded Coder

Configure Data Interface by Applying Custom Storage Classes

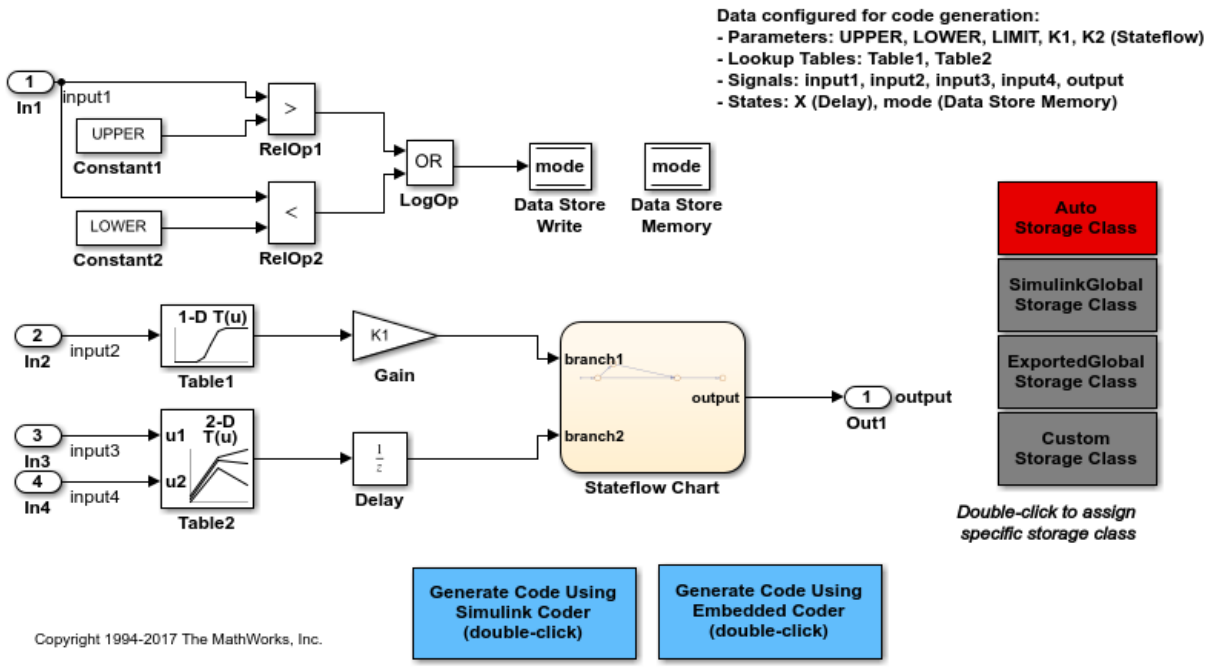
To integrate the generated code with your own external code, you can configure data items in a model, such as signal lines and block parameters, to appear in the generated code as global variables. Use custom storage classes and custom data types to:

- Export or import named numeric data types (`typedef`).
- Control placement of declarations and definitions in generated and external (exported and imported) files.
- Package multiple data items into structures.
- Apply the storage type qualifiers `const` and `volatile`.

Explore Example Model

Run the script `prepare_rtwdemo_advsc`, which prepares the example model `rtwdemo_advsc` for this example.

```
run(fullfile(matlabroot,'examples','ecoder','main','prepare_rtwdemo_advsc'))
```



In the model, select **View > Property Inspector**.

In the model, select the Gain block.

In the Property Inspector, next to the value of the **Gain** parameter, click the action button (with three vertical dots) and select **K1 > Explore**.

The Model Explorer shows you the contents of the model workspace. The workspace contains `Simulink.Parameter` and `Simulink.LookupTable` objects that set parameter values, such as constant scalars and lookup table data, for the blocks in the model.

In the model, select **Display > Signals and Ports > Port Data Types** to display the signal data types. Many of the signals use the custom data type `MYTYPE`. In the base workspace, a `Simulink.AliasType` object, `MYTYPE`, acts as an alias for the double-precision, floating-point data type `double`.

Configure Data Representation Through Custom Storage Classes

Suppose that you want to configure the generated code to:

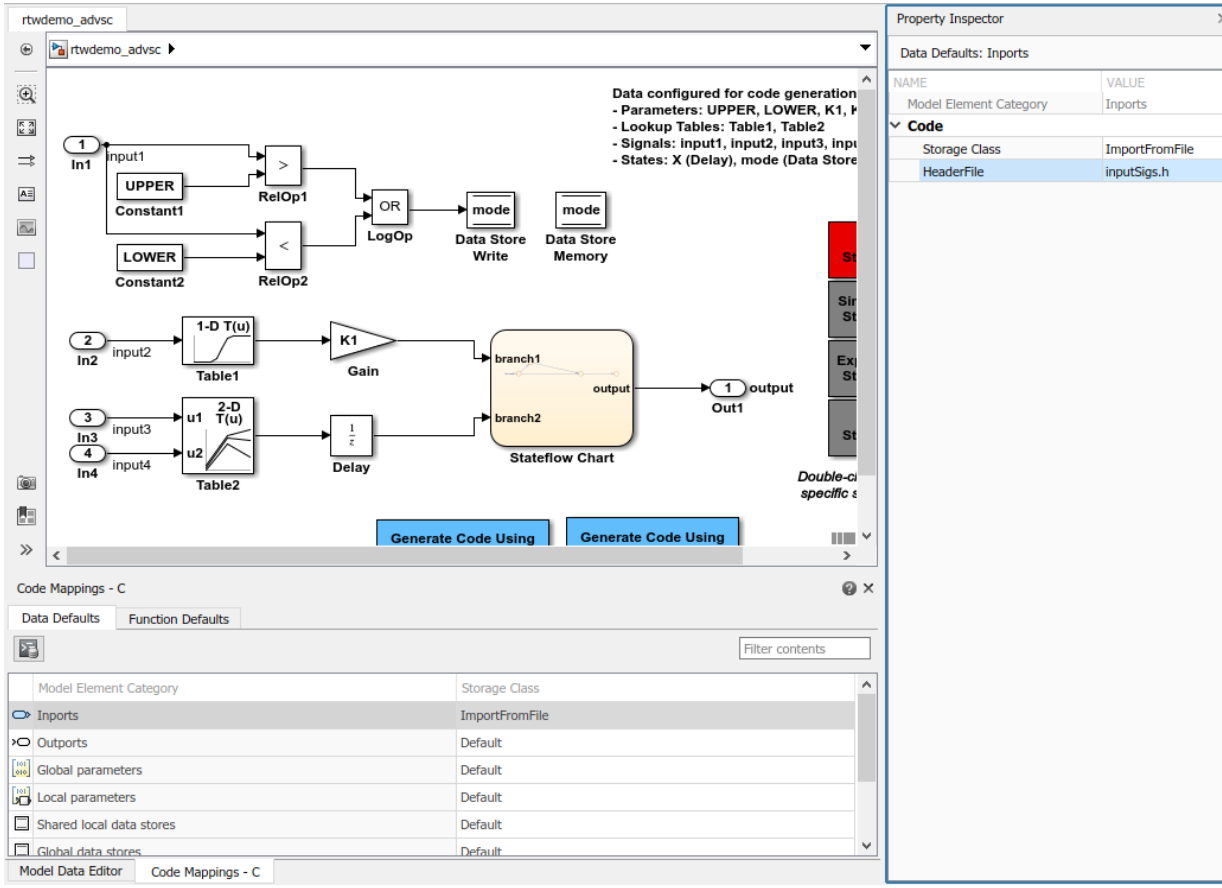
- Export the declaration of the output signal `output` to a generated header file named `outSigs.h`.
- Import the definitions (memory allocation) and declarations of the input signals `input1` through `input4` from your external code. You provide the declarations in a header file named `inputSigs.h` and the definitions in a source file named `globalSigs.c`.
- Export the parameters and lookup tables, such as `K1` and `Table1`, as `const volatile` global variables defined in `tunableParams.c` and declared in `tunableParams.h`.
- Apply the C storage type qualifier `volatile` to block states, such as the Unit Delay state `state_X`, and to data stores such as `mode`.

To achieve these goals, apply custom storage classes to the data items.

Place the model in the Code Perspective by selecting **Code > C/C++ Code > Configure Model in Code Perspective**.

Underneath the block diagram, under **Code Mappings > Data Defaults**, for the **Inports** row, set **Storage Class** to `ImportFromFile`.

In the Property Inspector, set **HeaderFile** to `inputSigs.h`.



Alternatively, to configure the signals, at the command prompt, use these commands:

```
coder.mapping.create('rtwdemo_advsc')
coder.mapping.defaults.set('rtwdemo_advsc','Inports',...
    'StorageClass','ImportFromFile',...
    'HeaderFile','inputSigs.h')
```

To include the external source file `globalSigs.c` when Simulink Coder compiles and links the generated code, you can use a configuration parameter such as **Configuration Parameters > Code Generation > Custom Code > Additional Build Information > Source files**.

In the Code Mapping Editor, for the **Outports** row, set **Storage Class** to `ExportToFile` and **HeaderFile** to `outSigs.h`.

For the **Local parameters** row, set **Storage Class** to `ConstVolatile`.

In the Property Inspector, set **HeaderFile** to `tunableParams.h` and **DefinitionFile** to `tunableParams.c`.

For the **Internal data** row, set **Storage Class** to `Volatile`.

```
coder.mapping.defaults.set('rtwdemo_advsc','Outports',...
    'StorageClass','ExportToFile',...
    'HeaderFile','outSigs.h')
coder.mapping.defaults.set('rtwdemo_advsc','LocalParameters',...
    'StorageClass','ConstVolatile',...
    'HeaderFile','tunableParams.h',...
    'DefinitionFile','tunableParams.c')
coder.mapping.defaults.set('rtwdemo_advsc','InternalData',...
    'StorageClass','Volatile')
```

Underneath the block diagram, open the Model Data Editor by selecting the **Model Data Editor** tab.

In the Model Data Editor, inspect the **Parameters** tab.

In the **Filter contents** box, enter `model workspace`.

For parameters and lookup tables in the model workspace, set **Storage Class** to `Model default`. With this setting, the parameters and lookup tables acquire the code generation settings that you specified for **Code Mappings > Data Defaults > Local parameters**.

```
mdlwks = get_param('rtwdemo_advsc','ModelWorkspace');
paramNames = evalin(mdlwks,'whos');
paramNames = {paramNames.name};
for i = 1:length(paramNames)
    temp = getVariable(mdlwks,paramNames{i});
    temp = copy(temp);
    temp.CoderInfo.StorageClass = 'Model default';
    assignin(mdlwks,paramNames{i},copy(temp))
end
```

On the **Data stores** tab, for the data store `mode`, set **Storage Class** to `Model default`. The data store acquires the code generation settings that you specified for **Internal data**.

```
set_param('rtwdemo_advsc/Data Store Memory','StateStorageClass',...
    'Model default')
```

Change the setting for **Configuration Parameters > Code Generation > Symbols > Global variables** from `$R$N$M` to `$N$M`. With this setting, global variables in the generated code have names that match the corresponding data elements in the model. In this case, the token `$R` represents the name of the model, `rtwdemo_advsc`.

```
set_param('rtwdemo_advsc','CustomSymbolStrGlobalVar','$N$M')
```

To export the data type definition (`typedef`) of `MYTYPE` from the generated code, configure the `DataScope` property of the data type object `MYTYPE` by using either the command prompt or the property dialog box. Export the definition to a header file named `myTypes.h`.

```
MYTYPE.DataScope = 'Exported';
MYTYPE.HeaderFile = 'myTypes.h';
```

You can include (`#include`) this exported header file in the external source file `globalSigs.c` in which you allocate memory for the input signals `input1` through `input4`.

Generate and Inspect Code

In the model, select **Configuration Parameters > Generate code only**. Then, generate code from the model.

```
set_param('rtwdemo_advsc','GenCodeOnly','on')
rtwbuild('rtwdemo_advsc')
```

```
### Starting build procedure for model: rtwdemo_advsc
### Successful completion of code generation for model: rtwdemo_advsc
```

In the code generation report, view the utility file `myTypes.h`. The file uses `typedef` statements to define the real and complex data types `MYTYPE` and `cMYTYPE`.

```
file = fullfile('rtwdemo_advsc_ert_rtw','myTypes.h');
rtwdemodbtype(file,'typedef real_T MYTYPE;','typedef creal_T cMYTYPE;',1,1)
```

```
typedef real_T MYTYPE;
typedef creal_T cMYTYPE;
```

View the data file `outSigs.h`. The file uses the `extern` keyword to export the declaration of the output signal `output`.

```
file = fullfile('rtwdemo_advsc_ert_rtw','outSigs.h');
rtwdemodbtype(file,'/* Exported data declaration */','extern MYTYPE output;',1,1)
```

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern MYTYPE output;
```

View the file `rtwdemo_advsc_private.h`. The file uses a `#include` statement to include the imported header file `inputSigs.h`.

View the data file `tunableParams.c`. The file defines global variables that correspond to the parameter objects and lookup table objects in the model workspace. The lookup table objects appear as structures, whose type definitions are in rtwdemo_advsc_types.h.

```
file = fullfile('rtwdemo_advsc_ert_rtw','tunableParams.c');
rtwdemodbtype(file,'/* Definition for custom storage class: ConstVolatile */',...
    '* File trailer for generated code.',1,0)
```

```
/* Definition for custom storage class: ConstVolatile */
const volatile int8_T K1 = 2;
const volatile int8_T K2 = 3;
const volatile MYTYPE LOWER = -10.0;
const volatile Table1_Type Table1 = {
  { -5.0, -4.0, -3.0, -2.0, -1.0, 0.0, 1.0, 2.0, 3.0, 4.0, 5.0 },

  { -1.0, -0.99, -0.98, -0.96, -0.76, 0.0, 0.76, 0.96, 0.98, 0.99, 1.0 }
} ;

const volatile Table2_Type Table2 = {
  { 1.0, 2.0, 3.0 },

  { 1.0, 2.0, 3.0 },

  { 4.0, 16.0, 10.0, 5.0, 19.0, 18.0, 6.0, 20.0, 23.0 }
} ;

const volatile MYTYPE UPPER = 10.0;

/*
```

View the file `rtwdemo_advsc.c`. The file allocates memory for the exported signal `output`, the state `state_X`, and the data store `mode`. The definitions of the state and the data store use the qualifier `volatile`.

```
file = fullfile('rtwdemo_advsc_ert_rtw','rtwdemo_advsc.c');
rtwdemodbtype(file,'/* Exported data definition */','volatile MYTYPE state_X;',1,1)
```

```
/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
MYTYPE output;

/* Volatile memory section */
/* Definition for custom storage class: Volatile */
volatile boolean_T mode;
volatile MYTYPE state_X;
```

Store Model Data in Data Dictionary

When you end your MATLAB session, variables and objects that you create in the base workspace, such as `MYTYPE`, do not persist. To permanently store these variables and objects, consider linking the model to a data dictionary.

1. In the example model, select **File > Model Properties > Link to Data Dictionary**.
2. In the Model Properties dialog box, click **New**.
3. In the Create a New Data Dictionary dialog box, set **File name** to `myDict` and click **Save**.
4. In the Model Properties dialog box, click **Apply**.
5. Click **Migrate data**.
6. Click **Migrate** in response to message about copying referenced variables.
7. Click **OK**.

Alternatively, to manually migrate the data into a data dictionary, you can use programmatic commands:

```
% Create a list of the variables and objects that the target
% model uses. In this case, the only member of the list is MYTYPE.
usedVars = {Simulink.findVars('rtwdemo_advsc','SourceType','base workspace').Name};
% Create a new data dictionary in your current folder. Link the model to
% this new dictionary.
myDictObj = Simulink.data.dictionary.create('myDict.sldd');
```

```
set_param('rtwdemo_advsc','DataDictionary','myDict.sldd')
% Import only the target variables (in this case, MYTYPE) from the base workspace to th
% dictionary.
importFromBaseWorkspace(myDictObj,'clearWorkspaceVars',true,'varList',usedVars);
```

The data dictionary now permanently stores `MYTYPE`. To view the contents of the dictionary, click the data dictionary badge in the lower-left corner of the model. Then, in the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

For more information about applying custom storage classes to data items, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28.

Reuse Parameter Data from External Code in the Generated Code

This example shows how to generate code that imports a parameter value from your external code.

Create External Code Files

Suppose your external code defines a vector parameter `myGains` with three elements. Save the definition in your current folder in a file called `ex_vector_import_src.c`.

```
#include "ex_vector_import_decs.h"

my_int8 myGains[3] = {
    2,
    4,
    6
};
```

Save the declaration in your current folder in a file called `ex_vector_import_decs.h`.

```
#include "ex_vector_import_cust_types.h"

extern my_int8 myGains[3];
```

Save the data type definition `my_int8` in your current folder in a file called `ex_vector_import_cust_types.h`.

```
typedef signed char my_int8;
```

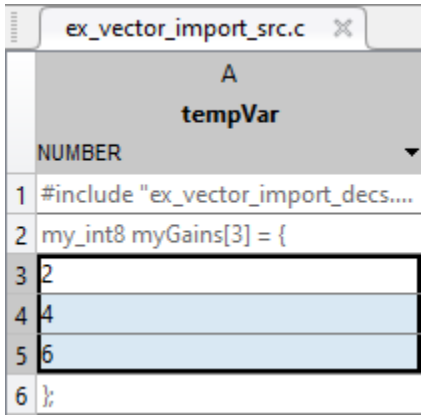
Import Parameter Value for Simulation

In your current folder, right-click the file `ex_vector_import_src.c` and select **Import Data**.

In the Import dialog box, set **Output Type** to `Numeric Matrix`.

Set the name of the generated MATLAB variable to `tempVar`.

Select only the parameter values (2, 4, and 6) to import.



Import the data by clicking the green check mark. The MATLAB variable `tempVar` appears in the base workspace.

Alternatively, use the command prompt to manually create `tempVar`.

```
tempVar = [2;4;6];
```

At the command prompt, create a `Simulink.Parameter` object that represents `myGains`.

```
myGains = Simulink.Parameter(tempVar);
```

Create and Configure Model

Create the model `ex_vector_import`.

```
open_system('ex_vector_import')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Use the **Value** column to set the value of the **Gain** parameter in the Gain block to `myGains`.

Click the **Show/refresh additional information** button. The data table now contains a row that represents the parameter object, `myGains`.

Use the **Data Type** column to set the data type of `myGains` to `my_int8`.

For the other row (which represents the **Gain** parameter of the Gain block), set **Data Type** to `Inherit: Inherit from 'Gain'`. With this setting, the **Gain** parameter inherits the data type `my_int8` from `myGains`.

Set the **Change view** drop-down list to `Code`.

Set these properties for `myGains`:

- **Storage Class** to `ImportFromFile`
- **Header File** to `ex_vector_import_decs.h`

Alternatively, use these commands at the command prompt to configure the object and the block:

```
set_param('ex_vector_import/Gain','Gain','myGains',...
    'ParamDataTypeStr','Inherit: Inherit from ''Gain''')
myGains.DataType = 'my_int8';
myGains.CoderInfo.StorageClass = 'Custom';
myGains.CoderInfo.CustomStorageClass = 'ImportFromFile';
myGains.CoderInfo.CustomAttributes.HeaderFile = 'ex_vector_import_decs.h';
```

At the command prompt, create a `Simulink.AliasType` object to represent your custom data type `my_int8`. Set the `DataScope` and `HeaderFile` properties to import the type definition from your external code.

```
my_int8 = Simulink.AliasType('int8');
my_int8.DataScope = 'Imported';
my_int8.HeaderFile = 'ex_vector_import_cust_types.h';
```

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_vector_import_src.c`.

```
set_param('ex_vector_import','CustomSource','ex_vector_import_src.c')
```

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('ex_vector_import')
```

```
### Starting build procedure for model: ex_vector_import
### Successful completion of build procedure for model: ex_vector_import
```

The generated file `ex_vector_import.h` includes the external header files `ex_vector_import_decs.h` and `ex_vector_import_cust_types.h`, which contain the parameter variable declaration (`myGains`) and custom type definition (`my_int8`).

```
file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.h');
rtwdemodbtype(file,'#include "ex_vector_import_cust_types.h"',...
    '#include "ex_vector_import_cust_types.h"',1,1)
rtwdemodbtype(file,'/* Includes for objects with custom storage classes. */',...
    '#include "ex_vector_import_decs.h"',1,1)
```

```
#include "ex_vector_import_cust_types.h"

/* Includes for objects with custom storage classes. */
#include "ex_vector_import_decs.h"
```

The generated code algorithm in the model `step` function in the generated file `ex_vector_import.c` uses `myGains` for calculations.

```
file = fullfile('ex_vector_import_ert_rtw','ex_vector_import.c');
rtwdemodbtype(file,'/* Model step function */','/* Model initialize function */',1,0)
```

```
/* Model step function */
void ex_vector_import_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/In1'
   */
  rtY.Out1[0] = (real_T)myGains[0] * rtU.In1;
  rtY.Out1[1] = (real_T)myGains[1] * rtU.In1;
  rtY.Out1[2] = (real_T)myGains[2] * rtU.In1;
}
```

The generated code does not define (allocate memory for) or initialize the global variable `myGains` because the data scope of the corresponding parameter object is imported.

When you simulate the model in Simulink, the model uses the value stored in the `Value` property of the parameter object. However, if you use external mode simulation, the

external executable begins the simulation by using the value from your code. See “Considerations for Other Modeling Goals” on page 53-112.

- “Import Parameter Data with Conditionally Compiled Dimension Length” on page 36-16

Import Parameter Data with Conditionally Compiled Dimension Length

Suppose your external code conditionally allocates memory for and initializes lookup table and breakpoint set data based on a dimension length that you specify as a `#define` macro. This example shows how to generate code that imports this external global data.

Create External Code Files

Save the definition of the breakpoint set data `T1Break` and lookup table data `T1Data` in your current folder in a file called `ex_vec_symdim_src.c`. These global variables have either 9 or 11 elements depending on the value of the macro `bpLen`.

```
#include "ex_vec_symdim_decs.h"

#if bpLen == 11
double T1Break[bpLen] = {
    -5.0,
    -4.0,
    -3.0,
    -2.0,
    -1.0,
    0.0,
    1.0,
    2.0,
    3.0,
    4.0,
    5.0
} ;

double T1Data[bpLen] = {
    -1.0,
    -0.99,
    -0.98,
    -0.96,
    -0.76,
    0.0,
    0.76,
    0.96,
    0.98,
    0.99,
    1.0
```

```
} ;
#endif

#if bpLen == 9
double T1Break[bpLen] = {
    -4.0,
    -3.0,
    -2.0,
    -1.0,
    0.0,
    1.0,
    2.0,
    3.0,
    4.0
} ;

double T1Data[bpLen] = {
    -0.99,
    -0.98,
    -0.96,
    -0.76,
    0.0,
    0.76,
    0.96,
    0.98,
    0.99
} ;
#endif
```

Save the declarations of the variables and the definition of the macro in your current folder in a file called `ex_vec_symdim_decs.h`.

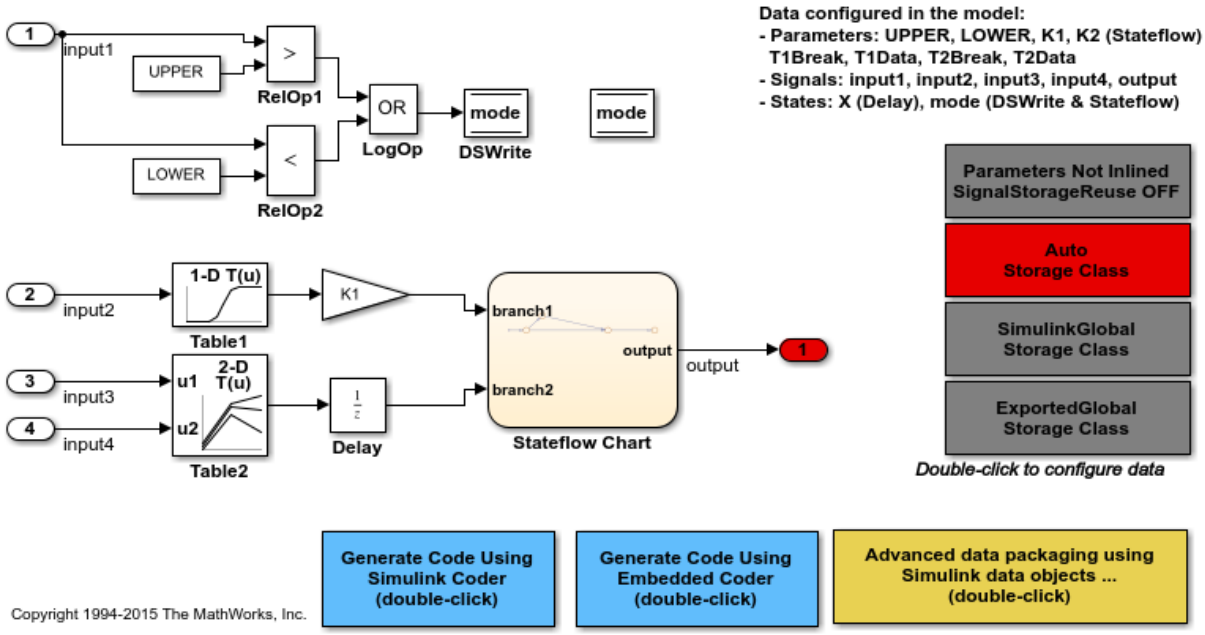
```
#define bpLen 11

extern double T1Break[bpLen];
extern double T1Data[bpLen];
```

Explore and Configure Example Model

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```



Open the Table1 block dialog box. The block refers to variables, `T1Data` and `T1Break`, in the base workspace. These variables store the lookup table and breakpoint set data with 11 elements.

At the command prompt, convert the variables to `Simulink.Parameter` objects.

```
T1Data = Simulink.Parameter(T1Data);
T1Break = Simulink.Parameter(T1Break);
```

Configure the objects to import the data definitions from your external code.

```
T1Data.CoderInfo.StorageClass = 'Custom';
T1Data.CoderInfo.CustomStorageClass = 'ImportFromFile';
T1Data.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_symdim_decs.h';

T1Break.CoderInfo.StorageClass = 'Custom';
T1Break.CoderInfo.CustomStorageClass = 'ImportFromFile';
T1Break.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_symdim_decs.h';
```

At the command prompt, create a `Simulink.Parameter` object to represent the custom macro `bpLen`.

```
bpLen = Simulink.Parameter(11);
bpLen.Min = 9;
bpLen.Max = 11;
bpLen.DataType = 'int32';
bpLen.CoderInfo.StorageClass = 'Custom';
bpLen.CoderInfo.CustomStorageClass = 'ImportedDefine';
bpLen.CoderInfo.CustomAttributes.HeaderFile = 'ex_vec_symdim_decs.h';
```

Use `bpLen` to set the dimensions of the lookup table and breakpoint set data. Configure the model to enable symbolic dimensions by selecting the configuration parameter **Allow symbolic dimension specification**.

```
T1Data.Dimensions = '[1 bpLen]';
T1Break.Dimensions = '[1 bpLen]';
set_param('rtwdemo_basicsc','AllowSymbolicDim','on')
```

Set **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files** to `ex_vec_symdim_src.c`.

```
set_param('rtwdemo_basicsc','CustomSource','ex_vec_symdim_src.c')
```

To generate code with custom storage classes such as `ImportFromFile`, you must use an ERT-based system target file. Set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`.

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')
```

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated code algorithm is in the model `step` function in the generated file `rtwdemo_basicsc.c`. The algorithm passes `T1Break`, `T1Data`, and `bpLen` as argument values to the function that performs the table lookup. In this case, `bpLen` controls the upper bound of the binary search that the function uses.

```
file = fullfile('rtwdemo_basicsc_ert_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'.X = look1_iflf_binlx','bpLen - 1U',1,1)
```

```
rtwdemo_basicsc_DW.X = look1_iflf_binlx(rtwdemo_basicsc_U.input2,
  (&(T1Break[0])), (&(T1Data[0])), bpLen - 1U) * 2.0F;
```

For more information about symbolic dimensions, see “Implement Dimension Variants for Array Sizes in Generated Code” on page 25-2.

- “Reuse Parameter Data from External Code in the Generated Code” on page 36-11

Access Structured Data Through a Pointer That External Code Defines

This example shows how to generate code that uses global data that some handwritten code defines. In the handwritten code, a pointer variable points to one of three structure variables that contain parameter data. A handwritten function switches the pointer between the structures. The generated code accesses the parameter data by dereferencing the pointer variable.

Explore External Code

Open the example source file `rtwdemo_importstruct_user.c`. The code defines a default data structure variable `ReferenceStruct` as constant (`const`) data and statically initializes each field. This structure represents the reference data set.

```
/* Constant default data structure (reference data set) */
const DataStruct_type ReferenceStruct =
{
  11,   /* OFFSET */
  2     /* GAIN */
};
```

The code defines two other structure variables, `WorkingStruct1` and `WorkingStruct2`, as volatile (`volatile`) data.

```
/* Volatile data structures (working data sets) */
volatile DataStruct_type WorkingStruct1;
volatile DataStruct_type WorkingStruct2;
```

The code defines a function that can initialize:

- An inactive working structure from the active working structure.
- Both working structures from the reference structure.

```
/* Function to initialize inactive working structures from active structure */
void InitInactiveWorkingStructs(void)
{
    if (StructPointer == &WorkingStruct1) {
        /* Copy values from WorkingStruct1 to WorkingStruct2 */
```

```
        memcpy((void*)&WorkingStruct2, (void*)&WorkingStruct1, sizeof(ReferenceStruct));

    } else if (StructPointer == &WorkingStruct2) {
        /* Copy values from WorkingStruct2 to WorkingStruct1 */
        memcpy((void*)&WorkingStruct1, (void*)&WorkingStruct2, sizeof(ReferenceStruct));

    } else {
        /* Initialize both working structures from ReferenceStruct */
        memcpy((void*)&WorkingStruct1, &ReferenceStruct, sizeof(ReferenceStruct));
        memcpy((void*)&WorkingStruct2, &ReferenceStruct, sizeof(ReferenceStruct));
    }
}
```

The code defines `StructPointer`, which is a `const volatile` pointer to a structure. The code initializes the pointer to the address of `ReferenceStruct`.

```
/* Define structure pointer.  Point to reference structure by default */
const volatile DataStruct_type *StructPointer = &ReferenceStruct;
```

Finally, the code defines a function that can dynamically set `StructPointer` to point to either `ReferenceStruct`, `WorkingStruct1`, or `WorkingStruct2`.

```
/* Function to switch between structures */
void SwitchStructPointer(Dataset_T Dataset)
{
    switch (Dataset) {
    case Working1:
        StructPointer = &WorkingStruct1;
        break;
    case Working2:
        StructPointer = &WorkingStruct2;
        break;
    default:
        StructPointer = &ReferenceStruct;
    }
}
```

The example header file `rtwdemo_importstruct_user.h` defines the enumeration `Dataset_T` and the structure type `Datastruct_type`. The file includes (`#include`) the built-in Simulink® Coder™ header file `rtwtypes.h`, which defines (`typedef`) Simulink Coder data types such as `int16_T`.

```
#include "rtwtypes.h"

typedef enum {
    Reference = 0,
    Working1,
    Working2
} Dataset_T;

typedef struct DataStruct_tag {
  int16_T   OFFSET; /* OFFSET */
  int16_T   GAIN;   /* GAIN */
} DataStruct_type;
```

The file also declares the global variables and the functions.

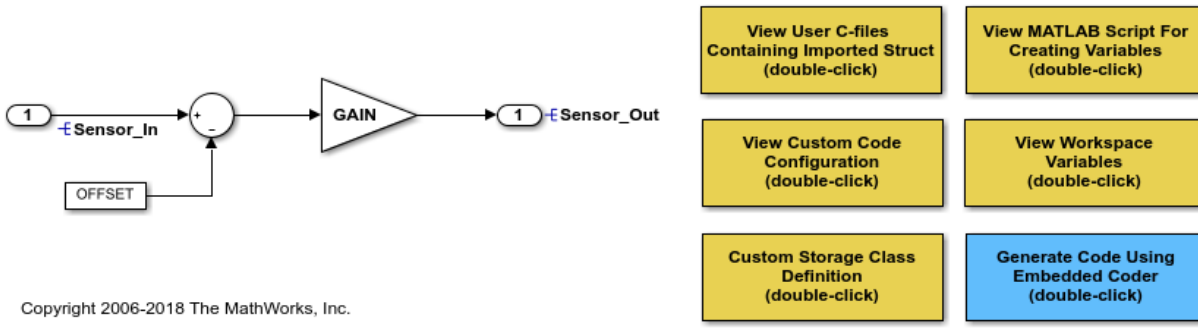
Purpose of External Code

The code is designed so that the source code of a control algorithm (whether generated or handwritten) can read data from `ReferenceStruct`, `WorkingStruct1`, or `WorkingStruct2` by dereferencing (`->`) `StructPointer`. The two working structures (`WorkingStruct1` and `WorkingStruct2`) are located in volatile memory and are intended to be changed during runtime by an external calibration tool. The calibration engineer does not change the active working structure. Instead, the engineer changes the parameter values in the inactive working structure and then activates it by switching working structures.

If necessary for safety or in preparation for shutting down the application, the calibration tool can point `StructPointer` to `ReferenceStruct` instead. `ReferenceStruct` stores default parameter values that do not change during execution.

Explore Example Model

Open the example model, `rtwdemo_importstruct`.



The model creates variables and objects in the base workspace. The Constant block and the Gain block use the `ECoderDemos.Parameter` objects `GAIN` and `OFFSET` to set the **Constant value** and **Gain** block parameters. `ECoderDemos` is an example custom package that defines two classes, `Parameter` and `Signal`, and some custom storage classes.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Set the **Change view** drop-down list to `Code`.

Click the **Show/refresh additional information** button.

The Model Data Editor shows rows that correspond to the **Constant value** and **Gain** parameters of the blocks and rows that corresponds to `OFFSET` and `GAIN`, which set the parameter values. In the **Storage Class** column, `OFFSET` and `GAIN` use the custom storage class `StructPointer`, which the `ECoderDemos` package defines.

Open the Custom Storage Class Designer and inspect the custom storage classes in the `ECoderDemos` package. At the command prompt, use this command:

```
cscdesigner('ECoderDemos')
```

This example package defines multiple custom storage classes, including `StructPointer`. You cannot edit the definitions. However, you can create your own packages and custom storage classes later. For an example that shows how to create a package and a custom storage class, see “Create and Apply a Custom Storage Class” on page 36-35.

Under **Custom storage class definitions**, click `StructPointer`. The settings for this custom storage class enable the generated code to interact with the pointer variable, `StructPointer`, from the external code. For example, the custom storage class uses these settings:

- **Data scope** is set to `Imported` because the example external code defines (allocates memory for) `StructPointer`. With this setting, the code generator avoids generating unnecessary, duplicate definitions for the data items, such as the `ECoderDemos.Parameter` objects, that use the custom storage class.
- **Data access** is set to `Pointer` because in the example external code, `StructPointer` is a pointer.
- **Memory section** is set to `ConstVolatile` because the example external code defines `StructPointer` as constant, volatile data (`const volatile`).
- **Type** is set to `FlatStructure` because in the example external code, `StructPointer` points to a structure. With this setting, the generated code treats each data item (`ECoderDemos.Parameter` object) as a field of a flat structure whose variable name and type name you can specify.
- On the **Structure Attributes** tab, **Struct name** is set to `StructPointer`. For a `FlatStructure` custom storage class, **Struct name** specifies the name of the structure variable in the generated code. In this example, `StructPointer` is the name of the variable that the external code defines.
- **Type name** is set to `DataStruct_type`, which is the name of the structure type that the example external code defines.

In the model, in the **Configuration Parameters** dialog box, inspect the **Code Generation > Custom Code** pane.

Under **Insert custom C code in generated**, select **Initialize function**. This parameter value specifies the code to include in the generated model initialize function. In this model, the configuration parameter is set so that the generated code calls the `InitInactiveWorkingStructs` function. `InitInactiveWorkingStructs` initializes the working structures with the values from `ReferenceStruct`. The initialization code then sets the pointer to the first working structure.

Under **Additional build information**, select **Source files**. This configuration parameter identifies the example external code file `rtwdemo_importstruct_user.c` for inclusion in the build process after code generation.

Generate and Inspect Code

Generate code from the model.

In the generated file `rtwdemo_importstruct.c`, the model initialization function calls `InitInactiveWorkingStructs`.

```
/* Model initialize function */
void rtwdemo_importstruct_initialize(void)
{
  /* user code (Initialize function Body) */

  /* Initialize the working structures to reference values */
  InitInactiveWorkingStructs();

  /* Switch to first working structure */
  SwitchStructPointer(Working1);
}

/*
```

The algorithm in the model execution (`step`) function dereferences the pointer variable `StructPointer`.

```
/* Model step function */
void rtwdemo_importstruct_step(void)
{
  /* Outport: '<Root>/Out' incorporates:
   *  Constant: '<Root>/Offset'
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/In'
   *  Sum: '<Root>/Sum'
   */
  Sensor_Out = (int16_T)((int16_T)(Sensor_In - StructPointer->OFFSET) *
```

```
    StructPointer->GAIN);
}
```

Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements

In “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81, you control the declaration and definition of global variables in the generated code by applying storage classes directly to individual data elements. With Embedded Coder and an ERT-based system target file, you can use custom storage classes for more precise control over the way that data appear in the generated code.

To achieve C code patterns such as grouping variables into flat structures and to control declaration and definition file placement, you can use the custom storage classes from the built-in package `Simulink`.

For information about applying storage classes to categories of data by default, by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 31-8.

Built-In Custom Storage Classes

For a list of built-in custom storage classes that you can choose, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69.

Create Your Own Custom Storage Class

If the custom storage classes from the `Simulink` package do not satisfy your requirements, you can define your own custom storage classes. For information about defining your own custom storage class, see “Create Code Definitions to Override Default Settings” on page 30-2.

Techniques to Apply Custom Storage Classes Interactively

To directly apply a custom storage class from the built-in package `Simulink` interactively, use the same techniques that you use to directly apply standard storage classes, described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.

To apply a custom storage class from a package other than `Simulink` (such as a package that you create):

- To apply the custom storage class to a signal, state, or Data Store Memory block (without creating a data object), configure the data item to use custom storage classes from the target package instead of the `Simulink` package. For example, if the name of the target package is `myPackage`, in a Signal Properties dialog box or the Property Inspector, set **Signal object class** to `myPackage.Signal`. If the target class does not appear in the list, see "Target Class Does Not Appear in List of Signal Object Classes" on page 36-29.

  If you use the Model Data Editor, to identify the target package, you must use a different technique. See "Apply Custom Storage Class from Specific Package to Signal, State, or Data Store Memory Block Using the Model Data Editor" on page 36-29.
- To apply the custom storage class by using a data object (required for block parameters), instead of creating a `Simulink.Signal` or `Simulink.Parameter` object, create a `myPackage.Signal` or `myPackage.Parameter` object. To create data objects from your package, see "Create Data Objects from Another Data Class Package" (Simulink). For an example that shows how to create and apply your own custom storage class, see "Create and Apply a Custom Storage Class" on page 36-35.

Target Class Does Not Appear in List of Signal Object Classes

When you use the **Signal object class** drop-down list in a dialog box or in the Property Inspector, if the class that you want does not appear in the list:

1. From the list, select `Customize class lists`.
2. In the dialog box, under **Signal classes**, select the check box next to the class that you want. For example, to use custom storage classes from the built-in package `mpt`, select the check box next to `mpt.Signal`. Click **OK**.

   If you created your own package, the classes that the package defines appear in the dialog box only if you put the package folder in your current folder or put the parent folder of the package folder on the MATLAB path.
3. From the drop-down list, select the option that corresponds to what you selected. For example, select `mpt.Signal`.

Apply Custom Storage Class from Specific Package to Signal, State, or Data Store Memory Block Using the Model Data Editor

When you use the Model Data Editor, to apply custom storage classes from a specific package, use the Model Explorer to create a signal object from the target package. Then, when you open the Model Data Editor, the **Storage class** column displays custom storage classes from the target package.

1. In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
2. In the toolbar, click the arrow next to the **Add Signal**  button.
3. In the drop-down list, select `Customize class lists`.
4. In the **Customize class lists** dialog box, select a signal class from the target package. Click **OK**.
5. In the Model Explorer toolbar, click the arrow next to the **Add Signal** button.
6. In the drop-down list, select the target signal class.

   An object of the target signal class appears in the base workspace. Optionally, delete this unnecessary object.
7. Use the Model Data Editor to apply custom storage classes from the target package to other data items. In the Model Data Editor, in the **Storage class** column, the drop-down list allows you to select custom storage classes from the target package.

To learn how to use the Model Data Editor to configure a data interface, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder).

Techniques to Apply Custom Storage Classes Programmatically

To apply a custom storage class to an individual data item programmatically:

1. Create a signal or parameter data object from the target package. For example, create a `Simulink.Signal` object or a `myPackage.Parameter` object.

   ```
   myParam = Simulink.Parameter(5.2);
   ```
2. In the nested `Simulink.CoderInfo` object, set the `StorageClass` property to `'Custom'`. Then, use the `CustomStorageClass` property to specify the custom storage class.

   ```
   myParam.CoderInfo.StorageClass = 'Custom';
   myParam.CoderInfo.CustomStorageClass = 'ExportToFile';
   ```
3. If the custom storage class allows you to specify additional settings such as **Header file** (see “Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)” on page 32-76), in the nested `Simulink.CoderInfo` object, use the `CustomAttributes` property to specify values for the additional settings.

   ```
   myParam.CoderInfo.CustomAttributes.HeaderFile = 'myHeader.h';
   ```

4 Choose one of these techniques to apply the custom storage class to a data item in a model:

- To apply the custom storage class directly to a signal, state, or Data Store Memory block, name the signal or state. Then, use the data object you created to set the `SignalObject` signal property, the `SignalObject` block parameter (for an Outport block), or the `StateSignalObject` block parameter. Clear the data object you created. For an example, see “Apply Custom Storage Class Directly to Signal Line Programmatically” on page 36-31.
- To apply the custom storage class by keeping the data object you created (required for parameters), associate the data object with the data item in the model. To make this association, see “Use Data Objects in Simulink Models” (Simulink).

Apply Custom Storage Class Directly to Signal Line Programmatically

This example shows how to apply a custom storage class directly to a signal line in a model, without an external data object.

1 Open the example model `rtwdemo_secondOrderSystem`.

```
rtwdemo_secondOrderSystem
```

2 Create a handle to the output of the block named Force: f(t).

```
portHandles = get_param('rtwdemo_secondOrderSystem/Force: f(t)','PortHandles');
outportHandle = portHandles.Outport;
```

3 Set the name of the corresponding signal to `ForceSignal`.

```
set_param(outportHandle,'Name','ForceSignal')
```

4 In the base workspace, create a signal object and specify a custom storage class and relevant additional settings such as `HeaderFile`.

```
tempObj = Simulink.Signal;
tempObj.CoderInfo.StorageClass = 'Custom';
tempObj.CoderInfo.CustomStorageClass = 'ExportToFile';
tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myHdrFile.h';
```

You can create the object from the data class package `Simulink`, or from any other package, such as a package that you create.

5 Embed the signal object in the target signal line by attaching a copy of the temporary workspace object.

```
set_param(outportHandle,'SignalObject',tempObj);
```

6 Clear the object from the base workspace. The signal now uses an embedded copy of the object.

```
clear tempObj
```

Modify Custom Storage Class Applied Directly to Signal Line

To modify an existing embedded signal object, copy the object into the base workspace, modify the copy, and reattach the copy to the signal or state. For example, to change the custom storage class of the embedded signal object that you attached to the signal `ForceSignal` in “Apply Custom Storage Class Directly to Signal Line Programmatically” on page 36-31:

1 Copy the existing embedded signal object into the base workspace.

```
tempObj = get_param(outportHandle,'SignalObject');
```

2 Modify the properties of the object in the workspace.

```
tempObj.CoderInfo.CustomStorageClass='ImportFromFile';
tempObj.CoderInfo.CustomAttributes.HeaderFile = 'myOtherHdrFile.h';
```

3 Reattach a copy of the signal object.

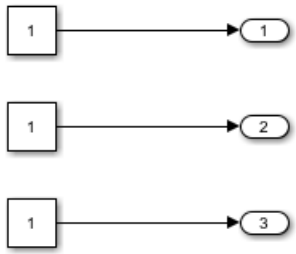
```
set_param(outportHandle,'SignalObject',tempObj);
clear tempObj
```

Organize Parameter Data into a Structure by Using the Struct Custom Storage Class

This example shows how to use the `Struct` custom storage class to organize block parameter values into a structure in the generated code. You apply the storage class directly to individual data items in a model.

To create a custom structure of parameter data in the generated code, consider creating a corresponding structure in Simulink. See “Organize Data into Structures in Generated Code” on page 32-181.

1 Create the `ex_struct_param` model with three Constant blocks and three Outport blocks.



2. In the model, select **View** > **Model Data Editor**.
3. In the Model Data Editor, select the **Parameters** tab.
4. In the model, select the upper Constant block.
5. In the Model Data Editor, use the **Value** column to set the constant value to `p1`.
6. Next to `p1`, click the action button ⋮ and select **Create**.
7. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(1.0)` and click **Create**.

   A `Simulink.Parameter` object named `p1` appears in the base workspace.
8. In the property dialog box for `p1`, click **OK**.
9. Use the Model Data Editor to set the other constant values by using parameter objects named `p2` (value `2.0`) and `p3` (value `3.0`).
10. In the Model Data Editor, set the **Change view** drop-down list to `Code`.
11. Click the **Show/refresh additional information** button.

    The data table now contains rows that correspond to the new parameter objects.
12. Use the **Storage Class** column to apply the custom storage class `Struct` to all three parameter objects.
13. Use the **Struct Name** column to set the structure name to `my_struct`.
14. Press **Ctrl+B** to generate code.

The file `ex_struct_param.h` defines a structure type, `my_struct_type`.

```
/* Type definition for custom storage class: Struct */
   typedef struct my_struct_tag {
      real_T p1;
      real_T p2;
```

```
     real_T p3;
  } my_struct_type;
```

The file `ex_struct_param.c` defines the global variable `my_struct`.

```
/* Definition for custom storage class: Struct */
my_struct_type my_struct = {
     /* p1 */
     1.0,

     /* p2 */
     2.0,

     /* p3 */
     3.0
};
```

Custom Storage Class Limitations

For information about limitations, see “Storage Class Limitations” on page 32-77.

Create Custom Storage Classes by Using the Custom Storage Class Designer

You can use built-in custom storage classes such as `ExportToFile` to control the appearance of data in the generated code (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28). If the built-in custom storage classes do not satisfy your requirements, you can create your own custom storage classes. As described in “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2, to create a custom storage class that you can apply to individual data elements (for example, in the Model Data Editor), you must create the storage class in a package by using the Custom Storage Class Designer.

To define a storage class that you can apply as the default storage class for a category of data elements, use the **Embedded Coder Dictionary**. See “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7.

A package also defines `Signal` and `Parameter` data classes (see “Data Objects” (Simulink)). A data object from a package such as `Simulink` can use custom storage classes defined in that package but not custom storage classes that are defined in packages.

For information about using the Custom Storage Class Designer to create memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2.

Create and Apply a Custom Storage Class

This example shows how to control code generated from a model by creating and applying your own custom storage class.

Explore Example Model

Open the model rtwdemo_cscpredef. You can control code generated from this model by defining your own data classes and creating your own custom storage classes.

In this example, you export the declarations and definitions of multiple signals and parameters in the model to one declaration header file and one definition file.

Create Data Class Package

To create custom storage classes, you first create a data class package to contain the custom storage class definitions. Data objects that you create from your package can use the custom storage classes that the package defines.

1. Create your own data class package by copying the example package folder `+SimulinkDemos`. Navigate to the example package folder.

   ```
   % Remember the current folder path
   currentPath = pwd;

   % Navigate to the example package folder
   demoPath = '\toolbox\simulink\simdemos\dataclasses';
   cd([matlabroot,demoPath])
   ```

2. Copy the `+SimulinkDemos` folder to your clipboard.
3. Return to your working folder.

   ```
   cd(currentPath)
   ```

4. Paste the `+SimulinkDemos` folder from your clipboard into your working folder. Rename the copied folder to `+myPackage`.
5. Navigate inside the `+myPackage` folder to the file `Signal.m` to edit the definition of the `Signal` class.
6. Uncomment the `methods` section that defines the method `setupCoderInfo`. In the call to the function `useLocalCustomStorageClasses`, replace `'packageName'` with `'myPackage'`. When you finish, the section appears as follows:

   ```
   methods
     function setupCoderInfo(h)
       % Use custom storage classes from this package
       useLocalCustomStorageClasses(h, 'myPackage');
     end
   end % methods
   ```

   The function `useLocalCustomStorageClasses` allows you to apply the custom storage classes that `myPackage` defines to data objects that you create from `myPackage`.
7. Save and close the file.
8. Navigate inside the `+myPackage` folder to the file `Parameter.m` to edit the definition of the `Parameter` class. Uncomment the `methods` section that defines the method `setupCoderInfo` and replace `'packageName'` with `'myPackage'`.

9 Save and close the file.

Create Custom Storage Class

You can use the Custom Storage Class Designer to create or to edit the custom storage classes that a data class package defines.

1 Set your current folder to the folder that contains the package `myPackage`.

2 Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

3 Select the custom storage class `ExportToFile`.

4 In the **Name** field, rename the custom storage class to `ExportToGlobal`.

5 In the **Header file** drop-down list, change the selection from `Instance specific` to `Specify`. In the new field, provide the header file name `global.h`.

6 In the **Definition file** drop-down list, change the selection from `Instance specific` to `Specify`. In the new field, provide the definition file name `global.c`.

7 Click **OK**. Click **Yes** to save changes to the data class package `myPackage`.

Apply Custom Storage Class

To apply your own custom storage class, you create data objects from your package and configure the objects to use your custom storage class.

1 Create data objects to represent some of the parameters and signals in the example model. Create the objects using the data class package `myPackage`.

```
% Parameters
templimit = myPackage.Parameter(202);
pressurelimit = myPackage.Parameter(45.2);
O2limit = myPackage.Parameter(0.96);
rpmlimit = myPackage.Parameter(7400);

% Signals
tempalarm = myPackage.Signal;
pressurealarm = myPackage.Signal;
O2alarm = myPackage.Signal;
rpmalarm = myPackage.Signal;
```

2 Set the custom storage class of each object to `ExportToGlobal`.

```
% Parameters
templimit.CoderInfo.StorageClass = 'Custom';
```

```
templimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurelimit.CoderInfo.StorageClass = 'Custom';
pressurelimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2limit.CoderInfo.StorageClass = 'Custom';
O2limit.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmlimit.CoderInfo.StorageClass = 'Custom';
rpmlimit.CoderInfo.CustomStorageClass = 'ExportToGlobal';

% Signals
tempalarm.CoderInfo.StorageClass = 'Custom';
tempalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
pressurealarm.CoderInfo.StorageClass = 'Custom';
pressurealarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
O2alarm.CoderInfo.StorageClass = 'Custom';
O2alarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
rpmalarm.CoderInfo.StorageClass = 'Custom';
rpmalarm.CoderInfo.CustomStorageClass = 'ExportToGlobal';
```

3 Select the **Signal name must resolve to Simulink signal object** option for each of the target signals in the model. You can select the option by using the Signal Properties dialog box, the **Resolve** column in the Model Data Editor, or by using the command prompt.

```
% Signal tempalarm
portHandles = get_param('rtwdemo_cscpredef/RelOp1','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal pressurealarm
portHandles = get_param('rtwdemo_cscpredef/RelOp2','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal O2alarm
portHandles = get_param('rtwdemo_cscpredef/RelOp3','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')

% Signal rpmalarm
portHandles = get_param('rtwdemo_cscpredef/RelOp4','PortHandles');
outputPortHandle = portHandles.Outport;
set_param(outputPortHandle,'MustResolveToSignalObject','on')
```

Generate Code

1. Generate code for the example model.

```
rtwbuild('rtwdemo_cscpredef')
```

2. In the code generation report, view the generated header file `global.h`. The file contains the `extern` declarations of the model signals and parameters that use the custom storage class `ExportToGlobal`.

```
/* Declaration for custom storage class: ExportToGlobal */
extern boolean_T O2alarm;
extern real_T O2limit;
extern boolean_T pressurealarm;
extern real_T pressurelimit;
extern boolean_T rpmalarm;
extern real_T rpmlimit;
extern boolean_T tempalarm;
extern real_T templimit;
```

3. View the generated file `global.c`. The file contains the definitions of the model signals and parameters that use the custom storage class `ExportToGlobal`.

```
/* Definition for custom storage class: ExportToGlobal */
boolean_T O2alarm;
real_T O2limit = 0.96;
boolean_T pressurealarm;
real_T pressurelimit = 45.2;
boolean_T rpmalarm;
real_T rpmlimit = 7400.0;
boolean_T tempalarm;
real_T templimit = 202.0;
```

Modify a Built-In Custom Storage Class

You cannot directly modify a built-in custom storage class, such as `ExportToFile` from the `Simulink` package, but you can create a copy, and then modify the copy. When you create a new package with no `csc_registration.m` file, and then open the Custom Storage Class Designer for the first time in that package, Simulink copies the definitions of the built-in custom storage classes into the package. Then, in the Custom Storage Class Designer, you can modify the copied definitions. Alternatively, to keep the built-in custom storage classes available in your package, copy one of them by clicking **Copy**, then modify the resulting copy.

Control Data Representation by Configuring Custom Storage Class Properties

The Custom Storage Class Designer is a tool for creating and managing custom storage classes and memory sections. To open the Custom Storage Class Designer for a specific package, for example, `+mypkg`, at the command prompt, use the `cscdesigner` function:

```
cscdesigner('mypkg')
```

The name of the folder that represents a package begins with a `+`. When you use `cscdesigner`, omit the `+` from the name of the target package.

To control the effect that a custom storage class has on data in a model, you specify properties of the storage class in the Custom Storage Class Designer. To determine how to generate a particular kind of code, use the information in the table.

Kind of Data in Generated Code	Technique
Structure	Set **Type** to `FlatStructure`. See "Generate Structured Data" on page 36-42.
Macro	Set **Data initialization** to `Macro` and clear **For signals**. See "Generate a Macro" on page 36-41.
Pointer	Set **Data access** to `Pointer` and **Data scope** to `Auto`, `Imported`, or `Instance specific`. Your external code must define the pointer variable.
`static` data (file-scoped data)	Set **Data scope** to `File`.
`const` or `volatile` data	Set **Memory section** to a memory section that specifies `const`, `volatile`, or both. For example, use one of the built-in memory sections `MemConst`, `MemVolatile`, and `MemConstVolatile`. To create your own memory section, see "Control Data and Function Placement in Memory by Inserting Pragmas" on page 40-2.

Kind of Data in Generated Code	Technique
Calls to external functions to read and write to data	See "Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables" on page 36-43.

Allow Users of Custom Storage Class to Specify Property Value

For some properties of a custom storage class, such as **Data scope**, instead of specifying a value in the Custom Storage Class Designer, you can allow users of the storage class to specify the value. You can create a single, flexible custom storage class instead of multiple custom storage classes that vary only by a few property values.

For example, suppose you create a custom storage class that yields a global variable in the generated code. You can configure the storage class so that a user can set the **Data scope** property to `Exported` for a signal in a model and set the property to `Imported` for a different signal.

In the Custom Storage Class Designer, for each property that you want to configure in this way, set the property value to `Instance specific`. Then, when a user applies the custom storage class to a data item, the property appears to the user as a custom attribute for that data item. For information about instance-specific custom attributes, see "Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)" on page 32-76.

Generate a Macro

To create a custom storage class that yields a macro in the generate code, set **Data initialization** to `Macro` and clear **For signals**.

When you set **Data initialization** to `Macro`, **Definition file** has no meaning. To prevent users of the custom storage class from specifying a meaningless definition file, in the Custom Storage Class Designer, set **Definition file** to `Specify` and leave the text box empty.

- To define the macro in a header file (`#define`), specify the name of the header file with the **Header file** property.
- To provide the macro definition as a compiler option or compiler flag, set **Data access** to `Imported` and **Header file** to `Specify`. Leave the **Header file** text box empty. Then, the generated code does not define the macro and does not include (`#include`) a header file.

To specify the compiler option or flag, use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines**. See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

Generate Structured Data

To create a custom storage class that aggregates data items into a flat structure (similar to the built-in custom storage class `Struct`), set **Type** to `FlatStructure`. The **Structure Attributes** tab appears.

- To control the name of the global structure variable that appears in the generated code, use the **Struct name** property and text box.
- If you set **Struct name** to `Instance specific`, users of the custom storage class specify the name of the structure variable. In this case, the code generator derives the name of the structure type from the name of the variable.

  To more precisely control the name and other characteristics of the structure type, set **Struct name** to `Specify`. Control the type characteristics by using the additional properties that appear.
- To generate a structure with bit fields (similar to the built-in custom storage class `BitField`), select **Bit-pack booleans**. Data items that use the data type `boolean` appear in the generated code as bit fields of the structure.

Control Assignment of Initial Value in Generated Code

- To use the default Simulink Coder initialization strategy, set **Data initialization** to the default value, `Auto`.

  - The generated code statically initializes parameter data with an assignment statement at the top of a `.c` or `.cpp` source file, outside of any function.
  - The generated code dynamically initializes signal and state data as part of the initialization function of the model (named *`model`*`_initialize` by default).
- To statically initialize the data, set **Data initialization** to `Static`.
- To dynamically initialize the data, set **Data initialization** to `Dynamic`.
- To prevent the generated code from initializing the data, set **Data initialization** to `None`. When your external code initializes the data, use this setting to prevent the generated code from overwriting your initialization.

Call Custom Accessor Functions or Macros Instead of Reading and Writing to Variables

Using the built-in custom storage class `GetSet`, you can generate code that calls your external, custom functions instead of directly interacting with variables. For general information about `GetSet`, see “Access Data Through Functions with Custom Storage Class GetSet” on page 36-51.

To create a similar custom storage class, set **Type** to `AccessFunction`.

- Specify the names of the external functions.
  - To apply the same `get` or `set` function naming scheme to data items that use the custom storage class, set **Get function** and **Set function** to `Specify`. Then, in the text boxes, specify the function naming scheme, for example, `get_myData_$N`. Use the token `$N` in a naming scheme to represent the name of each data item. If you do not use the token, each data item uses the same specified `get` or `set` function name, so the model generates an error when you generate code.
  - To specify a different `get` or `set` function name for each data item, set **Get function** or **Set function** to `Instance specific`. Later, when you create a data item and apply the custom storage class, specify the function name by configuring the custom attributes of the data item.
- Specify the name of the header file that declares the `get` and `set` functions with the **Header file** property. In this case, **Definition file** has no meaning. To prevent users of the custom storage class from specifying a meaningless definition file, set **Definition file** to `Specify` and leave the text box empty.
- If you implement the `get` mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data. On the **Access Function Attributes** tab, select **Get data through macro (omit parentheses)**.

Generate Code That Uses Data From External Code

When your external code defines data, to avoid generating a duplicate definition, you must configure the generated code to read and write to the existing data. In the Custom Storage Class Designer, set **Data scope** to `Imported`. The code generator does not generate a definition for the global variable or macro.

- If your code defines a pointer variable, to generate code that interacts with the pointer, set **Data access** to `Pointer`.

- If you generate structured data by setting **Type** to `FlatStructure`, your code must define the structure type and the global structure variable.
- If your code initializes state or signal data, you can prevent the generated code from overwriting your initialization by setting **Data initialization** to `None`. See “Prevent Duplicate Initialization Code for Global Variables” on page 53-115

Generate Code Comments with Data Definitions and Declarations

To customize the comments that appear in the generated code, on the **Comments** tab, set **Comment rules** to `Specify`. To specify a comment that appears with the declaration of each data item, use the **Declaration comment** box. To specify a comment that appears with the definition, use the **Definition comment** box.

For structured data (you set **Type** to `FlatStructure`), to specify a comment that appears with the structure type definition, use the **Type comment** box.

Avoid Errors During Code Generation by Validating Custom Storage Class Configuration

As you configure a custom storage class in the Custom Storage Class Designer, to check for possible errors in the configuration, click **Validate**.

For example, validating the custom storage class warns you if you accidentally set **Data initialization** to `Macro` with **For signals** selected. A signal cannot appear in the generated code as a macro.

Make Custom Storage Classes Available Outside the Current Folder

To use a custom storage class that you create, you must make the defining package available. Either set your current folder to the folder that contains the package or add the folder containing the package folder to the MATLAB path (see “What Is the MATLAB Search Path?” (MATLAB)). Adding the package to the MATLAB path enables you to use the custom storage classes no matter where you set your current folder.

Share Custom Storage Class Between Packages

When you create a package, you can refer to a custom storage class defined in another package such as the built-in package `Simulink` or a different package that you created.

Then, the defining package and any referencing packages can use the custom storage class. When you want to make a change to the custom storage class, you make the change only once, in the defining package.

To configure a package to refer to a custom storage class that another package defines:

1. In the Custom Storage Class Designer, select the **Custom Storage Class** tab.
2. Use **Select Package** to select the referencing package. The package must be writable.
3. In the **Custom storage class definitions** pane, select the existing definition below which you want to insert the reference.
4. Click **New Reference**.

   A new reference with a default name and properties appears below the previously selected definition. The new reference is selected and a **Reference** tab appears that shows the initial properties.
5. Use **Name** to specify a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package. The name cannot be a TLC keyword.
6. Set **Refer to custom storage class in package** to specify the package that contains the custom storage class that you want to reference.
7. Set **Custom storage class to reference** to specify the custom storage class to be referenced.
8. Click **OK** or **Apply**. To save the changes permanently, click **Save**.

Control Appearance of Storage Class Drop-Down List

When you apply a custom storage class to a data item, you select the custom storage class from a drop-down list.

- To control the order of the custom storage classes in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of the custom storage classes in drop-down lists matches the order that you specify in the Custom Storage Class Designer.
- To prevent a user of a custom storage class from applying the storage class to parameter data or to signal and state data, use the **For parameters** and **For signals** check boxes. When you clear one of these properties, for the corresponding kind of data, the custom storage class does not appear in the drop-down list.

For example, if your custom storage class yields a macro in the generated code because you set **Data initialization** to `Macro`, to prevent users from applying the custom storage class to signal data, clear **For signals**.

Protect Custom Storage Class Definitions

When you click **Save** in the Custom Storage Class Designer, the Designer saves memory section and custom storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of **Filename**.

You can prevent changes to the custom storage class definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep both `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you need to modify the custom storage classes by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, when both files exist in the package, the custom storage classes are protected and cannot be modified in the Custom Storage Class Designer.

Further Customize Generated Code by Writing TLC Code

If creating your own custom storage class by manipulating the properties in the Custom Storage Class Designer does not satisfy your requirements, you can finely control the generated code by writing TLC code for your custom storage class. Use an advanced mode of the Custom Storage Class Designer and, for the custom storage class, set **Type** to `Other`. See “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 36-48.

Finely Control Data Representation by Writing TLC Code for a Custom Storage Class

If creating your own custom storage class by using the properties in an Embedded Coder Dictionary or the Custom Storage Class Designer does not meet your requirements for controlling data representation in the generated code, you can write TLC code that explicitly controls the effect that a custom storage class has on the code. For example, to create a custom storage class that yields arbitrarily nested structures, you must write TLC code. In the Custom Storage Class Designer, these advanced custom storage classes have **Type** set to `Other`. You cannot create such a storage class in an Embedded Coder Dictionary, so you cannot use the storage class as a default code generation setting in the Code Mapping Editor.

For an example, see “Generate Code That Dereferences Data from a Literal Memory Address” on page 63-21. For general information about TLC code, see “Why Use the Target Language Compiler?” (Simulink Coder).

Create Custom Attributes Class for Custom Storage Class

As described in “Allow Users of Custom Storage Class to Specify Property Value” on page 36-41, instance-specific properties enable users of a custom storage class to control the effect that the storage class has on each data item. For example, the built-in custom storage class `ExportToFile` has several instance-specific properties such as **Header file** and **Definition file**.

When you create a custom storage class with **Type** set to `Other`, to add your own instance-specific properties that are not built into the Custom Storage Class Designer, create a custom attributes class for your package. A custom attributes class is a MATLAB class that you create as a subclass of `Simulink.CustomStorageClassAttributes`. Each property that you add to your custom attributes class appears to the user of the custom storage class as an instance-specific property.

To create your custom attributes class, see “Define Data Classes” (Simulink).

Write TLC Code for Custom Storage Class

To control the effect of your custom storage class, write TLC code that specifies the code to generate for each data item.

1. In your package folder (for example, `+myPackage`), create a `tlc` folder.
2. Copy a TLC template such as `TEMPLATE_v1.tlc` from the folder *matlabroot*`/toolbox/rtw/targets/ecoder/csc_templates` (open) into your `tlc` folder.
3. Write your TLC code, following the comments in the template file. The comments describe how to specify, for example, how the generated code declares, defines, and accesses (by value or by reference) each data item.

Create Custom Storage Class by Using Custom Storage Class Designer

To create your custom storage class in your package, you open the Custom Storage Class Designer in an advanced mode.

1. At the command prompt, enter:

   ```
   cscdesigner -advanced
   ```

2. Select your package and create a custom storage class.
3. For the custom storage class, set **Type** to `Other`. In the **Other Attributes** pane, specify the name of your TLC file and the name of your custom attributes class.
4. Set the properties on the **Other Attributes** pane.

   - **Is grouped**: Select this option if you intend to combine multiple data items into a single entity in the generated code. For example, the built-in custom storage classes `BitField` and `Struct` are grouped because they can aggregate multiple data items into a single structure variable.
   - **TLC file name**: Enter the name of your TLC file. The Custom Storage Class Designer assumes that the file exists in the package `tlc` folder, so specify only the name of the file, not the file path.
   - **CSC attributes class name**: (optional) If you created a custom attributes class, enter the full name of the class, including the package name. For example, specify `myPackage.myCustomAttsClass`. For more information, see “Create Custom Attributes Class for Custom Storage Class” on page 36-48.
5. On the **General** and **Comments** panes, specify values for the remaining properties.

Access Data Through Functions with Custom Storage Class GetSet

To integrate the generated code with legacy code that uses specialized functions to read from and write to data, you can use the custom storage class `GetSet`. Signals, block parameters, and states that use `GetSet` appear in the generated code as calls to accessor functions. You provide the function definitions.

You can also create your own custom storage class in Embedded Coder Dictionary to access data through functions. Creating your own custom storage class in Embedded Coder Dictionary gives you the flexibility of customizing function names and return types. For more information, see “Access Data Through Functions by Using Storage Classes in Embedded Coder Dictionary” on page 36-72.

To generate code that conforms to the AUTOSAR standard by accessing data through `Rte` function calls, use the AUTOSAR code perspective. See “AUTOSAR Component Configuration” (AUTOSAR Blockset).

Access Legacy Data Using Get and Set Functions

This example shows how to generate code that interfaces with legacy code by using specialized `get` and `set` functions to access data.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h','/* ComponentData */','} ComponentData;',1,1)
```

```
/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `scalars` is a substructure that uses the structure type `ScalarData`. The structure type `ScalarData` defines three scalar fields: `inSig`, `scalarParam`, and `outSig`.

```
rtwdemodbtype('ComponentDataHdr.h','/* ScalarData */','} ScalarData;',1,1)
```

```
/* ScalarData */

typedef struct {
    double inSig;
    double scalarParam;
    double outSig;
} ScalarData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `scalars`.

```
rtwdemodbtype('getsetSrc.c','/* Field "scalars" */','/* End of "scalars" */',1,1)
```

```
    /* Field "scalars" */
    {
    3.9,

    12.3,

    0.0
    },
    /* End of "scalars" */
```

The file also defines functions that read from and write to the fields of the substructure `scalars`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Scalar get() and set() functions */','/* End of scalar functions */',1,1)
```

```
/* Scalar get() and set() functions */

double get_inSig(void)
{
    return ex_getset_data.scalars.inSig;
}

void set_inSig(double value)
{
```

```
    ex_getset_data.scalars.inSig = value;
}

double get_scalarParam(void)
{
    return ex_getset_data.scalars.scalarParam;
}

void set_scalarParam(double value)
{
    ex_getset_data.scalars.scalarParam = value;
}

double get_outSig(void)
{
    return ex_getset_data.scalars.outSig;
}

void set_outSig(double value)
{
    ex_getset_data.scalars.outSig = value;
}
```

View the example legacy header file `getsetHdrScalar.h`. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_scalar`. The model creates the data objects `inSig`, `outSig`, and `scalarParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_scalar')
```

In the base workspace, double-click the object `inSig` to view its properties. The object uses the custom storage class `GetSet`. The `GetFunction` and `SetFunction` properties

are set to the defaults, `get_$N` and `set_$N`. The generated code uses the function names that you specify in `GetFunction` and `SetFunction` to read from and write to the data. The code replaces the token `$N` with the name of the data object. For example, for the data object `inSig`, the generated code uses calls to the legacy functions `get_inSig` and `set_inSig`.

For the data object `inSig`, the `HeaderFile` property is set to `getsetHdrScalar.h`. This legacy header file contains the `get` and `set` function prototypes. The data objects `outSig` and `scalarParam` also use the custom storage class `GetSet` and the header file `getsetHdrScalar.h`.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, under **Additional build information**, select **Source files**. The **Source files** box identifies the source file `getsetSrc.c` for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_scalar');
```

```
### Starting build procedure for model: rtwdemo_getset_scalar
### Successful completion of build procedure for model: rtwdemo_getset_scalar
```

In the code generation report, view the file `rtwdemo_getset_scalar.c`. The model `step` function uses the legacy `get` and `set` functions to execute the algorithm. The generated code accesses the legacy signal and parameter data by calling the custom, handwritten `get` and `set` functions.

```
rtwdemodbtype(fullfile('rtwdemo_getset_scalar_ert_rtw','rtwdemo_getset_scalar.c'),...
    '/* Model step function */','}',1,1)
```

```
/* Model step function */
void rtwdemo_getset_scalar_step(void)
{
  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   */
  set_outSig(get_scalarParam() * get_inSig());
}
```

You can generate code that calls your custom `get` and `set` functions as long as the functions that you write accept and return the expected values. For scalar data, the functions must have these characteristics:

- The `get` function must return a single scalar numeric value of the appropriate data type, and must not accept any arguments (`void`).
- The `set` function must not return anything (`void`), and must accept a single scalar numeric value of the appropriate data type.

Use GetSet with Vector Data

This example shows how to apply the custom storage class `GetSet` to signals and parameters that are vectors.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h','/* ComponentData */','} ComponentData;',1,1)
```

```
/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `vectors` is a substructure that uses the structure type `VectorData`. The structure type `VectorData` defines three vector fields: `inVector`, `vectorParam`, and `outVector`. The vectors each have five elements.

```
rtwdemodbtype('ComponentDataHdr.h','/* VectorData */','} VectorData;',1,1)
```

```
/* VectorData */

typedef struct {
    double inVector[5];
    double vectorParam[5];
    double outVector[5];
} VectorData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `vectors`.

```
rtwdemodbtype('getsetSrc.c','/* Field "vectors" */','/* End of "vectors" */',1,1)
```

```
    /* Field "vectors" */
    {
        {5.7, 6.8, 1.2, 3.5, 10.1},

        {12.3, 18.7, 21.2, 28, 32.9},

        {0.0, 0.0, 0.0, 0.0, 0.0}
    },
    /* End of "vectors" */
```

The file also defines functions that read from and write to the fields of the substructure `vectors`. The functions simplify data access by dereferencing the leaf fields of the global structure variable `ex_getset_data`. To access the vector data, the functions accept an integer index argument. The `get` function returns the vector value at the input index. The `set` function assigns the input `value` to the input index.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Vector get() and set() functions */','/* End of vector functions */',1,1)
```

```
/* Vector get() and set() functions */

double get_inVector(int index)
{
    return ex_getset_data.vectors.inVector[index];
}

void set_inVector(int index, double value)
{
    ex_getset_data.vectors.inVector[index] = value;
}

double get_vectorParam(int index)
{
    return ex_getset_data.vectors.vectorParam[index];
}

void set_vectorParam(int index, double value)
```

```
{
    ex_getset_data.vectors.vectorParam[index] = value;
}

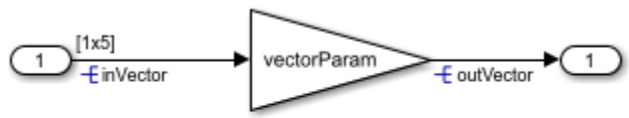
double get_outVector(int index)
{
    return ex_getset_data.vectors.outVector[index];
}

void set_outVector(int index, double value)
{
       ex_getset_data.vectors.outVector[index] = value;
}
```

View the example legacy header file `getsetHdrVector.h`. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_vector`. The model creates the data objects `inVector`, `outVector`, and `vectorParam` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_vector')
```



In the base workspace, double-click the object `inVector` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrVector.h`. This legacy header file contains the `get` and `set` function prototypes.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_vector');

### Starting build procedure for model: rtwdemo_getset_vector
### Successful completion of build procedure for model: rtwdemo_getset_vector
```

In the code generation report, view the file `rtwdemo_getset_vector.c`. The model `step` function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_vector_ert_rtw','rtwdemo_getset_vector.c'),...
    '/* Model step function */','}',1,1)

/* Model step function */
void rtwdemo_getset_vector_step(void)
{
  int32_T i;

  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   */
  for (i = 0; i < 5; i++) {
    set_outVector(i, get_vectorParam(i) * get_inVector(i));
  }
```

When you use the custom storage class `GetSet` with vector data, the `get` and `set` functions that you provide must accept an index input. The `get` function must return a single element of the vector. The `set` function must write to a single element of the vector.

Use GetSet with Structured Data

This example shows how to apply the custom storage class `GetSet` to nonvirtual bus signals and structure parameters in a model.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h',...
    '/* ComponentData */','} ComponentData;',1,1)

/* ComponentData */

typedef struct {
```

```
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `structs` is a substructure that uses the structure type `StructData`. The structure type `StructData` defines three fields: `inStruct`, `structParam`, and `outStruct`.

```
rtwdemodbtype('ComponentDataHdr.h','/* StructData */','} StructData;',1,1)
```

```
/* StructData */

typedef struct {
    SigBus inStruct;
    ParamBus structParam;
    SigBus outStruct;
} StructData;
```

The fields `inStruct`, `structParam`, and `outStruct` are also substructures that use the structure types `SigBus` and `ParamBus`. Each of these two structure types define three scalar fields.

```
rtwdemodbtype('ComponentDataHdr.h','/* SigBus */','} ParamBus',1,1)
```

```
/* SigBus */

typedef struct {
    double cmd;
    double sensor1;
    double sensor2;
} SigBus;

/* ParamBus */

typedef struct {
    double offset;
    double gain1;
    double gain2;
} ParamBus;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `structs`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Field "structs" */','/* End of "structs" */',1,1)
```

```
    /* Field "structs" */
    {
        {1.3, 5.7, 9.2},

        {12.3, 9.6, 1.76},

        {0.0, 0.0, 0.0}
    },
    /* End of "structs" */
```

The file also defines functions that read from and write to the fields of the substructure `structs`. The functions simplify data access by dereferencing the fields of the global structure variable `ex_getset_data`. The functions access the data in the fields `inStruct`, `structParam`, and `outStruct` by accepting and returning complete structures of the types `SigBus` and `ParamBus`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Structure get() and set() functions */',...
    '/* End of structure functions */',1,1)
```

```
/* Structure get() and set() functions */

SigBus get_inStruct(void)
{
    return ex_getset_data.structs.inStruct;
}

void set_inStruct(SigBus value)
{
    ex_getset_data.structs.inStruct = value;
}

ParamBus get_structParam(void)
{
    return ex_getset_data.structs.structParam;
}
```

```
void set_structParam(ParamBus value)
{
    ex_getset_data.structs.structParam = value;
}

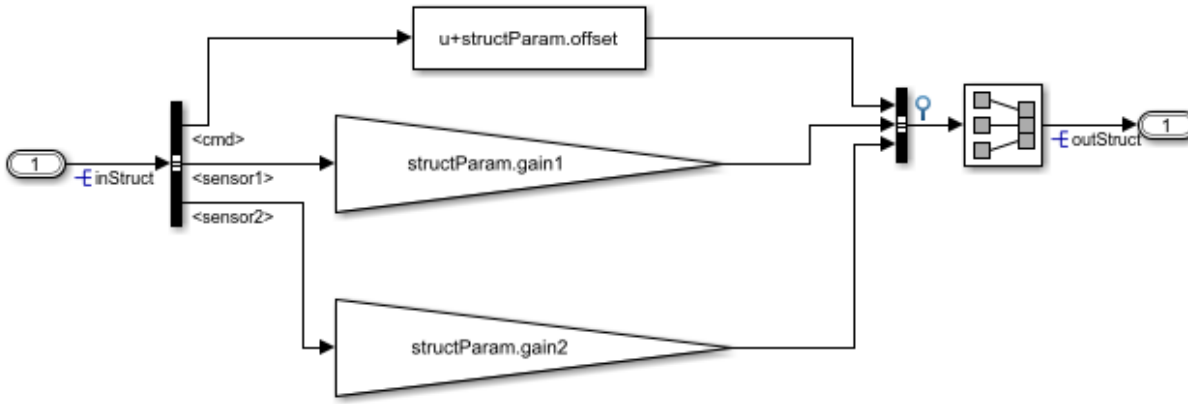
SigBus get_outStruct(void)
{
    return ex_getset_data.structs.outStruct;
}

void set_outStruct(SigBus value)
{
    ex_getset_data.structs.outStruct = value;
}
```

View the example legacy header file `getsetHdrStruct.h`. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_struct`. The model creates the data objects `inStruct`, `structParam`, and `outStruct` in the base workspace. The objects correspond to the signals and parameter in the model.

```
open_system('rtwdemo_getset_struct')
```



In the base workspace, double-click the object `inStruct` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrStruct.h`. This legacy header file contains the `get` and `set` function prototypes.

The model also creates the bus objects `ParamBus` and `SigBus` in the base workspace. The signals and parameter in the model use the bus types that these objects define. The property `DataScope` of each bus object is set to `Imported`. The property `HeaderFile` is set to `ComponentDataHdr.h`. The generated code imports these structure types from the legacy header file `ComponentDataHdr.h`.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_struct');
```

```
### Starting build procedure for model: rtwdemo_getset_struct
### Successful completion of build procedure for model: rtwdemo_getset_struct
```

In the code generation report, view the file `rtwdemo_getset_struct.c`. The model `step` function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_struct_ert_rtw',...
    'rtwdemo_getset_struct.c'),...
    '/* Model step function */','}',1,1)
```

```
/* Model step function */
void rtwdemo_getset_struct_step(void)
{
  /* Bias: '<Root>/Bias' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtDW.BusCreator.cmd = (get_inStruct()).cmd + (get_structParam()).offset;

  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtDW.BusCreator.sensor1 = (get_structParam()).gain1 * (get_inStruct()).sensor1;

  /* Gain: '<Root>/Gain1' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtDW.BusCreator.sensor2 = (get_structParam()).gain2 * (get_inStruct()).sensor2;

  /* SignalConversion: '<Root>/Signal Conversion' */
  set_outStruct(rtDW.BusCreator);
}
```

When you use the custom storage class `GetSet` with structured data, the `get` and `set` functions that you provide must return and accept complete structures. The generated code dereferences individual fields of the structure that the `get` function returns.

The output signal of the Bus Creator block is a test point. This signal is the input for a Signal Conversion block. The test point and the Signal Conversion block exist so that the generated code defines a variable for the output of the Bus Creator block. To provide a complete structure argument for the function `set_outStruct`, you must configure the model to create this variable.

Use GetSet with Matrix Data

This example shows how to apply the custom storage class `GetSet` to signals and parameters that are matrices.

View the example legacy header file `ComponentDataHdr.h`. The file defines a large structure type `ComponentData`.

```
rtwdemodbtype('ComponentDataHdr.h',...
    '/* ComponentData */','} ComponentData;',1,1)
```

```
/* ComponentData */

typedef struct {
    ScalarData scalars;
    VectorData vectors;
    StructData structs;
    MatricesData matrices;
} ComponentData;
```

The field `matrices` is a substructure that uses the structure type `MatricesData`. The structure type `MatricesData` defines three fields: `matrixInput`, `matrixParam`, and `matrixOutput`. The fields store matrix data as serial arrays. In this case, the input and parameter fields each have 15 elements. The output field has nine elements.

```
rtwdemodbtype('ComponentDataHdr.h'...
    ,'/* MatricesData */','} MatricesData;',1,1)
```

```
/* MatricesData */

typedef struct {
    double matrixInput[15];
    double matrixParam[15];
    double matrixOutput[9];
} MatricesData;
```

View the example legacy source file `getsetSrc.c`. The file defines and initializes a global variable `ex_getset_data` that uses the structure type `ComponentData`. The initialization includes values for the substructure `matrices`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Field "matrices" */','/* End of "matrices" */',1,1)
```

```
    /* Field "matrices" */
    {
        {12.0, 13.9, 7.4,
         0.5, 11.8, 6.4,
```

```
         4.7, 5.3, 13.0,
         0.7, 16.1, 13.5,
         1.6, 0.5, 3.1},

        {8.3, 12.0, 11.5, 2.0, 5.7,
         7.5, 12.8, 11.1, 8.4, 9.9,
         10.9, 4.6, 2.7, 16.3, 3.8},

        {0.0, 0.0, 0.0,
         0.0, 0.0, 0.0,
         0.0, 0.0, 0.0}
    }
    /* End of "matrices" */
```

The input matrix has five rows and three columns. The matrix parameter has three rows and five columns. The matrix output has three rows and three columns. The file defines macros that indicate these dimensions.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Matrix dimensions */','/* End of matrix dimensions */',1,1)
```

```
/* Matrix dimensions */

#define MATRIXINPUT_NROWS 5
#define MATRIXINPUT_NCOLS 3

#define MATRIXPARAM_NROWS 3
#define MATRIXPARAM_NCOLS 5

#define MATRIXOUTPUT_NROWS MATRIXPARAM_NROWS
#define MATRIXOUTPUT_NCOLS MATRIXINPUT_NCOLS
```

The file also defines functions that read from and write to the fields of the substructure `matrices`.

```
rtwdemodbtype('getsetSrc.c',...
    '/* Matrix get() and set() functions */','/* End of matrix functions */',1,1)
```

```
/* Matrix get() and set() functions */

double get_matrixInput(int colIndex)
{
```

```
    int rowIndexGetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colInde
    return ex_getset_data.matrices.matrixInput[rowIndexGetInput];
}

void set_matrixInput(int colIndex, double value)
{
    int rowIndexSetInput = MATRIXINPUT_NCOLS * (colIndex % MATRIXINPUT_NROWS) + colInde
    ex_getset_data.matrices.matrixInput[rowIndexSetInput] = value;
}

double get_matrixParam(int colIndex)
{
    int rowIndexGetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colInde
    return ex_getset_data.matrices.matrixParam[rowIndexGetParam];
}

void set_matrixParam(int colIndex, double value)
{
    int rowIndexSetParam = MATRIXPARAM_NCOLS * (colIndex % MATRIXPARAM_NROWS) + colInde
    ex_getset_data.matrices.matrixParam[rowIndexSetParam] = value;
}

double get_matrixOutput(int colIndex)
{
    int rowIndexGetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colInde
    return ex_getset_data.matrices.matrixOutput[rowIndexGetOut];
}

void set_matrixOutput(int colIndex, double value)
{
    int rowIndexSetOut = MATRIXOUTPUT_NCOLS * (colIndex % MATRIXOUTPUT_NROWS) + colInde
    ex_getset_data.matrices.matrixOutput[rowIndexSetOut] = value;
}
```

The code that you generate from a model represents matrices as serial arrays. Therefore, each of the `get` and `set` functions accept a single scalar index argument.

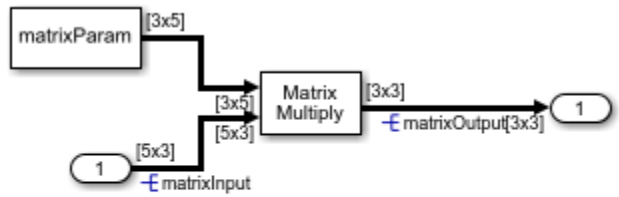
The generated code uses column-major format to store and to access matrix data. However, many C applications use row-major indexing. To integrate the generated code with the example legacy code, which stores the matrices `matrixInput` and `matrixParam` using row-major format, the custom `get` functions use the column-major index input to calculate an equivalent row-major index. The generated code algorithm, which interprets matrix data using column-major format by default, performs the correct

matrix math because the `get` functions effectively convert the legacy matrices to column-major format. The `set` function for the output, `matrixOutput`, also calculates a row-major index so the code writes the algorithm output to `matrixOutput` using row-major format. Alternatively, to integrate the column-major generated code with your row-major legacy code, you can manually convert the legacy code to column-major format by transposing your matrix data and algorithms.

View the example legacy header file `getsetHdrMatrix.h`. The file contains the `extern` prototypes for the `get` and `set` functions defined in `getsetSrc.c`.

Open the example model `rtwdemo_getset_matrix`. The model creates the data objects `matrixInput`, `matrixParam`, and `matrixOutput` in the base workspace. The objects correspond to the signals and parameter in the model.

```
load_system('rtwdemo_getset_matrix')
set_param('rtwdemo_getset_matrix','SimulationCommand','Update')
open_system('rtwdemo_getset_matrix')
```



In the base workspace, double-click the object `matrixInput` to view its properties. The object uses the custom storage class `GetSet`. The property `HeaderFile` is specified as `getsetHdrMatrix.h`. This legacy header file contains the `get` and `set` function prototypes.

In the model Configuration Parameters dialog box, on the **Code Generation > Custom Code** pane, the example legacy source file `getsetSrc.c` is identified for inclusion during the build process. This legacy source file contains the `get` and `set` function definitions and the definition of the global structure variable `ex_getset_data`.

Generate code with the example model.

```
rtwbuild('rtwdemo_getset_matrix');

### Starting build procedure for model: rtwdemo_getset_matrix
### Successful completion of build procedure for model: rtwdemo_getset_matrix
```

In the code generation report, view the file `rtwdemo_getset_matrix.c`. The model `step` function uses the legacy `get` and `set` functions to execute the algorithm.

```
rtwdemodbtype(fullfile('rtwdemo_getset_matrix_ert_rtw',...
    'rtwdemo_getset_matrix.c'),'/* Model step function */','}',1,1)

/* Model step function */
void rtwdemo_getset_matrix_step(void)
{
  int32_T i;
  int32_T i_0;
  int32_T i_1;
  int32_T matrixOutput_tmp;

  /* Product: '<Root>/Product' incorporates:
   *  Constant: '<Root>/Constant'
   *  Inport: '<Root>/In1'
   */
  for (i_0 = 0; i_0 < 3; i_0++) {
    for (i = 0; i < 3; i++) {
      matrixOutput_tmp = i + 3 * i_0;
      set_matrixOutput(matrixOutput_tmp, 0.0);
      for (i_1 = 0; i_1 < 5; i_1++) {
        set_matrixOutput(matrixOutput_tmp, get_matrixParam(3 * i_1 + i) *
                         get_matrixInput(5 * i_0 + i_1) + get_matrixOutput
                         (matrixOutput_tmp));
      }
```

Specify Header File or Function Naming Scheme for Data Items

By default, you specify a header file name, `get` function name, and `set` function name for each data item, such as a signal or parameter, that uses the custom storage class `GetSet`.

To configure a single header file, `get` function naming scheme, or `set` function naming scheme to use for every data item, you can use the Custom Storage Class Designer to create your own copy of `GetSet`. You can specify the header file or function names in a single location.

Follow these steps to create your own custom storage class by creating your own data class package, creating a copy of `GetSet`, and applying the new custom storage class to data items in your model.

1. Create your own data class package, `myPackage`, by copying the example package folder `+SimulinkDemos` and renaming the copied folder as `+myPackage`. Modify the `Parameter` and `Signal` class definitions so that they use the custom storage class definitions from `myPackage`. For an example, see “Create Data Class Package” on page 36-36.
2. Set your current folder to the folder that contains the package folder. Alternatively, add the folder containing the package folder to your MATLAB path.
3. Open the Custom Storage Class Designer.

   ```
   cscdesigner('myPackage')
   ```
4. Select the custom storage class `GetSet`. Click **Copy** to create a copy called `GetSet_1`.
5. Select the new custom storage class `GetSet_1`. In the **General** tab, set **Name** to `myGetSet`.
6. Set the drop-down list **Header file** to `Specify`. In the new text box, set **Header file** to `myFcnHdr.h`. Click **Apply**.
7. On the **Access Function Attributes** tab, set the drop-down lists **Get function** and **Set function** to `Specify`.
8. In the new boxes, set **Get function** to `myGetFcn_$N` and **Set function** to `mySetFcn_$N`. Click **OK**. Click **Yes** in response to the message about saving changes.

   When you generate code, the token `$N` expands into the name of the data item that uses this custom storage class.
9. Apply the custom storage class `myGetSet` from your package to a data item. For example, create a `myPackage.Parameter` object in the base workspace.

   ```
   myParam = myPackage.Parameter(15.23);
   myParam.CoderInfo.StorageClass = 'Custom';
   myParam.CoderInfo.CustomStorageClass = 'myGetSet';
   ```
10. Use the object to set a parameter value in your model. When you generate code, the code algorithm accesses the parameter through the functions that you specified. The code uses an `#include` directive to include the header file that you specified.

Access Scalar and Array Data Through Macro Instead of Function Call

If you implement the `get` mechanism for scalar or array data as a macro instead of a function, you can generate code that omits parentheses when reading that data.

- For scalar data, your macro must yield the scalar value.
- For array data, your macro must yield the starting memory address.

Create your own `AccessFunction` storage class by using the Custom Storage Class Designer, as described in “Specify Header File or Function Naming Scheme for Data Items” on page 36-68. In the Designer, on the **Access Function Attributes** tab, select **Get data through macro (omit parentheses)**.

GetSet Custom Storage Class Restrictions

- `GetSet` does not support complex signals.
- Multiple data in the same model cannot use the same `GetFunction` or `SetFunction`.
- Some blocks do not directly support `GetSet`.
- Custom S-functions do not directly support `GetSet`.

To use `GetSet` with an unsupported block or a custom S-function:

1. Insert a Signal Conversion block at the output of the block or function.
2. In the Signal Conversion block dialog box, select **Exclude this block from 'Block reduction' optimization**.
3. Assign the custom storage class `GetSet` to the output of the Signal Conversion block.

Access Data Through Functions by Using Storage Classes in Embedded Coder Dictionary

To replace the direct access to data in the generated code with your own or legacy functions that read and write data in a customized way, you can enable function access on your storage classes. You create these storage classes in the Embedded Coder Dictionary. Root-level inports, root-level outports, and local parameters that use your storage class appear in the generated code as calls to specified functions. You provide the function declarations and definitions in separate header and source files pointed to by the storage class.

Access Legacy Data by Value

You can define and apply a custom storage class to root-level inports, root-level outports, and local parameters so they can be accessed by customizable `get` and `set` functions. Such customization can be useful, for example, to abstract layers of software, gain access to data from an external file or to control access to critical sections of code.

This example shows how to set up a custom storage class in the Embedded Coder Dictionary and map the storage class to root-level inports/outports and local parameters in the Code Mappings editor.

1. Open example model `rtwdemo_roll`. In the MATLAB command window, run this command:

   ```
   addpath(fullfile(docroot,'toolbox','ecoder','examples'))
   ```

   Running the preceding command gives you these supporting files required for the example that define the `get` and `set` functions:

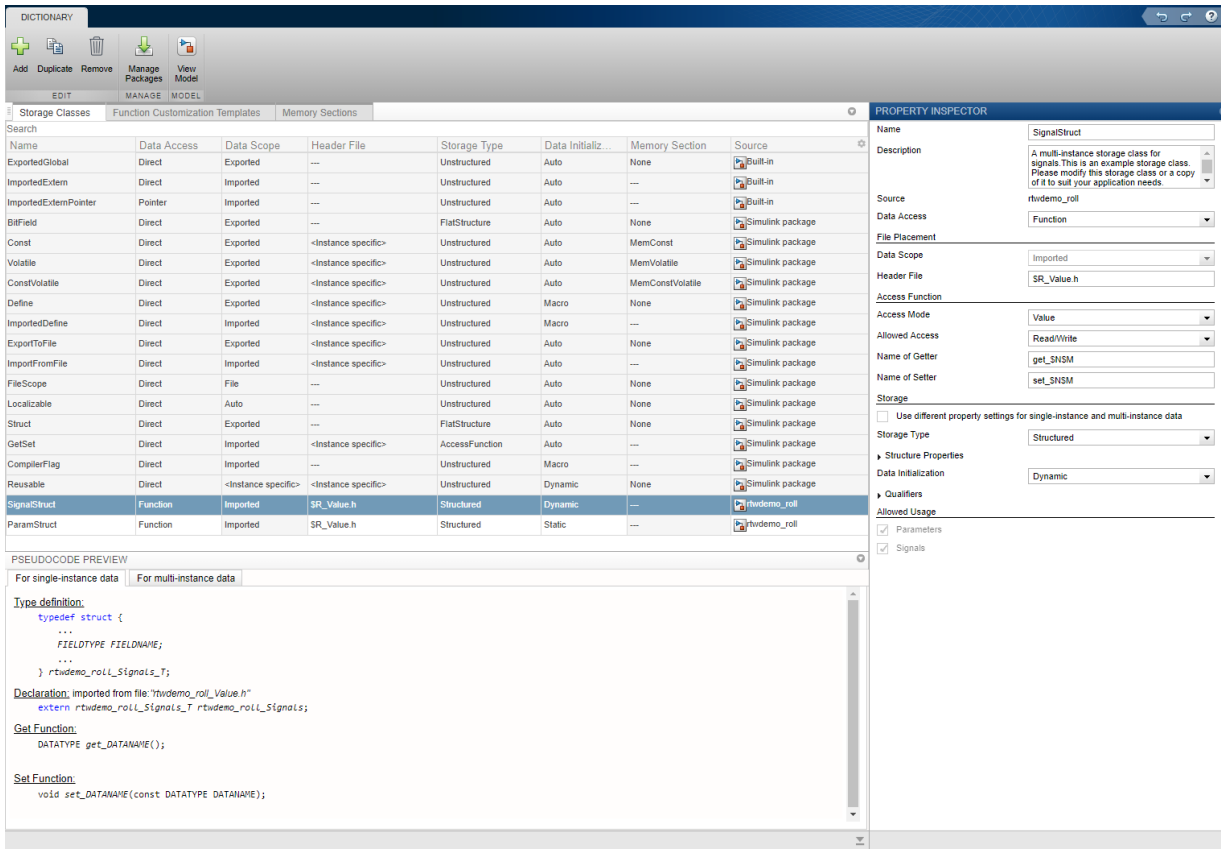
   - `rtwdemo_roll_Value.h`
   - `rtwdemo_roll_Value.c`
   - `rtwdemo_roll_Pointer.h`
   - `rtwdemo_roll_Pointer.c`

   Save these files to your local path.
2. Open the Code perspective. Select **Code > C/C++ Code > Configure Model in Code Perspective**.
3. Open the Embedded Coder Dictionary.

4. The `rtwdemo_roll` model has two custom storage classes: `SignalStruct` and `ParamStruct`. They are already created by using the **Add** button. This example uses these storage classes. You can perform the following steps for a storage class that you create as well.
5. For the `SignalStruct` storage class, in the **Property Inspector** pane, update these property values:

   - **Data Access** to `Function`
   - **Header File** to `$R_Value.h`

   Make sure that **Access Mode** is set to `Value`. **Data Scope** is set to `Imported` by default and cannot be changed.



For the `ParamStruct` storage class, in the **Property Inspector** pane, update these property values:

- **Data Access** to `Function`
- **Header File** to `$R_Value.h`

These properties are already set:

- **Access Mode** to `Value`
- **Data Initialization** to `Static`

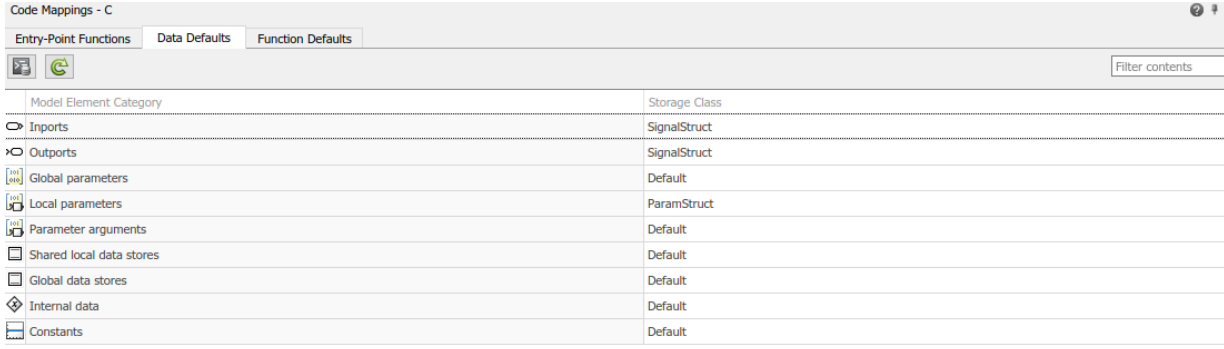
Storage classes used for parameters can have only **Data Initialization** set to `Static`.

6 Open the Configuration Parameters dialog box. Select **Code Generation > Custom Code > Additional build information > Source files** and specify:

```
rtwdemo_roll_Value.c
```

7 In the Code perspective, open the **Code Mappings > Data Defaults** tab. Map these model element categories:

- **Inports** to `SignalStruct`
- **Outports** to `SignalStruct`
- **Local parameters** to `ParamStruct`



8 Build the model and generate code.

In the generated code, view the file `rtwdemo_roll.c`. The model `step` function uses the specified `get` and `set` functions to execute the algorithm. The generated code accesses the legacy data by calling the custom, handwritten `get` and `set` functions. For example, here is the code snippet for the HDG_Ref inport:

```
if (get_HDG_Mode()) {
    /* Outputs for Atomic SubSystem: '<Root>/HeadingMode' */
    rtb_Sum1 = (get_HDG_Ref() - get_Psi()) * 0.015F * get_TAS();

    /* End of Outputs for SubSystem: '<Root>/HeadingMode' */
  } else {
    /* Outputs for Atomic SubSystem: '<Root>/RollAngleReference' */
    if ((real32_T)fabs(get_Turn_Knob()) >= 3.0F) {
      rtb_Sum1 = get_Turn_Knob();
    }
```

You can generate code that calls your custom `get` and `set` functions if the functions that you write accept and return the expected values.

Access Legacy Data by Pointer

To access data using a pointer, follow all the preceding steps but make these changes:

- In the Embedded Coder Dictionary, for storage classes `SignalStruct` and `ParamStruct`, specify:
  - **Access Mode** to `Pointer`
  - **Header File** to `$R_Pointer.h`
- Select **Configuration Parameters** > **Code Generation** > **Custom Code** > **Additional build information** > **Source files** and replace `rtwdemo_roll_Value.c` with:

  ```
  rtwdemo_roll_Pointer.c
  ```

With the pointer access, a `get` function now returns a pointer whose value must be dereferenced with the * before use. For example, the generated code for the HDG_Ref inport now looks like this code:

```
if (*get_HDG_Mode()) {
    /* Outputs for Atomic SubSystem: '<Root>/HeadingMode' */
    rtb_Sum1 = (*get_HDG_Ref() - *get_Psi()) * 0.015F * *get_TAS();

    /* End of Outputs for SubSystem: '<Root>/HeadingMode' */
  } else {
    /* Outputs for Atomic SubSystem: '<Root>/RollAngleReference' */
    if ((real32_T)fabs(tmp_1) >= 3.0F) {
      rtb_Sum1 = tmp_1;
    }
```

Creating your own custom storage class in Embedded Coder Dictionary gives you the flexibility of customizing function names and return types. You can also use the custom storage class `GetSet` to access data through `get` and `set` functions. For more information, see “Access Data Through Functions with Custom Storage Class GetSet” on page 36-51.

- “Access Structured Data Through a Pointer That External Code Defines” on page 36-21

Integrate External Application Code with Code Generated from PID Controller

This example shows how to generate C code from a control algorithm model and integrate that code with existing, external application code. In the complete application, which consists of three modules, the algorithm module must exchange data with other modules through global variables. In the example, you configure the generated code to interact with existing external variables, resemble the external code in appearance and organization, and conform to specific coding requirements.

Inspect External Code

Set your current folder to a writable location.

Copy the script `prepare_ext_code` to your current folder and run the script. The script copies external code files into several folders.

```
try
copyfile(fullfile(matlabroot,'examples','ecoder','main','prepare_ext_code.m'),...
    'prepare_ext_code.m','f');
catch
end
run('prepare_ext_code.m');
```

In your current folder, open `ext_code_main.c`. This application code represents an embedded system with a trivial scheduling algorithm (a `while` loop) and three modules whose algorithms run in every execution cycle: `ex_ext_inputs_proc`, `ex_ext_ctrl_alg`, and `ex_ext_outputs_proc`.

```
type('ext_code_main.c')
```

In the `shared` folder, inspect `ex_ext_projTypes.h`. The file defines two custom data types (`typedef`) that the data in the modules use.

```
type(fullfile('shared','ex_ext_projTypes.h'))
```

In the `io_drivers` folder, inspect `ex_sensor_accessors.c`. This file defines functions, `get_fromSensor_flow` and `get_fromSensor_temp`, that return raw data recorded by a flow sensor and a temperature sensor. For this example, the functions return trivial sinusoidal stimuli for the control algorithm.

```
type(fullfile('io_drivers','ex_sensor_accessors.c'))
```

In the `ex_ext_inputs_proc` folder, inspect `ex_ext_inputs_proc.c`. The `ex_ext_inputs_proc` module reads the sensor data (by calling the accessor functions), filters the data, and stores it in two global variables, `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. These global variables are defined in the file `ex_ext_proc_inputs.c` and declared in `ex_ext_proc_inputs.h`.

```
type(fullfile('ex_ext_inputs_proc','ex_ext_inputs_proc.c'))
```

The filter algorithm in this module and the algorithms in the other two modules require state data, which must persist between execution cycles of the application. Each module stores relevant state data as global variables. For example, in the `ex_ext_inputs_proc` module, `ex_ext_inputs_proc.c` defines these variables:

- `flowFilterIn_state_data`
- `tempFilterIn_state_data`
- `flowFilterIn_tmp_data`
- `tempFilterIn_tmp_data`

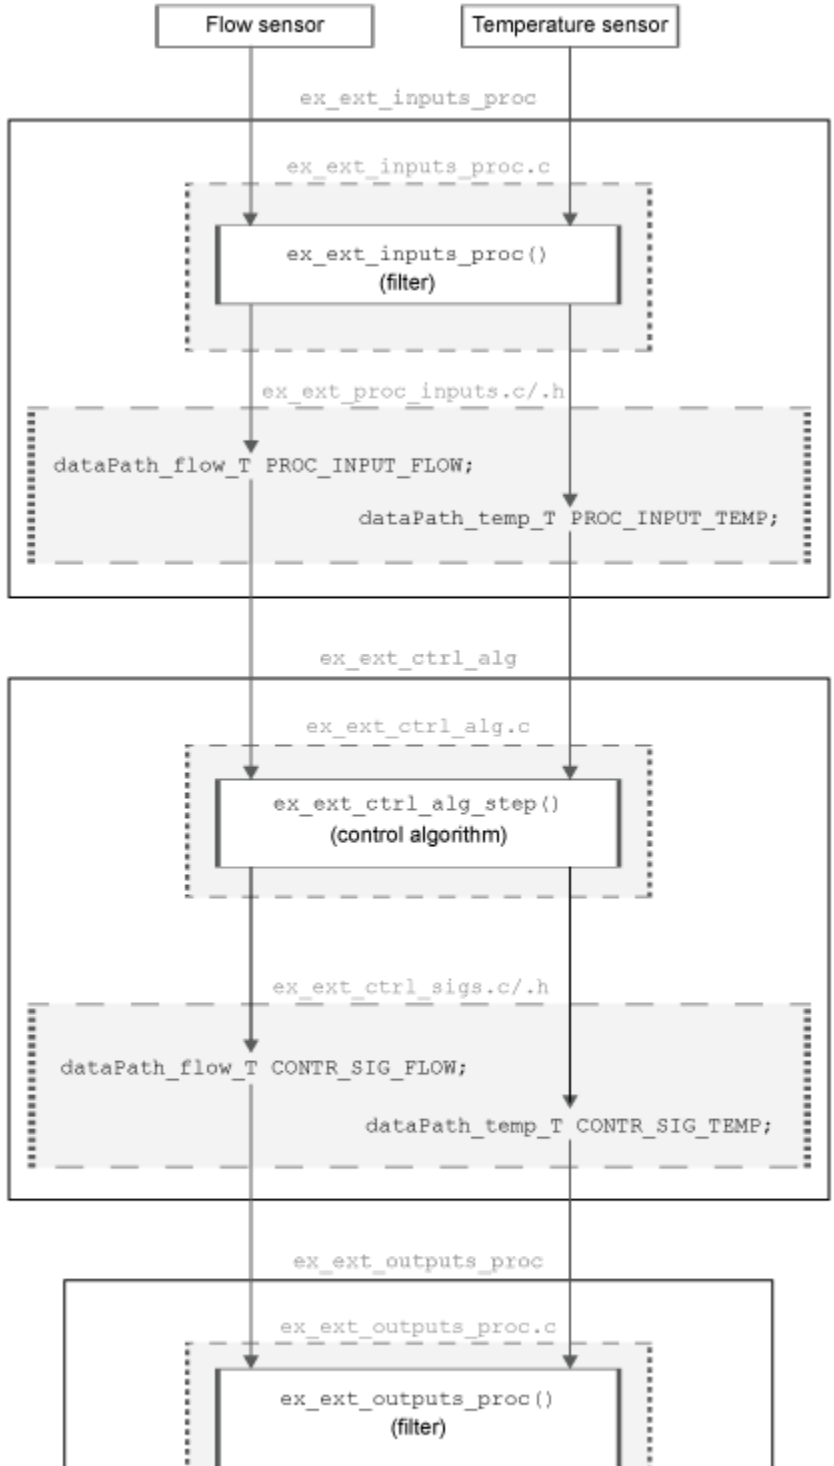
The empty `ex_ext_ctrl_alg` folder is a placeholder for the generated code. The `ex_ext_ctrl_alg` module must perform PID control on the filtered flow and temperature measurements. Later, you examine the requirements for this code, which are based on the code in the other modules.

In the `ex_ext_outputs_proc` folder, inspect `ex_ext_outputs_proc.c`. This module reads the PID output signals from global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The `ex_ext_ctrl_alg` module (the generated code) must define these variables. The `ex_ext_outputs_proc` module then filters these signals and passes the filtered values to functions that represent device drivers for actuators (for example, a valve and a heater filament).

```
type(fullfile('ex_ext_outputs_proc','ex_ext_outputs_proc.c'))
```

The actuator functions are defined in the `io_drivers` folder in the file `ex_actuator_accessors.c`.

The figure shows the intended flow of data through the system. The figure also shows the code files that define and declare the data (global variables) that cross the module boundaries.



Flow sensor
Temperature sensor
ex_ext_inputs_proc
ex_ext_inputs_proc.c
ex_ext_inputs_proc()
(filter)
ex_ext_proc_inputs.c/.h
dataPath_flow_T PROC_INPUT_FLOW;
dataPath_temp_T PROC_INPUT_TEMP;
ex_ext_ctrl_alg
ex_ext_ctrl_alg.c
ex_ext_ctrl_alg_step()
(control algorithm)
ex_ext_ctrl_sigs.c/.h
dataPath_flow_T CONTR_SIG_FLOW;
dataPath_temp_T CONTR_SIG_TEMP;
ex_ext_outputs_proc
ex_ext_outputs_proc.c
ex_ext_outputs_proc()
(filter)

Inspect Simulink Model and Determine Requirements for Generated Code

Open the example model `ex_ext_ctrl_alg`.

```
open_system('ex_ext_ctrl_alg')
```

The blocks in the model implement the required PID control algorithm. The model uses default code generation settings for an ERT-based system target file (`ert.tlc`).

To complete the application by performing the function of the `ex_ext_ctrl_alg` module, the code generated from this model must:

- Use the custom data types `dataPath_flow_T` and `dataPath_temp_T` from the external file `ex_ext_projTypes.h`.
- Read filtered sensor data from the global variables `PROC_INPUT_FLOW` and `PROC_INPUT_TEMP`. The generated code must not define these variables because the module `ex_ext_inputs_proc` defines them, declaring them in `ex_ext_proc_inputs.h`.
- Write PID control signals to global variables named `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`. The generated code must define these variables and declare them in a file named `ex_ext_ctrl_sigs.h`. Then, the `ex_ext_outputs_proc` module can read the raw control signals from them.
- Conform to variable naming standards that govern the external application. For example, the generated code must store state data in global variables whose names end in `_data`. In addition, for this example, the names of local function variables must end in `_local`.
- Conform to standards that govern the organization of the code in each of the external files. For example, each file contains sections, delimited by comments, that aggregate similar code constructs such as type definitions, variable declarations, and function definitions.

So that you and others can interact with the control algorithm during execution, for this example, you also configure the generated code to define and declare `const` global variables named `PARAM_setpoint_flow` and `PARAM_setpoint_temp`, which represent the PID controller setpoints. The definitions must appear in a file named `ex_ext_ctrl_params.c` and the declarations must appear in a file named `ex_ext_ctrl_params.h`.

Configure Model to Use Custom Data Types

Set your current folder to the `shared` folder.

Use the function `Simulink.importExternalCTypes` to generate `Simulink.AliasType` objects that represent the custom data types `dataPath_flow_T` and `dataPath_temp_T`.

```
cd('shared')
Simulink.importExternalCTypes('ex_ext_projTypes.h');
```

The objects appear in the base workspace.

In the `ex_ext_ctrl_alg` model, select **View > Model Data Editor**.

In the Model Data Editor, for the Inport block that represents `PROC_INPUT_FLOW`, set **Data Type** to `dataPath_flow_T`.

For the Inport block that represents `PROC_INPUT_TEMP`, set **Data Type** to `dataPath_temp_T`.

Select the **Signals** tab.

In the model, select the output signal of each Constant block. In the Model Data Editor, set **Data Type** to `Inherit: Inherit via back propagation`. With this setting, each Constant block inherits its output data type from the block immediately downstream, in this case, a Sum block.

Alternatively, to configure the data types, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg/In1','OutDataTypeStr','dataPath_flow_T')
set_param('ex_ext_ctrl_alg/In2','OutDataTypeStr','dataPath_temp_T')
set_param('ex_ext_ctrl_alg/Flow Setpt','OutDataTypeStr',...
    'Inherit: Inherit via back propagation')
set_param('ex_ext_ctrl_alg/Temp Setpt','OutDataTypeStr',...
    'Inherit: Inherit via back propagation')
```

Update the block diagram. The diagram shows that, due to data type inheritance and propagation, signals in the model use a custom data type.

Configure Interface Data

Configure the model to generate code that accesses and defines the correct global variables such as `PROC_INPUT_FLOW` and `CONTR_SIG_TEMP`.

In the Model Data Editor, select the **Inports/Outports** tab and set the **Change view** drop-down list to `Code`.

Select the rows that correspond to the two Inport blocks.

For either row, set **Storage Class** to `ImportFromFile` and **Header File** to `ex_ext_proc_inputs.h`. With the storage class `ImportFromFile`, each Inport block appears in the generated code as a global variable. However, the generated code does not define the variable, instead including (`#include`) the variable declaration from `ex_ext_proc_inputs.h`.

For the rows that correspond to the Outport blocks, set:

- **Storage Class** to `ExportToFile`
- **Header file** to `ex_ext_ctrl_sigs.h`
- **Definition File** to `ex_ext_ctrl_sigs.c`

With `ExportToFile`, the generated code defines the global variable.

Alternatively, to configure the signals, at the command prompt, use these commands.

```
temp = Simulink.Signal;
temp.CoderInfo.StorageClass = 'Custom';
temp.CoderInfo.CustomStorageClass = 'ImportFromFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_proc_inputs.h';

portHandles = get_param('ex_ext_ctrl_alg/In1','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'SignalObject',copy(temp))

portHandles = get_param('ex_ext_ctrl_alg/In2','portHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'SignalObject',copy(temp))

temp.CoderInfo.CustomStorageClass = 'ExportToFile';
temp.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_sigs.h';
temp.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_sigs.c';

set_param('ex_ext_ctrl_alg/Out1','SignalObject',copy(temp))
set_param('ex_ext_ctrl_alg/Out2','SignalObject',copy(temp))
```

To apply a storage class to a block parameter, such as the **Constant value** parameter of a Constant block, you must create a parameter object such as `Simulink.Parameter`. You can use the Model Data Editor to create parameter objects.

Select the **Parameters** tab and set **Change view** to `Design`.

In the model, select the Constant block labeled `Flow Setpt`.

In the Model Data Editor, set **Value** to `PARAM_setpoint_flow`.

Next to `PARAM_setpoint_flow`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(3)`.

Set **Location** to `Model Workspace` and click **Create**.

In the `PARAM_setpoint_flow` property dialog box, set **Storage class** to `Const`.

Set **HeaderFile** to `ex_ext_ctrl_params.h` and **DefinitionFile** to `ex_ext_ctrl_params.c`.

For the other Constant block, use the Model Data Editor to create a `Simulink.Parameter` object named `PARAM_setpoint_temp` with value 2.

Alternatively, to configure the blocks, at the command prompt, use these commands.

```
PARAM_setpoint_flow = Simulink.Parameter(3);
PARAM_setpoint_flow.CoderInfo.StorageClass = 'Custom';
PARAM_setpoint_flow.CoderInfo.CustomStorageClass = 'Const';
PARAM_setpoint_flow.CoderInfo.CustomAttributes.HeaderFile = 'ex_ext_ctrl_params.h';
PARAM_setpoint_flow.CoderInfo.CustomAttributes.DefinitionFile = 'ex_ext_ctrl_params.c';

PARAM_setpoint_temp = copy(PARAM_setpoint_flow);
PARAM_setpoint_temp.Value = 2;

mdlwks = get_param('ex_ext_ctrl_alg','ModelWorkspace');
assignin(mdlwks,'PARAM_setpoint_flow',copy(PARAM_setpoint_flow))
assignin(mdlwks,'PARAM_setpoint_temp',copy(PARAM_setpoint_temp))

set_param('ex_ext_ctrl_alg/Flow Setpt','Value','PARAM_setpoint_flow')
set_param('ex_ext_ctrl_alg/Temp Setpt','Value','PARAM_setpoint_temp')

clear temp PARAM_setpoint_flow PARAM_setpoint_temp mdlwks portHandles outportHandle
```

Configure Internal Data

In the external code, internal data that does not participate in the module interfaces, such as state data and local variables in functions, conform to naming schemes. In the model,

configure internal data that appears in the generated code to mimic these naming schemes.

In the model Configuration Parameters dialog box, inspect the **Code Generation > Symbols** pane. When you specify values for the naming schemes under **Identifier format control**:

- `$R` represents the name of the model, `ex_ext_ctrl_alg`.
- `$N` represents the name of each model element to which the scheme applies, such as a signal, block state, or standard data structure.
- `$M` represents name-mangling text that the code generator inserts, if necessary, to avoid name clashes. For most naming rules, this token is required.

Set **Global variables** to `$R$N_data$M`. This setting controls the names of global variables, such as those that represent state data. The naming scheme `$R$N_data_$M` most closely approximates the scheme that the state variables in the external code use.

Set **Local temporary variables** and **Local block output variables** to `$N_local$M`.

Alternatively, to set the configuration parameters, at the command prompt, use these commands.

```
set_param('ex_ext_ctrl_alg','CustomSymbolStrGlobalVar','$R$N_data$M')
set_param('ex_ext_ctrl_alg','CustomSymbolStrTmpVar','$N_local$M')
set_param('ex_ext_ctrl_alg','CustomSymbolStrBlkIO','$N_local$M')
```

Configure the state data in the model to appear in the generated code as separate global variables instead of fields of the standard DWork structure. In the model, select **Code > C/C++ Code > Configure Model in Code Perspective**.

Underneath the block diagram, under **Code Mappings > Data Defaults**, for the **Internal data** row, in the **Storage Class** column select `ExportedGlobal`.

Alternatively, to configure this default storage class, use these commands at the command prompt:

```
coder.mapping.create('ex_ext_ctrl_alg');
coder.mapping.defaults.set('ex_ext_ctrl_alg','InternalData',...
    'StorageClass','ExportedGlobal');
```

Configure Organization of Code in Each Generated File

Set your current folder to the `ex_ext_ctrl_alg` folder.

```
cd(fullfile('..','ex_ext_ctrl_alg'))
```

At the command prompt, navigate to the folder that contains the built-in code generation template `ert_code_template.cgt`. By default, when you generate code with the system target file `ert.tlc`, this template governs the organization and, in part, the appearance of the code in each generated file.

```
currentFolder = pwd;
cd(fullfile(matlabroot,'toolbox','rtw','targets','ecoder'))
```

Copy the `ert_code_template.cgt` file to your clipboard.

Return to the `ex_ext_ctrl_alg` folder. To avoid overwriting your clipboard, instead of using the command prompt to navigate to the folder, you can use the **Back** button in MATLAB.

```
cd(currentFolder)
clear currentFolder
```

Paste the file into the `ex_ext_ctrl_alg` folder. Rename the file as `ex_my_code_template.cgt`.

Open the file and replace the contents with this code.

```
type(fullfile(matlabroot,'examples','ecoder','ex_my_code_template.cgt'))
```

This new template conforms more closely to the organization of the external files. For example, the template organizes similar code constructs into named sections (delimited by comments) and, at the top of the template, specifies only minimal information about each generated file.

In the model, select **Configuration Parameters > Code Generation > Templates**.

Under **Code templates** and **Data templates**, set the four configuration parameters to `ex_my_code_template.cgt`.

Alternatively, to copy the file and set the parameters, at the command prompt, use these commands.

```
copyfile(fullfile(matlabroot,'examples','ecoder','ex_my_code_template.cgt'),...
    'ex_my_code_template.cgt','f')
set_param('ex_ext_ctrl_alg','ERTSrcFileBannerTemplate','ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg','ERTHdrFileBannerTemplate','ex_my_code_template.cgt')
```

```
set_param('ex_ext_ctrl_alg','ERTDataSrcFileTemplate','ex_my_code_template.cgt')
set_param('ex_ext_ctrl_alg','ERTDataHdrFileTemplate','ex_my_code_template.cgt')
```

Generate and Inspect Code

Because the external code already defines a `main` function, select **Configuration Parameters > Generate code only** and clear **Configuration Parameters > Generate an example main program**.

```
set_param('ex_ext_ctrl_alg','GenCodeOnly','on')
set_param('ex_ext_ctrl_alg','GenerateSampleERTMain','off')
```

Generate code from the model.

```
rtwbuild('ex_ext_ctrl_alg')
```

In the code generation report, inspect the generated files. The code meets the requirements. For example, `ex_ext_ctrl_sigs.c` defines the control output signals, `CONTR_SIG_FLOW` and `CONTR_SIG_TEMP`.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw','ex_ext_ctrl_sigs.c');
rtwdemodbtype(file,'dataPath_flow_T CONTR_SIG_FLOW;',...
    'dataPath_temp_T CONTR_SIG_TEMP;',1,1)
```

The setpoint parameters appear in `ex_ext_ctrl_params.c`.

```
file = fullfile('ex_ext_ctrl_alg_ert_rtw','ex_ext_ctrl_params.c');
rtwdemodbtype(file,'const dataPath_flow_T PARAM_setpoint_flow = 3.0;',...
    'const dataPath_temp_T PARAM_setpoint_temp = 2.0;',1,1)
```

The file `ex_ext_ctrl_alg.c` defines global variables to store state data. The variables follow the naming scheme that you specified. Code is similar to the following:

```
dataPath_temp_T ex_ext__Integrator_DSTATE_datag;
dataPath_flow_T ex_ext_c_Integrator_DSTATE_data;
dataPath_temp_T ex_ext_ctrl_Filter_DSTATE_datad;
dataPath_flow_T ex_ext_ctrl__Filter_DSTATE_data;
```

In the same file, the model execution function, `ex_ext_ctrl_alg_step`, creates local function variables to store temporary calculations. The variables follow the naming scheme that you specified. Code is similar to the following:

```
dataPath_flow_T Diff_local;
dataPath_flow_T FilterCoefficient_local;
```

```
dataPath_temp_T Diff1_local;
dataPath_temp_T FilterCoefficient_locali;
```

Some of the global and local variable names contain extra mangling characters that prevent name clashes. These extra characters correspond to the `$M` token that you specified in the naming schemes.

The generated code files are in the generated folders `ex_ext_ctrl_alg_ert_rtw` and `slprj`. You must configure file management systems and build tools to use these folders and files.

Configure Generated Code According to Interface Control Document Interactively

This example shows how to configure code generation settings for a model according to specifications in an interface control document (ICD). Store necessary Simulink variables and objects, such as `Simulink.Parameter` objects, in a data dictionary.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

Explore Interface Control Document

Navigate to the folder *`matlabroot`*`/examples/ecoder` (open). Copy this file to a writable, working folder:

- `ex_ICD_PCG_inter.xls`

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG_inter.xls` workbook and view the first worksheet, `Signals`. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The `Owner` column indicates the name of the component that allocates memory for each signal. The `DataType` column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus: EngSensors` to indicate a structure type named `EngSensors`.

In the `Parameters` worksheet, the `Value` column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the `Numeric Types` worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The `IsAlias` column indicates whether the C code uses the name of the data type (for example, `s16En3`) or uses the name of the primitive integer data type that corresponds to the word length (such as `short`). The `DataScope` column indicates whether the generated code exports or imports the definition of the type.

In the `Structure Types` worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the `DataType` column is `struct`. Subsequent rows that do not use `struct` represent fields of the preceding structure type. This ICD defines a structure type, `EngSensors`, with four fields: `throttle`, `speed`, `ego`, and `map`.

In the `Enumerated Types` worksheet, similar to the `Structure Types` worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type `sldemo_FuelModes`.

Write External Code

Some data items in the ICD belong to `other_component`, which is a component that exists outside of MATLAB. Create the code files that define and declare this external data.

Create the header file `ex_inter_types.h` in your current folder. This file defines the structure type `EngSensors` and numeric data types such as `u8En7`.

```
#ifndef INTER_TYPES_H__
#define INTER_TYPES_H__

typedef short s16En3;

typedef short s16En7;

typedef unsigned char u8En7;

typedef short s16En15;

/* Structure type for instrument measurements. */
typedef struct {
  /* Throttle angle. */
  s16En3 throttle;

  /* Engine speed. */
  s16En3 speed;

  /* EGO sensors. */
  s16En7 ego;

  /* Manifold pressure. */
  u8En7 map;
} EngSensors;
```

```
#endif
```

Create the source file `ex_inter_sigs.c` in your current folder. This file defines the imported signal `sensors`.

```
#include "ex_inter_sigs.h"

EngSensors sensors;                     /* Instrument measurements. */
```

Create the header file `ex_inter_sigs.h` in your current folder.

```
#include "ex_inter_types.h"

extern EngSensors sensors;   /* Instrument measurements. */
```

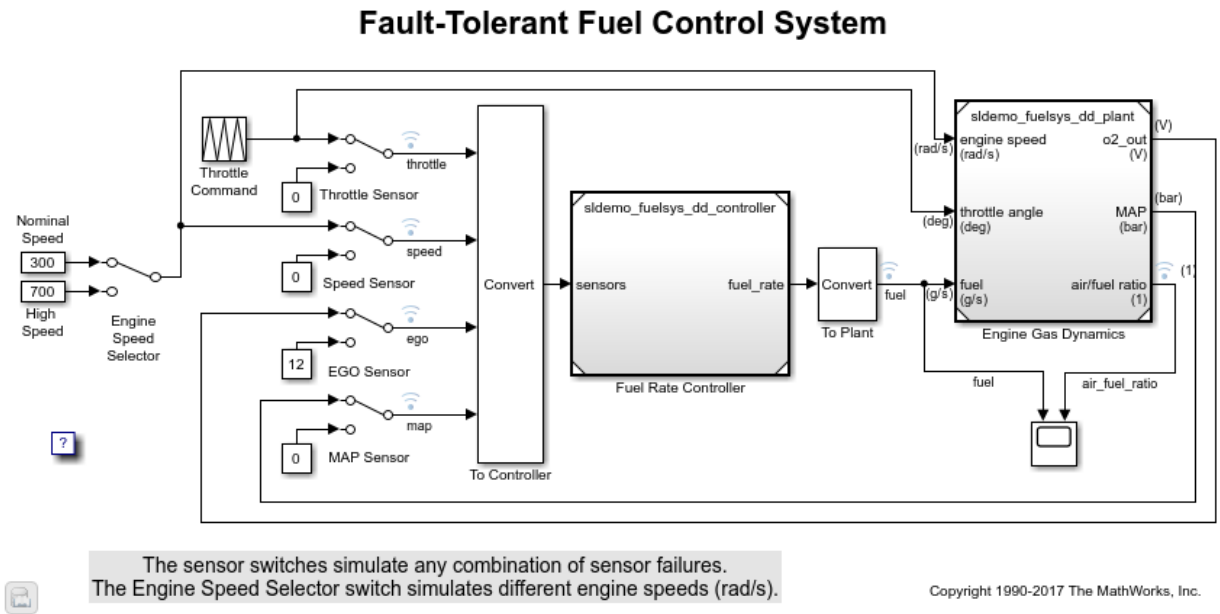
Explore Example Model

Run the script `prepare_sldemo_fuelsys_dd_inter`. For this example, the script prepares a system model, `sldemo_fuelsys_dd`.

```
run(fullfile(matlabroot,'examples','ecoder','main','prepare_sldemo_fuelsys_dd_inter'))
```

Open the system model `sldemo_fuelsys_dd`.

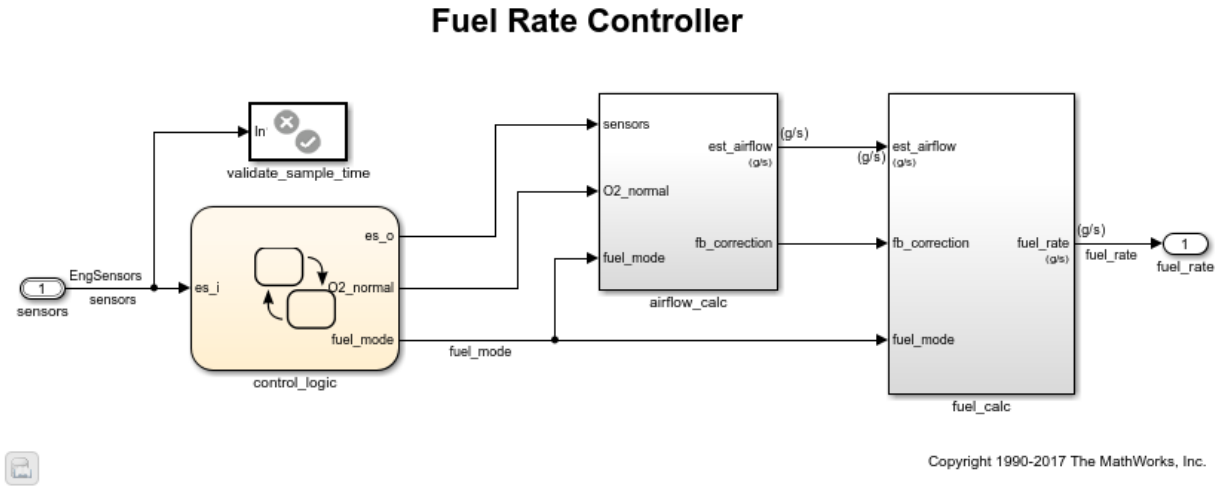
```
sldemo_fuelsys_dd
```



This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model `sldemo_fuelsys_dd_controller`.

```
sldemo_fuelsys_dd_controller
```



Some of the signals in the controller model have names, for example, the input signal `sensors`. Some block parameters in the model refer to `Simulink.Parameter` objects in a data dictionary. For example, in the `airflow_calc` subsystem, the `Pumping Constant` block uses the parameter objects `PumpCon`, `SpeedVect`, and `PressVect`. These parameter objects set the values of the corresponding block parameters. You can apply code generation settings to the signals and parameter objects.

The controller model is linked to a data dictionary, `sldemo_fuelsys_dd_controller.sldd`. In the lower-left corner of the model, click the dictionary badge to open the dictionary in the Model Explorer. Then, in the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

The dictionary already stores:

- The parameter objects
- `Simulink.NumericType` objects such as `u8En7`
- A `Simulink.Bus` object, `EngSensors`
- The definition of an enumerated data type, `sldemo_FuelModes`

Configure Model According to ICD

Navigate to the root level of the controller model and select **View > Model Data Editor**.

In the Model Data Editor, activate the **Change scope** button. The Model Data Editor now shows information about data items in the subsystems.

Click the **Show/refresh additional information** button. The Model Data Editor now shows information about data objects (the `Simulink.Parameter` objects in the data dictionary) that the model uses.

Select the **Inports/Outports** tab (which is selected by default).

In the model, select the Inport block labeled `sensors`. The Model Data Editor highlights the corresponding row.

In the ICD, select the **Signals** tab.

Use the Model Data Editor to configure the signal according to the information in the ICD:

- Set the value in the **Data Type** column to `Bus: EngSensors`. In this case, the value is already set.
- Set the **Change view** drop-down list to `Code` and, for `sensors`, set **Storage Class** to `ImportFromFile`. Use this storage class because the **Owner** column in the ICD implies that a different component, not `sldemo_fuelsys_dd_controller`, provides the C-code definition of the `sensors` variable. With this storage class, the generated code does not define the variable.
- Set **Header File** to `ex_inter_sigs.h`. When you use a storage class that represents imported data, such as `ImportFromFile`, you cannot specify **Definition File** in the Model Data Editor. Instead, include the definition file (in this case, `ex_inter_sigs.c`) in the code generation and build process by using **Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files**.

In the model, select the Outport block labeled `fuel_rate`.

Use the Model Data Editor to configure `fuel_rate` according to the ICD. To access design properties such as minimum value (**Min**) and physical unit (**Unit**), set **Change view** to `Design`. For code generation settings, because the ICD specifies `sldemo_fuelsys_dd_controller` as the owner of the other signals, set **Storage Class** to `ExportToFile`.

Inspect the **Signals** tab.

Set **Change view** to `Code` and configure code generation settings for the signal `fuel_mode`.

You cannot use the Model Data Editor to configure design properties for `fuel_mode` (such as data type) because `fuel_mode` is an output of a Stateflow chart. In the model, navigate into the chart.

Select **View > Model Explorer > Model Explorer**.

In the Model Explorer **Contents** pane (the middle pane), select the `fuel_mode` data item.

In the Dialog pane (the right pane), configure `fuel_mode` according to the ICD. In this case, the signal data type is already set, so you can specify only the description.

Navigate to the root level of the model.

In the ICD and the Model Data Editor, select the **Parameters** tab. In the Model Data Editor, set **Change view** to `Design`.

In the Model Data Editor, use the **Filter contents** box to search for the first parameter, `PressEst`. The Model Data Editor shows two rows: One row that corresponds to the parameter object `PressEst` and one row that corresponds to the block parameter that uses `PressEst`.

Use the Model Data Editor to configure `PressEst` according to the ICD. The parameter value (the **Value** column) is already set. Because the ICD specifies `sldemo_fuelsys_dd_controller` as the owner of `PressEst`, set **Storage Class** to `ExportToFile`.

Use the Model Data Editor to configure the other parameters. Optionally, to apply a change to multiple parameters at once, select multiple rows in the data table.

In the lower-left corner of the model, click the dictionary badge to open the data dictionary in the Model Explorer.

In the **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane (the middle pane), select the `Simulink.NumericType` object `u8En7`. This object represents one of the primitive `typedef` statements in `ex_inter_types.h`.

In the ICD, select the **Numeric Types** tab.

Use the Model Explorer Dialog pane (the right pane) to configure the object according to the ICD.

Use the Model Explorer to configure the other `Simulink.NumericType` objects. You can use the **Contents** pane to perform batch operations.

In the **Contents** pane, click the `Simulink.Bus` object `EngSensors`. This object represents the structure type that `ex_inter_types.h` defines.

In the Dialog pane (the right pane), click **Launch Bus Editor**.

In the ICD, select the **Structure Types** tab.

Use the Bus Editor to configure the bus object and the signal elements in the bus (such as `throttle`) according to the ICD.

In the ICD, select the **Enumerated Types** tab.

In the Model Explorer **Contents** pane, click the enumerated type definition `sldemo_FuelModes`.

Use the Dialog pane to configure the type according to the ICD. Set **Storage Type** to `Native Integer` and **Data Scope** to `Exported`.

Generate and Inspect Code

Configure the controller model to compile the generated code into an executable by clearing the model configuration parameter **Generate code only**.

Generate code from the controller model.

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated header file `sldemo_FuelModes.h` defines the enumeration `sldemo_FuelModes`.

```
typedef enum {
  LOW = 1,                             /* Default value */
  RICH,
  DISABLED
} sldemo_FuelModes;
```

The file `sldemo_fuelsys_dd_controller_types.h` includes (`#include`) the external header file `ex_inter_types.h`, which defines data types such as `u8En7` and the structure type `EngSensors`.

```
#include "ex_inter_types.h"
```

The file `sldemo_fuelsys_dd_controller_private.h` includes the header file `ex_inter_sigs.h`. This external header file contains the `extern` declaration of the signal `sensors`, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern u8En7 PressEst[855];
extern s16En15 PumpCon[551];
extern s16En15 RampRateKiZ[25];
extern s16En3 SpeedEst[1305];
extern s16En7 ThrotEst[551];
extern sldemo_FuelModes fuel_mode;
extern s16En7 fuel_rate;
```

The data definitions (memory allocation) appear in the source files that the ICD specifies: `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

```
s16En15 RampRateKiZ[25] = { 393, 786, 1180, 1573, 1966, 786, 1573, 2359, 3146,
  3932, 1180, 2359, 3539, 4719, 5898, 1573, 3146, 4719, 6291, 7864, 1966, 3932,
  5898, 7864, 9830 } ;
```

The algorithm is in the model `step` function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a `switch` block to control the flow of execution.

```
  /* SwitchCase: '<S10>/Switch Case' */
  switch (fuel_mode) {
   case LOW:
```

```
/* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates:
 *  ActionPort: '<S12>/Action Port'
 */
/* DiscreteFilter: '<S12>/Discrete Filter' incorporates:
 *  DiscreteIntegrator: '<S1>/Discrete Integrator'
 */
DiscreteFilter_tmp = (int16_T)(int32_T)((int32_T)((int32_T)((int32_T)
  rtDWork.DiscreteIntegrator_DSTATE << 14) - (int32_T)(-12137 * (int32_T)
  rtDWork.DiscreteFilter_states_g)) >> 14);
```

Configure Generated Code According to Interface Control Document

Import specifications from an interface control document (ICD), configure code generation settings for a model according to the specifications, and store the settings in data dictionaries.

An ICD describes the data interface between two software components. To exchange and share data, the components declare and define global variables that store signal and parameter values. The ICD names the variables and lists characteristics such as data type, physical units, and parameter values. When you create models of the components in Simulink, you can configure the generated code to conform to the interface specification.

In this example, the ICD is a Microsoft® Excel® workbook.

Explore Interface Control Document

Navigate to the folder *matlabroot*`/examples/ecoder` (open). Copy this file to a writable, working folder:

- `ex_ICD_PCG.xls`

Navigate to the folder *matlabroot*`/examples/ecoder/main` (open). Copy this file to the same writable, working folder:

- `ex_importICD_PCG.m`

In Microsoft® Excel® or another compatible program, open the `ex_ICD_PCG.xls` workbook and view the first worksheet, `Signals`. Each row of the worksheet describes a signal that crosses the interface boundary.

Inspect the cell values in the worksheet. The `Owner` column indicates the name of the component that allocates memory for each signal. The `DataType` column indicates the signal data type in memory. For example, the worksheet uses the expression `Bus: EngSensors` to represent a structure type named `EngSensors`.

In the `Parameters` worksheet, the `Value` column indicates the value of each parameter. If the value of the parameter is nonscalar, the value is stored in its own separate worksheet, which has the same name as the parameter.

In the `Numeric Types` worksheet, each row represents a named numeric data type. In this ICD, the data use fixed-point data types (Fixed-Point Designer). The `IsAlias` column

indicates whether the C code uses the name of the data type (for example, `u8En7`) or uses the name of the primitive integer data type that corresponds to the word length. The `DataScope` column indicates whether the generated code exports or imports the definition of the type.

In the `Structure Types` worksheet, each row represents either a structure type or a field of a structure type. For structure types, the value in the `DataType` column is `struct`. Subsequent rows that do not use `struct` represent fields of the preceding structure type. This ICD defines a structure type, `EngSensors`, with four fields: `throttle`, `speed`, `ego`, and `map`.

In the `Enumerated Types` worksheet, similar to the `Structure Types` worksheet, each row represents either an enumerated type or an enumeration member. This ICD defines an enumerated type `sldemo_FuelModes`.

Write External Code

Some data items in the ICD belong to `other component`, which is a component that exists outside of MATLAB. Create the code files that define and declare this external data.

Create the source file `ex_inter_sigs.c` in your current folder. This file defines the imported signal `sensors`.

```
#include "ex_inter_sigs.h"

EngSensors sensors;                     /* Instrument measurements. */
```

Create the header file `ex_inter_sigs.h` in your current folder.

```
#include "ex_inter_types.h"

extern EngSensors sensors;   /* Instrument measurements. */
```

Create the header file `ex_inter_types.h` in your current folder. This file defines the structure type `EngSensors` and numeric data types such as `u8En7`.

```
#ifndef INTER_TYPES_H__
#define INTER_TYPES_H__

typedef short s16En3;
```

```
typedef short s16En7;

typedef unsigned char u8En7;

typedef short s16En15;

/* Structure type for instrument measurements. */
typedef struct {
  /* Throttle angle. */
  s16En3 throttle;

  /* Engine speed. */
  s16En3 speed;

  /* EGO sensors. */
  s16En7 ego;

  /* Manifold pressure. */
  u8En7 map;
} EngSensors;

#endif
```

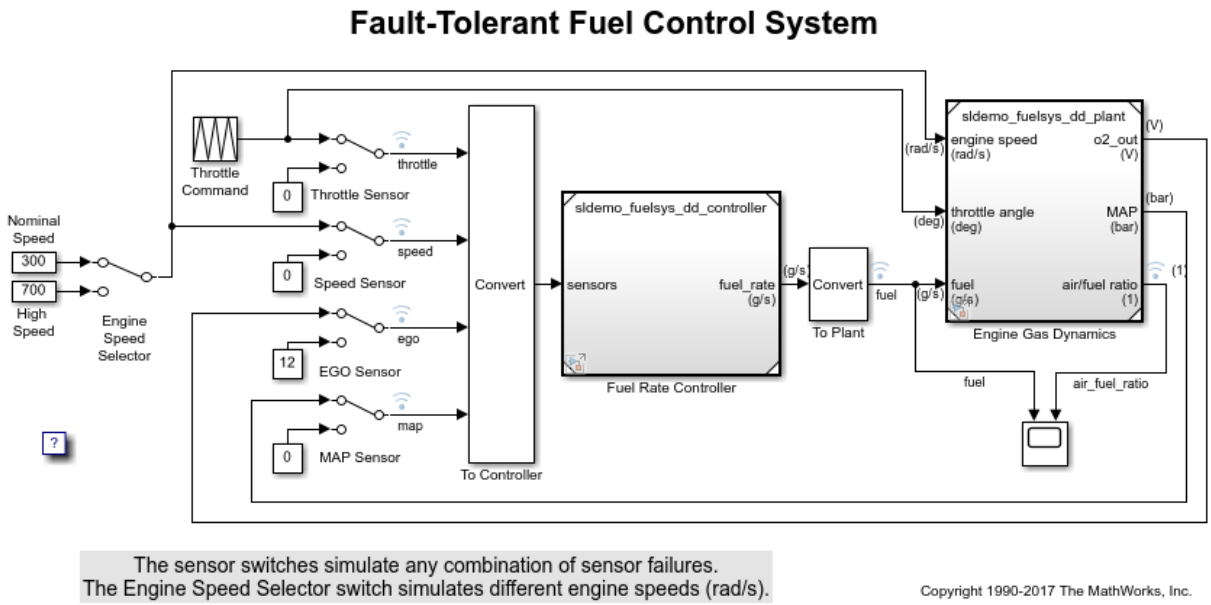
Explore Example Model

Run the script `prepare_sldemo_fuelsys_dd`. The script prepares a system model, `sldemo_fuelsys_dd`, for this example.

```
run(fullfile(matlabroot,'examples','ecoder','main','prepare_sldemo_fuelsys_dd'))
```

Open the system model, `sldemo_fuelsys_dd`.

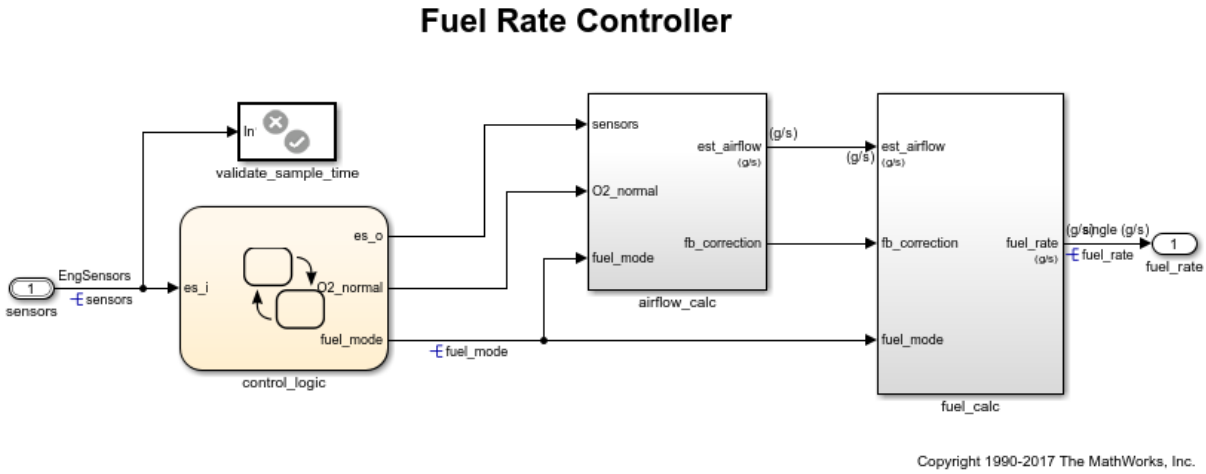
```
sldemo_fuelsys_dd
```



This system model references a controller model. In this example, you generate code from the controller model.

Open the controller model, `sldemo_fuelsys_dd_controller`.

```
sldemo_fuelsys_dd_controller
```



Data items in the controller model refer to `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace. For example, the input signal `sensors` refers to a `Simulink.Signal` object that has the same name. These objects store settings such as data types, block parameter values, and physical units. The names of these data items and objects match the names of the signals and parameters in the ICD.

Import ICD Specifications into Simulink

To configure code generation settings for the data items, import the settings from the ICD.

Open the example script `ex_importICD_PCG`. The script imports the data from each worksheet of the ICD into variables in the base workspace. It then configures the properties of the `Simulink.Signal` and `Simulink.Parameter` objects in the base workspace by using the imported data.

```
edit('ex_importICD_PCG')
```

If the base workspace already contains a data object that corresponds to a target data item in the ICD, the script configures the properties of the existing object. If the object does not exist, the script creates the object.

Run the `ex_importICD_PCG` script.

```
run('ex_importICD_PCG')
```

The script configures the data objects in the base workspace for code generation according to the specifications in the ICD. The `Simulink.Bus` object `EngSensors` represents the structure type from the ICD. The `Simulink.NumericType` objects, such as `u8En7`, represent the fixed-point data types.

```
ans =

    'Cannot redefine enumerated type sldemo_FuelModes because open models and existing
```

Generate and Inspect Code

Configure the controller model to compile the generated code into an executable by clearing the model configuration parameter **Generate code only**.

Generate code from the controller model.

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated header file `sldemo_FuelModes.h` defines the enumeration `sldemo_FuelModes`.

```
typedef enum {
  LOW = 1,                             /* Default value */
  RICH,
  DISABLED
} sldemo_FuelModes;
```

The file `sldemo_fuelsys_dd_controller_types.h` includes (`#include`) the external header file `ex_inter_types.h`, which defines data types such as `u8En7` and the structure type `EngSensors`.

```
#include "ex_inter_types.h"
```

The file `sldemo_fuelsys_dd_controller_private.h` includes the header file `ex_inter_sigs.h`. This external header file contains the `extern` declaration of the signal `sensors`, which a different software component owns.

The data header file `global_data.h` declares the exported parameters and signals that the ICD specifies. To share this data, other components can include this header file.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern u8En7 PressEst[855];
                      /* Lookup table to estimate pressure on sensor failure. */
extern s16En15 PumpCon[551];
/* Lookup table to determine pumping constant based on measured engine speed and manifo
extern s16En15 RampRateKiZ[25];   /* Lookup table to determine throttle rate. */
extern s16En3 SpeedEst[1305];
                  /* Lookup table to estimate engine speed on sensor failure. */
extern s16En7 ThrotEst[551];
                /* Lookup table to estimate throttle angle on sensor failure. */
extern sldemo_FuelModes fuel_mode;
        /* Fueling mode of engine. Enrich air/fuel mixture on sensor failure. */
extern int16_T fuel_rate;              /* Fuel rate setpoint. */
```

The data definitions (memory allocation) appear in the source files that the ICD specifies, `params.c` and `signals.c`. For example, `params.c` defines and initializes the parameter `RampRateKiZ`.

```
s16En15 RampRateKiZ[25] = { 393, 786, 1180, 1573, 1966, 786, 1573, 2359, 3146,
  3932, 1180, 2359, 3539, 4719, 5898, 1573, 3146, 4719, 6291, 7864, 1966, 3932,
  5898, 7864, 9830 } ;            /* Lookup table to determine throttle rate. */
```

The algorithm is in the model `step` function in the file `sldemo_fuelsys_dd_controller.c`. The algorithm uses the global data that the ICD identifies. For example, the algorithm uses the value of the signal `fuel_mode` in a `switch` block to control the flow of execution.

```
  /* SwitchCase: '<S10>/Switch Case' incorporates:
   *  Constant: '<S11>/shutoff'
   */
  switch (fuel_mode) {
   case LOW:
    /* Outputs for IfAction SubSystem: '<S10>/low_mode' incorporates:
     *  ActionPort: '<S12>/Action Port'
     */
    /* DiscreteFilter: '<S12>/Discrete Filter' incorporates:
```

```
     *  DiscreteIntegrator: '<S1>/Discrete Integrator'
     */
    DiscreteFilter_tmp = (int16_T)(int32_T)((int32_T)((int32_T)((int32_T)
      rtDWork.DiscreteIntegrator_DSTATE << 14) - (int32_T)(-12137 * (int32_T)
      rtDWork.DiscreteFilter_states_g)) >> 14);
```

Change Ownership of Data in ICD

When you make changes to the ICD, you can reuse the `ex_importICD_PCG` script to reconfigure the model. Change the ownership of the signal `sensors`, the structure type, and the fixed-point data types from `other_component` to `sldemo_fuelsys_dd_controller`.

In the ICD, on the `signals` worksheet, for the signal `sensors`, set these cell values:

- `Owner` to `sldemo_fuelsys_dd_controller`
- `HeaderFile` to `global_data.h`
- `DefinitionFile` to `signals.c`

On the `Numeric Types` worksheet, for the fixed-point data types, set:

- `DataScope` to `Exported`
- `HeaderFile` to `exported_types.h`.

On the `Structure Types` worksheet, for the structure type `EngSensors`, set:

- `DataScope` to `Exported`
- `HeaderFile` to `exported_types.h`.

Rerun the `ex_importICD_PCG` script.

```
ans =

    'Cannot redefine enumerated type sldemo_FuelModes because open models and existing
```

Generate code from the model.

```
### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of build procedure for model: sldemo_fuelsys_dd_controller
```

The generated file `exported_types.h` defines the structure type `EngSensors` and the fixed-point data types.

```
typedef int16_T s16En3;
typedef int16_T s16En7;
typedef uint8_T u8En7;

/* Structure type for instrument measurements. */
typedef struct {
  /* Throttle angle. */
  s16En3 throttle;

  /* Engine speed. */
  s16En3 speed;

  /* EGO sensors. */
  s16En7 ego;

  /* Manifold pressure. */
  u8En7 map;
} EngSensors;

typedef int16_T s16En15;
```

The file `signals.c` now includes the definition of the signal `sensors`.

```
/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
sldemo_FuelModes fuel_mode;
        /* Fueling mode of engine. Enrich air/fuel mixture on sensor failure. */
int16_T fuel_rate;                    /* Fuel rate setpoint. */
EngSensors sensors;                   /* Instrument measurements. */
```

Migrate Base Workspace Data to Data Dictionary

Objects and variables that you create in the base workspace (for example, `Simulink.Parameter` objects) are not saved with the model. When you end your MATLAB session, the objects and variables do not persist. To permanently store the objects and variables, link one or more models to one or more data dictionaries.

Data dictionaries also enable you to track changes made to the objects and variables, which helps you to:

- Reconcile the data stored in MATLAB with the data stored in the ICD.
- Export data from MATLAB to the ICD.

1. In the top model, `sldemo_fuelsys_dd`, select **File > Model Properties > Link to Data Dictionary**.
2. In the Model Properties dialog box, click **New**.
3. In the Create a new Data Dictionary dialog box, set **File name** to `sysDict` and click **Save**.
4. Click **Migrate data**.
5. Click **Change all models** in response to the message about using the dictionary for referenced models.
6. Click **Migrate** in response to the message about copying referenced variables.

The variables and objects that the models use exist in the new data dictionary `sysDict.sldd`, which is in your current folder. The three models in the model reference hierarchy are linked to this dictionary.

Store Enumerated Type Definition in Data Dictionary

You can import the definition of the enumerated type `sldemo_FuelModes` into the controller dictionary. See “Enumerations in Data Dictionary” (Simulink).

Store Signal and State Design Attributes Inside or Outside of Model File

In this example, you use `Simulink.Signal` objects to specify design attributes such as data types, minimum and maximum values, and physical units. The signal objects store these specifications outside of the model file.

Alternatively, you can store these specifications in the model file by using block and port parameters, which you can access through the Model Data Editor, the Property Inspector, and other dialog boxes.

To decide where to store the specifications, see “Store Design Attributes of Signals and States” (Simulink).

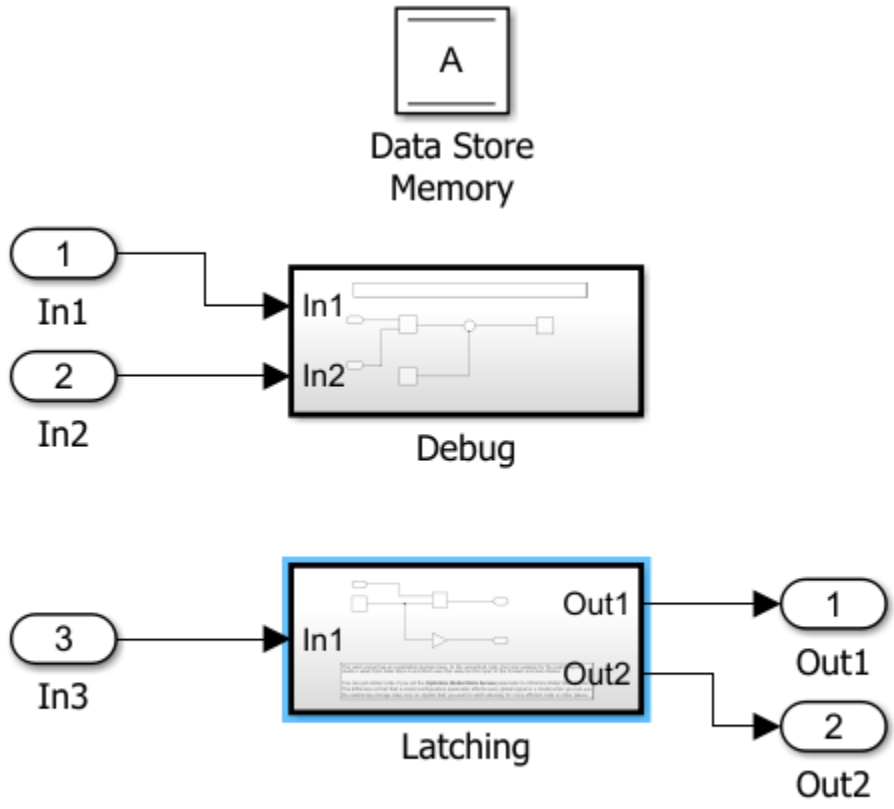
Generate Local Variables with Localizable Custom Storage Class

For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove these variables from the generated code. Local variables improve observability, readability, and are helpful in debugging the generated code.

Minimizing the use of global variables by using local variables interacts with stack usage control. For example, stack size can determine the number of local and global variables that the code generator can allocate in the generated code. For more information, see “Customize Stack Space Allocation” (Simulink Coder).

Example Model

The model `rtwdemo_localizable_csc` contains two signals that have a `Localizable` custom storage class. In the `Latching` subsystem, the signal with the label `Latch` has a `Localizable` custom storage class. In the `Debug` subsystem, the signal with the label `Debug` has a `Localizable` custom storage class.



Generate Code with Localizable Storage Class

1 Open the model.

```
model='rtwdemo_localizable_csc';
open_system(model);
```

2 To observe the specification, for each signal, open the Signal Properties dialog box and select the **Code Generation** tab. The **Signal object class** parameter is set to

`Simulink.Signal`. The **Storage class** parameter is set to `Localizable (Custom)`.

3. Build the model. The `Debug_b` function contains this code:

```
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
                    rtd_A[6])
{
  real_T Debug;
  int32_T i;
  for (i = 0; i < 6; i++) {
    Debug = rtu_In1[i] * rtu_In2[i];
    rtd_A[i] += Debug;
  }
}
```

The `Latching` function contains this code:

```
static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
                     rty_Out2[6], real_T rtd_A[6])
{
  real_T Latch[6];
  int32_T i;
  int32_T i_0;
  for (i = 0; i < 6; i++) {
    Latch[i] = rtd_A[i];
    rty_Out2[i] = -Latch[i];
  }

  for (i = 0; i < 6; i++) {
    rty_Out1[i] = 0.0;
    for (i_0 = 0; i_0 < 6; i_0++) {
      rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
    }
  }
}
```

Both functions contain variables for holding intermediate values. The `Debug_b` function contains the variable `Debug`. The `Latching` function contains the variable `Latch`.

Generate Code Without Localizable Storage Class

1. Change the signal storage class from `Localizable` to `ExportToFile`. For each signal, open the **Signal Properties** dialog box. On the **Code Generation** tab, for the **Storage class** parameter, select `ExportToFile`. The `rtwdemo_localizable_csc.c` file contains these two global variable declarations:

```
real_T Debug[6];
real_T Latch[6];
```

The `Debug_b` function contains this code:

```
static void Debug_b(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
                    rtd_A[6])
{
  int32_T i;
  for (i = 0; i < 6; i++) {
    Debug[i] = rtu_In1[i] * rtu_In2[i];
    rtd_A[i] += Debug[i];
  }
}
```

The `Latching` function contains this code:

```
static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
                     rty_Out2[6], real_T rtd_A[6])
{
  int32_T i;
  int32_T i_0;
  for (i = 0; i < 6; i++) {
    Latch[i] = rtd_A[i];
    rty_Out2[i] = -Latch[i];
  }

  for (i = 0; i < 6; i++) {
    rty_Out1[i] = 0.0;
    for (i_0 = 0; i_0 < 6; i_0++) {
      rty_Out1[i] += rtu_In1[6 * i_0 + i] * Latch[i_0];
    }
  }
}
```

The code readability and observability is the same as with the `Localizable` storage class specification except the labeled signals are global variables.

2. Remove the `Debug` and `Latch` labels. Build the model. The `Debug_b` function contains this code:

```
static void Debug(const real_T rtu_In1[6], const real_T rtu_In2[6], real_T
                  rtd_A[6])
{
  int32_T i;
  for (i = 0; i < 6; i++) {
    rtd_A[i] += rtu_In1[i] * rtu_In2[i];
  }
}
```

The `Latching` function contains this code:

```
static void Latching(const real_T rtu_In1[36], real_T rty_Out1[6], real_T
                     rty_Out2[6], real_T rtd_A[6])
{
  int32_T i;
  int32_T i_0;
  for (i = 0; i < 6; i++) {
    rty_Out2[i] = -rtd_A[i];
    rty_Out1[i] = 0.0;
    for (i_0 = 0; i_0 < 6; i_0++) {
      rty_Out1[i] += rtu_In1[6 * i_0 + i] * rtd_A[i_0];
    }
  }
}
```

Without the `Localizable` or `ExportToFile` custom storage classes, the code generator removes the `Debug` and `Latch` variables. Without these variables, the readability and observability of the generated code decreases.

Additional Information

- For the code generator to localize signals with the `Localizable` Custom storage class specification, in the Configuration Parameters dialog box, you must select the Enable Local Block Outputs parameter. This parameter is on by default.
- You can specify the same `Localizable` storage class on two signals that are in different reusable subsystems. Therefore, you can create a library block from a reusable subsystem with a `Localizable` custom storage class specification.
- The code generator does not create a local variable for a signal that must stay global. A few cases in which the code generator can not localize a signal are:
  - Input and output signals of a Nonreusable subsystem even when the **Function interface** parameter is set to `Allow arguments`.
  - Signal is holding a state because its receiver and drive blocks execute at different rates.
  - `Localizable` specification is on a signal that crosses the boundary of a conditionally executed subsystem.

Data Object Wizard in Embedded Coder

Create Data Objects for Code Generation with Data Object Wizard

To specify code generation options for signal lines, block parameters, and states in a model, you can use data objects that you store in a workspace or data dictionary. For basic information about data objects, see “Data Objects” (Simulink).

You can use the Data Object Wizard to create data objects for:

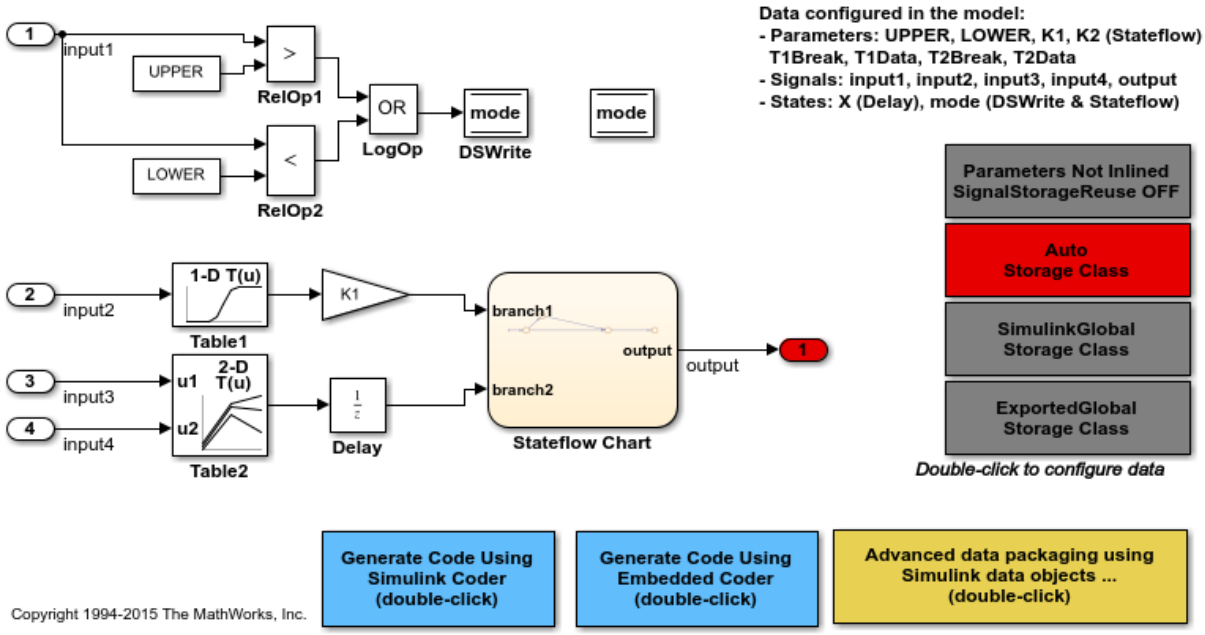
- New or existing models that do not use data objects.
- Existing models to which you have added signal lines or blocks.

This example shows how to use the Data Object Wizard to create and configure data objects for code generation from the built-in package `Simulink`.

Create Data Objects

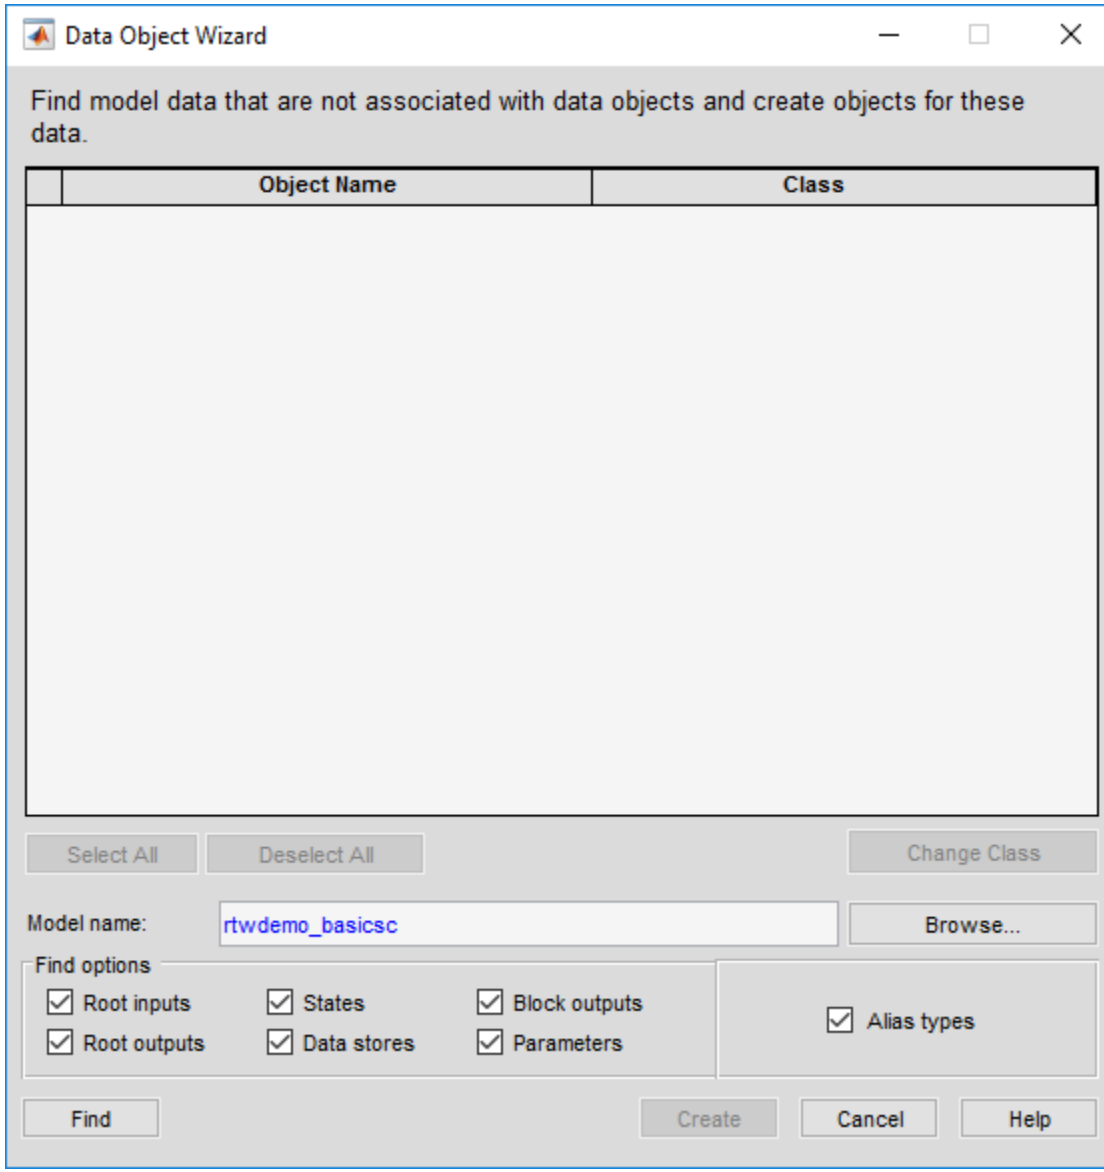
Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```



The model creates numeric variables in the base workspace. Blocks in the model use these variables to set parameter values (such as the **Gain** parameter of a Gain block). Some of the signals and block states in the model have explicit names, such as `input1`.

In the model, select **Code > Data Objects > Data Object Wizard**.



Data Object Wizard
Find model data that are not associated with data objects and create objects for these data.

Help

The wizard finds only signals, parameters, data stores, and states whose storage class is set to `Auto`. For example, if you use the Signal Properties dialog box to specify a storage class other than `Auto` for a signal line, the wizard does not propose a data object.

Click **Select All**.

Click **Create**. The data objects appear in the base workspace.

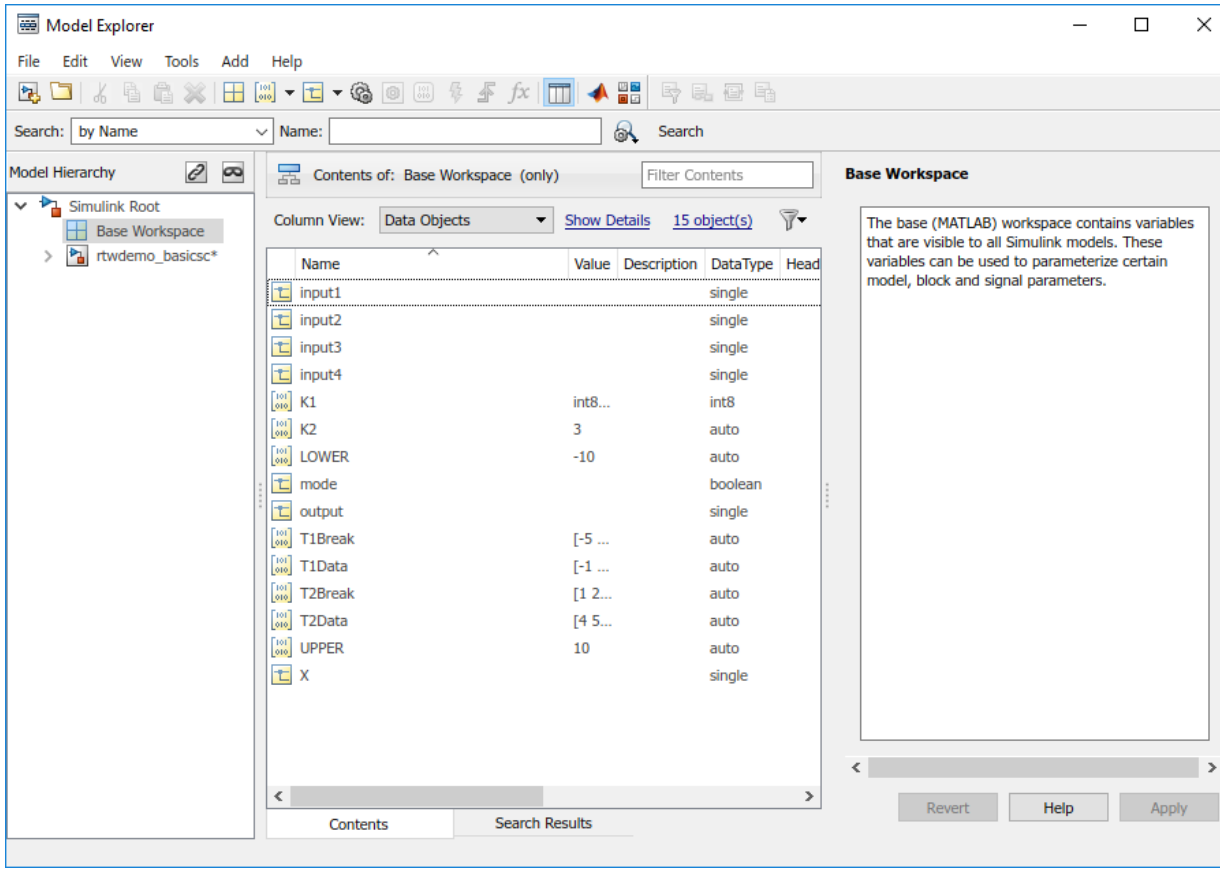
For detailed information about the options that you can choose in the Data Object Wizard, see “Create Data Objects for a Model Using Data Object Wizard” (Simulink).

Set Storage Class for Data Objects

Storage classes determine how the generated code uses variables to represent signals, parameters, and states. For data objects from the built-in package `Simulink`, the default storage class is `Auto`. To specify storage classes for the new data objects, you can use the Model Explorer.

Open the Model Explorer.

In the **Model Hierarchy** pane, select **Base Workspace**.



In the **Contents** pane, from the drop-down list **Column View**, select `Storage Class`.

Select all of the new data objects. For example, select the object `input1`, hold **Shift**, and select the object `X`.

Set the property `StorageClass` for all of the data objects to `ExportToFile`. To change the storage class for all of the selected objects, in the **StorageClass** column, click any of the objects. In the drop-down list, select `ExportToFile`. The change that you make propagates to all of the selected objects.

Specify the `HeaderFile` property for all of the objects as `myExportedHdrFile.h`.

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`. With this setting, the code generator honors custom storage classes such as `ExportToFile`.

Generate and Inspect Code

Generate code from the model.

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the generated file `myExportedHdrFile.h`. The file contains `extern` declarations for the global variables that correspond to the data objects.

```
/* Exported data declaration */

/* Declaration for custom storage class: ExportToFile */
extern int8_T K1;
extern real_T K2;
extern real32_T LOWER;
extern real32_T T1Break[11];
extern real32_T T1Data[11];
extern real32_T T2Break[3];
extern real32_T T2Data[9];
extern real32_T UPPER;
extern real32_T X;
extern real32_T input1;
extern real32_T input2;
extern real32_T input3;
extern real32_T input4;
extern boolean_T mode;
extern real32_T output;
```

View the file `rtwdemo_basicsc.c`. The file contains the definitions for the global variables. The code assigns numeric values for the variables that correspond to parameter objects.

```
/* Exported data definition */

/* Definition for custom storage class: ExportToFile */
int8_T K1 = 2;
real_T K2 = 3.0;
```

```
real32_T LOWER = -10.0F;
real32_T T1Break[11] = { -5.0F, -4.0F, -3.0F, -2.0F, -1.0F, 0.0F, 1.0F, 2.0F,
  3.0F, 4.0F, 5.0F } ;

real32_T T1Data[11] = { -1.0F, -0.99F, -0.98F, -0.96F, -0.76F, 0.0F, 0.76F,
  0.96F, 0.98F, 0.99F, 1.0F } ;

real32_T T2Break[3] = { 1.0F, 2.0F, 3.0F } ;

real32_T T2Data[9] = { 4.0F, 16.0F, 10.0F, 5.0F, 19.0F, 18.0F, 6.0F, 20.0F,
  23.0F } ;

real32_T UPPER = 10.0F;
real32_T X;
real32_T input1;
real32_T input2;
real32_T input3;
real32_T input4;
boolean_T mode;
real32_T output;
```

Entry-Point Functions and Scheduling in Simulink Coder

Configure Code Generation for Model Entry-Point Functions

What Is an Entry-Point Function?

An entry point is a location in code where a transfer of program control (execution) occurs. The main function (`main()`) is the entry point to a C/C++ program and is called when the application starts executing. Calls to other functions, for example from the `main` function, provide entry points to function code. Program control is transferred to the called function. The function code executes, and when finished, returns control to the `main` or other calling function.

When producing code for a model, the code generator defines a set of entry-point functions that you can call to execute the generated code. You can call the generated functions from external code or from a version of the generated main function that you modify.

The Code Interface Report section of the code generation report lists the entry-point functions that the code generator produces for a model. For more information, see “Analyze the Generated Code Interface” on page 49-20.

Categories and Types of Generated Entry-Point Functions

The type of entry-point functions that the code generator produces for a model and the calling interface for the functions depend on whether the model is:

- Rate-based or is an export-function model
- Configured for reusable, multi-instance code generation

Depending on the style and configuration of a model, the code generator produces one or more of these entry-point functions.

Function Category	Function	Description
Initialize/ Terminate	*model*`_initialize`	Initialization code for a model. At the start of the application code, call the function *once*. Do not use this function to reset the real-time model data structure (`rtM`).

Function Category	Function	Description
	*model*_terminate	Code for turning off a system. For ERT-based models, you can suppress generation of this function by clearing the model configuration parameter “Terminate function required” (Simulink Coder) (set by default).
Execution	*model*_step	For blocks in a rate-based model, output and update code. If you clear the model configuration parameter “Single output/ update function” (Simulink Coder) (selected by default), instead of producing a *model*_step function, the code generator produces functions *model*_output and *model*_update.
	model_function-name	For an exported-function model, the exported function for a subsystem.
	function-name	For an exported-function model, the exported function for a Simulink Function block.
	*model*_reset	If the model includes a Reset Function block, reset code generated. To reset conditions or state, call the function from the application code.
	ref-model	For a reference model, output and update code.
	isr_num*interrupt-number*_vec*interrupt-vector-offset*	For an Async Interrupt block, interrupt service routine (ISR) code.
Shared utility	*function-name*	For shared utility functions, output code.

Configure Whether Entry-Point Functions Are Reusable

By default, for top models, the code generator produces code that is not reusable or reentrant. Entry-point functions have a `void-void` interface. Code communicates with other code by directly accessing global data structures that reside in shared memory.

If your application requires reusable, multi-instance entry-point function code, you can configure the code generator to call each function (instance) with unique data. In this case, the code is reentrant.

You configure whether entry-point functions are reusable with the model configuration parameter “Code interface packaging” (Simulink Coder) and related parameters. The parameter settings that you choose depend on factors such as configuration selections for the system target file, programming language, and argument interface.

Default Configurations for Single-Instance C Entry-Point Functions

By default, for GRT- and ERT-based system target files, the code generator produces single-instance C entry-point functions. The generated code:

- Creates an execution function without arguments (`void-void`).
- Allocates memory statically (at compile time) for model data structures.

The default model configuration parameter settings for configuring single-instance entry-point function code are:

- “Language” (Simulink Coder) set to `C`.
- “Code interface packaging” (Simulink Coder) set to `Nonreusable function`.

Generate Reusable, Multi-Instance C Entry-Point Functions

You can configure the code generator to produce reusable entry-point functions in C for either a GRT- or ERT-based system target file. However, the function interfaces that the code generator produces by default varies. Assuming that model configuration parameter “Language” (Simulink Coder) is set to `C` and “Code interface packaging” (Simulink Coder) is set to `Reusable function`, the code generator produces this entry-point function code for each system target file scenario.

System Target File	Interface
GRT-based	• Reusable, multi-instance C entry-point functions that are reentrant. • Packs values of model root-level Inport blocks and Output blocks into the real-time model data structure. Passes that structure to the execution function as an argument by reference. • Allocates memory dynamically at runtime for the data of a model instance. Allocates the memory by calling a function, such as `malloc`.
ERT-based	• Reusable, multi-instance C entry-point functions that are reentrant. • Passes the value of each model root-level Inport block and Outport block to the execution function as a separate argument. • Allocates memory statically for model data structures.

If you are using an ERT-based system target file and want to generate reusable, multi-instance C entry-point functions that are reentrant, consider:

- Using dynamic memory allocation to initialize model data structures. Select “Use dynamic memory allocation for model initialization” (Simulink Coder).
- Packing values of model root-level Inport blocks into a structure, packing values of root-level Outport blocks into a second structure, and passing the structures to the execution function as arguments by reference. Set “Pass root-level I/O as” (Simulink Coder) to `Structure reference`.
- Packing values of model root-level Inport blocks and Output blocks into the real-time model data structure and passing that structure to the execution function as an argument by reference. Set “Pass root-level I/O as” (Simulink Coder) to `Part of model data structure`.

Generate Reusable, Multi-Instance C++ Entry-Point Functions

The C++ class interface encapsulates model data as class properties and entry-point functions as class methods. That interface is available for use with ERT-based system target files. To use the interface, set “Language” (Simulink Coder) to `C++` and set “Code interface packaging” (Simulink Coder) to `C++ class` . You can:

- Preview and customize the C++ class interface by clicking “Configure C++ Class Interface” (Simulink Coder). Customization means that you can generate code for integration with external code and verify that the code complies with coding standards.
- Configure the visibility of class inheritance by specifying whether to generate the block parameter structure as a public, private, or protected data member. Set “Parameter visibility” (Simulink Coder) to `public` , `private`, or `protected`.
- Generate C++ interface code for model block parameters that meet code execution speed or tunability requirements. The code can be noninlined or inlined access methods. Set “Parameter access” (Simulink Coder) to `Method` or `Inlined method`.
- Generate C++ interface code for model root-level Inport and Outport blockset that meets code execution speed, data tunability, or data packaging requirements. The code can be one of these types of access methods.

For Access Method Type	Set “External I/O access” (Simulink Coder) To
Noninlined	`Method`
Inlined	`Inlined method`
Noninlined structure-based	`Structure-based method`
Inlined structured-based	`Inlined structure-based method`

Configure Generated Entry-Point Function Declarations

Depending on application requirements, such as integration or compliance with code standards, you might need to configure how the code generator produces declarations for entry-point functions. Embedded Coder provides multiple configuration options.

- Apply a default function naming rule to a category of functions across a model. For example, a default naming rule can produce a *`model`*`_step` function for each rate in the multi-rate model. In the Code Mapping Editor, on the **Function Defaults** tab, map a function category to a function customization template that is defined to use the function naming rule (see Code Mapping Editor). You can override the default naming of a function by changing the name on the **Entry-Point Functions** tab (see “Override Default Naming for Individual C Entry-Point Functions” on page 39-5 or “Override Default C Step Function Interface” on page 39-7).
- Configure interfaces for individual entry-point functions. In the Code Mapping Editor, on the **Entry-Point Functions** tab, specify the names of individual functions (see

"Override Default Naming for Individual C Entry-Point Functions" on page 39-5). For a *`model`*`_step` (execution) function, you can customize the entire entry-point function interface (see "Override Default C Step Function Interface" on page 39-7).

Configure Placement of Entry-Point Functions in Memory

If your application requires that you configure the placement of entry-point functions in memory, for example, to optimize the generated code for specific hardware, you can apply a default memory section to a category of functions across a model. In the Code Mapping Editor, map a function category to a function customization template that is defined to use a specific memory section. See Code Mapping Editor.

How to Interface with Generated Entry-Point Functions

1. After generating code for a model, use the code perspective **Code** view to review the generated entry-point functions and, if applicable, variables representing external input and output ports.
2. Add `#include` statements to your external code that include the generated header files that declare the model entry-point functions.
3. Add an `#include` statement that includes the generated file `rtwtypes.h`. This file provides type definitions, `#define` statements, and enumerations.
4. Initialize target-specific data structures and hardware, such as ADCs or DACs.
5. If applicable, initialize data for each instance of a reusable model.
6. If applicable, write input data to generated variables that represent model Inport blocks.
7. Call the generated entry-point functions or set up use of the `rt_OneStep` function.
8. If applicable, read data from generated variables that represent model Outport blocks.

For more information, see "Deploy Generated Standalone Executable Programs To Target Hardware" on page 63-2.

Generate C++ Class Interface to Model or Subsystem Code

On the Configuration Parameters dialog box, set the **Code Generation > Interface** "Code interface packaging" (Simulink Coder) parameter to `C++ class` for generating a C ++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

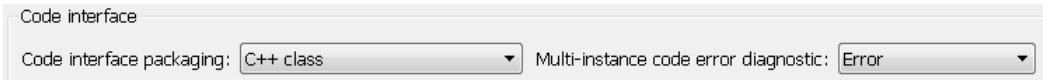
- Greater control over access to model data
- Ability to create multiple instances of model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see "Generate C++ Class Interface to Nonvirtual Subsystem Code" on page 38-10.)

Generate C++ Class Interface to Model Code

To generate encapsulated C++ class code from a GRT-based model:

1. Set the Configuration Parameters dialog box parameter **Code Generation > Language** to `C++`. This selection also enables C++ class code interface packaging for the model.
2. On the **Code Generation > Interface** pane, verify that the parameter **Code interface packaging** (Simulink Coder) is set to `C++ class`.
3. Examine the setting of **Multi-instance code error diagnostic** (Simulink Coder). Leave the parameter at its default value `Error` unless you need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.



4. Generate code for the model.
5. Examine the C++ model class code in the generated files *`model`*`.h` and *`model`*`.cpp`. For example, the following code excerpt from the H file generated for the example

model `rtwdemo_secondOrderSystem` shows the C++ class declaration for the model.

```
/* Class declaration for model rtwdemo_secondOrderSystem */
class rtwdemo_secondOrderSystemModelClass {
  /* public data and function members */
 public:
  /* External outputs */
  ExtY_rtwdemo_secondOrderSyste_T rtwdemo_secondOrderSystem_Y;

  /* Model entry point functions */

  /* model initialize function */
  void initialize();

  /* model step function */
  void step();

  /* model terminate function */
  void terminate();

  /* Constructor */
  rtwdemo_secondOrderSystemModelClass();

  /* Destructor */
  ~rtwdemo_secondOrderSystemModelClass();

  /* Real-Time Model get method */
  RT_MODEL_rtwdemo_secondOrderS_T * getRTM();
...
};
```

For more information about generating and calling model entry-point functions, see "Configure Code Generation for Model Entry-Point Functions" (Simulink Coder).

Note If you have an Embedded Coder license and you have selected an ERT target for your model, use additional **Code Generation** > **Interface** pane parameters to customize the generated C++ class interface.

Generate C++ Class Interface to Nonvirtual Subsystem Code

You can generate C++ class interfaces for right-click builds of nonvirtual subsystems in Simulink models, if the following requirements are met:

- The model is configured for the `C++` language and `C++ class` code interface packaging.

- The subsystem is convertible to a Model block using the function `Simulink.SubSystem.convertToModelReference`. For referenced model conversion requirements, see the Simulink reference page `Simulink.SubSystem.convertToModelReference`.

To configure C++ class interfaces for a subsystem that meets the requirements:

1. Open the containing model and select the subsystem block.
2. Right-click the subsystem and select **C/C++ Code** > **Build This Subsystem**.
3. When the subsystem build completes, examine the C++ class interfaces in the generated files and the HTML code generation report. For more information about generating and calling model entry-point methods, see “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder).

Note If you have an Embedded Coder license and you have selected an ERT target for your model, you can use the MATLAB command `RTW.configSubsystemBuild` to customize the generated C++ class interface to subsystem code.

C++ Class Interface Limitations

- Among the data exchange interfaces available on the **Interface** pane of the Configuration Parameters dialog box, only the C API interface is supported for `C++ class` code generation. If you select **External mode** or **ASAP2 interface**, code generation fails with a validation error.
- If a model root inport value connects to a Simscape conversion block, you must insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. On the Simulink Signal Conversion block parameter dialog box, select **Exclude this block from 'Block reduction' optimization**.
- You cannot use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that
  - Has a continuous sample time
  - Saves states

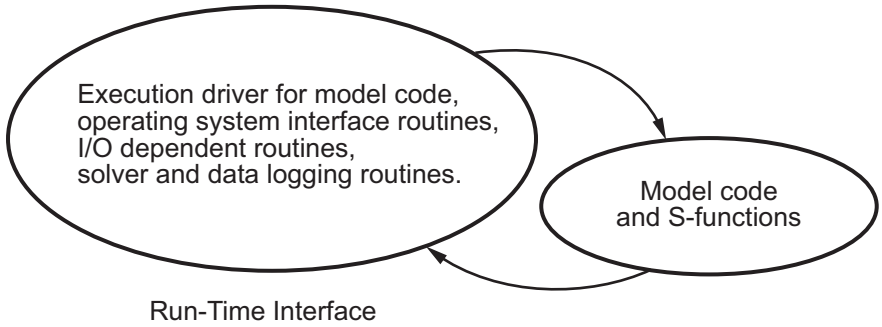
- “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder)
- “Execution of Code Generated from a Model” (Simulink Coder)
- “Rapid Prototyping Model Functions” (Simulink Coder)

Execution of Code Generated from a Model

The code generator produces algorithmic code as defined by your model. You can include external (for example, custom or legacy) code in a model by using techniques explained in "Choose an External Code Integration Workflow" (Simulink Coder).

The code generator also provides an interface that executes the generated model code. The interface and model code are compiled together to create an executable program. The next figure shows a high-level object-oriented view of the executable.



The Object-Oriented View of a Real-Time Program

In general, the conceptual design of the model execution driver does not change between the rapid prototyping and embedded style of generated code. The following sections describe model execution for single-tasking and multitasking environments both for simulation (non-real-time) and for real time. For most model code, the multitasking environment provides the most efficient model execution (that is, fastest sample rate).

The following concepts are useful in describing how model code executes.

- **Initialization**: *model*`_initialize` initializes the interface code and the model code.
- **ModelOutputs**: Calls blocks in your model that have a sample hit at the current time and has them produce their output. *model*`_output` can be done in major or minor time steps. In major time steps, the output is a given simulation time step. In minor time steps, the interface integrates the derivatives to update the continuous states.
- **ModelUpdate**: *model*`_update` calls blocks that have a sample hit at the current point in time and has them update their discrete states or similar type objects.

- **ModelDerivatives**: Calls blocks in your model that have continuous states and has them update their derivatives. *model*_derivatives is only called in minor time steps.
- **ModelTerminate**: *model*_terminate terminates the program if it is designed to run for a finite time. It destroys the real-time model data structure, deallocates memory, and can write data to a file.

Program Execution

A real-time program cannot require 100% of the CPU time. This requirement provides an opportunity to run background tasks during the free time.

Background tasks include operations such as writing data to a buffer or file, allowing access to program data by third-party data monitoring tools, or using Simulink external mode to update program parameters.

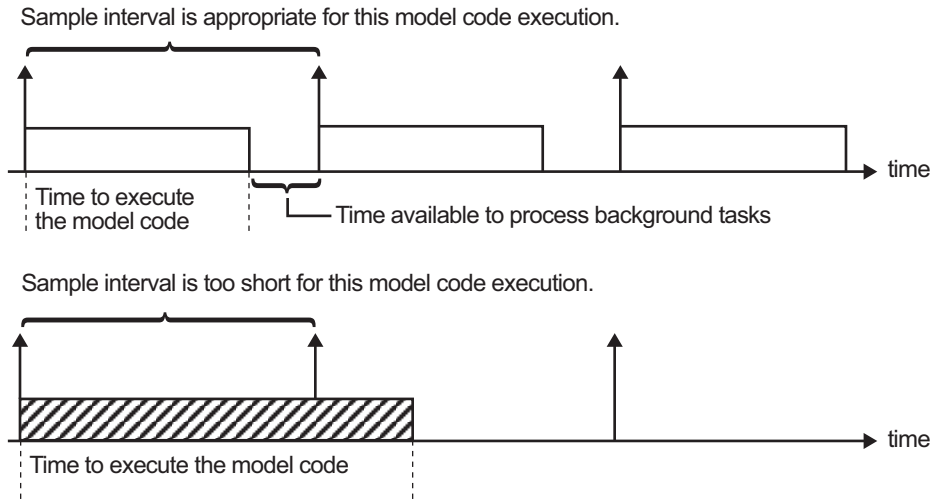
It is important, however, that the program be able to preempt the background task so the model code can execute in real time.

The way the program manages tasks depends on capabilities of the environment in which it operates.

Program Timing

Real-time programs require careful timing of the task invocations (either by using an interrupt or a real-time operating system tasking primitive) so that the model code executes to completion before another task invocation occurs. The timing includes time to read and write data to and from external hardware.

The next figure illustrates interrupt timing.



Task Timing

The sample interval must be long enough to allow model code execution between task invocations.

In the figure above, the time between two adjacent vertical arrows is the sample interval. The empty boxes in the upper diagram show an example of a program that can complete one step within the interval and still allow time for the background task. The gray box in the lower diagram indicates what happens if the sample interval is too short. Another task invocation occurs before the task is complete. Such timing results in an execution error.

Note also that, if the real-time program is designed to run forever (that is, the final time is 0 or infinite so that the `while` loop never exits), then the shutdown code does not execute.

For more information on how the timing engine works, see “Absolute and Elapsed Time Computation” (Simulink Coder).

External Mode Communication

External mode allows communication between the Simulink block diagram and the standalone program that is built from the generated code. In this mode, the real-time program functions as an interprocess communication server, responding to requests from the Simulink engine.

Data Logging in Single-Tasking and Multitasking Model Execution

"Debug" on page 42-42 explains how you can save system states, outputs, and time to a MAT-file at the completion of the model execution. The `LogTXY` function, which performs data logging, operates differently in single-tasking and multitasking environments.

If you examine how `LogTXY` is called in the single-tasking and multitasking environments, you will notice that for single-tasking `LogTXY` is called after `ModelOutputs`. During this `ModelOutputs` call, blocks that have a hit at time *t* execute, whereas in multitasking, `LogTXY` is called after `ModelOutputs(tid=0)`, which executes only the blocks that have a hit at time *t* and that have a task identifier of 0. This results in differences in the logged values between single-tasking and multitasking logging. Specifically, consider a model with two sample times, the faster sample time having a period of 1.0 second and the slower sample time having a period of 10.0 seconds. At time t = k*10, k=0,1,2... both the fast (`tid=0`) and slow (`tid=1`) blocks execute. When executing in multitasking mode, when `LogTXY` is called, the slow blocks execute, but the previous value is logged, whereas in single-tasking the current value is logged.

Another difference occurs when logging data in an enabled subsystem. Consider an enabled subsystem that has a slow signal driving the enable port and fast blocks within the enabled subsystem. In this case, the evaluation of the enable signal occurs in a slow task, and the fast blocks see a delay of one sample period; thus the logged values will show these differences.

To summarize differences in logged data between single-tasking and multitasking, differences will be seen when

- Any root outport block has a sample time that is slower than the fastest sample time
- Any block with states has a sample time that is slower than the fastest sample time
- Any block in an enabled subsystem where the signal driving the enable port is slower than the rate of the blocks in the enabled subsystem

For the first two cases, even though the logged values are different between single-tasking and multitasking, the model results are not different. The only real difference is where (at what point in time) the logging is done. The third (enabled subsystem) case results in a delay that can be seen in a real-time environment.

Non-Real-Time Single-Tasking Systems

The pseudocode below shows the execution of a model for a non-real-time single-tasking system.

```
main()
{
  Initialization
  While (time < final time)
    ModelOutputs     -- Major time step.
    LogTXY           -- Log time, states and root outports.
    ModelUpdate      -- Major time step.
    Integrate        -- Integration in minor time step for
                     -- models with continuous states.
      ModelDerivatives
      Do 0 or more
        ModelOutputs
        ModelDerivatives
      EndDo -- Number of iterations depends upon the solver
      Integrate derivatives to update continuous states.
    EndIntegrate
  EndWhile
  Termination
}
```

The initialization phase begins first. This consists of initializing model states and setting up the execution engine. The model then executes, one step at a time. First `ModelOutputs` executes at time t, then the workspace I/O data is logged, and then `ModelUpdate` updates the discrete states. Next, if your model has continuous states, `ModelDerivatives` integrates the continuous states' derivatives to generate the states for time $t_{new} = t + h$, where h is the step size. Time then moves forward to t_{new} and the process repeats.

During the `ModelOutputs` and `ModelUpdate` phases of model execution, only blocks that reach the current point in time execute.

Non-Real-Time Multitasking Systems

The pseudocode below shows the execution of a model for a non-real-time multitasking system.

```
main()
{
```

```
Initialization
While (time < final time)
  ModelOutputs(tid=0)   -- Major time step.
  LogTXY                -- Log time, states, and root
                        -- outports.
  ModelUpdate(tid=0)    -- Major time step.
  Integrate       -- Integration in minor time step for
                  -- models with continuous states.
    ModelDerivatives
    Do 0 or more
      ModelOutputs(tid=0)
      ModelDerivatives
    EndDo (Number of iterations depends upon the solver.)
    Integrate derivatives to update continuous states.
  EndIntegrate
  For i=1:NumTids
    ModelOutputs(tid=i) -- Major time step.
    ModelUpdate(tid=i)  -- Major time step.
  EndFor
EndWhile
Termination
}
```

Multitasking operation is more complex than single-tasking execution because the output and update functions are subdivided by the *task identifier* (`tid`) that is passed into these functions. This allows for multiple invocations of these functions with different task identifiers using overlapped interrupts, or for multiple tasks when using a real-time operating system. In simulation, multiple tasks are emulated by executing the code in the order that would occur if preemption did not exist in a real-time system.

Multitasking execution assumes that all task rates are multiples of the base rate. The Simulink product enforces this when you create a fixed-step multitasking model. The multitasking execution loop is very similar to that of single-tasking, except for the use of the task identifier (`tid`) argument to `ModelOutputs` and `ModelUpdate`.

Note You cannot use `tid` values from code generated by a target file and not by Simulink Coder. Simulink Coder tracks the use of `tid` when generating code for a specific subsystem or function type. When you generate code in a target file, this argument cannot be tracked because the scope does not have subsystem or function type. Therefore, `tid` becomes an undefined variable and your target file fails to compile.

Real-Time Single-Tasking Systems

The pseudocode below shows the execution of a model in a real-time single-tasking system where the model is run at interrupt level.

```
rtOneStep()
{
  Check for interrupt overflow
  Enable "rtOneStep" interrupt
  ModelOutputs    -- Major time step.
  LogTXY          -- Log time, states and root outports.
  ModelUpdate     -- Major time step.
  Integrate       -- Integration in minor time step for models
                  -- with continuous states.
     ModelDerivatives
     Do 0 or more
       ModelOutputs
       ModelDerivatives
     EndDo (Number of iterations depends upon the solver.)
     Integrate derivatives to update continuous states.
  EndIntegrate
}

main()
{
  Initialization (including installation of rtOneStep as an
  interrupt service routine, ISR, for a real-time clock).
  While(time < final time)
    Background task.
  EndWhile
  Mask interrupts (Disable rtOneStep from executing.)
  Complete any background tasks.
  Shutdown
}
```

Real-time single-tasking execution is very similar to non-real-time single-tasking execution, except that instead of free-running the code, the `rt_OneStep` function is driven by a periodic timer interrupt.

At the interval specified by the program's base sample rate, the interrupt service routine (ISR) preempts the background task to execute the model code. The base sample rate is the fastest in the model. If the model has continuous blocks, then the integration step size determines the base sample rate.

For example, if the model code is a controller operating at 100 Hz, then every 0.01 seconds the background task is interrupted. During this interrupt, the controller reads its inputs from the analog-to-digital converter (ADC), calculates its outputs, writes these outputs to the digital-to-analog converter (DAC), and updates its states. Program control then returns to the background task. All of these steps must occur before the next interrupt.

Real-Time Multitasking Systems

The following pseudocode shows how a model executes in a real-time multitasking system where the model is run at interrupt level.

```
rtOneStep()
{
  Check for interrupt overflow
  Enable "rtOneStep" interrupt
  ModelOutputs(tid=0)     -- Major time step.
  LogTXY                  -- Log time, states and root outports.
  ModelUpdate(tid=0)      -- Major time step.
  Integrate               -- Integration in minor time step for
                          -- models with continuous states.
     ModelDerivatives
     Do 0 or more
       ModelOutputs(tid=0)
       ModelDerivatives
     EndDo (Number of iterations depends upon the solver.)
     Integrate derivatives and update continuous states.
  EndIntegrate
  For i=1:NumTasks
    If (hit in task i)
      ModelOutputs(tid=i)
      ModelUpdate(tid=i)
    EndIf
  EndFor
}

main()
{
  Initialization (including installation of rtOneStep as an
    interrupt service routine, ISR, for a real-time clock).
  While(time < final time)
    Background task.
  EndWhile
```

```
  Mask interrupts (Disable rtOneStep from executing.)
  Complete any background tasks.
  Shutdown
}
```

Running models at interrupt level in a real-time multitasking environment is very similar to the previous single-tasking environment, except that overlapped interrupts are employed for concurrent execution of the tasks.

The execution of a model in a single-tasking or multitasking environment when using real-time operating system tasking primitives is very similar to the interrupt-level examples discussed above. The pseudocode below is for a single-tasking model using real-time tasking primitives.

```
tSingleRate()
{
  MainLoop:
    If clockSem already "given", then error out due to overflow.
    Wait on clockSem
    ModelOutputs            -- Major time step.
    LogTXY                  -- Log time, states and root
                            -- outports
    ModelUpdate             -- Major time step
    Integrate               -- Integration in minor time step
                            -- for models with continuous
                            -- states.
      ModelDeriviatives
      Do 0 or more
        ModelOutputs
        ModelDerivatives
      EndDo (Number of iterations depends upon the solver.)
      Integrate derivatives to update continuous states.
    EndIntegrate
  EndMainLoop
}

main()
{
  Initialization
  Start/spawn task "tSingleRate".
  Start clock that does a "semGive" on a clockSem semaphore.
  Wait on "model-running" semaphore.
  Shutdown
}
```

In this single-tasking environment, the model executes as real-time operating system tasking primitives. In this environment, create a single task (`tSingleRate`) to run the model code. This task is invoked when a clock tick occurs. The clock tick gives a `clockSem` (clock semaphore) to the model task (`tSingleRate`). The model task waits for the semaphore before executing. The clock ticks occur at the fundamental step size (base rate) for your model.

Multitasking Systems Using Real-Time Tasking Primitives

The pseudocode below is for a multitasking model using real-time tasking primitives.

```
tSubRate(subTaskSem,i)
{
  Loop:
    Wait on semaphore subTaskSem.
    ModelOutputs(tid=i)
    ModelUpdate(tid=i)
  EndLoop
}
tBaseRate()
{
  MainLoop:
    If clockSem already "given", then error out due to overflow.
    Wait on clockSem
    For i=1:NumTasks
      If (hit in task i)
        If task i is currently executing, then error out due to
          overflow.
        Do a "semGive" on subTaskSem for task i.
      EndIf
    EndFor
    ModelOutputs(tid=0)    -- major time step.
    LogTXY                 -- Log time, states and root outports.
    ModelUpdate(tid=0)     -- major time step.
    Loop:                  -- Integration in minor time step for
                           -- models with continuous states.
      ModelDeriviatives
      Do 0 or more
        ModelOutputs(tid=0)
        ModelDerivatives
      EndDo (number of iterations depends upon the solver).
      Integrate derivatives to update continuous states.
    EndLoop
```

```
  EndMainLoop
}
main()
{
  Initialization
  Start/spawn task "tSubRate".
  Start/spawn task "tBaseRate".

  Start clock that does a "semGive" on a clockSem semaphore.
  Wait on "model-running" semaphore.
  Shutdown
}
```

In this multitasking environment, the model is executed using real-time operating system tasking primitives. Such environments require several model tasks (`tBaseRate` and several `tSubRate` tasks) to run the model code. The base rate task (`tBaseRate`) has a higher priority than the subrate tasks. The subrate task for `tid=1` has a higher priority than the subrate task for `tid=2`, and so on. The base rate task is invoked when a clock tick occurs. The clock tick gives a `clockSem` to `tBaseRate`. The first thing `tBaseRate` does is give semaphores to the subtasks that have a hit at the current point in time. Because the base rate task has a higher priority, it continues to execute. Next it executes the fastest task (`tid=0`), consisting of blocks in your model that have the fastest sample time. After this execution, it resumes waiting for the clock semaphore. The clock ticks are configured to occur at the fundamental step size for your model.

Rapid Prototyping and Embedded Model Execution Differences

The rapid prototyping program framework provides a common application programming interface (API) that does not change between model definitions.

The Embedded Coder product provides a different framework called the embedded program framework. The embedded program framework provides an optimized API that is tailored to your model. When you use the embedded style of generated code, you are modeling how you would like your code to execute in your embedded system. Therefore, the definitions defined in your model should be specific to your embedded targets. Items such as the model name, parameter, and signal storage class are included as part of the API for the embedded style of code.

One major difference between the rapid prototyping and embedded style of generated code is that the latter contains fewer entry-point functions. The embedded style of code can be configured to have only one function, *`model`*`_step`.

Thus, model execution code eliminates `Loop...EndLoop` statements and groups `ModelOutputs`, `LogTXY`, and `ModelUpdate` into a single statement, *`model`*`_step`.

For more information about how generated embedded code executes, see “Configure Code Generation for Model Entry-Point Functions” on page 38-2.

Rapid Prototyping Model Functions

Rapid prototyping code defines the following functions that interface with the main program (`main.c` or `main.cpp`):

- `Model()`: The model registration function. This function initializes the work areas (for example, allocating and setting pointers to various data structures) used by the model. The model registration function calls the `MdlInitializeSizes` and `MdlInitializeSampleTimes` functions. These two functions are very similar to the S-function `mdlInitializeSizes` and `mdlInitializeSampleTimes` methods.
- `MdlStart(void)`: After the model registration functions `MdlInitializeSizes` and `MdlInitializeSampleTimes` execute, the main program starts execution by calling `MdlStart`. This routine is called once at startup.

  The function `MdlStart` has four basic sections:

  - Code to initialize the states for each block in the root model that has states. A subroutine call is made to the “initialize states” routines of conditionally executed subsystems.
  - Code generated by the one-time initialization (start) function for each block in the model.
  - Code to enable the blocks in the root model that have enable methods, and the blocks inside triggered or function-call subsystems residing in the root model. Simulink blocks can have enable and disable methods. An enable method is called just before a block starts executing, and the disable method is called just after the block stops executing.
  - Code for each block in the model whose output value is constant. The block code appears in the `MdlStart` function only if the block parameters are not tunable in the generated code and if the code generator cannot eliminate the block code through constant folding.
- `MdlOutputs(int_T tid)`: `MdlOutputs` updates the output of blocks. The `tid` (task identifier) parameter identifies the task that in turn maps when to execute blocks based upon their sample time. This routine is invoked by the main program during major and minor time steps. The major time steps are when the main program is taking an actual time step (that is, it is time to execute a specific task). If your model contains continuous states, the minor time steps will be taken. The minor time steps are when the solver is generating integration stages, which are points between major outputs. These integration stages are used to compute the derivatives used in advancing the continuous states.

- `MdlUpdate(int_T tid)`: `MdlUpdate` updates the states and work vector state information (that is, states that are neither continuous nor discrete) saved in work vectors. The `tid` (task identifier) parameter identifies the task that in turn indicates which sample times are active, allowing you to conditionally update only states of active blocks. This routine is invoked by the interface after the major `MdlOutputs` has been executed. The solver is also called, and *`model`*`_Derivatives` is called in minor steps by the solver during its integration stages. All blocks that have continuous states have an identical number of derivatives. These blocks are required to compute the derivatives so that the solvers can integrate the states.
- `MdlTerminate(void)`: `MdlTerminate` contains any block shutdown code. `MdlTerminate` is called by the interface, as part of the termination of the real-time program.

The contents of the above functions are directly related to the blocks in your model. A Simulink block can be generalized to the following set of equations.

$$y = f_0(t, x_c, x_d, u)$$

Output y is a function of continuous state x_c, discrete state x_d, and input u. Each block writes its specific equation in a section of `MdlOutputs`.

$$x_{d+1} = f_u(t, x_d, u)$$

The discrete states x_d are a function of the current state and input. Each block that has a discrete state updates its state in `MdlUpdate`.

$$\dot{x} = f_d(t, x_c, u)$$

The derivatives x are a function of the current input. Each block that has continuous states provides its derivatives to the solver (for example, `ode5`) in *`model`*`_Derivatives`. The derivatives are used by the solver to integrate the continuous state to produce the next value.

The output, y, is generally written to the block I/O structure. Root-level Outport blocks write to the external outputs structure. The continuous and discrete states are stored in the states structure. The input, u, can originate from another block's output, which is located in the block I/O structure, an external input (located in the external inputs structure), or a state. These structures are defined in the *`model`*`.h` file that the Simulink Coder software generates.

The next example shows the general contents of the rapid prototyping style of C code written to the *`model`*`.c` file.

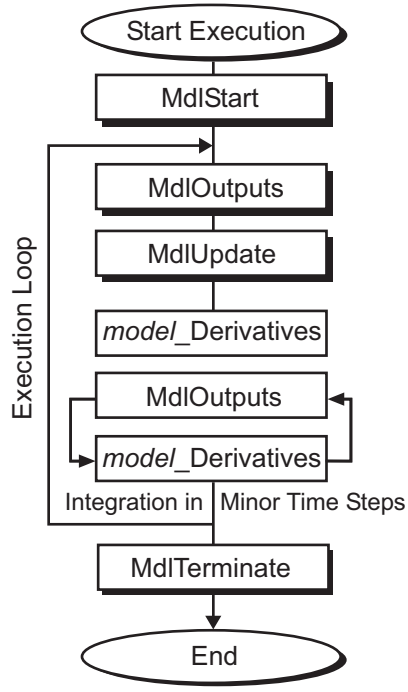
```
/*
 * Version, Model options, TLC options,
 * and code generation information are placed here.
*/
<includes>
void MdlStart(void)
{
  /*
   * State initialization code.
   * Model start-up code - one time initialization code.
   * Execute any block enable methods.
   * Initialize output of any blocks with constant sample times.
   */
}

void MdlOutputs(int_T tid)
{
  /* Compute: y = f0(t,xc,xd,u) for each block as needed. */
}

void MdlUpdate(int_T tid)
{
  /* Compute: xd+1 = fu(t,xd,u) for each block as needed. */

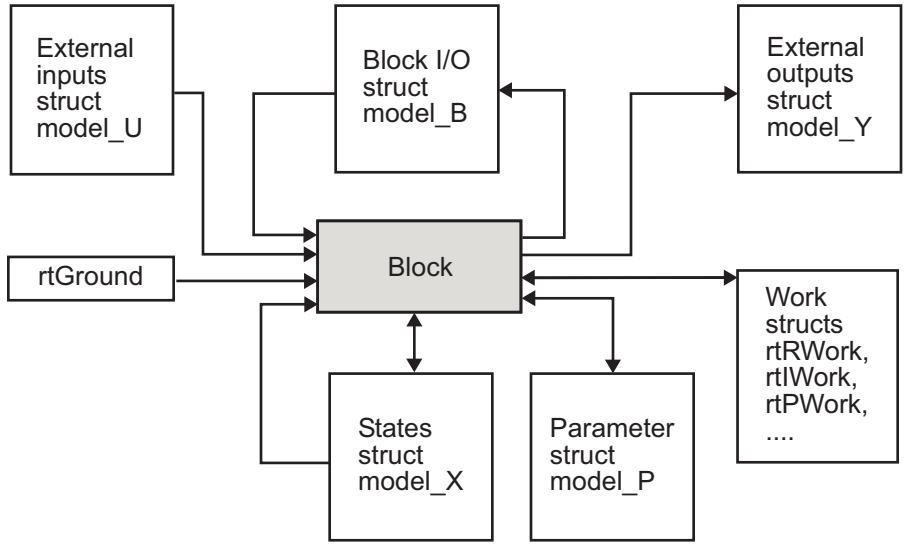
  /* Compute: dxc = fd(t,xc,u) for each block in model_derivatives
                               as needed. */
}
void MdlTerminate(void)
{
  /* Perform shutdown code for any blocks that
     have a termination action */
}
```

The next figure shows a flow chart describing the execution of the rapid prototyping generated code.



Rapid Prototyping Execution Flow Chart

Each block places code in specific `Mdl` routines according to the algorithm that it is implementing. Blocks have input, output, parameters, and states, as well as other general items. For example, in general, block inputs and outputs are written to a block I/O structure (*`model`*`_B`). Block inputs can also come from the external input structure (*`model`*`_U`) or the state structure when connected to a state port of an integrator (*`model`*`_X`), or ground (`rtGround`) if unconnected or grounded. Block outputs can also go to the external output structure (*`model`*`_Y`). The next figure shows the general mapping between these items.



Data View of the Generated Code

The following list defines the structures shown in the preceding figure:

- Block I/O structure (*`model`*`_B`): This structure consists of persistent block output signals. The number of block output signals is the sum of the widths of the data output ports of all nonvirtual blocks in your model. If you activate block I/O optimizations, the Simulink and Simulink Coder products reduce the size of the *`model`*`_B` structure by

  - Reusing the entries in the *`model`*`_B` structure
  - Making other entries local variables

  See “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder) for more information on these optimizations.

  Structure field names are determined either by the block's output signal name (when present) or by the block name and port number when the output signal is left unlabeled.

- Block states structures: The continuous states structure (*`model`*`_X`) contains the continuous state information for blocks in your model that have continuous states. Discrete states are stored in a data structure called the *`DWork vector`* (*`model`*`_DWork`).

- Block parameters structure (*model*_P): The parameters structure contains block parameters that can be changed during execution (for example, the parameter of a Gain block).
- External inputs structure (*model*_U): The external inputs structure consists of all root-level Inport block signals. Field names are determined by either the block's output signal name, when present, or by the Inport block's name when the output signal is left unlabeled.
- External outputs structure (*model*_Y): The external outputs structure consists of all root-level Outport blocks. Field names are determined by the root-level Outport block names in your model.
- Real work, integer work, and pointer work structures (*model*_RWork, *model*_IWork, *model*_PWork): Blocks might have a need for real, integer, or pointer work areas. For example, the Memory block uses a real work element for each signal. These areas are used to save internal states or similar information.

Function and Class Interfaces in Embedded Coder

Customize Generated C Function Interfaces

Options for Configuring Generated C Function Interfaces

To facilitate integration of external and generated code and achieve compliance with code standards and guidelines, you can configure how the code generator produces function interfaces from a model or subsystem. For this level of customization, you must configure the model with an ERT-based system target file.

Configuration	See
Default naming rules for categories of functions (initialize/terminate, execution, and shared utility) across a model	“Configure Default Code Generation for Functions” on page 31-16
Name for individual entry-point functions (override the default naming rule)	“Override Default Naming for Individual C Entry-Point Functions” on page 39-5
Step function interface (function name, return value, and argument C type qualifiers, names, and order) for the base rate step entry-point function interactively	“Override Default C Step Function Interface” on page 39-7
Function interface (function name, return value, and argument C type qualifiers, names, and order) for the base rate step entry-point function programmatically	“Customize C Step and Initialize Function Interfaces Programmatically” on page 39-19
Function interfaces (function name, return value, and argument C type qualifiers, names, and order) for Simulink Function and Function Caller blocks interactively	“Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-24
Function interfaces (function name and argument C type qualifiers and names) for initialize and step functions for nonvirtual subsystems interactively	“Customize Function Interfaces for Nonvirtual Subsystems” on page 39-31

You can use software-in-the-loop (SIL) testing to verify code generated for customized entry-point functions. Create a SIL block by using your generated code. Then, integrate the SIL block into a model to verify that the generated code provides the same result as the original model or nonvirtual subsystem. For more information, see “Choose a SIL or PIL Approach” on page 78-14.

Function Interface Customization Limitations

These limitations apply to customizations for generated function interfaces:

- You must select the model configuration parameter **Single output/update function**.
- Multirate models are supported, but you must configure the models for single tasking.
- You must configure root-level inports and outports to use the `Default` storage class.
- If you choose to customize a function interface, you must provide your own custom `main` program. You cannot configure the function interface with the static `rt_main.c` that MathWorks provides. Specifying a function interface configuration other than the default creates a mismatch between the generated code and the default static `rt_main.c`.
- The code generator removes the data structure for the root inports of the model unless a subsystem implemented by a nonreusable function uses the value of one or more of the inports.
- The code generator removes the data structure for the root outports of the model except when you enable MAT-file logging or if the sample time of one or more of the outports is not the fundamental base rate (including a constant rate).
- If you copy a subsystem block to create a block in a new model or the same model, the function interface information from the original subsystem block is not copied to the new subsystem block.
- If you have Stateflow, for a Stateflow chart that uses a model root inport value or that calls a subsystem that uses a model root inport value, do one of the following to generate code:
  - Clear the **Execute (enter) Chart At Initialization** check box in the Stateflow chart.
  - Make the Stateflow function a nonreusable function.
  - Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- If a model root inport value connects to a Simscape conversion block, insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.

- When building a referenced model that is configured with a function interface, do not use virtual buses as inputs or outputs to the referenced model. Use nonvirtual buses instead.
- If the C function interface is not the default, the value is ignored for the model configuration parameter **Pass fixed-size scalar root inputs by value for code generation**. For more information, see “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

Override Default Naming for Individual C Entry-Point Functions

For your generated C code to adhere to code standards and guidelines or to more easily integrate with your external code, you can customize the name of an entry-point function (initialize, execution, terminate).

This example shows how to change the name of the `initialize` function for the model `rtwdemo_fcnprotoctrl`.

1. Open and save the model `rtwdemo_fcnprotoctrl`.
2. Enter the Code perspective.
3. In the Code Mappings editor, select the **Entry-Point Functions** tab.
4. Change the function name by using one of these methods.

   - Under the **Function Name** column, directly edit the name of the function. The column automatically updates to reflect the new name.
   - Under the **Function Preview** column, click the prototype hyperlink of the function to open a configuration dialog box. In the `C Initialize Function Name` field edit the function name. Click **Apply** to view the change reflected in the `C function prototype` field or click **OK** to exit and view the function name reflected in the **Function Preview** column.

   For this example, change the `initialize` function name to `fcnprotoctrl_init`.
5. Save and build the model.
6. Verify the changes in the generated code by navigating to the Code view.

   - Verify the change in the generated header file, `rtwdemo_fcnprotoctrl.h`, by checking that the **Search** field includes the new function name (`fcnprotoctrl_init`).

     ```
     extern void fcnprotoctrl_init(void);
     ```
   - Verify the change in the generated C file, `rtwdemo_fcnprotoctrl.c`, by checking that the **Search** field includes the new function name (`fcnprotoctrl_init`).

     ```
     void fcnprotoctrl_init(void)
     {
       ...
     }
     ```

Override Default C Step Function Interface

This example shows how to open a configuration dialog box to customize the step function name and arguments for a rate-based model.To adhere to code guidelines and standards or easily integrate generated code with external code, you can customize these aspects of a step function:

- Function name
- Argument names
- Order of the arguments
- Return value and argument data qualifiers
- Buffering optimizations for arguments

You can make step function customizations by using a model-specific configuration dialog box opened from the Code Mappings editor.

Open the Configuration Dialog Box

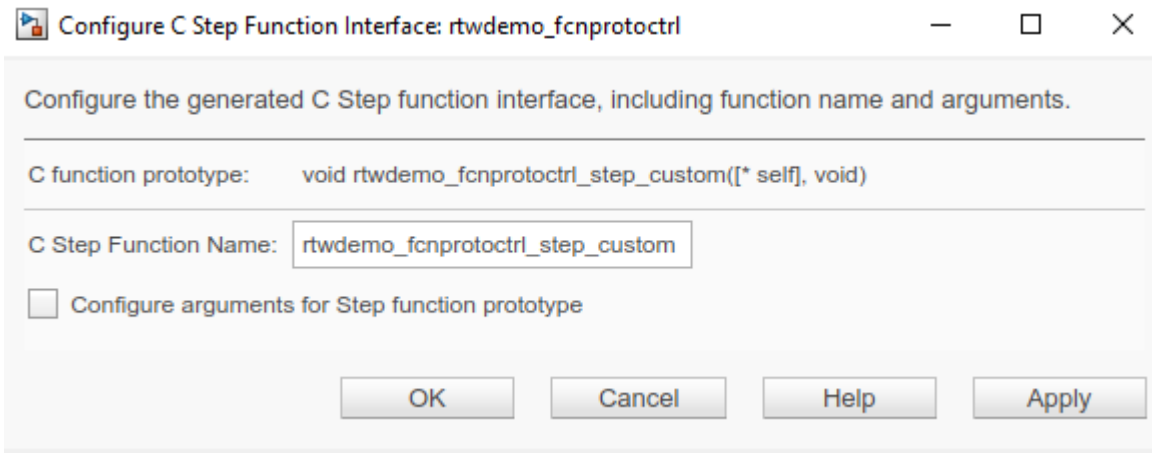
This example shows how to open the configuration dialog box for the step function of the rate-based model rtwdemo_fcnprotoctrl.

1. Open and save the model rtwdemo_fcnprotoctrl.

2. Enter the Code perspective.

3. In the Code Mapping Editor, select the **Entry-Point Functions** tab. If you open a model that is not yet configured with code mapping data, update the model to include code mappings by clicking the **update code mappings** button.

4. In the step function row, under the **Function Preview** column, click the prototype hyperlink to open the Configure C Step Function Interface:rtwdemo_fcnprotoctrl configuration dialog box (configuration dialog box).



The first field of the configuration dialog box, **C function prototype**, automatically updates to preview the changes to the step function prototype as you make them.

For models configured to generate multi-instance code (the prototype contains a reference to **self**), see “Generate Reentrant Code from Top Models” on page 6-25.

Customize the Function Name

You can customize the step function name for a rate-based model by using one of these methods:

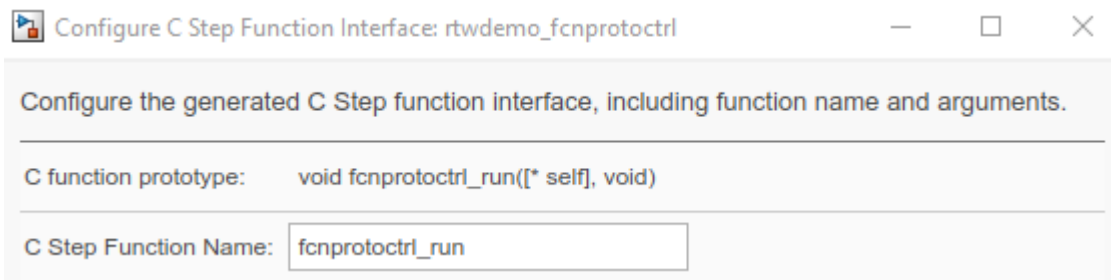
- If overriding only the function name, in the Code Mappings editor, on the **Entry-Point Functions** tab, specify the function name in the **Function Name** column.
- If overriding the function name and argument settings, in the configuration dialog box, specify the function name in the **C Step Function Name** field.

Example

This example shows how to customize the step function generated for example model `rtwdemo_fcnprotoctrl`.

1. Open the configuration dialog box of the model `rtwdemo_fcnprotoctrl`, .

2. Change the name in the **C Step Function Name** field to `fcnprotoctrl_run`. The function preview updates to reflect the new step function name.

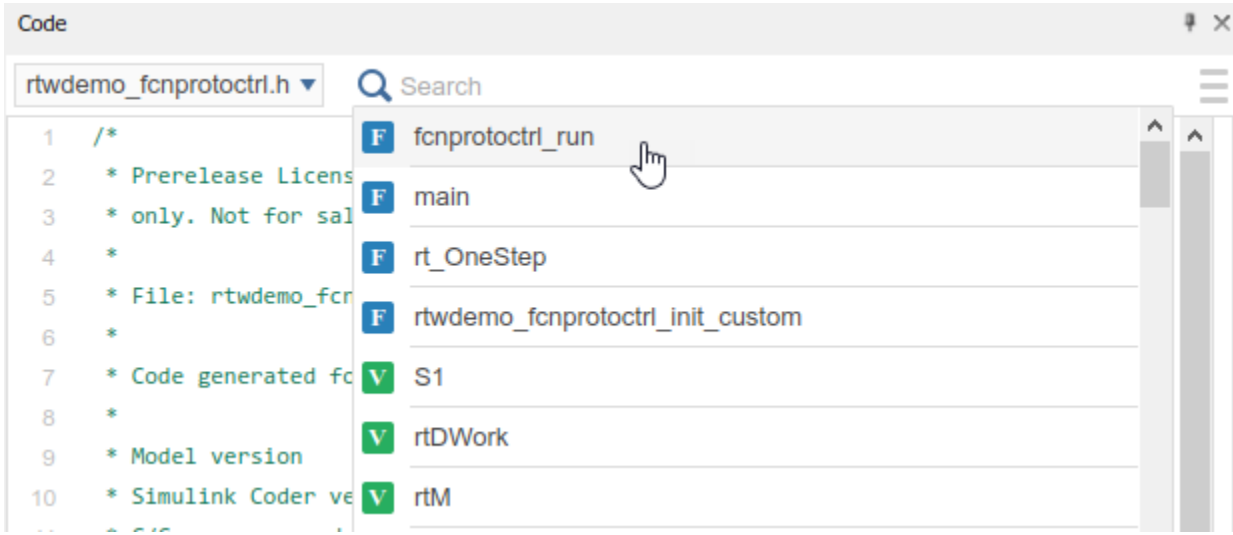


Apply the change, close the dialog box, and save the model.

3. Generate the code and verify the name change.

In the bottom-right corner of the Code perspective, select the **Code** tab. In the Code view, verify that the generated code for the step function reflects the name change.

- In the Code view file list, select file `rtwdemo_fcnprotoctrl.h`. In the **Search** field, verify that the list of code elements includes the new function name (`fcnprotoctrl_run`). To view the declaration, select the function name.



The declaration is highlighted in the code:

```
/* Model entry point functions */
extern void rtwdemo_fcnprotoctrl_init_custom(void);
extern void fcnprotoctrl_run(void);
```

- Verify your changes in the C file `rtwdemo_fcnprotoctrl.c`. In the **Search** field, verify that the list of code elements includes the new function name (`fcnprotoctrl_run`). To view the source code (definition) select the function name.

```
/* Model step function */
void fcnprotoctrl_run(void)
{
```

For addional examples, see “Override Default Naming for Individual C Entry-Point Functions” on page 39-5.

Customize Function Arguments

Configure Global Data Structures

By default, a top or referenced model uses a `void-void` step function to pass data. This type of function allows generated code to communicate with external code by accessing global data stored as data structures that reside in shared memory.

To configure a model to have a `void-void` step function, open the configuration dialog box and clear the **Configure arguments for Step function prototype** check box. Verify the updates in the prototype preview field.

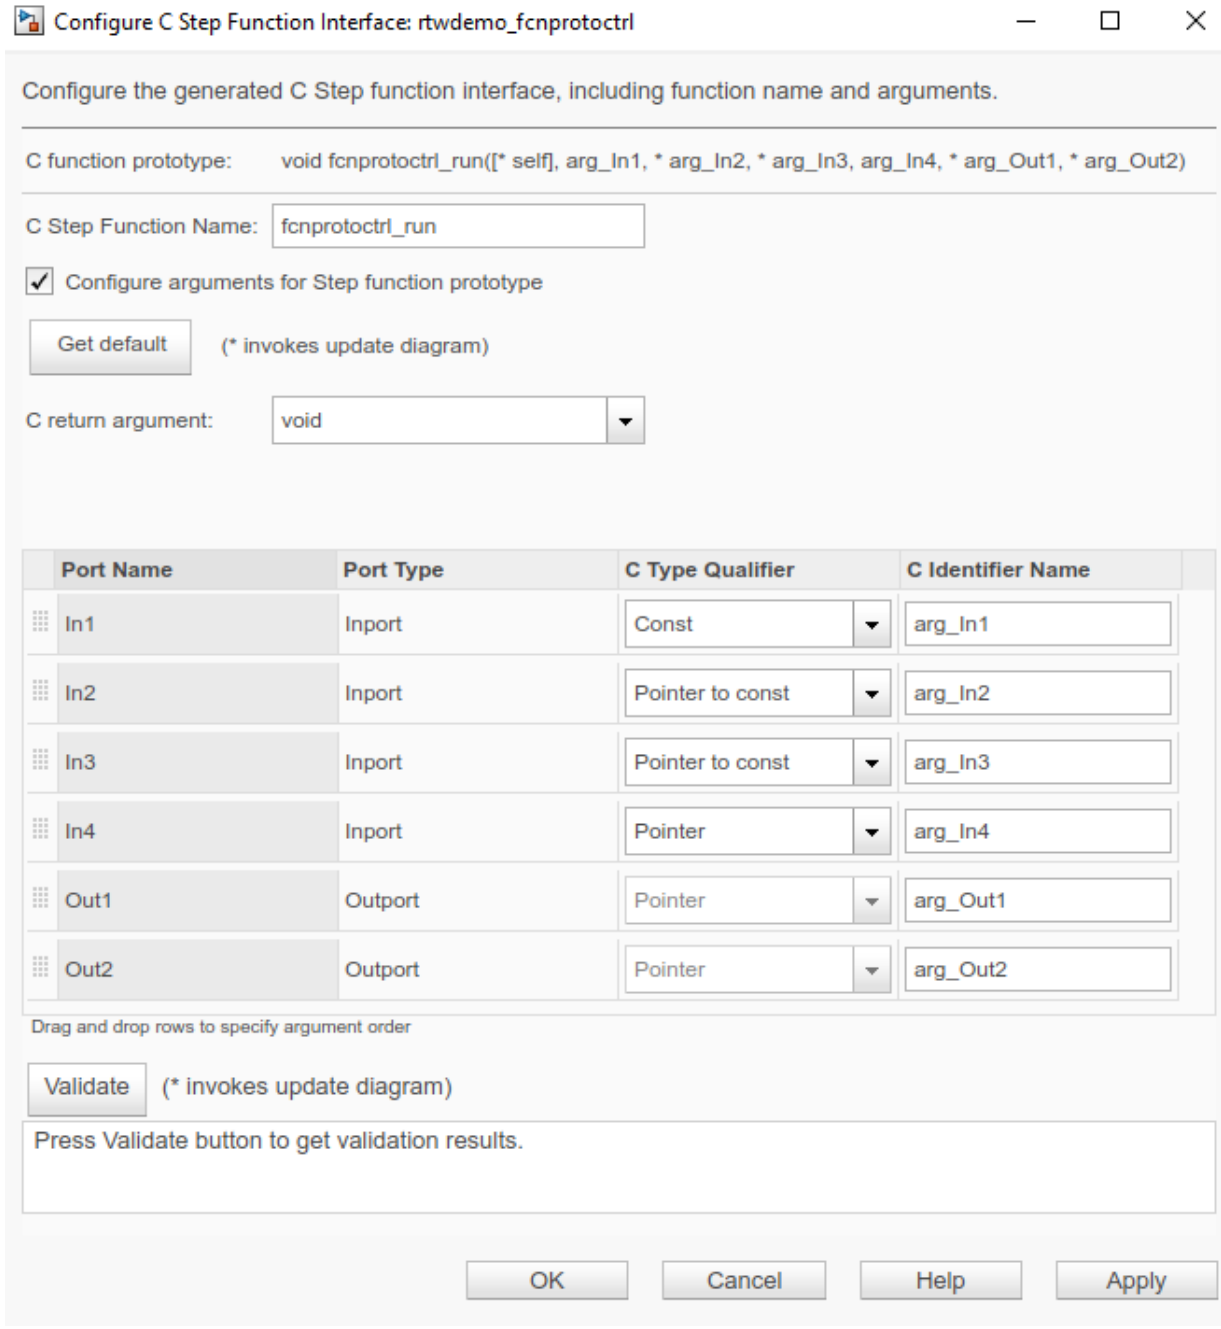
Configure Passing Arguments

Rate-based model step functions can also use arguments to pass data. You can customize argument settings for:

- Return value
- Type qualifiers
- Names
- Order

Example

1. Open the configuration dialog box for the model `rtwdemo_fcnprotoctrl`.
2. Select the **Configure arguments for Step function prototype** check box.
3. Click **Get default** to open a table that displays the default settings for the return value and arguments (Inports/Outports).



Configure C Step Function Interface: rtwdemo_fcnprotoctrl
Configure the generated C Step function interface, including function name and arguments.
C function prototype: void fcnprotoctrl_run([* self], arg_In1, * arg_In2, * arg_In3, arg_In4, * arg_Out1, * arg_Out2)

4. Customize the return value of the step function by selecting void or an Outport from the **C return argument** drop-down list.

For this example, select void.

5. Customize the argument data types from the **C Type Qualifier** drop-down list.

For this example, make no changes to the type qualifier.

Type Qualifers:

- `Auto`: Value - for example, `arg`
- `Const`: Value with the `const` qualifier - for example, `const arg`
- `Pointer to const`: Value with `const` qualifier and referenced by pointer - for example, `const *arg`
- `Pointer`: Reference by pointer - for example, `*arg`
- `Const pointer to const`: Value with `const` qualifier, reference by pointer, and the pointer itself - for example, `const *const arg`

When a model includes a referenced model:

- For a referenced model, the type qualifier for a root input argument in the step function interface is set to `Auto`. The code generator uses the interface specification by generating a type cast that discards the `const` qualifier from the source signal.
- For the parent of the reference model, the type qualifier for the source signal is set to a value other than `Auto.`To override this behavior, add a `const` type qualifier to the referenced model.

6. Customize the argument names by directly editing the **C Identifier Name** field.

For this example, change the names of the arguments by removing the underscores (for example, change the argument named arg_In1 to argIn1).

7. Customize the argument order by dragging and dropping rows in the table.

For this example, move the first outport, Out1, to the first position. Move the second outport, Out 2, to the third position.

8. Validate and apply your changes. Save the model.

9. Generate the code and verify the changes in the Code view.

- Verify your changes in the header file, `rtwdemo_fcnprotoctrl.h`, by checking that the **Search** field includes the new function name (`fcnprotoctrl_run`). To view the function declaration, select the function name.

```
/* Customized model step function */
extern void fcnprotoctrl_run(boolean_T *argOut1, real_T argIn1, BusObject
  *argOut2, BusObject *argIn2, BusObject *argIn3, uint8_T argIn4);
```

- Verify your changes in the C file, `rtwdemo_fcnprotoctrl.c`, by checking the **Search** field include the new function name (`fcnprotoctrl_run`). To view the source code (definition) for the function, select the function name.

```
/* Model step function */
void fcnprotoctrl_run(boolean_T *argOut1, real_T argIn1, BusObject *argOut2,
                      BusObject *argIn2, BusObject *argIn3, uint8_T argIn4)
{
```

Prototype Different Fom Preview

Referenced models can show a prototype preview in the configuration dialog box that has less arguments than its prototype in the generated code.

For example, consider a model named `mdlref_counter` with an inport (`arg_input`), outport (`arg_output`), and saturation block with limits that have workspace parameter argument names `lower_saturation_limit` and `upper_saturation_limit`. The configuration dialog box previews the function prototype as the following:

```
mdlref_counter_custom(arg_input, arg_output)
```

In the generated code, the prototype includes the parameter arguments:

```
mdlref_counter_custom(real_T arg_input, real_T arg_output, real_T
  rtp_lower_saturation_limit, real_T rtp_upper_saturation_limit)
```

Optimize Buffering for Arguments

You can optimize the buffering required for I/O arguments in the step function for a model. If you adhere to these requirements when configuring an inport and outport pair, the code generator merges the corresponding arguments and reuses the associated buffer:

- The Inport and Outport blocks must have the same properties, including data type, dimension, and sample rate.
- The sample rate of the Inport and Outport blocks must be the same as the base rate of the model.
- A conditionally executed subsystem cannot drive the Outport block.
- A single, nonvirtual block output must drive the Outport block. For example, a Mux block, which merges multiple buffers, cannot drive the Outport block.
- In the configuration dialog box, you must configure the Inport and Outport with the same C type qualifier and identifier name.

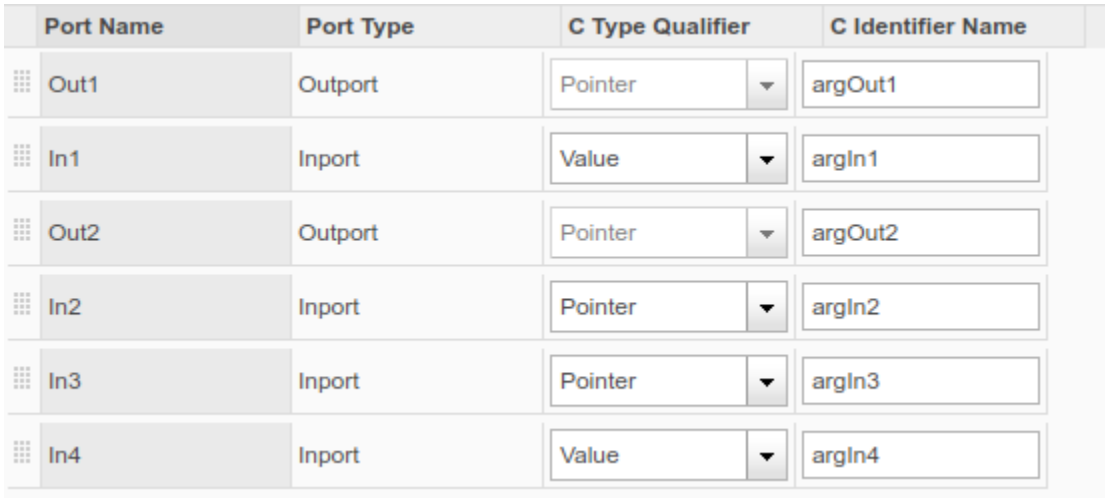
Example

This example shows how to merge arguments for ports `In3` and `Out2` for example model rtwdemo_fcnprotoctrl.

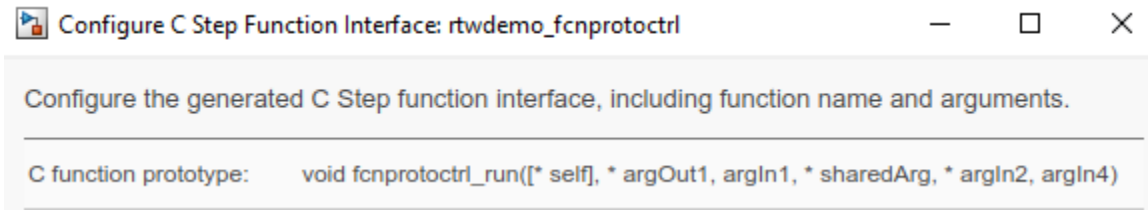
1. Open the configuration dialog box for the model `rtwdemo_fcnprotoctrl.`

2. Select the **Configure arguments for Step function prototype check box** to open the display for the arguments.

3. For ports `In3` and `Out2`, set **C Type Qualifier** to `Pointer` and **C Identifier Name** to `sharedArg`.



4. Verify that the preview shows the merged argument for `argIn3` and `argOut2`.



5. Validate and apply your changes. Save the model.

4. Generate and view the code. In the Code view, search for the `fcnprotoctrl_run` function and check the function interface. For this example, the shared argument appears in read code for the Inport block and write code for the Outport block.

```
/* Model step function */
void fcnprotoctrl_run(boolean_T *argOut1, real_T argIn1, BusObject *sharedArg,
                      BusObject *argIn2, uint8_T argIn4)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Constant: '<Root>/Constant1'
   *  Constant: '<Root>/Constant2'
   *  Inport: '<Root>/In1'
   *  Logic: '<Root>/LogOp'
   *  RelationalOperator: '<Root>/RelOp1'
   *  RelationalOperator: '<Root>/RelOp2'
   *  UnitDelay: '<Root>/Unit Delay'
   */
  *argOut1 = ((rtDWork.UnitDelay_DSTATE > 10.0) || (argIn1 < 2.0));

  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/In2'
   *  Inport: '<Root>/In4'
   */
  if (argIn4 != 0) {
    S1 = *argIn2;
  } else {
    S1 = *sharedArg;
  }

  /* End of Switch: '<Root>/Switch' */

  /* BusCreator: '<Root>/BusConversion_InsertedFor_Out2_at_inport_0' */
  *sharedArg = S1;

  /* Update for UnitDelay: '<Root>/Unit Delay' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtDWork.UnitDelay_DSTATE = argIn1;
}
```

Customize C Step and Initialize Function Interfaces Programmatically

To configure initialize and step entry-point function interfaces for a rate-based model programmatically, use these functions.

Function	Description
`RTW.ModelSpecificCPrototype.addArgConf`	Add step function argument configuration information for Simulink model port to model-specific C function prototype
`RTW.ModelSpecificCPrototype.attachToModel`	Attach model-specific C function prototype to loaded ERT-based Simulink model
`RTW.ModelSpecificCPrototype.getArgCategory`	Get step function argument category for Simulink model port from model-specific C function prototype
`RTW.ModelSpecificCPrototype.getArgName`	Get step function argument name for Simulink model port from model-specific C function prototype
`RTW.ModelSpecificCPrototype.getArgPosition`	Get step function argument position for Simulink model port from model-specific C function prototype
`RTW.ModelSpecificCPrototype.getArgQualifier`	Get step function argument type qualifier for Simulink model port from model-specific C function prototype
`RTW.ModelSpecificCPrototype.getDefaultConf`	Get default configuration information for model-specific C function prototype from Simulink model to which it is attached
`RTW.ModelSpecificCPrototype.getFunctionName`	Get function names from model-specific C function prototype
`RTW.ModelSpecificCPrototype.getNumArgs`	Get number of step function arguments from model-specific C function prototype
`RTW.ModelSpecificCPrototype.getPreview`	Get model-specific C function prototype code previews

Function	Description
`RTW.configSubsystemBuild`	Open UI to configure C function prototype or C++ class interface for right-click build of specified subsystem
`RTW.getFunctionSpecification`	Get handle to model-specific C function prototype object
`RTW.ModelSpecificCPrototype.runValidation`	Validate model-specific C function prototype against Simulink model to which it is attached
`RTW.ModelSpecificCPrototype.setArgCategory`	Set step function argument category for Simulink model port in model-specific C function prototype
`RTW.ModelSpecificCPrototype.setArgName`	Set step function argument name for Simulink model port in model-specific C function prototype
`RTW.ModelSpecificCPrototype.setArgPosition`	Set step function argument position for Simulink model port in model-specific C function prototype
`RTW.ModelSpecificCPrototype.setArgQualifier`	Set step function argument type qualifier for Simulink model port in model-specific C function prototype
`RTW.ModelSpecificCPrototype.setFunctionName`	Set function names in model-specific C function prototype

Typical uses of these functions include:

- Create and validate a function interface.
- Modify and validate an existing function interface.
- Create and validate a function interface, starting with default configuration information from a model.
- Reset the model function interface to the default ERT function configuration.

Create and Validate Function Interface

1. Create a model-specific C function interface with *`obj`* = `RTW.ModelSpecificCPrototype`, where *`obj`* returns a handle to a new, empty function interface.
2. Add argument configuration information for your model ports by using `RTW.ModelSpecificCPrototype.addArgConf`.
3. Attach the function interface to your loaded ERT-based model by using `RTW.ModelSpecificCPrototype.attachToModel`.
4. Validate the function interface by using `RTW.ModelSpecificCPrototype.runValidation`.
5. If validation succeeds, save your model. Then, generate code by using the `rtwbuild` function.

Modify and Validate an Existing Function Interface

1. Get the handle to an existing model-specific C function interface that is attached to your loaded ERT-based model with *`obj`* = `RTW.getFunctionSpecification(`*`modelName`*`)`. *`modelName`* is a character vector specifying the name of a loaded ERT-based model. *`obj`* returns a handle to a function interface attached to the specified model.

   You can use other functions on the returned handle only if the test `isa(obj,'RTW.ModelSpecificCPrototype')` returns 1. If the model does not have a function interface configuration, the function returns `[]`. If the function returns a handle to an object of type `RTW.FcnDefault`, you cannot modify the existing function interface.
2. Use the `Get` and `Set` functions to test and reset such items as the function names, argument names, argument positions, argument categories, and argument type qualifiers.
3. Validate the function interface by using `RTW.ModelSpecificCPrototype.runValidation`.
4. If validation succeeds, save your model, and then generate code by using the `rtwbuild` function.

Create and Validate Function Interface Starting With Default Configuration From Model

1. Create a model-specific C function interface by using *`obj`* = `RTW.ModelSpecificCPrototype`, where *`obj`* returns a handle to a new, empty function interface.
2. Attach the function interface to your loaded ERT-based model by using `RTW.ModelSpecificCPrototype.attachToModel`.
3. Get default configuration information from your model by using `RTW.ModelSpecificCPrototype.getDefaultConf`.
4. Use the `Get` and `Set` functions to test and reset such items as the function names, argument names, argument positions, argument categories, and argument type qualifiers.
5. Validate the function prototype by using `RTW.ModelSpecificCPrototype.runValidation`.
6. If validation succeeds, save your model. Then, generate code by using the `rtwbuild` function.

Reset Model Function Interface to Default ERT Function Configuration

Create an object of the ERT default function interface. Reset the model function interface and undo custom settings by calling the `RTW.FcnDefault` method, `attachToModel`:

```
obj = RTW.FcnDefault;
obj.attachToModel(model);
```

`model` must be a loaded ERT-based model.

Note Do not use the same model-specific C function interface object across multiple models. If you do, changes that you make to the step and initialize functions in one model are propagated to other models, which is usually not what you want.

Sample Script for Configuring Function Interfaces

This example MATLAB script configures the model function interfaces for example model `rtwdemo_counter`.

```
%% Open the rtwdemo_counter model
rtwdemo_counter

%% Select ert.tlc as the System Target File for the model
set_param(gcs,'SystemTargetFile','ert.tlc')

%% Create a model-specific C function prototype
a=RTW.ModelSpecificCPrototype

%% Add argument configuration information for Input and Output ports
addArgConf(a,'Input','Pointer','inputArg','const *')
addArgConf(a,'Output','Pointer','outputArg','none')

%% Attach the model-specific C function prototype to the model
attachToModel(a,gcs)

%% Rename the initialization function
setFunctionName(a,'InitFunction','init')

%% Rename the step function and change some argument attributes
setFunctionName(a,'StepFunction','step')
setArgPosition(a,'Output',1)
setArgCategory(a,'Input','Value')
setArgName(a,'Input','InputArg')
setArgQualifier(a,'Input','none')

%% Validate the function prototype against the model
[status,message]=runValidation(a)

%% if validation succeeded, generate code and build
if status
    rtwbuild(gcs)
end
```

Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks

With Embedded Coder, you can customize the generated C/C++ function interfaces for Simulink Function and Function Caller blocks. Function code interface configuration supports easier integration of generated code with functions or function calls in external code and customizations for coding standards or design requirements.

You can customize the generated C/C++ function interfaces for:

- Global Simulink functions
- Exported scoped Simulink functions

You cannot customize the generated C/C++ function interface for a scoped Simulink Function block that is not located at the root level of a model. For more information, see “Scoped and Global Simulink Function Blocks Overview” (Simulink).

By opening a dialog box from a selected Simulink Function or Function Caller block, you can customize the C/C++ function prototype generated for that block. Your changes for the selected block also update other corresponding Simulink Function and Function Caller blocks in the model. The function visibility, global or scoped, set in the function Trigger Port block, determines which function attributes you can modify:

- For a global function, you can change the function name, and the names, type qualifiers, and order of function arguments.
- For an exported scoped function, you can change the argument type qualifiers and the order of arguments. You cannot change the function and argument names.

Your changes do not graphically alter the model and do not affect the Simulink function prototype defined in the block.

Embedded Coder supports Simulink function code interface configuration for ERT and ERT-derived targets, except for the AUTOSAR target.

Configure Generated C/C++ Function Interface for Global Simulink Function Block

This example shows how to customize the generated C function interface for a Simulink Function block for automatic C code generation.

1. Open and save the example model `rtwdemo_functions`.
2. Customize the function interface for a Simulink Function block by opening a configuration dialog box using one of these methods:

   - Right-click the Simulink Function block `f3`. In the context menu, select **C/C++ Code** > **Configure C/C++ Function Interface**.
   - Open the Code perspective, navigate to the Code Mappings editor and select the Entry-Point Functions tab. In the Simulink Function f3 row, under the **Function Preview** column, click on the prototype hyperlink.

     A configuration dialog box opens to display the Simulink function prototype defined in the block, `y = f3(u)`, and a preview of the C/C++ function interface, `void f3(rtu_u, * rty_y)`. The C/C++ interface preview updates dynamically as you make changes.

   For models that you configure for C multi-instantiable code, the interface preview includes a `self` argument. The `self` argument is a pointer to a version of the real-time model (`RT_MODEL`) data structure that stores multi-instance data associated with reusable functions.

If model configuration parameter **Code interface packaging** is set to `Reusable function` and **Total number of instances allowed per top model** is set to `Multiple`, the argument appears as `self`, indicating that the code generator produces a self structure.

If model configuration parameter **Code interface packaging** is set to `Reusable function` or **Total number of instances allowed per top model** is set to `Multiple`, the argument appears as `[self]`, indicating that the argument is optional. The code generator produces a `self` structure only if you use the model as a top model and **Code interface packaging** is set to `Reusable function` or if you use the model as a referenced model and **Total number of instances allowed per top model** is set to `Multiple`.

For more information about configuring a model for multi-instantiable code generation, see “Generate Reentrant Code from Simulink Function Blocks” on page 6-31.

3 Examine the dialog box settings for **C/C++ Function Name** and the **C/C++ Identifier Name** — `$N` and `rt$I$N$M`.

The model configuration parameter **Subsystem method arguments** defines the default identifier format (naming rule) for Simulink Function arguments.

`rt` is a text prefix. `$I`, `$N`, and `$M` are identifier format macros. For more information, see “Subsystem method arguments” (Simulink Coder).

4 Modify the function and argument identifier names. Changes that you make in the dialog box override model configuration parameter defaults.

In the **C/C++ function name** field, and in the **C/C++ Identifier Name** column for each Simulink function argument, enter a custom name or identifier naming rule. Specify valid C-identifier characters, identifier format macros, or a combination. For this example, name the function `function3` and, for both arguments, enter the identifier naming rule `$N$M`.

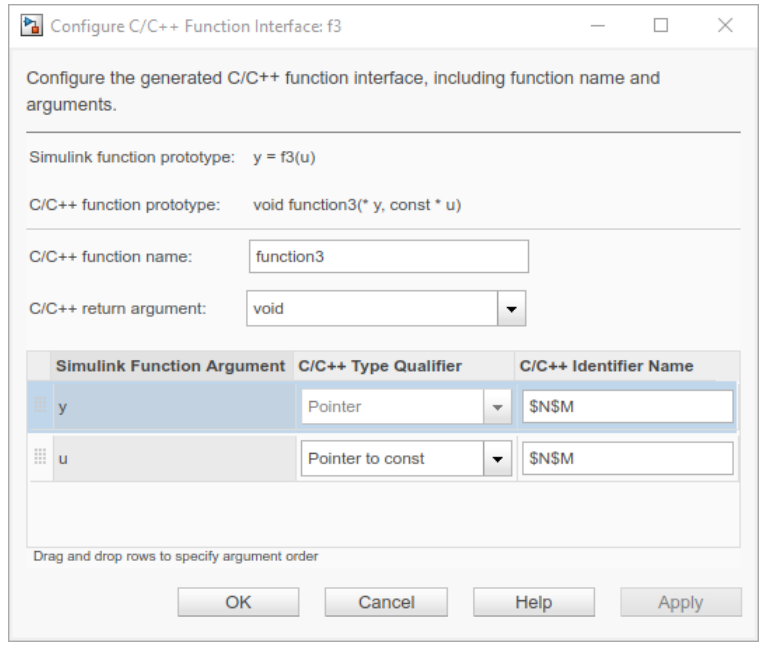
To see tips about available macros, place your cursor over **C/C++ function name** and **C/C++ Identifier Name**. For more information about the identifier naming rules, see “Identifier Format Control” on page 50-24.

5 For the u argument, set **C/C++ Type Qualifier** to `Pointer to const`.

6 Reorder the arguments. Drag the `y` argument row above the `u` argument row, and drop.

7 Click **Apply** and examine the updated C/C++ function prototype: `void function3(* y, const * u)`.

Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.



Optionally, you could change **C/C++ return argument** from `void` to `y`. The resulting C/C++ function is `y = function3(const * u)`.

8 Click **OK** to save your changes.

9 Generate code.

10 Open the generated file `rtwdemo_functions.c` and search for `function3`. The generated function code reflects the changes to the generated C/C++ function prototype.

```
void function3(real_T *y, const real_T *u)
{
```

```
  rtY.TicToc10 = rtDWork.Delay_DSTATE;

  rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

  adder(rtB.Subtract, rtU.U2, *u, &rtB.FunctionCaller);

  *y = rtB.FunctionCaller;
}
```

Configure Generated C/C++ Function Interface for Exported Scoped Simulink Function Block

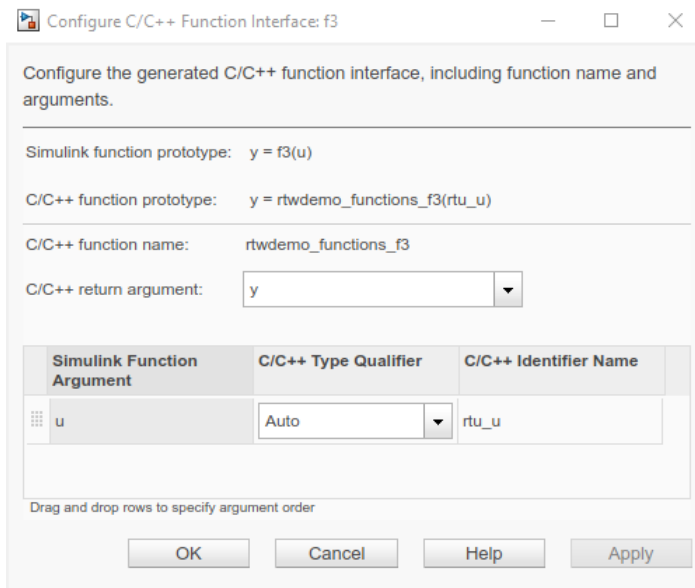
This example shows you how to modify the generated C/C++ function interface for an exported scoped Simulink Function block, and generate C code with the specified changes.

For an exported scoped function, you can modify the generated return argument, the argument type qualifiers, and the order of arguments. You cannot change the generated function name and argument names.

1. Open the model `rtwdemo_functions`. Save it to a writable work area.
2. Change the visibility of the global function `f3` from global to scoped. Open the Simulink Function block `f3`. Inside the function block, double-click the Trigger Port block `f3`. In the block parameters dialog box, set **Function visibility** to `scoped`. Click **Apply** and **OK**.
3. Customize the function interface by opening a configuration dialog box using one of these methods:

   - Right-click the Simulink Function block `f3`. In the context menu, select **C/C++ Code** > **Configure C/C++ Function Interface**.
   - Open the Code perspective, navigate to the Code Mappings editor and select the Entry-Point Functions tab. In the Simulink Function f3 row, under the **Function Preview** column, click on the prototype hyperlink.

   The Configure C/C++ Function Interface dialog box opens to display the Simulink function interface defined in the block, `y = f3(u)`, and the initial default C/C++ function interface, `y rtwdemo_functions_f3(rtu_u)`.



4. For the `u` argument, set **C/C++ Type Qualifier** to `Pointer to const`.
5. Click **Apply** and examine the updated C/C++ function interface: `y rtwdemo_functions_f3(const * rtu_u)`.

   Your modifications, whether made to a Simulink Function block or a Function Caller block, affect code generation for the Simulink Function block and corresponding Function Caller blocks in the model.

   Optionally, you can change **C/C++ return argument** from `y` to `void`. In that case, the function interface is `void = rtwdemo_functions_f3(* rty_y, const * rtu_u)`.
6. Click **OK** to save your changes.
7. Generate code.
8. Open the generated file `rtwdemo_functions.c` and search for `_f3`. The generated function code reflects the changes to the generated C/C++ function prototype.

```
real_T rtwdemo_functions_f3(const real_T *rtu_u)
{
  real_T rty_y_0;

  rtY.TicToc10 = rtDWork.Delay_DSTATE;
```

```
  rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

  adder(rtB.Subtract, rtU.U2, *rtu_u, &rtB.FunctionCaller);

  rty_y_0 = rtB.FunctionCaller;

  return rty_y_0;
}
```

Simulink Function Code Interface Limitations

- For C++ code generation, global Simulink functions are incompatible with C++ class interfaces for model entry-point functions.
- Simulink function code interface configuration does not support Simulink functions and function callers in Stateflow.

Customize Function Interfaces for Nonvirtual Subsystems

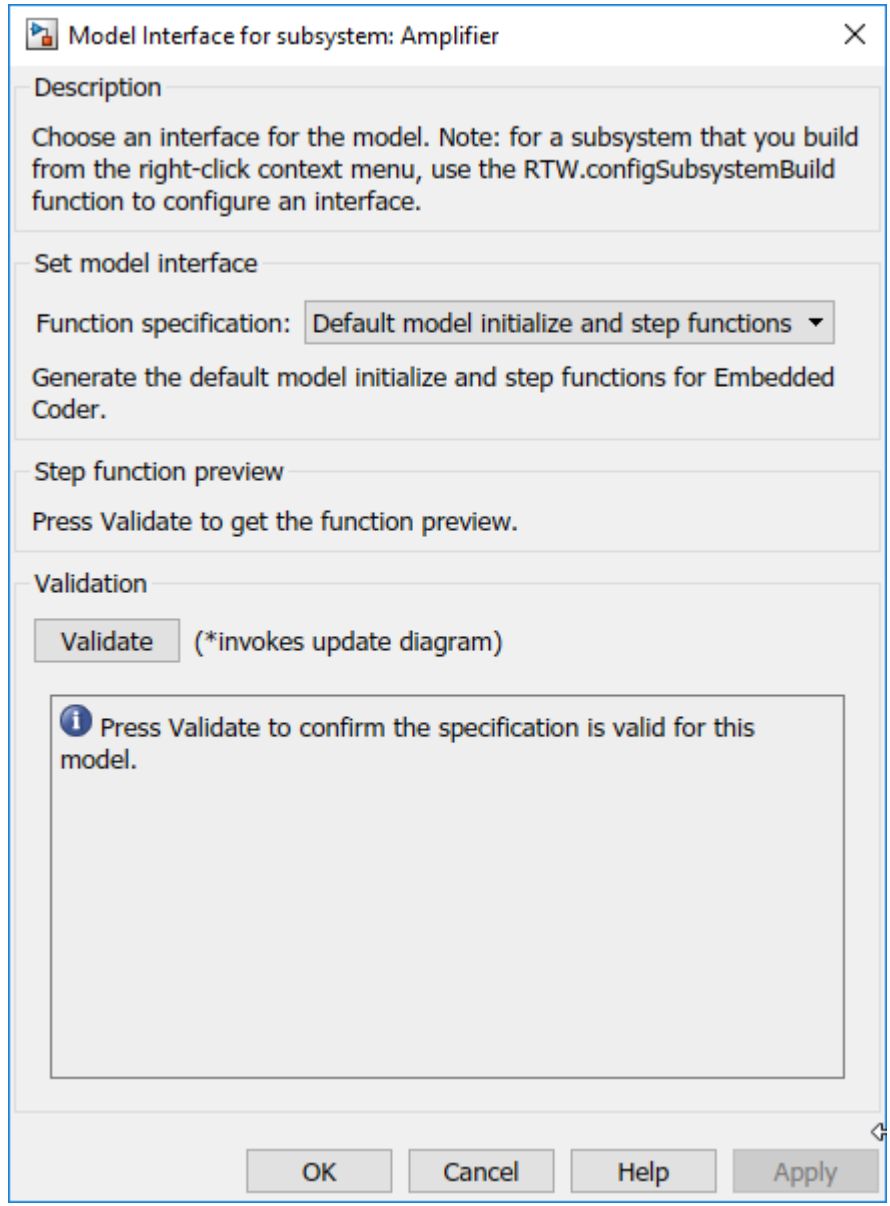
If you use the right-click build method to generate code for a nonvirtual subsystem in a rate-based model configured with an ERT-based system target file, you can configure the initialize and step function interfaces for the subsystem. You can configure the function interfaces for these types of nonvirtual subsystem blocks:

- Triggered subsystems
- Enabled subsystems
- Enabled trigger subsystems
- While subsystems
- For subsystems
- Stateflow blocks
- MATLAB function block

This example shows how to configure the function interfaces for the `Amplifier` subsystem in the example model `rtwdemo_counter`. In the Model Interface for the Subsystem dialog box, open the model containing the subsystem and invoke the function.

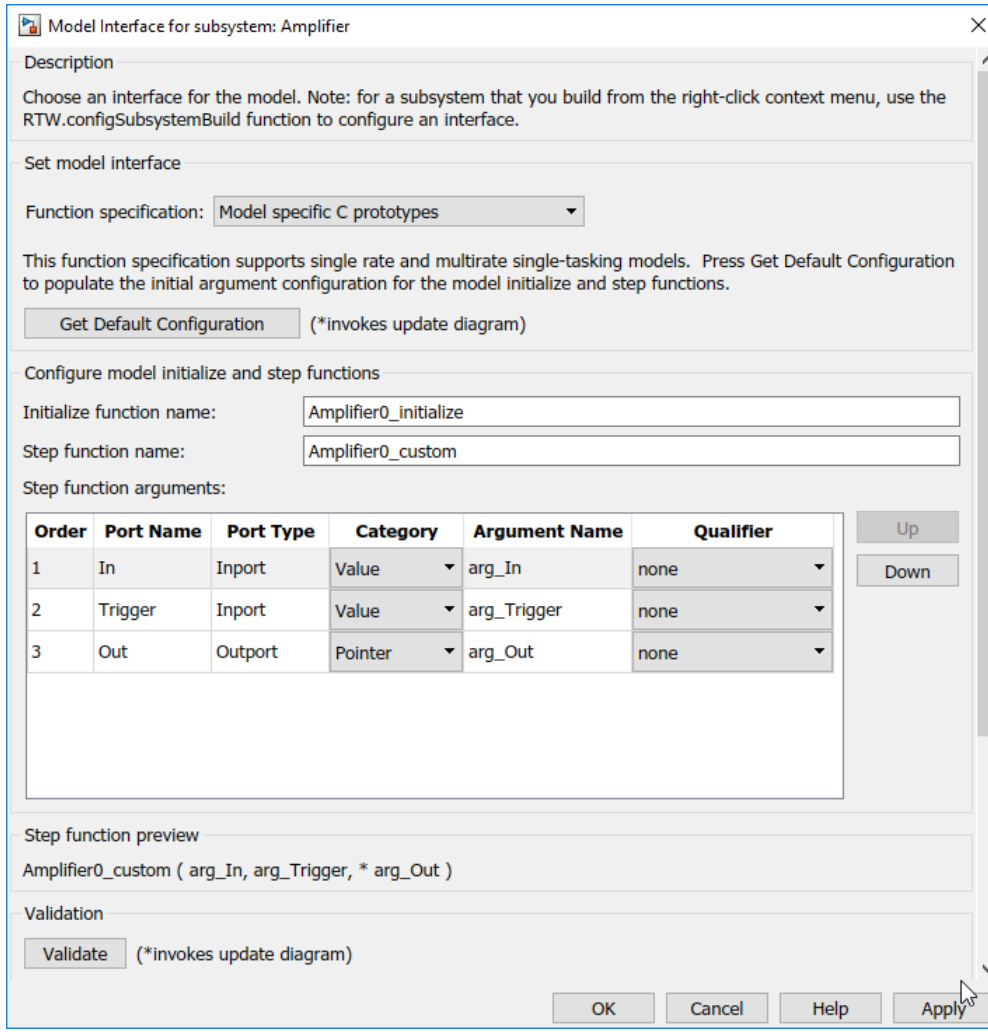
1. Open the model that contains the nonvirtual subsystem block.
2. Open the Model Interface for Subsystem dialog box by using the function `RTW.configSubsystemBuild`.

   ```
   RTW.configSubsystemBuild('rtwdemo_counter/Amplifier');
   ```



3 Choose a **Function specification**: default function prototypes or model-specific prototypes. For this example, select `Model specific C prototypes`.

4 Expand the interface for configuring the prototypes by clicking **Get Default Configuration**.



As you make changes, the step function preview (under the table) is updated.

5 Configure the function names. Specify values for **Initialize function name** and **Step function name**.

6. Configure the step function arguments. For each argument, you can specify whether the argument is passed by value or by reference with a pointer (**Category** column), a name, and whether to apply a C type qualifier. Click **Apply**.
7. Validate the prototypes. Check the step function preview and click **Validate**. The interface reports validation results.
8. Generate code for the subsystem. From the subsystem context menu, select **C/C++ Code > Build This Subsystem**. The code generator produces the initialize and step functions for the subsystem based on your customizations.

Customize Generated C++ Class Interfaces

Using the **Code interface packaging** (Simulink Coder) option `C++ class`, on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 39-54.)

The general procedure for generating C++ class interfaces to model code is as follows:

1. Configure your model to use an `ert.tlc` system target file provided by MathWorks.
2. Select the `C++` language for your model.
3. Select `C++ class` code interface packaging for your model.
4. Optionally, configure related C++ class interface settings for your model code, using either a graphical user interface (GUI) or application programming interface (API).
5. Generate model code and examine the results.

To get started with an example, see “Simple Use of C++ Class Control” on page 39-36. For more details about configuring C++ class interfaces for your model code, see “Customize C++ Class Interfaces Using Graphical Interfaces” on page 39-43 and “Customize C++ Class Interfaces Programmatically” on page 39-54. For limitations that apply, see “C++ Class Interface Control Limitations” on page 39-61.

Note For an example of C++ class code generation, see the example model `rtwdemo_cppclass`.

In this section...

In this section...

Simple Use of C++ Class Control

This example illustrates a simple use of `C++ class` code interface packaging. It generates C+ class code interfaces from an example model, without extensive modifications to default settings.

Note For details about setting C++ class parameters, see the sections that follow this example, beginning with “Customize C++ Class Interfaces Using Graphical Interfaces” on page 39-43.

To generate C++ class interfaces for a Simulink model:

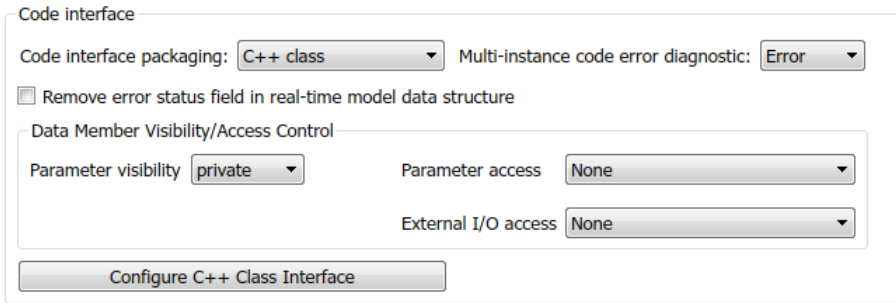
1. Open a model for which you would like to generate C++ class code interfaces. This example uses the model `rtwdemo_counter`.
2. Configure the model to use an `ert.tlc` system target file provided by MathWorks. For example, open the Configuration Parameters dialog box, go to the **Code Generation** pane, select a target value from the **System target file** menu, and click **Apply**.
3. On the **Code Generation** pane of the Configuration Parameters dialog box, set the **Language** parameter to `C++`.

   On the **Code Generation** > **Interface** pane, check that the **Code interface packaging** parameter is set to `C++ class`.

   
   Click **Apply**.

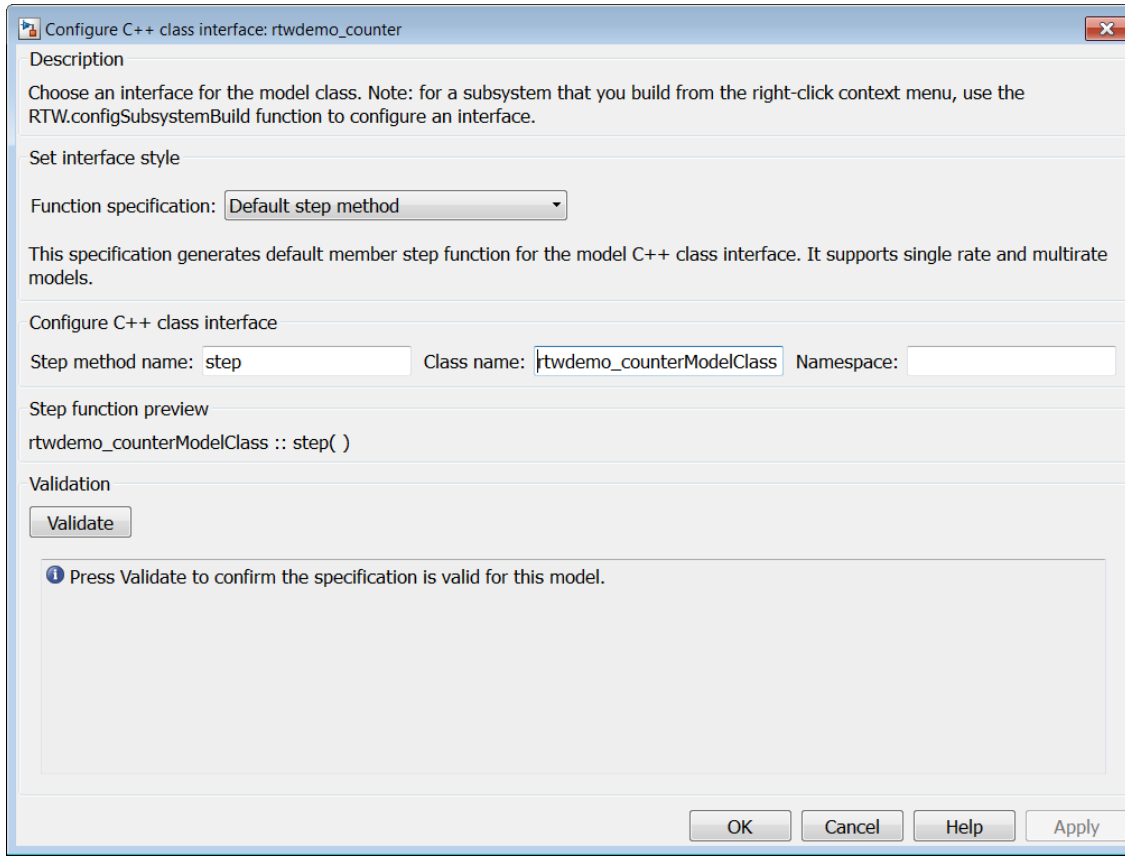
Note To immediately generate the default style of C++ class code, without exploring the related model configuration options, skip steps 4–8 and go directly to step 9.

4 Go to the **Interface** pane of the Configuration Parameters dialog box and examine the **Code interface** subpane.



When you select `C++ class` code interface packaging for your model, additional C++ class interface controls become available in the **Code interface** subpane. See “Configure Code Interface Options” on page 39-43 for descriptions of these controls. You might want to modify the default settings according to your application.

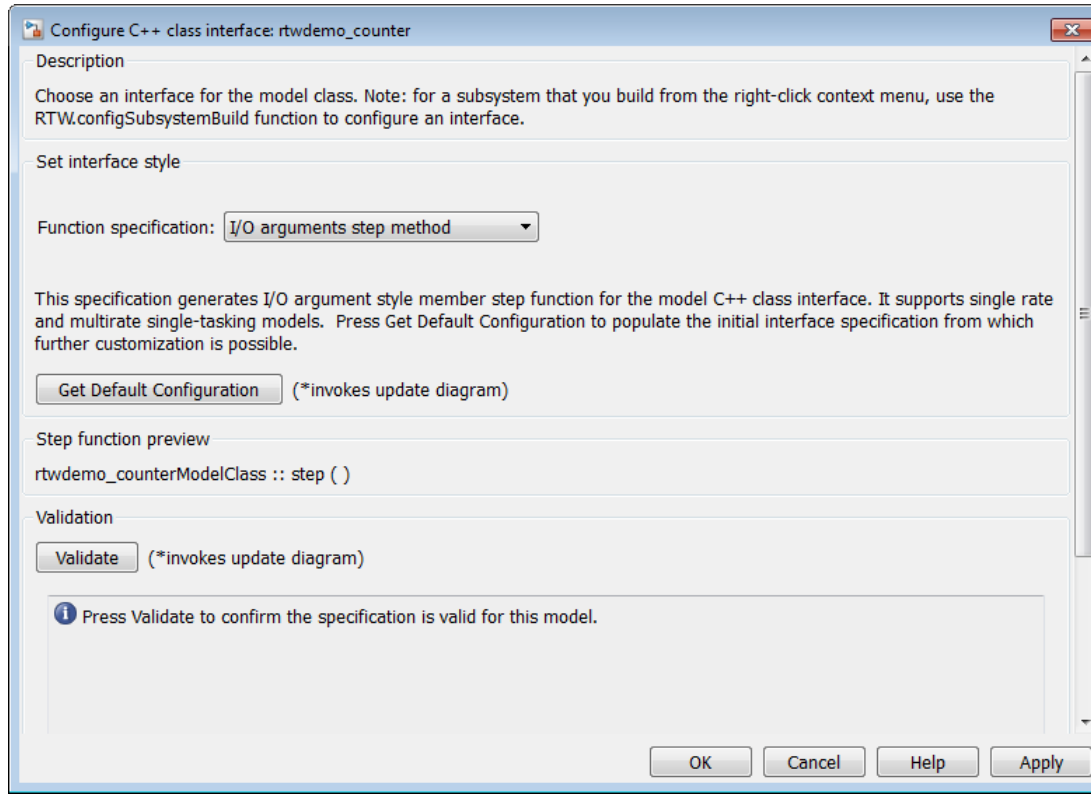
5 Click the **Configure C++ Class Interface** button. This action opens the Configure C++ class interface dialog box, which allows you to configure the step method for your generated model class. The dialog box initially displays a view for configuring a **Default step method** for the model class. In this view, you can specify the model class name, step method name, and namespace for your model.



See “Configure Step Method for Your Model Class” on page 39-46 for descriptions of these controls.

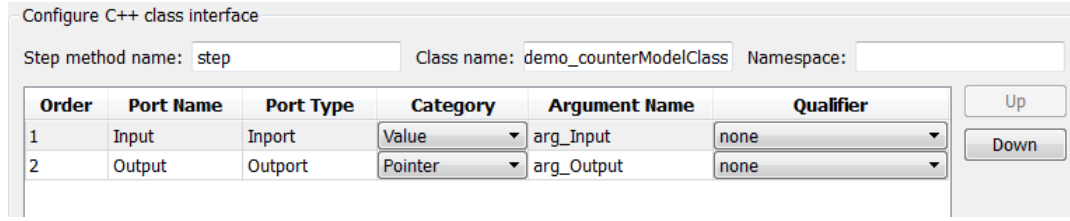
Note If the default interface style meets your needs, you can skip steps 6–8 and go directly to step 9.

6 If you want root-level model input and output to be arguments on the step method, select the value `I/O arguments step method` from the **Function specification** menu. The dialog box displays a view for configuring an I/O arguments style step method for the model class.



See “Configure Step Method for Your Model Class” on page 39-46 for descriptions of these controls.

7 Click the **Get Default Configuration** button. This action causes a **Configure C++ class interface** subpane to appear in the dialog box. The subpane displays the initial interface configuration for your model, which provides a starting point for further customization.



See “Passing I/O Arguments” on page 39-49 for descriptions of these controls.

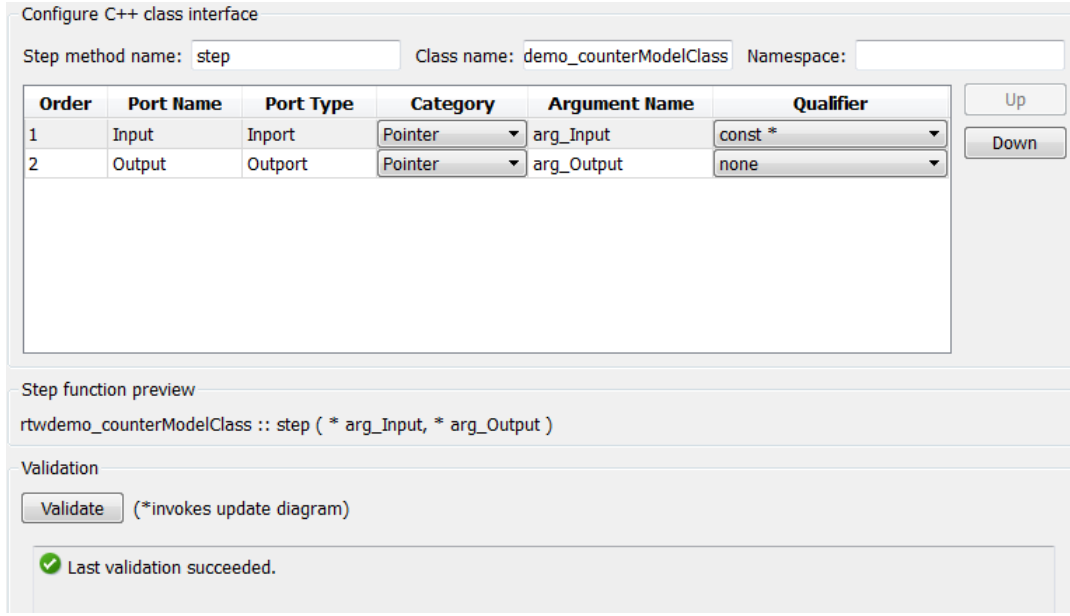
8 Perform this optional step only if you want to customize the configuration of the I/O arguments generated for your model step method.

Note If you choose to skip this step, you should click **Cancel** to exit the dialog box.

If you choose to perform this step, first you must check that the required option **Remove root level I/O zero initialization** is selected on the **Optimization** pane, and then navigate back to the `I/O arguments step method` view of the Configure C++ class interface dialog box.

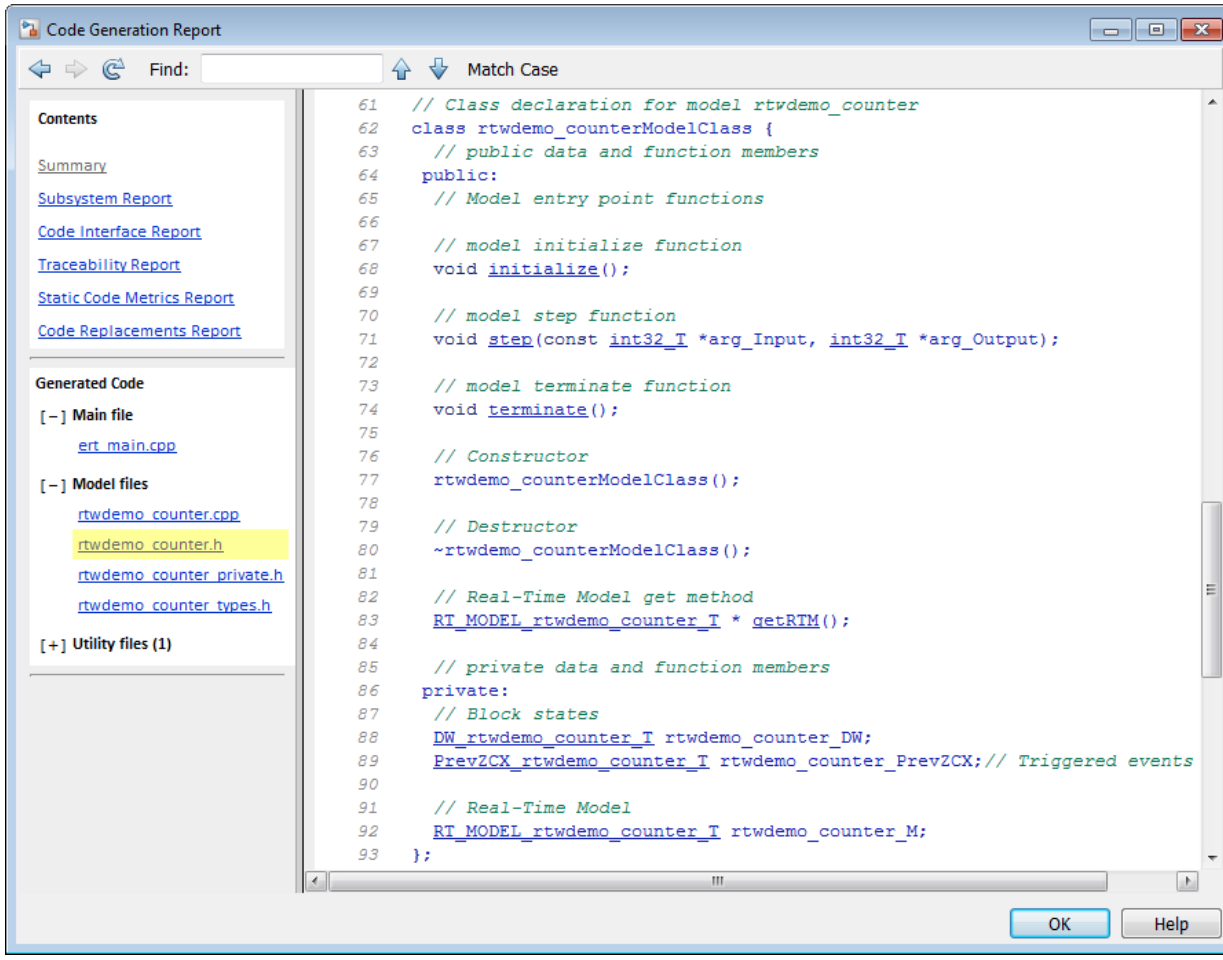
Now you can use the dialog box controls to configure I/O argument attributes. For example, in the **Configure C++ class interface** subpane, in the row for the `Input` argument, you can change the value of **Category** from `Value` to `Pointer` and change the value of **Qualifier** from `none` to `const *`. The preview updates to reflect your changes. Click the **Validate** button to validate the modified interface configuration.

Continue modifying and validating until you are satisfied with the step method configuration.



Click **Apply** and **OK**.

9 Generate code for the model. When the build completes, the code generation report for `rtwdemo_counter` appears. Examine the report and observe that required model data is encapsulated into C++ class attributes and model entry point functions are encapsulated into C++ class methods. For example, click the link for `rtwdemo_counter.h` to see the class declaration for the model.

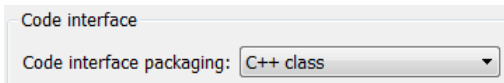


Note If you configured custom I/O arguments for the model step method (optional step 8), examine the generated code for the step method in `rtwdemo_counter.h` and `rtwdemo_counter.cpp`. The arguments should reflect your changes. For example, if you performed the `Input` argument modifications in step 8, the input argument should appear as `const int32_T *arg_Input`.

Customize C++ Class Interfaces Using Graphical Interfaces

Select C++ Class Code Interface Packaging

To select `C++ class` code interface packaging, in the Configuration Parameters dialog box, on the **Code Generation** pane, set the **Language** parameter to `C++`. Then, in the **Code Generation** > **Interface** pane, check that the **Code interface packaging** parameter is set to `C++ class`:

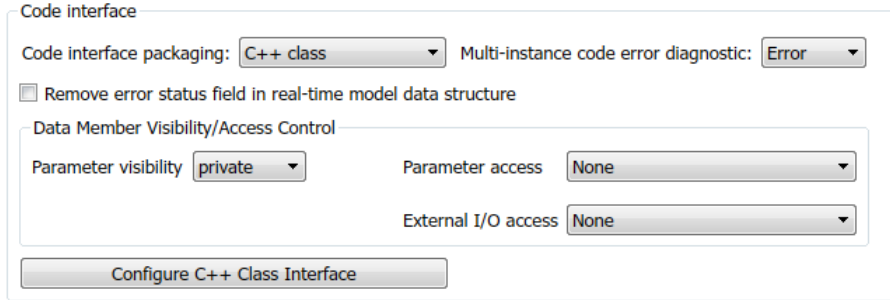


Selecting this value:

- Disables model configuration options that `C++ class` does not support. For details, see “C++ Class Interface Control Limitations” on page 39-61.
- Adds additional C++ class interface parameters, which are described in the next section.

Configure Code Interface Options

When you select `C++ class` code interface packaging for your model, the **Code interface** parameters shown below are displayed on the **Interface** pane.



- **Multi-instance code error diagnostic**

  Specifies the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.

  - `None` — Proceed with build without displaying a diagnostic message.
  - `Warning` — Proceed with build after displaying a warning message.
  - `Error` (default) — Abort build after displaying an error message.
- **Remove error status field in real-time model data structure**

  Specifies whether to omit the error status field from the generated real-time model data structure `rtModel` (off by default). Selecting this option reduces memory usage.

  Be aware that selecting this option can cause the code generator to omit the `rtModel` data structure from generated code.
- **Parameter visibility**

  Specifies whether to generate the block parameter structure as a `public`, `private`, or `protected` data member of the C++ model class (`private` by default).
- **Parameter access**

  Specifies whether to generate access methods for block parameters for the C++ model class (`None` by default). You can select noninlined access methods (`Method`) or inlined access methods (`Inlined method`).
- **External I/O access**

  Specifies whether to generate access methods for root-level I/O signals for the C++ model class (`None` by default). If you want to generate access methods, you have the following options:

  - Generate either noninlined or inlined access methods.
  - Generate either per-signal or structure-based access methods. That is, you can generate a series of set and get methods on a per-signal basis, or generate just one set method that takes the address of an external input structure as an argument and, for external outputs (if applicable), just one get method that returns a reference to an external output structure. The generated code for structure-based access methods has the following general form:

    ```
    class ModelClass {
    ...
    ```

```
    // Root inports set method
    void setExternalInputs(const ExternalInputs* pExternalInputs);

    // Root outports get method
    const ExternalOutputs & getExternalOutputs() const;
}
```

Note This parameter affects generated code only if you are using the default style step method for your model class; *not* if you are explicitly passing arguments for root-level I/O signals using an I/O arguments style step method. For more information, see “Passing Default Arguments” on page 39-47 and “Passing I/O Arguments” on page 39-49.

- **Configure C++ Class Interface**

  Opens the Configure C++ class interface dialog box, which allows you to configure the step method for your model class. For more information, see “Configure Step Method for Your Model Class” on page 39-46.

Interface parameters that are related, but are less commonly used, appear under **Advanced parameters**:

- **Terminate function required**

  Specifies whether to generate the *model*`_terminate` method (on by default). This function contains model termination code and should be called as part of system shutdown.

- **Combine signal/state structures**

  Specifies whether to combine global block signals and global state data into one data structure in the generated code (off by default). Selecting this option reduces RAM and improves readability of the generated code.

- **Internal data visibility**

  Specifies whether to generate internal data structures, such as Block I/O, DWork vectors, Runtime model, Zero-crossings, and continuous states, as `public`, `private`, or `protected` data members of the C++ model class (`private` by default).

- **Internal data access**

  Specifies whether to generate access methods for internal data structures, such as Block I/O, DWork vectors, Runtime model, Zero-crossings, and continuous states, for the C++ model class (`None` by default). You can select noninlined access methods (`Method`) or inlined access methods (`Inlined method`).

- **Generate destructor**

  Specifies whether to generate a destructor for the C++ model class (on by default).

- **Use dynamic memory allocation for model block instantiation** (Simulink Coder)

  For a model containing Model blocks, specifies whether generated code should use dynamic memory allocation, during model object registration, to instantiate objects for referenced models configured with a C++ class interface (off by default). If you select this option, during instantiation of an object for the top model in a model reference hierarchy, the generated code uses the operator `new` to instantiate objects for referenced models.

  Selecting this option frees a parent model from having to maintain information about referenced models beyond its direct children. Clearing this option means that a parent model maintains information about its referenced models, including its direct and indirect children.

  Note

  - If you select this option, be aware that a `bad_alloc` exception might be thrown, per the C++ standard, if an out-of-memory error occurs during the use of `new`. You must provide code to catch and process the `bad_alloc` exception in case an out-of-memory error occurs for a `new` call during construction of a top model object.
  - If **Use dynamic memory allocation for model block instantiation** is selected and the base model contains a Model block, the build process might generate copy constructor and assignment operator functions in the private section of the model class. The purpose of the functions is to prevent pointer members within the model class from being copied by other code. For more information, see “Model Class Copy Constructor and Assignment Operator” on page 39-60.

Configure Step Method for Your Model Class

To configure the step method for your model class, on the **Code Generation** > **Interface** pane, click the **Configure C++ Class Interface** button, which is available when you select `C++ class` code interface packaging for your model. This action opens the Configure C++ class interface dialog box, where you can configure the step method for your model class in either of two styles:

- “Passing Default Arguments” on page 39-47

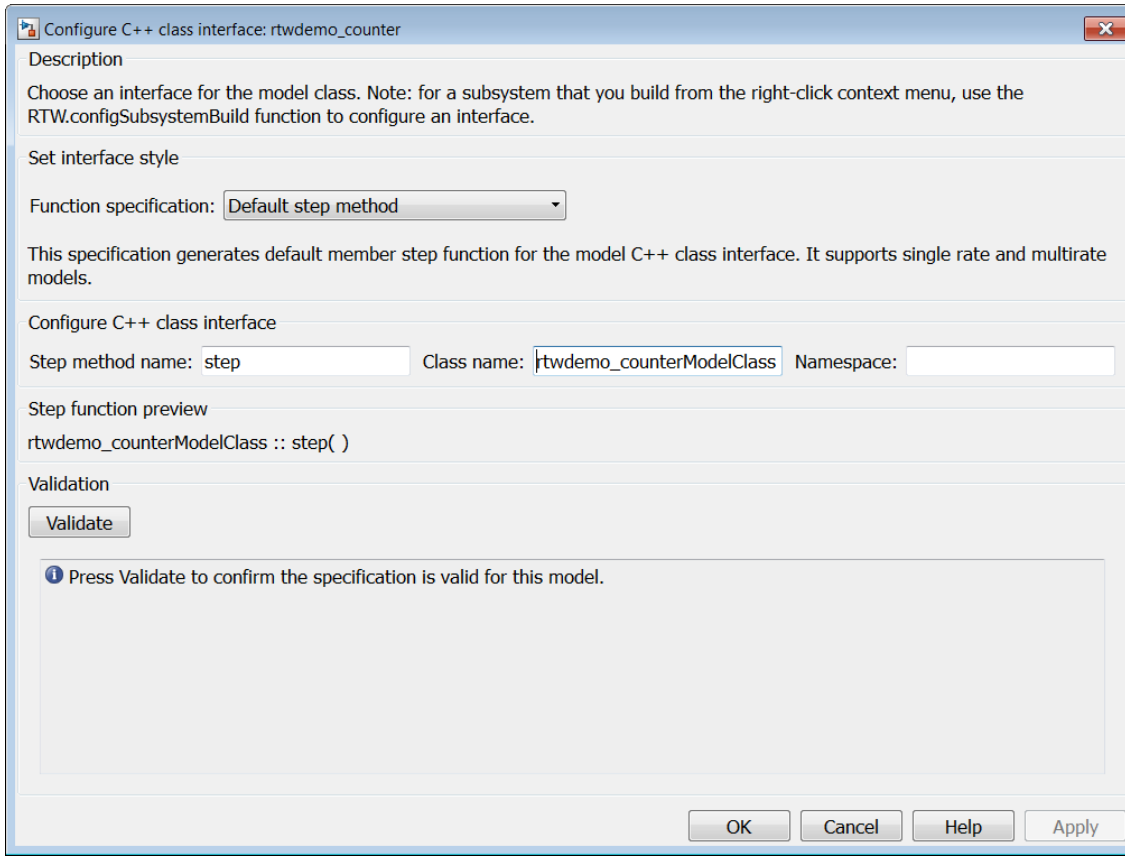
- “Passing I/O Arguments” on page 39-49

Note The `Default step method` supports single-rate models and multirate models. The model can be configured for single-tasking operation or multi-tasking operation. This method also supports virtual bus crossing boundaries.

The `I/O arguments step method` supports single-rate models and multirate models. The model can be configured for single-tasking operation.

Passing Default Arguments

The Configure C++ class interface dialog box initially displays a view for configuring a **Default step method** for the model class.



- **Step method name**

  Allows you to specify a step method name other than the default, `step`.
- **Class name**

  Allows you to specify a model class name other than the default, *`model`*`ModelClass`.
- **Namespace**

  Allows you to specify a namespace for the model class. If specified, the namespace is emitted in the generated code for the model class. The **Namespace** parameter provides a means of scoping C++ model classes. In a model reference hierarchy, you can specify a different namespace for each referenced model.

- **Step function preview**

  Displays a preview of the model step function prototype as currently configured. The preview display is dynamically updated after you validate your current configuration.

  Note The list of step function arguments has an entry for each of the model's root-level I/O ports. This list does not include model parameter arguments that can appear in the generated code when the model is used as a referenced model. For example, a model `sldemo_mdlref_counter_paramargs` has an inport with argument name `arg_input`, an outport with argument name `arg_output`, and a saturation block whose limits have workspace parameter argument names `lower_saturation_limit` and `upper_saturation_limit`.

  The step function preview for this model is:

  ```
  sldemo_mdlref_counter_paramargsModelClass :: step ( arg_input, * arg_output )
  ```

  The function prototype in the generated code differs from the preview. The prototype in the generated code (with the additional model parameter arguments) is:

  ```
  sldemo_mdlref_counter_paramargsModelClass::step (
     real_T arg_input,
     real_T *arg_output,
     real_T rtp_lower_saturation_limit,
     real_T rtp_upper_saturation_limit)
  ```

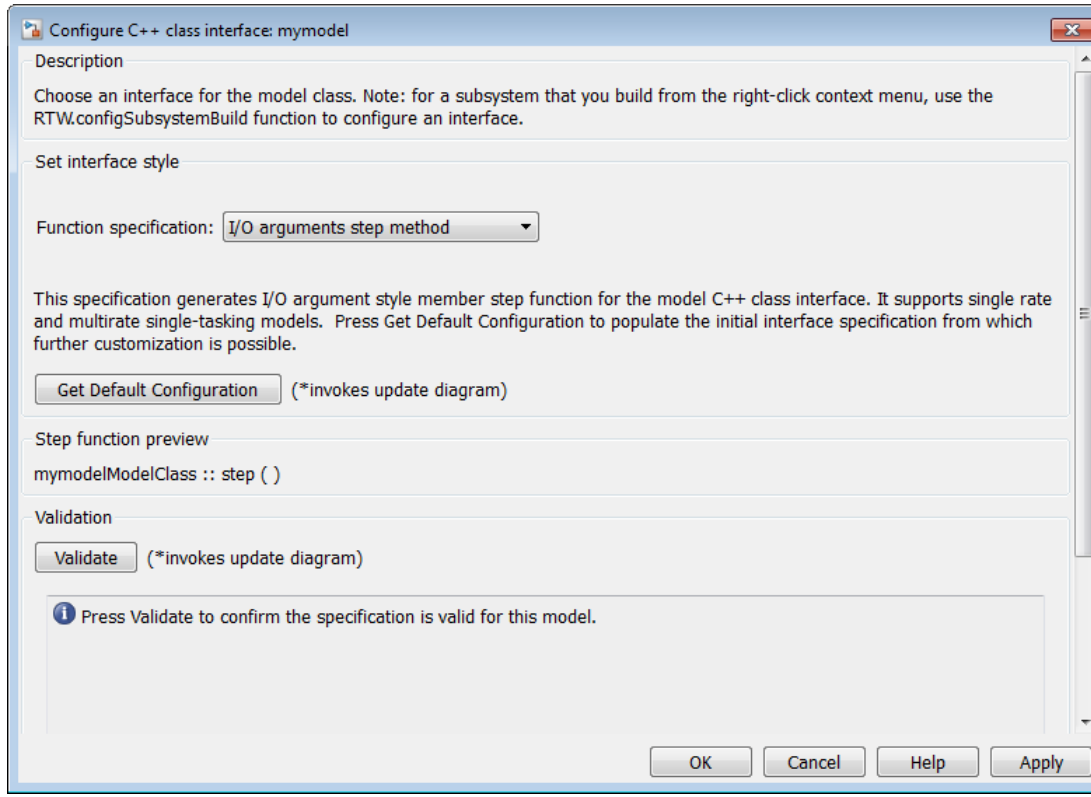
- **Validate**

  Validates your current model step function configuration. The **Validation** pane displays the status and an explanation of a failure.

Passing I/O Arguments

If you select `I/O arguments step method` from the **Function specification** menu, the dialog box displays a view for configuring an I/O arguments style step method for the model class.

Note To use the I/O arguments style step method, you must select the option **Remove root level I/O zero initialization** on the **Optimization** pane of the Configuration Parameters dialog box.



- **Get Default Configuration**

  Click this button to get the initial interface configuration that provides a starting point for further customization.

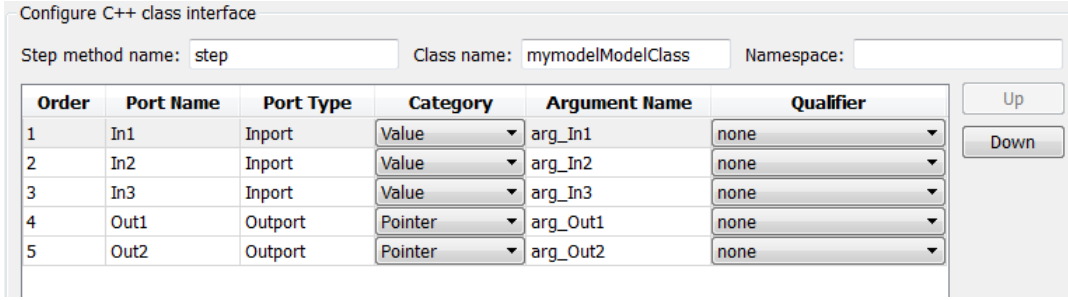
- **Step function preview**

  Displays a preview of the model step function prototype as currently configured. The preview dynamically updates as you make configuration changes.

- **Validate**

  Validates your current model step function configuration. The **Validation** pane displays the status and an explanation of a failure.

When you click **Get Default Configuration**, the **Configure C++ class interface** subpane appears in the dialog box, displaying the initial interface configuration. For example:



- **Step method name**

  Allows you to specify a step method name other than the default, `step`.

- **Class name**

  Allows you to specify a model class name other than the default, *`model`*`ModelClass`.

- **Namespace**

  Allows you to specify a namespace for the model class. If specified, the namespace is emitted in the generated code for the model class. The **Namespace** parameter provides a means of scoping C++ model classes. In a model reference hierarchy, you can specify a different namespace for each referenced model.

- **Order**

  Displays the numerical position of each argument. Use the **Up** and **Down** buttons to change argument order.

- **Port Name**

  Displays the port name of each argument (not configurable using this dialog box).

- **Port Type**

  Displays the port type, `Inport` or `Outport`, of each argument (not configurable using this dialog box).

- **Category**

Displays the passing mechanism for each argument. To change the passing mechanism for an argument, select `Value`, `Pointer`, or `Reference` from the argument's **Category** menu.

- **Argument Name**

  Displays the name of each argument. To change an argument name, click in the argument's **Argument name** field, position the cursor for text entry, and enter the new name.

- **Qualifier**

  Displays the `const` type qualifier for each argument. To change the qualifier for an argument, select an available value from the argument's **Qualifier** menu. The possible values are:

  - `none`
  - `const` (value)
  - `const*` (value referenced by the pointer)
  - `const*const` (value referenced by the pointer and the pointer itself)
  - `const &` (value referenced by the reference)

Tip When a model includes a referenced model, the `const` type qualifier for the root input argument of the referenced model's specified step function interface is set to `none` and the qualifier for the source signal in the referenced model's parent is set to a value other than `none`, code generation honors the referenced model's interface specification by generating a type cast that discards the `const` type qualifier from the source signal. To override this behavior, add a `const` type qualifier to the referenced model.

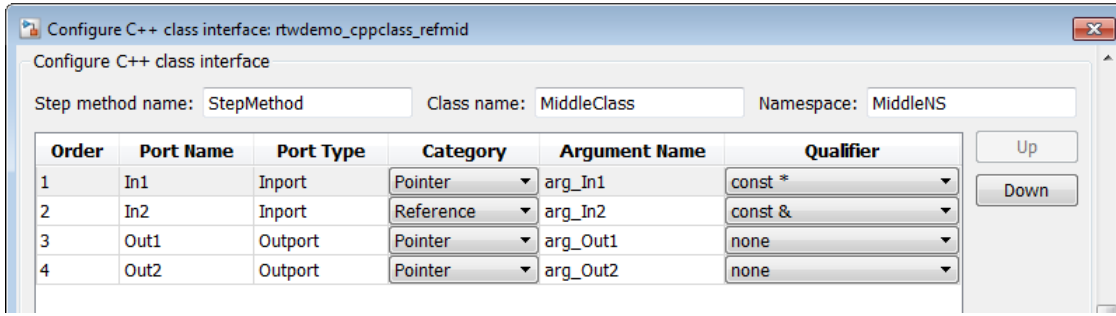
Use Namespaces to Scope C++ Model Classes

Embedded Coder provides namespace control for scoping model classes generated using C++ class code interface packaging. In the Configure C++ class interface dialog box, use the **Namespace** parameter to specify a namespace for a model class. If specified, the namespace is emitted in the generated code for the model class. To scope the C++ model classes in a model reference hierarchy, you can specify a different namespace for each referenced model.

For an example of namespace control, see the example model `rtwdemo_cppclass`. This model assigns namespaces as follows:

- `TopNS` for top-level model `rtwdemo_cppclass`
- `MiddleNS` for referenced model `rtwdemo_cppclass_refmid`
- `BottomNS` for referenced model `rtwdemo_cppclass_refbot`

If you build the model with its default settings, you can examine the generated header and source files for each model to see where the namespace is emitted. For example, the **Namespace** setting for the model `rtwdemo_cppclass_refmid` is shown below, followed by excerpts of the emitted namespace code in the model header and source files.



```
42   // Class declaration for model rtwdemo_cppclass_refmid
43   namespace MiddleNS {
44     class MiddleClass {
45       // public data and function members
46      public:
47       // Model entry point functions
...
52       // model step function
53       void StepMethod(const real_T *arg_In1, const real_T &arg_In2, real_T
54                       *arg_Out1, real_T *arg_Out2);
...
87     };
88   }
```

```
15   #include "rtwdemo_cppclass_refmid.h"
16   #include "rtwdemo_cppclass_refmid_private.h"
17
18   namespace MiddleNS
19   {
20     // Model step function
21     void MiddleClass::StepMethod(const real_T *arg_In1, const real_T &arg_In2,
22       real_T *arg_Out1, real_T *arg_Out2)
23     {
...
43     }
...
83   }
```

Configure C++ Class Interfaces for Nonvirtual Subsystems

You can configure C++ class interfaces for right-click builds of nonvirtual subsystems in Simulink models, if the following requirements are met:

- The model is configured for the `C++` language and `C++ class` code interface packaging.
- The subsystem is convertible to a Model block using the function `Simulink.SubSystem.convertToModelReference`. For referenced model conversion requirements, see the Simulink reference page `Simulink.SubSystem.convertToModelReference`.

To configure C++ class interfaces for a subsystem that meets the requirements:

1. Open the containing model and select the subsystem block.
2. Enter the following MATLAB command:

   ```
   RTW.configSubsystemBuild(gcb)
   ```

   where `gcb` is the Simulink function `gcb`, returning the full block path name of the current block.

   This command opens a subsystem equivalent of the Configure C++ class interface dialog sequence that is described in detail in the preceding section, “Configure Step Method for Your Model Class” on page 39-46. (For more information about using the MATLAB command, see `RTW.configSubsystemBuild`.)
3. Use the Configure C++ class interface dialog boxes to configure C++ class settings for the subsystem.
4. Right-click the subsystem and select **C/C++ Code** > **Build This Subsystem**.
5. When the subsystem build completes, you can examine the C++ class interfaces in the generated files and the HTML code generation report.

Customize C++ Class Interfaces Programmatically

If you select the **Code interface packaging** option `C++ class` for your model, you can use the C++ class interface control functions (listed in C++ Class Interface Control Functions) to programmatically configure the step method for your model class.

Typical uses of these functions include:

- **Create and validate a new step method interface, starting with default configuration information from your Simulink model**

  1. Create a model-specific C++ class interface with `obj = RTW.ModelCPPDefaultClass` or `obj = RTW.ModelCPPArgsClass`, where `obj` returns a handle to an newly created, empty C++ class interface.
  2. Attach the C++ class interface to your loaded ERT-based Simulink model using `attachToModel`.
  3. Get default C++ class interface configuration information from your model using `getDefaultConf`.
  4. Use the `Get` and `Set` functions listed in C++ Class Interface Control Functions to test or reset the model class name and model step method name. Additionally, if you are using the I/O arguments style step method, you can test and reset argument names, argument positions, argument categories, and argument type qualifiers.
  5. Validate the C++ class interface using `runValidation`. (If validation fails, use the error message information that`runValidation` returns to address the issues.)
  6. Save your model and then generate code using the `rtwbuild` function.

- **Modify and validate an existing step method interface for a Simulink model**

  1. Get the handle to an existing model-specific C++ class interface that is attached to your loaded ERT-based Simulink model using `obj = RTW.getClassInterfaceSpecification(modelName)`, where `modelName` is a character vector specifying the name of a loaded ERT-based Simulink model, and `obj` returns a handle to a C++ class interface attached to the specified model. If the model does not have an attached C++ class interface configuration, the function returns `[]`.
  2. Use the `Get` and `Set` functions listed in C++ Class Interface Control Functions to test or reset the model class name and model step method name. Additionally, if the returned interface uses the I/O arguments style step method, you can test and reset argument names, argument positions, argument categories, and argument type qualifiers.
  3. Validate the C++ class interface using `runValidation`. (If validation fails, use the error message information that `runValidation` returns to address the issues.)
  4. Save your model and then generate code using the `rtwbuild` function.

Note You should not use the same model-specific C++ class interface control object across multiple models. If you do, changes that you make to the step method configuration in one model propagate to other models, which is usually not desirable.

C++ Class Interface Control Functions

Function	Description
`attachToModel`	Attach model-specific C++ class interface to loaded ERT-based Simulink model
`getArgCategory`	Get argument category for Simulink model port from model-specific C++ class interface
`getArgName`	Get argument name for Simulink model port from model-specific C++ class interface
`getArgPosition`	Get argument position for Simulink model port from model-specific C++ class interface
`getArgQualifier`	Get argument type qualifier for Simulink model port from model-specific C++ class interface
`getClassName`	Get class name from model-specific C++ class interface
`getDefaultConf`	Get default configuration information for model-specific C++ class interface from Simulink model to which it is attached
`getNamespace`	Get namespace from model-specific C++ class interface
`getNumArgs`	Get number of step method arguments from model-specific C++ class interface
`getStepMethodName`	Get step method name from model-specific C++ class interface
`RTW.configSubsystemBuild`	Open GUI to configure C function prototype or C++ class interface for right-click build of specified subsystem
`RTW.getClass-InterfaceSpecification`	Get handle to model-specific C++ class interface control object
`runValidation`	Validate model-specific C++ class interface against Simulink model to which it is attached
`setArgCategory`	Set argument category for Simulink model port in model-specific C++ class interface
`setArgName`	Set argument name for Simulink model port in model-specific C++ class interface
`setArgPosition`	Set argument position for Simulink model port in model-specific C++ class interface

Function	Description
`setArgQualifier`	Set argument type qualifier for Simulink model port in model-specific C++ class interface
`setClassName`	Set class name in model-specific C++ class interface
`setNamespace`	Set namespace in model-specific C++ class interface
`setStepMethodName`	Set step method name in model-specific C++ class interface

Configure Step Method for Model Class

The following sample MATLAB script configures the step method for the `rtwdemo_counter` model class, using the C++ Class Interface Control Functions.

```
%% Open the rtwdemo_counter model
rtwdemo_counter

%% Select ert.tlc as the System Target File for the model
set_param(gcs,'SystemTargetFile','ert.tlc')

%% Select C++ as the target language for the model
set_param(gcs,'TargetLang','C++')

%% Select C++ class as the code interface packaging for the model
set_param(gcs,'CodeInterfacePackaging','C++ class')

%% Set required option for I/O arguments style step method (cmd off = GUI on)
set_param(gcs,'ZeroExternalMemoryAtStartup','off')

%% Create a C++ class interface using an I/O arguments style step method
a=RTW.ModelCPPArgsClass

%% Attach the C++ class interface to the model
attachToModel(a,gcs)

%% Get the default C++ class interface configuration from the model
getDefaultConf(a)

%% Move the Output port argument from position 2 to position 1
setArgPosition(a,'Output',1)

%% Reset the model step method name from step to StepMethod
setStepMethodName(a,'StepMethod')

%% Change the Input port argument name, category, and qualifier
setArgName(a,'Input','inputArg')
setArgCategory(a,'Input','Pointer')
setArgQualifier(a,'Input','const *')

%% Validate the function prototype against the model
[status,message]=runValidation(a)
```

```
%% if validation succeeded, generate code and build
if status
    rtwbuild(gcs)
end
```

Specify Custom Storage Class for C++ Class Code Generation

To configure a Simulink parameter, signal, or state to use a custom storage class (CSC) with C++ class code generation:

1. Open an ERT-based model for which **Language** is set to `C++` and **Code interface packaging** is set to `C++ class`.
2. Open the Configuration Parameters dialog box.
3. On the **Code Generation > Interface** pane, set the **Multi-instance code error diagnostic** (Simulink Coder) parameter to a value other than `Error`.

4. If the option **Configuration Parameters > Ignore custom storage classes** is selected, clear it.

   Apply the changes.
5. In the model, select a custom storage class for a parameter, signal, or state. For example, select a signal, open its Properties dialog box, and view its code generation options. In the **Storage class** drop-down list, select a custom storage class, and then configure its attributes. Apply the changes.

   Note C++ class code generation does not support the following CSCs:

   - CSCs with `Volatile` specifications.
   - CSCs of type `Other`, except `GetSet`.

   ---
6. Build the model.
7. In the code generation report, examine the files *`model`*`.h` and *`model`*`.cpp` to observe the use of CSCs in the generated C++ code.

Model Class Copy Constructor and Assignment Operator

Code generation automatically adds a copy constructor and an assignment operator to C++ class declarations when required to securely handle pointer members. The constructor and operator are added as private member functions when both of the following conditions exist:

- The model option **Use dynamic memory allocation for model block instantiation** (Simulink Coder) is set to `on`.
- The base model contains a Model block. The Model block is not directly or indirectly within a subsystem for which **Function packaging** is set to `Reusable function`.

Under these conditions, the software generates a private copy constructor and assignment operator to prevent pointer members within the model class from being copied by other code.

Note To prevent generation of these functions, consider clearing the option **Use dynamic memory allocation for model block instantiation**.

The code excerpt below shows generated *`model`*`.h` code for a model class that has a pointer member. (Look for instances of `MiddleClass_ptr`). The copy constructor and assignment operator declarations are shown in **bold**.

```
class MiddleClass;    // class forward declaration for <S1>/Bottom model instance
typedef MiddleClass* MiddleClass_ptr;
...

// Class declaration for model cppclass_top
class Top {
...
  // private data and function members
 private:
  // Block signals
  BlockIO_cppclass_top cppclass_top_B;

  // Block states
  D_Work_cppclass_top cppclass_top_DWork;

  // Real-Time Model
  RT_MODEL_cppclass_top cppclass_top_M;

  // private member function(s) for subsystem '<Root>/Subsystem'
  void cppclass_top_Subsystem_Init();
  void cppclass_top_Subsystem_Start();
  void cppclass_top_Subsystem();
```

```
  //Copy Constructor
  Top(const Top &rhs);

  //Assignment Operator
  Top& operator= (const Top &rhs);

  // model instance variable for '<S1>/Bottom model instance'
  MiddleClass_ptr Bottom_model_instanceMDLOBJ1;
};
```

C++ Class Interface Control Limitations

- If a model has a custom model step function for which a scalar output is passed by value and is updated in a conditionally executed context, configure the output to be passed by pointer. In the model C++ class interface configuration dialog box, set **Category** to `Pointer`. Examples of a conditionally executed context include:
  - Output has a slower sample time than the fundamental rate of the model when the model is used as a referenced model.
  - Output is written to in a conditionally executed subsystem.
  - Output is written to by an S-function that might conditionally update the output.
  - Output is written to by a Hit Crossing block.
  - Output is written to by a Rate Transition block.
- The `C++ class` code interface packaging option does not support some Simulink model configuration options. Selecting `C++ class` disables the following items in the Configuration Parameters dialog box:
  - **Identifier format control** subpane on the **Symbols** pane
  - **File customization template** parameter on the **Templates** pane

  ---

  Note The code and data templates on the **Templates** pane are supported for `C++ class` code generation. However, the following template file features that are supported for other language selections are not supported for C++ class generated code:

  - Free-form text outside template sections
  - Custom tokens
  - TLC commands (<! > tokens)

  - **Global data placement (custom storage classes only)** subpane on the **Code Placement** pane

  Selecting `C++ class` also disables the Code Mapping Editor (see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7). You cannot apply default storage classes, memory sections, or function templates to the model.
- Among the data exchange interfaces available on the **Interface** pane of the Configuration Parameters dialog box, only the C API interface is supported for `C++ class` code generation. If you select **External mode** or **ASAP2 interface**, code generation fails with a validation error.
- The I/O arguments style of step method specification supports single-rate models and multirate single-tasking models, but not multirate multitasking models.
- If you have a Stateflow license, for a Stateflow chart that resides in a root model configured to use the `I/O arguments step method` function specification, and that uses a model root inport value or calls a subsystem that uses a model root inport value, you must do one of the following to generate code:
  - Clear the **Execute (enter) Chart At Initialization** check box in the Stateflow chart.
  - Insert a Simulink Signal Conversion block immediately after the root inport. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- If a model root inport value connects to a Simscape conversion block, you must insert a Simulink Signal Conversion block between the root inport and the Simscape conversion block. In the Signal Conversion block parameters dialog box, select **Exclude this block from 'Block reduction' optimization**.
- When building a referenced model that is configured to generate a C++ class interface:
  - Do not use a C++ class interface in cases when a referenced model cannot have a combined output/update function. Cases include a model that has a continuous sample time or saves states.
  - Do not use virtual buses as inputs or outputs to the referenced model when the referenced model uses the I/O arguments step method. When bus signals cross referenced model boundaries, either use nonvirtual buses or use the Default step method.
- If the C++ encapsulation interface is not the default, the value is ignored for the **Configuration Parameters > Model Referencing > Pass fixed-size scalar root**

inputs by value for code generation parameter. For more information, see “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

Generate Modular Function Code for Nonvirtual Subsystems

The Embedded Coder software provides a Subsystem Parameters dialog box option, **Function with separate data**, that allows you to generate modular function code for nonvirtual subsystems, including atomic subsystems and conditionally executed subsystems.

By default, the generated code for a nonvirtual subsystem does not separate a subsystem's internal data from the data of its parent Simulink model. This can make it difficult to trace and test the code, particularly for nonreusable subsystems. Also, in large models containing nonvirtual subsystems, data structures can become large and potentially difficult to compile.

About Nonvirtual Subsystem Code Generation

Function with separate data allows you to generate subsystem function code in which the internal data for a nonvirtual subsystem is separated from its parent model and is owned by the subsystem. The subsystem data structure is declared independently from the parent model data structures. A subsystem with separate data has its own block I/O and `DWork` data structure. As a result, the generated code for the subsystem is easier to trace and test. The data separation also tends to reduce the maximum size of global data structures throughout the model, because they are split into multiple data structures.

To use the **Function with separate data** parameter,

- Your model must use an ERT-based system target file (requires a Embedded Coder license).
- Your subsystem must be configured to be atomic or conditionally executed. For more information, see “Systems and Subsystems” (Simulink).
- Your subsystem must use the `Nonreusable function` setting for **Code Generation > Function packaging**.

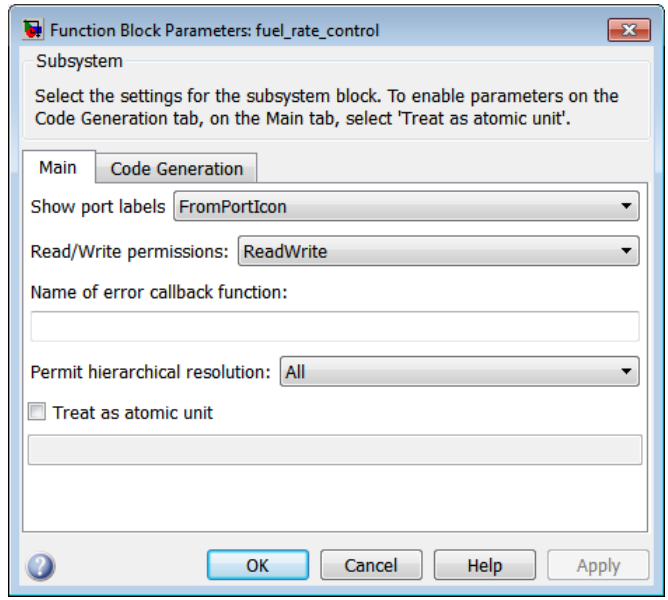
To configure your subsystem for generating modular function code, you invoke the Subsystem Parameters dialog box and make a series of selections to display and enable the **Function with separate data** option. See “Configure Subsystem for Generating Modular Function Code” on page 39-65 and “Modular Function Code for Nonvirtual Subsystems” on page 39-69 for details. For limitations that apply, see “Nonvirtual Subsystem Modular Function Code Limitations” on page 39-85.

For more information about generating code for atomic subsystems, see the sections “Control Generation of Functions for Subsystems” (Simulink Coder) and “Generate Code and Executables for Individual Subsystems” (Simulink Coder).

Configure Subsystem for Generating Modular Function Code

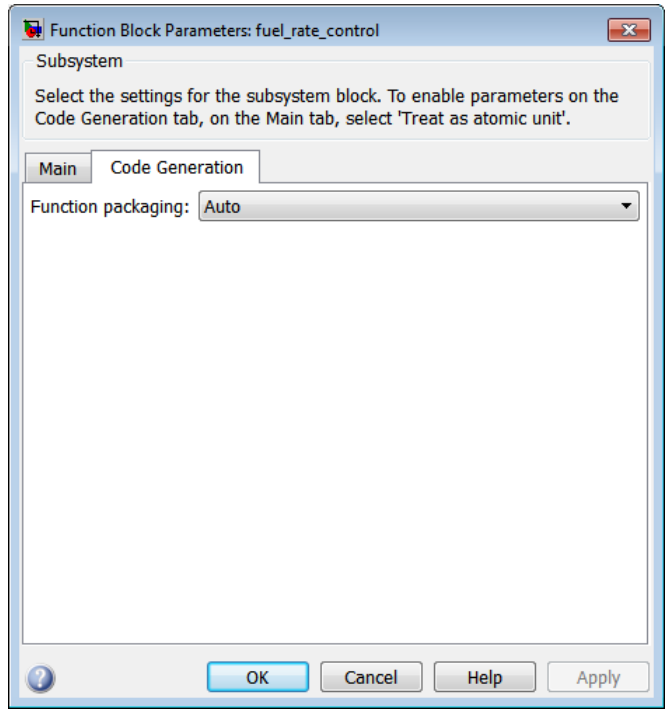
This section summarizes the steps to configure a nonvirtual subsystem in a Simulink model for modular function code generation.

1. Verify that the Simulink model containing the subsystem uses an ERT-based system target file (see the **System target file** parameter on the **Code Generation** pane of the Configuration Parameters dialog box).
2. In your Simulink model, select the subsystem for which you want to generate modular function code and open the Subsystem Parameters dialog box (for example, right-click the subsystem and select **Block Parameters (Subsystem)**). The dialog box for an atomic subsystem is shown below. (In the dialog box for a conditionally executed subsystem, the dialog box option **Treat as atomic unit** is greyed out, and you can skip Step 3.)

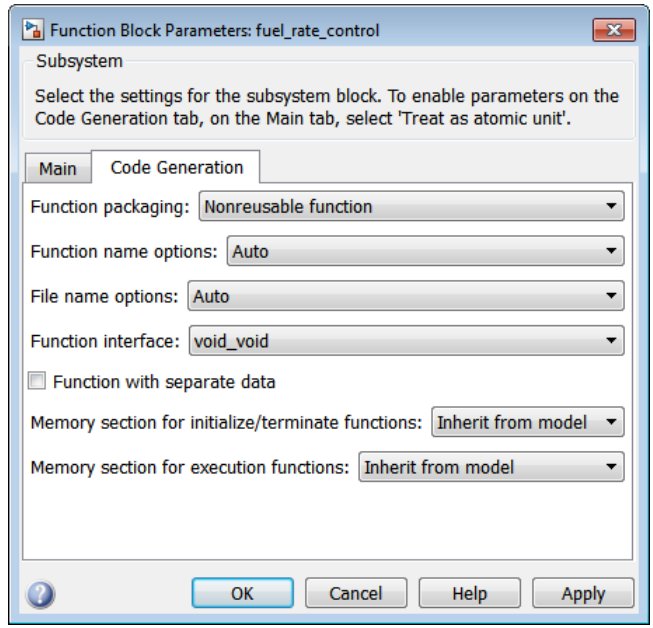


3. If the Subsystem Parameters dialog box option **Treat as atomic unit** is available for selection but not selected, the subsystem is neither atomic nor conditionally

executed. Select the option **Treat as atomic unit**, which enables **Function packaging** on the **Code Generation** tab. Select the **Code Generation** tab.

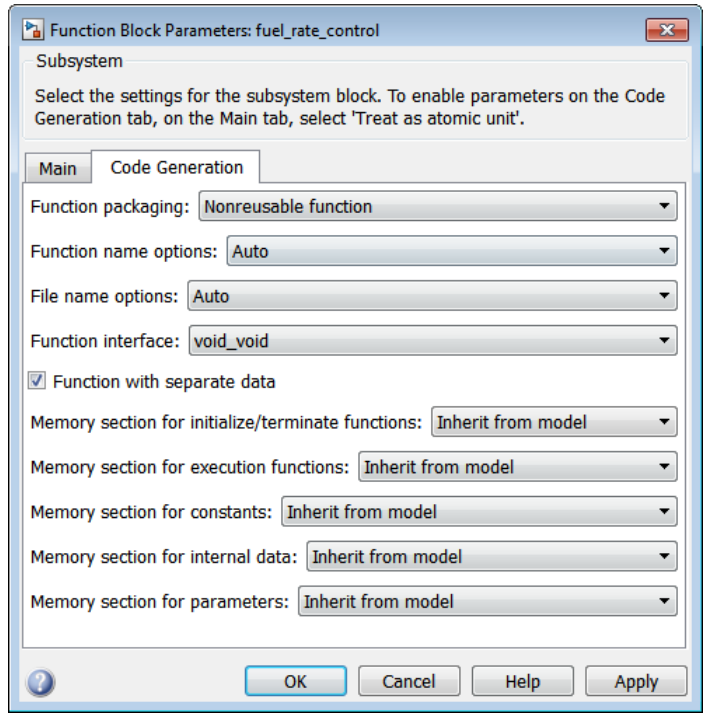


4 For the **Function packaging** parameter, select the value `Nonreusable function`. After you make this selection, the **Function with separate data** option is displayed.



Note Before you generate nonvirtual subsystem function code with the **Function with separate data** option selected, you might want to generate function code with the option *deselected* and save the generated function `.c` and `.h` files in a separate directory for later comparison.

5 Select the **Function with separate data** option. After you make this selection, additional configuration parameters are displayed.



Note To control the naming of the subsystem function and the subsystem files in the generated code, you can modify the subsystem parameters **Function name options** and **File name options**.

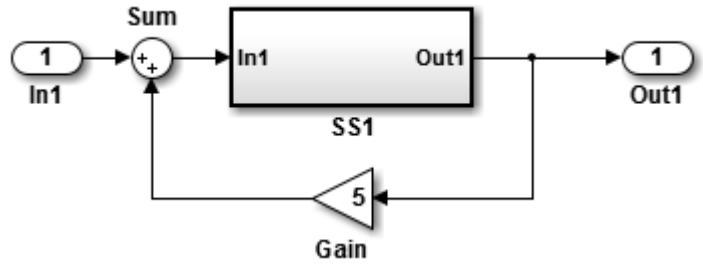
6 To save your subsystem parameter settings and exit the dialog box, click **OK**.

This completes the subsystem configuration for generating modular function code. You can now generate the code for the subsystem and examine the generated files, including the function `.c` and `.h` files named according to your subsystem parameter specifications. For more information on generating code for nonvirtual subsystems, see “Control Generation of Functions for Subsystems” (Simulink Coder). For examples of generated subsystem function code, see “Modular Function Code for Nonvirtual Subsystems” on page 39-69.

Modular Function Code for Nonvirtual Subsystems

To illustrate the selection of the **Function with separate data** option for a nonvirtual subsystem, the following procedure generates atomic subsystem function code with and without the option selected and compares the results.

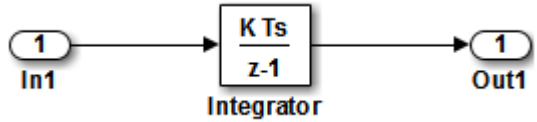
1 Open MATLAB and open the model `rtwdemo_atomic` using the MATLAB command `rtwdemo_atomic`.



Examine the Simulink model. This model shows how to preserve the boundary of a virtual subsystem. By selecting the Subsystem Parameters option **Treat as atomic unit**, you guarantee that the code for that subsystem executes as an atomic unit. When a system is marked as atomic, you can specify how the subsystem is represented in code with the Subsystem Parameters option **Code Generation Function Packaging**. You can specify that the subsystem is translated to one of these types of implementation:

- `Inline`: Inline the subsystem code at the call sites
- `Function`: A void/void function with I/O and internal data in global data structure
- `Reusable Function`: A reentrant function with data passed in as part of function arguments
- `Auto`: Let the code generator optimize the implementation based on context

2 Double-click the SS1 subsystem and examine the contents.



Close the subsystem window when you are finished.

3. Right-click the SS1 subsystem, select Block Parameters (Subsystem) from the context menu, and examine the settings. Simulink and the code generator can avoid "artificial" algebraic loops when the subsystem is made atomic with the subsystem option **Minimize algebraic loop occurrences**.

   Close the Block Parameters dialog box when you are finished.

4. Change the **System target file** for the mode from `grt.tlc` to `ert.tlc`. Select the **Configuration Parameters** > **Code Generation** tab and specify `ert.tlc` for the **System target file** parameter. Click **OK** twice to confirm the change. Using the ERT target provides more code generation options for the atomic subsystem.

5. Create a variant of `rtwdemo_atomic` that illustrates function code *without* data separation.

   a. In the `rtwdemo_atomic` model, right-click the SS1 subsystem and select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box that appears, verify that

      - On the **Main** tab, **Treat as atomic unit** is selected
      - On the **Code Generation** tab, `User specified` is selected for **Function name options**
      - On the **Code Generation** tab, `myfun` is specified for **Function name**

   b. In the Subsystem Parameters dialog box, on the **Code Generation** tab verify that

      i. `Nonreusable function` is selected for the **Function packaging** parameter. After this selection, additional parameters and options appear.

      ii. `Use function name` is selected for the **File name options** parameter. This selection is optional but simplifies the later task of code comparison by causing the atomic subsystem function code to be generated into the files `myfun.c` and `myfun.h`.

      Do *not* select the option **Function with separate data**. Click **Apply** to apply the changes and click **OK** to exit the dialog box.

   c. Save this model variant to a personal work directory, for example, `rtwdemo_atomic1` in `d:/atomic`.

6. Create a variant of `rtwdemo_atomic` that illustrates function code *with* data separation.

a. In the `rtwdemo_atomic1` model (or `rtwdemo_atomic` with step 3 reapplied), right-click the SS1 subsystem and select **Block Parameters (Subsystem)**. In the Subsystem Parameters dialog box, verify that

   - On the **Main** tab, **Treat as atomic unit** is selected
   - On the **Code Generation** tab, `Function` is selected for **Function packaging**
   - On the **Code Generation** tab, `User specified` is selected for **Function name options**
   - On the **Code Generation** tab, `myfun` is specified for **Function name**
   - On the **Code Generation** tab, `Use function name` is specified for **File name options**

b. In the Subsystem Parameters dialog box, on the **Code Generation** tab, select the option **Function with separate data**. Click **Apply** to apply the change and click **OK** to exit the dialog box.

c. Save this model variant, using a different name than the first variant, to a personal work directory, for example, `rtwdemo_atomic2` in `d:/atomic`.

7. Generate code for each model, `rtwdemo_atomic1` and `rtwdemo_atomic2`.

8. In the generated code directories, compare the *`model`*`.c/.h` and `myfun.c/.h` files generated for the two models. For code comparison discussion, see “H File Differences for Nonvirtual Subsystem Function Data Separation” on page 39-71 and “H File Differences for Nonvirtual Subsystem Function Data Separation” on page 39-71“C File Differences for Nonvirtual Subsystem Function Data Separation” on page 39-72.

   In this example, there are not significant differences in the generated variants of `ert_main.c`, *`model`*`_private.h`, *`model`*`_types.h`, or `rtwtypes.h`.

H File Differences for Nonvirtual Subsystem Function Data Separation

The differences between the H files generated for `rtwdemo_atomic1` and `rtwdemo_atomic2` help illustrate the selection of the **Function with separate data** option for nonvirtual subsystems.

1. Selecting **Function with separate data** causes `typedefs` for subsystem data to be generated in the `myfun.h` file for `rtwdemo_atomic2`:

```
/* Block signals for system '<Root>/SS1' */
typedef struct {
```

```
  real_T Integrator;                   /* '<S1>/Integrator' */
} rtB_myfun;

/* Block states (auto storage) for system '<Root>/SS1' */
typedef struct {
  real_T Integrator_DSTATE;            /* '<S1>/Integrator' */
} rtDW_myfun;
```

By contrast, for `rtwdemo_atomic1`, `typedef`s for subsystem data belong to the model and appear in `rtwdemo_atomic1.h`:

```
/* Block signals (auto storage) */
typedef struct {
...
    real_T Integrator;                 /* '<S1>/Integrator' */
} BlockIO_rtwdemo_atomic1;

/* Block states (auto storage) for system '<Root>' */
typedef struct {
  real_T Integrator_DSTATE;            /* '<S1>/Integrator' */
} D_Work_rtwdemo_atomic1;
```

2 Selecting **Function with separate data** generates the following external declarations in the `myfun.h` file for `rtwdemo_atomic2`:

```
/* Extern declarations of internal data for 'system '<Root>/SS1'' */
extern rtB_myfun rtwdemo_atomic2_myfunB;

extern rtDW_myfun rtwdemo_atomic2_myfunDW;

extern void myfun_initialize(void);
```

By contrast, the generated code for `rtwdemo_atomic1` contains model-level external declarations for the subsystem's `BlockIO` and `D_Work` data, in `rtwdemo_atomic1.h`:

```
/* Block signals (auto storage) */
extern BlockIO_rtwdemo_atomic1 rtwdemo_atomic1_B;

/* Block states (auto storage) */
extern D_Work_rtwdemo_atomic1 rtwdemo_atomic1_DWork;
```

C File Differences for Nonvirtual Subsystem Function Data Separation

The differences between the C files generated for `rtwdemo_atomic1` and `rtwdemo_atomic2` illustrate the selection of the **Function with separate data** option for nonvirtual subsystems.

1 Selecting **Function with separate data** causes a separate subsystem initialize function, `myfun_initialize`, to be generated in the `myfun.c` file for `rtwdemo_atomic2`:

```
void myfun_initialize(void) {
  {
    ((real_T*)&rtwdemo_atomic2_myfunB.Integrator)[0] = 0.0;
  }
  rtwdemo_atomic2_myfunDW.Integrator_DSTATE = 0.0;
}
```

The subsystem initialize function in `myfun.c` is invoked by the model initialize function in `rtwdemo_atomic2.c`:

```
/* Model initialize function */

void rtwdemo_atomic2_initialize(void)
{
...

  /* Initialize subsystem data */
  myfun_initialize();
}
```

By contrast, for `rtwdemo_atomic1`, subsystem data is initialized by the model initialize function in `rtwdemo_atomic1.c`:

```
/* Model initialize function */

void rtwdemo_atomic1_initialize(void)
{
...
  /* block I/O */
  {
 ...
    ((real_T*)&rtwdemo_atomic1_B.Integrator)[0] = 0.0;
  }

  /* states (dwork) */

  rtwdemo_atomic1_DWork.Integrator_DSTATE = 0.0;
...
}
```

2. Selecting **Function with separate data** generates the following declarations in the `myfun.c` file for `rtwdemo_atomic2`:

   ```
   /* Declare variables for internal data of system '<Root>/SS1' */
   rtB_myfun rtwdemo_atomic2_myfunB;

   rtDW_myfun rtwdemo_atomic2_myfunDW;
   ```

   By contrast, the generated code for `rtwdemo_atomic1` contains model-level declarations for the subsystem's `BlockIO` and `D_Work` data, in `rtwdemo_atomic1.c`:

   ```
   /* Block signals (auto storage) */
   BlockIO_rtwdemo_atomic1 rtwdemo_atomic1_B;

   /* Block states (auto storage) */
   D_Work_rtwdemo_atomic1 rtwdemo_atomic1_DWork;
   ```

3. Selecting **Function with separate data** generates identifier naming that reflects the subsystem orientation of data items. Notice the references to subsystem data in subsystem functions such as `myfun` and `myfun_update` or in the model's *`model`*`_step` function. For example, compare this code from `myfun` for `rtwdemo_atomic2`

   ```
   /* DiscreteIntegrator: '<S1>/Integrator' */
   rtwdemo_atomic2_myfunB.Integrator = rtwdemo_atomic2_myfunDW.Integrator_DSTATE;
   ```

   to the corresponding code from `myfun` for `rtwdemo_atomic1`.

   ```
   /* DiscreteIntegrator: '<S1>/Integrator' */
   rtwdemo_atomic1_B.Integrator = rtwdemo_atomic1_DWork.Integrator_DSTATE;
   ```

Partition Functions in Generated Code

Associate subsystems in a model with function names and files.

Learn how to:

- Specify function and file names in the generated code.
- Identify the parts of the generated code that are required for integration.
- Generate code for atomic subsystems.
- Identify data that are required to execute a generated function.

For information about the example model and other examples in this series, see "Generate C Code from a Control Algorithm for an Embedded System".

Atomic and Virtual Subsystems

The example models in "Generate C Code from a Control Algorithm for an Embedded System" and "Configure Data Interface in the Generated Code" use *virtual subsystems*. Virtual subsystems visually organize blocks but do not affect the model functionality *Atomic subsystems* evaluate all of the included blocks as a unit. With atomic subsystems, you can specify additional function partitioning information. In a model, atomic subsystems appear with a bold border.

View Changes in Model Architecture

Open the example model, `rtwdemo_PCG_Eval_P3`.

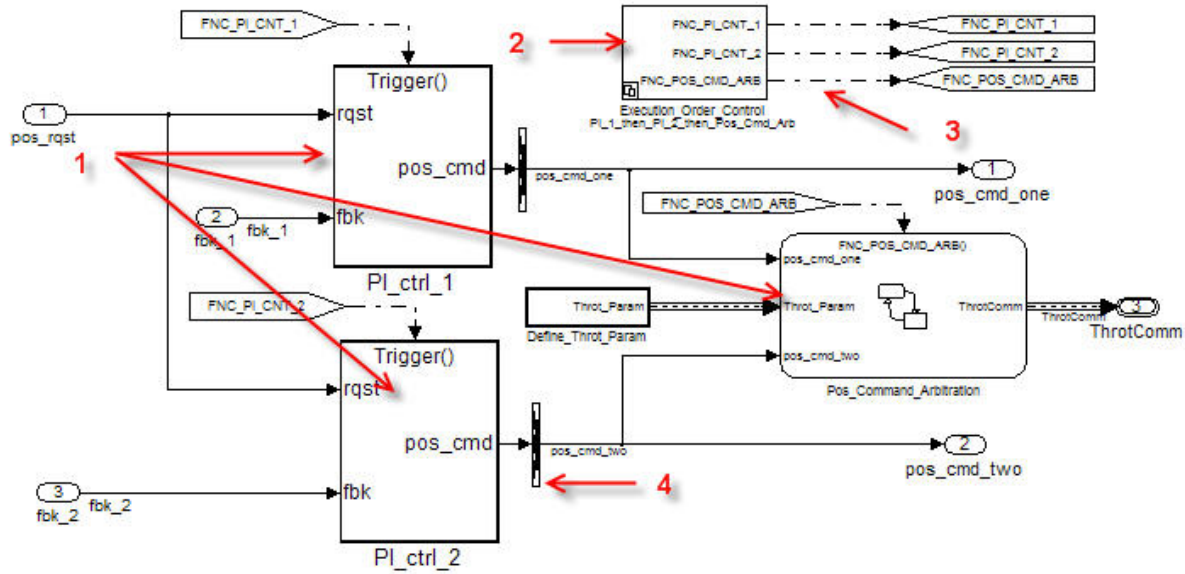
Save a copy of the model to your current folder.

This example shows how to replace the virtual subsystems with *function call subsystems*. Function call subsystems:

- Are atomic subsystems
- Enable you to control subsystem execution order
- Execute when a *function call signal* triggers

By controlling the execution order of the subsystems, you can match the model with an existing system that has a specific execution order.

The figure identifies the function call subsystems (1) `PI_ctrl_1`, `PI_ctrl_2`, and `Pos_Command_Arbitration`.



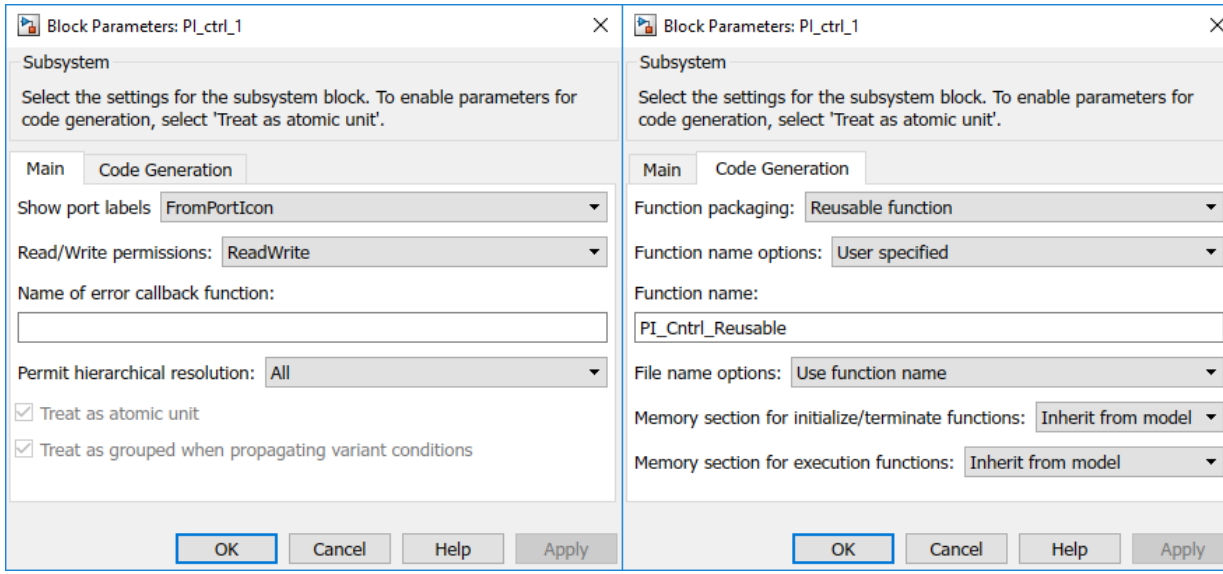
This version of the model contains the new subsystem `Execution_Order_Control` (2), which contains a Stateflow® chart that models the calling functionality of a scheduler. The subsystem controls the execution order of the function call subsystems through function call signals (3). Later in this example, you examine how changing the execution order can change the simulation results.

This version of the model contains new Signal Conversion blocks (4) at the outputs of the PI controllers. With these additional blocks in place, the code generator can generate a single reentrant function for the PI controllers.

Control Function Location and File Placement in the Generated Code

In “Generate C Code from a Control Algorithm for an Embedded System” and “Configure Data Interface in the Generated Code”, the code generator creates a single *`model`*`_step` function that contains the control algorithm code. However, many applications require a greater level of control over the file placement of functions. By modifying the parameters of atomic subsystems, you can specify multiple functions within a single model.

The figure shows the subsystem parameters for `PI_ctrl_1`.



Treat as atomic unit

- Enables other submenus. For atomic subsystems, this parameter is automatically selected and disabled.

Sample time

- Specifies a sample time for execution. Not available for function-call subsystems.

Function packaging options

- **Auto** -- Determines how the subsystem appears in the generated code. This value is the default.
- **Inline** -- Places the subsystem code inline with the rest of the model code.
- **Function** -- Generates the code for the subsystem as a function.
- **Reusable function** -- Generates a reusable (reentrant) function from the subsystem. The function passes all input and output data through formal parameters. The function does not directly access global variables.

Function name options

- Selecting **Function** or **Reusable function** for **Function packaging** enables function name options.
- **Auto** -- Determines the function.
- **Use subsystem name** -- Bases the function on the subsystem name.
- **User specified** -- Applies the specified file name.

File name options

- Selecting **Function** or **Reusable function** for **Function packaging** enables file name options.
- **Auto** -- Places the function definition in the module generated for the parent system, or, if the model root is the parent, in `model.c`.
- **Use subsystem name** -- Generates a separate file. The name of the file is the name of the subsystem or library block.
- **Use function name** -- Generates a separate file. The name of the file is the name that you specify with **Function name options**.
- **User specified** -- Applies the specified, unique file name.

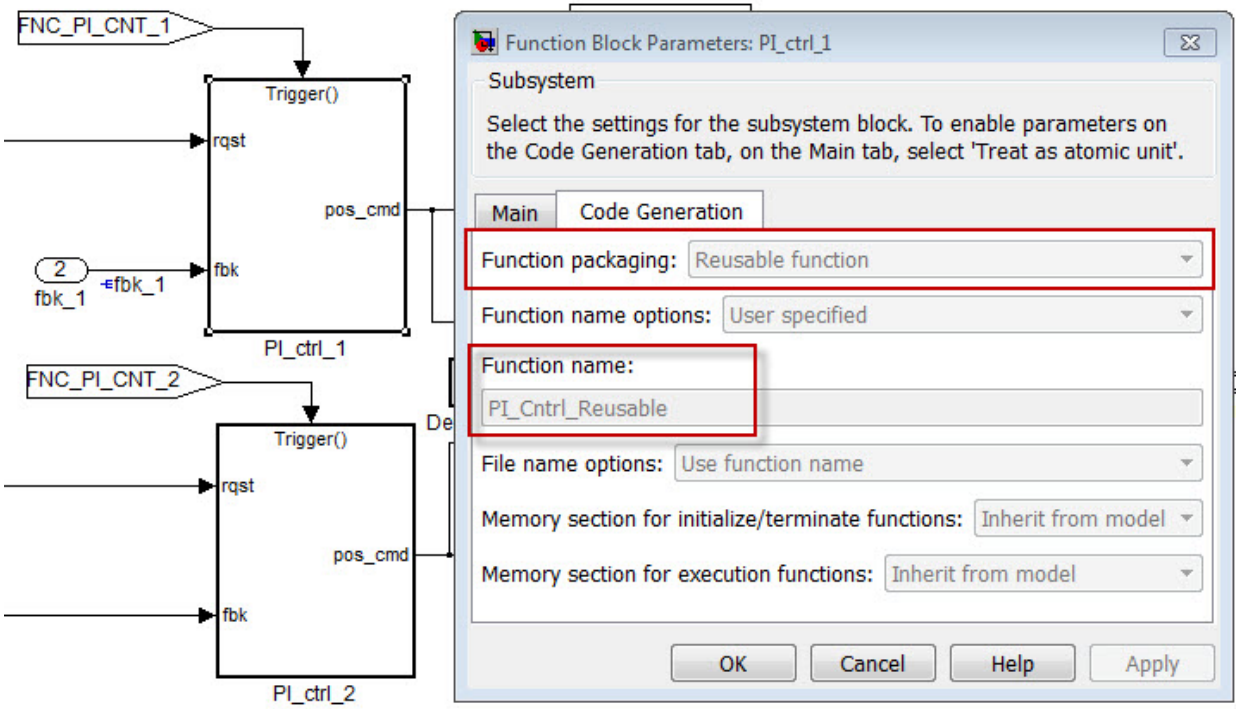
Function with separate data

- Enabled when you set **Function packaging** to **Function**. When selected, the code generator separates the internal data of the subsystem (for example, signals) from the data of the parent model. The subsystem owns this separate data.

Generate Reentrant Code

Embedded Coder® supports *reentrant code*. Reentrant code is a reusable programming routine that multiple programs can use simultaneously. Reentrant code is used in operating systems and other system software that uses multithreading to handle concurrent events. Reentrant code does not maintain state data, so there are no persistent variables in the function. Calling programs maintain state variables and must pass the state data into the function. Multiple users or processes can share one copy of a reentrant function.

To generate reentrant code, you must first specify the subsystem as reusable by configuring the subsystem parameter **Function packaging**.



In some cases, the configuration of the model prevents reusable code. The table lists common issues.

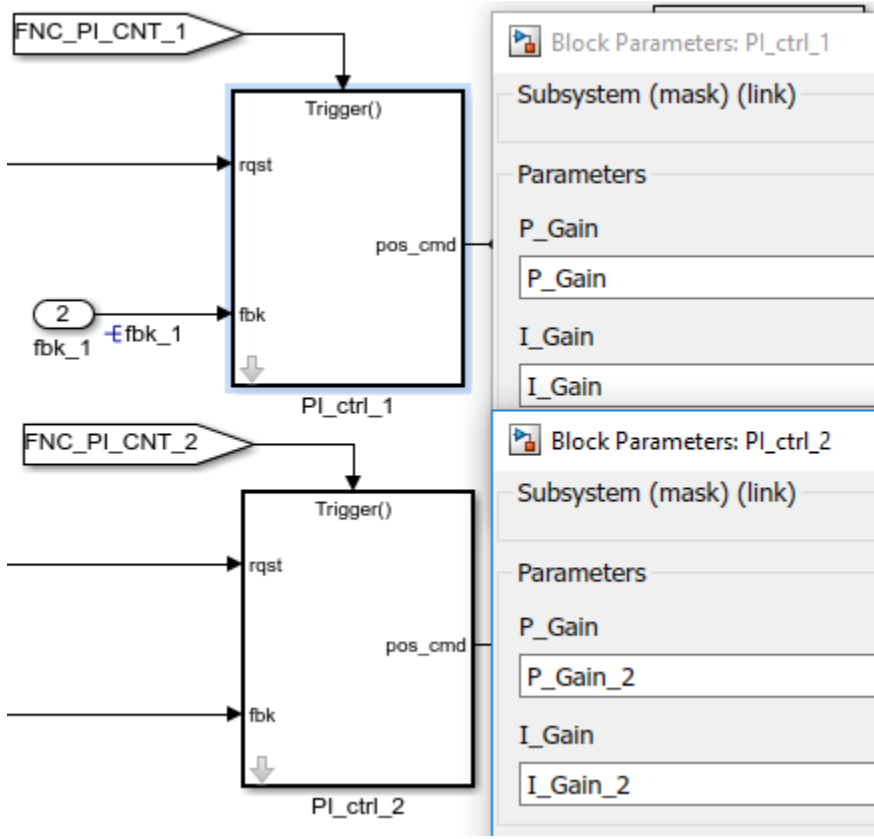
Cause	Solution
Subsystem output feeds global signal data	Add a Signal Conversion block between the subsystem and the global signal.
Generated function receives data (formal parameters) through pointers	Select Configuration Parameters > Model Referencing > Pass fixed-size scalar ro inputs by value for code generation.
Subsystem uses global signal data in internal algorithm	Use a port to pass the global data in and out of the subsystem.

Use a Mask to Pass Parameter Values into Library Subsystem

To define algorithmic parameter data (such as a gain or coefficient) outside the scope of a reusable library block or subsystem, you can apply a *mask* to the block or subsystem and

create a mask parameter. You can then specify a different parameter value for each instance of the block or subsystem. Each mask parameter appears in the generated code as a formal parameter of the reentrant function.

In this version of the model, the subsystems `PI_ctrl_1` and `PI_ctrl_2` are masked. In each mask, the values of the `P` and `I` gains are set by data objects such as `I_Gain_2` and `P_Gain_2`.



Generate Code for Atomic Subsystem

In “Generate C Code from a Control Algorithm for an Embedded System” and “Configure Data Interface in the Generated Code”, you generate code at the root level of the model. Alternatively, you can build a specific subsystem.

Build This Subsystem
Generate S-Function

To initiate a subsystem build, use the context menu. You can choose from these options:

1. **Build Subsystem**: Treats the subsystem as a separate mode and creates the full set of source C files and header files. This option does not support function-call subsystems.
2. **Generate S-Function**: Generates C code for the subsystem and creates an S-Function wrapper. You can then simulate the code in the original model. This option does not support function-call subsystems.
3. **Export Functions**: Generates C code without the scheduling code that comes with the **Build Subsystem** option. Use this option to build subsystems that use triggers, such as function-call subsystems.

Examine Generated Code

This example compares the files that are generated for the full system build with the files that are generated for exported functions. You also examine how the masked data appears in the code.

Run the build script for the three options. Then, examine the generated files by clicking the hyperlinks.

1. Generate code from the entire model.
2. Export the function `PI_ctrl_1`.
3. Export the function `Pos_Command_Arbitration`.

rtwdemo_PCG_Eval_P3.c

- Full Build: Yes, Step function
- PI_ctrl_1: No
- Pos_Command_Arbitration: No

PI_ctrl_1.c

- Full Build: No
- PI_ctrl_1: Yes, Trigger function
- Pos_Command_Arbitration: No

Pos_Command_Arbitration.c

- Full Build: No
- PI_ctrl_1: No
- Pos_Command_Arbitration: Yes, Init and Function

PI_Ctrl_Reusable.c

- Full Build: Yes
- PI_ctrl_1: Yes
- Pos_Command_Arbitration: No

ert_main.c

- Full Build: Yes
- PI_ctrl_1: Yes
- Pos_Command_Arbitration: Yes

eval_data.c

- Full Build: Yes(1)
- PI_ctrl_1: Yes(1)
- Pos_Command_Arbitration: No, Eval data not used in diagram

(1) `eval_data.c` has different content in the full and export function builds. The full build includes all of the parameters that the model uses. The export function contains only the variables that the subsystem uses.

Masked Data in the Generated Code

In the file `rtwdemo_PCG_Eval_P3.c`, the call sites of the reentrant function use the data objects `P_Gain`, `I_Gain`, `P_Gain_2`, and `I_Gain_2` as arguments.

```
PI_Cntrl_Reusable(*pos_rqst, fbk_1, &rtwdemo_PCG_Eval_P3_B->PI_ctrl_1,
                  &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_1, I_Gain, P_Gain);
PI_Cntrl_Reusable(*pos_rqst, fbk_2, &rtwdemo_PCG_Eval_P3_B->PI_ctrl_2,
                  &rtwdemo_PCG_Eval_P3_DWork->PI_ctrl_2, I_Gain_2, P_Gain_2);
```

Effect of Execution Order on Simulation Results

By default, Simulink® executes the subsystems in this order:

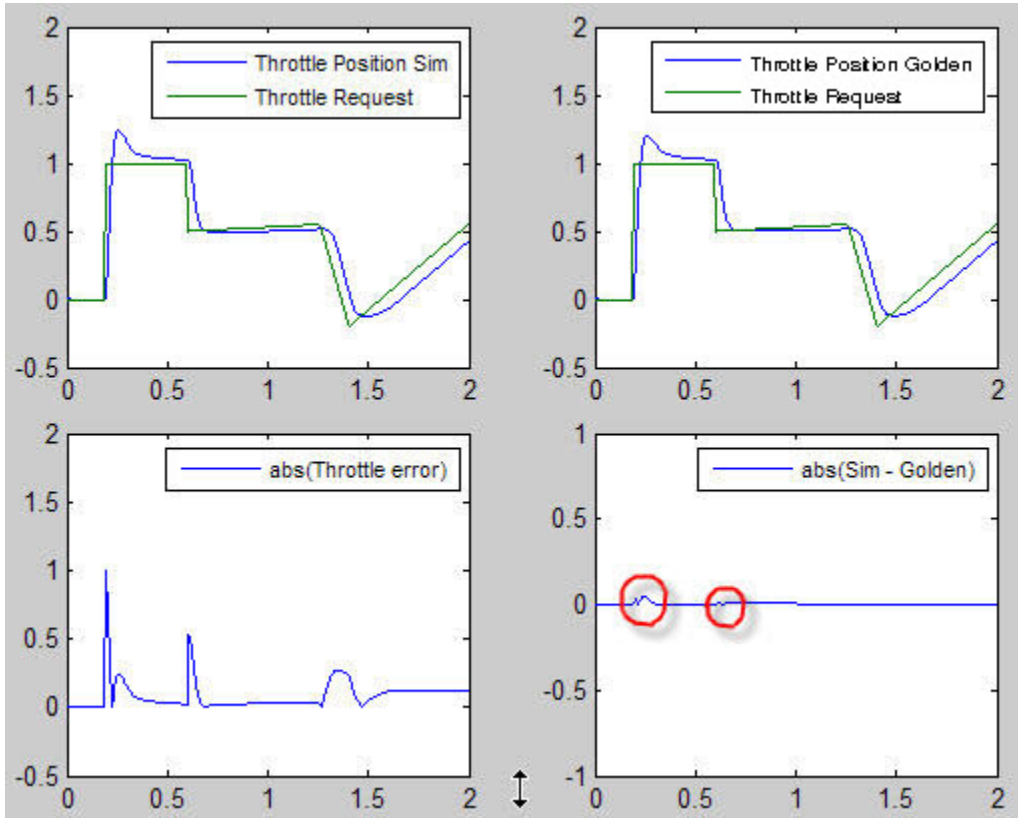
1. `PI_ctrl_1`
2. `PI_ctrl_2`
3. `Pos_Command_Arbitration`

For this example, you can specify one of two alternative orders of execution. You can then use the test harness to observe the effect of the execution order on the simulation results. The subsystem `Execution_Order_Control` has two configurations that control the execution order. To choose a configuration, use the subsystem context menu.

Change the execution order and observe the results.

1. Set the execution order to `PI_ctrl_1`, `PI_ctrl_2`, `Pos_Command_Arbitration`.
2. Open the test harness.
3. Run the test harness.
4. Change the execution order to `Pos_Command_Arbitration`, `PI_ctrl_1`, `PI_ctrl_2`.
5. Run the test harness.

The simulation results (throttle position over time) vary slightly depending on the order of execution. You can see the difference most clearly when the throttle request changes.



For the next example in this series, see “Call External C Code from Model and Generated Code”.

Nonvirtual Subsystem Modular Function Code Limitations

The nonvirtual subsystem option **Function with separate data** has the following limitations:

- The **Function with separate data** option is available only in ERT-based Simulink models (requires a Embedded Coder license).
- The nonvirtual subsystem to which the option is applied cannot have multiple sample times or continuous sample times; that is, the subsystem must be single-rate with a discrete sample time.

- The nonvirtual subsystem cannot contain continuous states.
- The nonvirtual subsystem cannot output function call signals.
- The nonvirtual subsystem cannot contain noninlined S-functions.
- The generated files for the nonvirtual subsystem will reference model-wide header files, such as *`model`*`.h` and *`model`*`_private.h`.
- The **Function with separate data** option is incompatible with the **Classic call interface** option, located on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. Selecting both generates an error.
- The **Function with separate data** option is incompatible with setting **Code interface packaging** to `Reusable function` (**Code Generation > Interface** pane). Selecting both generates an error.
- When you select **Function with separate data** for a subsystem, the model that contains the subsystem cannot contain a Data Store Memory block with **Share across model instances** selected. See Data Store Memory.

- “Design Models for Generated Embedded Code Deployment” on page 1-2

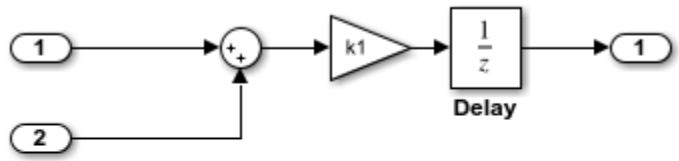
Generate Reentrant, Multi-Instance Code

This example shows you how to configure a model for reentrant, multi-instance code generation. Multiple programs can use reentrant code simultaneously. When you configure a model for reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures. After examining the configuration settings, generate and review the generated code.

Open the Model

Open the model `rtwdemo_reusable`. The model contains two root Inport blocks and a root Outport block.

```
model='rtwdemo_reusable';
open_system(model);
```



In your working folder, create a temporary folder for generating and reviewing the code.

```
currentDir=pwd;
[~,cgDir] = rtwdemodir();
```

Examine Relevant Model Configuration Settings

1. Open the Model Configuration Parameters dialog box.

2. **System target file** is set to `ert.tlc`. Although you can generate reentrant code for a model configured with the **System target file** set to `grt.tlc`, ERT and ERT-based system target files provide more control over how the code passes root-level I/O.

3. Open the **Code Generation > Interface** pane and explore relevant parameter settings.

- **Code interface packaging** is set to `Reusable function`. This parameter setting instructs the code generator to produce reusable, multi-instance code.
- The `Reusable function` parameter setting also displays the **Multi-instance code error diagnostic** parameter. That parameter is set to `Error`, indicating that the code generator abort if the model violates requirements for generating multi-instance code.
- **Pass root-level I/O as** is set to `Part of model data structure`. This setting packages root-level model input and output into the real-time model data structure (`rtModel`), which is an optimized data structure that replaces `SimStruct` as the top-level data structure for a model.
- **Remove error status field in real-time model data structure** is selected. This parameter setting reduces memory usage by omitting the error status field from the generated real-time model data structure.

Generate and Review Code

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_reusable
### Successful completion of build procedure for model: rtwdemo_reusable
```

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_reusable_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_reusable.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_reusable.h` declare model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework.

1. Include the generated header file by adding directive `#include rtwdemo_reusable.h`.

2. Write input data to the generated code for model Inport blocks.

3. Call the generated entry-point functions.

4. Read data from the generated code for the model Outport block.

Input ports:

- `<Root>/In1` of data `real_T` with dimension of 1
- `<Root>/In2` of data `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_reusable_initialize(RT_MODEL *const rtM)`. At startup, call this function once.
- Output and update (step) entry-point function, `void rtwdemo_reusable_step(RT_MODEL *const rtM)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output port:

- `<Root>/Out1` of data type `real_T` with dimension of 1

```
Examine the |rtwdemo_reusable_step| function code in |rtwdemo_reusable.c|.

cfile = fullfile(cgDir,'rtwdemo_reusable_ert_rtw','rtwdemo_reusable.c');
rtwdemodbtype(cfile,'/* Model step function', '/* Model initialize function ', 1, 0);

/* Model step function */
void rtwdemo_reusable_step(RT_MODEL *const rtM)
{
  D_Work *rtDWork = ((D_Work *) rtM->dwork);
  ExternalInputs *rtU = (ExternalInputs *) rtM->inputs;
  ExternalOutputs *rtY = (ExternalOutputs *) rtM->outputs;

  /* Outport: '<Root>/Out1' incorporates:
   *  UnitDelay: '<Root>/Delay'
   */
  rtY->Out1 = rtDWork->Delay_DSTATE;

  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
```

```
   *  Sum: '<Root>/Sum'
   *  UnitDelay: '<Root>/Delay'
   */
  rtDWork->Delay_DSTATE = (rtU->In1 + rtU->In2) * rtP.k1;
}
```

The code generator passes model data to the `rtwdemo_reusable_step` function as part of the real-time model data structure. Try different settings for the **Code interface packaging** and **Pass root-level I/O** parameters and regenerate code. Observe how the function signature for the `rtwdemo_reusable_step` function changes.

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Memory Sections in Embedded Coder

Control Data and Function Placement in Memory by Inserting Pragmas

For some applications, you can use pragmas and other code decorations to control the placement of data (global variables) and function definitions in memory. For example, a linker configuration file can define named sections in a `SECTIONS` directive and map each section to a range of memory addresses. In the C code, you include pragmas that assign global variables and functions to these named sections and, by extension, to the memory ranges. By controlling memory placement, you can:

- Generate code that is more efficient for your hardware.
- Modularize your application code for easier maintenance and modification later in the development process and after deployment.

With Embedded Coder and memory sections, you can:

- Apply default pragmas or other decorations to categories of model data and entry-point functions. To configure these defaults, use the Code Mapping Editor. For example, you can:
  - Apply a default pragma to internal data, which includes block states that the code generator cannot eliminate through optimizations. You can apply a different default pragma to constant parameters, such as nonscalar parameters that the generated code must store in memory.
  - Apply a default pragma to categories of generated functions, including entry-point functions such as *`model`*`_step`.
- Override the default pragmas for individual data items such as block parameters, states, and signals. To do so, create your own storage class.
- Override the default pragmas for individual functions that correspond to atomic subsystems, which you can configure to appear in the generated code as separate functions with separate data. Use the subsystem parameters dialog box.

Insert Pragmas by Using Memory Sections

In this example, you configure the default memory placement for all of the data and functions of the algorithm represented by the example model `rtwdemo_roll`. Then, for some signal data, you override the default placement.

Explore Example Model and Inspect Default Generated Code

1. Open the example model.

```
open_system('rtwdemo_roll')
```

   The model is configured to generate efficient production code. For example, the configuration parameter **Default parameter behavior** is set to `Inlined`.
2. Generate code from the model.
3. In the code generation report, inspect the file `rtwdemo_roll.h`. The file defines structure types that represent data that the algorithm needs. For example, the file defines a structure type that represents block states such as the states of Discrete-Time Integrator blocks.

```
/* Block states (default storage) for system '<Root>' */
typedef struct {
  real32_T FixPtUnitDelay1_DSTATE;     /* '<S7>/FixPt Unit Delay1' */
  real32_T Integrator_DSTATE;          /* '<S1>/Integrator' */
  int8_T Integrator_PrevResetState;    /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;
```

   The file also declares entry-point functions for the model.

```
/* Model entry point functions */
extern void rtwdemo_roll_initialize(void);
extern void rtwdemo_roll_step(void);
```

4 Inspect `rtwdemo_roll.c`. This file defines global structure variables to store the data. The file also defines the functions.

In this example, assume your linker configuration file defines named sections `MYALGORITHM_DATA` and `MYALGORITHM_CODE` in a `SECTIONS` directive. You can configure the model so that the generated code includes pragmas, placing the memory allocated for the data and functions in these named sections.

- For a global variable named `myVar`, the pragma syntax is:

  ```
  #pragma SEC_MYALGORITHM_DATA("myVar")

  double myVar;
  ```

- For a function named `myFunction`, the pragma syntax is the same except for the section name:

  ```
  #pragma SEC_MYALGORITHM_CODE("myFunction")

  void myFunction(void)
  ```

Create Memory Sections

In this example, you use two pragmas with different syntaxes, so you must create two memory sections.

1 In the model window, select **Code > C/C++ Code > Configure Model in Code Perspective**. Simulink places the model in the code perspective, which you can use to configure code generation settings for the model.
2 Underneath the block diagram, under **Code Mappings > Data Defaults**, click the **Embedded Coder Dictionary** icon.
3 In the **Embedded Coder Dictionary** dialog box, select the **Memory Sections** tab.
4 Click the **Add** button.
5 For the new memory section, set these options:

   - **Name** to `MYALGORITHM_DATA`.
   - **Statements Surround** to `Each variable`.
   - **Pre Statement** to `#pragma SEC_MYALGORITHM_DATA("$N")`. The token `$N` stands for the name of each variable that uses the memory section.

6 Create another, similar memory section that corresponds to `MYALGORITHM_CODE`.

Configure Default Pragmas for Data and Functions

1 In the model, inspect the **Code Mappings > Data Defaults** tab.
2 In the table, select the **Inports** row.
3 In the Property Inspector, set **Memory Section** to `MYALGORITHM_DATA`.
4 For the other rows in the table, set **Memory Section** to `MYALGORITHM_DATA`.
5 Under **Function Defaults**, for each row in the table, set **Memory Section** to `MYALGORITHM_CODE`.
6 In your current folder, delete the existing `slprj` folder.
7 Configure the model to generate only code. Select the configuration parameter **Configuration Parameters > Generate code only**.
8 Generate code from the model.

Now, the `rtwdemo_roll.c` file applies the pragmas to the definitions of the structure variables and the functions. For each category of data and functions that you configured in the Code Mapping Editor, the code applies a pragma. For example, the code applies the `MYALGORITHM_DATA` pragma to each of the structures that store block states, root-level inputs, and root-level outputs.

```
/* Block states (default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_DW")

DW_rtwdemo_roll_T rtwdemo_roll_DW;

/* External inputs (root inport signals with default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_U")

ExtU_rtwdemo_roll_T rtwdemo_roll_U;

/* External outputs (root outports fed by signals with default storage) */
#pragma SEC_MYALGORITHM_DATA("rtwdemo_roll_Y")

ExtY_rtwdemo_roll_T rtwdemo_roll_Y;
```

Retain Default Memory Section After Applying a Default Storage Class or Function Template

In the Code Mapping Editor, you can use the **Storage Class** and **Function Customization Template** columns to control the default appearance of data and functions in the generated code. When you use these columns to apply a setting other than `Default`, the Code Mapping Editor discards the memory section that you applied in the Property Inspector. To retain the memory section, use the Embedded Coder Dictionary to create a storage class or function template, then apply the memory section to that storage class or function template.

In this example, you configure the nonparameter data of the model, such as signals and states, to appear in the same structure by creating a storage class. To retain the `MYALGORITHM_DATA` memory section, you apply the memory section to the storage class.

1. In the Embedded Coder Dictionary for the model, select the **Storage Classes** tab and click the **Add** button.
2. For the new storage class, set:
   - **Name** to `STRUCT_DATA`.
   - **Storage Type** to `Structured`.
   - **Memory Section** to `MYALGORITHM_DATA`.
3. In the Code Mapping Editor, under **Data Defaults**, in the **Storage Class** column, select `STRUCT_DATA` for all of the rows except:
   - **Global parameters**
   - **Local parameters**
   - **Global data stores**
   - **Constants**
4. Generate code from the model.
5. Inspect `rtwdemo_roll.c`. Now, the file defines a single structure variable that contains the nonparameter data, applying the pragma to that variable.

```
/* Storage class 'STRUCT_DATA' */
#pragma SEC_MYALGORITHM_DATA("STRUCT_DATA_rtwdemo_roll")

rtwdemo_roll_STRUCT_DATA STRUCT_DATA_rtwdemo_roll;
```

Retain Default Memory Section After Directly Applying a Storage Class

To override the default storage classes that you specify in **Code Mappings** > **Data Defaults**, you can apply a storage class directly to a data item by using the Model Data Editor. Directly applying any storage class other than `Auto` or `Model default` bypasses the default memory section that you specify in **Data Defaults**. To retain the memory section, you must migrate the memory section definition out of the Embedded Coder Dictionary and into a package, which is a folder that can contain storage class and memory section definitions. Then, you can create a storage class in the package, apply the memory section to the storage class, and apply the storage class directly to individual data items in the Model Data Editor.

In `rtwdemo_roll`, in the `BasicRollMode` subsystem, the three Gain blocks represent the parameters of a PID control algorithm. In this example, you configure the output

signals of these blocks so that the generated code allocates memory for them and places the memory in the `MYALGORITHM_DATA` section. You also configure the signals so that the code defines them in `mySigs.c` and declares them in `mySigs.h`.

To create the memory section and the storage class:

1. In your current folder, create a folder named `+myPackage`. The folder defines a package named `myPackage`.

   To make the package available outside of your current folder, optionally, you can add the folder containing the `+myPackage` folder to the MATLAB path.
2. Open the Custom Storage Class designer.

   ```
   cscdesigner('myPackage');
   ```
3. In the Custom Storage Class Designer, select the **Memory Section** tab.
4. Click **New**.
5. For the new memory section, set these options, which match the options that you set for `MYALGORITHM_DATA` in the Embedded Coder Dictionary:

   - **Name** to `MYALGORITHM_DATA`.
   - **Statements surround** to `Each variable`.
   - **Pre statement** to `#pragma SEC_MYALGORITHM_DATA("$N")`.
6. Click **Apply** and **Save**.
7. In the `myPackage` package folder, create a folder named `@Signal`.
8. In the `@Signal` folder, create a file named `Signal.m`.

   ```
   classdef Signal < Simulink.Signal

       methods

           function setupCoderInfo(h)
               useLocalCustomStorageClasses(h, 'myPackage');
           end

           function h = Signal()
               % SIGNAL  Class constructor.
           end % End of constructor

       end % methods
   end % classdef
   ```

   The file defines a class named `myPackage.Signal`, which is derived from the built-in class `Simulink.Signal`. The class definition overrides the `setupCoderInfo`

method, which the `Simulink.Signal` class already implements. The new implementation specifies that objects of the `myPackage.Signal` class use custom storage classes from the `myPackage` package instead of custom storage classes from the built-in `Simulink` package.

9. Set your current folder to the folder that contains the `+myPackage` folder.
10. In the Custom Storage Class Designer for `myPackage`, select the **Custom Storage Class** tab.
11. Click **New**.
12. For the new custom storage class, set these properties:
    - **Name** to `myCSC`.
    - Clear **For parameters**.
    - **Memory section** to `MYALGORITHM_DATA`.
    - **Data scope** to `Exported`.
    - **Header file** to `mySigs.h`.
    - **Definition file** to `mySigs.c`.
13. Click **Apply** and **Save**.

To apply the storage class in the model:

1. In the model, select **View > Model Explorer > Model Explorer**.
2. In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
3. In the Model Explorer toolbar, click the arrow next to the **Add Signal** button and select **Customize class lists**.
4. In the **Customize class lists** dialog box, under **Signal classes**, select the check box next to **myPackage.Signal** and click **OK**.
5. In the Model Explorer, click the arrow next to **Add Signal** again and select **myPackage Signal**. A `myPackage.Signal` object appears in the base workspace.
6. Delete the `myPackage.Signal` object from the base workspace. Now, when you use the Model Data Editor to apply storage classes to signals, you can choose storage classes from the `myPackage` package.
7. In the model, navigate into the `BasicRollMode` subsystem.
8. Underneath the block diagram, select the **Model Data Editor > Signals** tab.
9. In the model, select the three Gain blocks.
10. In the Model Data Editor, in the data table, for any of the highlighted rows, set **Storage Class** to `myCSC`.
11. Generate code from the model.

12 Inspect the generated file `mySigs.c`. The file defines the global variables that correspond to the Gain block outputs in the model. The pragma applies to the definitions.

```
/* Definition for custom storage class: myCSC */
#pragma SEC_MYALGORITHM_DATA("DispGain")

real32_T DispGain;

#pragma SEC_MYALGORITHM_DATA("IntGain")

real32_T IntGain;

#pragma SEC_MYALGORITHM_DATA("RateGain")

real32_T RateGain;
```

Now, two definitions of the `MYALGORITHM_DATA` memory section exist: One in the Embedded Coder Dictionary and one in `myPackage`. When you make changes to the memory section, make the same changes for each definition.

Configure Pragma to Surround Groups of Definitions

If your build toolchain requires that a pragma or other decoration surround multiple definitions of variables or functions at once, in an Embedded Coder Dictionary or the Custom Storage Class Designer, set **Statements surround** to `Group of variables` (the default in the Custom Storage Class Designer).

Override Default Memory Placement for Individual Data Elements

After you configure memory section defaults in the Code Mapping Editor (see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7), to override these default settings for individual data elements (signals, parameters, and states), create a storage class and any required memory sections by using the Custom Storage Class Designer. In the Designer, when you create the storage class, set the **Memory section** property to the appropriate memory section. Then, use the Model Data Editor to apply the storage class to individual data elements.

Choose Where to Create and Store Memory Section Definition

To define a memory section, you must choose where to create it: in an Embedded Coder Dictionary or in a package (by using the Custom Storage Class Designer).

- If you need to use the memory section only in the Code Mapping Editor, define the memory section in an Embedded Coder Dictionary.
- If you need to use the memory section outside of the Code Mapping Editor, for example, in the Model Data Editor, define the memory section in a package.

  Optionally, you can enable use of the package memory section in the Code Mapping Editor by loading the package into an Embedded Coder Dictionary (see "Refer to Code Generation Definitions in a Package"). However, if you create storage classes in the dictionary, you cannot apply the package memory section to them. To associate a memory section with storage classes that you define in an Embedded Coder Dictionary and with other storage classes that you define in a package, maintain two definitions of the memory section: one in the dictionary and one in the package.

Share Memory Section Definition Between Models

- If you define the memory section in the Embedded Coder Dictionary of a model, you cannot use the memory section in other models. To share the memory section, migrate the definition to a Simulink data dictionary (`sldd`). Then, share the dictionary between the target models. For more information, see "Share Embedded Coder Dictionary Definition Between Models" on page 30-10.
- If you define the memory section in a package, any model can use the memory section. Add the folder containing the package folder to the MATLAB path (see "What Is the MATLAB Search Path?" (MATLAB)).

Share Memory Section Between Packages (Package Memory Sections Only)

Packages can access and use memory sections that are defined in other packages, including custom packages and built-in packages such as `Simulink`. Only one copy of the memory section exists, in the package that defines it. Other packages refer to the memory section by pointing to it in its original location. Changes to the memory section, including changes to a built-in memory section in later MathWorks product releases, are immediately available in every referencing package.

To configure a package to refer to a memory section that is defined in another package:

1. Open the Custom Storage Class Designer. At the command prompt, enter `cscdesigner`.
2. Select the **Memory Section** tab.
3. Use **Select Package** to select the package in which you want to reference a class or section defined in some other package.
4. In the **Memory section definitions** pane, select the existing definition below which you want to insert the reference.
5. Click **New Reference**.

   A new reference with a default name and properties appears below the previously selected definition. The new reference is selected, and a **Reference** tab appears that shows the reference's initial properties.
6. Use the **Name** field to enter a name for the new reference. The name must be unique in the importing package, but can duplicate the name in the source package.
7. Set **Refer to memory section in package** to specify the package that contains the memory section that you want to reference.
8. Set **Memory section to reference** to specify the memory section to be referenced.
9. Click **OK** or **Apply** to save the changes to memory. To save the changes permanently, click **Save**.

Control Appearance of Memory Section Drop-Down List (Package Memory Sections Only)

When you apply a package memory section, you select the memory section from a drop-down list. To control the order of the memory sections in the list, in the Custom Storage Class Designer, use the **Up** and **Down** buttons. The order of memory sections in drop-down lists matches the order in the Custom Storage Class Designer.

Protect Definitions of Package Memory Sections (Package Memory Sections Only)

When you click **Save** in the Custom Storage Class Designer, the Designer saves memory section and custom storage class definitions into the `csc_registration.m` file in the package folder. To determine the location of this file, in the Custom Storage Class Designer, inspect the value of **Filename**.

You can prevent changes to the memory section definitions of an entire package by converting the `csc_registration.m` file from a MATLAB file to a P-file. Use the `pcode` function.

A best practice is to keep `csc_registration.m` and `csc_registration.p` in your package folder. That way, if you need to modify the memory sections by using the Designer, you can delete `csc_registration.p` and later regenerate it after you finish the modifications. Because the P-coded version of the file takes precedence, while both files exist in the package, the memory sections are protected.

.

Override Default Memory Placement for Subsystem Functions and Data

When you use atomic subsystems to partition the generated code into functions (see “Generate Subsystem Code as Separate Function and Files” on page 3-11), you can apply different memory sections to the functions and data of each subsystem. You can also specify that a subsystem not use a memory section.

- To use different memory sections to override the model-level defaults that you set in the Code Mapping Editor, see “Override Memory Section for Atomic Subsystem” on page 40-12.
- To specify that a subsystem not use a memory section (in other words, to prevent the subsystem from inheriting the model-level defaults), see “Specify That Atomic Subsystem Not Use a Memory Section” on page 40-13.

Override Memory Section for Atomic Subsystem

The memory sections that you specify for a subsystem override the model-level defaults that you set in the Code Mapping Editor. Use this technique to aggregate the data and instruction code for subroutines or subcomponents (represented by subsystems) into different regions of memory. To apply a memory section directly to an atomic subsystem:

1. Define the memory sections in a package. You cannot use a memory section that you define in an Embedded Coder Dictionary.
2. In the target model, set **Configuration Parameters > Code Generation > Advanced parameters > Memory Sections > Package** to the name of the package. If the package does not appear in the list, click **Refresh package list**.

3. Configure the Embedded Coder Dictionary of the model to load the target package as described in “Refer to Code Generation Definitions in a Package”.
4. Configure the target subsystem to use the memory section. In the subsystem parameters dialog box, on the **Code Generation** tab:
   - Set **Function packaging** to `Nonreusable function` or `Reusable function` (for reentrant code).
   - If you set **Function packaging** to `Nonreusable function`, to enable configuration of memory sections for the subsystem data, select **Function with separate data**. If you do not select **Function with separate data**, the subsystem data inherit memory sections from the model or, if applicable, a parent subsystem.
   - Use parameters such as **Memory section for initialize/terminate functions** to apply default memory sections to the subsystem functions and data.

Specify That Atomic Subsystem Not Use a Memory Section

By default, subsystem functions and data inherit the model-level memory sections that you specify for relevant function and data categories in the Code Mapping Editor. For example, if you specify a function customization template for the **Execution** category, and that template carries a memory section, the memory section applies to subsystem execution functions as well as model entry-point execution functions.

To specify that a subsystem not use a memory section:

1. In the target model, set **Configuration Parameters > Code Generation > Advanced parameters > Memory Sections > Package** to one of these values:
   - If the Embedded Coder Dictionary of the model does not refer to code generation definitions in a package (see “Refer to Code Generation Definitions in a Package”), set **Package** to `Simulink`.
   - If the Embedded Coder Dictionary of the model refers to a package, set **Package** to that package.
2. In the target subsystem, on the **Code Generation** tab, set parameters such as **Memory section for initialize/terminate functions** to `Default`. With this setting, the subsystem does not use a memory section for the data or functions that each parameter represents.

Limitations and Other Considerations

- The settings that you specify for an atomic, nonreusable subsystem with separate data apply only to the data and functions of that subsystem, not to data in similarly configured child subsystems. Atomic, nonreusable child subsystems with separate data can inherit memory sections from the containing model, not from the parent subsystem.
- If you use **Build This Subsystem** or **Build Selected Subsystem** to generate code for an atomic subsystem that specifies memory sections, the code generator ignores the subsystem-level specifications and uses the model-level specifications instead. For information about building subsystems, see “Generate Code and Executables for Individual Subsystems” (Simulink Coder).

Create Fewer Custom Storage Classes (Package Memory Sections Only)

In the example “Insert Pragmas by Using Memory Sections” on page 40-2, to apply a memory section to individual signal data items, you create a custom storage class by using the Custom Storage Class Designer. Suppose you want to apply a different memory section to each of the signals. Instead of copying the custom storage class (`myCSC`) and associating a different memory section with the copy, which results in two very similar custom storage classes, in the Custom Storage Class Designer, for `myCSC`, set **Memory section** to `Instance specific`. Then, when you apply the custom storage class to a data item, you can choose a memory section for that data item.

Limitations

- The code generator does not apply memory sections to data that uses these built-in storage classes:
  - `ExportedGlobal`
  - `ImportedExtern`
  - `ImportedExternPointer`
- In the Custom Storage Class Designer, the storage type qualifier that you specify for a memory section by using the **Qualifier** text box affects only data items that use a storage class setting other than these built-in storage classes:
  - `ExportedGlobal`

- `ImportedExtern`
- `ImportedExternPointer`

The code generator omits the qualifier from other data categories.

- When you create a subsystem in a custom block library, you cannot specify memory sections for the subsystem definition in the library. Instead, specify memory sections for the subsystem instances that you place in your models.

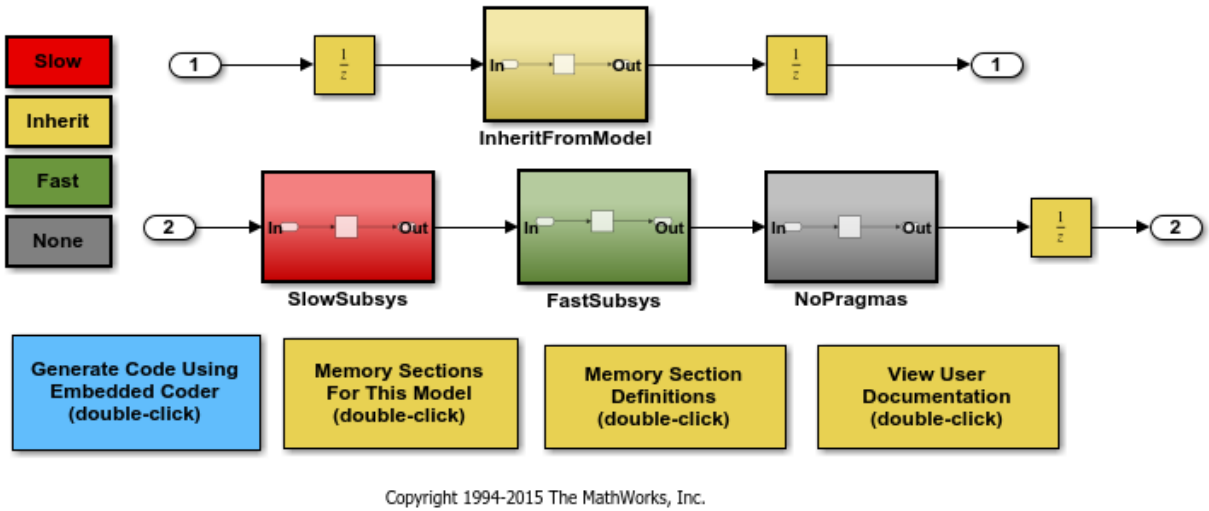
Insert Pragmas for Functions and Data in Generated Code

This model shows how to insert pragmas for functions and data in generated code.

Explore Example Model

Open the example model.

```
open_system('rtwdemo_memsec')
```



Instructions

1. Learn about memory sections by clicking the documentation link in the model.
2. View the memory sections in the ECoderDemos package by clicking the button in the model and then selecting the **Memory Sections** tab.

3. View the memory sections selected for this model by clicking the button in the model. The model-level settings are also the default settings for atomic subsystems.
4. Open the SubSystem Parameters dialog for the subsystems to see the memory section settings for each of the atomic subsystems in the model.
5. Generate code by clicking the button in the model. An HTML report is displayed automatically. Inspect the data and function definitions in the `.c` files and observe how the generated pragmas correspond to the specified memory sections.

- "Standard Data Structures in the Generated Code" (Simulink Coder)

Protect Global Data with const and volatile Type Qualifiers

In C, you use the type qualifier `const` to prevent code in an application from assigning a new value to a variable. In an application where an external actor (for example, a hardware device) can manipulate the value of a variable, you use the keyword `volatile` to prevent a compiler from optimizing the assembly code in a way that compromises the integrity of the variable value. You can also use `volatile` to prevent a compiler from eliminating storage for `const` data, such as a parameter that has a value that you want to tune during execution.

- To apply the qualifiers to an individual data item in a model, including a custom structure that you create by using a nonvirtual bus or a parameter structure, apply the appropriate built-in custom storage class directly to the data item. The custom storage class prevents optimizations such as **Default parameter behavior** from eliminating storage for the data item. For an example, see “Type Qualifiers” on page 24-15. For information about optimizations that a directly applied storage class prevents, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50.

  If the built-in custom storage classes do not meet your requirements, you can create your own custom storage class. To make your custom storage class apply the qualifiers, in the Custom Storage Class Designer, set **Memory section** to the appropriate built-in memory section or to a memory section that you create. For more information, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 36-35.
- You can apply the qualifiers to a category of model data by default, such as parameters or states. As you add blocks to a model, new data items in these categories carry the qualifiers that you specify. For more information, see “Configure Default Code Generation for Data” on page 31-8.

  If the built-in storage classes do not meet your requirements, you can create your own by using an Embedded Coder Dictionary. In the Dictionary, for your new storage class, select the appropriate check boxes under **Qualifiers**. For more information, see “Create Code Definitions for Use as Default Code Generation Settings” on page 30-2.

Maintain const Correctness for Arguments of Entry-Point Functions

When your external code calls a generated entry-point function and passes `const` data through an argument (formal parameter) of the function, to make the corresponding argument in the function definition `const`, customize the execution (step) entry-point function interface.

- To configure the step entry-point function interface for a model, see “Override Default C Step Function Interface” on page 39-7.
- To configure the step entry-point function interface for a Simulink Function block, see “Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-24.

Incorrect Results or Undefined Behavior When Passing Volatile Data to a Generated Function

The generated code can define and call functions other than model entry-point functions. For example, you can configure an atomic subsystem to appear in the code as a separate function. Also, lookup table blocks, such as n-D Lookup Table, typically yield separate utility functions.

When the generated code defines a function that has an argument (formal parameter), the function definition does not apply `volatile` to the argument. Therefore, when other generated code or your external code calls the function and passes a volatile variable as the value of the argument, the called function implicitly casts away the volatility.

If your application executes the called function while the value of the volatile data changes, the function can yield incorrect results or undefined behavior. In particular, for lookup table data that you prepare for calibration, by applying `const` and `volatile`, make sure that you do not calibrate the data while your application executes the lookup utilities.

Array Layout

Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks

Simulink® Coder™ supports row-major array layout for code generation. You can integrate existing applications that use row-major array layout with the generated code in row-major array layout. When you switch an existing model with lookup table (LUT) blocks from the column-major array layout to the row-major array layout, it is recommended to convert the LUT blocks from the column-major algorithm to the row-major algorithm. The code generated by using row-major algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

This example shows the workflow of converting a model with LUT blocks from column-major layout to row-major layout to achieve the best performance on a row-major array layout.

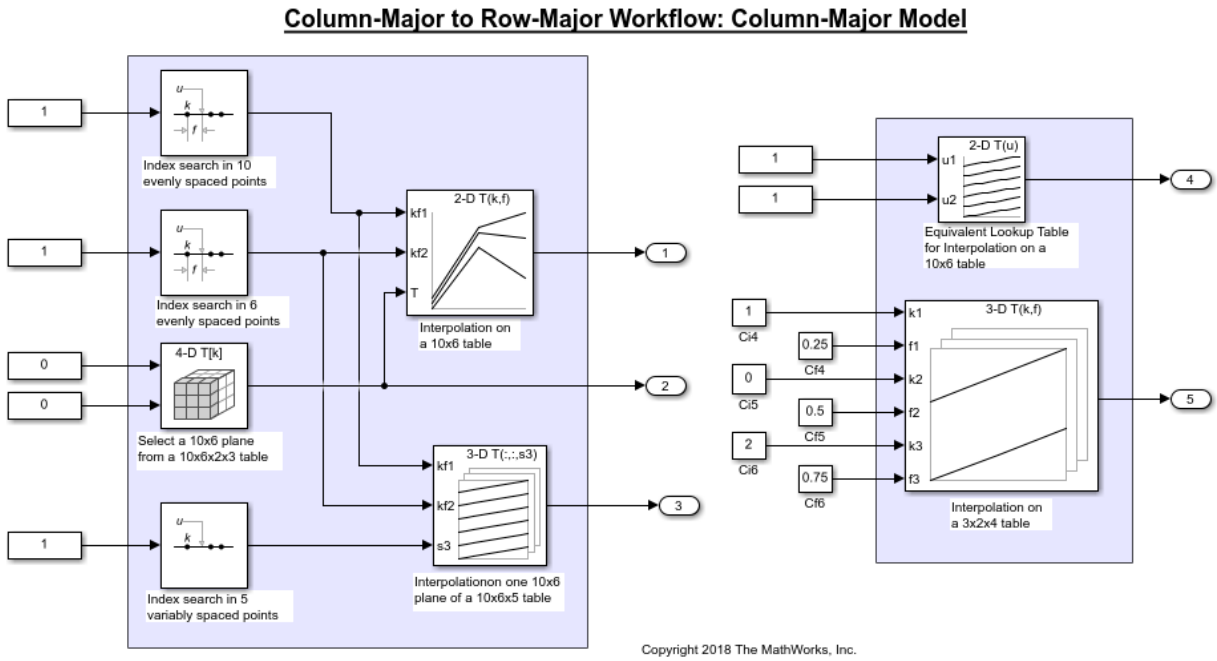
In this example, you:

- Identify the array layout and select the optimized algorithm.
- Preserve semantics through table permutation.
- Generate code by using a row-major algorithm and an array layout.

Simulate and Generate Code by Using Column-Major Algorithms

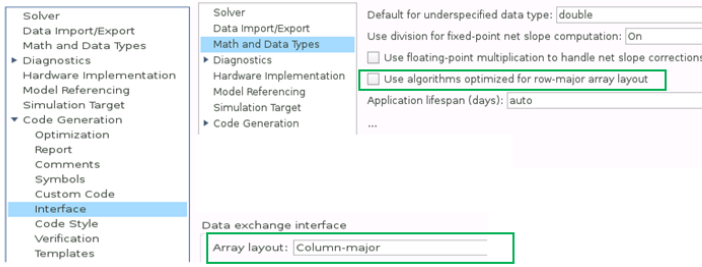
1. Open the example model `rtwdemo_row_lutcol2row_workflow`.

```
open_system('rtwdemo_row_lutcol2row_workflow');
```



By default, Simulink configures a model to use column-major algorithms and a column-major array layout. These parameters are the configuration parameters in the Model Configuration Parameters dialog box.

- Math and Data Types > **Use algorithms optimized for row-major array layout** — This parameter affects simulation and code generation.
- Code Generation > Interface > **Array layout** — This parameter affects only code generation.



2. On the model toolstrip, click **Run** to simulate the model and observe the output logged in workspace variable `yout`.

3. Change your current folder in MATLAB® to a writable folder. Click **Build model** to generate C code.

Select Optimized Algorithms for Row-Major Array Layout

Table data with row-major array layout is frequently used in the field of calibration. To interface the row-major table data with the existing model, update the column-major model to operate efficiently on row-major table data.

Use the algorithm that is optimized for the specified array layout to achieve the best performance. For example, use row-major algorithms when **Array layout** is set as `Row-major` during code generation.

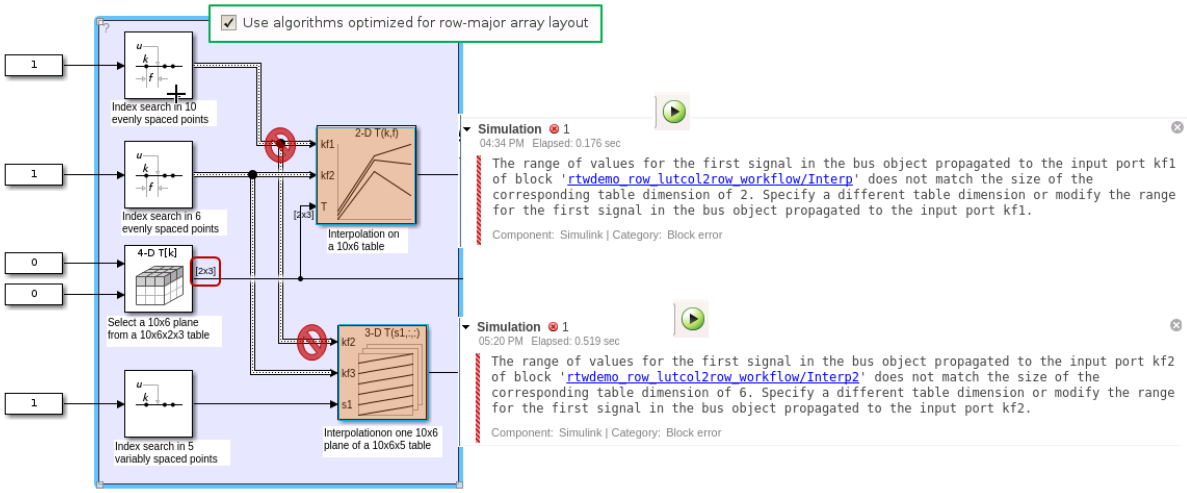
Array Layout	Algorithm	Cache-Friendly Algorithm
Column-major	Column-major	✓ (Recommended)
Row-major	Row-major	✓ (Recommended)
Row-major	Column-major	⚠ (Not recommended)
Column-major	Row-major	⚠ (Not recommended)

1. To enable row-major algorithms, open the Model Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter **Use algorithms optimized for row-major array layout**. Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_row_lutcol2row_workflow','UseRowMajorAlgorithm','on');
```

2. Click **Run** to simulate the model. Simulink reports errors because it encounters inconsistent breakpoint and table data between prelookup and interpolation blocks. The causes of this error are the two semantic changes that occur when you switch from column-major algorithms to row-major algorithms, that is, when you:

- Select a plane from a 3-D table in interpolation block.
- Select a plane from a 4-D table through a direct lookup table block.



Dimension of the Selected Plane (Semantic Changes)

	Column-major algorithm	Row-major algorithm
Select a plane from a 4-D table (10x6x2x3)	10x6	2x3
Select a plane from a 3-D table (10x6x5)	10x6	6x5

Preserve Semantics by Using Table Permutation

1. For subtable selection before interpolation, or direct lookup that outputs a vector or 2-D matrix, the model semantics change when you switch from a column-major algorithm to a row-major algorithm by selecting the configuration parameter **Use algorithms optimized for row-major array layout**. To preserve the semantics and fix the previous errors, permute the table data by using these commands:

```
T4d_str = get_param('rtwdemo_row_lutcol2row_workflow/Direct LUT','Table');
set_param('rtwdemo_row_lutcol2row_workflow/Direct LUT','Table',...
['permute(',T4d_str,',[3,4,1,2])']);
```

```
T3d_str = get_param('rtwdemo_row_lutcol2row_workflow/Interp2','Table');
set_param('rtwdemo_row_lutcol2row_workflow/Interp2','Table',...
['permute(',T3d_str,',[3,1,2])']);
```

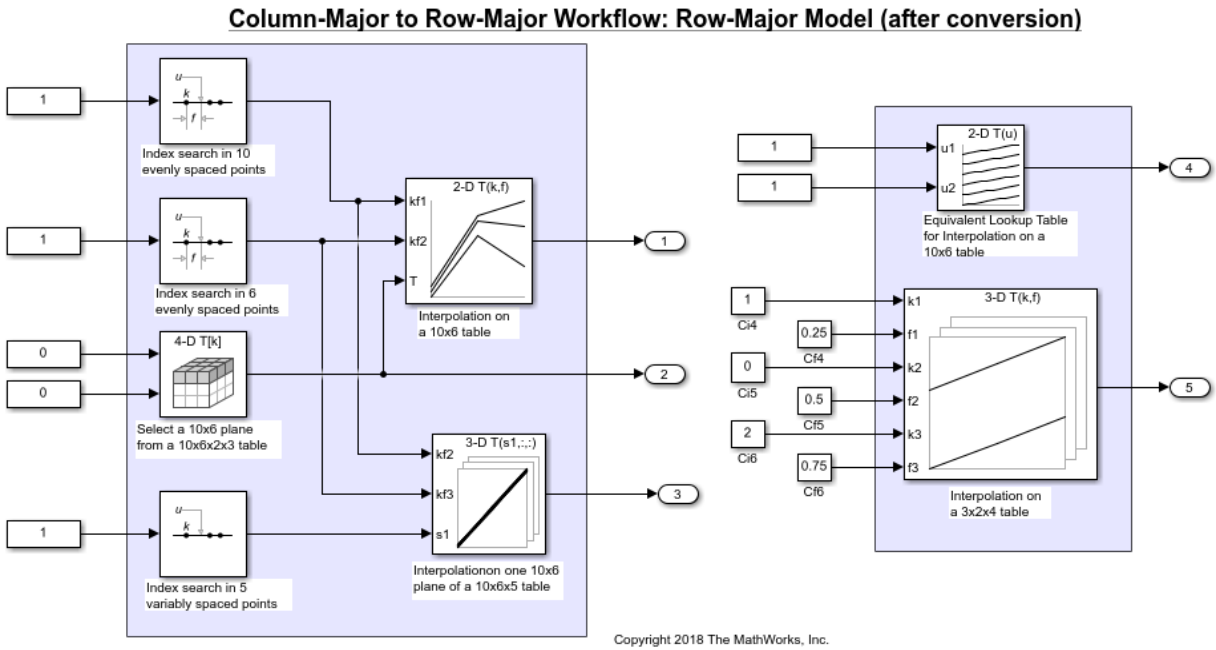
2. Before you import table data from a file, you must permute the table data in the file. This permutation keeps the table tunable throughout the simulation and code generation workflow.

Code Generation by Using Row-Major Algorithm and Array Layout

After permuting the table data, Simulink configures the model `rtwdemo_row_lutcol2row_workflow` for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_lutcol2row_workflow_rowrow` that has permuted table data and uses a row-major algorithm.

1. Open the example model `rtwdemo_row_lutcol2row_workflow_rowrow`.

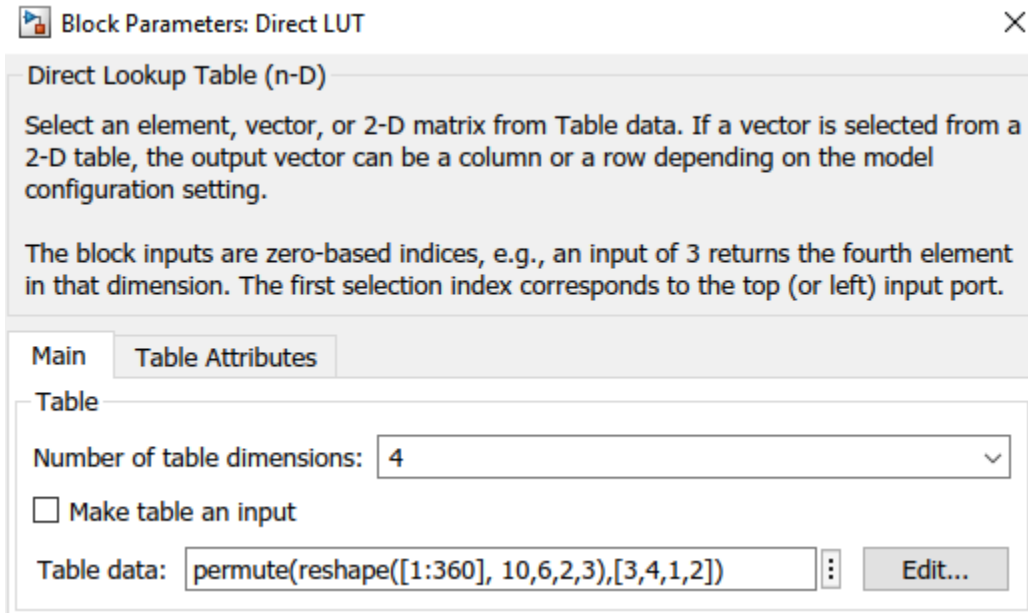
```
open_system('rtwdemo_row_lutcol2row_workflow_rowrow');
```

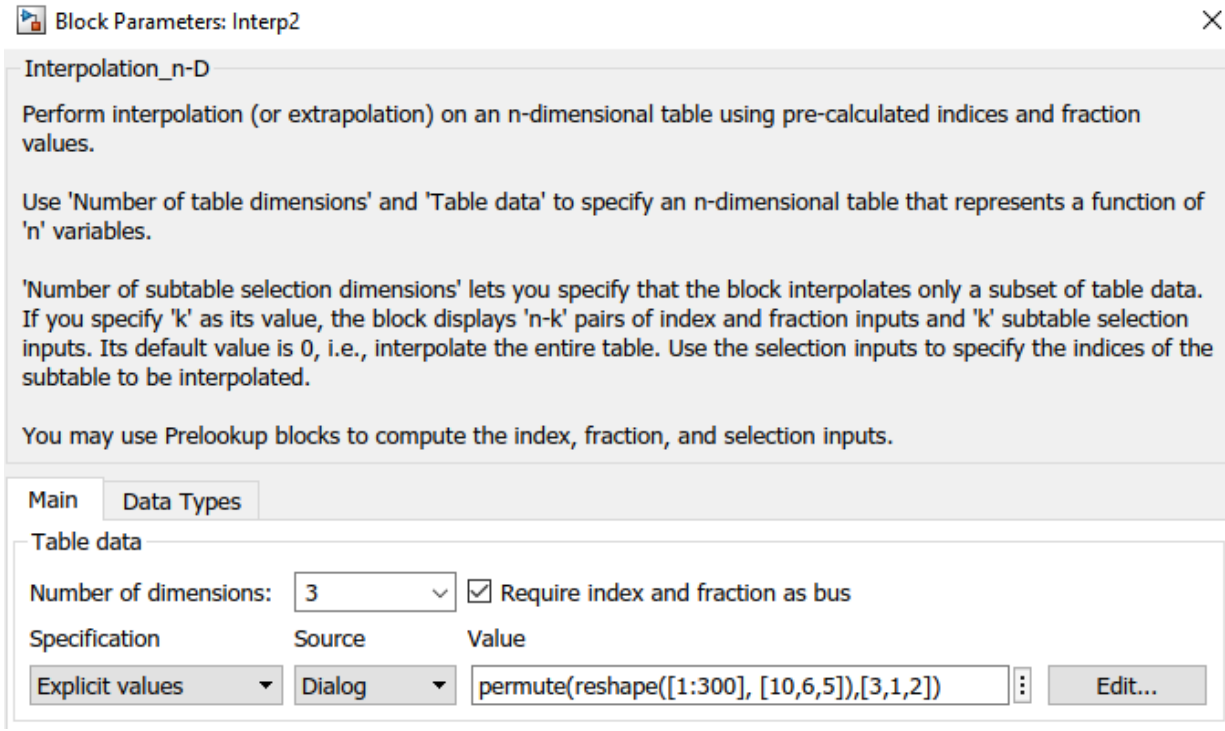


2. To set up these models for row-major code generation, open the Model Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter **Array Layout** to `Row-Major` option. The **Array Layout** parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
% For model 'rtwdemo_row_lutcol2row_workflow_rowrow'
set_param('rtwdemo_row_lutcol2row_workflow_rowrow', 'ArrayLayout','Row-major');
% For model 'rtwdemo_row_lutcol2row_workflow'
set_param('rtwdemo_row_lutcol2row_workflow', 'ArrayLayout','Row-major');
```

3. In the block dialog boxes, examine the permuted 3-D table.





4. Change your current folder in MATLAB to a writable folder. On the model toolstrip, click **Build model** to generate C code. In the generated code, observe the table data with row-major array layout

```
/* Block parameters (default storage) */
P rtP = {
  /* Variable: Tbl_1
   * Referenced by: '<Root>/2-D Lookup Table'
   */
  { 1.0, 11.0, 21.0, 31.0, 41.0, 51.0, 2.0, 12.0, 22.0, 32.0, 42.0, 52.0, 3.0,
    13.0, 23.0, 33.0, 43.0, 53.0, 4.0, 14.0, 24.0, 34.0, 44.0, 54.0, 5.0, 15.0,
    25.0, 35.0, 45.0, 55.0, 6.0, 16.0, 26.0, 36.0, 46.0, 56.0, 7.0, 17.0, 27.0,
    37.0, 47.0, 57.0, 8.0, 18.0, 28.0, 38.0, 48.0, 58.0, 9.0, 19.0, 29.0, 39.0,
    49.0, 59.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0 }
};
```

In the generated code, the `memcpy` function replaces the `for` loops. Using `memcpy` reduces the amount of memory for storing data. This optimization improves execution speed.

```
83  /* Model step function */
84  void rtwdemo_row_lutcol2row_workflow_rowrow_step(void)
85  {
86    uint32_T rtb_Prelookup_Index;
87    real_T rtb_Prelookup_Fraction;
88    uint32_T rtb_Prelookup1_Index;
89    real_T rtb_Prelookup1_Fraction;
90    uint32_T rtb_Prelookup2;
91    real_T frac[2];
92    uint32_T bpIndex[2];
93    real_T frac_0[2];
94    uint32_T bpIndex_0[3];
95    real_T frac_1[3];
96    uint32_T bpIndex_1[3];
97
98    /* LookupNDDirect: '<Root>/Direct LUT'
99     *
100    * About '<Root>/Direct LUT':
101    *  4-dimensional Direct Look-Up returning a 2-D Matrix,
102    *  which is contiguous for row-major array
103    */
104   memcpy(&rtY.Out2[0], &rtCP_DirectLUT_table[0], 60U * sizeof(real_T));
105
106   /* PreLookup: '<Root>/Prelookup' incorporates:
107    *  Constant: '<Root>/Constant1'
108    */
109   rtb_Prelookup_Index = plook_evenca(1.0, rtCP_Prelookup_BreakpointsData[0],
110     rtCP_Prelookup_BreakpointsData[1] - rtCP_Prelookup_BreakpointsData[0], 9U,
111     &rtb_Prelookup_Fraction);
```

Observe the algorithms optimized for row-major data.

```
real_T intrp2d_la(const uint32_T bpIndex[], const real_T frac[], const real_T
                  table[], const uint32_T stride, const uint32_T maxIndex[])
{
  real_T y;
  real_T yR_1d;
  uint32_T offset_1d;

  /* Row-major Interpolation 2-D
     Interpolation method: 'Linear point-slope'
     Use last breakpoint for index at or above upper limit: 'on'
     Overflow mode: 'wrapping'
   */
  offset_1d = bpIndex[1U] * stride + bpIndex[0U];
  if (bpIndex[0U] == maxIndex[0U]) {
    y = table[offset_1d];
  } else {
    y = (table[offset_1d + 1U] - table[offset_1d]) * frac[0U] + table[offset_1d];
  }

  if (bpIndex[1U] == maxIndex[1U]) {
  } else {
    offset_1d += stride;
    if (bpIndex[0U] == maxIndex[0U]) {
      yR_1d = table[offset_1d];

    close_system('rtwdemo_row_lutcol2row_workflow',0);
    close_system('rtwdemo_row_lutcol2row_workflow_rowrow',0);
```

Interpolation Algorithm for Row-Major Array Layout

This example illustrates the interpolation algorithm in 2-D and 3-D Lookup Table that is optimized for row-major array layout. The interpolation algorithm that is optimized for column-major array layout is also presented as a reference. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major interpolation algorithm performs best with column-major array layout.

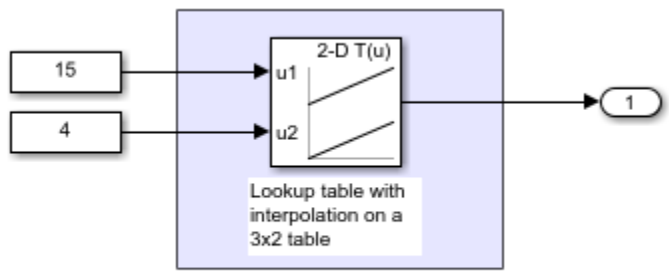
In this example, you:

- Interpolate on a 2-D Lookup Table with column-major and row-major algorithm.
- Generate code with a row-major algorithm and an array layout.
- Identify the array layout and select the optimized algorithm.
- Interpolate on a 3-D Lookup Table with column-major and row-major algorithm.

Simulate with 2-D Row-Major Algorithm

1. Open the example model `rtwdemo_row_lut2d`.

```
model = 'rtwdemo_row_lut2d';
open_system(model);
```



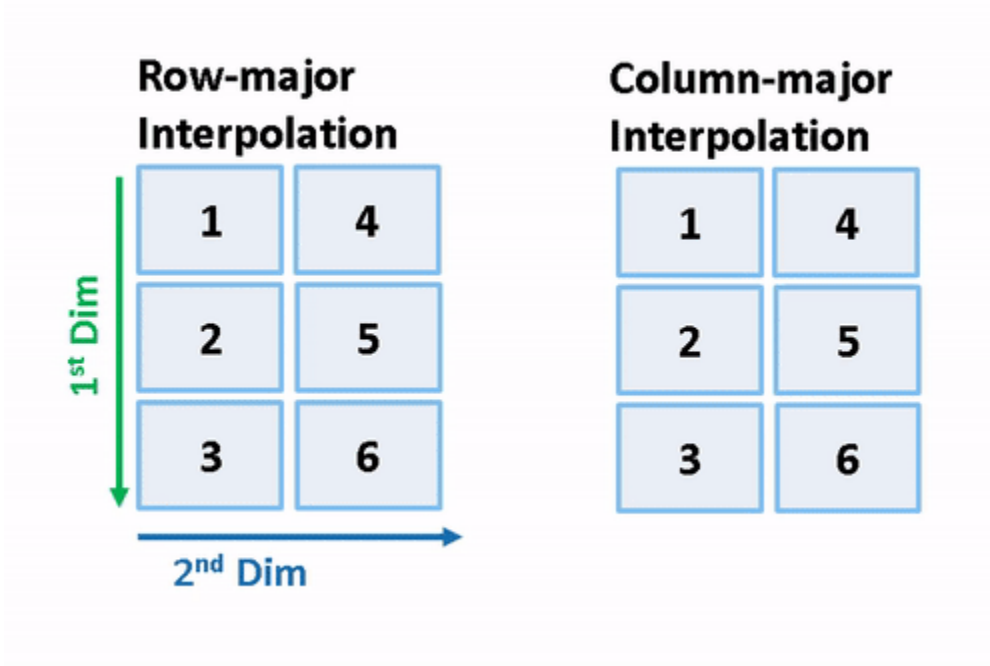
2. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_row_lut2d` is configured to use column-major algorithm. Simulate the model. To observe the output, open the Simulation Data Inspector from the Simulink Editor toolbar. The output value is 4.

3. To enable row-major algorithms, open the Model Configuration Parameters dialog box. On the **Math and Data Types** pane, enable the configuration parameter **Use algorithms optimized for row-major array layout**. Alternatively, in the MATLAB Command Window, enter:

```
set_param(model,'UseRowMajorAlgorithm','on');
```

4. Simulate the model and observe those results in the Simulation Data Inspector. The output value is 4.

The column-major and row-major algorithms differ only in the interpolation order. In some cases, due to different operation order on the same data set, you might experience minor numeric differences in the outputs of column-major and row-major algorithms. For the 2-D Lookup Table used in the example model, the interpolation algorithm is illustrated here.



Generate Code by Using Row-Major Algorithm and Array Layout

The 2-D table data used in model `rtwdemo_row_lut2d` is:

```
Table_3by2.Value
```

```
ans =

     1     4
     2     5
     3     6
```

1. Open the Model Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter **Array Layout** to **Row-Major** option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
set_param(model, 'ArrayLayout','Row-major');
```

2. Change your current folder in MATLAB to a writable folder. To generate code, build the model by using **Ctrl+B** or by clicking the **Build Model** button on the toolstrip.

3. In the generated code, observe the table data with row-major array layout. For comparison, here is the table data in the generated code for column-major array layout.

2-D Table with row-major array layout

```
/* Block parameters (default storage) */
P_rtwdemo_row_lut2d_T rtwdemo_row_lut2d_P = {
  /* Variable: Table_3by2
   * Referenced by: '<Root>/2-D Lookup Table'
   */
  { 1.0, 4.0, 2.0, 5.0, 3.0, 6.0 }
};
```

2-D Table with column-major array layout

```
/* Block parameters (default storage) */
P_rtwdemo_row_lut2d_T rtwdemo_row_lut2d_P = {
  /* Variable: Table_3by2
   * Referenced by: '<Root>/2-D Lookup Table'
   */
  { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0 }
};
```

In the generated code, the table data is in row-major order and the interpolation algorithm is optimized for row-major array layout. The row-major algorithm operates on table data that is contiguous in memory. This leads to faster cache access, making these algorithms cache-friendly.

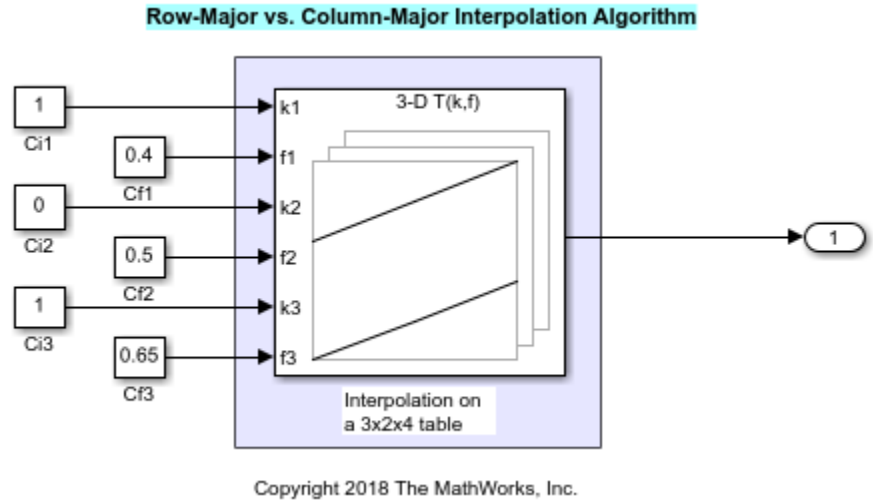
This table summarizes the relationship between array layout and cache-friendly algorithms. It is recommended to use the algorithm that is optimized for the specified array layout to achieve good performance. For example, use row-major interpolation algorithm when the array layout is set to **Row-Major** for code generation.

Array Layout	Algorithm	Cache-Friendly Algorithm
Column-major	Column-major	✓ (Recommended)
Row-major	Row-major	✓ (Recommended)
Row-major	Column-major	⚠ (Not recommended)
Column-major	Row-major	⚠ (Not recommended)

Interpolation on a 3-D Table

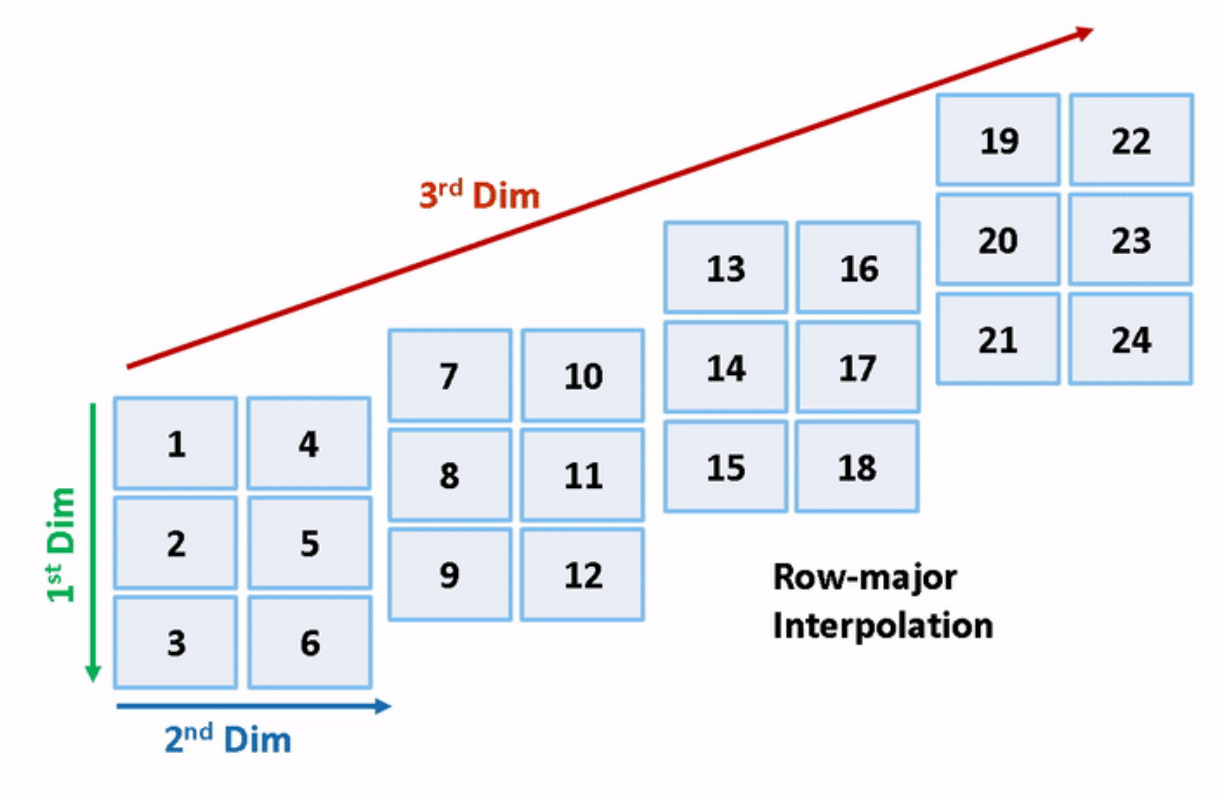
1. Open the example model `rtwdemo_row_interpalg`.

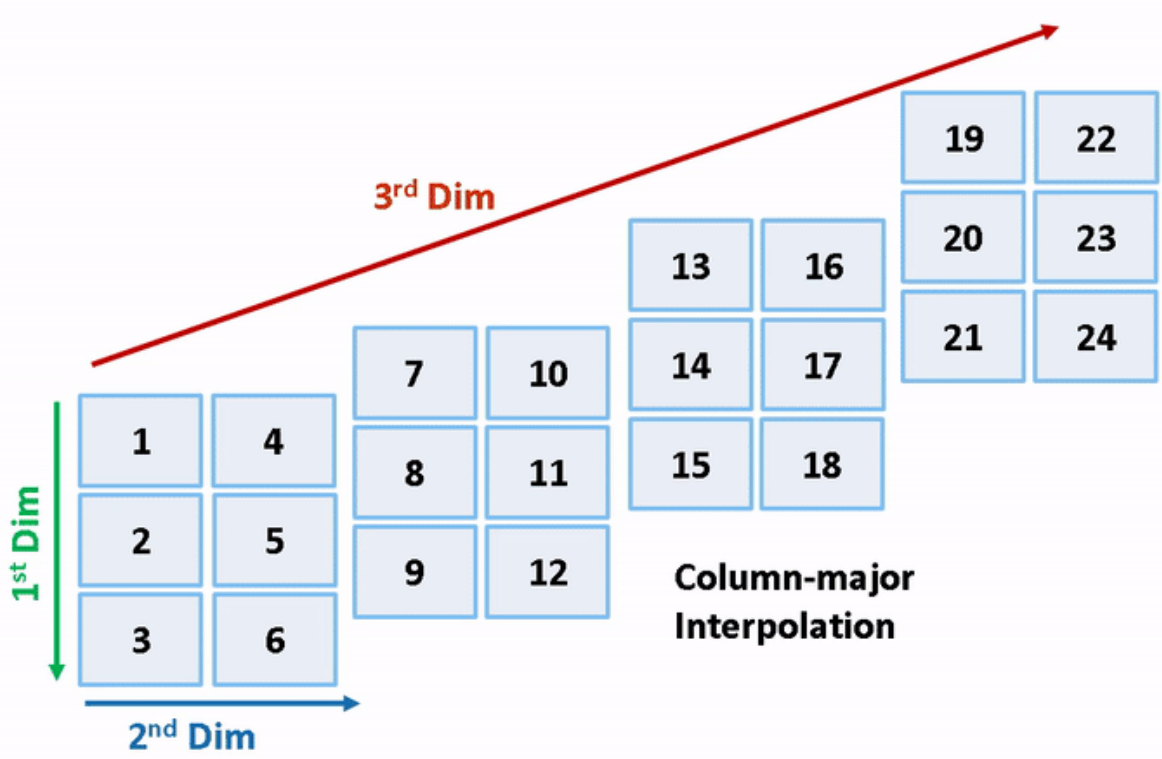
```
open_system('rtwdemo_row_interpalg');
```



2. Generate code for the model by using the preceding procedure. Simulate and generate code from the model by repeating the steps performed on `rtwdemo_row_lut2d` model.

The row-major and column-major interpolations on the 3-D table used in the example model are illustrated here.





```
close_system('rtwdemo_row_lut2d',0);
close_system('rtwdemo_row_interpalg', 0);
```

Interpolation with Subtable Selection Algorithm for Row-Major Array Layout

This example illustrates the algorithm for interpolating a subtable that the interpolation block selects from a higher dimension table. The interpolation algorithm with subtable selection is optimized for row-major array layout. As a reference, see the interpolation algorithm with subtable selection that is optimized for column-major array layout. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

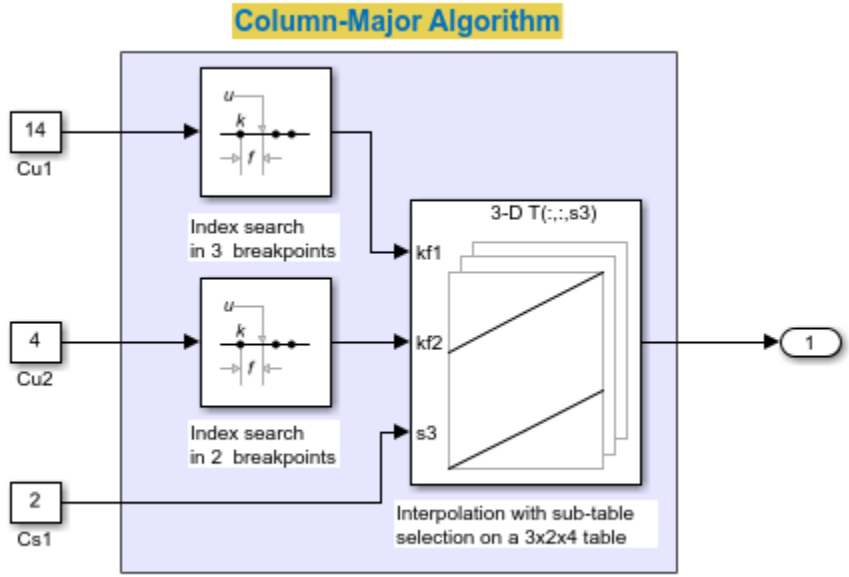
In this example, you:

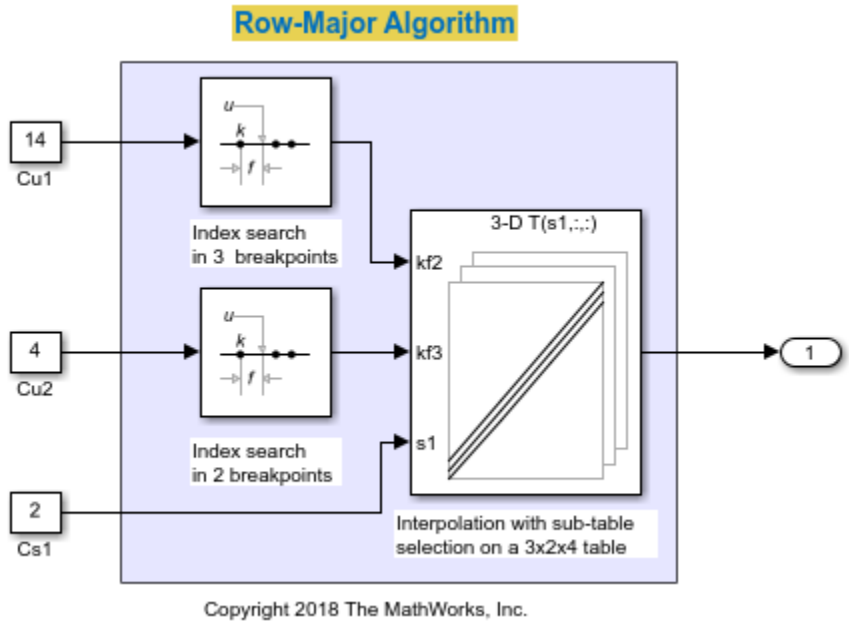
- Interpolate on a selected subtable with column-major and row-major algorithm.
- Preserve block semantics through table permutation.
- Generate code with row-major algorithm and array layout.

Simulate by Using Row-Major Algorithm

1. Open example model `rtwdemo_col_interpselsubtable` and `rtwdemo_row_interpselsubtable`.

```
open_system('rtwdemo_col_interpselsubtable');
open_system('rtwdemo_row_interpselsubtable');
```





2. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_col_interpselsubtable` is configured to use a column-major algorithm. Run the model and observe the output stored in workspace variable `yout`.

3. To enable row-major algorithms, open the Model Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter **Use algorithms optimized for row-major array layout**. Alternatively, in the MATLAB Command Window, enter:

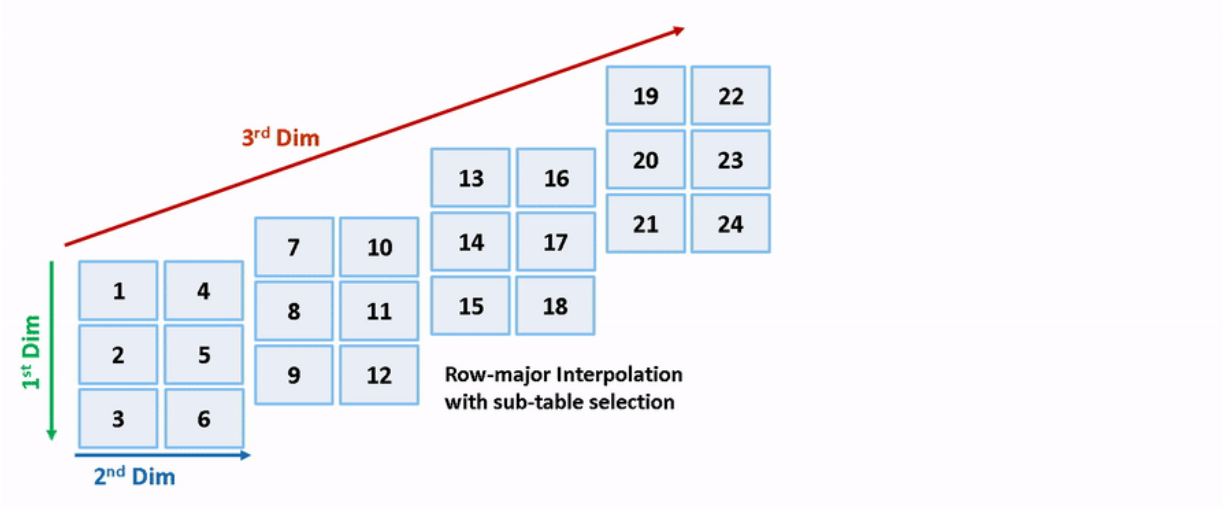
```
set_param('rtwdemo_col_interpselsubtable','UseRowMajorAlgorithm','on');
```

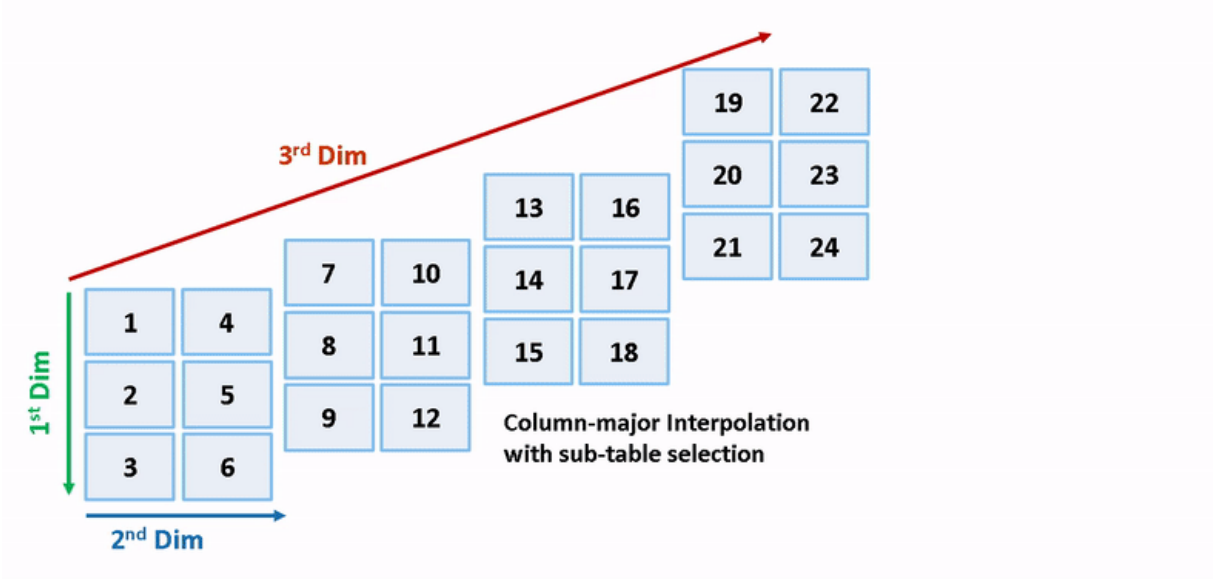
4. Simulate the model and observe the error.

```
The range of values for the first signal in the bus object propagated to the input port kf2
of block 'rtwdemo_col_interpselsubtable/Interp' does not match the size of the corresponding
table dimension of 2. Specify a different table dimension or modify the range for the first
signal in the bus object propagated to the input port kf2.

Component: Simulink | Category: Block error
```

The column-major and row-major algorithms differ in terms of subtable selection and interpolation order. The subtable selection is performed inside the original table. No extra memory is allocated for the subtable. The selected subtable is contiguous in memory. The interpolation order is cache-friendly for column-major algorithms with column-major array layouts and row-major algorithms with row-major array layouts. This illustration compares the row-major and column-major interpolations with subtable selection.





Due to a change in semantics, column-major and row-major interpolations are performed on different subtables or data sets. This interpolation leads to different numeric outputs or an error.

Preserve Semantics Through Table Permutation

With subtable selection, the model semantics change when switching from a column-major algorithm to a row-major algorithm. To preserve the semantics or ensure that the same subtable is selected for interpolation, you need to permute the table data. Otherwise, Simulink might report error if it encounters inconsistent breakpoint and table data between prelookup and interpolation blocks.

1. The block `rtwdemo_col_interpselsubtable/Interp` has 3-D table data given as **T3d = reshape([1:24], 3,2,4)** and one selection port with input **2** (0-based index). The selected subtable is **T3d(:,:,3)** (1-based index in MATLAB) for the column-major algorithm. To preserve the semantics for the row-major algorithm on the same model, that is, select the same subtable with same index and selection port inputs, permute the table as **T3d_p = permute(T3d, [3,1,2])**. The selected subtable is **T3d_p(3,:,:)** (1-based index) for the row-major algorithm.

```
T3d_str = get_param('rtwdemo_col_interpselsubtable/Interp','Table');
set_param('rtwdemo_col_interpselsubtable/Interp','Table', ...
    ['permute(',T3d_str,',[3,1,2])']);
```

2. When you import table data from a file, you must permute the table data in the file before importing it. This permutation keeps the table tunable throughout the simulation and code generation workflow.

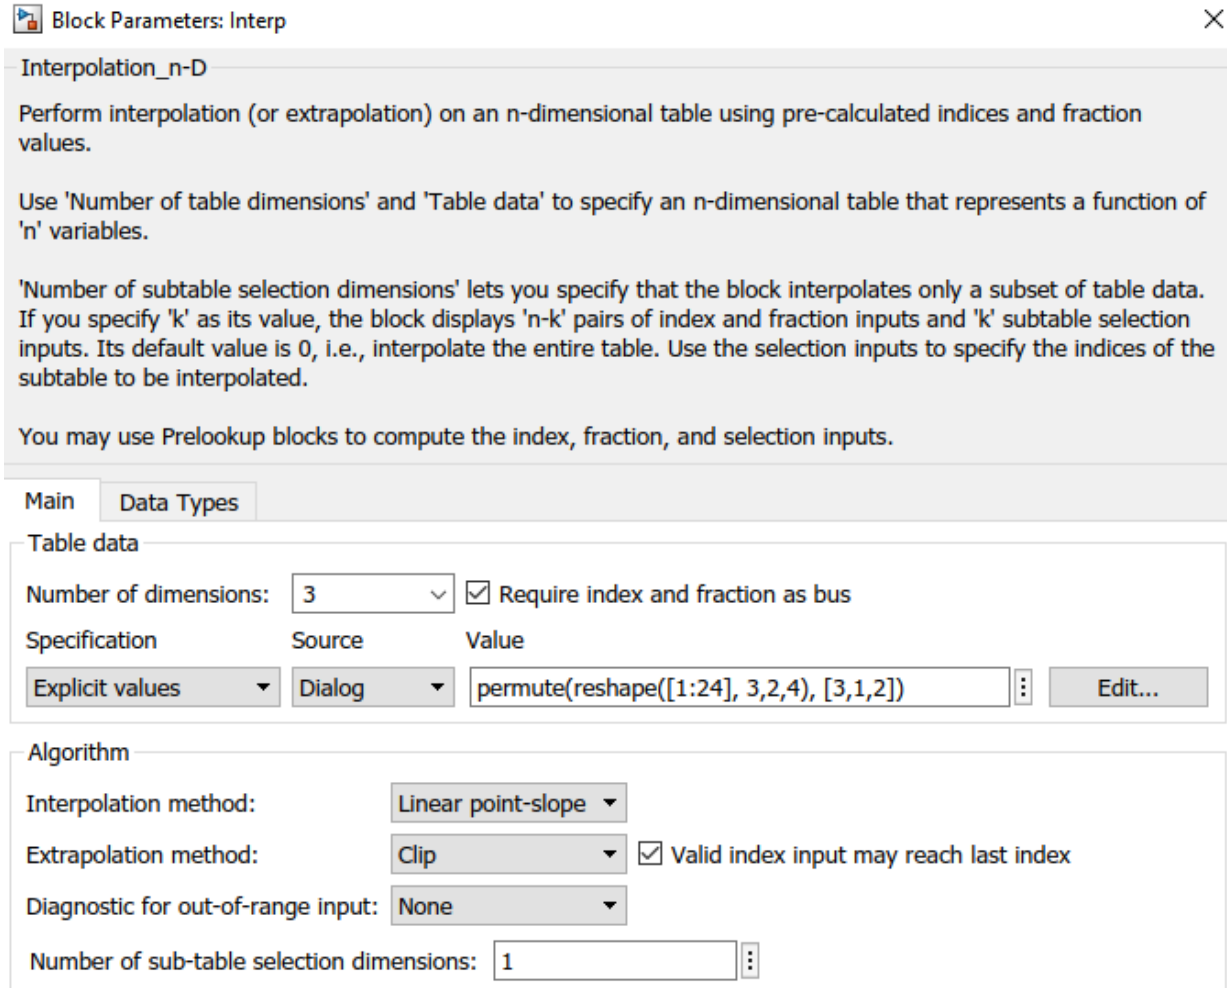
Generate Code by Using Row-Major Algorithm and Array Layout

After permuting the table data, model `rtwdemo_col_interpselsubtable` is configured for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_interpselsubtable` that uses a row-major algorithm.

1. To set up the model for row-major code generation, open the Model Configuration Parameters dialog box. In addition to selecting the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter **Array Layout** to `Row-Major` option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_col_interpselsubtable', 'ArrayLayout','Row-major');
```

2. In the dialog box, examine the permuted 3-D table data and the selected 2-D subtable.



3. Change your current folder in MATLAB to a writable folder. On the model toolstrip, click **Build model** to generate C code. In the generated code, observe the 2-D interpolation algorithm optimized for row-major data.

```
93  static real_T intrp2d_la(const uint32_T bpIndex[], const real_T frac[], const
94    real_T table[], const uint32_T stride, const uint32_T maxIndex[])
95  {
96    real_T y;
97    real_T yR_1d;
98    uint32_T offset_1d;
99
100   /* Row-major Interpolation 2-D
101      Interpolation method: 'Linear point-slope'
102      Use last breakpoint for index at or above upper limit: 'on'
103      Overflow mode: 'wrapping'
104    */
105   offset_1d = bpIndex[1U] * stride + bpIndex[0U];
106   if (bpIndex[0U] == maxIndex[0U]) {
107     y = table[offset_1d];
108   } else {
109     y = (table[offset_1d + 1U] - table[offset_1d]) * frac[0U] + table[offset_1d];
110   }
111
112   if (bpIndex[1U] == maxIndex[1U]) {
113   } else {
114     offset_1d += stride;
115     if (bpIndex[0U] == maxIndex[0U]) {
116       yR_1d = table[offset_1d];
117     } else {
118       yR_1d = (table[offset_1d + 1U] - table[offset_1d]) * frac[0U] +
119         table[offset_1d];
120     }
121
122     y += (yR_1d - y) * frac[1U];
123   }
124
125   return y;
126 }
```

```
close_system('rtwdemo_col_interpselsubtable',0);
```

Direct Lookup Table Algorithm for Row-Major Array Layout

This example shows how Simulink selects a vector or a 2-D matrix from table data. In a 2-D table, the output vector can be a column or a row depending on the model configuration setting **Use algorithms optimized for row-major array layout**. In this example, the Direct Lookup Table algorithm is optimized for row-major array layout. The Direct Lookup Table algorithm that is optimized for column-major array layout is also presented as a reference. The code generated by using row-major interpolation algorithm performs with the best speed and memory usage when operating on table data with row-major array layout. The code generated by using column-major algorithm performs best with column-major array layout.

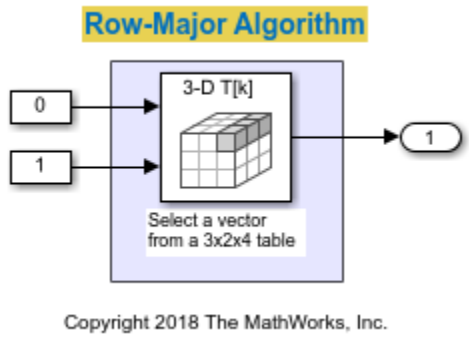
In this example, you:

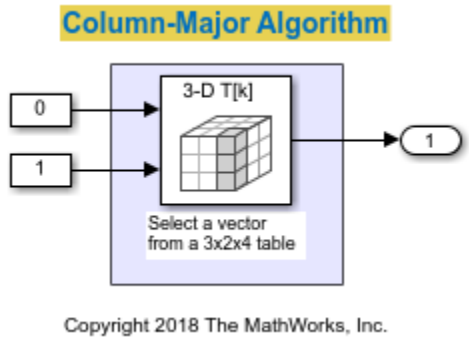
- Output a vector or a plane by using direct lookup with a column-major or a row-major algorithm.
- Preserve semantics when switching from a column-major algorithm to a row-major algorithm.
- Generate code by using a row-major algorithm and an array layout.

Simulate by Using Row-Major Algorithm — Output a Vector from 3-D Table

Open example models `rtwdemo_row_dlut3d_selvector` and `rtwdemo_col_dlut3d_selvector`.

```
open_system('rtwdemo_row_dlut3d_selvector');
open_system('rtwdemo_col_dlut3d_selvector');
```





1. By default, Simulink configures a model with column-major algorithm and column-major array layout. The model `rtwdemo_col_dlut3d_selvector` is preconfigured to use column-major algorithms. Simulate the model and observe the output stored in workspace variable `yout`.

2. To enable row-major algorithms, open the Model Configuration Parameters dialog box. On the **Math and Data Types** pane, select the configuration parameter **Use algorithms optimized for row-major array layout**. Alternatively, in the MATLAB Command Window, enter:

```
set_param('rtwdemo_col_dlut3d_selvector','UseRowMajorAlgorithm','on');
```

3. Click **Run** to simulate the model. Observe the change in output dimension and numeric values logged in workspace variable `yout`.

The column-major and row-major algorithms differ semantically in the selection of output vector. For example, in a 2-D table, Simulink selects a column vector as output for column-major algorithm and a row vector for row-major algorithm. In a table with a 3-D or higher dimension, Simulink selects the output vector from the first dimension of the table for a column-major algorithm and from the last dimension of the table for a row-major algorithm. The elements of the selected vector are contiguous in the table storage memory. In this example, the last dimension is the third dimension of the 3-D table. Due to semantic change, column-major and row-major direct lookup table algorithms output different vector size and numeric values.

These illustrations compare the vector output of row-major and column-major direct lookup table algorithms in a 3-D table.

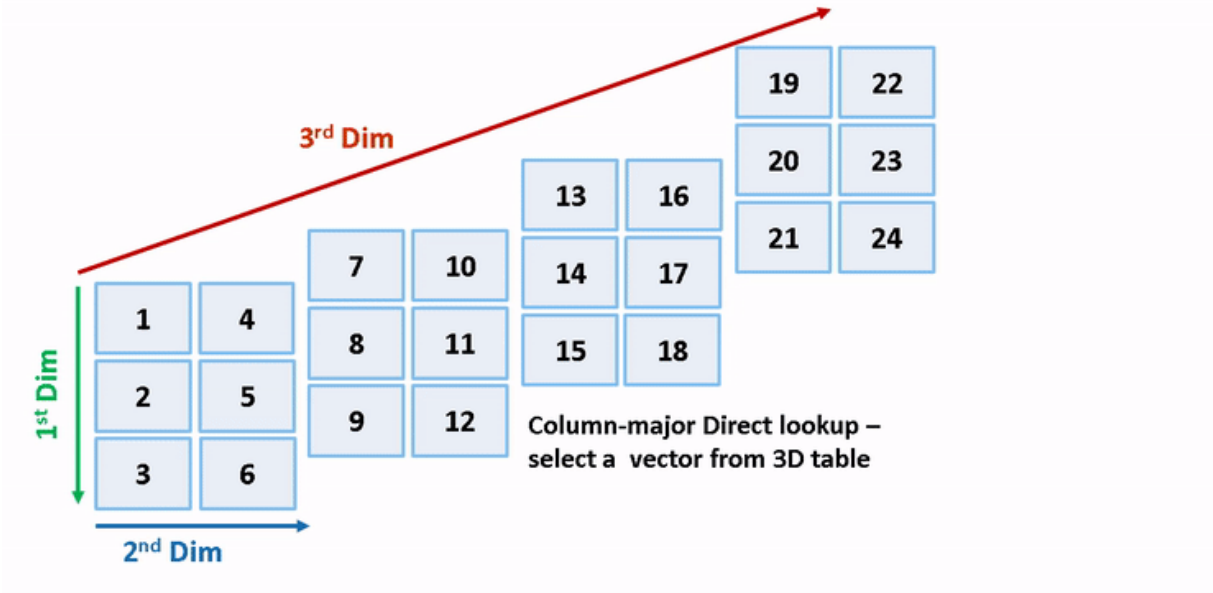
Row-major Direct lookup –
select a vector from 3D table



Preserve Semantics by Using Table Permutation

For a direct lookup table that outputs a vector or 2-D matrix, the model semantics change when you switch from a column-major algorithm to a row-major algorithm. To preserve the semantics or ensure the same output given the same block I/O connections, you must permute the table data. Otherwise, Simulink propogates incorrect dimensions to downstream blocks.

1. The block `rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)` has 3-D table data **T3d = reshape([1:24], 3,2,4)** and two input ports with value **0** and **1** (both are 0-based indices). The selected output vector is **T3d(:,1,2)** (1-based index) for a column-major algorithm. To preserve the semantics for a row-major algorithm on the same model, that is, select the same vector with same index port inputs, permute the table as **T3d_p = permute(T3d, [2,3,1])**. For a row-major algorithm, the selected vector is **T3d_p(1,2,:)**.

```
T3d_str = get_param('rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)','Table');
set_param('rtwdemo_col_dlut3d_selvector/Direct Lookup Table (n-D)','Table',...
['permute(',T3d_str,',[2,3,1])']);
```

2. When you import table data from a file, you must permute the table data in the file before importing it. This permutation keeps the table tunable throughout the simulation and code generation workflow.

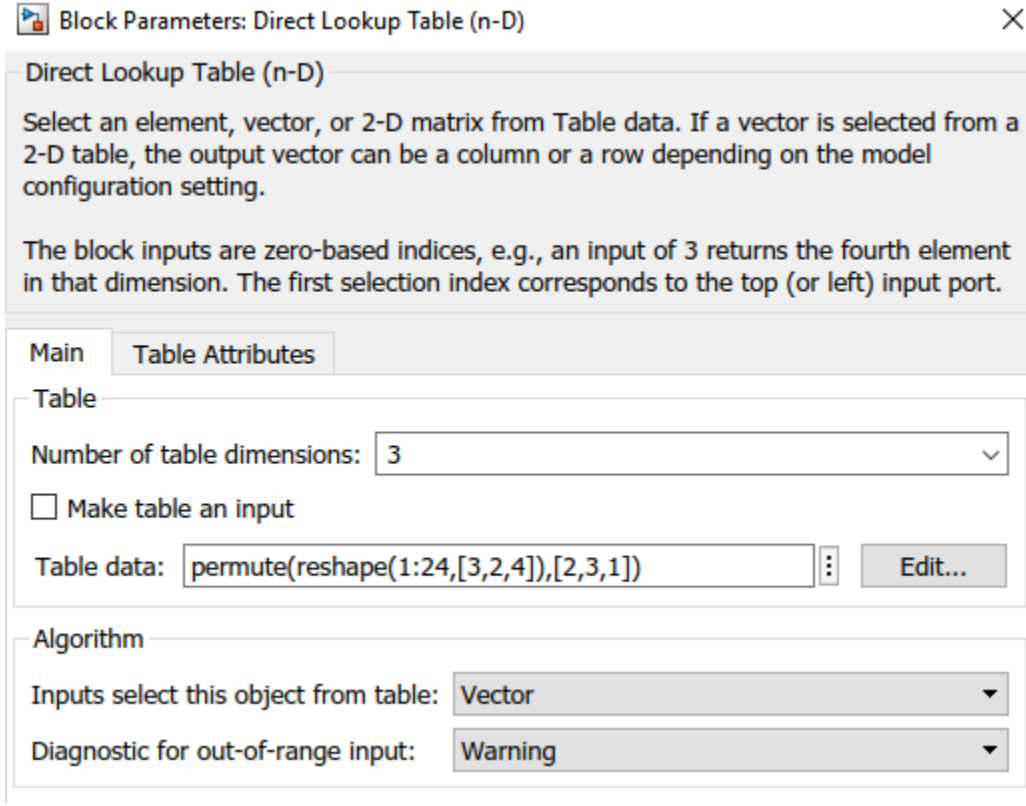
Code Generation by Using Row-Major Algorithm and Array Layout

After permuting the table data, Simulink configures the model `rtwdemo_col_dlut3d_selvector` for row-major simulation. The model is equivalent to the preconfigured model `rtwdemo_row_dlut3d_selvector` that has permuted table data and uses a row-major algorithm.

1. To set up these models for row-major code generation, open the Model Configuration Parameters dialog box. In addition to enabling the **Use algorithms optimized for row-major array layout** configuration parameter, on the **Code Generation > Interface** pane, set the configuration parameter **Array Layout** to the `Row-Major` option. This configuration parameter enables the model for row-major code generation. Alternatively, in the MATLAB Command Window, enter:

```
% For model 'rtwdemo_col_dlut3d_selvector'
set_param('rtwdemo_col_dlut3d_selvector', 'ArrayLayout','Row-major');
% For model 'rtwdemo_row_dlut3d_selvector'
set_param('rtwdemo_row_dlut3d_selvector', 'ArrayLayout','Row-major');
```

2. In the Direct Lookup Table (n-D) block dialog box, examine the permuted 3-D table data.

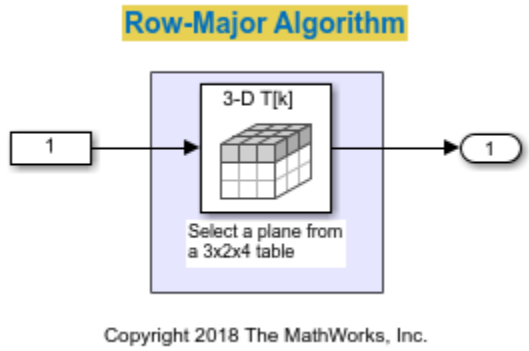


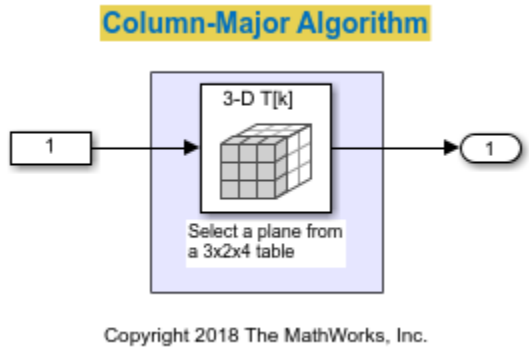
3. Change your current folder in MATLAB to a writable folder. On the model toolstrip, click **Build model** to generate C code. In the generated code, the `memcpy` function replaces the `for` loops. Using `memcpy` reduces the amount of memory for storing data. This optimization improves execution speed.

```
34  void rtwdemo_row_dlut3d_selvector_step(void)
35  {
36    /* Outport: '<Root>/Out2' incorporates:
37     *  LookupNDDirect: '<Root>/Direct Lookup Table (n-D)'
38     *
39     * About '<Root>/Direct Lookup Table (n-D)':
40     *  3-dimensional Direct Look-Up returning a Vector,
41     *  which is contiguous for row-major array
42     */
43    memcpy(&rtY.Out2[0], &rtCP_DirectLookupTablenD_table[3], 3U * sizeof(real_T));
44  }
```

Simulate by Using Row-Major Algorithm — Output a Plane from 3-D Table

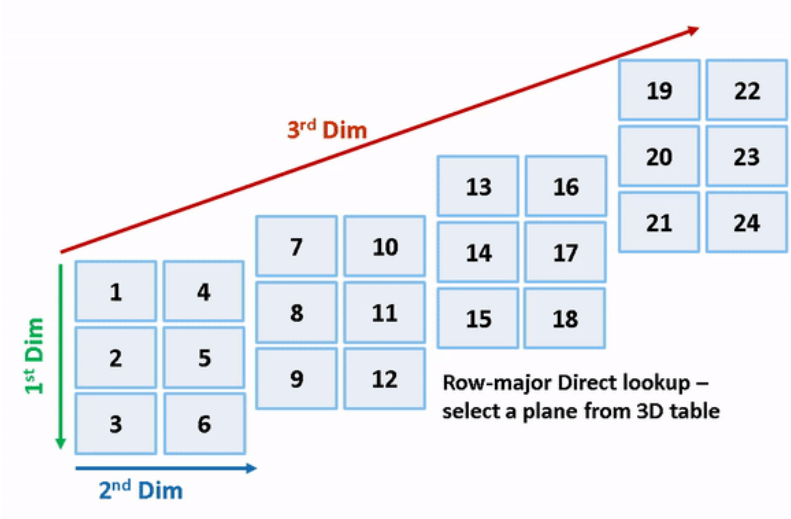
```
open_system('rtwdemo_row_dlut3d_selplane');
open_system('rtwdemo_col_dlut3d_selplane');
```

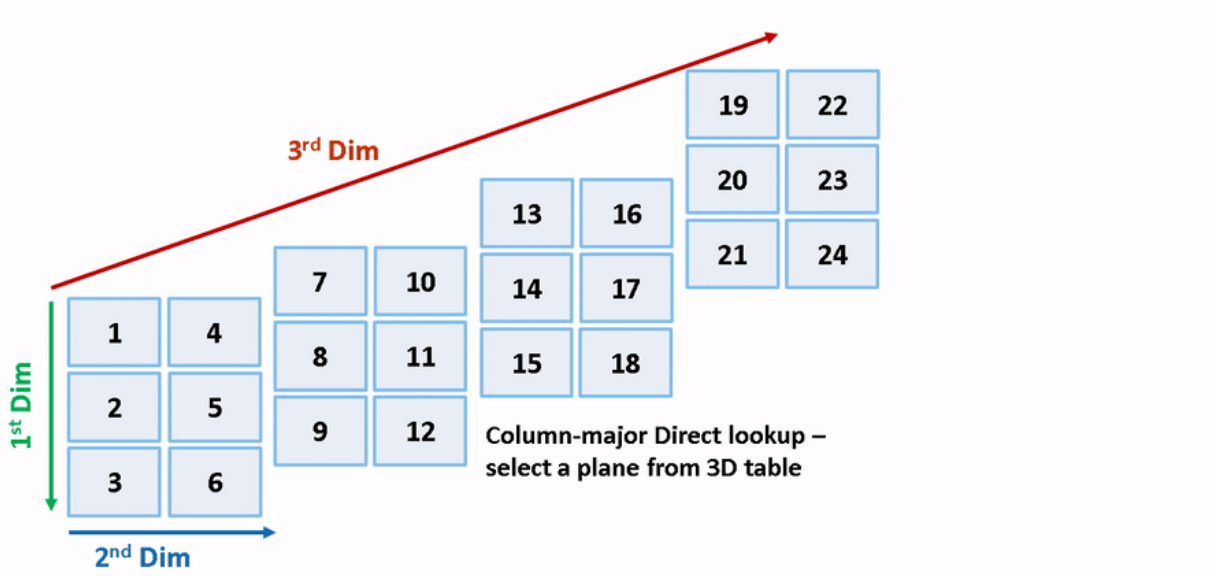




1. Open the example model `rtwdemo_row_dlut3d_selplane` that outputs a plane or 2-D matrix from a 3-D table.

2. Simulate and generate code from the model by repeating the steps performed on `rtwdemo_col_dlut3d_selvector`. The row-major and column-major direct lookup algorithms that output a 2-D matrix from a 3-D table are illustrated here.





```
close_system('rtwdemo_row_dlut3d_selvector',0);
close_system('rtwdemo_col_dlut3d_selvector',0);
close_system('rtwdemo_row_dlut3d_selplane',0);
close_system('rtwdemo_col_dlut3d_selplane',0);
```

Generate Row-Major Code for S-Functions

You can generate row-major code for models that contain S-functions. By default, the code generator generates column-major code. To learn more about row-major code generation, see “Code Generation of Matrices and Arrays” (Simulink Coder).

For an existing model that contains S-functions, when you set the configuration parameter “Array layout” (Simulink Coder) as `Row-major`, the configuration parameter “External functions compatibility for row-major code generation” (Simulink Coder) is enabled and set to `error` by default. When you try to build the existing model, you get an error because the S-functions are not enabled for row-major code generation by default. You can test the compatibility of your S-function for row-major code generation by using the **External functions compatibility for row-major code generation** configuration parameter.

This workflow is also applicable to C Caller blocks in a model.

Example

1. Open example model `ex_sfcn_rowmajor_unset`. The model needs these additional files:

- S-function: `ex_sfcn_rowmajor.c`
- TLC: `ex_sfcn_rowmajor.tlc`.

Save these files to your local folder.

```
open_system('ex_sfcn_rowmajor_unset');
```

2. The model is configured with **Array layout** set to `Column-major`. To enable row-major code generation, set **Array layout** to `Row-major`.

3. When you build the model, the code generator terminates the build and you see this error message:

```
### Build procedure for model: 'ex_sfcn_rowmajor_unset' aborted due to an error.

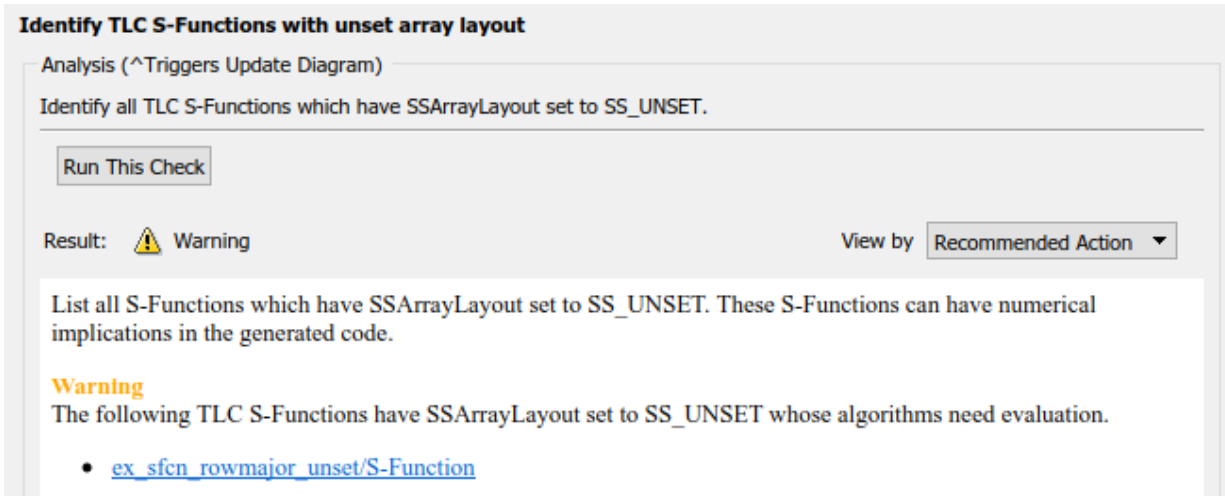
S-function "ex_sfcn_rowmajor" with SSArrayLayout set to 'SS_UNSET' does not support row major code
generation. To test this S-function, set the configuration parameter 'External functions
compatibility for row-major code generation' to 'warning' or 'none'.

Component: Simulink | Category: Block diagram error
```

4. To proceed, do one of the following:

- If you want to test your existing S-functions with the row-major code for the model, change the setting of the configuration parameter **External functions compatibility for row-major code generation** to `warning` or `none`. The code generator completes the build without generating row-major code for the S-functions.
- If you want to update your S-functions so that they are compatible with row-major array layout, use the S-function API to enable the S-function for row-major code generation.

To test your model for S-functions with unspecified array layout, you can also run the Model Advisor checks on the model. Select the **Identify TLC S-functions with unset array layout** check and click the **Run This Check** button. If the model includes S-functions with unspecified array layout, you see a warning such as:



To specify the array layout of the user-defined S-function, use the `ssSetArrayLayoutForCodeGen` function of the SimStruct API. You can set the enumerated type `SSArrayLayout` to:

- `SS_UNSET` – This setting is the default setting that disables the block for row-major code generation.
- `SS_COLUMN_MAJOR` – Specify the block for column-major code generation only.
- `SS_ROW_MAJOR` – Specify the block for row-major code generation only.
- SS_ALL – Specify the block as allowed for code generation regardless of the array layout.

5. Update the `ex_sfcn_rowmajor.c` file by adding the `ssSetArrayLayoutForCodeGen` in the `mdlInitializeSizes` method:

```
static void mdlInitializeSizes(SimStruct *S)
{
    /* Specify array layout of the S-function */
    ssSetArrayLayoutForCodeGen(S, SS_ROW_MAJOR);
    .
    .
    .
}
```

If your S-function is not affected by an array layout, set `SSArrayLayout` to `SS_ALL`.

6. Compile the S-function by using this command in the MATLAB Command Window:

```
mex ex_sfcn_rowmajor.c
```

```
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
```

7. To build the model and generate code, press **Ctrl+B**.

If you generate S-functions by using S-Function Builder, use the parameter **Array layout** to specify the majority of the S-function. For more information, see “S-Function Builder Dialog Box” (Simulink). If you use the Legacy Code Tool to integrate C functions, use the `convertNDArrayToRowMajor` option in `legacy_code`. The S-Function Builder and

Legacy Code Tool apply preceding transposes when the S-function is set to row-major array layout during simulation in normal mode.

Code Generation

Configuration for Simulink Coder

Code Generation Configuration

When you are ready to generate code for a model, you can modify the model configuration parameters specific to code generation. The code generation parameters determine how the code generator produces code and builds an executable program from your model.

The model configuration parameters for code generation are in the **Code Generation** and **Optimization** panes in the Configuration Parameters dialog box. The content of the **Code Generation** pane and its subpanes can change depending on the target that you specify. Some configuration options are available only with the Embedded Coder product. The **Optimization** pane includes code generation parameters that help to improve the performance of the generated code.

Your application objectives can include a combination of these code generation objectives: debugging, traceability, execution efficiency, and safety precaution. There are tradeoffs associated with these configuration choices, such as execution speed and memory usage. To help configure a model to achieve your application objectives, use the Model Advisor and the Code Generation Advisor.

Open the Model Configuration for Code Generation

To modify the model configuration parameters for code generation, open the **Code Generation** pane. There are several different ways to open the **Code Generation** pane from the Simulink editor:

- To open the Configuration Parameters dialog box, click the model configuration parameters icon.

  

  Then, click **Code Generation** in the **Select** (left) pane.
- From the **Simulation** menu, select **Model Configuration Parameters**. When the Configuration Parameters dialog box opens, click **Code Generation** in the **Select** (left) pane.
- From the **Code** menu, select **C/C++ Code > Code Generation Options**.
- From the **View** menu in the model window, select **Model Explorer**, or from the MATLAB command line, type `daexplr` and press **Enter**. In the Model Explorer, expand the node for the current model in the left pane and click the Configurations

node. In the **Contents** pane, right-click the configuration and select **Open** from the context menu. Then click **Code Generation** in the left pane.

Note In the Configuration Parameters dialog box, when you change the value of a check box, menu selection, or edit field, the white background of the element changes color to indicate that you made an unsaved change. When you click **OK**, **Cancel**, or **Apply**, the background resets to white.

Configuration Tools

To help you configure your model for code generation and to check your configuration against your code generation objectives, Simulink Coder and Embedded Coder provide several tools.

Goal	Approach	More Information
Automate configuration.	At the MATLAB command line, use the `set_param` function	"Configure Code Generation Parameters for Model Programmatically" on page 42-5
Configure your model for code generation quickly and easily (Embedded Coder).	Embedded Coder Quick Start tool	"Generate Code by Using the Quick Start Tool" on page 48-10
Use a template to create a model configured for code generation, ready for you to add your own blocks.	Code generation templates	• "Generate Code and Simulate Models in a Project" (Simulink Coder) • "Generate Code and Simulate Models in a Project"
To configure your model for code generation, use Simulink blocks and predefined or custom MATLAB scripts.	Code Generation Wizards blocks	"Configure and Optimize Model with Configuration Wizard Blocks" on page 43-23

Goal	Approach	More Information
Verify that your model meets standards and guidelines.	Model Advisor	“Select and Run Model Advisor Checks” (Simulink)
Verify that your model meets your application objectives.	Code Generation Advisor	“Application Objectives Using Code Generation Advisor” on page 42-21

Configure Code Generation Parameters for Model Programmatically

You can modify code generation parameters for the active configuration set in the Configuration Parameters dialog box or from the MATLAB command line. Use the command-line approach for creating a script that automates setting parameters for an established model configuration.

Modify Parameters to Support Execution efficiency

In this example, you modify the configuration parameters to support the Code Generation Advisor application objective, `Execution efficiency`.

Step 1. Open a model.

```
slexAircraftExample
```

Step 2. Get the active configuration set.

```
cs = getActiveConfigSet(model);
```

Step 3. Select the Generic Real-Time (GRT) target.

```
switchTarget(cs,'grt.tlc',[]);
```

Step 4. To optimize execution speed, modify parameters.

If your application objective is `Execution efficiency`, use `set_param` to modify these parameters:

```
set_param(cs,'MatFileLogging','off');
set_param(cs,'SupportNonFinite','off');
set_param(cs,'RTWCompilerOptimization','on');
set_param(cs,'OptimizeBlockIOStorage','on');
set_param(cs,'EnhancedBackFolding','on');
set_param(cs,'ConditionallyExecuteInputs','on')
set_param(cs,'DefaultParameterBehavior','Inlined');
set_param(cs,'BooleanDataType','on');
set_param(cs,'BlockReduction','on');
set_param(cs,'ExpressionFolding','on');
set_param(cs,'LocalBlockOutputs','on');
set_param(cs,'EfficientFloat2IntCast','on');
set_param(cs,'BufferReuse','on');
```

Step 5. Save the model configuration to a file.

Save the model configuration to a file, `'Exec_efficiency_cs.m'`, and view the parameter settings.

```
saveAs(cs,'Exec_Efficiency_cs');
dbtype Exec_Efficiency_cs 1:50
```

More About

- “Code Generation Configuration” on page 42-2
- “Application Objectives Using Code Generation Advisor” on page 42-21

Configure Model from Command Line

The code generator provides model configuration parameters for customizing generated code. Depending on how you use and interact with the generated code, you make configuration decisions. You choose a configuration that best matches your needs for debugging, traceability, code efficiency, and safety precaution.

It is common to automate the model configuration process by using a MATLAB® script once you have decided upon a desired configuration.

The example describes:

- Concepts of working with configuration parameters
- Documentation to understand the code generation options
- Tools and scripts to automate the configuration of a model

Configuration Parameter Workflows

There are many workflows for Configuration Parameters that include persistence within a single model or persistence across multiple models. Depending on your needs, you can work with configuration sets as copies or references. This example shows the basics steps for working directly with the active configuration set of a model. For a comprehensive description of configuration set features and workflows, see Configuration Sets in the Simulink® documentation.

Configuration Set Basics

Load a model into memory.

```
model='rtwdemo_configwizard';
load_system(model)
```

Obtain the model's active configuration set.

```
cs = getActiveConfigSet(model);
```

Simulink® Coder™ exposes a subset of the code generation options. If you are using Simulink® Coder™, select the Generic Real-Time (GRT) target.

```
switchTarget(cs,'grt.tlc',[]);
```

Embedded Coder® exposes the complete set of code generation options. If you are using Embedded Coder®, select the Embedded Real-Time (ERT) target.

```
switchTarget(cs,'ert.tlc',[]);
```

To automate configuration of models built for GRT- and ERT-based targets, the configuration set **`IsERTTarget`** attribute is useful.

```
isERT = strcmp(get_param(cs,'IsERTTarget'),'on');
```

You can interact with code generation options via the model or the configuration set. This example gets and sets options indirectly via the model.

```
deftParamBehvr = get_param(model,'DefaultParameterBehavior');  % Get
set_param(model,'DefaultParameterBehavior',deftParamBehvr)     % Set
```

This example gets and sets options directly via the configuration set.

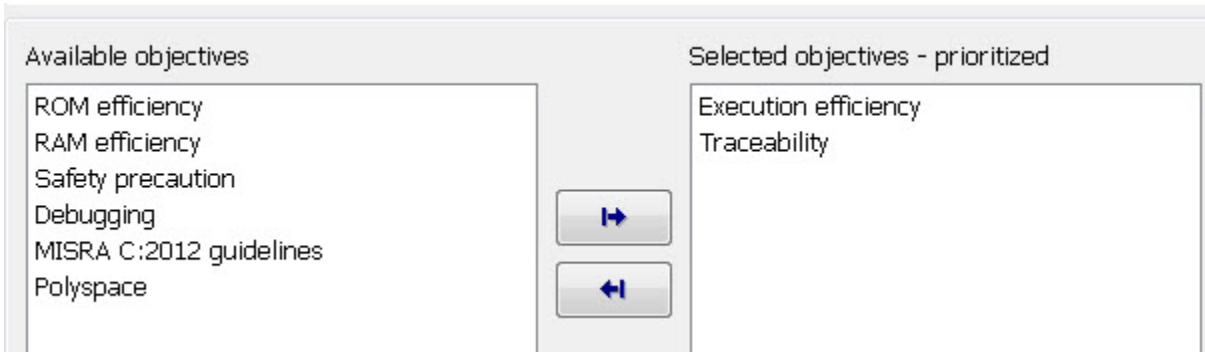
```
if isERT
    lifespan = get_param(cs,'LifeSpan');  % Get LifeSpan
    set_param(cs,'LifeSpan',lifespan)     % Set LifeSpan
end
```

Configuration Option Summary

The full list of code generation options are documented with tradeoffs for debugging, traceability, code efficiency, and safety precaution.

- Simulink® Coder™ options
- Embedded Coder® options

Use Code Generation Advisor to obtain a model configuration optimized for your goals. In the Set Objectives dialog box, you can set and prioritize objectives.



You can find documentation about the Code Generation Advisor in the Simulink Coder documentation and additional documentation specific to Embedded Coder®.

Parameter Configuration Scripts

Simulink® Coder™ provides an example configuration script that you can use as a starting point for your application. A list of the most relevant GRT and ERT code generation options are contained in rtwconfiguremodel.m.

Alternatively, you can generate a MATLAB function that contains the complete list of model configuration parameters by using the configuration set `saveAs` function.

```
% Go to a temporary writable directory.
currentDir = pwd;
rtwdemodir();

% Save the model's configuration parameters to file 'MyConfig.m'.
saveAs(cs,'MyConfig')

% Display the first 50 lines of MyConfig.m.
dbtype MyConfig 1:50
```

```
1     function cs = MyConfig()
2     % MATLAB function for configuration set generated on 03-Mar-2019 16:36:20
3     % MATLAB version: 9.6.0.1065788 (R2019a)
4
5     cs = Simulink.ConfigSet;
6
7     % Original configuration set version: 19.0.0
8     if cs.versionCompare('19.0.0') < 0
9         error('Simulink:MFileVersionViolation', 'The version of the target configurat
10    end
11
12    % Original environment character encoding: windows-1252
13    if ~strcmpi(get_param(0, 'CharacterEncoding'), 'windows-1252')
14        warning('Simulink:EncodingUnMatched', 'The target character encoding (%s) is
15    end
16
17    % Do not change the order of the following commands. There are dependencies betwe
18    cs.set_param('Name', 'Configuration'); % Name
19    cs.set_param('Description', ''); % Description
20
21    % Original configuration set target is ert.tlc
```

```
22    cs.switchTarget('ert.tlc','');
23
24    cs.set_param('HardwareBoard', 'None');   % Hardware board
25
26    cs.set_param('Solver', 'FixedStepDiscrete');   % Solver
27
28    % Solver
29    cs.set_param('StartTime', '0.0');   % Start time
30    cs.set_param('StopTime', '48');   % Stop time
31    cs.set_param('SampleTimeConstraint', 'STIndependent');   % Periodic sample time c
32    cs.set_param('SolverType', 'Fixed-step');   % Type
33
34    % Data Import/Export
35    cs.set_param('Decimation', '1');   % Decimation
36    cs.set_param('LoadExternalInput', 'off');   % Load external input
37    cs.set_param('SaveFinalState', 'off');   % Save final state
38    cs.set_param('LoadInitialState', 'off');   % Load initial state
39    cs.set_param('LimitDataPoints', 'off');   % Limit data points
40    cs.set_param('SaveFormat', 'StructureWithTime');   % Format
41    cs.set_param('SaveOutput', 'off');   % Save output
42    cs.set_param('SaveState', 'off');   % Save states
43    cs.set_param('SignalLogging', 'on');   % Signal logging
44    cs.set_param('DSMLogging', 'on');   % Data stores
45    cs.set_param('InspectSignalLogs', 'off');   % Record logged workspace data in Sir
46    cs.set_param('SaveTime', 'off');   % Save time
47    cs.set_param('ReturnWorkspaceOutputs', 'off');   % Single simulation output
48    cs.set_param('SignalLoggingName', 'sigsOut');   % Signal logging name
49    cs.set_param('DSMLoggingName', 'dsmout');   % Data stores logging name
50    cs.set_param('LoggingToFile', 'off');   % Log Dataset data to file
```

Each parameter setting in the generated file includes a comment for the corresponding parameter string in the Configuration Parameters dialog box.

```
% Return to previous working directory.
cd(currentDir)
```

Configuration Wizard Blocks

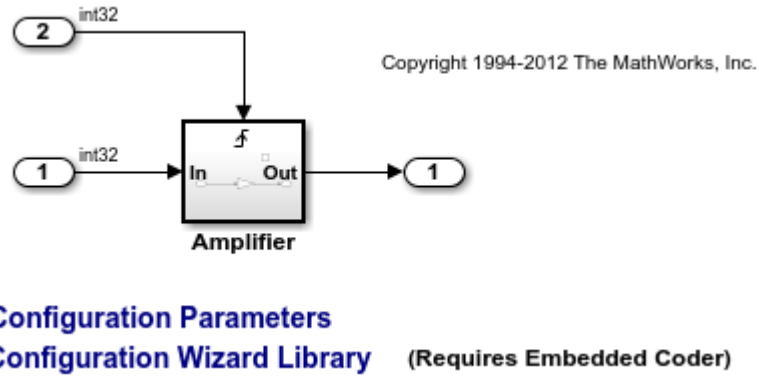
Embedded Coder® provides a set of Configuration Wizard blocks to obtain an initial configuration of a model for a specific goal. The predefined blocks provide configuration for:

- ERT optimized for fixed point
- ERT optimized for floating point

- GRT optimized for fixed and floating point
- GRT debug settings for fixed and floating point
- Custom (you provide the script)

Put the block into a model and double-click it to configure the model. Open model rtwdemo_configwizard and click **Open Configuration Wizard Library** to interact with the blocks.

```
open_system(model)
```



To use configuration wizard blocks in the rtwdemo_configwizard model follow these steps:

- Open the Configuration Wizard Library by clicking the link provided in the model.
- Open the Model's Configuration Parameters by clicking the link provided in the model.
- Drag and drop a Configuration Wizard Block, for example ERT (optimized for fixed point), from the wizard library into the model.
- Double-click the wizard block.

The Configuration Parameter options are modified automatically.

```
% cleanup
rtwdemoclean;
close_system(model,0)
```

Summary

Simulink provides a rich set of MATLAB functions to automate the configuring a model for simulation and code generation. Simulink Coder and Embedded Coder® provide

additional functionality specific for code generation. The Code Generation Advisor optimizes the model configuration based on a set of prioritized goals. You can save the optimal configuration to a MATLAB file by using the configuration set saveAs function, and reuse it across models and projects.

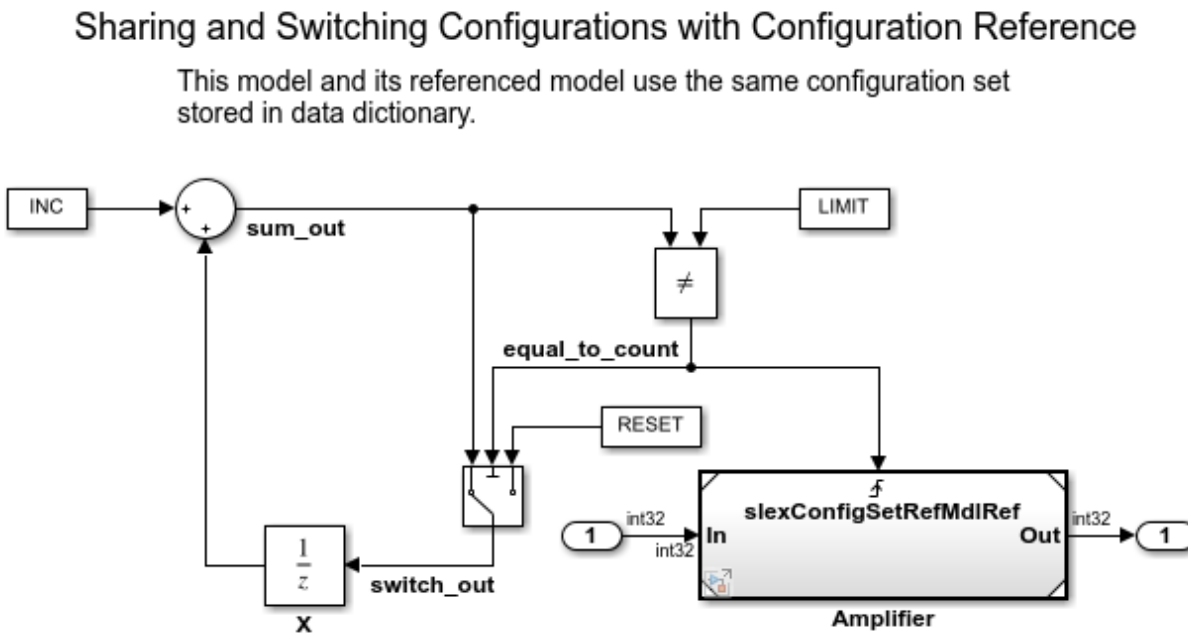
Use Configuration Reference to Select Code Generation Target

This example shows how to use a configuration reference to select a code generation target for a model reference hierarchy without modifying individual models.

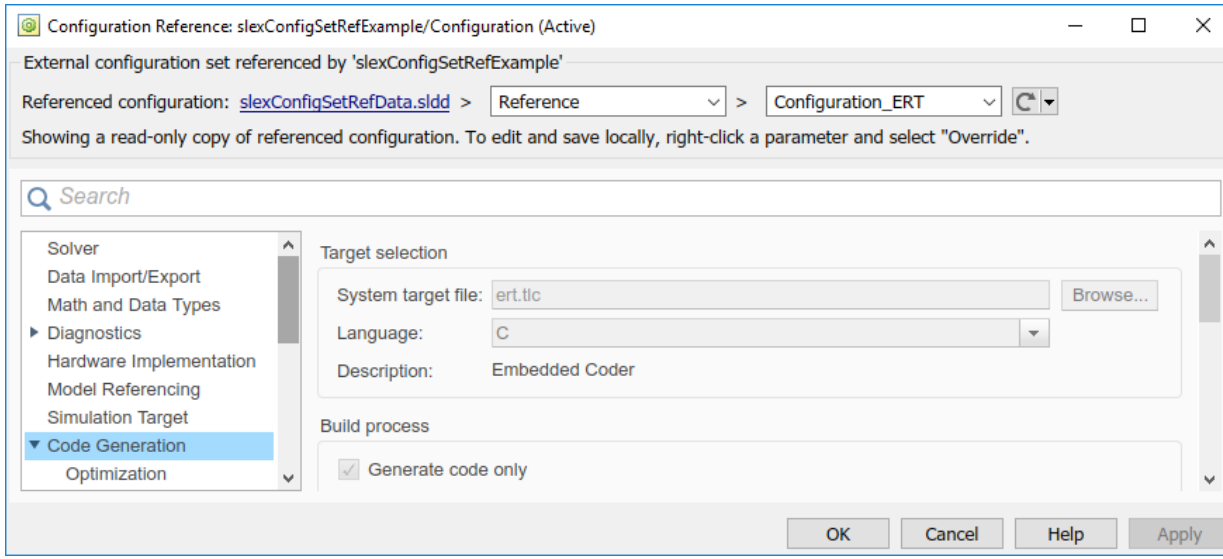
Open Example Model

Open the example model `slexConfigSetRefExample`.

```
open_system('slexConfigSetRefExample');
```



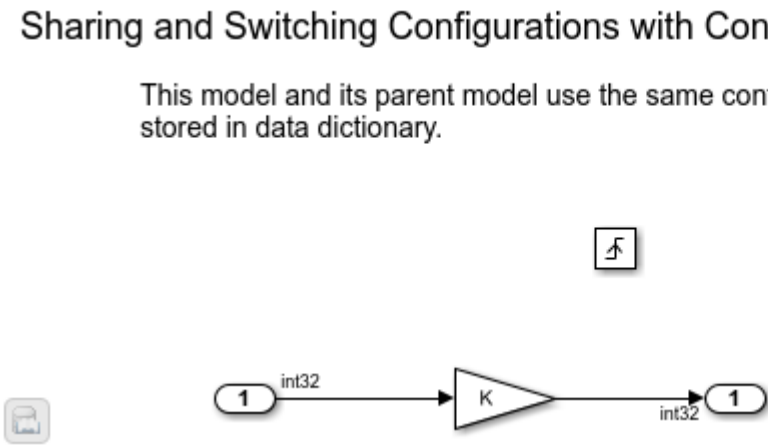
To open the active configuration set for the model `slexConfigSetRefExample`, from the model editor menu, select **Simulation > Model Configuration Parameters**.



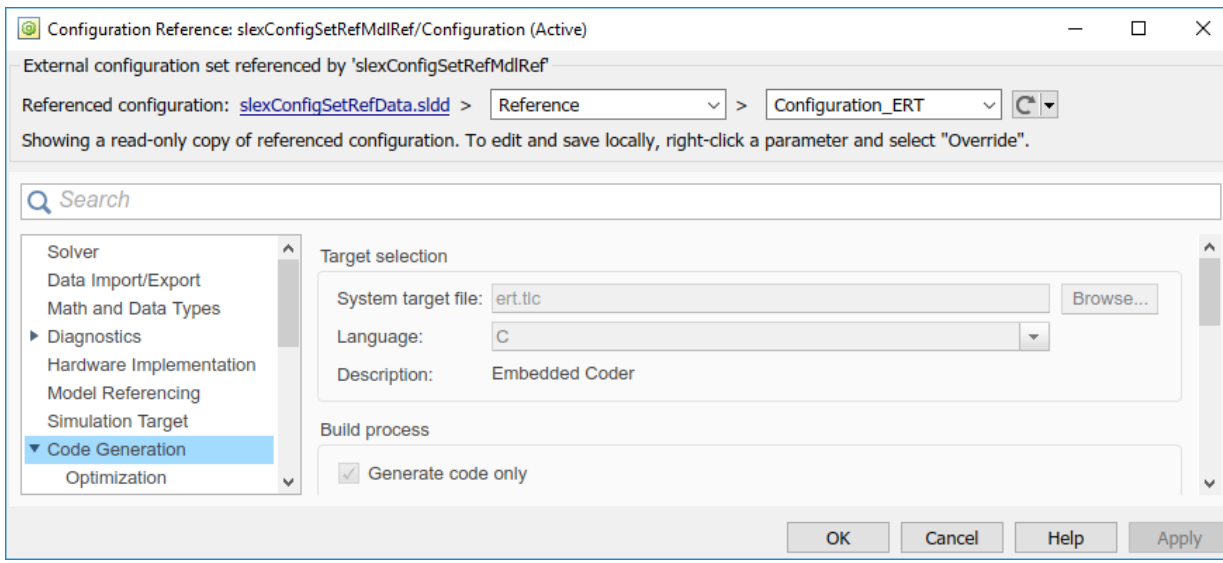
Because the model is using a referenced configuration, the Configuration Reference dialog box opens and displays a read-only view of the referenced configuration set. Information at the top of the dialog box indicates that the model is using the configuration set, `Reference`, located in the data dictionary, `slexConfigSetRefData.sldd`. In this example, `Reference` is another configuration reference, `Configuration_ERT`.

In the model editor, right-click the Model block, `Amplifier`, and select **Open As Root Model**.

```
open_system('slexConfigSetRefExample/Amplifier');
```



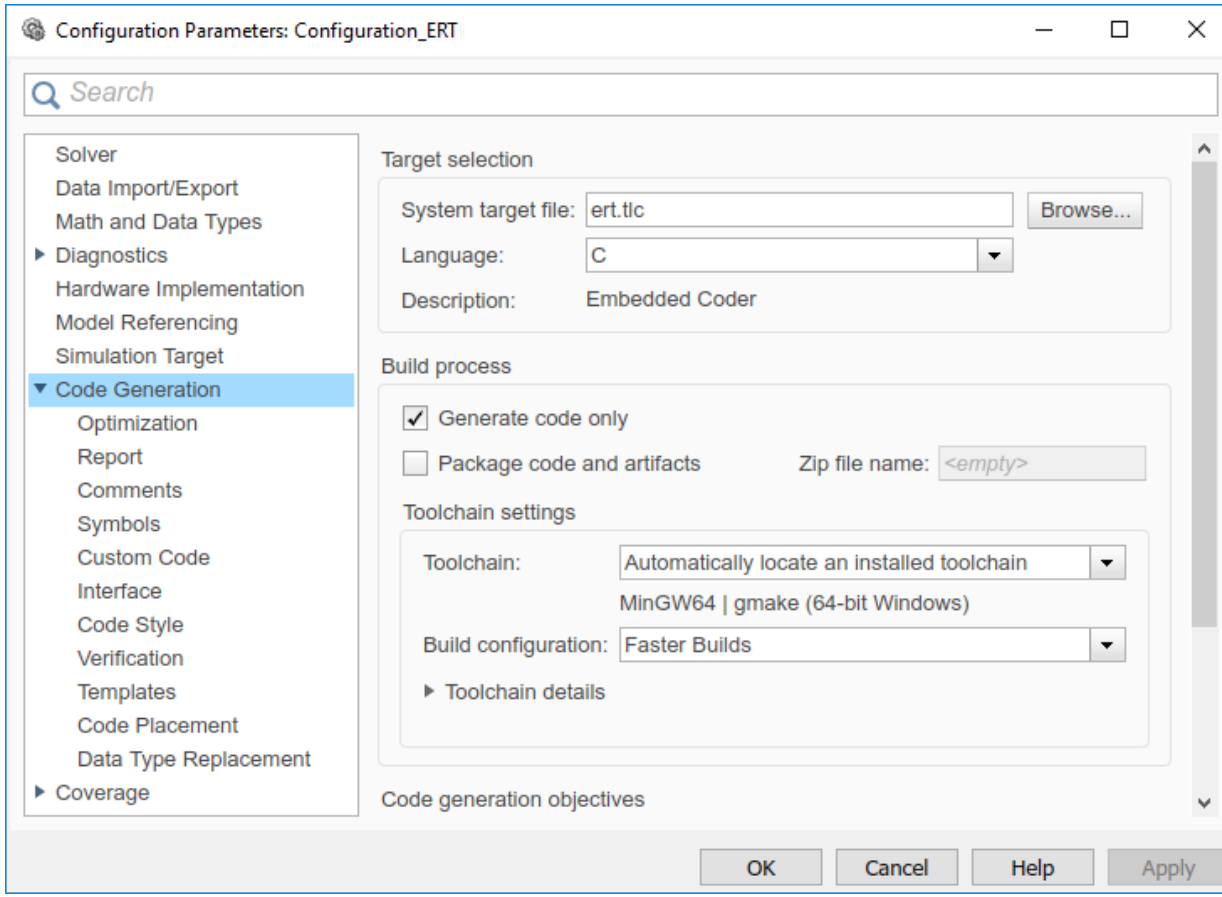
Open the active configuration set for this model. The name and location for the referenced configuration is the same as in `slexConfigSetRefExample`.



Open the Referenced Configuration Set

If you need to change and apply parameter values in the configuration set, open `Configuration_ERT` for edit in the Configuration Parameters dialog box. At the top of

either of the Configuration Reference dialog boxes, expand the drop-down list to the right of the Refresh icon and select `Open referenced configuration`.



Generate Code for ERT Target

The referenced configuration set is customized for ERT code generation. To generate code, press **Ctrl+B**.

```
rtwbuild('slexConfigSetRefExample');

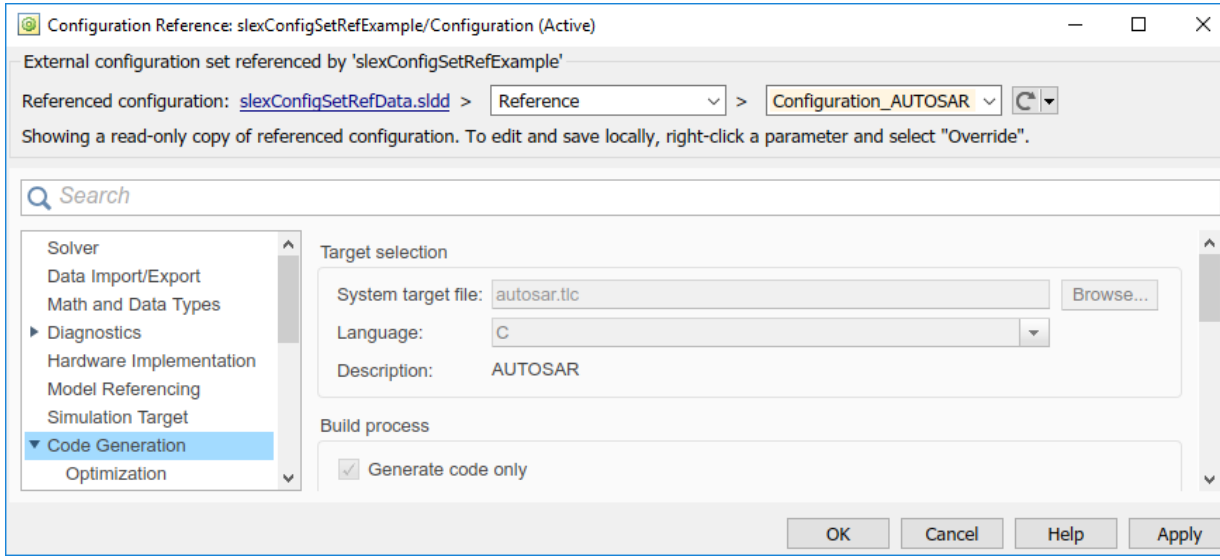
### Starting build procedure for model: slexConfigSetRefMdlRef
### Successful completion of code generation for model: slexConfigSetRefMdlRef
```

```
### Starting build procedure for model: slexConfigSetRefExample
### Successful completion of code generation for model: slexConfigSetRefExample
```

The code generation report displays once code generation is complete.

Switch Targets and Generate Code for AUTOSAR Target

For this model there is another configuration set, Configuration_AUTOSAR, that is customized for AUTOSAR code generation. At the top of the Configuration Reference dialog box, in the rightmost drop-down list, select Configuration_AUTOSAR. `slexConfigSetREfExample` and its referenced model, `slexConfigSetMdlRef`, now both use the configuration set, `Configuration_AUTOSAR`.



Because you edited the configuration reference, the data dictionary has unsaved changes. The configurations are stored outside of the models so the models do not have unsaved changes.

If you have downloaded the AUTOSAR package, you can now generate code for an AUTOSAR target. In the model editor window, press **Ctrl+B**.

Check Model and Configuration for Code Generation

You can use the Model Advisor checks to assess model readiness to generate code. To check and configure your model for code generation application objectives such as traceability or debugging, use the Code Generation Advisor.

For information about	See
Model Advisor	“Run Model Checks” (Simulink)
Code Generation Advisor	“Application Objectives Using Code Generation Advisor” (Simulink Coder)
Checks available with Simulink Coder	“Simulink Coder Checks” (Simulink Coder)
Checks available with Embedded Coder	“Embedded Coder Checks”

Check Mode for Code Efficiency with Model Advisor

To check model `rtwdemo_throttlecntrl` for code efficiency, use the Model Advisor.

1. Open `rtwdemo_throttlecntrl`. Save a copy as `throttlecntrl` in a writable location on your MATLAB path.
2. To start the Model Advisor, select **Analysis > Model Advisor > Model Advisor**. A dialog box opens showing the model system hierarchy.
3. Click `throttlecntrl` and then click **OK**. The Model Advisor window opens.
4. Expand **By Task > Code Generation Efficiency**. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
5. In the left pane, select the remaining checks, and then select **Code Generation Efficiency**.
6. In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
7. Review the report. The warnings highlight issues that impact code efficiency. For more information about the report, see “View Model Advisor Reports” (Simulink).

Check Model During Code Generation with Code Generation Advisor

To review a model as part of the code generation process, use the Code Generation Advisor.

1. To specify your code generation objectives, on the **Configuration Parameters > Code Generation** pane, choose a value for the **Select objective** parameter.
2. On the **Configuration Parameters > Code Generation > General** pane, select one of the following from **Check model before generating code**:
   - `On (proceed with warnings)`
   - `On (stop for warnings)`
3. If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.
4. Apply your changes, and then click **Generate Code/Build**. The Code Generation Advisor starts and reviews the top model and subsystems.

   If the Code Generation Advisor issues failures or warnings, and you specified:

   - `On (proceed with warnings)` — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
   - `On (stop for warnings)` — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.
5. In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.
6. After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Check Warning or Failure” (Simulink).

Note When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)

Application Objectives Using Code Generation Advisor

In this section...

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation options in a model configuration set. Parameters that you set in the **Solver**, **Data Import/Export**, **Diagnostics**, and **Code Generation** panes in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in “Recommended Settings Summary for Model Configuration Parameters” to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference (Simulink), you can run the Code Generation Advisor to review your configuration parameter settings. However, the Code Generation Advisor cannot modify the configuration parameter settings.

High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability might be more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- Execution efficiency (all targets) — Configure code generation settings to achieve fast execution time.
- ROM efficiency (ERT-based targets) — Configure code generation settings to reduce ROM usage.
- RAM efficiency (ERT-based targets) — Configure code generation settings to reduce RAM usage.
- Traceability (ERT-based targets) — Configure code generation settings to provide mapping between model elements and code.
- Safety precaution (ERT-based targets) — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- Debugging (all targets) — Configure code generation settings to debug the code generation build process.
- MISRA C:2012 guidelines (ERT-based targets) — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- Polyspace (ERT-based targets) — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

Configure Model for Code Generation Objectives Using Code Generation Advisor

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

1. On the menu bar, select **Code > C/C++ Code > Code Generation Advisor**.
2. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
3. In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives from the drop-down list (GRT-based targets). As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it will run on your model. If your model is configured with an ERT-based target, more objectives are available.
4. Click **Run Selected Checks** to run the checks listed in the left pane of the Code Generation Advisor.
5. In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

   Check model configuration settings against code generation objectives triggers a warning for these issues:

   - Parameters are set to values other than the value recommended for the specified code generation objectives.
   - Selected code generation objectives differ from the objectives set in the model.

   Click **Modify Parameters** to set:

   - Parameters to the value recommended for the specified code generation objectives.
   - Code generation objectives in the model to the objectives specified in the Code Generation Advisor.
6. In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.
7. After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

This example shows how to check and configure the code generation objectives in the Configuration Parameters dialog box:

1. Open the Configuration Parameters dialog box and select **Code Generation**.
2. Select or confirm selection of a System target file.
3. Specify the objectives using the **Select objectives** drop-down list (GRT-based targets) or clicking **Set Objectives** button (ERT-based targets). Clicking **Set Objectives** opens the “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder) dialog box.
4. Click **Check Model** to run the model checks. The Code Generation Advisor dialog box opens. The Code Generation Advisor uses the code generation objectives to determine which model checks to run.
5. On the left pane, the Code Generation Advisor lists the checks run on the model and the results. Click each warning to see the suggestions for changes that you can make to your model to pass the check.
6. Determine which changes to make to your model. On the right pane of the Code Generation Advisor, follow the instructions listed for each check to modify the model.

Simulink Coder Model Advisor Checks for Standards and Code Efficiency

To check that your model meets standards and is ready to generate code, you can use the Model Advisor checks available with Simulink Coder.

- To start the Model Advisor, in the model window, select **Analysis > Model Advisor > Model Advisor**.
- In the Model Advisor window, expand the **By Task** folder. The folder contains Model Advisor checks that you can run to help accomplish the task.

For more information about the Model Advisor, see “Run Model Checks” (Simulink).

The table summarizes the Simulink Coder Model Advisor checks that are available in the **By Task** folders.

By Task folder	Model Advisor checks
Code Generation Efficiency	“Identify blocks using one-based indexing” (Simulink Coder)
Modeling Standards for DO-178C/ DO-331	“Check solver for code generation” (Simulink Coder) “Check for blocks that have constraints on tunable parameters” (Simulink Coder) “Check sample times and tasking mode” (Simulink Coder)

Configure Code Comments

Configure how the code generator inserts comments into generated code by modifying parameters on the **Code Generation > Comments** pane.

Goal	Action
Include comments in generated code	**Include comments** (Simulink Coder). Selecting this parameter allows you to select one or more autogenerated comment types to be placed in the code.
Include comments that describe a Simulink block's code	**Simulink block comments** (Simulink Coder). Selecting this parameter includes the comments before the Simulink block's code in the generated code. In Embedded Coder, use **Trace to model using** (Simulink Coder) to select `Block path` or `Simulink identifier` as the comment format.
Include comments that describe Stateflow objects	**Stateflow object comments** (Simulink Coder). Selecting this parameter includes the comments describing Stateflowobjects in the generated code. In Embedded Coder, use **Trace to model using** (Simulink Coder) to select `Block path` or `Simulink identifier` as the comment format.
Include MATLAB source code as comments	**MATLAB source code as comments** (Simulink Coder). Selecting this parameter inserts these comments preceding the associated generated code. The function signature is included in the function banner.
Include comments for eliminated blocks	**Show eliminated blocks** (Simulink Coder). Selecting this parameter includes comments for blocks that were eliminated as the result of optimizations, such as inlining parameters.
Include parameter comments regardless of the number of parameters	**Verbose comments for SimulinkGlobal storage class** (Simulink Coder). Selecting this parameter includes comments for parameter variable names and names of source blocks in the model parameter structure declaration in *`model`*`_prm.h`. If you do not select this parameter, parameter comments are generated if less than 1000 parameters are declared. This reduces the size of the generated file for models with a large number of parameters.
Include MATLAB user comments	**MATLAB user comments** (Simulink Coder). Selecting this parameter includes function description comments and other user comments from MATLAB code as comments in the generated code.
Specify comment style	**Comment style** (Simulink Coder). Select `Auto`, `Multi-line` or `Single-line` as the style of comments in the generated code.

Note When you configure the code generator to produce code that includes comments, the code generator includes text for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ア with the escape sequence `ア`. For more information, see “Internationalization and Code Generation” (Simulink Coder).

Include MATLAB Code as Comments in Generated Code

If you have a Simulink Coder license, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select **MATLAB source code as comments** parameter, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires an Embedded Coder license), the traceability tags are hyperlinks to the source code. For more information on traceability for the MATLAB Function block, see “Use Traceability in MATLAB Function Blocks” on page 75-42.

  For examples and information on the location of the comments in the generated code, see “Location of Comments in Generated Code” on page 42-30.
- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

  Note With an Embedded Coder license, you can also include the function help text in the function banner of the generated code. For more information, see “Including MATLAB user comments in Generated Code” on page 42-32.

How to Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

1. In the model, select **Simulation > Model Configuration Parameters**.
2. In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

Location of Comments in Generated Code

The automatically generated comments containing the source code appear after the traceability tag in the generated code as follows.

```
/* '<S2>:1:18' for y = 1 : 2 : (HEIGHT-4) */
```

Selecting the **Stateflow object comments** parameter generates the traceability comment `'<S2>:1:18'`. Selecting the **MATLAB source code as comments** parameter generates the `for y = 1 : 2 : (HEIGHT-4)` comment.

Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after comments that you add that precede the generated code. The comments are separated from the generated code because the statements are assigned to function outputs.

MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
        /*  Convert polar to Cartesian */
        /* '<S1>:1:4' x = r * cos(theta); */
        /* '<S1>:1:5' y = r * sin(theta); */
        straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

        /* Outport: '<Root>/y' incorporates:
         *  Inport: '<Root>/r'
         *  Inport: '<Root>/theta'
         *  MATLAB Function Block: '<Root>/straightline'
         */
        straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

If Statements

The comment for the `if` statement immediately precedes the code that implements the statement. This comment appears after comments that you add that precede the

generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause, and before the code generated for statements in the clause.

MATLAB Code

```
function y = ifstmt(u,v)
%#codegen
if u > v
    y = v + 10;
elseif u == v
    y = u * 2;
else
    y = v - 10;
end
```

Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
        /* '<S1>:1:3' if u > v */
        if (MLFcn_U.u > MLFcn_U.v) {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:4' y = v + 10; */
          MLFcn_Y.y = MLFcn_U.v + 10.0;
        } else if (MLFcn_U.u == MLFcn_U.v) {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:5' elseif u == v */
          /* '<S1>:1:6' y = u * 2; */
          MLFcn_Y.y = MLFcn_U.u * 2.0;
        } else {
          /* Outport: '<Root>/y' */
          /* '<S1>:1:7' else */
          /* '<S1>:1:8' y = v - 10; */
          MLFcn_Y.y = MLFcn_U.v - 10.0;
```

For Statements

The comment for the `for` statement header immediately precedes the generated code that implements the header. This comment appears after comments that you add that precede the generated code.

MATLAB Code

```
function y = forstmt(u)
%#codegen
```

```
y = 0;
for i=1:u
    y = y + 1;
end
```

Commented C Code

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
        /* '<S1>:1:3' y = 0; */
        rtb_y = 0.0;

        /* '<S1>:1:5' for i=1:u */
        for (i = 1.0; i <= MLFcn_U.u; i++) {
          /* '<S1>:1:6' y = y + 1; */
          rtb_y++;
```

While Statements

The comment for the `while` statement header immediately precedes the generated code that implements the statement header. This comment appears after comments that you add that precede the generated code.

Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

Including MATLAB user comments in Generated Code

MATLAB user comments include the function help text and other comments. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it. You can include the MATLAB user comments in the code generated for a MATLAB Function block.

1. In the model, select **Simulation > Model Configuration Parameters**.
2. In the **Code Generation > Comments** pane, select “MATLAB user comments” (Simulink Coder) and click **Apply**.

Limitations of MATLAB Source Code as Comments

The MATLAB Function block has the following limitations for including MATLAB source code as comments.

- You cannot include MATLAB source code as comments for:
  - MathWorks toolbox functions
  - P-code
  - Simulation targets
  - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on the following conditions:
  - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
  - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
  - For certain optimizations, the comments might be separated from the generated code.
  - The generated code includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

Construction of Generated Identifiers

For GRT and RSim targets, the code generator automatically constructs identifiers for variables and functions in the generated code. These identifiers represent:

- Signals and parameters that have `Auto` storage class
- Subsystem function names that are not user-defined
- Stateflow names

The components of a generated identifier include

- The root model name, followed by
- The name of the generating object (signal, parameter, state, and so on), followed by
- Unique *name-mangling* text

The code generator conditionally generates the name-mangling text to resolve potential conflicts with other generated identifiers.

To configure how the code generator names identifiers and objects, see:

- “Specify Identifier Length to Avoid Naming Collisions” on page 42-36
- “Specify Reserved Names for Generated Identifiers” on page 42-37

The code generator reserves certain words for its own use as keywords of the generated code language. For more information, see “Reserved Keywords” on page 42-38.

With an Embedded Coder license, you can specify parameters to control identifier formats, mangle length, scalar inlined parameters, and Simulink data object naming rules. For more information, see “Customize Generated Identifier Naming Rules” on page 50-16.

Identifier Name Collisions and Mangling

In identifier generation, a circumstance that would cause generation of two or more identical identifiers is called a *name collision*. When a potential name collision exists, unique *name-mangling* text is generated and inserted into each of the potentially conflicting identifiers. Each set of name-mangling characters is unique for each generated identifier.

Identifier Name Collisions with Referenced Models

Referenced models can introduce additional naming constraints. Within a model that uses referenced models, collisions between the names of the models cannot exist. When you generate code from a model that includes referenced models, the **Maximum identifier length** parameter must be large enough to accommodate the root model name and name-mangling text. A code generation error occurs if **Maximum identifier length** is too small.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

For more information on referenced models, see “Parameterize Instances of a Reusable Referenced Model” (Simulink).

Specify Identifier Length to Avoid Naming Collisions

The length of a generated identifier is limited by the **Maximum identifier length** parameter specified on the **Symbols** pane of the Configuration Parameters dialog box. The **Maximum identifier length** field allows you to limit the number of characters in function, type definition, and variable names. The default is 31 characters. This is also the minimum length you can specify. The maximum is 256 characters.

When there is a potential name collision between two identifiers, name-mangling text is generated. The text has the minimum number of characters required to avoid the collision. The other symbol components are then inserted. If **Maximum identifier length** is not large enough to accommodate full expansions of the other components, they are truncated. To avoid this outcome, it is good practice to:

- Avoid name collisions by not using default block names (for example, `Gain1`, `Gain2...`) when the model includes multiple blocks of the same type.
- For subsystems, make them atomic and reusable.
- Increase the **Maximum identifier length** parameter to accommodate the length of the identifier you expect to generate.

Specify Reserved Names for Generated Identifiers

You can specify a set of reserved keywords that the code generation process should not use, facilitating code integration where functions and variables from external environments are unknown in the Simulink model. To create a list of reserved names, open the Configuration Parameters dialog box. On the **Code Generation > Symbols** pane, enter the keywords in the “Reserved names” (Simulink Coder) field.

If your model contains MATLAB Function or Stateflow blocks, the code generation process can use the reserved names specified for those blocks if you select **Use the same reserved names as Simulation Target** (Simulink Coder) on the **Code Generation > Symbols** pane.

Reserved Keywords

In this section...

Generator keywords are reserved for internal use. Do not use them in models as identifiers or function names. Also avoid using C reserved keywords in models as identifiers or function names. If your model contains reserved keywords, code generation does not complete and an error message appears. To address the error, modify your model to use identifiers or names that are not reserved.

If you use the code generator to produce C++ code, your model must not contain the “Reserved Keywords for Code Generation” on page 42-39 nor the “C++ Reserved Keywords” on page 42-39.

Note You can register additional reserved identifiers in the Simulink environment. For more information, see “Specify Reserved Names for Generated Identifiers” on page 42-37.

C Reserved Keywords

`auto`	`double`	`int`	`struct`
`break`	`else`	`long`	`switch`
`case`	`enum`	`register`	`typedef`
`char`	`extern`	`return`	`union`
`const`	`float`	`short`	`unsigned`
`continue`	`for`	`signed`	`void`
`default`	`goto`	`sizeof`	`volatile`
`do`	`if`	`static`	`while`

C++ Reserved Keywords

catch	friend	protected	try
class	inline	public	typeid
const_cast	mutable	reinterpret_cast	typename
delete	namespace	static_cast	using
dynamic_cast	new	template	virtual
explicit	operator	this	wchar_t
export	private	throw	

Reserved Keywords for Code Generation

abs	int8_T	MAX_uint8_T*	rtInf
asm	int16_T	MAX_uint16_T*	rtMinusInf
bool	int32_T	MAX_uint32_T*	rtNaN
boolean_T	int64_T	MAX_uint64_T	SeedFileBuffer
byte_T	INTEGER_CODE	MIN_int8_T*	SeedFileBufferLen
char_T	LINK_DATA_BUFFER_SIZE	MIN_int16_T*	single
cint8_T	LINK_DATA_STREAM	MIN_int32_T*	TID01EQ
cint16_T	localB	MIN_int64_T	time_T
cint32_T	localC	MODEL	true
creal_T	localDWork	MT	uint_T
creal32_T	localP	NCSTATES	uint8_T
creal64_T	localX	NULL	uint16_T
cuint8_T	localXdis	NUMST	uint32_T
cuint16_T	localXdot	pointer_T	uint64_T

ERT	localZCSV	PROFILING_NUM_SAMPLES	USE_RTMODEL
false	matrix	real_T	VCAST_FLUSH_DATA

fortran	MAX_int8_T*	real32_T	vector
HAVESTDIO	MAX_int16_T*	real64_T	
id_t	MAX_int32_T*	RT	
int_T	MAX_int64_T	RT_MALLOC	
*Not reserved if you specify a replacement identifier.			

Code Generation Code Replacement Library Keywords

The list of code replacement library reserved keywords for your development environment varies depending on which libraries are registered. The list of available code replacement libraries varies depending on other installed products (for example, a target product), or if you used Embedded Coder to create and register custom code replacement libraries.

To generate a list of reserved keywords for libraries currently registered in your environment, use the following MATLAB function:

```
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers()
```

This function returns an array of library keywords. Specifying the input argument is optional.

Note To list the libraries currently registered in your environment, use the MATLAB command `crviewer`.

To generate a list of reserved keywords for a specific library that you are using to generate code, call the function passing the name of the library as displayed in the **Code replacement library** menu on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. For example,

```
lib_ids = RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 Extensions')
```

Here is a partial example of the function output:

```
>> lib_ids = ...
   RTW.TargetRegistry.getInstance.getTflReservedIdentifiers('GNU C99 Extensions')

lib_ids =

    'exp10'
    'exp10f'
```

```
    'acosf'
    'acoshf'
    'asinf'
    'asinhf'
    'atanf'
    'atanhf'
...
    'rt_lu_cplx'
    'rt_lu_cplx_sgl'
    'rt_lu_real'
    'rt_lu_real_sgl'
    'rt_mod_boolean'
    'rt_rem_boolean'
    'strcpy'
    'utAssert'
```

Note Some of the returned keywords appear with the suffix `$N`, for example, `'rt_atan2$N'`. `$N` expands into the suffix `_snf` only if nonfinite numbers are supported. For example, `'rt_atan2$N'` represents `'rt_atan2_snf'` if nonfinite numbers are supported and `'rt_atan2'` if nonfinite numbers are not supported. As a precaution, you should treat both forms of the keyword as reserved.

Debug

In the Configuration Parameters dialog box, use parameters on the **Diagnostics** pane and debugging parameters to configure a model such that the generated code and the build process are set for debugging. You can set parameters that apply to the model compilation phase, the target language code generation phase, or both.

Parameters in the following table will be helpful if you are writing TLC code for customizing targets, integrating legacy code, or developing new blocks.

To...	Select...
Display progress information during code generation in the MATLAB Command Window	“Verbose build” (Simulink Coder).Compiler output also displays.
Prevent the build process from deleting the *`model`*`.rtw` file from the build folder at the end of the build	“Retain .rtw file” (Simulink Coder). This parameter is useful if you are modifying the target files, in which case you need to look at the *`model`*`.rtw` file.
Instruct the TLC profiler to analyze the performance of TLC code executed during code generation and generate a report	“Profile TLC” (Simulink Coder). The report is in HTML format and can be read in your web browser.
Start the TLC debugger during code generation	“Start TLC debugger when generating code” (Simulink Coder). Alternatively, enter the argument `-dc` for the “System target file” (Simulink Coder) parameter on the **Code Generation** pane. To start the debugger and run a debugger script, enter `-df filename` for **System target file**.

To...	Select...
Generate a report containing statistics indicating how many times the code generator reads each line of TLC code during code generation	“Start TLC coverage when generating code” (Simulink Coder). Alternatively, enter the argument `-dg` for the **System Target File** parameter on the **Code Generation** pane.

Halt a build if a user-supplied TLC file contains an `%assert` directive that evaluates to `FALSE`	“Enable TLC assertion” (Simulink Coder). Alternatively, you can use MATLAB commands to control TLC assertion handling.
	
	To set the flag on or off, use the `set_param` command. The default is off.
	
	`set_param(model, 'TLCAssertion', 'on|off')`
	
	To check the current setting, use `get_param`.
	
	`get_param(model, 'TLCAssertion')`

Detect loss of tunability	“Detect loss of tunability” (Simulink) on the **Diagnostics > Data Validity** pane. You can use this parameter to report loss of tunability when an expression is reduced to a numeric expression. This can occur if a tunable workspace variable is modified by Mask Initialization code, or is used in an arithmetic expression with unsupported operators or functions. Possible values are: • `none` — Loss of tunability can occur without notification. • `warning` — Loss of tunability generates a warning (default). • `error` — Loss of tunability generates an error. For a list of supported operators and functions, see “Tunable Expression Limitations” (Simulink Coder)

To...	Select...

Enable model verification (assertion) blocks	"Model Verification block enabling" (Simulink). Use this parameter to enable or disable model verification blocks such as Assert, Check Static Gap, and related range check blocks. The diagnostic applies to generated code and simulation behavior. For example, simulation and code generation ignore this parameter when model verification blocks are inside an S-function. Possible values are:
	• `User local settings`
	• `Enable All`
	• `Disable All`
	
	For Assertion blocks not disabled, generated code for a model includes one of the following statements, depending on the blocks input signal type (Boolean, real, or integer, respectively).
	
	`utAssert(input_signal);`
	`utAssert(input_signal != 0.0);`
	`utAssert(input_signal != 0);`
	
	By default, `utAssert` does not change generated code. For assertions to abort execution, you must enable them by specifying the following `make_rtw` command for **Code Generation >** "Make command" (Simulink Coder) parameter:
	
	`make_rtw OPTS="-DDOASSERTS"`
	
	Use the following variant if you want triggered assertions to print the assertion statement instead of aborting execution:
	
	`make_rtw OPTS="-DDOASSERTS -DPRINT_ASSERTS"`
	
	utAssert is defined as `#define utAssert(exp) assert(exp)`.
	
	To customize assertion behavior, provide your own definition of `utAssert` in a handwritten header file that overrides the default `utAssert.h`. For details on how to include a customized header file in generated code, see "Integrate

To...	Select...
	External Code by Using Model Configuration Parameters” (Simulink Coder). When running a model in accelerator mode, the Simulink engine calls back to itself to execute assertion blocks instead of using generated code. Thus, user-defined callbacks are still called when assertions fail.

For more information about the TLC debugging options, see Debugging on “Target Language Compiler” (Simulink Coder). Also, consider using the Model Advisor as a tool for troubleshooting model builds.

Configuration in Embedded Coder

Configure Model for Code Generation Objectives by Using Code Generation Advisor

In this section...

Consider how your application objectives, such as efficiency, traceability, and safety, map to code generation parameters in a model configuration set. Parameters that you set in the **Solver**, **Data Import/Export**, **Diagnostics**, and **Code Generation** panes in the Configuration Parameters dialog box specify the behavior of a model in simulation and the code generated for the model.

Before generating code, or as part of the code generation process, you can use the Code Generation Advisor to review a model. When you choose to review a model before generating code, you specify which model, subsystem, or referenced model the Code Generation Advisor reviews. When you choose to review a model as part of the code generation process, the Code Generation Advisor reviews the entire system. The Code Generation Advisor uses the information presented in “Recommended Settings Summary for Model Configuration Parameters” to determine the parameter values that meet your objectives. When there is a conflict between multiple objectives, the higher-priority objective takes precedence.

Setting code generation objectives, and then running the Code Generation Advisor provides information on how to meet code generation objectives for your model. The Code Generation Advisor does not alter the generated code. You can use the Code Generation Advisor to make the suggested changes to your model. The generated code is changed only after you modify your model and regenerate code. When you use the Code Generation Advisor to set code generation objectives and check your model, the generated code includes comments identifying which objectives you specified, the checks that the Code Generation Advisor ran on the model, and the results of running the checks.

If a model uses a configuration reference (Simulink), you can run the Code Generation Advisor to review your configuration parameter settings. but the Code Generation Advisor cannot modify the configuration parameter settings.

High-Level Code Generation Objectives

Depending on the type of application that your model represents, you are likely to have specific high-level code generation objectives. For example, safety and traceability are more critical than efficient use of memory. If you have specific objectives, you can quickly configure your model to meet those objectives by selecting and prioritizing from these code generation objectives:

- Execution efficiency (all targets) — Configure code generation settings to achieve fast execution time.
- ROM efficiency (ERT-based targets) — Configure code generation settings to reduce ROM usage.
- RAM efficiency (ERT-based targets) — Configure code generation settings to reduce RAM usage.
- Traceability (ERT-based targets) — Configure code generation settings to provide mapping between model elements and code.
- Safety precaution (ERT-based targets) — Configure code generation settings to increase clarity, determinism, robustness, and verifiability of the code.
- Debugging (all targets) — Configure code generation settings to debug the code generation build process.
- MISRA C:2012 guidelines (ERT-based targets) — Configure code generation settings to increase compliance with MISRA C:2012 guidelines.
- Polyspace (ERT-based targets) — Configure code generation settings to prepare the code for Polyspace analysis.

If you select the MISRA C:2012 guidelines code generation objective, the Code Generation Advisor:

- Checks the model configuration settings for compliance with the MISRA C:2012 configuration setting recommendations.
- Checks for blocks that are not supported or recommended for MISRA C:2012 compliant code generation.

Specify Objectives in Referenced Models

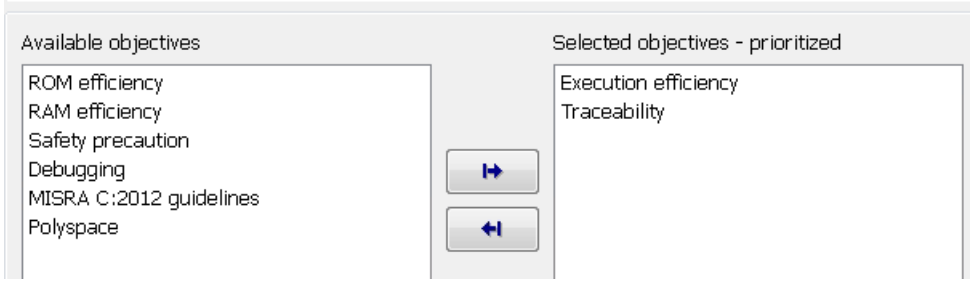
When you check a model during the code generation process, you must specify the same objectives in the top model and referenced models. If you specify different objectives for the top model and referenced model, the build process generates an error.

To specify different objectives for the top model and each referenced model, review the models separately without generating code.

Configure Model Using Code Generation Advisor

This example shows how to use the Code Generation Advisor to check and configure your model to meet code generation objectives:

1. On the menu bar, select **Code > C/C++ Code > Code Generation Advisor**.
2. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.
3. In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. If your model is configured with an ERT-based target, more objectives are available. For this example, the model is configured with an ERT-based target. If your objectives are execution efficiency and traceability, in that priority, do the following:
   a. In **Available objectives**, double-click `Execution efficiency`. `Execution efficiency` is added to **Selected objectives - prioritized**.
   b. In **Available objectives**, double-click `Traceability`. `Traceability` is added to **Selected objectives - prioritized** under `Execution efficiency`.



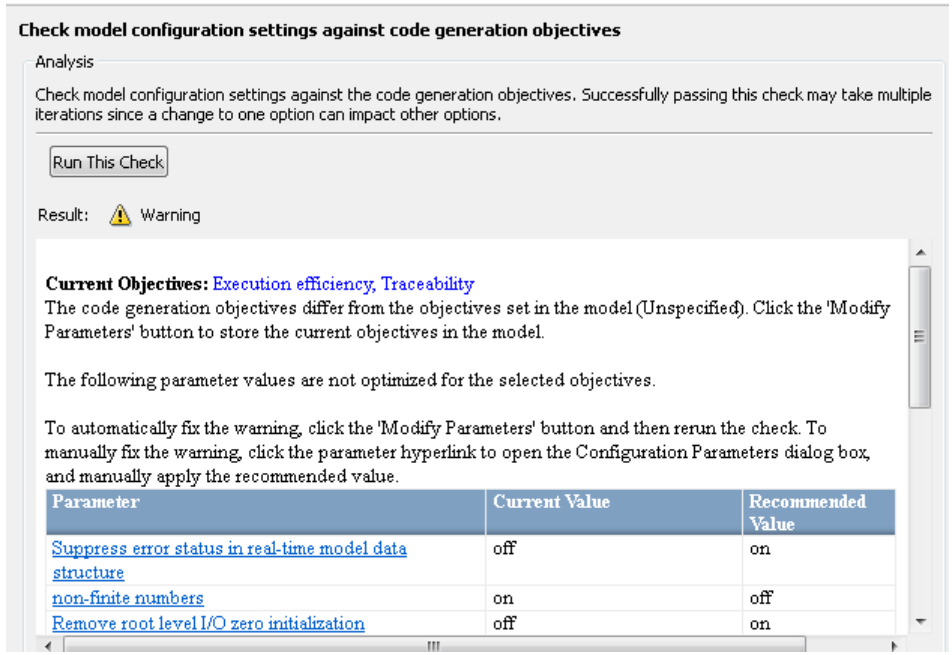
4. To run the checks listed in the left pane of the Code Generation Advisor, click **Run Selected Checks**.
5. In the Code Generation Advisor window, review the results for **Check model configuration settings against code generation objectives** by selecting it from the left pane. The results for that check are displayed in the right pane.

Check model configuration settings against code generation objectives triggers a warning for these issues:

- Parameters are set to values other than the value recommended for the specified code generation objectives.
- Selected code generation objectives differ from the objectives set in the model.

Click **Modify Parameters** to set:

- Parameters to the value recommended for the specified code generation objectives.
- Code generation objectives in the model to the objectives specified in the Code Generation Advisor.



6 In the Code Generation Advisor window, review the results for the remaining checks by selecting them from the left pane. The results for the checks display in the right pane.

7 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

Configure Model for Code Generation Objectives by Using Configuration Parameters Dialog Box

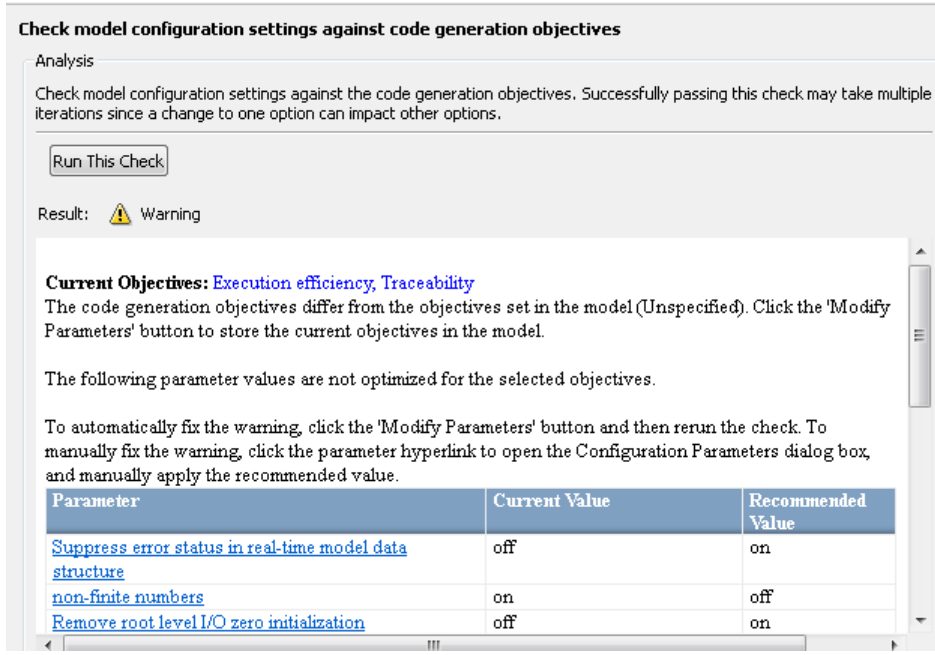
This example shows how to configure and check your model to meet code generation objectives via the Configuration Parameters dialog box:

1. Open the Configuration Parameters dialog box. Select **Code Generation**.
2. Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, choose an ERT-based target such as `ert.tlc`.
3. Click **Set Objectives**.
4. In the "Set Objectives — Code Generation Advisor Dialog Box" (Simulink Coder), specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, do the following:
   a. In **Available objectives**, double-click `Execution efficiency`. `Execution efficiency` is added to **Selected objectives - prioritized**.
   b. In **Available objectives**, double-click `Traceability`. `Traceability` is added to **Selected objectives - prioritized** under `Execution efficiency`.

   c. To accept the objectives, click **OK**. In the Configuration Parameters dialog box, **Code Generation** > **General** > **Prioritized objectives** is updated.
5. On the **Configuration Parameters** > **Code Generation** > **General** pane, click **Check Model**.

6 In the System Selector window, select the model or subsystem that you want to review, and then click **OK**. The Code Generation Advisor opens and reviews the model or subsystem that you specified.

7 In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.



8 After reviewing the check results, you can choose to fix warnings and failures, as described in “Fix a Model Check Warning or Failure” (Simulink).

When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)

Configure Code Generation Objectives Programmatically

This example shows how to configure code generation objectives by writing a MATLAB script or entering commands at the command line.

1. Specify a system target file. If you specify an ERT-based target, more objectives are available. For this example, specify `ert.tlc`. *`model_name`* is the name or handle to the model.

   ```
   set_param(model_name, 'SystemTargetFile', 'ert.tlc');
   ```

2. Specify your objectives. For example, if your objectives are execution efficiency and traceability, in that priority, enter:

   ```
   set_param(model_name, 'ObjectivePriorities',...
   {'Execution efficiency', 'Traceability'});
   ```

3. Execute the Code Generation Advisor, by using either the Code Generation Advisor or in the Configuration Parameters dialog box. For more information, see “Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 43-2.

When you specify a GRT-based system target file, you can specify an objective at the command line. If you specify `ROM efficiency`, `RAM efficiency`, `Traceability`, `MISRA C:2012 guidelines`, `Polyspace`, or `Safety precaution`, the build process changes the objective to `Unspecified` because you have specified a value that is invalid when using a GRT-based target.

Check Model and Configuration for Code Generation

You can use the Model Advisor checks to assess model readiness to generate code. To check and configure your model for code generation application objectives such as traceability or debugging, use the Code Generation Advisor.

For information about	See
Model Advisor	“Run Model Checks” (Simulink)
Code Generation Advisor	“Configure Model for Code Generation Objectives by Using Code Generation Advisor” on page 43-2
Checks available with Simulink Coder	“Simulink Coder Checks” (Simulink Coder)
Checks available with Embedded Coder	“Embedded Coder Checks”

To check model `rtwdemo_throttlecntrl` for code efficiency, use the Model Advisor.

1. Open `rtwdemo_throttlecntrl`. Save a copy as `throttlecntrl` in a writable location on your MATLAB path.
2. To start the Model Advisor, select **Analysis > Model Advisor > Model Advisor**. A dialog box opens showing the model system hierarchy.
3. Click `throttlecntrl` and then click **OK**. The Model Advisor window opens.
4. Expand **By Task > Code Generation Efficiency**. To check your model for code generation efficiency, use the checks in the folder. By default, checks that do not trigger an Update Diagram are selected. The checks available for code generation efficiency depend on whether you have a Simulink Coder or Embedded Coder license.
5. In the left pane, select the remaining checks, and then select **Code Generation Efficiency**.
6. In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
7. Review the report. The warnings highlight issues that impact code efficiency. For more information about the report, see “View Model Advisor Reports” (Simulink).

Check Model During Code Generation

To review a model as part of the code generation process, use the Code Generation Advisor .

1. To select and prioritize your code generation objectives, on the **Configuration Parameters > Code Generation** pane, click **Set Objectives**.
2. On the **Configuration Parameters > Code Generation > General** pane, select one of the following from **Check model before generating code**:
   - `On (proceed with warnings)`
   - `On (stop for warnings)`
3. If you want to only generate code, select **Generate code only**. Otherwise clear the check box to build an executable.
4. Apply your changes. In the model window, press **Ctrl+B** to generate code or build the model.

   If the Code Generation Advisor issues failures or warnings, and you specified:

   - `On (proceed with warnings)` — The Code Generation Advisor window opens while the build process proceeds. After the build process is complete, you can review the results.
   - `On (stop for warnings)` — The build process halts and displays the Diagnostic Viewer. To continue, you must review and resolve the Code Generation Advisor results or clear the **Check model before generating code** parameter.
5. In the Code Generation Advisor window, review the results by selecting a check from the left pane. The results for that check display in the right pane.
6. After reviewing the check results, you can choose to fix warnings and failures as described in “Fix a Model Check Warning or Failure” (Simulink).

Note When you specify an efficiency or Safety precaution objective, the Code Generation Advisor includes additional checks. When you make changes to one of these additional checks, previous check results can potentially become invalid and need to be rerun.

For more information, see “Set Objectives — Code Generation Advisor Dialog Box” (Simulink Coder)

Embedded Coder Model Advisor Checks for Standards, Guidelines, and Code Efficiency

To check that your model meets guidelines, standards, and is ready to generate code, you can use the Model Advisor checks available with Embedded Coder.

- To start the Model Advisor, in the model window, select **Analysis > Model Advisor > Model Advisor**.
- In the Model Advisor window, expand the **By Task** folder. The folder contains Model Advisor checks that you can run to help accomplish the task.

For more information about the Model Advisor, see “Run Model Checks” (Simulink).

The table summarizes the Embedded Coder Model Advisor checks that are available in the **By Task** folders.

By Task folder	Model Advisor checks
Modeling Standards for MAAB	Check for blocks not recommended for C/C++ production code deployment
Code Generation Efficiency	Identify lookup table blocks that generate expensive out-of-range checking code Check output types of logic blocks Identify questionable software environment specifications Identify questionable code instrumentation (data I/O) Identify blocks that generate expensive fixed-point and saturation code Identify blocks that generate expensive rounding code Identify questionable fixed-point operations

By Task folder	Model Advisor checks
Modeling Standards for • **IEC 61508, IEC 62304, ISO 26262, and EN 50128**	Check for blocks not recommended for C/C++ production code deployment
Modeling Standards for DO-178C/DO-331	Check for blocks not recommended for C/C++ production code deployment Check the hardware implementation Identify questionable subsystem settings
Modeling Guidelines for MISRA C:2012	Check configuration parameters for MISRA C:2012 Check for blocks not recommended for C/C++ production code deployment Check for blocks not recommended for MISRA C:2012 Check for unsupported block names Check usage of Assignment blocks Check for switch case expressions without a default case Check for missing error ports for AUTOSAR receiver interfaces Check for bitwise operations on signed integers Check for recursive function calls Check for equality and inequality operations on floating-point values Check for missing const qualifiers in model functions Check bus object names that are used as element names

By Task folder	Model Advisor checks
Modeling Guidelines for secure coding standards (CERT C, CWE, ISO/IEC TS 17961)	Check configuration parameters for secure coding standards Check for blocks not recommended for C/C++ production code deployment Check for blocks not recommended for secure coding standards Check usage of Assignment blocks Check for switch case expressions without a default case Check for bitwise operations on signed integers Check for equality and inequality operations on floating-point values Check integer word length If you have a Simulink Design Verifier™ license, the following checks are also available. Detect Dead Logic Detect Integer Overflow Detect Division by Zero Detect Out Of Bound Array Access Detect Violation of Specified Minimum and Maximum Values

Create Custom Code Generation Objectives

In this section...

The Code Generation Advisor reviews your model based on objectives that you specify. If the predefined efficiency, traceability, Safety precaution, and debugging objectives do not meet your requirements, you can create custom objectives.

To create custom objectives:

- Create an objective and add parameters and checks to this new objective.
- Create an objective based on an existing objective, then add, modify, and remove the parameters and checks within that new objective.

Specify Parameters in Custom Objectives

When you create a custom objective, you specify the values of configuration parameters that the Code Generation Advisor reviews. You can use the following methods:

- `addParam` — Add parameters and specify the values that the Code Generation Advisor reviews in **Check model configuration settings against code generation objectives**.
- `modifyInheritedParam` — Modify inherited parameter values that the Code Generation Advisor reviews in **Check model configuration settings against code generation objectives**.
- `removeInheritedParam` — Remove inherited parameters from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this parameter, the Code Generation Advisor reviews the parameter value in **Check model configuration settings against code generation objectives**.

Specify Checks in Custom Objectives

Objectives include the **Check model configuration settings against code generation objectives** check by default. When you create a custom objective, you specify the list of additional checks that are associated with the custom objective. You can use the following methods:

- `addCheck` — Add checks to the Code Generation Advisor. When you select the custom objective, the Code Generation Advisor displays the check, unless you specify an additional objective with a higher priority that excludes the check.

  For example, add a check to the Code Generation Advisor to include a custom check in the automatic model checking process.
- `excludeCheck` — Exclude checks from the Code Generation Advisor. When you select multiple objectives, if you specify an additional objective that includes this check as a higher priority objective, the Code Generation Advisor displays this check.

  For example, exclude a check from the Code Generation Advisor when a check takes a long time to process.
- `removeInheritedCheck` — Remove inherited checks from a new objective that is based on an existing objective. When you select multiple objectives, if another selected objective includes this check, the Code Generation Advisor displays the check.

  For example, remove an inherited check, rather than exclude the check, when the check takes a long time to process, but the check is important for another objective.

Determine Checks and Parameters in Existing Objectives

When you base a new objective on an existing objective, you can determine what checks and parameters the existing objective contains. The Code Generation Advisor contains the list of checks in each objective.

For example, the `Efficiency` objective includes checks that you can see in the Code Generation Advisor.

1. Open the `rtwdemo_rtwecintro` model.
2. Specify an ERT-based target.
3. On the model toolbar, select **Code > C/C++ Code > Code Generation Advisor**.
4. In the System Selector window, select the model or subsystem that you want to review, and then click **OK**.

5 In the Code Generation Advisor, on the **Code Generation Objectives** pane, select the code generation objectives. As you select objectives, on the left pane, the Code Generation Advisor updates the list of checks it runs on your model. For this example, select `Execution efficiency`. In **Available objectives**, double-click `Execution efficiency`. `Execution efficiency` is added to **Selected objectives - prioritized**.

In the left pane, the Code Generation Advisor lists the checks for the `Execution efficiency` objective. The first check, **Check model configuration settings against code generation objectives**, lists parameters and values specified by the objective. For example, the Code Generation Advisor displays the list of parameters and the recommended values in the `Execution efficiency` objective. To see the list of parameters and values:

1 Run **Check model configuration settings against code generation objectives**.

2 Click **Modify Parameters**.

3 Rerun the check.

In the check results, the Code Generation Advisor displays the list of parameters and recommended values for the `Execution efficiency` objective.

Passed
Current Objectives: Execution efficiency

The following parameters have been checked and confirmed with the recommended value

Parameter	Value
non-inlined S-functions	off
Suppress error status in real-time model data structure	on
MAT-file logging	off
Classic call interface	off
continuous time	off
non-finite numbers	off
Single output/update function	on
Minimize algebraic loop occurrences	off

Steps to Create Custom Objectives

To create a custom objective:

1 Create an `sl_customization.m` file.

- Specify custom objectives in a single `sl_customization.m` file only or the software generates an error. This issue is true even if you have more than one `sl_customization.m` file on your MATLAB path.

- Except for the *matlabroot*`/work` folder, do not place an `sl_customization.m` file in your root MATLAB folder or its subfolders. Otherwise, the software ignores the customizations that the file specifies.

2 Create an `sl_customization` function that takes a single argument. When the software invokes the function, the value of this argument is the Simulink customization manager. In the function:

- To create a handle to the code generation objective, use the `ObjectiveCustomizer` constructor.
- To register a callback function for the custom objectives, use the `ObjectiveCustomizer.addCallbackObjFcn` method.
- To add a call to execute the callback function, use the `ObjectiveCustomizer.callbackFcn` method.

For example:

```
function sl_customization(cm)
%SL_CUSTOMIZATION objective customization callback

objCustomizer = cm.ObjectiveCustomizer;
index = objCustomizer.addCallbackObjFcn(@addObjectives);
objCustomizer.callbackFcn{index}();

end
```

3 Create a MATLAB callback function that:

- Creates code generation objective objects by using the `rtw.codegenObjectives.Objective` constructor.
- Adds, modifies, and removes configuration parameters for each objective by using the `addParam`, `modifyInheritedParam`, and `removeInheritedParam` methods.
- Includes and excludes checks for each objective by using the `addCheck`, `excludeCheck`, and `removeInheritedCheck` methods.
- Registers objectives by using the `register` method.

The following example shows how to create an objective `Reduce RAM Example`. `Reduce RAM Example` includes five parameters and three checks that the Code Generation Advisor reviews.

```
function addObjectives

% Create the custom objective
obj = rtw.codegenObjectives.Objective('ex_ram_1');
```

```
setObjectiveName(obj, 'Reduce RAM Example');

% Add parameters to the objective
addParam(obj, 'DefaultParameterBehavior', 'Inlined');
addParam(obj, 'BooleanDataType', 'on');
addParam(obj, 'OptimizeBlockIOStorage', 'on');
addParam(obj, 'EnhancedBackFolding', 'on');
addParam(obj, 'BooleansAsBitfields', 'on');

% Add additional checks to the objective
% The Code Generation Advisor automatically includes 'Check model
% configuration settings against code generation objectives' in every
% objective.
addCheck(obj, 'mathworks.design.UnconnectedLinesPorts');
addCheck(obj, 'mathworks.design.Update');

%Register the objective
register(obj);

end
```

The following example shows you how to create an objective `My Traceability Example` based on the existing Traceability objective. The custom objective modifies, removes, and adds parameters that the Code Generation Advisor reviews. It also adds and removes checks from the Code Generation Advisor.

```
function addObjectives

% Create the custom objective from an existing objective
obj = rtw.codegenObjectives.Objective('ex_my_trace_1', 'Traceability');
setObjectiveName(obj, 'My Traceability Example');

% Modify parameters in the objective
modifyInheritedParam(obj, 'GenerateTraceReportSf', 'Off');
removeInheritedParam(obj, 'ConditionallyExecuteInputs');
addParam(obj, 'MatFileLogging', 'On');

% Modify checks in the objective
addCheck(obj, 'mathworks.codegen.SWEnvironmentSpec');
removeInheritedCheck(obj, 'mathworks.codegen.CodeInstrumentation');

%Register the objective
register(obj);

end
```

4. If you previously opened the Code Generation Advisor, close the model from which you opened the Code Generation Advisor.
5. Refresh the customization manager. At the MATLAB command line, enter `sl_refresh_customizations`.
6. Open your model and review the new objectives.

Configuration Variations

Every model contains one or more named configuration sets that specify model parameters such as solver options, code generation options, and other choices. A model can contain multiple configuration sets, but only one configuration set is active at a time. For more information on configuration sets and how to view and edit them in the Configuration Parameters dialog box, see “About Model Configurations” (Simulink).

A configuration set includes parameters that specify code generation in general. For more information, see “Configure a Model for Code Generation” (Simulink Coder). With Embedded Coder and an ERT system target file, more parameters are available for fine-tuning to optimize and customize the appearance of the generated code.

Multiple configuration sets can be useful in embedded systems development. By defining multiple configuration sets in a model, you can easily retarget code generation from that model. For example, one configuration set can specify the default ERT target with external mode support enabled for rapid prototyping. Another configuration set can specify the ERT-based target for Visual C++ to generate production code for deployment of the application. Activation of either configuration set fully reconfigures the model for that type of code generation.

Configure and Optimize Model with Configuration Wizard Blocks

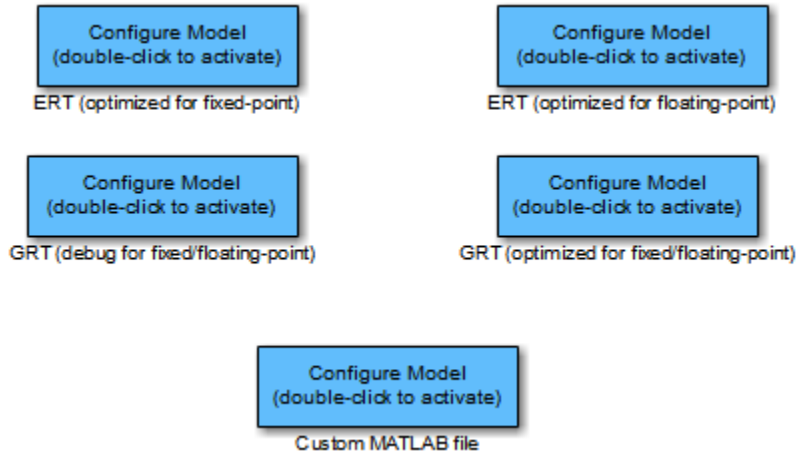
The Embedded Coder software provides a library of Configuration Wizard blocks and scripts to help you configure and optimize code generation from your models.

In this section...

Configuration Wizard Block Library

The library provides a Configuration Wizard block that you can customize. It also provides four preset Configuration Wizard blocks that update the active configuration parameters for a specified goal.

Block	Description
Custom MATLAB file	Update active configuration parameters of parent model by using a custom file
ERT (optimized for fixed-point)	Update active configuration parameters of parent model for ERT fixed-point code generation
ERT (optimized for floating-point)	Update active configuration parameters of parent model for ERT floating-point code generation
GRT (debug for fixed/floating-point)	Update active configuration parameters of parent model for GRT fixed- or floating-point code generation with debugging enabled
GRT (optimized for fixed/floating-point)	Update active configuration parameters of parent model for GRT fixed- or floating-point code generation



When you add one of the preset Configuration Wizard blocks to your model and double-click it, a predefined MATLAB file script configures parameters of the active configuration set without manual intervention. The preset blocks optimally configure the parameters for one of the following cases:

- Fixed-point code generation with the ERT target
- Floating-point code generation with the ERT target
- Fixed-point or floating-point code generation with TLC debugging parameters enabled, with the GRT target.
- Fixed-point or floating-point code generation with the GRT target

The Custom block provides an example MATLAB file script that you can adapt to your requirements.

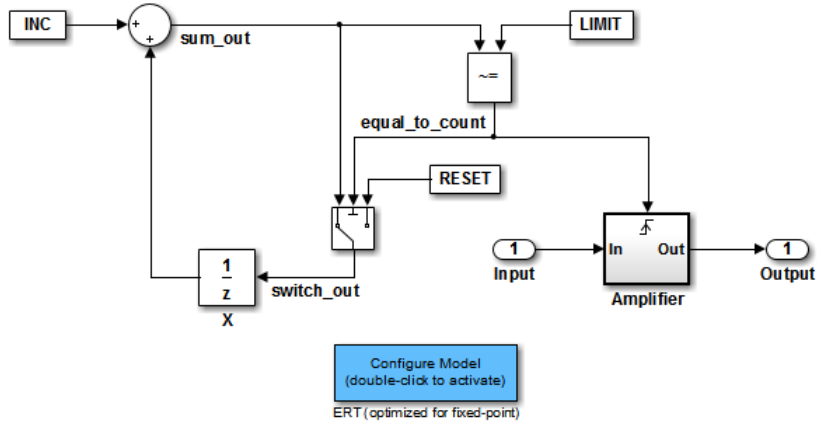
You can also set up the Configuration Wizard blocks to invoke the build process after configuring the model.

Add a Configuration Wizard Block

The Configuration Wizard blocks are available in the Embedded Coder block library. To use a Configuration Wizard block:

1 Open the model that you want to configure.

2. Open the Embedded Coder block library by typing the command `rtweclib`.
3. Double-click the Configuration Wizards icon. The Configuration Wizards sublibrary opens.
4. Select the Configuration Wizard block that you want to use and drag it into your model. This model contains the `ERT (optimized for fixed-point)` Configuration Wizard block.



5. If you want the Configuration Wizard block to invoke the build process after configuration, right-click the Configuration Wizard block in your model, and select **Mask > Mask Parameters** from the context menu. Then, select the **Invoke build process after configuration** parameter. Do not change the **Configure the model for** block parameter, unless you want to create a custom block and script. In that case, see “Create a Custom Configuration Wizard Block” on page 43-26.
6. Click **Apply** and close the Mask Parameters dialog box.
7. Save the model.

Use Configuration Wizard Blocks to Configure Your Model

After you add a Configuration Wizard block to your model, to configure your model, double-click the block. The script associated with the block sets parameters of the active configuration set that are relevant to code generation (including selection of the target). You can see that the parameters have changed by opening the Configuration Parameters dialog box and examining the parameter settings.

If you selected the **Invoke build process after configuration** block parameter, the script also initiates the code generation and build process.

Note To provide a quick way to switch between configurations, you can add more than one Configuration Wizard block to your model.

Create a Custom Configuration Wizard Block

The Custom Configuration Wizard block and the associated MATLAB file script, *matlabroot*/toolbox/rtw/rtw/rtwsampleconfig.m, provide a starting point for customization.

Set Up a Configuration Wizard Block

Set up a custom Configuration Wizard block and link it to a script. If you want to use the block in more than one mode, it is advisable to create a Simulink library to contain the block.

To begin, make a copy of the example script for later customization:

1. To store your custom script, create a folder. This folder must not be anywhere inside the MATLAB folder structure (that is, it must not be under *matlabroot*).

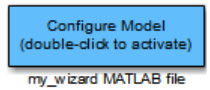
   The example refers to this folder as /my_wizards.
2. Add the folder to the MATLAB path. Save the path for future sessions.
3. Copy the example script rtwsampleconfig.m in the folder *matlabroot*/toolbox/rtw/rtw (open) to the /my_wizards folder that you created. Then, rename the script. This example uses the name my_configscript.m.
4. Open the example script into the MATLAB editor. Scroll to the end of the file and enter the following line of code:

   ```
   disp('Custom Configuration Wizard Script completed.');
   ```

   This statement is used later as a test to see that your custom block has executed the script.
5. Save your script and close the MATLAB editor.

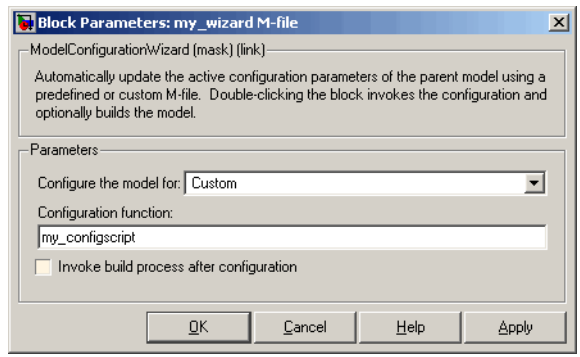
The next task is to create a Simulink library and add a custom block to it.

1. Open the Embedded Coder block library and the Configuration Wizards sublibrary, as described in “Add a Configuration Wizard Block” on page 43-24.
2. Select **New > Library** from the **File** menu of the Configuration Wizards sublibrary window. An empty library window opens.
3. Select the Custom MATLAB file block from the Configuration Wizards sublibrary and drag it into the empty library window.
4. To distinguish your custom block from the original, edit the Custom MATLAB file label under the block.
5. Select **Save as** from the **File** menu of the new library window. Save the library to the `/my_wizards` folder, under your library name of choice. In this figure, the library is saved as `ex_custom_button` and the block is labeled `my_wizard MATLAB-file`.



The next task is to link the custom block to the custom script:

1. Right-click the block in your model and select **Mask > Mask Parameters** from the context menu. The **Configure the model for** menu is set to `Custom`. When `Custom` is selected, the **Configuration function** edit field is enabled so that you can enter the name of a custom script.
2. In the **Configuration function** field, enter the name of your custom script . (Do not enter the `.m` file name extension, which is implicit.)



3. By default, the **Invoke build process after configuration** parameter is cleared. You can change the default for your custom block by selecting this option. For now, leave this parameter cleared.
4. Click **Apply** and close the Mask Parameters dialog box.
5. Save the library.
6. Close the Embedded Coder block library and the Configuration Wizards sublibrary. Leave your custom library open for use in the next task.

Test your block and script in a model.

1. Open the `vdp` model by typing the command:

   ```
   vdp
   ```

2. Open the Configuration Parameters dialog box and view the parameters by clicking **Code Generation** in the list in the left pane of the dialog box.
3. Observe that `vdp` is configured, by default, for the GRT target. Close the Configuration Parameters dialog box.
4. Select your custom block from your custom library. Drag the block into the `vdp` model.
5. In the `vdp` model, double-click your custom block.
6. In the MATLAB window, you see the test message that you previously added to your script:

   ```
   Custom Configuration Wizard Script completed.
   ```

   The test message indicates that the custom block executed the script.
7. Reopen the Configuration Parameters dialog box and view the **Code Generation** pane again. The model is now configured for the ERT target.

Before applying further edits to your custom script, proceed to the next section to learn about the operation and conventions of Configuration Wizard scripts.

Create a Configuration Wizard Script

Create your custom Configuration Wizard script by copying and modifying the example script, `rtwsampleconfig.m`.

The Configuration Function

The example script implements a single function without a return value. The function takes a single argument `cs`:

```
function rtwsampleconfig(cs)
```

The argument `cs` is a handle to a proprietary object that contains information about the active configuration set. The Simulink software obtains this handle and passes it in to the configuration function when you double-click a Configuration Wizard block.

Your custom script must conform to this prototype. Your code must use `cs` as a "black-box" object that transmits information to and from the active configuration set.

Access Configuration Set Parameters

To set parameters or obtain parameter values, use the Simulink `set_param` and `get_param` functions.

Option names are passed in to `set_param` and `get_param` as character vectors specifying an *internal option name*. The internal option name can be different from the option label on the UI (for example, the Configuration Parameters dialog box). The example configuration accompanies each `set_param` and `get_param` call with a comment that correlates internal option names to UI option labels. For example:

```
set_param(cs,'LifeSpan','1'); % Application lifespan (days)
```

To obtain the current setting of an option in the active configuration set, call `get_param`. Pass in the `cs` object as the first argument, followed by the internal option name. For example, the following code excerpt tests the setting of the **Create code generation report** option:

```
if strcmp(get_param(cs, 'GenerateReport'), 'on')
    ...
```

To set an option in the active configuration set, call `set_param`. Pass in the `cs` object as the first argument, followed by one or more parameter/value pairs that specify the internal option name and its value. For example, the following code excerpt turns off the **Support absolute time** option:

```
set_param(cs,'SupportAbsoluteTime','off');
```

Select a Target

A Configuration Wizard script must select a target configuration. The example script uses the ERT target as a default. The script first stores character vector variables that correspond to the required **System target file**, **Template makefile**, and **Make command** settings:

```
stf = 'ert.tlc';
tmf = 'ert_default_tmf';
mc  = 'make_rtw';
```

You select the system target file by passing the `cs` object and the `stf` character vector to the `switchTarget` function:

```
switchTarget(cs,stf,[]);
```

Set the template makefile and make command options by using `set_param` calls:

```
set_param(cs,'TemplateMakefile',tmf);
set_param(cs,'MakeCommand',mc);
```

To select a target, your custom script must set up the character vector variables `stf`, `tmf`, and `mc` and pass them to the calls.

Obtain Target and Configuration Set Information

The following utility functions and properties are provided so that your code can obtain information about the current target and configuration set with the `cs` object:

- `isValidParam(cs, 'option')`: The `option` argument is an internal option name. `isValidParam` returns true if `option` is a valid option in the context of the active configuration set.
- `getPropEnabled(cs, 'option')`: The `option` argument is an internal option name. Returns true if this `option` is enabled (that is, writable).
- `IsERTTarget` property: Your code can detect whether the currently selected target is derived from the ERT target by checking the `IsERTTarget` property, as follows:

  ```
  isERT = strcmp(get_param(cs,'IsERTTarget'),'on');
  ```

You can use this information to determine whether the script must configure ERT-specific parameters, for example:

```
if isERT
  set_param(cs,'ZeroExternalMemoryAtStartup','off');
```

```
  set_param(cs,'ZeroInternalMemoryAtStartup','off');
  set_param(cs,'InitFltsAndDblsToZero','off');
  set_param(cs,'NoFixptDivByZeroProtection','on')
end
```

Invoke a Configuration Wizard Script from the Command Line

Configuration Wizard scripts can be run from the MATLAB command line.

Before invoking the script, you must open a model and instantiate a `cs` object to pass in as an argument to the script. After running the script, you can invoke the build process with the `rtwbuild` command. The following example opens, configures, and builds a model.

```
open my_model;
cs = getActiveConfigSet ('my_model');
rtwsampleconfig(cs);
rtwbuild('my_model');
```

Create a Model Configured for Code Generation Using Model Templates

Model templates provide you with a starting point for quickly developing models for code generation. Embedded Coder templates provide starting models for the following applications:

- Code Generation System. Create a model to get started with code generation.
- Exported functions. Create a model for generating code from function-call subsystems.
- Fixed-step, multirate. Create a fixed-step model with multiple rates for production code generation.
- Fixed-step, single-rate. Create a fixed-step model with a single rate for production code generation.

In the templates, traceability and reporting are turned on so that you can easily evaluate your generated code. The model has **System target file** set to `ert.tlc` and is configured to meet code generation objectives prioritized in the following order:

1. Execution efficiency
2. Traceability

To create a model using a model template:

1. On the MATLAB home tab, click **Simulink**.
2. In the Simulink start page, expand **Embedded Coder**.
3. Select a template.
4. Click **Create**. A new model that uses the template contents and settings appears in the Simulink Editor window.

For more information, for example to create and use a template as a reference design, see “Create a Template from a Model” (Simulink).

Aircraft Position Radar Model

This model shows the code generated for a Simulink model containing a MATLAB script.

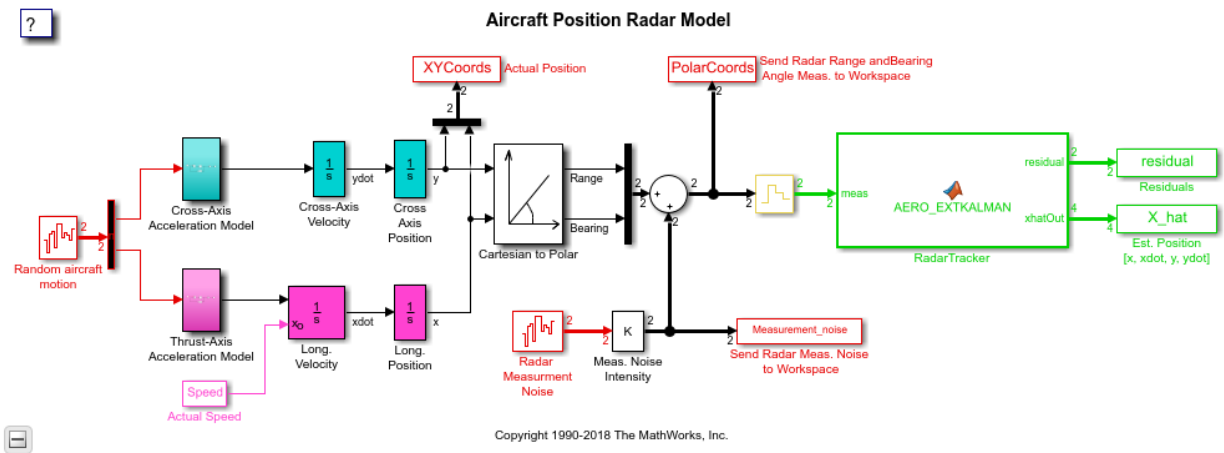
The model contains an Extended Kalman Filter that estimates aircraft position from radar measurements. The MATLAB script rtwdemo_eml_aero_radar.m contains data for running the model. The estimated and actual positions are saved to the workspace and are plotted at the end of the simulation by the program rtwdemo_aero_radplot (called from the simulation automatically).

Review and Simulate the Model

In this section you should review the model and perform a simulation.

Open the Simulink model.

```
model='rtwdemo_eml_aero_radar';
open_system(model)
rtwdemo_eml_aero_radar([],[],[],'compile');
rtwdemo_eml_aero_radar([],[],[],'term');
```



Open the MATLAB Function block `RadarTracker` in the MATLAB Editor.

```
open_system([model,'/RadarTracker'])
```

Block: rtwdemo_eml_aero_radar/RadarTracker

Generate Code for the Model

In this section you will generate code for the Kalman Filter portion of the model using the subsystem build functionality provided by Simulink Coder. In the first build, the model is configured to generate code using Simulink Coder. In the second build, the model is configured to generate code using Embedded Coder.

```
% Create a temporary folder (in your system's temporary folder) for the
% build and inspection process.
```

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Configure and build the model using Simulink Coder.

```
rtwconfiguredemo(model,'GRT')
rtwbuild([model,'/RadarTracker'])
```

```
### Starting build procedure for model: RadarTracker
### Successful completion of build procedure for model: RadarTracker
```

Configure and build the model using Embedded Coder.

```
rtwconfiguredemo(model,'ERT')
rtwbuild([model,'/RadarTracker'])
```

```
### Starting build procedure for model: RadarTracker
### Successful completion of build procedure for model: RadarTracker
```

A portion of `RadarTracker.c` is listed below.

```
cfile = fullfile(cgDir,'RadarTracker_ert_rtw','RadarTracker.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */

    /* Outport: '<Root>/xhatOut' incorporates:
     *  MATLAB Function: '<Root>/RadarTracker'
     */
    rtY.xhatOut[0] = rtDW.xhat[0];
    rtY.xhatOut[1] = rtDW.xhat[1];
    rtY.xhatOut[2] = rtDW.xhat[2];
    rtY.xhatOut[3] = rtDW.xhat[3];
  }
```

You can view the entire generated code in a detailed HTML report, with bi-directional traceability between model and code.

```
web(fullfile(cgDir,'RadarTracker_ert_rtw','html','RadarTracker_codegen_rpt.html'))
```

Close the model and cleanup.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

System Target File Configuration

Configure a System Target File

To configure a model for code generation, follow the steps in “Select a Solver That Supports Code Generation” (Simulink Coder) and “Select a System Target File from STF Browser” (Simulink Coder). When you select a system target file, other model configuration parameters change to serve requirements of the execution environment. For example:

- Code interface parameters
- Build process parameters, such as the toolchain or template makefile
- Target hardware parameters, such as word size and byte ordering

After selecting a system target file, you can modify model configuration parameter settings.

You can switch between different system target files in a single workflow for different code generation purposes (for example, rapid prototyping versus production code deployment). To switch, set up different configuration sets for the same model and switch the active configuration set for the current operation. For more information on how to set up configuration sets and change the active configuration set, see “Manage a Configuration Set” (Simulink).

Select a Solver That Supports Code Generation

To build a model, the model configuration must select a solver that is compatible with code generation for the system target file. Few system target files support code generation with variable-step solvers or for models with a nonzero start time.

- Use **Configuration Parameters** > **Solver** > **Type** and select `Fixed-step` for GRT, ERT, and ERT-based system target files.
- Use **Configuration Parameters** > **Solver** > **Type** and select `Fixed-step` or `Variable-step` for Rapid Simulation (Rsim) or S-Function (rtwsfcn) system target files.

For more information about the requirement that you use a fixed-step solver to generate code for a realtime system target file, see “Time-Based Scheduling and Code Generation” on page 27-2.

When you try to build models with a nonzero start time using a system target file does not support a nonzero start time, the code generator does not produce code. The build

process displays an error message. The Rapid Simulation (RSim) system target file supports a nonzero start time when **Configuration Parameters > RSim Target > Solver selection** is set to `Use Simulink solver module`. Other system target files do not support a nonzero start time.

Select a System Target File from STF Browser

After you select a solver (see “Select a Solver That Supports Code Generation” (Simulink Coder)), use **Configuration Parameters > Code Generation > System target file** and click the **Browse** button to open the System Target File Browser. Select a system target file from the list. Your selection appears in the **System target file** field (*`target`*`.tlc`).

If you use a system target file that does not appear in the System Target File Browser, enter the name of your system target file in the **System target file** field.

You also can select a system target file programmatically from MATLAB code, as described in “Select a System Target File Programmatically” on page 44-4.

After selecting a system target file, you can modify model configuration parameter settings. Selecting a system target file for your model selects either the toolchain approach or template makefile approach for build process control. For more information about these approaches, see “Choose Build Approach and Configure Build Process” on page 54-14.

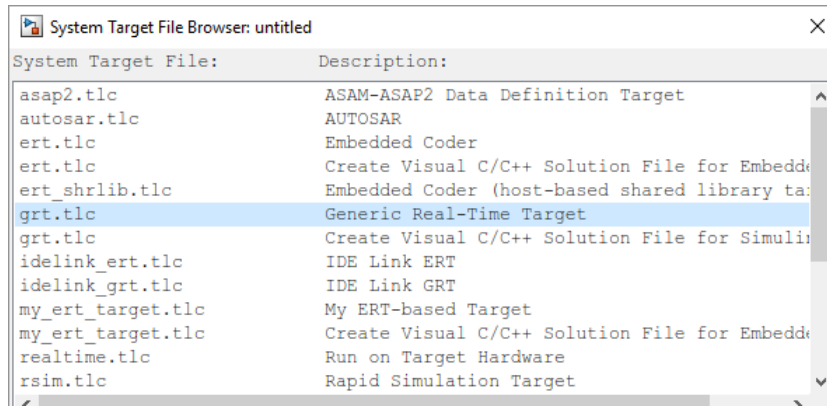
If you want to switch between different system target files in a single workflow for different code generation purposes, set up different configuration sets for the same model. Switch the active configuration set for the current operation. This approach is useful for switching between rapid prototyping and production code deployment. For more information on how to set up configuration sets and change the active configuration set, see “Manage a Configuration Set” (Simulink).

To select a system target file using the System Target File Browser,

1. Open the **Code Generation** pane of the Configuration Parameters dialog box.
2. Click the **Browse** button next to the **System target file** field. This button opens the System Target File Browser. The browser displays a list of currently available system target files, including customizations. When you select a system target file, the code generator automatically chooses the system target file, toolchain or template makefile, and/or `make` command for that configuration.

The next step shows the System Target File Browser with the GRT system target file selected.

3 Click the desired entry in the list of available configurations. The background of the list box turns yellow to indicate that an unapplied choice has been made. To apply it, click **Apply** or **OK**.



System Target File Browser

When you choose a system target file, the code generator selects the toolchain or template makefile and/or `make` command for that configuration and displays them in the **System target file** field. The description of the system target file from the browser is placed below its name in the **Code Generation** pane. For information each system target file, see “Compare System Target File Support Across Products” on page 44-21.

Select a System Target File Programmatically

Simulink models store model-wide parameters and system target file-specific data in *configuration sets*. Every configuration set contains a component that defines the structure of a particular system target file and the current values of relevant options. Simulink loads some of this information from the system target file that you specify. You can configure models to generate alternative code by copying and modifying old or adding new configuration sets and browsing to select a new system target file. Then, you can interactively select an active configuration from among these sets (only one configuration set can be active at a given time).

Scripts that automate system target file selection must emulate this process.

To program system target file selection:

1. Obtain a handle to the active configuration set with a call to the `getActiveConfigSet` function.
2. Define character vector variables that correspond to the required system target file, toolchain or template makefile, and/or `make` command settings. For example, for the ERT system target file, you would define variables for the character vectors `'ert.tlc'`, `'ert_default_tmf'`, and `'make_rtw'`.
3. Select the system target file with a call to the `switchTarget` function. In the function call, specify the handle for the active configuration set and the system target file.
4. Set the `TemplateMakefile` and `MakeCommand` configuration parameters to the corresponding variables created in step 2.

For example:

```
cs = getActiveConfigSet(model);
stf = 'ert.tlc';
tmf = 'ert_default_tmf';
mc  = 'make_rtw';
switchTarget(cs,stf,[]);
set_param(cs,'TemplateMakefile',tmf);
set_param(cs,'MakeCommand',mc);
```

For more information about selecting system target files programmatically, see `switchTarget`.

Develop Custom System Target Files

You can create your own system target files that interface with external code or operating environments.

For more information on how to make custom system target files appear in the System Target File Browser and display relevant controls, see “About Embedded Target Development” (Simulink Coder) and the topics it references.

- “Compare System Target File Support Across Products” on page 44-21
- “About Embedded Target Development” (Simulink Coder)

Configure STF-Related Code Generation Parameters

Many model configuration parameters for code generation are specific to GRT, ERT, or ERT-based system target files.

Specify Generated Code Interfaces

Use interface model configuration parameters to control which libraries to use when generating code, whether to include support for an API in generated code, and other interface options.

To...	Select or Enter...
Specify the standard math library that the code generator uses when generating code.	Select `C89/C90 (ANSI)`, `C99 (ISO)`, or `C++03 (ISO)` for the **Standard math library** parameter. Selecting `C89/C90 (ANSI)` provides the ANSI[a] C set of library functions. For example, selecting `C89/C90 (ANSI)` results in generated code that calls `sin()` whether the input argument is double precision or single precision. However, if you select `C99 (ISO)`, the generated code calls the function `sinf()` when the input argument is single precision. If your compiler supports the ISO®[b] C math extensions, selecting the ISO C library can result in more efficient code. For more information, see “Standard math library” (Simulink Coder). The options for this parameter have dependencies. See Interface Dependencies.
Specify an application-specific library that the code generator uses when generating code.	If you generate application-specific C or C++ code for math functions or operations, select a value for **Code replacement library**. Otherwise, specify `None`. For more information about code replacement libraries, see “Choose a Code Replacement Library” on page 51-8 and “Code replacement library” (Simulink Coder). The options for this parameter have dependencies. See Interface Dependencies.

To...	Select or Enter...
Direct where the code generator places fixed-point and other utility code.	Select `Auto` or `Shared location` for **Shared code placement**. The shared location directs code for utilities to be placed within the `slprj` folder in your working folder, which is used for building referenced models. If you select `Auto`, • When the model contains Model blocks, places utility code within the `slprj/`*`target`*`/_sharedutils` folder. • When the model does not contain Model blocks, places utility code in the build folder (generally, in *`model`*`.c` or *`model`*`.cpp`).
Specify text to be added to the variable names used when logging data to MAT-files and to distinguish logging data from code generation and simulation applications.	Enter a prefix or suffix, such as `rt_` or `_rt`, for the **MAT-file variable name modifier** parameter. The code generator prefixes or appends the text to the variable names for system outputs, states, and simulation time specified in the **Data Import/Export** pane. See “Log Program Execution Results” on page 56-2 for information on MAT-file data logging.
Specify data exchange APIs to be included in generated code.	Select one or more **C API** options, the **ASAP2 interface** option, or the **External mode** option. When you select **External mode**, other options appear. The data exchange APIs are independent, and you can select combinations of these APIs. For example, you could choose C API and external mode. For more information on working with these interfaces, see “Exchange Data Between Generated and External Code Using C API” on page 57-2, “Export ASAP2 File for Data Measurement and Calibration” on page 58-2, and “Host-Target Communication with External Mode Simulation” (Simulink Coder). The options for this parameter have dependencies. See Interface Dependencies.

a. ANSI is a registered trademark of the American National Standards Institute, Inc.
b. ISO is a registered trademark of the International Organization for Standardization.

Note Before setting **Standard math library** or **Code replacement library**, verify that your compiler supports the library you want to use. If you select a parameter value that your toolchain does not support, compiler errors can occur. For example, if you select

standard math library `C99 (ISO)` and your compiler does not support the ISO C math extensions, compile-time errors could occur.

When the Embedded Coder product is installed on your system, the **Code Generation > Interface** pane expands to include several additional options. For descriptions of **Code Generation > Interface** pane parameters, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Several interface parameters have dependencies on settings of other parameters. The following table summarizes the dependencies.

Interface Dependencies

Parameter	Dependencies?	Dependency Details
Standard math library	Yes	Available values depend on **Language** selection.
Code replacement library	Yes	Available values depend on product licensing and other parameters. For more information, see “Code replacement library” (Simulink Coder).
Shared code placement	No	
Support: floating-point numbers (ERT system target files only)	No	
Support: non-finite numbers	Yes (ERT) No (GRT)	For ERT system target files, enabled by **Support floating-point numbers**
Support: complex numbers (ERT system target files only)	No	
Support: absolute time (ERT system target files only)	No	
Support: continuous time (ERT system target files only)	Yes	Requires that you disable **Remove error status field in real-time model data structure**.
Support: non-inlined S-functions (ERT system target files only)	Yes	Requires that you enable **Support floating-point numbers** and **Support non-finite numbers**
Classic call interface	Yes	Requires that you disable **Single output/update function**. For ERT system target files, requires that you enable **Support floating-point numbers**.
Single output/update function	Yes	Disable for **Classic call interface**
Terminate function required (ERT system target files only)	Yes	
Code interface packaging	Yes	Available values depend on **Language** selection.

Parameter	Dependencies?	Dependency Details
Multi-instance code error diagnostic	Yes	Set **Code interface packaging** to `Reusable function` or `C++ class`
Pass root-level I/O as (ERT system target files only)	Yes	Set **Code interface packaging** to `Reusable function`
Use dynamic memory allocation for model initialization (ERT system target files only)	Yes	Set **Code interface packaging** to `Reusable function`
MAT-file logging	Yes	For GRT system target files, requires that you enable **Support non-finite numbers**; for ERT system target files, requires that you enable **Support floating-point numbers**, **Support non-finite numbers**, and **Terminate function required**
MAT-file file variable name modifier	Yes	Enabled by **MAT-file logging**
Remove error status field in real-time model data structure (ERT system target files only)	Yes	Requires that you disable **Support: continuous time**.
Generate C API for: signals	No	
Generate C API for: parameters	No	
Generate C API for: states	No	
Generate C API for: root-level I/O	No	
ASAP2 interface	No	
External mode	No	
Transport layer	Yes	Enable **External mode**
MEX-file arguments	Yes	Enable **External mode**
Static memory allocation	Yes	Enable **External mode**
Static memory buffer size	Yes	Enable **Static memory allocation**

Configure Numeric Data Support

By default, ERT system target files support code generation for integer, floating-point, nonfinite, and complex numbers.

To Generate Code That Supports...	Do...
Integer data only	Clear **Support floating-point numbers**. If noninteger data or expressions are encountered during code generation, an error message reports the offending blocks and parameters.
Floating-point data	Select **Support floating-point numbers**.
Nonfinite values (for example, `NaN`, `Inf`)	Select **Support floating-point numbers** and **Support non-finite numbers**.
Complex data	Select **Support complex numbers**.

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Configure Time Value Support

Certain blocks require the value of absolute time, elapsed time, or continuous time. Absolute time is the time from the start of program execution to the present time. Elapsed time is the time elapsed between two trigger events. Depending on the blocks used, your model could require adjustment of the configuration settings for supported time values.

To...	Select...
Generate code that creates and maintains integer counters for blocks that use absolute or elapsed time values (default).	**Support absolute time**. For further information on the allocation and operation of absolute and elapsed timers, see “Absolute and Elapsed Time Computation” (Simulink Coder). If you do not select this parameter and the model includes a block that uses absolute or elapsed time values, the build process generates an error.
Generate code for blocks that rely on continuous time.	**Support continuous time**. If you do not select this parameter and the model includes continuous-time blocks, the build process generates an error.

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Configure Noninlined S-Function Support

To generate code for noninlined S-Functions in a model, select **Support noninlined S-functions**. The generation of noninlined S-functions requires floating-point and nonfinite numbers. Thus, when you select **Support non-inlined S-functions**, the ERT system target file selects **Support floating-point numbers** and **Support non-finite numbers**.

When you select **Support non-finite numbers** and the model includes a C MEX S-function that does not have a corresponding TLC implementation (for inlining code generation), the build process generates an error.

Inlining S-functions is highly advantageous in production code generation, for example in implementing device drivers. To enforce the use of inlined S-functions for code generation, clear **Support non-inlined S-functions**.

When generating code for a model that contains noninlined S-functions with an ERT system target file, there could be a mismatch between the simulation and code generation results when either of the following is true:

- Model configuration parameter `GenCodeOnly` is set to `off` or **Configuration Parameters** > **Code Generation** > **Generate code only** is cleared.
- Model configuration parameter `ProdEqTarget` is set to `off`.

To avoid such a mismatch, set `ProdEqTarget` to `on` or select **Configuration Parameters** > **Code Generation** > **Generate code only** (or set `GenCodeOnly` to `on`).

Configure Model Function Generation and Argument Passing

For ERT system target files, you can configure model for how functions are generated and how arguments are passed to the functions.

To...	Do...
Generate model function calls that are compatible with the main program module of the pre-R2012a GRT system target file (`grt_main.c` or `.cpp`).	Select **Classic call interface** and **MAT-file logging**. In addition, clearing **Remove error status field in real-time model data structure**. **Classic call interface** provides a quick way to use code generated in R2012a or higher with a pre-R2012a GRT-based custom system target file by generating wrapper function calls that interface to the generated code.

To...	Do...
Reduce overhead and use more local variables by combining the output and update functions in a single *`model`*`_step` function.	Select **Single output/update function** Errors or unexpected behavior can occur if a Model block is part of a cycle and the model configuration enables "Single output/update function" (Simulink Coder) (the default). For more information about direct feed through, see "Algebraic Loop Concepts" (Simulink).
Generate a *`model`*`_terminate` function for a model not designed to run indefinitely.	Select **Terminate function required** (Simulink Coder). For more information, see the description of `model_terminate`.
Generate reusable, reentrant code from a model or subsystem.	Select **Generate reusable code**. See "Configure Code Reuse Support" on page 44-15 for details.
Statically allocate model data structures and access them directly in the model code.	Clear **Generate reusable code**. The generated code is not reusable or reentrant. See "Configure Code Generation for Model Entry-Point Functions" (Simulink Coder) for information on the calling interface generated for model functions in this case.
Suppress the generation of an error status field in the real-time model data structure, `rtModel`, for example, if you do not require to log or monitor error messages.	Select **Remove error status field in real-time model data structure**. Selecting this parameter can also cause the code generator to omit the `rtModel` structure from the generated code. When generating code for multiple integrated models, set this parameter the same for all of the models. Otherwise, the integrated application could exhibit unexpected behavior. For example, if you select the option in one model but not in another, it is possible that the integrated application could not register the error status. Do not select this parameter if you select the **MAT-file logging** option. The two options are incompatible.

To...	Do...
Open the Configure C Step Function Interface dialog box and modify the *`model`*`_step` function prototype.	In the Code Mapping Editor, on the **Entry-Point Functions** tab, click in the Function Name column for the base-rate step function. Click the three vertical dots that appear. Then click **Configure Prototype**. Unless a function prototype was previously configured, the dialog box opens showing a preview of the step function interface without arguments (`void-void`). The dialog box also shows the current function name. If arguments have previously been configured for the model, the dialog box displays the current settings. You can change the name and argument settings for the step function. For more information, see “Override Default C Step Function Interface” on page 39-7.

For more information, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Configure Code Reuse Support

For GRT, ERT, GRT-based, and ERT-based system target files, you can configure how a model reuses code by setting the **Configuration Parameters** > **Code Generation** > **Code interface packaging** parameter value to `Reusable function`.

The **Configuration Parameters** > **Code Generation** > **Pass root-level I/O as** parameter provides options that control how model inputs and outputs at the root level of the model are passed to the *`model`*`_step` function.

To...	Select...
Pass each root-level model input and output argument to the *`model`*`_step` function individually (the default)	**Code interface packaging** > `Reusable function` and **Pass root-level I/O as** > `Individual arguments`.
Pack root-level input arguments and root-level output arguments into separate structures that are then passed to the *`model`*`_step` function	**Code interface packaging** > `Reusable function` and **Pass root-level I/O as** > `Structure reference`.
Pack root-level input arguments and root-level output arguments into the model data structure to support reentrant multi-instance code from a model for ERT system target file	**Code interface packaging** > `Reusable function` and **Pass root-level I/O as** > `Part of model data structure`.

If using the **Code interface packaging** > `Reusable function` selection, consider using the **Use dynamic memory allocation for model initialization** option to control whether an allocation function is generated. This option applies for ERT system target files.

Sometimes, selecting **Code interface packaging** as `Reusable function` can generate code that compiles but is not reentrant. For example, if a signal, `DWork` structure, or parameter data has a storage class other than `Auto`, global data structures are generated. To handle such cases, use the **Multi-instance code error diagnostic** parameter to choose the severity levels for diagnostics.

Sometimes, the code generator is unable to generate valid and compilable code. For example, if the model contains one of the following, the generated code is invalid.

- An S-function that is not code-reuse compliant
- A subsystem triggered by a wide function-call trigger

In these cases, the build terminates after reporting the problem.

For more information, see “Generate Reentrant Code from Top Models” on page 6-25 and “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

Configure a Code Replacement Library

You can configure the code generator to change the code that it generates for functions and operators such that the code meets application requirements. Configure the code generator to apply a code replacement library (CRL) during code generation. If you have Embedded Coder, you can develop and apply custom code replacement libraries.

For more information about replacing code, using code replacement libraries that MathWorks provides, see “What Is Code Replacement?” on page 52-2 and “Code Replacement Libraries” (Simulink Coder). For information about developing code replacement libraries, see “What Is Code Replacement Customization?” on page 65-3.

- “Configure Standard Math Library for Target System” on page 44-18
- “Compare System Target File Support Across Products” on page 44-21
- “Specify Generated Code Interfaces” on page 44-7

Configure Standard Math Library for Target System

Specify standard library extensions that the code generator uses for math operations. When you generate code for a new model or with a new configuration set object, the code generator uses the ISO®/IEC 9899:1999 C (C99 (ISO)) library by default. For preexisting models and configuration set objects, the code generator uses the library specified by the **Standard math library** parameter.

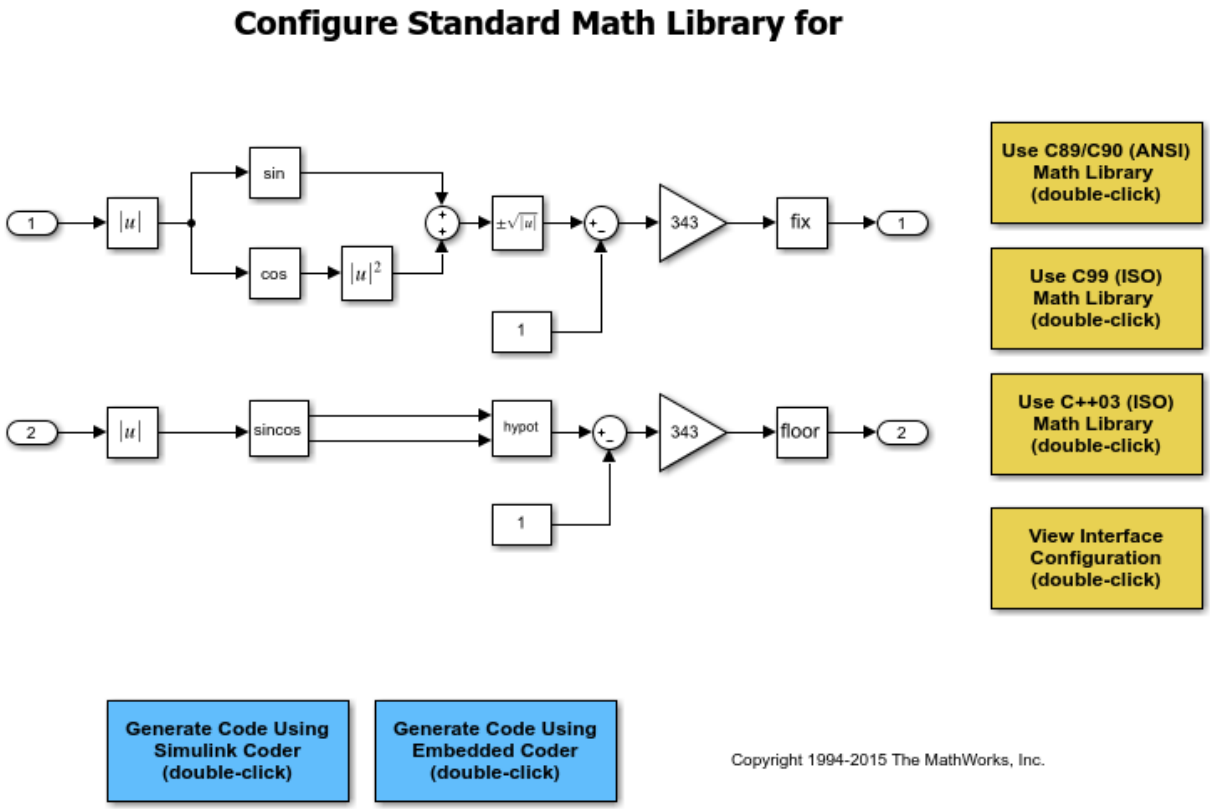
If your compiler supports the ISO®/IEC 9899:1990 (C89/C90 (ANSI)) or ISO/IEC 14882:2003(C++03 (ISO)) math library extensions, you can change the standard math library setting. The C++03 (ISO) library is an option when you select C++ for the programming language.

The C99 library leverages the performance that a compiler offers over standard ANSI C. When using the C99 library, the code generator produces calls to ISO C functions when possible. For example, the generated code calls the function `sqrtf()`, which operates on single-precision data, instead of `sqrt()`.

To change the library setting, use the **Configuration Parameters>Standard math library** parameter. The command-line equivalent is `TargetLangStandard`.

Generate and Inspect ANSI C Code

1. Open the example model `rtwdemo_clibsup`.



2. Generate code.

```
### Starting build procedure for model: rtwdemo_clibsup
### Successful completion of code generation for model: rtwdemo_clibsup
```

3. Examine the code in the generated file `rtwdemo_clibsup.c`. Note that the code calls the `sqrt` function.

```
  if (rtb_Abs2 < 0.0F) {
    rtb_Abs2 = -(real32_T)sqrt((real32_T)fabs(rtb_Abs2));
  } else {
    rtb_Abs2 = (real32_T)sqrt(rtb_Abs2);
  }
```

Generate and Inspect ISO C Code

1. Change the setting of **Standard math library** to `C99 (ISO)`. Alternatively, at the command line, set `TargetLangStandard` to `C99 (ISO)`.

2. Regenerate the code.

```
### Starting build procedure for model: rtwdemo_clibsup
### Successful completion of code generation for model: rtwdemo_clibsup
```

3. Reexamine the code in the generated file `rtwdemo_clibsup.c`. Now the generated code calls the function `sqrtf` instead of `sqrt`.

```
if (rtb_Abs2 < 0.0F) {
  rtb_Abs2 = -sqrtf(fabsf(rtb_Abs2));
} else {
  rtb_Abs2 = sqrtf(rtb_Abs2);
}
```

Compare System Target File Support Across Products

When you select a system target file (such as `grt.tlc`), the selection defines the run-time environment and the code generation features. Identify the system target file features that match your code generation workflow goals.

The code generator uses the system target file to produce code intended for execution on certain target hardware or on a certain operating system. The system target file invokes other run-time environment-specific files. For more information on configuring model code generation parameters for target hardware, see “Configure Run-Time Environment Options” (Simulink Coder).

Different types of system target files support a selection of generated code features. In the system target file, the value of the `CodeFormat` TLC variable and corresponding `rtwgensettings.DerivedFrom` field value identify the system target file type and generated code features. These selections apply your code generation control decisions at several points in the code generation process. Your selections include whether and how the model build generates:

- Certain data structures (for example, `SimStruct` or `rtModel`)
- Static or dynamic memory allocation code
- Calling interface for generated model functions

For custom system target file development, the `CodeFormat` value differs among code generation targets:

- If the system target file does not include a value for the `CodeFormat` TLC variable, the default value is `RealTime` for generic real-time target (GRT). The corresponding `rtwgensettings.DerivedFrom` field value is `grt.tlc` (default value).
- If you are developing a custom system target file and you have Embedded Coder software, consider setting the `CodeFormat` TLC variable value to `Embedded-C` for embedded real-time target (ERT). The corresponding `rtwgensettings.DerivedFrom` field value is `ert.tlc`. The ERT system target file supports more generated code features than the GRT system target file.

This example shows how the value for the `CodeFormat` TLC variable and corresponding `rtwgensettings.DerivedFrom` field value are set in `ert.tlc`.

```
%assign CodeFormat = "Embedded-C"
```

```
/%
  BEGIN_RTW_OPTIONS
  rtwgensettings.DerivedFrom = 'ert.tlc';
  END_RTW_OPTIONS
%/
```

Note Use the value for the `CodeFormat` TLC variable with its corresponding `rtwgensettings.DerivedFrom` field value to generate code for the model. If you do not select a value explicitly, the default values correspond. For more information, see "System Target File Structure" (Simulink Coder).

For a description of the optimized call interface generated by default for the GRT and ERT system target files, see "Configure Code Generation for Model Entry-Point Functions" (Simulink Coder).

Code generation with the GRT and ERT system target files uses the real-time model data structure (`rtModel`). This structure encapsulates model-specific information in a much more compact form than the simulation structure, `SimStruct`. Many efficient features of generated code depend on generation of `rtModel` rather than `SimStruct`, including:

- Integer absolute and elapsed timing services
- Independent timers for asynchronous tasks
- Generation of improved C API code for signal, state, and parameter monitoring
- Pruning the data structure to minimize its size (ERT-derived system target files only)

For a description of the `rtModel`data structure, see "Use the Real-Time Model Data Structure" (Simulink Coder).

Compare Product System Target Files

You can select from a range of system target files by using the System Target File Browser. This selection lets you experiment with configuration options and save your model with different configurations.

You cannot build or generate code for non-GRT system target files, unless you have the required software on your system. For example, you require Embedded Coder for ERT system target files, Simulink Desktop Real-Time for SLDRT system target files, and so on.

Selecting a system target file for your model selects either the toolchain approach or the template makefile approach for build process control. For more information about these approaches, see “Choose Build Approach and Configure Build Process” on page 54-14.

Compare Code Styles and STF Support

The code generator produces two styles of code. One code style is suitable for rapid prototyping (and simulation by using code generation). The other style is suitable for embedded applications. This table maps system target files to corresponding code styles.

Code Styles Listed by System Target File

System Target File	Code Style	Purpose
Embedded Coder embedded real-time (ERT)	Embedded	A starting point for embedded application development of C/C++ generated code.
Simulink Coder generic real-time (GRT)	Rapid prototyping	A starting point for creating a rapid prototyping target hardware that does not use real-time operating system tasking primitives and for verifying the generated C/C++ code on your desktop computer.
Rapid simulation (RSim)	Rapid prototyping	Provides non-real-time simulation on your desktop computer and a high-speed or batch simulation tool.
S-function	Rapid prototyping	Creates a C MEX S-function for simulation within another Simulink model.
Simulink Desktop Real-Time	Rapid prototyping	Runs a model in real time at interrupt level while your desktop computer runs Microsoft Windows in the background.
Simulink Real-Time	Rapid prototyping	Runs a model in real time on a desktop computer running the Simulink Real-Time kernel.

Third-party vendors supply additional system target files to support code generation for their products. For more information about third-party products, see the vendor website or the MathWorks Connections program web page: `https://www.mathworks.com/products/connections`.

Compare Generated Code Features by Product

The code generation process for real-time system target files (such as GRT) provides many embedded code optimizations. Selecting an ERT-based system target file offers more extensive features than GRT. The system target file selection determines the available features for the code generation product. As you select the code generation target that matches your development process, use this table to compare code generation features available with Simulink Coder and features available with Embedded Coder.

Compare Code Generation Features for Simulink Coder Versus Embedded Coder

Feature	Simulink Coder	Embedded Coder
`rtModel` data structure	• Full `rtModel` structure generated • GRT variable declaration: `rtModel_`*`model model`*`_M_;`	• `rtModel` is optimized for the model • Optional suppression of error status field and data logging fields • ERT variable declaration: `RT_MODEL_`*`model model`*`_M_;`
Custom storage classes (CSCs)	Code generation ignores CSCs. Objects are assigned a CSC default to `Auto` storage class.	Code generation with CSCs is supported
HTML code generation report	Basic HTML code generation report	Enhanced report with additional detail and hyperlinks to the model
Symbol formatting	Symbols (for signals, parameters, and so on) are generated in accordance with hard-coded default	Detailed control over generated symbols
User-defined maximum identifier length for generated symbols	Supported	Supported
Generation of terminate function	Generated	Option to suppress the terminate function
Combined output/ update function	Separate output/update functions are generated	Option to generate combined output/ update function
Optimized data initialization	Not available	Options to suppress generation of unnecessary initialization code for zero-valued memory, I/O ports, and so on
Comments generation	Basic options to include or suppress comment generation	Options to include Simulink block descriptions, Stateflow object descriptions, and Simulink data object descriptions in comments

Feature	Simulink Coder	Embedded Coder
Module Packaging Features (MPF)	Not supported	Extensive code customization features See “Control Data Type Names in Generated Code” on page 34-2 and “MPT Data Object Properties” on page 35-2.
System target file-optimized data types header file	Requires full `tmwtypes.h` header file	Generates optimized `rtwtypes.h` header file, including definitions required by the system target file
User-defined types	User-defined types default to base types in code generation	User-defined data type aliases are supported in code generation
Rate grouping	Not supported	Supported
Auto-generation of main program module	Not supported. Static main program module is provided.	Automated and customizable generation of main program module is supported (static main program also available)
Reusable (multi-instance) code generation	Option to generate reusable code with dynamic memory allocation	Option to generate reusable code with static or dynamic memory allocation
Software constraint options	Support for floating-point, complex, and nonfinite numbers is enabled	Options to enable or disable support for floating-point, complex, and nonfinite numbers
Application life span	Defaults to `inf`	User-specified. Determines most efficient word size for integer timers
Software-in-the-loop (SIL) testing	Model reference simulation target can be used for SIL testing	Additional SIL testing support by using auto-generation of SIL block
ANSI-C/C++ code generation	Supported	Supported
ISO-C/C++ code generation	Supported	Supported
GNU®-C/C++ code generation	Supported	Supported

Feature	Simulink Coder	Embedded Coder
Generate scalar inlined parameters as `#DEFINE` statements	Not supported	Supported
MAT-file variable name modifier	Supported	Supported
Data exchange: C API, ASAP2, external mode	Supported	Supported

Compare Generated Code Features by STF

The code generator supports a selection of generated code features for different types of system target files. In each system target file, the value of the `CodeFormat` TLC variable identifies the set of features.

This table summarizes how different system target files support applications.

Application	System Target File (STF)
Fixed- or variable-step acceleration	RSIM, S-Function, Model Reference
Fixed-step real-time deployment	GRT, ERT, Simulink Real-Time, Simulink Desktop Real-Time, ...

This table summarizes the various options available for each **System target file** selection, with the exceptions noted.

Features Supported in Code Generated for System Target Files (STF)

	System Target Files (STF)							
Feature	**grt.tlc (See note 1.)**	**ert.tlc (See note 1.)**	**ert_shrlib.tlc (See note 1.)**	**rtwsfcn.tlc (See note 1.)**	**rsim.tlc (See note 1.)**	**sldrt.tlc (See note 1.)**	**slrt.tlc (See note 1.)**	**Other (See note 1.)**
Static memory allocation	X	X				X	X	X
Dynamic memory allocation	X (See notes 4, 5.)	X (See notes 4, 5.)		X	X		X	
Continuous time	X	X		X	X	X	X	
C/C++ MEX S-functions (noninlined)	X	X		X	X	X	X	
S-function (inlined)	X	X		X	X	X	X	X
Minimize RAM/ROM usage		X					X[2]	X
Supports external mode	X	X			X	X	X	
Rapid prototyping	X					X	X	X
Production code		X					X[2]	X (See note 3.)

	System Target Files (STF)							
Feature	**grt.tlc (See note 1.)**	**ert.tlc (See note 1.)**	**ert_shrlib.tlc (See note 1.)**	**rtwsfcn.tlc (See note 1.)**	**rsim.tlc (See note 1.)**	**sldrt.tlc (See note 1.)**	**slrt.tlc (See note 1.)**	**Other (See note 1.)**
Batch parameter tuning and Monte Carlo methods			X		X			
System-level Simulator			X					
Executes in hard real time	X (See note 3.)	X (See note 3.)				X	X	X[5]
Non-real-time executable included	X	X			X			
Multiple instances of model	X (See notes 4, 5.)	X (See notes 4, 5.)		X[4]			X (See notes 4, 5.)	X (See notes 4, 5.)
Supports variable-step solvers				X	X			
Supports SIL/PIL		X						X

Notes

1 System Target Files:

- **grt.tlc** - generic real-time target
- **ert.tlc** - embedded real-time target
- **ert_shrlib.tlc** - embedded real-time target shared library)
- **rtwsfcn.tlc** - S-Function
- **rsim.tlc** - rapid simulation
- **sldrt.tlc** - Simulink Desktop Real-Time
- **slrt.tlc** - Simulink Real-Time
- **Other** - The embedded real-time capabilities in Simulink Coder support other system target files

2 Does not apply to GRT-based system target files. Applies to only ERT-based system target files.

3 The default GRT and ERT `rt_main` files emulate execution of hard real time. When explicitly connected to a real-time clock, they execute in hard real time.

4 You can generate code for multiple instances of a Stateflow chart or subsystem containing a chart, except when the chart contains exported graphical functions or the Stateflow model contains machine-parented events.

5 Select the value `Reusable function` for **Code interface packaging** (Simulink Coder) in the **Code Generation** > **Interface** pane in the Configuration Parameters dialog box.

Internationalization Support in Simulink Coder

Internationalization and Code Generation

Internationalization support in software development tooling is vital for enabling efficient globalization. If there is any possibility of future collaboration with others across locales, consider internationalization from project inception. Internationalization can prevent rework or having to develop a new model design. The relevant requirement concerns locale settings.

Locale Settings

On a computer, a locale setting defines the language (character set encoding) for the user interface and the display formats for information such as time, date, and currency. The encoding dictates the number of characters that a locale can render. For example, the US-ASCII coded character set (codeset) defines 128 characters. A Unicode® codeset, such as UTF-8, defines more than 1,100,000 characters.

For code generation, the locale setting determines the character set encoding of generated file content. To avoid garbled text or incorrectly displayed characters, the locale setting for your MATLAB session must be compatible with the setting for your compiler and operating system. For information on finding and changing the operating system setting, see “Internationalization” (MATLAB) or see the operating system documentation.

To check a model for characters that cannot be represented in the locale setting of your current MATLAB session, use the Simulink Model Advisor check “Check model for foreign characters” (Simulink).

Prepare to Generate Code for Mixed Languages and Locales

To prepare to generate code for a model, identify:

- The operating system locale.
- The locale of the MATLAB session.
- Code generation requirements for:
  - Target Language Compiler files
  - Code generation template files that include comments (requires Embedded Coder)

Character Set Limitations

Target language compiler files support user default encoding only. To produce international, custom generated code that is portable, use the 7-bit ASCII character set.

XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding of a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in:

- Generated code comments
- Code generation reports
- Block paths logged to MAT-files
- Block paths logged to C API files *`model`*`_capi.c` (or `.cpp`) and *`model`*`_capi.h`

Generate and Review Code with Mixed Languages and Mixed Locales

This example shows how to use the code generator to generate and review code for use in mixed languages and mixed locales.

Before using this example, see “Internationalization and Code Generation” (Simulink Coder) or “Internationalization and Code Generation” on page 46-2.

The `rtwdemo_unicode` model configuration uses the Embedded Coder (R) `ert.tlc` system target file. To see internationalization and localization support with Simulink Coder®, configure the model to use the `grt.tlc` system target file. The example indicates the support that is specific to Embedded Coder® (for example, code generation templates).

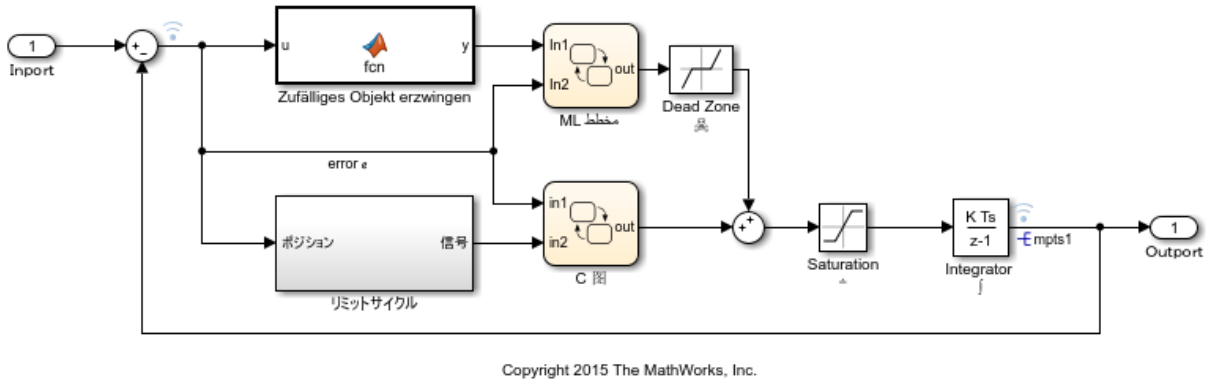
The model configuration specifies files and settings that control how the code generator handles localization for:

- C and C++ API interfaces
- Code generation template (CGT) files (requires Embedded Coder®)
- Target Language Compiler (TLC) files that apply code customizations (requires Embedded Coder®)

Open the example model `rtwdemo_unicode`.

Labels in the model appear in multiple languages (Arabic, Chinese, English, German, and Japanese) and various Unicode symbols.

```
model = 'rtwdemo_unicode';
open_system(model);
```



Verify Locale Settings

Verify that the locale setting for your MATLAB® software is compatible with your compiler. See the documentation for your operating system or the following MATLAB documentation:

- “Set Locale on Windows Platforms” (MATLAB)
- “Set Locale on Linux Platforms” (MATLAB)
- “Set Locale on macOS Platforms” (MATLAB)

Verify Model for Use of Foreign Characters

to verify the model for characters that the code generator cannot represent in the model's current character set encoding, use the Simulink® Model Advisor check **Check model for foreign characters**.

1. Open the Model Advisor in Simulink®. Select **Analysis > Model Advisor > Model Advisor**. Or, in the Command Window, type:

```
modeladvisor('rtwdemo_unicode')
```

2. Expand **By Product**.

3. Expand **Simulink**.

4. Select **Check model for foreign characters**

5. Click **Run This Check**.

6. Review the results. Several warnings appear. Verify that the characters in the model can be represented in the current character set encoding.

7. Close the Model Advisor.

Code Generation Template Files

To use a code generation template file with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code generation template file `rtwdemo_unicode.cgt`. That file adds comments to the top of generated code files. For the code generator to apply escape sequence replacements for the `.cgt` file, enable replacements by specifying:

```
<encodingIn = "encoding-name">
```

3. Open the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

```
edit rtwdemo_unicode.cgt
```

4. Find the line of code that enables escape sequence replacements for the character set encoding `UTF-8`.

```
<encodingIn = "UTF-8">
```

5. Close the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

Generated File Customization Template

To use file customization templates with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

You can specify customizations to generated code files by using TLC code. TLC files support user default encoding only. To produce international custom generated code that is portable, use the 7-bit ASCII character set.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code customization file `example_file_process.tlc`. That file customizes the generated code just before the code generator writes the code files. For example, the file adds a C source file, corresponding include file, and `#define` and `#include` statements.

3. Open the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

```
edit example_file_process.tlc
```

4. Before generating code, uncomment the following line of code:

```
%% %assign ERTCustomFileTest = TLC_TRUE%
```

5. Close the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

Generate C Code

Generate C code and a code generation report.

```
evalc('rtwbuild(''rtwdemo_unicode'')');
```

Review the Generated Code

For characters that are not in the current MATLAB® character set encoding, the code generator uses escape sequence replacements to render characters correctly in the code generation report.

1. If the code generation report for model `rtwdemo_unicode` is not open, in the Command Window, type:

```
coder.report.open('rtwdemo_unicode')
```

2. Review the generated code in `rtwdemo_unicode.c` and `rtwdemo_unicode.h`. Names of model elements appear in code comments as replacement names in the local language.

3. Open the Traceability Report. The report maintains traceability information, even when the name contains characters that are not represented in the current encoding. Names of model elements appear in the report as replacement names in the local language.

4. Scroll down to and click the code location link for the first Chart (`State 'Selection' <S2>:23`). The report view changes to show the corresponding code in `rtwdemo_unicode.c`.

5. In the code comment, click the `<S2>:23` link. The model window shows the chart in a new tab.

6. In the model window, right-click that chart. Select **C/C++ Code > Navigate to C/C++ Code**. The report view changes to show the named constant section of code for that chart.

7. Close the code generation report, Model Advisor, and model. In the Command Window, type:

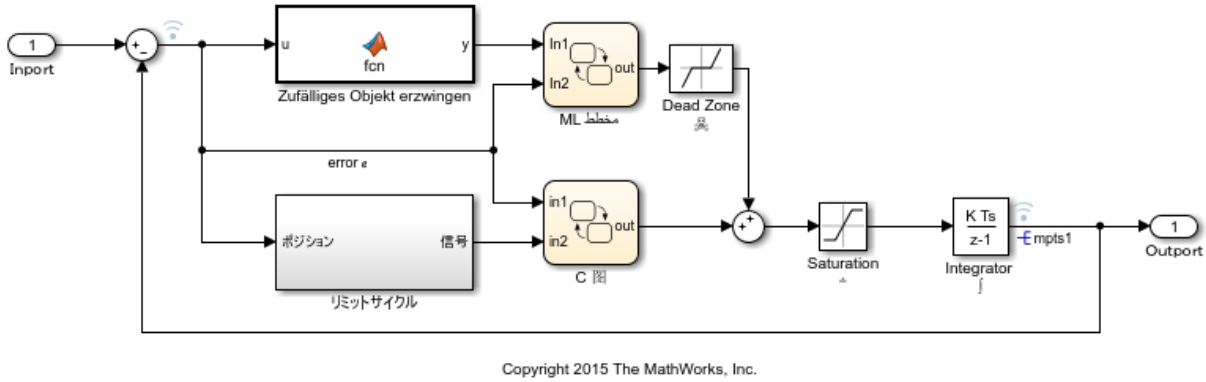
```
coder.report.close();
bdclose('all');
```

Generate C++ Code

Generate C++ code and a code generation report.

1. Open the model.

```
model = 'rtwdemo_unicode';
open_system(model);
```



2. Change **Configuration Parameters** > **Code Generation** > **Language** to `C++`. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','TargetLang','C++');
```

3. Change **Configuration Parameters** > **Code Generation** > **Interface** > **Code interface packaging** to `C++ class`. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','CodeInterfacePackaging','C++ class');
```

4. Generate C++ code and a code generation report.

```
evalc('rtwrebuild(''rtwdemo_unicode'')');
```

5. To see internationalization and localization support, review the generated code. See **Review the Generated Code**.

6. Close the code generation report and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

Internationalization Support in Embedded Coder

Internationalization and Code Generation

Internationalization support in software development tooling is vital to enabling efficient globalization. If there is a remote possibility that you could collaborate in the future with others across locales, consider internationalization from project inception. Internationalization can prevent rework or having to develop a new model design. The relevant requirement concerns locale settings.

In this section...

Locale Settings

On a computer, a locale setting defines the language (character set encoding) for the user interface and the display formats for information such as time, date, and currency. The encoding dictates the number of characters that a locale can render. For example, the US-ASCII coded character set (codeset) defines 128 characters. A Unicode codeset, such as UTF-8, defines more than 1,100,000 characters.

For code generation, the locale setting determines the character set encoding of generated file content. To avoid garbled text or incorrectly displayed characters, the locale setting for your MATLAB session must be compatible with the setting for your compiler and operating system. For information on finding and changing the operating system setting, see “Internationalization” (MATLAB) or see the operating system documentation.

To check a model for characters that cannot be represented in the locale setting of your current MATLAB session, use the Simulink Model Advisor check “Check model for foreign characters” (Simulink).

Prepare to Generate Code for Mixed Languages and Locales

To prepare to generate code for a model, identify:

- The operating system locale.
- The locale of the MATLAB session.
- Code generation requirements for:
  - Target Language Compiler files
  - Code generation template files that include comments (requires Embedded Coder)

Character Set Limitations

Target language compiler files support user default encoding only. To produce international, custom generated code that is portable, use the 7-bit ASCII character set.

XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding of a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in:

- Generated code comments
- Code generation reports
- Block paths logged to MAT-files
- Block paths logged to C API files *`model`*`_capi.c` (or `.cpp`) and *`model`*`_capi.h`

CGT Files and XML Escape Sequence Replacements

The code generator replaces characters that are not represented in the character set encoding for a model with XML escape sequences. Escape sequence replacements occur for block, signal, and Stateflow object names that appear in Comments in code generation template (CGT) files.

By default, code generation template files do not contain character set encoding information. The operating system reads the files, using its current encoding, regardless of the encoding that you use to write the file. You can enable escape sequence replacements by adding the following token at the top of the template file:

```
<encodingIn = "encoding">
```

Replace *encoding* with a string that names a standard character encoding scheme, such as `UTF-8`, `ISO-8859–1`, or `windows-1251`.

This example shows content from the file rtwdemo_unicode.cgt in a MATLAB session for `windows-1251`. The example uses the `encodingIn` token to set the encoding to `UTF–8`, which is the correct value for code generation.

```
17  <encodingIn = "UTF-8">
18  <FileBanner style = "box">
19  File: %<FileName>
20

22
23  Model version                  : %<ModelVersion>
24  Simulink Coder version         : %<RTWFileVersion>
25  TLC version                    : %<TLCVersion>
26  C/C++ source code generated on : %<SourceGeneratedOn>
27
28  You can customize this banner by specifying a different template.
29   Unicode characters written in cgt file:
30   ï¼³ï½●ï½‰ï½"ï½": â™  â™¡ â™¢ â™£ â™¤ â™¥ â™¦
31   Greek Symbols: â™ƒ â™„ â™… â™† â™‡ â™ˆ â™‰ â™Š â™‹ â™Œ â™ â™Ž â™ â™ â™‘ â™’ â™“
```

Generate and Review Code with Mixed Languages and Mixed Locales

This example shows how to use the code generator to generate and review code for use in mixed languages and mixed locales.

Before using this example, see “Internationalization and Code Generation” (Simulink Coder) or “Internationalization and Code Generation” on page 46-2.

The `rtwdemo_unicode` model configuration uses the Embedded Coder (R) `ert.tlc` system target file. To see internationalization and localization support with Simulink Coder®, configure the model to use the `grt.tlc` system target file. The example indicates the support that is specific to Embedded Coder® (for example, code generation templates).

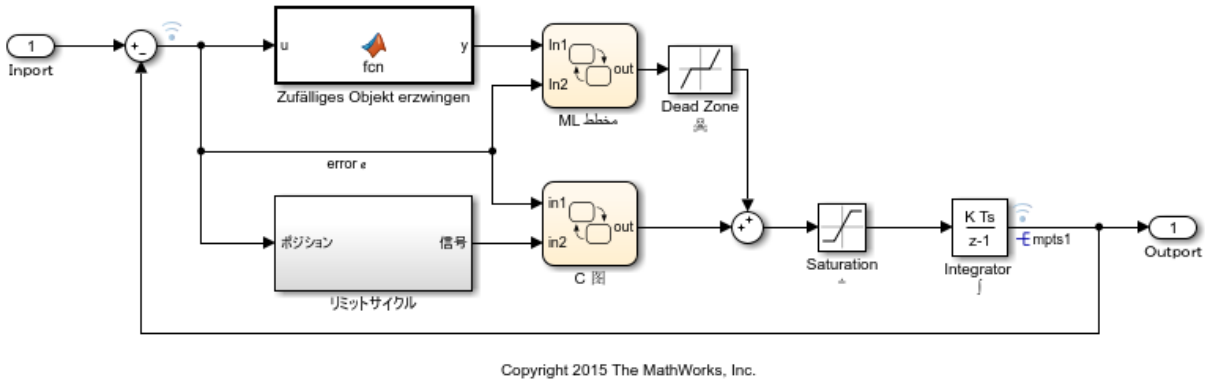
The model configuration specifies files and settings that control how the code generator handles localization for:

- C and C++ API interfaces
- Code generation template (CGT) files (requires Embedded Coder®)
- Target Language Compiler (TLC) files that apply code customizations (requires Embedded Coder®)

Open the example model `rtwdemo_unicode`.

Labels in the model appear in multiple languages (Arabic, Chinese, English, German, and Japanese) and various Unicode symbols.

```
model = 'rtwdemo_unicode';
open_system(model);
```



Verify Locale Settings

Verify that the locale setting for your MATLAB® software is compatible with your compiler. See the documentation for your operating system or the following MATLAB documentation:

- “Set Locale on Windows Platforms” (MATLAB)
- “Set Locale on Linux Platforms” (MATLAB)
- “Set Locale on macOS Platforms” (MATLAB)

Verify Model for Use of Foreign Characters

to verify the model for characters that the code generator cannot represent in the model's current character set encoding, use the Simulink® Model Advisor check **Check model for foreign characters**.

1. Open the Model Advisor in Simulink®. Select **Analysis > Model Advisor > Model Advisor**. Or, in the Command Window, type:

```
modeladvisor('rtwdemo_unicode')
```

2. Expand **By Product**.

3. Expand **Simulink**.

4. Select **Check model for foreign characters**

5. Click **Run This Check**.

6. Review the results. Several warnings appear. Verify that the characters in the model can be represented in the current character set encoding.

7. Close the Model Advisor.

Code Generation Template Files

To use a code generation template file with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code generation template file `rtwdemo_unicode.cgt`. That file adds comments to the top of generated code files. For the code generator to apply escape sequence replacements for the `.cgt` file, enable replacements by specifying:

```
<encodingIn = "encoding-name">
```

3. Open the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

```
edit rtwdemo_unicode.cgt
```

4. Find the line of code that enables escape sequence replacements for the character set encoding `UTF-8`.

```
<encodingIn = "UTF-8">
```

5. Close the file `/toolbox/rtw/rtwdemos/rtwdemo_unicode.cgt`.

Generated File Customization Template

To use file customization templates with unicode characters when generating code, complete these steps (requires Embedded Coder®). Otherwise, go to the next section.

You can specify customizations to generated code files by using TLC code. TLC files support user default encoding only. To produce international custom generated code that is portable, use the 7-bit ASCII character set.

1. Open the Configuration Parameters dialog box.

2. Navigate to the **Code Generation > Template** pane. The model is configured to use the code customization file `example_file_process.tlc`. That file customizes the generated code just before the code generator writes the code files. For example, the file adds a C source file, corresponding include file, and `#define` and `#include` statements.

3. Open the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

```
edit example_file_process.tlc
```

4. Before generating code, uncomment the following line of code:

```
%% %assign ERTCustomFileTest = TLC_TRUE%
```

5. Close the file `/toolbox/rtw/rtwdemos/example_file_process.tlc`.

Generate C Code

Generate C code and a code generation report.

```
evalc('rtwbuild(''rtwdemo_unicode'')');
```

Review the Generated Code

For characters that are not in the current MATLAB® character set encoding, the code generator uses escape sequence replacements to render characters correctly in the code generation report.

1. If the code generation report for model `rtwdemo_unicode` is not open, in the Command Window, type:

```
coder.report.open('rtwdemo_unicode')
```

2. Review the generated code in `rtwdemo_unicode.c` and `rtwdemo_unicode.h`. Names of model elements appear in code comments as replacement names in the local language.

3. Open the Traceability Report. The report maintains traceability information, even when the name contains characters that are not represented in the current encoding. Names of model elements appear in the report as replacement names in the local language.

4. Scroll down to and click the code location link for the first Chart (`State 'Selection' <S2>:23`). The report view changes to show the corresponding code in `rtwdemo_unicode.c`.

5. In the code comment, click the `<S2>:23` link. The model window shows the chart in a new tab.

6. In the model window, right-click that chart. Select **C/C++ Code > Navigate to C/C++ Code**. The report view changes to show the named constant section of code for that chart.

7. Close the code generation report, Model Advisor, and model. In the Command Window, type:

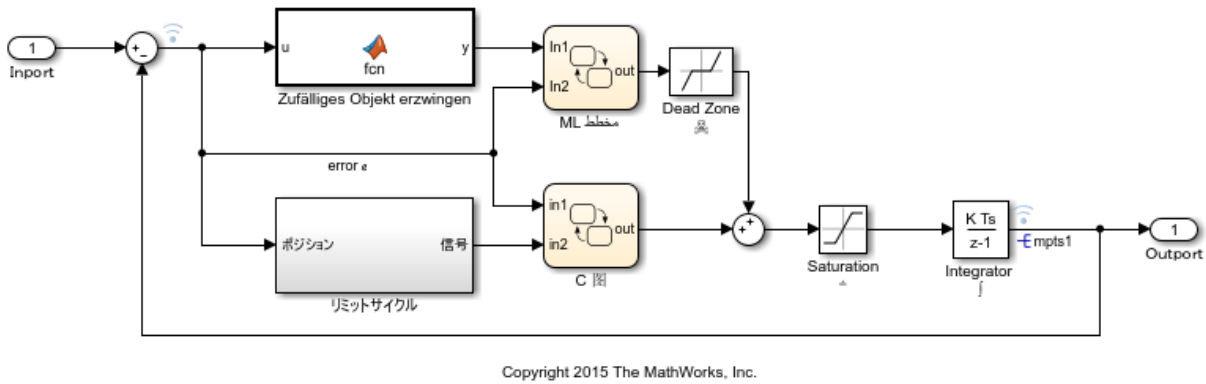
```
coder.report.close();
bdclose('all');
```

Generate C++ Code

Generate C++ code and a code generation report.

1. Open the model.

```
model = 'rtwdemo_unicode';
open_system(model);
```



2. Change **Configuration Parameters** > **Code Generation** > **Language** to `C++`. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','TargetLang','C++');
```

3. Change **Configuration Parameters** > **Code Generation** > **Interface** > **Code interface packaging** to `C++ class`. Or, in the Command Window, type:

```
set_param('rtwdemo_unicode','CodeInterfacePackaging','C++ class');
```

4. Generate C++ code and a code generation report.

```
evalc('rtwrebuild(''rtwdemo_unicode'')');
```

5. To see internationalization and localization support, review the generated code. See **Review the Generated Code**.

6. Close the code generation report and model. In the Command Window, type:

```
coder.report.close();
bdclose('all');
```

Source Code Generation in Simulink Coder

Configure Model, Generate Code, and Simulate

In this section...

About This Example

Learning Objectives

- Learn about the functional behavior of the example model.
- Learn about the role of the example test harness and its components.
- Run simulation tests on a model.

Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Understand subsystems and how to view subsystem details.
- Understand referenced models and how to view referenced model details.
- Ability to set model configuration parameters.

Required Files

Before you use each example model file, place a copy in a writable location and add it to your MATLAB path.

- `rtwdemo_throttlecntrl` model file
- `rtwdemo_throttlecntrl_testharness` model file

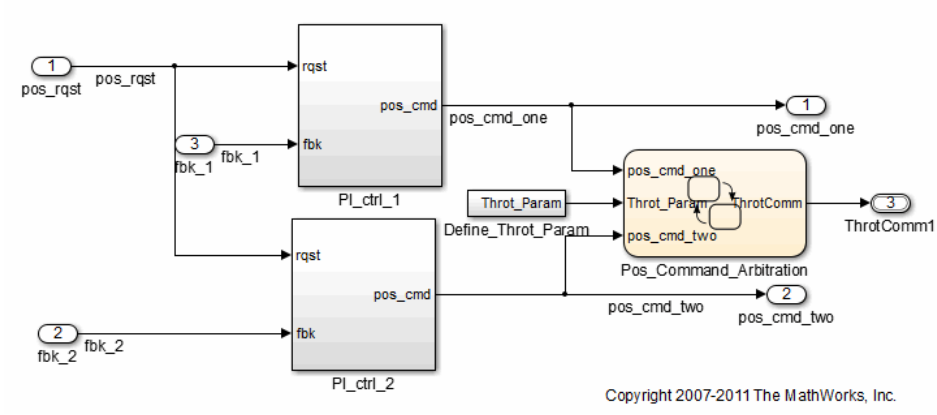
Functional Design of the Model

This example uses a simple, but functionally complete, example model of a throttle controller. The model features redundant control algorithms. The model highlights a standard model structure and a set of basic blocks in algorithm design.

View the Top Model

Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

Note This model uses Stateflow software.



The top level of the model consists of the following elements:

Subsystems	`PI_ctrl_1`
	`PI_ctrl_2`
	`Define_Throt_Param`
	`Pos_Command_Arbitration`

Top-level input	`pos_rqst`
	`fbk_1`
	`fbk_2`

Top-level output	`pos_cmd_one`
	`pos_cmd_two`
	`ThrotComm1`

Signal routing	
Omit blocks that change the value of a signal, such as Sum and Integrator	

The layout uses a basic architectural style for models:

- Separation of calculations from signal routing (lines and buses)
- Partitioning into subsystems

You can apply this style to a wide range of models.

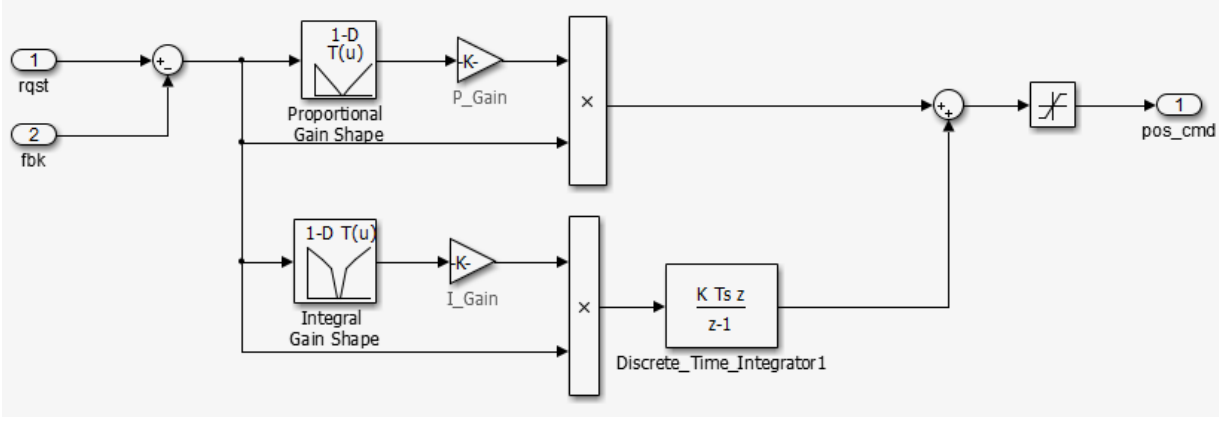
View the Subsystems

Explore two of the subsystems in the top model.

1 If not already open, open `throttlecntrl`.

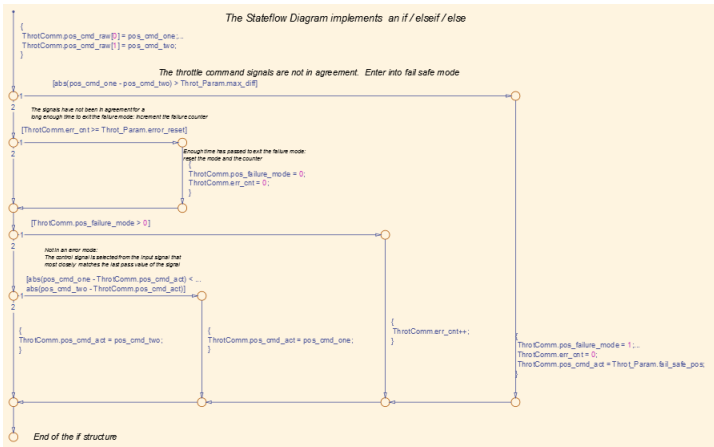
Two subsystems in the top model represent proportional-integral (PI) controllers, `PI_ctrl_1` and `PI_ctrl_2`. At this stage, these identical subsystems, use identical data.

2 Open the `PI_ctrl_1` subsystem.



The PI controllers in the model are from a *library*, a group of related blocks or models for reuse. Libraries provide one of two methods for including and reusing models. The second method, model referencing, is described in “Simulation Test Environment” on page 47-5. You cannot edit a block that you add to a model from a library. Edit the block in the library so that instances of the block in different models remain consistent.

3 Open the `Pos_Command_Arbitration` subsystem. This Stateflow chart performs basic error checking on the two command signals. If the command signals are too far apart, the Stateflow diagram sets the output to a `fail_safe` position.



4 Close `throttlecntrl`.

Simulation Test Environment

To test the throttle controller algorithm, incorporate it into a test harness. A test harness is a model that evaluates the control algorithm and offers the following benefits:

- Separates test data from the control algorithm.
- Separates the plant or feedback model from the control algorithm.
- Provides a reusable environment for multiple versions of the control algorithm.

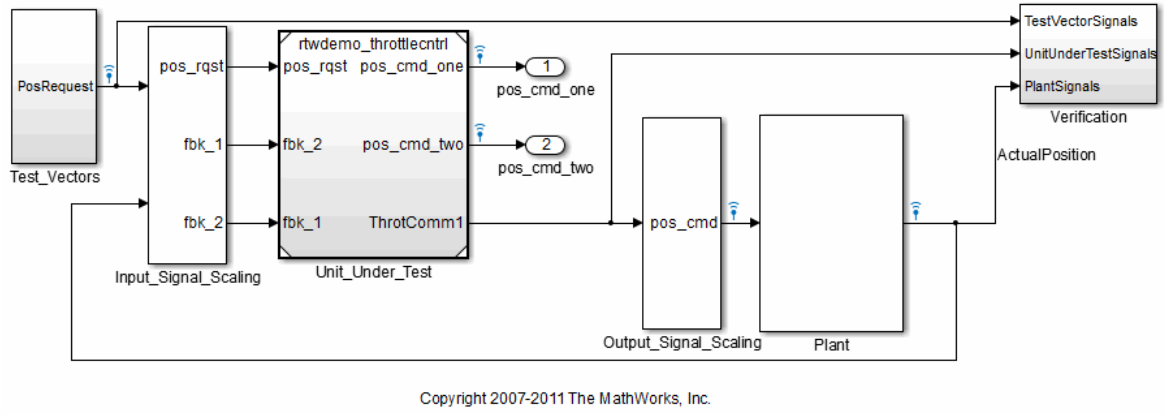
The test harness model for this example implements a common simulation testing environment consisting of the following parts:

- Unit under test

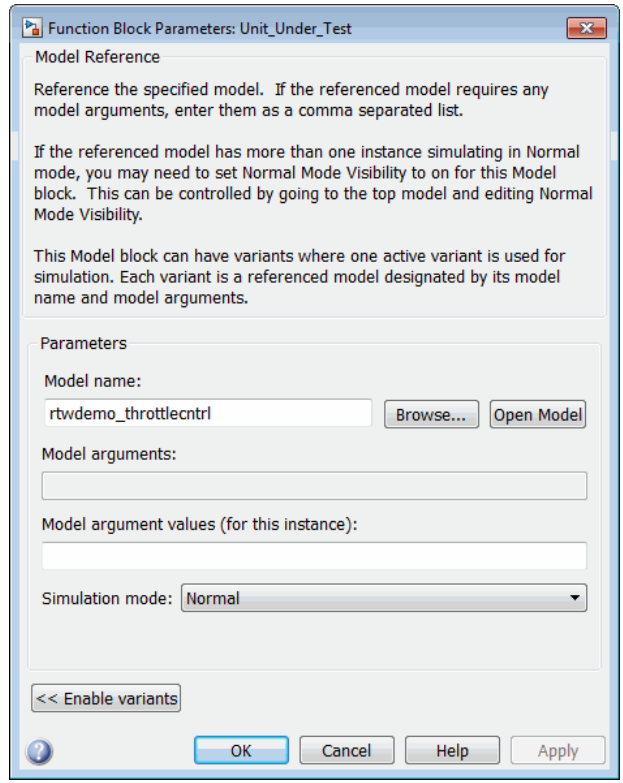
- Test vector source
- Evaluation and logging
- Plant or feedback system
- Input and output scaling

Explore the simulation testing environment.

1. Open the test harness model `rtwdemo_throttlecntrl_testharness` and save a copy as `throttlecntrl_testharness` in a writable location on your MATLAB path.



2. Set up your `throttlecntrl` model as the control algorithm of the test harness.
   a. Open the `Unit_Under_Test` block and view the control algorithm.
   b. View the model reference parameters by right-clicking the `Unit_Under_Test` block and selecting **Block Parameters (ModelReference)**.



`rtwdemo_throttlecntrl` appears as the name of the referenced model.

c Change the value of **Model name** to `throttlecntrl`.

d Update the test harness model diagram by clicking **Simulation** > **Update Diagram**.

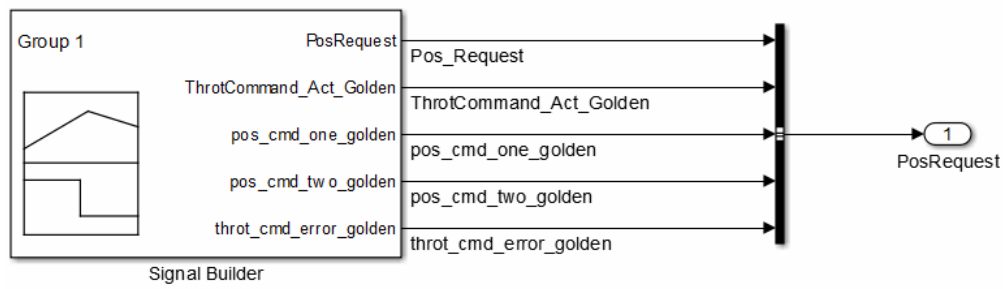
The control algorithm is the unit under test, as indicated by the name of the Model block, `Unit_Under_Test`.

The Model block provides a method for reusing components. From the top model, it allows you to reference other models (directly or indirectly) as compiled functions. By default, Simulink software recompiles the model when the referenced models change. Compiled functions have the following advantages over libraries:

- Simulation time is faster for large models.

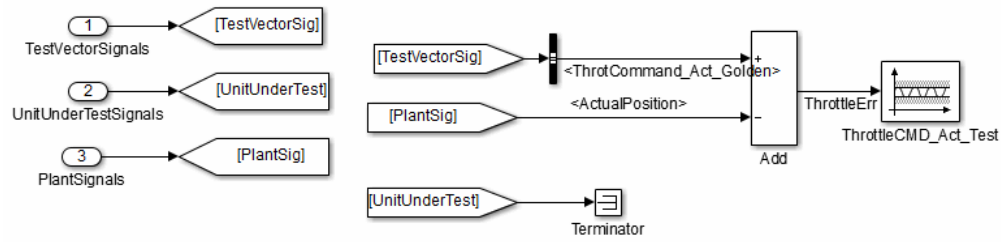
- You can directly simulate compiled functions.
- Simulation requires less memory. Only one copy of the compiled model is in memory, even when the model is referenced multiple times.

3 Open the test vector source, implemented in this test harness as the `Test_Vectors` subsystem.



The subsystem uses a Signal Builder block for the test vector source. The block has data that drives the simulation (`PosRequest`) and provides the expected results used by the `Verification` subsystem. This example test harness uses only one set of test data. Typically, create a test suite that fully exercises the system.

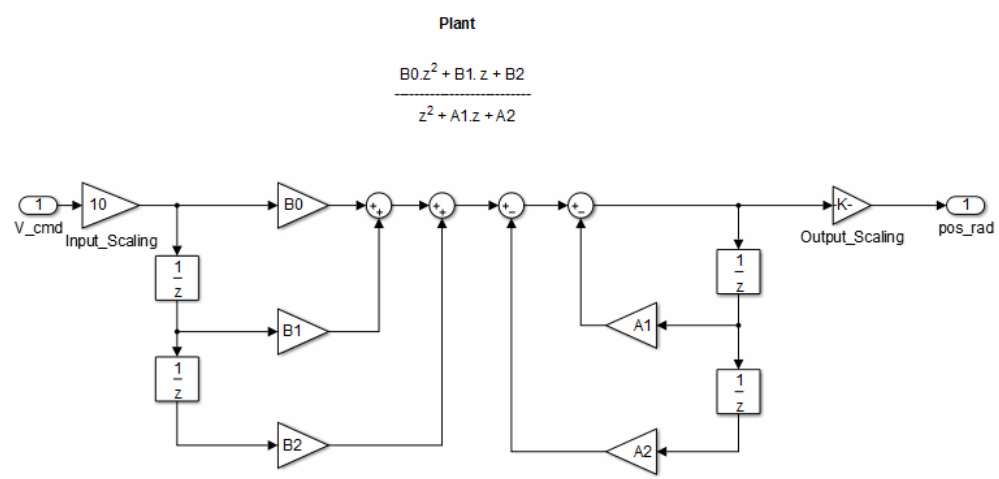
4 Open the evaluation and logging subsystem, implemented in this test harness as subsystem `Verification`.



A test harness compares control algorithm simulation results against golden data — test results that exhibit the desired behavior for the control algorithm as certified by an expert. In the `Verification` subsystem, an Assertion block compares the simulated throttle value position from the plant against the golden value from the test harness. If the difference between the two signals is greater than 5%, the test fails and the Assertion block stops the simulation.

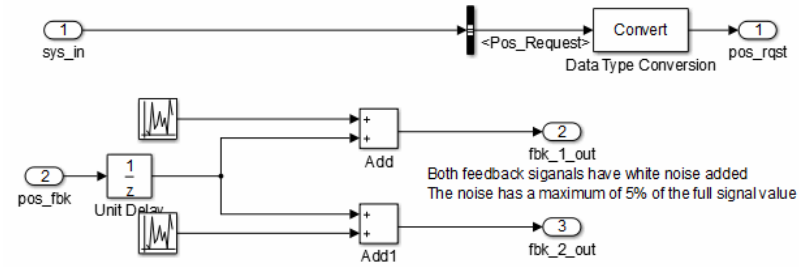
Alternatively, you can evaluate the simulation data after the simulation completes execution. Perform the evaluation with either MATLAB scripts or third-party tools. Post-execution evaluation provides greater flexibility in the analysis of data. However, it requires waiting until execution is complete. Combining the two methods can provide a highly flexible and efficient test environment.

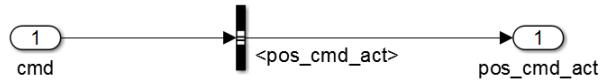
5 Open the plant or feedback system, implemented in this test harness as the `Plant` subsystem.



The `Plant` subsystem models the throttle dynamics with a transfer function in canonical form. You can create plant models to varying levels of fidelity. It is common to use different plant models at different stages of testing.

6 Open the input and output scaling subsystems, implemented in this test harness as `Input_Signal_Scaling` and `Output_Signal_Scaling`.





The subsystems that scale input and output perform the following primary functions:

- Select input signals to route to the unit under test.
- Select output signals to route to the plant.
- Rescale signals between engineering units and units that are writable for the unit under test.
- Handle rate transitions between the plant and the unit under test.

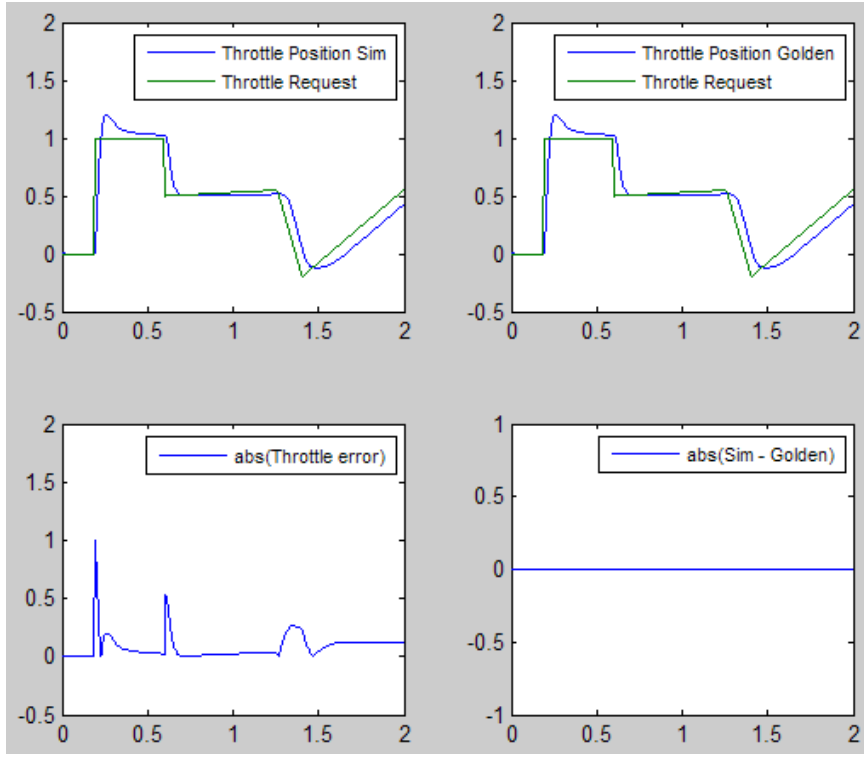
7 Save and close `throttlecntrl_testharness`.

Run Simulation Tests

1 Check that your working folder is set to a writable folder, such as the folder into which you placed copies of the example model files.

2 Open your copy of the test harness model, `throttlecntrl_testharness`.

3 Start a test harness model simulation. When the simulation is complete, the following results appear.



The lower-right hand plot shows the difference between the expected (golden) throttle position and the throttle position that the plant calculates. If the difference between the two values is greater than ±0.05, the simulation stops.

4 Save and close throttle controller and test harness models.

Key Points

- A basic model architecture separates calculations from signal routing and partitions the model into subsystems
- Two options for model reuse include block libraries and model referencing.
- If you represent your control algorithm in a test harness as a Model block, specify the name of the control algorithm model in the Model Reference Parameters dialog box.

- A test harness is a model that evaluates a control algorithm. Typically, a harness consists of a unit under test, a test vector source, evaluation and logging, a plant or feedback system, and input and output scaling components.
- The unit under test is the control algorithm being tested.
- The test vector source provides the data that drives the simulation which generates results used for verification.
- During verification, the test harness compares control algorithm simulation results against golden data and logs the results.
- The plant or feedback component of a test harness models the environment that is being controlled.
- When developing a test harness,
  - Scale input and output components.
  - Select input signals to route to the unit under test.
  - Select output signals to route to the plant.
  - Rescale signals between engineering units and units that are writable for the unit under test.
  - Handle rate transitions between the plant and the unit under test.
- Before running simulation or completing verification, consider checking a model with the Model Advisor.

- “Signal Groups” (Simulink)

Configure Model and Generate Code

In this section...

About This Example

Learning Objectives

- Configure a model for code generation.
- Apply model checking tools to discover conditions and configuration settings resulting in generation of inaccurate or inefficient code.
- Generate code from a model.
- Locate and identify generated code files.
- Review generated code.

Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Ability to set model configuration parameters.
- Ability to use the Simulink Model Advisor.
- Ability to read C code.
- An installed, supported C compiler.

Required Files

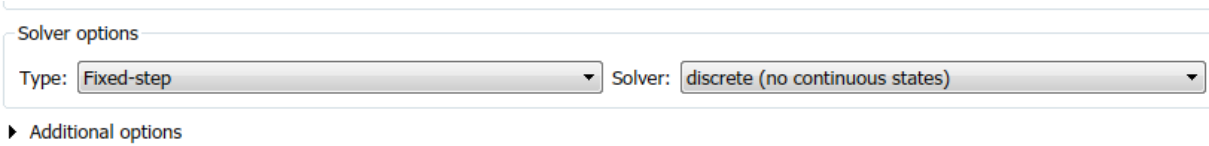
`rtwdemo_throttlecntrl` model file

Configure the Model for Code Generation

Model configuration parameters determine the method for generating the code and the resulting format.

1. Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.
2. Open the Configuration Parameters dialog box, **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. The following table shows the solver configuration for this example.

Parameter	Setting	Effect on Generated Code
Type	`Fixed-step`	Maintains a constant (fixed) step size, which is required for code generation
Solver	`discrete (no continuous states)`	Applies a fixed-step integration technique for computing the state derivative of the model
Fixed-step size	`.001`	Sets the base rate; must be the lowest common multiple of the rates in the system



3. Open the **Code Generation** > **General** pane and note that the **System target file** is set to `grt.tlc`.

Note The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the `rsim.tlc` system target file supports variable step code generation.

The system target file (STF) defines an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a system target file is the value for the `CodeFormat` TLC variable. The GRT configuration requires a fixed step solver and the rsim.tlc supports variable step code generation.

4. Open the **Code Generation > Custom Code** pane and under **Additional build information**, select **Include directories**. The following path appears in the text field:

   ```
   "$matlabroot$\toolbox\rtw\rtwdemos\EmbeddedCoderOverview\"
   ```

   This folder includes files that are required to build an executable for the model.

5. Close the dialog box.

Save Your Model Configuration as a MATLAB Function

You can save the settings of model configuration parameters as a MATLAB function by using the `getActiveConfigSet` function. In the MATLAB Command Window, enter:

```
thcntrlAcs = getActiveConfigSet('throttlecntrl');
thcntrlAcs.saveAs('throttlecntrlModelConfig');
```

You can then use the resulting function (for example, `throttlecntrlModelConfig`) to:

- Archive the model configuration.
- Compare different model configurations by using differencing tools.
- Set the configuration of other models.

For example, you can set the configuration of model `myModel` to match the configuration of the throttle controller model by opening `myModel` and entering:

```
myModelAcs = throttlecntrlModelConfig;
attachConfigSet('myModel', myModelAcs, true);
setActiveConfigSet('myModel', myModelAcs.Name);
```

For more information, see “Save a Configuration Set” (Simulink) and “Load a Saved Configuration Set” (Simulink).

Check Model Conditions and Configuration Settings

Before generating code for a model, use the Simulink Model Advisor to check the model for conditions and configuration settings. This check finds issues that can result in inaccurate or inefficient code.

1. Open `throttlecntrl`.
2. Start the Model Advisor by selecting **Analysis > Model Advisor > Model Advisor**. A dialog box opens showing the model system hierarchy.
3. Click `throttlecntrl` and then click **OK**. The Model Advisor window opens.
4. Expand **By Product** and **Embedded Coder**. By default, checks that do not trigger an Update Diagram, with one exception, are selected.
5. In the left pane, select the remaining checks and select **Embedded Coder**.
6. In the right pane, select **Show report after run** and click **Run Selected Checks**. The report shows a **Run Summary** that flags check warnings.
7. Review the report. The warnings highlight issues for embedded systems. At this point, you can ignore them. For more information about reports, see “View Model Advisor Reports” (Simulink).

Generate Code for the Model

1. Open `throttlecntrl`.
2. In the Configuration Parameters dialog box, select **Code Generation > Generate code only** and click **Apply**.
3. On the **Code Generation > Report** pane, select **Create code generation report** and click **Apply**.
4. With the model open, initiate code generation and the build process for the model by using any of the following options:

   - Click the **Build Model** button.
   - Press **Ctrl+B**.
   - Select **Code > C/C++ Code > Build Model**.
   - Invoke the `rtwbuild` command from the MATLAB command line.
   - Invoke the `slbuild` command from the MATLAB command line.

   Watch the messages that appear in the MATLAB Command Window. The code generator produces standard C and header files, and an HTML code generation

report. The code generator places the files in a *build folder*, a subfolder named `throttlecntrl_grt_rtw` under your current working folder.

Review the Generated Code

1. Open Model Explorer, and in the **Model Hierarchy** pane, expand the node for the `throttlecntrl` model, and select the **Code for** node.
2. In the **Contents** pane, select **HTML Report**. Model Explorer displays the HTML code generation report for the throttle controller model.
3. In the HTML report, click the link for the generated C model file and review the generated code. Look for these items in the report:
   - Identification, version, timestamp, and configuration comments.
   - Links to help you navigate within and between files
   - Data definitions
   - Scheduler code
   - Controller code
   - Model initialization and termination functions
   - Call interface for the GRT system target file — output, update, initialization, start, and terminate
4. Save and close `throttlecntrl`.

Consider examining the following files. In the HTML report **Contents** pane, click the links. Or, in your working folder, explore the generated code subfolder.

File	Description
`throttlecntrl.c`	C file that contains the scheduler, controller, initialization, and interface code
`throttlecntrl_data.c`	C file that assigns values to generated data structures
`throttlecntrl.h`	Header file that defines data structures
`throttlecntrl_private.h`	Header file that defines data used only by the generated code
`throttlecntrl_types.h`	Header file that defines the model data structure

For more information, see “Manage Build Process File Dependencies” (Simulink Coder).

At this point, consider logging data to a MAT-file. For an example, see “Log Data for Analysis” (Simulink Coder).

Generate an Executable

1. Open `throttlecntrl`.
2. In the Configuration Parameters dialog box, clear the **Code Generation** > **Generate code only** check box and click **Apply**.
3. Press **Ctrl+B**. Watch the messages in the MATLAB Command Window. The code generator uses a template make file associated with your system target file selection to create an executable file. You can run this program on your workstation, independent of external timing and events.
4. Check your working folder for the file `throttlecntrl.exe`.
5. Run the executable. In the Command Window, enter `!throttlecntrl`. The `!` character passes the command that follows it to the operating system, which runs the standalone program.

   The program produces one line of output in the Command Window:

   ```
   ** starting the model **
   ```

   At this point, consider logging data to a MAT-file. For an example, see “Log Data for Analysis” (Simulink Coder).

Tip For UNIX platforms, run the executable in the Command Window with the syntax `!./`*`executable_name`*. If preferred, run the executable from an OS shell with the syntax `./`*`executable_name`*. For more information, see “Run External Commands, Scripts, and Programs” (MATLAB).

Key Points

- To generate code, change the model configuration to specify a fixed-step solver then select a system target file. Using the `grt.tlc` file requires a fixed-step solver. If the model contains continuous time blocks, you can use a variable-step solver with the `rsim.tlc` system target file.

- After debugging a model, consider configuring a model with parameter inlining enabled.
- Use the `getActiveConfigSet` function to save a model configuration for future use or to apply it to another model.
- Before generating code, consider checking a model with the Model Advisor.
- The code generator places generated files in a subfolder (*model*`_grt_rtw`) of your working folder.

Configure Data Interface

About This Example

Learning Objectives

- Configure the data interface for code generated for a model.
- Control the name, data type, and data storage class of signals and parameters in generated code.

Prerequisites

- Understanding ways to represent and use data and signals in models.
- Familiarity with representing data constructs as data objects.
- Ability to read C code.

Required File

`rtwdemo_throttlecntrl_datainterface` model file

Declare Data

Most programming languages require that you declare data before using it. The declaration specifies the following information:

Data Attribute	Description
Scope	The region of the program that has access to the data
Duration	The period during which the data is resident in memory
Data type	The amount of memory allocated for the data
Initialization	An initial value, a pointer to memory, or NULL. If you do not provide an initial value, most compilers assign a zero value or a null pointer.

The following data types are supported for code generation.

Supported Data Types

Name	Description
`double`	Double-precision floating point
`single`	Single-precision floating point
`int8`	Signed 8-bit integer
`uint8`	Unsigned 8-bit integer
`int16`	Signed 16-bit integer
`uint16`	Unsigned 16-bit integer
`int32`	Signed 32-bit integer
`uint32`	Unsigned 32-bit integer
Fixed-point data types	8-, 16-, 32-bit word lengths

A storage class is the scope and duration of a data item. For more information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.

Use Data Objects

In Simulink models and Stateflow charts, the following methods are available for declaring data: data objects and direct specification. This example uses the data object method. Both methods allow full control over the data type and storage class. You can mix the two methods in a single model.

In the MATLAB and Simulink environment, you can use data objects in various ways. This example focuses on the following types of data objects:

- Signal
- Parameter
- Bus

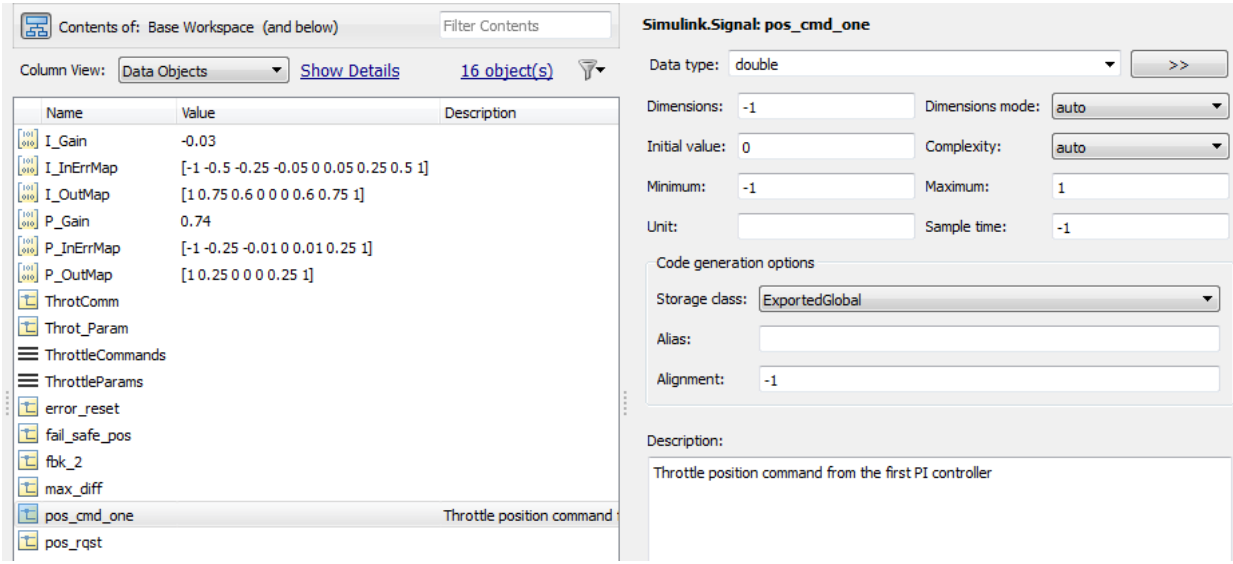
To configure the data interface for your model using the data object method, in the MATLAB base workspace, you define data objects. Then, associate them with your Simulink model or embedded Stateflow chart. When you build your model, the build process uses the associated base workspace data objects in the generated code.

You can set the values of the data object properties, which include:

- Data type
- Storage class
- Value (parameters)
- Initial value (signals)
- Alias (define a different name in the generated code)
- Dimension (typically inherited for parameters)
- Complexity (inherited for parameters)
- Unit (physical measurement unit)
- Minimum value
- Maximum value
- Description (used to document your data objects — does not affect simulation or code generation)

You can create and inspect base workspace data objects by entering commands in the MATLAB Command Window or by using Model Explorer. To explore base workspace signal data objects, use these steps:

1. Open `rtwdemo_throttlecntrl_datainterface` and save a copy as `throttlecntrl_datainterface` in a writable location on your MATLAB path.
2. Open Model Explorer.
3. Select **Base Workspace**.
4. Select the `pos_cmd_one` signal object for viewing.



You can also view the definition of a signal object. In the MATLAB Command Window, enter `pos_cmd_one`:

```
pos_cmd_one =

Signal with properties:

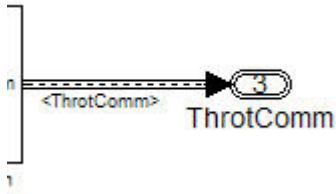
       CoderInfo: [1x1 Simulink.CoderInfo]
     Description: 'Throttle position command from the first PI controller'
        DataType: 'double'
             Min: -1
             Max: 1
            Unit: ''
      Dimensions: -1
  DimensionsMode: 'auto'
      Complexity: 'auto'
      SampleTime: -1
    InitialValue: '0'
```

5 To view other signal objects, in Model Explorer, click the object name or in the MATLAB Command Window, enter the object name. The following table summarizes object characteristics for some of the data objects in this model.

Object Characteristics	pos_cmd_one	pos_rqst	P_InErrMap	ThrotComm*	ThrottleCommands*
Description	Top-level output	Top-level input	Calibration parameter	Top-level output structure	Bus definition
Data type	Double	Double	Auto	Auto	Structure
Storage class	Exported global	Imported extern pointer	Constant	Exported global	None

* `ThrottleCommands` defines a Bus object; `ThrotComm` is an instantiation of the bus. If the bus is a nonvirtual bus, the signal generates a structure in the C code.

You can use a bus definition (`ThrottleCommands`) to instantiate multiple instances of the structure. In a model diagram, a bus object appears as a wide line with central dashes, as shown.



Add New Data Objects

You can create data objects for named signals, states, and parameters. To associate a data object with a construct, the construct must have a name.

To find constructs for which you can create data objects, use the Data Object Wizard. This tool finds the constructs and then creates the objects for you. The model includes two signals that are not associated with data objects: `fbk_1` and `pos_cmd_two`.

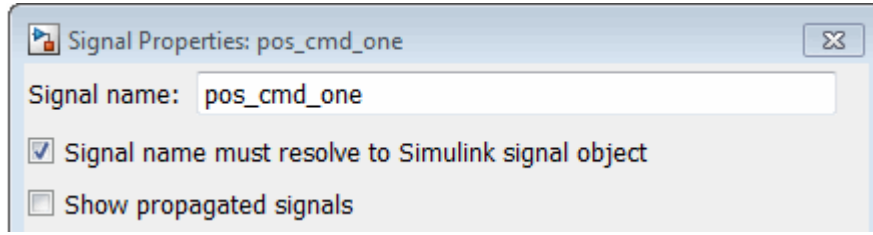
To find the signals and create data objects for them:

1. In the model window, select **Code > Data Objects > Data Object Wizard**. The Data Object Wizard dialog box opens.
2. To find candidate constructs, click **Find**. Constructs `fbk_1` and `pos_cmd_two` appear in the dialog box.

3. To select both constructs, click **Select All**.
4. In the table, under **Class**, make sure that each proposed data object uses the class `Simulink.Signal`. To change the class of the objects, click **Change Class**.
5. To create the data objects, click **Create**. Constructs `fbk_1` and `pos_cmd_two` are removed from the dialog box.
6. Close the Data Object Wizard.
7. In the **Contents** pane of the Model Explorer, find the newly created objects `fbk_1` and `pos_cmd_two`.

Enable Data Objects for Generated Code

1. Enable a signal to appear in generated code.
   a. In the model window, right-click the `pos_cmd_one` signal line and select **Properties**. A Signal Properties dialog box opens.
   b. Make sure that you select the **Signal name must resolve to Simulink signal object** parameter.



2. Enable signal object resolution for the signals in the model. In the MATLAB Command Window, enter:

```
disableimplicitsignalresolution('throttlecntrl_datainterface')
```

3. Save and close `throttlecntrl_datainterface`.

Effects of Simulation on Data Typing

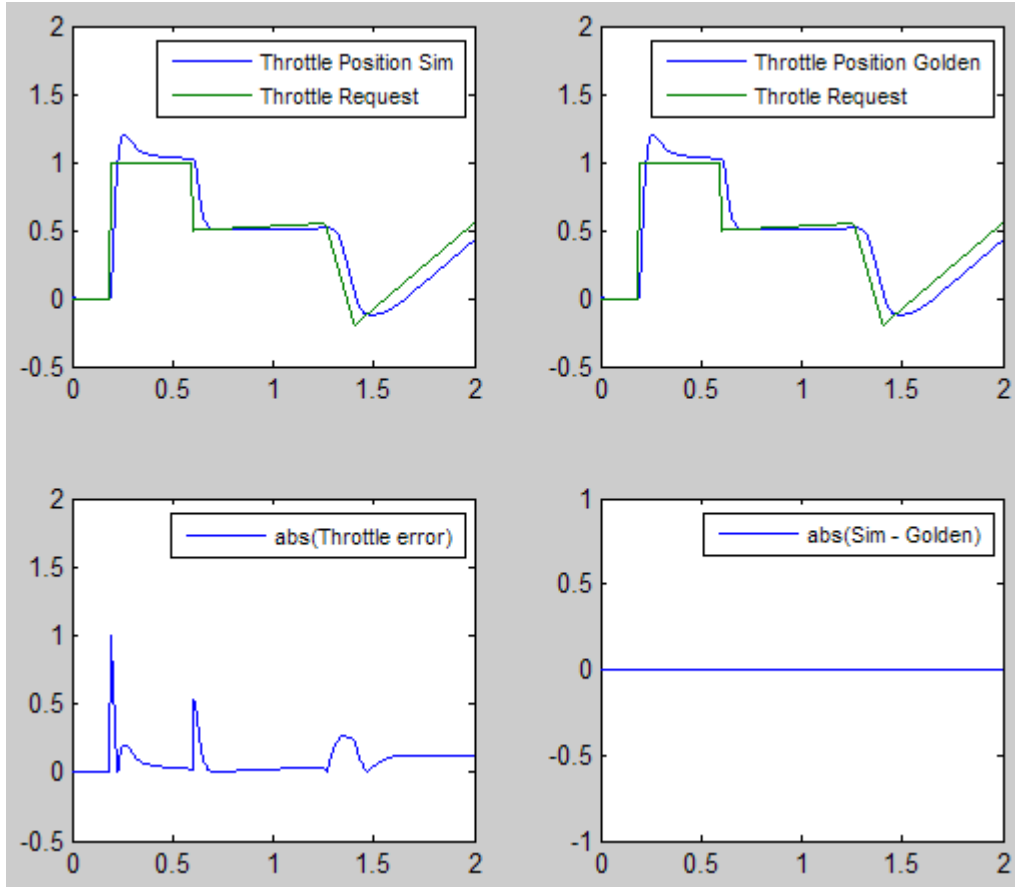
In the throttle controller model, the data types are set to `double`. Because Simulink software uses the `double` data type for simulation, do not expect changes in the model behavior when you run the generated code. You verify this effect by running the test harness.

Before you run your test harness, update it to include the `throttlecntrl_datainterface` model.

Note The following procedure requires a Stateflow license.

1. Open `throttlecntrl_datainterface`.
2. Open your copy of test harness, `throttlecntrl_testharness`.
3. Right-click the `Unit_Under_Test` Model block and select **Block Parameters (ModelReference)**.
4. Set **Model name** to `throttlecntrl_datainterface`. Click **OK**.
5. Update the test harness model diagram.
6. Simulate the test harness.

   The resulting plot shows that the difference between the golden and simulated versions of the model remains zero.



7 Save and close `throttlecntrl_testharness`.

Manage Data

Data objects exist in a separate file from the model in the base workspace. To save the data manually, in the MATLAB Command Window, enter `save`.

The separation of data from the model provides the following benefits:

- One model, multiple data sets:

  - Use of different parameter values to change the behavior of the control algorithm (for example, for reusable components with different calibration values)
  - Use of different data types to change targeted hardware (for example, for floating-point and fixed-point targeted hardware)
- Multiple models, one data set:
  - Sharing data between models in a system
  - Sharing data between projects (for example, transmission, engine, and wheel controllers can use the same CAN message data set)

Key Points

- You can declare data in Simulink models and Stateflow charts by using data objects or direct specification.
- From the Model Explorer or from the command line in the MATLAB Command Window, manage (create, view, configure, and so on) base workspace data.
- The Data Object Wizard provides a quick way to create data objects for constructs such as signals, buses, and parameters.
- Configure data objects explicitly to appear by name in generated code.
- Separation of data from model provides several benefits.

Call External C Functions

In this section...

About This Example

Learning Objectives

- Evaluate a C function as part of a model simulation.
- Call an external C function from generated code.

Prerequisites

- Ability to open and modify Simulink models and subsystems.
- Ability to set model configuration parameters.
- Ability to read C code.
- An installed, supported C compiler.

Required Files

- `rtwdemo_throttlecntrl_extfunccall` model file
- `rtwdemo_ValidateLegacyCodeVrsSim` model file
- `/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.c`
- `/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files/SimpleTable.h`

Include External C Functions in a Model

Simulink models are one part of Model-Based Design. For many applications, a design also includes a set of pre-existing C functions created, tested (verified), and validated outside of a MATLAB and Simulink environment. You can integrate these functions easily into a model and the generated code. You can use external C code in the generated code to access hardware devices and external data files during rapid simulation runs.

This example shows you how to create a custom block that calls an external C function. When the block is part of the model, you can take advantage of the simulation environment to test the system further.

Create a Block That Calls a C Function

To specify a call to an external C function, use an S-Function block. You can automate the process of creating the S-Function block by using the Simulink Legacy Code Tool. Using this tool, specify an interface for your external C function. The tool then uses that interface to automate creation of an S-Function block.

1. Make copies of the files `SimpleTable.c` and `SimpleTable.h`, located in the folder *`matlabroot`*`/toolbox/rtw/rtwdemos/EmbeddedCoderOverview/stage_4_files` (open). Put the copies in your working folder.
2. Create an S-Function block that calls the specified function at each time step during simulation:

   a. In the MATLAB Command Window, create a function interface definition structure:

   ```
   def=legacy_code('initialize')
   ```

   The data structure `def` defines the function interface to the external C code.

   ```
   def =

                       SFunctionName: ''
       InitializeConditionsFcnSpec: ''
                       OutputFcnSpec: ''
                        StartFcnSpec: ''
                    TerminateFcnSpec: ''
                         HeaderFiles: {}
                         SourceFiles: {}
                        HostLibFiles: {}
   ```

```
    TargetLibFiles: {}
          IncPaths: {}
          SrcPaths: {}
          LibPaths: {}
        SampleTime: 'inherited'
           Options: [1x1 struct]
```

b Populate the function interface definition structure by entering the following commands:

```
def.OutputFcnSpec=['double y1 = SimpleTable(double u1,',...
   'double p1[], double p2[], int16 p3)'];
def.HeaderFiles = {'SimpleTable.h'};
def.SourceFiles = {'SimpleTable.c'};
def.SFunctionName = 'SimpTableWrap';
```

c Create the S-function:

```
legacy_code('sfcn_cmex_generate', def)
```

d Compile the S-function:

```
legacy_code('compile', def)
```

e Create the S-Function block:

```
legacy_code('slblock_generate', def)
```

A new model window opens that contains the `SimpTableWrap` block.

Tip Creating the S-Function block is a one-time task. Once the block exists, you can reuse it in multiple models.

---

3 Save the model to your working folder as: `s_func_simptablewrap`.

4 Create a Target Language Compiler (TLC) file for the S-Function block:

```
legacy_code('sfcn_tlc_generate', def)
```

The TLC file is the component of an S-function that specifies how the code generator produces the code for a block.

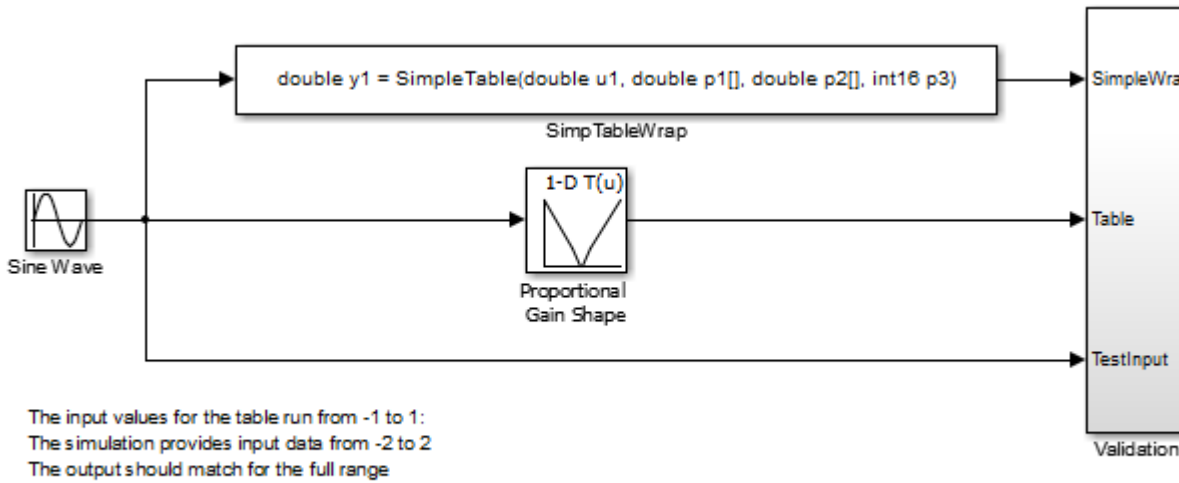
For more information on using the Legacy Code Tool, see:

- “Integrate C Functions Using Legacy Code Tool” (Simulink)
- “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder)

Validate External Code in the Simulink Environment

When you integrate external C code with a Simulink model, before using the code, validate the functionality of the external C function code as a standalone component.

1 Open the model `rtwdemo_ValidateLegacyCodeVrsSim`. This model validates the S-function block that you created.

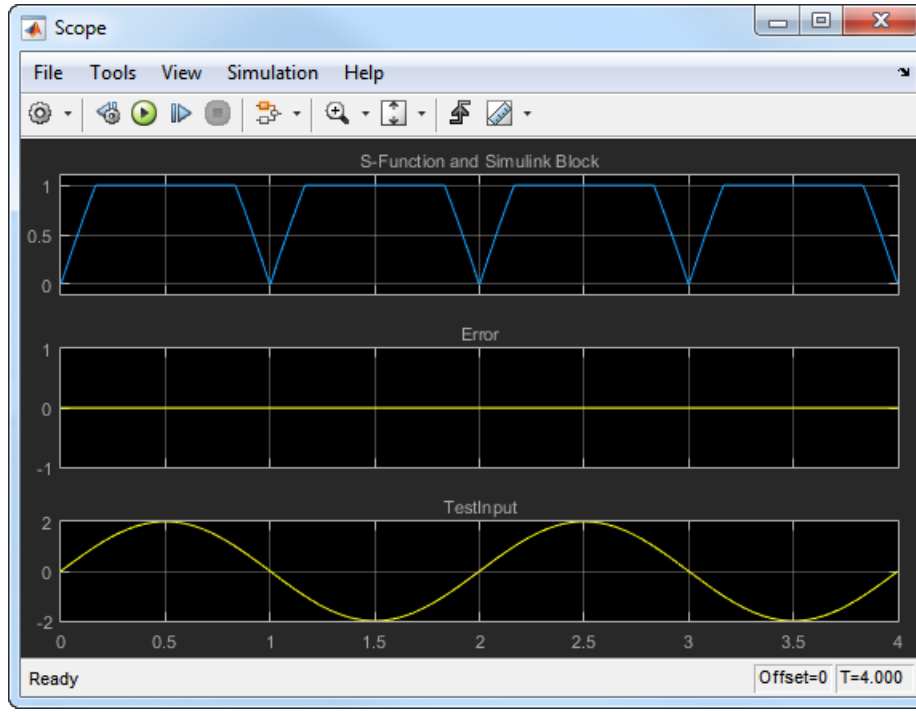


- The Sine Wave block produces output values from [-2 : 2].
- The input range of the lookup table is from [-1 : 1].
- The output from the lookup table is the absolute value of the input.
- The lookup table output clips the output at the input limits.

2 Simulate the model.

3 View the validation results by opening the `Validation` subsystem and, in that subsystem, clicking the Scope block.

The following figure shows the validation results. The external C code and the Simulink Lookup table block provide the same output values.



4 Close the validation model.

Validate C Code as Part of a Model

After you validate the functionality of the external C function code as a standalone component, validate the S-function in the model. Use the test harness model to complete the validation.

Note The following procedure requires a Stateflow license.

1 Open `rtwdemo_throttlecntrl_extfunccall` and save a copy to `throttlecntrl_extfunccall` in a writable folder on your MATLAB path.

2 Examine the `PI_ctrl_1` and `PI_ctrl_2` subsystems.

   a Lookup blocks have been replaced with the block you created using the Legacy Code Tool.

b Note the block parameter settings for `SimpTableWrap` and `SimpTableWrap1`.

c Close the Block Parameter dialog boxes and the PI subsystem windows.

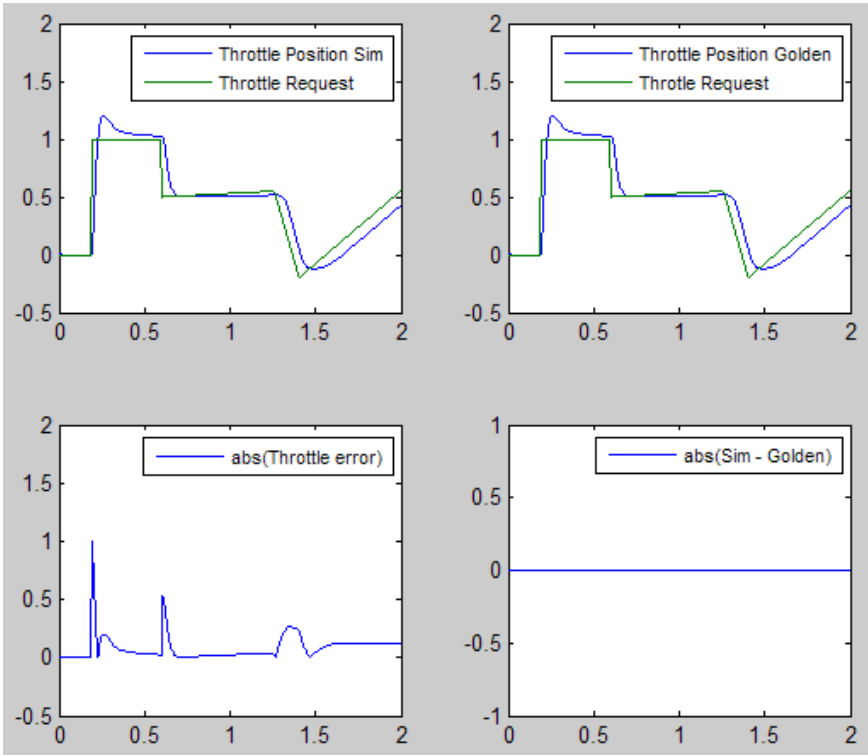
3 Open the test harness model, right-click the `Unit_Under_Test` Model block, and select **Block Parameters (ModelReference)**.

4 Set **Model name** to `throttlecntrl_extfunccall`. Click **OK**.

5 Update the test harness model diagram.

6 Simulate the test harness.

The simulation results match the expected golden values.



7 Save and close `throttlecntrl_extfunccall` and `throttlecntrl_testharness`.

Call a C Function from Generated Code

The code generator uses a TLC file to process the S-Function block. Calls to C code embedded in an S-Function block:

- Can use data objects.
- Are subject to expression folding, an operation that combines multiple computations into a single output calculation.

1. Open `throttlecntrl_extfunccall`.
2. Generate code for the model.
3. Examine the generated code in the file`throttlecntrl_extfunccall.c`.
4. Close `throttlecntrl_extfunccall` and `throttlecntrl_testharness`.

Key Points

- You can easily integrate external functions into a model and generated code by using the Legacy Code Tool.
- Validate the functionality of external C function code which you integrate into a model as a standalone component.
- After you validate the functionality of external C function code as a standalone component, validate the S-function in the model.

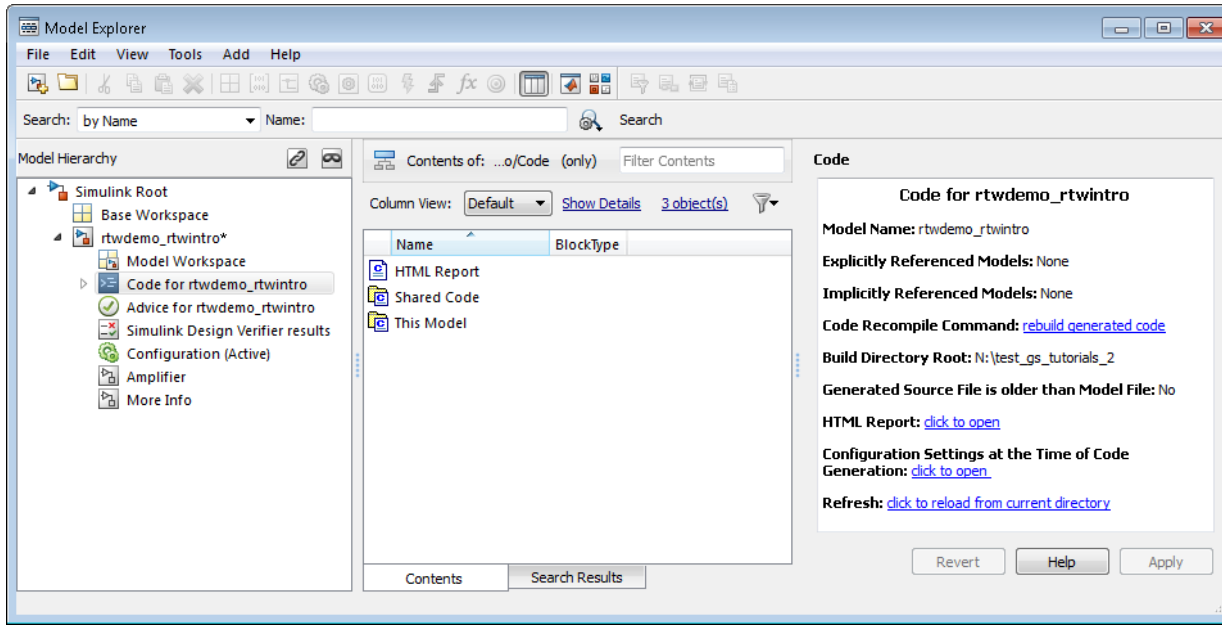
Reload Generated Code

You can reload the code generated for a model from the Model Explorer.

1. Click the **Code for *model*** node in the **Model Hierarchy** pane.
2. In the **Code** pane, click the **Refresh** link.



The code generator reloads the code for the model from the build folder.

- “Rebuild a Model” (Simulink Coder)
- “Control Regeneration of Top Model Code” (Simulink Coder)

Manage Build Process Folders

The build process places generated files from Simulink diagram updates and model builds into a hierarchy of folders that is specified by default. You can change the default specification for build process folders, if, for example:

- Your company does not use the current working folder as the location for the code generation folder or the simulation cache folder.
- You place the code generation folder under version control, but do not place the simulation cache folder under version control.

The MATLAB session parameters `CacheFolder`, `CodeGenFolder`, and `CodeGenFolderStructure` are file generation control parameters that specify the folder locations for the build process. At the start of a MATLAB session, these Simulink preferences determine the values of the parameters:

Simulation cache folder (Simulink) – `CacheFolder`

Code generation folder (Simulink) – `CodeGenFolder`

Code generation folder structure (Simulink) – `CodeGenFolderStructure`

To modify the parameters during a MATLAB session, use `Simulink.fileGenControl`. The parameter values that you set expire at the end of the MATLAB session.

File Generation Control Parameters

This table provides information about how you can use the parameters to manage build process folders.

MATLAB Session Parameter	Simulink Preference	Description
`CacheFolder`	**Simulation cache folder** (Simulink)	The build process places generated files from Simulink diagram updates and model build artifacts for simulation in the simulation cache folder *`simulationCacheFolder`*. The folder is a root folder. By default (`CacheFolder = ''`), *`simulationCacheFolder`* is the current working folder, `pwd`. You can use the parameter to specify another folder. For example, if you want to: • Separate generated files from the models and other source material. • Reuse or share previously built simulation targets without having to set the current working folder back to a previous working folder.

MATLAB Session Parameter	Simulink Preference	Description
`CodeGenFolder`	**Code generation folder** (Simulink)	The build process, which uses system target files to generate production code from a Simulink model, places the production code in the code generation folder *`codeGenerationFolder`*. The folder is a root folder. If you choose to generate an executable program file, the build process writes the file *`model`*`.exe` (Windows) or *`model`* (UNIX) to the folder. By default (`CodeGenFolder = ''`), *`codeGenerationFolder`* is the current working folder, `pwd`. You can use the parameter to specify another folder. For example, if you want to separate generated production code from: • Models and other source material. • Generated simulation artifacts. If you specify the root folder of a drive as the code generation folder, the build process cannot generate code for your model. For example, `C:\`.
`CodeGenFolderStructure`	**Code generation folder structure** (Simulink)	To specify the folder structure within the code generation folder, use the parameter. For example, if you configure models for different target environments, you can specify a separate subfolder for the generated code from each model.

Build Process Folders

This table provides information about how `CodeGenFolderStructure` controls the folder structure within the simulation cache folder and the code generation folder.

Folder Name when `CodeGenFolderStructure = 'ModelSpecific'`	**Folder Name when `CodeGenFolderStructure = 'TargetEnvironmentSubfolder'`**	**Description**
codeGenerationFolder`/`*model*`_`*target*`_rtw` The default for *`target`* is the name of the selected system target file, for example, `grt`, `ert`, and `rsim`. You can change *`target`* with the `rtwgensettings.BuildDirSuffix` field in the system target file.	*codeGenerationFolder*`/`*targetSpecific*`/`*model* The build process uses configuration information for the system target file and the hardware device to produce a unique label for the subfolder, *`targetSpecific`*.	Build folder, which stores generated source code and other files created by the build process. Contains the generated code modules, *`model`*`.c` and *`model`*`.h`, and generated makefile, *`model`*`.mk`. *`model`*`.mk` is for compiling and linking code generated from model components. *`model`* is the name of the source model.
codeGenerationFolder`/`*model*`_target_rtw/html`	*codeGenerationFolder*`/`*targetSpecific*`/`*model*`/html`	Code generation report folder that contains report files generated by the build process.
codeGenerationFolder`/slprj/`*target*`/`*model*	*codeGenerationFolder*`/`*targetSpecific*`/_ref/`*model*	Model reference target files.
codeGenerationFolder`/slprj/`*target*`/`*model*`/referenced_model_includes`	*codeGenerationFolder*`/`*targetSpecific*`/_ref/`*model*`/referenced_model_includes`	Header files from models referenced by *`model`*.

Folder Name when CodeGenFolderStructure = 'ModelSpecific'	Folder Name when CodeGenFolderStructure = 'TargetEnvironmentSubfolder'	Description
codeGenerationFolder/slprj/*target*/*model*/tmwinternal	*codeGenerationFolder*/*targetSpecific*/_ref/*model*/tmwinternal	MAT-files used during code generation.
codeGenerationFolder/slprj/*target*/_sharedutils	*codeGenerationFolder*/*targetSpecific*/_shared	Utility functions for model reference system target files, which are shared across models. Folder also contains `rtwshared.mk` for compiling generated shared utility code
simulationCacheFolder/slprj/sim/*model*	*simulationCacheFolder*/slprj/sim/*model*	Simulation target files for referenced models.
simulationCacheFolder/slprj/sim/*model*/*tmwinternal*	*simulationCacheFolder*/slprj/sim/*model*/*tmwinternal*	MAT-files used during code generation.
simulationCacheFolder/slprj/sim/_sharedutils	*simulationCacheFolder*/slprj/sim/_sharedutils	Utility functions for simulation system target files, which are shared across models.

If the system target file is ERT-based, then these configuration parameters also control the location of shared utility code:

- Shared code placement (Simulink Coder) (`UtilityFuncGeneration`)
- Existing shared code (`ExistingSharedCode`)

You can use `RTW.getBuildDir` to display build folder information for the model.

Manage Build Process Files

To apply generated code source and header files from the build process, it is helpful to understand the files that the build process generates and the conditions that control file generation. This information provides access to generated code resources, such as:

- Public interface to the model entry points
- Enumerated types corresponding to built-in data types
- Data structures that describe the model signals, states, and parameters

The code generator creates *`model`*`.*` files during the code generation and build process. You can customize the file names for generated header, source, and data files. For more information, see “Customize Generated File Names” on page 50-74. The code generator creates additional folders and dependency files to support shared utilities and model references. For more information about the folders that the build process creates, see “Manage Build Process Folders” (Simulink Coder). For an example that shows how to use a project to manage build process folders, see “Generate Code and Simulate Models in a Project” (Simulink Coder).

Depending on model architectures and code generation options, the build process for a GRT-based system target file can produce files that the build process does not generate for an ERT-based system target file. Also, for ERT-based system target files, the build process packages generated files differently than for GRT-based system target files. See “Manage File Packaging of Generated Code Modules” on page 48-14.

Note By default, the build process deletes foreign (not generated) source files in the build folder. It is possible to preserve foreign source files in the build folder by following the guidelines in “Preserve External Code Files in Build Folder” (Simulink Coder).

The table describes the principal generated files. Within the generated file names shown in the table, the *`model`* represents the name of the model for which you are generating code. The *`subsystem`* represents the name of a subsystem within the model. When you select the **Create code generation report** parameter, the code generator produces a set of HTML files. There is one HTML file for each source file plus a *`model`*`_contents.html` index file in the `html` subfolder within your build folder. The source and header files in the table have dependency relationships. For descriptions of other file dependencies, see “Manage Build Process File Dependencies” (Simulink Coder) and “Add Build Process Dependencies” (Simulink Coder).

File	Description
`builtin_typeid_types.h`	Defines an enumerated type corresponding to built-in data types. A model build generates this file when one or more of these conditions apply: • Your model contains a Stateflow chart that uses messages. • Your model configuration enables **MAT-file logging**. • Your model configuration enables C API options in **Code Generation > Interface**.
`modelsources.txt`	Lists additional sources to include in the compilation.
`model``.bat`	Contains Windows batch file commands that set the compiler environment and invoke the `make` utility. For more information about using this file, see “model.bat” on page 47-49.
`model``.c` *`model`*`.cpp`	Corresponds to the model file. The Target Language Compiler generates this C or C++ source code file. The file contains: • Include files *`model`*`.h` and *`model`*`_private.h` • Data, except data placed in *`model`*`_data.c` • Model-specific scheduler code • Model-specific solver code • Model registration code • Algorithm code • Optional GRT wrapper functions
`model``.exe` (Windows platform) *`model`* (UNIX and Macintosh platforms)	Executable program file. A model build generates this file unless you explicitly specify that the code generator produce code only. The build generates the executable in the current folder (not the build folder) under control of the `make` utility of your development system.

File	Description
model.h	Defines model data structures and a public interface to the model entry points and data structures. Provides an interface to the real-time model data structure (*model*_rtM) via access macros. Subsystem .c or .cpp files in the model include *model*.h. This file includes: • Exported Simulink data symbols • Exported Stateflow machine parented data • Model data structures, including rtM • Model entry-point functions For more information, see “model.h” (Simulink Coder).
model.mk	Generated makefile that controls compiling and linking the generated code into the final binary file by the make utility of your development system. If you set the MAKEFLAGS environment variable, do not select options with this variable that conflict with the current make utility used by the build process.
model.rtw	Represents the compiled model. By default, the build process deletes this ASCII file when the build process is complete. You can choose to retain the file for inspection.
*model*_capi.h *model*_capi.c	(optional files) Contain data structures that describe the model signals, states, and parameters without using external mode. For more information, see “Exchange Data Between Generated and External Code Using C API” (Simulink Coder).

File	Description
*model*_data.c	Contains (if conditionally generated) declarations for the parameters data structure and the constant block I/O data structure, and zero representations for structure data types that the model uses. A model build generates this file when the model uses these data structures. The `extern` declarations for structures appear in *model*.h. When present, this file contains: • Constant block I/O parameters • Include files *model*.h and *model*_private.h • Definitions for the zero representations for user-defined structure data types that the model uses • Constant parameters
*model*_dt.h	(optional file) Declares structures that contain data type and data type transition information for generated model data structures for supporting external mode.
*model*_private.h	Contains local `define` constants and local data for the model and subsystems. The generated source files from the model build include this file. When you interface external code with generated code from a model, include *model*_private.h. The file contains: • Imported Simulink data symbols • Imported Stateflow machine parented data • Stateflow entry points • Simulink Coder details (various macros, `enum`s, and so forth, that are private to the code) For more information, see “Manage Build Process File Dependencies” (Simulink Coder).
model_reference_types.h	Contains type definitions for timing bridges. A model build generates this file for a referenced model or a model containing model reference blocks.

File	Description
*model*_targ_data_map.m	(optional file) Contains MATLAB language commands that external mode uses to initialize the external mode connection.
*model*_types.h	Provides forward declarations for the real-time model data structure and the parameters data structure. The generated header files from the model build include this file. Function declarations of reusable functions can use these structures.
multiword_types.h	Contains type definitions for multiple-word wide data types and their word-size chunks. If your code uses multiword data types, include this header file. A model build generates this file when one or more of these conditions apply: • Your model uses multiword data types. • Your model configuration enables **MAT-file logging**. • Your model configuration enables **Code Generation** > **Interface** > **External mode**.
rtGetInf.c rtGetInf.h rtGetNaN.c rtGetNaN.h rt_nonfinite.c rt_nonfinite.h	Declares and initializes global nonfinite values for `inf`, minus `inf`, and `nan`. Provides nonfinite comparison functions. A model build generates these files when one or more of these conditions apply: • The model contains S-functions. • The generated code from the model requires nonfinite numbers. • Your model configuration enables **MAT-file logging**. • Your model configuration selects `grt.tlc` as the **System target file** and enables the **Classic call interface**.
rtmodel.h	Contains `#include` directives required by static main program modules such as `rt_main.c`. The build process does not create these modules at code generation time. The modules include `rtmodel.h` to access model-specific data structures and entry points. If you create your own main program module, make sure to include `rtmodel.h`.

File	Description
`rtwtypes.h`	Provides the essential type definitions, `#define` statements, and enumerations. For GRT-based system target files, `rtwtypes.h` includes `simstruc_types.h` which, in turn, includes `tmwtypes.h`. For ERT-based system target files that do not generate a GRT interface and do not have noninlined S-functions, `rtwtypes.h` does not include `simstruc_types.h`. For more information, see “rtwtypes.h” (Simulink Coder) and “Manage Build Process File Dependencies” (Simulink Coder).

`rtw_proj.tmw`
 	
`sl_proj.tmw`
	Marker files.
	
	The build process generates these files to help the `make` utility determine when to recompile and link the generated code.

`rt_defines.h`	Contains type definitions for special mathematical constants (such as π and *e*) and defines the `UNUSED_PARAMETER` macro. A model build generates this file when the generated code requires a mathematical constant definition or when the function body does not access a required model function argument.

`rt_sfcn_helper.h`
 	
`rt_sfcn_helper.c`
	(optional files) Provide functions that the noninlined S-functions use in a model.
	
	The noninlined S-functions use functions `rt_CallSys`, `rt_enableSys`, and `rt_DisableSys` to call downstream function-call subsystems.

`subsystem``.c`	(optional file) Contains C source code for each noninlined nonvirtual subsystem or copy the code when the subsystem is configured to place code in a separate file.
`subsystem``.h`	(optional file) Contains exported symbols for noninlined nonvirtual subsystems.

model.bat

This file contains Windows batch file commands that set the compiler environment and invoke the `make` utility.

If you are using the toolchain approach for the build process, you also can use this batch file to extract information from the generated makefile, *`model`*`.mk`. The information includes macro definitions and values that appear in the makefile, such as `CFLAGS` (C compiler flags) and `CPP_FLAGS` (C++ compiler flags). With the folder containing *`model`*`.bat` selected as the current working folder, in the Command Window, type:

```
>> system('model.bat info')
```

On UNIX and Macintosh platforms, the code generator does not create the *`model`*`.bat` file. To extract information for toolchain approach builds from the generated makefile on these systems, in the Command Window, type:

```
>> system('gmake -f model.mk info')
```

model.h

The header file *`model`*`.h` declares model data structures and a public interface to the model entry points and data structures. This header file also provides an interface to the real-time model data structure (*`model`*`_M`) by using access macros. If your code interfaces to model functions or model data structures, include *`model`*`.h`:

- Exported global signals

  ```
  extern int32_T INPUT;    /* '<Root>/In' */
  ```

- Global structure definitions

  ```
  /* Block parameters (auto storage) */
  extern Parameters_mymodel mymodel_P;
  ```

- Real-time model (RTM) macro definitions

  ```
  #ifndef rtmGetSampleTime
  # define rtmGetSampleTime(rtm, idx)
  ((rtm)->Timing.sampleTimes[idx])
  #endif
  ```

- Model entry point functions (ERT example)

```
extern void mymodel_initialize(void);
extern void mymodel_step(void);
extern void mymodel_terminate(void);
```

The `main.c` (or `.cpp`) file includes *`model`*`.h`. If the model build generates the `main.c` (or `.cpp`) file from a TLC script, the TLC source can include *`model`*`.h`.

```
#include "%<CompiledModel.Name>.h"
```

If `main.c` is a static source file, you can use the fixed header file name `rtmodel.h`. This file includes the *`model`*`.h` header file:

```
#include "model.h"     /* If main.c is generated */
```

or

```
#include "rtmodel.h"   /* If static main.c is used */
```

Other external source files can require to include *`model`*`.h` to interface to model data, for example exported global parameters or signals. The *`model`*`.h` file itself can have additional header dependencies due to requirements of generated code. See “System Header Files” (Simulink Coder) and “Code Generator Header Files” (Simulink Coder).

To reduce dependencies and reduce the number of included header files, see “Manage Build Process File Dependencies” (Simulink Coder).

rtwtypes.h

The header file `rtwtypes.h` defines data types, structures, and macros required by the generated code. You include `rtwtypes.h` for GRT and ERT system target files, instead of including `tmwtypes.h` or `simstruc_types.h`.

Often, the generated code requires that integer operations overflow or underflow at specific values. For example, when the code expects a 16-bit integer, the code does not accept an 8-bit or a 32-bit integer type. The C language does not set a standard for the number of bits in types such as `char`, `int`, and others. So, there is no universally accepted data type in C to use for sized-integers.

To accommodate this feature of the C language, the generated code uses sized integer types, such as `int8_T`, `uint32_T`, and others, which are not standard C types. In `rtwtypes.h`, the generated code maps these sized-integer types to the corresponding C keyword base type using information in the **Hardware Implementation** pane of the configuration parameters.

The code generator produces the optimized version of `rtwtypes.h` for ERT-based system target files when these conditions apply:

- **Configuration Parameters > Code Generation > Interface > Advanced parameters > Classic call interface** is not selected.
- The model does not contain noninlined S-functions.

Include `rtwtypes.h`. If you include it for GRT system target files, for example, it is easier to use your code with ERT-based system target files.

For GRT and ERT system target files, the location of `rtwtypes.h` depends on whether the build process uses the *shared utilities* location. If it uses a shared location, the code generator places `rtwtypes.h` in `slprj/target/_sharedutils`; otherwise, it places `rtwtypes.h` in the build folder (*`model_target`*`_rtw`). See “Specify Generated Code Interfaces” (Simulink Coder).

Source files include the `rtwtypes.h` header file when the source files use code generator type names or other code generator definitions. A typical example is for files that declare variables by using a code generator data type, for example, `uint32_T myvar`.

A source file that the code generator and an S-function use can use the preprocessor macro `MATLAB_MEX_FILE`. The macro definition comes from the `mex` function:

```
#ifdef  MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
```

A source file for the code generator `main.c` (or `.cpp`) file includes `rtwtypes.h` without preprocessor checks.

```
#include "rtwtypes.h"
```

Custom source files that the Target Language Compiler generates can also emit these `include` statements into their generated file.

See “Control Placement of rtwtypes.h for Shared Utility Code” (Simulink Coder).

Manage Build Process File Dependencies

An important control of the size of generated code is managing the number and size of included files (dependencies). To reduce the number of system header files and generated header files that generated code requires, it is helpful to understand the dependencies that the build process generates and the conditions that lead to dependencies.

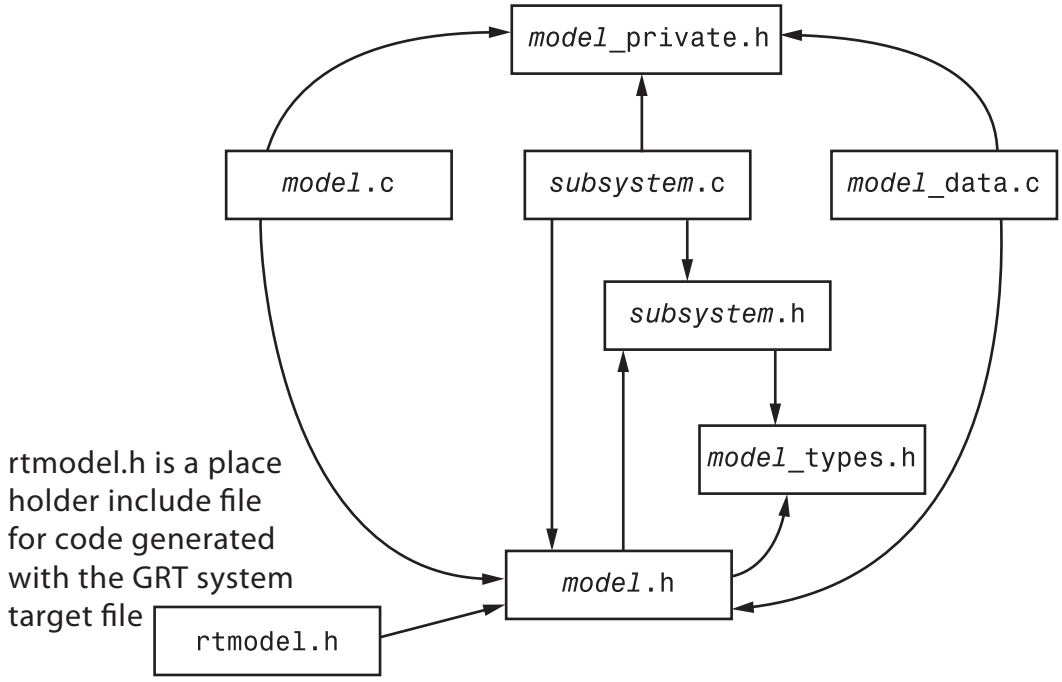
The dependency relationships among generated source and header files appear in the figure. Arrows coming from a file point to files it includes. Other dependencies exist, for example, on Simulink header files `tmwtypes.h` and `simstruc_types.h`, plus C or C++ library files. The figure maps inclusion relations between only those files that are generated in the build folder. These files can reference utility and model reference code located in a code generation folder. For more information about the folders and files that the build process creates, see “Manage Build Process Folders” (Simulink Coder) and “Manage Build Process Files” (Simulink Coder).

The two tables identify the conditions that control creation of dependency files for GRT and ERT targets. To manage build-related dependencies, consider how these conditions apply to your model and code generation process. Then, configure model parameters and code generation options to manage build process file dependencies.

Due to differences in file packaging options for code generated with ERT-based system target files, the file dependencies differ slightly from file packaging for code generated with GRT-based system target files. See “Manage File Packaging of Generated Code Modules” on page 48-14.

The parent system header files (*`model`*`.h`) include child subsystem header files (*`subsystem`*`.h`). In more layered models, subsystems similarly include their children's header files in the model hierarchy. As a consequence, subsystems are able to view recursively into their descendant subsystems and view into the root system because every *`subsystem`*`.c` or *`subsystem`*`.cpp` includes *`model`*`.h` and *`model`*`_private.h`.

In the figure, files *`model`*`.h`, *`model`*`_private.h`, and *`subsystem`*`.h` depend on the header file `rtwtypes.h`. If you use system target files that are not based on the ERT system target file, the source files that you generate can have additional dependencies on `tmwtypes.h` and `simstruc_types.h`.



System Header Files

The system header files make function declarations, type definitions, and macro definitions available to the legacy or external code. Some code generation scenarios require including header files that are specific to the code generator product.

The code generator includes some system header files for broadly defined cases. For example, generated code includes `<stddef.h>` when the model contains a utility function that requires this header file. This approach helps identify header file dependencies:

1. Set the Shared code placement parameter to `'Shared location'` and build the model. The code generator places the utility functions in `__sharedutils` folder.
2. Use a find-in-file utility (for example, grep utility) to search the `.c` and `.h` files in the `__sharedutils` folder for `#include`. The search results list the utilities with header file dependencies.

3. Use this information to identify utilities to remove from the model and reduce header file dependencies in the generated code.

For more information, see “Generate Shared Utility Code for Fixed-Point Functions” (Simulink Coder).

System Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`<math.h>`	Defines math constants GRT—Generated code does not include this file. ERT—Generated code includes this file when the code honors your model configuration for solver **Stop time** and either: • Your model configuration enables **MAT-file logging**. See “MAT-file logging” (Simulink Coder). • Your model configuration enables **Code Generation > Interface > External mode**.
`<float.h>`	Provides floating-point math functions GRT—Generated code includes this file when your model contains a floating-point math function. ERT—Generated code includes this file when your model contains a floating-point math function, unless a code replacement library entry overrides the function. For more information, see “Choose a Code Replacement Library” (Simulink Coder).
`<stddef.h>`	Defines NULL GRT and ERT—Generated code includes this file when your model contains a utility function that requires this file.

System Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`<stdio.h>`	Provides file I/O functions GRT—Generated code includes this file when your model includes a To File block. ERT—Generated code includes this file when either: • Your model includes a To File block. • Your model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder).
`<stdlib.h>`	Provides utility functions such as the integer versions of `div()` and `abs()` GRT—Generated code includes this file when either: • Your model includes a Stateflow chart. • Your model includes a math function block configured for `mod()` or `rem()`, which generate calls to `div()`. ERT—Generated code includes this file when either: • Your model includes a Stateflow chart, and you select **Support: floating-point numbers**. • Your model includes a math function block configured for `mod()` or `rem()`, which generate calls to `div()`.

System Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`<string.h>`	Provides memory functions such as `memset()` and `memcpy()` GRT—Generated code includes this file when your model initialization code calls `memset()`. ERT—Generated code includes this file when a block or model initialization code calls `memcpy()` or `memset()`. For a list of relevant blocks, in the Command Window, type: `showblockdatatypetable` Look for blocks with the N2 note. To omit calls to `memset()` from model initialization code, select the **Remove root level I/O zero initialization** and **Remove internal data zero initialization** optimization configuration parameters.

Code Generator Header Files

Dependencies in the table for generated header files apply to the system target files `grt.tlc` and `ert.tlc`. System target files derived from these base system target files can have additional header dependencies. Code generation for blocks from blocksets, embedded targets, and custom S-functions can introduce additional header dependencies.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`builtin_typeid_types.h`	Defines an enumerated type corresponding to built-in data types GRT and ERT—Generated code includes this file when one or more of these conditions apply: • Your model contains a Stateflow chart that uses messages. • Your model configuration enables: **MAT-file logging**. See “MAT-file logging” (Simulink Coder). • Your model configuration selects C API options at **Code Generation > Interface**.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`dt_info.h`	Defines data structures for external mode GRT and ERT—Generated code includes this file when your model configuration enables external mode.
`ext_work.h`	Defines external mode functions GRT and ERT—Generated code includes this file when your model configuration enables external mode.
`fixedpoint.h`	Provides fixed-point support for noninlined S-functions GRT—Generated code includes this file. ERT—Generated code includes this file when either: • Your model uses noninlined S-functions. • Your model configuration selects **Classic call interface**.
`model_reference_types.h`	Contains type definitions for timing bridges GRT and ERT—Generated code includes this file when building a reference model or building a model that contains model blocks.
`model``_types.h`	Defines model-specific data types GRT and ERT—Generated code includes this file.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`multiword_types.h`	Contains type definitions for multiword-wide data types and their word-size chunks GRT and ERT—Generated code includes this file when one or more of these conditions apply: • Your model uses multiword data types. • Your model configuration enables **MAT-file logging**. See “MAT-file logging” (Simulink Coder). • Your model configuration enables **Code Generation > Interface > External mode**. For a model that uses multiword data types, the code generator overwrites the file if the data types are greater in length than those of the model for which code was last generated. To avoid overwriting this file, set: • `ERTMultiwordTypeDef` to `'User defined'` • `ERTMultiwordLength` to the biggest length that is required by your models.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files

`rtGetInf.h`
 	
`rtGetNaN.h`
 	
`rt_nonfinite.h`
	Support nonfinite numbers
	
	GRT—Generated code includes this file when one or more of these conditions apply:
	• Your model contains S-functions.
	• The generated code requires nonfinite numbers.
	• Your model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder).
	• Your model configuration selects the **Classic call interface**.
	
	ERT—Generated code includes this file when one or more of these conditions apply:
	• Your model contains S-functions.
	• The generated code requires nonfinite numbers.
	• Your model configuration enables **MAT-file logging**. See "MAT-file logging" (Simulink Coder).

`rt_defines.h`	Contains type definitions for special mathematical constants (such as π and *e*) and defines the `UNUSED_PARAMETER` macro GRT and ERT—Generated code includes this file when either: • The generated code requires a mathematical constant definition. • The function body does not access a required model function argument.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files

`rt_logging.h`	Supports MAT-file logging and includes:
	
	`rtwtypes.h`
	`builtin_typeid_types.h`
	`multiword_types.h`
	`rt_mxclassid.h`
	`rtw_matlogging.h`
	
	GRT—Generated code includes this file.
	
	ERT—Generated code includes this file when you model configuration enables **MAT-file logging**. See “MAT-file logging” (Simulink Coder).

`rt_mxclassid.h`	Defines `mxArray` class ID enumerations GRT and ERT—Generated code includes this file when the code includes `rt_logging.c`.
`rtw_continuous.h`	Supports continuous time GRT—Generated code includes this file when the code includes `simstruc_types.h`. ERT—Generated code includes this file when your model configuration selects **Support: continuous time** and when the code does not already include `simstruc.h`.
`rtw_extmode.h`	Supports external mode GRT—Generated code includes this file when the code includes `simstruc_types.h`. ERT—Generated code includes this file when your model configuration selects external mode and when the code does not already include `simstruc.h`.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`rtw_matlogging.h`	Supports MAT-file logging GRT—Generated code includes this file when the code includes `simstruc_types.h` and `rt_logging.h`. ERT—Generated code includes this file when the code includes `rt_logging.h`.
`rtw_solver.h`	Supports continuous states GRT—Generated code includes this file when the code includes `simstruc_types.h`. ERT—Generated code includes this file when your model configuration selects **Support: continuous time** and when the code does not already include `simstruc.h`.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files
`rtwtypes.h`	Defines code generator data types GRT—Generated code includes this file. Uses a verbose version of the file, which includes `tmwtypes.h` and `simstruc_types.h`. See `simstruc_types.h` for dependencies. ERT—Generated code includes this file. See “rtwtypes.h” on page 47-50. The code generator overwrites the previously generated rtwtypes.h when you enable (previously disabled) support for: • Complex numbers (`SupportComplex` set to `'on'`). • Noninlined S-functions (`SupportNonInlinedSFcns` set to `'on'`) To avoid rewriting `rtwtypes.h`, you can: • Specify support for complex datatypes for your models even if the models do not currently use complex data types. • Disable support for noninlined S-functions. In this case, the use of a noninlined S-function produces an error. To avoid the error, convert the S-function to an inlined S-function. For more information, see “Inlining S-Functions” on page 14-9.

`simstruc.h`	Supports calling noninlined S-functions that use the `Simstruct` definition; also includes:
	
	`limits.h`
	`string.h`
	`tmwtypes.h`
	`simstruc_types.h`
	
	GRT—Generated code includes this file.
	
	ERT—Generated code includes this file when either:
	
	• Your model uses noninlined S-functions.
	• Your model configuration selects **Classic call interface**.

Header File	Description and Inclusion Conditions for GRT or ERT System Target Files

`simstruc_types.h`	Provides definitions that the generated code uses and includes the header files:
	
	`rtw_matlogging.h`
	`rtw_extmode.h`
	`rtw_continuous.h`
	`rtw_solver.h`
	`sysran_types.h`
	
	GRT—Generated code includes this file when the code includes `rtwtypes.h`.
	
	ERT—Generated code does not include this file. For ERT, `rtwtypes.h` contains definitions, and *`model`*`.h` contains header files.

`sysran_types.h`	Supports external mode GRT—Generated code includes this file when the code includes `simstruc_types.h`. ERT—Generated code includes this file when your model configuration selects external mode and when the code does not already include `simstruc.h`.
`zero_crossing_types.h`	Contains zero-crossing definitions for models with triggered subsystems where the trigger is rising, falling, or either. File is generated only if required by the model as determined by the data type of the trigger signal. For example, if the data type of the trigger signal is Boolean, zero-crossing detection not needed. GRT—Generated code does not include this file for GRT code generation targets. ERT—Generated code includes this file when a model has a conditionally executed subsystem where a trigger uses zero crossing detection. If generated, the content of `zero_crossing_types.h` is always the same.

Add Build Process Dependencies

When you specify a system target file for code generation, the code generator can build a standalone executable program that can run on the development computer. To build the executable program, the code generator uses the selected compiler and the makefile generated by the toolchain or template makefile (TMF) build process approach. Part of the makefile generation process is to add source file, header file, and library file information (the dependencies) in the generated makefile for a compilation. Or, for a specific application, you can add the generated files and file dependencies through a configuration management system.

The generated code for a model consists of a small set of files. (See “Manage Build Process Files” (Simulink Coder).) These files have dependencies on other files, which occur due to:

- Header file inclusions
- Macro declarations
- Function calls
- Variable declarations

The model or external code introduces dependencies for various reasons:

- Blocks in a model generate code that makes function calls. These calls can occur in several forms:
  - Included source files (not generated) declare the called functions. In cases such as a blockset, manage these source file dependencies by compiling them into a library file.
  - The generated code makes calls to functions in the run-time library provided by the compiler.
  - Some function dependencies also are generated files, which are referred to as shared utilities. Some examples are fixed-point utilities and non-finite support functions. These dependencies are referred to as shared utilities. The generated functions can appear in files in the build folder for standalone models or in the `_sharedutils` folder under the `slprj` folder for builds that involve model reference.
- Models with continuous time require solver source code files.
- Code generator options such as external mode, C API, and MAT-file logging.

- External code specifies dependencies.

File Dependency Information for the Build Process

The code generator provides several mechanisms to input file dependency information into the build process. The mechanisms depend on whether your dependencies are block-based or are model- or system target file-based.

For block dependencies, consider using:

- S-functions and blocksets
  - Add folders that contain S-function MEX-files that the model uses to the header include path.
  - Create makefile rules for these folders to allow for finding source code.
  - Specify additional source file names with the S-Function block parameter `SFunctionModules`.
  - Specify additional dependencies with the `rtwmakecfg.m` mechanism. See "Use rtwmakecfg.m API to Customize Generated Makefiles" (Simulink Coder).

  For more information on applying these approaches to legacy or external code integration, see "Import Calls to External Code into Generated Code with Legacy Code Tool" (Simulink Coder).
- S-Function Builder block, which provides its own UI for specifying dependency information

For model- or system target file-based dependencies, such as external header files, consider using:

- The **Code Generation > Custom Code** pane in the Configuration Parameters dialog box. You can specify additional libraries, source files, and include folders.
- TLC functions `LibAddToCommonIncludes()` and `LibAddToModelSources()`. You can specify dependencies during the TLC phase. See "LibAddToCommonIncludes(incFileName)" (Simulink Coder) and "LibAddSourceFileCustomSection(file, builtInSection, newSection)" (Simulink Coder). The Embedded Coder product also provides a TLC-based customization template for generating additional source files.

Generated Makefile Dependencies

For toolchain approach or template makefile (TMF) approach build processes, the code generator generates a makefile. For TMFs, the generated makefile provides token expansion in which the build process expands different tokens in the makefile to include the additional dependency information. The resulting makefile contains the complete dependency information. See “Customize Template Makefiles” (Simulink Coder).

The generated makefile contains:

- Names of the source file dependencies
- Folders where source files are located
- Location of the header files
- Precompiled library dependencies
- Libraries that the `make` utility compiles and creates

A property of `make` utilities is that you do not have to specify the specific location for a given source C or C++ file. If a rule exists for that folder and the source file name is a prerequisite in the makefile, the make utility can find the source file and compile it. The C or C++ compiler (preprocessor) does not require absolute paths to the headers. The compiler finds header file with the name of the header file by using an `#include` directive and an include path. The generated C or C++ source code depends on this standard compiler capability.

Libraries are created and linked against, but occlude the specific functions that the program calls.

These properties can make it difficult to determine the minimum list of file dependencies manually. You can use the makefile as a starting point to determine the dependencies in the generated code. For an example that shows how to identify dependencies, see “Relocate Code to Another Development Environment with packNGo” (Simulink Coder).

Another approach to determining the dependencies is using linker information, such as a linker map file, to determine the symbol dependencies. The map file provides the location of code generator and blockset source and header files to help in locating the dependencies.

Code Generator Static File Dependencies

Several locations in the MATLAB folder tree contain static file dependencies specific to the code generator:

- *matlabroot*/rtw/c/src (open)

  This folder has subfolders and contains additional files must be compiled. Examples include solver functions (for continuous time support), external mode support files, C API support files, and S-function support files. Include source files in this folder into the build process with the SRC variables of the makefile.
- Header files in the folder matlabroot/rtw/extern/include
- Header files in the folder matlabroot/simulink/include

  These folders contain additional header file dependencies such as tmwtypes.h, simstruc_types.h, and simstruc.h.

Note For ERT-based system target files, you can avoid several header dependencies. ERT-based system target files generate the minimum set of type definitions, macros, and so on, in the file rtwtypes.h.

Blockset Static File Dependencies

Blockset products with S-function code apply the rtwmakecfg.m mechanism to provide the code generator with dependency information. The rtwmakecfg.m file from the blockset contains the list of include path and source path dependencies for the blockset. Typically, blocksets create a library from the source files to which the generated model code can link. The libraries are created and identified when you use the rtwmakecfg.m mechanism.

To locate the rtwmakecfg.m files for blocksets in your MATLAB installed tree, use the following command:

```
>> which -all rtwmakecfg.m
```

If the model that you are compiling uses one or more of the blocksets listed by the which command, you can determine folder and file dependency information from the respective rtwmakecfg.m file.

Folder Dependency Information for the Build Process

You can add #include statements to generated code. Such references can come from several sources, including TLC scripts for inlining S-functions, custom storage classes, bus objects, and data type objects. The included files consist of header files for external code or other customizations. You can specify compiler include paths with the -I

compiler option. The build process uses the specified paths to search for included header files.

Usage scenarios for the generated code include, but are not limited to, the following:

- A custom build process compiles generated code that requires an environment-specific set of `#include` statements.

  In this scenario, the build process invokes the code generator when you select the **Generate code only** check box. Consider using fully qualified paths, relative paths, or just the header file names in the `#include` statements. Use include paths.
- The build process compiles the generated code.

  In this case, you can specify compiler include paths (`-I`) for the build process in several ways:

  - Specify additional include paths on the **Code Generation** > **Custom Code** pane in the Configuration Parameters dialog box. The code generator propagates the include paths into the generated makefile.
  - The `rtwmakecfg.m` mechanism allows S-functions to introduce additional include paths into the build process. The code generator propagates the include paths into the generated makefile.
  - When building a model that uses a custom system target file and is makefile-based, you can directly add the include paths into the template makefile that the system target file uses.
  - Use the `make` command to specify a `USER_INCLUDES` make variable that defines a folder in which the build process searches for included files. For example:

    ```
    make_rtw USER_INCLUDES=-Id:\work\feature1
    ```

    The build process passes the custom includes to the command-line invocation of the make utility, which adds them to the overall flags passed to the compiler.

Use #include Statements and Include Paths

Consider the following approaches for using `#include` statements and include paths with the build process to generate code that remains portable and minimizes compatibility problems with future versions.

Assume that additional header files are:

```
c:\work\feature1\foo.h
c:\work\feature2\bar.h
```

- An approach is to include in the `#include` statements only the file name, such as:

  ```
  #include "foo.h"
  #include "bar.h"
  ```

  Then, the include path passed to the compiler contains folders in which the headers files exist:

  ```
  cc -Ic:\work\feature1 -Ic:\work\feature2     ...
  ```

- Another approach is to use relative paths in `#include` statements and provide an anchor folder for these relative paths using an include path, for example:

  ```
  #include "feature1\foo.h"
  #include "feature2\bar.h"
  ```

Then, specify the anchor folder (for example `\work`) to the compiler:

```
 cc -Ic:\work   ...
```

Avoid These Folder Dependencies

When using the build process, avoid dependencies on folders in the build process “Code generation folder” (Simulink), such as the *`model`*`_ert_rtw` folder or the `slprj` folder. Do not use paths in `#include` statements that are relative to the location of the generated source file. For example, if your MATLAB code generation folder is `c:\work`, the build process generates the *`model`*`.c` source file into a subfolder such as:

```
c:\work\model_ert_rtw\model.c
```

The *`model`*`.c` file has `#include` statements of the form:

```
#include "..\feature1\foo.h"
#include "..\feature2\bar.h"
```

It is preferable to use one of the other suggested approaches because the relative path creates a dependency on the code generator folder structure.

Build Process Support for Folder Names with Spaces or Special Characters

Folder Names with Spaces

On a Windows system, the code generator maps a drive corresponding to the MATLAB installation folder for either of these conditions:

- The `matlabroot` folder is a UNC location.
- The path the `matlabroot` folder contains spaces, and the system has no alternative name support.

These folder paths can contain spaces:

- The path to your MATLAB installation folder (`matlabroot`). For example, `C:\Program Files\MATLAB\R2015b`
- The path to the current working folder where you start the build (`pwd`). For example, `C:\Users\username\Documents\My Work`.
- The path to the installation folder for a compiler that the build process uses.

If your work environment includes one or more of the preceding scenarios, use the following support mechanisms for the build process:

- If you are using the toolchain approach to build generated code, the system support for spaces in folder names influences toolchain operation:
  - For Linux systems and Windows systems with 8.3 name creation enabled, the toolchain manages spaces in folder names by using alternative names from the operating system. The toolchain uses the `TransformPathsWithSpaces` attribute to manage these names.

    ```
    addAttribute(toolchainObject, 'TransformPathsWithSpaces', true);
    ```
  - For Windows systems with 8.3 name creation disabled, the toolchain manages spaces in folder names by mapping a network drive using a batch file (.bat). This operation requires adding the `RequiresBatchFile` attribute to the toolchain definition.

    ```
    addAttribute(toolchainObject, 'RequiresBatchFile', true);
    ```

When developing a toolchain for a Windows system, set both attributes. For more information about the toolchain attributes, see `addAttribute`.

- If you are using the template makefile approach to build generated code, the template makefile (`.tmf`) requires code to manage spaces in folder names. When the alternative folder names (Windows short names) differ from the file system folder names (Windows long names), add this code to the makefile.

```
ALT_MATLAB_ROOT         = |>ALT_MATLAB_ROOT<|
ALT_MATLAB_BIN          = |>ALT_MATLAB_BIN<|
!if "$(MATLAB_ROOT)" != "$(ALT_MATLAB_ROOT)"
MATLAB_ROOT = $(ALT_MATLAB_ROOT)
!endif
!if "$(MATLAB_BIN)" != "$(ALT_MATLAB_BIN)"
MATLAB_BIN = $(ALT_MATLAB_BIN)
!endif
```

  When the values of the location tokens are not equal, this code replaces `MATLAB_ROOT` with `ALT_MATLAB_ROOT`. The replacement indicates that the path to your MATLAB installation folder includes spaces. This code applies the same type of replacement for `MATLAB_BIN` with `ALT_MATLAB_BIN`. The preceding code is specific to `nmake`. For platform-specific examples, see the supplied template makefiles.

With either build approach, when there is an issue with support for creation of alternate names (short names), build errors can occur on Windows. If a build generates an error message similar to the following message, see “Troubleshooting Errors When Folder Names Have Spaces” (Simulink Coder).

```
NMAKE : fatal error U1073: don't know how to make ' ...
```

When using operating system commands, such as `system` or `dos`, enclose paths that specify executable files or command parameters in double quotes (`" "`). For example:

```
system('dir "D:\Applications\Common Files"')
```

This table provides a summary of build folder support and limitations forWindows.

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows

`matlabroot` folder
 	
Note: The `matlabroot` value is derived from the MATLAB installation location.
	During a build, a UNC location such as:
	
	`\\networkdrive\matlab\R20xxb`
	
	could be remapped as:
	
	`T:\`
	
	During a build on a Windows system with short file name (8.3) support (default for Windows using NTFS), the build process uses the Windows API `getShortPathName()` for the folder location.
	
	During a build on a Windows system without short file name (8.3) support (systems using ReFS or using NTFS with 8.3 support disabled), a location with spaces in the path such as:
	
	`C:\Program Files\MATLAB\R20xxb`
	
	could be remapped as:
	
	`T:\R20xxb`
		Build process folder support available independent of file system (NTFS or ReFS) or file system configuration for short file name support.
		
		Limitations:
		
		On systems that require drive mapping for the installation location, the build process requires that a drive letter is available for mapping.
		
		On systems without short file name (8.3) support (using ReFS or using NTFS with 8.3 support disabled), the final folder in the installation location cannot contain spaces. For example, a final folder name:
		
		`C:\Program Files\MATLAB\R20xxb sp1`
		
		is not supported.

Code generation folder Simulation cache folder Custom code source file locations—among others, these locations	For UNC locations, build process temporarily maps a drive by using the shell commands `pushd` and `popd`.	Build process folder support is available independent of file system (NTFS or ReFS) or file system configuration for short path name support.

Build Process Folders	Approach for Paths with UNC or Spaces	Support for Windows
include folders specified by: • `rtwmakecfg.m` • **Configuration Parameters > Code Generation > Custom Code > Additional build information** • Code replacement library	For paths with spaces, build process uses the Windows short path name (8.3) by using the Windows API: `getShortPathName()`	Build process folder support depends on NTFS file system and requires Windows default support. Registry sets value of 2 or 0 for: `NtfsDisable8dot3NameCreation` **Limitations:** Build process does not support spaces in the path to these folders for: • NTFS file system with short path name support disabled • ReFS file system (this file system does not support short path names)

Folder Names with Special Characters

If a build-related folder path contains a Japanese (multibyte) character where the final byte is equal to the `5C` hexadecimal character, the build process might produce an error. The make and compiler tools might incorrectly interpret the final byte as the `'\'` (backslash) character.

Troubleshooting Errors When Folder Names Have Spaces

On Windows, when there is an issue with support for creation of short file names, build process errors can occur. When this issue affects a build, you see an error message similar to:

```
NMAKE : fatal error U1073: don't know how to make 'C:\Work\My'
```

This message can occur if a space in the folder name (`C:\Work\My Models`) prevents the build process from finding the model or a file to build. For descriptions of the build-related folders that are sensitive to a space in the folder name or path, see “Folder Names with Spaces” (Simulink Coder).

To avoid issues from folder names with spaces when Windows short file name support for file names is disabled, do not use paths with spaces. For example, install third-party software to paths without spaces. Do not use paths with spaces for folders containing your models, source files, or libraries.

An issue can occur with builds that use folder names with spaces, because it is possible to disable Windows alternate name support. The build process uses this alternate name support on Windows systems. There are many terms for this file, folder, and path alternate name support:

- 8.3 name
- DOS path
- short file name (SFN, ShortFileName)
- long name alias
- Windows path alias

Verify the type of file system that the drive uses. In Windows Explorer, right-click the drive icon and select properties.

- If the file system is ReFS (Resilient File System), it is an issue. The ReFS does not provide short file name support. Except for the MATLAB installation folder, the build process does not support folder names with spaces for the ReFS file system. If your work environment requires short file name support for the build folder or for additional external code folders, do not use ReFS.
- If the file system is NTFS (New Technology File System), it is possible that the build error is related to a registry setting incompatibility. Continue with troubleshooting steps.

The error could stem from an issue with short file name support on a system using NTFS. Check the Windows registry setting that enables the creation of short names for files, folders, and paths.

1. Open the Windows command prompt, running as administrator. For example, from the Windows Start menu, type `cmd`, right-click the `cmd.exe` icon, and select `Run as administrator`.
2. Change to the `windows\system32` folder and query the `NtfsDisable8dot3NameCreation` status by typing:

   ```
   > fsutil 8dot3name query
   ```

3. If the registry state of `NtfsDisable8dot3NameCreation` is not 2, the default (Volume level setting), change the value to 2 by typing:

   ```
   > fsutil 8dot3name set 2
   ```

   For more information about enabling creation of short names. See https://technet.microsoft.com/en-us/library/ff621566.aspx.

   Changing the registry setting enables creation of short names only for files and folders that are created after the change.

4. To create short names for files created while short name creation was disabled, at the Windows command line, use the `fsutil` utility.

   To set the short name, the syntax is:

   ```
   > fsutil file setshortname <FileName> <ShortName>
   ```

   For example, to create the short name `PROGRA~1` for the long name `C:\Program Files`, type:

   ```
   > fsutil file setshortname "C:\Program Files" PROGRA~1
   ```

   The `C:\Program Files` folder name is in quotations because it has spaces.

5. To verify that the short name was created, use the `dir` command with `/x` option to show short names.

   ```
   > dir C:\ /x
   ```

Code Generation of Matrices and Arrays

MATLAB stores matrix data and arrays (1–D, 2–D, ...) in column-major format as a vector. Simulink and the code generator can store array data in column-major or row-major format. For an array stored in column-major layout, the elements of the columns are contiguous in memory. In row-major layout, the elements of the rows are contiguous. Array layout is also referred to as order, format, and representation. The order in which elements are stored can be important for integration, usability, and performance. Certain algorithms perform better on data stored in a particular order.

Programming languages and environments typically assume a single array layout for all data. MATLAB and Fortran use column-major layout by default, whereas C and C++ use row-major layout. With Simulink Coder, you can generate C/C++ code that uses row-major layout or column-major layout.

Array Storage in Computer Memory

Computer memory stores data in terms of one-dimensional arrays. For example, when you declare a 3-by-3 matrix, the software stores this matrix as a one-dimensional array with nine elements. By default, MATLAB stores these elements with a column-major array layout. The elements of each column are contiguous in memory.

Consider the matrix `A`:

```
A =
    1   2   3
    4   5   6
    7   8   9
```

`A` translates to an array of length 9 in this order:

```
A(1) = A(1,1) = 1;
A(2) = A(2,1) = 4;
A(3) = A(3,1) = 7;
A(4) = A(1,2) = 2;
A(5) = A(2,2) = 5;
```

and so on.

In column-major format, the next element of an array in memory is accessed by incrementing the first index of the array. For example, these element pairs are stored sequentially in memory:

- `A(i)` and `A(i+1)`
- `B(i,j)` and `B(i+1,j)`
- `C(i,j,k)` and `C(i+1,j,k)`

The matrix `A` is represented in memory by default with this arrangement:

```
1     4     7     2     5     8     3     6     9
```

In row-major array layout, the programming language stores row elements contiguously in memory. In row-major layout, the elements of the array are stored as:

```
1     2     3     4     5     6     7     8     9
```

You can store the N-dimensional arrays in column-major or row-major layout. In column-major layout, the elements from the first (leftmost) dimension or index are contiguous in memory. In row-major layout, the elements from the last (rightmost) dimension or index are contiguous.

For more information on the internal representation of MATLAB data, see “MATLAB Data” (MATLAB).

Code generation software uses column-major format by default for several reasons:

- The world of signal and array processing is largely in column-major array layout: MATLAB, LAPack, Fortran90, and DSP libraries.
- A column is equivalent to a channel in frame-based processing. In this case, column-major storage is more efficient.
- A column-major array is self-consistent with its component submatrices:
  - A column-major 2-D array is a simple concatenation of 1-D arrays.
  - A column-major 3-D array is a simple concatenation of 2-D arrays.
  - The stride is the number of memory locations to index to the next element in the same dimension. The stride of the first dimension is one element. The stride of the nth dimension element is the product of the sizes of the lower dimensions.
  - Row-major n-D arrays have their stride of 1 for the highest dimension. Submatrix manipulations are typically accessing a scattered data set in memory, which does not allow for efficient indexing.

C uses row-major format. MATLAB and Simulink use column-major format by default. You can configure the code generation software to generate code with a row-major array

layout. If you are integrating external C code with the generated code, see the considerations listed in this table.

Action	Consider
Configure array layout of the model for code generation.	In the Configuration Parameters dialog box, specify the **Array layout** (Simulink Coder) parameter as `Column-major` or `Row-major`.
Enable efficient row-major algorithms for simulation and code generation.	In the Configuration Parameters dialog box, enable the **Use algorithms optimized for row-major array layout** (Simulink) parameter.
Integrate external C code functions in row-major array layout with the generated code.	Create S-functions that integrate external code functions with the generated code by using: • The SimStruct function `ssSetArrayLayoutForCodeGen`. • The **Array layout** (Simulink) setting in the S-Function Builder block. • The Legacy Code Tool option `convert2DMatrixToRowMajor` in `legacy_code`. Using `convert2DMatrixToRowMajor` impacts code efficiency. Use the C Caller block to call external C functions into Simulink. Specify array layout of custom C functions by using configuration parameter **Default function array layout** (Simulink).

Code Generator Matrix Parameters

The compiled model file, *`model`*`.rtw`, represents matrices as character vectors in MATLAB syntax, without an implied storage format. This format enables you to copy the character vector out of an `.rtw` file, paste it into a MATLAB file, and have MATLAB recognize it.

Column-Major Layout

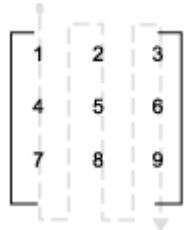
For example, the 3-by-3 matrix in the Constant block

```
    1   2   3
    4   5   6
    7   8   9
```

is stored in *`model`*`.rtw` as

```
Parameter {
      Identifier          "Constant_Value"
      LogicalSrc          P0
      Protected             no
      Value              [1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0]
      CGTypeIdx             18
      ContainerCGTypeIdx      19
      ReferencedBy          Matrix(1,4)
[[0, -1, 0, 0];]
      GraphicalRef          Matrix(1,2)
[[0, 1];]
      BHMPrmIdx              0
      GraphicalSource          [0, 1]
      OwnerSysIdx          [0, -1]
      VarGroupIdx          [1, 0]
      WasAccessedAsVariable   1
    }
```

The *`model`*`_data.c` file declares the actual storage for the matrix parameter. You can see that the format is in column-major layout.



```
Parameters model_P = {
  /* Expression: [ [1,2,3] ; [4,5,6] ;[7,8,9]]
   * Referenced by: '<Root>/Constant  '
   */
```

```
  { 1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0 }
};
```

Row-Major Layout

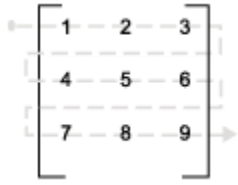
For example, the 3-by-3 matrix in the Constant block

```
    1   2   3
    4   5   6
    7   8   9
```

is stored in *model*`.rtw` as

```
Parameter {
      Identifier          "Constant_Value"
      LogicalSrc          P0
      Protected             no
      Value               [1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0]
      CGTypeIdx             18
      ContainerCGTypeIdx      19
      ReferencedBy          Matrix(1,4)
[[0, -1, 0, 0];]
      GraphicalRef          Matrix(1,2)
[[0, 1];]
      BHMPrmIdx             0
      GraphicalSource         [0, 1]
      OwnerSysIdx          [0, -1]
      VarGroupIdx          [1, 0]
      WasAccessedAsVariable   1
    }
```

The *model*`_data.h` file declares the actual storage for the matrix parameter. You can see that the format is in row-major layout.



```
Parameters model_P = {
  /* Expression: [ [1,2,3] ; [4,5,6] ;[7,8,9]]
   * Referenced by: '<Root>/Constant  '
```

```
   */
  { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0 }
};
```

Internal Data Storage for Complex Number Arrays

Simulink and code generator internal data storage formatting differs from MATLAB internal data storage formatting only in the storage of complex number arrays. In MATLAB, the real and imaginary parts are stored in separate arrays. In Simulink and the code generator, the parts are stored in an interleaved format. The numbers in memory alternate real, imaginary, real, imaginary, and so forth. This convention allows efficient implementations of small signals on Simulink lines, for Mux blocks, and other virtual signal manipulation blocks. For example, the signals do not actively copy their inputs, just the references.

Unsupported Blocks for Row-Major Code Generation

The code generator does not support these blocks for code generation in row-major array layout.

Cross-Release Shared Utility Code Reuse

In this section...

When you generate code for a model, the code generator by default creates shared utility files that the model requires. When you generate code with different releases, the code generators can produce functionally identical shared files that contain some nonfunctional differences. For example, different comments and different coding style. When you use the same release to generate code for different models in different folders, you can also produce shared files with nonfunctional differences. For example, if you specify different `ParenthesesLevel` or `ExpressionFolding` values for the models, the code generator can produce shared files that contain different comments or different coding styles.

Integrated code that includes functionally identical shared files:

- Is more expensive to verify because each shared file requires verification.
- Produces compilation errors if the shared files define duplicate symbols.

If you have an Embedded Coder license, you can avoid these issues by specifying the reuse of shared code from an existing folder, for example, a read-only library of verified code. In this case, the code generator does not create new shared utility files. The build process uses external code or previously generated shared utility code from the folder. An administrator maintains and updates the read-only library.

Workflow to Reuse Shared Utility Code

1. In the **Configuration Parameters > Code Generation > Interface > Advanced parameters > Existing shared code** field, enter the full path to your shared code folder.
2. Verify that the **Configuration Parameters > Diagnostics > Advanced parameters > Use only existing shared code** diagnostic is set to `error` (default).
3. Remove the `slprj` folder or move to a new working folder.
4. Build your model. If you do not see an error, your shared code folder contains the required shared utility files.

5 If files are missing from the existing shared code folder, you see an error. To continue code generation with a locally generated version of the missing shared utility files:

   a Set **Configuration Parameters > Diagnostics > Advanced parameters > Use only existing shared code** to `warning`.

   b Rebuild your model. The code generation process uses a locally generated version of the missing shared utility files.

   c Provide the administrator of the verified code library with your model and information about missing shared utility files. With the model, the administrator generates the required shared utility files. Using `sharedCodeUpdate`, the administrator adds the files to the existing shared code folder.

      If you require reuse of shared code for a component exported from a previous release, provide the administrator with information about the build folder location for the component. The administrator can use `sharedCodeUpdate` to copy the shared code for the component to the existing shared code folder.

   d When the files are available in the existing shared code folder, repeat steps 1–4.

If the shared utility code is generated from library subsystems that are shared across models (Simulink Coder), you cannot reuse the code *across* releases because the code is release-specific—the symbol name and file name mangling includes the release number. The administrator must add the shared utility code generated for each release to the shared code folder.

The `sharedCodeUpdate` function can add files to the shared code folder that have identical content but different file and function names. This behavior is useful when you have different model components that require their own shared utility functions. Although some code is duplicated, the different model components can access the shared utility functions with which they were verified. To force model components to have their own versions of shared utility functions, configure naming rules to insert the model name into shared utility identifiers (Simulink Coder).

Required Editing for Shared Utility Code Reuse

For most shared utility code files, you can specify master copies that you can reuse across releases without modifying the files. With some files, for example, `rtwtypes.h`, and `zero_crossing_types.h`, there are situations where manual editing is required to produce master copies that you can use with generated code from different releases. For example:

- The `rtwtypes.h` file generated by releases up to and including R2013a contains a checksum.

  ```
  /* This ID is used to detect inclusion
     of an incompatible rtwtypes.h */
  #define RTWTYPES_ID_C08S16I32L64N64F0
  ```

  For each version of this `rtwtypes.h` file that you want to include in your integration, copy the corresponding `#define` statement into your master copy of `rtwtypes.h`.
- In R2015a, the zero-crossing definitions moved from `rtwtypes.h` into `zero_crossing_types.h`. To create an `rtwtypes.h` file that is compatible with generated model code from different releases, in your master copy of `rtwtypes.h`, insert this statement.

  ```
  #include "zero_crossing_types.h"
  ```

  Remove definitions from `rtwtypes.h` that `zero_crossing_types.h` provides.

Cross-Release Code Integration

In this section...

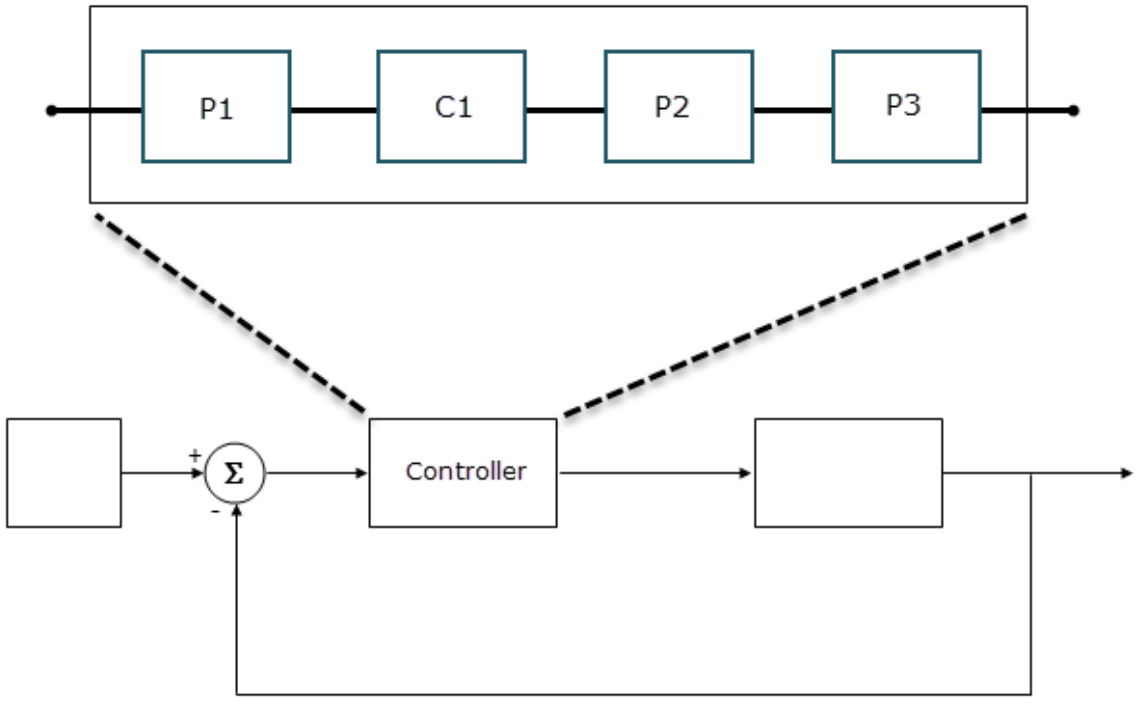
If you have an Embedded Coder license, you can integrate generated C code from previous releases (R2010a and later) with generated code from the current release when the source models are single-rate and the generated C code is from:

- Top-model or subsystem build processes that use the nonreusable function code interface.
- Single or multiple instance model reference build processes that suppress error status monitoring (`SuppressErrorStatus` is `on`).

If you can reuse existing code without modification, you can reduce the cost of reverification.

Workflow

Consider this control system model.



The `Controller` Model block references a model that consists of three components:

- `P1` is a Model block, which references a model developed with a previous release, for example, R2015b. The generated model code, with the standalone code interface, is in the folder `P1_ert_rtw`.
- `C1` is a Model block, which references a model that you are developing in the current release.
- `P2` is a subsystem block developed with a previous release, for example, R2016a. The generated subsystem code is in the folder `P2_ert_rtw`.

- `P3` is a Model block, which references a model developed with a previous release, for example, R2016b. The generated model code, with the model reference code interface, is in the folder `slprj/ert/P3`.

To integrate code from previous releases with generated code from the current release, use this workflow:

1 **Specify an existing shared code folder**

You can specify the reuse of shared code (Simulink Coder) from an existing folder, for example, a library of verified code that an administrator maintains and updates. Specify the shared code folder for model components that require code generation in the current release, for example, `Controller` and `C1`.

In the **Configuration Parameters > Code Generation > Interface > Advanced parameters > Existing shared code** field, enter the full path to the shared code folder.

2 **Import components into current release**

From the current release, import generated component code from previous releases as software-in-the-loop (SIL) blocks or processor-in-the-loop (PIL) blocks. For example:

```
crossReleaseImport(folderPathForP1_ert_rtw,'Controller', ...
'SimulationMode','SIL');
crossReleaseImport(folderPathForP2_ert_rtw,'Controller', ...
'SimulationMode','SIL');
crossReleaseImport(folderPathForP3,'Controller', ...
'SimulationMode','SIL');
```

In the current working folder, the `crossReleaseImport` function creates the `xrel` subfolder that contains software-in-the-loop (SIL) blocks and subfolders:

- `P1_R2015b_sil` and `P1_R2015b_sil_resources`
- `P2_R2016a_sil` and `P2_R2016a_sil_resources`
- `P3_R2016b_sil` and `P3_R2016b_sil_resources`

3 **Incorporate components into current release model**

To replace components with SIL or PIL blocks, use the Simulink Editor or the `pil_block_replace` command. For example, replace:

- `P1` with `P1_R2015b_sil`.

- `P2` with `P2_R2016a_sil`.
- `P3` with `P3_R2016b_sil`.

When you run a model simulation, the simulation runs the previous release code through the SIL or PIL blocks.

When you build the `Controller` model (`rtwbuild('Controller')`), the code generator does not generate new code for the components represented by the SIL or PIL blocks. The model code calls code generated by previous releases.

The Simulink Code Inspector supports call-site validation for a cross-release SIL or PIL block. The block provides a specification of the expected function call, which is derived from the generated code. During analysis, the Simulink Code Inspector compares the expected function call with the block behavior. For information about analysis limitations, see “S-Function” (Simulink Code Inspector).

Limitations

The cross-release code integration workflow does not support:

- Export-function models for ERT code.
- Simulink Function and Function Caller blocks across the boundaries of ERT code generated by different releases.
- The integration of generated code from releases before R2010a.
- The import of generated code from the current release into a previous release (forward compatibility).
- The export of files located in the MATLAB root folder of the previous release, for example, blockset library files.
- The export and import of generated code from models with noninlined S-functions.
- C-API on page 57-2.

At the end of the model build process, the code generation report displays shared files that are directly used by the integration model, for example, `Controller`. The report does not display shared files used by the components of the model, for example, `P1` and `P2`.

If your model has:

- A cross-release SIL or PIL block, you cannot run rapid accelerator mode simulations.
- A Model block that references a model containing a cross-release SIL or PIL block, you cannot run accelerator mode or rapid accelerator mode simulations.

You can run:

- Top-model SIL simulations of models that contain cross-release SIL or PIL blocks. The models must not contain cross-release AUTOSAR Model blocks.
- Model block SIL simulations of referenced models that contain cross-release SIL or PIL blocks. The referenced models must not contain cross-release AUTOSAR Model blocks.

For information about other cross-release AUTOSAR code integration limitations, see “Import AUTOSAR Code from Previous Releases” on page 47-103.

Simulink.Bus Support

To use a bus object as a data type in cross-release ERT code integration, use one of these approaches.

Approach	Code Export	Code Import
Automatic	In the previous release, before generating code, set the `DataScope` property of the `Simulink.Bus` object to `Auto`. Do not assign a value to the `HeaderFile` property. The code generator creates the `Simulink.Bus` data type definition in the default header file on page 48-18, which is located in the code generation folder for the model.	In the current release, before running `crossReleaseImport`, set the `DataScope` property of the `Simulink.Bus` object to `Auto`. When you build the integration model, the build process uses the `Simulink.Bus` data type from the header file in the imported code.

Approach	Code Export	Code Import
Exported bus	In the previous release, before generating code, specify these properties of the `Simulink.Bus` object: • `DataScope` — Set to `Exported`. • `HeaderFile` — Specify a file name, for example, `prevRelBusType`. The code generator creates `prevRelBusType.h` in the shared utility code folder. This header file contains the definition for the `Simulink.Bus` data type. Use `sharedCodeUpdate` to add `prevRelBusType.h` to the shared code folder that `ExistingSharedCode` specifies. For R2010a and R2010b, the `DataScope` property is not available. Do not assign a value to the `HeaderFile` property. The code generator creates the `Simulink.Bus` data type definition in `modelName_types.h`, which is located in the code generation folder for the model.	In the current release, before running `crossReleaseImport`, set the `DataScope` property of the `Simulink.Bus` object to `Imported`. When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the `Simulink.Bus` data type definition in `prevRelBusType.h`. If the imported code is from R2010a or R2010b, specify these properties of the `Simulink.Bus` object: • `DataScope` — Set to `Imported`. • `HeaderFile` — Set to file path for `modelName_types.h`, which is in the imported code folder. When you build the integration model, the build process uses the `Simulink.Bus` data type definition in `modelName_types.h`.

Approach	Code Export	Code Import
Imported bus	In the previous release, before generating code, specify these properties of the `Simulink.Bus` object: • `DataScope` — Set to `Imported`. • `HeaderFile` — Specify a path to a file that contains the `Simulink.Bus` data type definition, for example, `aBusType.h`. For R2010a and R2010b, the `DataScope` property is not available. For the `HeaderFile` property, specify a path to a file that contains the `Simulink.Bus` data type definition, for example, `aBusType.h`.	In the current release, after importing generated code, you do not have to change the `Simulink.Bus`. When you build the integration model that incorporates the imported SIL or PIL block, the build process uses the `Simulink.Bus` data type definition from `aBusType.h`. If the imported code is from R2010a or R2010b, specify these properties of the `Simulink.Bus` object: • `DataScope` — Set to `Imported`. • `HeaderFile` — Set to `aBusType.h`. When you build the integration model, the build process uses the `Simulink.Bus` data type definition in `aBusType.h`.

Root-Level I/O Through Global Variables in Generated Code

When imported ERT code from a previous release implements an input or output port through a global variable, the code that is generated from the integration model depends on the properties of the signal connected to the port in the integration model.

If the integration model signal does not map to a generated code variable that has the same name as the signal in the imported code, the generated code:

- Defines the variable if it is declared but undefined in the imported code.
- Creates additional code to copy data between the variable generated from the integration model and the variable in the imported code.

If the integration model signal maps to a variable with the same name as the signal in the imported code, the variable used by the imported code is also used by the code generated from the integration model. You must use a compatible storage class for the signal.

Storage Class Property	Property Value Support
Type	`Unstructured` only
Data access	Cannot connect a port implemented as a `Pointer` variable in the imported code to a signal of the same name that is implemented through a `Direct` storage class in the integration model Cannot connect a port implemented as a `Direct` variable in the imported code to a signal of the same name that is implemented as a `Pointer` in the integration model

Storage Class Property	Property Value Support

Data scope	If the imported code declares but does not define the variable (i.e. code is generated from a signal that uses the `Imported` value), then one of the following is required:
	• The integration model uses the `Exported` value.
	• External code defines the variable.
	If the imported code defines the variable (i.e. code is generated from a signal that uses the `Exported` value):
	• For signals in the integration model that are connected to root-level I/O ports:
	  • Set the `EnableDataOwnership` configuration parameter to `on`.
	  • Use a custom storage class with these properties:
	  • **Type** – `Unstructured`
	  • **Data access** – `Direct`
	  • **Data scope** – `Exported`
	  • **Owner** – Non-empty value that is not the name of the integration model. For example, the value can be the name of the imported component.
	• For signals in the integration model that are not connected to root-level I/O ports, use a custom storage class with these property values:
	  • **Data scope** - `Imported`
	  • **Data access** - `Direct`

Communicate Between Current and Previous Release Components Through Global Data Stores

Current and previous release components can communicate through global data stores associated with `Simulink.Signal` objects in the MATLAB base workspace or a Simulink data dictionary. The workflow described here applies to cross-release ERT code integration.

Code Generation Configuration

Before generating model component code in the old release, configure data store memory to use a storage class that imports external code.

If a top-model or subsystem build process generates the code, set the **Storage class** property of the `Simulink.Signal` objects to one of these classes:

- `ImportedExtern`
- `ImportedExternPointer`
- `ImportFromFile` custom storage class

If a model reference build process generates the code, you can also use these classes:

- `ExportedGlobal`
- `ExportToFile` custom storage class

Import Configuration

In the current release, before you run `crossReleaseImport`, define a `Simulink.Signal` object in the MATLAB base workspace or a Simulink data dictionary for each global data store of the component that you want to import:

1. For the object name and the **Data type**, **Complexity**, and **Dimensions** object properties, specify values that match values of the corresponding object in the component that you want to import.
2. For the **Storage class** property, specify a value that is compatible. If the previous release value is `ImportedExtern`, specify one of these values for the current release:
   - `ImportedExtern`
   - `ExportedGlobal`

- `ImportFromFile` or `ExportToFile` custom storage class.

If the previous release value is `ImportedExternPointer`, then specify `ImportedExternPointer` for the current release.

3. For the **Alias** property, specify a matching value only if the property is specified for the object in the component that you want to import.
4. Save the `Simulink.Signal` objects. The objects are required each time you simulate or build the imported SIL or PIL block.

For more information, see "Data Stores in Generated Code" (Simulink Coder).

Parameter Tuning

The cross-release ERT code integration workflow supports parameter tuning in an integration model that contains component code with tunable parameters from previous releases.

In the current release, before you run `crossReleaseImport`, for each tunable parameter of the component that you want to import:

1. Define a `Simulink.Parameter` object in the MATLAB base workspace or a Simulink data dictionary.
2. For the object name and the **Data type**, **Complexity**, and **Dimensions** object properties, specify values that match the previous release object values. If the variable in the imported source code does not have the same name as the object, for the **Alias** property, specify a value that matches the variable name.
3. If the previous release object uses the `GetSet` custom storage class, specify:

   - A matching value for the **Storage class** object property.
   - The header file that defines the `get` and `set` access functions. For details, see "Control Data Representation by Configuring Custom Storage Class Properties" on page 36-40 and "Access Data Through Functions with Custom Storage Class GetSet" on page 36-51.

   Support of the `GetSet` custom storage class from a previous release applies only for R2011a and later releases.

For code generated by a top-model or subsystem build process in a previous release, these limitations apply:

- If a tunable parameter specified by a `Simulink.Parameter` object in the previous release has storage class set to `ExportedGlobal` and the storage class of the `Simulink.Parameter` object in the current release is also `ExportedGlobal`, an error occurs when you build the integration model.
- On a Mac operating system, if a tunable parameter specified by a `Simulink.Parameter` object in the previous release has storage class set to `ExportedGlobal`, you cannot build the integration model if the storage class of the `Simulink.Parameter` object in the current release (with the same name or alias) is `ImportedExtern`. To work around this limitation, modify the default settings:

  1. Get the build tool from the default toolchain.

     ```
     tc = coder.make.getDefaultToolchain;
     cComp = tc.getBuildTool('C Compiler');
     ```

  2. Extract the C compiler standard options.

     ```
     stdMaps = cComp.SupportedStandard.getLangStandardMaps;
     optionValues = stdMaps.getCompilerOptions('*');
     ```

  3. Remove `-fno-common` from the standard options for the C and C++ compilers.

     ```
     optionToRemove = '-fno-common';
     optionsToKeep = strrep(optionValues, optionToRemove, '');
     c_standard_opts_id = '$(C_STANDARD_OPTS)';

     custToolChainOpts = get_param(model,'CustomToolchainOptions');
     custToolChainOpts{2} = ...
        strrep(custToolChainOpts{2}, c_standard_opts_id, optionsToKeep);

     set_param(model, 'CustomToolchainOptions',custToolChainOpts);
     ```

Use Multiple Instances of Code Generated from Reusable Referenced Model

Using a reusable referenced model, you can specify unique model argument values (Simulink) for each instance of the referenced model in a parent model. Import previously generated code for the reusable referenced model into the current release as a parameterized cross-release SIL or PIL block, and then insert multiple instances of the block into an integration model. For each block instance, you can specify unique model argument values.

1. Update existing shared code folder.

   ```
   sharedCodeUpdate(sourceFolder,destinationFolder)
   ```

2. Import generated code for the reusable referenced model into the current release as a parameterized cross-release block, for example, a SIL block.

```
handleSILBlock = crossReleaseImport(reusableReferencedModelcodeLocation, ...
 configSetIntegrationModel, 'SimulationMode', 'SIL');
```

3. In the integration model, replace, for example, two instances of the referenced model with instances of the cross-release SIL block.

```
open_system(integrationModel);

blockInstanceName1 = 'refModelInstanceName1';
blockinstanceName2 = 'refModelInstanceName2';

SILBlockFullName = getfullname(handleSILBlock);
replace_block(integrationModel, 'Name', blockInstanceName1, ...
              SILBlockFullName, 'noprompt');
replace_block(integrationModel, 'Name', blockInstanceName2, ...
              SILBlockFullName, 'noprompt');
```

4. Suppose the reusable referenced model has model arguments *paramA* and *paramB*, and the values for the referenced model instances, *refModelInstanceName1* and *refModelInstanceName2*, are workspace variables. In this case, you can specify argument values for the cross-release block instances that are workspace variables.

```
pathToBlockInstanceName1 = [integrationModel, '/', blockInstanceName1];
pathToBlockInstanceName2 = [integrationModel, '/', blockInstanceName2];

set_param(pathToBlockInstanceName1, 'paramA', 'paramA_instName1');
set_param(pathToBlockInstanceName1, 'paramB', 'paramB_instName1');

set_param(pathToBlockInstanceName2, 'paramA', 'paramA_instName2');
set_param(pathToBlockInstanceName2, 'paramB', 'paramB_instName2');
```

5. To specify unique model argument values for the block instances in the integration model, assign values to the workspace variables, *paramA_instName1*, *paramB_instName1*, *paramA_instName2*, and *paramB_instName2*.

Compare Simulation Behavior of Model Component in Current Release and Generated Code from Previous Release

In a previous release, suppose that you developed a model component, generated code for the component, and tested and deployed the generated code. Now, in the current release, you want to add features to the model component and use the model component in system

development and code generation. Before you proceed, you can compare the functional behavior of the model component and the generated code from the previous release.

To test the numerical equivalence between the model component and the generated code from the previous release, use Simulink Test. With the Test Manager (Simulink Test), you can perform back-to-back tests and output comparisons:

1. Bring the model component into the current release as a Model block with the **Simulation mode** block parameter set to `Normal`.
2. With the Model block, create a top model that specifies test input data.
3. Import the code generated in the previous release into the current release as a SIL block.
4. With the SIL block, create another top model that specifies the same the test input data.
5. In the Test Manager, create an equivalence test case that runs simulations of the top models and compares outputs.
6. Run the test case and review results.

For more information, see “Test Two Simulations for Equivalence” (Simulink Test).

Note If you want to compare the behavior of generated code from the current and previous release, in step 1, specify these Model block parameters:

- Set **Simulation mode** to `Software-in-the-loop (SIL)` or `Processor-in-the-loop (PIL)`.
- Set **Code interface** to `Top model`.

Import AUTOSAR Code from Previous Releases

If you install the Embedded Coder Support Package for AUTOSAR Standard, you can import into the current release AUTOSAR component code that you generated in a previous release.

When you run `crossReleaseImport`, the function imports the AUTOSAR code as a cross-release Model block instead of a SIL or PIL block. The **Simulation mode** parameter of the Model block is set to `Software-in-the-loop (SIL)` or `Processor-in-the-loop (PIL)`. Incorporate the Model block into the current release model.

These limitations apply:

- The cross-release workflow does not support per-instance memory that accesses NVRAM.
- Tunable parameters must be mapped to AUTOSAR calibration parameters or AUTOSAR internal calibration parameters.
- If the original model uses variants or symbolic dimensions (dimension variants), the imported model can use only the same variant and symbolic dimension configuration that was used when generating the code in the previous release.

Integration of Code from Multiple Folders

To help you to integrate generated code from multiple code generation folders, this table provides information about actions you can take.

Action	Information	Type of Integration Supported
Use consistent configuration parameters across models	If you want to integrate a group of models, aim to use a configuration set that is consistent across the models. For each model, you can create a hash table from the shared utilities checksum file, `checksummap.mat`. The key-value pairs in the hash table give you information about model parameters. This information can help you to determine the parameter values that you must use across the models. For more information, see “Manage the Shared Utility Code Checksum” on page 6-72 To determine whether parameter values are consistent across the models, for each model, you can run checks for compliance with modeling guidelines that specify parameter values. For more information, see “Model Advisor Checks for High-Integrity Modeling Guidelines” (Simulink). You can specify the same configuration parameters for a group of models. For example, for each model, use a configuration reference to access the same configuration set from a data dictionary. When you use the same configuration set, the generated data types for each model are the same and the corresponding `rtwtypes.h` files are equivalent except for comments. To integrate code from the different models, you can choose a single `rtwtypes.h` file. For more information, see:	Same-release, cross-release

Action	Information	Type of Integration Supported
	• "About Configuration References" (Simulink) • "What Is a Data Dictionary?" (Simulink)	
Reuse shared utility code	You can reuse data and functions across software components by specifying a shared utilities folder for your models. Set **Configuration Parameters > Code Generation > Interface > Shared code placement** to `Shared location`. If you want software components to share a utilities folder, generate code from a common working folder or specify the same code generation folder through the file generation control parameter, `CodeGenFolder`. For more information, see "Manage Build Process Folders" on page 47-37. Identically-named utility files generated in different releases are functionally equivalent even if file style or comments differ. For cross-release code integration, you can use the `ExistingSharedCode` parameter to specify the reuse of shared utility code from an existing folder. For more information, see: • "Workflow to Reuse Shared Utility Code" on page 47-87 • "Existing shared code"	Same release, cross-release

Action	Information	Type of Integration Supported
Avoid generated header file updates	In general, when you build a model, existing header files (and source files) in the `_sharedutils` or `_shared` folder are not regenerated. However, there are instances when the code generator overwrites existing header files in the folder. The table in "Code Generator Header Files" on page 47-57, which describes header file generation dependencies, provides information about how you can avoid overwriting some header files, for example, `rtwtypes.h` and `multiword_types.h`. For more information, see: • "Build Process Folders" on page 47-40 • "Control Placement of rtwtypes.h for Shared Utility Code" on page 6-70	N/A
Use cross-release SIL or PIL block	You can use the cross-release SIL or PIL block to integrate generated code from previous releases (R2010a and later) with generated code from the current release. For more information, see "Cross-Release Code Integration" on page 47-90.	Same release, cross-release

Action	Information	Type of Integration Supported
Use CRL and `ExistingSharedCode`	You can use the code replacement library (CRL) and `ExistingSharedCode` parameter approaches either separately or jointly: • The CRL approach supports customization of code generation and eliminates the generation of some shared utility files. You must manage the use of utility files that are not replaced by CRL. For more information, see “Develop a Code Replacement Library” on page 65-27. • The `ExistingSharedCode` approach, which is based on previously generated utility files, also supports customization and suppresses regeneration of utility files. If customization is not required, the `ExistingSharedCode` approach is simpler to set up and manage. For more information, see “Cross-Release Shared Utility Code Reuse” on page 47-87.	Same release, cross-release

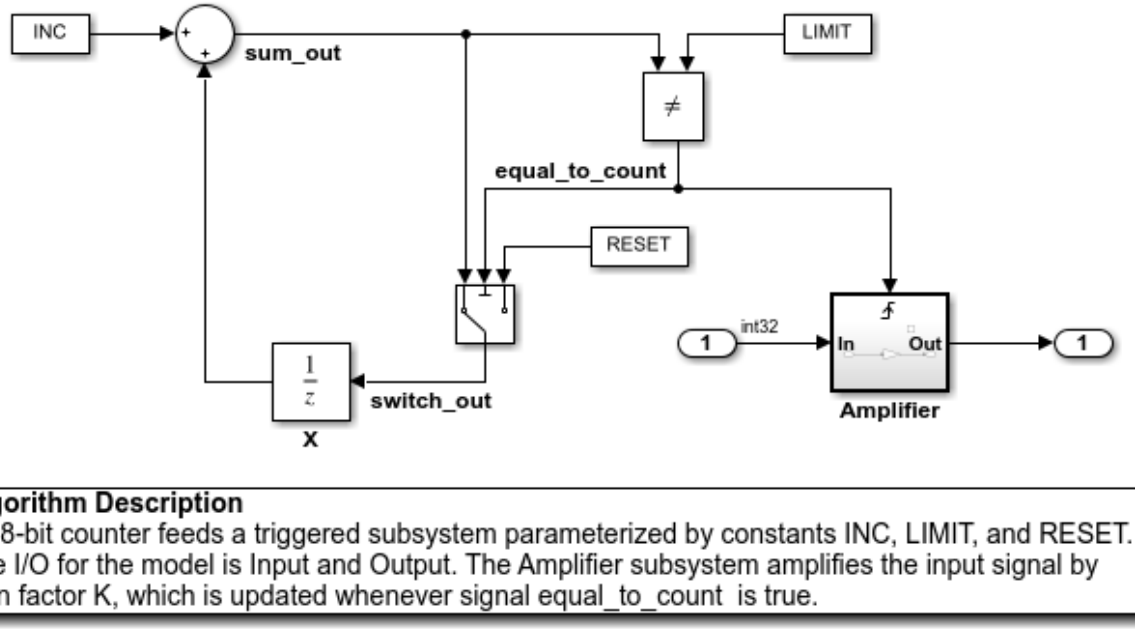
Generate Code Using Simulink® Coder™

This example shows how to select a system target file for a Simulink® model, generate C code for real-time simulation, and view generated files.

The model represents an 8-bit counter that feeds a triggered subsystem that is parameterized by constant blocks `INC`, `LIMIT`, and `RESET`. `Input` and `Output` represent I/O for the model. The `Amplifier` subsystem amplifies the input signal by gain factor `K`, which updates when signal `equal_to_count` is `true`.

1. Open the model. For example, type the following commands at the MATLAB® command prompt.

```
model='rtwdemo_rtwintro';
open_system(model)
```

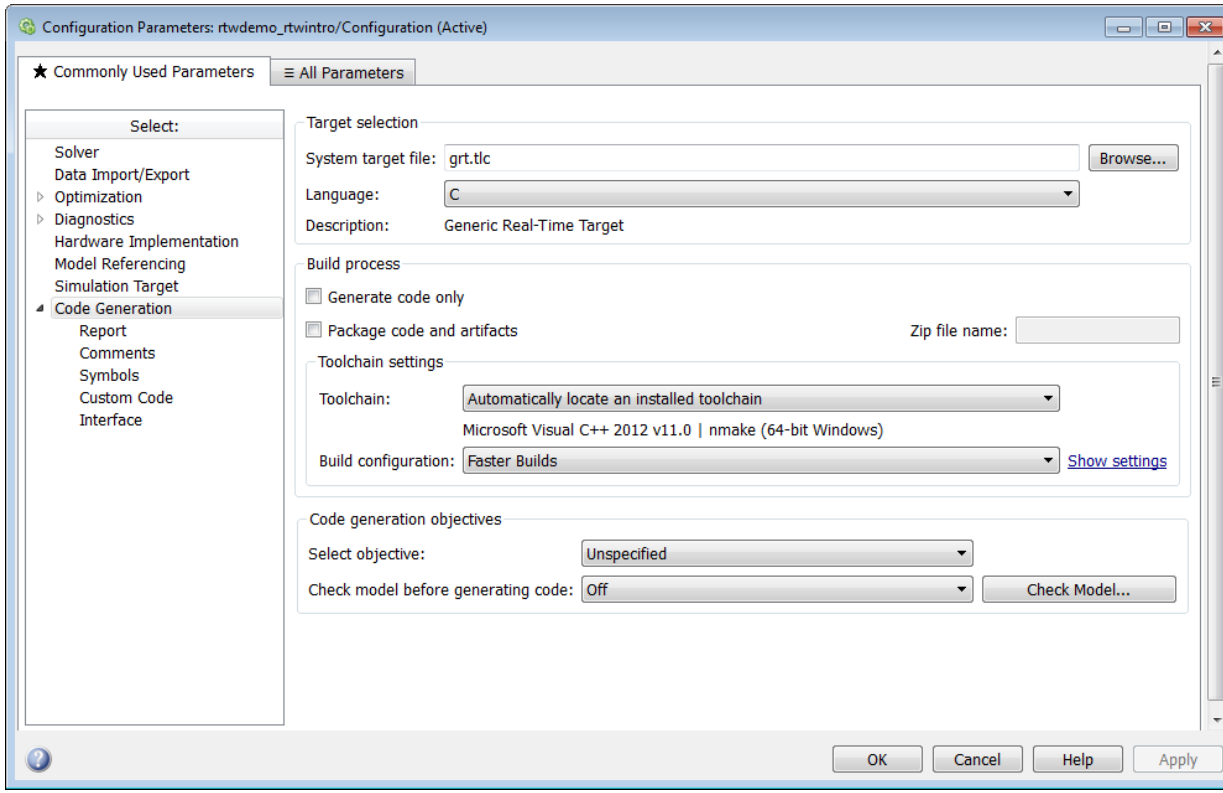


2. Open the Configuration Parameters dialog box from the model editor by clicking **Simulation > Configuration Parameters**.

Alternately, type the following commands at the MATLAB® command prompt.

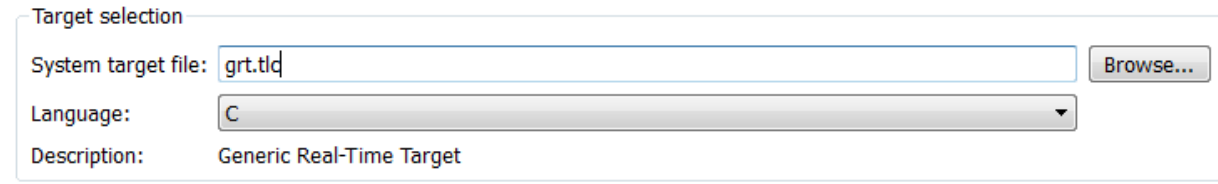
```
cs = getActiveConfigSet(model);
openDialog(cs);
```

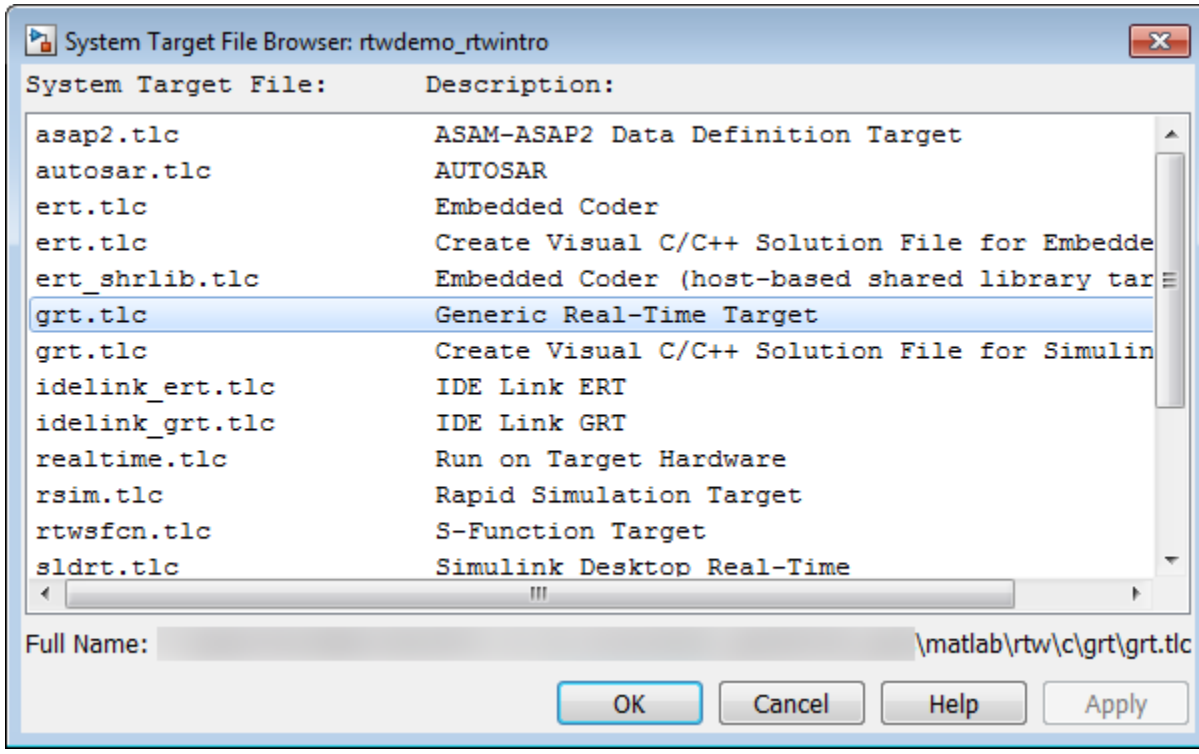
3. Select the **Code Generation** node.



4. In the **Target Selection** pane, click **Browse** to select a target.

You can generate code for a particular target environment or purpose. Some built-in targeting options are provided using system target files, which control the code generation process for a target.





5. Select the **Generic Real-Time (GRT)** target and click **Apply**.

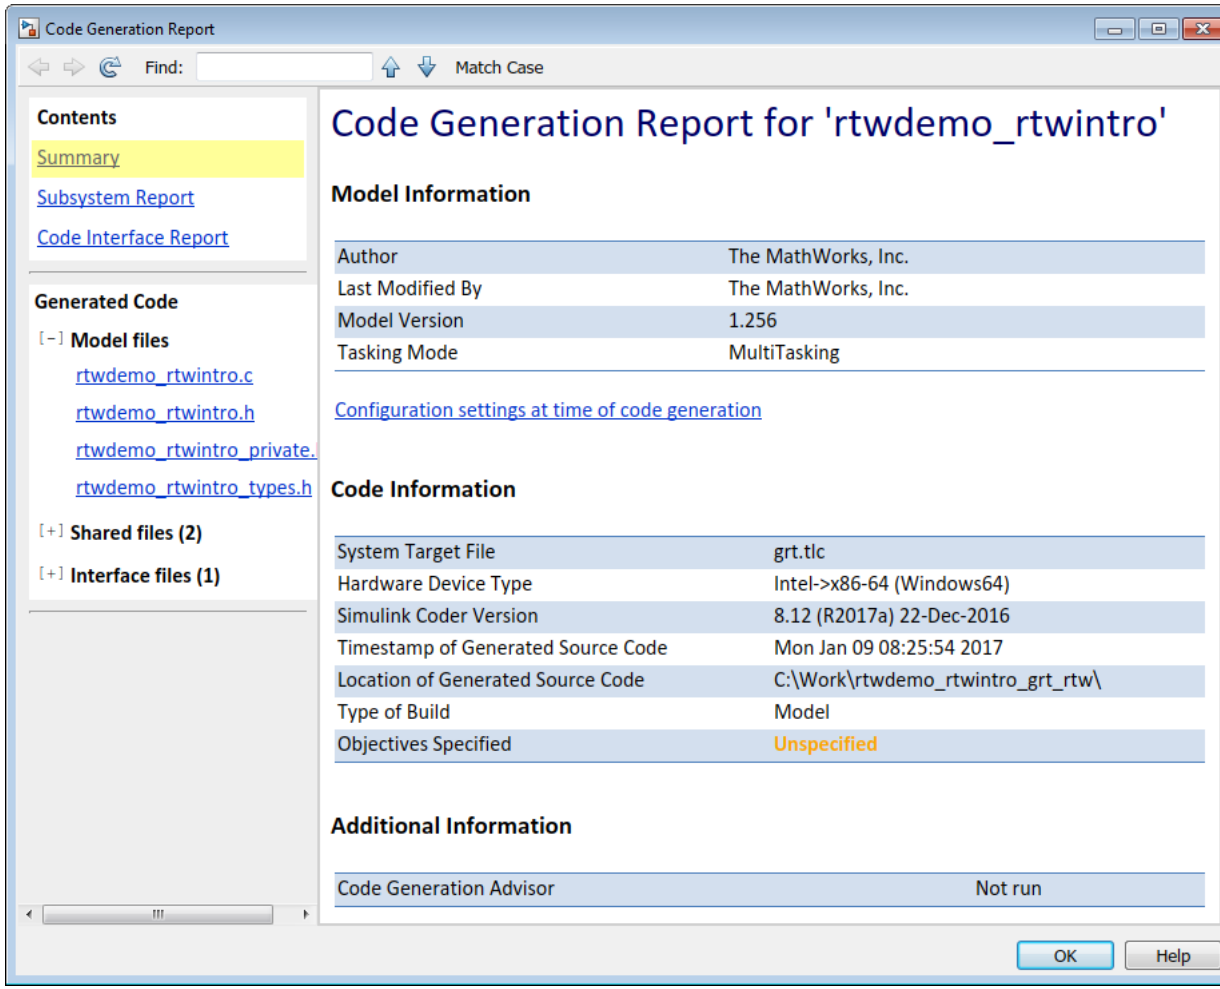
Optionally, in the **Code Generation Advisor** pane set the **Select objective** field to **Execution efficiency** or **Debugging**. Then click **Check model...** to identify and systematically change parameters to meet your objectives.

6. In the model window, initiate code generation and the build process for the model by using any of the following options:

- Click the Build Model button.
- Press **Ctrl+B**.
- Select **Code > C/C++ Code > Build Model**.
- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

7. View the code generation report that appears.

The report includes links to model files such as `rtwdemo_rtwintro.c` and associated utility and header files.



The figure below contains a portion of `rtwdemo_rtwintro.c`

Step function for model: rtwdemo_rtwintro

File: rtwdemo_rtwintro.c

```
1   /* Model step function */
2   void rtwdemo_rtwintro_step(void)
3   {
4     uint8_T rtb_sum_out;
5     boolean_T rtb_equal_to_count;
6
7     /* Sum: '<Root>/Sum' incorporates:
8      *  Constant: '<Root>/INC'
9      *  UnitDelay: '<Root>/X'
10     */
11    rtb_sum_out = (uint8_T)(1U + (uint32_T)rtwdemo_rtwintro_DWork.X);
12
13    /* RelationalOperator: '<Root>/RelOpt' incorporates:
14     *  Constant: '<Root>/LIMIT'
15     */
16    rtb_equal_to_count = (rtb_sum_out != 16);
17
18    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
19     *  TriggerPort: '<S1>/Trigger'
20     */
21    if (rtb_equal_to_count && (rtwdemo_rtwintro_PrevZCSigState.Amplifier_Trig_ZCE
22          != POS_ZCSIG)) {
23      /* Outport: '<Root>/Output' incorporates:
24       *  Gain: '<S1>/Gain'
25       *  Inport: '<Root>/Input'
26       */
27      rtwdemo_rtwintro_Y.Output = rtwdemo_rtwintro_U.Input << 1;
28    }
29
30    rtwdemo_rtwintro_PrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)
31      (rtb_equal_to_count ? (int32_T)POS_ZCSIG : (int32_T)ZERO_ZCSIG);
32
33    /* End of Outputs for SubSystem: '<Root>/Amplifier' */
34
35    /* Switch: '<Root>/Switch' */
36    if (rtb_equal_to_count) {
37      /* Update for UnitDelay: '<Root>/X' */
38      rtwdemo_rtwintro_DWork.X = rtb_sum_out;
39    } else {
40      /* Update for UnitDelay: '<Root>/X' incorporates:
41       *  Constant: '<Root>/RESET'
42       */
43      rtwdemo_rtwintro_DWork.X = 0U;
44    }
45
46    /* End of Switch: '<Root>/Switch' */
47  }
```

8. Close the model.

```
bdclose(model)
rtwdemoclean;
```

Source Code Generation in Embedded Coder

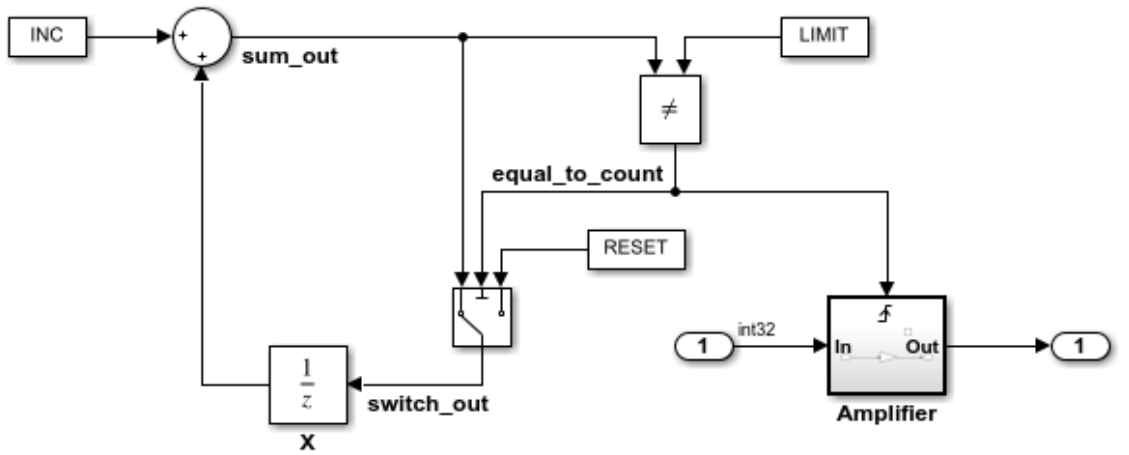
Generate Code Using Embedded Coder®

This example shows how to select a target for a Simulink® model, configure options, generate C code for embedded systems, and view generated files.

The model represents an 8-bit counter that feeds a triggered subsystem that is parameterized by constant blocks `INC`, `LIMIT`, and `RESET`. `Input` and `Output` represent I/O for the model. The `Amplifier` subsystem amplifies the input signal by gain factor `K`, which updates when signal `equal_to_count` is `true`.

1. Open the model.

```
model='rtwdemo_rtwecintro';
open_system(model)
```

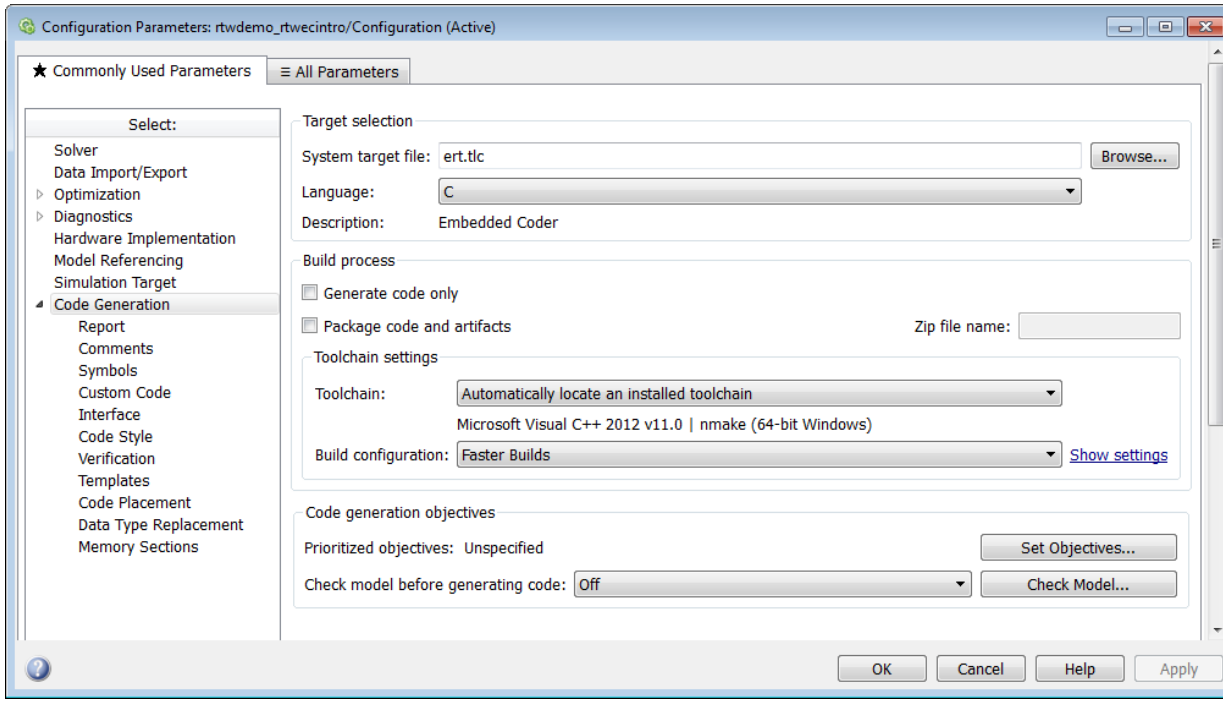


2. Open the **Configuration Parameters** dialog box from the model editor by clicking **Simulation > Model Configuration Parameters**.

Alternately, type the following commands at the MATLAB® command prompt.

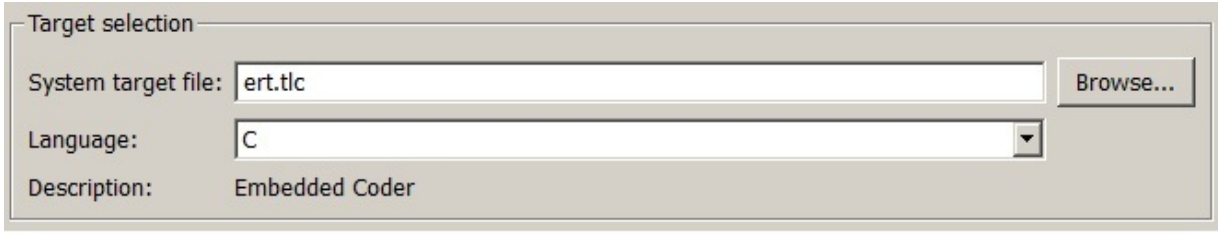
```
cs = getActiveConfigSet(model);
openDialog(cs);
```

3. Select the **Code Generation** node.

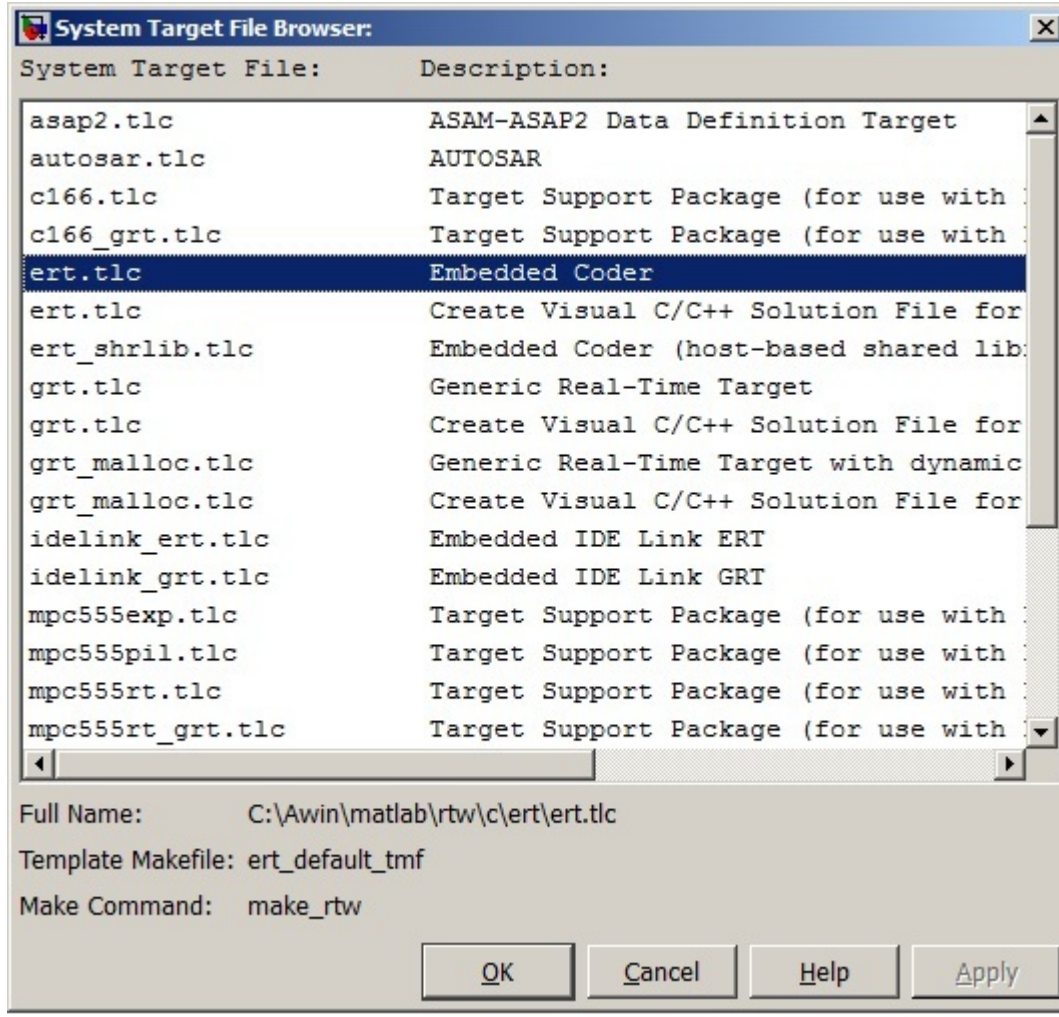


4. In the **Target Selection** pane, click **Browse** to select a target.

You can generate code for a particular target environment or purpose. Some built-in targeting options are provided using system target files, which control the code generation process for a target.



Target selection
System target file:
ert.tlc
Browse...
Language:
C
Description:
Embedded Coder

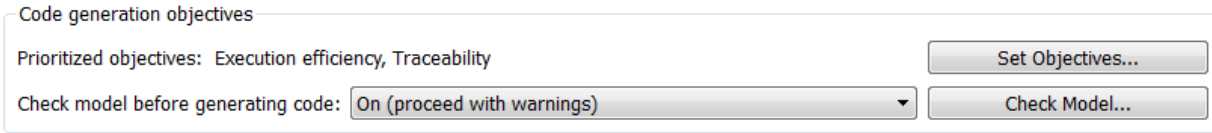


5. Select the **Embedded Real-Time (ERT)** target and click **Apply**.

The ERT target includes a utility to specify and prioritize code generation settings based on your application objectives.

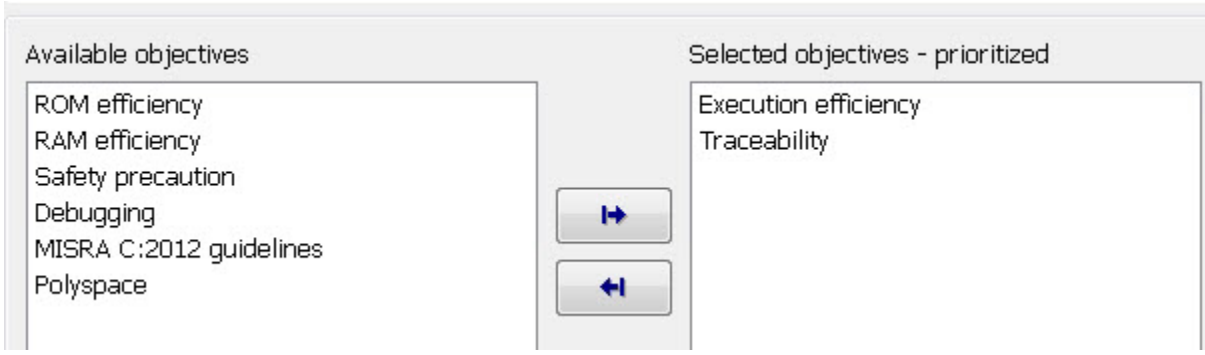
6. In the **Code Generation Advisor** pane, click **Set Objectives**.

You can set and prioritize objectives for the generated code. For example, while code traceability might be a very important criterion for your application, you might not want to prioritize it at the cost of code execution efficiency.



7. In the **Set Objectives** pane, select **Execution efficiency** and **Traceability**. Click **OK**.

You can select and prioritize a combination of objectives before generating code.

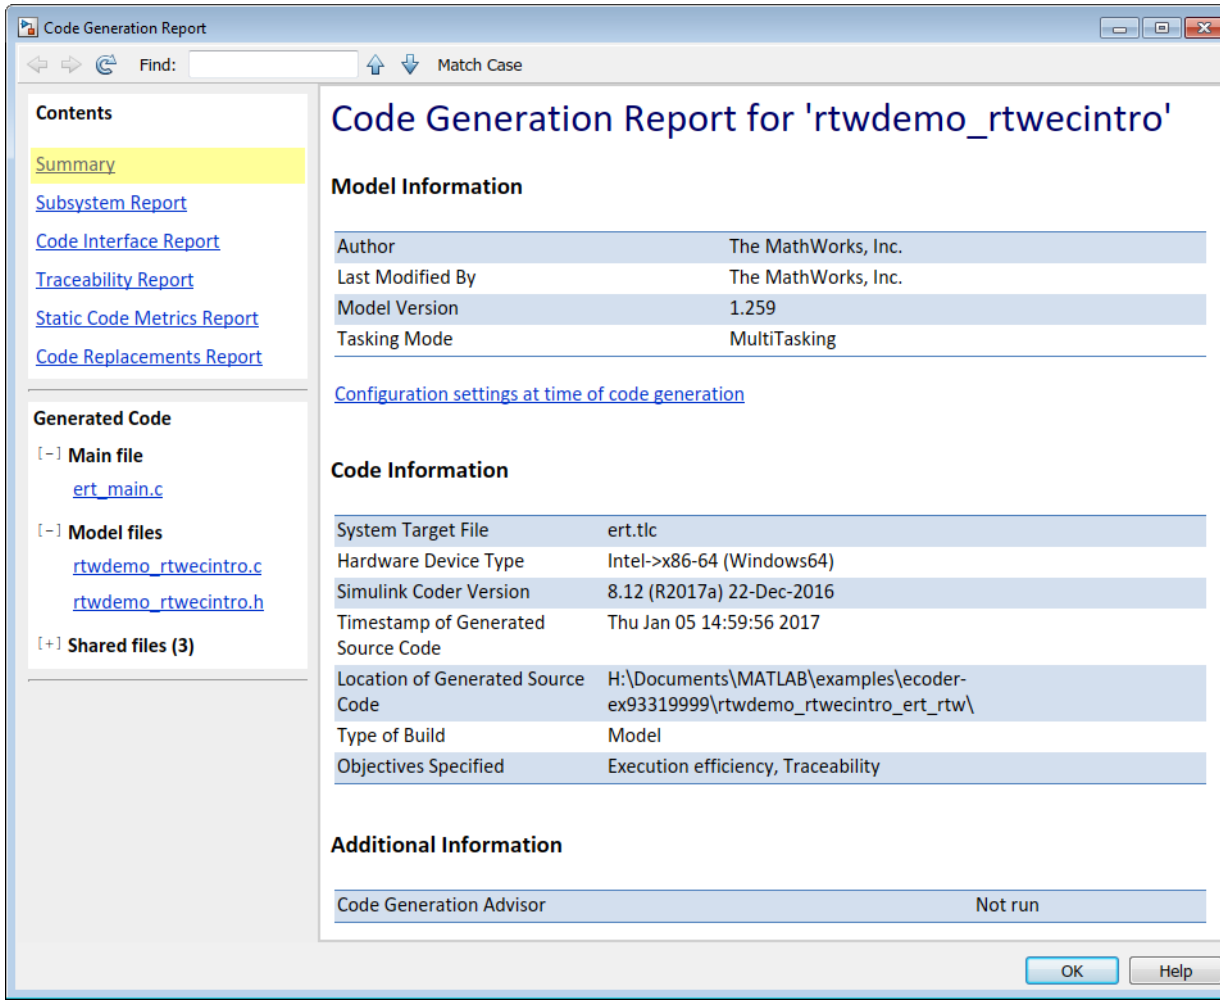


8. In the model window, initiate code generation and the build process for the model by using any of the following options:

- Click the Build Model button.
- Press **Ctrl+B**.
- Select **Code** > **C/C++ Code** > **Build Model**.
- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

9. View the code generation report that appears.

The report includes `rtwdemo_rtwecintro.c`, associated utility and header files, and traceability and validation reports.



The figure below contains a portion of `rtwdemo_rtwecintro.c`

Step function for model: rtwdemo_rtwecintro

File: rtwdemo_rtwecintro.c

```
1   /* Model step function */
2   void rtwdemo_rtwecintro_step(void)
3   {
4     boolean_T rtb_equal_to_count;
5
6     /* Sum: '<Root>/Sum' incorporates:
7      *  Constant: '<Root>/INC'
8      *  UnitDelay: '<Root>/X'
9      */
10    rtDWork.X = (uint8_T)(1U + (uint32_T)rtDWork.X);
11
12    /* RelationalOperator: '<Root>/RelOpt' incorporates:
13     *  Constant: '<Root>/LIMIT'
14     */
15    rtb_equal_to_count = (rtDWork.X != 16);
16
17    /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
18     *  TriggerPort: '<S1>/Trigger'
19     */
20    if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
21    {
22      /* Outport: '<Root>/Output' incorporates:
23       *  Gain: '<S1>/Gain'
24       *  Inport: '<Root>/Input'
25       */
26      rtY.Output = rtU.Input << 1;
27    }
28
29    rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
30      POS_ZCSIG : (int32_T)ZERO_ZCSIG);
31
32    /* End of Outputs for SubSystem: '<Root>/Amplifier' */
33
34    /* Switch: '<Root>/Switch' */
35    if (!rtb_equal_to_count) {
36      /* Update for UnitDelay: '<Root>/X' incorporates:
37       *  Constant: '<Root>/RESET'
38       */
39      rtDWork.X = 0U;
40    }
41
42    /* End of Switch: '<Root>/Switch' */
43  }
```

10. Close the model.

```
bdclose(model)
rtwdemoclean;
```

Generate Code by Using the Quick Start Tool

The Quick Start tool helps you prepare a model for generating readable, efficient code. To start the tool, from the model window, select **Code > C/C++ > Embedded Coder Quick Start**.

After you start the tool, you must answer these questions about the code that you want to generate:

- What is the model or subsystem for code generation?
- What is the type of code output for your generated code?
- Does your application require reentrant, multi-instance code?
- What is the target hardware processor type?
- What is your primary code generation objective?

The tool validates your choices against the model and presents the parameter changes required to generate code. If you choose to generate code, the tool applies the changes to your configuration set and generates the code. After code generation, you can view the code generation report and find information on building, customizing, optimizing, and packaging the code. To further customize your generated code, click **Finish** and you are immediately brought into the Code Perspective environment in the editor window. The Code Perspective provides the tools to control the names and representation of the model data and functions in the generated code. For more information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 31-2.

Quick Start Model Analysis

At each step of the quick start process, the tool validates your model against your selections. The tool determines if there are model conditions that prevent you from proceeding with code generation. During the analysis step, the tool must also examine your model or subsystem for answers to the following questions. The answers help determine the best configuration for the deployment of your code.

How many sample rates are in your system?

The Quick Start tool evaluates your model to determine the number of periodic sample rates in your system.

Single rate	Your model has only one periodic sample rate. The generated code has a single-entry point function that runs at the time interval of the sample rate.
Multirate	Your model has more than one periodic sample rate. It is possible that the generated code does not execute at the same time intervals. After the analysis step, you can choose to generate a single-entry point function for each of the sample rates or generate a different entry point function for each sample rate. If you choose to generate multitasking code, the code generator produces multiple entry-point functions. These functions run as multiple tasks. Each entry-point function is called at an interval defined by the sample rate that is configured in the model.

Note If your model contains an asynchronous rate, an additional entry-point function is generated to run at the specific interrupt time.

For more information about sample rates, see “Time-Based Scheduling and Code Generation” (Simulink Coder).

Does your system contain continuous states?

The Quick Start tool evaluates your model for continuous blocks to determine the correct solver to use.

No	If your system does not contain continuous states, the Quick Start tool configures your model to use a fixed-step discrete solver for code generation if you have not selected one.
Yes	If your system does contain continuous states, the Quick Start tool configures your model to use a fixed-step continuous solver for code generation if you have not selected one. The tool also selects the `SupportContinuous` configuration parameter.

For more information on solvers, see “Solver Types” (Simulink).

Did you configure your system for export function calls?

The Quick Start tool evaluates your model to see if scheduler code must be generated.

No	If you did not configure your system for export function calls, the generated code includes code for the system algorithm and the scheduler code.
Yes	If you configured your system for export function calls, the generated code includes code for the system algorithm. You can manually write the scheduler code or generate it from other models.

For more information, see “Export-Function Models” (Simulink).

Does your system contain referenced models?

The Quick Start tool evaluates your model to see if it depends on code from other models.

No	If your system does not contain referenced models, the generated code does not depend on code from other models.
Yes	If your system contains referenced models, the generated code for your model depends on other modules generated from referenced models. The code generator can optimize the generated code because it is aware of the relationship between your model and the referenced models.

For more information, see “Code Generation of Referenced Models” (Simulink Coder).

Configuration Parameter Changes for Models with a Configuration Reference

To apply configuration parameter changes to a model with an active configuration reference, the Quick Start tool:

- Creates a `Simulink.ConfigSet` object, `QuickStart_`*`timestamp`*, in the workspace or data dictionary that contains the original configuration set. The new object is a copy of the original configuration set that has the parameter changes applied.
- Creates a `Simulink.ConfigSetRef` object that points to the new configuration set object.
- Attaches the new configuration reference to the model and makes it the active configuration.

To restore the original configuration set, activate the original `Simulink.ConfigSetRef` object.

Note If the Quick Start tool creates the configuration set object in the MATLAB workspace, you must save it to preserve the configuration set after the MATLAB session ends. For more information, see “Save a Configuration Set” (Simulink).

Next Steps

After you have generated code by using Quick Start, possible next steps are:

- “Open Code Generation Report” on page 49-9
- “Code Appearance”
- “Build Process”
- “Application Objectives Using Code Generation Advisor” (Simulink Coder)
- “Manage a Configuration Set” (Simulink)
- “Configure Model and Generate Code” (Simulink Coder)
- “Relocate Code to Another Development Environment” (Simulink Coder)

To control the names and representation of the model data and functions in the generated code, use the Code Perspective in the Simulink Editor. When you are done with Quick Start and you click **Finish**, you are immediately brought into the Code Perspective environment in the editor window. To enter the perspective from outside of the Quick Start tool, in the model window, select **Code > C/C++ Code > Configure Model in Code Perspective**. For more information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 31-2.

Manage File Packaging of Generated Code Modules

The code generator produces code modules. The file packaging configuration controls where the code generator places code into code modules and header files.

To locate and examine the generated code files, use the HTML code generation report. The code generation report provides hyperlinks in the comments that you click to view the generated code in the MATLAB Help browser. For more information, see “Traceability in Code Generation Report” on page 75-3.

In this section...

Generated Code Modules

The code generator creates a build folder in your working folder to store generated source code. The build folder contains object files, a makefile, and other files created during the code generation process. The default name of the build folder is *model*_ert_rtw.

Code Modules and Header Files Affected by File Packaging summarizes the structure of source code that the code generator produces.

You can customize the generated set of files in several ways:

- File packaging formats: Manage the number of source files generated for your model. In the Configuration Parameter dialog box, on the **Code Generation > Code Placement** pane, specify the **File packaging format** parameter. For more information, see “Customize Generated Code Modules” on page 48-18.
- Nonvirtual subsystem code generation: Instruct the code generation software to generate separate functions within separate code files for nonvirtual subsystems. You can control the names of the functions and of the code files. For further information, see “Control Generation of Functions for Subsystems” (Simulink Coder).
- Custom storage classes: Use custom storage classes to partition generated data structures into different files based on file names that you specify. For further

information, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28.

- Module Packaging Features (MPF): Direct the generated code into a required set of `.c` or `.cpp` and `.h` files, and control the internal organization of the generated files. For details, see “Data, Function, and File Configuration”.

Code Modules and Header Files Affected by File Packaging

File	Description
model.c or .cpp	Contains entry points for code implementing the model algorithm (for example, *model*_step, *model*_initialize, and *model*_terminate).
*model*_private.h	Contains local macros and local data that the model and subsystems require. This file is included in the model.c file as a #include statement. You do not need to include *model*_private.h when interfacing handwritten code to the generated code of a model.
model.h	Declares model data structures and a public interface to the model entry-points and data structures. Provides an interface to the real-time model data structure (*model*_M) with accessor macros. The code generator: • Produces a separate header file for each Simulink Function block in a model. • Includes *model*.h in the subsystem .c or .cpp files of a model. If you interface handwritten code to generated code for one or more models, include *model*.h for each of those models.
*model*_data.c or .cpp	Contains (if conditionally generated) the declarations for the parameters data structure, the constant block I/O data structure, and any zero representations for the model structure data types. If the model does not use these data structures and zero representations, *model*_data.c or .cpp is not generated. These structures and zero representations are declared extern in *model*.h.
*model*_types.h	Provides forward declarations for the real-time model data structure and the parameters data structure. Function declarations of reusable functions can require these declarations. Provides type definitions for user-defined types that the model uses.
rtwtypes.h	Defines data types, structures, and macros required by generated code. For more information, see “Control Placement of rtwtypes.h for Shared Utility Code” (Simulink Coder).

File	Description
`multiword_types.h`	Contains type definitions for wide data types and their chunks. File is generated when multiword data types are used or when you select one or more of these configuration parameters: • **MAT-file logging** • **Code Generation > Interface > External mode**
`model_reference_types.h`	Contains type definitions for timing bridges. File is generated for a model reference target or a model containing model reference blocks.
`builtin_typeid_types.h`	Defines an enumerated type corresponding to built-in data types. File is generated when your model contains a Stateflow chart that uses messages or when you select one or more of these configuration parameters: • **MAT-file logging** • Any C API option at **Code Generation > Interface**
`zero_crossing_types.h`	Contains zero-crossing definitions for models with triggered subsystems where the trigger is `rising`, `falling`, or `either`. File is generated only if required by the model.
`ert_main.c` or `.cpp`	(optional file) If the **Generate an example main program** option is on (default), this file is generated. For more information, see "Generate an example main program".
`rtmodel.h`	(optional file) If the **Generate an example main program** option is off, this file is generated. For more information, see "Generate an example main program". Contains `#include` directives required by the `rt_main.c` or `rt_cppclass_main.cpp` static main program module. Includes `rtmodel.h` to access model-specific data structures and entry points, because the static main program module is not created at code generation time. For more information, see "Static Main Program Module" on page 63-11.

File	Description
*model*_capi.c or .cpp *model*_capi.h	(optional file) Provides data structures that enable a running program to access model signals, states, and parameters without external mode. To learn how to generate and use the *model*_capi.c or .cpp and .h files, see "Exchange Data Between Generated and External Code Using C API" (Simulink Coder).

User-Written Code Modules

Code that you write to interface with generated model code usually includes a customized main module. Base this module on a main program provided by the code generation software. This customized main module can also include interrupt handlers, device driver blocks and other S-functions, and other supervisory or supporting code. Steps to set up the development environment to support a customized main module include:

1. Establish a working folder for your own code modules.
2. Put your working folder on the MATLAB path.
3. At minimum, inform the build process about the location of your source and object files with **Additional build information** in the **Code Generation > Custom Code** pane.
4. Your development process could require generating code for a particular microprocessor or development board and deploying the code on target hardware with a cross-development system. To accomplish these goals, make more extensive modifications to the ERT-based system target file.

For information on how to customize your ERT-based system target file for your production requirements, see "Target Development" (Simulink Coder).

Customize Generated Code Modules

A configuration parameter is available to specify how the code generator packages generated source code into files. The configuration parameter **File packaging format** options are located in the Configuration Parameter dialog box, on the **Code Generation > Code Placement** pane, in the **Code packaging** section. The options are `Modular`, `Compact (with separate data file)`, and `Compact`. The table describes the generated files and the removed files for each file packaging format.

Generated Files According to File Packaging Format

File Packaging Format	Generated Files	Removed Files
`Modular` (default)	*model*`.c` subsystem files (optional) *model*`.h` *model*`_types.h` *model*`_private.h` *model*`_data.c` (conditional)	None
`Compact (with separate data file)`	*model*`.c` *model*`.h` *model*`_data.c` (conditional)	*model*`_private.h` *model*`_types.h` (conditional, see Removed Files According to File Packaging Format)
`Compact`	*model*`.c` *model*`.h`	*model*`_data.c` *model*`_private.h` *model*`_types.h` (conditional, see Removed Files According to File Packaging Format)

The table describes content placement from the removed files.

Removed Files According to File Packaging Format

Removed File	Generated Content In File
model`_private.h`	*model*`.c` and *model*`.h`
model`_types.h`	*model*`.h`
model`_data.c`	*model*`.c`

You can specify a different file packaging format for each referenced model.

The **Configuration Parameter > Code Generation > Interface > Shared code placement** selection interacts with file packaging operations. If you specify **Shared code placement** as `Shared location`, the code generator generates separate files for utility code in a shared location, regardless of the file packaging format. If you specify the **Shared code placement** as `Auto`, the code generator generates code for utilities according to the file packaging format selection.

- `Modular`: Some shared utility files are in the build folder.
- `Compact (with separate data file)`: Utility code is generated in *`model`*`.c`.
- `Compact`: Utility code is generated in *`model`*`.c`.

File packaging formats `Compact` and `Compact (with separate data file)` generate *`model`*`_types.h` for models containing:

- A Variant Subsystem block. The *`model`*`_types.h` file includes preprocessor directives defining the variant objects associated with a variant block.
- Custom storage classes generating a separate header file.

File packaging formats `Compact` and `Compact (with separate data file)` are not compatible with:

- A model containing a subsystem, which is configured to generate separate source files
- A model containing a noninlined S-function
- A model for which **Shared code placement** is set to `Auto`, which uses data objects for which **Data scope** is set to `Exported`

Report Generation in Embedded Coder

Reports for Code Generation

In this section...

The code generator software produces an HTML code generation report so that you can view and analyze the generated code. When your model is built, the code generation process produces an HTML file that is displayed in an HTML browser or in the Model Explorer. The code generation report includes:

- The **Summary** section that contains model and code information, including **Author**, **Tasking Mode**, **System Target File**, **Hardware Device Type**, and code generation objectives information. The **Configuration settings at the time of code generation** link opens a noneditable view of the Configuration Parameters dialog box. The dialog box shows the Simulink model settings at the time of code generation, including TLC options.
- The **Subsystem Report** section that contains information on nonvirtual subsystems in the model.
- In the **Generated Files** section on the **Contents** pane, you can click the names of source code files generated from your model to view their contents in a MATLAB Web browser window. In the displayed source code, global variables are hypertext that links to their definitions.

For an example, see “Generate a Code Generation Report” on page 49-6.

If you have a Simulink Report Generator license, you can document your code generation project in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. For an example of how to create a Microsoft Word report, see “Document Generated Code with Simulink Report Generator” on page 49-50.

HTML Code Generation Report Location

The default location for the code generation report files is in the `html` subfolder of the build folder, *`model_target`*`_rtw/html/`. *`target`* is the name of the **System target file** specified on the **Code Generation** pane. The default name for the top-level HTML report file is *`model`*`_codegen_rpt.html` or *`subsystem`*`_codegen_rpt.html`. For more

information on the location of the build folder, see “Manage Build Process Folders” (Simulink Coder).

HTML Code Generation Report for Referenced Models

To generate a code generation report for a top model and code generation reports for each referenced model, you need to specify the **Create code generation report** on the **Code Generation > Report** pane for the top model and each referenced model. You can open the code generation report of a referenced model in one of two ways:

- From the top-model code generation report, you can access the referenced model code generation report by clicking a link under **Referenced Models** in the left navigation pane. Clicking a link opens the code generation report for the referenced model in the browser. To navigate back to the top model code generation report, use the **Back** button at the top of the left navigation pane.
- From the referenced model diagram window, select **Code > C/C++ Code > Code Generation Report > Open Model Report**.

For more information, see “Generate Code for Referenced Models” (Simulink Coder)

HTML Code Generation Report Extensions

If you have an Embedded Coder license, the code generator enhances the HTML code generation report. Configure your model to include the following sections in the report:

- The **Code Interface Report** section provides information about the generated code interface, including model entry-point functions and input/output data. For more information, see “Analyze the Generated Code Interface” on page 49-20.
- The **Traceability Report** section allows you to account for **Eliminated / Virtual Blocks** that are untraceable versus the listed **Traceable Simulink Blocks / Stateflow Objects / MATLAB Scripts**. This provides a complete mapping between model elements and code. For more information, see “Customize Traceability Reports” on page 75-36.
- The **Static Code Metrics Report** section provides statistics of the generated code. Metrics are estimated from static analysis of the generated code. For more information, see “Static Code Metrics” on page 49-34.
- The **Code Replacements Report** section allows you to account for code replacement library (CRL) functions that were used during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the

replacement. For more information, see “Analyze Code Replacements in Generated Code” on page 49-48.

- The **Coder Assumptions** section provides a list of:
  - Code generation assumptions for your target hardware that you can check.
  - Expected results for the assumption checks.

  For more information, see “Check Code Generation Assumptions” on page 53-15.
- The model Web view displays an interactive model diagram within the code generation report and supports traceability between the source code and the model. Therefore, you can share your model and generated code outside of the MATLAB environment. For more information, see “Web View of Model in Code Generation Report” on page 49-16.

On the **Contents** pane, in the **Generated Files** section, you can click the names of source code files generated from your model to view their contents in a MATLAB Web browser window. In the displayed source code:

- If you enable code-to-model traceability, hyperlinks within the displayed source code navigate to the blocks or subsystems from which the code is generated. For more information, see “Code-to-Model Traceability” on page 75-8.
- If you enable model-to-code traceability, you can navigate to the generated code for a block in the model. For more information, see “Model-to-Code Traceability” on page 75-10.
- If you set the **Code coverage tool** parameter on the **Code Generation > Verification** pane, you can view the code coverage data and annotations. For more information, see “Configure Code Coverage with Third-Party Tools” on page 81-11.
- If you select the **Static code metrics** check box on the **Code Generation > Report** pane, you can view code metrics information and navigate to code definitions and declarations in the generated code. For more information, see “View Static Code Metrics and Definitions Within the Generated Code” on page 49-36.

Note To view the contents of your generated code and navigate between model and code, you can also use the code view in the code perspective. In the perspective, click the **Code** tab in the bottom-right corner.

- “Verify Generated Code by Using Code Tracing” on page 75-2

Generate a Code Generation Report

To generate a code generation report when the model is built:

1. In the Simulink Editor, select **Code > C/C++ Code > Code Generation Report > Options**. The Configuration Parameters dialog box opens with the **Code Generation > Report** pane visible.
2. Select the **Create code generation report** (Simulink Coder) parameter.
3. If you want the code generation report to automatically open after generating code, select the **Open report automatically** (Simulink Coder) parameter (which is enabled by selecting **Create code generation report**).
4. Generate code.

The build process writes the code generation report files to the `html` subfolder of the build folder (see “HTML Code Generation Report Location” on page 49-2). Next, the build process automatically opens a MATLAB Web browser window and displays the code generation report.

To open an HTML code generation report at any time after a build, see “Open Code Generation Report” on page 49-9 and “Generate Code Generation Report After Build Process” on page 49-7.

Generate Code Generation Report After Build Process

After generating code, if you did not configure your model to create a code generation report, you can generate a code generation report without rebuilding your model.

1. In the model diagram window, select **Code** > **C/C++ Code** > **Code Generation Report** > **Open Model Report**.
2. If your current working folder contains the code generation files the following dialog opens.

   Click **Generate Report**.
3. If the code generation files are not in your current working directory, the following dialog opens.

   Enter the full path of the build folder for your model, `../model_target_rtw` and click **Open Report**.

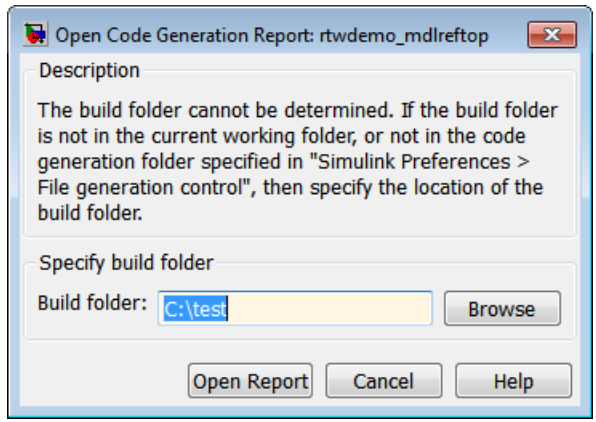
The software generates a report, *model*_codgen_rpt.html, from the code generation files in the build folder you specified.

Note An alternative method for generating the report after the build process is complete is to configure your model to generate a report and build your model. In this case, the software generates the report without regenerating the code.

Open Code Generation Report

You can refer to existing code generation reports at any time. If you generated a code generation report, in the Simulink Editor, you can open the report by selecting the menu option **Code > C/C++ Code > Code Generation Report > Open Model Report**. If you are opening a report for a subsystem, select **Open Subsystem Report**. A Simulink Coder license is required to view the code generation report. An Embedded Coder license is required to view a code generation report enhanced with Embedded Coder features.

If your current working folder does not contain the code generation files and the code generation report, the following dialog box opens:



Enter the full path of the build folder for your model, `../model_target_rtw` and click **Open Report**.

Alternatively, you can open the code generation report (`model_codegen_rpt.html` or `subsystem_codegen_rpt.html`) manually into a MATLAB Web browser window, or in another Web browser. For the location of the generated report files, see “HTML Code Generation Report Location” on page 49-2.

Limitation

After building your model or generating the code generation report, if you modify legacy or custom code, you must rebuild your model or regenerate the report for the code generation report to include the updated legacy source files. For example, if you modify your legacy code, and then use the **Code > C/C++ Code > Code Generation Report >**

Open Model Report menu to open an existing report, the software does not check if the legacy source file is out of date compared to the generated code. Therefore, the code generation report is not regenerated and the report includes the out-of-date legacy code. This issue also occurs if you open a code generation report using the `coder.report.open` function.

To regenerate the code generation report, do one of the following:

- Rebuild your model.
- Generate the report using the `coder.report.generate` function.

Generate Code Generation Report Programmatically

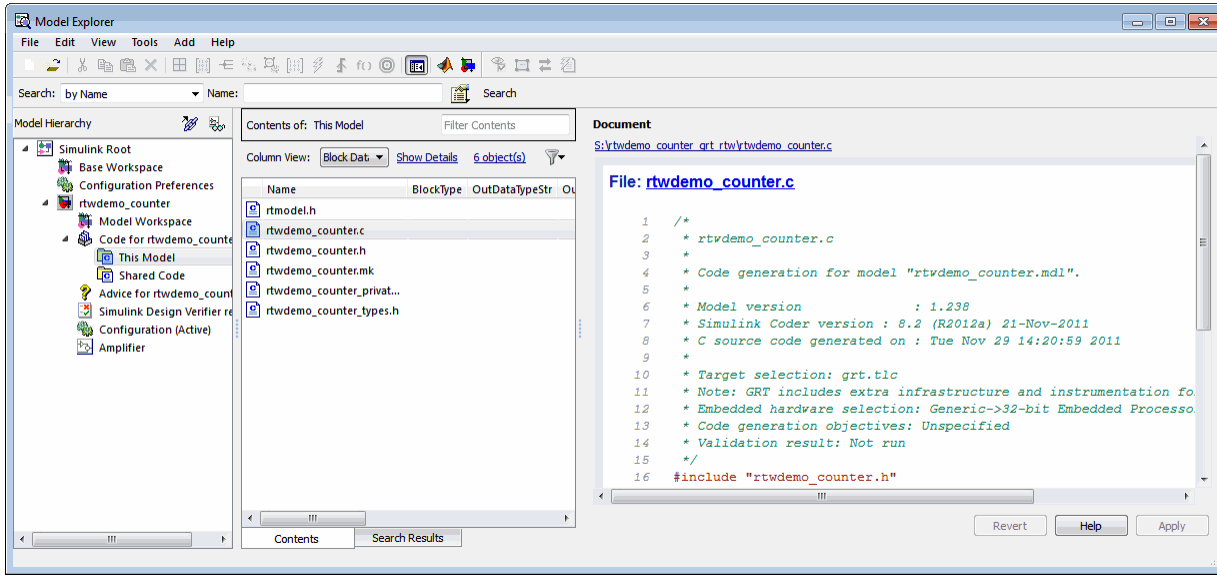
At the MATLAB command line, you can generate, open, and close an HTML Code Generation Report with the following functions:

- `coder.report.generate` generates the code generation report for the specified model.
- `coder.report.open` opens an existing code generation report.
- `coder.report.close` closes the code generation report.

View Code Generation Report in Model Explorer

After generating an HTML code generation report, you can view the report in the right pane of the Model Explorer. You can also browse the generated files directly in the Model Explorer.

When you generate code, or open a model that has generated code for its current target configuration in your working folder, the **Hierarchy** (left) pane of Model Explorer contains a node named **Code for *`model`***. Under that node are other nodes, typically called `This Model` and `Shared Code`. Clicking `This Model` displays in the **Contents** (middle) pane a list of generated source code files in the build folder of that model. The next figure shows code for the `rtwdemo_counter` model.



In this example, the file `S:/rtwdemo_counter_grt_rtw/rtwdemo_counter.c` is being displayed. To view a file in the **Contents** pane, click it once.

The views in the **Document** (right) pane are read only. The code listings there contain hyperlinks to functions and macros in the generated code. Clicking the file hyperlink opens that source file in a text editing window where you can modify its contents.

If an open model contains Model blocks, and if generated code for these models exists in the current `slprj` folder, nodes for the referenced models appear in the **Hierarchy** pane

one level below the node for the top model. Such referenced models do not need to be open for you to browse and read their generated source files.

If the code generator produces shared utility code for a model, a node named `Shared Code` appears directly under the **This Model** node. It collects source files that exist in the `./slprj/`*`target`*`/_sharedutils` subfolder.

Note You cannot use the **Search** tool built into Model Explorer toolbar to search generated code displayed in the Code Viewer. On PCs, typing **Ctrl+F** when focused on the **Document** pane opens a Find dialog box that you can use to search for text in the currently displayed file. You can also search for text in the HTML report window, and you can open the files in the editor.

Package and Share the Code Generation Report

In this section...

Package the Code Generation Report

To share the code generation report, you can package the code generation report files and supporting files into a zip file for transfer. The default location for the code generation report files is in two folders:

- `/slprj`
- `html` subfolder of the build folder, *`model_target`*`_rtw`, for example `rtwdemo_counter_grt_rtw/html`

To create a zip file from the MATLAB command window:

1. In the Current Folder browser, select the two folders:
   - `/slprj`
   - Build folder: *`model_target`*`_rtw`
2. Right-click to open the context menu.
3. In the context menu, select **Create Zip File**. A file appears in the Current Folder browser.
4. Name the zip file.

Alternatively, you can use the MATLAB `zip` command to zip the code generation report files:

```
zip('myzip',{'slprj','rtwdemo_counter_grt_rtw'})
```

Note If you need to relocate the static and generated code files for a model to another development environment, such as a system or an integrated development environment (IDE) that does not include MATLAB and Simulink products, use the code generator pack-and-go utility. For more information, see “Relocate Code to Another Development Environment” (Simulink Coder).

View the Code Generation Report

To view the code generation report after transfer, unzip the file and save the two folders at the same folder level in the hierarchy. Navigate to the *model_target*_rtw/html/ folder and open the top-level HTML report file named *model*_codgen_rpt.html or *subsystem*_codegen_rpt.html in a Web browser.

Web View of Model in Code Generation Report

In this section...

About Model Web View

To review and analyze the generated code, it is helpful to navigate between the code and model. You can include a Web view of the model within the HTML code generation report. You can then share your model and generated code outside of the MATLAB environment. When you generate the report, the Web view includes the block diagram attributes displayed in the Simulink Editor, such as, block sorted execution order, signal properties, and port data types.

A Simulink Report Generator license is required to include a Web view (Simulink Report Generator) of the model in the code generation report.

Browser Requirements for Web View

Web view requires a Web browser that supports Scalable Vector Graphics (SVG). Web view uses SVG to render and navigate models.

You can use the following Web browsers:

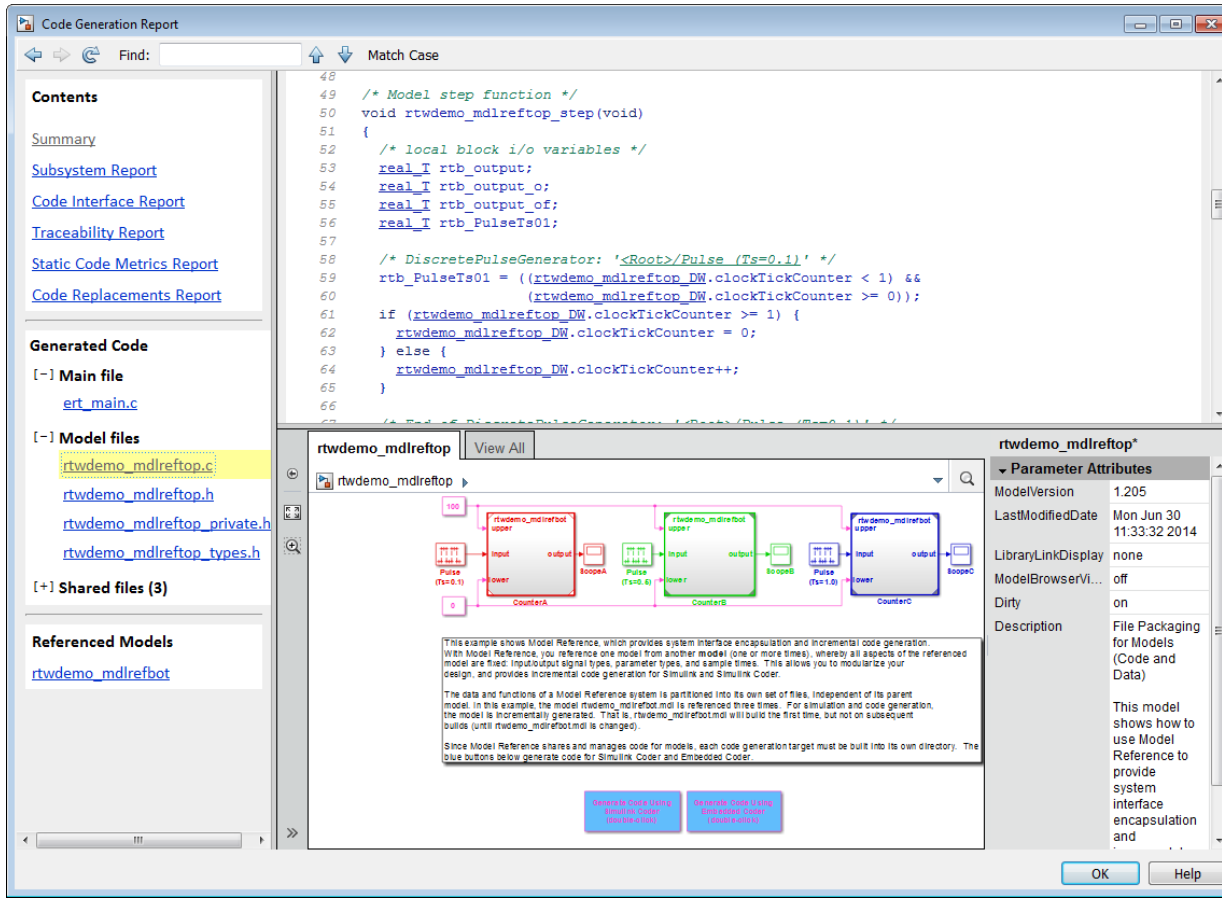
- Mozilla Firefox Version 1.5 or later, which has native support for SVG. To download the Firefox browser, go to `www.mozilla.com/`.
- The Microsoft Internet Explorer® Web browser with the Adobe® SVG Viewer plug-in. To download the Adobe SVG Viewer plug-in, go to `www.adobe.com/svg/`.
- Apple Safari Web browser

Generate HTML Code Generation Report with Model Web View

This example shows how to create an HTML code generation report which includes a Web view of the model diagram.

1. Open the `rtwdemo_mdlreftop` model.
2. Open the Configuration Parameters dialog box or Model Explorer and navigate to the **Code Generation** pane.
3. Specify `ert.tlc` for the **System target file** parameter.
4. Open the **Code Generation** > **Report** pane.
5. Select the following parameters:
   - **Create code generation report**
   - **Open report automatically**
   - **Generate model Web view**
6. Select the parameters **Code-to-model** and **Model-to-code**.

   Note These settings specify only the top model, not referenced models.
7. Open the Configuration Parameters for the referenced model, `rtwdemo_mdlrefbot` and perform steps 3–6.
8. Save the models, `rtwdemo_mdlreftop` and `rtwdemo_mdlrefbot`.
9. From the top model diagram, press Ctrl+B. After building the model and generating code, the code generation report for the top model opens in a MATLAB Web browser.
10. In the left navigation pane, select a source code file. The corresponding source code is displayed in the right pane and includes hyperlinks.



11 Click a link in the code. The model Web view displays and highlights the corresponding block in the model.

12 To highlight the generated code for a referenced model block in your model, click `CounterB`. The corresponding code is highlighted in the source code pane.

Note You cannot open the referenced model diagram in the Web view by double-clicking the referenced model block in the top model.

---

13 To open the code generation report for a referenced model, in the left navigation pane, below **Referenced Models**, click the link, `rtwdemo_mdlrefbot`. The source files for the referenced model are displayed along with the Web view of the referenced model.

14 To go back to the code generation report for the top model, at the top of the left navigation pane, click the **Back** button until the top model's report is displayed.

For more information about exploring a model in a Web view, see "Navigate the Web View" (Simulink Report Generator).

For more information about navigating between the generated code and the model diagram, see "Trace Simulink Model Elements in Generated Code" on page 75-8.

Model Web View Limitations

The HTML code generation report includes the following limitations when using the model Web view:

- Code is not generated for virtual blocks. In the model Web view of the code generation report, when tracing between the model and the code, when you click a virtual block, it is highlighted yellow.
- In the model Web view, you cannot open a referenced model diagram by double-clicking the referenced model block in the top model. Instead, open the code generation report for the referenced model by clicking a link under **Referenced Models** in the left navigation pane.
- Stateflow truth tables, events, and links to library charts are not supported in the model Web view.
- Searching in the code generation report does not find or highlight text in the model Web view.
- If you navigate from the actual model diagram (not the model Web view in the report), to the source code in the HTML code generation report, the model Web view is disabled and not visible. To enable the model Web view, open the report again, see "Open Code Generation Report" (Simulink Coder).
- For a subsystem build, the traceability hyperlinks of the root level inport and outport blocks are disabled.
- "Traceability Limitations" on page 75-6 that apply to tracing between the code and the actual model diagram.

Analyze the Generated Code Interface

In this section...

Code Interface Report Overview

When you select the **Create code generation report** option for an ERT-based model, a **Code Interface Report** section is automatically included in the generated HTML report. The **Code Interface Report** section provides documentation of the generated code interface, including model entry-point functions and interface data, for consumers of the generated code. The information in the report can help facilitate code review and code integration.

The code interface report includes the following subsections:

- **Entry-Point Functions** — interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.
- **Inports** and **Outports** — interface information about each model inport and outport.
- **Interface Parameters** — interface information about tunable parameters that are associated with the model.
- **Data Stores** — interface information about global data stores and data stores with non-`auto` storage that are associated with the model.

For limitations that apply to code interface reports, see “Code Interface Report Limitations” on page 49-32.

For illustration purposes, this section uses the following models:

- `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window) for examples of report subsections
- `rtwdemo_mrmtbb` for examples of timing information
- `rtwdemo_fcnprotoctrl` for examples of function argument and return value information

Generating a Code Interface Report

To generate a code interface report for your model:

1. Open your model, go to the **Code Generation** pane of the Configuration Parameters dialog box, and select `ert.tlc` or an ERT-based **System target file**, if one is not already selected.
2. Go to the **Code Generation > Report** pane of the Configuration Parameters dialog box and select the option **Create code generation report**, if it is not already selected. The `rtwdemo_basicsc`, `rtwdemo_mrmtbb`, and `rtwdemo_fcnprotoctrl` models used in this section select multiple **Report** pane options by default. But selecting only **Create code generation report**, generates a **Code Interface Report** section in the HTML report.

   Alternatively, you can programmatically select the option by issuing the following MATLAB command:

   ```
   set_param(bdroot, 'GenerateReport', 'on')
   ```

   If the **Code-to-model** parameter is selected, the generated report contains hyperlinks to the model. Leave this value selected unless you plan to use the report outside the MATLAB environment.
3. Build the model. If you selected the **Report** pane option **Open report automatically**, the code generation report opens automatically after the build process is complete. (Otherwise, you can open it manually from within the model build folder.)
4. To display the code interface report for your model, go to the **Contents** pane of the HTML report and click the **Code Interface Report** link. For example, here is the generated code interface report for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

Code Interface Report for rtwdemo_basicsc

Table of Contents

Entry-Point Functions

Function: rtwdemo_basicsc_initialize

Prototype	**void rtwdemo_basicsc_initialize(void)**
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	rtwdemo_basicsc.h

Function: rtwdemo_basicsc_step

Prototype	**void rtwdemo_basicsc_step(void)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	rtwdemo_basicsc.h

Inports

[-]

Block Name	Code Identifier	Data Type	Dimension
<Root>/In1	input1	real32_T	1
<Root>/In2	input2	real32_T	1
<Root>/In3	input3	real32_T	1
<Root>/In4	input4	real32_T	1

Outports

Block Name	Code Identifier	Data Type	Dimension
<Root>/Out1	output	real32_T	1

Interface Parameters

[-]

Parameter Source	Code Identifier	Data Type	Dimension
K2	K2	real_T	1
LOWER	LOWER	real32_T	1
T1Break	T1Break	real32_T	[1 11]
T1Data	T1Data	real32_T	[1 11]
T2Break	T2Break	real32_T	[1 3]
T2Data	T2Data	real32_T	[3 3]
UPPER	UPPER	real32_T	1
K1	K1	int8_T	1

Data Stores

Data Store Source	Code Identifier	Data Type	Dimension
<Root>/Data Store Memory	mode	boolean_T	1

For help navigating the content of the code interface report subsections, see “Navigating Code Interface Report Subsections” on page 49-23. For help interpreting the content of the code interface report subsections, see the sections beginning with “Interpreting the Entry-Point Functions Subsection” on page 49-24.

Navigating Code Interface Report Subsections

To help you navigate code interface descriptions, the code interface report provides collapse/expand tokens and hyperlinks, as follows:

- For a large subsection, the report provides `[-]` and `[+]` symbols that allow you to collapse or expand that section. In the example in the previous section, the symbols are provided for the **Inports** and **Interface Parameters** sections.
- Several forms of hyperlink navigation are provided in the code interface report. For example:
  - The **Table of Contents** located at the top of the code interface report provides links to each subsection.
  - You can click each function name to go to its definition in *`model`*`.c`.
  - You can click each function's header file name to go to the header file source listing.
  - If you selected the **Code-to-model** parameter for your model, to go to the corresponding location in the model display, you can click hyperlinks for any of the following:
    - Function argument
    - Function return value
    - Inport
    - Outport
    - Interface parameter (if the parameter source is a block)
    - Data store (if the data store source is a Data Store Memory block)

For backward and forward navigation within the HTML code generation report, use the **Back** and **Forward** buttons above the **Contents** section in the upper-left corner of the report.

Interpreting the Entry-Point Functions Subsection

The **Entry-Point Functions** subsection of the code interface report provides the following interface information about each model entry-point function, including `model_initialize`, `model_step`, and (if applicable) `model_reset` and `model_terminate`.

Field	Description
Function:	Lists the function name. You can click the function name to go to its definition in *`model`*`.c`.
Prototype	Displays the function prototype, including the function return value, name, and arguments.
Description	Provides a text description of the function's purpose in the application.
Timing	Describes the timing characteristics of the function, such as how many times the function is called, or if it is called periodically, and at what time interval. For a multirate timing example, see the following `rtwdemo_mrmtbb` report excerpt.
Arguments	If the function has arguments, displays the number, name, data type, and Simulink description for each argument. If you select the **Code-to-model** parameter for your model, you can click the hyperlink in the description to go to the block corresponding to the argument in the model display. For argument examples, see the `rtwdemo_fcnprotoctrl` report excerpt below.
Return value	If the function has a return value, this field displays the return value data type and Simulink description. If you selected the **Code-to-model** parameter for your model, you can click the hyperlink in the description to go to the block corresponding to the return value in the model display. For a return value example, see the following `rtwdemo_fcnprotoctrl` report excerpt.
Header file	Lists the name of the header file for the function. You can click the header file name to go to the header file source listing.

For example, here is the **Entry-Point Functions** subsection for the model `rtwdemo_basicsc`.

Entry-Point Functions

Function: rtwdemo_basicsc_initialize

Prototype	**void rtwdemo_basicsc_initialize(void)**
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	rtwdemo_basicsc.h

Function: rtwdemo_basicsc_step

Prototype	**void rtwdemo_basicsc_step(void)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	rtwdemo_basicsc.h

To illustrate how timing information might be listed for a multirate model, here are the **Entry-Point Functions** and **Inports** subsections for the model `rtwdemo_mrmtbb`. This multirate, discrete-time, multitasking model contains Inport blocks 1 and 2, which specify 1-second and 2-second sample times, respectively. The sample times are constrained to the specified times by the **Periodic sample time constraint** option on the **Solver** pane of the Configuration Parameters dialog box.

Entry-Point Functions

Function: rtwdemo_mrmtbb_initialize

Prototype	**void rtwdemo_mrmtbb_initialize(void)**
Description	Initialization entry point of generated code
Timing	Must be called exactly once
Arguments	None
Return value	None
Header file	rtwdemo_mrmtbb.h

Function: rtwdemo_mrmtbb_step0

Prototype	**void rtwdemo_mrmtbb_step0(void)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 1 second
Arguments	None
Return value	None
Header file	rtwdemo_mrmtbb.h

Function: rtwdemo_mrmtbb_step1

Prototype	**void rtwdemo_mrmtbb_step1(void)**
Description	Output entry point of generated code
Timing	Must be called periodically, every 2 seconds
Arguments	None
Return value	None
Header file	rtwdemo_mrmtbb.h

Inports

Block Name	Code Identifier	Data Type	Dimension
<Root>/In1_1s	rtU.In1_1s	real_T	1
<Root>/In2_2s	rtU.In2_2s	real_T	1

To illustrate how function arguments and return values are displayed in the report, here is the entry-point function description of the model step function for model `rtwdemo_fcnprotoctrl`.

Function: rtwdemo_fcnprotoctrl_step_custom

Prototype	**boolean_T rtwdemo_fcnprotoctrl_step_custom(const real_T argIn1, const BusObject *const argIn2, BusObject *argOut2, const BusObject *const argIn3, uint8_T *argIn4)**
Description	Output entry point of generated code
Timing	Can be called at any time
Arguments	[-]

#	Name	Data Type	Description
1	argIn1	const real_T	*<Root>/In1*
2	argIn2	const BusObject *const	*<Root>/In2*
3	argOut2	BusObject *	*<Root>/Out2*
4	argIn3	const BusObject *const	*<Root>/In3*
5	argIn4	uint8_T *	*<Root>/In4*

Return value	Data Type	Description
	boolean_T	*<Root>/Out1*

Header file	rtwdemo_fcnprotoctrl.h

Interpreting the Inports and Outports Subsections

The **Inports** and **Outports** subsections of the code interface report provide the following interface information about each inport and outport in the model.

Field	Description
Block Name	Displays the Simulink block name of the inport or outport. If you selected the **Code-to-model** parameter for your model, you can click on each inport or outport **Block Name** value to go to its location in the model display.

Field	Description
Code Identifier	Lists the identifier associated with the inport or outport data in the generated code, as follows: • If the data is defined in the generated code, the field displays the identifier text. • If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label '`Imported data:`'. • If the data is neither defined nor declared in the generated code — for example, if **Reusable function** code interface packaging is selected for the model — the field displays the text '`Defined externally`'.
Data Type	Lists the data type of the inport or outport.
Scaling	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. **Note** You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).
Dimension	Lists the dimensions of the inport or outport (for example, `1` or `[4, 5]`).

For example, here are the **Inports** and **Outports** subsections for the model `rtwdemo_basicsc`.

Inports

[-]

Block Name	Code Identifier	Data Type	Dimension
<Root>/In1	input1	real32_T	1
<Root>/In2	input2	real32_T	1
<Root>/In3	input3	real32_T	1
<Root>/In4	input4	real32_T	1

Outports

Block Name	Code Identifier	Data Type	Dimension
<Root>/Out1	output	real32_T	1

Interpreting the Interface Parameters Subsection

The **Interface Parameters** subsection of the code interface report provides the following interface information about tunable parameters that are associated with the model.

Field	Description
Parameter Source	Lists the source of the parameter value, as follows: • If the source of the parameter value is a block, the field displays the block name, such as `<Root>/Gain2` or `<S1>/Lookup1`. If you selected the **Code-to-model** parameter for your model, you can click the **Parameter Source** value to go to the parameter's location in the model display. • If the source of the parameter value is a workspace variable, the field displays the name of the workspace variable.

Field	Description
Code Identifier	Lists the identifier associated with the tunable parameter data in the generated code, as follows: • If the data is defined in the generated code, the field displays the identifier text. • If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label '`Imported data:`'. • If the data is neither defined nor declared in the generated code — for example, if **Reusable function** code interface packaging is selected for the model — the field displays the text '`Defined externally`'.
Data Type	Lists the data type of the tunable parameter.
Scaling	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. **Note** You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).
Dimension	Lists the dimensions of the tunable parameter (for example, `1` or `[4, 5, 6]`).

For example, here is the **Interface Parameters** subsection for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

Interface Parameters

[-]

Parameter Source	Code Identifier	Data Type	Dimension
K2	K2	real_T	1
LOWER	LOWER	real32_T	1
T1Break	T1Break	real32_T	[1 11]
T1Data	T1Data	real32_T	[1 11]
T2Break	T2Break	real32_T	[1 3]
T2Data	T2Data	real32_T	[3 3]
UPPER	UPPER	real32_T	1
K1	K1	int8_T	1

Interpreting the Data Stores Subsection

The **Data Stores** subsection of the code interface report provides the following interface information about global data stores and data stores with non-`auto` storage that are associated with the model.

Field	Description
Data Store Source	Lists the source of the data store memory, as follows: • If the data store is defined using a Data Store Memory block, the field displays the block name, such as `<Root>/DS1`. If you selected the **Code-to-model** parameter for your model, you can click on the **Data Store Source** value to go to the data store's location in the model display. • If the data store is defined using a `Simulink.Signal` object, the field displays the name of the `Simulink.Signal` object.

Field	Description
Code Identifier	Lists the identifier associated with the data store data in the generated code, as follows: • If the data is defined in the generated code, the field displays the identifier text. • If the data is declared but not defined in the generated code — for example, if the data is resolved with an imported storage class — the field displays the identifier text prefixed with the label '`Imported data:`'. • If the data is neither defined nor declared in the generated code — for example, if **Reusable function** code interface packaging is selected for the model — the field displays the text '`Defined externally`'.
Data Type	Lists the data type of the data store.
Scaling	For fixed-point entries, lists the data type and fraction length using Simulink fixed-point data type notation. **Note** You must have a Fixed-Point Designer license to see fixed-point scaling information in the report. For more information on how scaling is represented in the table, see “Fixed-Point Data Type and Scaling Notation” (Fixed-Point Designer).
Dimension	Lists the dimensions of the data store (for example, `1` or `[1, 2]`).

For example, here is the **Data Stores** subsection for the model `rtwdemo_basicsc` (with the **ExportedGlobal Storage Class** button selected in the model window).

Data Stores

Data Store Source	Code Identifier	Data Type	Dimension
<Root>/Data Store Memory	mode	boolean_T	1

Code Interface Report Limitations

The following limitations apply to the code interface section of the HTML code generation reports.

- The code interface report does not support the GRT interface with an ERT target or **C ++ class** code interface packaging. For these configurations, the code interface report is not generated and does not appear in the HTML code generation report **Contents** pane.
- The code interface report supports data resolved with most custom storage classes (CSCs), except when the CSC properties are set in any of the following ways:
  - The CSC property **Type** is set to `FlatStructure`. For example, the `BitField` and `Struct` CSCs in the Simulink package have **Type** set to `FlatStructure`.
  - The CSC property **Type** is set to `Other`. For example, the `GetSet` CSC in the Simulink package has **Type** set to `Other`.
  - The CSC property **Data access** is set to `Pointer`, indicating that imported symbols are declared as pointer variables rather than simple variables. This property is accessible only when the CSC property **Data scope** is set to `Imported` or `Instance-specific`.

  In these cases, the report displays empty **Data Type** and **Dimension** fields.
- For outports, the code interface report cannot describe the associated memory (data type and dimensions) if the memory is optimized. In these cases, the report displays empty **Data Type** and **Dimension** fields.
- The code interface report does not support data type replacement using the **Code Generation > Data Type Replacement** pane of the Configuration Parameters dialog box. The data types listed in the report will link to built-in data types rather than their specified replacement data types.

Static Code Metrics

In this section...

Static Code Metrics

The code generator performs static analysis on page 49-35 of the generated C or C++ code and provides these metrics in the **Static Code Metrics Report** section of the HTML Code Generation Report. When you place your cursor over a function or a variable in the generated code, you can also see metrics.

You can use the information in the report to:

- Find the number of files and lines of code in each file.
- Estimate the number of lines of code and stack usage per function.
- Compare the difference in terms of how many files, functions, variables, and lines of code are generated every time you change the model or MATLAB algorithm.
- Determine a target platform and allocation of RAM to the stack, based on the size of global variables plus the estimated stack size.
- Determine possible performance slow points, such as the largest global variables or the most costly call path in terms of stack usage.
- View the cyclomatic complexity of a function, which counts the number of linearly independent paths through a function.
- View the function call tree. Determine the longest call path to estimate the worst case execution timing.
- View how target functions, provided by the selected code replacement library, are used in the generated code.

For examples, see:

- “Generate Static Code Metrics Report for Simulink Model” on page 49-39

- “Generating a Static Code Metrics Report for Code Generated from MATLAB Code” on page 49-44

Static Code Metrics Analysis

Static analysis of the generated code is performed only on the source code without executing the program. The results of the static code metrics analysis are included in the **Static Code Metrics** section of the HTML Code Generation Report. The report is not available if you generate a MEX function from MATLAB code.

Static analysis of the generated source code files:

- Uses the specified C data types. For Simulink models, you specify these data types in the **Hardware Implementation > Production hardware** pane of the Configuration Parameters dialog box. For code generation from MATLAB code, you specify them in the **Hardware** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. Actual object code metrics might differ due to target-specific compiler and platform settings.
- Includes custom code only if you specify it. For Simulink models, you specify custom code on the **Code Generation > Custom Code** pane in the model configuration. For code generation from MATLAB code, you specify it on the **Debugging** tab of the MATLAB Coder project settings dialog box or using a code generation configuration object. An error report is generated if the generated code includes platform-specific files not contained in the standard C run-time library.
- For Simulink models, includes the generated code from referenced models.
- Uses 1-byte alignment for all members of a structure for estimating global and local data structure sizes. The size of a structure is calculated by summing the sizes of all of its fields. This estimation represents the smallest possible size for a structure.
- Calculates the self stack size of a function as the size of local data within a function, excluding input arguments. The accumulated stack size of a function is the self stack size plus the maximum of the accumulated stack sizes of its called functions. For example, if the accumulated stacks sizes for the called functions are represented as `accum_size1...accum_sizeN`, then the accumulated stack size for a function is

  ```
  accumulated_stack_size = self_stack_size + max(accum_size1,...,accum_sizeN)
  ```
- When estimating the stack size of a function, static analysis stops at the first instance of a recursive call. The **Function Information** table indicates when recursion occurs in a function call path. Code generation generates only recursive code for Stateflow event broadcasting and for graphical functions if it is written as a recursive function.

- Calculates the cyclomatic complexity of a function as the number of decisions plus one:

  ```
  CC = Number of decisions + 1
  ```

  The following constructs add a decision:

  - If statement
  - Else-If statement
  - Switch statement (1 decision for each `case` branch)
  - Loop statements: While, For, Do-while

  Note Boolean operators in the preceding constructs do not add extra decisions.

- Does not include `ert_main.c`, because you have the option to provide your own `main.c`.

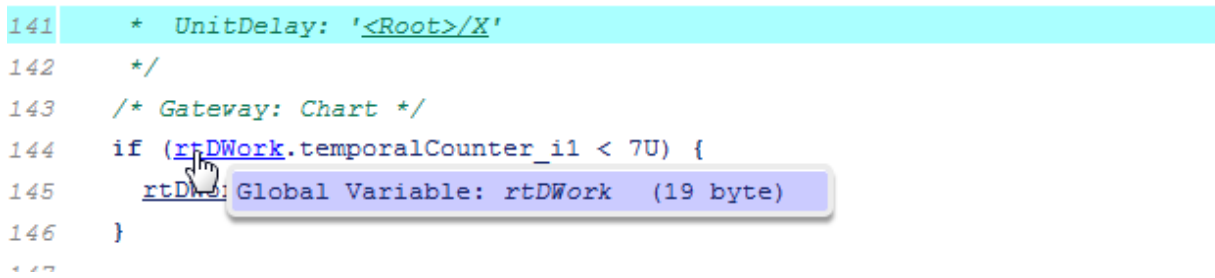
View Static Code Metrics and Definitions Within the Generated Code

- "Code Generation Report" on page 49-36
- "Code View" on page 49-37

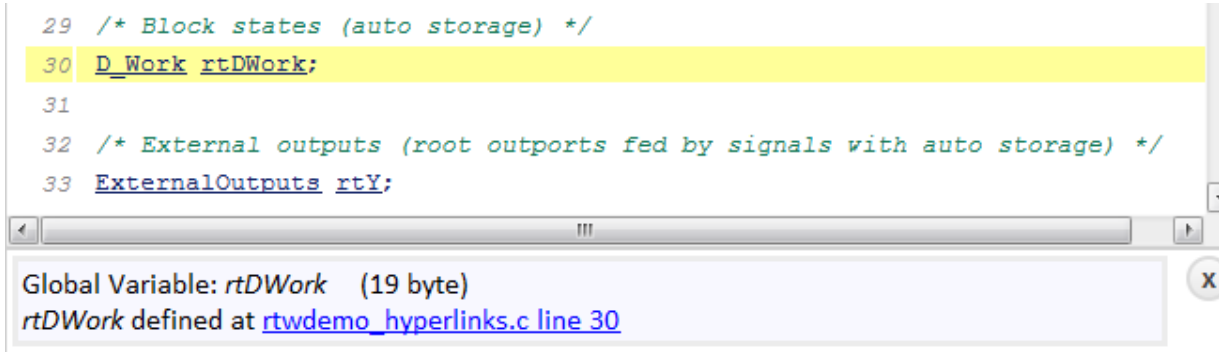
Code Generation Report

When you view code in the code generation report, to access code metrics and definitions:

- On the **Code Generation > Report** pane, if you select the **Static code metrics** check box, you can place your cursor over global variables and functions in the code window to see code metrics information.



- In the code window, if you click linked variables or functions, the code inspect window opens. The window provides links to definitions for the variables or functions. On the **Code Generation > Report** pane, if you selected the **Static code metrics** check box, you can also see code metrics information for the variable or function.



Code View

When you view code in the Code view of the Code perspective, place your cursor over the ellipsis menu above global variables and functions to see code metrics information.

The tooltip provides a link to the definition for the variable or function.

Static Code Metrics Report Limitations

Static code metrics are not available if the target configuration for a model results in generated code that:

- Includes a header file that is not generated by the model hierarchy and is not a system header file
- Uses a macro that is not recognized

Generate Static Code Metrics Report for Simulink Model

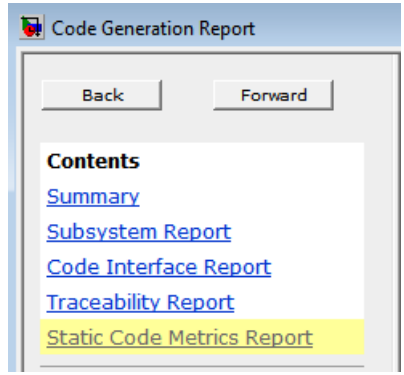
The **Static Code Metrics Report** is a section included in the HTML Code Generation Report. For more information on the static analysis of the generated code, see “Static Code Metrics Analysis” on page 49-35.

1. Before generating the HTML Code Generation Report, open the Configuration Parameters dialog box for your model. On the **Code Generation > Report** pane, select the “Static code metrics” (Simulink Coder) check box.

   If your model includes referenced models, select the **Static code metrics** check box in each referenced model’s configuration set. Otherwise, you cannot view a separate static code metrics report for a referenced model.

2. Press **Ctrl+B** to build your model and generate the HTML code generation report. For more information, see “Generate a Code Generation Report” on page 49-6.

3. If the HTML Code Generation Report is not already open, open the report. On the left navigation pane, in the **Contents** section, select **Static Code Metrics Report**.



4. To see the generated files and how many lines of code are generated per file, look at the **File Information** section.

1. File Information [hide]

[-] Summary (excludes ert_main.c)

Number of .c files : 2
Number of .h files : 4
Lines of code : 1,132
Lines : 1,958

[-] File details

File Name	Lines of Code	Lines	Generated On
fuel_rate_control.c	665	1,107	06/10/2016 4:17 PM
fuel_rate_control_data.c	253	342	06/10/2016 4:17 PM
rtwtypes.h	97	177	06/10/2016 4:17 PM
fuel_rate_control.h	88	249	06/10/2016 4:17 PM
fuel_rate_control_types.h	22	52	06/10/2016 4:17 PM
fuel_rate_control_private.h	7	31	06/10/2016 4:17 PM

5. Hover your cursor over column titles and some column values to see a description of the corresponding data.
6. If your model includes referenced models, the File information section includes a **Referenced Model** column. In this column, click the referenced model name to open its static code metrics report. If the static code metrics report is not available for a referenced model, specify the **Static code metrics** parameter in the referenced model's configuration set and rebuild your model.
7. To view the global variables in the generated code, their size, and the number of accesses, see the **Global Variables** section.

2. Global Variables [hide]

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[+] fuel_rate_control_DW	23	175	78
[+] fuel_rate_control_B	21	42	26
[+] fuel_rate_control_U	16	27	24
[+] fuel_rate_control_M_	8	0*	0*
[+] fuel_rate_control_Y	4	4	3
Total	**72**	**248**	

* The global variable is not directly used in any function.

The **Reads/Writes** column displays the total number of read and write accesses to the global variable. The **Reads/Writes in a Function** column displays the maximum

number of read and write accesses to the global variable within a function. You use this information is to estimate the benefit of turning on optimizations, which reduce the number of global references. For more information, see “Optimize Global Variable Usage” on page 69-2.

Click [+] to expand structures.

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
[−] fuel_rate_control_DW	23	175	78
DiscreteIntegrator_DSTATE	4	5	4
ThrottleTransient_states	4	4	3
DiscreteFilter_states	4	4	3
DiscreteFilter_states_i	4	4	3
[+] bitsForTID0	5	156	60
temporalCounter_i1	2	7	5
[−] fuel_rate_control_B	21	42	26
[+] es_o	16	23	18
fuel_mode	4	15	8
O2_normal	1	6	4
[−] fuel_rate_control_U	16	27	24
[+] sensors	16	27	24
[−] fuel_rate_control_M_	8	0*	0*
errorStatus	8	0	0
[−] fuel_rate_control_Y	4	4	3
fuel_rate	4	4	3
Total	**72**	**248**	

* The global variable is not directly used in any function.

8. To navigate from the report to the source code, click a global variable or function name. These names are hyperlinks to their definitions.
9. To view the function call tree of the generated code, in the **Function Information** section, click **Call Tree** at the top of the table.

3. Function Information [hide]

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View:Call Tree | Table

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[-] fuel_rate_control_step	52	16	272	504	43
look2_iflf_linlca	36	36	55	100	12
[-] fuel_rate_control_Fail	4	4	67	103	13
fuel_rate_control_Fueling_Mode	0	0	166	240	19
fuel_rate_control_Fueling_Mode	0	0	166	240	19
[+] fuel_rate_control_initialize	0	0	43	67	1
fuel_rate_control_terminate	0	0	0	4	1

`ert_main.c` is not included in the code metrics analysis, therefore it is not shown in the call tree format. The **Complexity** column includes the cyclomatic complexity of each function.

10 To view the functions in a table format, click **Table**.

3. Function Information [hide]

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: Call Tree | Table

Function Name	Called By (number of call sites)	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
fuel_rate_control_Fail	fuel_rate_control_step (9)	4	4	67	103	13
fuel_rate_control_Fueling_Mode	fuel_rate_control_step fuel_rate_control_Fail (2)	0	0	166	240	19
fuel_rate_control_initialize		0	0	43	67	1
fuel_rate_control_step		52	16	272	504	43
fuel_rate_control_terminate		0	0	0	4	1
look2_iflf_linlca	fuel_rate_control_step (5)	36	36	55	100	12
memset	fuel_rate_control_initialize (2)	*Not available*	-	-	-	-

The second column, **Called By**, lists functions that call the function listed in the first column, using the following criteria:

- If a function is called by multiple functions, all functions are listed.
- If a function has no called function, this column is empty.

For example, `Fueling_Mode` is called by `Fail` and `fuel_rate_control_step`. The number of call sites is included in parentheses. `Fail` calls `Fueling_Mode` twice.

Generating a Static Code Metrics Report for Code Generated from MATLAB Code

The static code metrics report contains the results of static analysis of the generated C/C++ code, including generated file information, number of lines, and memory usage. For more information, see “Static Code Metrics” on page 49-34. To produce a static code metrics report, you must use Embedded Coder to generate standalone C/C++ code and produce a code generation report. See “Code Generation Reports” (MATLAB Coder).

By default, static code metrics analysis does not run at code generation time. Instead, if and when you want to run the analysis and view the results, click **Code Metrics** on the **Summary** tab of the code generation report.

Example Static Code Metrics Report

This example runs static code metrics analysis and examines a static code metrics report.

Create the example function `averaging_filter`.

```
function y = averaging_filter(x) %#codegen
% Use a persistent variable 'buffer' that represents a sliding window of
% 16 samples at a time.
persistent buffer;
if isempty(buffer)
    buffer = zeros(16,1);
end
y = zeros(size(x), class(x));
for i = 1:numel(x)
    % Scroll the buffer
    buffer(2:end) = buffer(1:end-1);
    % Add a new sample value to the buffer
    buffer(1) = x(i);
    % Compute the current average value of the window and
    % write result
    y(i) = sum(buffer)/numel(buffer);
end
```

Create sample data.

```
v = 0:0.00614:2*pi;
x = sin(v) + 0.3*rand(1,numel(v));
```

Enable production of a code generation report by using a configuration object for standalone code generation (static library, dynamically linked library, or executable program).

```
cfg = coder.config('lib', 'ecoder', true);
cfg.GenerateReport=true;
```

Alternatively, use the `codegen -report` option.

Generate code by using `codegen`. Specify the type of the input argument by providing an example input with the `-args` option. Specify the configuration object by using the `-config` option.

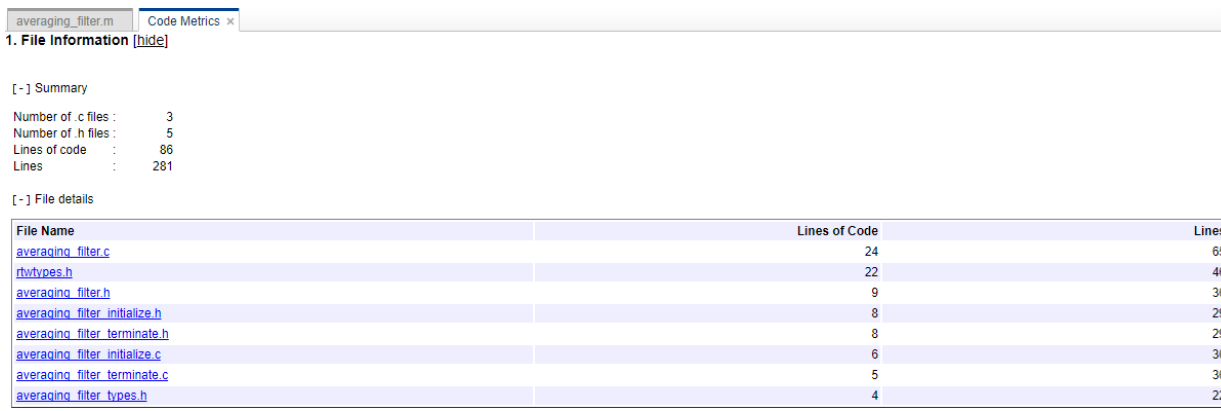
```
codegen averaging_filter -config cfg -args {x}
```

To open the code generation report, click **View report**.

To run the static code metrics analysis and view the code metrics report, on the **Summary** tab of the code generation report, click **Code Metrics**.

Explore the code metrics report.

1. To see the generated files and the number of lines of code per file, click **File Information**.



averaging_filter.m | Code Metrics ×

1. File Information [hide]

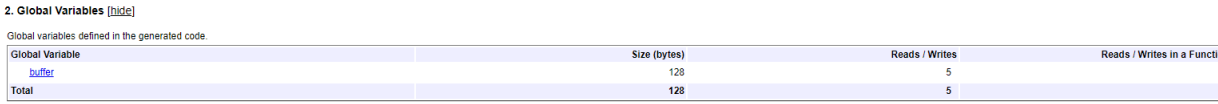
[-] Summary

Number of .c files : 3
Number of .h files : 5
Lines of code : 86
Lines : 281

[-] File details

File Name	Lines of Code	Lines
averaging_filter.c	24	65
rtwtypes.h	22	46
averaging_filter.h	9	30
averaging_filter_initialize.h	8	29
averaging_filter_terminate.h	8	29
averaging_filter_initialize.c	6	30
averaging_filter_terminate.c	5	30
averaging_filter_types.h	4	22

2. To see the global variables in the generated code, go to the **Global Variables** section.



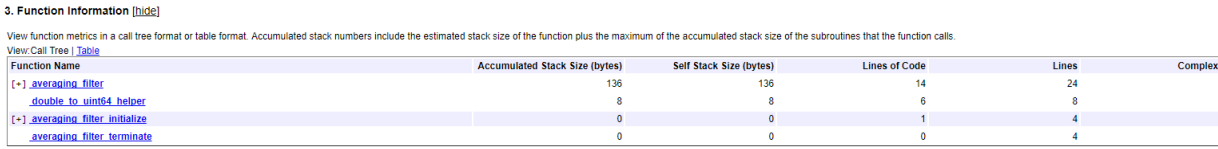
2. Global Variables [hide]

Global variables defined in the generated code.

Global Variable	Size (bytes)	Reads / Writes	Reads / Writes in a Function
buffer	128	5	4
Total	**128**	**5**	

To navigate from the report to the source code, click a global variable name.

3. To view the function call tree of the generated code, in the **Function Information** section, click **Call Tree**.



3. Function Information [hide]

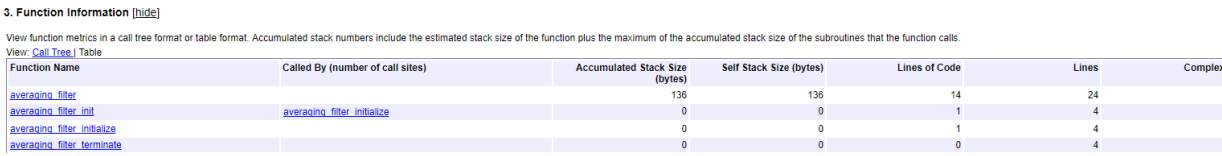
View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View:Call Tree | Table

Function Name	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
[+] averaging_filter	136	136	14	24	3
double_to_uint64_helper	8	8	6	8	1
[+] averaging_filter_initialize	0	0	1	4	1
averaging_filter_terminate	0	0	0	4	1

To navigate from the report to the function code, click a function name.

4. To view the functions in a table format, click **Table**.



3. Function Information [hide]

View function metrics in a call tree format or table format. Accumulated stack numbers include the estimated stack size of the function plus the maximum of the accumulated stack size of the subroutines that the function calls.

View: Call Tree | Table

Function Name	Called By (number of call sites)	Accumulated Stack Size (bytes)	Self Stack Size (bytes)	Lines of Code	Lines	Complexity
averaging_filter		136	136	14	24	3
averaging_filter_init	averaging_filter_initialize	0	0	1	4	1
averaging_filter_initialize		0	0	1	4	1
averaging_filter_terminate		0	0	0	4	1

The second column, **Called By**, lists functions that call the function listed in the first column. If multiple functions call that function, all functions are listed. If no functions call that function, this column is empty.

Requirements for Running Static Code Metrics Analysis After Code Generation

By default, static code metrics analysis does not run at code generation time. Instead, you can run the analysis later by clicking **Code Metrics** in the code generation report. Running static code metrics analysis after code generation has these requirements and limitations:

- You must have Embedded Coder and use the platform that you used for code generation. Once you run the static code metrics analysis, you can open the code metrics report without Embedded Coder or open it on a different platform.
- If you make the code generation report read-only before you run the analysis, each time that you click **Code Metrics**, the analysis runs.

Running Static Code Metrics at Code Generation Time

If you want the code generator to run static code metrics analysis and produce the code metrics report at code generation time:

- In an Embedded Coder code generation configuration object, set `GenerateCodeMetricsReport` to `true`.
- In the MATLAB Coder app, on the **Debugging** tab, set **Static code metrics** to `Yes`.

- “Code Generation Reports” (MATLAB Coder)

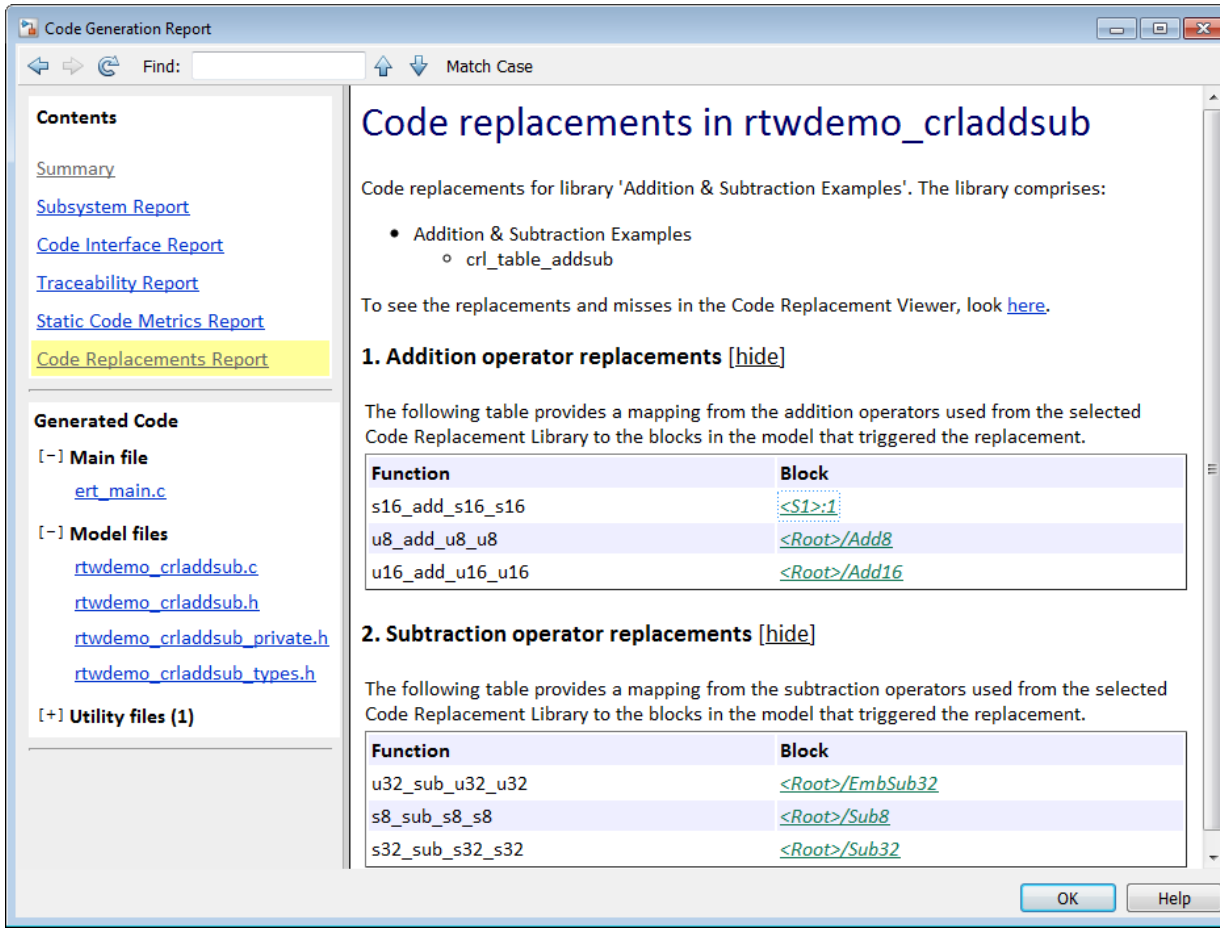
Analyze Code Replacements in Generated Code

When you select the check box **Summarize which blocks triggered code replacements** (Simulink Coder) for an ERT-based model, a Code Replacements Report section is automatically included in the generated HTML report. The Code Replacements Report section documents the code replacement library (CRL) functions that were used for code replacements during code generation, providing a mapping between each replacement instance and the Simulink block that triggered the replacement. To enable display of the Simulink block information, select the **Code Generation > Comments** check box **Include comments**. On the same pane, select either the **Simulink block comments** checkbox or the **Simulink block descriptions** check box if present, or both.

You can use the report to:

- Determine which replacement functions were used in the generated code.
- Trace each replacement instance back to the block that triggered the replacement.

The figure below shows a Code Replacements Report generated for the CRL model `rtwdemo_crladdsub`. Each replacement function used is listed with a link to the block that triggered the replacement.



If you click a block path in the report, the block that triggered the replacement is highlighted in the model diagram. If the replacement was triggered by a Stateflow chart or a MATLAB function, a window opens to display the chart or function.

For more information, see Trace Code Replacements Generated Using Your Code Replacement Library on page 65-86.

Document Generated Code with Simulink Report Generator

In this section...

The Simulink Report Generator software creates documentation from your model in multiple formats, including HTML, PDF, RTF, Microsoft Word, and XML. This example shows one way to document a code generation project in Microsoft Word. The generated report includes:

- System snapshots (model and subsystem diagrams)
- Block execution order list
- Simulink Coder and model version information for generated code
- List of generated files
- Optimization configuration parameter settings
- System target file selection and build process configuration parameter settings
- Subsystem map
- File name, path, and generated code listings for the source code

To adjust Simulink Report Generator settings to include custom code and then generate a report for a model, complete the following tasks:

1. “Generate Code for the Model” on page 49-51
2. “Open the Report Generator” on page 49-51
3. “Set Report Name, Location, and Format” on page 49-53
4. “Include Models and Subsystems in a Report” on page 49-54
5. “Customize the Report” on page 49-55

6 “Generate the Report” on page 49-56

A Simulink Report Generator license is required for the following report formats: PDF, RTF, Microsoft Word, and XML. For more information on generating reports in these formats, see the Simulink Report Generator documentation.

Generate Code for the Model

Before you use the Report Generator to document your project, generate code for the model.

1. In the MATLAB Current Folder browser, navigate to a folder where you have write access.
2. Create a working folder from the MATLAB command line by typing:

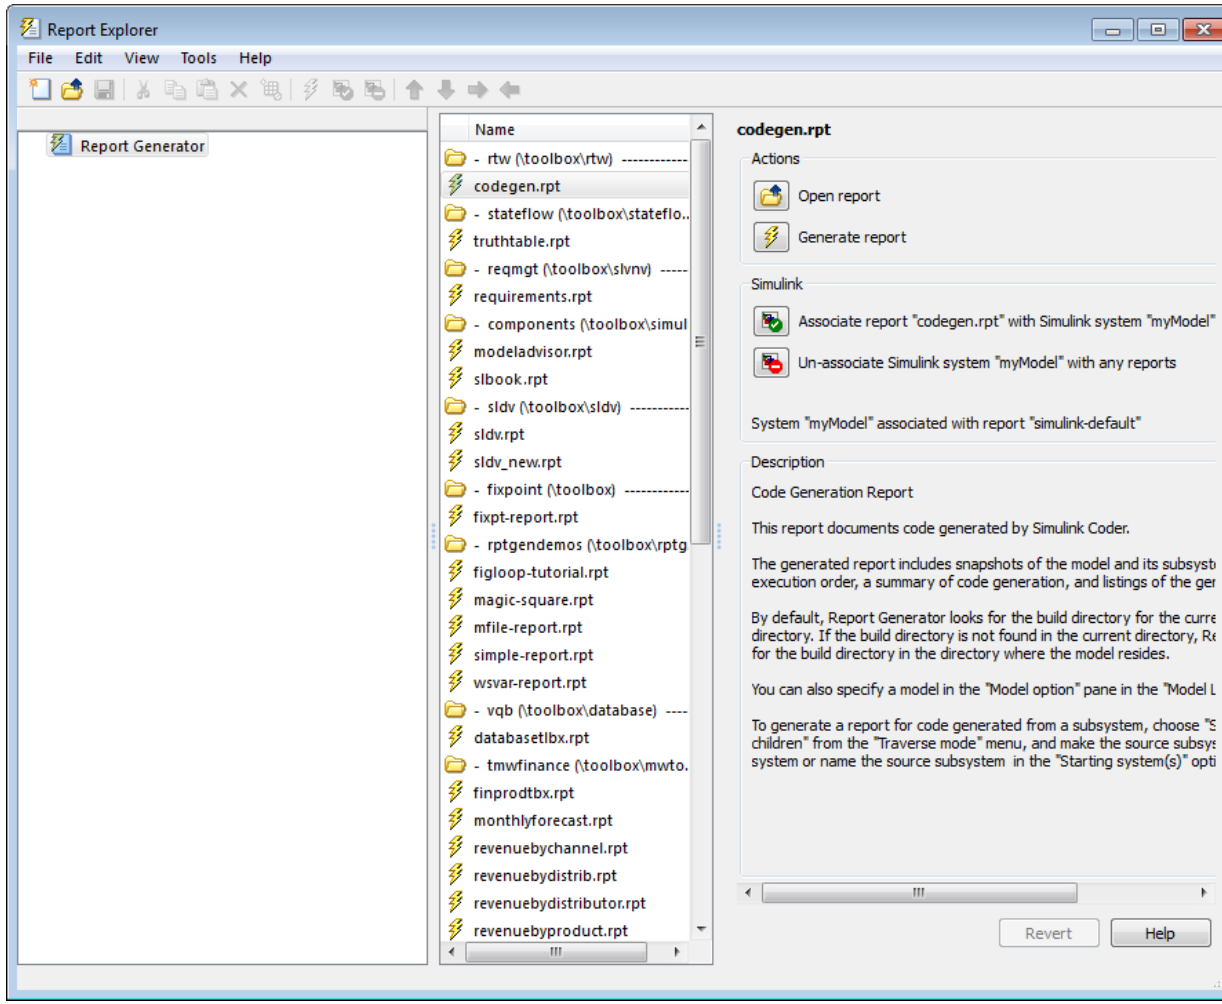
   ```
   mkdir report_ex
   ```
3. Make `report_ex` your working folder:

   ```
   cd report_ex
   ```
4. Open the `slexAircraftExample` model by entering the model name on the MATLAB command line.
5. In the model window, choose **File > Save As**, navigate to the working folder, `report_ex`, and save a copy of the `slexAircraftExample` model as `myModel`.
6. Open the Configuration Parameters dialog box by selecting **Model Configuration Parameters** from the **Simulation** menu.
7. Select the **Solver** pane. In the **Solver selection** section, specify the **Type** parameter as `Fixed-step`.
8. Select the **Code Generation** pane. Select **Generate code only**.
9. Click **Apply**.
10. In the model window, press **Ctrl+B**. The build process generates code for the model.

Open the Report Generator

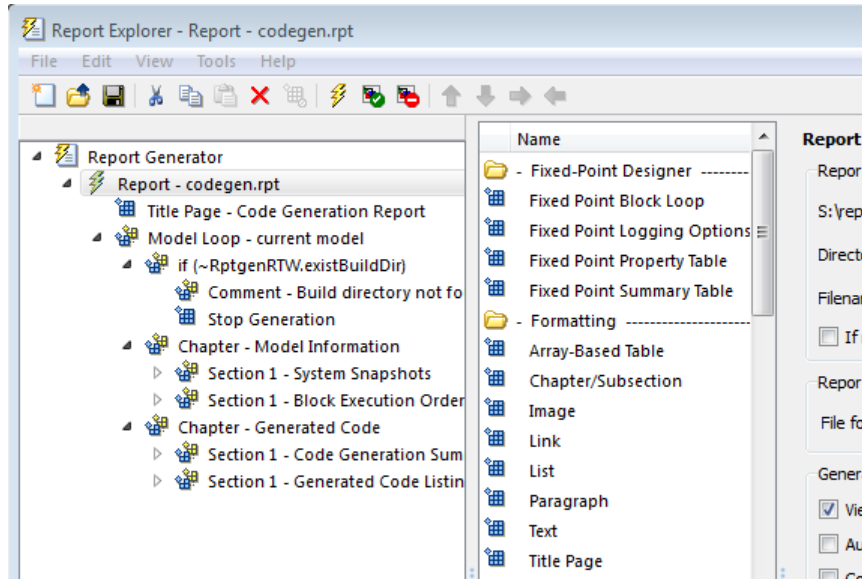
After you generate the code, open the Report Generator.

1. In the model diagram window, select **Tools > Report Generator**.
2. In the Report Explorer window, in the options pane (center), click the folder **rtw (\toolbox\rtw)**. Click the setup file that it contains, **codegen.rpt**.



3

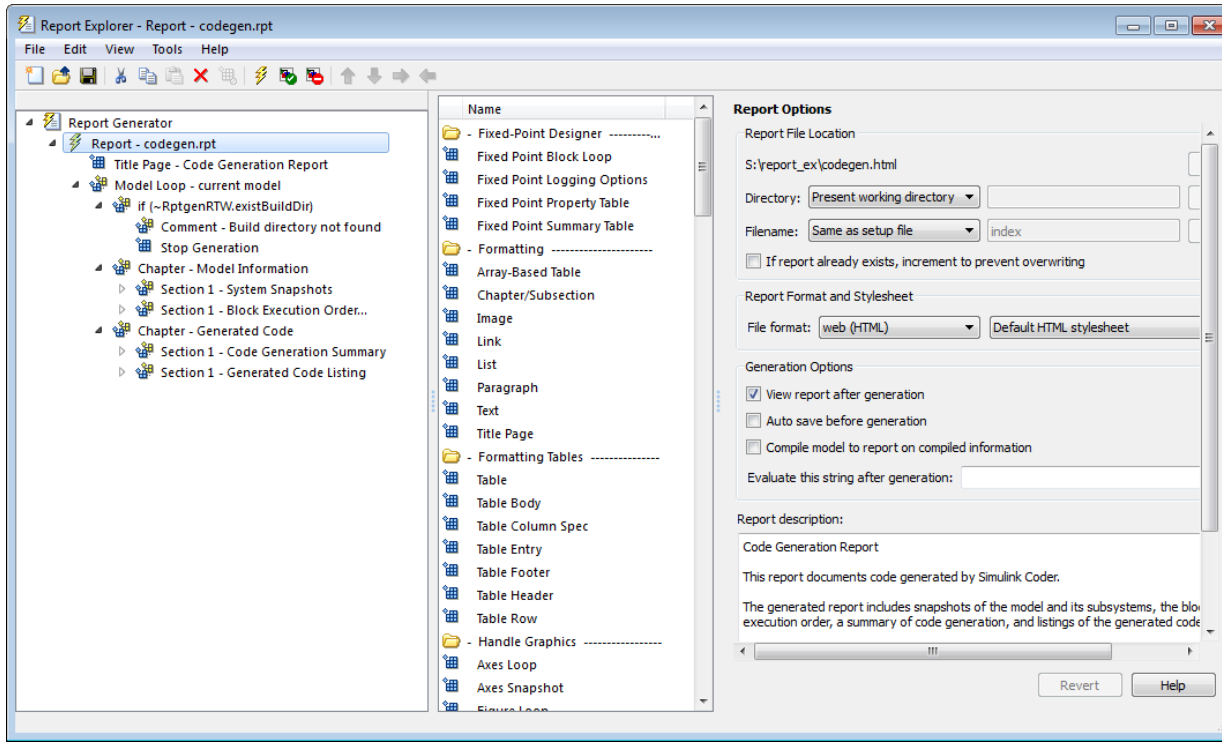
Double-click **codegen.rpt** or select it and click the **Open report** button  . The Report Explorer displays the structure of the setup file in the outline pane (left).



Set Report Name, Location, and Format

Before generating a report, you can specify report output options, such as the folder, file name, and format. For example, to generate a Microsoft Word report named `MyCGModelReport.rtf`:

1 In the properties pane, under **Report Options**, review the options listed.



2 Leave the **Directory** field set to `Present working directory`.

3 For **Filename**, select `Custom:` and replace `index` with the name `MyModelCGReport`.

4 For **File format**, specify `Rich Text Format` and replace `Standard Print` with `Numbered Chapters & Sections`.

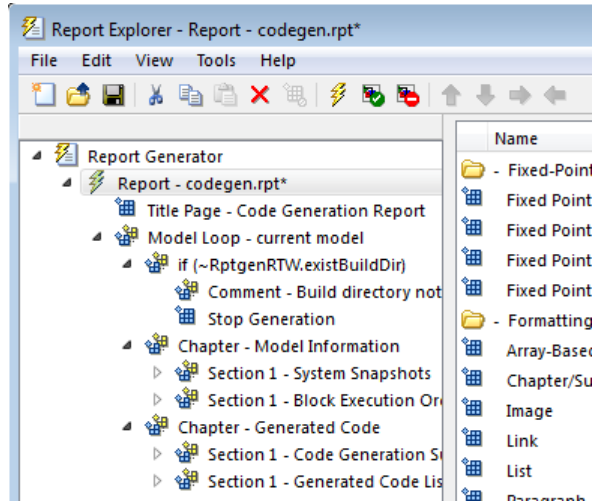
Include Models and Subsystems in a Report

Specify the models and subsystems that you want to include in the generated report by setting options in the Model Loop component.

1 In the outline pane (left), select **Model Loop**. Report Generator displays Model Loop component options in the properties pane.

2 If not already selected, select `Current block diagram` for the **Model name** option.

3 In the outline pane, click **Report - codegen.rpt***.



Customize the Report

After specifying the models and subsystems to include in the report, you can customize the sections included in the report.

1 In the outline pane (left), expand the node **Chapter - Generated Code**. By default, the report includes two sections, each containing one of two report components.

2 Expand the node **Section 1 — Code Generation Summary**.

3 Select **Code Generation Summary**. Options for the component are displayed in the properties pane.

4 Click **Help** to review the report customizations that you can make with the Code Generation Summary component. For this example, do not customize the component.

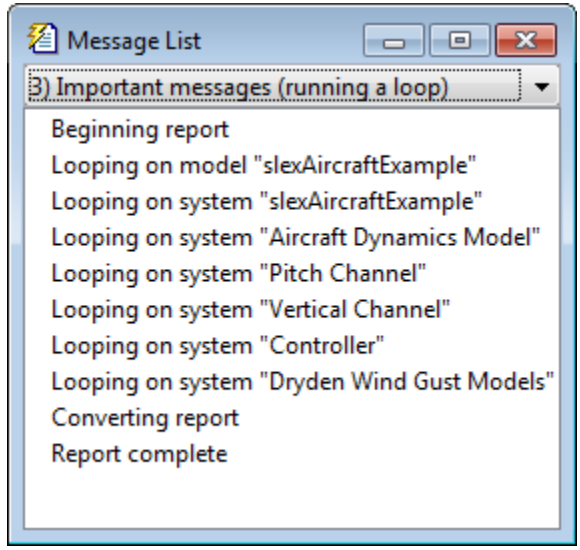
5 In the Report Explorer window, expand the node **Section 1 — Generated Code Listing**.

6 Select **Import Generated Code**. Options for the component are displayed in the properties pane.

7 Click **Help** to review the report customizations that you can make with the Import Generated Code component.

Generate the Report

After you adjust the report options, from the **Report Explorer** window, generate the report by clicking **File** > **Report**. A **Message List** dialog box opens, which displays messages that you can monitor as the report is generated. Model snapshots also appear during report generation. The **Message List** dialog box might be hidden behind other dialog boxes.

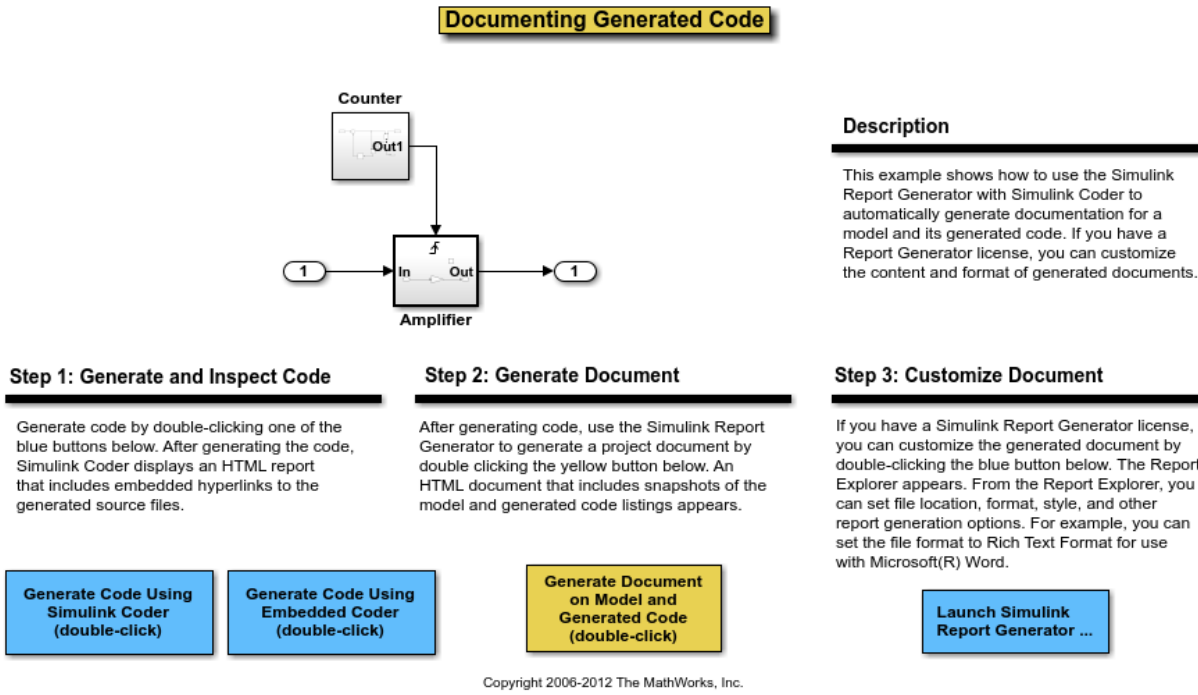


When the report is complete, open the report, `MyModelCGReport.rtf` in the folder `report_ex` (in this example).

Document Generated Code

This example shows how to use the Simulink® Report Generator with Simulink® Coder™ to automatically generate documentation for a model and its generated code.

```
model='rtwdemo_codegenrpt';
open_system(model)
```



```
% Cleanup
rtwdemoclean;
close_system(model,0)
```

More About

- “Document Generated Code with Simulink Report Generator” on page 49-50

Get Code Description of Generated Code

You can use the code descriptor API to obtain meta-information about the generated code. For each model build, the code generator, by default, creates a `codedescriptor.dmr` file in the build folder. When simulating the model in Accelerator and Rapid Accelerator modes, the `codedescriptor.dmr` is not generated.

You can use the code descriptor API once the code is generated. Use the code descriptor API to describe these items in the generated code:

- Data Interfaces: inports, outports, parameters, and global data stores.
- Function Interfaces: initialize, output, update, and terminate.
- Run-time information of the data and function interfaces, such as timing requirements of each interface entity.
- Model hierarchy information and code description of referenced models.

Get Data Interface Information

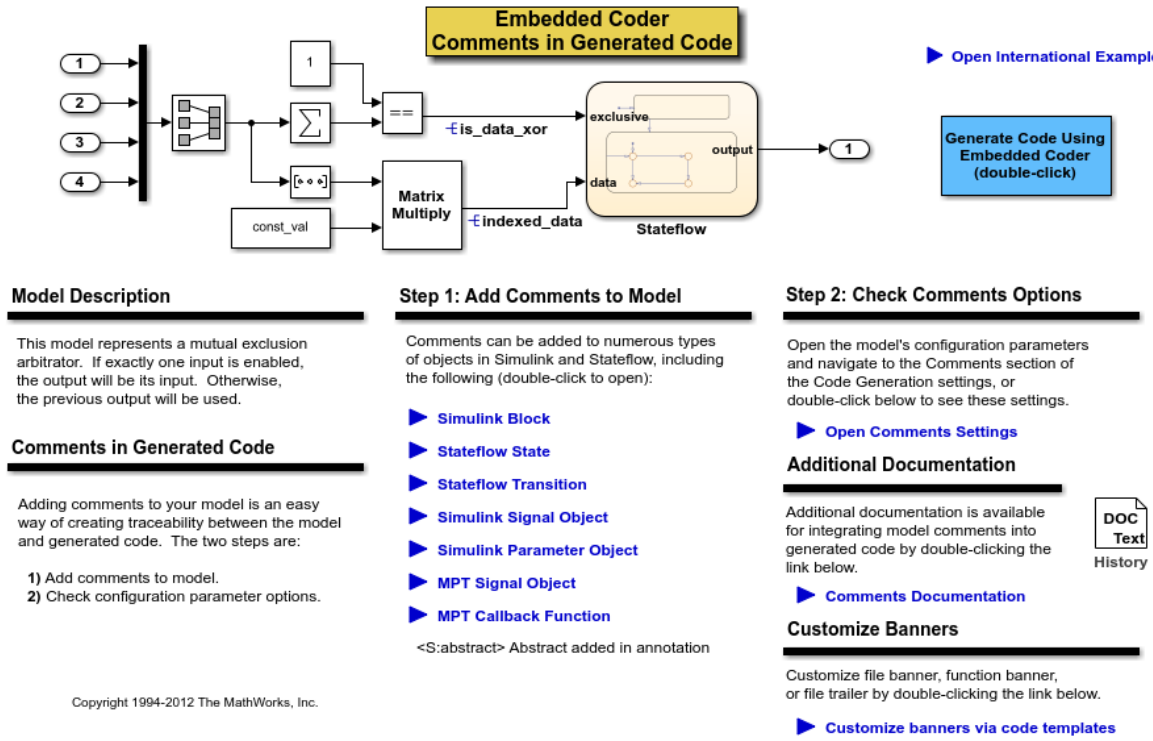
The `coder.codedescriptor.CodeDescriptor` object describes various properties for a specified data interface in the generated code. In the model `rtwdemo_comments`, there are four inports, one outport, and a tunable global parameter. For more information about the data interfaces in your model, use the `coder.codedescriptor.CodeDescriptor` object and its methods.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_comments');
evalc('rtwbuild(''rtwdemo_comments'')');
```



3. Create a `coder.codedescriptor.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_comments');
```

4. To obtain a list of all the data interface types in the generated code, use the `getDataInterfaceTypes` method.

```
dataInterfaceTypes = codeDescriptor.getDataInterfaceTypes()
```

```
dataInterfaceTypes =

  5x1 cell array

    {'Inports'        }
    {'Outports'       }
```

```
    {'Parameters'      }
    {'GlobalParameters'}
    {'InternalData'    }
```

To obtain a list of all the supported data interfaces, use the `getAllDataInterfaceTypes` method.

5. To obtain more information about a particular data interface type, use the `getDataInterfaces` method.

```
dataInterface = codeDescriptor.getDataInterfaces('Inports');
```

This method returns properties of the Inport blocks in the generated code.

6. Because this model has four inports, `dataInterface` is an array of `coder.descriptor.DataInterface` objects. Obtain the details of the first Inport of the model by accessing the first location in the array.

```
dataInterface(1)
```

```
ans =

  DataInterface with properties:
             Type: [1x1 coder.descriptor.types.Double]
              SID: 'rtwdemo_comments:1'
     GraphicalName: 'In1'
       VariantInfo: [0x0 coder.descriptor.VariantInfo]
    Implementation: [1x1 coder.descriptor.StructExpression]
            Timing: [1x1 coder.descriptor.TimingInterface]
```

Get Function Interface Information

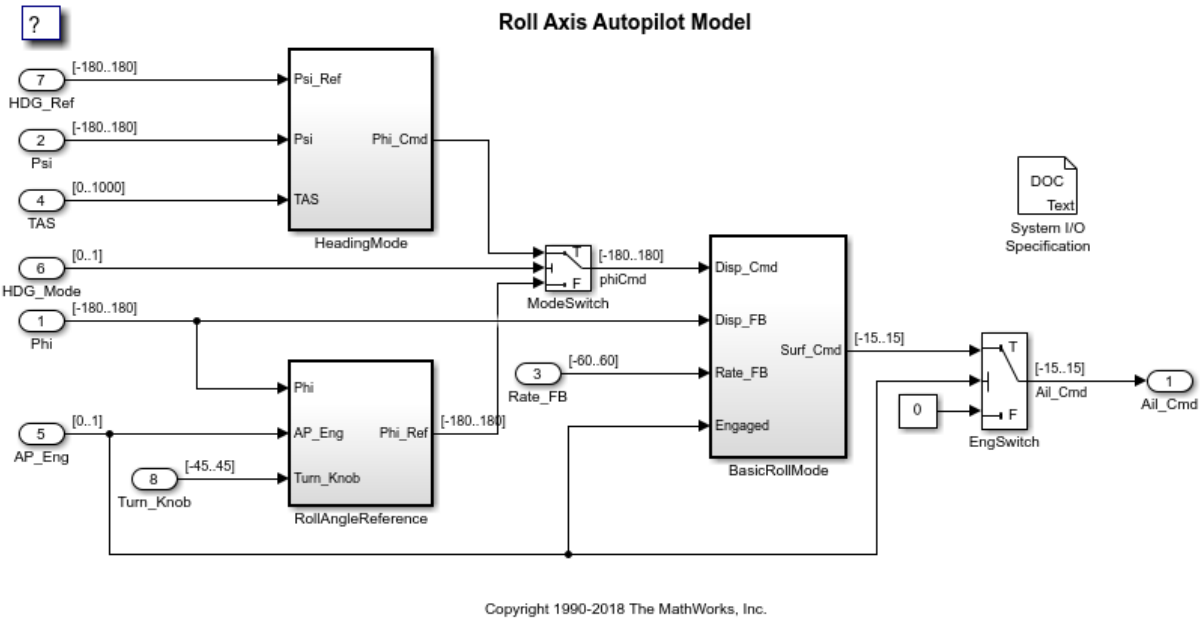
The function interfaces are the entry-point functions in the generated code. In the model `rtwdemo_roll`, the entry-point functions are `model_initialize`, `model_step`, and `model_terminate`. For more information about the function interfaces in your model, use the `coder.codedescriptor.CodeDescriptor` object.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_roll');
evalc('rtwbuild(''rtwdemo_roll'')');
```



3. Create a `coder.codedescriptor.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_roll');
```

4. To obtain a list of all the function interface types in the generated code, use the `getFunctionInterfaceTypes` method.

```
functionInterfaceTypes = codeDescriptor.getFunctionInterfaceTypes()
```

```
functionInterfaceTypes =

  2x1 cell array

    {'Initialize'}
    {'Output'    }
```

To obtain a list of all the supported function interfaces, use the `getAllFunctionInterfaceTypes` method.

5. To obtain more information about a particular function interface type, use the `getFunctionInterfaces` method.

```
functionInterface = codeDescriptor.getFunctionInterfaces('Initialize')
```

```
functionInterface =

  FunctionInterface with properties:
        Prototype: [1x1 coder.descriptor.types.Prototype]
     ActualReturn: [0x0 coder.descriptor.DataInterface]
      VariantInfo: [0x0 coder.descriptor.VariantInfo]
    FunctionOwner: [0x0 coder.descriptor.TypedRegion]
           Timing: [1x1 coder.descriptor.TimingInterface]
       ActualArgs: [1x0 coder.descriptor.DataInterface List]
```

6. You can further expand on the properties to obtain detailed information. To get the function return value, name, and arguments:

```
functionInterface.Prototype
```

```
ans =

  Prototype with properties:
          Name: 'rtwdemo_roll_initialize'
        Return: [0x0 coder.descriptor.types.Argument]
    HeaderFile: 'rtwdemo_roll.h'
    SourceFile: 'rtwdemo_roll.c'
     Arguments: [1x0 coder.descriptor.types.Argument List]
```

Get Model Hierarchy Information

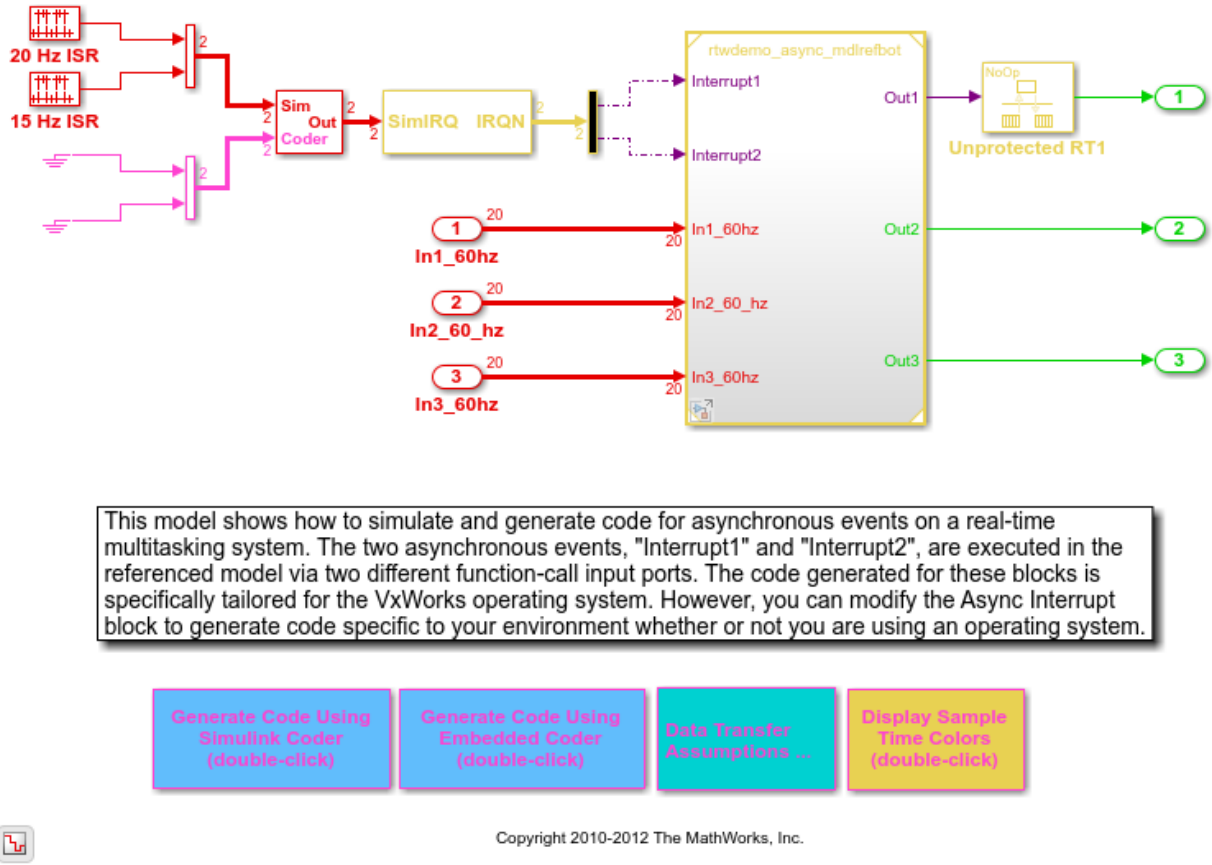
Use the `coder.codedescriptor.CodeDescriptor` object to get the entire model hierarchy information. The model `rtwdemo_async_mdlreftop` has model `rtwdemo_async_mdlrefbot` as the referenced model.

1. Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

2. Open and build the model.

```
open_system('rtwdemo_async_mdlreftop');
evalc('rtwbuild(''rtwdemo_async_mdlreftop'')');
```



3. Create a `coder.codedescriptor.CodeDescriptor` object for the required model by using the `getCodeDescriptor` function.

```
codeDescriptor = coder.getCodeDescriptor('rtwdemo_async_mdlreftop');
```

4. Get a list of all the referenced models by using the `getReferencedModelNames` method.

```
refModels = codeDescriptor.getReferencedModelNames()
```

```
refModels =

  1x1 cell array

    {'rtwdemo_async_mdlrefbot'}
```

5. To obtain the `coder.codedescriptor.CodeDescriptor` object for the referenced model, use the `getReferencedModelCodeDescriptor` method.

```
refCodeDescriptor = codeDescriptor.getReferencedModelCodeDescriptor('rtwdemo_async_mdl
```

You can now use the `refCodeDescriptor` object to obtain more information about the referenced model by using all the available methods in the Code Descriptor API.

Code Appearance in Embedded Coder

Add Custom Comments to Generated Code

You can include auto-generated comments in the generated code as described in "Configure Code Comments" (Simulink Coder). For ERT targets, include additional custom comments by setting parameters on the **Code Generation > Comments** pane in the Configuration Parameters dialog box. With these parameters, you can enable or suppress generation of descriptive information in comments for blocks and other model elements.

Goal	Specify
Include the text specified in the **Description** field of a block's Block Properties dialog box as comments in the code generated for each block.	**Simulink block descriptions**
Add a comment that includes the block name at the start of the code for each block.	**Simulink block descriptions**
Include the text specified in the **Description** field of a Simulink data object (such as a signal, parameter, data type, or bus) in the Simulink Model Explorer as comments in the code generated for each object.	**Simulink data object descriptions**
Include comments just above signals and parameter identifiers in the generated code as specified in the MATLAB or TLC function.	**Custom comments (MPT objects only)**
Include the text specified in the **Description** field in the Properties dialog box for a Stateflow object as comments just above the code generated for each object.	**Stateflow object descriptions**
Include requirements assigned to Simulink blocks in the generated code comments (for more information, see "Generate Code for Models with Requirements Links" (Simulink Requirements)).	**Requirements in block comments**
Include MATLAB function description comments and other user comments in the generated code.	**MATLAB user comments**

When you select **Simulink block descriptions**:

- The code generator includes strings for model parameters, block names, signal names, and Stateflow object names in the generated code comments. If those strings are unrepresented in the character set encoding for the model, the code generator replaces the strings with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ア with the escape sequence `ア`. For more information, see “Internationalization and Code Generation” (Simulink Coder).
- The code generation software automatically inserts comments into the generated code for custom blocks. Therefore, you do not need to include block comments in the associated TLC file for a custom block.

  Note If you have existing TLC files with manually inserted comments for block descriptions, the code generation process emits these comments instead of the automatically generated comments. Consider removing existing block comments from your TLC files. Manually inserted comments might be poorly formatted in the generated code and code-to-model traceability might not work.

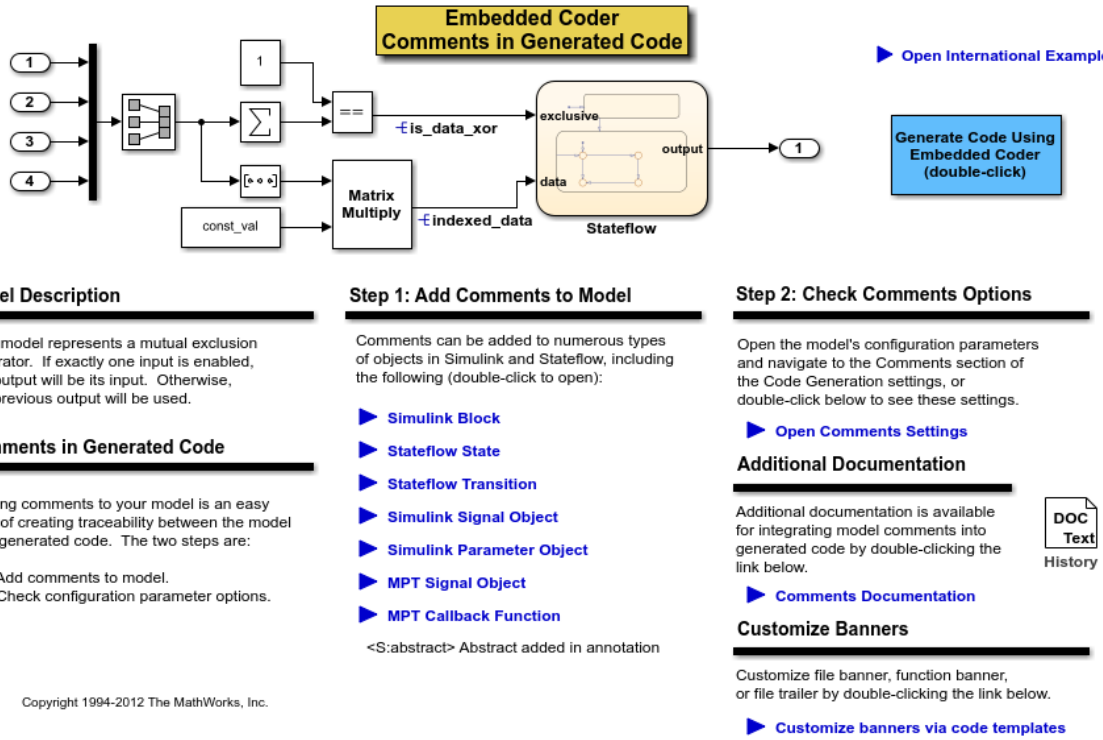
- For virtual blocks or blocks that have been removed due to block reduction, comments are not generated.

For more information, see “Model Configuration Parameters: Code Generation Comments” (Simulink Coder).

Customize Code Comments to Enhance Readability and Traceability

This example shows how to add comments to numerous types of objects in Simulink® and Stateflow®.

```
model='rtwdemo_comments';
open_system(model)
```



```
% Cleanup
rtwdemoclean;
close_system(model,0)
```

More About

- “Add Custom Comments to Generated Code” on page 50-3

Add Custom Comments for Variables in the Generated Code

To control code generation options for signals, states, and parameters in a model, you can create data objects in a workspace or data dictionary. You can generate comments in the code that help you to document the purpose and properties of the data in each object. Associate handwritten comments with each object, or write a function that generates comments based on the properties of the object.

For more information about data objects, see “Data Objects” (Simulink).

Embed Handwritten Comments for Signals or Parameters

To embed handwritten comments in the generated code near the definition of a signal, state, or parameter:

1. Create a data object to represent a signal, state, or parameter. You can use a data object from any package. For example, use a data object of the classes `Simulink.Signal` or `Simulink.Parameter`, which are defined in the package `Simulink`.

   ```
   myParam = Simulink.Parameter(15.23);
   ```

2. Set the storage class of the data object so that optimizations do not eliminate the signal or parameter from the generated code. For example, use the storage class `ExportedGlobal`.

   ```
   myParam.StorageClass = 'ExportedGlobal';
   ```

3. Set the `Description` property of the object. The description that you specify appears in the generated code as lines of comments.

   ```
   myParam.Description = 'This parameter represents wind speed.';
   ```

4. Set **Configuration Parameters** > **Code Generation** > **System target file** to an ERT-based target such as `ert.tlc`.

   To generate comments from data object descriptions, you must use an ERT-based target.

5. Select **Configuration Parameters** > **Code Generation** > **Comments** > **Simulink data object descriptions**.

6 Generate code from the model. In the code, the data object description appears near the definition of the corresponding variable.

```
/* Exported block parameters */
real_T myParam = 15.23;     /* Variable: myParam
                             * Referenced by: '<S1>/Gain'
                             * This parameter represents wind speed.
                             */
```

Generate Dynamic Comments Based on Data Properties

You can generate dynamic comments that include the properties of the data object such as data type, units, and dimensions. If you change the properties of the data object in Simulink, the code generator maintains the accuracy of the comments. For example, this comment displays some of the property values for a data object named `MAP`:

```
/*     Unit:       psi                                          */
/*     Owner:                                                   */
/*     DefinitionFile: specialDef                               */
real_T MAP = 0.0;
```

1 Create a data object from the package `mpt` and apply a custom storage class to the object. The default storage class for objects that you create from the package `mpt` is the custom storage class `Global (Custom)`.

```
MAP = mpt.Signal;
```

To generate dynamic comments, you must use a data object from the package `mpt`, and you must apply a custom storage class to the object.

2 Write a MATLAB or TLC function that generates the comment text. For an example MATLAB function, see the function *`matlabroot`*`/toolbox/rtw/rtwdemos/rtwdemo_comments_mptfun.m`.

The function must accept three input arguments that correspond to `objectName`, `modelName`, and `request`. If you write a TLC file, you can use the library function `LibGetSLDataObjectInfo` to get the property values of the data object.

3 Save the function as a MATLAB file or a TLC file, and place the file in a folder that is on your MATLAB path.

4 In the model, select **Configuration Parameters** > **Code Generation** > **Comments** > **Custom comments (MPT objects only)**.

5. Set **Custom comments function** to the name of the MATLAB file or TLC file that you created.
6. Generate code from the model. The comments that your function generates appear near the code that represents each data object.

Limitations

- To generate comments by using the **Custom comments (MPT objects only)** and **Custom comments function** options, you must create data objects from the package `mpt`. The data objects must use a custom storage class.
- Only the custom storage classes from the `mpt` package that create unstructured variables support a custom comments function.

Add Global Comments

In this section...

The following examples show how to add a global comment to a Simulink model so that the comment text appears in the generated file or files where you want. Specify a template symbol name with a Simulink DocBlock, a Simulink annotation, or a Stateflow note. You can also use a sorted-notes capability that works with Simulink annotations or Stateflow notes (but not DocBlocks). For more information about template symbols, see “Template Symbols and Rules” on page 50-101.

Note Template symbol names `Description` and `ModifiedHistory` also are fields in the Model Properties dialog box. If you use one of these symbol names for global comment text, and its Model Properties field also has text in it, both names appear in the generated files.

Use a Simulink DocBlock to Add a Comment

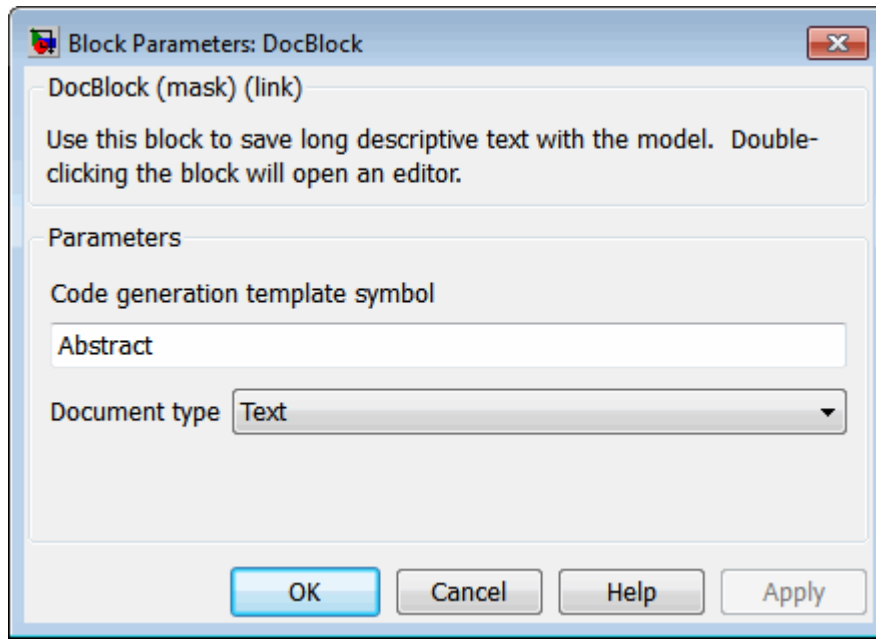
1. With the model open, from the **View** menu, select **Library Browser**.
2. Drag the DocBlock from **Model-Wide Utilities** in the Simulink library into the model.
3. Double-click the DocBlock and type the comment that you want in the editor. Save and close the editor.
4. Right-click the DocBlock and select **Mask > Mask Parameters**.
5. In the **Code generation template symbol** box, type one of the following:

   - `Abstract`
   - `Description`
   - `History`
   - `ModifiedHistory`

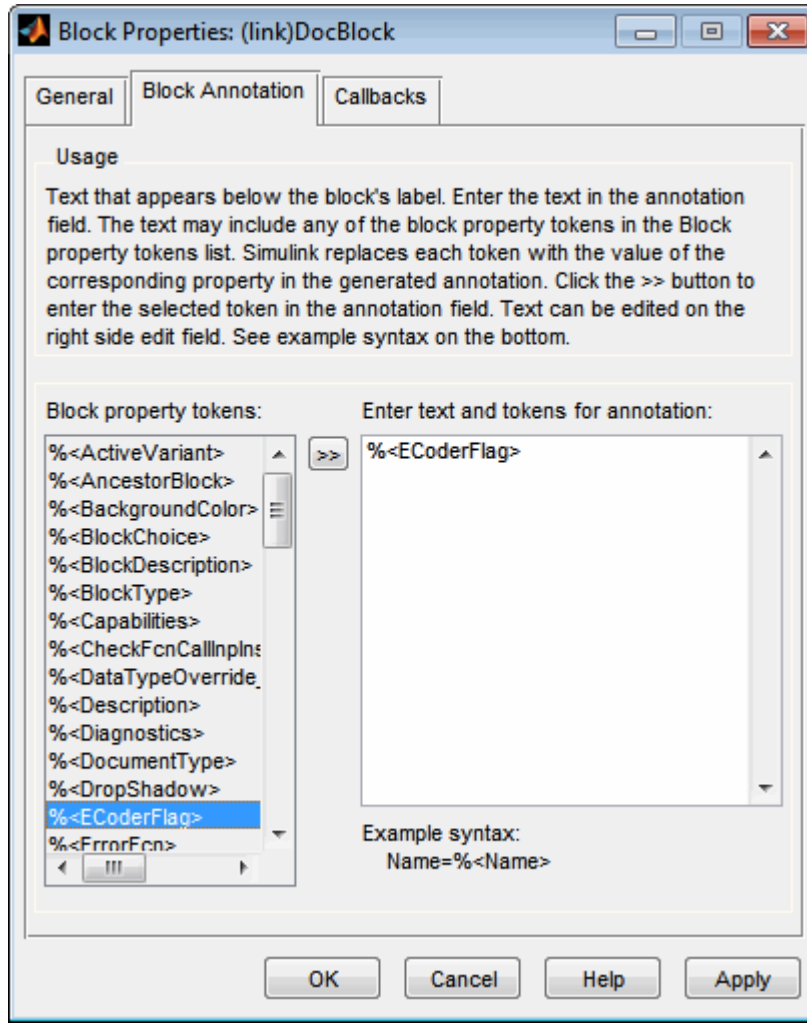
- `Notes`

Click **OK**. Template symbol names are case-sensitive.

If you are using a DocBlock to add comments to your code, set the **Document type** to `Text`. If you set **Document type** to `RTF` or `HTML`, your comments will not appear in the code.



6 In the Block Properties dialog box, on the **Block Annotation** tab, select `%<ECoderFlag>` and click **OK**. The symbol name that you typed in the previous step now appears under the DocBlock in the model.



7 Save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.

8 To add more comments to the generated files, repeat steps 1–7.

Use a Simulink Annotation to Add a Comment

1. Double-click the unoccupied area on the model where you want to place the comment. See “Describe Models Using Annotations” (Simulink).
2. Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:

   - `Abstract`
   - `Description`
   - `History`
   - `ModifiedHistory`
   - `Notes`

   For example, type `<S:Description>This is the description I want`. Template symbol names are case-sensitive. (The `"S"` before the colon indicates "symbol.") If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 50-14.
3. Click outside the rectangle and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file. If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 50-14.
4. To add one or more other comments to the generated files, repeat steps 1–3.

Use a Stateflow Note to Add a Comment

1. Right-click the unoccupied area on the Stateflow chart where you want to place the comment.
2. Select the annotation icon from the palette.
3. Type `<S:Symbol_name>` followed by the comment. `Symbol_name` is one of the following:

   - `Abstract`

- `Description`
- `History`
- `ModifiedHistory`
- `Notes`

For example, type `<S:Description>This is the description I want`. Template symbol names are case-sensitive. If you want the code generator to sort multiple comments for the `Notes` symbol name, replace the next step with “Use Sorted Notes to Add Comments” on page 50-14.

4. Click outside the note and save the model. After you generate code, the code generator places the comment in each generated file whose template has the symbol name that you typed. The code generator places the comment in the generated file at the location that corresponds to where the symbol name is located in the template file.
5. To add one or more other comments to the generated files, repeat steps 1–4.

Use Sorted Notes to Add Comments

The sorted-notes capability allows you to add automatically sorted comments to the generated files. The code generator places these comments in each generated file at the location that corresponds to where the `Notes` symbol is located in the template file.

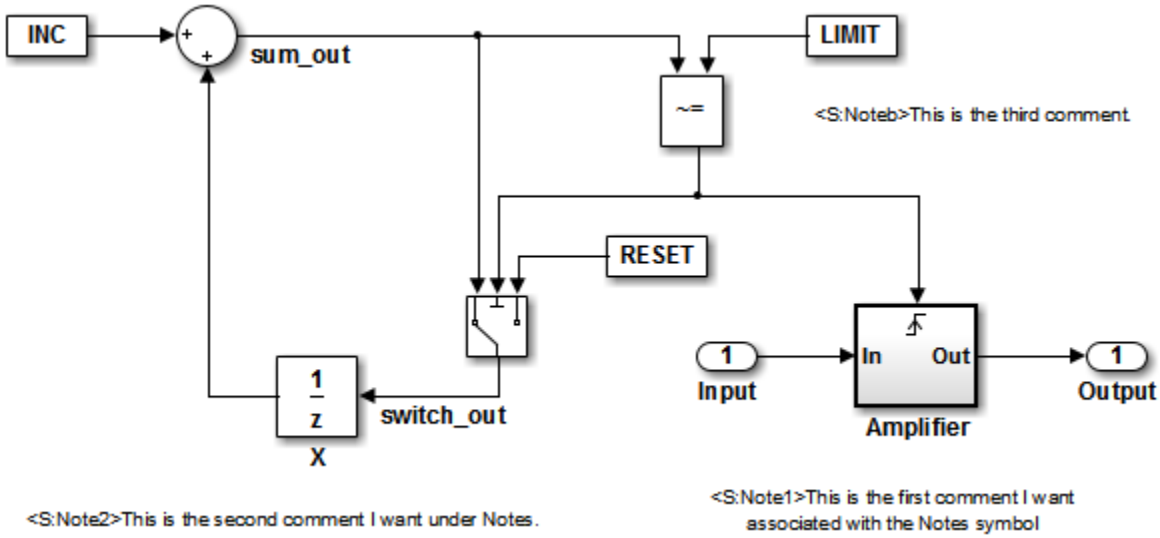
The code generator uses the following sorting order:

- Numbers before letters.
- Among numbers, 0 is first.
- Among letters, uppercases are before lowercases.

You can use sorted notes with a Simulink annotation or a Stateflow note, but not with a DocBlock.

- In the Simulink annotation or the Stateflow note, type `<S:NoteY>` followed by the first comment. `Y` is a number or a letter.
- Repeat for as many additional comments you want. Replace `Y` with a subsequent number or letter.

The figure illustrates sorted notes on a model, and where the code generator places each note in a generated file.



The relevant fragment from the generated file for this model is:

```
** NOTES

** Note1: This is the first comment I want
associated with the Notes symbol.
Note2: This is the second comment I want under Notes.
Noteb: This is the third comment.

**
```

Customize Generated Identifier Naming Rules

In this section...

For GRT and RSim targets, the code generator constructs identifiers for variables and functions in the generated code. For ERT targets, you can customize the naming of identifiers in the generated code by specifying parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box. You can also specify parameters that control identifiers generated from Simulink data objects. For detailed information about these parameters, see “Model Configuration Parameters: Code Generation Symbols” (Simulink Coder).

Apply Naming Rules to Identifiers Globally

Goal	Specify
Set the maximum number of characters that the code generator uses for function, `typedef`, and variable names (default 31).	An integer value for the “Maximum identifier length” (Simulink Coder) parameter. For more information, see “Specify Identifier Length to Avoid Naming Collisions” (Simulink Coder). If you expect your model to generate lengthy identifiers (due to use of long signal or parameter names, for example), or if identifiers are mangled more than you expect, increase the value of this parameter.

Goal	Specify
Define a macro that specifies certain text included within generated identifiers for: • Global variables • Global types • Field names of global types • Subsystem methods • Subsystem method arguments • Local temporary variables • Local block output variables • Constant macros • Shared utilities identifier format	A macro for the **Identifier format control** parameters. For more information, see "Identifier Format Control" on page 50-24. See also "Exceptions to Identifier Formatting Conventions" on page 50-37 and "Identifier Format Control Parameters Limitations" on page 50-38.
Set the minimum number of characters that the code generator uses for the mangling text.	An integer value for the "Minimum mangle length" (Simulink Coder) parameter. For more information, see "Control Name Mangling in Generated Identifiers" on page 50-32
Control whether the software uses shortened names for system-generated identifiers.	`Shortened` for the "System-generated identifiers" (Simulink Coder) parameter. This setting: • Provides more space for user names. • Provides a more predictable and consistent naming system that uses camel case. • Does not include underscores or plurals. • Provides consistent abbreviations for both a type and a variable.

Goal	Specify
Control whether the generated code expresses scalar inlined parameter values as literal values or as macros.	The value `Literals` or `Macros` for the "Generate scalar inlined parameters as" (Simulink Coder) parameter. • `Literals`: If you set **Default parameter behavior** to `Inlined`, parameters are expressed as numeric constants. • `Macros`: Parameters are expressed as variables (with `#define` macros). This setting makes code more readable.

Apply Naming Rules to Simulink Data Objects

When your model uses Simulink data objects from the `Simulink` package, identifiers in generated code copy the names of the objects by default. For example, a `Simulink.Signal` object named `Speed` appears as the identifier `Speed` in generated code.

You can control these identifiers by specifying naming rules that are specific to Simulink data objects. On the **Code Generation > Symbols** pane of the Configuration Parameters dialog box, adjust the settings in the **Simulink data object naming rules** section.

When you specify naming rules for generated code, follow ANSI C[5]/C++ rules for naming identifiers.

Specify Naming Rule Using a Function

This example shows how to customize identifiers in generated code by defining a MATLAB function.

1 Write a MATLAB function that returns an identifier by modifying a data object name, and save the function in your working folder. For example, the following function returns an identifier name by appending the text `_param` to a data object name.

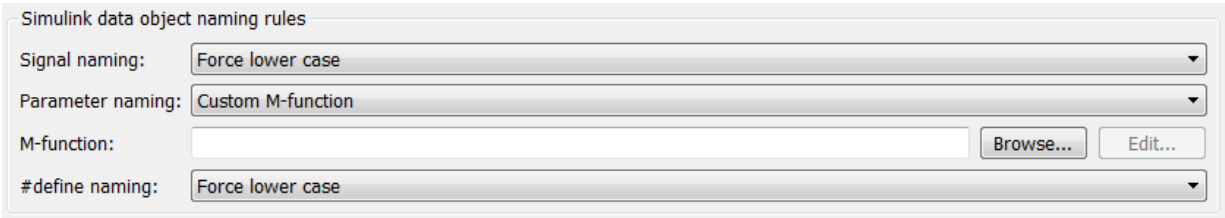
```
function revisedName = append_text(name, object)
% APPEND_TEXT: Returns an identifier for generated
% code by appending text to a data object name.
%
```

5. ANSI is a registered trademark of the American National Standards Institute, Inc.

```
% Input arguments:
% name: data object name as spelled in model
% object: target data object
%
% Output arguments:
% revisedName: altered identifier returned for use in
% generated code.
%
%
text = '_param';

revisedName = [name,text];
```

2. Open the model `rtwdemo_namerules`.
3. Double-click the yellow box labeled **View Symbols Configuration** to open the **Code Generation > Symbols** pane in the Configuration Parameters dialog box.
4. From the **Parameter naming** (Simulink Coder) drop-down list, select **Custom M-function**.



5. In the **M-function** field, type the name of the file that defines the MATLAB function, `append_text.m`.
6. Click **Apply**.
7. Generate code for the model.
8. Inspect the code generation report to confirm the parameter object naming rule. For example, the generated file `rtwdemo_namerules.h` represents the parameter objects `G1`, `G2`, and `G3` with the variables `G1_param`, `G2_param`, and `G3_param`.

Specify Naming Rule for Storage Class Define

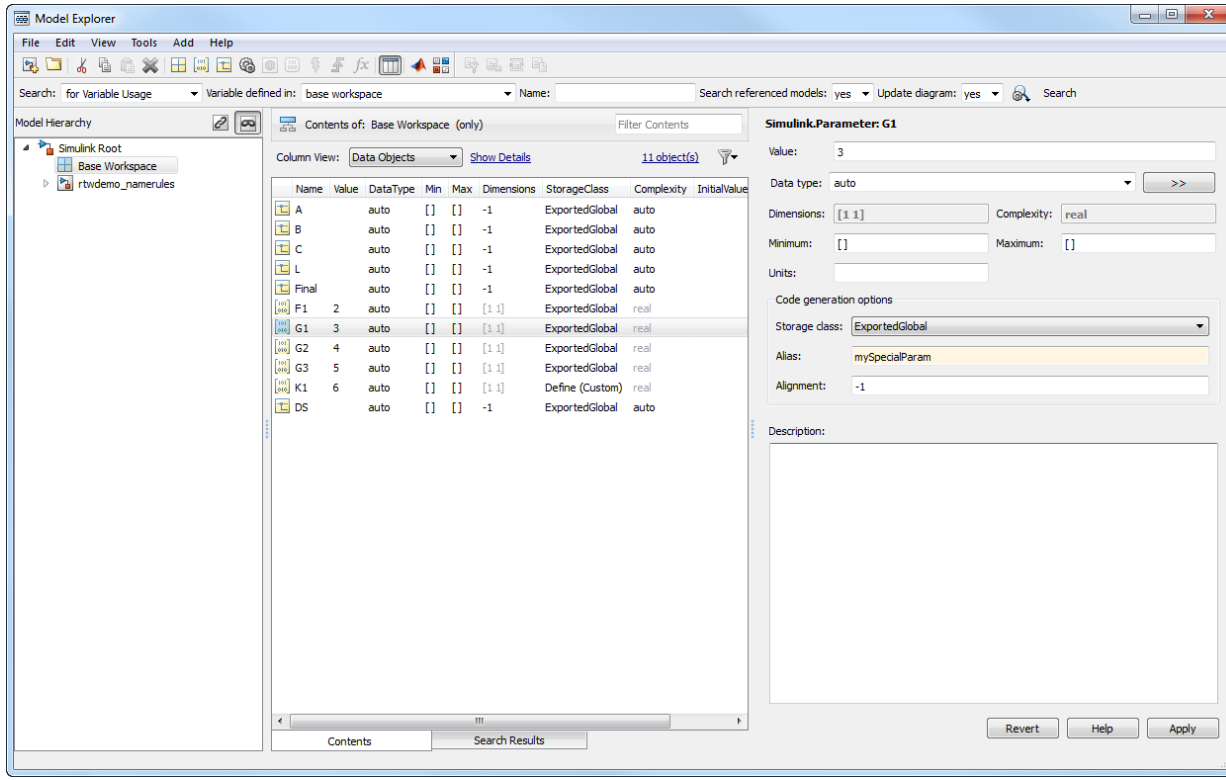
You can specify a naming rule that applies only to Simulink data objects whose storage class you set to `Define`. For these data objects, the specified naming rule overrides the other parameter and signal object naming rules. On the **Code Generation > Symbols** pane in the Configuration Parameters dialog box, adjust the **#define naming** (Simulink Coder) setting.

Override Data Object Naming Rules

This example shows how to override a data object naming rule for a single data object.

You can override data object naming rules by specifying the `Alias` property of an individual Simulink data object. Generated code uses the text that you specify as the identifier to represent the data object, regardless of naming rules.

1. Open the model `rtwdemo_namerules`.
2. In the model, select **View** > **Model Data Editor**.
3. In the Model Data Editor, on the **Parameters** tab, click the **Show/refresh additional information** button.
4. In the data table, find the row that corresponds to the `Simulink.Parameter` object `G1`, which resides in the base workspace.
5. In the row, double-click the parameter icon  .
6. In the Model Explorer Dialog pane (the right pane), for `G1`, specify the `Alias` property as `mySpecialParam`. Click **Apply**.



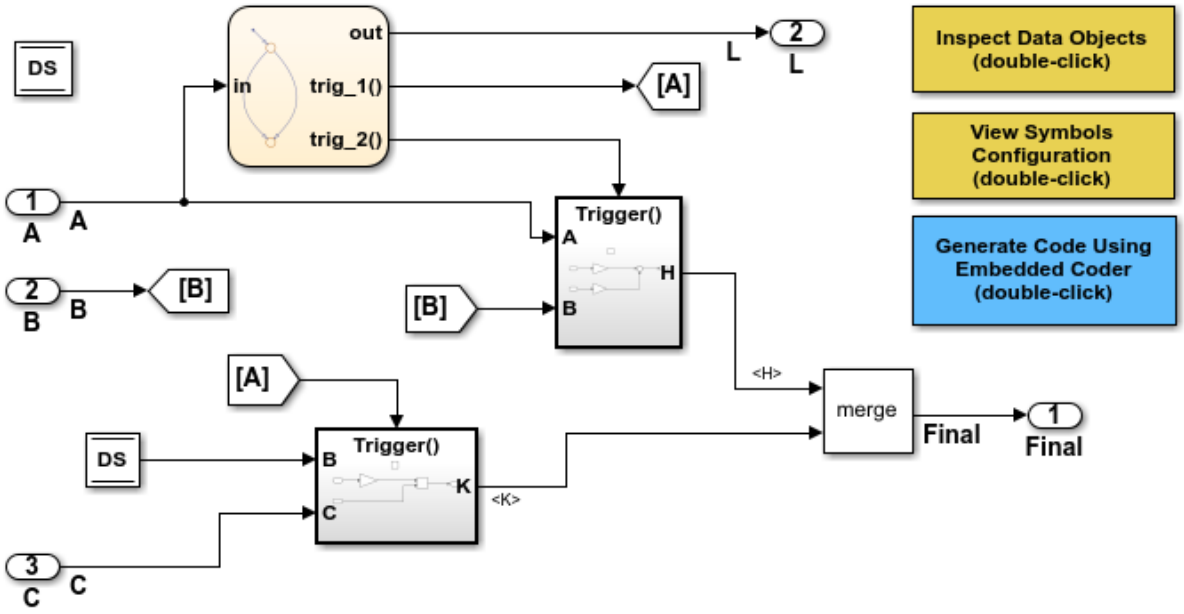
7 Generate code for the model.

8 In the code generation report, confirm the alias for the parameter object `G1`. The generated file `rtwdemo_namerules.h` represents `G1` with the variable `mySpecialParam`.

Apply Custom Naming Conventions to Identifiers

This example shows how to apply uniform naming rules for Simulink® data objects, including signals, parameters, and data store memory variables.

```
model='rtwdemo_namerules';
open_system(model)
```



Description
Many organizations employ coding standards that include naming rules for variables. This model shows how to apply uniform naming rules for Simulink data objects, including signals, parameters, and data store memory variables. Predefined conventions exist to apply upper and lower case naming, and arbitrary custom rules can be defined in a user-supplied MATLAB script.

Instructions
1. Double-click the yellow View Symbols Configuration button to inspect the "Simulink data object naming rules."
2. Double-click the yellow Inspect Data Objects button to inspect the data objects for this model.
3. Generate code using the blue button in the upper right of the diagram. An HTML report automatically appears.
4. Inspect the data that is defined toward the top of rtwdemo_namerules.c.

Note
The model is configured to "Force lower case." Therefore, the variables in the code are defined in lower case even though the data is declared upper case in the model.

```
% Cleanup
rtwdemoclean;
close_system(model,0)
```

Identifier Format Control

You can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box. For each parameter, you can enter a macro that specifies whether, and in what order, certain text is included within generated identifiers. For example, you can specify that the root model name be inserted into each identifier using the `$R` token.

The macro can include:

- Valid tokens, which are listed in Identifier Format Tokens. You can use or omit tokens depending on what you want to include in the identifier name. The **Shared utilities identifier format** parameter requires you to specify the checksum token, `$C`. The other parameters require the mangling token, `$M`. For more information, see “Control Name Mangling in Generated Identifiers” on page 50-32. The mangling token is subject to the use and ordering restrictions noted in Identifier Format Control Parameter Values.
- Token decorators, which are listed in “Control Case with Token Decorators” on page 50-29. You can use token decorators to control the case of generated identifiers for each token.
- Valid C or C++ language identifier characters (`a-z, A-Z, _ , 0-9`).

The build process generates each identifier by expanding tokens and inserting the resultant text into the identifier. The tokens are expanded in the order listed in Identifier Format Tokens. Groups of characters are inserted in the positions that you specify around tokens directly into the identifier. Contiguous token expansions are separated by the underscore (_) character.

Identifier Format Tokens

Token	Description
`$C`	This token is required for **Shared utilities identifier format**. If the identifier exceeds the **Maximum identifier length**, the code generator inserts an 8-character checksum to avoid naming collisions. The position of the `$C` token in the **Identifier format control** parameter specification determines the position of the checksum in the generated identifier. For example, if you use the specification `$N$C`, the checksum is appended to the end of the identifier. This token is available only for shared utilities.
`$M`	This token is required. If necessary, the code generator inserts name-mangling text to avoid naming collisions. Modify checksum character length by using **Shared checksum length** parameter. The position of the `$M` token in the **Identifier format control** parameter specification determines the position of the name-mangling text in the generated identifier. For example, if you use the specification `$R$N$M`, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Control Name Mangling in Generated Identifiers” on page 50-32.
`$U`	Insert text that you specify for the `$U` token. Use the **Custom token text** parameter to specify this text.
`$F`	Insert method name (for example, `_Update` for update method). This token is available only for subsystem methods.
`$N`	Insert name of object (block, signal or signal object, state, parameter, shared utility function or parameter object) for which identifier is being generated.
`$R`	Insert root model name into identifier, replacing unsupported characters with the underscore (_) character. When you use referenced models, this token is required in addition to `$M` (see “Avoid Identifier Name Collisions with Referenced Models” on page 50-34). **Note:** This token replaces the **Prefix model name to global identifiers** option in previous releases.

Token	Description
`$H`	Insert tag indicating system hierarchy level. For root-level blocks, the tag is the text `root_`. For blocks at the subsystem level, the tag is of the form `sN_`. `N` is a unique system number assigned by the Simulink software. This token is available only for subsystem methods and field names of global types. **Note:** This token replaces the **Include System Hierarchy Number in Identifiers** option in previous releases.
`$A`	Insert data type acronym (for example, `i32` for integers) to signal and work vector identifiers. This token is available for local block output variables, local temporary variables, and field names of global types. **Note:** This token replaces the **Include data type acronym in identifier** option in previous releases.
`$I`	• Insert `u` if the argument is an input. • Insert `y` if the argument is an output. • Insert `uy` if the argument is an input and output. For example, `rtu_` for an input argument, `rty_` for an output argument, and `rtuy_` for an input and output argument. This token is available only for subsystem method arguments.
`$G`	Insert the name of a storage class that is associated with the data item. This token is also available in the naming rule that you specify for the **Header File** for a storage class in the Embedded Coder Dictionary.
`$E`	Insert the file type. `$E` represents these instances of file types: • `capi` • `capi_host` • `dt` • `testinterface` • `private` • `types` This token is required for **Header files** and **Source files**.

Identifier Format Control Parameter Values lists the default macro value, the supported tokens, and the applicable restrictions for each **Identifier format control** parameter.

Identifier Format Control Parameter Values

Parameter	Default Value	Supported Tokens	Restrictions
Global variables (Simulink Coder)	`$R$N$M`	`$M`, `$R`, `$G`,`$N`,`$U`	`$F`, `$H`, `$A`, `$E`, and `$I` are not allowed.
Global types (Simulink Coder)	`$N$R$M_T`	`$M`, `$R`, `$G`,`$N`,`$U`	`$F`, `$H`, `$A`, `$E`, and `$I` are not allowed.
Field name of global types (Simulink Coder)	`$N$M`	`$M`, `$N`, `$H`, `$A`, `$U`	`$R`, `$F`, `$G`, `$E`, and `$I` are not allowed.
Subsystem methods (Simulink Coder)	`$R$N$M$F`	`$M`, `$R`, `$N`, `$H`, `$F`, `$U`	`$F` and `$H` are empty for Stateflow functions; `$A`, `$G`, `$E`, and `$I` are not allowed.
Subsystem method arguments (Simulink Coder)	`rt$I$N$M`	`$M`, `$N`, `$I`, `$U`	`$R`, `$F`, `$H`, `$G`, `$E`, and `$A` are not allowed.
Local temporary variables (Simulink Coder)	`$N$M`	`$M`, `$R`, `$N`, `$A`, `$U`	`$F`, `$H`, `$G`, `$E`, and `$I` are not allowed.
Local block output variables (Simulink Coder)	`rtb_$N$M`	`$M`, `$N`, `$A`, `$U`	`$R`, `$F`, `$H`, `$G`, `$E`, and `$I` are not allowed.
Constant macros (Simulink Coder)	`$R$N$M`	`$M`, `$R`, `$N`, `$U`	`$F`, `$H`, `$A`, `$G`, `$E`, and `$I` are not allowed.
Shared utilities identifier format (Simulink Coder)	`$N$C`	`$N`, `$C`, `$R`, `$U`	`$C` is required. `$M`, `$F`, `$H`, `$A`, `$G`, `$E`, and `$I` are not allowed.
EMX array utility functions identifier format (Simulink Coder)	`emx$M$N`	`$M`, `$N`,`$R`	`$C`, `$U`, `$F`, `$H`, `$A`, `$G`, `$E`, and `$I` are not allowed.
EMX array types identifier format (Simulink Coder)	`emxArray_ $M$N`	`$M`, `$N`,`$R`	`$C`, `$U`, `$F`, `$H`, `$A`, `$G`, `$E`, and `$I` are not allowed.

Parameter	Default Value	Supported Tokens	Restrictions
Header files	`$R$E`	`$R`,`$U`,`$E`	`$C`, `$M`, `$N`, `$F`, `$H`, `$A`, `$G`, and `$I` are not allowed.
Source files	`$R$E`	`$R`,`$U`,`$E`	`$C`, `$M`, `$N`, `$F`, `$H`, `$A`, `$G`, and `$I` are not allowed.
Data files	`$R_data`	`$R`,`$U`	`$C`, `$M`, `$N`, `$F`, `$H`, `$A`, `$G`, `$E`, and `$I` are not allowed.

Non-ERT-based targets (such as the GRT target) implicitly use a default `$R$N$M` specification. This default specification consists of the root model name, followed by the name of the generating object (signal, parameter, state, and so on), followed by name-mangling text.

For limitations that apply to **Identifier format control** parameters, see “Exceptions to Identifier Formatting Conventions” on page 50-37 and “Identifier Format Control Parameters Limitations” on page 50-38.

Control Case with Token Decorators

On the **Code Generation > Symbols** pane, you can use token decorators to control the case of generated identifiers. Place a decorator immediately after the target token and enclose the decorator in square brackets `[ ]`. For example, you can set **Global variables** to `$R[uL]$N$M`, which capitalizes the first letter of the model name and forces the remaining characters in the model name to lowercase.

The table shows how to manipulate the expansion of the `$R` token for a model whose name is `modelName`.

Desired Expansion	Description	Token and Decorator
`ModelName`	First letter of model name is uppercase. Remaining characters are not modified.	`$R[u]`
`Modelname`	First letter of model name is uppercase. Remaining characters are lowercase.	`$R[uL]`

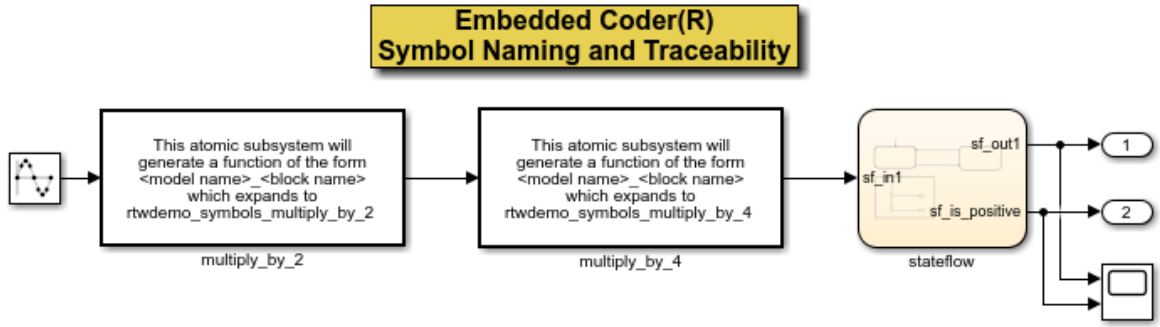
Desired Expansion	Description	Token and Decorator
`MODELNAME`	All characters are uppercase.	`$R[U]`
`modelname`	All characters are lowercase.	`$R[L]`
`mODELNAME`	First letter of model name is lowercase. Remaining characters are uppercase.	`$R[lU]`
`modelName`	First letter of model name is lowercase. Remaining characters are not modified.	`$R[l]`

When you use a decorator, the code generator removes the underscore character (_) that appears between tokens by default. However, you can append each decorator with an underscore: `$R[U_]$N`. For example, if you set the **Global variables** parameter to `$R[u_]$N[uL]$M` for a model named `modelName` and a `DWork` structure represented by `DW`, the result is `ModelName_Dw`.

Control Formatting of Identifiers

This example shows how you can customize generated identifiers by specifying the **Identifier format control** parameters on the **Code Generation > Symbols** pane in the Configuration Parameters dialog box.

```
model='rtwdemo_symbols';
open_system(model)
```



```
% Cleanup
rtwdemoclean;
close_system(model,0)
```

Control Name Mangling in Generated Identifiers

The position of the `$M` token in the **Identifier format control** parameter specification determines the position of the name-mangling text in the generated identifiers. For example, if you use the specification `$R$N$M`, the name-mangling text is appended (if required) to the end of the identifier. For more information, see “Identifier Format Control” on page 50-24.

Name-Mangling Text Per Object

Object Type	Source of Mangling Text
Block diagram	Name of block diagram
Simulink block	Simulink identifier (for details, see “Locate Diagram Components Using Simulink Identifiers” (Simulink))
Simulink parameter	Full name of parameter owner (model or block) and parameter name
Simulink signal	Signal name, full name of source block, and port number
Stateflow objects	Complete path to Stateflow block and Stateflow computed name (unique within chart)

The length of the name-mangling text is specified by the **Minimum mangle length** (Simulink Coder) parameter. The default value is `1`, but this automatically increases during code generation as a function of the number of collisions. To minimize disturbance to the generated code during development, specify a larger **Minimum mangle length**. A **Minimum mangle length** of 4 is a conservative value. A value of 4 allows for over 1.5 million collisions for a particular identifier before the mangle length is increased.

Minimize Name Mangling

The length of generated identifiers is limited by the **Maximum identifier length** (Simulink Coder) parameter. When a name collision exists, the `$M` token is expanded to the minimum number of characters required to avoid the collision. Other tokens are expanded in the order listed in Identifier Format Tokens. If the **Maximum identifier length** is not large enough to accommodate full expansions of the other tokens, partial expansions are used. To avoid partial expansions, it is good practice to:

- Avoid name collisions. One way to avoid name collisions is to not use default block names (for example, `Gain1`, `Gain2...`) when there are many blocks of the same type in the model.

- Where possible, increase the **Maximum identifier length** to accommodate the length of the identifiers that you expect to generate.
- Set the **Maximum identifier length** parameter to reserve at least three characters for the name-mangling text. The length of the name-mangling text increases as the number of name collisions increases.

  If changes to the model create more or fewer collisions, existing name-mangling text increases or decreases in length. If the length of the name-mangling text increases, additional characters are appended to the existing text. For example, the mangling text `'xyz'` can change to `'xyzQ'`. For fewer collisions, the name-mangling text `'xyz'` changes to `'xy'`.

Avoid Identifier Name Collisions with Referenced Models

Within a model that uses referenced models, collisions between the names of the models are not allowed. When generating code from a model that uses model referencing:

- You must include the `$R` token in the **Identifier format control** parameter specifications (in addition to the `$M` token).
- The **Maximum identifier length** must be large enough to accommodate full expansions of the `$R` and `$M` tokens. If **Maximum identifier length** is too small, a code generation error occurs.

When a name conflict occurs between an identifier within the scope of a higher-level model and an identifier within the scope of a referenced model, the identifier from the referenced model is preserved. Name mangling is performed on the identifier from the higher-level model.

If your model contains two referenced models with the same input or output port names, and one of the referenced models contains an atomic subsystem with "Function packaging" (Simulink) set to `Nonreuseable function`, a name conflict can occur and the build process produces an error.

Use Model Advisor to Detect Identifier Names Changed During Code Generation

For a referenced model, if the following **Configuration Parameters > Code Generation > Symbols** parameters have settings that do not contain a `$R` token (which represents the name of the reference model), code generation prepends the `$R` token to the identifier format.

- **Global variables**
- **Global types**
- **Subsystem methods**
- **Constant macros**

You can use the Model Advisor to identify referenced models in a model referencing hierarchy for which code generation changes these configuration parameter settings.

1 In the Simulink Editor, select **Analysis > Model Advisor**.

2. Select **By Task**.
3. Run the **Check code generation identifier formats used for model reference** check.

Maintain Traceability for Generated Identifiers

To verify your model, you can trace back and forth between generated identifiers and corresponding entities within the model. To maintain traceability, it is important that incremental revisions to a model have minimal impact on the identifier names that appear in generated code. There are two ways to minimally impact the identifier names:

- Choose unique names for Simulink objects (blocks, signals, states, and so on) as much as possible.
- Use name mangling when conflicts cannot be avoided.

The position of the name-mangling text is specified by the placement of the `$M` token in the **Identifier format control** parameters. Mangle characters consist of alphanumeric characters that are unique to each object. For more information, see “Control Name Mangling in Generated Identifiers” on page 50-32.

Exceptions to Identifier Formatting Conventions

There are some exceptions to the identifier formatting conventions described in “Identifier Format Control” on page 50-24.

- Type name generation: name mangling conventions do not apply to type names (that is, `typedef` statements) generated for global data types. If the `$R` token is included in the **Identifier format control** parameter specification, the model name is included in the `typedef`. When generating type definitions, the **Maximum identifier length** parameter is not respected.
- Non-`Auto` storage classes: the **Identifier format control** parameters specification does not affect objects (such as signals and parameters) that have a storage class other than `Auto` (such as `ImportedExtern` or `ExportedGlobal`).
- For shared utilities, code generation inserts the checksum specified by `$C` to prevent name collisions in the following situations:

  - `$C` is specified without `$N`.
  - The length of `$N` plus the length of the text that you specify exceeds the **Maximum identifier length**. Code generation truncates `$N` and inserts an 8-character checksum where you specified `$C` in the formatting scheme.

  .

Identifier Format Control Parameters Limitations

The following limitations apply to the **Identifier format control** parameters:

- The following autogenerated identifiers currently do not fully comply with the setting of the **Maximum identifier length** parameter on the **Code Generation > Symbols** pane of the Configuration Parameters dialog box.
  - Model methods
    - The applicable format scheme is `$R$F`, and the longest `$F` is `_derivatives`, which is 12 characters long. The model name can be up to 19 characters without exceeding the default **Maximum identifier length** of 31.
  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - `DW` identifiers generated by S-functions in referenced models
  - Fixed-point shared utility macros or shared utility functions
  - Simulink `rtm` macros
    - Most are within the default **Maximum identifier length** of 31, but some exceed the limit. Examples are `RTMSpecAccsGetStopRequestedValStoredAsPtr`, `RTMSpecAccsGetErrorStatusPointer`, and `RTMSpecAccsGetErrorStatusPointerPointer`.
  - Define protection guard macros
    - Header file guards, such as `_RTW_HEADER_$(filename)_h_`, which can exceed the default **Maximum identifier length** of 31 given a filename such as `$R_private.h`.
    - Include file guards, such as `_$R_COMMON_INCLUDES_`.
    - `typedef` guards, such as `_CSCI_$R_CHARTSTRUCT_`.
- In some situations, the following identifiers potentially can conflict with others.
  - Model methods
  - Reentrant model function arguments

  - Local functions generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Local variables generated by S-functions or by add-on products such as DSP System Toolbox that rely on S-functions
  - Fixed-point shared utility macros or shared utility functions
  - Include header guard macros
- The following external identifiers that are unknown to the Simulink software might conflict with autogenerated identifiers.
  - Identifiers defined in custom code
  - Identifiers defined in custom header files
  - Identifiers introduced through a non-ANSI C standard library
  - Identifiers defined by custom TLC code
- Identifiers generated for simulation targets might exceed the **Maximum identifier length**. Simulation targets include the model reference simulation target, the accelerated simulation target, the RSim target, and the S-function target.
- Identifiers generated using a model name and bus object data type name, which are both long names, might exceed the **Maximum identifier length**. For example, a ground value variable name is generated as `<`*model_name*`>_rtZ<`*bus_name*`>`. If the *model_name* and *bus_name* are close to the maximum identifier length, the name exceeds the maximum identifier length.

Control Code Style

In this section...

You can change the code style, cast expressions, and indentation of your generated code to conform to certain coding standards. Modify style options by setting parameters on the **Code Generation > Code Style** pane.

Goal	Action
Specify parenthesization style for generated code	See “Control Parentheses in Generated Code” on page 50-41.
Specify whether to preserve order of operands in expressions	See “Optimize Code by Reordering Commutable Operands” on page 50-44.
Specify whether to preserve empty primary condition expressions in `if` statements	See “Preserve condition expression in if statement”.
Specify whether to generate code for `if-elseif-else` decision logic as `switch-case` statements	See “Convert if-elseif-else patterns to switch-case statements”.
Specify whether to include the `extern` keyword in function declarations in the generated code	See “Preserve extern keyword in function declarations”.
Specify whether to include the `static` keyword in function declarations in the generated code	See “Preserve static keyword in function declarations”.

Goal	Action
Specify whether to generate `default` cases for `switch-case` statements in the code for Stateflow charts	See “Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements” on page 50-45.
Specify whether to replace multiplications by powers of two with signed bitwise shifts	See “Replace Multiplication by Powers of Two with Signed Bitwise Shifts” on page 50-48.
Specify whether to allow signed right bitwise shifts in the generated C/C++ code	See “Generate Code with Right Shifts on Signed Integers” on page 50-50.
Specify how the code generator casts data types for variables	See “Control Cast Expressions in Generated Code” on page 50-53.
Specify indent style for the generated code	See “Control Indentation Style in Generated Code” on page 50-51.
Specify the newline character in the generated code	See “Control Newline Style in Generated Code” on page 50-57.
Specify the maximum line width for wrapping the generated code.	See “Control Maximum Line Width of the Generated Code” on page 50-58.

Control Parentheses in Generated Code

C code contains some syntactically required parentheses, and can contain additional parentheses that change semantics by overriding default operator precedence. C code can also contain optional parentheses that have no functional significance, but only increase the readability of the code. Optional C parentheses vary between two stylistic extremes:

- Include the minimum parentheses required by C syntax and precedence overrides so that C precedence rules specify all semantics unless overridden by parentheses.
- Include the maximum parentheses that can exist without duplication so that C precedence rules become irrelevant. Parentheses alone completely specify all semantics.

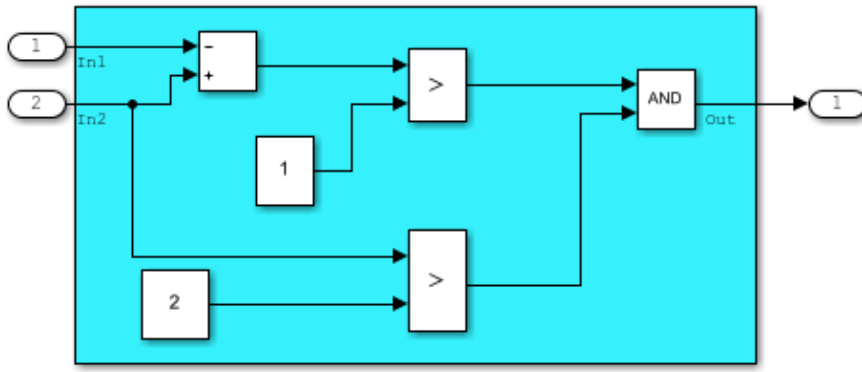
Understanding code with minimum parentheses can require applying nonobvious precedence rules. Maximum parentheses can hinder code reading by belaboring obvious precedence rules. Various parenthesization standards exist that specify one or the other extreme, or define an intermediate style useful to people who read code.

For more information on this parameter, see “Parentheses level”.

Control Use of Parentheses

This example shows that Embedded Coder® provides three levels of control for parentheses in the generated code.

```
model='rtwdemo_parentheses';
open_system(model)
```



View Code Style Configuration (double-click)

Generate Code Using Embedded Coder (double-click)

Parentheses level "Minimum": `Out = In2 - In1 > 1.0 && In2 > 2.0;`

Parentheses level "Nominal": `Out = ((In2 - In1 > 1.0) && (In2 > 2.0));`

Parentheses level "Maximum": `Out = (((In2 - In1) > 1.0) && (In2 > 2.0));`

Description

Embedded Coder(R) provides three levels of control for parentheses in the generated code. The control level "Minimum" generates the most compact code, with the smallest number of parentheses allowed under C syntax rules. The control level "Nominal" adds parentheses as needed to optimize readability. The control level "Maximum" generates the largest number of parentheses. The parentheses explicitly define the sequence of operations in an expression without relying on C precedence rules. Specifying control level "Maximum" provides full compliance with the MISRA-C(TM) standard.

Instructions

1. View and set the parentheses level by double-clicking the yellow button to the right.
2. Generate code by double-clicking the blue button to the right.
   An HTML report is displayed automatically.
3. Inspect the generated source files, comparing them with the three code examples above.

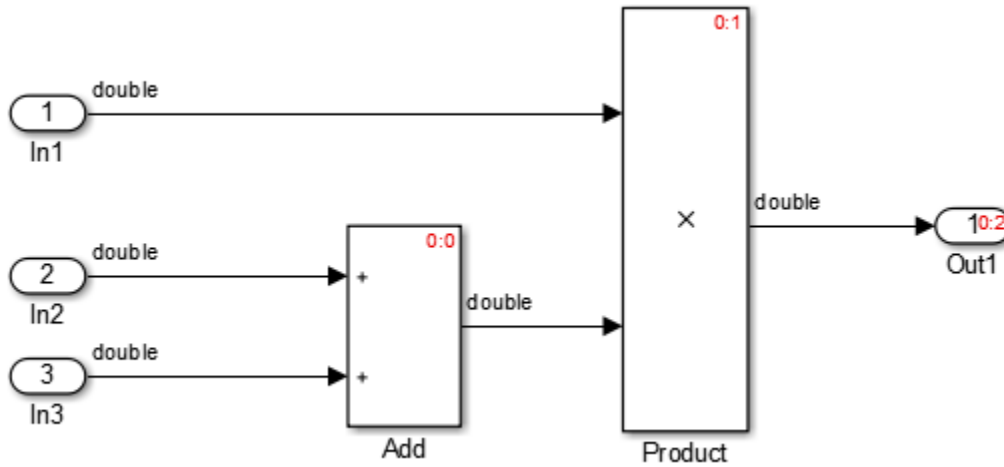
```
rtwdemoclean;
close_system(model,0)
```

Optimize Code by Reordering Commutable Operands

This example shows how to reorder commutable operands to make expressions left-recursive. This optimization improves code efficiency.

Example Model

To reorder commutable operands, create the following model and name it `operand_order`. In this model, the output signal is the result of multiplying the signal from Inport block `In1` by the sum of the signals from Inport blocks `In2` and `In3`.



Generate Code

1. Open the Model Configuration Parameters dialog box. On the **Code Style** tab, select the **Preserve operand order in expression** parameter.
2. Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains the following code:

```
operand_order_Y.Out1 = operand_order_U.In1 * (operand_order_U.In2 +
    operand_order_U.In3);
```

The code generator preserves the specified expression order in the model. Preserving the specified expression order increases the readability of the code for code traceability purposes.

Generate Code with Optimization

1. Open the Model Configuration Parameters dialog box. On the **Code Style** tab, clear the **Preserve operand order in expression** parameter.
2. Generate code for the model.

In the `operand_order.c` file, the `operand_order_step` function contains the following code:

```
operand_order_Y.Out1 = (operand_order_U.In2 + operand_order_U.In3) *
    operand_order_U.In1;
```

The code generator optimizes the code by reordering the commutable operands to make the expression left-recursive. Left-recursive expressions improve code efficiency.

For more information on the **Preserve operand order in expression** parameter, see “Preserve operand order in expression”.

Suppress Generation of Default Cases for Unreachable Stateflow Switch Statements

This example shows how to specify whether to generate default cases for switch-case statements in the code for Stateflow charts. Generated code that does not contain default cases conserves ROM consumption and enables better code coverage because every branch in the generated code is falsifiable.

Some coding standards, such as MISRA, require the default case for switch-case statements. If you want to increase your chances of producing MISRA C compliant code, generate default cases for unreachable Stateflow switch statements.

Example

Figures 1, 2, and 3 show relevant portions of the `sldemo_fuelsys` model, a closed-loop system containing a plant and controller. The Air-fuel rate controller logic is a Stateflow chart that specifies the different operation modes.

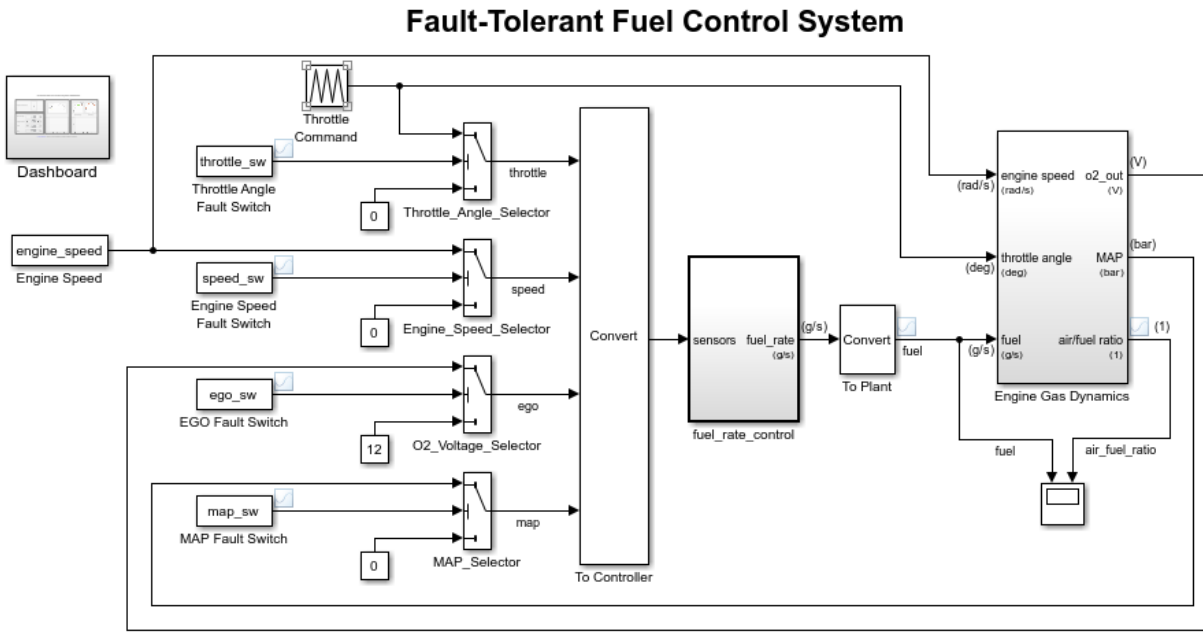


Figure 1: Top-level model of the plant and controller

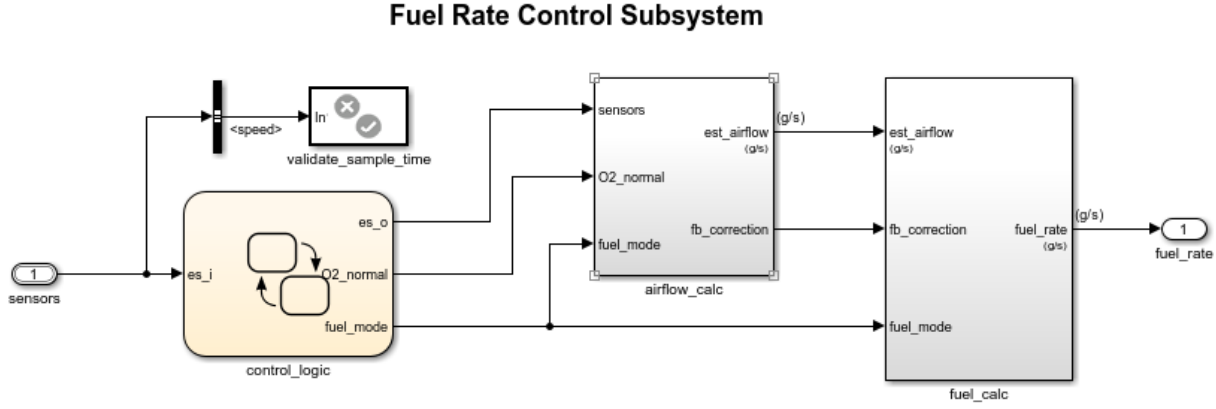

Figure 2: Fuel rate controller subsystem

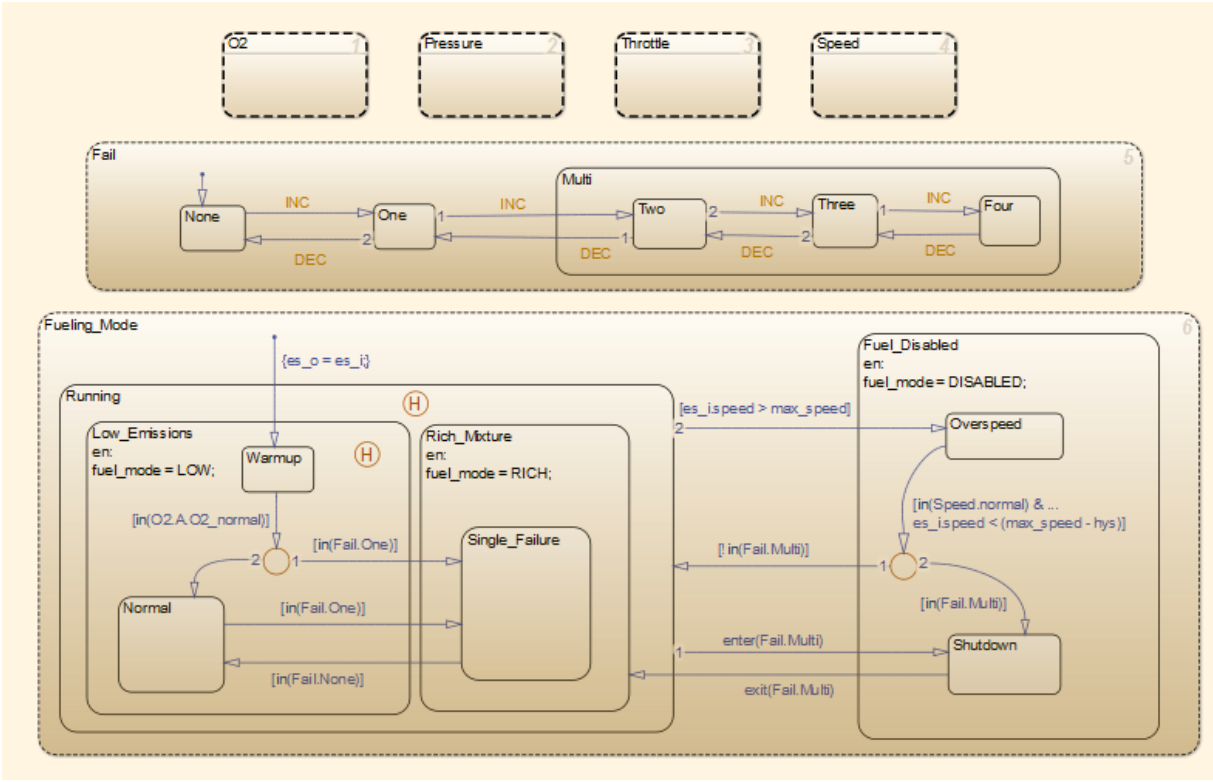

Figure 3: Fuel rate controller logic

Generate Code with Default Cases for Unreachable Stateflow Switch Statements

1. In the MATLAB Command Window, to open `sldemo_fuelsys` via `rtwdemo_fuelsys` enter:

   ```
   rtwdemo_fuelsys
   ```

2. Open the Model Configuration parameters dialog box. On the **Code Generation** > **Code Style** tab, clear the **Suppress generation of default cases for Stateflow statements if unreachable** parameter.

3. In the MATLAB Command Window, to build the model, enter:

   ```
   rtwbuild('sldemo_fuelsys/fuel_rate_control');
   ```

For the different operation modes, the `fuel_rate_control.c` file contains default cases for unreachable switch statements. For example, for the Shutdown operation mode, the generated code contains this default statement:

```
default:
 /* Unreachable state, for coverage only */
 rtDWork.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
 break;
```

For the Warmup operation mode, the generated code contains this default statement:

```
default:
 /* Unreachable state, for coverage only */
 rtDWork.bitsForTID0.is_Low_Emissions = IN_NO_ACTIVE_CHILD;
 break;
```

Suppress Default Cases for Unreachable Stateflow Switch Statements

1. Open the Configuration Parameters dialog box. On the **Code Generation > Code Style** tab, select the **Suppress generation of default cases for Stateflow statements if unreachable** parameter.
2. Build the model.

Read through the `fuel_rate_control.c` file. The default cases for unreachable switch statements are not in the generated code.

For more information on the **Suppress generation of default cases for Stateflow statements if unreachable** parameter, see “Suppress generation of default cases for Stateflow switch statements if unreachable”.

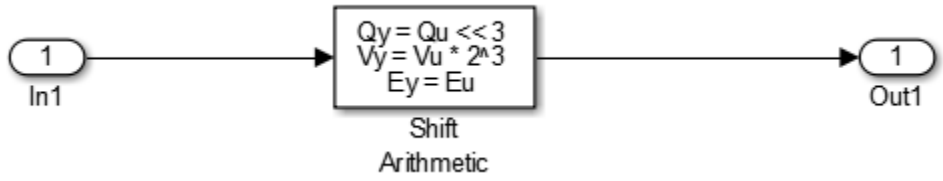
Replace Multiplication by Powers of Two with Signed Bitwise Shifts

This example shows how to generate code that replaces multiplication by powers of two with signed bitwise shifts. Code that contains bitwise shifts is more efficient than code that contains multiplication by powers of two.

Some coding standards, such as MISRA, do not allow bitwise operations on signed integers. If you want to increase your chances of producing MISRA C compliant code, do not replace multiplication by powers of two with bitwise shifts.

Example

To replace multiplication by powers of two with bitwise shifts, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift** > **Direction** parameter is set to `Left`. The **Bits to shift** > **Number** parameter is set to 3. This parameter corresponds to a value of 8, or raising 2 to the power of 3.



Generate Code with Signed Bitwise Shifts

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Replace multiplications by powers of two with signed bitwise shifts** parameter is on by default.
2. Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 << 3);
```

The signed integer, `bitwise_multiplication_U.In1`, is shifted three bits to the left.

Generate Code with Multiplication by Powers of Two

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab.
2. Clear the **Replace multiplications by powers of two with signed bitwise shifts** parameter.
3. Generate code for the model.

In the `bitwise_multiplication.c` file, the `bitwise_multiplication` step function contains this code:

```
bitwise_multiplication_Y.Out1 = (int16_T)(bitwise_multiplication_U.In1 * 8);
```

The signed integer `bitwise_multiplication_U.In1` is multiplied by 8.

For more information on the **Replace multiplications by powers of two with signed bitwise shifts** parameter, see “Replace multiplications by powers of two with signed bitwise shifts”.

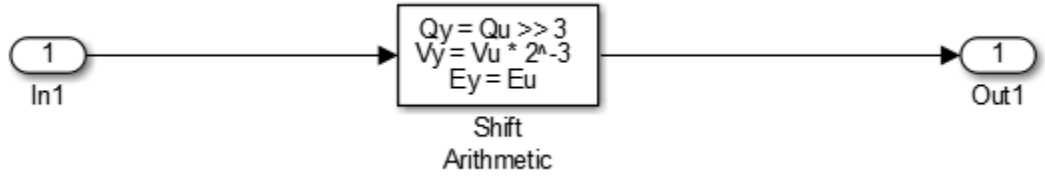
Generate Code with Right Shifts on Signed Integers

This example shows how to control whether the generated code contains right shifts on signed integers. Generated code that does not contain right shifts on signed integers first casts the signed integers to unsigned integers, and then right shifts the unsigned integers.

Some coding standards, such as MISRA, do not allow right shifts on signed integers because different hardware can store negative integers differently. For negative integers, you can get different answers depending on the hardware. If you want to increase your chances of producing MISRA C compliant code, do not allow right shifts on signed integers.

Example Model

To generate code with right shifts on signed integers, create the following model. In this model, a signal of **Data type** `int16` feeds into a Shift Arithmetic block. In the Shift Arithmetic Block Parameters dialog box, the **Bits to shift** > **Direction** parameter is set to `Right`. The **Bits to shift** > **Number** parameter is set to `3`.



Generate Code with Right Shifts on Signed Integers

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab. The **Allow right shifts on signed integers** parameter is on by default.
2. Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)(rightshift_U.In1 >> 3);
```

The signed integer `rightshift_U.In1` is shifted three bits to the right.

Generate Code That Does Not Allow Right Shifts on Signed Integers

1. Open the Model Configuration Parameters dialog box and select the **Code Style** tab. Clear the **Allow right shifts on signed integers** parameter.
2. Generate code for the model.

In the `rightshift.c` file, the `rightshift_step` function contains this code:

```
rightshift_Y.Out1 = (int16_T)asr_s32(rightshift_U.In1, 3U);
```

When you clear the **Allow right shifts on signed integers** parameter, the generated code contains a function call instead of a right shift on a signed integer. The function `asr_s32` contains this code:

```
int32_T asr_s32(int32_T u, uint32_T n)
{
  int32_T y;
  if (u >= 0) {
    y = (int32_T)((uint32_T)u >> n);
  } else {
    y = -(int32_T)((uint32_T)-(u + 1) >> n) - 1;
  }

  return y;
}
```

The `asr_s32` function casts a signed integer to an unsigned integer, and then right shifts the unsigned integer.

For more information on the **Allow right shifts on signed integers** parameter, see "Allow right shifts on signed integers".

Control Indentation Style in Generated Code

For code indentation, you can set the following parameters:

- **Indent style** controls the placement of braces in generated code.
- **Indent size** controls the number of characters per indent level in generated code (2–8 characters).

You can set **Indent style** to `K&R` or `Allman` style.

K&R

K&R stands for Kernighan and Ritchie. Each function has the opening and closing brace on its own line at the same level of indentation as the function header. Code within the function is indented according to the **Indent size**.

For blocks within a function, opening braces are on the same line as the control statement. Closing braces are on a new line at the same level of indentation as the control statement. Code within the block is indented according to the **Indent size**.

For example, here is generated code with the **Indent style** set to K&R with an **Indent size** of 2:

```
void rt_OneStep(void)
{
  static boolean_T OverrunFlag = 0;
  if (OverrunFlag) {
    rtmSetErrorStatus(rtwdemo_counter_M, "Overrun");
    return;
  }

  OverrunFlag = TRUE;
  rtwdemo_counter_step();
  OverrunFlag = FALSE;
}
```

Allman

Each function has the opening and closing brace on its own line at the same level of indentation as the function header. Code within the function is indented according to the **Indent size**.

For blocks within a function, opening and closing braces for control statements are on a new line at the same level of indentation as the control statement. This is the key difference between K&R and `Allman` styles. Code within the block is indented according to the **Indent size**.

For example, here is generated code with the **Indent style** set to `Allman` with an **Indent size** of 4:

```
void rt_OneStep(void)
{
    static boolean_T OverrunFlag = 0;
```

```
    if (OverrunFlag)
    {
        rtmSetErrorStatus(rtwdemo_counter_M, "Overrun");
        return;
    }

    OverrunFlag = TRUE;
    rtwdemo_counter_step();
    OverrunFlag = FALSE;
}
```

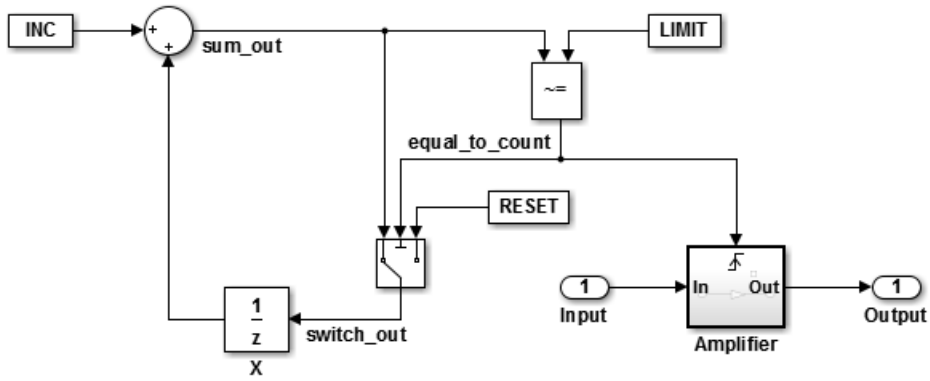
Control Cast Expressions in Generated Code

You can choose how the code generator specifies data type casts in the generated code. In the Configuration Parameters dialog box, select **Code Generation > Code Style**. From the **Casting modes** drop-down list, three parameter options control how the code generator casts data types.

- `Nominal` instructs the code generator to generate code that has minimal data type casting. When you do not have special data type information requirements, choose `Nominal`.
- `Standards Compliant` instructs the code generator to cast data types to conform to MISRA standards when it generates code. The MISRA data type casting eliminates common MISRA standard violations, including address arithmetic and assignment. It reduces 10.1, 10.2, 10.3, and 10.4 violations.

  For more information, see “MISRA C Guidelines” on page 22-6.
- `Explicit` instructs the code generator to cast data type values explicitly when it generates code. You can see how a value is stored, which tells you how much memory space the code uses for the variable. The data type informs you how much precision is possible in calculations involving the variable.

Open the example model `rtwdemo_rtwecintro`.



Enable Nominal Casting Mode and Generate Code

When you choose `Nominal` casting mode, the code generator does not create data type casts for variables in the generated code.

1. On the **Code Generation > Code Style** pane, from the **Casting modes** drop-down list, select `Nominal`.
2. On the **Code Generation > Report** pane, select **Create code generation report**.
3. On the **Code Generation** pane, select **Generate code only**.
4. Click **Apply**.
5. In the model window, press **Ctrl+B** to generate code.
6. In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```
/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
  boolean_T rtb_equal_to_count;

  /* Sum: 'XRootX/Sum' incorporates:
   *  Constant: 'XRootX/INC'
   *  UnitDelay: 'XRootX/X'
   */
  rtDWork.X++;

  /* RelationalOperator: 'XRootX/RelOpt' incorporates:
   *  Constant: 'XRootX/LIMIT'
   */
  rtb_equal_to_count = (rtDWork.X != 16);

  /* Outputs for Triggered SubSystem: 'XRootX/Amplifier' incorporates:
   *  TriggerPort: 'XS1X/Trigger'
```

```
   */
  if (rtb_equal_to_count && (rtPrevZCSigState.Amplifier_Trig_ZCE != POS_ZCSIG))
  {
    /* Outport: 'XRootX/Output' incorporates:
     *  Gain: 'XS1X/Gain'
     *  Inport: 'XRootX/Input'
     */
    rtY.Output = rtU.Input << 1;
  }

  rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
    POS_ZCSIG : (int32_T)ZERO_ZCSIG);

  /* End of Outputs for SubSystem: 'XRootX/Amplifier' */

  /* Switch: 'XRootX/Switch' */
  if (!rtb_equal_to_count) {
    /* Update for UnitDelay: 'XRootX/X' incorporates:
     *  Constant: 'XRootX/RESET'
     */
    rtDWork.X = 0U;
  }

  /* End of Switch: 'XRootX/Switch' */
}
```

Enable Standards Compliant Casting Mode and Generate Code

When you choose `Standards Compliant` casting mode, the code generator creates MISRA standards compliant data type casts for variables in the generated code.

1. On the **Code Style** pane, from the **Casting modes** drop-down list, select `Standards Compliant`.
2. On the **Code Generation** pane, click **Apply**.
3. In the model window, press **Ctrl+B** to generate code.
4. In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```
void rtwdemo_rtwecintro_step(void)
{
  boolean_T rtb_equal_to_count;

  /* Sum: '<Root>/Sum' incorporates:
   *  Constant: '<Root>/INC'
   *  UnitDelay: '<Root>/X'
   */
  rtDWork.X++;

  /* RelationalOperator: '<Root>/RelOpt' incorporates:
   *  Constant: '<Root>/LIMIT'
   */
  rtb_equal_to_count = (boolean_T)(int32_T)((int32_T)rtDWork.X != (int32_T)16);

  /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
   *  TriggerPort: '<S1>/Trigger'
```

```
   */
  if (((int32_T)rtb_equal_to_count) && (rtPrevZCSigState.Amplifier_Trig_ZCE !=
       POS_ZCSIG)) {
    /* Outport: '<Root>/Output' incorporates:
     *  Gain: '<S1>/Gain'
     *  Inport: '<Root>/Input'
     */
    rtY.Output = (int32_T)(uint32_T)((uint32_T)rtU.Input << (uint32_T)(int8_T)1);
  }

  rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(int32_T)(rtb_equal_to_count ?
    (int32_T)(uint8_T)POS_ZCSIG : (int32_T)(uint8_T)ZERO_ZCSIG);

  /* End of Outputs for SubSystem: '<Root>/Amplifier' */

  /* Switch: '<Root>/Switch' */
  if (!rtb_equal_to_count) {
    /* Update for UnitDelay: '<Root>/X' incorporates:
     *  Constant: '<Root>/RESET'
     */
    rtDWork.X = 0U;
  }

  /* End of Switch: '<Root>/Switch' */
}
```

Enable Explicit Casting Mode and Generate Code

When you choose `Explicit` casting mode, the code generator creates explicit data type casts for variables in the generated code.

1. On the **Code Style** pane, from the **Casting modes** drop-down list, select `Explicit`.
2. On the **Code Generation** pane, click **Apply**.
3. In the model window, press **Ctrl+B** to generate code.
4. In the Code Generation report left pane, click `rtwdemo_rtwecintro.c` to see the code.

```
/* Model step function */
void rtwdemo_rtwecintro_step(void)
{
  boolean_T rtb_equal_to_count;

  /* Sum: '<Root>/Sum' incorporates:
   *  Constant: '<Root>/INC'
   *  UnitDelay: '<Root>/X'
   */
  rtDWork.X = (uint8_T)(1U + (uint32_T)(int32_T)rtDWork.X);

  /* RelationalOperator: '<Root>/RelOpt' incorporates:
   *  Constant: '<Root>/LIMIT'
   */
  rtb_equal_to_count = (boolean_T)((int32_T)rtDWork.X != 16);

  /* Outputs for Triggered SubSystem: '<Root>/Amplifier' incorporates:
   *  TriggerPort: '<S1>/Trigger'
   */
```

```
  if (((int32_T)rtb_equal_to_count) && ((int32_T)((int32_T)
        rtPrevZCSigState.Amplifier_Trig_ZCE != (int32_T)POS_ZCSIG))) {
    /* Outport: '<Root>/Output' incorporates:
     *  Gain: '<S1>/Gain'
     *  Inport: '<Root>/Input'
     */
    rtY.Output = rtU.Input << 1;
  }

  rtPrevZCSigState.Amplifier_Trig_ZCE = (uint8_T)(rtb_equal_to_count ? (int32_T)
        POS_ZCSIG : (int32_T)ZERO_ZCSIG);

  /* End of Outputs for SubSystem: '<Root>/Amplifier' */

  /* Switch: '<Root>/Switch' */
  if (!(int32_T)rtb_equal_to_count) {
    /* Update for UnitDelay: '<Root>/X' incorporates:
     *  Constant: '<Root>/RESET'
     */
    rtDWork.X = 0U;
  }

  /* End of Switch: '<Root>/Switch' */
}
```

Control Newline Style in Generated Code

In the generated code, the newline character differs according to the operating system that the code is generated on. You can customize the newline character irrespective of the operating system. Set the style of the newline character by using the **Newline style** parameter.

You can set **Newline style** to any of these options:

Default

This option is selected by default. It generates the newline character based on the operating system that the code is generated on. For example, if the code is generated on a Windows machine, the newline character inserted by default is `"\r\n"`. If the code is generated on a UNIX machine, the newline character inserted by default is `"\n"`.

LF (Linefeed)

This option enables you to add the Line Feed (LF) character. `"\n"` is inserted as the newline character.

CR+LF (Carriage Return + Line Feed)

This option enables you to add the Carriage Return + Line Feed (CR+LF) character. `"\r\n"` is inserted as the newline character.

Control Maximum Line Width of the Generated Code

You can customize the maximum line width for wrapping the generated code. To specify any integer in the range of `50-1000`, use the **Maximum line width** parameter. The default value is `80`.

If the comments exceed the maximum line width specified, the tail comments are generated on a new line with right justification. Other types of comments are not wrapped:

- `#define` tail comments
- Simulink block comments
- Stateflow object comments
- Banner comments

For example, here is generated code that is wrapped using the default **Maximum line width** value `80`:

```
/* Definition for custom storage class: Default */
real_T const_val[4] = { 1.0, 2.0, 3.0, 4.0 } ;
                  /* This parameter defines the vector of output index values */
```

The tail comments are generated on a new line with right justification.

Here is the same code wrapped with **Maximum line width** set to `120`:

```
/* Definition for custom storage class: Default */
real_T const_val[4] = { 1.0, 2.0, 3.0, 4.0 } ;/* This parameter defines the vector of output index values */
```

- “Model Configuration Parameters: Code Generation Code Style”

Customize Code Organization and Format

In this section...

Custom file processing (CFP) tools allow you to customize the organization and formatting of generated code. With these tools, you can:

- Generate a source (`.c` or `.cpp`) or header (`.h`) file. If you configure the **Code interface packaging** for a model to be `Reusable function` or `Nonreuseable function` (not `C++ class`), you can use a *custom file processing template* to control how the code generator:
  - Emits code to standard generated files---*`model`*`.c` or `.cpp` and *`model`*`.h`
  - Produces files that are independent of model code
- Organize generated code into sections (such as includes, `typedef`s, functions, and more). Your CFP template can emit code (for example, functions), directives (such as `#define` or `#include` statements), or comments into each section.
- Generate custom *file banners* (comment sections) at the start and end of generated code files and custom *function banners* that precede functions in the generated code.
- Generate code to call model functions, such as *`model`*`_initialize`, *`model`*`_step`, and so on.
- Generate code to read and write model inputs and outputs.
- Generate a main program module.
- Obtain information about the model and the generated files from the model.

Custom File Processing Components

The custom file processing features are based on the following interrelated components:

- *Code generation template* (CGT) files: a CGT file defines the top-level organization and formatting of generated code. See “Code Generation Template (CGT) Files” on page 50-63.
- The *code template API*: a high-level Target Language Compiler (TLC) API that provides functions with which you can organize code into named sections and subsections of

generated source and header files. The code template API also provides utilities that return information about generated files, generate standard model calls, and perform other functions. See “Code Template API Summary” on page 50-89.

- *Custom file processing (CFP) templates*: a CFP template is a TLC file that manages the process of custom code generation. A CFP template assembles code to be generated into buffers. A CFP template also calls the code template API to emit the buffered code into specified sections of generated source and header files. A CFP template interacts with a CGT file, which defines the ordering of major sections of the generated code. See “Custom File Processing (CFP) Templates” on page 50-70.

To use CFP templates, you must understand TLC programming, for more information, see “Target Language Compiler” (Simulink Coder).

Custom File Processing Configuration

Customize generated code by specifying code and data templates on the **Code Generation > Templates** pane:

Goal	Action
Specify a template that defines the top-level organization and formatting of generated source code (`.c` or `.cpp`) files	Enter a code generation template (CGT) file for the **Source file (*.c) template** parameter.
Specify a template that defines the top-level organization and formatting of generated header (`.h`) files	Enter a CGT file for the **Header file (*.h) template** parameter. This template file can be the same template file that you specify for **Source file (.c) template**. If you use the same template file, source and header files contain identical banners. The default template is *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.
Specify a template that organizes generated code into sections (such as includes, `typedefs`, functions, and more)	Enter a custom file processing (CFP) template file for the “File customization template” parameter. A CFP template can emit code, directives, or comments into each section. For more information, see “Custom File Processing (CFP) Templates” on page 50-70.
Generate a model-specific example main program module	Select **Generate an example main program**. For more information, see “Generate a Standalone Program” on page 63-2.

Note Place the template files that you specify on the MATLAB path.

Specify Templates For Code Generation

To use custom file processing features, create CGT files and CFP templates. These files are based on default templates provided by the code generation software. Once you have created your templates, you must integrate them into the code generation process.

Select and edit CGT files and CFP templates, and specify their use in the code generation process in the **Code Generation** > **Templates** pane of a model configuration set. The following figure shows options configured for their defaults.

The options related to custom file processing are:

- The **Source file (.c) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating source (`.c` or `.cpp`) files. You must place this file on the MATLAB path.
- The **Header file (.h) template** field in the **Code templates** and **Data templates** sections. This field specifies the name of a CGT file to use when generating header (`.h`) files. You must place this file on the MATLAB path.

  By default, the template for both source and header files is *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.
- The **File customization template** edit field in the **Custom templates** section. This field specifies the name of a CFP template file to use when generating code files. You must place this file on the MATLAB path. The default CFP template is *`matlabroot`*`/toolbox/rtw/targets/ecoder/example_file_process.tlc`.

In each of these fields, click **Browse** to navigate to and select an existing CFP template or CGT file. Click **Edit** to open the specified file into the MATLAB editor where you can customize it.

Code Generation Template (CGT) Files

Code Generation Template (CGT) files define the top-level organization and formatting of generated source code and header files. CGT files have the following applications:

- Generation of custom banners (comments sections) in code files. See “Generate Custom File and Function Banners” on page 50-93.
- Generation of custom code using a CFP template requires a CGT file. To use CFP templates, you must understand the CGT file structure. In many cases, however, you can use the default CGT file without modifying it.

Default CGT file

The code generation software provides a default CGT file, *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt`. Base your custom CGT files on the default file.

CGT File Structure

A CGT file consists of one required section and four optional sections:

Code Insertion Section

(Required) This section contains tokens that define an ordered partitioning of the generated code into a number of sections (such as `Includes` and `Defines` sections). Tokens have the form of:

```
%<SectionName>
```

For example,

```
%<Includes>
```

The code generation software defines a minimal set of required tokens. These tokens generate C or C++ source or header code. They are *built-in* tokens (see “Built-In Tokens and Sections” on page 50-64). You can also define custom tokens on page 50-84 and custom sections on page 50-82.

Each token functions as a placeholder for a corresponding section of generated code. The ordering of the tokens defines the order in which the corresponding sections appear in

the generated code. If you do not include a token, then the corresponding section is not generated. To generate code into a given section, explicitly call the code template API from a CFP template, as described in “Custom File Processing (CFP) Templates” on page 50-70.

The CGT tokens define the high-level organization of generated code. Using the code template API, you can partition each code section into named subsections, as described in “Subsections” on page 50-66.

In the code insertion section, you can also insert C or C++ comments between tokens. Such comments emit directly into the generated code.

File Banner Section

(Optional) This section contains comments and tokens you use in generating a custom file banner.

Function Banner Section

(Optional) This section contains comments and tokens for use in generating a custom function banner.

Shared Utility Function Banner Section

(Optional) This section contains comments and tokens for use in generating a custom shared utility function banner.

File Trailer Section

(Optional) This section contains comments for use in generating a custom trailer banner.

For more information on these sections, see “Generate Custom File and Function Banners” on page 50-93.

Built-In Tokens and Sections

The following code extract shows the required code insertion section of the default CGT file with the required built-in tokens.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Code insertion section (required)
%%   These are required tokens. You can insert comments and other tokens in
%% between them, but do not change their order or remove them.
```

```
%%
%<Includes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Note the following requirements for customizing a CGT file:

- Do not remove required built-in tokens.
- Built-in tokens must appear in the order shown because each successive section has dependencies on previous sections.
- Only one token per line.
- Do not repeat tokens.
- You can add custom tokens and comments to the code insertion section as long as you do not violate the previous requirements.

Note If you modify a CGT file and then rebuild your model, the code generation process does not force a top model build. To regenerate the code, see “Force Regeneration of Top Model Code” (Simulink Coder).

The following table summarizes the built-in tokens and corresponding section names, and describes the code sections.

Built-In CGT Tokens and Corresponding Code Sections

Token and Section Name	Description
`Includes`	`#include` directives section
`Defines`	`#define` directives section
`Types`	`typedef` section.`Typedefs` can depend on a previously defined type
`Enums`	Enumerated types section
`Definitions`	Data definitions (for example, `double x = 3.0;`)
`Declarations`	Data declarations (for example, `extern double x;`)
`Functions`	C or C++ functions

Subsections

You can define one or more named subsections for any section. Some of the built-in sections have predefined subsections summarized in table Subsections Defined for Built-In Sections.

Note Sections and subsections emit to the source or header file in the order listed in the CGT file.

Using the custom section feature, you can define additional sections. See “Generate a Custom Section” on page 50-82.

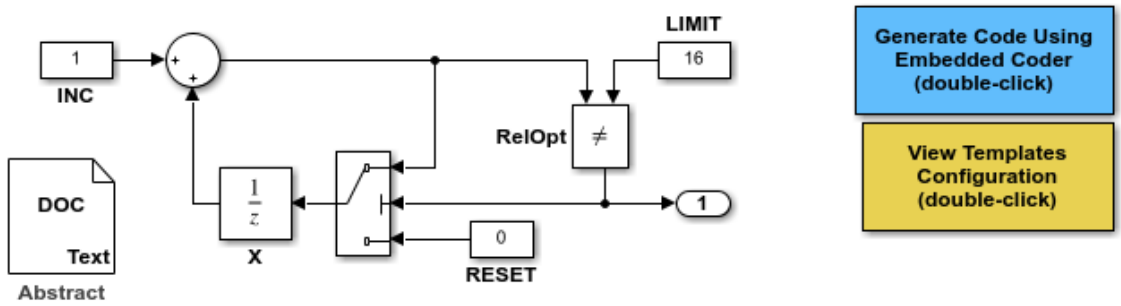
Subsections Defined for Built-In Sections

Section	Subsections	Subsection Description
`Includes`	N/A	
`Defines`	N/A	
`Types`	`IntrinsicTypes`	Intrinsic `typedef` section. Intrinsic types depend only on intrinsic C or C++ types.
`Types`	`PrimitiveTypedefs`	Primitive `typedef` section. Primitive `typedef`s depend only on intrinsic C or C++ types and on `typedef`s previously defined in the `IntrinsicTypes` section.
`Types`	`UserTop`	You can place any type of code in this section, including code that has dependencies on the previous sections.
`Types`	`Typedefs`	`typedef` section. `Typedef`s can depend on previously defined types
`Enums`	N/A	
`Definitions`	N/A	
`Declarations`	N/A	
`Functions`		C or C++ functions
`Functions`	`CompilerErrors`	`#error` directives
`Functions`	`CompilerWarnings`	`#warning` directives
`Functions`	`Documentation`	Documentation (comment) section
`Functions`	`UserBottom`	You can place any code in this section.

Format Generated Code Files Using Templates

This example shows how to use code generation templates to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files.

```
model='rtwdemo_codetemplate';
open_system(model)
```



<S:Note>This Simulink annotation maps to the code template %<Note> symbol.

Description
This model extracts text from the Model Description, a DOC block, and a Simulink annotation. The Simulink annotation maps to the code template %<Note> symbol. Many symbols are available that extract information from a model automatically. Refer to Module Packaging Features in the Embedded Coder documentation to see a complete list.

Many organizations employ coding standards that include consistent file layout and elaboration. Embedded Coder provides extensible code generation templates for formatting generated code. The layout and format of the code template file controls the output of the generated code.

Code generation templates (.cgt files) allow you to add custom code banners, rearrange data and functions, and insert additional code segments and documentation into generated code files. Code generation templates are picked up automatically from the MATLAB path and employed during the code generation process. For this model, the code generation template "rtwdemocodetemplate.cgt" is used.

Instructions
1. Double-click the yellow View Templates Configuration button to view the templates configuration.
2. Click the Edit button to the right of the "rtwdemocodetemplate.cgt" template, and inspect the code template.
3. Double-click the blue button in the upper right to generate code. An HTML report appears automatically.
4. Open rtwdemo_codetemplate.c to inspect the generated code for this model.

```
rtwdemoclean;
close_system(model,0)
```

Custom File Processing (CFP) Templates

The files provided to support custom file processing are:

- *matlabroot*/rtw/c/tlc/mw/codetemplatelib.tlc: A TLC function library that implements the code template API. codetemplatelib.tlc also provides the comprehensive documentation of the API in the comments headers preceding each function.
- *matlabroot*/toolbox/rtw/targets/ecoder/example_file_process.tlc: An example custom file processing (CFP) template, which you should use as the starting point for creating your own CFP templates. Guidelines and examples for creating a CFP template are provided in “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 50-77.
- TLC files supporting generation of single-rate and multirate main program modules (see “Customizing Main Program Module Generation” on page 50-81).

Once you have created a CFP template, you must integrate it into the code generation process, using the **File customization template** edit field. See “Specify Templates For Code Generation” on page 50-62.

Custom File Processing (CFP) Template Structure

A custom file processing (CFP) template imposes a simple structure on the code generation process. The template, a code generation template (CGT) file, partitions the code generated for each file into a number of sections. These sections are summarized in Built-In CGT Tokens and Corresponding Code Sections and Subsections Defined for Built-In Sections.

Code for each section is assembled in buffers and then emitted, in the order listed, to the file being generated.

To generate a file section, your CFP template must first assemble the code to be generated into a buffer. Then, to emit the section, your template calls the TLC function

```
LibSetSourceFileSection(fileH, section, tmpBuf)
```

where

- fileH is a file reference to a file being generated.

- `section` is the code section or subsection to which code is to be emitted. section must be one of the section or subsection names listed in Subsections Defined for Built-In Sections.

  Determine the `section` argument as follows:

  - If Subsections Defined for Built-In Sections does not define subsections for a given section, use the section name as the `section` argument.
  - If Subsections Defined for Built-In Sections defines one or more subsections for a given section, you can use either the section name or a subsection name as the `section` argument.
  - If you have defined a custom token denoting a custom section, do not call `LibSetSourceFileSection`. Special API calls are provided for custom sections (see “Generate a Custom Section” on page 50-82).
- `tmpBuf` is the buffer containing the code to be emitted.

There is no requirement to generate all of the available sections. Your template need only generate the sections you require in a particular file.

Note that legality or syntax checking is not performed on the custom code within each section.

See “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 50-77, for typical usage examples.

Change the Organization of a Generated File

The files created during code generation are organized according to the general code generation template. This template has the filename `ert_code_template.cgt`, and is specified by default in **Code Generation** > **Templates** pane of the Configuration Parameters dialog box.

The following fragment shows the `rtwdemo_basicsc.c` file header that is generated using this default template:

```
/*
* File: rtwdemo_basicsc.c
*
* Code generated for Simulink model 'rtwdemo_basicsc'.
*
* Model version                  : 1.299
* Simulink Coder version         : 8.11 (R2017a) 01-Aug-2016
* C/C++ source code generated on : Fri Aug 19 12:45:59 2016
*
* Target selection: ert.tlc
* Embedded hardware selection: Intel->x86-64 (Windows64)
* Code generation objectives: Unspecified
* Validation result: Not run
*/
```

You can change the organization of generated files using code templates and data templates. Code templates organize the files that contain functions, primarily. Data templates organize the files that contain identifiers. In this procedure, you organize the generated files, using the supplied code and data templates:

1. Display the active **Templates** configuration parameters.
2. In the **Code templates** section of the **Templates** pane, type `code_c_template.cgt` into the **Source file (*.c) templates** text box.
3. Type `code_h_template.cgt` into the **Header file (*.h) templates** text box.
4. In the **Data templates** section, type `data_c_template.cgt` into the **Source file (*.c) templates** text box.
5. Type `data_h_template.cgt` into the **Header file (*.h) templates** text box, and click **Apply**.
6. In the model window, press **Ctrl+B**. Now the files are organized using the templates you specified. For example, the `rtwdemo_basicsc.c` file header now is organized like this:

```
/**
 ***************************************************************************
 **  FILE INFORMATION:
 **  Filename:           rtwdemo_basicsc.c
 **  File Creation Date: 19-Aug-2016
 **
 **  ABSTRACT:
 **
 **
 **  NOTES:
 **
 **
 **  MODEL INFORMATION:
 **  Model Name:         rtwdemo_basicsc
 **  Model Description:  Specifying Storage Class Within a Diagram

   This model shows how to define data storage class as part of
   the diagram.
 **  Model Version:      1.299
 **  Model Author:       The MathWorks, Inc. - Mon Nov 27 14:36:56 2000

 **
 **  Last Saved Modification:  The MathWorks, Inc. - Sat Aug 06 14:37:49 2016
 **
 **
 ***************************************************************************
 **/
```

Customize Generated File Names

The code generator creates *`model`*`.*` files during the code generation and build process. When you generate C/C++ code for ERT-based models, you can customize the names of the generated header, source, and data files. Custom file names enable you to:

- Comply with naming standards of the company or industry.
- Integrate with external code.

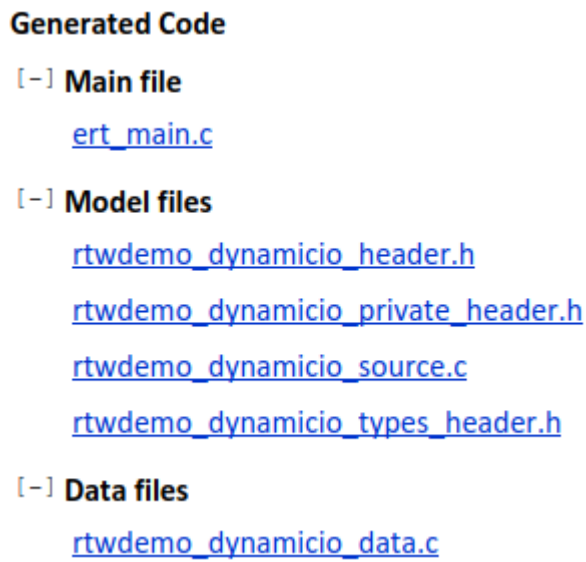
In the Configuration Parameters dialog box, on the **Code Generation** > **Code Placement** pane, use the **Auto-generated file naming rules** group to customize the names of generated files. When you use `Modular` or `Compact(with separate date file)` file packaging, you can specify custom names for generated header, source, and data files. When you use `Compact` file packaging, you can specify custom names for generated header and source files.

1. Open any ERT-based model, for example, `rtwdemo_dynamicio`. In the Configuration Parameters dialog box, change the **System target file** to `ert.tlc`.
2. On the **Code Generation** > **Code Placement** pane, select **File packaging format** as `Compact(with separate date file)`.
3. Specify custom file names by using the naming rules for these parameters:

   - **Header files**: `$R$E_header`
   - **Source files**: `$R$E_source`
   - **Data files**: `$R_data`

   `$E` is mandatory for **Header files** and **Source files**. `$E` represents these instances of file types:

   - `capi`
   - `capi_host`
   - `dt`
   - `testinterface`
   - `private`
   - `types`
4. To build the model, press **Ctrl + B**. In the code generation report, the generated files are listed on the left pane under **Model files** and **Data files** section.



In this example, `$E` resolves to `private` and `types`. The generated header files resolve to the model name with the value for `$E` and custom text `header`. The generated source files resolve to the model name with custom text `source`. The generated data file resolves to the model name with custom text `data`. Here is a summary of naming rules applied and the corresponding generated files:

Type of File	Token Specification	Custom Text	Generated File Name
Header file	`$R$E`	`header`	`rtwdemo_dynamicio_header.h`
Header file	`$R$E`	`header`	`rtwdemo_dynamicio_private_header.h`
Source file	`$R$E`	`source`	`rtwdemo_dynamicio_source.c`
Header file	`$R$E`	`header`	`rtwdemo_dynamicio_types_header.h`

Type of File	Token Specification	Custom Text	Generated File Name
Data file	`$R`	`data`	`rtwdemo_dynamicio_data.c`

Generate Source and Header Files with a Custom File Processing (CFP) Template

In this section...

This example shows you the process of generating a simple source (`.c` or `.cpp`) and header (`.h`) file using the example CFP template. Then, it examines the template and the code generated by the template.

The example CFP template, *`matlabroot`*`/toolbox/rtw/targets/ecoder/example_file_process.tlc`, demonstrates some of the capabilities of the code template API, including

- Generation of simple source (`.c` or `.cpp`) and header (`.h`) files
- Use of buffers to generate file sections for includes, functions, and so on
- Generation of includes, defines, into the standard generated files (for example, *`model`*`.h`)
- Generation of a main program module

Generate Code with a CFP Template

This section sets up a CFP template and configures a model to use the template in code generation. The template generates (in addition to the standard model files) a source file (`timestwo.c` or `.cpp`) and a header file (`timestwo.h`).

Follow the steps below to become acquainted with the use of CFP templates:

1. Copy the example CFP template, *`matlabroot`*`/toolbox/rtw/targets/ecoder/example_file_process.tlc`, to a folder outside of the MATLAB folder structure (that is, not under *`matlabroot`*). If the folder is not on the MATLAB path or the TLC path, then add it to the MATLAB path. It is good practice to locate the CFP template in the same folder as your system target file, which is on the TLC path.

2. Rename the copied `example_file_process.tlc` to `test_example_file_process.tlc`.
3. Open `test_example_file_process.tlc` into the MATLAB editor.
4. Uncomment the following line:

   ```
   %%  %assign ERTCustomFileTest = TLC_TRUE
   ```

   It now reads:

   ```
     %assign ERTCustomFileTest = TLC_TRUE
   ```

   If `ERTCustomFileTest` is not assigned as shown, the CFP template is ignored in code generation.
5. Save your changes to the file. Keep `test_example_file_process.tlc` open, so you can refer to it later.
6. Open the `rtwdemo_udt` model.
7. Open the Simulink Model Explorer. Select the active configuration set of the model, and open the **Code Generation** pane of the active configuration set.
8. On the **Templates** tab, in the **File customization template** field, specify `test_example_file_process.tlc`. This is the file you previously edited and is now the specified CFP template for your model.
9. On the **General** tab, select the **Generate code only** check box.
10. Click **Apply**.
11. In the model window, press **Ctrl+B**. During code generation, notice the following message in the **Diagnostic Viewer**:

    ```
    Warning:  Overriding example ert_main.c!
    ```

    This message is displayed because `test_example_file_process.tlc` generates the main program module, overriding the default action of the ERT target. This is explained in greater detail below.
12. The `rtwdemo_udt` model is configured to generate an HTML code generation report. After code generation is complete, view the report.

    Notice that the **Generated Code** list contains the following files:

    - Under **Main file**, `ert_main.c`.
    - Under **Other files**, `timestwo.c` and `timestwo.h`.

The files were generated by the CFP template. The next section examines the template to learn how this was done.

13. Keep the model, the code generation report, and the `test_example_file_process.tlc` file open so you can refer to them in the next section.

Analysis of the Example CFP Template and Generated Code

This section examines excerpts from `test_example_file_process.tlc` and some of the code it generates. Refer to the comments in *`matlabroot`*`/rtw/c/tlc/mw/codetemplatelib.tlc` while reading the following discussion.

Generating Code Files

Source (`.c` or `.cpp`) and header (`.h`) files are created by calling `LibCreateSourceFile`, as in the following excerpts:

```
%assign cFile = LibCreateSourceFile("Source", "Custom", "timestwo")
...
%assign hFile = LibCreateSourceFile("Header", "Custom", "timestwo")
```

Subsequent code refers to the files by the file reference returned from `LibCreateSourceFile`.

File Sections and Buffers

The code template API lets you partition the code generated to each file into sections, tagged as `Definitions`, `Includes`, `Functions`, `Banner`, and so on. You can append code to each section as many times as required. This technique gives you a great deal of flexibility in the formatting of your custom code files.

Subsections Defined for Built-In Sections describes the available file sections and their order in the generated file.

For each section of a generated file, use `%openfile` and `%closefile` to store the text for that section in temporary buffers. Then, to write (append) the buffer contents to a file section, call `LibSetSourceFileSection`, passing in the desired section tag and file reference. For example, the following code uses two buffers (`typesBuf` and `tmpBuf`) to generate two sections (tagged `"Includes"` and `"Functions"`) of the source file `timestwo.c` or `.cpp` (referenced as `cFile`):

```
%openfile typesBuf
```

```
#include "rtwtypes.h"

%closefile typesBuf

%<LibSetSourceFileSection(cFile,"Includes",typesBuf)>

 %openfile tmpBuf

 /* Times two function */
 real_T timestwofcn(real_T input) {
   return (input * 2.0);
}

%closefile tmpBuf

%<LibSetSourceFileSection(cFile,"Functions",tmpBuf)>
```

These two sections generate the entire `timestwo.c` or `.cpp` file:

```
#include "rtwtypes.h"

/* Times two function */
FLOAT64 timestwofcn(FLOAT64 input)
{
  return (input * 2.0);
}
```

Adding Code to Standard Generated Files

The `timestwo.c` or `.cpp` file generated in the previous example was independent of the standard code files generated from a model (for example, *`model`*`.c` or `.cpp`, *`model`*`.h`, and so on). You can use similar techniques to generate custom code within the model files. The code template API includes functions to obtain the names of the standard models files and other model-related information. The following excerpt calls `LibGetMdlPubHdrBaseName` to obtain the name for the *`model`*`.h` file. It then obtains a file reference and generates a definition in the `Defines` section of *`model`*`.h`:

```
%% Add a #define to the model's public header file model.h

%assign pubName = LibGetMdlPubHdrBaseName()
%assign modelH  = LibCreateSourceFile("Header", "Simulink", pubName)

%openfile tmpBuf

 #define ACCELERATION 9.81
```

```
 %closefile tmpBuf

%<LibSetSourceFileSection(modelH,"Defines",tmpBuf)>
```

Examine the generated `rtwdemo_udt.h` file to see the generated `#define` directive.

Customizing Main Program Module Generation

Normally, the ERT target determines whether and how to generate an `ert_main.c` or `.cpp` module based on the settings of the **Generate an example main program** and **Target operating system** options on the **Templates** pane of the Configuration Parameters dialog box. You can use a CFP template to override the normal behavior and generate a main program module customized for your target environment.

To support generation of main program modules, two TLC files are provided:

- `bareboard_srmain.tlc`: TLC code to generate an example single-rate main program module for a bareboard target environment. Code is generated by a single TLC function, `FcnSingleTaskingMain`.
- `bareboard_mrmain.tlc`: TLC code to generate a multirate main program module for a bareboard target environment. Code is generated by a single TLC function, `FcnMultiTaskingMain`.

In the example CFP template file *`matlabroot`*`/toolbox/rtw/targets/ecoder/example_file_process.tlc`, the following code generates either a single- or multitasking `ert_main.c` or `.cpp` module. The logic depends on information obtained from the code template API calls `LibIsSingleRateModel` and `LibIsSingleTasking`:

```
%% Create a simple main.  Files are located in MATLAB/rtw/c/tlc/mw.

 %if LibIsSingleRateModel() || LibIsSingleTasking()
   %include "bareboard_srmain.tlc"
   %<FcnSingleTaskingMain()>
 %else
   %include "bareboard_mrmain.tlc"
   %<FcnMultiTaskingMain()>
 %endif
```

Note that `bareboard_srmain.tlc` and `bareboard_mrmain.tlc` use the code template API to generate `ert_main.c` or `.cpp`.

When generating your own main program module, you disable the default generation of `ert_main.c` or `.cpp`. The TLC variable `GenerateSampleERTMain` controls generation of `ert_main.c` or `.cpp`. You can directly force this variable to `TLC_FALSE`. The examples `bareboard_mrmain.tlc` and `bareboard_srmain.tlc` use this technique, as shown in the following excerpt from `bareboard_srmain.tlc`.

```
%if GenerateSampleERTMain
    %assign CompiledModel.GenerateSampleERTMain = TLC_FALSE
    %warning Overriding example ert_main.c!
%endif
```

Alternatively, you can implement a `SelectCallback` function for your target. A `SelectCallback` function is a MATLAB function that is triggered when you:

- Load the model.
- Update any configuration settings in the Configuration Parameters dialog box.
- Build the model.

Your `SelectCallback` function should deselect and disable the **Generate an example main program** option. This prevents the TLC variable `GenerateSampleERTMain` from being set to TLC_TRUE.

See the “rtwgensettings Structure” (Simulink Coder) section for information on creating a `SelectCallback` function.

The following code illustrates how to deselect and disable the **Generate an example main program** option in the context of a `SelectCallback` function.

```
slConfigUISetVal(hDlg, hSrc, 'GenerateSampleERTMain', 'off');
slConfigUISetEnabled(hDlg, hSrc, 'GenerateSampleERTMain',0);
```

Note Creation of a main program for your target environment requires some customization; for example, in a bareboard environment you need to attach `rt_OneStep` to a timer interrupt. It is expected that you will customize either the generated code, the generating TLC code, or both. See “Guidelines for Modifying the Main Program” on page 63-4 and “Guidelines for Modifying rt_OneStep” on page 63-9 for further information.

Generate a Custom Section

You can define custom tokens on page 50-84 in a CGT file and direct generated code into an associated built-in section. This feature gives you additional control over the formatting of code within each built-in section. For example, you could add subsections to built-in sections that do not already define subsections. Custom sections must be associated with one of the built-in sections: `Includes`, `Defines`, `Types`, `Enums`, `Definitions`, `Declarations`, or `Functions`. To create custom sections, you must

- Add a custom token to the code insertion section of your CGT file.
- In your CFP file:
  - Assemble code to be generated to the custom section into a buffer.
  - Declare an association between the custom section and a built-in section, with the code template API function `LibAddSourceFileCustomSection`.
  - Emit code to the custom section with the code template API function `LibSetSourceFileCustomSection`.

The following code examples illustrate the addition of a custom token, `Myincludes`, to a CGT file, and the subsequent association of the custom section `Myincludes` with the built-in section `Includes` in a CFP file.

Note If you have not already created custom CGT and CFP files for your model, copy the default template files *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt` and *`matlabroot`*`/toolbox/rtw/targets/ecoder/example_file_process.tlc` to a work folder that is outside the MATLAB folder structure but on the MATLAB or TLC path, rename them (for example, add the prefix `test_` to each file), and update the **Templates** pane of the Configuration Parameters dialog box to reference them.

First, add the token `Myincludes` to the code insertion section of your CGT file. For example:

```
%<Includes>
%<Myincludes>
%<Defines>
%<Types>
%<Enums>
%<Definitions>
%<Declarations>
%<Functions>
```

Next, in the CFP file, add code to generate `include` directives into a buffer. For example, in your copy of the example CFP file, you could insert the following section between the `Includes` section and the `Create a simple main` section:

```
%% Add a custom section to the model's C file model.c

%openfile tmpBuf
```

```
#include "moretables1.h"
#include "moretables2.h"
%closefile tmpBuf

%<LibAddSourceFileCustomSection(modelC,"Includes","Myincludes")>
%<LibSetSourceFileCustomSection(modelC,"Myincludes",tmpBuf)>
```

The `LibAddSourceFileCustomSection` function call declares an association between the built-in section `Includes` and the custom section `Myincludes`. `Myincludes` is a subsection of `Includes`. The `LibSetSourceFileCustomSection` function call directs the code in the `tmpBuf` buffer to the `Myincludes` section of the generated file. `LibSetSourceFileCustomSection` is syntactically identical to `LibSetSourceFileSection`.

In the generated code, the include directives generated to the custom section appear after other code directed to `Includes`.

```
#include "rtwdemo_udt.h"
#include "rtwdemo_udt_private.h"

/* #include "mytables.h" */
#include "moretables1.h"
#include "moretables2.h"
```

Note The placement of the custom token in this example CGT file is arbitrary. By locating `%<Myincludes>` after `%<Includes>`, the CGT file specifies only that the `Myincludes` code appears after `Includes` code.

Custom Tokens

Custom tokens are automatically translated to TLC syntax as a part of the build process. To escape a token, that is to prepare it for normal TLC expansion, use the '!' character. For example, the token `%<!TokenName>` is expanded to `%<TokenName>` by the template conversion program. You can specify valid TLC code, including TLC function calls: `%<!MyTLCFcn()>`.

Comparison of a Template and Its Generated File

This figure shows part of a user-modified custom file processing (CFP) template and the resulting generated code. The figure illustrates how you can use a template to:

- Define what code the code generation software should add to the generated file
- Control the location of code in the file
- Optionally insert comments in the generated file

Notice `%<Includes>`, for example, on the template. The term `Includes` is a symbol name. A percent sign and brackets (`%< >`) must enclose every symbol name. You can add the desired symbol name (within the `%< >` delimiter) at a particular location in the template. This is how you control where the code generator places an item in the generated file.

Template and Generated File

Mapping Template Specification to Code Generation

This part of the template...		Generates in the file...		Explanation
		Line	Description	
(1)	`/*#INCLUDES*/` `%<Includes>`	26–28	An `/*#INCLUDES*/` comment, followed by `#include` statements	The code generator adds the C/C++ comment as a header, and then interprets the `%<Includes>` template symbol to list the required `#include` statements in the file. This code is first in this section of the file because the template entries are first.
(2)	`/*#DEFINES*/` `%<Defines>`	30	A `/*#DEFINES*/` comment, but no `#define` statements	Next, the code generator places the comment as a header for `#define` statements, but the file does not need `#define`. No code is added.
(3)	`#pragma string1`	31	`#pragma` statements	While the code generator requires `%<>` delimiters for template symbols, it can also interpret C/C++ statements in the template without delimiters. In this case, the generator adds the specified statements to the code, following the order in which the statements appear in the template.
(5)	`#pragma string2`	42		
(4)	`/*DEFINITIONS*/` `%<Definitions>`	32–41	`/*DEFINITIONS*/` comment, followed by definitions	The code generator places the comment and definitions in the file between the `#pragma` statements, according to the order in the template. It also inserts comments (lines 33 and 36) that are preset in the model's Configuration Parameters dialog box.

This part of the template...		Generates in the file...		Explanation
		Line	Description	
(6)	`%<Declarations>`	43	No declarations	The file needs no declarations, so the code generator does not generate declarations for this file. The template does not have a comment to provide a header. Line 43 is left blank.
(7)	`%<Functions>`	44–74	Functions	Finally, the code generator adds functions from the model, plus comments that are preset in the Configuration Parameters dialog box. But it adds no comments as a header for the functions, because the template does not have one. This code is last because the template entry is last.

For a list of template symbols and the rules for using them, see “Template Symbol Groups” on page 50-102, “Template Symbols” on page 50-105, and “Rules for Modifying or Creating a Template” on page 50-108. To set comment options, from the **Simulation** menu, select **Model Configuration Parameters**. On the Configuration Parameters dialog box, select the **Code Generation > Comments** pane. For details, see “Configure Code Comments” (Simulink Coder).

Code Template API Summary

Code Template API Functions summarizes the code template API. See the source code in *matlabroot*`/rtw/c/tlc/mw/codetemplatelib.tlc` for detailed information on the arguments, return values, and operation of these calls.

Code Template API Functions

Function	Description
`LibClearFileSectionContents`	Clears a file section with custom values before writing file to disk.
`LibGetNumSourceFiles`	Returns the number of created source files (`.c` or `.cpp` and `.h`).
`LibGetSourceFileTag`	Returns `<filename>_h` and `<filename>_c` for header and source files, respectively, where `filename` is the name of the model file.
`LibCreateSourceFile`	Creates a new C or C++ file and returns its reference. If the file already exists, simply returns its reference.
`LibGetFileRecordName`	Returns a model file name (including the path) without the extension.
`LibGetSourceFileFromIdx`	Returns a model file reference based on its index. This is useful for a common operation on all files, such as to set the leading file banner of all files.
`LibSetSourceFileSection`	Adds to the contents of a specified section within a specified file (see also “Custom File Processing (CFP) Template Structure” on page 50-70).
`LibIndentSourceFile`	Indents a file (from within the TLC environment).
`LibCallModelInitialize`	Returns code for calling the model's *`model`*`_initialize` function (valid for ERT only).
`LibCallModelStep`	Returns code for calling the model's *`model`*`_step` function (valid for ERT only).
`LibCallModelTerminate`	Returns code for calling the model's *`model`*`_terminate` function (valid for ERT only).

Function	Description
`LibCallSetEventForThisBaseStep`	Returns code for calling the model's set events function (valid for ERT only).
`LibWriteModelData`	Returns data for the model (valid for ERT only).
`LibSetRTModelErrorStatus`	Returns the code to set the model error status.
`LibGetRTModelErrorStatus`	Returns the code to get the model error status.
`LibIsSingleRateModel`	Returns true if model is single rate and false otherwise.
`LibGetModelName`	Returns name of the model (without an extension).
`LibGetMdlSrcBaseName`	Returns the name of model's main source file (for example, *`model`*`.c` or `.cpp`).
`LibGetMdlPubHdrBaseName`	Returns the name of model's public header file (for example, *`model`*`.h`).
`LibGetMdlPrvHdrBaseName`	Returns the name of the model's private header file (for example, *`model`*`_private.h`).
`LibIsSingleTasking`	Returns `true` if the model is configured for single-tasking execution.
`LibWriteModelInput`	Returns the code to write to a particular root input (that is, a model inport block). (valid for ERT only).
`LibWriteModelOutput`	Returns the code to write to a particular root output (that is, a model outport block). (valid for ERT only).
`LibWriteModelInputs`	Returns the code to write to root inputs (that is, all model inport blocks). (valid for ERT only)
`LibWriteModelOutputs`	Returns the code to write to root outputs (that is, all model outport blocks). (valid for ERT only).

Function	Description
`LibNumDiscreteSampleTimes`	Returns the number of discrete sample times in the model.
`LibSetSourceFileCodeTemplate`	Set the code template to be used for generating a specified source file.
`LibSetSourceFileOutputDirectory`	Set the folder into which a specified source file is to be generated.
`LibAddSourceFileCustomSection`	Add a custom section to a source file. The custom section must be associated with one of the built-in (required) sections: `Includes`, `Defines`, `Types`, `Enums`, `Definitions`, `Declarations`, or `Functions`.
`LibSetSourceFileCustomSection`	Adds to the contents of a specified custom section within a specified file. The custom section must have been previously created with `LibAddSourceFileCustomSection`.

Generate Custom File and Function Banners

Using code generation template (CGT) files, you can specify custom file banners and function banners for the generated code files. File banners are comment sections in the header and trailer sections of a generated file. Function banners are comment sections for each function in the generated code. Use these banners to add a company copyright statement, specify a special version symbol for your configuration management system, remove time stamps, and for many other purposes. These banners can contain characters, which propagate to the generated code.

To specify banners, create a custom CGT file with customized banner sections. The build process creates an executable TLC file from the CGT file. The code generation process then invokes the TLC file.

You do not need to be familiar with TLC programming to generate custom banners. You can modify example files that are supplied with the ERT target.

Note Prior releases supported direct use of customized TLC files as banner templates. You specified these with the **Source file (.c) banner template** and **Header file (.h) banner template** options of the ERT target. You can still use a custom TLC file banner template, however, you can now use CGT files instead.

ERT template options on the **Code Generation > Templates** pane of a configuration set, in the **Code templates** section, support banner generation.

The options for function and file banner generation are:

- “Code templates: Source file (*.c) template”: CGT file to use when generating source (`.c` or `.cpp`) files. Place this file on the MATLAB path.
- “Code templates: Header file (*.h) template”: CGT file to use when generating header (`.h`) files. You must place this file on the MATLAB path. This file can be the same template specified in the **Code templates: Source file (*.c) template** field, in which case identical banners are generated in source and header files.

  By default, the template for both source and header files is *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.
- In each of these fields, click **Browse** to navigate to and select an existing CGT file for use as a template. Click **Edit** to open the specified file into the MATLAB editor, where you can customize it.

Create a Custom File and Function Banner Template

To customize a CGT file for custom banner generation, make a local copy of the default code template and edit it, as follows:

1. Activate the configuration set that you want to work with.
2. Open the **Code Generation** pane of the active configuration set.
3. Click the **Templates** tab.
4. By default, the code template specified in the **Code templates: Source file (*.c) template** and **Code templates: Header file (*.h) template** fields is *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.
5. If you want to use a different template as your starting point, click **Browse** to locate and select a CGT file.
6. Click **Edit** button to open the CGT file into the MATLAB editor.
7. Save a local copy of the CGT file. Store the copy in a folder that is outside of the MATLAB folder structure, but on the MATLAB path. If required, add the folder to the MATLAB path.
8. If you intend to use the CGT file with a custom target, locate the CGT file in a folder under your target root folder.
9. Rename your local copy of the CGT file. When you rename the CGT file, update the associated **Code templates: Source file (*.c) template** or **Code templates: Header file (*.h) template** field to match the new file name.
10. Edit and customize the local copy of the CGT file for banner generation, using the information provided in “Customize a Code Generation Template (CGT) File for File and Function Banner Generation” on page 50-95.
11. Save your changes to the CGT file.
12. Click **Apply** to update the configuration set.
13. Save your model.
14. Generate code. Examine the generated source and header files to confirm that they contain the banners specified by the template or templates.

Customize a Code Generation Template (CGT) File for File and Function Banner Generation

This section describes how to edit a CGT file for custom file and function banner generation. For a description of CGT files, see “Code Generation Template (CGT) Files” on page 50-63.

Components of the File and Function Banner Sections in the CGT file

In a CGT file, you can modify the following sections: file banner, function banner, shared utility function banner, and file trailer. Each section is defined by open and close tags. The tags specific to each section are shown in the following table.

CGT File Section	Open Tag	Close Tag
File Banner on page 50-97	`<FileBanner>`	`</FileBanner>`
Function Banner on page 50-99	`<FunctionBanner>`	`</FunctionBanner>`
Shared-utility Banner on page 50-99	`<SharedUtilityBanner>`	`</SharedUtilityBanner>`
File Trailer on page 50-100	`<FileTrailer>`	`</FileTrailer>`

You can customize your banners by including tokens and comments between the open and close tag for each section. Tokens are typically TLC variables, for example `<ModelVersion>`, which are replaced with values in the generated code.

Note Including C comment indicators, '/*' or a '*/', in the contents of your banner might introduce an error in the generated code.

An open tag includes tag attributes. Enclose the value of the attribute in double quotes. The attributes available for an open tag are:

- `width`: specifies the width of the file or function banner comments in the generated code. The default value is 80.
- `style`: specifies the boundary for the file or function banner comments in the generated code.

The open tag syntax is as follows:

```
<OpenTag style = "style_value" width = "num_width">
```

Note If the **Configuration Parameters > Code Generation > Language** parameter is set to C++, to select a comment style that uses C comment notation (`/*...*/`), you must also set the **Configuration Parameters > Comments > Comment style** parameter to `Multi-line`.

The built-in style options for the `style` attribute are:

- `classic`

  ```
  /* single line comments */
  /*
   * multiple line comments
   * second line
   */
  ```

- `classic_cpp`

  ```
  // single line comments
  //
  // multiple line comments
  // second line
  //
  ```

- `box`

  ```
  /*********************************************************/
  /* banner contents                                       */
  /*********************************************************/
  ```

- `box_cpp`

  ```
  ///////////////////////////////////////////////////////////
  // banner contents                                       //
  ///////////////////////////////////////////////////////////
  ```

- `open_box`

  ```
  /*********************************************************
   * banner contents
   *********************************************************/
  ```

- `open_box_cpp`

```
////////////////////////////////////////////////////////////
// banner contents
////////////////////////////////////////////////////////////
```

- doxygen

```
/** single line comments */

/**
 * multiple line comments
 * second line
 */
```

- doxygen_cpp

```
/// single line comments

///
/// multiple line comments
/// second line
///
```

- doxygen_qt

```
/*! single line comments */

/*!
 * multiple line comments
 * second line
 */
```

- doxygen_qt_cpp

```
//! single line comments

//!
//! multiple line comments
//! second line
//!
```

File Banner

This section contains comments and tokens for use in generating a custom file banner. The file banner precedes C or C++ code generated by the model. If you omit the file banner section from the CGT file, then no file banner emits to the generated code.

Note If you customize your file banner, the software does not emit the customized banner for the file `const_params.c`.

The following section is the file banner section provided with the default CGT file, *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file banner section (optional)
%%
<FileBanner style="classic">
File: %<FileName>

Code generated for Simulink model %<ModelName>.

Model version                        : %<ModelVersion>
Simulink Coder version               : %<RTWFileVersion>
TLC version                          : %<TLCVersion>
C/C++ source code generated on       : %<SourceGeneratedOn>
%<CodeGenSettings>
</FileBanner>
```

Summary of Tokens for File Banner Generation

`FileName`	Name of the generated file (for example, `"rtwdemo_udt.c"`).
`FileType`	Either `"source"` or `"header"`. Designates whether generated file is a `.c` or `.cpp` file or an `.h` file.
`FileTag`	Given file names `file.c` or `.cpp` and `file.h`; the file tags are `"file_c"` and `"file_h"`, respectively.
`ModelName`	Name of generating model.
`ModelVersion`	Version number of model.
`RTWFileVersion`	Version number of *`model`*`.rtw` file.
`RTWFileGeneratedOn`	Timestamp of *`model`*`.rtw` file.
`TLCVersion`	Version of Target Language Compiler.
`SourceGeneratedOn`	Timestamp of generated file.
`CodeGenSettings`	Code generation settings for model: target language, target selection, production hardware selection, test hardware selection, code generation objectives (in priority order), and Code Generation Advisor validation result.

Function Banner

This section contains comments and tokens for use in generating a custom function banner. The function banner precedes C or C++ function generated during the build process. If you omit the function banner section from the CGT file, the default function banner emits to the generated code. The following section is the default function banner section provided with the default CGT file, *matlabroot*/toolbox/rtw/targets/ecoder/ert_code_template.cgt.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom function banner section (optional)
%%   Customize function banners by using the following predefined tokens:
%% %<ModelName>, %<FunctionName>, %<FunctionDescription>, %<Arguments>,
%% %<ReturnType>, %<GeneratedFor>, %<BlockDescription>.
%%
<FunctionBanner style="classic">
%<FunctionDescription>
%<BlockDescription>
</FunctionBanner>
```

Summary of Tokens for Function Banner Generation

FunctionName	Name of function
Arguments	List of function arguments
ReturnType	Return type of function
ModelName	Name of generating model
FunctionDescription	Short abstract about the function
GeneratedFor	Full block path for the generated function
BlockDescription	User input from the **Block Description** parameter of the block properties dialog box. BlockDescription contains an optional token attribute, style. The only valid value forstyle is content_only, which is case-sensitive and enclosed in double quotes. Use the content_only style when you want to include only the block description content that you entered in the block parameter dialog. The syntax for the token attribute style is: %<BlockDescription style = "content_only">

Shared Utility Function Banner

The shared utility function banner section contains comments and tokens for use in generating a custom shared utility function banner. The shared utility function banner

precedes C or C++ shared utility function generated during the build process. If you omit the shared utility function banner section from the CGT file, the default shared utility function banner emits to the generated code. The following section is the default shared utility function banner section provided with the default CGT file, *`matlabroot`*`/toolbox/rtw/targets/ecoder/ert_code_template.cgt`.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom shared utility function banner section (optional)
%%   Customize banners for functions generated in shared location by using the
%% following predefined tokens: %<FunctionName>, %<FunctionDescription>,
%% %<Arguments>, %<ReturnType>.
%%
<SharedUtilityBanner style="classic">
%<FunctionDescription>
</SharedUtilityBanner>
```

Summary of Tokens for Shared Utility Function Banner Generation

`FunctionName`	Name of function
`Arguments`	List of function arguments
`ReturnType`	Return type of function
`FunctionDescription`	Short abstract about function

File Trailer

The file trailer section contains comments for generating a custom file trailer. The file trailer follows C or C++ code generated from the model. If you omit the file trailer section from the CGT file, no file trailer emits to the generated code. The following section is the default file trailer provided in the default CGT file.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
%% Custom file trailer section (optional)
%%
<FileTrailer style="classic">
File trailer for generated code.

[EOF]
</FileTrailer>
```

Tokens available for the file banner are available for the file trailer. See Summary of Tokens for File Banner Generation.

Template Symbols and Rules

In this section...

Introduction

“Template Symbol Groups” on page 50-102 and “Template Symbols” on page 50-105 describe custom file processing (CFP) template symbols and rules for using them. The location of a symbol in one of the supplied template files (`code_c_template.cgt`, `code_h_template.cgt`, `data_c_template.cgt`, or `data_h_template.cgt`) determines where the items associated with that symbol are located in the corresponding generated file. “Template Symbol Groups” on page 50-102 identifies the symbol groups, starting with the parent (“Base”) group, followed by the children of each parent. “Template Symbols” on page 50-105 lists the symbols alphabetically.

Note If you are using custom CGT sections, for files generated to the `_sharedutils` folder, you can only use symbol names in the Base symbol group.

Template Symbol Groups

Symbol Group	Symbol Names in This Group

Base (Parents)	`Declarations`

Template Symbols

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
`Abstract`	Documentation	N/A	User-supplied description of the model or file. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
`Banner`	Documentation	N/A	Comments located near top of the file. Contains information that includes model and software versions, and date file was generated.
`CFunctionCode`	Functions	File	C/C++ functions. Must be at the bottom of the template.
`Created`	Documentation	N/A	Date when model was created. From **Created on** field on Model Properties dialog box.
`Creator`	Documentation	N/A	User who created model. From **Created by** field on Model Properties dialog box.
`Date`	Documentation	N/A	Date file was generated. Taken from computer clock.
`Declarations`	Base		Data declaration of a signal or parameter. For example, `extern real_T globalvar;`.
`Defines`	Base	File	Required `#defines` of `.h` files.
`Definitions`	Base	File	Data definitions of signals or parameters.
`Description`	Documentation	N/A	Description of model. From **Model description** field on Model Properties dialog box.**

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
`Documentation`	Base	N/A	Comments about how to interpret the generated files.
`Enums`	Base	File	Enumerated data type definitions.
`ExternalCalibrationLookup1D`	Declarations	External	***
`ExternalCalibrationLookup2D`	Declarations	External	***
`ExternalCalibrationScalar`	Declarations	External	***
`ExternalVariableScalar`	Declarations	External	***
`FileName`	Documentation	N/A	Name of the generated file.
`FilescopeCalibrationLookup1D`	Definitions	File	***
`FilescopeCalibrationLookup2D`	Definitions	File	***
`FilescopeCalibrationScalar`	Definitions	File	***
`FilescopeVariableScalar`	Definitions	File	***
`Functions`	Base	File	Generated function code.
`GlobalCalibrationLookup1D`	Definitions	Global	***
`GlobalCalibrationLookup2D`	Definitions	Global	***
`GlobalCalibrationScalar`	Definitions	Global	***
`GlobalVariableScalar`	Definitions	Global	***
`History`	Documentation	N/A	User-supplied revision history of the generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**
`Includes`	Base	File	`#include` preprocessor directives.

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
`LastModifiedDate`	Documentation	N/A	Date when model was last saved. From **Last saved on** field on Model Properties dialog box.
`LastModifiedBy`	Documentation	N/A	User who last saved model. From **Last saved by** field on Model Properties dialog box.
`LocalDefines`	Defines	File	`#define` preprocessor directives from code-generation data objects.
`LocalMacros`	Defines	File	C/C++ macros local to the file.
`ModelName`	Documentation	N/A	Name of the model.
`ModelVersion`	Documentation	N/A	Version number of the Simulink model. From **Model version** field on Model Properties dialog box.
`ModifiedBy`	Documentation	N/A	Name of user who last modified the model.
`ModifiedComment`	Documentation	N/A	Comment user enters in the **Modified Comment** field on the Log Change dialog box. For more information, see “Log Comments History” (Simulink).
`ModifiedHistory`	Documentation	N/A	Text from **Model history** field on Model Properties dialog box.**
`Notes`	Documentation	N/A	User-supplied miscellaneous notes about the model or generated files. Placed in the generated file based on the Stateflow note, Simulink annotation, or DocBlock on the model.**

Symbol Name*	Symbol Group	Symbol Scope	Symbol Description (What the symbol puts in the generated file)
`ToolVersion`	Documentation	N/A	A list of the versions of the toolboxes used in generating the code.
`Types`	Base		Data types of generated code.

* Symbol names must be enclosed between `%< >`. For example, `%<Functions>`.

** This symbol can be used to add a comment to the generated files. See “Add Global Comments” on page 50-10. The code generator places the comment in each generated file whose template has this symbol name. The code generator places the comment at the location that corresponds to where the symbol name is located in the template file.

*** The description can be deduced from the symbol name. For example, `GlobalCalibrationScalar` is a symbol that identifies a scalar. It contains data of global scope that you can calibrate.

Rules for Modifying or Creating a Template

The following are the rules for creating an MPF template. “Comparison of a Template and Its Generated File” on page 50-85 illustrates several of these rules.

1. Place a symbol on a template within the `%< >` delimiter. For example, the symbol named `Includes` should look like this on a template: `%<Includes>`. *Note that symbol names are case-sensitive.*
2. Place a symbol on a template where desired. Its location on the template determines where the item associated with this symbol is located in the generated file. If no item is associated with it, the symbol is ignored.
3. Place a C/C++ statement outside of the `%< >` delimiter, and on a different line than a `%< >` delimiter, for that statement to appear in the generated file. For example, `#pragma message ("my text")` in the template results in `#pragma message ("my text")` at the corresponding location in the generated file. Note that the statement must be compatible with your C/C++ compiler.
4. Use the `.cgt` extension for every template filename. ("`cgt`" stands for *c*ode *g*eneration *t*emplate.)

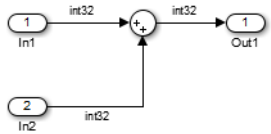
5. Note that `%% $Revision: 1.1.4.10.4.1 $` appears at the top of the MathWorks supplied templates. This is for internal MathWorks use only. It does not need to be placed on a user-defined template and does not show in a generated file.
6. Place a comment on the template between `/* */` as in standard ANSI C[6]. This results in `/*comment*/` on the generated file.
7. Each MPF template must have all of the Base group symbols, in predefined order. They are listed in “Template Symbol Groups” on page 50-102. Each symbol in the Base group is a parent. For example, `Declarations` is a parent symbol.
8. Each symbol in a non-Base group is a child. For example, `LocalMacros` is a child.
9. Except for Documentation children, children must be placed after their parent, before the next parent, and before the `Functions` symbol.
10. Documentation children can be located before or after their parent in any order anywhere in the template.
11. If a non-Documentation child is missing from the template, the code generator places the information associated with this child at its parent location in the generated file.
12. If a Documentation child is missing from the template, the code generator omits the information associated with that child from the generated file.

6. ANSI is a registered trademark of the American National Standards Institute, Inc.

Annotate Code for Justifying Polyspace Checks

With the Polyspace Code Prover product you can apply Polyspace verification to Embedded Coder generated code. The software detects run-time errors in the generated code and helps you to locate and fix model faults.

Polyspace might highlight overflows for certain operations that are legitimate because of the way the code generator implements these operations. Consider the following model and the corresponding generated code.



```
32 /* Sum: '<Root>/Sum' incorporates:
33   *  Inport: '<Root>/In1'
34   *  Inport: '<Root>/In2'
35   */
36  qY_0 = sat_add_U.In1 + sat_add_U.In2;
37  if ((sat_add_U.In1 < 0) && ((sat_add_U.In2 < 0) && (qY_0 >= 0))) {
38    qY_0 = MIN_int32_T;
39  } else {
40   if ((sat_add_U.In1 > 0) && ((sat_add_U.In2 > 0) && (qY_0 <= 0))) {
41      qY_0 = MAX_int32_T;
42    }
43  }
```

The code generator recognizes that the largest built-in data type is 32-bit. It is not possible to saturate the results of the additions and subtractions using `MIN_INT32` and `MAX_INT32` and a bigger single-word integer data type. Instead the software detects the results overflow and the direction of the overflow, and saturates the result.

If you do not provide justification for the addition operator on line 36, Polyspace verification generates an orange check that indicates a potential overflow. The verification does not take into account the saturation function of lines 37 to 43. In addition, the trace-back functionality of Polyspace Code Prover does not identify the reason for the orange check.

To justify overflows from operators that are legitimate, on the **Configuration Parameters > Code Generation > Comments** pane:

- Under **Overall control**, select the **Include comments** check box.
- Under **Auto generate comments**, select the **Operator annotations** check box.

The code generator annotates generated code with comments for Polyspace. For example:

```
32 /* Sum: '<Root>/Sum' incorporates:
33   *  Inport: '<Root>/In1'
34   *  Inport: '<Root>/In2'
35   */
36  qY_0 = sat_add_U.In1 +/*MW:OvOk*/ sat_add_U.In2;
```

When you run a verification using Polyspace Code Prover, the Polyspace software uses the annotations to justify the operator-related orange checks and assigns the `Not a defect` classification to the checks.

Enhance Readability of Code for Flow Charts

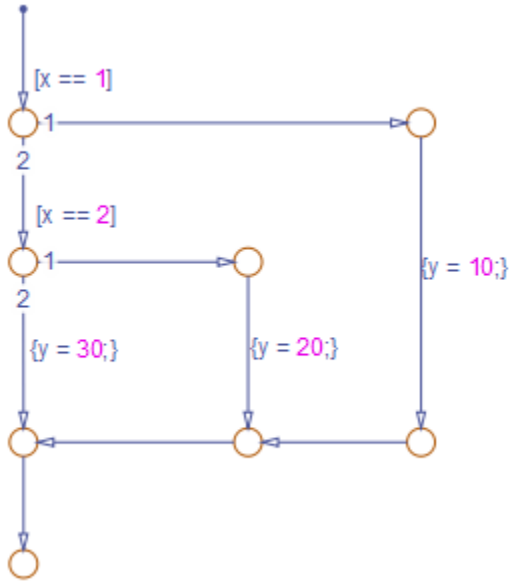
In this section...

Appearance of Generated Code for Flow Charts

If you have an Embedded Coder license and you generate code for models that include Stateflow objects, the code from a flow chart resembles the samples that follow.

The following characteristics apply:

- By default, the generated code uses `if-elseif-else` statements to represent `switch` patterns. To convert the code to use `switch-case` statements, see “Convert If-Elseif-Else Code to Switch-Case Statements” on page 50-115.
- By default, variables that appear in the flow chart do not retain their names in the generated code. Modified identifiers make sure that no naming conflicts occur.
- Traceability comments for the transitions appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Trace Stateflow Elements in Generated Code” on page 75-13.

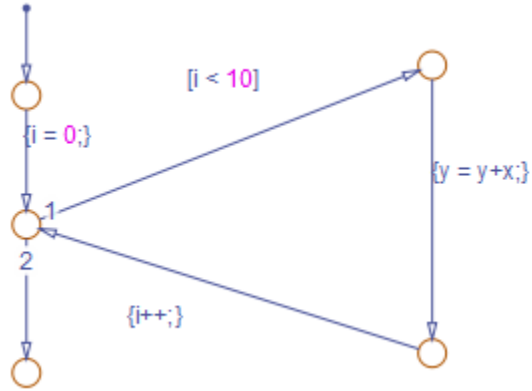


```
if (modelname_U.In1 == 1.0) {
  /* Transition: '<S1>:11' */
  /* Transition: '<S1>:12' */
  modelname_Y.Out1 = 10.0;

  /* Transition: '<S1>:15' */
  /* Transition: '<S1>:16' */
} else {
  /* Transition: '<S1>:10' */
  if (modelname_U.In1 == 2.0) {
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    modelname_Y.Out1 = 20.0;

    /* Transition: '<S1>:16' */
  } else {
    /* Transition: '<S1>:17' */
    modelname_Y.Out1 = 30.0;
  }
}
```

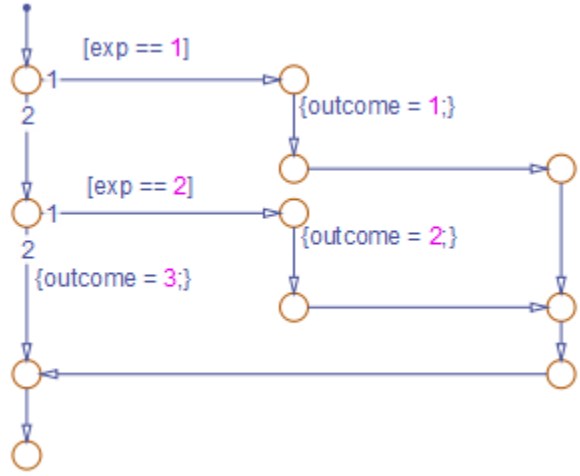
Sample Code for a Decision Logic Pattern



```
for (sf_i = 0; sf_i < 10; sf_i++) {
  /* Transition: '<S1>:40' */
  /* Transition: '<S1>:41' */
  modelname_B.y = modelname_B.y +
    modelname_U.In1;

  /* Transition: '<S1>:39' */
}
```

Sample Code for an Iterative Loop Pattern



```
if (modelname_U.In1 == 1.0) {
  /* Transition: '<S1>:149' */
  /* Transition: '<S1>:150' */
  modelname_Y.Out1 = 1.0;

  /* Transition: '<S1>:151' */
  /* Transition: '<S1>:152' */
  /* Transition: '<S1>:158' */
  /* Transition: '<S1>:159' */
} else {
  /* Transition: '<S1>:156' */
  if (modelname_U.In1 == 2.0) {
    /* Transition: '<S1>:153' */
    /* Transition: '<S1>:154' */
    modelname_Y.Out1 = 2.0;

    /* Transition: '<S1>:155' */
    /* Transition: '<S1>:158' */
    /* Transition: '<S1>:159' */
  } else {
    /* Transition: '<S1>:161' */
    modelname_Y.Out1 = 3.0;
  }
}
```

Sample Code for a Switch Pattern

Convert If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` code to `switch-case` statements. This conversion can enhance readability of the code. For example, when a flow chart contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the flow chart from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your flow chart follows the rules for conversion.	"Verify the Contents of the Flow Chart" on page 50-120
2	Enable the conversion.	"Enable the Conversion" on page 50-120
3	Generate code for your model.	"Generate Code for Your Model" on page 50-121
4	Troubleshoot the generated code. • If you see `switch-case` statements for your flow chart, you can stop. • If you see `if-elseif-else` statements for your flow chart, update the chart and repeat the previous step.	"Troubleshoot the Generated Code" on page 50-121

Rules of Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
Flow chart	Must have two or more *unique* conditions, in addition to a default. For more information, see "How the Conversion Handles Duplicate Conditions" on page 50-117.
Each condition	Must test equality only.
	Must use the same variable or expression for the LHS. **Note** You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression.
	Cannot be a constant.
	Must have an integer or enumerated data type.

Construct	Rules to Follow
	Cannot have any side effects on simulation. For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant or a parameter.
	Must have an integer or enumerated data type.

How the Conversion Handles Duplicate Conditions

If a flow chart has duplicate conditions, the conversion preserves only the first condition. The code discards the other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. If not, the conversion does not occur and the code contains all duplicate conditions.

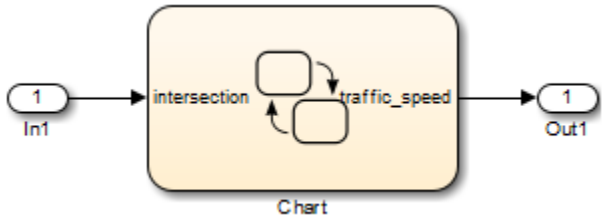
Example of Generated Code	Code After Conversion

`if (x == 1) {`
`  block1`
`} else if (x == 2) {`
`  block2`
`} else if (x == 1) {  // duplicate`
`  block3`
`} else if (x == 3) {`
`  block4`
`} else if (x == 1) {  // duplicate`
`  block5`
`} else {`
`  block6`
`}`
	`switch (x) {`
	`  case 1:`
	`  block1; break;`
	`  case 2:`
	`  block2; break;`
	`  case 3:`
	`  block4; break;`
	`  default:`
	`  block6; break;`
	`}`

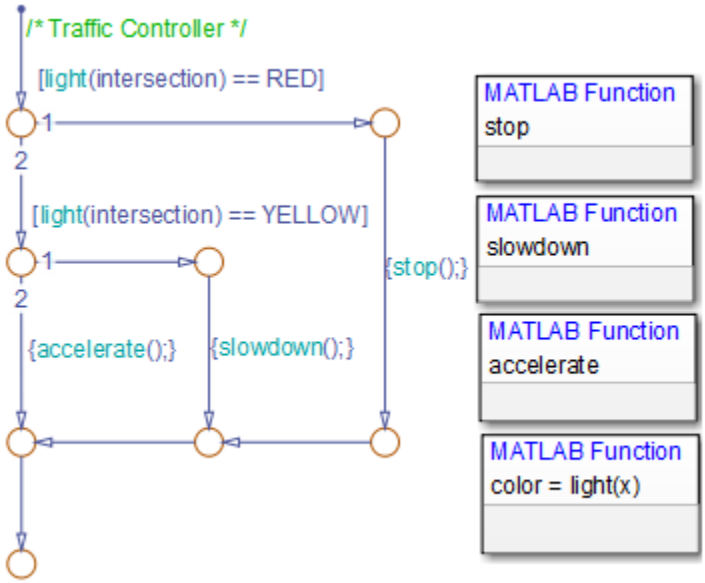
`if (x == 1) {`
`  block1`
`} else if (x == 1) {  // duplicate`
`  block2`
`} else {`
`  block3`
`}`
	No change, because only one unique condition exists

Example of Converting Code to Switch-Case Statements

Suppose that you have the following model with a single chart.



The chart contains a flow chart and four MATLAB functions:



The MATLAB functions in the chart contain the code in the following table. In each case, the **Function Inline Option** is `Auto`. For more information about function inlining, see “Specify Graphical Function Properties” (Stateflow).

MATLAB Function	Code

`stop`	`function stop`
	`%#codegen`
	`coder.extrinsic('disp');`
	`disp('Not moving.')`
	
	`traffic_speed = 0;`

`slowdown`	`function slowdown`
	`%#codegen`
	`coder.extrinsic('disp')`
	`disp('Slowing down.')`
	
	`traffic_speed = 1;`

`accelerate`	`function accelerate`
	`%#codegen`
	`coder.extrinsic('disp');`
	`disp('Moving along.')`
	
	`traffic_speed = 2;`

`light`	`function color = light(x)`
	`%#codegen`
	`if (x < 20)`
	`    color = TrafficLights.GREEN;`
	`elseif (x >= 20 && x < 25)`
	`    color = TrafficLights.YELLOW;`
	`else`
	`    color = TrafficLights.RED;`
	`end`

The output `color` of the function `light` uses the enumerated type `TrafficLights`. The enumerated type definition in `TrafficLights.m` is:

```
classdef TrafficLights < Simulink.IntEnumType
  enumeration
    RED(0)
    YELLOW(5)
    GREEN(10)
  end
end
```

For more information, see “Define Enumerated Data Types” (Stateflow).

Verify the Contents of the Flow Chart

Check that the flow chart in your chart follows the rules in “Rules of Conversion” on page 50-116.

Construct	How the Construct Follows the Rules
Flow chart	Two unique conditions exist, in addition to the default: • `[light(intersection) == RED]` • `[light(intersection) == YELLOW]`
Each condition	Each condition: • Tests equality • Uses the same function call `light(intersection)` for the LHS
Each LHS	Each LHS: • Contains a single expression • Is the output of a function call and therefore not a constant • Is of enumerated type `TrafficLights`, which you define in `TrafficLights.m` on the MATLAB path (see “Define Enumerated Data Types” (Stateflow)) • Uses a function call that does not have side effects
Each RHS	Each RHS: • Is an enumerated value and therefore a constant • Is of enumerated type `TrafficLights`

Enable the Conversion

1. Open the Model Configuration Parameters dialog box.
2. In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

   This step specifies an ERT-based target for your model.
3. In the **Code Generation** > **Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

Tip This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- Flow charts in all charts of a model
- MATLAB functions in all charts of a model
- All MATLAB Function blocks in that model

Generate Code for Your Model

In the model, select **Code > C/C++ Code > Build Model** to generate source code from the model.

Troubleshoot the Generated Code

The generated code for the flow chart appears something like this:

```
if (sf_color == RED) {
  /* Transition: '<S1>:11' */
  /* Transition: '<S1>:12' */
  /* MATLAB Function 'stop': '<S1>:23' */
  /* '<S1>:23:6' */
  rtb_traffic_speed = 0;

  /* Transition: '<S1>:15' */
  /* Transition: '<S1>:16' */
} else {
  /* Transition: '<S1>:10' */
  /* MATLAB Function 'light': '<S1>:19' */
  if (ifelse_using_enums_U.In1 < 20.0) {
    /* '<S1>:19:3' */
    /* '<S1>:19:4' */
    sf_color = GREEN;
  } else if ((ifelse_using_enums_U.In1 >= 20.0) &&
             (ifelse_using_enums_U.In1 < 25.0)) {
    /* '<S1>:19:5' */
    /* '<S1>:19:6' */
    sf_color = YELLOW;
  } else {
    /* '<S1>:19:8' */
    sf_color = RED;
  }

  if (sf_color == YELLOW) {
```

```
    /* Transition: '<S1>:13' */
    /* Transition: '<S1>:14' */
    /* MATLAB Function 'slowdown': '<S1>:24' */
    /* '<S1>:24:6' */
    rtb_traffic_speed = 1;

    /* Transition: '<S1>:16' */
  } else {
    /* Transition: '<S1>:17' */
    /* MATLAB Function 'accelerate': '<S1>:25' */
    /* '<S1>:25:6' */
    rtb_traffic_speed = 2;
  }
}
```

Because the MATLAB function `light` appears inlined, inequality comparisons appear in these lines of code:

```
if (ifelse_using_enums_U.In1 < 20.0) {
....
} else if ((ifelse_using_enums_U.In1 >= 20.0) &&
             (ifelse_using_enums_U.In1 < 25.0)) {
....
```

Because inequalities appear in the body of the `if-elseif-else` code for the flow chart, the conversion to `switch-case` statements does not occur. To prevent this behavior, do one of the following:

- Specify that the function `light` does not appear inlined. See “Change the Inlining Property for the Function” on page 50-122.
- Modify the flow chart. See “Modify the Flow Chart to Ensure Switch-Case Statements” on page 50-124.

Change the Inlining Property for the Function

If you do not want to modify your flow chart, change the inlining property for the function `light`:

1. Right-click the function box for `light` and select **Properties**.

   The properties dialog box appears.
2. For **Function Inline Option**, select `Function`.

3 Click **OK** to close the dialog box.

Note You do not have to change the inlining property for the other three MATLAB functions in the chart. Because the flow chart does not call those functions during evaluation of conditions, the inlining property for those functions can remain `Auto`.

When you regenerate code for your model, the code for the flow chart now appears something like this:

```
switch (ifelse_using_enums_light(ifelse_using_enums_U.In1)) {
 case RED:
  /* Transition: '<S1>:11' */
  /* Transition: '<S1>:12' */
  /* MATLAB Function 'stop': '<S1>:23' */
  /* '<S1>:23:6' */
  ifelse_using_enums_Y.Out1 = 0.0;

  /* Transition: '<S1>:15' */
  /* Transition: '<S1>:16' */
  break;

 case YELLOW:
  /* Transition: '<S1>:10' */
  /* Transition: '<S1>:13' */
  /* Transition: '<S1>:14' */
  /* MATLAB Function 'slowdown': '<S1>:24' */
  /* '<S1>:24:6' */
  ifelse_using_enums_Y.Out1 = 1.0;

  /* Transition: '<S1>:16' */
  break;

 default:
  /* Transition: '<S1>:17' */
  /* MATLAB Function 'accelerate': '<S1>:25' */
  /* '<S1>:25:6' */
  ifelse_using_enums_Y.Out1 = 2.0;
  break;
}
```

Because the MATLAB function `light` no longer appears inlined, the conversion to `switch-case` statements occurs. The `switch-case` statements provide the following benefits to enhance readability:

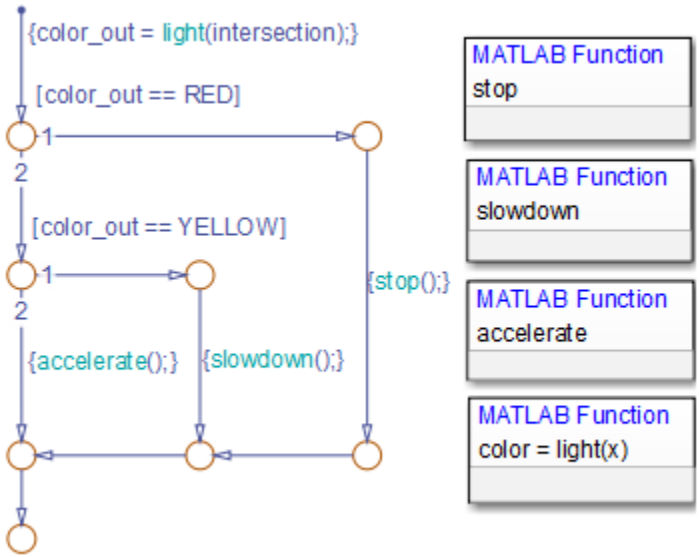
- The code reduces the use of parentheses and braces.
- The LHS expression `ifelse_using_enums_light(ifelse_using_enums_U.In1)` appears only once, minimizing repetition in the code.

Modify the Flow Chart to Ensure Switch-Case Statements

If you do not want to change the inlining property for the function `light`, modify your flow chart:

1. Add chart local data `color_out` with the enumerated type `TrafficLights`.
2. Replace each instance of `light(intersection)` with `color_out`.
3. Add the action `{color_out = light(intersection)}` to the default transition of the flow chart.

The chart should now look something like this:



When you regenerate code for your model, the code for the flow chart uses `switch-case` statements.

Enhance Code Readability for MATLAB Function Blocks

In this section...

Requirements for Using Readability Optimizations

To use readability optimizations in your code, you must have an Embedded Coder license. These optimizations appear only in code that you generate for an embedded real-time (`ert`) target.

Note These optimizations do not apply to MATLAB files that you call from the MATLAB Function block.

For more information, see “Configure a System Target File” on page 44-2.

Converting If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` decision logic to `switch-case` statements. This conversion can enhance readability of the code.

For example, when a MATLAB Function block contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the MATLAB Function block from `if-elseif-else` to `switch-case` statements.

Step	Task	Reference
1	Verify that your block follows the rules for conversion.	"Verifying the Contents of the Block" on page 50-130
2	Enable the conversion.	"Enabling the Conversion" on page 50-131
3	Generate code for your model.	"Generating Code for Your Model" on page 50-132

Rules for Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

Construct	Rules to Follow
MATLAB Function block	Must have two or more *unique* conditions, in addition to a default. For more information, see "How the Conversion Handles Duplicate Conditions" on page 50-128.
Each condition	Must test equality only.
	Must use the same variable or expression for the LHS. **Note** You can reverse the LHS and RHS.
Each LHS	Must be a single variable or expression, not a compound statement.
	Cannot be a constant.
	Must have an integer or enumerated data type.
	Must not have side effects on simulation. For example, the LHS can read from but not write to global variables.
Each RHS	Must be a constant.
	Must have an integer or enumerated data type.

How the Conversion Handles Duplicate Conditions

If a MATLAB Function block has duplicate conditions, the conversion preserves only the first condition. The generated code discards other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. Otherwise, a conversion does not occur and the generated code contains instances of duplicate conditions.

The following examples show how the conversion handles duplicate conditions.

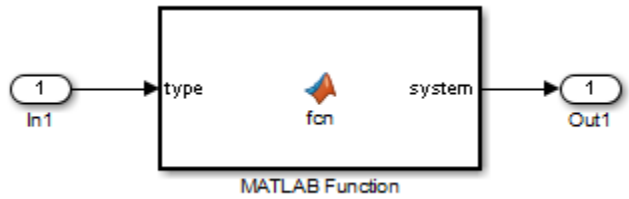
Example of Generated Code	Code After Conversion

`if (x == 1) {`
`  block1`
`} else if (x == 2) {`
`  block2`
`} else if (x == 1) {  // duplicate`
`  block3`
`} else if (x == 3) {`
`  block4`
`} else if (x == 1) {  // duplicate`
`  block5`
`} else {`
`  block6`
`}`
	`switch (x) {`
	`  case 1:`
	`  block1; break;`
	`  case 2:`
	`  block2; break;`
	`  case 3:`
	`  block4; break;`
	`  default:`
	`  block6; break;`
	`}`

`if (x == 1) {`
`  block1`
`} else if (x == 1) {  // duplicate`
`  block2`
`} else {`
`  block3`
`}`
	Does not change, because only one unique condition exists

Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements

Suppose that you have the following model with a MATLAB Function block. Assume that the output data type is `double` and the input data type is `Controller`, an enumerated type that you define.



The block contains the following code:

```
function system = fcn(type)
%#codegen

if (type == Controller.P)
    system = 0;
elseif (type == Controller.I)
    system = 1;
elseif (type == Controller.PD)
    system = 2;
elseif (type == Controller.PI)
    system = 3;
elseif (type == Controller.PID)
    system = 4;
else
    system = 10;
end
```

The enumerated type definition in `Controller.m` is:

```
classdef Controller < Simulink.IntEnumType
  enumeration
    P(0)
    I(1)
    PD(2)
    PI(3)
    PID(4)
    UNKNOWN(10)
  end
end
```

If you generate code for an embedded real-time target using default settings, you see something like this:

```
if (if_to_switch_eml_blocks_U.In1 == P) {
  /* '<S1>:1:4' */
  /* '<S1>:1:5' */
  if_to_switch_eml_blocks_Y.Out1 = 0.0;
} else if (if_to_switch_eml_blocks_U.In1 == I) {
  /* '<S1>:1:6' */
  /* '<S1>:1:7' */
  if_to_switch_eml_blocks_Y.Out1 = 1.0;
} else if (if_to_switch_eml_blocks_U.In1 == PD) {
  /* '<S1>:1:8' */
  /* '<S1>:1:9' */
  if_to_switch_eml_blocks_Y.Out1 = 2.0;
} else if (if_to_switch_eml_blocks_U.In1 == PI) {
  /* '<S1>:1:10' */
  /* '<S1>:1:11' */
  if_to_switch_eml_blocks_Y.Out1 = 3.0;
} else if (if_to_switch_eml_blocks_U.In1 == PID) {
  /* '<S1>:1:12' */
  /* '<S1>:1:13' */
  if_to_switch_eml_blocks_Y.Out1 = 4.0;
} else {
  /* '<S1>:1:15' */
  if_to_switch_eml_blocks_Y.Out1 = 10.0;
}
```

The LHS variable `if_to_switch_eml_blocks_U.In1` appears multiple times in the generated code.

Note By default, variables that appear in the block do not retain their names in the generated code. Modified identifiers prevent naming conflicts.

Traceability comments appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Use Traceability in MATLAB Function Blocks” on page 75-42.

Verifying the Contents of the Block

Check that the block follows the rules in “Rules for Conversion” on page 50-127.

Construct	How the Construct Follows the Rules
MATLAB Function block	Five unique conditions exist, in addition to the default: • `(type == Controller.P)` • `(type == Controller.I)` • `(type == Controller.PD)` • `(type == Controller.PI)` • `(type == Controller.PID)`
Each condition	Each condition: • Tests equality • Uses the same input for the LHS
Each LHS	Each LHS: • Contains a single variable • Is the input to the block and therefore not a constant • Is of enumerated type `Controller`, which you define in `Controller.m` on the MATLAB path • Does not impact simulation
Each RHS	Each RHS: • Is an enumerated value and therefore a constant • Is of enumerated type `Controller`

Enabling the Conversion

1. Open the Configuration Parameters dialog box.
2. In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

   This step specifies an embedded real-time target for your model.
3. In the **Code Generation** > **Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

   Tip This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- MATLAB Function blocks in a model
- MATLAB functions in Stateflow charts of that model
- Flow charts in Stateflow charts of that model

For more information, see “Enhance Readability of Code for Flow Charts” on page 50-112.

Generating Code for Your Model

In the model window, press **Ctrl+B**.

The code for the MATLAB Function block uses `switch-case` statements instead of `if-elseif-else` code:

```
switch (if_to_switch_eml_blocks_U.In1) {
 case P:
  /* '<S1>:1:4' */
  /* '<S1>:1:5' */
  if_to_switch_eml_blocks_Y.Out1 = 0.0;
  break;

 case I:
  /* '<S1>:1:6' */
  /* '<S1>:1:7' */
  if_to_switch_eml_blocks_Y.Out1 = 1.0;
  break;

 case PD:
  /* '<S1>:1:8' */
  /* '<S1>:1:9' */
  if_to_switch_eml_blocks_Y.Out1 = 2.0;
  break;

 case PI:
  /* '<S1>:1:10' */
  /* '<S1>:1:11' */
  if_to_switch_eml_blocks_Y.Out1 = 3.0;
  break;

 case PID:
  /* '<S1>:1:12' */
  /* '<S1>:1:13' */
  if_to_switch_eml_blocks_Y.Out1 = 4.0;
```

```
  break;

 default:
  /* '<S1>:1:15' */
  if_to_switch_eml_blocks_Y.Out1 = 10.0;
  break;
}
```

The `switch-case` statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS variable `if_to_switch_eml_blocks_U.In1` appears only once, minimizing repetition in the code.

Generate Inlined Subsystem Code

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, the **Function packaging** parameter specifies the format of the subsystem's generated code. This parameter has four settings: `Auto`, `Inline`, `Nonreusable function`, and `Reusable function`. The code generator can generate inlined code for the `Auto` or `Inline` settings.

The `Inline` setting explicitly directs the code generator to inline the subsystem code unconditionally.

The default `Auto` setting directs the code generator to generate the most efficient code for the subsystem based on the type and number of instances of the subsystem that exist in the model. When there is only one instance of a subsystem, the `Auto` setting inlines the subsystem code. When there are multiple instances of a subsystem, that is not too complex, the `Auto` setting inlines the code for each subsystem. Otherwise, the `Auto` setting generates a single copy of the function (as a reusable function). For a function-call subsystem with multiple callers, the `Auto` setting generates subsystem code that is consistent with the `Nonreusable function` setting.

Configure Subsystem to Inline Code

To configure your subsystem for inlining:

1. Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.
3. Click the **Code Generation** tab and select `Auto` or `Inline` from the **Function packaging** parameter.
4. Click **Apply** and close the dialog box.

   The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within *`model`*`.c` or *`model`*`.cpp` (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though you select the `Inline` setting.

- If a noninlined S-function calls a function-call subsystem, the code generator ignores the `Inline` setting. Because noninlined S-functions use function pointers to make function calls, the code generator must generate a function with all arguments present.
- In a feedback loop involving function-call subsystems, the code generator generates a function instead of inlined code for one of the subsystems. Based on the internal, sorted order of the subsystems, the code generator selects which subsystem to generate a function.
- If an S-function, an Async Interrupt, or a Task Sync block with the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` set to `TRUE` calls a subsystem, the code generator generates a function instead of inlined code for the subsystem. The VxWorks block library (`vxlib1`), contains the user-defined Async Interrupt and Task Sync blocks.[7]

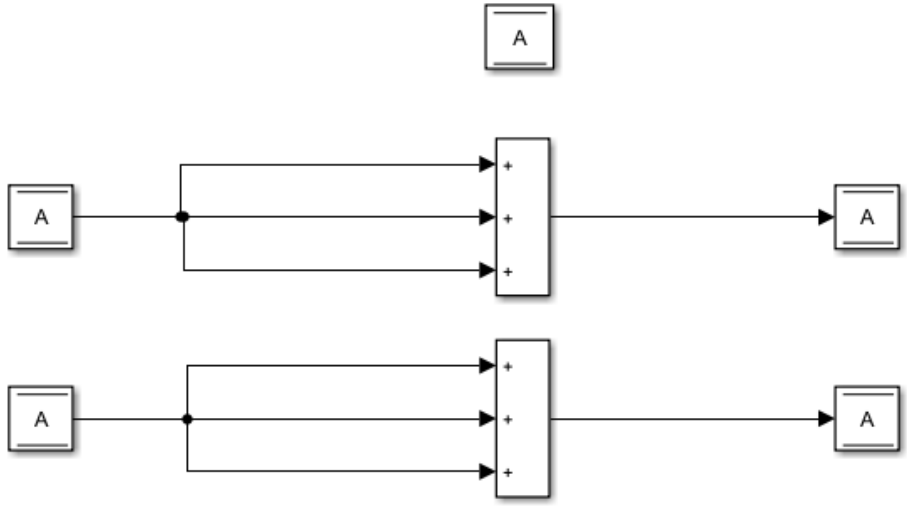
Improve Data Coherency in Generated Code

For models containing read and write operations for Data Store Memory blocks, you can generate code that contains a single variable to hold the value for each Data Store Read and Write operation. Generating one variable for each operation improves data access coherency.

Example Model

The `data_store_latching` model contains a single Data Store Memory block that is accessed by two different Data Store Memory Read and two Data Store Memory Write blocks. Two Sum blocks perform addition on the input generated by the Data Store Read blocks and output the data to the Data Store Write blocks .



Generate Code Without Parameter Enabled

Building the model with the **Implement each data store block as a unique access point** parameter turned off by default, generates this code:

```
void data_store_latching_step(void)
    {
      /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
       *  DataStoreRead: '<Root>/Data Store Read'
       *  Sum: '<Root>/Add'
       */
      data_store_latching_DW.A += data_store_latching_DW.A +
        data_store_latching_DW.A;

      /* DataStoreWrite: '<Root>/Data Store Write1' incorporates:
       *  DataStoreRead: '<Root>/Data Store Read1'
       *  Sum: '<Root>/Add1'
       */
      data_store_latching_DW.A += data_store_latching_DW.A +
        data_store_latching_DW.A;
    }
```

For both data read and write operations, the code contains the global variable `data_store_latching_DW.A`.

Generate Code With Parameter Enabled

In the Configuration Parameters dialog box, on the **Interface** pane, select the **Implement each data store block as a unique access point** parameter. Click **Apply**.

The generated code is now:

```
void data_store_latching_step(void)
    {
      real_T rtb_DataStoreRead;
      real_T rtb_DataStoreRead1;

      /* DataStoreRead: '<Root>/Data Store Read' */
      rtb_DataStoreRead = data_store_latching_DW.A;

      /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
       *  Sum: '<Root>/Add'
       */
      data_store_latching_DW.A = (rtb_DataStoreRead + rtb_DataStoreRead) +
        rtb_DataStoreRead;

      /* DataStoreRead: '<Root>/Data Store Read1' */
      rtb_DataStoreRead1 = data_store_latching_DW.A;

      /* DataStoreWrite: '<Root>/Data Store Write1' incorporates:
       *  Sum: '<Root>/Add1'
       */
      data_store_latching_DW.A = (rtb_DataStoreRead1 + rtb_DataStoreRead1) +
```

```
        rtb_DataStoreRead1;
    }
```

For each data store read operation, the code contains a variable. The variables are `rtb_DataStoreRead` and `rtb_DataStoreRead1`. These separate variables improve data access coherency.

Code Replacement in Simulink Coder

What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for

a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

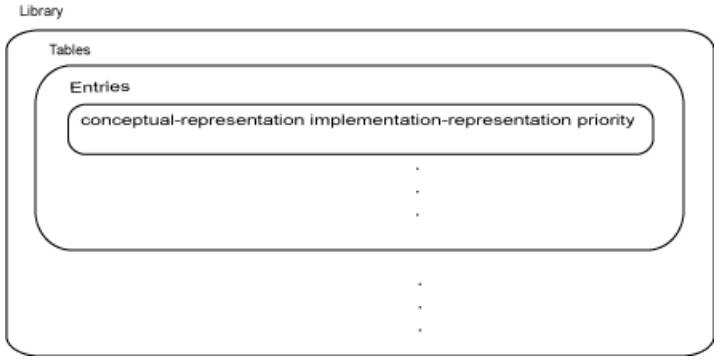

Table Entry Component	Description
Conceptual representation	Identifies the table entry and contains match criteria for the code generator. Consists of: • Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name `'cos'` and operator key `'RTW_OP_ADD'`. • Conceptual arguments that observe code generator naming (`'y1'`, `'u1'`, `'u2'`, ...), with corresponding I/O types (output or input) and data types. • Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.

Table Entry Component	Description
Implementation representation	Specifies replacement code. Consists of: • Function name. For example, `'cos_dbl'` or `'u8_add_u8_u8'`. • Implementation arguments, with corresponding I/O types (output or input) and data types. • Parameters that provide additional implementation details, such as header and source file names and paths of build resources.
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.

Term	Definition
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.

Term	Definition
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: • Function or operator name or key • Conceptual arguments with type, dimension, and complexity specification for inputs and output • Attributes, such as an algorithm and fixed-point saturation and rounding modes
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.
Implementation representation	Specifies C or C++ replacement function prototype. Consists of: • Function name (for example, `'cos_dbl'` or `'u8_add_u8_u8'`) • Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output • Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags
Key	Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key `RTW_OP_ADD` identifies the addition operator.

Term	Definition
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

Choose a Code Replacement Library

In this section...

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 52-2.
   - See “Explore Available Code Replacement Libraries” on page 51-8.
2. Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 51-8.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

Select the “Code replacement library” (Simulink Coder) to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane (Simulink Coder). To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

Explore Code Replacement Library Contents

Use the **Code Replacement Viewer** to explore the content of a code replacement library.

1. At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

2. In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
3. In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
4. In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

   If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as elimination of `math.h`, system header files, or calls to `memcpy` or `memset`, or use of BLAS.

Prepare for Code Replacement

1. Make sure that MATLAB®, Simulink®, Simulink Coder™, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can require Embedded Coder®.

To install MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

2. Identify an existing Simulink model or create a model for which you want the code generator to replace code.

Choose a Code Replacement Library

By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks® provides and that you create and register by using the Embedded Coder® product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder® product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

Configure Code Generator to Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation > Interface** pane, select a library for the “Code replacement library” (Simulink Coder) parameter.
- Set the `CodeReplacementLibrary` parameter at the command line or programmatically.

2. Configure the code generator to produce code only (not build an executable program) so you can verify your code replacements before building an executable program. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only” (Simulink Coder).
- Set the `GenCodeOnly` parameter at the command line or programmatically.

Include Code Replacement Information in Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report” (Simulink Coder). Consider having the report open automatically. Select Open report automatically.

2. Include the code replacement section in the report. Select “Summarize which blocks triggered code replacements” (Simulink Coder).

Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Code Replacement for Simulink Models in Embedded Coder

What Is Code Replacement?

Code replacement is a technique to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as:
  - Elimination of `math.h`.
  - Elimination of system header files.
  - Elimination of calls to `memcpy` or `memset`.
  - Use of BLAS.
  - Use of a specific BLAS.

To apply this technique, configure the code generator to apply a code replacement library (CRL) during code generation. By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks provides and that you create and register by using the Embedded Coder product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Code Replacement Libraries

A code replacement library consists of one or more code replacement tables that specify application-specific implementations of functions and operators. For example, a library for

a specific embedded processor specifies function and operator replacements that optimize generated code for that processor.

A code replacement table contains one or more code replacement entries, with each entry representing a potential replacement for a function or operator. Each entry maps a conceptual representation of a function or operator to an implementation representation and priority.

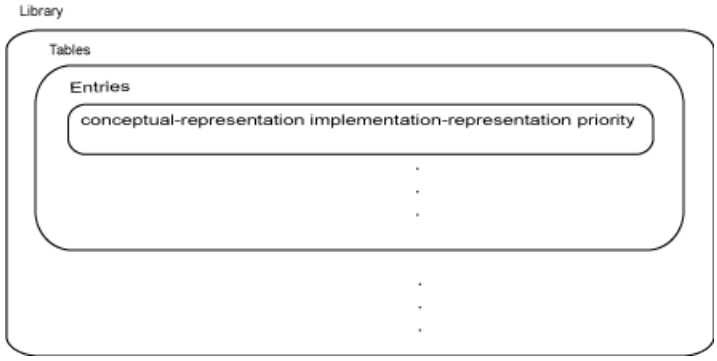

Table Entry Component	Description
Conceptual representation	Identifies the table entry and contains match criteria for the code generator. Consists of: • Function name or a key. The function name identifies most functions. For operators and some functions, a series of characters, called a key identifies a function or operator. For example, function name `'cos'` and operator key `'RTW_OP_ADD'`. • Conceptual arguments that observe code generator naming (`'y1'`, `'u1'`, `'u2'`, ...), with corresponding I/O types (output or input) and data types. • Other attributes, such as an algorithm, fixed-point saturation, and rounding modes, which identify matching criteria for the function or operator.

Table Entry Component	Description
Implementation representation	Specifies replacement code. Consists of: • Function name. For example, `'cos_dbl'` or `'u8_add_u8_u8'`. • Implementation arguments, with corresponding I/O types (output or input) and data types. • Parameters that provide additional implementation details, such as header and source file names and paths of build resources.
Priority	Defines the entry priority relative to other entries in the table. The value can range from 0 to 100, with 0 being the highest priority. If multiple entries have the same priority, the code generator uses the first match with that priority.

When the code generator looks for a match in a code replacement library, it creates and populates a call site object with the function or operator conceptual representation. If a match exists, the code generator uses the matched code replacement entry populated with the implementation representation and uses it to generate code.

The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. If the code generator finds multiple matches within a table, the priority determines the match. The code generator uses a higher-priority entry over a similar entry with a lower priority.

Code Replacement Terminology

Term	Definition
Cache hit	A code replacement entry for a function or operator, defined in the specified code replacement library, for which the code generator finds a match.
Cache miss	A conceptual representation of a function or operator for which the code generator does not find a match.

Term	Definition
Call site object	Conceptual representation of a function or operator that the code generator uses when it encounters a call site for a function or operator. The code generator uses the object to query the code replacement library for a conceptual representation match. If a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority, and uses that object to generate replacement code.
Code replacement library	One or more code replacement tables that specify application-specific implementations of functions and operators. When configured to use a code replacement library, the code generator uses criteria defined in the library to search for matches. If a match is found, the code generator replaces code that it generates by default with application-specific code defined in the library.
Code replacement table	One or more code replacement table entries. Provides a way to group related or shared entries for use in different libraries.
Code replacement entry	Represents a potential replacement for a function or operator. Maps a conceptual representation of a function or operator to an implementation representation and priority.
Conceptual argument	Represents an input or output argument for a function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.

Term	Definition
Conceptual representation	Represents match criteria that the code generator uses to qualify functions and operators for replacement. Consists of: • Function or operator name or key • Conceptual arguments with type, dimension, and complexity specification for inputs and output • Attributes, such as an algorithm and fixed-point saturation and rounding modes
Implementation argument	Represents an input or output argument for a C or C++ replacement function. Implementation arguments observe C/C++ name and data type specifications.
Implementation representation	Specifies C or C++ replacement function prototype. Consists of: • Function name (for example, `'cos_dbl'` or `'u8_add_u8_u8'`) • Implementation arguments specifying type, type qualifiers, and complexity for the function inputs and output • Parameters that provide build information, such as header and source file names and paths of build resources and compile and link flags
Key	Identifies a function or operator that is being replaced. A function name or key appears in the conceptual representation of a code replacement entry. The key `RTW_OP_ADD` identifies the addition operator.

Term	Definition
Priority	Defines the match priority for a code replacement entry relative to other entries, which have the same name and conceptual argument list, within a code replacement library. The priority can range from 0 to 100, with 0 being the highest priority. The default is 100. If a library provides two implementations for a function or operator, the implementation with the higher priority shadows the one with the lower priority.

Code Replacement Limitations

Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code.

Code replacement for matrices — Code replacement libraries do not support Dynamic and Symbolic sized matrices.

About Choosing a Code Replacement Library

By default, the code generator does not use a code replacement library.

If you are considering using a code replacement library:

1. Explore available libraries. Identify one that best meets your application needs.
   - Consider the lists of application code replacement requirements and libraries that MathWorks provides in “What Is Code Replacement?” on page 52-2.
   - See “Explore Available Code Replacement Libraries” on page 52-8.
2. Explore the contents of the library. See “Explore Code Replacement Library Contents” on page 52-8.

If you do not find a suitable library and you have an Embedded Coder license, you can create a custom code replacement library.

Explore Available Code Replacement Libraries

Select the “Code replacement library” (Simulink Coder) to use for code generation from the **Configuration Parameters > Code Generation > Interface** pane (Simulink Coder). To view a description of a library, select and hover your cursor over the library name. A tooltip describes the library and lists the tables that it contains. The tooltip lists the tables in the order that the code generator searches for a function or operator match.

Explore Code Replacement Library Contents

Use the **Code Replacement Viewer** to explore the content of a code replacement library.

1. At the command prompt, type `crviewer`.

```
>> crviewer
```

The viewer opens. To view the content of a specific library, specify the name of the library as an argument in single quotes. For example:

```
>> crviewer('GNU C99 extensions')
```

2. In the left pane, select the name of a library. The viewer displays information about the library in the right pane.
3. In the left pane, expand the library, explore the list of tables it contains, and select a table from the list. In the middle pane, the viewer displays the function and operator entries that are in that table, along with abbreviated information for each entry.
4. In the middle pane, select a function or operator. The viewer displays information from the table entry in the right pane.

   If you select an operator entry that specifies net slope fixed-point parameters (instantiated from entry class `RTW.TflCOperationEntryGenerator` or `RTW.TflCOperationEntryGenerator_NetSlope`), the viewer displays an additional tab that shows fixed-point settings.

See **Code Replacement Viewer** for details on what the viewer displays.

Replace Code Generated from Simulink Models

This example shows how to replace generated code, using a code replacement library. Code replacement is a technique you can use to change the code that the code generator produces for functions and operators to meet application code requirements. For example, you can replace generated code to meet requirements such as:

- Optimization for a specific run-time environment, including, but not limited to, specific target hardware.
- Integration with existing application code.
- Compliance with a standard, such as AUTOSAR.
- Modification of code behavior, such as enabling or disabling nonfinite or inline support.
- Application- or project-specific code requirements, such as elimination of `math.h`, system header files, or calls to `memcpy` or `memset`, or use of BLAS.

Prepare for Code Replacement

1. Make sure that MATLAB®, Simulink®, Simulink Coder™, and a C compiler are installed on your system. Some code replacement libraries available in your development environment can require Embedded Coder®.

To install MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see which other MathWorks products are installed, in the Command Window, enter `ver`.

2. Identify an existing Simulink model or create a model for which you want the code generator to replace code.

Choose a Code Replacement Library

By default, the code generator does not apply a code replacement library. You can choose from libraries that MathWorks® provides and that you create and register by using the Embedded Coder® product. The list of available libraries depends on:

- Installed support packages.
- System target file, language, standard math library, and device vendor configuration.
- Whether you have created and registered libraries, using the Embedded Coder® product.

Libraries that include GNU99 extensions are intended for use with the GCC compiler. If you use one of those libraries with another compiler, generated code might not compile.

Depending on the product licenses that you have, other libraries might be available. If you have an Embedded Coder license, you can view and choose from other libraries and you can create custom code replacement libraries.

Configure Code Generator to Use Code Replacement Library

1. Configure the code generator to apply a code replacement library during code generation for the model. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation > Interface** pane, select a library for the “Code replacement library” (Simulink Coder) parameter.
- Set the `CodeReplacementLibrary` parameter at the command line or programmatically.

2. Configure the code generator to produce code only (not build an executable program) so you can verify your code replacements before building an executable program. Do one of the following:

- In the Configuration Parameters dialog box, on the **Code Generation** pane, select “Generate code only” (Simulink Coder).
- Set the `GenCodeOnly` parameter at the command line or programmatically.

Include Code Replacement Information in Code Generation Report

If you have an Embedded Coder license, you can configure the code generator to include a code replacement section in the code generation report. The additional information can help you verify code replacements.

1. Configure the code generator to generate a report. In the Configuration Parameters dialog box, on the **Code Generation > Report** pane, select “Create code generation report” (Simulink Coder). Consider having the report open automatically. Select Open report automatically.

2. Include the code replacement section in the report. Select “Summarize which blocks triggered code replacements” (Simulink Coder).

Generate Replacement Code

Generate C/C++ code from the model and, if you configured the code generator accordingly, a code generation report. For example, in the model window, press **Ctrl+B**.

The code generator produces the code and displays the report.

Verify Code Replacements

Verify code replacements by examining the generated code. It is possible that code replacement behaves differently than you expect. For example, data types that you observe in the code generator input might not match what the code generator uses as intermediate data types during an operation.

Deployment

External Code Integration in Simulink Coder

The code generator includes multiple approaches for integrating legacy or custom code with generated code. Legacy code is existing handwritten code or code for environments that you integrate with code produced by the code generator. Custom code is legacy code or other user-specified lines of code that you include in the code generator build process. Collectively, legacy and custom code are called external code.

You integrate external code by importing existing external code into code produced by the code generator, exporting generated code into an existing external code base, or you can do both. For example, you can import code by calling an external function, by using the Legacy Code Tool, or place external code at specific locations in generated code by including Custom Code blocks in a model. When you import external code, the resulting generated code interfaces with generated scheduling code.

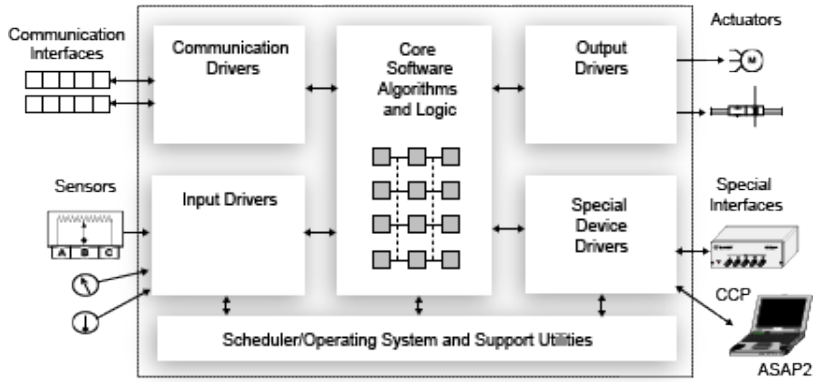
You can export generated code as a plug-in function for use in an external development environment. When you export generated code, you intend to interface that code manually with a scheduling mechanism in your application run-time environment.

For guidance on choosing an approach based on your application, see “Choose an External Code Integration Workflow” (Simulink Coder) .

What Is External Code Integration?

Software projects typically involve combining code from multiple sources. A typical system structure for a code generation application consists of a framework that combines code from multiple sources, including external code and code generated from Simulink models.

This figure shows an application that requires integration of existing driver code for hardware devices. The core software algorithms and logic can be a combination of code modules for external reusable algorithms integrated into the Simulink environment and code generated as part of an overall model design.



Several workflows and tools are available for you to integrate external and generated code. Each workflow identifies tooling for generating code that aligns interfaces, code appearance, and other factors, such as optimization between external and generated code.

Choose an External Code Integration Workflow

In this section...

Completing these tasks helps you choose external code integration workflows and tooling that align with your project.

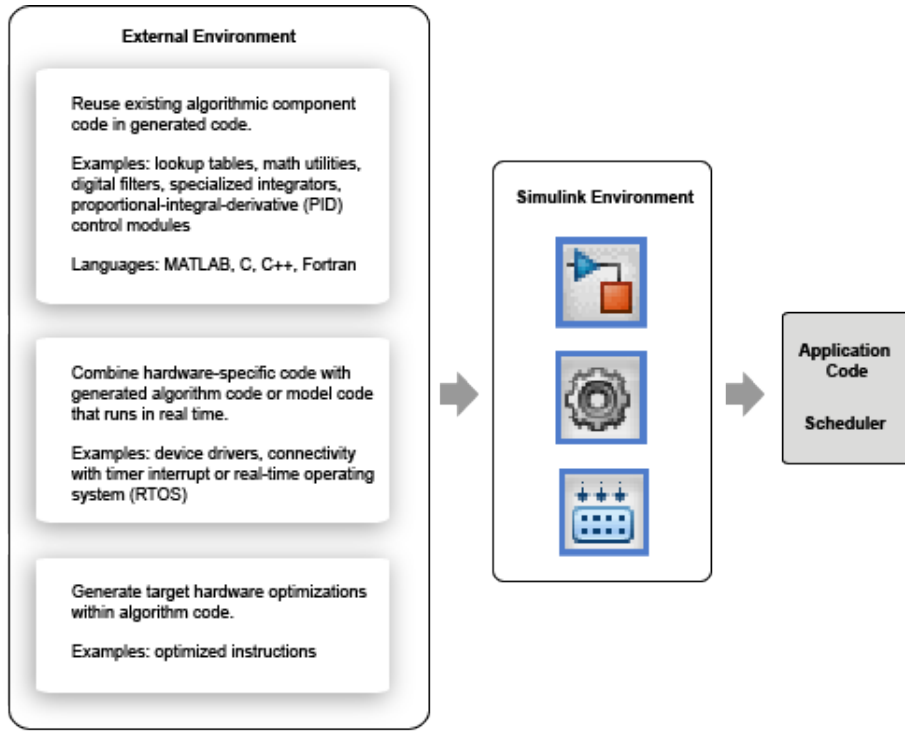
Task	Action	More Information
1	Partition your application, map algorithms to components, and identify integration points.	“Design Models for Generated Embedded Code Deployment” on page 1-2
2	Determine whether you can rely on scheduling code that the code generator produces, or whether you must integrate generated code with scheduling mechanisms that are specific to your run-time environment.	“Choose a Software Execution Framework for Scheduling Code Execution” on page 53-5
3	Evaluate the characteristics of the external code that you are importing or to which you are exporting generated code.	“Evaluate Characteristics of External Code” on page 53-7
4	Identify integration requirements, which assists with choosing optimal tooling for your integration.	“Identify Integration Requirements” on page 53-8
5	Based on the results of tasks 1–4, choose a workflow.	“Choose a Workflow” on page 53-10

Choose a Software Execution Framework for Scheduling Code Execution

The code generator supports two types of software execution frameworks—single top model and multiple top-level, as described in “Design Models for Generated Embedded Code Deployment” on page 1-2. The first question to answer concerns which of the two frameworks meets the scheduling and other needs of your project. For example, you can import external code into a single, rate-based top model. You can export code from a single top model or multiple top-level models for integration with custom (external) scheduling mechanisms.

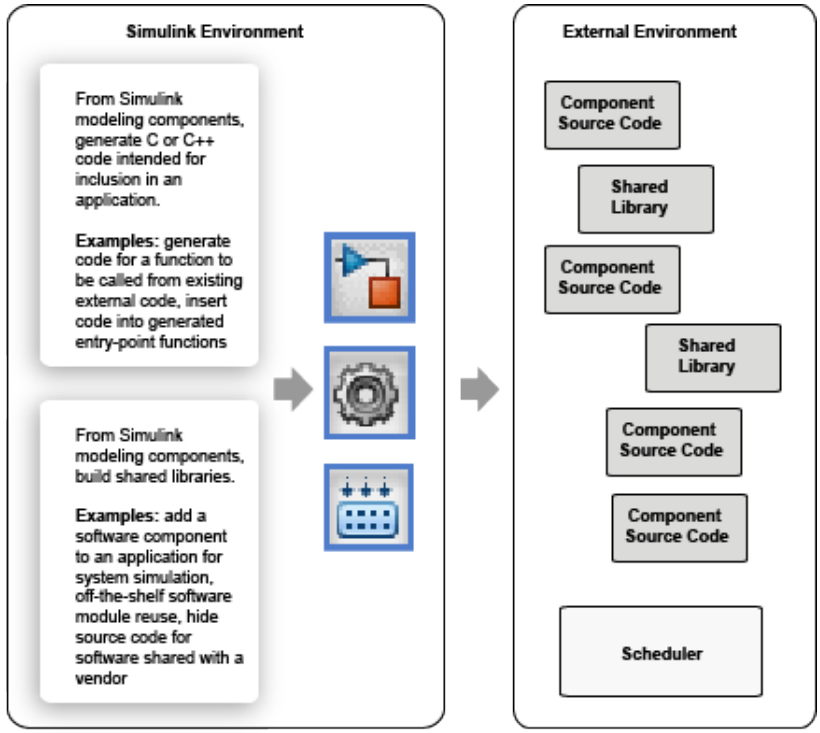
- Single top model

  Generate one set of application code files from external code and code that the Simulink C/C++ code generator produces. The generated code includes a scheduler. In this case, you *import* code into the Simulink code generation environment.



- Single top model or multiple top-level models

  Integrate C or C++ code that the code generator produces from model components with external application code and an external scheduler. You *export* generated code from the Simulink code generation environment.



Importing calls to external device driver code into a model and generating code for that model for export involves importing and exporting code.

Based on goals and requirements, external code integration is characterized in several ways, requiring different workflows and integration tooling:

- Import existing external code into generated code.
  - Call reusable external algorithm code for simulation and code generation.
  - Place external C/C++ code in generated code.

    - Call external device drivers.
    - Apply function and operator code replacements.
    - Interface with external timer interrupt or scheduler.
    - Generate replacement code for specific run-time environment.
- Export generated code for inclusion in external code base.
    - Generate component source code for export.
    - Generate shared library for export.

Next, see “Evaluate Characteristics of External Code” on page 53-7.

Evaluate Characteristics of External Code

Before choosing an external integration workflow, evaluate these characteristics of the external code. To interface with external code, generated C or C++ code handles one or more of the external code characteristics. An understanding of these characteristics and your requirements for modeling, simulation, and code generation helps you choose the optimal workflow for your integration scenario. (See “Identify Integration Requirements” on page 53-8.)

Characteristic	What to Consider
Hardware dependency	Is the external code hardware-dependent? Utility functions, lookup tables, and filters are examples of hardware-independent code. Device drivers interact directly with hardware. They depend on characteristics of the hardware. For example, a device driver for an analog-to-digital converter initializes, reads data from, and writes data to hardware registers. Hardware differences and dependencies concern data type size, endianess, shift operations, compiler directives, and optimized function and operator support. Other code interfaces with device drivers by using an API and data mapped to specific memory addresses. Typically, simulation on a development computer is not possible. Reading from and writing to a register during simulation on a development computer produces unexpected and unwanted results.

Characteristic	What to Consider
Reusable	Is the external code a reusable software module? Examples include utility functions, lookup tables, filters, specialized integrators, and proportional-integral-derivative (PID) control modules.
Dependency on data persistence between function calls	Does the external code require persistent data? For example, a call to a first order filter function uses the output of the previous call to the function to calculate a new output value. You have the option of defining the data as global or using shared memory outside the context of the function.
Data typing and interface	How complex is the data that the external code uses? What does the data interface look like? It consists of arguments, a return value, global variables, and access functions. What data types does the code use? Are the types limited to basic ANSI C integers, floating-point types, arrays of integers or floating-point types, and pointers to these types? Does the interface include structures or pointers to structures?
Fixed-point code	Is the external code designed to run on integer-only processors? If yes, the code exchanges and uses data represented as integers only. Data can be associated with fixed-point scaling or offsets.
External resource dependencies	Does the external code use data, functions, or macros defined outside the scope of the code? For example, the function can use a standard ANSI function, a shared library, or predefined constants. In these cases, you must inform the compiler and linker of the paths and file names of the external resources.
External solver required	Are you using the external function for advanced development or rapid prototyping to describe a system with a continuous transfer function or a set of differential equations? If yes, the external code relies on an external solver.

Next, see “Identify Integration Requirements” on page 53-8.

Identify Integration Requirements

Before choosing an external integration workflow, review these integration requirements. An understanding of these requirements and the characteristics of your external code helps you choose the optimal workflow for your integration scenario. (See “Evaluate Characteristics of External Code” on page 53-7.)

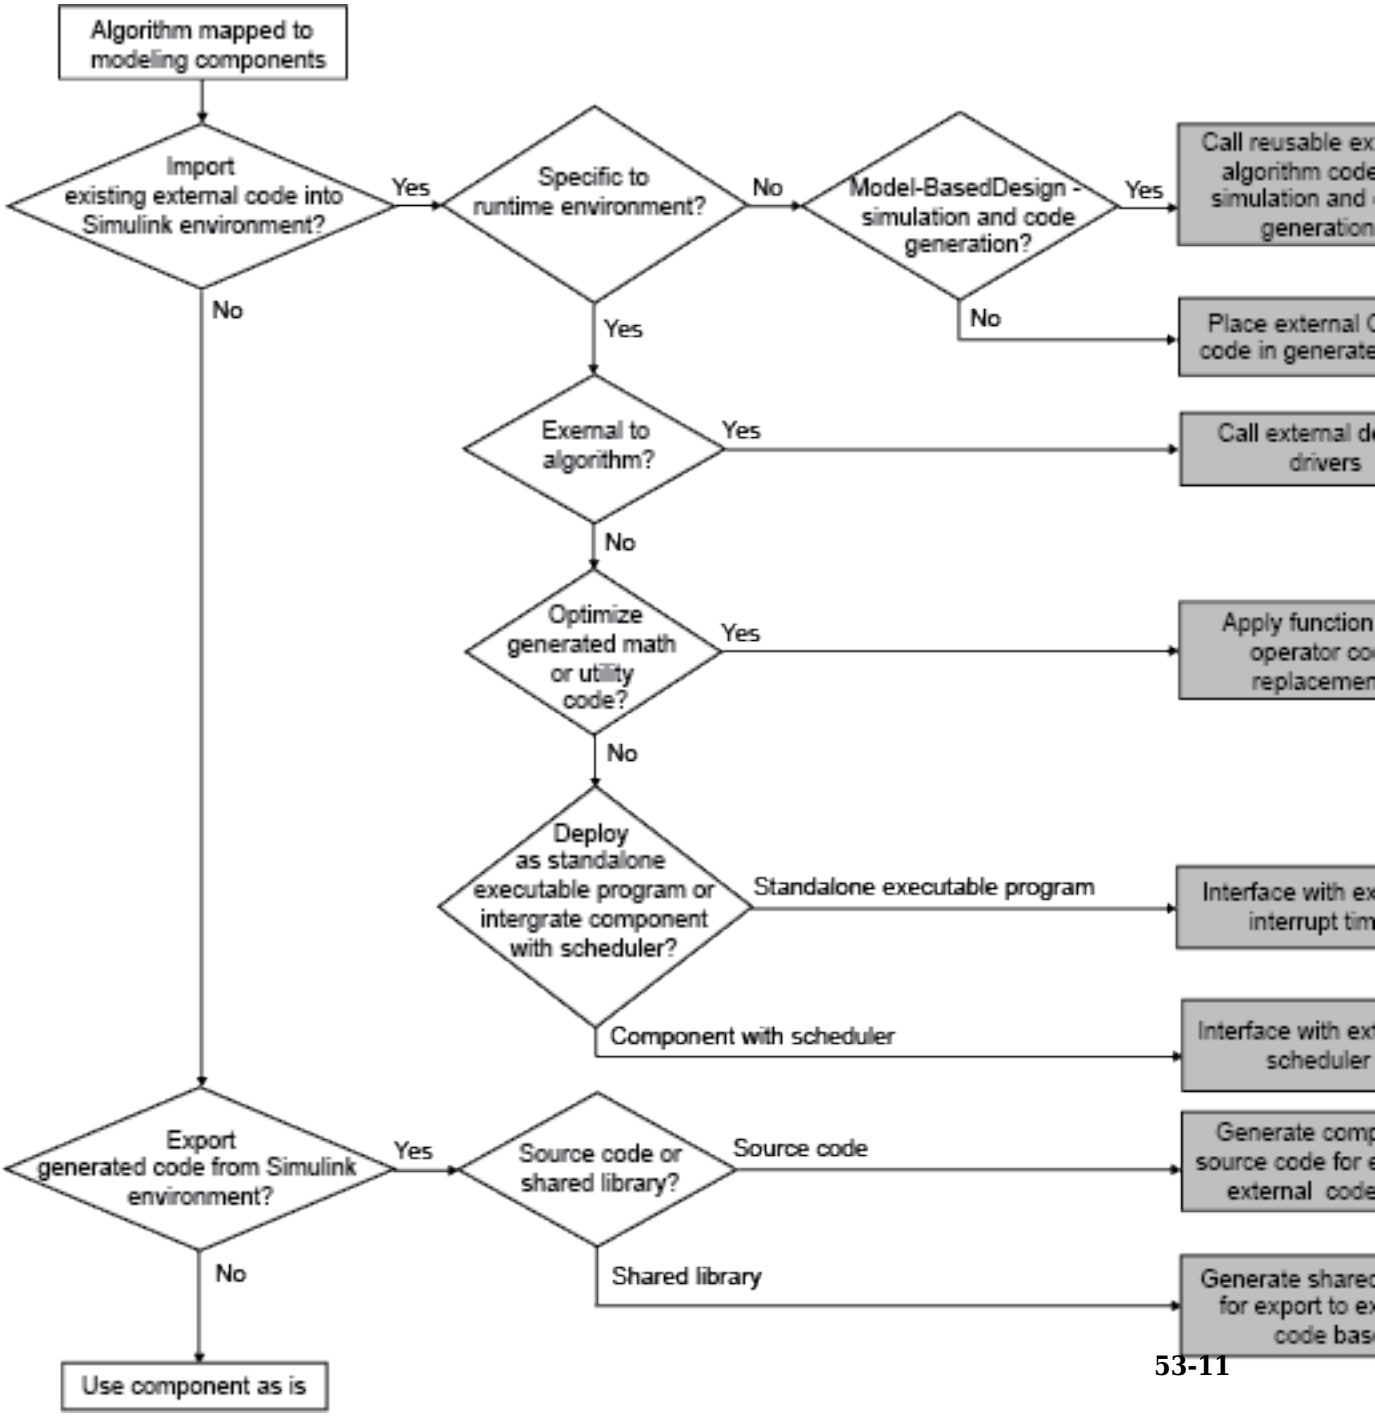
Requirement	What to Consider
Effort	What level of effort is planned for the integration project—low, medium, or high?
Learning effort	What is the programming experience of assigned project resources? How much experience do assigned resources have with Simulink and MathWorks C/C++ code generation products?
Simulation and code generation behaviors	Do you want to take advantage of Model-Based Design? To take full advantage of Model-Based Design, convert code to modeling elements, which you can then use in the Simulink and Stateflow simulation environment. Then, simulate and generate code for the integrated component. Use software-in-the-loop (SIL) or processor-in-the-loop (PIL) testing to verify whether algorithm behavior is the same in both environments.
Data interface and typing	• Does your model or generated code need to exchange data with the external function? If so, map inputs, outputs, and parameters to the external function interface. Typical function interfaces involve function arguments and return values, global variables, and access functions, such as `getRPM`. • Do you want to represent arrays, structures, or enumerated types? In the Simulink environment, you can represent these types as vectors, buses, and `IntEnum`, respectively. • Is fixed-point support required? If you use the Simulink fixed-point interface, you can scale and specify offsets. • Does the external code use company-specific data types? If yes and you have Embedded Coder software, create alias types to represent those external types. The code generator uses the alias types in the code that it produces. For example, once defined, you can specify an alias type in a function prototype, for a temporary variable, or for block output. • Does the code exchange data with shared memory? If yes, define and use memory sections.
Direct function call	Do you want to call C external code directly from a model? You can choose from mechanisms, such as the Legacy Code Tool, Stateflow external code interface and chart action language, and the MATLAB Function block.

Requirement	What to Consider
Insertion of external code into generated code	Do you want to control the placement of external code within generated code? Do you want to insert code into generated entry-point functions? You can place code within generated code by using model configuration parameters or custom code blocks.
Code generation optimization support	Do you want to optimize the code that the code generator produces? If so, you can configure the model for the code generator to optimize the code it produces based on application objectives, such as execution, ROM, and RAM efficiency. You also have the option of using code replacement libraries.
Files required	Do you want to minimize the number of files that you maintain? Some external code integration tools require that you maintain separate files for defining simulation and code generation.

Next, see “Choose a Workflow” on page 53-10.

Choose a Workflow

To choose a workflow for each integration point, use the following flow diagram . The gray boxes identify common workflows and provide links to more information. Click the gray box that best addresses the requirements of an integration point.



Algorithm mapped to modeling components
Import existing external code into Simulink environment?
Yes
No
Specific to runtime environment?
No
Yes
Model-BasedDesign - simulation and code generation?
Yes
No
Call reusable ex algorithm code simulation and generation
Place external C code in generate
Yes
Exernal to algorithm?
Yes
No
Call external de drivers
Optimize generated math or utility code?
Yes
No
Apply function operator co replacemen
Deploy as standalone executable program or intergrate component with scheduler?
Standalone executable program
Component with scheduler
Interface with ex interrupt tim
Interface with ex scheduler
Export generated code from Simulink environment?
Yes
No
Source code or shared library?
Source code
Shared library
Generate comp source code for e external code
Generate shared for export to ex code bas
Use component as is

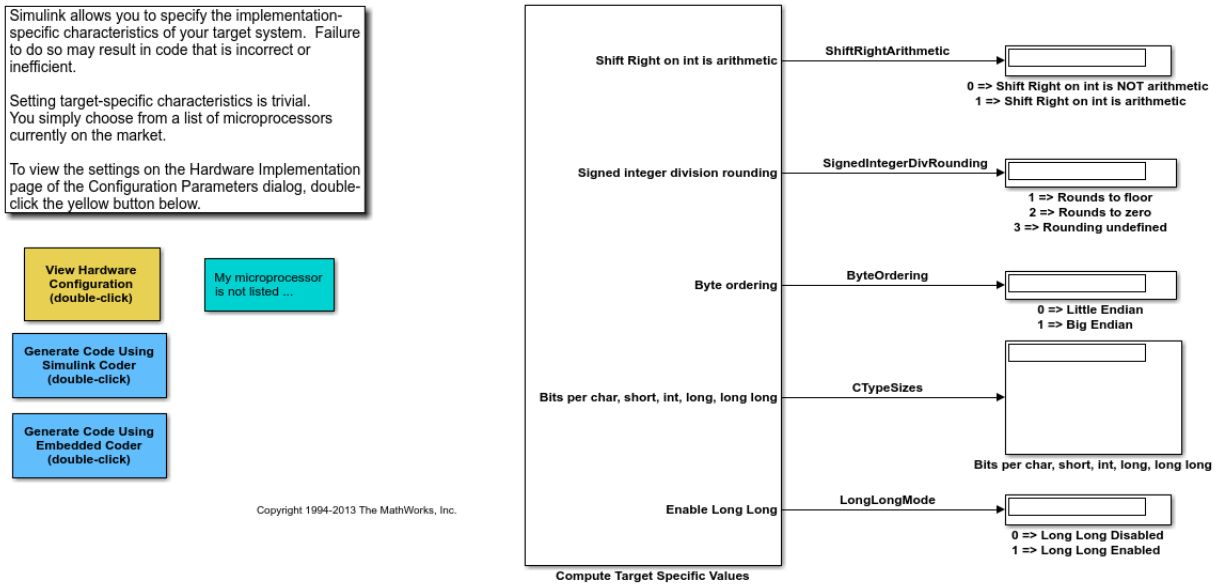
Configure Target Hardware Characteristics

Simulink® allows you to configure the hardware implementation characteristics of your target system. Failure to do so can result in code that is incorrect or inefficient.

Open Example Model

Open the example model `rtwdemo_targetsettings`.

```
open_system('rtwdemo_targetsettings');
```



Open the **Hardware Implementation** pane of the Configuration Parameters dialog box by double-clicking the yellow button in the model.

Hardware Board Configuration

By default, the model is configured for the code generator to determine the hardware board configuration based on the specified system target file. The default system target file setting is `grt.tlc`.

If you have installed support for a hardware board, that board should appear in the **Hardware board** menu. If you select it, the dialog box displays parameters that are relevant to your hardware board.

My Hardware Board is Not Listed

If you are using a hardware board that is not listed, add it to the menu by installing the corresponding target support package. Start the Support Package Installer by setting **Hardware board** to `Get hardware Support Packages`, or by entering `supportPackageInstaller` in the MATLAB® Command Window.

After installing support for a hardware board, reopen the Configuration Parameters dialog box and select the hardware board.

Cross-Development Systems that Include Source Level Debuggers

If you use a cross-development system that includes a source level debugger:

1. Configure the model for your hardware board.

2. Generate code and build an executable using your target development system. For details about retrieving file and path information, see the documentation on the Simulink Coder® Build Information API.

3. Download the executable to the target hardware and set breakpoints at the model output code for each outport of the model.

4. Run a debugging session and observe the behavior of the code as it executes on the target hardware. As you step through the code, it computes the values for target hardware device characteristics.

If your target development system does not support source level debugging, generate code and add `printf` statements or other code that gets the results.

5. On the **Hardware Implementation** pane of the Configuration Parameters dialog box, set **Device vendor** to `Custom processor`, click the **Device details** arrow, and adjust the microprocessor device settings manually.

Check Code Generation Assumptions

The code generator implements assumptions that depend, for example, on the hardware implementation settings for your model. It is important to check that the assumptions are valid for your target hardware. Use the `buildStandaloneCoderAssumptions` function to create an application that performs assumption checks on your target hardware.

When you configure your model, try to specify hardware implementation and build configuration settings that match your target hardware. Then, to check code generator assumptions for your target hardware, use this workflow:

1. With `GenerateReport` set to `'on'`, build (**Ctrl+B**) your model.
2. To view the list of code generator assumptions that you can check, open the code generation report and click the **Coder Assumptions** link.

   For more information, see “Coder Assumptions List” on page 53-17.
3. Run `buildStandaloneCoderAssumptions`, which uses the generated code in the build folder to create an application that runs code generation assumption checks.
4. Download the application onto the target hardware or target environment, and then run the application.
5. While the application runs, use a debug tool to view check results that are in a data structure.

Check Code Generator Assumptions for Development Computer

If the target hardware is, for example, your Windowsdevelopment computer, you can use Microsoft Visual Studio® to run and debug the application:

1. To open a model, in the Command Window, enter `rtwdemo_sil_topmodel`.
2. On the **Configuration Parameters > Hardware Implementation** pane, specify settings to match the target hardware. For example, for a 64-bit Windows computer specify these settings:

   - **Device vendor** –– `Intel`
   - **Device type** –– `x86-64 (Windows 64)`
3. On the **Configuration Parameters > Code Generation > Verification** pane, clear the **Enable portable word sizes** check box.

4. Build the model (**Ctrl+B**).
5. To view the list of code generator assumptions, select **Code** > **C/C++ Code** > **Code Generation Report** > **Open Model Report** and click the **Coder Assumptions** link.
6. From the Command Window, in the working folder, run:

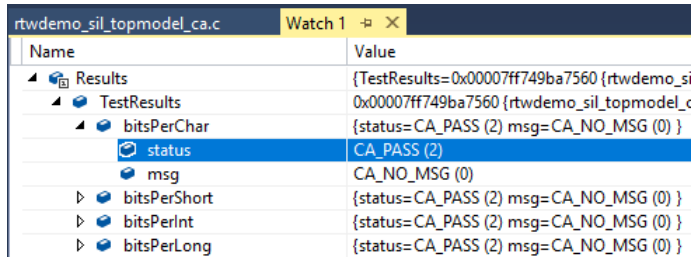
   ```
   buildStandaloneCoderAssumptions('rtwdemo_sil_topmodel_ert_rtw')
   ```

   In the build folder, the function creates the `coderassumptions\standalone` subfolder, which contains the target application, `rtwdemo_sil_topmodel_ca`.
7. Open Microsoft Visual Studio and select **File** > **Open** > **Project/Solution**
8. Using the Open Project dialog box, navigate to the `coderassumptions\standalone` subfolder and select `rtwdemo_sil_topmodel_ca`. Then click **Open**.
9. Select **File** > **Open** > **File**. Using the Open File dialog box, select `coderassumptions\standalone\rtwdemo_sil_topmodel_ca.c`
10. At the `return` statement, insert a break point.
11. Select **Debug** > **Start Debugging**.
12. To verify code generator assumptions, use a Watch window to inspect the `Results` data structure:
    a. In the `rtwdemo_sil_topmodel_ca.c` code, right-click `Results`.
    b. From the context menu, select **Add Watch**.

The variables in the data structure contain:

- Check outcomes (`TestResults`)
- Target hardware truths (`ActualValues`)
- Code generator assumptions (`ExpectedValues`)

For example, if the code generator assumption for `bitsPerChar` is accurate, you see the `CA_PASS` value in the `status` variable.



Coder Assumptions List

The contents section of the code generation report has a link to the Coder Assumptions page. The page provides a list of:

- Code generation assumptions that you can check
- Expected results for the assumption checks

This table describes the labels that you see in the list.

Category	Label	Assumption You Can Check
C/C++ Language Configuration for Target Hardware or Development Computer	`BitPerChar`	Number of bits per `char` (`ProdBitPerChar`)
	`BitPerShort`	Number of bits per `short` (`ProdBitPerShort`)
	`BitPerInt`	Number of bits per `int` (`ProdBitPerInt`)
	`BitPerLong`	Number of bits per `long` (`ProdBitPerLong`)
	`BitPerFloat`	Size of `float` (Only if `PurelyIntegerCode` is `'off'`)
	`BitPerDouble`	Size of `double` (Only if `PurelyIntegerCode` is `'off'`)
	`BitPerPointer`	Number of bits per `pointer` (`ProdBitPerPointer`)
	`BitPerSizeT`	Number of bits per `size_t` (`ProdBitPerSizeT`)
	`BitPerPtrDiffT`	Number of bits per `ptrdiff_t` (`ProdBitPerPtrDiffT`)
	`Endianess`	Byte ordering (`ProdEndianess`)
	`Shift right for signed integer is arithmetic shift`	Sign bit behavior (`ProdShiftRightIntArith`)
	`Signed integer division rounds to`	Rounding behavior for integer division (`ProdIntDivRoundTo`)

Category	Label	Assumption You Can Check
C/C++ Language Standard	`Initial value of a global integer variable is zero`	Zero initialization of memory (`ZeroExternalMemoryAtStartup` and `ZeroInternalMemoryAtStartup`)
Floating-Point Numbers	`Flush-to-zero computed subnormal values (FTZ)`	Flush-to-zero subnormal number processing
	`Flush-to-zero incoming subnormal values (DAZ)`	Denormals-are-zero subnormal number processing

Call Reusable External Algorithm Code for Simulation and Code Generation

Code reuse offers business and technological advantages. From a business perspective, code reuse saves time and resources. From a technological perspective, code reuse promotes consistency and reduces memory requirements. Other considerations include:

- Modularizing an application
- Reusing an optimized algorithm
- Interfacing with a predefined dataset
- Developing application variants

Examples of reusable hardware-independent algorithmic code to consider importing into the Simulink environment for simulation and code generation include:

- Utility functions
- Lookup tables
- Digital filters
- Specialized integrators
- Proportional-integral-derivative (PID) control modules

Workflow

To call reusable external algorithm code for simulation and code generation, iterate through the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 53-4
2	Based on the programming language of the external code, choose an integration approach to add the external code to a Simulink model.	“Choose an Integration Approach” on page 53-20

Task	Action	More Information
3	Verify algorithm behavior and performance by simulating the model.	“Simulation” (Simulink)
4	Define the representation of model data for code generation.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 53-102
5	Configure the model for code generation.	“Generate Code That Matches Appearance of External Code” on page 53-118 and “Model Configuration”
6	Generate code and a code generation report.	“Code Generation”
7	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 49-20 and “Static Code Metrics” on page 49-34
8	Build an executable program from the model.	“Build Integrated Code Within the Simulink Environment” on page 53-54
9	Verify that executable program behaves as expected.	“Numerical Equivalence Testing”
10	Verify that executable program performs as expected.	“Code Execution Profiling”

Choose an Integration Approach

Several approaches are available for integrating reusable algorithmic code into the Simulink environment for code generation. Some approaches integrate external code directly. Other approaches convert the external code to Simulink or Stateflow modeling elements for simulation, and later for code generation from the modeled design. The integration approach that you choose depends on:

- Programming language of the external code — MATLAB, C, C++, or Fortran
- Your programming language experience and preference
- Performance requirements
- Whether the algorithm must model continuous time dynamics or you are integrating the algorithm into an application that uses discrete and continuous time

- Whether you want to take advantage of Model-Based Design
- Level of control required over the code that the code generator produces

To choose an approach for a reusable algorithm, see the subsection that matches the programming language of your external algorithm code.

- “Integration Approaches for External MATLAB Code” on page 53-21
- “Integration Approaches for External C or C++ Code” on page 53-24
- “Integration Approaches for External Fortran Code” on page 53-30

Integration Approaches for External MATLAB Code

Multiple approaches are available for integrating external MATLAB code into the Simulink environment. The following diagram and table help you choose the best integration approach for your application based on integration requirements.

	Condition or Requirement	Action	More Information
1	The algorithm must model continuous state dynamics.	Write a MATLAB S-function and, for generating code, a corresponding TLC file for the algorithm. Add the S-function to your model.	• “Create and Configure MATLAB S-Functions” (Simulink) • “S-Functions” (Simulink Coder) • “Target Language Compiler” (Simulink Coder)

	Condition or Requirement	Action	More Information
2	External code complies with the MATLAB code for code generation subset and you want to call MATLAB code from a Simulink model.	Add a MATLAB Function block to the model. Embed the MATLAB code in that block.	• "Integrate C Code Using the MATLAB Function Block" (Simulink) • MATLAB Function
3	External code complies with the MATLAB code for code generation subset, you want to call MATLAB code from a Simulink model, and your algorithm includes iterative computations that process large streams of data.	Add a MATLAB System block to the model. Embed the MATLAB code in that block as a System object™.	• "Integrate C Code Using the MATLAB Function Block" (Simulink) • MATLAB System
4	External code complies with the MATLAB code for code generation subset, you want to call MATLAB code from a Simulink model, and your algorithm includes design logic that is based on state machines and flow charts.	Add a Stateflow chart to the model. Call the external code from the chart, using MATLAB as the action language.	• "Chart Programming Basics" (Stateflow) • "Insert External Code into Stateflow Charts" on page 53-30
5	You want to use the `parfor` function for parallel computing or interface data types that are available to MATLAB Coder, Simulink Coder, and Embedded Coder.	Use software to generate C code. Then, call that generated code as external C code.	• "Generate C Code by Using the MATLAB Coder App" (MATLAB Coder) • "Getting Started with MATLAB Coder" (MATLAB Coder)

	Condition or Requirement	Action	More Information
6	You have C or C++ programming experience and the external MATLAB code is compact and primarily uses C or C++ constructs.	Manually convert the MATLAB code to C or C++ code. Choose an integration approach for C or C++ code.	"Integration Approaches for External C or C++ Code" on page 53-24
7	Sections of the external MATLAB code map to built-in blocks.	Develop the algorithm in the context of a model, using the applicable built-in blocks.	• "Interactive Model Editing" (Simulink) and "Project Management" (Simulink) • "Blocks and Products Supported for Code Generation" (Simulink Coder)

To embed external MATLAB code in a MATLAB Function block or generate C or C++ code from MATLAB code with the MATLAB Coder software, the MATLAB code must use functions and classes supported for C/C++ code generation.

- "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" (MATLAB Coder)
- "Functions and Objects Supported for C/C++ Code Generation — Category List" (MATLAB Coder)

Integration Approaches for External C or C++ Code

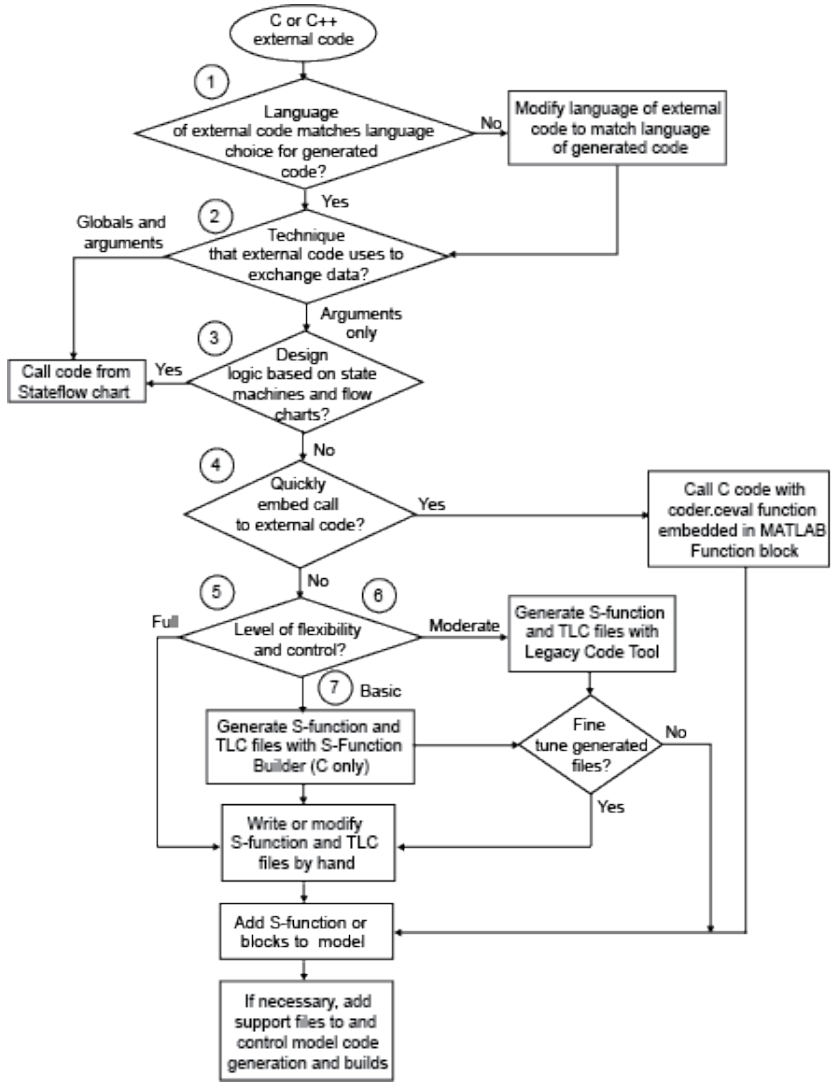
Under most circumstances, you can integrate external code written in C or C++ into the Simulink environment by generating S-functions and TLC files with the Legacy Code Tool. This tool uses specifications that you supply as MATLAB code to transform existing MATLAB functions into C MEX S-functions that you can include in Simulink models and call from generated code. For details, see "Integrate Legacy Code" (Simulink) and "Import Calls to External Code into Generated Code with Legacy Code Tool" on page 12-7.

In comparison to alternative approaches, Legacy Code Tool is the most optimal choice for generating code optimized enough for embedded systems. Consider alternative approaches if one or more of the following conditions exist:

- The external code uses global variables to exchange data.

- Programming experience is limited.
- The algorithm must model discrete and continuous state dynamics.
- You want to include the integrated external code in a Stateflow chart.
- The external code requires a fixed-point interface.
- You want maximum flexibility for controlling what code the code generator produces.
- You quickly want to embed a call to the external code in a call to the `coder.ceval` function that is embedded in the MATLAB Function block, and performance is not an issue.

This diagram and table help you choose the best integration approach based on your integration requirements.



C or C++ external code
1
Language of external code matches language choice for generated code?
No
Modify language of external code to match language of generated code
Yes
2
Technique that external code uses to exchange data?
Globals and arguments
Arguments only
3
Design logic based on state machines and flow charts?
Yes
Call code from Stateflow chart
No
4
Quickly embed call to external code?
Yes
Call C code with coder.ceval function embedded in MATLAB Function block
No
5
Level of flexibility and control?
6
Full
Moderate
Generate S-function and TLC files with Legacy Code Tool
7
Basic
Generate S-function and TLC files with S-Function Builder (C only)
Fine tune generated files?
No
Yes
Write or modify S-function and TLC files by hand
Add S-function or blocks to model
If necessary, add support files to and control model code generation and builds

	Condition or Requirement	Action	More Information
1	You want to integrate external C code with generated C++ code or conversely	Match the language choice for the generated code by modifying the language of the external code.	"Modify Programming Language of External Code to Match Generated Code" on page 53-29
2	Your algorithm includes design logic that is based on state machines and flow charts. Or, a function that you want to integrate must exchange data with a model by using global variables. The function defines the global variables and uses them to write output rather than returning a value (return) or writing output to an argument.	Add a Stateflow chart to the model. Call the external code from the chart, using C as the action language. In the chart, write code that calls the external function and reads from and writes to the global variables. To perform calculations with output of the external code, the model must read from the global variable during execution.	"Insert External Code into Stateflow Charts" on page 53-30
3	You want to include external C or C++ code in a Stateflow chart for simulation and code generation.	Configure the model that contains the chart to apply the external C or C ++ code.	• "Custom Code" (Stateflow) • "Call C Library Functions in C Charts" (Stateflow) • "Insert External Code into Stateflow Charts" on page 53-30
4	You quickly want to embed a call to external C or C++ code in a model. Performance is not an issue.	Call the C or C++ code with the `coder.ceval` function from within a MATLAB Function block.	• `coder.ceval` function • "Integrate C Code Using the MATLAB Function Block" (Simulink) • MATLAB Function block

	Condition or Requirement	Action	More Information
5	The application requires more entry-point functions than the code generator typically produces—for example, more than *model*_step, *model*_initialize, and *model*_terminate. You want maximum flexibility for controlling what code the code generator produces.	Manually write an S-function and TLC file.	• "C/C++ S-Function Basics" (Simulink) • "S-Functions and Code Generation" on page 12-2 • "C S-Function Examples" (Simulink) and "C++ S-Function Examples" (Simulink)
6	You want to simulate and generate external code for a discrete time application. Optimizing generated code is essential. You want ease of use with moderate flexibility for controlling what code the code generator produces. You have C or C++ programming experience, but you prefer to generate the files for adding the code to a model.	Generate S-function and TLC files by using the Legacy Code Tool. If necessary, refine the generated code manually to meet application requirements. (If you change the generated code, you lose the changes if you regenerate the S-function and TLC files.) For simple algorithms written in C, consider using the Simulink C Caller block.	• "Integrate C Functions Using Legacy Code Tool" (Simulink) • "Import Calls to External Code into Generated Code with Legacy Code Tool" (Simulink Coder) • "Integrate C Code Using C Caller Blocks" (Simulink)

	Condition or Requirement	Action	More Information
7	The algorithm must model discrete and continuous state dynamics for simulation and rapid prototyping. The external code requires a fixed-point interface. Programming experience is limited. You want ease of use with basic flexibility for controlling what code the code generator produces for rapid prototyping.	Generate S-function and TLC files by using the S-Function Builder. If necessary, refine the generated code manually to meet application requirements. (If you change the generated code, you lose the changes if you regenerate the S-function and TLC files.)	• "Build S-Functions Automatically" (Simulink) • "Generate S-Function from Subsystem" on page 12-74

Modify Programming Language of External Code to Match Generated Code

To integrate external C code with generated C++ code or conversely, modify the language of the external code to match the programming language choice for the generated code. Options for making the programming language match include:

- Writing or rewriting the external code in the language choice for the generated code.
- If you are generating C++ code and the external code is C code, for each C function, create a header file that prototypes the function. Use this format:

  ```
  #ifdef __cplusplus
  extern "C" {
  #endif
  int my_c_function_wrapper();
  #ifdef __cplusplus
  }
  #endif
  ```

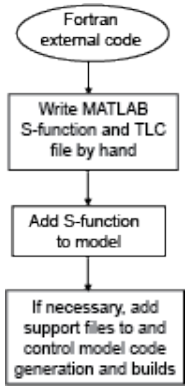
  The prototype serves as a function wrapper. If your compiler supports C++ code, the value `__cplusplus` is defined. The linkage specification `extern "C"` specifies C linkage without name mangling.
- If you are generating C code and the external code is C++ code, include an `extern "C"` linkage specification in each `.cpp` file. For example, the following example shows C++ code in the file `my_func.cpp`:

```
extern "C" {

int my_cpp_function()
{
  ...
}
}
```

Integration Approaches for External Fortran Code

To integrate external Fortran code, write an S-function and corresponding TLC file.



See “C/C++ S-Function Basics” (Simulink), “Integrate Fortran Code” (Simulink), “S-Functions and Code Generation” on page 12-2, and“Fortran S-Function Examples” (Simulink).

Insert External Code into Stateflow Charts

Integrate External Code for Library Charts

To integrate external code that applies only to Stateflow library charts for code generation, for each library model that contributes a chart to your main model, complete these steps. Then, generate code.

1 In the Stateflow Editor, select **Code** > **C/C++ Code** > **Code Generation Options**.

2. In the Model Configuration Parameters dialog box, select **Code Generation > Use local custom code settings (do not inherit from main model)**.

   The library model retains its own custom code settings during code generation.

3. Specify your custom code in the subpanes.

   Follow the guidelines in “Specify Relative Paths to Your Custom Code” (Stateflow).

   If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

4. Click **OK**.

After completing these steps for each library model, generate code.

Integrate External Code for All Charts

To integrate external code that applies to all charts for code generation:

1. Specify custom code options for code generation of your main model.

   a. In the Model Configuration Parameters dialog box, select **Code Generation > Custom Code**.

   b. In the custom code text fields, specify your custom code.

      Follow the guidelines in “Specify Relative Paths to Your Custom Code” (Stateflow).

      If you specified custom code settings for simulation, you can apply these settings to code generation. To avoid entering the same information twice, select **Use the same custom code settings as Simulation Target**.

2. Configure code generation for each library model that contributes a chart to your main model.

   a. In the Stateflow Editor, select **Code > C/C++ Code > Code Generation Options**.

   b. In the **Code Generation** pane, clear the **Use local custom code settings (do not inherit from main model)** check box.

      The library charts inherit the custom code settings of your main model.

c Click **OK**.

3 Generate code.

Call External C Code from Model and Generated Code

Call existing, external functions from a simulation or from the generated code by using the Legacy Code Tool.

Learn how to:

- Evaluate a C function as part of a Simulink® model simulation.
- Call a C function from the code that you generate from a model.

For information about the example model and other examples in this series, see "Generate C Code from a Control Algorithm for an Embedded System".

Replacement Process

Open the example model, `rtwdemo_PCG_Eval_P4`.

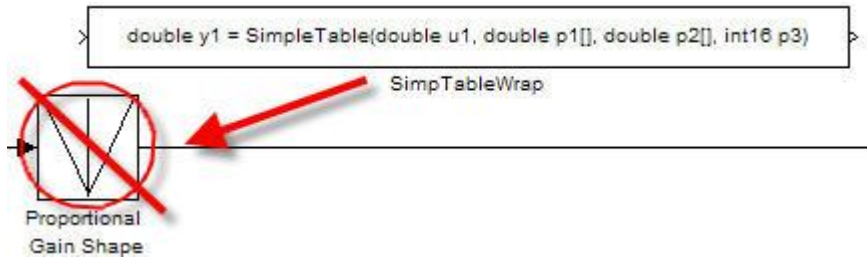
For many Model-Based Design applications, in addition to Simulink® models, a design includes a set of existing C functions that have been tested and validated. You can integrate these functions into a Simulink® model and generate code that uses the functions.

In this example, you create a custom Simulink® block that calls an existing C function. You then include the block in a model and test the overall system through model simulation in Simulink®.

In the example model, you can replace the Lookup blocks (lookup tables) in the PI controllers with calls to an existing C function. The function is defined in the files `SimpleTable.c` and `SimpleTable.h`.

View `SimpleTable.c`.

View `SimpleTable.h`.



Create Block That Calls C Function

To specify a call to an existing C function, use an S-Function block. You can automate the creation of the S-Function block by using the Legacy Code Tool. In the tool, you first specify an interface for your existing C function. The tool then uses that interface to create an S-Function block.

Use the Legacy Code Tool to create an S-Function block for the existing C function in `SimpleTable.c`.

1. Create a structure to contain the definition of the function interface.

```
def = legacy_code('initialize')
```

You can use the structure `def` to define the function interface to the existing C code.

2. Populate the fields of the structure.

```
% Defines the function interface, inputs, return values and parameters
def.OutputFcnSpec = ['double y1 = SimpleTable(double u1,',...
                     'double p1[], double p2[], int16 p3)'];

% the C and H files where the external code is defined
def.HeaderFiles   = {'SimpleTable.h'};
def.SourceFiles   = {'SimpleTable.c'};
% The name of the created S-Function
def.SFunctionName = 'SimpTableWrap';
```

3. Create the S-function.

```
legacy_code('sfcn_cmex_generate',def)
```

4. Compile the S-function.

```
legacy_code('compile',def)
```

5. Create the S-Function block.

```
legacy_code('slblock_generate',def)
```

The generated S-Function block calls the C function in `SimpleTable.c`. You can now use and reuse this S-Function block in models.

6. Create the TLC file.

```
legacy_code('sfcn_tlc_generate',def)
```

This command creates a TLC file, which is the component of an S-Function that specifies how to generate code for the block.

Validate External Code Through Simulation

When you integrate existing C code in a Simulink® model, first validate the generated S-Function block.

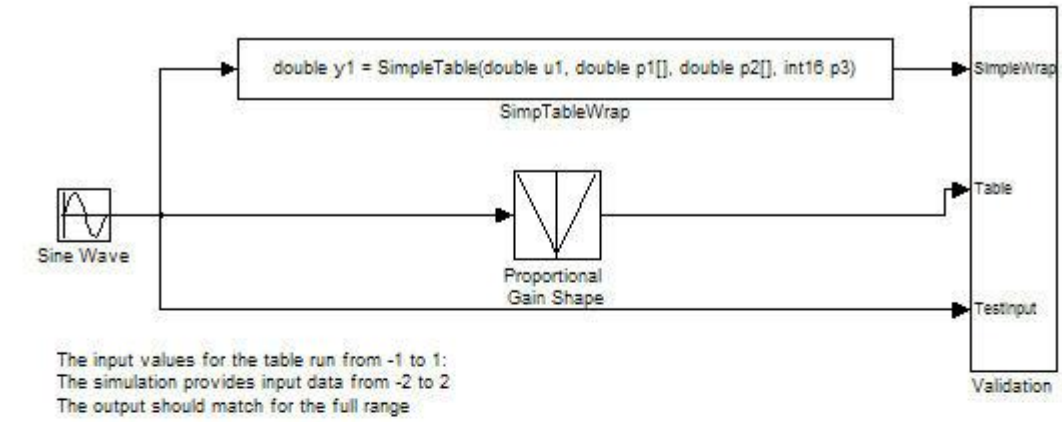
To validate the replacement of the Lookup blocks, compare the simulation results produced by the Lookup blocks with the results produced by the new S-Function block.

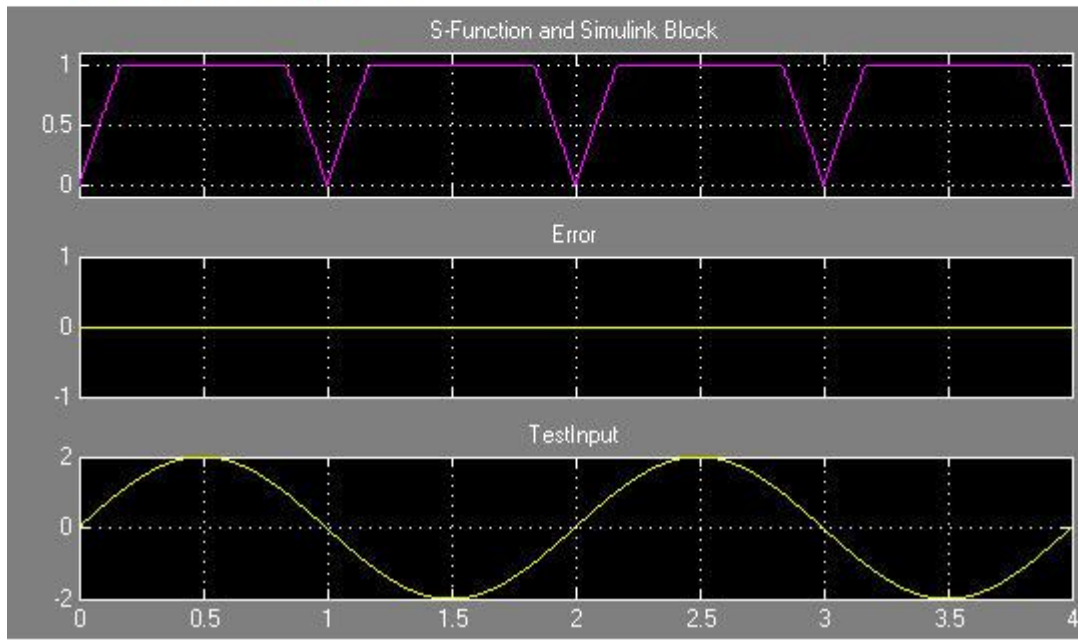
1. Open the validation model.

- The Sine Wave block produces output values from [-2 : 2].
- The input range of the lookup table is from [-1 : 1].
- The lookup table outputs the absolute value of the input.
- The lookup table clips the output at the input limits.

2. Run the validation model.

The figure shows the validation results. The existing C code and the Simulink® table block produce the same output values.





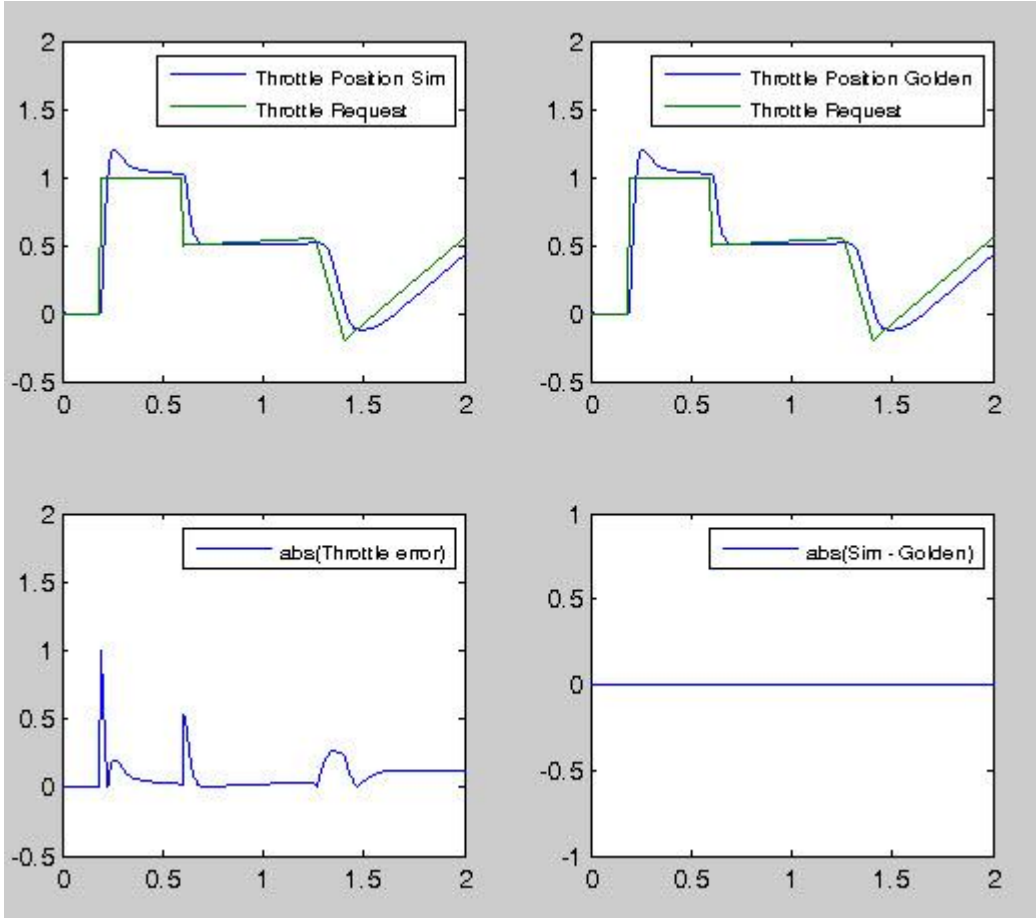
Validate C Code as Part of Simulink® Model

After validating the existing C function code as a standalone component, you can validate the S-function in the model. To complete the validation, use the test harness model.

1. Open the test harness.

2. Run the test harness.

The simulation results match the golden values.



Call C Function from the Generated Code

The code generator uses the TLC file to process the S-Function block like any other block. The code generator can implement *expression folding* with the S-Function block, an operation that combines multiple computations into a single output calculation.

1. Build the full model.

2. Examine the generated code in `PI_Control_Reusable.c`.

The generated code now calls the `SimpleTable` C function.

The figures show the generated code before and after the C code integration. Before the integration, the code calls a generated lookup routine. After the integration, the generated code calls the C function `SimpleTable`.

```
Discrete_Time_Integrator1 = rtp_Masked_I_Gain * look1_binlx(rtb_Sum2,
  (&(I_InErrMap[0])), (&(I_OutMap[0])), 8U) * rtb_Sum2 * 0.001 +
  localDW->Discrete_Time_Integrator1_DSTAT;
```

```
/* DiscreteIntegrator: '<S3>/Discrete_Time_Integrator1' incorporates:
 *  Gain: '<S3>/Int_Gain1'
 *  Product: '<S3>/Product3'
 *  S-Function (SimpTableWrap): '<S3>/SimpTableWrap1'
 */
Discrete_Time_Integrator1 = I_Gain * SimpleTable(rtb_Sum2, (real_T*)
  (&(I_InErrMap[0])), (real_T*)(&(I_OutMap[0])), 7) * rtb_Sum2 * 0.001 +
  localDW->Discrete_Time_Integrator1_DSTAT;
```

For the next example in this series, see “Build Integrated Code Outside the Simulink Environment”.

Place External C/C++ Code in Generated Code

In this section...

You can customize code that the code generator produces for a model by specifying external code with custom code blocks or model configuration parameters.

- Place code at the start and end of the generated code for the root model.
- Place declaration, body, and exit code in generated function code for blocks in the root model or nonvirtual subsystems.

The functions that you can augment with external code depends on the functions that the code generator produces for blocks that are in the model. For example, if a model or atomic subsystem includes blocks that have states, you can specify code for a disable function. Likewise, if you need the code for a block to save data, free memory, or reset target hardware, specify code for a terminate function. For more information, see “Block Target File Methods” (Simulink Coder).

Workflow

To place external C or C++ code at specific locations in code that the code generator produces for root models and subsystems, iterate through the tasks listed in this table.

Task	Action	More Information
1	If you want to integrate external C code with generated C++ code or conversely, modify the language of the external code to match the language choice for the generated code.	“Modify Programming Language of External Code to Match Generated Code” (Simulink Coder)

Task	Action	More Information
2	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 53-4
3	If necessary, rewrite code in C or C++.	
4	Choose an integration approach to add the external code to a Simulink model.	“Choose an Integration Approach” on page 53-40
5	Define the representation of model data for code generation.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 53-102
6	Configure the model for code generation.	“Generate Code That Matches Appearance of External Code” on page 53-118 and “Model Configuration”
7	Generate code and a code generation report.	“Code Generation”
8	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 49-20 and “Static Code Metrics” on page 49-34
9	Build an executable program from the model.	“Build Integrated Code Within the Simulink Environment” on page 53-54
10	Verify that executable program performs as expected.	“Numerical Equivalence Testing” and “Code Execution Profiling”

Choose an Integration Approach

Within the Simulink modeling environment, two approaches are available for placing external C or C++ code into sections of code that the code generator produces:

- Add blocks from the Custom Code library to a root model or atomic subsystem.
- Set model configuration parameters on the **Code Generation** > **Custom Code** pane.

The following table compares the two approaches. Choose the approach that aligns best with your integration requirements. For more information about how to apply each

approach, see “Integrate External Code by Using Custom Code Blocks” on page 53-42 and “Integrate External Code by Using Model Configuration Parameters” on page 53-45.

Requirement	Blocks	Model Configuration Parameters
Include a representation of your external code in the modeling canvas	✓	
Place code in functions generated for root models	✓	✓
Place code in functions generated for atomic subsystems	✓	
Save code placement in a model configuration set		✓
Place code at the top and bottom of the header and source files generated for a model	✓	✓
Place code within declaration, execution, and exit sections of the `SystemInitialize` and`SystemTerminate` functions that the code generator creates	✓	✓
Place code within declaration, execution, and exit sections of the `SystemStart`, `SystemEnable`, `SystemDisable`, `SystemOutputs`, `SystemUpdate`, or`SystemDerivatives` functions that the code generator creates	✓	
Add preprocessor macro definitions to generated code		✓
Use the custom code settings that are specified for the simulation target		✓
Configure a library model to use custom code settings of the parent model to which the library is linked		✓

Integrate External Code by Using Custom Code Blocks

Custom Code Block Library

The Custom Code block library contains blocks that you can use to place external C or C++ code into specific locations and functions within code that the code generator produces. The library consists of 10 blocks that add your code to the model header (`model.h`) and source (`model.c` or `model.cpp`) files that the code generator produces.

The Model Header and Model Source blocks add external code at the top and bottom of header and source files that the code generator produces for a root model. These blocks display two text fields into which you can type or paste code. One field specifies code that you want to place at the top of the generated header or source file. The second field specifies code that you want to place at the bottom of the file.

The remaining blocks add external code to functions that the code generator produces for the root model or atomic subsystem that contains the block. The blocks display text fields into which you can type or paste code that customizes functions that the code generator produces. The text fields correspond to the declaration, execution, and exit sections of code for a given function.

To Customize Code That	Use This Block
Computes continuous states	System Derivatives
Disables state	System Disable
Enables state	System Enable
Resets state	System Initialize
Produces output	System Outputs
Executes once	System Start
Saves data, free memory, reset target hardware	System Terminate
Requires updates at each major time step	System Update

The block and its location within a model determines where the code generator places the external code. For example, if the System Outputs block is at the root model level, the

code generator places the code in the model `Outputs` function. If the block resides in a triggered or enabled subsystem, the code generator places the code in the subsystem `Outputs` function.

If the code generator does not need to generate a function that corresponds to a Custom Code block that you include in a model, the code generator does one of the following:

- Omits the external code that you specify in the Custom Code block.
- Returns an error, indicating that the model does not include a relevant block. In this case, remove the Custom Code block from the model.

For more information, see “Block Target File Methods” (Simulink Coder).

Add Custom Code Blocks to the Modeling Canvas

To add the Custom Code library blocks to a model:

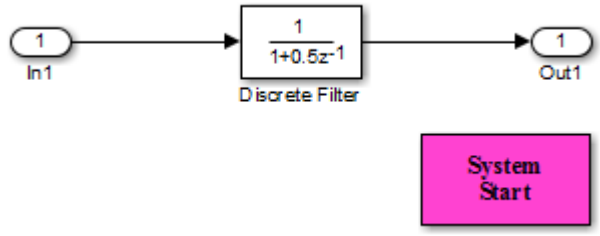
1. In the Simulink Library Browser, open the Custom Code block library. You can gain access to the library by:
   - Navigating to **Simulink Coder > Custom Code** in the browser.
   - Entering the MATLAB command `custcode`.
2. Drag the blocks that you want into your model or subsystem. Drag Model Header and Model Source blocks into root models only. Drag function-based Custom Code blocks into root models or atomic subsystems.

You can use models that contain Custom Code blocks as referenced models. The code generator ignores the blocks when producing code for a simulation target. When producing code for a code generation target, the code generator includes and compiles the custom code.

Add External Code to Generated Start Function

This example shows how to use the System Start block to place external C code in the code that the code generator produces for a model that includes a discrete filter.

1. Create the following model.



2. Configure the model for code generation.
3. Double-click the System Start block.
4. In the block parameters dialog box, in the **System Start Function Declaration Code** field, enter this code:

   ```
   unsigned int *ptr = 0xFFEE;
   ```

5. In the **System Start Function Execution Code** field, enter this code:

   ```
   /* Initialize hardware */
   *ptr = 0;
   ```

6. Click **OK**.
7. Generate code and a code generation report.
8. View the generated *`model`*`.c` file. Search for the string `start function`. You should find the following code, which includes the external code that you entered in steps 4 and 5.

   ```
   {
     {
       /* user code (Start function Header) */
       /* System '<Root>' */
       unsigned int *ptr = 0xFFEE;

       /* user code (Start function Body) */
       /* System '<Root>' */
       /* Initialize hardware */
       *ptr = 0;
     }
   }
   ```

For another example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 53-47.

Integrate External Code by Using Model Configuration Parameters

Model configuration parameters provide a way to place external C or C++ code into specific locations and functions within code that the code generator produces.

To	Select
Insert external code near the top of the generated *model*.c or *model*.cpp file	**Source file**, and enter the external code to insert. **Note** If you generate subsystem code into separate files, that code does not have access to external code that you specify with the **Source file** parameter. For example, if you specify an include file as a **Source file** setting, the code generator inserts the `#include` near the top of the *model*.c or *model*.cpp file. The subsystem code that the code generator places in a separate file does not have access to declarations inside your included file. In this case, consider specifying your external code with the **Header file** parameter.
Insert external code near the top of the generated *model*.h file	**Header file**, and enter the external code to insert.
Insert external code inside the model initialize function in the *model*.c or *model*.cpp file	**Initialize function**, and enter the external code to insert.
Insert external code inside the model terminate function in the *model*.c or *model*.cpp file	**Terminate function**, and enter the external code to insert. Also select the **Terminate function required** parameter on the **Interface** pane.
Add preprocessor macro definitions	**Defines**, and enter a space-separated list of preprocessor macro definitions to add to the generated code. The list can include simple definitions (for example, `-DEF1`) and definitions with a value (for example, `-DDEF2=1`). Definitions can omit the `-D` (for example, `-DFOO=1` and `FOO=1` are equivalent). If a definition includes `-D`, the toolchain can override the flag if the toolchain uses a different flag for defines.

To	Select
Use the same custom code parameter settings as the settings specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	**Use the same custom code settings as Simulation Target** This parameter refers to the **Simulation Target** pane in the Configuration Parameters dialog box.
Enable a library model to use custom code settings unique from the parent model to which the library is linked	**Use local custom code settings (do not inherit from main model)** This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.

To include a header file in an external header file, add `#ifndef` code. Using this code avoids multiple inclusions. For example, in `rtwtypes.h`, the following `#include` guards are added:

```
#ifndef RTW_HEADER_rtwtypes_h_
#define RTW_HEADER_rtwtypes_h_
...
#endif /* RTW_HEADER_rtwtypes_h_ */
```

For more information on how to add files names and locations of header, source, and shared library files to the build process, see “Build Integrated Code Within the Simulink Environment” on page 53-54.

Note The code generator includes external code that you include in a configuration set when generating code for software-in-the-loop (SIL) and processor-in-the-loop (PIL) simulations. However, the code generator ignores external code that you include in a configuration set when producing code with the S-function, rapid simulation, or simulation system target file.

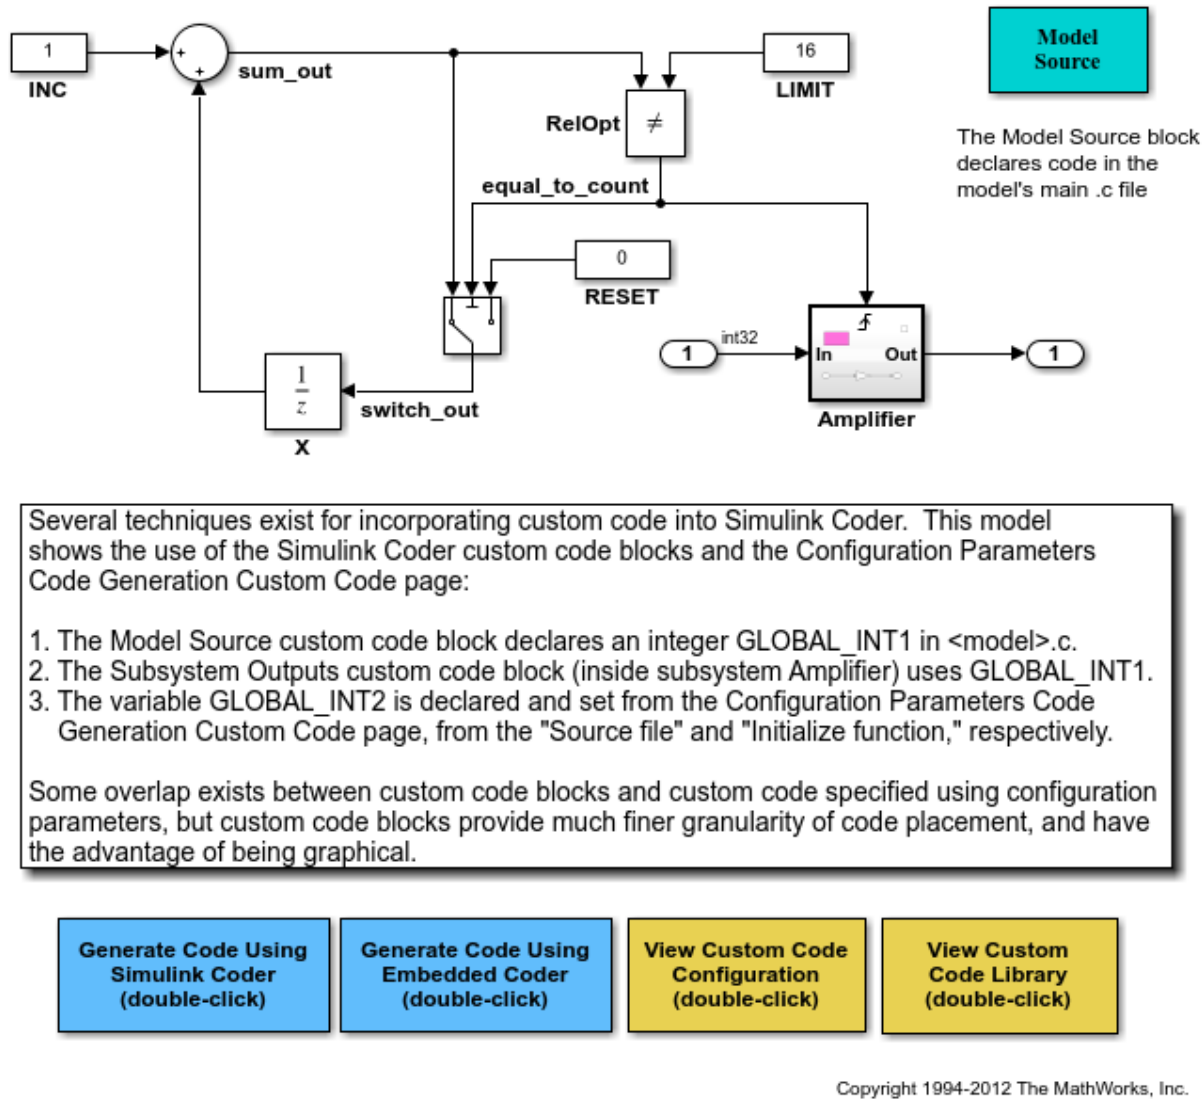
For more information about **Custom Code** parameters, see “Model Configuration Parameters: Code Generation Custom Code” (Simulink Coder). For an example, see “Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters” on page 53-47.

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```



2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

3. Examine the settings for parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
- **Initialize function** initializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem `Amplifier`. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the `Amplifier` subsystem. The external code:

- Declares the pointer variable `*intPtr` and initializes it with the value of variable `GLOBAL_INT1`.
- Sets the pointer variable to -1 during execution.
- Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;

int_T GLOBAL_INT1 = 0;
```

The Output function for the `Amplifier` subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the `Amplifier` subsystem.

```
int_T *intPtr = &GLOBAL_INT1;

*intPtr = -1;

rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
```

```
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

```
GLOBAL_INT2 = 1;
```

Call External Device Drivers

Device drivers for protocols and target hardware are essential to many real-time development projects. For example, you can have a working device driver that you want to integrate with algorithmic code that has to read data from and write data to the I/O device that the driver supports. The code generator can produce a single set of application source files from an algorithm model and integrated driver code written in C or C++.

To call external device driver code from the Simulink environment, iterate through the tasks in this table.

Apply Function and Operator Code Replacements

If your generated code must use functions and operators that are consistent with external code, configure the code generator to use a code replacement library (CRL). By default, the code generator does not apply a code replacement library. You can choose from several libraries that MathWorks provides, including GNU C99 extensions, AUTOSAR 4.0, and several Intel® platform-specific IPP and IPP/SSE libraries. Depending on the products that you have, other libraries might be available. If you have Embedded Coder software, you can view and choose from additional libraries and you can create custom code replacement libraries.

Build Integrated Code Within the Simulink Environment

Workflow

To build executable programs that integrate generated code and external C or C++ code, iterate through the tasks in this table.

Task	Action	More Information
1	Choose whether to use the toolchain approach or template makefile approach build process.	"Choose Build Approach and Configure Build Process" on page 54-14 For an example, see "Build Process Workflow for Real-Time Systems" on page 54-32.
2	Configure build process support for your external code.	"Configure Parameters for Integrated Code Build Process" on page 53-55
3	Configure S-Function build support for your external code.	"Build Support for S-Functions" on page 53-57 "Use makecfg to Customize Generated Makefiles for S-Functions" on page 84-24 For examples, see "Call External C Code from Model and Generated Code" and "Call Reusable External Algorithm Code for Simulation and Code Generation" on page 53-19.
4	Configure build process to find the external code source, library, and header files.	"Manage Build Process File Dependencies" on page 47-53 "Control Library Location and Naming During Build" on page 84-7

Task	Action	More Information
5	Set up custom build processing required for your external code integration.	For the build process customization workflow, see “Customize Post-Code-Generation Build Processing” on page 84-14. To automate applying build customizations to a toolchain approach build, see “Customize Build Process with sl_customization.m” on page 84-55. To automate applying build customizations to a template makefile approach build, see “Customize Build Process with STF_make_rtw_hook File” on page 84-50.

Configure Parameters for Integrated Code Build Process

The table provides a guide to configuration parameters that support the build process for external code integration. For information about folders for your external code, see “Manage Build Process Folders” on page 47-37. If you choose to place your external code in the “Code generation folder” (Simulink), see “Preserve External Code Files in Build Folder” on page 53-57.

To	Select
Add include folders, which contain header files, to the build process	**Configuration Parameters > Code Generation > Custom Code > Additional build information > Include directories**, and enter the absolute or relative paths to the folders. If you specify relative paths, the paths must be relative to the folder containing your model files, not relative to the build folder. The order in which you specify the folders is the order in which they are searched for header, source, and library files.

To	Select

Add source files to be compiled and linked	**Configuration Parameters > Code Generation > Custom Code > Additional build information > Source files**, and enter the full paths or just the file names for the files.
	
	Enter just the file name if the file is in the current MATLAB folder or in one of the include folders. For each additional source that you specify, the build process expands a generic rule in the template makefile for the folder in which the source file is located. For example, if a source file is located in folder `inc`, the build process adds a rule similar to the following:
	
	`%.obj: buildir\inc\%.c`
	`$(CC) -c -Fo$(@F) $(CFLAGS) $<`
	
	The build process adds the rules in the order that you list the source files.

Add libraries to be linked	**Configuration Parameters > Code Generation > Custom Code > Additional build information > Libraries**, and enter the full paths or just the file names for the libraries. Enter just the file name if the library is located in the current MATLAB folder or in one of the include folders.
Use the same custom code settings as those specified for simulation of MATLAB Function blocks, Stateflow charts, and Truth Table blocks	**Configuration Parameters > Code Generation > Custom Code > Use the same custom code settings as Simulation Target** **Note** This parameter refers to the **Simulation Target** pane in the Configuration Parameters dialog box.
Enable a library model to use custom code settings unique from the parent model to which the library is linked	**Configuration Parameters > Code Generation > Custom Code > Use local custom code settings (do not inherit from main model)** **Note** This parameter is available only for library models that contain MATLAB Function blocks, Stateflow charts, or Truth Table blocks.

Preserve External Code Files in Build Folder

By default, the build process deletes foreign source files. You can preserve foreign source files by following these guidelines.

If you put a `.c/.cpp` or `.h` source file in a build folder, and you want to prevent the code generator from deleting it during the TLC code generation process, insert the text `target specific file` in the first line of the `.c/.cpp` or `.h` file. For example:

```
/*  COMPANY-NAME target specific file
 *
 *   This file is created for use with the
 *   COMPANY-NAME target.
 *   It is used for ...
 */
...
```

Make sure that you spell the text “target specific file” as shown in the preceding example, and that the text is in the first line of the source file. Other text can appear before or after this text.

Flagging user files in this manner prevents postprocessing these files to indent them with generated source files. Auto-indenting occurred in previous releases to build folder files with names having the pattern *`model`*`_*.c/.cpp` (where * was text). The indenting is harmless, but can cause differences detected by source control software that can potentially trigger unnecessary updates.

Build Support for S-Functions

User-written S-Function blocks provide a powerful way to incorporate external code into the Simulink development environment. In most cases, you use S-functions to integrate existing external code with generated code. Several approaches to writing S-functions are available:

- “Write Noninlined S-Function” on page 12-107
- “Write Wrapper S-Function and TLC Files” on page 12-110
- “Write Fully Inlined S-Functions” on page 12-119
- “Write Fully Inlined S-Functions with mdlRTW Routine” on page 12-121
- “S-Functions That Support Code Reuse” on page 12-99
- “S-Functions for Multirate Multitasking Environments” on page 12-100

S-functions also provide the most flexible and capable way of including build information for legacy and custom code files in the build process.

There are different ways of adding S-functions to the build process.

Implicit Build Support

When building models with S-functions, the build process adds rules, include paths, and source file names to the generated makefile. The source files (`.h`, `.c`, and `.cpp`) for the S-function must be in the same folder as the S-function MEX-file. Whether using the toolchain approach or template makefile approach for builds, the build process propagates this information through the toolchain or template makefile.

- If the file *`sfcnname`*`.h` exists in the same folder as the S-function MEX-file (for example, *`sfcnname`*`.`*`mexext`*), the folder is added to the include path.
- If the file *`sfcnname`*`.c` or *`sfcnname`*`.cpp` exists in the same folder as the S-function MEX-file, the build process adds a makefile rule for compiling files from that folder.
- When an S-function is not inlined with a TLC file, the build process must compile the S-function source file. To determine the name of the source file to add to the list of files to compile, the build process searches for *`sfcnname`*`.cpp` on the MATLAB path. If the source file is found, the build process adds the source file name to the makefile. If *`sfcnname`*`.cpp` is not found on the path, the build process adds the file name *`sfcnname`*`.c` to the makefile, whether or not it is on the MATLAB path.

> **Note** For the Simulink engine to find the MEX-file for simulation and code generation, it must exist on the MATLAB path or exist in our current MATLAB working folder.

Specify Additional Source Files for an S-Function

If your S-function has additional source file dependencies, you must add the names of the additional modules to the build process. Specify the file names:

- In the **S-function modules** field in the S-Function block parameter dialog box
- With the `SFunctionModules` parameter in a call to the `set_param` function

For example, suppose you build your S-function with multiple modules.

```
mex sfun_main.c sfun_module1.c sfun_module2.c
```

You can then add the modules to the build process by doing one of the following:

- In the S-function block dialog box, specify `sfun_main`, `sfun_module1`, and `sfun_module2` in the **S-function modules** field.
- At the MATLAB command prompt, enter:

  ```
  set_param(sfun_block,'SFunctionModules','sfun_module1 sfun_module2')
  ```

  Alternatively, you can define a variable to represent the parameter value.

  ```
  modules = 'sfun_module1 sfun_module2'
            set_param(sfun_block,'SFunctionModules', modules)
  ```

The **S-function modules** field and `SFunctionModules` parameter do not support complete source file path specifications. To use the parameter, the code generator must find the additional source files when executing the makefile. For the code generator to locate the additional files, place them in the same folder as the S-function MEX-file. You can then leverage the implicit build support described in “Implicit Build Support” on page 53-58.

When you are ready to generate code, force the code generator to rebuild the top model, as described in “Control Regeneration of Top Model Code” (Simulink Coder).

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use rtwmakecfg.m API to Customize Generated Makefiles” on page 84-26.

Use TLC Library Functions

If you inline your S-function by writing a TLC file, you can add source file names to the build process by using the TLC library function `LibAddToModelSources`. For details, see “LibAddSourceFileCustomSection(file, builtInSection, newSection)” (Simulink Coder).

Note This function does not support complete source file path specifications. The function assumes that the code generator can find the additional source files when executing the makefile.

Another useful TLC library function is `LibAddToCommonIncludes`. Use this function in a `#include` statement to include S-function header files in the generated *`model`*`.h` header file. For details, see “LibAddToCommonIncludes(incFileName)” (Simulink Coder).

For more complicated S-function file dependencies, such as specifying source files in other locations or specifying libraries or object files, use the `rtwmakecfg.m` API, as described in “Use rtwmakecfg.m API to Customize Generated Makefiles” on page 84-26.

Precompile S-Function Libraries

You can precompile new or updated S-function libraries (MEX-files) for a model by using the MATLAB language function `rtw_precompile_libs`. Using a specified model and a library build specification, this function builds and places the libraries in a precompiled library folder.

By precompiling S-function libraries, you can optimize system builds. Once your precompiled libraries exist, the build process can omit library compilation from subsequent builds. For models that use numerous libraries, the time savings for build processing can be significant.

To use `rtw_precompile_libs`:

1. Set the library file suffix, including the file type extension, based on your system platform.

   Consider determining the type of platform, and then use the `TargetLibSuffix` parameter to set the library suffix accordingly. For example, when applying a suffix for a GRT target, you can set the suffix to `_std.a` for a UNIX platform and `_vcx64.lib` for a Windows platform.

   ```
   if isunix
     suffix = '_std.a';
   else
     suffix = '_vcx64.lib';
   end

   set_param(my_model,'TargetLibSuffix', suffix);
   ```

   There are a number of factors that influence the precompiled library suffix and extension. The following table provides examples for typical selections of system target file, the compiler toolchain, and other options that affect your choice of suffix and extension. For more information, examine the template make files in the `matlab/rtw/c/grt` folder or `matlab/rtw/c/ert` folder.

TMF File	COMPILER_TOOL_CHAIN Value	Precompiler Libraries (PRECOMP_LIBRARIES)			
		Library Suffix S-Function (EXPAND_LIBRARY_NAME Value)	Library Suffix Integer- Only Code (EXPAND_LIBRARY_NAME Value)	Library Suffix Optimize for Speed (EXPAND_LIBRARY_NAME Value)	Library Extension (EXPAND_LIBRARY_NAME Value)
ert_lcc64.tmf	lcc	_rtwsfcn_lcc	_int_ert_lcc	_ert_lcc	.lib
ert_vcx64.tmf	vcx64	_rtwsfcn_vcx64	_int_ert_vcx64	_ert_vcx64	.lib
ert_unix.tmf	unix	_rtwsfcn	_int_ert	_ert	.a
grt_lcc64.tmf	lcc	n/a	n/a	_lcc	.lib
grt_vcx64.tmf	vcx64	n/a	n/a	_vcx64	.lib
grt_unix.tmf	unix	n/a	n/a	_std	.a

2 Set the precompiled library folder.

Use one of the following methods to set the precompiled library folder:

- Set the `TargetPreCompLibLocation` parameter, as described in “Specify the Location of Precompiled Libraries” on page 84-8.
- Set the `makeInfo.precompile` field in an `rtwmakecfg.m` function file. (For more information, see “Use rtwmakecfg.m API to Customize Generated Makefiles” on page 84-26.)

If you set `TargetPreCompLibLocation` and `makeInfo.precompile`, the setting for `TargetPreCompLibLocation` takes precedence.

The following command sets the precompiled library folder for model `my_model` to folder `lib` under the current working folder.

```
set_param(my_model,'TargetPreCompLibLocation', fullfile(pwd,'lib'));
```

Note If you set both the target folder for the precompiled library files and a target library file suffix, the build process detects whether any precompiled library files are missing while processing builds.

3 Define a build specification.

Set up a structure that defines a build specification. The following table describes fields that you can define in the structure. These fields are optional, except for `rtwmakecfgDirs`.

Field	Description
`rtwmakecfgDirs`	A cell array of character vectors that name the folders containing `rtwmakecfg` files for libraries to be precompiled. The function uses the `Name` and `Location` elements of `makeInfo.library`, as returned by `rtwmakecfg`, to specify the name and location of the precompiled libraries. If you set the `TargetPreCompLibLocation` parameter to specify the library folder, that setting overrides the `makeInfo.library.Location` setting. **Note:** The specified model must contain blocks that use precompiled libraries specified by the `rtwmakecfg` files because the TMF-to-makefile conversion generates the library rules only if the build process uses the libraries.
`libSuffix`	A character vector that specifies the suffix, including the file type extension, to be appended to the name of each library (for example, `.a` or `_vc.lib`). The character vector must include a period (.). You must set the suffix with either this field or the `TargetLibSuffix` parameter. If you specify a suffix with both mechanisms, the `TargetLibSuffix` setting overrides the setting of this field.
`intOnlyBuild`	A Boolean flag. When set to true, the flag indicates the libraries are to be optimized such that they are compiled from integer code only. This field applies to ERT targets only.
`makeOpts`	A character vector that specifies an option to be included in the `rtwMake` command line.
`addLibs`	A cell array of structures that specify libraries to be built that are not specified by an `rtwmakecfg` function. Each structure must be defined with two fields that are character arrays: • `libName` — the name of the library without a suffix • `libLoc` — the location for the precompiled library The target makefile (TMF) can specify other libraries and how those libraries are built. Use this field to precompile those libraries.

The following commands set up build specification `build_spec`, which indicates that the files to be compiled are in folder `src` under the current working folder.

```
build_spec = [];
build_spec.rtwmakecfgDirs = {fullfile(pwd,'src')};
```

4 Issue a call to `rtw_precompile_libs`.

The call must specify the model for which you want to build the precompiled libraries and the build specification. For example:

```
rtw_precompile_libs(my_model,build_spec);
```

Generate Component Source Code for Export to External Code Base

In this section...

If you have Embedded Coder software, you can generate function source code from modeling components to use in an external code base. The generated code does not include supporting scheduling code (for example, a step function). Controlling logic outside of the Simulink environment invokes the generated function code.

Modeling Options

You can generate function code to export for these modeling components:

- Export-function models (model containing functional blocks that consist exclusively of function-call subsystems, function-call model blocks, or other export-function models, as described in “Export-Function Models” (Simulink))
- Export-function subsystems (virtual subsystem that contains function-call subsystems)

To export code that the code generator produces for these modeling components, the modeling components must meet specific requirements on page 53-65.

For models designed in earlier releases, the code generator can export functions from triggered subsystems. The requirements stated for export-function subsystems also apply to exporting functions from triggered subsystems, with the following exceptions:

- Encapsulate triggered subsystems from which you intend to export functions in a top-level virtual subsystem.

- Triggered subsystems do not have to meet requirements and limitations identified for virtual subsystems that contain function-call subsystem.
- "Export Functions That Use Absolute or Elapsed Time" on page 53-66 does not apply to exporting functions from triggered subsystems.

Requirements

- Model solver must be a fixed-step discrete solver.
- You must configure each root-level Inport block that triggers a function-call subsystem to output a function-call trigger. These Inport blocks cannot connect to an Asynchronous Task Specification block.
- Model or subsystem, must contain only the following blocks at the root level:
  - Function-call blocks (such as Function-Call Subsystem, Simulink Function, S-Functions, and Function-Call Model blocks at the root level if the solver parameter **Tasking and sample time options > Periodic sample time constraint** is set to `Ensure sample time independent`)
  - Inport and Outport blocks (ports)
  - Constant blocks (including blocks that resolve to constants, such as Add)
  - Blocks with a sample time of Inf
  - Merge and data store memory blocks
  - Virtual connection blocks (such as, Function-Call Split, Mux, Demux, Bus Creator, Bus Selector, Signal Specification, and virtual subsystems that contain these blocks)
  - Signal-viewer blocks, such as Scope blocks (export-function subsystems only)
- When a constant block appears at the top level of the model or subsystem, you must set the model configuration parameter **Optimization > Default parameter behavior** for the model or containing model to `Inlined`.
- Blocks inside the model or subsystem must support code generation.
- Blocks that use absolute or elapsed time must be inside a periodic function-call subsystem with a discrete sample time specified on the corresponding function-call root-level Inport block. See "Export Functions That Use Absolute or Elapsed Time" on page 53-66.
- Data signals that cross the boundary of an exported system cannot be a virtual bus and cannot be implemented as a Goto-From connection. Data signals that cross the export boundary must be scalar, muxed, or a nonvirtual bus.

In addition, for export-function models:

- Data logging and signal-viewer blocks, such as the Scope block, are not allowed at the root level or within the function-call blocks.
- You cannot generate code for a rate-based model that includes multiple instances of an export-function model. For example, you cannot generate code for a test harness model that you use for scheduling reusable export-function models during simulation.

For export-function subsystems, the following additional requirements apply:

- A trigger signal that crosses the boundary of an export-function subsystem must be scalar. Input and output data signals that do not act as triggers do not have to be scalar.
- When a constant signal drives an output port of an export-function subsystem, the signal must specify a storage class.

Export Functions That Use Absolute or Elapsed Time

If you want to export function code for a modeling component with blocks that use absolute or elapsed time, those blocks must be inside a function-call subsystem that:

- You configure for periodic execution
- You configure the root-level Inport block with a discrete sample time

To configure a function-call subsystem for periodic execution:

1. In the function-call subsystem, right-click the Trigger block and choose **Block Parameters** from the context menu.
2. In the **Sample time type** field, specify `periodic`.
3. Set the **Sample time** to the same granularity specified (directly or by inheritance) in the function-call initiator.
4. Click **OK** or **Apply**.

For more information, see “Absolute and Elapsed Time Computation” (Simulink Coder).

Limitations for Export-Function Subsystems

- Subsystem block parameters do not control the names of the files containing the generated code. The file names begin with the name of the exported subsystem.

- Subsystem block parameters do not control the names of top-level functions in the generated code. Each function name reflects the name of the signal that triggers the function or (for an unnamed signal) reflects the block from which the signal originates.
- You can export function-call systems for the C++ class code interface packaging only when its function specification is set to **Default step method**. See “Customize Generated C++ Class Interfaces” on page 39-35. The exported function is compatible with single-threaded execution. To avoid potential data race conditions for shared signals, invoke all members for the class from the same execution thread.
- The code generator supports a SIL or PIL block in accelerator mode only if its function-call initiator is noninlined in accelerator mode. Examples of noninlined initiators include Stateflow charts.
- A Level-2 S-function initiator block, such as a Stateflow chart or the built-in Function-Call Generator block, must drive a SIL block.
- You can export an asynchronous (sample-time) function-call system, but the software does not support the SIL or PIL block for an asynchronous system.
- The software does not support MAT-file logging for export-function subsystems. Specifications that enable MAT-file logging are ignored.
- The use of the TLC function `LibIsFirstInit` has been removed for export-function subsystems.

Workflow

To generate code for an exported function, iterate through the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	“Choose an External Code Integration Workflow” on page 53-4
2	Verify that the model or subsystem that you are exporting satisfies function exporting requirements.	“Requirements” on page 53-65
3	Address data interface requirements by modifying the model or subsystem.	“Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” on page 53-102

Task	Action	More Information
4	If necessary, configure function prototype.	“Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-24 and, for fixed-step rate-based models, “Customize Generated C Function Interfaces” on page 39-2 or “Customize Generated C++ Class Interfaces” on page 39-35
5	If necessary , update the model to place external application-specific code in generated system functions.	“Place External C/C++ Code in Generated Code” on page 53-39
6	Verify that the functions behave and perform as expected during simulation by creating and using a test harness model. The test harness model schedules execution of the functions during simulation.	“Configure Model, Generate Code, and Simulate” on page 47-2 and, if you have Simulink Test software, “Test Authoring” (Simulink Test)
7	Configure the model or subsystem for code generation.	“Generate Code Using Embedded Coder®”, “Generate Code That Matches Appearance of External Code” on page 53-118, and“Model Configuration”
8	Generate code and a code generation report.	“Code Generation”
9	Review the generated code interface and static code metrics.	“Analyze the Generated Code Interface” on page 49-20 and “Static Code Metrics” on page 49-34
10	Build an executable program that includes the exported function code.	“Build Integrated Code Outside the Simulink Environment” on page 53-95
11	Verify that executable program behaves and performs as expected.	

Choose an Integration Approach

Multiple approaches are available for generating function code for export to an external development environment. The following table compares approaches. Choose the approach that aligns best with your integration requirements. For more information on

how to create export-function models, see “Export-Function Models” (Simulink). For more information on generating code for function call subsystems, see “Generate Component Source Code for Export to External Code Base” on page 53-64.

Generate C Function Code for Export-Function Model

This example shows how to generate function code for individual Simulink function blocks and function-call subsystems in a model without generating scheduling code.

To generate function code for export:

1. Create a model that contains the functions for export.
2. Create a test harness model that schedules execution of the functions during simulation.
3. Simulate the model that contains the functions by using the test harness model.

4 Generate code for the model that contains the functions.

Create Model That Contains Functions for Export

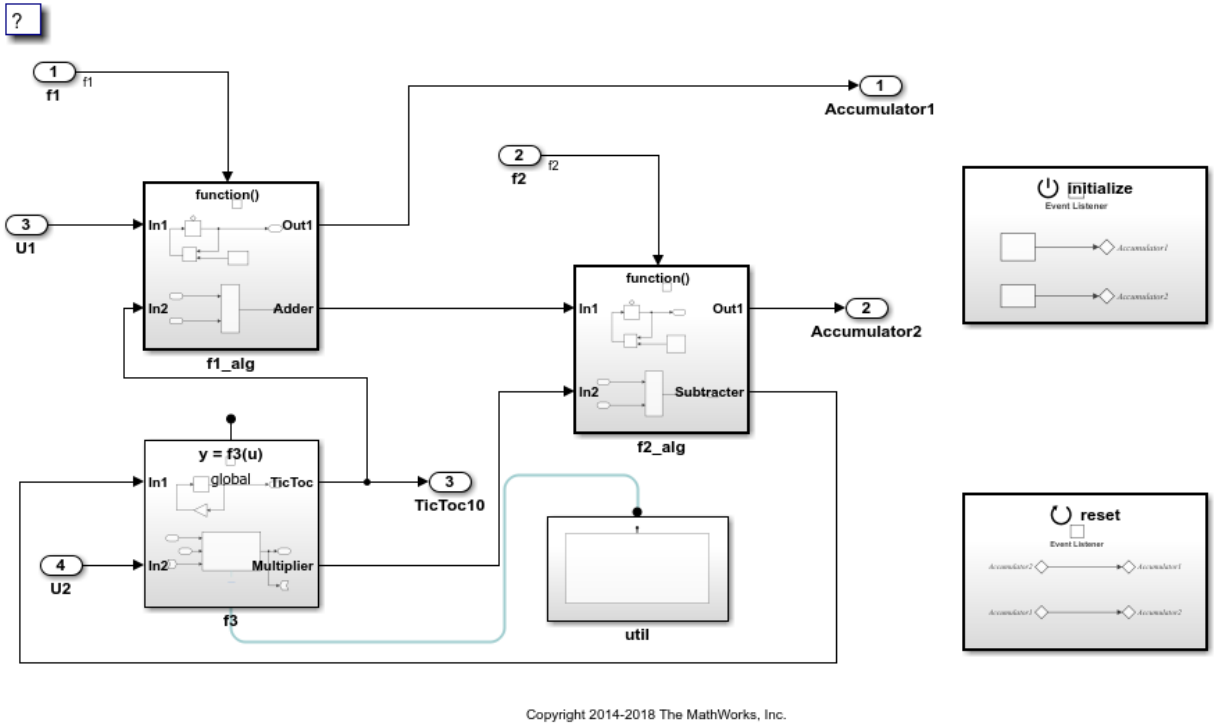
The model with functions for export must satisfy architectural constraints at the model root level. At the root level, valid blocks are:

- Inport
- Outport
- Function-Call Subsystem
- Simulink Function
- Goto
- From
- Merge

The code generator produces function code for Function-Call Subsystem and Simulink Function blocks and Initialize and Reset Function blocks. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives. A Simulink Function block is executed in response to the execution of a corresponding Function Caller block or Stateflow chart. An Initialize Function block is executed on a model initialize event and a Reset Function block is executed on a user-defined reset event.

For exporting functions, model `rtwdemo_functions` contains two function-call subsystems (`f1_alg` and `f2_alg`) and a Simulink Function block (`f3`) for exporting functions. The model also contains an Initialize Function block (`Initialize Function`) and a Reset Function block (`Reset Function`). To calculate initial conditions for blocks with state in other parts of the model, the State Writer blocks are used inside the Initialize and Reset Function blocks.

```
open_system('rtwdemo_functions')
```



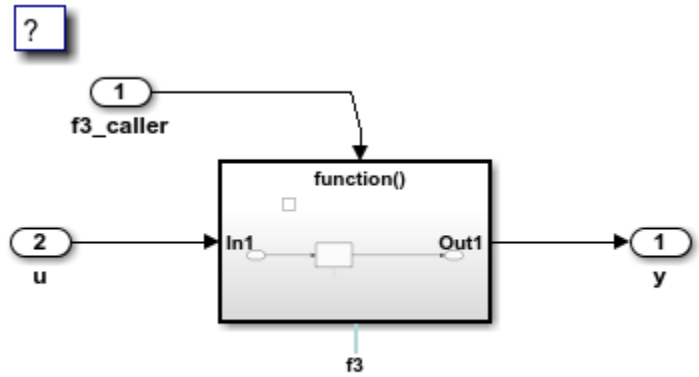
Create Model That Contains Function Caller Block

Use a Function Caller block to invoke a Simulink Function block. The Function Caller block can be in the same model or in a different model as the Simulink Function block.

Multiple Function Caller blocks can invoke a Simulink Function block. You can place the Function Caller block inside a function-call subsystem. During code generation, the code generator exports a function from the function-call subsystem.

The model `rtwdemo_caller` exports a function-call subsystem that contains a Function Caller block.

```
open_system('rtwdemo_caller')
```



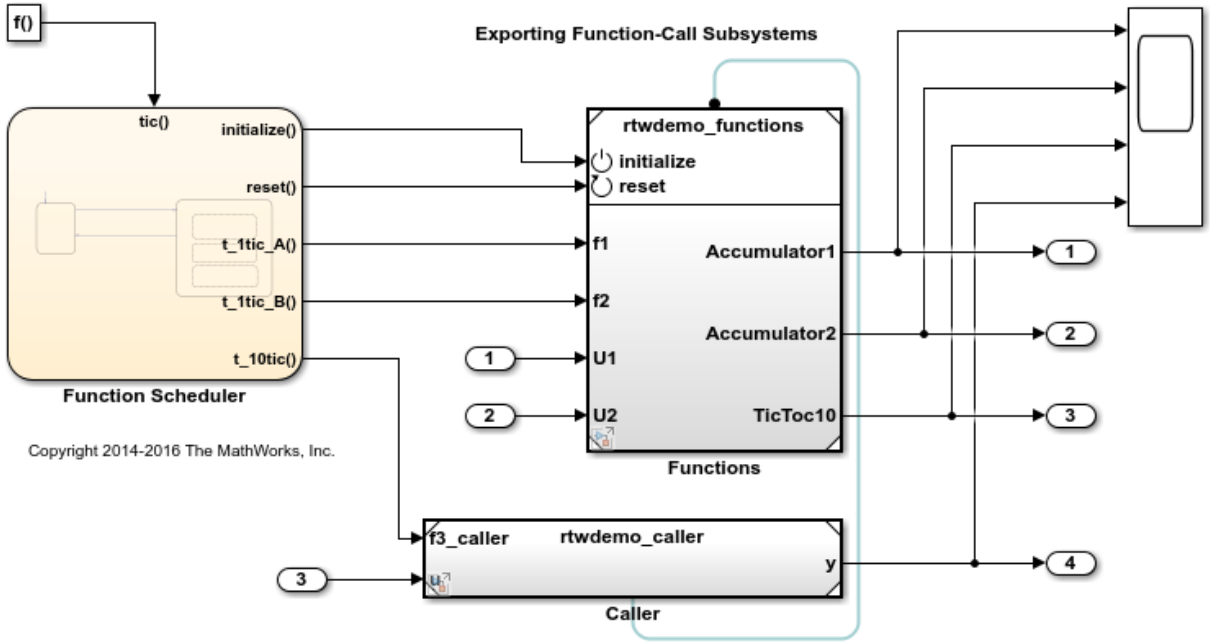
Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_export_functions` is a test harness. The model:

- Schedules the Simulink Function block with the Function Caller block in `rtwdemo_caller`.
- Provides function-call signals to other models in this example to schedule the model contents, including the model initialize and reset events.

```
open_system('rtwdemo_export_functions')
```



Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_export_functions`.

```
sim('rtwdemo_export_functions')
```

Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_functions`.

```
rtwbuild('rtwdemo_functions')
```

```
### Starting build procedure for model: rtwdemo_functions
### Successful completion of code generation for model: rtwdemo_functions
```

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_functions.c` calls the initialization function, including `Initialize Function`, and exported functions for model components `f1_alg`, `f2_alg`, and `f3`.
- `rtwdemo_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `f3.h` is a shared file that declares the call interface for the Simulink function `f3`.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

1. Include the generated header files by adding directives `#include rtwdemo_functions.h`, `#include f3.h`, and `#include rtwtypes.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.U1` of type `real_T` with dimension 1
- `rtU.U2` of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_functions_initialize(void)`. At startup, call this function once.
- Reset entry-point function, `void rtwdemo_functions_reset(void)`. Call this function as needed.
- Exported function, `void f1(void)`. Call this function as needed.
- Exported function, `void f2(void)`. Call this function as needed.
- Simulink function, `void f3(real_T rtu_u, real_T *rty_y)`. Call this function as needed.

Output ports:

- `rtY.Accumulator1` of type `int8_T` with dimension [2]
- `rtY.Accumulator2` of type `int8_T` with dimension [2]
- `rtY.TicToc10` of type `int8_T` with dimension 1

Close Example Models

```
bdclose('rtwdemo_export_functions')
bdclose('rtwdemo_functions')
bdclose('rtwdemo_caller')
```

Generate C++ Function and Class Code for Export-Function Model

This example shows how to generate function code for an export-function model that includes a function-call subsystem. The code generator produces function and class code that does not include scheduling code.

To generate function code for export:

1. Create a model that contains the functions for export.
2. Create a test harness model that schedules execution of the functions during simulation.
3. Simulate the model that contains the functions by using the test harness model.
4. Generate code for the model that contains the functions.

Create Model That Contains Functions and C++ Class Interface for Export

The model with functions for export with a C++ model class interface must satisfy architectural constraints at the model root level. For C++ class generation, blocks that are valid at the root level are:

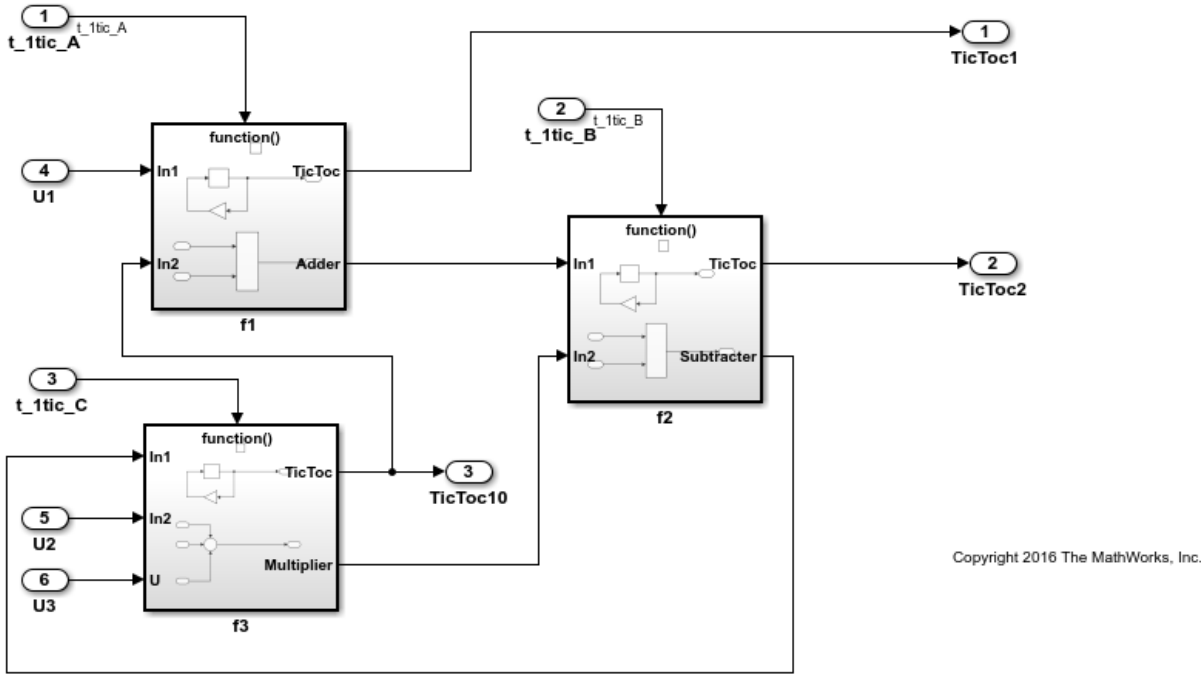
- Inport
- Outport
- Function-Call Subsystem
- Goto
- From
- Merge

Note: Export Function-Call Subsystem with C++ class interface does not support Simulink Function blocks.

The code generator produces function code for the Function-Call Subsystem block. For a Function-call Subsystem block, you connect the block input ports to root Inport blocks that assert function-call signals. The subsystem is executed based on the function-call signal that it receives.

Model `rtwdemo_cppclass_functions` contains function-call subsystems `f1`, `f2`, and `f3` for exporting functions.

```
open_system('rtwdemo_cppclass_functions')
```

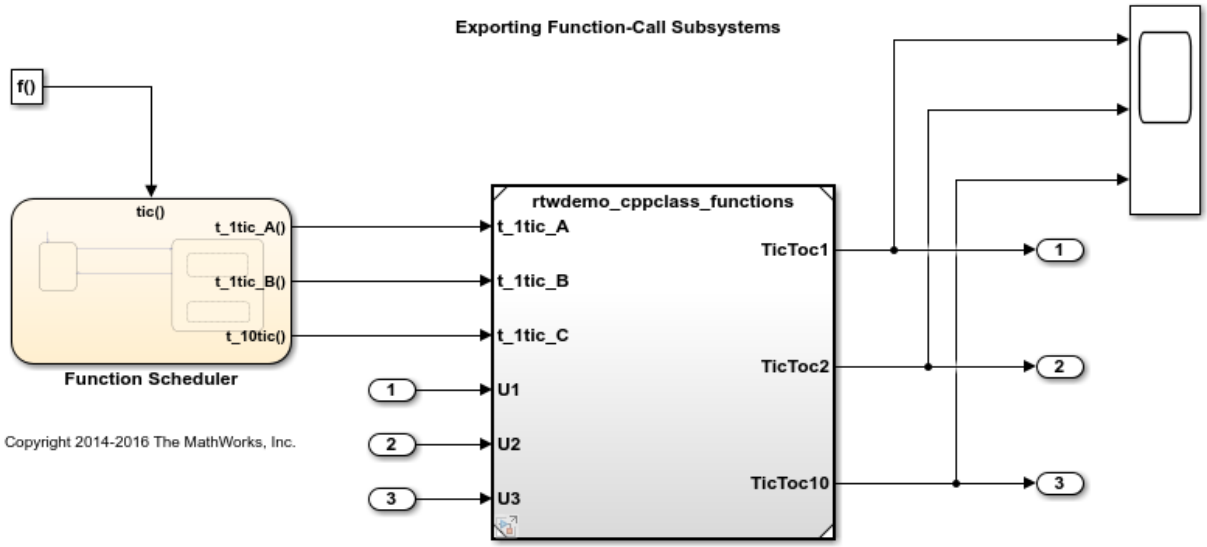


Create Test Harness Model for Simulation

When you export functions, the generated code does not include a scheduler. Create a test harness model to handle scheduling during simulation. Do not use the test harness model to generate code that you deploy.

Model `rtwdemo_cppclass_export_functions` is a test harness. The model provides function-call signals to other models in this example to schedule the model contents.

```
open_system('rtwdemo_cppclass_export_functions')
```



Simulate the Test Harness Model

Verify that the model containing the functions that you want to export is executed as you expect by simulating the test harness model. For example, simulate `rtwdemo_cppclass_export_functions`.

```
sim('rtwdemo_cppclass_export_functions')
```

Generate Function Code and Report

Generate code and a code generation report for the functions that you want to export. For example, generate code for `rtwdemo_cppclass_functions`.

```
rtwbuild('rtwdemo_cppclass_functions')
```

```
### Starting build procedure for model: rtwdemo_cppclass_functions
### Successful completion of build procedure for model: rtwdemo_cppclass_functions
```

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.cpp` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize and execute the generated code.
- `rtwdemo_cppclass_functions.cpp` calls the initialization function, including `Initialize Function`, and exported functions for model subsystem components `f1`, `f2`, and `f3`.
- `rtwdemo_cppclass_functions.h` declares model data structures and a public interface to the exported entry-point functions and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Write Interface Code

Open and review the Code Interface Report. To write the interface code for your execution framework, use the information in that report.

1. Include the generated header files by adding directives `#include rtwdemo_cppclass_functions.h` and `#include rtwtypes.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.U1` of type `real_T` with dimension 1
- `rtU.U2` of type `real_T` with dimension 1
- `rtU.U3` of type `real_T` with dimension 1

Entry-point functions:

- Initialize entry-point function, `void initialize(void)`. At startup, call this function once.
- Exported function, `void t_1tic_A(void)`. Call this function as needed.
- Exported function, `void t_1tic_B(void)`. Call this function as needed.
- Exported function, `void t_1tic_C(void)`. Call this function as needed.

Output ports:

- `rtY.TicToc1` of type `int8_T` with dimension [2]
- `rtY.TicToc2` of type `int8_T` with dimension [2]
- `rtY.TicToc10` of type `int8_T` with dimension 1

Generate Code for Export-Function Subsystems

- “Specify a Custom Initialize Function Name” on page 53-82
- “Specify a Custom Description” on page 53-82
- “Optimize Code Generated for Export-Function Subsystems” on page 53-83

To generate code for an export-function subsystem:

1. Verify that the subsystem for which you are generating code satisfies exporting requirements on page 53-65.
2. In the Configuration Parameters dialog box:
   a. On the **Code Generation** pane, specify an ERT-based system target file, such as `ert.tlc`.
   b. If you want a SIL block with the generated code, for verification purposes, from the **Configuration Parameters** > **Code Generation** > **Verification** > **Advanced parameters** > **Create block** drop-down list, select `SIL`.
   c. Click **OK** or **Apply**.
3. Right-click the subsystem block and choose **C/C++ Code > Export Functions** from the context menu.

The operation creates a new model, *subsystem*.slx, that contains the content of the original subsystem and creates a ScratchModel that contains a Model block. This block references the newly created *subsystem*.slx model.

The **Build code for subsystem: *Subsystem*** dialog box opens. This dialog box is not specific to export-function subsystems. Generating code does not require entering information in the dialog box.

4 Click **Build** to build the newly created *subsystem*.slx model.

The code generator produces code and places it in the working folder.

If you set **Create block** to SIL in step 2b, Simulink opens a new window that contains an S-function block that represents the generated code. This block has the same size, shape, and connectors as the original subsystem.

Code generation and optional block creation are now complete. You can test and use the code and optional block as you do for generated ERT code and S-function block. For optional workflow tasks, see “Specify a Custom Initialize Function Name” on page 53-82 and “Specify a Custom Description” on page 53-82.

Specify a Custom Initialize Function Name

You can specify a custom name for the initialize function of your exported function as an argument to the rtwbuild command. The command takes the following form:

```
blockHandle = rtwbuild('subsystem', 'Mode', 'ExportFunctionCalls',..
            'ExportFunctionInitializeFunctionName', 'fcnname')
```

fcnname specifies the function name. For example, if you specify the name 'myinitfcn', the build process emits code similar to:

```
/* Model initialize function */
void myinitfcn(void){
...
}
```

Specify a Custom Description

You can enter a custom description for an exported function by using the Block Properties dialog box of an Inport block.

1 Right-click the Inport block that drives the control port of the subsystem for which you are exporting code.

2. Select **Properties**.
3. In the **General** tab, in the **Description** field, enter your descriptive text.

During function export, the text you enter is emitted to the generated code in the header for the Inport block. For example, if you open the example program `rtwdemo_exporting_functions` and enter a description in the Block Properties dialog box for port `t_1tic_A`, the code generator produces code that is similar to:

```
/*
 * Output and update for exported function: t_1tic_A
 *
 *  My custom description of the exported function
*/
void t_1tic_A(void)
{
...
}
```

Optimize Code Generated for Export-Function Subsystems

To optimize the code generated for an export-function subsystem, specify a separate storage class for each input signal and output signal that crosses the boundary of the subsystem.

For each function-call subsystem that you are exporting:

1. Right-click the subsystem.
2. From the context menu, choose **Block Parameters (Subsystem)**.
3. Select the **Code Generation** tab.
4. Set **Function packaging** to `Auto`.
5. Click **OK** or **Apply**.

Generate Shared Library for Export to External Code Base

In this section...

About Generated Shared Libraries

If you have Embedded Coder software, you can generate a shared library—Windows dynamic link library (`.dll`), UNIX shared object (`.so`), or Macintosh OS X dynamic library (`.dylib`)— from a model component. You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. Uses of shared libraries include:

- Adding a software component to an application for system simulation
- Reusing software modules among applications on a development computer
- Hiding intellectual property associated with software that you share with vendors

When producing a shared library, the code generator exports:

- Variables and signals of type `ExportedGlobal` as data
- Real-time model structure (*`model`*`_M`) as data
- Functions essential to executing the model code

Workflow

To generate a shared library from a model component and use the library, complete the tasks listed in this table.

Task	Action	More Information
1	Review your assessment of external code characteristics and integration requirements.	• "Choose an External Code Integration Workflow" on page 53-4 • "Shared Library Limitations" on page 61-7
2	Configure the model for code generation.	"Generate Code That Matches Appearance of External Code" on page 53-118 and "Model Configuration"
3	Configure the model for the code generator to produce a shared library and initiate code generation.	"Generate Shared Libraries" on page 53-86
4	Verify that the generated shared library meets requirements. For example, review the code generation report and view the list of symbols in the library. • On Windows, use the Dependency Walker utility, downloadable from www.dependencywalker.com • On UNIX, use `nm -D model.so` • On Macintosh OS X, use `nm -g model.dylib`	
5	Use the shared library in application code.	"Create Application Code That Uses Generated Shared Libraries" on page 53-87
6	Compile and link application code that loads and uses the generated shared library.	"Build Integrated Code Outside the Simulink Environment" on page 53-95
7	Verify that executable program behaves and performs as expected.	

Generate Shared Libraries

1 When configuring the model for code generation, select the system target file `ert_shrlib.tlc`.

2 Build the model. The code generator produces source code for the model and a shared library version of the code. The code generator places the source code in the code generation folder and the shared library (`.dll`, `.so`, or `.dylib` file) in your current working folder. The code generator also produces and retains a `.lib` file to support implicit linking.

Create Application Code That Uses Generated Shared Libraries

This example application code is generated for the example “Interface to a Development Computer Simulator By Using a Shared Library” on page 53-92.

1 Create an application header file that contains type declarations for model external input and output. For example:

```
#ifndef _APP_MAIN_HEADER_
#define _APP_MAIN_HEADER_

typedef struct {
    int32_T Input;
} ExternalInputs_rtwdemo_shrlib;

typedef struct {
    int32_T Output;
} ExternalOutputs_rtwdemo_shrlib;

#endif /*_APP_MAIN_HEADER_*/
```

2 In the application C source code, dynamically load the shared library. Use preprocessing conditional statements to invoke platform-specific commands. For example:

```
#if (defined(_WIN32)||defined(_WIN64)) /* WINDOWS */
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#else /* UNIX */
#include <dlfcn.h>
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose
```

```
#endif

int main()
{
    void* handleLib;
...
#if defined(_WIN64)
    handleLib = LOADLIB("./rtwdemo_shrlib_win64.dll");
#else #if defined(_WIN32)
    handleLib = LOADLIB("./rtwdemo_shrlib_win32.dll");
#else /* UNIX */
    handleLib = LOADLIB("./rtwdemo_shrlib.so", RTLD_LAZY);
#endif
#endif
...
    return(CLOSELIB(handleLib));
}
```

3 From the application C source code, access exported data and functions generated from the model. The code uses hooks to add user-defined initialization, step, and termination code.

```
   int32_T i;
 ...
    void (*mdl_initialize)(boolean_T);
    void (*mdl_step)(void);
    void (*mdl_terminate)(void);

    ExternalInputs_rtwdemo_shrlib (*mdl_Uptr);
    ExternalOutputs_rtwdemo_shrlib (*mdl_Yptr);

    uint8_T (*sum_outptr);
...
#if (defined(LCCDLL)||defined(BORLANDCDLL))
    /* Exported symbols contain leading underscores
       when DLL is linked with LCC or BORLANDC */
    mdl_initialize =
        (void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
        "_rtwdemo_shrlib_initialize");
    mdl_step =
        (void(*)(void))GETSYMBOLADDR(handleLib ,
        "_rtwdemo_shrlib_step");
    mdl_terminate =
        (void(*)(void))GETSYMBOLADDR(handleLib ,
```

```
        "_rtwdemo_shrlib_terminate");
    mdl_Uptr =
        (ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
        "_rtwdemo_shrlib_U");
    mdl_Yptr =
        (ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
        "_rtwdemo_shrlib_Y");
    sum_outptr =
        (uint8_T*)GETSYMBOLADDR(handleLib , "_sum_out");
#else
    mdl_initialize =
        (void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
        "rtwdemo_shrlib_initialize");
    mdl_step =
        (void(*)(void))GETSYMBOLADDR(handleLib ,
        "rtwdemo_shrlib_step");
    mdl_terminate  =
        (void(*)(void))GETSYMBOLADDR(handleLib ,
        "rtwdemo_shrlib_terminate");
    mdl_Uptr =
        (ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
        "rtwdemo_shrlib_U");
    mdl_Yptr =
        (ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
        "rtwdemo_shrlib_Y");
    sum_outptr =
        (uint8_T*)GETSYMBOLADDR(handleLib , "sum_out");
#endif

    if ((mdl_initialize &&
         mdl_step &&
         mdl_terminate &&
         mdl_Uptr &&
         mdl_Yptr &&
         sum_outptr)) {
        /* user application
           initialization function */
        mdl_initialize(1);
        /* insert other user defined
           application initialization code here */

        /* user application
           step function */
        for(i=0;i<=12;i++){
```

```
            mdl_Uptr->Input = i;
            mdl_step();
            printf("Counter out(sum_out):
                   %d\tAmplifier in(Input):
                   %d\tout(Output):
                   %d\n", *sum_outptr, i,
                   mdl_Yptr->Output);
            /* insert other user defined
               application step function
               code here */
        }

        /* user application
           terminate function */
        mdl_terminate();
        /* insert other user defined
           application termination
           code here */
    }
    else {
        printf("Cannot locate the specified
                reference(s) in the shared library.\n");
        return(-1);
    }
```

Limitations

- Code generation for the `ert_shrlib.tlc` system target file exports the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (*`model`*_M)
- Code generation for the `ert_shrlib.tlc` system target file supports the C language only (not C++). When you select `ert_shrlib.tlc`, language selection is unavailable on the **Code Generation** pane in the Configuration Parameters dialog box.
- To reconstruct a model simulation by using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing must be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables model configuration parameters **Support: continuous time** and **Single output/update function**. For more information, see Single output/update function (Simulink Coder) dependencies.

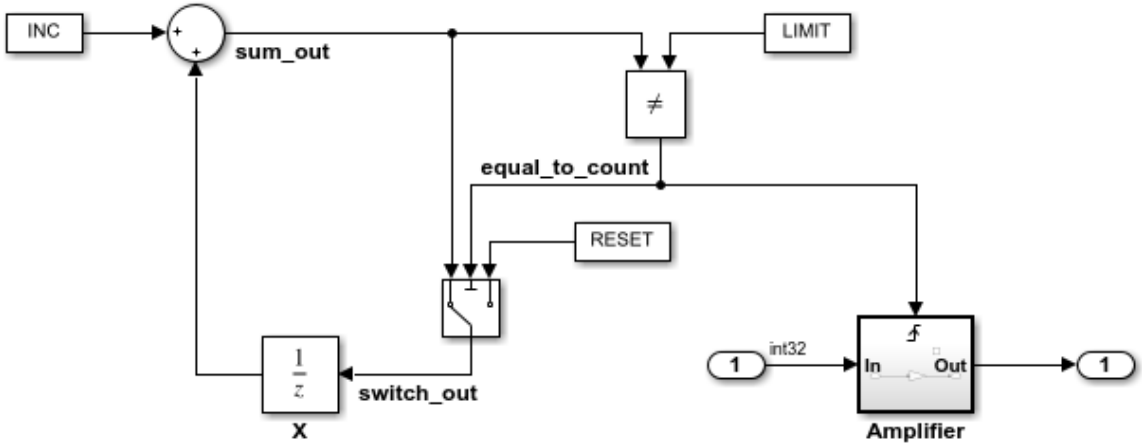
Interface to a Development Computer Simulator By Using a Shared Library

This example generates a shared library for interfacing to a simulator that runs on your development computer. Generate the shared library by using the system target file `ert_shrlib.tlc`.

To build a shared library from the model and use the library in an application:

1. Develop your model. For this example, open the model `rtwdemo_shrlib`.

```
open_system('rtwdemo_shrlib');
```



The model is a single-rate, discrete-time model. An 8-bit counter feeds the triggered subsystem named `Amplifier`. Parameters `INC`, `LIMIT`, and `RESET` are set to constant

values 1, 4, and 0, respectively. When signal `equal_to_count` is true, the subsystem amplifies its input signal by a gain factor `K=3` and the output signal is updated.

2. Configure the model for code generation, specifying `ert_shrlib.tlc` as the system target file. Click the yellow button on the model to view the configuration settings on the **Code Generation** pane in the Configuration Parameters dialog box.

3. Build the shared library file. The file that the code generator produces depends on your development platform. For example, on a Windows system, the code generator produces the library file `rtwdemo_shrlib_win64.dll`.

4. Create application code that uses the shared library. This example uses application code that is available in these files:

```
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.h
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\rtwdemo_shrlib_app.c
```

To view the source code in these files, in the model, click the white buttons for the `.h` and `.c` files.

5. Compile and link the file application and shared library files to produce an executable program. The following script compiles, builds, and runs the program.

```
matlabroot\toolbox\rtw\rtwdemos\shrlib_demo\run_rtwdemo_shrlib_app.m
```

To view the script code, in the model, click the white button for the `.m` file.

To build the model and run the application that uses the generated shared library, in the model, double-click the blue button.

For more information about using a shared library, see “Package Generated Code as Shared Libraries” on page 61-2.

More About

- “Generate Shared Library for Export to External Code Base” on page 53-85

Build Integrated Code Outside the Simulink Environment

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

- Collect files required for building integrated code outside of Simulink®.
- Interface with external variables and functions.

For information about the example model and related examples, see “Generate C Code from a Control Algorithm for an Embedded System”.

Collect and Build Required Data and Files

The code that Embedded Coder® generates requires support files that MathWorks® provides. To relocate the generated code to another development environment, such as a dedicated build system, you must relocate these support files. You can package these files in a zip file by using the `packNGo` utility. This utility finds and packages the files that you need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a `buildinfo_data` structure, and a `packNGo` function. These files include external files that you identify in the **Code Generation > Custom Code** pane in the Model Configuration Parameters dialog box. The utility saves the `buildinfo` MAT-file in the *`model`*`_ert_rtw` folder.

Open the example model, `rtwdemo_PCG_Eval_P5`.

This model is configured to run `packNGo` after code generation.

Generate code from the entire model.

To generate the zip file manually:

1. Load the file `buildInfo.mat` (located in the `rtwdemo_PCG_Eval_P5_ert_rtw` subfolder).
2. At the command prompt, enter the command `packNGo(buildInfo)`.

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler might require a subset of the files in the zip file. The compiled executable size (RAM/ROM) depends on the linking process. The linker likely includes only the object files that are necessary.

Integrating the Generated Code into an Existing System

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to integration environments.

Overview of Integration Environment

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O
- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View `example_main.c`.

```
int_T main(void)
{
  /* Initialize model */
  rt_Pos_Command_Arbitration_Init(); /* Set up the data structures for chart*/
  rtwdemo_PCG__Define_Throt_Param(); /* SubSystem: '<Root>/Define_Throt_Param' */
  defineImportData();                /* Defines the memory and values of inputs */

  do /* This is the "Schedule" loop.
      Functions would be called based on a scheduling algorithm */
  {
    /* HARDWARE I/O */

    /* Call control algorithms */
    PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                      &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
    PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                      &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
    pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
    pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

    rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                    &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

The file:

- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines `extern` data.
- Initializes data.
- Calls simulated hardware.
- Calls algorithmic functions.

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.

Match System Interfaces

Integration requires matching the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

Connect Input Data

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically comes from other software components or from hardware devices.

View `defineImportedData.c`.

```
/* Define imported data */
#include "rtwtypes.h"
#include "defineImportedData.h"

real_T fbk_1;
real_T fbk_2;
real_T dummy_pos_value = 10.0;
real_T *pos_rqst;
void defineImportData(void)
{
    pos_rqst = &dummy_pos_value;
}
```

View `rtwdemo_PCG_Eval_P5_Private.h`.

```
/* Imported (extern) block signals */
extern real_T fbk_1;                   /* '<Root>/fbk_1' */
extern real_T fbk_2;                   /* '<Root>/fbk_2' */

/* Imported (extern) pointer block signals */
extern real_T *pos_rqst;               /* '<Root>/pos_rqst' */
```

Connect Output Data

In this example, you do not access the output data of the system. The example “Test Generated Code” shows how you can save the output data to a standard log file. You can access the output data by referring to the file `rtwdemo_PCG_Eval_P5.h`.

View `rtwdemo_PCG_Eval_P5.h`.

Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time

The table lists the common data structures. Depending on the configuration of the model, a combination of these structures appear in the generated code. The data is declared in the file `rtwdemo_PCG_Eval_P5.h`, but in this example, you do not access this data.

```
Data Type      Data Name     Data Purpose

Constants      |model_cP|    Constant parameters
Constants      |model_cB|    Constant block I/O
Output         |model_U|     Root and atomic subsystem input
Output         |model_Y|     Root and atomic subsystem output
Internal data  |model_B|     Value of block output
Internal data  |model_D|     State information vectors
Internal data  |model_M|     Time and other system level data
Internal data  |model_Zero|  Zero-crossings
Parameters     |model_P|     Parameters
```

Match Function Call Interfaces

By default, functions that the code generator generates have a `void` *`Func`*`(void)` interface. If you configure the model or atomic subsystem to generate reentrant code, the

code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with valid input arguments.

```
PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                  &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                  &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCG_Eval_P5.h`.

Build Project in Eclipse™ Environment

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:

- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3
- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse”.

You can install the files for this example by clicking this hyperlink:

Set up the build folder.

Alternatively, to install the files manually:

1. Create a build folder (`Eclipse_Build_P5`).
2. Unzip the file `rtwdemo_PCG_Eval_P5.zip` into the build folder.
3. Delete the files `rtwdemo_PCG_Eval_P5.c`, `ert_main.c` and `rt_logging.c`, which are replaced by `example_main.c`.

You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example “Install and Use Cygwin and Eclipse”.

To exercise the model with input data, see “Test Generated Code”.

Exchange Data Between External C/C++ Code and Simulink Model or Generated Code

Whether you import your external code into a Simulink model (for example, by using the Legacy Code Tool) or export the generated code to an external environment, the model or the generated code typically exchange data (signals, states, and parameters) with your code.

Functions in C or C++ code, including your external functions, can exchange data with a caller or a called function through:

- Arguments (formal parameters) of functions. When a function exchanges data through arguments, an application can call the function multiple times. Each instance of the called function can manipulate its own independent set of data so that the instances do not interfere with each other.
- Direct access to global variables. Global variables can:
  - Enable different algorithms (functions) and instances of the same algorithm to share data such as calibration parameters and error status.
  - Enable the different rates (functions) of a multitasking system to exchange data.
  - Enable different algorithms to exchange data asynchronously.

In Simulink, you can organize and configure data so that a model uses these exchange mechanisms to provide, extract, and share data with your code.

Before you attempt to match data interfaces, to choose an overall integration approach, see “Choose an External Code Integration Workflow” on page 53-4.

Import External Code into Model

To exchange data between your model and your external function, choose an exchange mechanism based on the technique that you chose to integrate the function.

- To exchange data through the arguments of your external function, construct and configure your model to create and package the data according to the data types of the arguments. Then, you connect and configure the block that calls or represents your function to accept, produce, or refer to the data from the model.

  For example, if you use the Legacy Code Tool to generate an S-Function block that calls your function, the ports and parameters of the block correspond to the

arguments of the function. You connect the output signals of upstream blocks to the input ports and set parameter values in the block mask. Then, you can create signal lines from the output ports of the block and connect those signals to downstream blocks.

- To exchange data through global variables that your external code already defines, a best practice is to use a Stateflow chart to call your function and to access the variables. You write algorithmic C code in the chart so that during simulation or execution of the generated code, the model reads and writes to the variables.

  To use such a global variable as an item of parameter data (not signal or state data) elsewhere in a model, you can create a numeric MATLAB variable or `Simulink.Parameter` object that represents the variable. If you change the value of the C-code variable in between simulation runs, you must manually synchronize the value of the Simulink variable or object. If your algorithmic code (function) changes the value of the C-code variable during simulation, the corresponding Simulink variable or object does not change.

  If you choose to create a Simulink representation of the C-code variable, you can configure the Simulink representation so that the generated code reads and writes to the variable but does not duplicate the variable definition. Apply a storage class to the Simulink representation.

Technique for Integrating External Function	Mechanism to Exchange Data with Model	Examples and More Information
S-Function block	Function arguments	To call your function through an S-function that you create by using the Legacy Code Tool, see “Integrate C Functions into Simulink Models with Legacy Code Tool” (Simulink).
Stateflow chart	Function arguments and direct access to global variables	To call your function and access global variables in a Stateflow chart, see “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow). For information about creating data items in a chart (which you can pass to your function as arguments), see “Add Stateflow Data” (Stateflow).

Technique for Integrating External Function	Mechanism to Exchange Data with Model	Examples and More Information
`coder.ceval` in MATLAB Function block	Function arguments	To call your function in a MATLAB Function block by using `coder.ceval`, see “Integrate C Code Using the MATLAB Function Block” (Simulink). For information about creating data items in a MATLAB Function block (which you can pass to your function as arguments), see “Ports and Data Manager” (Simulink).

Export Generated Code to External Environment

To export the generated code into your external code, see “Exchange Data Between External Calling Code and Generated Code” (Simulink Coder).

Simulink Representations of C Data Types and Constructs

To model and reuse your custom C data such as structures, enumerations, and `typedef` aliases, use the information in these tables.

Modeling Patterns for Matching Data in External C Code

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Primitive type alias (`typedef`)	`typedef float mySinglePrec_T;`	Create a `Simulink.AliasType` object. Use the object to: • Set the data types of signals and block parameters in a model. • Configure data type replacements for code generation. Generating code that uses an alias data type requires Embedded Coder.	For information about defining custom data types for your model, see `Simulink.AliasType` and "Control Data Type Names in Generated Code" on page 34-2. For an example that shows how to export the generated code into your external code, see "Replace and Rename Data Types to Conform to Coding Standards" on page 34-27.

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Array	`int myArray[6];`	Specify signal and parameter dimensions as described in “Signal Dimensions” (Simulink). The generated code defines and accesses multidimensional data, including matrices, as column-major serialized vectors. If your external code uses a different format, consider using alternative techniques to integrate the generated code. See “Code Generation of Matrices and Arrays” on page 47-80.	For information about how the generated code stores nonscalar data (including limitations), see “Code Generation of Matrices and Arrays” (Simulink Coder). For an example that shows how to export the generated code into your external code, see “Reuse Parameter Data from External Code in the Generated Code” on page 36-11. To model lookup tables, see `Simulink.LookupTable`.

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information

Enumeration	`typedef enum myColorsType {`
	`  Red = 0,`
	`  Yellow,`
	`  Blue`
	`} myColorsType;`
		Define a Simulink enumeration that corresponds to your enumeration definition. Use the Simulink enumeration to set data types in a model.	To use enumerated data in a Simulink model, see “Use Enumerated Data in Simulink Models” (Simulink).
			
			For an example that shows how to generate enumerated parameter data, see “Enumeration” on page 24-25.
			
			For an example that shows how to export the generated code into your external code by exchanging enumerated data, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 34-34.

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information

Structure	`typedef struct myStructType {`
	`  int count;`
	`  double coeff;`
	`} myStructType;`
		Create a `Simulink.Bus` object that corresponds to your structure type.
		
		To create structured signal or state data, package multiple signal lines in a model into a single nonvirtual bus signal.
		
		To create structured parameter data, create a parameter object (such as `Simulink.Parameter`) that stores a MATLAB structure. Use the bus object as the data type of the parameter object.
		
		To package lookup table data into a structure, use `Simulink.LookupTable` and, optionally, `Simulink.Breakpoint` objects.
			For information about bus signals, see "Getting Started with Buses" (Simulink). For information about structures of parameters, see "Organize Related Block Parameter Definitions in Structures" (Simulink).
			
			For an example that shows how to import your external code into a model by using the Legacy Code Tool, see "Integrate C Function Whose Arguments Are Pointers to Structures" (Simulink).
			
			For examples that show how to export the generated code into your external code, see "Exchange Structured and Enumerated Data Between Generated and External Code" on page 34-34 and "Access Structured Data Through a Pointer That External

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
			Code Defines” on page 36-21. To package lookup table data into a structure, `Simulink.LookupTable`. For general information about creating structures in the generated code, see “Organize Data into Structures in Generated Code” (Simulink Coder).

Additional Modeling Patterns for Code Generation (Embedded Coder)

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information
Macro	`#define myParam 9.8`	Apply the custom storage classes `Define` and `ImportedDefine` to parameters. With macros, you can reuse a parameter value in multiple locations in an algorithm and change the parameter value between code compilations without consuming memory to store the value. Typically, macros represent engineering constants that you do not expect to change during code execution. This technique requires Embedded Coder.	"Macro Definitions (#define)" on page 24-69
Storage type qualifiers such as `const` and `volatile`	`const myParam = 9.8;`	Apply the custom storage classes `Const`, `Volatile`, and `ConstVolatile` to data items.	"Protect Global Data with Keywords const and volatile" (Simulink Coder)

C Data Type or Construct	Example C Code	Simulink Equivalent	More Information

Bit field	`typedef struct myBitField {`
	`  unsigned short int MODE : 1;`
	`  unsigned short int FAIL : 1;`
	`  unsigned short int OK : 1;`
	`} myBitField`
		• Apply the custom storage class `BitField` to signals, states, and parameters whose data type is `boolean`.
		• Use a model configuration parameter to aggregate Boolean data into bit fields.
		
		These techniques require Embedded Coder.
			"Bitfields" on page 24-87
			
			"Optimize Generated Code By Packing Boolean Data Into Bitfields" on page 71-12

Call to custom external function that reads or writes to data	External code:
	
	`/* Call this function`
	`to acquire the value of`
	`the signal. */`
	`double get_inSig(void)`
	`{`
	`  return myBigGlobalStruct.inSig;`
	`}`
	
	Generated algorithmic code:
	
	`algorithmInput = get_inSig();`
		Apply the custom storage class `GetSet` to signals, states, and parameters. Each data item appears in the generated code as a call to your custom functions that read and write to the target data.
		
		This technique requires Embedded Coder.
			"Access Data Through Functions with Custom Storage Class GetSet" on page 36-51

Considerations for Other Modeling Goals

Goal	Considerations and More Information
Use Simulink to run and interact with the generated code	You can use SIL, PIL, and external mode simulations to connect your model to the corresponding generated application for simulation. When you import parameter data from your external code: • At the time that you begin an external mode simulation, the external executable uses the value that your code uses to initialize the parameter data. However, when you change the corresponding value in Simulink during the simulation (for example by modifying the `Value` property of the corresponding parameter object), Simulink downloads the new value to the executable. • SIL and PIL simulations do not import the parameter value from your code. Instead, the simulations use the parameter value from Simulink. If you include your external code in the Simulink Coder build process, duplicate data definitions can prevent the generated code from compiling. For information about SIL and PIL, see “Choose a SIL or PIL Approach” on page 78-14. For information about external mode simulation, see “Host-Target Communication with External Mode Simulation” (Simulink Coder).
Generate code comments that describe attributes of exported data including physical units, real-world initial value, and data type	Generating these comments can help you match data interfaces while handwriting integration code. See “Add Custom Comments for Variables in the Generated Code” on page 50-7.

- “Generate Code That Dereferences Data from a Literal Memory Address” on page 63-21

Exchange Data Between External Calling Code and Generated Code

To export the generated code into your external code, you configure the generated code to match the data interface of your external code. For example, if your external code defines a global variable for storing output data and you need the generated code to read that data as input, you can configure a corresponding Inport block so that the generated code interacts with the existing variable.

- You can generate reentrant code from a model. The generated entry-point functions typically accept data through arguments. Your calling code passes data through these arguments. You can call the functions multiple times in a single application—the application can maintain multiple instances of the model. See “Data Exchange for Reentrant Generated Code” (Simulink Coder).
- When you generate nonreentrant code, by default, the entry-point functions exchange data between the generated code and your code through global variables. You can generate variable definitions for your code to use or you can share and reuse existing variables that your code already defines. See “Data Exchange for Nonreentrant Generated Code” (Simulink Coder).

  Alternatively, you can configure the entry-point functions to exchange system inputs and outputs (root-level Inport and Outport blocks) through arguments instead of global variables. Apply function prototype control to the model, which requires Embedded Coder. For more information about function prototype control, see “Customize Generated C Function Interfaces” on page 39-2.

For general information about exchanging data between generated and external code, including how to match specific C code patterns, see “Exchange Data Between External C/C++ Code and Simulink Model or Generated Code” (Simulink Coder).

Data Exchange for Reentrant Generated Code

When you generate reentrant code, the model entry-point functions exchange data through arguments. You can control some of the characteristics of the arguments. For more information, see “Control Data and Function Interface in Generated Code” (Simulink Coder).

For information about creating a separate set of data for each call site in your external code, see “Modify Static Main to Allocate and Access Model Instance Data” on page 63-14.

Data Exchange for Nonreentrant Generated Code

To make the generated code read or write to an item of signal, state, or parameter data as a global variable, apply a storage class or custom storage class to the data in the model. The storage class also determines whether the generated code exports the variable definition to your external code or imports the definition from your code. For general information about controlling the data interface of a model that you configure to generate nonreentrant code, see "Control Data Interface for Nonreentrant Code" (Simulink Coder). For examples, see "Design Data Interface by Configuring Inport and Outport Blocks" (Simulink Coder) and "Integrate External Application Code with Code Generated from PID Controller" on page 36-77.

When you generate code that defines (allocates memory for) global data, the generated code exports that data. When your external code defines data, the generated code imports that data. Typically, storage classes that import data have the word `Import` in the storage class name, for example, `ImportedExternPointer`.

Control File Placement of Exported Global Data (Embedded Coder)

When you export data from the generated code by using storage classes or custom storage classes, the code generator creates an `extern` declaration. By default, this declaration typically appears in the generated header file *`model`*`.h`. You can include (`#include`) this header file in your external code.

By default, the definition (memory allocation) of exported data typically appears in *`model`*`.c`.

You can control the file placement of the declarations and definitions to:

- Create separate object files that store only global parameter data.
- Modularize the generated code by organizing declarations into separate files.

For more information about controlling file placement of declarations and definitions, see "Control Placement of Global Data Definitions and Declarations in Generated Files" on page 33-2. For an example, see "Definition, Initialization, and Declaration of Parameter Data" on page 24-7.

Prevent Duplicate Initialization Code for Global Variables

When your external code defines global variables, you can generate code that interacts with those variables. For example, use the custom storage class `ImportFromFile` (see

"Choose Storage Class for Controlling Data Representation in Generated Code" (Simulink Coder)).

For imported variables that represent signal or state data, the code generator can produce initialization code as described in "Initialization of Signal, State, and Parameter Data in the Generated Code" (Simulink Coder). If your code already initializes a variable, consider preventing the generation of duplicate initialization code. Create your own custom storage class and, for that storage class, set **Data initialization** to `None`. For information about creating and applying your own custom storage class, see "Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 30-2.

Protect Global Data with Keywords const and volatile

When your external code and the generated code exchange data through global variables, you can generate code that uses C type qualifiers `const` and `volatile` to protect data integrity and improve the safety of your application. For example:

- Apply `const` to a calibration parameter.
- Apply `volatile` to a global variable that stores the output of a hardware device operating asynchronously.
- Apply `const` and `volatile` to signals, states, and parameters that represent data defined by your external code. Then, the generated code declares and interacts with the external data by using the corresponding storage type qualifiers.

You must have Embedded Coder. For more information, see "Protect Global Data with const and volatile Type Qualifiers" on page 40-17.

Generate Code That Matches Appearance of External Code

A key aspect of code integration, especially for larger projects, is adherence to guidelines and standards for code appearance. If code appearance requirements apply to your project, review the requirements in this table. To learn more, see the relevant information.

Requirement	More Information
Thoroughly document code or document code in a specific way.	• "Configure Code Comments" on page 42-27 • "Add Custom Comments to Generated Code" on page 50-3 • "Add Custom Comments for Variables in the Generated Code" on page 50-7 • "Add Global Comments" on page 50-10 • "Annotate Code for Justifying Polyspace Checks" on page 50-110
Control the length and naming of code identifiers (symbols), including the use of reserved names.	• "Identifier Format Control" on page 50-24 • "Specify Identifier Length to Avoid Naming Collisions" on page 42-36 • "Specify Reserved Names for Generated Identifiers" on page 42-37 • "Customize Generated Identifier Naming Rules" on page 50-16 • "Avoid Identifier Name Collisions with Referenced Models" on page 50-34 • "Control Name Mangling in Generated Identifiers" on page 50-32 • "Specify Boolean and Data Type Limit Identifiers" on page 34-42

Requirement	More Information
Control style aspects of code: • Level of parenthesization • Order of operations in expressions • Empty primary condition expressions in `if` statements • `if-elseif-else` or `switch-case` statements for decision logic • Use of `extern` keyword in function declarations • Use of `static` keyword in function declarations • Use of `default` cases for `switch-case` statements • Use multiplications by powers of two or signed bitwise shifts • Cast expressions • Indent style (Kernighan and Ritchie or Allman) and size • Newline style	“Control Code Style” on page 50-40
Placement of data definitions and declarations, including location of global identifiers and global data declarations (`extern`)	“Control Placement of Global Data Definitions and Declarations in Generated Files” on page 33-2
Appearance of code for flow charts	“Enhance Readability of Code for Flow Charts” on page 50-112

Requirement	More Information
Apply code templates to control organization of code and use of banners	• “Customize Code Organization and Format” on page 50-59 • “Template Symbols and Rules” on page 50-101 • “Specify Templates For Code Generation” on page 50-62 • “Generate Custom File and Function Banners” on page 50-93 • “Change the Organization of a Generated File” on page 50-72 • “Generate Source and Header Files with a Custom File Processing (CFP) Template” on page 50-77 • “Customize Generated File Names” on page 50-74

- “Code Appearance”
- “Choose an External Code Integration Workflow” on page 53-4

Program Building, Interaction, and Debugging in Simulink Coder

Select C or C++ Programming Language

The default programming language selection for code generation is C language. In the code generation workflow, after the steps in “Select a Solver That Supports Code Generation” (Simulink Coder) and “Select a System Target File from STF Browser” (Simulink Coder), an optional step is to change the programming language selection for code generation.

To change the programming language setting:

1. From **Configuration Parameters** > **Code Generation** > **Language**, select `C` or `C++` for the code generation language. Alternatively, set the `TargetLang` parameter at the command line.

   The code generator produces `.c` or `.cpp` files, depending on your selection, and places the generated files in your build folder.

   For more information, see “Language” (Simulink Coder).
2. Check whether you must choose and configure a compiler. If you select C++, you must choose and configure a compiler. For details, see “Select and Configure C or C++ Compiler” (Simulink Coder).
3. Check whether the standard math library is configured for your compiler. By default, the code generator uses the ISO/IEC 9899:1999 C (`C99 (ISO)`) library for the C language and the ISO/IEC 14882:2003 C++ (`C++03 (ISO)`) library for the C++ language.

   For more information, see “Standard math library” (Simulink Coder).

See Also

More About

- “Select and Configure C or C++ Compiler” (Simulink Coder)
- “Troubleshoot Compiler Issues” (Simulink Coder)

Select and Configure C or C++ Compiler

The build process requires a supported compiler. *Compiler*, in this context, refers to a development environment containing a linker and make utility, and a high-level language compiler. For details on supported compiler versions, see:

`https://www.mathworks.com/support/compilers/current_release`

When creating an executable program, the build process must be able to access a supported compiler. The build process can find a compiler to use based on your default MEX compiler.

The build process also requires the selection of a toolchain or template makefile. The toolchain or template makefile determines which compiler runs, during the make phase of the build. For more information, see “Choose Build Approach and Configure Build Process” (Simulink Coder)

To determine which templates makefiles are available for your compiler and system target file, see “Compare System Target File Support Across Products” (Simulink Coder).

For both generated files and user-supplied files, the file extension, `.c` or `.cpp`, determines whether the build process uses a C or a C++ compiler. If the file extension is `.c`, the build process uses C compiler to compile the file, and the symbols use the C linkage convention. If the file extension is `.cpp`, the build process uses a C++ compiler to compile the file, and the symbols use the C++ linkage specification.

Language Standards Compliance

The code generator produces code that is compliant with the following standards:

Language	Supported Standard
C	ISO/IEC 9899:1990, also known as C89/C90
C++	ISO/IEC 14882:2003

Code that the code generator produces from these sources is ANSI C/C++ compliant:

- Simulink built-in block algorithmic code
- Generated system-level code (task ID [TID] checks, management, functions, and so on)
- Code from other blocksets, including the Fixed-Point Designer product and the Communications Toolbox product

- Code from other code generators, such as MATLAB functions

Also, the code generator can incorporate code from:

- Embedded system target files (for example, startup code, device driver blocks)
- Custom S-functions or TLC files

Note Coding standards for these two sources are beyond the control of the code generator. These standards can be a source for compliance problems, such as code that uses C99 features not supported in the ANSI C, C89/C90 subset.

Programming Language Considerations

The code generator produces C and C++ code. Consider the following as you choose a programming language:

- Does your project require you to configure the code generator to use a specific compiler? C/C++ code generation on Windows requires this selection.
- Does your project require you to change the default language configuration setting for the model? See “Select C or C++ Programming Language” on page 54-2.
- Does your project require you to integrate legacy or custom code with generated code? For a summary of integration options, see “What Is External Code Integration?” on page 53-3.
- Does your project require you to integrate C and C++ code? If so, see “What Is External Code Integration?” on page 53-3.

  Note You can mix C and C++ code when integrating generated code with custom code. However, you must be aware of the differences between C and default C++ linkage conventions, and add the `extern "C"` linkage specifier where required. For the details of the differing linkage conventions and how to apply `extern "C"`, refer to a C++ programming language reference book.
- Does your project require code generation support from other products? See “C++ Language Support Limitations” on page 54-5.

For C++ code generation examples with Stateflow, see the `sfcndemo_cppcount` model or `sf_cpp` model.

C++ Language Support Limitations

To use C++ language support, you could need to configure the code generator to use a specific compiler. For example, if a supported compiler is not installed on your Microsoft Windows computer, the default compiler is the `lcc` C compiler shipped with the MATLAB product. This compiler does not support C++. If you do not configure the code generator to use a C++ compiler before you specify C++ for code generation, the software produces an error message.

Code generator limitations on C++ support include:

- The code generator does not support C++ code generation for the following:
  Simscape Driveline
  Simscape Multibody First Generation (Simscape Multibody Second Generation is supported)
  Simscape Electrical Power Systems
  Simulink Real-Time
- For ERT and ERT-based system target files with **Configuration Parameters** > **Data Placement** > **Interface** > **Code interface packaging** set to `Nonreusable function`, the following fields currently do not accept the `.cpp` extension. If you specify a file name with a `.c` extension or without an extension and specify C++ for the code generation language, the code generator produces a `.cpp` file.
  - **Configuration Parameters** > **Code Placement** > **Data definition filename** field (available when **Configuration Parameters** > **Code Placement** > **Data definition** is set to `Data defined in a single separate source file`)
  - **Definition file** field for a data object in Model Explorer. Data objects are objects of the class `Simulink.Signal`, `Simulink.Parameter`, and subclasses.

Code Generator Assumes Wrap on Signed Integer Overflows

The code generator reduces memory usage and enhances generated code execution by assuming signed integer C operations wrap on overflow. A signed integer overflow occurs when the result of an arithmetic operation is outside the range of values that the output data type can represent. The C programming language does not define the results of such operations. Some C compilers aggressively optimize signed operations for in-range values at the expense of overflow conditions. Other compilers preserve the full wrap-on-overflow behavior. For example, the gcc and MinGW compilers provide an option to wrap on overflow reliably for signed integer overflows. The generated program image for a model

can produce results that differ from model simulation results because the handling of overflows varies, depending on your compiler.

When you generate code, if you use a supported compiler with the default options configured by the code generator, the compiler preserves the full wrap-on-overflow behavior. If you change the compiler options or compile the code in another development environment, it is possible that the compiler does not preserve the full wrap-on-overflow behavior. In this case, the executable program can produce unpredictable results.

If this issue is a concern for your application, consider one or more of the following actions:

- Verify that the compiled code produces expected results.
- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, configure the build process to use the compiler option `-fwrapv`.
- Choose a compiler that wraps on integer overflow.
- If you have Embedded Coder installed, develop and apply a custom code replacement library to replace code generated for signed integers. For more information, see “Code Replacement Customization”.

Choose and Configure Compiler

The compiler for your model build appears in the build process parameters in **Configuration Parameters > Code Generation**. To view the installed compilers and select the default compiler, in the Command Window type:

```
mex -setup
```

On a Windows computer, you can install supported compilers and select a default compiler.

On a UNIX platform, the default compiler is GNU `gcc/g++` for GNU or Xcode for Mac.

Unless the build approach configuration selects a specific compiler, the code generator uses the default compiler for the build process.

Primarily, the specified system target file determines the compiler that the code generator requires:

- If you select a toolchain-based system target file such as `grt.tlc` (Generic Real-Time Target), `ert.tlc` (Embedded Coder), or `autosar.tlc` (Embedded Coder for AUTOSAR), the **Build process** subpane displays toolchain parameters for configuring the build process. Use the **Toolchain** parameter to select a compiler and associated tools for your model build. To validate the selected toolchain, click the **Validate** button for the **Configuration Parameters > Code Generation > Build process > Toolchain settings** box.
- If you select a template makefile (TMF) based system target file, such as `rsim.tlc`, the **Build process** subpane displays template makefile parameters for configuring the build process. The **Template makefile** parameter displays the default TMF file for the selected system target file. If the system target file supports compiler-specific template makefiles (for example, Rapid Simulation or S-Function system target files), you can set **Template makefile** to a compiler-specific TMF, such as `rsim_lcc.tmf` or `rsim_unix.tmf`. (See “Compare System Target File Support Across Products” (Simulink Coder) for valid TMF names.)

Include S-Function Source Code

When the code generator builds models with S-functions, source code for the S-functions can be either in the current folder or in the same folder as their MEX-file. The code generator adds an include path to the generated makefiles whenever it finds a file named *`sfncname`*`.h` in the same folder as the S-function MEX-file. This folder must be on the MATLAB path.

Similarly, the code generator adds a rule for the folder when it finds a file *`sfncname`*`.c` (or `.cpp`) in the same folder as the S-function MEX-file is in.

Troubleshoot Compiler Issues

In this section...

Compiler Version Mismatch Errors

Description

The build process produces a compiler version mismatch error.

Action

1. Check the list of supported and compatible compilers available at `www.mathworks.com/support/compilers/current_release/`.
2. Upgrade or change your compiler. For more information, see “Choose and Configure Compiler” on page 54-6.
3. Rebuild the model.

Results for Model Simulation and Program Execution Differ

Description

The program generated for the model produces different results from model simulation results. The generated source code includes an arithmetic operation that produces a signed integer overflow. It is possible that your compiler does not implement wrapping behavior for signed integer overflow conditions. Or, if you are using a compiler that supports wrapping, it is possible that you did not configure it to use the `-fwrapv` option.

For more information, see “Code Generator Relies on Undefined Behavior of C Language for Integer Overflows.”

Action

- If your compiler can force wrapping behavior, turn it on. For example, for the gcc compiler or a compiler based on gcc, such as MinGW, specify the compiler option `-fwrapv`.
- Choose a compiler that checks for integer overflows.
- If you have Embedded Coder, develop and apply a code replacement library to replace code generated for signed integers.

Generates Expected Code and Produces Unexpected Results

Description

The build process generates expected source code, but the executable program produces unexpected results. The generated source code appears as expected. However, the executable program produces unexpected results.

Action

Do one of the following:

- Lower the compiler optimization level.
  1. Select `Custom` for the Model Configuration parameter **Code Generation** > **Compiler optimization level**.
  2. In the **Custom compiler optimization flags** field, specify a lower optimization level.
  3. Rebuild the model.
- Disable compiler optimizations.
  1. Select `Optimizations off (faster builds)` for the Model Configuration parameter **Code Generation** > **Compiler optimization level**.
  2. Rebuild the model.

For more information, see “Control Compiler Optimizations” (Simulink Coder) and your compiler documentation.

Compile-Time Issues

Issue	Action
Error is present in the compiler configuration.	Make sure that MATLAB supports the compiler and version that you want to use. For a list of currently supported and compatible compilers, see `www.mathworks.com/support/compilers/current_release/`. If necessary, upgrade or change your compiler (see “Choose and Configure Compiler” on page 54-6 or “Choose and Configure Compiler” on page 54-6).
Environment variables are incorrectly set up for your make utility, compiler, or linker. For example, installation of Cygwin tools on a Windows platform affects environment variables used by other compilers.	Review the environment variable settings for your system by using the `set` command on a Windows platform or `setenv` on a UNIX platform. Make sure that the settings match what is required for the tools you are using.
Error is present in custom code specified as an S-function block or in **Configuration Parameters > Code Generation > Custom Code**. For example, the code refers to a header file that the compiler cannot find.	To isolate the source of the problem, remove the custom code from the model, debug, and rebuild the model.
The model includes a block, such as a device driver block, which is not intended for use with the currently selected system target file.	Remove the system target file-specific block or configure the model for use with another system target file.

Issue	Action
A linker error about an undefined reference to the data appears when the model build generates an executable program from the model reference hierarchy and these conditions are true: • You represent signal, state, or parameter data by creating a data object such as `Simulink.Signal`. You use the object in a model reference hierarchy. • You use a custom storage class with the data object. Custom storage classes require Embedded Coder. • You set the owner of the object to a model that does not directly access the data. • You use the toolchain `lcc-win64`.	To resolve the issue, choose one of these methods: • In the data object, clear the `Owner` property. Alternatively, set the owner to a model that directly accesses the data. • Use a different toolchain, such as `gcc`, instead of `lcc`.

LCC Compiler Does Not Support Ampersands in Source Folder Paths

Description

If you use the LCC compiler and your model folder path contains an ampersand (&), the build process produces an error.

Action

Remove the ampersand from the model folder path. Then, rebuild the model.

LCC Compiler Might Not Support Line Lengths of Rapid Accelerator Code

Description

If you are compiling Rapid Accelerator code, the LCC compiler might produce an error related to line limits. Rapid Accelerator code can have longer line lengths due to obfuscation.

Action

Compile your Rapid Accelerator code using a compiler that supports longer code lines.

Choose Build Approach and Configure Build Process

The code generator supports these approaches for building (compiling and linking) code that you generate from Simulink models:

- Toolchain — A build process that generates makefiles and supports custom toolchains. This approach:
  - Provides control of your build process with toolchain information objects. You can define these objects using MATLAB scripts.
  - Supports model referencing, SIL, and PIL.
  - Supports Simulink Coder, Embedded Coder, and MATLAB Coder.
- Template makefile — A build process that uses a template makefile with a toolchain that you specify. This approach:
  - Optionally uses a toolchain information object.
  - Supports model referencing, SIL, and PIL.
  - Supports Simulink Coder and Embedded Coder.

The “System target file” (Simulink Coder) parameter, located in the **Configuration Parameters > Code Generation** pane, lets you select the build process for a model. When you set the **System target file** to:

- `ert.tlc`, `ert_shrlib.tlc`, `grt.tlc`, or any toolchain-compliant system target file, the build process uses the toolchain approach on page 54-14 by default.
- Any non-toolchain-compliant system target file, the build process uses the template makefile approach on page 54-20.

You can switch from the toolchain approach to the template makefile approach with this command:

```
set_param(model, 'MakeCommand', 'make_rtw TMF=1')
```

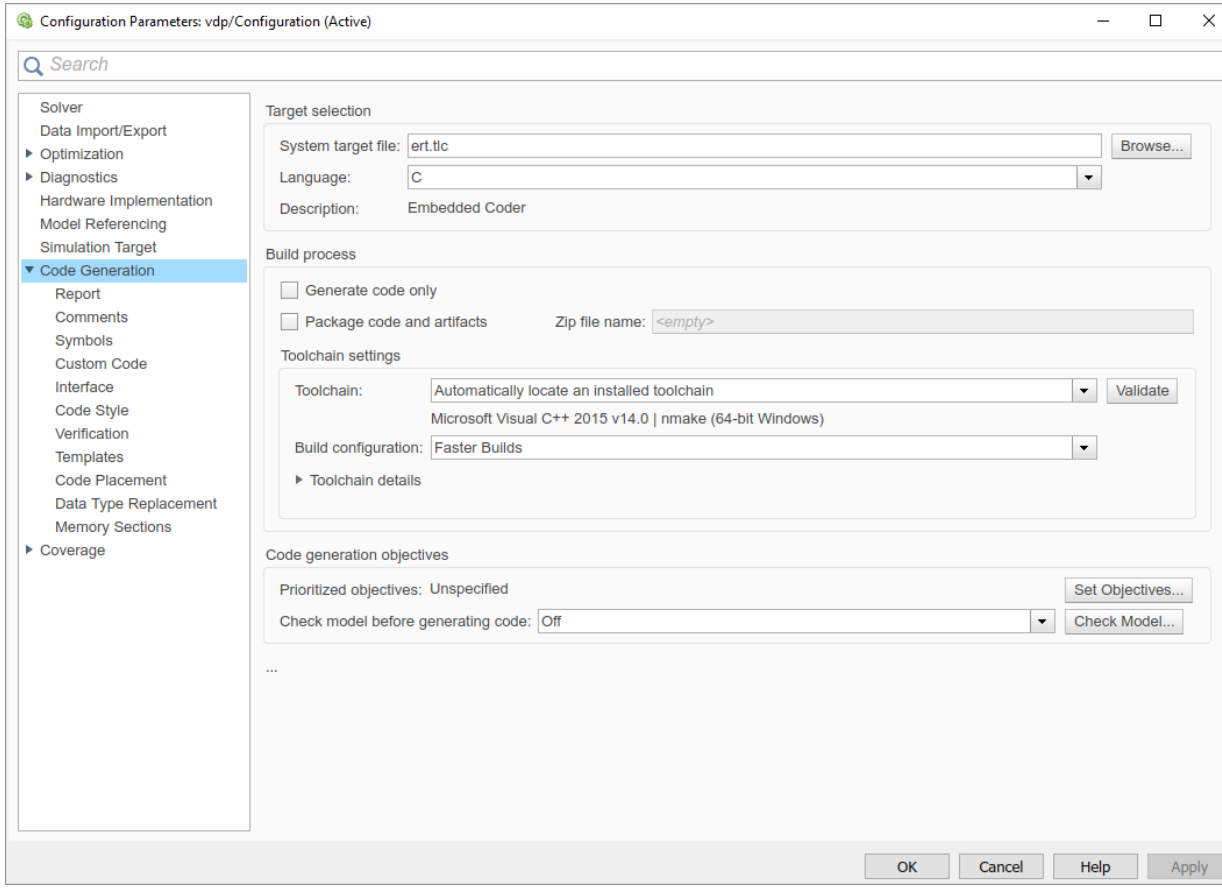
Toolchain Approach

Toolchain settings appear under **Build process** when you set **System target file** to:

- `grt.tlc — Generic Real-Time Target`

- `ert.tlc` — `Embedded Coder` (requires the Embedded Coder product)
- `ert_shrlib.tlc` — `Embedded Coder (host-based shared library target)` (requires Embedded Coder)
- Any toolchain-compliant system target file (If ERT-based, requires Embedded Coder)

For more information about toolchain-compliant system target files, see “Support Toolchain Approach with Custom Target” (Simulink Coder).



The **Toolchain settings** include:

- The “Toolchain” (Simulink Coder) parameter specifies the collection of third-party software tools that builds the generated code. A toolchain can include a compiler,

linker, archiver, and other prebuild or postbuild tools that download and run the executable on the target hardware.

The default value of **Toolchain** is `Automatically locate an installed toolchain`. The **Toolchain** parameter displays name of the located toolchain just below `Automatically locate an installed toolchain`.

Click the **Validate** button for the **Configuration Parameters > Code Generation > Build process > Toolchain settings** parameter to check that the toolchain is present and validate that the code generator has the information required to use the toolchain. The resulting Validation Report gives a pass/fail for the selected toolchain, and identifies issues to resolve.

- The “Build configuration” (Simulink Coder) parameter lets you choose or customize the optimization settings. By default, **Build Configuration** is set to `Faster Builds`. You can also select `Faster Runs`, `Debug`, and `Specify`. When you select `Specify` and click **Apply**, you can customize the toolchain options for each toolchain. These custom toolchain settings only apply to the current model.

Note The following system target files, which use the template makefile approach, have the same names but different descriptions from system target files that use the toolchain approach:

- `ert.tlc — Create Visual C/C++ Solution File for Embedded Coder`
- `grt.tlc — Create Visual C/C++ Solution File for Simulink Coder`

To avoid confusion, click **Browse** to select the system target file and look at the description of each file.

Upgrade Model to Use Toolchain Approach

When you open a model created before R2013b that uses the following system target files, the software tries to upgrade the model. The upgrade changes the configuration from using template makefile settings to using the toolchain settings:

- `ert.tlc — Embedded Coder`
- `ert_shrlib.tlc — Embedded Coder (host-based shared library target)`
- `grt.tlc — Generic Real-Time Target`

Note To upgrade models using a custom system target file to use the toolchain approach, see “Support Toolchain Approach with Custom Target” on page 85-80.

Some model configuration parameter values prevent the software from upgrading a model to use toolchain settings. The following instructions show you ways to complete the upgrade process.

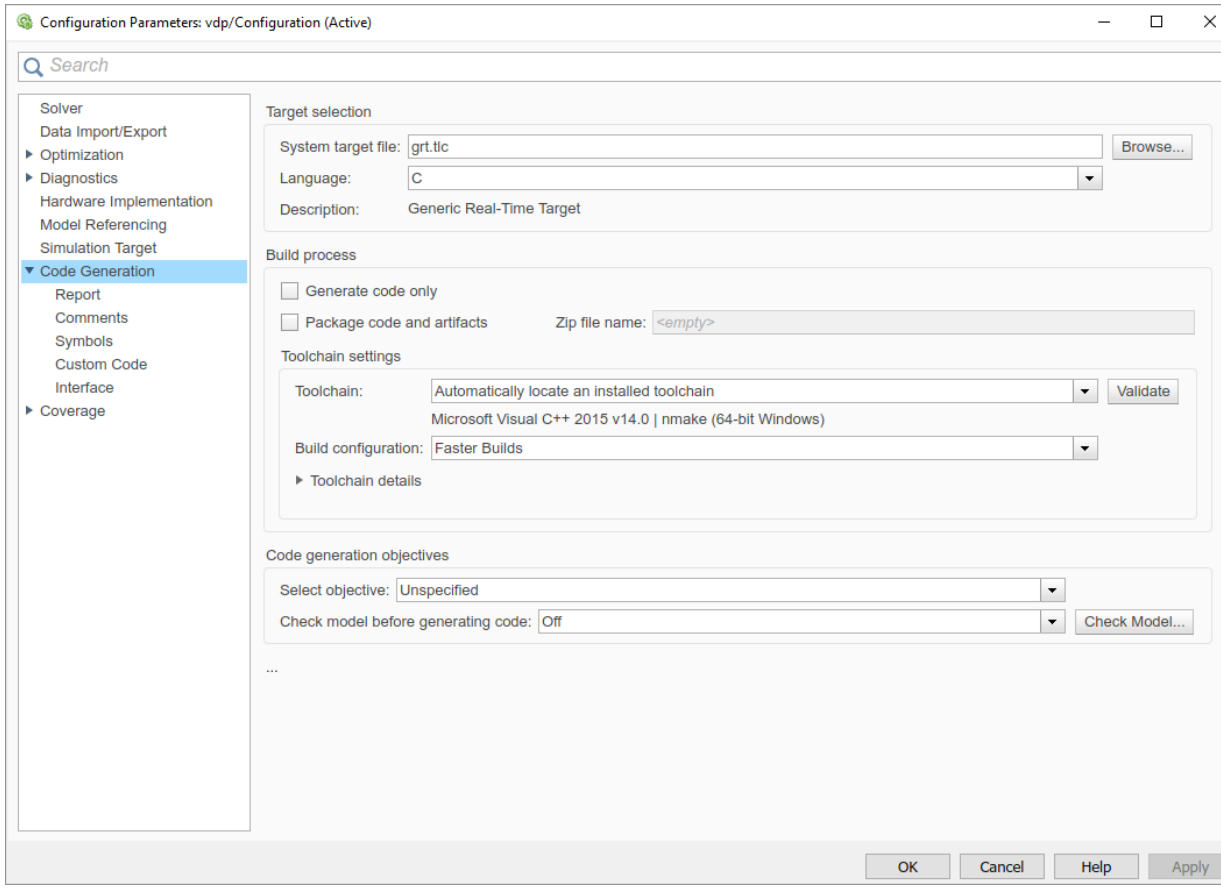
Consider upgrading your models and use the toolchain build approach. Doing so is not required. You can continue generating code from a model that has not been upgraded.

Note The software does not upgrade models that use the following system target files:

- `ert.tlc — Create Visual C/C++ Solution File for Embedded Coder`
- `grt.tlc — Create Visual C/C++ Solution File for Simulink Coder`

To see if a model was upgraded:

1. Open the model configuration parameters by pressing **Ctrl+E**.
2. Select **Configuration Parameters** > **Code Generation**.
3. If the **Build process** subpane contains the **Toolchain** and **Build configuration** parameters, the model has already been upgraded.



If the **Build process** area displays **Makefile configuration** parameters, such as **Generate makefile**, **Make command**, and **Template makefile**, the software has not upgraded the model.

Start by creating a working copy of the model using **File > Save As**. This action preserves the original model and configuration parameters for reference.

Try to upgrade the model using Upgrade Advisor:

1. In your model, select **Analysis > Model Advisor > Upgrade Advisor**.
2. In Upgrade Advisor, select **Check and update model to use toolchain approach to build generated code** and click **Run This Check**.

3. Perform the suggested actions and/or click **Update Model**.

When you cannot upgrade the model using Upgrade Advisor, one or more of the following parameters is not set to its default value, shown here:

- **Compiler optimization level** — `Optimizations off (faster builds)`
- **Generate makefile** — Enabled
- **Template makefile** — System target file-specific template makefile
- **Make command** — `make_rtw` without arguments

Sometimes, a model cannot be upgraded. Try the following procedure:

- If **Generate makefile** is disabled, this case cannot be upgradable. However, you can try enabling it and try upgrading the model using Upgrade Advisor.
- If **Compiler optimization level** is set to `Optimizations on (faster runs)`:
  1. Set **Compiler optimization level** is to `Optimizations off (faster builds)`.
  2. Upgrade the model using Upgrade Advisor.
  3. Set **Build configuration** to `Faster Runs`.
- If **Compiler optimization level** is set to `Custom`:
  1. Copy the **Custom compiler optimization flags** to a text file.
  2. Set **Compiler optimization level** to `Optimizations off (faster builds)`.
  3. Upgrade the model using Upgrade Advisor.
  4. Set **Build configuration** to `Specify`.
  5. To perform the same optimizations, edit the compiler options.
- If **Template makefile** uses a customized template makefile, this case cannot be upgradable. However, you can try the following:
  1. Update **Template makefile** to use the default makefile for the system target file.

     Note To get the default makefile name, change the **System target file**, click **Apply**, change it back, and click **Apply** again.
  2. Upgrade the model using Upgrade Advisor.
  3. If the template makefile contains build tool options, such as compiler optimization flags, set **Build configuration** to `Specify` and update the options.

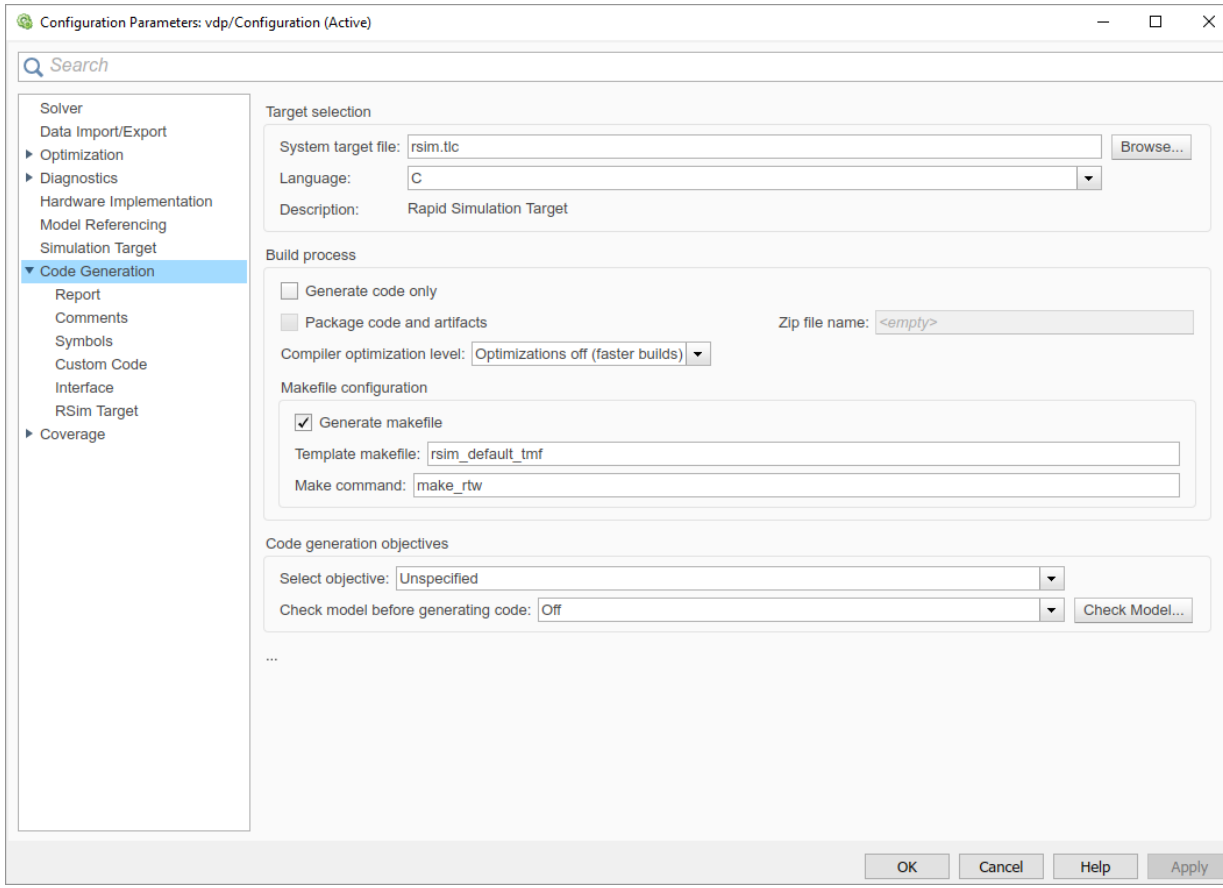
4. If the template makefile uses custom build tools, create and register a custom toolchain, as described in “Custom Toolchain Registration” (MATLAB Coder) . Then, set the **Toolchain** parameter to use the custom toolchain.

   Note After registering the custom toolchain, update **Toolchain** to use the custom toolchain.

5. If the template makefile contains custom rules and logic, these customizations cannot be applied to the upgraded model.

Template Makefile Approach

When the **System target file** is set to a `tlc` file that uses the template makefile approach, the software displays **Compiler optimization level**, **Generate makefile**, **Make command**, and **Template makefile** parameters.



Specify Whether to Generate a Makefile

The **Generate makefile** option specifies whether the build process is to generate a makefile for a model. By default, the build process generates a makefile. Suppress generation of a makefile, for example in support of custom build processing that is not based on makefiles, by clearing **Generate makefile**. When you clear this parameter:

- The **Make command** and **Template makefile** options are unavailable.
- Set up post code generation build processing using a user-defined command, as explained in “Customize Post-Code-Generation Build Processing” (Simulink Coder).

Specify a Make Command

Each template makefile-based system target file has an associated `make` command. The code generator uses this internal MATLAB command to control the build process. The command appears in the **Make command** field and runs when you start a build.

Most system target files use the default command, `make_rtw`. Third-party system target files could supply another `make` command. See the documentation from the vendor.

In addition to the name of the `make` command, you can supply makefile options in the **Make command** field. These options could include compiler-specific options, include paths, and other parameters. When the build process invokes the `make` utility, these options are passed on the `make` command line, which adds them to the overall flags passed to the compiler.

“Template Makefiles and Make Options” on page 54-26 lists the **Make command** options you can use with each supported compiler.

Specify the Template Makefile

The **Template makefile** field has these functions:

- If you selected a system target file with the System Target File Browser, this field displays the name of a MATLAB language file that selects a template makefile for your development environment. For example, in “Model Configuration Parameters: Code Generation” (Simulink Coder), the **Template makefile** field displays `grt_default_tmf`, indicating that the build process invokes `grt_default_tmf.m`.

  “Template Makefiles and Make Options” on page 54-26 gives a detailed description of the logic by which the build process selects a template makefile.
- Alternatively, you can explicitly enter the name of a specific template makefile (including the extension) or a MATLAB language file that returns a template makefile in this field. Use this approach if you are using a system target file that does not appear in the System Target File Browser. For example, use this approach if you have written your own template makefile for a custom system target file.

If you specify your own template makefile, be sure to include the file name extension. If you omit the extension, the build process attempts to find and execute a file with the extension `.m` (that is, a MATLAB language file). The template make file (or a MATLAB language file that returns a template make file) must be on the MATLAB path. To determine whether the file is on the MATLAB path, enter the following command in the MATLAB Command Window:

```
which tmf_filename
```

Associate the Template Makefile with a Toolchain

Specify a toolchain for the template makefile build process. This example provides a definition for a minimal toolchain and shows how you can associate the toolchain with a template makefile that is a copy of `ert_unix.tmf` or `ert_vcx64.tmf`.

Use this code for the toolchain definition file.

```
function tc = minimalToolchainForTMF
% Create a toolchain object
tc = coder.make.ToolchainInfo('Name', 'Minimal Toolchain for TMF Build');

% Specify that the linker requires a response file instead of
% including all object file modules on the linker command line
tc.addAttribute('RequiresCommandFile', true);

if ispc
    objExt = '.obj';
else
    objExt = '.o';
end

% Specify source file and object file extension used by the C compiler
tool = tc.getBuildTool('C Compiler');
tool.setFileExtension(  'Source', '.c');
tool.setFileExtension(  'Header', '.h');
tool.setFileExtension(  'Object',   objExt);

% Specify source file and object file extension used by the C++ compiler
tool = tc.getBuildTool('C++ Compiler');
tool.setFileExtension(  'Source', '.cpp');
tool.setFileExtension(  'Header', '.hpp');
tool.setFileExtension(  'Object',   objExt);
```

Use a copy of `ert_unix.tmf` or `ert_vcx64.tmf` as the template makefile.

```
copyfile(fullfile(matlabroot,'rtw','c','ert','ert_vcx64.tmf'), 'ert_copy.tmf')
```

In the template makefile, i.e. `ert_copy.tmf`, edit the `TOOLCHAIN_NAME` macro.

```
TOOLCHAIN_NAME = "Minimal Toolchain for TMF Build"
```

Associate the toolchain with the template make file.

1. Run the toolchain definition file, which generates a `ToolchainInfo` object, `tc`.

   ```
   tc = minimalToolchainForTMF;
   ```

2. Save the `ToolchainInfo` object to a MAT file.

   ```
   save('tcMinimal','tc')
   ```

3. Register the toolchain in `RTW.TargetRegistry`.

   a. Place this code in an `rtwTargetInfo.m` file.

   ```
   function rtwTargetInfo(tr)
   tr.registerTargetInfo(@loc_createToolchain);
   end

   function config = loc_createToolchain
   config(1) = coder.make.ToolchainInfoRegistry;
   config(1).Name = 'Minimal Toolchain for TMF Build';
   config(1).FileName = fullfile(fileparts(mfilename('fullpath')),...
       'tcMinimal.mat');
   config(1).TargetHWDeviceType = {'*'};
   config(1).Platform =  {computer('arch')};
   end
   ```

   b. Save the file in the current working folder or in a folder that is on the MATLAB search path.

   c. Reset the `TargetRegistry`.

   ```
   RTW.TargetRegistry.getInstance('reset');
   ```

Associate the template makefile with your model and build the model.

```
set_param(model, 'TemplateMakefile', 'ert_copy.tmf');
rtwbuild(model);
```

Specify TLC for Code Generation

Target Language Compiler (TLC) is an integral part of the code generator. It enables you to customize generated code. Through customization, you can produce platform-specific code, or you can incorporate your own algorithmic changes for execution speed, code size, or compatibility with existing methods that you prefer to maintain. For additional information, see “Target Language Compiler Overview” (Simulink Coder).

TLC options that you specify for code generation appear in the summary section of the generated HTML code generation report.

Note Specifying TLC command-line options does not add flags to the make command line.

You can specify Target Language Compiler (TLC) command-line options and arguments for code generation using the model parameter `TLCOptions` in a `set_param` function call. For example,

```
>> set_param(gcs,'TLCOptions','-p0 -aWarnNonSaturatedBlocks=0')
```

Some common uses of TLC options include the following:

- `-aVarName=1` to declare a TLC variable and/or assign a value to it
- `-IC:\Work` to specify an include path
- `-v` to obtain verbose output from TLC processing (for example, when debugging)

- “Executable Program Generation” on page 54-74

Template Makefiles and Make Options

The code generator includes a set of built-in template makefiles that build programs for specific system target files.

Types of Template Makefiles

There are two types of template makefiles:

- *Compiler-specific* template makefiles are for a particular compiler or development system.

  By convention, compiler-specific template makefiles names correspond to the system target file and compiler (or development system). For example, `grt_vcx64.tmf` is the template makefile for building a generic real-time program under the Visual C++ compiler; `ert_lcc.tmf` is the template makefile for building an Embedded Coder program under the `lcc` compiler.
- *Default* template makefiles make your model designs more portable, by choosing the compiler-specific makefile and compiler for your installation. “Select and Configure C or C++ Compiler” on page 54-3 describes the operation of default template makefiles in detail.

  Default template makefiles have names that follow the pattern *`target`*`_default_tmf`. They are MATLAB language files that, when run, select the TMF for the specified system target file configuration. For example, `grt_default_tmf` is the default template makefile for building a generic real-time program; `ert_default_tmf` is the default template makefile for building an Embedded Coder program.

For details on the structure of template makefiles, see “Customize Template Makefiles” on page 85-62. This section describes compiler-specific template makefiles and common options you can use with each.

Specify Template Makefile Options

You can specify template makefile options by using the **Make command** box in **Configuration Parameters** > **Code Generation**. Append the options after `make_rtw` (or other `make` command), as in the following example:

```
make_rtw OPTS="-DMYDEFINE=1"
```

The syntax for `make` command options differs slightly for different compilers.

Note To control compiler optimizations for a makefile build at the Simulink GUI level, use the **Configuration Parameters > Code Generation > Build process > Compiler optimization level** parameter. The **Compiler optimization level** parameter provides

- System target file-independent values `Optimizations on (faster runs)` and `Optimizations off (faster builds)`, which easily allow you to toggle compiler optimizations on and off during code development
- The value `Custom` for entering custom compiler optimization flags at Simulink GUI level (rather than at other levels of the build process)

If you specify compiler options for your makefile build using `OPT_OPTS`, `MEX_OPTS` (except `MEX_OPTS="-v"`), or `MEX_OPT_FILE`, the value of **Compiler optimization level** is ignored and a warning is issued about the ignored parameter.

Template Makefiles for UNIX Platforms

The template makefiles for UNIX platforms are for the Free Software Foundation's GNU Make. These makefiles conform to the guidelines specified in the IEEE[8] Std 1003.2-1992 (POSIX) standard.

- `ert_unix.tmf`
- `grt_unix.tmf`
- `rsim_unix.tmf`
- `rtwsfcn_unix.tmf`

You can supply options to makefiles using the **Make command** box in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,

  ```
  OPTS="-DMYDEFINE=1"
  ```

8. IEEE is a registered trademark of The Institute of Electrical and Electronics Engineers, Inc.

- `OPT_OPTS`— Optimization options. Default is `-O`. To enable debugging, specify the option as `OPT_OPTS=-g`. Because of optimization problems in IBM_RS, the default is to not optimize.
- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```
- `DEBUG_BUILD` — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

Template Makefiles for the Microsoft Visual C++ Compiler

Visual C++ Executable Build

To build an executable using the Visual C++ compiler within the build process, use one of the *`target`*`_vcx64.tmf` template makefiles:

- `ert_vcx64.tmf`
- `grt_vcx64.tmf`
- `rsim_vcx64.tmf`
- `rtwsfcn_vcx64.tmf`

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters** > **Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPT_OPTS` — Optimization option. Default is `-O2`. To enable debugging, specify the option as `OPT_OPTS=-Zi`.

- `OPTS` — User-specific options.
- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```

- `DEBUG_BUILD` — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

Visual C++ Code Generation Only

To create a Visual C++ project makefile (*`model`*`.mak`) without building an executable, use one of the *`target`*`_msvc.tmf` template makefiles:

- `ert_msvc.tmf`
- `grt_msvc.tmf`

These template makefiles are for `nmake`, which is bundled with the Visual C++ compiler.

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,

  ```
  OPTS="/D MYDEFINE=1"
  ```

- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths, for example,

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```

- `DEBUG_BUILD` — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

Template Makefiles for the LCC Compiler

The code generator provides template makefiles to create an executable for the Windows platform using Lcc compiler Version 2.4 and GNU Make (`gmake`).

- `ert_lcc.tmf`
- `grt_lcc.tmf`
- `rsim_lcc.tmf`
- `rtwsfcn_lcc.tmf`

You can supply options to makefiles using the **Make command** field in the **Configuration Parameters > Code Generation** pane. Options specified in **Make command** are passed to the command-line invocation of the `make` utility, which adds them to the overall flags passed to the compiler. The following options can be used to modify the behavior of the build:

- `OPTS` — User-specific options, for example,

  ```
  OPTS="-DMYDEFINE=1"
  ```

- `OPT_OPTS` — Optimization options. Default is to not use options. To enable debugging, specify `-g4`:

  ```
  OPT_OPTS="-g4"
  ```

- `CPP_OPTS` — C++ compiler options.
- `USER_SRCS` — Additional user sources, such as files used by S-functions.
- `USER_INCLUDES` — Additional include paths. For example:

  ```
  USER_INCLUDES="-Iwhere-ever -Iwhere-ever2"
  ```

  For `lcc`, use `/` as file separator before the file name instead of `\`, for example, `d:\work\proj1/myfile.c`.

- `DEBUG_BUILD` — Add debug information to generated code, for example,

  ```
  DEBUG_BUILD=1
  ```

These options are also documented in the comments at the head of the respective template makefiles.

- “Customize System Target Files” (Simulink Coder)
- “Associate the Template Makefile with a Toolchain” on page 54-23

Build Process Workflow for Real-Time Systems

The building process includes generating code in C or C++ from a model and building an executable program from the generated code. This example can use a generic real-time (GRT) or an embedded real-time (ERT) system target file (STF) for code generation. The resulting standalone program runs on your development computer, independent of external timing and events.

Working Folder

This example uses a local copy of the `slexAircraftExample` model, stored in its own folder, `aircraftexample`. Set up your *working folder* as follows:

1. In the MATLAB Current Folder browser, navigate to a folder to which you have write access.
2. To create the working folder, enter the following MATLAB command:

   ```
   mkdir aircraftexample
   ```
3. Make `aircraftexample` your working folder:

   ```
   cd aircraftexample
   ```
4. Open the `slexAircraftExample` model:

   ```
   slexAircraftExample
   ```

   The model appears in the Simulink Editor model window.
5. In the model window, choose **File** > **Save As**. Navigate to your working folder, `aircraftexample`. Save a copy of the `slexAircraftExample` model as `myAircraftExample`.

Build Folder and Code Generation Folders

While producing code, the code generator creates a *build folder* within your working folder. The build folder name is *`model_target`*`_rtw`, derived from the name of the source model and the chosen system target file. The build folder stores generated source code and other files created during the build process. Examine the build folder contents at the end of this example.

When a model contains Model blocks (references to other models), the model build creates special subfolders in your “Code generation folder” (Simulink) to organize code

for the referenced models. These code generation folders exist alongside product build folders and are named `slprj`. “Generate Code for Referenced Models” on page 4-4 describes navigating code generation folder structures in Model Explorer.

Under the `slprj` folder, a subfolder named `_sharedutils` contains generated code that can be shared between models.

Set Model Parameters for Code Generation

To generate code from your model, you must change some of the model configuration parameters. In particular, the generic real-time (GRT) system target file and most other system target files require that the model specifies a fixed-step solver.

Note The code generator produces code for models, using variable-step solvers, for rapid simulation (`rsim`) and S-function system target files only.

To set model configuration parameters by using the Configuration Parameters dialog box:

1. Open the `myAircraftExample` model if it is not already open.
2. From the model window, open the Configuration Parameters dialog box by selecting **Simulation** > **Model Configuration Parameters**.
3. Select **Configuration Parameters** > **Solver**. Enter the following parameter values (some could already be set):
   - **Start time**: `0.0`
   - **Stop time**: `60`
   - **Type**: `Fixed-step`
   - **Solver**: `ode5 (Dormand-Prince)`
   - **Fixed step size (fundamental sample time)**: `0.1`
   - **Treat each discrete rate as a separate task**: `Off`
4. Click **Apply**.
5. Save the model. Simulation parameters persist with the model for use in future sessions.

Configure Build Process

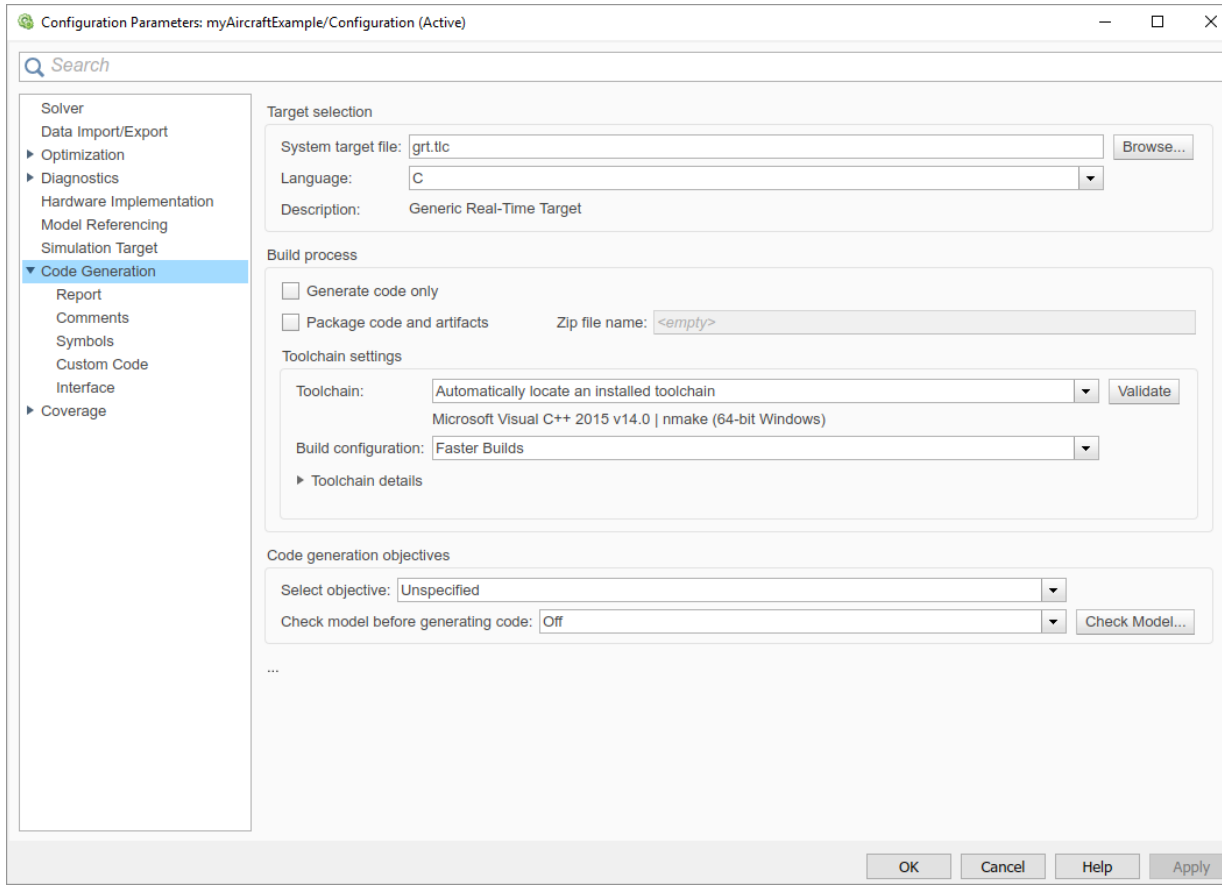
To configure the build process for your model, choose a system target file, a toolchain or template makefile, and a `make` command.

In these examples and in most applications, you do not need to specify these parameters individually. The examples use the ready-to-run generic real-time target (GRT) configuration. The GRT system target file builds a standalone executable program that runs on your desktop computer.

To select the GRT system target file using the Configuration Parameters dialog box:

1. With the `myAircraftExample` model open, select **Simulation** > **Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. Select **Configuration Parameters** > **Code Generation**.
3. For **System target file**, enter `grt.tlc`, and click **Apply**.

   The **Configuration Parameters** > **Code Generation** pane displays selections for the **System target file** (`grt.tlc`), **Toolchain** (`Automatically locate an installed toolchain`), and **Build Configuration** (`Faster Builds`).



Note If you click **Browse**, a System Target File Browser opens and displays the system target files on the MATLAB path. Some system target files require additional products. For example, `ert.tlc` requires Embedded Coder.

4 Save the model.

Set Code Generation Parameters

With the `myAircraftExample` model open, select **Simulation** > **Model Configuration Parameters**:

1. Select **Code Generation** > **Report** > **Create code generation report**. This action enables the software to create and display a code generation report for the `myAircraftExample` model.
2. Use the default **Code Generation** > **Comments**settings.
3. The **Code Generation** > **Symbols** options control the look and feel of generated code. Use the default settings.
4. These **Code Generation** > **Advanced parameters** parameters control build verbosity and debugging:

   - **Verbose build** (`RTWVerbose` parameter)
   - **Retain .rtw file** (`RetainRTWFile` parameter)
   - **Profile TLC** (`ProfileTLC` parameter)
   - **Start TLC debugger when generating code** (`TLCDebug` parameter)
   - **Start TLC coverage when generating code** (`TLCCoverage` parameter)
   - **Enable TLC assertion** (`TLCAssert` parameter)

   Use the default settings.
5. Select **Code Generation** > **Interface**.

   - For the **Shared code placement** parameter, select `Shared location`. The build process places generated code for utilities in a subfolder within your “Code generation folder” (Simulink).
   - Clear the **Advanced parameters** > **Classic call interface**check box.
6. Click **Apply** and save the model.

Build and Run a Program

The build process generates C code from the model. It then compiles and links the generated program to create an executable image. To build and run the program:

1. With the `myAircraftExample` model open, initiate code generation and the build process for the model by using any of the following options:

   - Click the **Build Model** button.
   - Press **Ctrl+B**.
   - Select **Code** > **C/C++ Code** > **Build Model**.

- Invoke the `rtwbuild` command from the MATLAB command line.
- Invoke the `slbuild` command from the MATLAB command line.

Some messages concerning code generation and compilation appear in the Command Window. The initial message is:

```
### Starting build procedure for model: myAircraftExample
```

The contents of many of the succeeding messages depends on your compiler and operating system. The final messages include:

```
### Created executable myAircraftExample.exe
### Successful completion of build procedure for model: myAircraftExample
### Creating HTML report file myAircraftExample_codegen_rpt.html
```

The code generation folder now contains an executable, `myAircraftExample.exe` (Microsoft Windows platforms) or `myAircraftExample` (UNIX platforms). In addition, the build process has created an `slprj` folder and a `myAircraftExample_grt_rtw` folder in your "Code generation folder" (Simulink).

Note After generating the code for the `myAircraftExample` model, the build process displays a code generation report. See "Report Generation" (Simulink Coder) for more information about how to create and use a code generation report.

---

2 To see the contents of the working folder after the build, enter the `dir` or `ls` command:

```
>> dir

.                              myAircraftExample.slx          slprj
..                             myAircraftExample.slx.autosave
myAircraftExample.exe          myAircraftExample_grt_rtw
```

3 To run the executable from the Command Window, type `!myAircraftExample`. The `!` character passes the command that follows it to the operating system, which runs the standalone `myAircraftExample` program.

```
>> !myAircraftExample

** starting the model **
** created myAircraftExample.mat **
```

4 To see the files created in the build folder, use the `dir` or `ls` command again. The exact list of files produced varies among MATLAB platforms and versions. Here is a sample list from a Windows platform:

```
>> dir myAircraftExample_grt_rtw
```

```
.                    rt_main.obj                 myAircraftExample_data.c
..                   rtmodel.h                   myAircraftExample_data.obj
buildInfo.mat        rtw_proj.tmw                myAircraftExample_private.h
codeInfo.mat         myAircraftExample.bat       myAircraftExample_ref.rsp
defines.txt          myAircraftExample.c         myAircraftExample_types.h
html                 myAircraftExample.h
modelsources.txt     myAircraftExample.mk
rt_logging.obj       myAircraftExample.obj
```

Contents of the Build Folder

The build process creates a build folder and names it *`model_target`*`_rtw`, where *`model`* is the name of the source model and *`target`* is the system target file selected for the model. In this example, the build folder is named `myAircraftExample_grt_rtw`.

The build folder includes the following generated files.

File	Description
`myAircraftExample.c`	Standalone C code that implements the model
`myAircraftExample.h`	An include header file containing definitions of parameters and state variables
`myAircraftExample_private.h`	Header file containing common include definitions
`myAircraftExample_types.h`	Forward declarations of data types used in the code
`rtmodel.h`	Master header file for including generated code in the static main program (its name does not change, and it simply includes `myAircraftExample.h`)

The code generation report that you created for the `myAircraftExample` model displays a link for each of these files. You can click the link explore the file contents.

The build folder contains other files used in the build process. They include:

- `myAircraftExample.mk` — Makefile for building executable using the specified Toolchain.
- Object (`.obj`) files
- `myAircraftExample.bat` — Batch control file

- `rtw_proj.tmw` — Marker file
- `buildInfo.mat` — Build information for relocating generated code to another development environment
- `defines.txt` — Preprocessor definitions required for compiling the generated code
- `myAircraftExample_ref.rsp` — Data to include as command-line arguments to `mex` (Windows systems only)

The build folder also contains a subfolder, `html`, which contains the files that make up the code generation report. For more information, see "Reports for Code Generation" (Simulink Coder).

Customized Makefile Generation

After producing code, the code generator produces a customized makefile, *`model`*`.mk`. The generated makefile instructs the `make` system utility to compile and link source code generated from the model, any required harness program, libraries, or user-provided modules. The code generator produces the file *`model`*`.mk` regardless of the approach that you use for build process control:

- If you use the toolchain approach, the code generator creates *`model`*`.mk` based on the model **Toolchain settings**. You can modify generation of the makefile through the `rtwmakecfg.m` API.
- If you use the template makefile approach, the code generator creates *`model`*`.mk` from a system template file, *`system`*`.tmf` (where *`system`* stands for the selected system target file name). The system template makefile is designed for your system target file. You can modify the template makefile to specify compilers, compiler options, and additional information for the creation of the executable.

For more information, see "Choose Build Approach and Configure Build Process" on page 54-14.

Build Models from a Windows Command Prompt Window

This example shows how to build models by using a batch file, entering commands at the Command Prompt in Windows.

About MATLAB Command-Line (Start Up) Arguments

When you start MATLAB from a Command Prompt in Windows (as done in a batch file), you can control MATLAB start up with a number of command-line arguments.

For a description of these command-line arguments, in the Command Prompt window, type `matlab -help`.

To start MATLAB from a Command Prompt window, use these steps:

1. From the Windows Start menu, open a Command Prompt window.
2. From the Windows Command Prompt, type: `matlab`.

Tip: To display the path to the MATLAB root folder, at the MATLAB command prompt type: `matlabroot`.

Run MATLAB with a Batch File

When you run MATLAB with a batch file, you can:

- Control MATLAB start up with command-line arguments
- Run a series of operating system commands (such as source control checkout/commit)
- Run a series of MATLAB scripts

A batch approach also lets you automate your overall build process. Such a process can generate code from one or more Simulink models, then use your makefile to compile custom code and generated code.

This batch file sets the `MATLABROOT` environment variable, sets the `PATH` environment variable to include `MATLABROOT`, and starts MATLAB with an input script argument `%1` and a logfile argument.

Note: Customize the `MATLABROOT` value in the batch file to match your system. The batch file assumes that a `c:\temp` folder exists on your system.

Create a batch file named `mat.bat`

```
SET MATLABROOT="C:\Program Files\MATLAB\R2019a"
PATH=%MATLABROOT%;%PATH%
START matlab.exe -batch %1 -logfile c:\temp\logfile
PAUSE
```

Create a MATLAB script `myFilesToBuild.m`

```
my_rtwdemo_counter_builder
my_rtwdemo_rtwintro_builder
exit
```

Create a MATLAB script `my_rtwdemo_counter_builder.m`

```
open_system('rtwdemo_counter');
save_system('rtwdemo_counter','my_rtwdemo_counter')
rtwbuild('my_rtwdemo_counter');
close_system('my_rtwdemo_counter');
```

Create a MATLAB script `my_rtwdemo_rtwintro_builder.m`

```
open_system('rtwdemo_rtwintro');
save_system('rtwdemo_rtwintro','my_rtwdemo_rtwintro')
rtwbuild('my_rtwdemo_rtwintro');
close_system('my_rtwdemo_rtwintro');
```

Run the batch file

From the Windows Start menu, open a Command Prompt window, change folders to the folder containing the batch file, and type:

```
mat myFilesToBuild
```

When you run the batch file with the input MATLAB script, the batch file runs MATLAB and loads, builds, and closes each of the example Simulink models.

Observe the log of MATLAB operations

After the batch file runs, view the `c:\temp\logfile` file.

Tip: Omitting the semicolon (;) from the `rtwbuild` line in each script provides more build information in the log file.

Optimize Your Batch File

Use the MATLAB command-line arguments to optimize the batch file. Some options to consider include:

- Suppress the MATLAB splash screen on startup with the `-nosplash` argument.
- Provide command-line input to the input script or function selected with the `-batch` argument.

For example, you can call a function `myfile.m`, which accepts two arguments:

```
matlab -batch myfile(arg1,arg2)
```

To pass numeric values into `myfile.m`, replace `arg1` and `arg2` with numeric values.

To pass string or character values into `myfile.m`, replace `arg1` and `arg2` with the string or character values surrounded in single quotes. For example, to pass the string values `hello` and `world` into `myfile.m`, in the Command Prompt window, type:

```
matlab -batch myfile('hello','world')
```

Rebuild a Model

If you update generated source code or makefiles manually to add customizations, you can rebuild the files with the `rtwrebuild` command. This command recompiles the modified files by invoking the generated makefile. Alternatively, you can use this command from the Model Explorer:

1. Open the top model. To open the Model Explorer window, select **View > Model Explorer**.
2. In the **Model Hierarchy** pane, expand the node for the model.
3. Click the **Code for *`model`*** node.
4. In the **Code** pane, next to **Code Recompile Command**, click **rebuild generated code**.

Control Regeneration of Top Model Code

When you rebuild a model, by default, the build process performs checks to determine whether changes to the model or relevant settings require regeneration of the top model code. The model build regenerates top model code if any of the following conditions is true:

- The structural checksum of the model has changed.
- The top-model-only checksum has changed. The top-model-only checksum provides information about top model parameters, such as application lifespan, maximum stack size, make command, verbose and `.rtw` file debug settings, and `TLCOptions`.
- Any of the following TLC debugging model options, on the **Configuration Parameters > Code Generation > Advanced parameters** tab, is `on`:
  - **Start TLC debugger when generating code** (`TLCDebug`)
  - **Start TLC coverage when generating code** (`TLCCoverage`)
  - **Enable TLC assertion** (`TLCAssert`)
  - **Profile TLC** (`ProfileTLC`)

Whether the top model code is regenerated, the build process calls the build process hooks and reruns the makefile. The hooks include the *STF*`_make_rtw_hook` functions and the post code generation command. This process recompiles and links the external dependencies.

System target file authors can perform actions related to code regeneration in the *STF*`_make_rtw_hook` functions that the build process calls. These actions include forcing or reacting to code regeneration. For more information, see “Control Code Regeneration Using STF_make_rtw_hook.m” on page 84-53.

Regeneration of Top Model Code

If the checks determine that top model code generation is required, the build process fully regenerates and compiles the model code. An example check is whether previously generated code is not current due to a model update.

The build process omits regeneration of the top model code when the checks indicate both:

- The top model generated code is current for the model.
- Model settings do not require full regeneration.

This omission can significantly reduce model build times.

With an Embedded Coder license, if you modify a code generation template (CGT) file then rebuild your model, the code generation process does not force a top model build. In this case, see “Force Regeneration of Top Model Code” on page 54-47.

Force Regeneration of Top Model Code

If you want to control or override the default top model build behavior, use one of the following command-line options:

- To ignore the checksum and force regeneration of the top model code:
  - `rtwbuild(`*`model`*`,'ForceTopModelBuild',true)`
  - `slbuild(`*`model`*`,'StandaloneCoderTarget','ForceTopModelBuild',true)`
- To clean the model build area enough to trigger regeneration of the top model code at the next build (`slbuild` only):
  `slbuild(`*`model`*`,'CleanTopModel')`

You can force regeneration of the top model code by deleting the `slprj` folder or the generated model code folder from the “Code generation folder” (Simulink) .

- “Reduce Build Time for Referenced Models” on page 54-48

Reduce Build Time for Referenced Models

In a parallel computing environment, you can increase the speed of code generation and compilation for models containing large model reference hierarchies. Achieve the speed by building referenced models in parallel whenever conditions allow. For example, if you have Parallel Computing Toolbox software, code generation and compilation for each referenced model can be distributed across the cores of a multicore host computer. If you also have MATLAB Parallel Server™ software, you can distribute code generation and compilation for each referenced model across remote workers in your MATLAB Parallel Server configuration.

Parallel Building for Large Model Reference Hierarchies

The execution speed improvement realized by using parallel builds for referenced models depends on several factors. These factors include how many models can be built in parallel for a given model referencing hierarchy, the size of the referenced models, and parallel computing resources. The resources include the number of local and/or remote workers available and the hardware attributes of the local and remote machines. Examples of hardware attributes are the amount of RAM and number of cores.

For configuration requirements that could apply to your parallel computing environment, see “Parallel Building Configuration Requirements” on page 54-48.

For a description of the general workflow for building referenced models in parallel whenever conditions allow, see “Build Models in a Parallel Computing Environment” on page 54-49.

For information on how to configure a custom embedded system target file to support parallel builds, see “Support Model Referencing” (Simulink Coder).

Note In a MATLAB Parallel Server parallel computing configuration, parallel building is designed to work interactively with the software. You can initiate builds from the Simulink user interface or from the MATLAB Command Window using commands such as `slbuild`. You cannot initiate builds using `batch` or other batch mode workflows.

Parallel Building Configuration Requirements

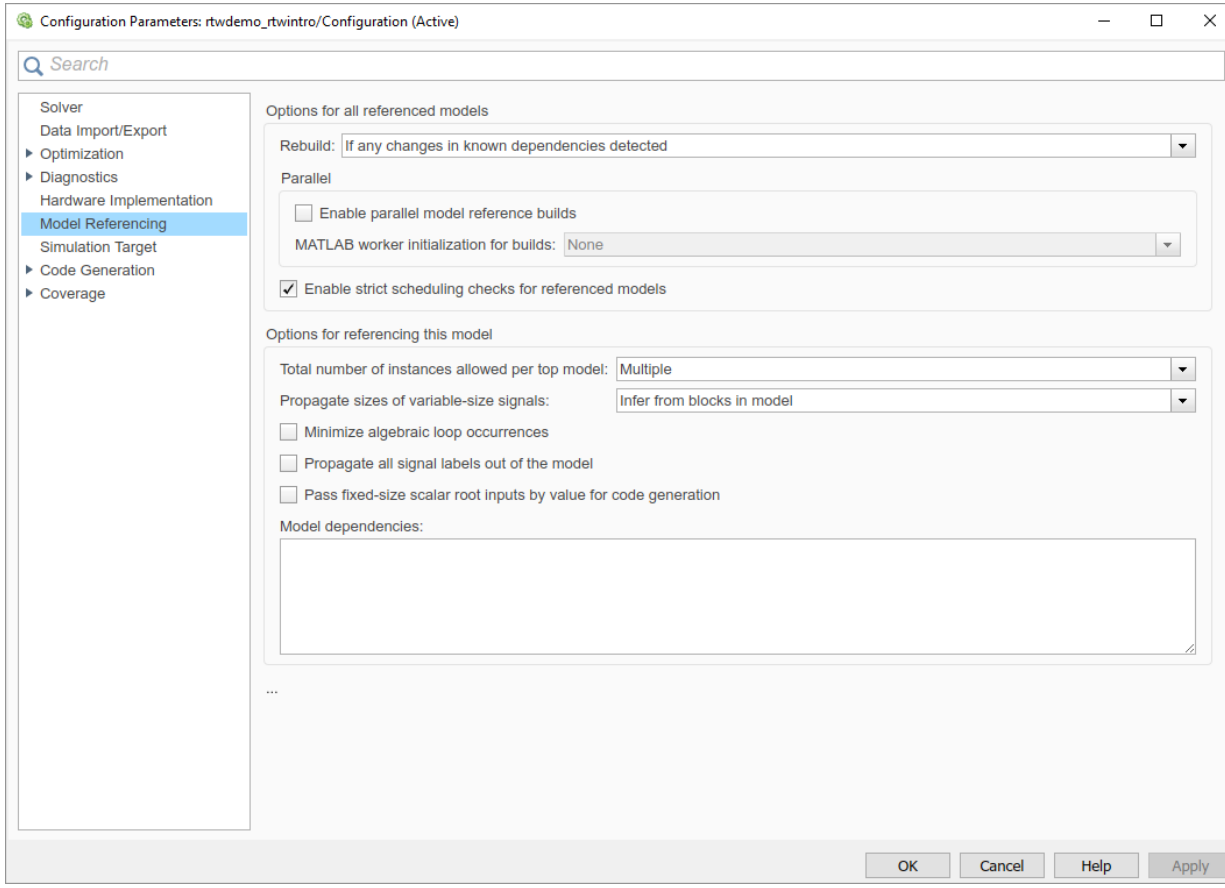
The following requirements apply to configuring your parallel computing environment for building model reference hierarchies in parallel whenever conditions allow:

- For local pools, the host machine must have enough RAM to support the number of local workers (MATLAB sessions) that you plan to use. For example, using `parpool(4)` to create a parallel pool with four workers results in five MATLAB sessions on your machine. Each pool uses the amount of memory required for MATLAB and the code generator at startup. For memory requirements, see System Requirements for MATLAB & Simulink.
- Remote MATLAB Parallel Server workers participating in a parallel build and the client machine must use a common platform and compiler.
- A consistent MATLAB environment must be set up in each MATLAB worker session as in the MATLAB client session — for example, shared base workspace variables, MATLAB path settings, and so forth. One approach is to use the `PreLoadFcn` callback of the top model. If you configure your model to load the top model with each MATLAB worker session, its preload function can be used for any MATLAB worker session setup.
- It is possible to cause a build error by relying on callbacks to load variables when executing an incremental parallel build (referenced model hierarchy build). To avoid this issue during parallel builds, use one of these options:
  - Do not rely on callback to manage workspace variable of referenced models,
  - Between builds, run the commands `spmd, bdclose all, end` to close all models on the parallel build workers.
  - Between builds, restart the parallel pool.

Build Models in a Parallel Computing Environment

To take advantage of parallel building for a model reference hierarchy:

1. Set up a pool of local and/or remote MATLAB workers in your parallel computing environment.
   a. Make sure that Parallel Computing Toolbox software is licensed and installed.
   b. To use remote workers, make sure that MATLAB Parallel Server software is licensed and installed.
   c. Issue MATLAB commands to set up the parallel pool, for example, `parpool(4)`.
2. From the top model of the model reference hierarchy, open the Configuration Parameters dialog box. Go to the **Model Referencing** pane and select the **Enable parallel model reference builds** (Simulink) option. This selection enables the parameter **MATLAB worker initialization for builds** (Simulink).



For **MATLAB worker initialization for builds**, select one of the following values:

- `None` if it is preferable that the software does not perform special worker initialization. Specify this value if the child models in the model reference hierarchy do not rely on anything in the base workspace beyond what they explicitly set up. An example is a model load function.
- `Copy base workspace` if it is preferable that the software attempts to copy the base workspace to each worker. Specify this value if you use a setup script to prepare the base workspace for multiple models to use.

- `Load top model` if it is preferable that the software loads the top model on each worker. Specify this value if the top model in the model reference hierarchy handles the base workspace setup. An example is a model load function.

Note Only set **Enable parallel model reference builds** for the top model of the model reference hierarchy to which it applies.

3. Optionally, turn on verbose messages for simulation builds, code generation builds, or both. If you select verbose builds, the build messages report the progress of each parallel build with the name of the model.

   - To turn on verbose messages in model builds for simulation, go to **Configuration Parameters > Simulation Target > Advanced parameters** and select **Verbose accelerator builds**.
   - To turn on verbose messages in model builds for code generation, go to **Configuration Parameters > Code Generation > Advanced parameters** and select **Verbose build**.

   Verbose options control the build messages in the MATLAB Command Window and in parallel build log files.

4. Optionally, inspect the model reference hierarchy to determine, based on model dependencies, which models are built in parallel. For example, you can use the Model Dependency Viewer from the Simulink **Analysis > Model Dependencies** menu.

5. Build your model. Messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. The order in which referenced models build is nondeterministic. They could build in a different order each time the model is built.

   If you need more information about a parallel build, for example, if a build fails, see “Locate Parallel Build Logs” on page 54-51.

Locate Parallel Build Logs

If verbose builds are turned on when you build a model for which referenced models are built in parallel, messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. For example,

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model001'
### Starting parallel model reference SIM build for 'bot_model002'
```

```
### Starting parallel model reference SIM build for 'bot_model003'
### Starting parallel model reference SIM build for 'bot_model004'
### Finished parallel model reference SIM build for 'bot_model001'
### Finished parallel model reference SIM build for 'bot_model002'
### Finished parallel model reference SIM build for 'bot_model003'
### Finished parallel model reference SIM build for 'bot_model004'
### Starting parallel model reference RTW build for 'bot_model001'
### Starting parallel model reference RTW build for 'bot_model002'
### Starting parallel model reference RTW build for 'bot_model003'
### Starting parallel model reference RTW build for 'bot_model004'
### Finished parallel model reference RTW build for 'bot_model001'
### Finished parallel model reference RTW build for 'bot_model002'
### Finished parallel model reference RTW build for 'bot_model003'
### Finished parallel model reference RTW build for 'bot_model004'
```

To obtain more detailed information about a parallel build, you can examine the parallel build log. For each referenced model built in parallel, the build process generates a file named *`model`*`_buildlog.txt`, where *`model`* is the name of the referenced model. This file contains the full build log for that model.

If a parallel build completes, you can find the build log file in the build subfolder corresponding to the referenced model. For example, for a build of referenced model `bot_model004`, look for the build log file `bot_model004_buildlog.txt` in a referenced model subfolder such as *`build_folder`*`/slprj/grt/bot_model004`, *`build_folder`*`/slprj/ert/bot_model004`, or *`build_folder`*`/slprj/sim/bot_model004`. The build log (diagnostic viewer) provides a relative path to the location of each build log file.

If a parallel builds fails, you could see output similar to the following:

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
...
### Starting parallel model reference RTW build for 'bot_model002'
### Starting parallel model reference RTW build for 'bot_model003'
### Finished parallel model reference RTW build for 'bot_model002'
### Finished parallel model reference RTW build for 'bot_model003'
### Starting parallel model reference RTW build for 'bot_model001'
### Starting parallel model reference RTW build for 'bot_model004'
### Finished parallel model reference RTW build for 'bot_model004'
### The following error occurred during the parallel model reference RTW build for
'bot_model001':

Error(s) encountered while building model "bot_model001"

### Cleaning up parallel workers.
```

If a parallel build fails, you can find the build log file in a referenced model subfolder under the build subfolder `/par_mdl_ref/`*`model`*. For example, for a failed parallel build of model `bot_model001`, look for the build log file `bot_model001_buildlog.txt` in a

subfolder such as *build_folder*/par_mdl_ref/bot_model001/slprj/grt/bot_model001, *build_folder*/par_mdl_ref/bot_model001/slprj/ert/bot_model001, or *build_folder*/par_mdl_ref/bot_model001/slprj/sim/bot_model001.

View Build Process Status

The **Build Process Status** window lets you view in-progress build status or cancel in-progress parallel builds of models. After completing a model build, you can view the completion status by using the **Build Process Status** window. For more information, see “Apply Build Process Status to Improve Parallel Builds” on page 54-54.

Note The **Build Process Status** window support parallel builds of referenced model hierarchies. Do not use the **Build Process Status** window for sequential (non-parallel) builds.

To open the **Build Process Status** window, use any of these options:

- To open the **Build Process Status** window for a *model*, in the command window, type:

  ```
  coder.buildstatus.open('model')
  ```

- To open the **Build Process Status** window for a *model* with the `rtwbuild` function, in the command window, type:

  ```
  rtwbuild('model', ...
      'OpenBuildStatusAutomatically',true)
  ```

- To open the **Build Process Status** window for a *model* with the `slbuild` function, in the command window, type:

  ```
  slbuild('model','StandaloneCoderTarget', ...
      'OpenBuildStatusAutomatically',true)
  ```

To cancel an in-progress model build, the **Build Process Status** window provides a **Cancel** button. This button cancels the build after completion of the current model or referenced model build. Using cancel to stop a build ends a build process without creating out-dated build artifacts that require post-build clean up.

Apply Build Process Status to Improve Parallel Builds

The **Build Process Status** window lets you view in-progress build status or cancel in-progress parallel builds of models. For more information, see “View Build Process Status” on page 54-53.

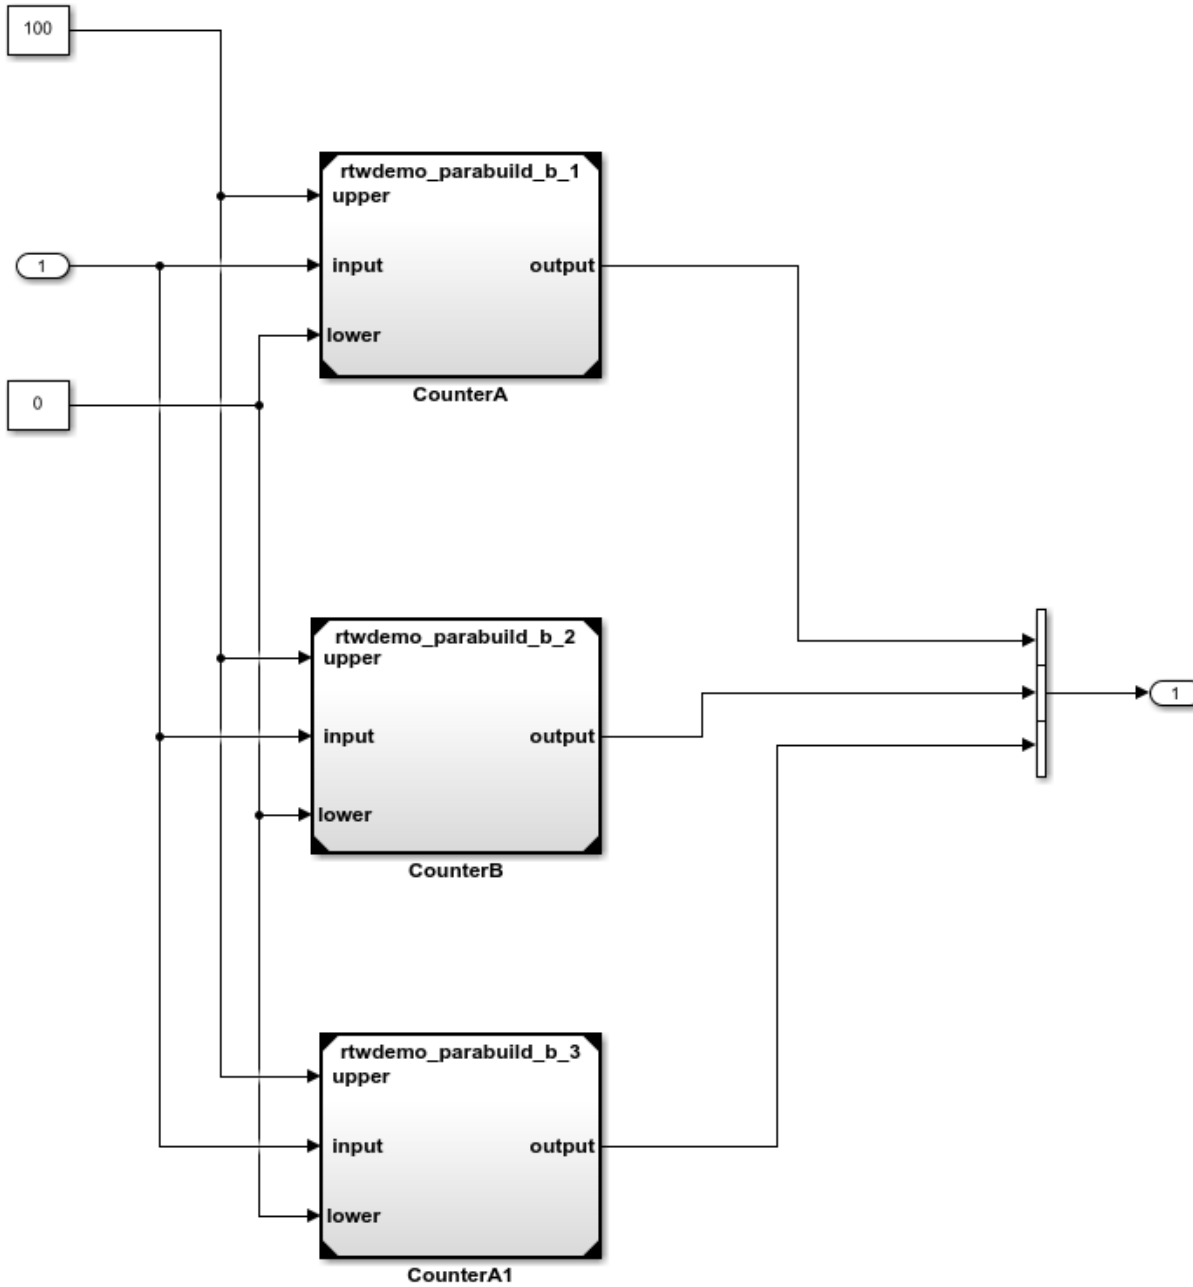
This example shows how apply build process status from parallel builds. The status information can help you identify ways to improve parallel builds by modifying the referenced model hierarchy.

1. Open a parallel pool for the build process and add the model folder to the path for all workers.

   ```
   parpool('local', 2)
   addpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','rtwdemo_parallelbuild'))
   spmd
   addpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','rtwdemo_parallelbuild'))
   end
   ```

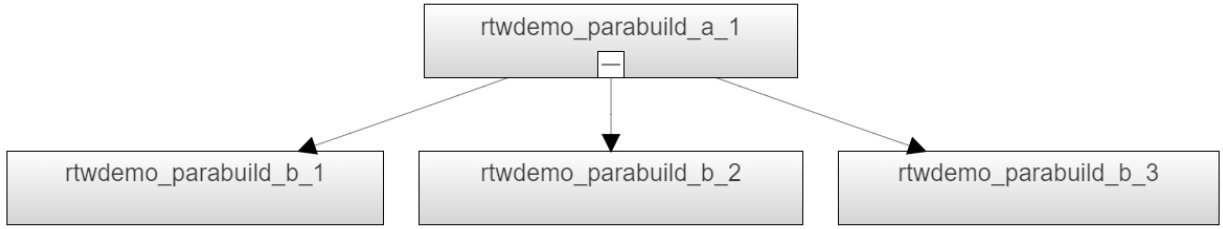
2. Open the top-level model in a reference model hierarchy. The `rtwdemo_parabuild_a_1` model refers to a number of referenced models.

   ```
   open_system('rtwdemo_parabuild_a_1')
   ```



100
rtwdemo_parabuild_b_1
upper
1
input
output
lower
0
CounterA
rtwdemo_parabuild_b_2
upper
input
output
lower
CounterB
1
rtwdemo_parabuild_b_3
upper
input
output
lower
CounterA1

3. View the model dependencies with **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**. This view displays the dependencies for the referenced model hierarchy.

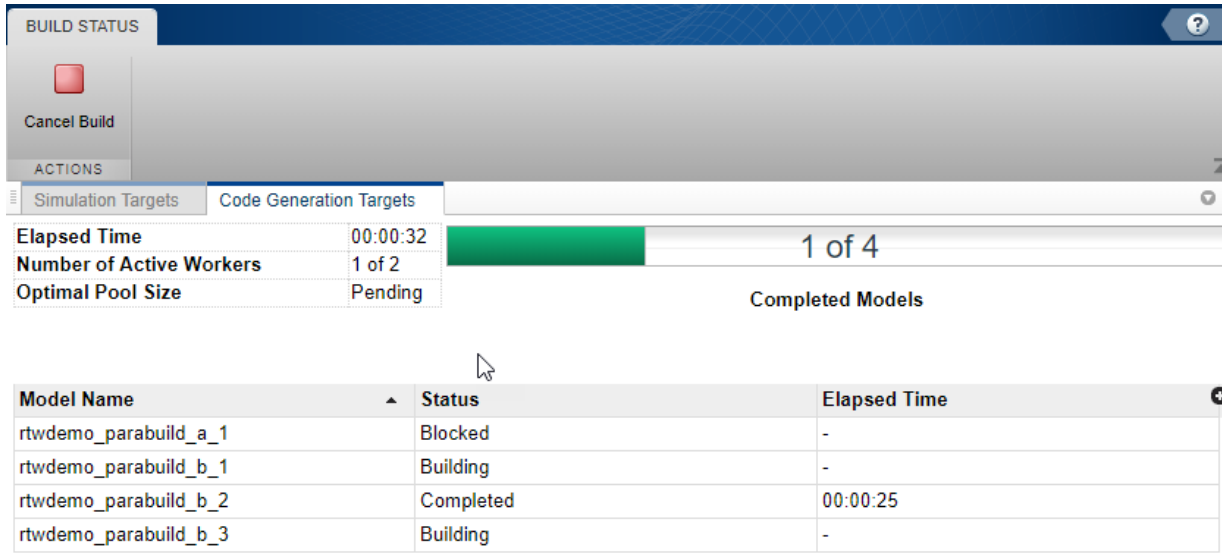


During the build process, the Build Process Status window displays the progress of the code generator as it works its way up the referenced model hierarchy. The code generator builds the referenced models in the order that they block building of models further up the dependency tree.

4. Start a parallel build of the referenced model hierarchy and open the Build Process Status window.

```
rtwbuild('rtwdemo_parabuild_a_1','OpenBuildStatusAutomatically',true)
```

5. As the build progresses, the Build Process Status window displays the status for each referenced model.



The table describes the types of build status.

Build Process Status	Description
Blocked	The code generator cannot schedule the model build because the build is blocked by dependencies. For example, another model build must complete before the blocked build can be scheduled.
Scheduled	For parallel build processes, the code generator schedules the model build when it is not blocked by dependencies. The model build waits at the scheduled status until a parallel core is available to process the model build.
Building	The code generator is executing the build process for the model.
Completed or **Error**	When the build process exits successfully, the status is Completed. When the build process is not success, the status is Error.
Up To Date	When the build process detects that it does not need to generate code (for example, generated code is current with the model), the status is Up to Date.
Canceling or **Canceled**	When you use the **Cancel Build** button, the build process changes the status of incomplete builds to Canceling. After processing the Canceling operation, the build process changes the status of these builds to Canceled.

The elapse time shows you where the build process spends time. Use the dependency tree of the model hierarchy and the elapse time of reference model builds to identify locations where the build process spends the most time and restricts the build progress. Some options for reducing the parallel build time include:

- Restructure the referenced model hierarchy to reduce build time for individual models.
- Provide sufficient parallel workers in the pool to match the number of referenced model dependencies being built.

Relocate Code to Another Development Environment

If you require relocating the static and generated code files for a model to another development environment, use the pack-and-go utility. This condition occurs when your system or integrated development environment (IDE) does not include MATLAB and Simulink products.

Code Relocation

The pack-n-go utility uses the tools for customizing the build process after code generation and a `packNGo` function to find and package files for building an executable image. The files are packaged in a compressed file that you can relocate and unpack using a standard `zip` utility.

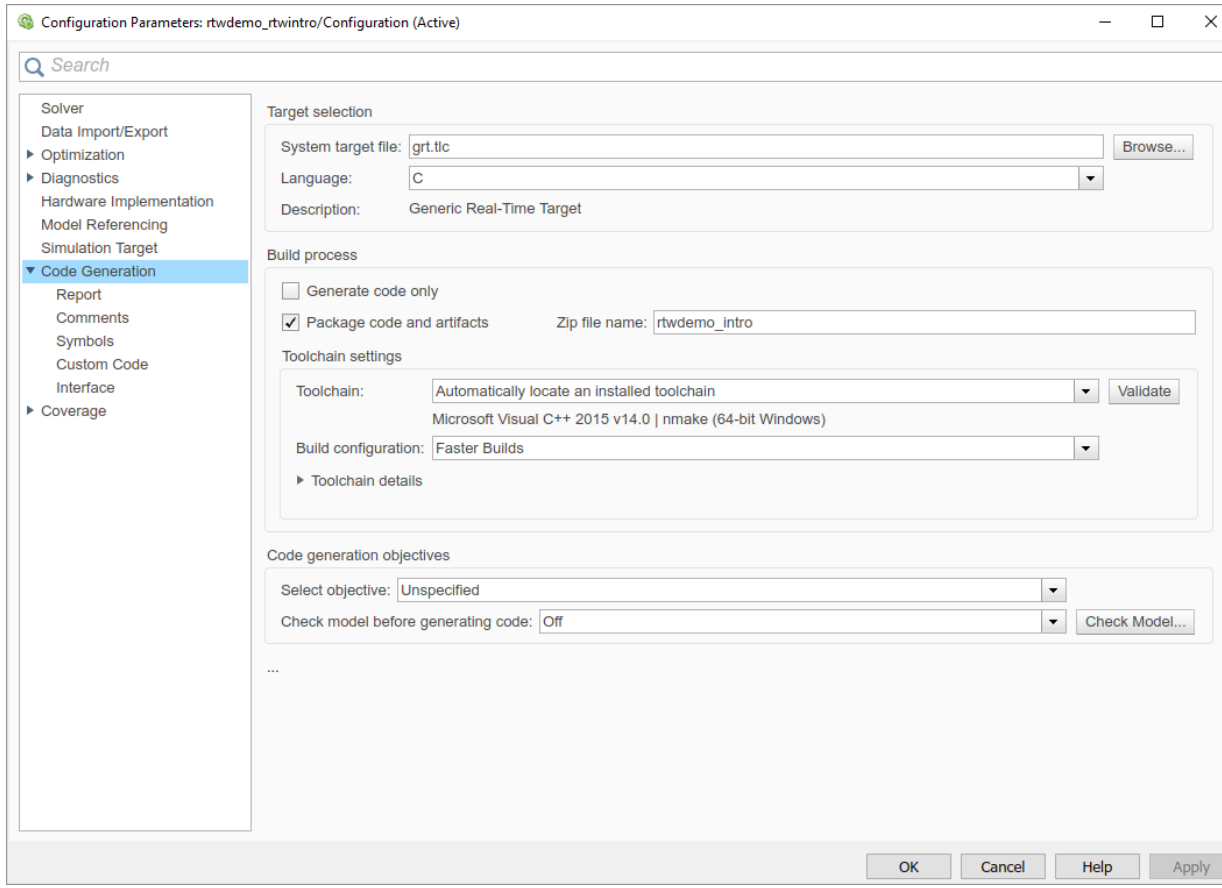
To package model code files, you can do either of the following:

- Use the model option **Package code and artifacts** (Simulink Coder) in the **Configuration Parameters > Code Generation** pane. See “Package Code Using the User Interface” on page 54-60.
- Use MATLAB commands to configure a `PostCodeGenCommand` parameter with a call to the `packNGo` function. See “Package Code Using the Command-Line Interface” on page 54-61. The command-line interface provides more control over the details of code packaging.

Package Code Using the User Interface

To package and relocate code for your model using the user interface:

1. Open **Configuration Parameters > Code Generation**.
2. Select the option **Package code and artifacts** (Simulink Coder). This option configures the build process to run the `packNGo` function after code generation to package generated code and artifacts for relocation.
3. In the **Zip file name** (Simulink Coder) field, enter the name of the `zip` file in which to package generated code and artifacts for relocation. You can specify the file name with or without the `.zip` extension. If you do not specify an extension or an extension other than `.zip`, the `zip` utility adds the `.zip` extension. If you do not specify a value, the build process uses the name *`model`*`.zip`, where *`model`* is the name of the top model for which code is being generated.



4. Apply changes and generate code for your model. To verify that it is ready for relocation, inspect the resulting `zip` file. Depending on the `zip` tool that you use, you could be able to open and inspect the file without unpacking it.
5. Relocate the `zip` file to the destination development environment and unpack the file.

Package Code Using the Command-Line Interface

To package and relocate code for your model using the command-line interface:

1. Select a structure for the `zip` file. on page 54-62

2 Select a name for the `zip` file. on page 54-62

3 Package the model code files in the `zip` file. on page 54-63

4 Inspect the generated `zip` file. on page 54-64

5 Relocate and unpack the `zip` file. on page 54-64

Select a Structure for the Zip File

Before you generate and package the files for a model build, decide whether you want the files to be packaged in a flat or hierarchical folder structure. By default, the `packNGo` function packages the files in a single, flat folder structure.

If...	Then Use a...
You are relocating files to an IDE that does not use the generated makefile, or the code is not dependent on the relative location of required static files	Single, flat folder structure
The destination development environment must maintain the folder structure of the source environment because it uses the generated makefile, or the code depends on the relative location of files	Hierarchical structure

If you use a hierarchical structure, the `packNGo` function creates two levels of `zip` files, a primary `zip` file, which in turn contains the following secondary `zip` files:

- `mlrFiles.zip` — files in your *`matlabroot`* folder tree
- `sDirFiles.zip` — files in and under your build folder where you initiated code generation for the model
- `otherFiles.zip` — required files not in the *`matlabroot`* or `start` folder trees

Paths for the secondary `zip` files are relative to the root folder of the primary `zip` file, maintaining the source development folder structure.

Select a Name for the Zip File

By default, the `packNGo` function names the primary `zip` file *`model`*. You have the option of specifying a different name. If you specify a file name and omit the file type extension, the function appends `.` to the name that you specify.

Package Model Code in a Zip File

Package model code files by using the `PostCodeGenCommand` configuration parameter, `packNGo` function, and build information object for the model. You can set up the packaging operation to use:

- A system generated build information object.

  In this case, before generating the model code, use `set_param` to set the configuration parameter `PostCodeGenCommand` to an explicit call to the `packNGo` function. For example:

  ```
  set_param(bdroot, 'PostCodeGenCommand', 'packNGo(buildInfo);');
  ```

  After generating and writing the model code to disk and before generating a makefile, this command instructs the build process to evaluate the call to `packNGo`. This command uses the system generated build information object for the currently selected model.

- A build information object that you construct programmatically.

  In this case, you could use other build information functions to include paths and files selectively in the build information object that you then specify with the `packNGo` function. For example:

  ```
  .
  .
  .
  myModelBuildInfo = RTW.BuildInfo;
  addSourceFiles(myModelBuildInfo, {'test1.c' 'test2.c' 'driver.c'});
  .
  .
  .
  packNGo(myModelBuildInfo);
  ```

The following examples show how you can change the default behavior of `packNGo`.

To...	Specify...
Change the structure of the file packaging to hierarchical	`packNGo(buildInfo, {'packType' 'hierarchical'});`
Rename the primary `zip` file	`packNGo(buildInfo, {'fileName' 'zippedsrcs'});`

To...	Specify...
Change the structure of the file packaging to hierarchical and rename the primary `zip` file	`packNGo(buildInfo, {'packType' 'hierarchical'... 'fileName' 'zippedsrcs'});`
Include header files found on the include path in the `zip` file	`packNGo(buildInfo, {'minimalHeaders' false});`
Generate warnings for parse errors and missing files	`packNGo(buildInfo, {'ignoreParseError' true... 'ignoreFileMissing' true});`

Note The `packNGo` function can potentially modify the build information passed in the first `packNGo` argument. As part of packaging model code, `packNGo` could find additional files from source and include paths recorded in build information for the model and add them to the build information.

Inspect a Generated Zip File

To verify that it is ready for relocation, inspect the generated `zip` file. Depending on the `zip` tool that you use, you could be able to open and inspect the file without unpacking it. If unpacking the file and you packaged the model code files as a hierarchical structure, unpacking requires you to unpack the primary and secondary `zip` files. When you unpack the secondary `zip` files, relative paths of the files are preserved.

Relocate and Unpack a Zip File

Relocate the generated `zip` file to the destination development environment and unpack the file.

Code Packaging Example

This example shows how to package code files generated for the example model `rtwdemo_rtwintro` using the command-line interface:

1. Set your working folder to a writable folder.
2. Open the model `rtwdemo_rtwintro` and save a copy to your working folder.
3. Enter the following MATLAB command:

```
set_param('rtwdemo_rtwintro', 'PostCodeGenCommand',...
'packNGo(buildInfo, {''packType'' ''hierarchical''})');
```

You must double the single-quotes due to the nesting of character arrays `'packType'` and `'hierarchical'` within the character array that specifies the call to `packNGo`.

4. Generate code for the model.
5. Inspect the generated `zip` file, `rtwdemo_rtwintro.zip`. The `zip` file contains the two secondary `zip` files, `mlrFiles.zip` and `sDirFiles.zip`.
6. Inspect the `zip` files `mlrFiles.zip` and `sDirFiles.zip`.
7. Relocate the `zip` file to a destination environment and unpack it.

Build Integrated Code Outside the Simulink Environment

Identify required files and interfaces for calling generated code in an external build process.

Learn how to:

- Collect files required for building integrated code outside of Simulink®.
- Interface with external variables and functions.

For information about the example model and related examples, see “Generate C Code from a Control Algorithm for an Embedded System”.

Collect and Build Required Data and Files

The code that Embedded Coder® generates requires support files that MathWorks® provides. To relocate the generated code to another development environment, such as a dedicated build system, you must relocate these support files. You can package these files in a zip file by using the `packNGo` utility. This utility finds and packages the files that you need to build an executable image. The utility uses tools for customizing the build process after code generation, which include a `buildinfo_data` structure, and a `packNGo` function. These files include external files that you identify in the **Code Generation > Custom Code** pane in the Model Configuration Parameters dialog box. The utility saves the `buildinfo` MAT-file in the *`model`*`_ert_rtw` folder.

Open the example model, `rtwdemo_PCG_Eval_P5`.

This model is configured to run `packNGo` after code generation.

Generate code from the entire model.

To generate the zip file manually:

1. Load the file `buildInfo.mat` (located in the `rtwdemo_PCG_Eval_P5_ert_rtw` subfolder).
2. At the command prompt, enter the command `packNGo(buildInfo)`.

The number of files in the zip file depends on the version of Embedded Coder® and on the configuration of the model that you use. The compiler might require a subset of the files in the zip file. The compiled executable size (RAM/ROM) depends on the linking process. The linker likely includes only the object files that are necessary.

Integrating the Generated Code into an Existing System

This example shows how to integrate the generated code into an existing code base. The example uses the Eclipse™ IDE and the Cygwin™/gcc compiler. The required integration tasks are common to integration environments.

Overview of Integration Environment

A full embedded controls system consists of multiple hardware and software components. Control algorithms are just one type of component. Other components can be:

- An operating system (OS)
- A scheduling layer
- Physical hardware I/O
- Low-level hardware device drivers

Typically, you do not use the generated code in these components. Instead, the generated code includes interfaces that connect with these components. MathWorks® provides hardware interface block libraries for many common embedded controllers. For examples, see the Embedded Targets block library.

This example provides files to show how you can build a full system. The main file is `example_main.c`, which contains a simple main function that performs only basic actions to exercise the code.

View `example_main.c`.

```
int_T main(void)
{
  /* Initialize model */
  rt_Pos_Command_Arbitration_Init(); /* Set up the data structures for chart*/
  rtwdemo_PCG__Define_Throt_Param(); /* SubSystem: '<Root>/Define_Throt_Param' */
  defineImportData();                /* Defines the memory and values of inputs */

  do /* This is the "Schedule" loop.
      Functions would be called based on a scheduling algorithm */
  {
    /* HARDWARE I/O */

    /* Call control algorithms */
    PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                      &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
    PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                      &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
    pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
    pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

    rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                    &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

The file:

- Defines function interfaces (function prototypes).
- Includes files that declare external data.
- Defines `extern` data.
- Initializes data.
- Calls simulated hardware.
- Calls algorithmic functions.

The order of function execution matches the order of subsystem execution in the test harness model and in `rtwdemo_PCG_Eval_P5.h`. If you change the order of execution in `example_main.c`, results that the executable image produces differ from simulation results.

Match System Interfaces

Integration requires matching the *Data* and *Function* interfaces of the generated code and the existing system code. In this example, the `example_main.c` file imports and exports the data through `#include` statements and `extern` declarations. The file also calls the functions from the generated code.

Connect Input Data

The system has three input signals: `pos_rqst`, `fbk_1`, and `fbk_2`. The generated code accesses the two feedback signals through direct reference to imported global variables (storage class `ImportedExtern`). The code accesses the position signal through an imported pointer (storage class `ImportedExternPointer`).

The handwritten file `defineImportedData.c` defines the variables and the pointer. The generated code does not define the variables and the pointer because the handwritten code defines them. Instead, the generated code declares the imported data (`extern`) in the file `rtwdemo_PCG_Eval_P5_Private.h`. In a real system, the data typically comes from other software components or from hardware devices.

View `defineImportedData.c`.

```
/* Define imported data */
#include "rtwtypes.h"
#include "defineImportedData.h"

real_T fbk_1;
real_T fbk_2;
real_T dummy_pos_value = 10.0;
real_T *pos_rqst;
void defineImportData(void)
{
    pos_rqst = &dummy_pos_value;
}
```

View `rtwdemo_PCG_Eval_P5_Private.h`.

```
/* Imported (extern) block signals */
extern real_T fbk_1;                   /* '<Root>/fbk_1' */
extern real_T fbk_2;                   /* '<Root>/fbk_2' */

/* Imported (extern) pointer block signals */
extern real_T *pos_rqst;               /* '<Root>/pos_rqst' */
```

Connect Output Data

In this example, you do not access the output data of the system. The example “Test Generated Code” shows how you can save the output data to a standard log file. You can access the output data by referring to the file `rtwdemo_PCG_Eval_P5.h`.

View `rtwdemo_PCG_Eval_P5.h`.

Access Additional Data

The generated code contains several structures that store commonly used data including:

- Block state values (integrator, transfer functions)
- Local parameters
- Time

The table lists the common data structures. Depending on the configuration of the model, a combination of these structures appear in the generated code. The data is declared in the file `rtwdemo_PCG_Eval_P5.h`, but in this example, you do not access this data.

```
Data Type      Data Name     Data Purpose

Constants      |model_cP|    Constant parameters
Constants      |model_cB|    Constant block I/O
Output         |model_U|     Root and atomic subsystem input
Output         |model_Y|     Root and atomic subsystem output
Internal data  |model_B|     Value of block output
Internal data  |model_D|     State information vectors
Internal data  |model_M|     Time and other system level data
Internal data  |model_Zero|  Zero-crossings
Parameters     |model_P|     Parameters
```

Match Function Call Interfaces

By default, functions that the code generator generates have a `void` *`Func`*`(void)` interface. If you configure the model or atomic subsystem to generate reentrant code, the

code generator creates a more complex function prototype. In this example, the `example_main` function calls the generated functions with valid input arguments.

```
PI_Cntrl_Reusable((*pos_rqst),fbk_1,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_1,
                  &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_1);
PI_Cntrl_Reusable((*pos_rqst),fbk_2,&rtwdemo_PCG_Eval_P5_B.PI_ctrl_2,
                  &rtwdemo_PCG_Eval_P5_DWork.PI_ctrl_2);
pos_cmd_one = rtwdemo_PCG_Eval_P5_B.PI_ctrl_1.Saturation1;
pos_cmd_two = rtwdemo_PCG_Eval_P5_B.PI_ctrl_2.Saturation1;

rtwdemo_Pos_Command_Arbitration(pos_cmd_one, &Throt_Param, pos_cmd_two,
                                &rtwdemo_PCG_Eval_P5_B.sf_Pos_Command_Arbitration);
```

Calls to the function `PI_Cntrl_Reusable` use a mixture of separate, unstructured global variables and Simulink® Coder™ data structures. The handwritten code defines these variables. The structure types are defined in `rtwdemo_PCG_Eval_P5.h`.

Build Project in Eclipse™ Environment

This example uses the Eclipse™ IDE and the Cygwin™ GCC debugger to build the embedded system. The example provides installation files for both programs. Software components and versions numbers are:

- Eclipse™ SDK 3.2
- Eclipse™ CDT 3.3
- Cygwin™/GCC 3.4.4-1
- Cygwin™/GDB 20060706-2

To install and use Eclipse™ and GCC, see “Install and Use Cygwin and Eclipse”.

You can install the files for this example by clicking this hyperlink:

Set up the build folder.

Alternatively, to install the files manually:

1. Create a build folder (`Eclipse_Build_P5`).
2. Unzip the file `rtwdemo_PCG_Eval_P5.zip` into the build folder.
3. Delete the files `rtwdemo_PCG_Eval_P5.c`, `ert_main.c` and `rt_logging.c`, which are replaced by `example_main.c`.

You can use the Eclipse™ debugger to step through and evaluate the execution behavior of the generated C code. See the example “Install and Use Cygwin and Eclipse”.

To exercise the model with input data, see “Test Generated Code”.

Limitations

packNGo Function

For information about limitations that apply to this function, see `packNGo`.

Executable File with Nondefault Extension

If a build process uses the template makefile approach, then `packNGo` uses the executable file extension specified by the linker tool to determine binary artifacts that require packaging.

If you generate an executable file with an extension that is not a default value, check that the extension is saved in the toolchain associated with the template makefile. For more information, see “Associate the Template Makefile with a Toolchain” (Simulink Coder).

If the build process generates an executable file with an extension that is different from the extension saved in the toolchain, `packNGo` does not package the executable file.

Compile and Debug Generated C Code with Microsoft® Visual Studio®

This example shows how to generate code from a model and produce a Visual Studio Solution. For the base example, see `rtwdemo_counter`.

About This Example

Building this example model generates a Visual Studio Solution. These configuration settings control this code generation:

- Target - Select **Configuration Parameters** > **Code Generation** > **System target file** as `grt.tlc Create Visual C/C++ Solution file for Simulink Coder`.
- Template makefile - Select **Configuration Parameters** > **Code Generation** > **Template makefile** as `RTW.MSVCBuild`.

When you build the model with this configuration, Simulink Coder generates code in a Visual Studio Solution. Add this solution to a Visual Studio C/C++ project to integrate generated code with your custom Visual Studio code.

Before You Start

- This example builds code for Microsoft Visual Studio running on Microsoft Windows® platforms.
- This example works with Microsoft Visual Studio, but not with Visual Studio Express.
- Simulink Coder uses the GRT code format, which is intended for rapid prototyping.
- Embedded Coder uses the ERT code format, which is intended for production deployment.

Example Steps

1. Open the example model `rtwdemo_counter_msvc`. In the Command Window, type: open_system('rtwdemo_counter_msvc');
2. To generated debug output in the generated Visual Studio Solution, set the **Configuration Parameters** > **Code Generation** > **Make command** parameter to `make_rtw DEBUG_BUILD=1`. (Omit this step if debug output is not required in the solution.)
3. To generate code, double click the **Generate Code Using Simulink Coder** button in the model or at the command prompt, type: rtwbuild('rtwdemo_counter_msvc');

4. After the build process is complete, you can see a Visual Studio Solution was generated and placed in the `msvc` folder under the `rtwdemo_counter_msvc_grt_rtw` folder.
5. In Microsoft Visual Studio, open the `rtwdemo_counter_msvc.sln` solution file.

Use the solution to build and debug the generated code in Visual Studio.

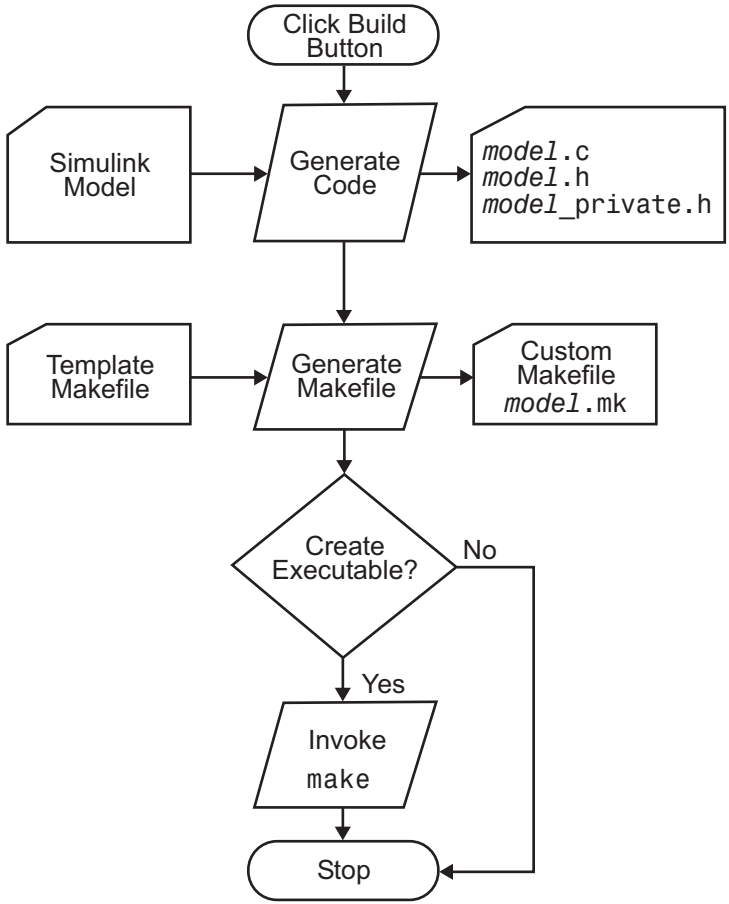
Executable Program Generation

The following figure shows how the process for program building.



During the final stage of processing, the build process invokes the generated makefile, *model*`.mk`, which in turn compiles and links the generated code. On PC platforms, a batch file is created to invoke the generated makefile. The batch file sets up the environment for invoking the `make` utility and related compiler tools. To avoid recompiling C files, the `make` utility performs date checking on the dependencies between the object and C files; only out-of-date source files are compiled. Optionally, the makefile can download the resulting executable image to your target hardware.

This stage is optional, as illustrated by the control logic in the preceding figure. You could choose to omit this stage (for example, if you are targeting an embedded microcontroller board).

To omit this stage of processing, select the **Configuration Parameters > Code Generation** pane and select the **Generate code only** check box. You can then cross-compile your code and download it to your target hardware.

If you select the **Configuration Parameters > Code Generation > Report** pane and select **Create code generation report**, the code generator produces a navigable summary of source files when the model is built. The report files occupy a folder called `html` within the build folder. The following display shows an example of an HTML code generation report for a generic real-time (GRT) system target file.

Profile Code Execution Speed

By profiling the execution speed of generated code, you can help verify that the code meets execution speed requirements.

Profiling can be especially important early in the development cycle for identifying potential architectural issues that can be more expensive to address later in the process. Profiling can also identify bottlenecks and procedural issues that indicate a need for optimization, for example, with an inner loop or inline code.

Note If you have an Embedded Coder license, see “Code Execution Profiling” for an alternative and simpler approach based on software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations.

Use the Profile Hook Function Interface

You can profile code generated with code generation technology by using a Target Language Compiler (TLC) hook function interface.

To use the profile hook function interface:

1. For your system target file, create a TLC file that defines the following hook functions. Write the functions so that they specify profiling code. The code generator adds the hook function code to code generated for atomic systems in the model.

Function	Input Arguments	Output Type	Description
`ProfilerHeaders`	`void`	Array of header file names	Return an array of the header file names to be included in the generated code.
`ProfilerTypedefs`	`void`	`typedefs`	Generate code statements for profiler type definitions.
`ProfilerGlobal-Data`	`system`	Global data for the specified `system`	Generate code statements that declare global data.

Function	Input Arguments	Output Type	Description
`ProfilerExtern-DataDecls`	`system`	`extern` declarations for the specified `system`	Generate code statements that create global `extern` declarations.
`ProfilerSystem-Decls`	`system`, `functionType`	Declarations for the specified `system` for the specified `functionType`	Generate code for required variable declarations within the scope of an atomic subsystem `Output`, `Update`, `OutputUpdate`, or `Derivatives` function.
`ProfilerSystem-Start`	`system`, `functionType`	Profiler start commands for the specified `system` and `functionType`	Generate code that starts the profiler within the scope of an atomic subsystem `Output`, `Update`, `OutputUpdate`, or `Derivatives` function.
`ProfilerSystem-Finish`	`system`, `functionType`	Profiler end commands for the specified `system` and `functionType`	Generate code that stops the profiler within the scope of the `Output`, `Update`, `OutputUpdate`, or `Derivatives` functions of an atomic subsystem.
`ProfilerSystem-Terminate`	`system`	Profiler termination code for the specified `system`	Generate code that terminates profiling (and possibly reports results) for an atomic subsystem.

For an example TLC file, see *`matlabroot`*`/toolbox/rtw/rtwdemos/rtwdemo_profile_hook.tlc`.

2 In your *target*.tlc file, define the following global variables.

Define...	To Be...
ProfileGenCode	TLC_TRUE or 1 to turn on profiling (TLC_FALSE or 0 to turn off profiling)
ProfilerTLC	The name of the TLC file that you created in step 1

A quick way to define global variables is to define the parameters with the -a option. You can apply this option by using the set_param command to set the model configuration parameter TLCOptions. For example,

```
>> set_param(gcs,'TLCOptions', ...
     '-aProfileGenCode=1 -aProfilerTLC="rtwdemo_profile_hook.tlc"')
```

3 Consider setting configuration parameters for generating a code generation report. You can then examine the profiling code in the context of the code generated for the model.

4 Build the model. The build process embeds the profiling code in the hook function locations in the generated code for the model.

5 Run the generated executable file. In the MATLAB Command Window, enter !*model-name*. You see the profiling report you programmed in the profiling TLC file that you created. For example, a profile report could list the number of calls made to each system in a model and the number of CPU cycles spent in each system.

For details on programming a .tlc file and defining TLC configuration variables, see "Target Language Compiler" (Simulink Coder).

Profile Hook Function Interface Limitation

The TLC hook function interface for profiling code execution speed does not support the S-function system target file (rtwsfcn.tlc).

Host/Target Communication in Simulink Coder

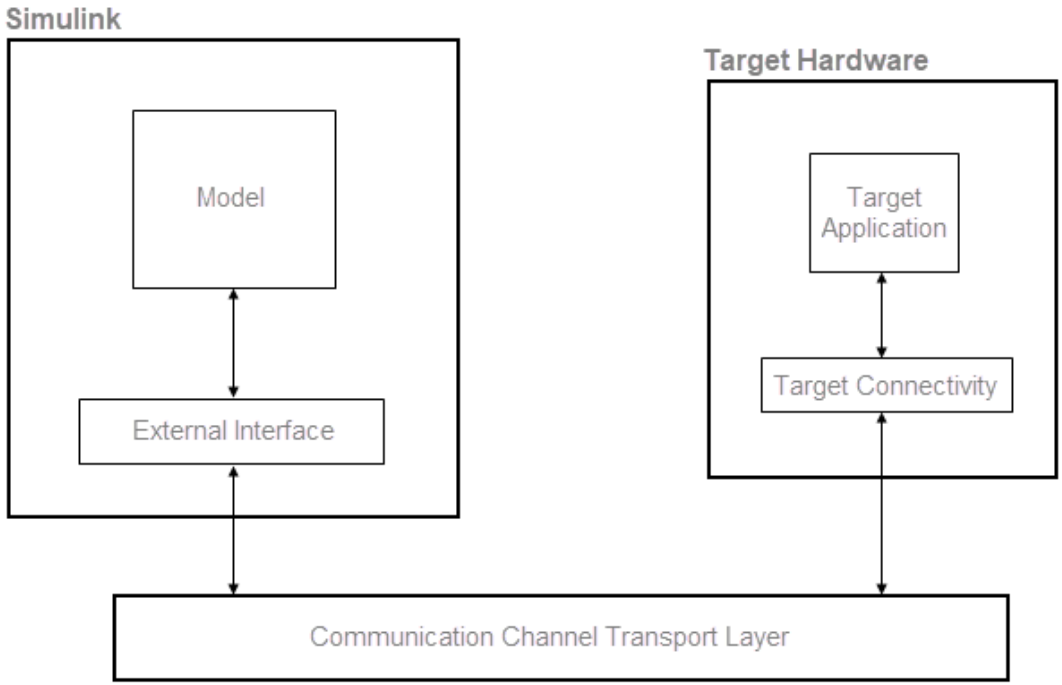
Host-Target Communication with External Mode Simulation

You can use external mode simulations for rapid prototyping. An external mode simulation establishes a communication channel between Simulink on your development computer (host) and the target hardware that runs the executable file created by the code generation and build process.

Through the communication channel, you can:

- Modify or tune block parameters in real time. When you change parameters in the model, Simulink downloads the new values to the executing target application.
- Monitor and save signal data from the executing target application.

The low-level transport layer of the channel handles the physical transmission of messages. Simulink and the generated model code are independent of this layer. The transport layer and its interface code are isolated in separate modules that format, transmit, and receive messages and data packets.



Simulink supports two communication mechanisms for external mode simulation. Use the information in this table to decide which mechanism to use.

Communication Mechanism	Supported By	Why Select
XCP, the Universal Measurement and Calibration Protocol	ERT and GRT system target files. Some Simulink support packages. For details, see https://www.mathworks.com/hardware-support.html?q=&page=1.	XCP external mode: • Uses a standard communication protocol. • Requires only a lightweight communication software stack on the target hardware. • Supports signal logging and streaming for Dashboard blocks and the Simulation Data Inspector. You can stream signals from within a referenced model hierarchy. • Provides documented `ext_mode.h` API for external mode target connectivity. • Supports streaming of execution-time metrics to the Simulation Data Inspector for host-based and support package external mode simulations. For information about running XCP external mode simulations, see: • “External Mode Simulation with XCP Communication” on page 55-8 • “Customize XCP Slave Software” on page 55-22

Communication Mechanism	Supported By	Why Select
TCP/IP and serial (RS-232)	ERT, GRT, and RSim system target files. Simulink support packages.	You do not use the Simulation Data Inspector for visualizing, exporting, and saving data. You want to use signal triggering. For information about running TCP/IP and serial external mode simulations, see: • "External Mode Simulation with TCP/IP or Serial Communication" on page 55-36 • "Create a Transport Layer for TCP/IP or Serial External Mode Communication" on page 55-89

This table summarizes feature support for both forms of external mode simulations.

Feature		XCP Support	TCP/IP and Serial Support
Parameter tuning	With Dashboard blocks	Yes	Yes
	Of tunable (Simulink) block parameters	Yes	Yes
Simulation Data Inspector		Yes. Includes signals within referenced models.	No
Logic Analyzer		Yes. Includes signals within referenced models.	No
Blocks that receive and	Dashboard	Yes	No

Feature		XCP Support	TCP/IP and Serial Support
display signals from target application	Floating Scope, Scope	Yes, provided signal logging is enabled for block input.	Yes
	Spectrum Analyzer, Time Scope (DSP System Toolbox)	Yes, provided signal logging is enabled for block input.	Yes
	Display	Yes, provided signal logging is enabled for block input.	Yes
	To Workspace	Yes, provided signal logging is enabled for block input.	Yes
	User-written S-Function. A method, which enables user-written blocks to support external mode, is built into the S-function API. See *matlabroot*`/simulink/include/simstruc.h`.	Yes, provided signal logging is enabled for block input.	Yes
	XY Graph	Yes, provided signal logging is enabled for block input.	Yes
Signal Viewing Subsystem on page 55-63		Yes, provided signal logging is enabled for subsystem input.	Yes

External Mode Simulation with XCP Communication

Set up and run external mode simulations (Simulink Coder) that use an XCP communication channel.

Run XCP External Mode Simulation From Simulink Editor

Configure and run an external mode simulation (Simulink Coder) that uses the XCP communication protocol. During the simulation:

- Monitor a signal by using a Scope block, a Dashboard block, and the Simulation Data Inspector.
- Tune a parameter by using a Dashboard block.

Configure Signal Monitoring and Parameter Tuning for XCP External Mode

1. Create a folder for this example.

   ```
   mkdir ext_mode_xcp_example
   cd ext_mode_xcp_example
   ```

2. Open Simulink and create a simple model, `xcpExample`, which contains these blocks:

   - Sine Wave
   - Scope
   - Half Gauge
   - Knob

3. Double-click the Sine Wave block. Set **Sample time** to 0.1, and then click **OK**.
4. Connect the Sine Wave block to the Scope block and name the connection, for example, `Test Signal`.
5. Configure the signal for logging:

   a. Right-click `Test Signal`.

   b. From the context menu, select `Log Selected Signals`. If you do not enable signal logging, you cannot view the signal by using the Scope block or stream signal data to the Simulation Data Inspector.

6. Configure the Half Gauge block to monitor the value of `Test Signal`:

a Double-click the Half Gauge block.

b In the Simulink Editor, select `Test Signal`.

c In the Block Parameters dialog box:

- Connect the block to `Test Signal`.
- In the **Maximum** field, enter a value, for example, `1`.

d Click **OK**.

7 Configure the Knob block to tune the **Amplitude** parameter of the Sine Wave block:

a Double-click the Knob block.

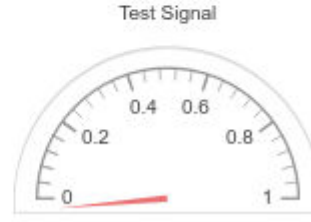
b In the Simulink Editor, select the Sine Wave block.

c In the Block Parameters dialog box:

- Connect the block to the **Amplitude** parameter of the Sine Wave block.
- In the **Minimum** and **Maximum** fields, enter values, for example, 0.1 and 1 respectively.

d Click **OK**.

8 Save the model.



Build Target Application for XCP External Mode

1. Select **Simulation** > **Model Configuration Parameters**.
2. On the **Solver** pane:
   a. In the **Type** field, specify `Fixed-step`.
   b. Under **Solver details**, in the **Fixed-step size** field, specify a value, for example, 0.1.
3. On the **Code Generation** pane, set **System target file** to `grt.tlc` or `ert.tlc` (requires Embedded Coder).
4. On the **Code Generation** > **Optimization** pane, set **Default parameter behavior** to `Tunable`.
5. On the **Code Generation** > **Interface** pane, select the **External mode** check box.
6. Set **Transport layer** to `XCP on TCP/IP`, which specifies `ext_xcp` for **MEX-file name**.
7. In the **Mex-file arguments** field, enter `'localhost' 1 5555`. These arguments specify that the:
   - Target hardware is your development computer.
   - Verbosity level is 1.
   - Port number of the TCP/IP server is 5555.
8. You cannot disable **Static memory allocation**. The **Static memory buffer size** value specifies the size of XCP slave memory that is allocated for signal logging. For this example, use the default value.
9. If **System target file** is `ert.tlc`, on the **Code Generation** > **Templates** pane:
   - Select the **Generate an example main program** check box. The code generator uses *`matlabroot`*`\toolbox\coder\xcp\src\target\ext_mode\include\ext_mode.h` to produce an example main file, `ert_main.c`.
   - Set **Target operating system** to `BareBoardExample`.
10. Click **OK**. Then save the model.
11. Press **Ctrl+B**. The build process generates source code and creates the executable file.

In Windows, the build process creates:

- `xcpExample.exe` –– The executable file.
- `xcpExample.pdb` –– A debugging symbols file for signals and parameters.

In Linux, the build process places DWARF format debugging information in the created ELF executable file, `xcpExample`.

Run Target Application

1. Open a command prompt for your operating system and navigate to the `ext_mode_xcp_example` folder.
2. In the command prompt, enter:

   ```
   xcpExample -w -tf inf -port 5555
   ```

   The target application runs as a separate process on your development computer:

   - `-w` (optional) specifies that the target application enters a wait state until it receives a message from Simulink. The target application runs but does not yet execute model code.

     If you do not specify `-w`, the target application executes model code immediately. The model code runs with parameter values from the time when you built the model.
   - `-tf inf` (optional) specifies that, when model code is executed, the model runs indefinitely. Use this option to override the model parameter `StopTime`.
3. Connect Simulink to the target application:

   a. Select **Simulation** > **Mode** > **External**.

   b. On the Simulink Editor toolbar, click the Connect to Target button  . Simulink downloads current parameter values from the model to the target application.
4. To run the generated model code, click the Run button.

Monitor Signal and Tune Parameter

You can monitor `Test Signal` through the:

- Scope block –– Double-click the block.
- Simulation Data Inspector –– Click the Simulation Data Inspector button. When the Simulation Data Inspector opens, select the **Test Signal** check box, which displays streamed data.

- Half-Gauge block.

To change the amplitude of the sine wave, rotate the pointer on the Knob block to the required value.

To tune tunable (Simulink) block parameters during a simulation, you can also use these methods:

- If a block parameter is a variable in the MATLAB workspace, from the Command Window, assign a new value to the variable. Then, in the Simulink Editor, select **Simulation > Update Diagram**. Simulink downloads the new value to the target application.
- Open the Block Parameter dialog box. In the parameter field, specify the required value. When you click **Apply** or **OK**, Simulink downloads the new parameter value to the target application.

For more information about parameter tuning with generated code, see:

- “External Mode Simulation with TCP/IP or Serial Communication” on page 55-36
- “Create Tunable Calibration Parameter in the Generated Code” on page 32-121

If your model contains a Stateflow chart, you can view state activity. For more information, see “Animate Stateflow Charts” (Stateflow).

Stop Target Application

To stop the execution of generated model code (before `StopTime` is reached) and disconnect the target application, on the Simulink Editor toolbar, click the Stop button.

If you want to disconnect the target application from Simulink without stopping code execution, click the Disconnect from Target button  .

Target Application Arguments

You can run your target application with optional arguments.

Argument	Description
`-w`	Specify that the target application enters and stays in a wait state until it receives a message from Simulink. If you do not specify `-w`, the target application executes model code immediately. The model code runs with parameter values from the time when you built the model.
`-tf` *`time`*	Override the model parameter `StopTime`. `-tf inf` specifies that the model runs indefinitely when model code is executed.

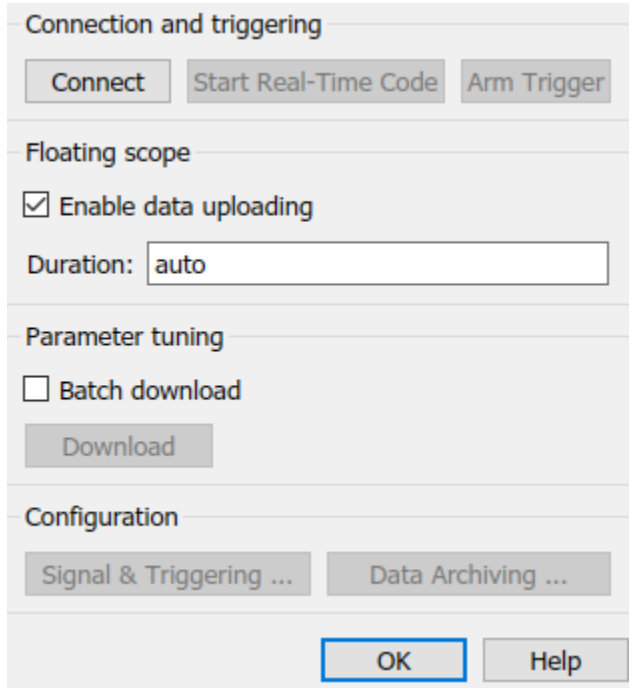
For host-based external mode simulations, you can specify additional `rtiostream` on page 78-50 arguments.

Argument	Description
`-verbose` *`level`*	Specify verbosity level: • 0 –- No information • 1 –- Detailed information
`-port` *`number`*	For `XCP on TCP/IP` transport layer, specify the port number of TCP/IP server. An integer value between 256 and 65535. Default is 17725. For `XCP on Serial` transport layer, specify the serial port ID. For example: On Windows, `'COM1'` or 1 for `COM1`, `'COM2'` or 2 for `COM2`, and so on. On Linux, `'/dev/ttyS0'`, etc.
`-baud` *`value`*	For `XCP on Serial` transport layer, specify baud value. 1200, 2400, 4800, 9600, 14400, 19200, 38400, 57600 (default), or 115200.

Graphical Controls for XCP External Mode Simulations

You can control an XCP external mode simulation through:

- The Simulink Editor toolbar.
- A Simulink Editor menu.
- The External Mode Control Panel. To open this dialog box, in Simulink Editor, select **Code > External Mode Control Panel**.



This table gives the controls that you can use for an XCP external mode simulation.

External Mode Action	Toolbar	Menu	External Mode Control Panel
Set simulation mode of model to external mode.	From the simulation mode drop-down list, select `External`.	**Simulation > Mode > External**	**Connect** If the model simulation mode is not already set, clicking **Connect** sets the simulation mode to external.

External Mode Action	Toolbar	Menu	External Mode Control Panel
Connect Simulink to a waiting or running target application.	Connect to Target button 	**Simulation** > **Connect to Target**	**Connect** When Simulink is connected to the target application, **Connect** changes to **Disconnect**.
Start real-time execution of generated code in the target environment.	Run button	**Simulation** > **Run** (keyboard shortcut **Ctrl+T**)	**Start Real-Time Code** When the generated code starts executing, the button changes to **Stop Real-Time Code**.
Disconnect Simulink from the target environment, but do not stop real-time execution of code.	Disconnect from Target button 	**Simulation** > **Disconnect from Target**	**Disconnect**
Stop target application execution and disconnect Simulink from the target environment.	Stop button	**Simulation** > **Stop** (keyboard shortcut **Ctrl+Shift+T**)	**Stop Real-Time Code**

External Mode Action	Toolbar	Menu	External Mode Control Panel
Tune batch of block parameters.	N/A	N/A	**Batch download** To tune a batch of block parameters: **1** In the External Mode Control Panel, select **Batch download**. **2** In Simulink Editor, modify the required block parameters. **3** When you modify parameters, the External Mode Control Panel displays this message next to **Download**: `Parameter changes pending...` Simulink stores the modified parameters locally. **4** Click **Download**. Simulink downloads the batch of modified parameters to the target application.

Run XCP External Mode Simulation From Command Line

You can use commands or scripts to run XCP external mode simulations. Use `get_param` and `set_param` commands to retrieve and set the values of model parameters.

To run these commands, you must have a Simulink model open and a target application running:

1. Set simulation mode of the model to external mode.

   ```
   set_param(gcs,'SimulationMode','external');
   ```

2. Connect Simulink to the target application.

   ```
   set_param(gcs,'SimulationCommand','connect')
   ```

3. Run generated model code.

   ```
   set_param(gcs,'SimulationCommand','start');
   ```

4. To tune a parameter, change its workspace variable value through a line command. For example, if a block parameter value is specified as a `Simulink.Parameter` object, assign the new value to the `Value` property.

   ```
   myParamObj.Value = 5.23;
   ```

5. To download the new value to the target application, update the model.

   ```
   set_param(gcs,'SimulationCommand','update');
   ```

6. Stop the target application and disconnect Simulink from the target environment.

   ```
   set_param(gcs,'SimulationCommand','stop');
   ```

   To disconnect Simulink from the target application without stopping execution of generated code, use this command:

   ```
   set_param(gcs,'SimulationCommand','disconnect');
   ```

XCP External Mode Limitations

This table describes limitations that apply to external mode simulations that use XCP communication.

Feature	Details
Parameter updates that change model structure	You cannot change, for example: • The number of states, inputs, or outputs of a block • The sample time or the number of sample times • The integration algorithm for continuous systems • The name of the model or of a block • The parameters to the Fcn block If you make parameter updates that change the model structure, you must rebuild the target application. You can change numerator and denominator polynomial parameters for the Transfer Fcn, Discrete Transfer Fcn, and Discrete Filter blocks if the number of states does not change. You cannot change zero entries in the State-Space, Zero-Pole, and Discrete Zero-Pole blocks in the user-specified or computed parameters, that is, the A, B, C, and D matrices obtained by a zero-pole to state-space transformation. In the State-Space block, if you specify the matrices in the controllable canonical realization, then changes to the A, B, C, and D matrices that preserve this realization and the dimensions of the matrices are allowed. If the Simulink block diagram does not match the target application, Simulink produces an error stating that the checksums do not match. The checksums take into account the top models, but not referenced models. Use the updated block diagram to rebuild the target application.

Feature	Details
Signal value display	The graphical display of signal values during a simulation is not supported. For example, you cannot use the **Data Display in Simulation** menu items **Show Value Labels When Hovering**, **Toggle Value Labels When Clicked**, and **Show Value Label of Selected Port**. For more information, see "Displaying Signal Values in Model Diagrams" (Simulink).
Signal triggering and data archiving	The **Signal & Triggering**, **Arm Trigger**, **Cancel Trigger**, and **Data Archiving** features, which are available on the **External Mode Control Panel**, are not supported.
Signal streaming	Dynamic selection of signals for streaming is not supported. If want to select different signals for streaming, you must rebuild the model.
Overriding signal logging settings	Overriding signal logging settings by using the Signal Logging Selector is not supported.
Compiler debug symbol format	Your toolchain must generate debug information in one of these formats: • DWARF • PDB
Inlined parameters	If you set `DefaultParameterBehavior` to `'Inlined'`, the code generator embeds numeric model parameter values (instead of symbolic parameter names) in the generated code. You can use `Simulink.Parameter` objects to remove remove parameters from inlining and declare the parameters tunable. However, when you connect Simulink to the target application, the numeric values of the tunable parameters are not automatically uploaded to the model. Simulink produces a warning.

Feature	Details
Global variables	Signals, parameters, and states must be specified as global variables. The target memory addresses at which the variables are stored must lie in the range 0 – 4294967295.
Parameter structures	You cannot tune parameters that are structures.
Pure integer code	Pure integer code is supported. For code generation, if `'PurelyIntegerCode'` is `'on'`, specify `'FixedStep'` with a resolution that is greater or equal to 1 microsecond. For example, specify 1.000001, but not 1.0000001. If you do not specify `-tf` *`finalTime`* in the execution command, the target application runs the generated model code indefinitely, ignoring `StopTime`. If you specify `-tf` *`finalTime`* in the execution command: • The *`finalTime`* value represents base rate clock ticks, not seconds. • The maximum value for *`finalTime`*, in ticks, is `MAX_int32_T`.
Variable-size signals	Uploading of variable-size signals is not supported.
Compiler support	`lcc-win64` is not supported.
Mac operating system	You cannot run host-based XCP external mode simulations on a Mac system because the default XCP slave platform abstraction layer supports only Linux and Windows systems.
Endianess	Target hardware that uses big endian architecture is not supported.
Address granularity	Target hardware that uses word addresses is not supported.
Scope and Floating Scope blocks, and Scope Viewer	Some signal data types are not supported. The simulation produces a warning.

Feature	Details
Scopes in referenced models	In a model hierarchy, if the top model runs in external mode and a referenced model runs in normal or accelerator mode, scopes in the referenced model are not displayed.
Nonzero simulation start time	Nonzero simulation start times are not supported. Use the default value for **Solver > Start time**, that is, `0.0`.
File-scoped data	File-scoped data is not supported. For example, data items to which you apply the built-in custom storage class `FileScope`. The simulation produces a warning.
Row-major code generation	Code generated with the row-major format is not supported.
Concurrent execution	Concurrent execution is not supported. If **System target file** is `ert.tlc` and **Target operating system** is `NativeThreadsExample`, you cannot build the target application.
VxWorks example	If **System target file** is `ert.tlc` and **Target operating system** is `VxWorksExample`, you cannot build the target application.

Customize XCP Slave Software

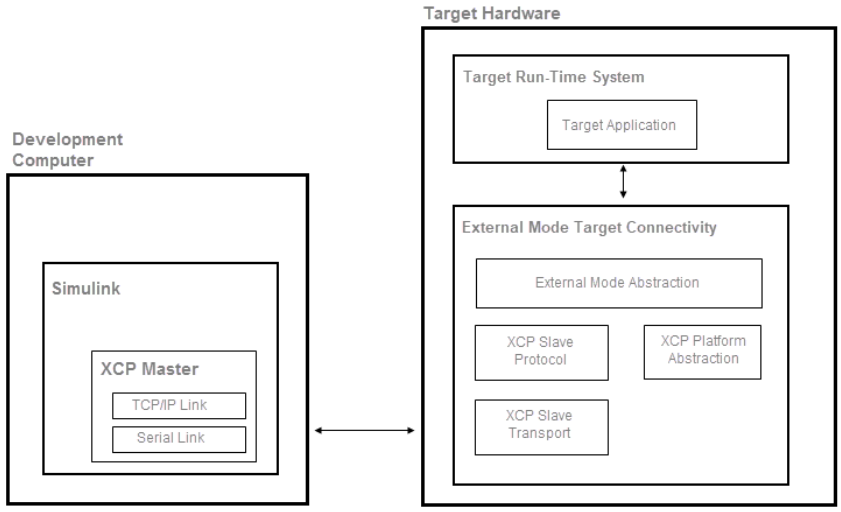
The XCP communication protocol for Simulink external mode simulations is a master-slave communication protocol. By default, the software supports XCP external mode simulations:

- On your development computer for code that is generated by using ERT (`ert.tlc`) and GRT (`grt.tlc`) system target files.
- For some support packages on page 55-2.

If your system target file for custom target hardware is derived from the ERT or GRT system target files, you can use supplied APIs to provide XCP target connectivity. XCP external mode limitations on page 55-17 apply.

The external mode target connectivity software comprises:

- External mode abstraction layer
- XCP slave protocol layer
- XCP slave transport layer
- XCP platform abstraction layer



External Mode Abstraction Layer

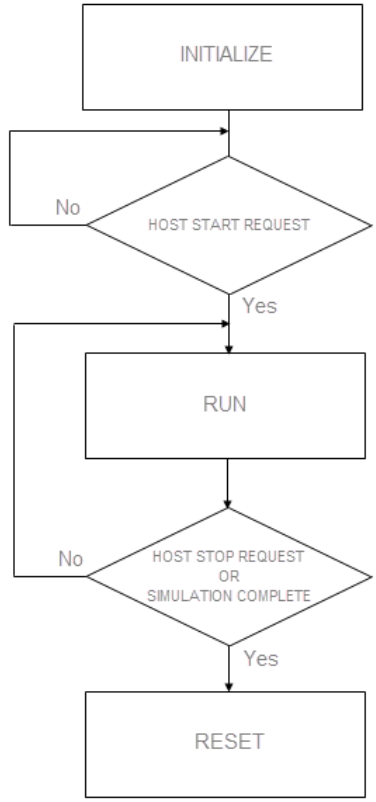
To communicate with Simulink during an external mode simulation, your target application must invoke functions from the external mode abstraction layer.

The parent folder for source code files is:

matlabroot`\toolbox\coder\xcp\src\target\ext_mode`

The layer APIs are declared in `include\ext_mode.h` and implemented in `src\xcp_ext_mode.c`.

To communicate with Simulink, the target application uses services exposed by the external mode abstraction layer. This flow chart shows the required target application steps to establish communication with Simulink.



This tables lists the functions that your target application must invoke at each stage.

Stage	Function	Purpose
INITIALIZE	extmodeParseArgs	Extract external mode command-line arguments.
	*modelName*_initialize	Initialize generated Simulink model code.
	extmodeInit	Initialize external mode target connectivity.
HOST START REQUEST	extmodeWaitForHostRequest	Wait for a start request from development computer, which is created when you click Run button.
RUN	*modelName*_step	Run single step of generated Simulink model code.
	extmodeEvent	For sample time ID of the model, sample signals generated by model step function and pass packet content to transport layer of communication protocol for transmission to development computer.
	extmodeBackgroundRun	Transmit and receive packet from physical communication interface and process packet content in accordance with selected communication protocol.
HOST STOP REQUEST OR SIMULATION COMPLETE	extmodeStopRequested	Check whether a request to stop external mode simulation is received from the model on the development computer. The request is created when you click the Stop button.
	extmodeSimulationComplete	Check whether execution of generated model code is complete.
RESET	*modelName*_terminate	Terminate generated Simulink model code.

Stage	Function	Purpose
	`extmodeReset`	Reset the external mode target connectivity to initial state.

This pseudo-code example shows how you can implement the various flowchart stages in your target application. During the RUN stage, the external mode run-time environment requires at least two threads:

- A periodic thread that is responsible for the execution of the generated model code.
- A background thread that is responsible for running the external mode communication stack and transmitting and receiving packets.

The pseudo-code simulates multithreading by running `periodicThread` and `extmodeBackgroundRun` sequentially within the same `while()` loop.

```
/*------------- Pseudo-Code Example -------------*/
/* Define periodic thread */
void periodicThread(void)
{
  /* Run model step function */
  modelName_step();
  /* Notify external mode abstraction layer about periodic event */
  extmodeEvent(PERIODIC_EVENT_ID, currentSimulationTime);
}

/* Main function for target application */
main(int argc, char *argv[])
{
  /*------------- INITIALIZE -------------*/
  /* Parse external mode command line arguments */
  extmodeParseArgs(argc, argv);

  /* Initialize model */
  modelName_initialize();

  /* Initialize external mode target connectivity */
  extmodeInit(extModeInfo, finalSimulationTime);

  /*------------- HOST START REQUEST -------------*/
  /* Wait until a start request is received from development computer */
  extmodeWaitForHostRequest(EXTMODE_WAIT_FOREVER);

  /*------- HOST STOP REQUEST OR SIMULATION COMPLETE -------*/
  /* While simulation is not complete and stop request is not received */
  while (!extmodeSimulationComplete() && !extmodeStopRequested()) {

    /*------------- RUN -------------*/
    periodicThread();
    extmodeBackgroundRun();
  }

  /*------------- RESET -------------*/
  /* Terminate model */
```

```
  modelName_terminate();

  /* Reset external mode target connectivity */
  extmodeReset();
  return 0;
}
```

To see code that invokes the functions, complete the example in "External Mode Simulation with XCP Communication" on page 55-8 with **System target file** set to `ert.tlc`. Then, from the code generation folder, open `ert_main.c`.

XCP Slave Protocol Layer

The XCP slave protocol layer interprets XCP commands and data according to the Association for Standardisation of Automation and Measuring Systems (ASAM) standard, ASAM MCD-1 XCP.

The source code folder is:

matlabroot`\toolbox\coder\xcp\src\target\slave\protocol\src`

In an external mode simulation, the build process automatically adds the required files to the build information object (Simulink Coder).

XCP Slave Transport Layer

The XCP slave transport layer transmits and receives messages from the communication medium according to ASAM specifications.

The source folder is:

matlabroot`\toolbox\coder\xcp\src\target\slave\transport\src`

In an external mode simulation, the build process automatically adds the required files to the build information object (Simulink Coder).

XCP Platform Abstraction Layer

The XCP platform abstraction layer provides:

- An XCP driver on page 55-28 for sending and receiving raw data through the physical communication interface.

- The implementation of a static memory allocator on page 55-28.
- Other target hardware-specific functionality (Simulink Coder).

For a customization example, see "Create Custom Abstraction Layer" on page 55-33.

XCP Driver

The XCP driver sends and receives XCP messages through the communication channel. In an external mode simulation, the build process automatically adds the driver files to the build information object.

The XCP driver is based on the `rtiostream on page 78-50` API. For example, host-based external mode simulations use these `rtiostream` files:

- *matlabroot*`\toolbox\coder\rtiostream\src\rtiostreamtcpip.c`
- *matlabroot*`\toolbox\coder\rtiostream\src\rtiostream_serial.c`

For a custom platform abstraction layer, you must add your `rtiostream` files to the build information object (Simulink Coder). For an example, see "Create Custom Abstraction Layer" on page 55-33.

Memory Allocator

The XCP slave software requires the dynamic allocation of variable-size, contiguous memory blocks to hold internal data structures.

In an external mode simulation, the build process automatically adds memory allocator files to the build information object.

The `xcpMemBlockSizes` and `xcpMemBlockCounts` preprocessor macros define memory allocation.

The default memory allocator can allocate and deallocate up to 16 different sets of memory blocks. For each set, you can override the default allocations during compilation. You can specify:

- The block size through the `XCP_MEM_BLOCK_`*`N`*`_SIZE` preprocessor macro.
- The number of blocks in each set through the `XCP_MEM_BLOCK_`*`N`*`_NUMBER` preprocessor macro.

For example, these preprocessor macros create four blocks of 64 bytes and eight blocks of 256 bytes.

```
#define XCP_MEM_BLOCK_1_SIZE 64
#define XCP_MEM_BLOCK_1_NUMBER 4
#define XCP_MEM_BLOCK_2_SIZE 256
#define XCP_MEM_BLOCK_2_NUMBER 8
```

Configure the block sizes of the different sets in ascending order:

`XCP_MEM_BLOCK_`*`N`*`_SIZE < XCP_MEM_BLOCK_`*`N`*`+1_SIZE`

The smallest block size, `XCP_MEM_BLOCK_1_SIZE`, must be large enough to hold a pointer.

Configure alignment for the memory allocator through the `XCP_MEM_ALIGNMENT` preprocessor macro. For example:

```
#define XCP_MEM_ALIGNMENT 8
```

Other Platform Abstraction Layer Functionality

This file defines the platform abstraction layer interface:

matlabroot`\toolbox\coder\xcp\src\target\slave\platform\include\xcp_platform.h`

To implement custom platform abstraction layer functionality, add the `XCP_CUSTOM_PLATFORM` preprocessor macro to the build information object. Provide the implementation of the custom functionality in a file named `xcp_platform_custom.h`. If you do not define `XCP_CUSTOM_PLATFORM`, the build process uses default files that support Linux and Windows systems.

This table describes the functionality that you must provide for the XCP slave software that you deploy on your target hardware.

Functionality	Details

Mutual exclusion	To access system data structures with *mutual exclusion* support, the XCP driver depends on basic APIs for definition, initialization, lock, and unlock.
	
	To support mutual exclusion for your target hardware, provide a custom implementation.
	
	The default implementation for Linux and Windows supports mutual exclusion.
	
	`#if defined(_WIN32) || defined(__WIN32__) || defined(WIN32)`
	`...`
	`#define XCP_MUTEX_DEFINE(lock) HANDLE lock`
	`#define XCP_MUTEX_INIT(lock) lock = CreateMutex(0, FALSE, 0)`
	`#define XCP_MUTEX_LOCK(lock) WaitForSingleObject((lock), INFINITE`
	`#define XCP_MUTEX_UNLOCK(lock) ReleaseMutex(lock)`
	
	`#else`
	`...`
	`#include <pthread.h>`
	`#define XCP_MUTEX_DEFINE(lock) pthread_mutex_t lock`
	`#define XCP_MUTEX_INIT(lock) pthread_mutex_init(&(lock), NULL)`
	`#define XCP_MUTEX_LOCK(lock) pthread_mutex_lock(&(lock))`
	`#define XCP_MUTEX_UNLOCK(lock) pthread_mutex_unlock(&(lock))`
	`...`
	`#endif`

Functionality	Details

Sleep	Provide a sleep API that makes the calling thread sleep until a specified time has elapsed. The default implementation for Linux and Windows systems is:
	
	`#if defined(_WIN32) || defined(__WIN32__) || defined(WIN32)`
	`...`
	`#define XCP_SLEEP(seconds,microseconds)  Sleep((seconds) * 1000 \`
	`+ (((microseconds) + 1000 - 1) / 1000))`
	
	`#else`
	`...`
	`#if _POSIX_C_SOURCE >= 199309L`
	`#define XCP_SLEEP(seconds,microseconds)  do {struct timespec t;\`
	` t.tv_sec = seconds; t.tv_nsec = microseconds * 1000; nanosleep(&`
	`#else`
	`/* nanosleep is not available. Use select instead. */`
	`#define XCP_SLEEP(seconds,microseconds)  do {struct timeval t; t.`
	` t.tv_usec = microseconds; select(0, NULL, NULL, NULL, &t);} whil`
	`#endif /* _POSIX_C_SOURCE >= 199309L */`
	`...`
	`#endif`

Logging	To generate diagnostic messages, the XCP slave software requires a custom print API that supports logging services provided by the target hardware. If you do not define the `XCP_PRINTF` preprocessor macro, the default implementation is empty.

Functionality	Details

Address conversion	The XCP standard expresses the address of a variable in memory as a 32-bit address with an 8-bit extension.
	
	The XCP Master extracts the addresses of signals and parameters of the model by parsing the debug information that the build process creates. The debug information is in DWARF or PDB format.
	
	The XCP Master requests access to parameters and signals by sending an XCP command that contains the arguments `addressExtension` and `address`.
	
	When `addressExtension` and `address` information is received by the target hardware, the XCP Slave must convert the address to the location of the variable in the target hardware memory. The variable location is assigned by the loader and is target-specific.
	
	Use the `XCP_ADDRESS_GET()` macro to specify the conversion logic. The default implementation for Linux and Windows systems is:
	
	`#if defined(__MINGW32__) || defined(__MINGW64__)`
	`#define XCP_ADDRESS_GET(addressExtension, address) \`
	`(uint8_T*) ((uintptr_t) address)`
	`#else`
	`#define XCP_ADDRESS_GET(addressExtension, address) \`
	`(uint8_T*) ((address) + (uint8_T*)&__ImageBase)`
	`#endif`
	
	Currently, only 32-bit hardware architectures are supported, so `addressExtension` is 0.

Functionality	Details

Set and copy memory	You can specify an optimized version of copy memory and set memory operations.
	
	If you do not define the `XCP_MEMCPY` and `XCP_MEMSET` preprocessor macros, the default implementation specifies the standard C functions, `memcpy` and `memset`.
	
	`#ifndef XCP_MEMCPY`
	`#define XCP_MEMCPY memcpy`
	`#endif`
	
	`#ifndef XCP_MEMSET`
	`#define XCP_MEMSET memset`
	`#endif`

Parsing command-line arguments	If your target hardware does not support the parsing of command-line arguments, define the preprocessor macro `EXTMODE_DISABLE_ARGS_PROCESSING`. To replace the `-w` option, you can use this command to specify that the target application enters and stays in a wait state until it receives a Connect message from Simulink: `set_param(`*`modelName`*`, 'OnTargetWaitForStart', 'on');` The build process provides the required option (`-DON_TARGET_WAIT_FOR_START=1`) to the compiler.

Create Custom Abstraction Layer

For the build process, you can define a post-code generation command that creates a custom platform abstraction layer.

1. Specify the header file `xcp_platform_custom.h`. This Linux example defines the required functions.

```
#ifndef XCP_PLATFORM_CUSTOM_H
#define XCP_PLATFORM_CUSTOM_H

/* XCP_ADDRESS_GET */
#include <stdint.h>
#define XCP_ADDRESS_GET(addressExtension, address)  (uint8_T*) ((uintptr_t) address)

/* XCP_MUTEX */
```

```
#include <pthread.h>
#define XCP_MUTEX_DEFINE(lock)    pthread_mutex_t lock
#define XCP_MUTEX_INIT(lock)      pthread_mutex_init(&(lock), NULL)
#define XCP_MUTEX_LOCK(lock)      pthread_mutex_lock(&(lock))
#define XCP_MUTEX_UNLOCK(lock)    pthread_mutex_unlock(&(lock))

/* XCP_SLEEP */
#include <sys/time.h>    /* gettimeofday */
#if _POSIX_C_SOURCE >= 199309L
#include <time.h>       /* for nanosleep */
#else
#include <stddef.h>
#include <sys/select.h> /* for select */
#endif

/* _POSIX_C_SOURCE >= 199309L */
#if _POSIX_C_SOURCE >= 199309L
#define XCP_SLEEP(seconds,microseconds)  do {struct timespec t;\
 t.tv_sec = seconds; t.tv_nsec = microseconds * 1000; nanosleep(&t, NULL);} while(0)
#else
/* nanosleep is not available. Use select instead. */
#define XCP_SLEEP(seconds,microseconds)  do {struct timeval t; t.tv_sec = seconds;\
 t.tv_usec = microseconds; select(0, NULL, NULL, NULL, &t);} while(0)
#endif /* _POSIX_C_SOURCE >= 199309L */
#endif
```

2 Define the post-code generation command.

```
function myXCPTargetPostCodeGenCommand(buildInfo)

  buildInfo.addDefines('-DXCP_CUSTOM_PLATFORM', 'OPTS');

  % Configure the default memory allocator
  buildInfo.addDefines('-DXCP_MEM_BLOCK_1_SIZE=64', 'OPTS');
  buildInfo.addDefines('-DXCP_MEM_BLOCK_1_NUMBER=46', 'OPTS');
  buildInfo.addDefines('-DXCP_MEM_BLOCK_2_SIZE=256', 'OPTS');
  buildInfo.addDefines('-DXCP_MEM_BLOCK_2_NUMBER=10', 'OPTS');

  % Add my rtiostream
  buildInfo.addSourceFiles(customRtIOStreamFileName, customRtIOStreamSrcPath);

  % If the target hardware does not support parsing of command
  % line arguments
    buildInfo.addDefines('-DEXTMODE_DISABLE_ARGS_PROCESSING', 'OPTS');

end
```

External Mode Simulation with TCP/IP or Serial Communication

Set up and run an external mode simulation that uses a TCP/IP or serial (RS-232) communication channel.

1. Create and configure a simple model.
2. Build the target executable file.
3. Run the target application.
4. Tune parameters.

The example, which uses the GRT target, does not require external hardware. The generated executable file runs:

- On the development computer that hosts Simulink and Simulink Coder.
- As a separate process from MATLAB and Simulink.

Create and Configure Model

In this part of the example, you create a simple model, `ex_extModeExample`. You also create a folder called `ext_mode_example` to store the model and the generated executable.

To create the folder and the model:

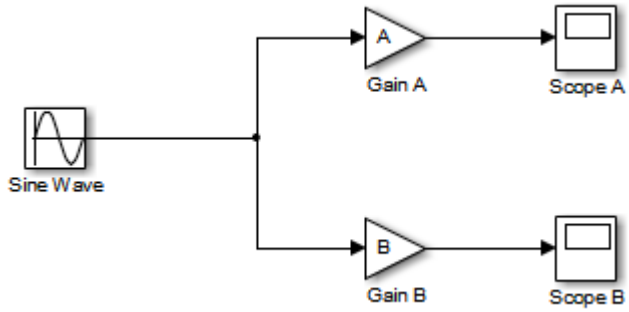
1. From the MATLAB command line, type:

   ```
   mkdir ext_mode_example
   ```

2. Make `ext_mode_example` your working folder:

   ```
   cd ext_mode_example
   ```

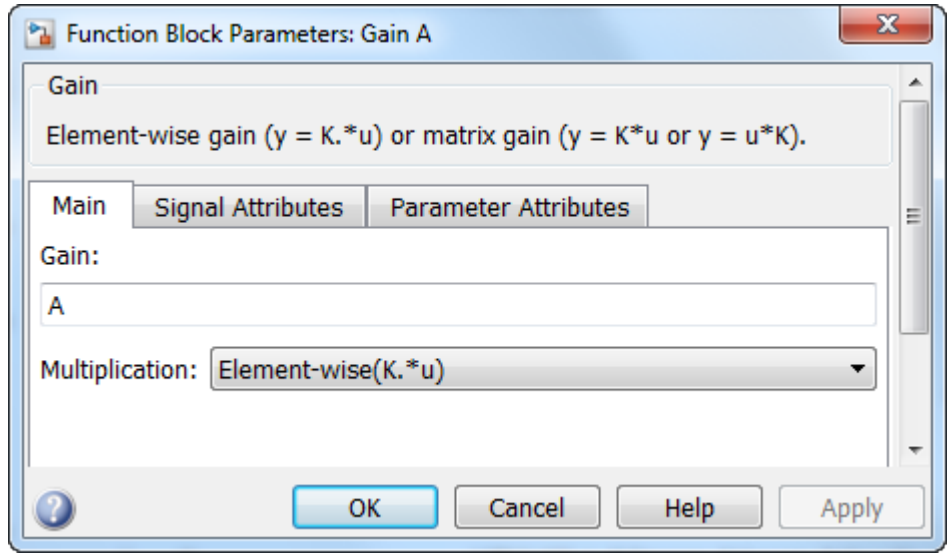
3. Create a model in Simulink with a Sine Wave block for the input signal, two Gain blocks in parallel, and two Scope blocks. Be sure to label the Gain and Scope blocks as shown.



4 Define and assign two MATLAB workspace variables, A and B:

```
A = 2;
B = 3;
```

5 Open Gain block A and set its **Gain** parameter to the variable A.

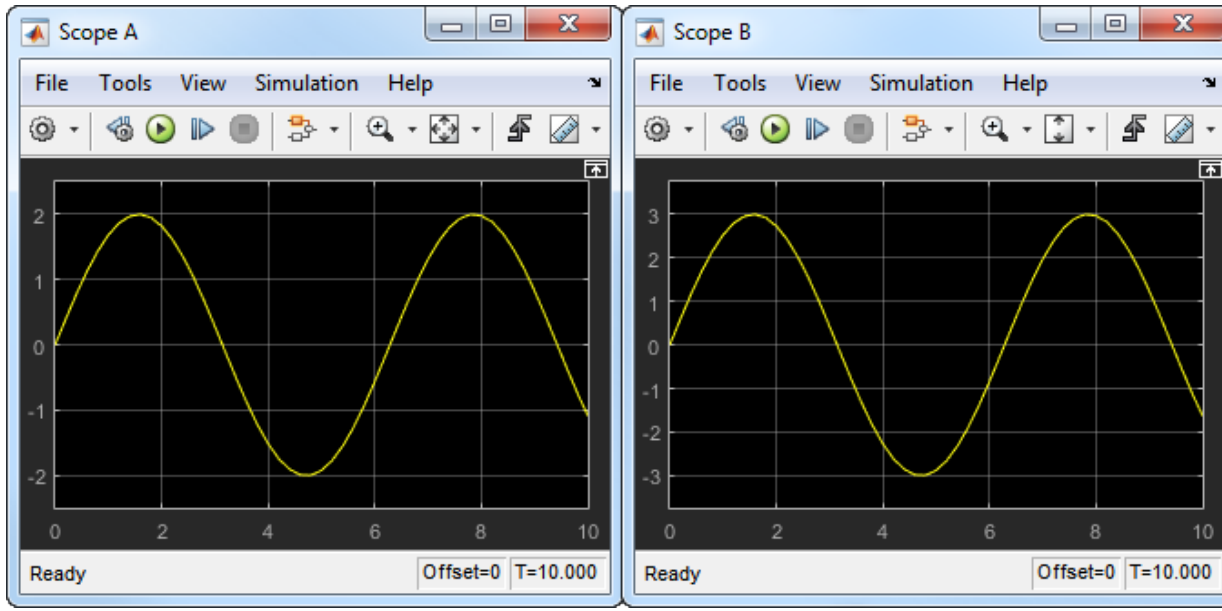


6 Open Gain block B and set its **Gain** parameter to the variable B.

When the target application is built and connected to Simulink in external mode, you can download new gain values to the executing target application. To do this, you can

assign new values to workspace variables `A` and `B`, or edit the values in the block parameters dialog box. For more information, see “Tune Parameters” on page 55-44.

7 Verify operation of the model. Open the Scope blocks and run the model. When `A = 2` and `B = 3`, the output appears as shown.



8 Save the model as `ex_extModeExample`.

Build Target Executable

Set up the model and code generation parameters required for an external mode target application. Then, generate code and build the target application.

1 Open the Configuration Parameters dialog box by selecting **Simulation** > **Model Configuration Parameters**.

2 Select the **Solver** pane:

   a In the **Type** field, select `Fixed-step`.

   b In the **Solver** field, select `discrete (no continuous states)`.

c Click **Solver details**. In the **Fixed-step size** field, specify `0.1`. (Otherwise, when you generate code, the Simulink Coder build process produces a warning and supplies a value.)

d Click **Apply**.

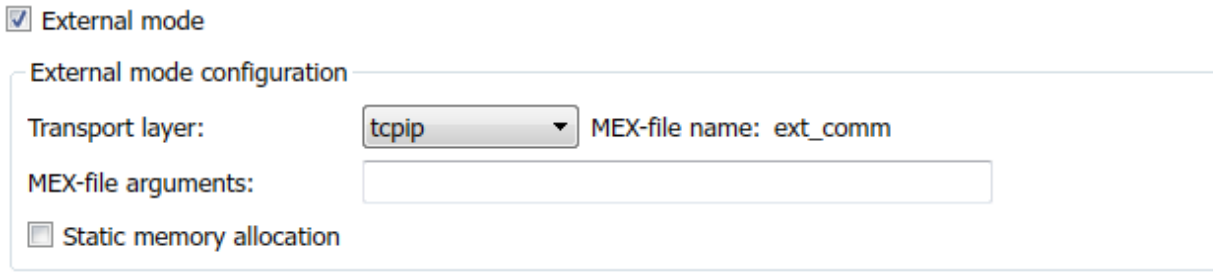
3 Select the **Data Import/Export** pane, and clear the **Time** and **Output** check boxes. In this example, data is not logged to the workspace or to a MAT-file. Click **Apply**.

4 Select the **Code Generation** pane. By default, the generic real-time (GRT) target is selected.

5 Select the **Code Generation** > **Optimization** pane. Make sure that **Default parameter behavior** is set to `Tunable`. Inlined parameters are not part of this example. If you make a change, click **Apply**.

6 Select the **Code Generation** > **Interface** pane. In the **Data exchange interface** section, select **External mode**. This selection enables generation of external mode support code and displays additional external mode configuration parameters.

7 In the **External mode configuration** section, make sure that the default value `tcpip` is selected for the **Transport layer** parameter.



External mode supports communication via TCP/IP, serial, and custom transport protocols. The **MEX-file name** field specifies the name of a MEX-file that implements host and target communication on the host side. The default for TCP/IP is `ext_comm`, a MEX-file provided with the Simulink Coder software. You can override this default by supplying other files. If you need to support other transport layers, see “Create a Transport Layer for TCP/IP or Serial External Mode Communication” (Simulink Coder).

The **MEX-file arguments** field lets you specify arguments, such as a TCP/IP server port number, to be passed to the external interface program. These arguments are specific to the external interface that you are using. For information on setting these

arguments, see “MEX-File Optional Arguments for TCP/IP Transport” (Simulink Coder) and “MEX-File Optional Arguments for Serial Transport” (Simulink Coder).

This example uses the default arguments. Leave the **MEX-file arguments** field blank.

The **Static memory allocation** check box controls how memory is allocated for external mode communication buffers in the target. For this example, do not select the check box. For more information, see “Control Memory Allocation for Communication Buffers in Target” on page 55-46.

8 Click **Apply** to save the external mode settings.

9 Save the model.

10 Select the **Code Generation** pane. Make sure that **Generate code only** is cleared, and then, in the model window, press **Ctrl+B** to generate code and create the target application. The software creates the `ex_extModeExample` target executable in your working folder.

Run Target Application

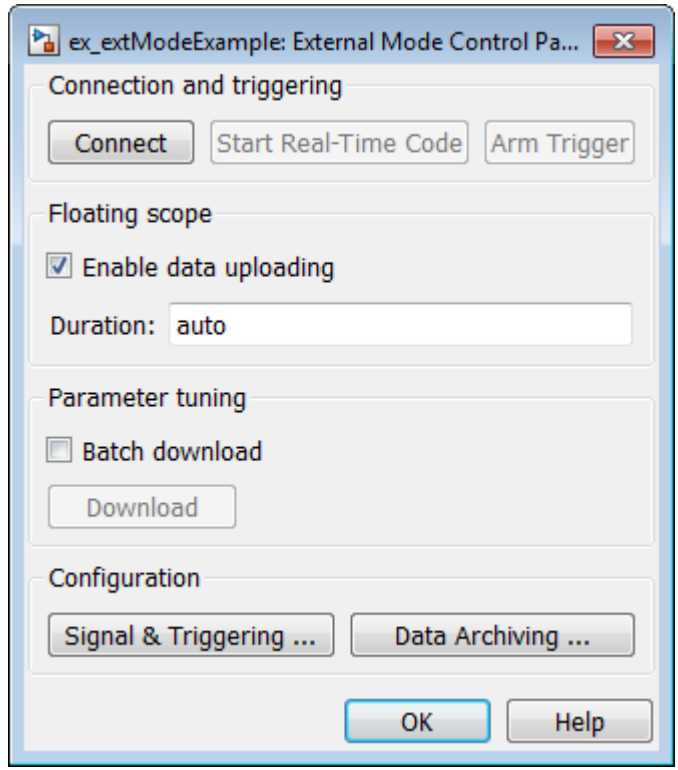
You now run the `ex_extModeExample` target executable and use Simulink as an interactive front end to the running target application. The executable file is in your working folder. Run the target application and establish communication between Simulink and the target.

Note An external mode program like `ex_extModeExample` is a host-based executable. Its execution is not tied to a real-time operating system (RTOS) or a periodic timer interrupt, and it does not run in real time. The program just runs as fast as possible, and the time units it counts off are simulated time units that do not correspond to time in the world outside the program.

The External Signal & Triggering dialog box (accessed from the External Mode Control Panel) displays a list of blocks in your model that support external mode signal monitoring and logging. In the dialog box, you can configure the signals that are viewed, how they are acquired, and how they are displayed.

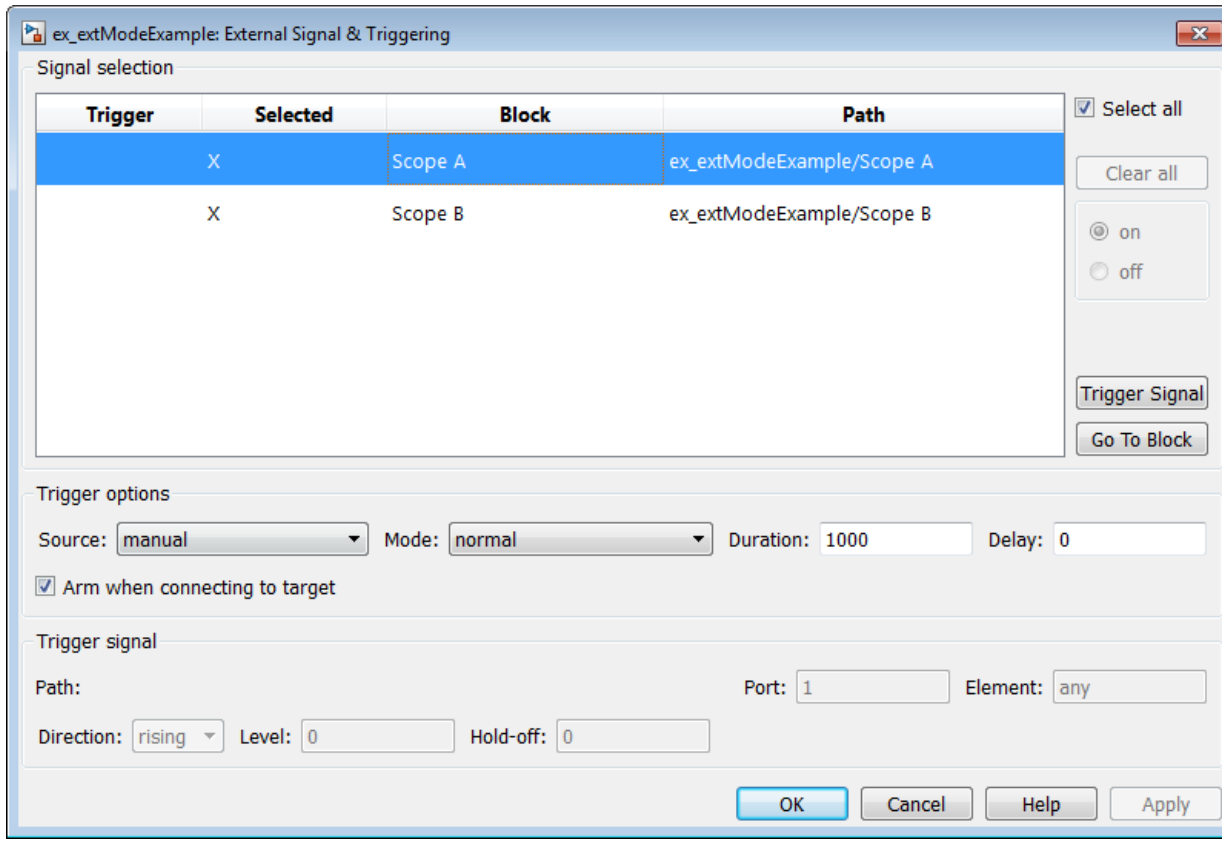
In this example, you observe and use the default settings of the External Signal & Triggering dialog box.

1 From the **Code** menu of the model diagram, select **External Mode Control Panel**. This control panel is where you configure signal monitoring and data archiving. You can also connect to the target application, and start and stop execution of the model code.



- After the target application starts, you use the top row of buttons.
- The **Signal & Triggering** button opens the External Signal & Triggering dialog box. Use this dialog box to select the signals that are collected from the target system and viewed in external mode. You can also select a signal that triggers uploading of data when certain signal conditions are met, and define the triggering conditions.
- The **Data Archiving** button opens the Enable Data Archiving dialog box. Use data archiving to save data sets generated by the target application for future analysis. This example does not use data archiving. See “Configure Host Archiving of Target Application Signal Data” on page 55-59 .

2 Click the **Signal & Triggering** button to open the External Signal & Triggering dialog box. The default configuration selects all signals for monitoring and sets signal monitoring to begin once the host and target application are connected.



3 Make sure that the External Signal & Triggering dialog box options are set to these defaults:

- **Select all** check box is selected. Signals in the **Signal selection** list are marked with an X in the **Selected** column.
- Under **Trigger options:**
  - **Source**: `manual`
  - **Mode**: `normal`

- **Duration**: `1000`
- **Delay**: `0`
- **Arm when connecting to target**: selected

To close the External Signal & Triggering dialog box, click **OK**. Then, close the External Mode Control Panel.

For descriptions of the External Signal & Triggering dialog box parameters, see “Configure Host Monitoring of Target Application Signal Data” on page 55-51.

4 To run the target application, open an operating system command window (on UNIX systems, a terminal emulator window). At the command prompt, use `cd` to navigate to the `ext_mode_example` folder in which you generated the target application.

Enter this command:

```
ex_extModeExample -tf inf -w
```

Note Alternatively, you can run the target application from the MATLAB Command Window, using the following syntax.

```
!ex_extModeExample -tf inf -w &
```

The target application begins execution, and enters a wait state.

The `-tf` switch overrides the stop time set for the model in Simulink. The `inf` value directs the model to run indefinitely. The model code runs until the target application receives a stop message from Simulink.

The `-w` switch instructs the target application to enter a wait state until it receives a **Start Real-Time Code** message from the host. If you want to view target application execution data from time step 0, or if you want to modify parameters before the target application begins execution of model code, this switch is required.

5 Open the Scope blocks in the model. Signals are not visible on the scopes. When you connect Simulink to the target application and begin model execution, the signals generated by the target application become visible on the scope displays.

6 Before communication between the model and the target application can begin, the model must be in external mode. To enable external mode, from the **Simulation** > **Mode** menu, select **External**.

7. Reopen the External Mode Control Panel (found in the **Code** menu) and click **Connect**. This action initiates a handshake between Simulink and the target application. When Simulink and the target are connected, the **Start Real-Time Code** button becomes enabled, and the label of the **Connect** button changes to **Disconnect**.
8. Click **Start Real-Time Code**. The outputs of Gain blocks A and B are displayed on the two scopes in your model.

You have established communication between Simulink and the running target application. You can now tune block parameters in Simulink and observe the effects the parameter changes have on the target application.

Tune Parameters

You can change the gain factor of either Gain block by assigning a new value to the variable `A` or `B` in the MATLAB workspace. When you change block parameter values in the workspace during a simulation, you must explicitly update the block diagram with these changes. When you update the block diagram, the new values are downloaded to the target application.

Under certain conditions, you can also tune the expressions that you use to specify block parameter values. To change an expression during simulation, open the block dialog box.

1. At the command prompt, assign new values to both variables, for example:

   ```
   A = 0.5;
   B = 3.5;
   ```

2. Open the `ex_extModeExample` model window. From the **Simulation** menu, select **Update Diagram**. As soon as Simulink has updated the block parameters, the new gain values are downloaded to the target application, and the scopes are changed because of the gain change.
3. In the Sine Wave block dialog box, set **Amplitude** to `0.5`. Click **Apply** or **OK**.

   When you click **Apply** or **OK**, the simulation downloads the new block parameter value to the target application. The Scope block displays the change to reflect the new amplitude value.
4. To simultaneously disconnect host/target communication and end execution of the target application, from the **Simulation** menu, select **Stop**. Alternatively, in the External Mode Control Panel, click **Stop Real-Time Code**.

You cannot change the sample time of the Sine Wave block during simulation. Block sample times are part of the structural definition of the model and are part of the generated code. Therefore, if you want to change a block sample time, you must stop the external mode simulation, reset the sample time of the block, and rebuild the executable.

Block parameter tunability during external mode simulation depends on the way that the generated code represents block parameters.

For example, in the Gain A block dialog box, you cannot change the expression `A` in the **Gain** parameter during simulation. Instead, you must change the value of the variable `A` in the base workspace. You cannot change the expression because the generated code does not allocate storage in memory for the **Gain** parameter. Instead, the code creates a field `A` in a structure:

```
/* Parameters (auto storage) */
struct P_ex_extModeExample_T_ {
  real_T A;                            /* Variable: A
                                        */
  real_T B;                            /* Variable: B
                                        */
  real_T SineWave_Amp;                 /* Expression: 1
                                        */
  real_T SineWave_Bias;                /* Expression: 0
                                        */
  real_T SineWave_Freq;                /* Expression: 1
                                        */
  real_T SineWave_Phase;               /* Expression: 0
                                        */
};
```

The generated code algorithm uses that field in the code that represents the block Gain A. In this case, the global structure variable `ex_extModeExample_P` uses the type `P_ex_extModeExample_T_`:

```
ex_extModeExample_B.GainA = ex_extModeExample_P.A * rtb_SineWave;
```

When you change the value of `A` in the base workspace, the simulation downloads the new value to the field `A` in the target application.

You can change the expressions in the Sine Wave block parameters during simulation because the generated code creates a field in the global structure `ex_extModeExample_P` to represent each parameter in the block. When you change an expression in the block dialog box, the simulation first evaluates the new expression. The

simulation then downloads the resulting numeric value to the corresponding structure field in the target application.

See “Create Tunable Calibration Parameter in the Generated Code” on page 32-121.

Control Memory Allocation for Communication Buffers in Target

If you select the **Code Generation > Interface > Static memory allocation** check box (for GRT and ERT targets), the code generator produces code for external mode that uses only static memory allocation (“malloc-free” code). Selecting **Static memory allocation** enables the **Static memory buffer size** parameter. Use this parameter to specify the size of the external mode static memory buffer. The default value is 1,000,000 bytes. If you enter too small a value for your program, external mode issues an out-of-memory error when it tries to allocate more memory than you allowed. In such cases, increase the value in the **Static memory buffer size** field and regenerate the code.

To determine how much memory to allocate, enable verbose mode on the target (by including `OPTS="-DVERBOSE"` on the `make` command line). As it executes, external mode displays the amount of memory it tries to allocate and the amount of memory available to it each time it attempts an allocation. If an allocation fails, you can use this console log to adjust the size in the **Static memory buffer size** field.

Control External Mode Simulation Through Editor Toolbar

This table gives Simulink Editor features that you can use to control an external mode simulation.

External Mode Action	Toolbar Control	Menu Control	External Mode Control Panel Button
Set the simulation mode of your model to external mode	From the simulation mode drop-down list, select `External`	**Simulation > Mode > External**	**Connect** (if the model simulation mode is not already set, sets the simulation mode to external mode)
Connect your model to a waiting or running target application	**Connect to Target** button 	**Simulation > Connect to Target**	**Connect**

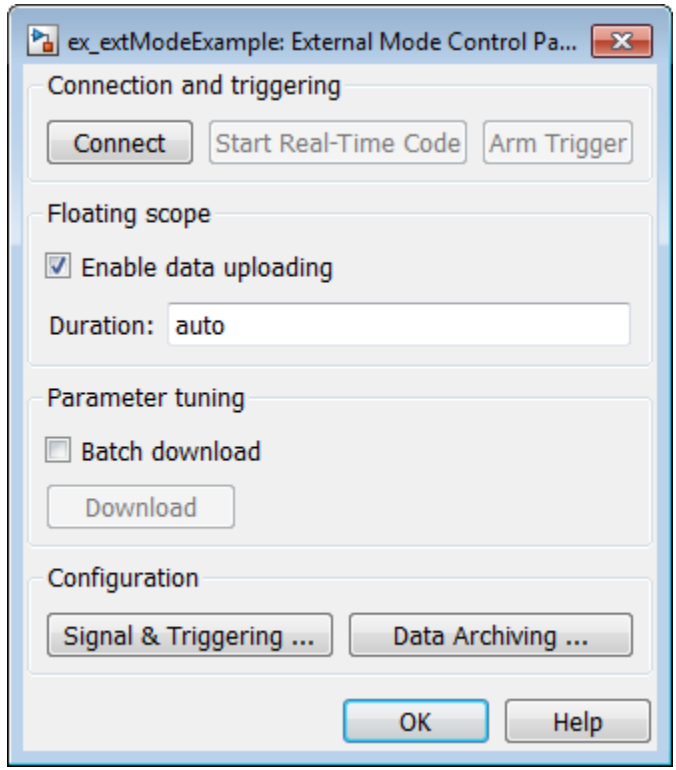
External Mode Action	Toolbar Control	Menu Control	External Mode Control Panel Button
Start running real-time code in the target environment	**Run** button	**Simulation > Run** (keyboard shortcut **Ctrl +T**)	**Start Real-Time Code**
Disconnect your model from the target environment (does not halt running real-time code)	**Disconnect from Target** button 	**Simulation > Disconnect from Target**	**Disconnect**
Stop target application execution and disconnect your model from the target environment	**Stop** button	**Simulation > Stop** (keyboard shortcut **Ctrl +Shift+T**)	**Stop Real-Time Code**

Control External Mode Simulation Through External Mode Control Panel

The External Mode Control Panel provides centralized control of external mode operations, including:

- “Connect, Start, and Stop” on page 55-48
- “Upload Target Application Signal Data to Host” on page 55-49
- “Download Parameters to Target Application” on page 55-50
- “Configure Host Monitoring of Target Application Signal Data” on page 55-51
- “Configure Host Archiving of Target Application Signal Data” on page 55-59

To open the External Mode Control Panel dialog box, in the model window, select **Code > External Mode Control Panel**.



Connect, Start, and Stop

The External Mode Control Panel performs the same connect/disconnect and start/stop functions found in the **Simulation** menu and the Simulink toolbar (see “Control External Mode Simulation Through Editor Toolbar” on page 55-46).

Clicking the **Connect** button connects your model to a waiting or running target application. While you are connected, the button changes to a **Disconnect** button. **Disconnect** disconnects your model from the target environment, but does not halt real-time code running in the target environment.

Connect sets the model simulation mode to external mode.

Clicking the **Start Real-Time Code** button commands the target to start running real-time code. While real-time code is running in the target environment, the button changes

to a **Stop Real-Time Code** button. **Stop Real-Time Code** stops target application execution and disconnects your model from the target environment.

Upload Target Application Signal Data to Host

The External Mode Control Panel allows you to trigger and cancel data uploads to the host. The destination for the uploaded data can be a scope block, Display block, To Workspace block, or another block or subsystem listed in “Blocks and Subsystems Compatible with External Mode” on page 55-62.

The **Arm Trigger** and **Cancel Trigger** buttons provide manual control of data uploading to compatible blocks or subsystems, except floating scopes. (For floating scopes, use the **Floating scope** section of the External Mode Control Panel.)

- To trigger data uploading to compatible blocks or subsystems, click the **Arm Trigger** button. The button changes to **Cancel Trigger**.
- To cancel data uploading, click the **Cancel Trigger** button. The button reverts to **Arm Trigger**.

You can trigger data uploads manually or automatically. To configure signals and triggers for data uploads, see “Configure Host Monitoring of Target Application Signal Data” on page 55-51.

A subset of external mode compatible blocks, including Scope, Time Scope, and To Workspace, allow you to log uploaded data to disk. To configure data archiving, see “Configure Host Archiving of Target Application Signal Data” on page 55-59.

The **Floating scope** section of the External Mode Control Panel controls when and for how long data is uploaded to Floating Scope blocks. When used in external mode, floating scopes:

- Do not appear in the External Signal & Triggering dialog box.
- Do not log data to external mode archiving.
- Support manual triggering only.

The **Floating scope** section contains the following parameters:

- **Enable data uploading** option, which functions as an **Arm Trigger** button for floating scopes. When the target is disconnected, the option controls whether to arm the trigger when connecting the floating scopes. When the target is connected, the option acts as a toggle button to arm or cancel the trigger.

  - To trigger data uploading to floating scopes, select **Enable data uploading**.
  - To cancel data uploading to floating scopes, clear **Enable data uploading**.
- **Duration** edit field, which specifies the number of base-rate steps for which external mode logs floating scopes data after a trigger event. By default, it is set to `auto`, which causes the duration value set in the External Signal & Triggering dialog box to be used. The default duration value is 1000 base rate steps.

Download Parameters to Target Application

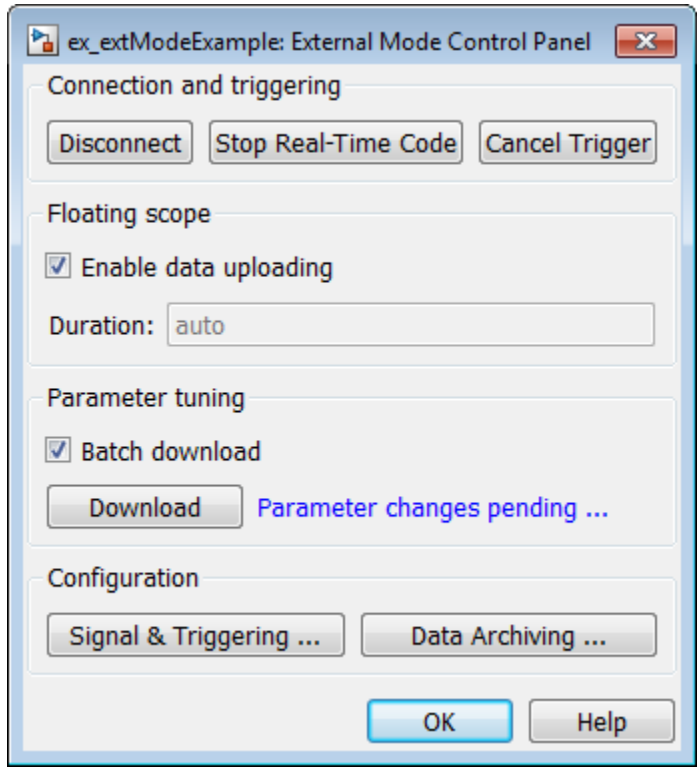
The **Batch download** option on the External Mode Control Panel enables or disables batch parameter changes.

By default, batch download is disabled. If batch download is disabled, when you click **OK** or **Apply**, changes made directly to block parameters by editing block parameter dialog boxes are sent to the target. When you perform an **Update Diagram**, changes to MATLAB workspace variables are sent.

If you select **Batch download**, the **Download** button is enabled. Until you click **Download**, changes made to block parameters are stored locally. When you click **Download**, the changes are sent in a single transmission.

When parameter changes are awaiting batch download, the External Mode Control Panel displays the message `Parameter changes pending...` to the right of the **Download** button. This message remains visible until the Simulink engine receives notification that the new parameters have been installed in the parameter vector of the target system.

The next figure shows the External Mode Control Panel with the **Batch download** option activated and parameter changes pending.



Configure Host Monitoring of Target Application Signal Data

Role of Trigger in Signal Data Uploading

In external mode, uploading target application signal data to the host depends on a *trigger*. The trigger is a set of conditions that must be met for data uploading to begin. The trigger can be armed or not armed.

- When the trigger is armed, the software checks for the trigger conditions that allow data uploading to begin.
- If the trigger is not armed, the software does not check for the trigger conditions and data uploading cannot begin.
- The trigger can be armed automatically, when the host connects to the target, or manually, by clicking the **Arm Trigger** button on the External Mode Control Panel.

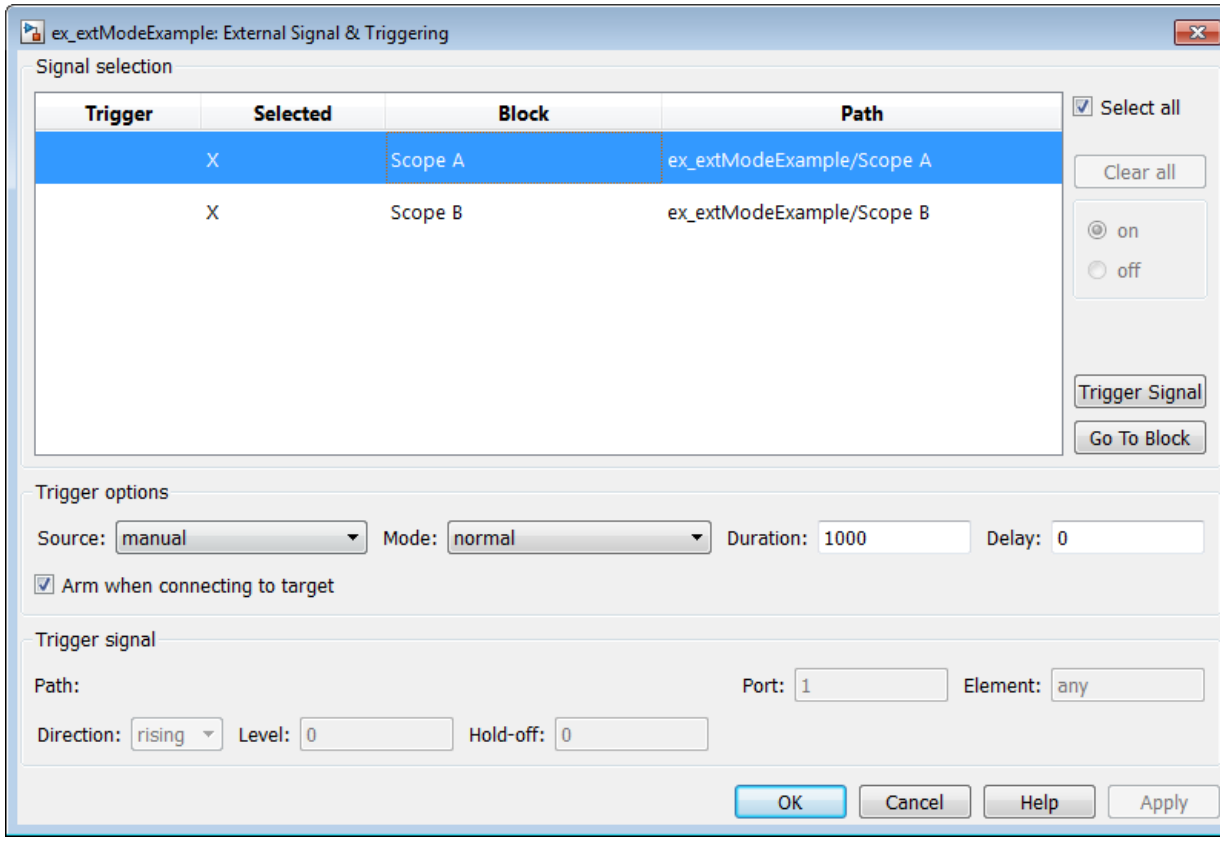
When the trigger is armed and the trigger conditions are met, the trigger fires and data uploading begins.

When data has been collected for a defined duration, the trigger event completes and data uploading stops. The trigger can then rearm, or remain unarmed until you click the **Arm Trigger** button.

To select the target application signals to upload and configure how uploads are triggered, see “Configure Signal Data Uploading” on page 55-52.

Configure Signal Data Uploading

Clicking the **Signal & Triggering** button of the External Mode Control Panel opens the External Signal & Triggering dialog box.



The External Signal & Triggering dialog box displays a list of blocks and subsystems in your model that support external mode signal uploading. For information on which types of blocks are external mode compatible, see “Blocks and Subsystems Compatible with External Mode” on page 55-62.

In the External Signal & Triggering dialog box, you can select the signals that are collected from the target system and viewed in external mode. You can also select a trigger signal, which triggers uploading of data based on meeting certain signal conditions, and define the triggering conditions.

Default Trigger Options

The preceding figure shows the default settings of the External Signal & Triggering dialog box. The default operation of the External Signal & Triggering dialog box simplifies

monitoring the target application. If you use the default settings, you do not need to preconfigure signals and triggers. You start the target application and connect the Simulink engine to it. External mode compatible blocks are selected and the trigger is armed. Signal uploading begins immediately upon connection to the target application.

The default configuration of trigger options is:

- `Select all`: on
- `Source`: manual
- `Mode`: normal
- `Duration`: 1000
- `Delay`: 0
- `Arm when connecting to target`: on

Select Signals to Upload

External mode compatible blocks in your model appear in the **Signal selection** list of the External Signal & Triggering dialog box. You use this list to select signals that you want to view. In the **Selected** column, an X appears for each selected block.

The **Select all** check box selects all signals. By default, **Select all** is selected.

If **Select all** is cleared, you can select or clear individual signals using the **on** and **off** options. To select a signal, click its list entry and select the **on** option. To clear a signal, click its list entry and select the **off** option.

The **Clear all** button clears all signals.

Configure Trigger Options

As described in “Role of Trigger in Signal Data Uploading” on page 55-52, signal data uploading depends on a trigger. The trigger defines conditions that must be met for uploading to begin. Also, the trigger must be armed for data uploading to begin. When the trigger is armed and trigger conditions are met, the trigger fires and uploading begins. When data has been collected for a defined duration, the trigger event completes and data uploading stops.

To control when and how signal data is collected (uploaded) from the target system, configure the following **Trigger options** in the External Signal & Triggering dialog box.

- **Source**: `manual` or `signal`. Controls whether a button or a signal triggers data uploading.

  Selecting `manual` directs external mode to use the **Arm Trigger** button on the External Mode Control Panel as the trigger to start uploading data. When you click **Arm Trigger**, data uploading begins.

  Selecting `signal` directs external mode to use a trigger signal as the trigger to start uploading data. When the trigger signal satisfies trigger conditions (that is, the signal crosses the trigger level in the specified direction), a *trigger event* occurs. (Specify trigger conditions in the **Trigger signal** section.) If the trigger is *armed*, external mode monitors for the occurrence of a trigger event. When a trigger event occurs, data uploading begins.
- **Mode**: `normal` or `one-shot`. Controls whether the trigger rearms after a trigger event completes.

  In `normal` mode, external mode automatically rearms the trigger after each trigger event. The next data upload begins when the trigger fires.

  In `one-shot` mode, external mode collects only one buffer of data each time you arm the trigger.

  For more information on the **Mode** setting, see “Configure Host Archiving of Target Application Signal Data” on page 55-59.
- **Duration**: Specifies the number of base rate steps for which external mode uploads data after a trigger event (default is 1000). For example, if **Duration** is set to 1000, and the base (fastest) rate of the model is one second:

  - For a signal sampled at the base rate, one second (1.0 Hz), external mode collects 1000 contiguous samples during a trigger event.
  - For a signal sampled at two seconds (0.5 Hz), external mode collects 500 samples during a trigger event.
- **Delay**: Specifies a delay to be applied to data collection. The delay represents the amount of time that elapses between a trigger event and the start of data collection. The delay is expressed in base rate steps. It can be positive or negative (default is 0). A negative delay corresponds to pretriggering. When the delay is negative, data from the time preceding the trigger event is collected and uploaded.
- **Arm when connecting to target**: Selected or cleared. Whether a button or a signal triggers data uploading (as defined by **Source**), the trigger must be armed to allow data uploading to begin.

If you select this option, connecting to the target arms the trigger.

- If the trigger **Source** is `manual`, data uploading begins immediately.
- If the trigger **Source** is `signal`, monitoring of the trigger signal begins immediately. Data uploading begins when the trigger signal satisfies trigger conditions (as defined in the **Trigger signal** section).

If you clear **Arm when connecting to target**, manually arm the trigger by clicking the **Arm Trigger** button on the External Mode Control Panel.

When simulating in external mode, each rate in the model creates a buffer on the target. Each entry in the buffer is big enough to hold all of the data required of every signal in that rate for one time step (time plus data plus external mode indices identifying the signal). The number of entries in the circular buffer is determined by the external mode trigger **Duration** parameter (`ExtModeTrigDuration`). The memory allocated on the target for buffering signals is proportional to the **Duration** and the number of signals uploading. The **Duration** also provides an indication of the number of base rate steps with log data after a trigger event in external mode.

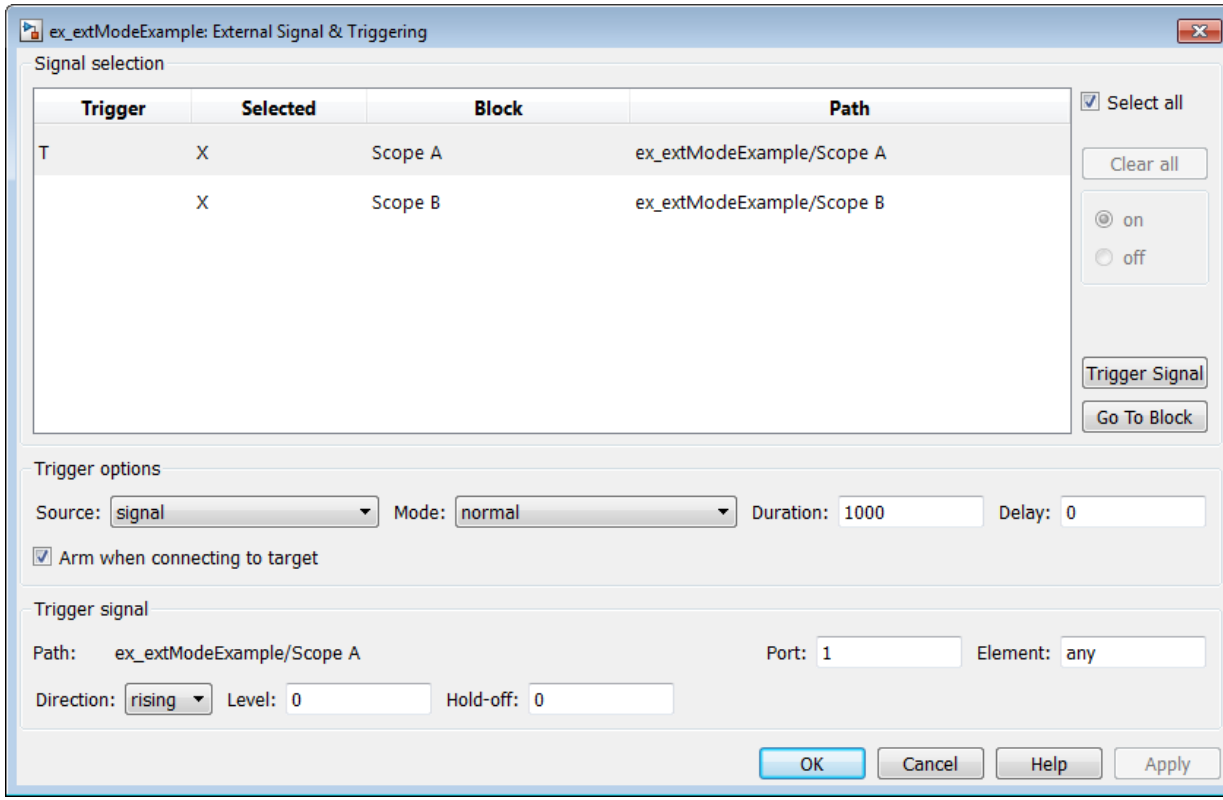
The **Duration** value specifies the number of contiguous points of data to be collected in each buffer of data. You should enter a **Duration** value equal to the number of continuous sample points that you need to collect rather than relying on a series of buffers to be continuous. If you enter a value less than the total number of sample points, you may lose sample points during the time spent transferring values from the data buffer to the MATLAB workspace. The Simulink software maintains point continuity only within one buffer. Between buffers, because of transfer time, some samples may be omitted.

The **Duration** value can affect the **Limit data points to last** value of Scope and To Workspace blocks. The number of sample points that the blocks save to the MATLAB workspace is the smaller of the two values. To set the number of sample points that the blocks save, clear **Limit data points to last**. Then, use **Duration** to specify the number of sample points saved.

Select Trigger Signal

You can designate one signal as a trigger signal. To select a trigger signal, from the **Source** menu in the **Trigger options** section, select `signal`. This action enables the parameters in the **Trigger signal** section. Then, select a signal in the **Signal selection** list, and click the **Trigger Signal** button.

When you select a signal to be a trigger, a T appears in the **Trigger** column of the **Signal selection** list. In the next figure, the `Scope A` signal is the trigger. `Scope B` is also selected for viewing, as indicated by the X in the **Selected** column.



After selecting the trigger signal, you can use the **Trigger signal** section to define the trigger conditions and set the trigger signal **Port** and **Element** parameters.

Set Trigger Conditions

Use the **Trigger signal** section of the External Signal & Triggering dialog box to set trigger conditions and attributes. **Trigger signal** parameters are enabled only when the trigger parameter **Source** is set to `signal` in the **Trigger options** section.

By default, any element of the first input port of a specified trigger block can cause the trigger to fire (that is, Port 1, any element). You can modify this behavior by adjusting the

Port and **Element** values in the **Trigger signal** section. The **Port** field accepts a number or the keyword `last`. The **Element** field accepts a number or the keywords `any` or `last`.

In the **Trigger signal** section, you also define the conditions under which a trigger event occurs.

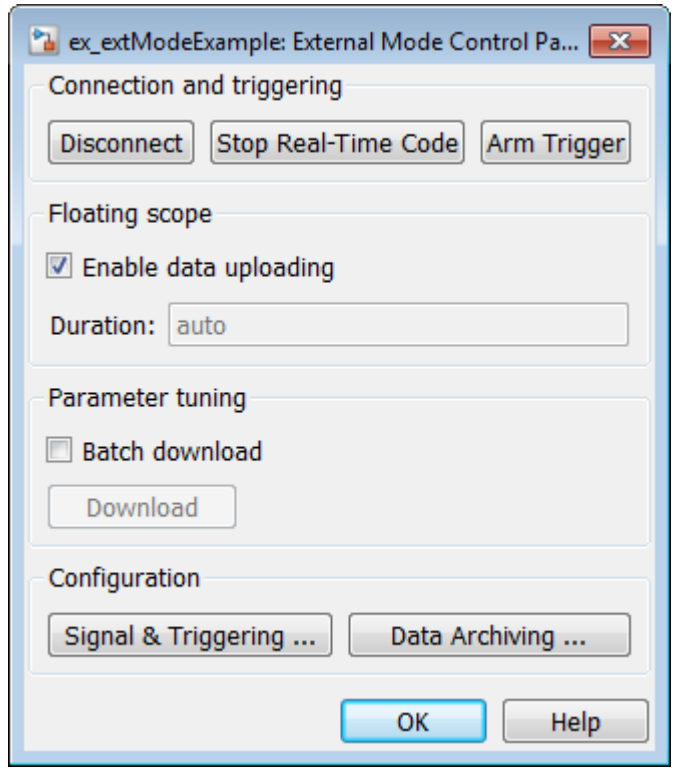
- **Direction**: `rising`, `falling`, or `either`. The direction in which the signal must be traveling when it crosses the threshold value. The default is `rising`.
- **Level**: A value indicating the threshold the signal must cross in a designated direction to fire the trigger. By default, the level is 0.
- **Hold-off**: Applies only to `normal` mode. Expressed in base rate steps, **Hold-off** is the time between the termination of one trigger event and the rearming of the trigger.

Modify Signal and Triggering Options While Connected

After you configure signal data uploading, and connect Simulink to a running target executable, you can modify signal and triggering options without disconnecting from the target.

If the trigger is armed (for example, if the trigger option **Arm when connecting to the target** is selected, which is the default), the External Signal & Triggering dialog box cannot be modified. To modify signal and triggering options:

1. Open the External Mode Control Panel.
2. Click **Cancel Trigger**. Triggering and display of uploaded data stops.
3. Open the External Signal & Triggering dialog box and modify signal and trigger options as required. For example, in the **Signal selection** section, you can enable or disable a scope, and in the **Trigger options** section, change the trigger **Mode**, for example, from `normal` to `one-shot`.
4. Click **Arm Trigger**. Triggering and display of uploaded data resumes, with your modifications.



Configure Host Archiving of Target Application Signal Data

In external mode, you can use the Simulink Scope and To Workspace blocks to archive data to disk.

To understand how the archiving features work, consider the handling of data when archiving is not enabled. There are two cases, one-shot mode and normal mode.

- In one-shot mode, after a trigger event occurs, each selected block writes its data to the workspace, as it would at the end of a simulation. If another one-shot is triggered, the existing workspace data is overwritten.
- In normal mode, external mode automatically rearms the trigger after each trigger event. Consequently, you can think of normal mode as a series of one-shots. Each one-shot in this series, except for the last, is referred to as an *intermediate result*. Because the trigger can fire at any time, writing intermediate results to the workspace can

result in unpredictable overwriting of the workspace variables. For this reason, the default behavior is to write only the results from the final one-shot to the workspace. The intermediate results are discarded. If you know that enough time exists between triggers for inspection of the intermediate results, you can override the default behavior by selecting the **Write intermediate results to workspace** option. This option does not protect the workspace data from being overwritten by subsequent triggers.

If you use a Simulink Scope block to archive data to disk, open the Scope parameters dialog box and select the option **Log data to workspace**. The option is required for these reasons:

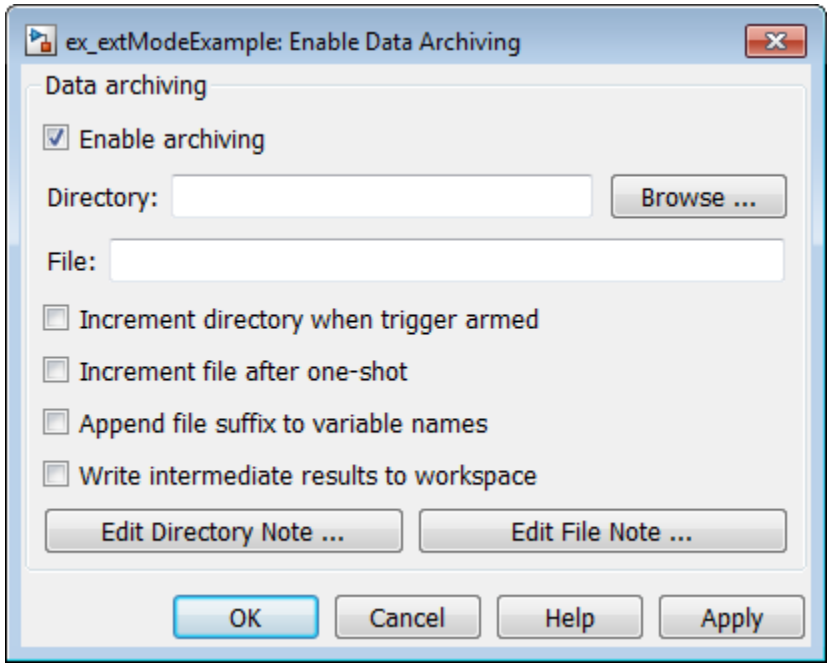
- The data is first transferred from the scope data buffer to the MATLAB workspace, before being written to a MAT-file.
- The **Variable name** entered in the Scope parameters dialog box is the same as the one in the MATLAB workspace and the MAT-file. Enabling the data to be saved enables a variable named with the **Variable name** parameter to be saved to a MAT-file.

Note If you do not select the Scope block option **Log data to workspace**, the MAT-files for data logging are created, but they are empty.

The Enable Data Archiving dialog box supports:

- Folder notes
- File notes
- Automated data archiving

On the External Mode Control Panel, click the **Data Archiving** button to open the Enable Data Archiving dialog box. If your model is connected to the target environment, disconnect it while you configure data archiving. To enable the other controls in the dialog box, select **Enable archiving**.



These operations are supported by the Enable Data Archiving dialog box.

Folder Notes

To add annotations for a collection of related data files in a folder, in the Enable Data Archiving dialog box, click **Edit Directory Note**. The MATLAB editor opens. Place comments that you want saved to a file in the specified folder in this window. By default, the comments are saved to the folder last written to by data archiving.

File Notes

To add annotations for an individual data file, in the Enable Data Archiving dialog box, click **Edit File Note**. A file finder window opens, which by default is set to the last file to which you have written. Selecting a MAT-file opens an edit window. In this window, add or edit comments that you want saved with your individual MAT-file.

Automated Data Archiving

To configure automatic writing of logging results to disk, optionally including intermediate results, use the **Enable archiving** option and the controls it enables . The dialog box provides the following related controls:

- **Directory**: Specifies the folder in which data is saved. If you select **Increment directory when trigger armed**, external mode appends a suffix.
- **File**: Specifies the name of the file in which data is saved. If you select **Increment file after one-shot**, external mode appends a suffix.
- **Increment directory when trigger armed**: Each time that you click the **Arm Trigger** button, external mode uses a different folder for writing log files. The folders are named incrementally, for example, `dirname1`, `dirname2`, and so on.
- **Increment file after one-shot**: New data buffers are saved in incremental files: `filename1`, `filename2`, and so on. File incrementing happens automatically in normal mode.
- **Append file suffix to variable names**: Whenever external mode increments file names, each file contains variables with identical names. Selecting **Append file suffix to variable name** results in each file containing unique variable names. For example, external mode saves a variable named `xdata` in incremental files (`file_1`, `file_2`, and so on) as `xdata_1`, `xdata_2`, and so on. This approach supports loading the MAT-files into the workspace and comparing variables at the MATLAB command prompt. Without the unique names, each instance of `xdata` would overwrite the previous one in the MATLAB workspace.
- **Write intermediate results to workspace**: If you want the Simulink Coder software to write intermediate results to the workspace, select this option.

Blocks and Subsystems Compatible with External Mode

Compatible Blocks

In external mode, you can use the following types of blocks to receive and view signals uploaded from the target application:

- Floating Scope and Scope blocks
- Spectrum Analyzer and Time Scope blocks from the DSP System Toolbox product
- Display blocks
- To Workspace blocks
- User-written S-Function blocks

  An external mode method is built into the S-function API. This method allows user-written blocks to support external mode. See *`matlabroot`*`/simulink/include/simstruc.h`.
- XY Graph blocks

You can designate certain subsystems as Signal Viewing Subsystems and use them to receive and view signals uploaded from the target application. See “Signal Viewing Subsystems” on page 55-63 for more information.

You select external mode compatible blocks and subsystems, and arm the trigger, by using the External Signal & Triggering dialog box. By default, such blocks in a model are selected, and a manual trigger is set to be armed when connected to the target application.

Signal Viewing Subsystems

A Signal Viewing Subsystem is an atomic subsystem that encapsulates processing and viewing of signals received from the target system. A Signal Viewing Subsystem runs only on the host, and does not generate code in the target system. Signal Viewing Subsystems run in normal, accelerator, rapid accelerator, and external simulation modes.

Note Signal Viewing Subsystems are inactive if placed inside a SIL or PIL component, such as a top model in SIL or PIL mode, a Model block in SIL or PIL mode, or a SIL or PIL block. However, a SIL or PIL component can feed a Signal Viewing Subsystem running in a supported mode.

Signal Viewing Subsystems are useful in situations where you want to process or condition signals before viewing or logging them, but you do not want to perform these tasks on the target system. By using a Signal Viewing Subsystem, you can generate smaller and more efficient code on the target system.

Like other external mode compatible blocks, Signal Viewing Subsystems are displayed in the External Signal & Triggering dialog box.

To declare a subsystem to be a Signal Viewing Subsystem:

1. In the Block Parameters dialog box, select the **Treat as atomic unit** option.

   For more information on atomic subsystems, see “Control Generation of Functions for Subsystems” (Simulink Coder).

2. To turn the SimViewingDevice property on, use the `set_param` command:

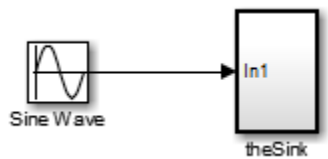
   ```
   set_param('blockname', 'SimViewingDevice','on')
   ```

   `'blockname'` is the name of the subsystem.

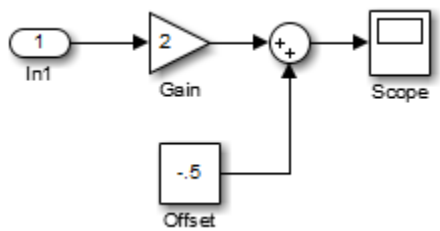
3. Make sure the subsystem meets the following requirements:

   - It must be a pure Sink block. That is, it must not contain Outport blocks or Data Store blocks. It can contain Goto blocks only if the corresponding From blocks are contained within the subsystem boundaries.
   - It must not have continuous states.

The following model, `sink_examp`, contains an atomic subsystem, `theSink`.



The subsystem `theSink` applies a gain and an offset to its input signal and displays it on a Scope block.



If `theSink` is declared as a Signal Viewing Subsystem, the generated target application includes only the code for the Sine Wave block. If `theSink` is selected and armed in the

External Signal & Triggering dialog box, the target application uploads the sine wave signal to `theSink` during simulation. You can then modify the parameters of the blocks within `theSink` and observe the uploaded signal.

If `theSink` were not declared as a Signal Viewing Subsystem, its Gain, Constant, and Sum blocks would run as subsystem code on the target system. The Sine Wave signal would be uploaded to the Simulink engine after being processed by these blocks, and viewed on `sink_examp/theSink/Scope2`. Processing demands on the target system would be increased by the additional signal processing, and by the downloading of changes in block parameters from the host.

Supported Blocks for Data Archiving

In external mode, you can use the following types of blocks to archive data to disk:

- Scope blocks
- To Workspace blocks

You configure data archiving by using the Enable Data Archiving dialog box, as described in “Configure Host Archiving of Target Application Signal Data” on page 55-59.

External Mode Mechanism for Downloading Tunable Parameters

Depending on the setting of the **Default parameter behavior** option when the target application is generated, there are differences in the way parameter updates are handled. “Download Mechanism” on page 55-65 describes the operation of external mode communication with **Default parameter behavior** set to `Tunable`. “Inlined and Tunable Parameters” on page 55-67 describes the operation of external mode with **Default parameter behavior** set to `Inlined`.

Download Mechanism

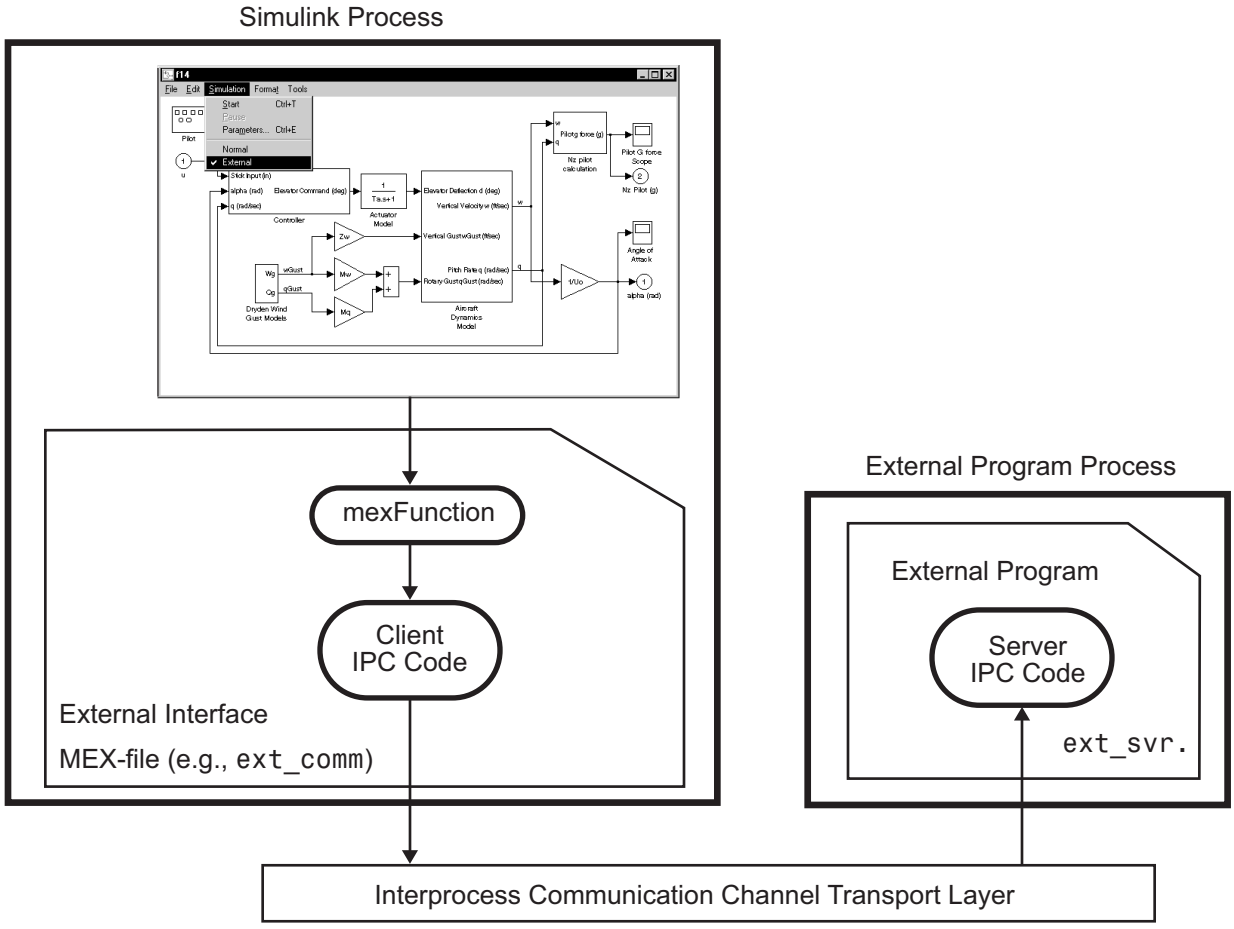
In external mode, the Simulink engine does not simulate the system represented by the block diagram. By default, when external mode is enabled, the Simulink engine downloads parameters to the target system. After the initial download, the engine remains in a waiting mode until you change parameters in the block diagram or until the engine receives data from the target.

When you change a parameter in the block diagram, the Simulink engine calls the external interface MEX-file, passing new parameter values (along with other information) as arguments. The external interface MEX-file contains code that implements one side of the interprocess communication (IPC) channel. This channel connects the Simulink process (where the MEX-file executes) to the process that is executing the external program. The MEX-file transfers the new parameter values by using this channel to the external program.

The other side of the communication channel is implemented within the external program. This side writes the new parameter values into the target's parameter structure (*model*_P).

The Simulink side initiates the parameter download operation by sending a message containing parameter information to the external program. In the terminology of client/server computing, the Simulink side is the client and the external program is the server. The two processes can be remote, or they can be local. Where the client and server are remote, a protocol such as TCP/IP is used to transfer data. Where the client and server are local, a serial connection or shared memory can be used to transfer data.

The next figure shows this relationship. The Simulink engine calls the external interface MEX-file whenever you change parameters in the block diagram. The MEX-file then downloads the parameters to the external program by using the communication channel.



External Mode Architecture

Inlined and Tunable Parameters

By default, parameters (except those listed in “TCP/IP and Serial External Mode Limitations” on page 55-85) in an external mode program are tunable; that is, you can change them by using the download mechanism described in this section.

If you set **Default parameter behavior** to `Inlined` (on the **Optimization** pane of the Configuration Parameters dialog box), the Simulink Coder code generator embeds the numerical values of model parameters (constants), instead of symbolic parameter names,

in the generated code. Inlining parameters generates smaller and more efficient code. However, inlined parameters, because they effectively become constants, are not tunable.

The Simulink Coder software lets you improve overall efficiency by inlining most parameters, while at the same time retaining the flexibility of run-time tuning for selected parameters that are important to your application. When you inline parameters, you can use `Simulink.Parameter` objects to remove individual parameters from inlining and declare them to be tunable. In addition, you can use these objects to control how parameters are represented in the generated code.

For more information on tunable parameters, see “Create Tunable Calibration Parameter in the Generated Code” on page 32-121.

Automatic Parameter Uploading on Host/Target Connection

Each time the Simulink engine connects to a target application that was generated with **Default parameter behavior** set to `Inlined`, the target application uploads the current value of its tunable parameters to the host. These values are assigned to the corresponding MATLAB workspace variables. This procedure synchronizes the host and target with respect to parameter values.

Workspace variables required by the model must be initialized at the time of host/target connection. Otherwise the uploading cannot proceed and an error results. Once the connection is made, these variables are updated to reflect the current parameter values on the target system.

Automatic parameter uploading takes place only if the target application was generated with **Default parameter behavior** set to `Inlined`. “Download Mechanism” on page 55-65 describes the operation of external mode communication with **Default parameter behavior** set to `Tunable`.

Choose Communication Protocol for Client and Server

Introduction

The Simulink Coder product provides code to implement both the client and server side of external mode communication using either TCP/IP or serial protocols. You can use the socket-based external mode implementation provided by the Simulink Coder product with the generated code, provided that your target system supports TCP/IP. If not, use or customize the serial transport layer option provided.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

Using the TCP/IP Implementation

You can use TCP/IP-based client/server implementation of external mode with real-time programs on The Open Group UNIX or PC systems. For help in customizing external mode transport layers, see “Create a Transport Layer for TCP/IP or Serial External Mode Communication” (Simulink Coder).

To use Simulink external mode over TCP/IP:

- Make sure that the external interface MEX-file for your target's TCP/IP transport is specified.

  Targets provided by MathWorks specify the name of the external interface MEX-file in *`matlabroot`*`/toolbox/simulink/simulink/extmode_transports.m`. The name of the interface appears as uneditable text in the **External mode configuration** section of the **Interface** pane of the Configuration Parameters dialog box. The TCP/IP default is `ext_comm`.

  To specify a TCP/IP transport for a custom target, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

  ```
  function sl_customization(cm)
    cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
  %end function
  ```

  - *`stf`*`.tlc` is the name of the system target file for which you are registering the transport (for example, `'mytarget.tlc'`)
  - *`transport`* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, `'tcpip'`)

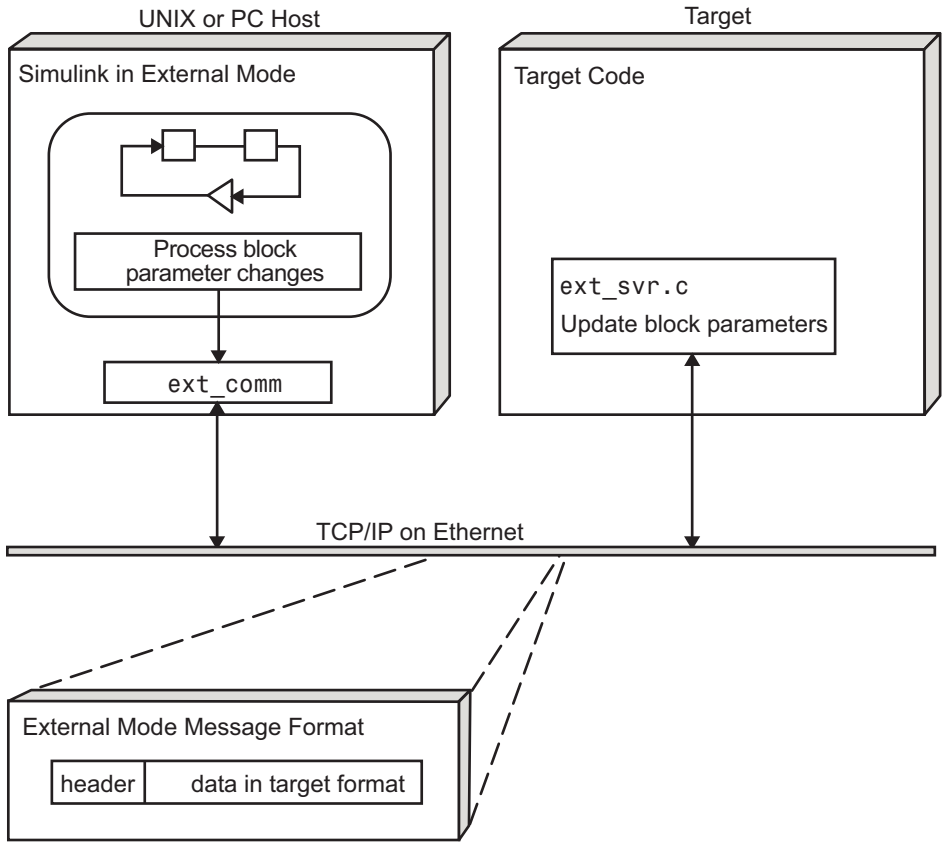
- *`mexfile`* is the name of the transport's associated external interface MEX-file (for example, `'ext_comm'`)

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
  cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
                           'ext_serial_win32_comm', 'Level1');
%end function
```

- Be sure that the template makefile is configured to link the source files for the TCP/IP server code and that it defines the compiler flags when building the generated code.
- Build the external program.
- Run the external program.
- Set the Simulink model to external mode and connect to the target.

The next figure shows the structure of the TCP/IP-based implementation.



TCP/IP-Based Client/Server Implementation for External Mode

MEX-File Optional Arguments for TCP/IP Transport

In the External Target Interface dialog box, you can specify optional arguments that are passed to the external mode interface MEX-file for communicating with executing targets.

- Target network name: the network name of the computer running the external program. By default, this is the computer on which the Simulink product is running, for example, `'myComputer'`. You can also use the IP address, for example, `'148.27.151.12'`.
- Verbosity level: controls the level of detail of the information displayed during the data transfer. The value is either `0` or `1` and has the following meaning:

`0` — No information
`1` — Detailed information

- TCP/IP server port number: The default value is `17725`. You can change the port number to a value between `256` and `65535` to avoid a port conflict.

The arguments are positional and must be specified in the following order:

```
<TargetNetworkName> <VerbosityLevel> <ServerPortNumber>
```

For example, if you want to specify the verbosity level (the second argument), then you must also specify the target network name (the first argument). Arguments can be delimited by white space or commas. For example:

```
'148.27.151.12' 1 30000
```

You can specify command-line options to the external program when you launch it. See “Run the External Program” on page 55-74.

Using the Serial Implementation

Controlling host/target communication on a serial channel is similar to controlling host/target communication on a TCP/IP channel.

To use Simulink external mode over a serial channel, you must:

- Make sure that the external interface MEX-file for your target's serial transport is specified.

  Targets provided by MathWorks specify the name of the external interface MEX-file in *`matlabroot`*`/toolbox/simulink/simulink/extmode_transports.m`. The name of the interface appears as uneditable text in the **External mode configuration** section of the **Interface** pane of the Configuration Parameters dialog box. The serial default is `serial`.

  To specify a serial transport for a custom target, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

  ```
  function sl_customization(cm)
    cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
  %end function
  ```

  - *`stf`*`.tlc` is the name of the system target file for which you are registering the transport (for example, `'mytarget.tlc'`)

- *`transport`* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, `'serial'`)
- *`mexfile`* is the name of the transport's associated external interface MEX-file (for example, `'ext_serial_win32_comm'`)

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('mytarget.tlc', 'tcpip', 'ext_comm', 'Level1');
  cm.ExtModeTransports.add('mytarget.tlc', 'serial', ...
                           'ext_serial_win32_comm', 'Level1');
%end function
```

- Be sure that the template makefile is configured to link the source files for the serial server code and that it defines the compiler flags when building the generated code.
- Build the external program.
- Run the external program.
- Set the Simulink model to external mode and connect to the target.

MEX-File Optional Arguments for Serial Transport

In the **MEX-file arguments** field of the **Interface** pane of the Configuration Parameters dialog box, you can specify arguments that are passed to the external mode interface MEX-file for communicating with the executing targets. For serial transport, the optional arguments to `ext_serial_win32_comm` are as follows:

- Verbosity level: This argument controls the level of detail of the information displayed during data transfer. The value of this argument is:
  - `0` (no information), or
  - `1` (detailed information)
- Serial port ID: The port ID of the host, specified as an integer or character vector. For example, specify the port ID of a USB to serial converter as `'/dev/ttyusb0'`.Simulink Coder prefixes integer port IDs with `\\.\COM` on Windows and by `/dev/ttyS` on Unix.

  When you start the target application using a serial connection, you must specify the port ID to use to connect it to the host. Do this by including the `-port` command-line option. For example:

  ```
  mytarget.exe -port 2 -w
  ```

- Baud rate: Specify an integer value. The default value is `57600`.

The MEX-file options arguments are positional and must be specified in the following order:

```
<VerbosityLevel> <SerialPortID> <BaudRate>
```

For example, if you want to specify the serial port ID (the second argument), then you must also specify the verbosity level (the first argument). Arguments can be delimited by white space or commas. For example:

```
1 '/dev/ttyusb0' 57600
```

When you launch the external program, you can specify command-line options.

Run the External Program

Before you can use the Simulink product in external mode, the external program must be running.

If the target application is executing on the same machine as the host and communication is through a loopback serial cable, the target's port ID must differ from that of the host (as specified in the **MEX-file arguments** edit field).

To run the external program, you type a command of the form:

```
model -opt1 ... -optN
```

`model` is the name of the external program and *`-opt1 ... -optN`* are options. (See “Command-Line Options for the External Program” on page 55-75.) In the examples in this section, the name of the external program is `ext_example`.

Running the External Program in the Windows Environment

In the Windows environment, you can run the external programs in either of the following ways:

- Open a Command Prompt window. At the command prompt, type the name of the target executable, followed by possible options, such as:

  ```
  ext_example -tf inf -w
  ```

- Alternatively, you can launch the target executable from the MATLAB Command Window. The command must be preceded by an exclamation point (`!`) and followed by an ampersand (&), as in the following example:

```
!ext_example -tf inf -w &
```

The ampersand (&) causes the operating system to spawn another process to run the target executable. If you do not include the ampersand, the program still runs, but you cannot enter commands at the MATLAB command prompt or manually terminate the executable.

Running the External Program in the UNIX Environment

In the UNIX environment, you can run the external programs in either of the following ways:

- Open an `Xterm` window. At the command prompt, type the name of the target executable, followed by possible options, such as:

  ```
  ./ext_example -tf inf -w
  ```

- Alternatively, you can launch the target executable from the MATLAB Command Window. You must run it in the background so that you can still access the Simulink environment. The command must be preceded by an exclamation point (`!`), dot slash (./ indicating the current directory), and followed by an ampersand (&), as in the following example:

  ```
  !./ext_example -tf inf -w &
  ```

  The ampersand (&) causes the operating system to spawn another process to run the target executable.

Command-Line Options for the External Program

External mode target executables generated by the Simulink Coder code generator support the following command-line options:

- `-tf n`

  The `-tf` option overrides the stop time set in the Simulink model. The argument `n` specifies the number of seconds the program will run. The value `inf` directs the model to run indefinitely. In this case, the model code runs until the target application receives a stop message from the Simulink engine.

  The following example sets the stop time to 10 seconds.

  ```
  ext_example -tf 10
  ```

When integer-only ERT targets are built and executed in external mode, the stop time parameter (`-tf`) is interpreted by the target as the number of base rate ticks rather than the number of seconds to execute.

- `-w`

  Instructs the target application to enter a wait state until it receives a message from the host. At this point, the target is running, but not executing the model code. The start message is sent when you select **Start Real-Time Code** from the **Simulation** menu or click the **Start Real-Time Code** button in the External Mode Control Panel.

  Use the `-w` option if you want to view target application execution data from time step 0, or if you want to modify parameters before the target application begins execution of model code.

- `-port n`

  Specifies the TCP/IP port number or the serial port ID, `n`, for the target application. The port number of the target application must match that of the host for TCP/IP transport. The port number depends on the type of transport.

  - For TCP/IP transport: Port number is an integer between `256` and `65535`, with the default value being `17725`.
  - For serial transport: Port ID is an integer or a character vector. For example, specify the port ID of a USB to serial converter as `'/dev/ttyusb0'`

- `-baud r`

  Specified as an integer, this option is only available for serial transport.

Implement an External Mode Protocol Layer

If you want to implement your own transport layer for external mode communication, you must modify certain code modules provided by the Simulink Coder product and create a new external interface MEX-file. See “Create a Transport Layer for TCP/IP or Serial External Mode Communication” (Simulink Coder).

Use External Mode Programmatically

You can run external mode simulations from the MATLAB command line or programmatically in scripts. Use the `get_param` and `set_param` commands to retrieve and set the values of model simulation command-line parameters, such as

`SimulationMode` and `SimulationCommand`, and external mode command-line parameters, such as `ExtModeCommand` and `ExtModeTrigType`.

The following model simulation commands assume that a Simulink model is open and that you have loaded a target application to which the model will connect using external mode.

1. Change the Simulink model to external mode:

   ```
   set_param(gcs,'SimulationMode','external')
   ```

2. Connect the open model to the loaded target application:

   ```
   set_param(gcs,'SimulationCommand','connect')
   ```

3. Start running the target application:

   ```
   set_param(gcs,'SimulationCommand','start')
   ```

4. Stop running the target application:

   ```
   set_param(gcs,'SimulationCommand','stop')
   ```

5. Disconnect the target application from the model:

   ```
   set_param(gcs,'SimulationCommand','disconnect')
   ```

To tune a workspace parameter, change its value at the command prompt. If the workspace parameter is a `Simulink.Parameter` object, assign the new value to the `Value` property.

```
myVariable = 5.23;
myParamObj.Value = 5.23;
```

To download the workspace parameter in external mode, you update the model diagram. The following model simulation command initiates a model update:

```
set_param(gcs,'SimulationCommand','update')
```

To trigger or cancel data uploading to scopes, use the `ExtModeCommand` values `armFloating` and `cancelFloating`, or `armWired` and `cancelWired`. For example, to trigger and then cancel data uploading to wired (nonfloating) scopes:

```
set_param(gcs,'ExtModeCommand','armWired')
set_param(gcs,'ExtModeCommand','cancelWired')
```

The next table lists external mode command-line parameters that you can use in `get_param` and `set_param` commands. The table provides brief descriptions, valid

values (bold type highlights defaults), and a mapping to External Mode dialog box equivalents. For external mode parameters that are equivalent to **Interface** pane options in the Configuration Parameters dialog box, see “Model Configuration Parameters: Code Generation Interface” (Simulink Coder).

External Mode Command-Line Parameters

Parameter and Values	Dialog Box Equivalent	Description
`ExtModeAddSuffixToVar` **`off`**, `on`	Enable Data Archiving: **Append file suffix to variable names** check box	Increment variable names for each incremented filename.
`ExtModeArchiveDirName` *`character vector`*	Enable Data Archiving: **Directory** text field	Save data in specified folder.
`ExtModeArchiveFileName` *`character vector`*	Enable Data Archiving: **File** text field	Save data in specified file.
`ExtModeArchiveMode` *`character vector`* - **`off`**, `auto`, `manual`	Enable Data Archiving: **Enable archiving** check box	Activate automated data archiving features. To specify `manual`, run `set_param(gcs, 'ExtModeArchiveMode', 'manual')`. Note that if you specify `auto`, `ExtModeAutoIncOneShot` is set to `on`.
`ExtModeArmWhenConnect` `off`, **`on`**	External Signal & Triggering: **Arm when connecting to target** check box	Arm the trigger as soon as the Simulink Coder software connects to the target.
`ExtModeAutoIncOneShot` **`off`**, `on`	Enable Data Archiving: **Increment file after one-shot** check box	Save new data buffers in incremental files.
`ExtModeAutoUpdateStatusClock` (Microsoft Windows platforms only) `off`, **`on`**	Not available	Continuously upload and display target time on the model window status bar.
`ExtModeBatchMode` **`off`**, `on`	External Mode Control Panel: **Batch download** check box	Enable or disable downloading of parameters in batch mode.

Parameter and Values	Dialog Box Equivalent	Description
`ExtModeChangesPending` **`off`**, `on`	Not available	When `ExtModeBatchMode` is enabled, indicates whether parameters remain in the queue of parameters to be downloaded to the target.
`ExtModeCommand` *`character vector`* - `armFloating`, `armWired`, `cancelFloating`, `cancelWired`	• `armFloating` and `cancelFloating` are equivalent to selecting and clearing External Mode Control Panel check box **Floating scope** > **Enable data uploading** • `armWired` and `cancelWired` are equivalent to External Mode Control Panel buttons **Arm Trigger** and **Cancel Trigger**	Issue an external mode command to the target application.
`ExtModeConnected` **`off`**, `on`	External Mode Control Panel: **Connect/Disconnect** button	Indicate the state of the connection with the target application.
`ExtModeEnableFloating` `off`, **`on`**	External Mode Control Panel: **Enable data uploading** check box	Enable or disable the arming and canceling of triggers when a connection is established with floating scopes.
`ExtModeIncDirWhenArm` **`off`**, `on`	Enable Data Archiving: **Increment directory when trigger armed** check box	Write log files to incremental folders each time the trigger is armed.
`ExtModeLogAll` `off`, **`on`**	External Signal & Triggering: **Select all** check box	Upload available signals from the target to the host.

Parameter and Values	Dialog Box Equivalent	Description
`ExtModeParamChangesPending` **`off`**, `on`	Not available	When the Simulink Coder software is connected to the target and `ExtModeBatchMode` is enabled, indicates whether parameters remain in the queue of parameters to be downloaded to the target. More efficient than `ExtModeChangesPending`, because it checks for a connection to the target.
`ExtModeSkipDownloadWhenConnect` **`off`**, `on`	Not available	Connect to the target application without downloading parameters.
`ExtModeTrigDelay` *`integer`* (**`0`**)	External Signal & Triggering: **Delay** text field	Specify the amount of time (expressed in base rate steps) that elapses between a trigger occurrence and the start of data collection.
`ExtModeTrigDirection` *`character vector`* - **`rising`**, `falling`, `either`	External Signal & Triggering: **Direction** menu	Specify the direction in which the signal must be traveling when it crosses the threshold value.
`ExtModeTrigDuration` *`integer`* (**`1000`**)	External Signal & Triggering: **Duration** text field	Specify the number of base rate steps for which external mode is to log data after a trigger event.
`ExtModeTrigDurationFloating` *`character vector`* - *`integer`* (**`auto`**)	External Mode Control Panel: **Duration** text field	Specify the duration for floating scopes. If `auto` is specified, the value of `ExtModeTrigDuration` is used.

Parameter and Values	Dialog Box Equivalent	Description
`ExtModeTrigElement` *`character vector`* - *`integer`*, **`any`**, `last`	External Signal & Triggering: **Element** text field	Specify the elements of the input port of the specified trigger block that can cause the trigger to fire.
`ExtModeTrigHoldOff` *`integer`* (**`0`**)	External Signal & Triggering: **Hold-off** text field	Specify the base rate steps between when a trigger event terminates and the trigger is rearmed.
`ExtModeTrigLevel` *`integer`* (**`0`**)	External Signal & Triggering: **Level** text field	Specify the threshold value the trigger signal must cross to fire the trigger.
`ExtModeTrigMode` *`character vector`* - **`normal`**, `oneshot`	External Signal & Triggering: **Mode** menu	Specify whether the trigger is to rearm automatically after each trigger event or whether only one buffer of data is to be collected each time the trigger is armed.
`ExtModeTrigPort` *`character vector`* - *`integer`* (**`1`**), `last`	External Signal & Triggering: **Port** text field	Specify the input port of the specified trigger block for which elements can cause the trigger to fire.
`ExtModeTrigType` *`character vector`* - **`manual`**, `signal`	External Signal & Triggering: **Source** menu	Specify whether to start logging data when the trigger is armed or when a specified trigger signal satisfies trigger conditions.
`ExtModeUploadStatus` *`character vector`* - `inactive`, `armed`, `uploading`	Not available	Return the status of the external mode upload mechanism — inactive, armed, or uploading.
`ExtModeWriteAllDataToWs` **`off`**, `on`	Enable Data Archiving: **Write intermediate results to workspace** check box	Write intermediate results to the workspace.

Animate Stateflow Charts in External Mode

If you have Stateflow, you can animate a chart in external mode. In external mode, you can animate states in a chart, and view test point signals in a floating scope or signal viewer.

Animate States During Simulation in External Mode

To animate states in a chart in external mode:

1. Load the chart you want to animate to the target machine.
2. Open the Model Configuration Parameters dialog box.
3. In the left Select pane, select **Code Generation > Interface**.
4. In the **Data exchange interface** section, select **External mode** and click **OK**.
5. In the Simulink Editor, select **Code > External Mode Control Panel**.
6. In the External Mode Control Panel dialog box, click **Signal & Triggering**.
7. In the External Signal & Triggering dialog box, set these parameters.

In:	Select:
Signal selection pane	Chart you want to animate
Trigger pane	**Arm when connecting to target** check box
Trigger pane	`normal` from drop-down menu in **Mode** field

8. Build the model to generate an executable file.
9. Start the target in the background. At the MATLAB prompt, type:

   ```
   !model_name.exe -w &
   ```

   For example, if the name of your model is `my_control_sys`, enter this command:

   ```
   !my_control_sys.exe -w &
   ```

   `-w` allows the target code to wait for the Simulink model connection.
10. In the Model Editor, select **Simulation > Mode > External**, and then select **Simulation > Connect to Target**.

11 Start simulation. The chart highlights states as they execute.

View Test Point Data in Floating Scopes and Signal Viewers

When you simulate a chart in external mode, you can designate chart data of local scope to be test points and view the test point data in floating scopes and signal viewers.

To view test point data during simulation in external mode:

1 Open the Model Explorer and for each data you want to view, follow these steps:

   a In the middle **Contents** pane, select the state or local data of interest.

   b In the right **Dialog** pane, select the **Logging** tab and select **Test point** check box.

2 From a floating scope or signal viewer, click the signal selection button:

   The Signal Selector dialog box opens.

3 In the Signal Selector **Model hierarchy** pane, select the chart.

4 In the Signal Selector **List contents** menu, select **Testpointed/Logged signals only** and then select the signals you want to view.

5 Simulate the model in external mode as described in “Animate States During Simulation in External Mode” on page 55-83.

   The scope or viewer displays the values of the test point signals as the simulation runs.

For more information, see “Behavior of Scopes and Viewers with Rapid Accelerator Mode” (Simulink).

TCP/IP and Serial External Mode Limitations

Feature	Details
Changing parameters	In general, you cannot change a parameter if doing so results in a change in the structure of the model. For example, you cannot change • The number of states, inputs, or outputs of a block • The sample time or the number of sample times • The integration algorithm for continuous systems • The name of the model or of a block • The parameters to the Fcn block If you make these changes to the block diagram, then you must rebuild the program with newly generated code. You can change parameters in transfer function and state space representation blocks in specific ways: • The parameters (numerator and denominator polynomials) for the Transfer Fcn (continuous and discrete) and Discrete Filter blocks can be changed (as long as the number of states does not change). • Zero entries in the State-Space and Zero Pole (both continuous and discrete) blocks in the user-specified or computed parameters (that is, the A, B, C, and D matrices obtained by a zero-pole to state-space transformation) cannot be changed once external simulation is started. • In the State-Space block, if you specify the matrices in the controllable canonical realization, then all changes to the A, B, C, D matrices that preserve this realization and the dimensions of the matrices are allowed. If the Simulink block diagram does not match the external program, Simulink produces an error stating that the checksums do not match. The checksums take into account the top models, but not referenced models. Use the updated block diagram to rebuild the target application.

Feature	Details
Uploading data	Uploading of data values for fixed-point or enumerated types to workspace parameters is not supported.
Uploading variable-size signals	Uploading of variable-size signals is not supported for these targets: • Simulink Real-Time • Texas Instruments™ C2000™
Signal value display in simulation	Graphical display of signal values in models (described in "Displaying Signal Values in Model Diagrams" (Simulink)) is not supported. For example, you cannot use the **Data Display in Simulation** menu selections **Show Value Labels When Hovering**, **Toggle Value Labels When Clicked**, and **Show Value Label of Selected Port**.
Tunable structure parameters	Uploading or downloading of tunable structure parameters is not supported.
Pure integer code	Pure integer code is supported. If you do not specify `-tf` *`finalTime`* in the execution command, the target application runs the generated model code indefinitely, ignoring `StopTime`. If you specify `-tf` *`finalTime`* in the execution command: • The *`finalTime`* value represents base rate clock ticks, not seconds. • The maximum value for *`finalTime`*, in ticks, is `MAX_int32_T`. • When the 16-bit or 32-bit tick counter overflows, the simulation time in Scope blocks returns to zero.
Archiving data	For archiving data to disk, Scope and To Workspace blocks are supported. However, other scopes are not supported for data archiving. For example, you cannot use Floating Scope blocks or Signal and Scope Manager viewer objects to archive data.

Feature	Details
Scopes in referenced models	In a model hierarchy, if the top model simulates in external mode and a referenced model simulates in normal or accelerator mode, scopes in the referenced model are not displayed. However, if the top model is changed to simulate in normal mode, the behavior of scopes in the referenced models differs between normal and accelerator mode. Scopes in a referenced model simulating in normal mode are displayed, while scopes in a referenced model simulating in accelerator mode are not displayed.
Simulation start time	Nonzero simulation start times are not supported. In the Configuration Parameters dialog box, **Solver** pane, leave **Start time** set to the default value of `0.0`.
File-scoped data	File-scoped data are not supported, for example, data items to which you apply the built-in custom storage class, `FileScope`. File-scoped data are not externally accessible.
Signals with custom storage classes	Uploading of signals with custom storage classes (CSC) is not supported.
Use of `printf` Statements	To show target application error and information messages on the target hardware display, you can use `printf` calls. For some target hardware, the use of `printf` statements can increase the external mode binary file size. To disable `printf` calls, specify the preprocessor macro definition `EXTMODE_DISABLEPRINTF` for your target application compiler.

Feature	Details
Command-line arguments	You can use command-line arguments for running target applications. These limitations apply: • Parsing of the command-line arguments requires the `sscanf` function, which increases the program size for some target hardware. • Some target applications do not accept command-line arguments. If your target hardware does not support the parsing of command-line arguments, specify the preprocessor macro definition `EXTMODE_DISABLE_ARGS_PROCESSING=1` for your target application compiler. To replace the `-w` option, you can use this command to specify that the target application enters and stays in a wait state until it receives a Connect message from Simulink: `set_param(`*`modelName`*`, 'OnTargetWaitForStart', 'on');` The build process provides the required option (`-DON_TARGET_WAIT_FOR_START=1`) to the compiler.
Row-major code generation	Code generated with the row-major format is not supported.

Create a Transport Layer for TCP/IP or Serial External Mode Communication

In this section...

This section helps you to connect your custom target by using external mode using your own low-level communications layer. The topics include:

- An overview of the design and operation of external mode
- A description of external mode source files
- Guidelines for modifying the external mode source files and building an executable to handle the tasks of the default `ext_comm` MEX-file

This section assumes that you are familiar with the execution of Simulink Coder programs, and with the basic operation of external mode.

Design of External Mode

External mode communication between the Simulink engine and a target system is based on a client/server architecture. The client (the Simulink engine) transmits messages requesting the server (target) to accept parameter changes or to upload signal data. The server responds by executing the request.

A low-level *transport layer* handles physical transmission of messages. Both the Simulink engine and the model code are independent of this layer. Both the transport layer and code directly interfacing to the transport layer are isolated in separate modules that format, transmit, and receive messages and data packets.

This design makes it possible for different targets to use different transport layers. The GRT, ERT, and RSim targets support host/target communication by using TCP/IP and RS-232 (serial) communication. The Simulink Desktop Real-Time target supports shared memory communication. The Wind River Systems Tornado® target supports TCP/IP only.

The Simulink Coder product provides full source code for both the client and server-side external mode modules, as used by the GRT, ERT, Rapid Simulation, and Tornado targets, and the Simulink Desktop Real-Time and Simulink Real-Time products. The main client-side module is `ext_comm.c`. The main server-side module is `ext_svr.c`.

These two modules call the specified transport layer through the following source files.

Built-In Transport Layer Implementations

Protocol	Client or Server?	Source Files
TCP/IP	Client (host)	• *matlabroot*/toolbox/coder/simulinkcoder_core/ext_mode/host/common/rtiostream_interface.c • *matlabroot*/toolbox/coder/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c
	Server (target)	• *matlabroot*/rtw/c/src/ext_mode/common/rtiostream_interface.c • *matlabroot*/toolbox/coder/rtiostream/rtiostreamtcpip/rtiostream_tcpip.c
Serial	Client (host)	• *matlabroot*/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_transport.c • *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c
	Server (target)	• *matlabroot*/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c • *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c

For serial communication, the modules `ext_serial_transport.c` and `rtiostream_serial.c` implement the client-side transport functions and the modules `ext_svr_serial_transport.c` and `rtiostream_serial.c` implement the corresponding server-side functions. For TCP/IP communication, the modules `rtiostream_interface.c` and `rtiostream_tcpip.c` implement both client-side and server-side functions. You can edit copies of these files (but do not modify the originals). You can support external mode using your own low-level communications layer by creating similar files using the following templates:

- Client (host) side: *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c (TCP/IP) or *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c (serial)
- Server (target) side: *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c (TCP/IP) or *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c (serial)

The file `rtiostream_interface.c` is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see "Communications rtiostream API" on page 78-50. Implement your `rtiostream` communications channel by using the documented interface to avoid having to make changes to the file `rtiostream_interface.c` or other external mode related files.

Note Do not modify working source files. Use the templates provided in the `/custom` or `/rtiostream` folder as starting points, guided by the comments within them.

You need only provide code that implements low-level communications. You need not be concerned with issues such as data conversions between host and target, or with the formatting of messages. The Simulink Coder software handles these functions.

On the client (Simulink engine) side, communications are handled by `ext_comm` (for TCP/IP) and `ext_serial_win32_comm` (for serial) MEX-files.

On the server (target) side, external mode modules are linked into the target executable. This takes place automatically if the **External mode** code generation option is selected at code generation time, based on the **External mode transport** option selected in the target code generation options dialog box. These modules, called from the main program and the model execution engine, are independent of the generated model code.

The general procedure for implementing your own client-side low-level transport protocol is as follows:

1. Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.
2. Generate a MEX-file executable for your custom transport.
3. Register your new transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box.

For more details, see “Create a Custom Client (Host) Transport Protocol” on page 55-98.

The general procedure for implementing your own server-side low-level transport protocol is as follows:

1. Edit the template `rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls. Typically this involves writing or integrating device drivers for your target hardware.
2. Modify template makefiles to support the new transport.

For more details, see “Create a Custom Server (Target) Transport Protocol” on page 55-101.

External Mode Communications Overview

This section gives a high-level overview of how a Simulink Coder generated program communicates with Simulink external mode. This description is based on the TCP/IP version of external mode that ships with the Simulink Coder product.

For communication to take place, both the server (target) program and the Simulink software must be executing. This does not mean that the model code in the server system must be executing. The server can be waiting for the Simulink engine to issue a command to start model execution.

The client and server communicate by using bidirectional sockets carrying packets. Packets consist either of *messages* (commands, parameter downloads, and responses) or *data* (signal uploads).

If the target application was invoked with the `-w` command-line option, the program enters a wait state until it receives a message from the host. Otherwise, the program begins execution of the model. While the target application is in a wait state, the Simulink engine can download parameters to the target and configure data uploading.

When the user chooses the **Connect to Target** option from the **Simulation** menu, the host initiates a handshake by sending an `EXT_CONNECT message`. The server responds with information about itself. This information includes

- Checksums. The host uses model checksums to determine that the target code is an exact representation of the current Simulink model.
- Data format information. The host uses this information when formatting data to be downloaded, or interpreting data that has been uploaded.

At this point, host and server are connected. The server is either executing the model or in the wait state. (In the latter case, the user can begin model execution by selecting **Start Real-Time Code** from the **Simulation** menu.)

During model execution, the message server runs as a background task. This task receives and processes messages such as parameter downloads.

Data uploading comprises both foreground execution and background servicing of the signal packets. As the target computes model outputs, it also copies signal values into data upload buffers. This occurs as part of the task associated with each task identifier (`tid`). Therefore, data collection occurs in the foreground. Transmission of the collected data, however, occurs as a background task. The background task sends the data in the collection buffers to the Simulink engine by using data packets.

The host initiates most exchanges as messages. The target usually sends a response confirming that it has received and processed the message. Examples of messages and commands are:

- Connection message / connection response
- Start target simulation / start response
- Parameter download / parameter download response
- Arm trigger for data uploading / arm trigger response
- Terminate target simulation / target shutdown response

Model execution terminates when the model reaches its final time, when the host sends a terminate command, or when a Stop Simulation block terminates execution. On termination, the server informs the host that model execution has stopped, and shuts down its socket. The host also shuts down its socket, and exits external mode.

External Mode Source Files

Client (Host) MEX-file Interface Source Files

The source files for the MEX-file interface component are located in the folder *`matlabroot`*`/toolbox/coder/simulinkcoder_core/ext_mode/host` (open), except as noted:

- `common/ext_comm.c`

  This file is the core of external mode communication. It acts as a relay station between the target and the Simulink engine. `ext_comm.c` communicates to the Simulink engine by using a shared data structure, `ExternalSim`. It communicates to the target by using calls to the transport layer.

  Tasks carried out by `ext_comm.c` include establishment of a connection with the target, downloading of parameters, and termination of the connection with the target.

- `common/rtiostream_interface.c`

  This file is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see “Communications rtiostream API” on page 78-50. Implement your `rtiostream` communications channel using the documented interface to avoid having to change the file `rtiostream_interface.c` or other external mode related files.

- *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c`

  This file implements required TCP/IP transport layer functions. The version of `rtiostream_tcpip.c` shipped with the Simulink Coder software uses TCP/IP functions including `recv()`, `send()`, and `socket()`.

- *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c`

  This file implements required serial transport layer functions. The version of `rtiostream_serial.c` shipped with the Simulink Coder software uses serial functions including `ReadFile()`, `WriteFile()`, and `CreateFile()`.

- `serial/ext_serial_transport.c`

  This file implements required serial transport layer functions. `ext_serial_transport.c` includes `ext_serial_utils.c`, which is located in *`matlabroot`*`/rtw/c/src/ext_mode/serial` (open) and contains functions common to client and server sides.

- `common/ext_main.c`

  This file is a MEX-file wrapper for external mode. `ext_main.c` interfaces to the Simulink engine by using the standard `mexFunction` call. (See the `mexFunction` reference page and “Choosing a MATLAB API for Your Application” (MATLAB) for

more information.) `ext_main.c` contains a function dispatcher, `esGetAction`, that sends requests from the Simulink engine to `ext_comm.c`.

- `common/ext_convert.c` and `ext_convert.h`

  This file contains functions used for converting data from host to target formats (and vice versa). Functions include byte-swapping (big to little- endian), conversion from non-IEEE floats to IEEE doubles, and other conversions. These functions are called both by `ext_comm.c` and directly by the Simulink engine (by using function pointers).

  Note You do not need to customize `ext_convert` to implement a custom transport layer. However, you might want to customize `ext_convert` for the intended target. For example, if the target represents the `float` data type in Texas Instruments format, `ext_convert` must be modified to perform a Texas Instruments to IEEE conversion.

- `common/extsim.h`

  This file defines the `ExternalSim` data structure and access macros. This structure is used for communication between the Simulink engine and `ext_comm.c`.

- `common/extutil.h`

  This file contains only conditionals for compilation of the `assert` macro.

- `common/ext_transport.h`

  This file defines functions that must be implemented by the transport layer.

Server (Target) Source Files

These files are linked into the *`model`*`.exe` executable. They are located within *`matlabroot`*`/rtw/c/src/ext_mode` (open) except as noted.

- `common/ext_svr.c`

  `ext_svr.c` is analogous to `ext_comm.c` on the host, but generally is responsible for more tasks. It acts as a relay station between the host and the generated code. Like `ext_comm.c`, `ext_svr.c` carries out tasks such as establishing and terminating connection with the host. `ext_svr.c` also contains the background task functions that either write downloaded parameters to the target model, or extract data from the target data buffers and send it back to the host.

- `common/rtiostream_interface.c`

This file is an interface between the external mode protocol and an `rtiostream` communications channel. For more details on implementing an `rtiostream` communications channel, see “Communications rtiostream API” on page 78-50. Implement your `rtiostream` communications channel by using the documented interface to avoid having to change the file `rtiostream_interface.c` or other external mode related files.

- *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c`

  This file implements required TCP/IP transport layer functions. The version of `rtiostream_tcpip.c` shipped with the Simulink Coder software uses TCP/IP functions including `recv()`, `send()`, and `socket()`.

- *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c`

  This file implements required serial transport layer functions. The version of rtiostream_serial.c shipped with the software uses serial functions including `ReadFile()`, `WriteFile()`, and `CreateFile()`.

- *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostream.h`

  This file defines the `rtIOStream*` functions implemented in `rtiostream_tcpip.c`.

- `serial/ext_svr_serial_transport.c`

  This file implements required serial transport layer functions. `ext_svr_serial_transport.c` includes `serial/ext_serial_utils.c`, which contains functions common to client and server sides.

- `common/updown.c`

  `updown.c` handles the details of interacting with the target model. During parameter downloads, `updown.c` does the work of installing the new parameters into the model's parameter vector. For data uploading, `updown.c` contains the functions that extract data from the model's `blockio` vector and write the data to the upload buffers. `updown.c` provides services both to `ext_svr.c` and to the model code (for example, `grt_main.c`). It contains code that is called by using the background tasks of `ext_svr.c` as well as code that is called as part of the higher priority model execution.

- *`matlabroot`*`/rtw/c/src/dt_info.h` (included by generated model build file *`model`*`.h`)

These files contain data type transition information that allows access to multi-data type structures across different computer architectures. This information is used in data conversions between host and target formats.

- `common/updown_util.h`

  This file contains only conditionals for compilation of the `assert` macro.

- `common/ext_svr_transport.h`

  This file defines the `Ext*` functions that must be implemented by the server (target) transport layer.

Other Files in the Server Folder

- `common/ext_share.h`

  Contains message code definitions and other definitions required by both the host and target modules.

- `serial/ext_serial_utils.c`

  Contains functions and data structures for communication, MEX link, and generated code required by both the host and target modules of the transport layer for serial protocols.

- The serial transport implementation includes the additional files
  - `serial/ext_serial_pkt.c` and `ext_serial_pkt.h`
  - `serial/ext_serial_port.h`

Implement a Custom Transport Layer

Requirements for Custom Transport Layers

- By default, `ext_svr.c` and `updown.c` use `malloc` to allocate buffers in target memory for messages, data collection, and other purposes, although there is also an option to preallocate static memory. If your target uses another memory allocation scheme, you must modify these modules.
- The target is assumed to support both `int32_T` and `uint32_T` data types.

Create a Custom Client (Host) Transport Protocol

To implement the client (host) side of your low-level transport protocol,

1. Edit the template file *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c` to replace low-level communication calls with your own communication calls.

   a. Copy and rename the file to `rtiostream_`*`name`*`.c` (replacing *`name`* with a name meaningful to you).

   b. Replace the functions `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamSend`, and `rtIOStreamRecv` with functions (of the same name) that call your low-level communication primitives. These functions are called from other external mode modules via `rtiostream_interface.c`. For more information, see “Communications rtiostream API” on page 78-50.

   c. Build your `rtiostream` implementation into a shared library that exports the `rtIOStreamOpen`, `rtIOStreamClose`, `rtIOStreamRecv` and `rtIOStreamSend` functions.

2. Build the customized MEX-file executable using the MATLAB `mex` function. See “MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files” on page 55-99 for examples of `mex` invocations.

   Do not replace the existing `ext_comm` MEX-file if you want to preserve its functionality. Instead, use the `-output` option to name the new executable file, for example, `my_ext_comm`. For more information, see `mex`.

3. Register your new client transport layer with the Simulink software, so that the transport can be selected for a model using the **Interface** pane of the Configuration Parameters dialog box. For details, see “Register a Custom Client (Host) Transport Protocol” on page 55-100.

Sample commands for rebuilding external mode MEX-files are listed in “MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files” on page 55-99.

MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files

The following table lists the commands for building the standard `ext_comm` and `ext_serial_win32` modules on PC and UNIX platforms.

Platform	Commands

Windows, TCP/IP	`>> cd (matlabroot)`
	`>> mex toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_comm.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_convert.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\rtiostream_interface.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_util.c ...`
	`-Irtw\c\src -Itoolbox\coder\rtiostream\src\utils ...`
	`-Irtw\c\src\ext_mode\common ...`
	`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common ...`
	`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common\include ...`
	`-lmwrtiostreamutils -lmwsl_services ...`
	`-DEXTMODE_TCPIP_TRANSPORT ...`
	`-DSL_EXT_DLL -output my_ext_comm`
	
	Note The `rtiostream_interface.c` function defines RTIOSTREAM_SHARED_LIB as `libmwrtiostreamtcpip` and dynamically loads the MathWorks TCP/IP `rtiostream` shared library. Modify this file if you need to load a different `rtiostream` shared library.

Linux, TCP/IP	Use the Windows commands, with these changes: • Change `-DSL_EXT_DLL` to `-DSL_EXT_SO`. • Replace back slashes with forward slashes.
Mac, TCP/IP	Use the Windows commands, with these changes: • Change `-DSL_EXT_DLL` to `-DSL_EXT_DYLIB`. • Replace back slashes with forward slashes.

Platform	Commands

Windows, serial	`>> cd (matlabroot)`
	`>> mex toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_comm.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_convert.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\ext_serial_transport.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\ext_serial_pkt.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\serial\rtiostream_serial_interface.c ...`
	`toolbox\coder\simulinkcoder_core\ext_mode\host\common\ext_util.c ...`
	`-Irtw\c\src -Itoolbox\coder\rtiostream\src\utils ...`
	`-Irtw\c\src\ext_mode\common ...`
	`-Irtw\c\src\ext_mode\serial ...`
	`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common ...`
	`-Itoolbox\coder\simulinkcoder_core\ext_mode\host\common\include ...`
	`-lmwrtiostreamutils -lmwsl_services ...`
	`-DEXTMODE_SERIAL_TRANSPORT -DSL_EXT_DLL ...`
	`-output my_ext_serial_comm`
	
	Note The `rtiostream_interface.c` function defines RTIOSTREAM_SHARED_LIB as `libmwrtiostreamserial` and dynamically loads the MathWorks serial `rtiostream` shared library. Modify this file if you need to load a different `rtiostream` shared library.

Linux, serial	Use the Windows commands, with these changes: • Change `-DSL_EXT_DLL` to `-DSL_EXT_SO`. • Replace back slashes with forward slashes.
Mac, serial	Use the Windows commands, with these changes: • Change `-DSL_EXT_DLL` to `-DSL_EXT_DYLIB`. • Replace back slashes with forward slashes.

Note `mex` requires a compiler supported by the MATLAB API. See the `mex` reference page and “Choosing a MATLAB API for Your Application” (MATLAB) for more information about the `mex` function.

Register a Custom Client (Host) Transport Protocol

To register a custom client transport protocol with the Simulink software, you must add an entry of the following form to an `sl_customization.m` file on the MATLAB path:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('stf.tlc', 'transport', 'mexfile', 'Level1');
% -- end of sl_customization
```

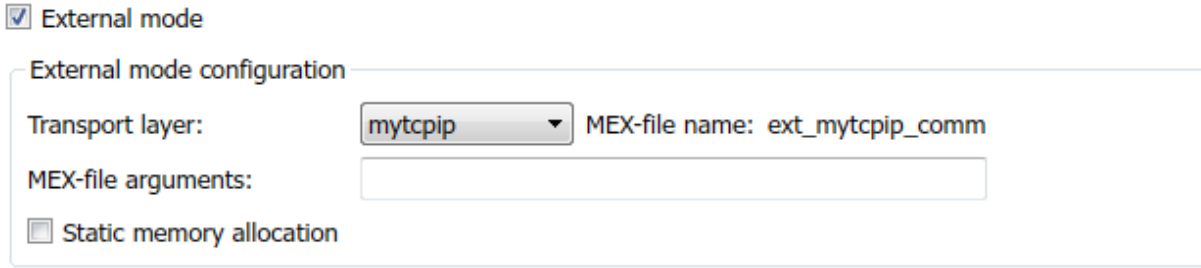
where

- *`stf`*`.tlc` is the name of the system target file for which the transport will be registered (for example, `'grt.tlc'`)
- *`transport`* is the transport name to display in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box (for example, `'mytcpip'`)
- *`mexfile`* is the name of the transport's associated external interface MEX-file (for example, `'ext_mytcpip_comm'`)

You can specify multiple targets and/or transports with additional `cm.ExtModeTransports.add` lines, for example:

```
function sl_customization(cm)
  cm.ExtModeTransports.add('grt.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
  cm.ExtModeTransports.add('ert.tlc', 'mytcpip', 'ext_mytcpip_comm', 'Level1');
% -- end of sl_customization
```

If you place the `sl_customization.m` file containing the transport registration information on the MATLAB path, your custom client transport protocol will be registered with each subsequent Simulink session. The name of the transport will appear in the **Transport layer** menu on the **Interface** pane of the Configuration Parameters dialog box. When you select the transport for your model, the name of the associated external interface MEX-file will appear in the noneditable **MEX-file name** field, as shown in the following figure.



Create a Custom Server (Target) Transport Protocol

The `rtIOStream*` function prototypes in *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostream.h` define the calling interface for both the server (target) and client (host) side transport layer functions.

- The TCP/IP implementations are in *`matlabroot`*`/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c`.

- The serial implementations are in *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c.

Note The Ext* function prototypes in *matlabroot*/rtw/c/src/ext_mode/common/ext_svr_transport.h are implemented in *matlabroot*/rtw/c/src/ext_mode/common/rtiostream_interface.c or *matlabroot*/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c. In most cases you will not need to modify rtiostream_interface.c or rtiostream_serial_interface.c for your custom TCP/IP or serial transport layer.

To implement the server (target) side of your low-level TCP/IP or serial transport protocol:

1. Edit the template *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamtcpip/rtiostream_tcpip.c or *matlabroot*/toolbox/coder/rtiostream/src/rtiostreamserial/rtiostream_serial.c to replace low-level communication calls with your own communication calls.

   a. Copy and rename the file to rtiostream_*name*.c (replacing *name* with a name meaningful to you).

   b. Replace the functions rtIOStreamOpen, rtIOStreamClose, rtIOStreamSend, and rtIOStreamRecv with functions (of the same name) that call your low-level communication drivers.

      You must implement the functions defined in rtiostream.h, and your implementations must conform to the prototypes defined in that file. Refer to the original rtiostream_tcpip.c or rtiostream_serial.c for guidance.

2. Incorporate the external mode source files for your transport layer into the model build process. Use a build process mechanism such as a post code generation command or a before_make hook function to make the transport files available to the build process. For more information on the build process mechanisms, see "Customize Post-Code-Generation Build Processing" (Simulink Coder), "Customize Build Process with STF_make_rtw_hook File" (Simulink Coder), and "Customize Build Process with sl_customization.m" (Simulink Coder).

   For example:

   - Add the file created in the previous step to the build information:

     path/rtiostream_*name*.c

- For TCP/IP, add the following file to the build information:

  matlabroot/rtw/c/src/ext_mode/common/rtiostream_interface.c

- For serial, add the following files to the build information:

  matlabroot/rtw/c/src/ext_mode/serial/ext_serial_pkt.c
  matlabroot/rtw/c/src/ext_mode/serial/rtiostream_serial_interface.c
  matlabroot/rtw/c/src/ext_mode/serial/ext_svr_serial_transport.c

Note For external mode, check that `rtIOStreamRecv` is not a blocking implementation. Otherwise, it might cause the external mode server to block until the host sends data through the `comm` layer.

Serial Receive Buffer Smaller than 64 Bytes

For serial communication, if the serial receive buffer of your target is smaller than 64 bytes:

1. Update the following macro with the actual target buffer size:

   ```
   #define TARGET_SERIAL_RECEIVE_BUFFER_SIZE 64
   ```

   Implement the change in the following files:

   matlabroot/rtw/c/src/ext_mode/serial/ext_serial_utils.c
   matlabroot/toolbox/coder/simulinkcoder_core/ext_mode/host/serial/ext_serial_utils.c

2. Run the command to rebuild the `ext_serial_win32` MEX-file. See “MATLAB Commands to Rebuild ext_comm and ext_serial_win32 MEX-Files” on page 55-99.

Logging in Simulink Coder

Log Program Execution Results

Multiple techniques are available by which a program generated by the Simulink Coder software can save data to a MAT-file for analysis. A generated executable can save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) *`model`*`.mat`, where *`model`* is the name of your model. See “Log Data for Analysis” on page 56-2 for a data logging tutorial.

Note Data logging is available only for system target files that have access to a file system. In addition, only the RSim target executables are capable of accessing MATLAB workspace data.

For MAT-file logging limitations, see the configuration parameter “MAT-file logging” (Simulink Coder).

Log Data for Analysis

Set Up and Configure Model

This example shows how data generated by a copy of the model `slexAircraftExample` is logged to the file `myAircraftExample.mat`. Refer to “Build Process Workflow for Real-Time Systems” on page 54-32 for instructions on setting up a copy of `slexAircraftExample` as`myAircraftExample` in a working folder if you have not done so already.

Note When you configure the code generator to produce code that includes support for data logging during execution, the code generator can include text for block names in the block paths included in the log file. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ｱ with the escape sequence `ア`. For more information, see “Internationalization and Code Generation” (Simulink Coder).

To configure data logging, open the Configuration Parameters dialog box and select the **Data Import/Export** pane. The process is the same as configuring a Simulink model to save output to the MATLAB workspace. For each workspace return variable you define and enable, the Simulink Coder software defines a parallel MAT-file variable. For example, if you save simulation time to the variable `tout`, your generated program logs the same data to a variable named `rt_tout`. You can change the prefix `rt_` to a suffix (`_rt`), or eliminate it entirely. You do this by setting **Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file variable name modifier**.

Simulink lets you log signal data from anywhere in a model. In the Simulink Editor, select the signals that you want to log and then in the **Simulation Data Inspector** button drop-down, select **Log Selected Signals**. However, the Simulink Coder software does not use this method of signal logging in generated code. To log signals in generated code, you must either use the **Data Import/Export** options described below or include To File or To Workspace blocks in your model.

Note If you enable MAT-file and signal logging (through the **Data Import/Export** pane) and select signals for logging (through the Simulink Editor), you see the following warning when you build the model:

```
Warning: MAT-file logging does not support signal logging.
When your model code executes, the signal logging variable 'rt_logsout' will
not be saved to the MAT-file.
```

To avoid this warning, clear the **Data Import/Export > Signal logging** check box.

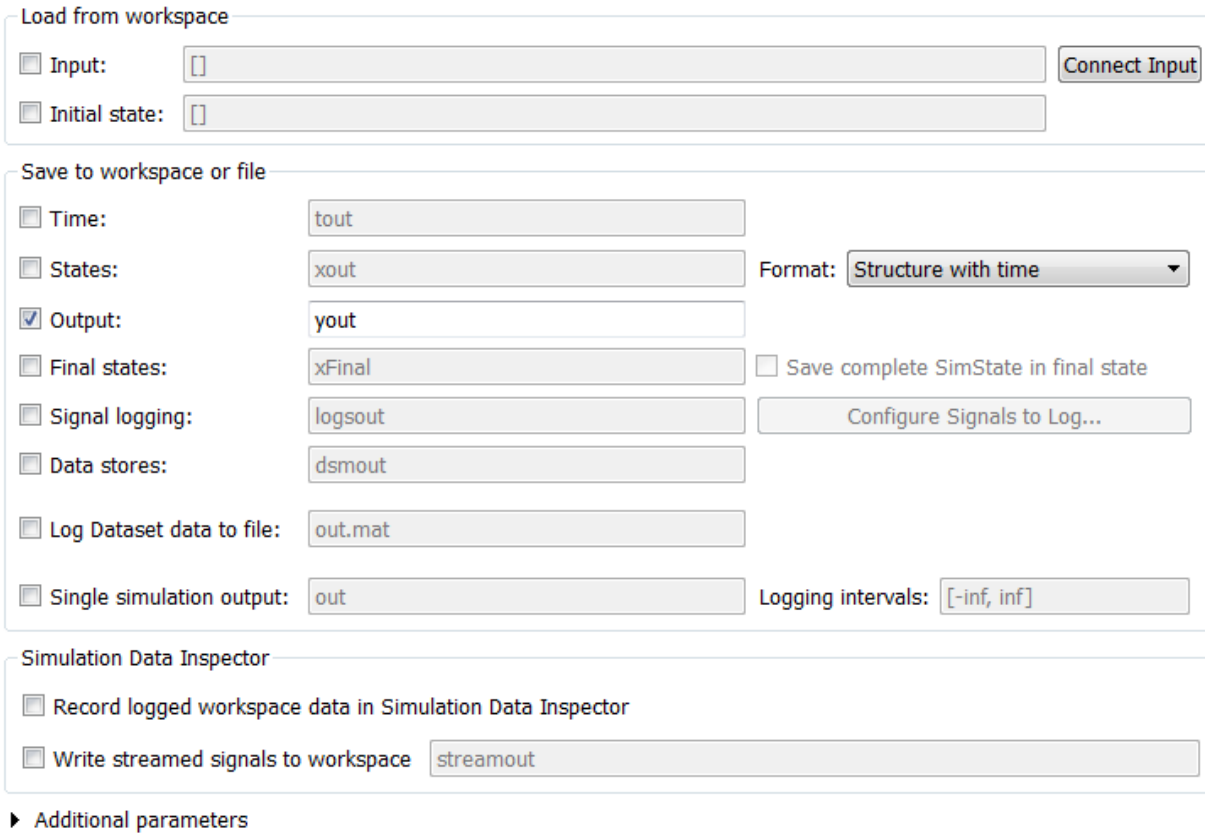
In this example, you modify the `myAircraftExample` model so that the generated program saves the simulation time and system outputs to the file `myAircraftExample.mat`. Then you load the data into the base workspace and plot simulation time against one of the outputs. The `myAircraftExample` model should be configured as described in “Build Process Workflow for Real-Time Systems” on page 54-32.

Data Logging During Simulation

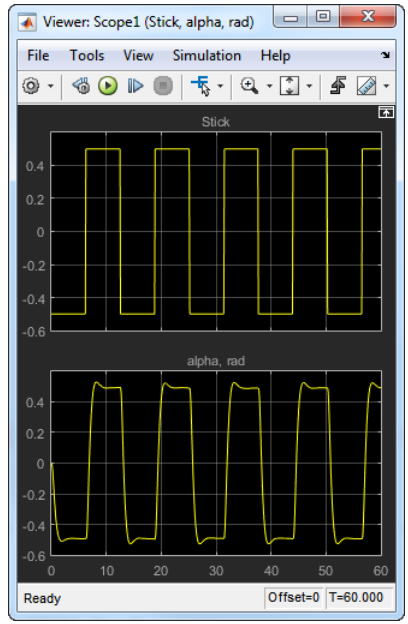
To use the data logging feature:

1. Open the `myAircraftExample` model if it is not already open.
2. Open the Configuration Parameters dialog box by selecting **Simulation > Model Configuration Parameters** from the model window.

3. Select the **Data Import/Export** pane. The **Data Import/Export** pane lets you specify which outport data is to be saved to the workspace and what variable names to use for it.
4. Set **Format** to `Structure with time`. When you select this format, Simulink saves the model states and outputs in structures that have their names specified in the **Save to workspace or file** area. By default, the structures are `xout` for states and `yout` for output. The structure used to save output has two top-level fields: `time` and `signals`. The `time` field contains a vector of simulation times and `signals` contains an array of substructures, each of which corresponds to a model output port.
5. Select the **Output** option. This tells Simulink to save output signal data during simulation as a variable named `yout`. Selecting **Output** enables the code generator to create code that logs the root Output block (`alpha, rad`) to a MAT-file.
6. Set **Decimation** to `1`.
7. If other options are enabled, clear them. The figure below shows how the dialog box should appear.



8. Click **Apply** and **OK** to register your changes and close the dialog box.
9. Save the model.
10. In the model window, double-click the scope symbol next to the Aircraft Dynamics Model block, then run the model by choosing **Simulation** > **Run** in the model window. The resulting scope display is shown below.



11 Verify that the simulation time and outputs have been saved to the base workspace in MAT-files. At the MATLAB prompt, type:

```
whos yout
```

Simulink displays:

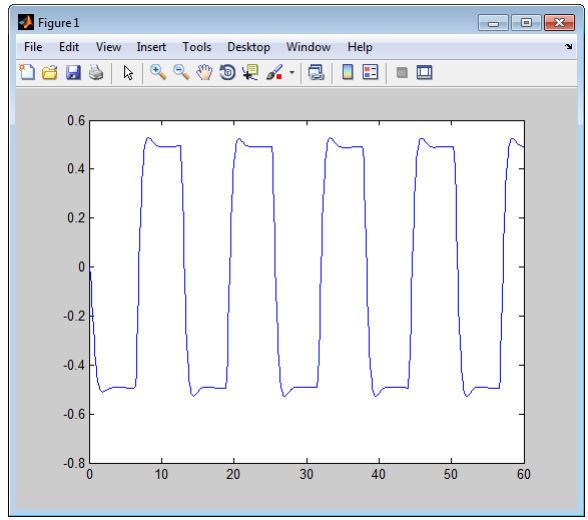
```
  Name        Size            Bytes  Class     Attributes

  yout        1x1             10756  struct
```

12 Verify that `alpha, rad` was logged by plotting simulation time versus that variable. In the Command Window, type:

```
plot(yout.time,yout.signals.values)
```

The resulting plot is shown below.



Data Logging from Generated Code

In the second part of this example, you build and run a Simulink Coder executable of the `myAircraftExample` model that outputs a MAT-file containing the simulation time and output you previously examined. Even though you have already generated code for the `myAircraftExample` model, you must now regenerate that code because you have changed the model by enabling data logging. The steps below explain this procedure.

To avoid overwriting workspace data with data from simulation runs, the code generator modifies identifiers for variables logged by Simulink. You can control these modifications.

1. Set **Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file variable name modifier** to `_rt`. This adds the suffix `_rt` to each variable that you selected to be logged in the first part of this example.
2. Click **Apply** and **OK** to register your changes and close the dialog box.
3. Save the model.
4. Build an executable.
5. When the build concludes, run the executable with the command:

   ```
   !myAircraftExample
   ```
6. The program now produces two message lines, indicating that the MAT-file has been written.

```
** starting the model **
** created myAircraftExample.mat **
```

7 Load the MAT-file data created by the executable and look at the workspace variables from simulation and the generated program by typing:

```
load myAircraftExample.mat
whos yout*
```

Simulink displays:

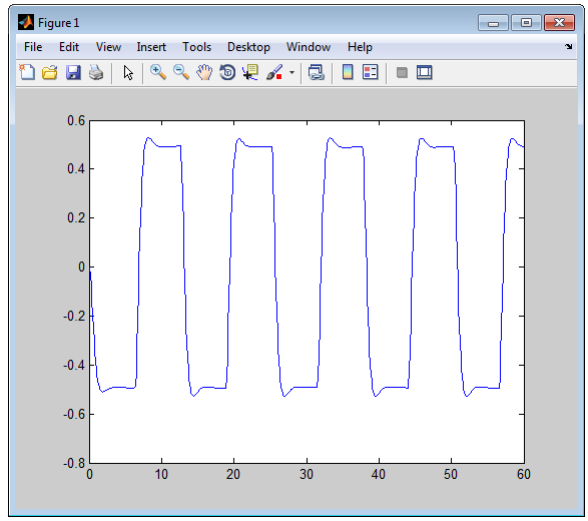
```
  Name           Size            Bytes  Class     Attributes

  yout           1x1             10756  struct
  yout_rt        1x1             10756  struct
```

Note the size and bytes of the structures resulting from the simulation run and generated code are the same.

8 Plot the generated code output by entering the following command in the Command Window:

```
plot(yout_rt.time,yout_rt.signals.values)
```



The plot should be identical to the plot that you produced in the previous part of this example.

Tip For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see "Run External Commands, Scripts, and Programs" (MATLAB).

Configure State, Time, and Output Logging

The **Data Import/Export** pane enables a generated program to save system states, outputs, and simulation time at each model execution time step. The data is written to a MAT-file, named (by default) `model.mat`.

Before using this data logging feature, you should learn how to configure a Simulink model to return output to the MATLAB workspace. This is discussed in "Export Simulation Data" (Simulink).

For each workspace return variable that you define and enable, the code generator defines a MAT-file variable. For example, if your model saves simulation time to the workspace variable `tout`, your generated program logs the same data to a variable named (by default) `rt_tout`.

The code generated by the code generator logs the following data:

- Root Outport blocks

  The default MAT-file variable name for system outputs is `rt_yout`.

  The sort order of the `rt_yout` array is based on the port number of the Outport block, starting with 1.
- Continuous and discrete states in the model

  The default MAT-file variable name for system states is `rt_xout`.
- Simulation time

  The default MAT-file variable name for simulation time is `rt_tout`.

- "Override Default MAT-File Variable Names" on page 56-9
- "Override Default MAT-File Name or Buffer Size" on page 56-10

Override Default MAT-File Variable Names

By default, the code generation software prefixes the text `rt_` to the variable names for system outputs, states, and simulation time to form MAT-file variable names. To change

this prefix for a model, select a prefix (`rt_`), a suffix (`_rt`), or no modifier (`none`) for **Configuration Parameters > Code Generation > Interface > Advanced parameters > MAT-file variable name modifier**. Other system target files might not support this parameter.

Override Default MAT-File Name or Buffer Size

You can specify compiler options to override the following MAT-file attributes in generated code:

MAT-File Attribute	Default	Compiler Option
Name	*`model`*`.mat`	`-DSAVEFILE=`*`filename`*
Size of data logging buffer	1024 bytes	`-DDEFAULT_BUFFER_SIZE=`*`n`*

Note Valid option syntax can vary among compilers. For example, Microsoft Visual C++ compilers typically accept `/DSAVEFILE=`*`filename`* as well as `-DSAVEFILE=`*`filename`*.

For a template makefile (TMF) based target, append the compiler option to the **Make command** field on the **Code Generation** pane of the Configuration Parameters dialog box. For example:

For a toolchain-based target such as GRT or ERT, add the compiler option to the **Build configuration** settings on the **Code Generation** pane of the Configuration Parameters dialog box. Set **Build configuration** to `Specify`, and add the compiler option to the **C Compiler** row of the **Tool/Options** table. For example:

To add the compiler option to a custom toolchain, you can modify and reregister the custom toolchain using the procedures shown in the example “Adding a Custom Toolchain” (MATLAB Coder). For example, to add the compiler option to the MATLAB source file for the custom toolchain, you could define `myCompilerOpts` as follows:

```
optimsOffOpts    = {'/c /Od'};
optimsOnOpts     = {'/c /O2'};
```

```
cCompilerOpts    = '$(cflags) $(CVARSFLAG) $(CFLAGS_ADDITIONAL)';
cppCompilerOpts  = '$(cflags) $(CVARSFLAG) $(CPPFLAGS_ADDITIONAL)';
myCompilerOpts   = {' -DSAVEFILE=myCodeLog.mat '};
...
```

Then you can add `myCompilerOpts` to the flags for each configuration and compiler to which it applies, for example:

```
cfg = tc.getBuildConfiguration('Faster Builds');
cfg.setOption('C Compiler', horzcat(cCompilerOpts, myCompilerOpts, optimsOffOpts));
```

As shown in “Adding a Custom Toolchain” (MATLAB Coder), after modifying the custom toolchain, you save the configuration to a MAT-file and refresh the target registry.

Log Data with Scope and To Workspace Blocks

The code generated by the code generator also logs data from these sources:

- Scope blocks that have the **Log data to workspace** parameter enabled

  You must specify the variable name and data format in each Scope block's dialog box.
- To Workspace blocks in the model

  You must specify the variable name and data format in each To Workspace block's dialog box.

The variables are written to `model.mat`, along with variables logged from the **Workspace I/O** pane.

Log Data with To File Blocks

You can also log data to a To File block. The generated program creates a separate MAT-file (distinct from `model.mat`) for each To File block in the model. The file contains the block time and input variable(s). You must specify the filename, variable names, decimation, and sample time in the To File block dialog box.

Note Models referenced by Model blocks do not perform data logging in that context except for states, which you can include in the state logged for top models. Code generated by the Simulink Coder software for referenced models does not perform data logging to MAT-files.

Data Logging Differences Between Single- and Multitasking

When logging data in single-tasking and multitasking systems, you will notice differences in the logging of

- Noncontinuous root Outport blocks
- Discrete states

In multitasking mode, the logging of states and outputs is done after the first task execution (and not at the end of the first time step). In single-tasking mode, the code generated by the build procedure logs states and outputs after the first time step.

See Data Logging in Single-Tasking and Multitasking Model Execution (Simulink Coder) for more details on the differences between single-tasking and multitasking data logging.

Note The rapid simulation target (RSim) provides enhanced logging options. See "Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File" (Simulink Coder) for more information.

Data Interchange Using the C API in Simulink Coder

Exchange Data Between Generated and External Code Using C API

Some Simulink Coder applications must interact with signals, states, root-level inputs/outputs, or parameters in the generated code for a model. For example, calibration applications monitor and modify parameters. Signal monitoring or data logging applications interface with signal, state, and root-level input/output data. Using the Simulink Coder C API, you can build target applications that log signals, states, and root-level inputs/outputs, monitor signals, states, and root-level inputs/outputs, and tune parameters, while the generated code executes.

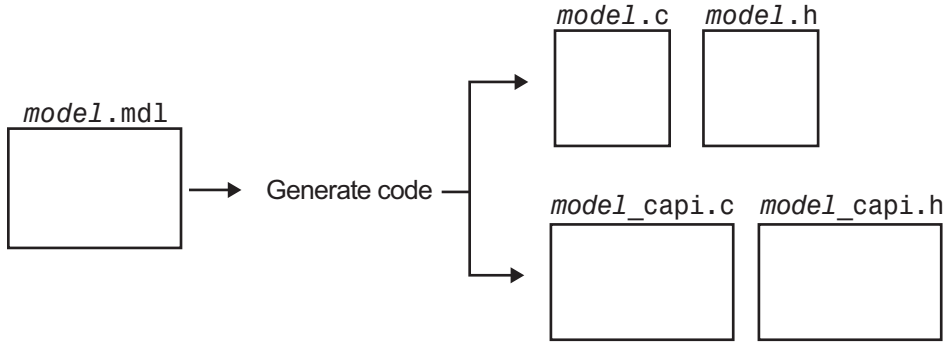
The C API minimizes its memory footprint by sharing information common to signals, states, root-level inputs/outputs, and parameters in smaller structures. Signal, state, root-level input/output, and parameter structures include an index into the structure map, allowing multiple signals, states, root-level inputs/outputs, or parameters to share data.

To get started with an example, see “Use C API to Access Model Signals and States” on page 57-24 or “Use C API to Access Model Parameters” on page 57-30.

In this section...

Generated C API Files

When you configure a model to use the C API, the Simulink Coder code generator generates two additional files, *`model`*`_capi.c` (or `.cpp`) and *`model`*`_capi.h`, where *`model`* is the name of the model. The code generator places the two C API files in the build folder, based on settings in the Configuration Parameters dialog box. The C API source code file contains information about global block output signals, states, root-level inputs/outputs, and global parameters defined in the generated code model source code. The C API header file is an interface header file between the model source code and the generated C API. You can use the information in these C API files to create your application. Among the files generated are those shown in the next figure.



Generated Files with C API Selected

Note When you configure the code generator to produce code that includes support for the C API interface and data logging, the code generator can include text for block names in the block paths logged to C API files *model*`_capi.c` (or `.cpp`) and *model*`_capi.h`. If the text includes characters that are unrepresented in the character set encoding for the model, the code generator replaces the characters with XML escape sequences. For example, the code generator replaces the Japanese full-width Katakana letter ア with the escape sequence `ア`. For more information, see "Internationalization and Code Generation" (Simulink Coder).

Generate C API Files

To generate C API files for your model:

1. Select the C API interface for your model. There are two ways to select the C API interface for your model, as described in the following sections.
   - "Select C API with Configuration Parameters Dialog" on page 57-4
   - "Select C API from the Command Line" on page 57-4
2. Generate code for your model.

After generating code, you can examine the files *model*`_capi.c` (or `.cpp`) and *model*`_capi.h` in the model build folder.

Select C API with Configuration Parameters Dialog

1. Open your model, and open the Configuration Parameters dialog box.
2. In the **Code Generation > Interface** pane, in the **Data exchange interface** subgroup, select one or more `C API` options. Based on the options you select, support for accessing signals, parameters, states, and root-level I/O will appear in the C API generated code.

   - If you want to generate C API code for global block output signals, select **Generate C API for: signals**.
   - If you want to generate C API code for global block parameters, select **Generate C API for: parameters**.
   - If you want to generate C API code for discrete and continuous states, select **Generate C API for: states**.
   - If you want to generate C API code for root-level inputs and outputs, select **Generate C API for: root-level I/O**.

Select C API from the Command Line

From the MATLAB command line, you can use the `set_param` function to select or clear the C API check boxes on the **Interface** pane of the Configuration Parameters dialog box. At the MATLAB command line, enter one or more of the following commands, where `modelname` is the name of your model.

To select **Generate C API for: signals**, enter:

```
set_param('modelname','RTWCAPISignals','on')
```

To clear **Generate C API for: signals**, enter:

```
set_param('modelname','RTWCAPISignals','off')
```

To select **Generate C API for: parameters**, enter:

```
set_param('modelname','RTWCAPIParams','on')
```

To clear **Generate C API for: parameters**, enter:

```
set_param('modelname','RTWCAPIParams','off')
```

To select **Generate C API for: states**, enter:

```
set_param('modelname','RTWCAPIStates','on')
```

To clear **Generate C API for: states**, enter:

```
set_param('modelname','RTWCAPIStates','off')
```

To select **Generate C API for: root-level I/O**, enter:

```
set_param('modelname','RTWCAPIRootIO','on')
```

To clear **Generate C API for: root-level I/O**, enter:

```
set_param('modelname','RTWCAPIRootIO','off')
```

Description of C API Files

About C API Files

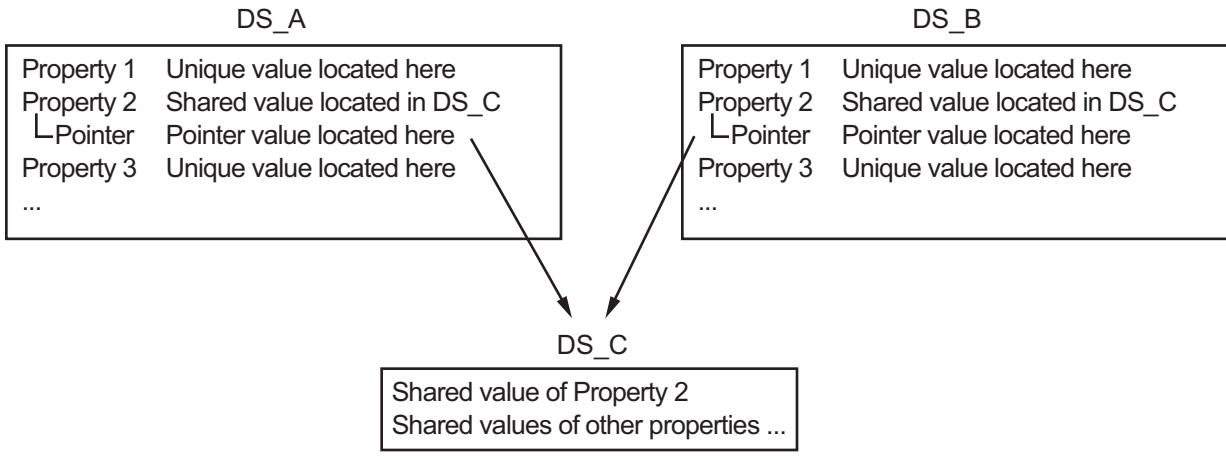
The *model*_capi.c (or .cpp) file provides external applications with a consistent interface to model data. Depending on your configuration settings, the data could be a signal, state, root-level input or output, or parameter. In this document, the term data item refers to either a signal, a state, a root-level input or output, or a parameter. The C API uses structures that provide an interface to the data item properties. The interface packages the properties of each data item in a data structure. If the model contains multiple data items, the interface generates an array of data structures. The members of a data structure map to data properties.

To interface with data items, an application requires the following properties for each data item:

- Name
- Block path

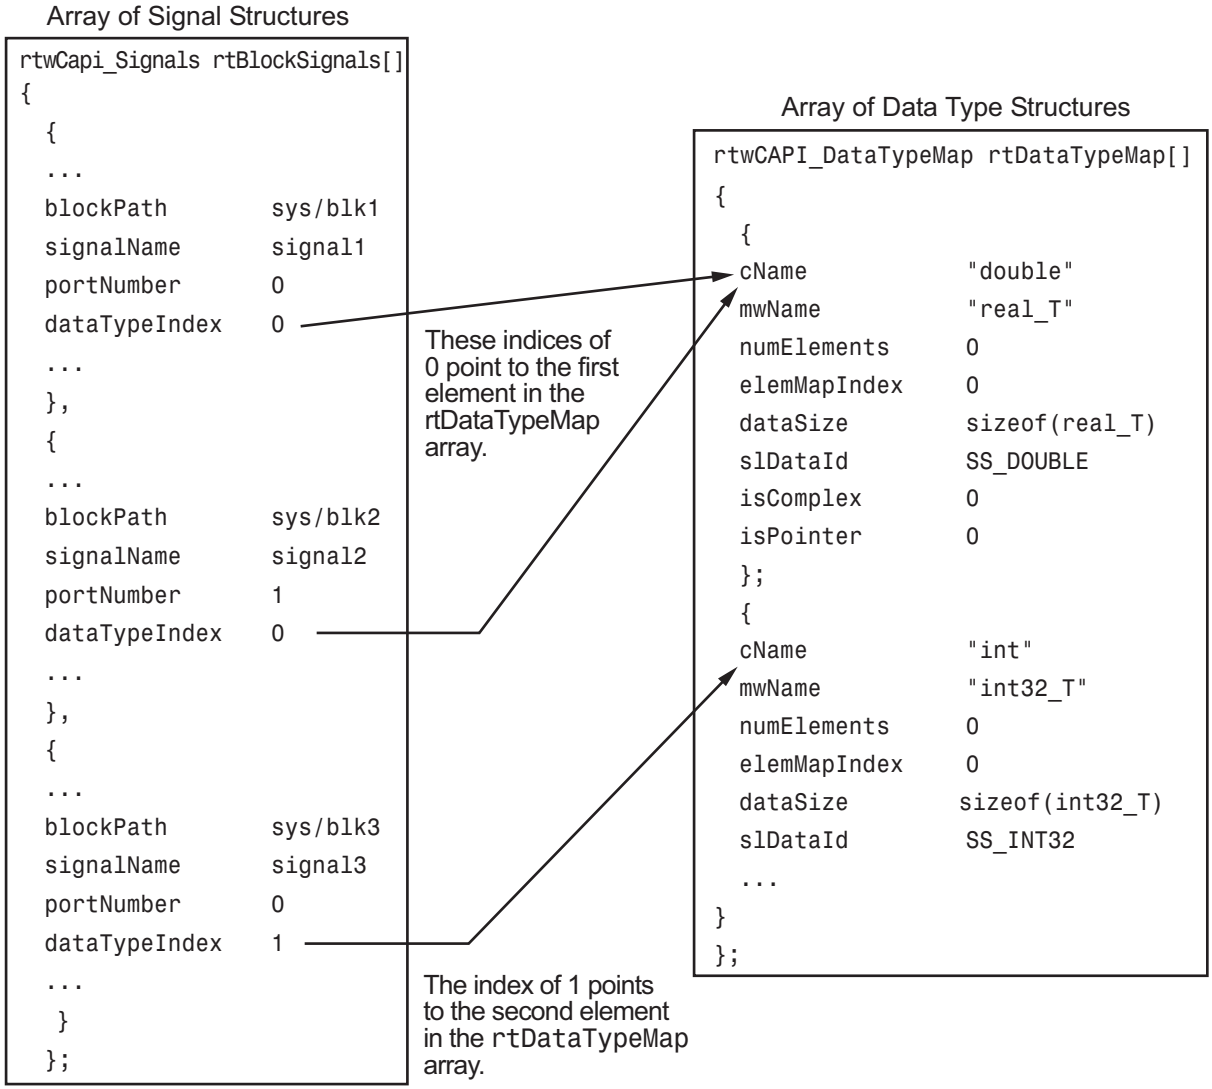
- Port number (for signals and root-level inputs/outputs only)
- Address
- Data type information: native data type, data size, complexity, and other attributes
- Dimensions information: number of rows, number of columns, and data orientation (scalar, vector, matrix, or *n*-dimensional)
- Fixed-point information: slope, bias, scale type, word length, exponent, and other attributes
- Sample-time information (for signals, states, and root-level inputs/outputs only): sample time, task identifier, frames

As illustrated in the next figure, the properties of data item A, for example, are located in data structure DS_A. The properties of data item B are located in data structure DS_B.



Some property *values* can be unique to each data item, and there are some property values that several data items can share in common. Name, for example, has a unique value for each data item. The interface places the unique property values directly in the structure for the data item. The name value of data item A is in DS_A, and the name value of data item B is in DS_B.

But data type could be a property whose value several data items have in common. The ability of some data items to share a property allows the C API to have a reuse feature. In this case, the interface places only an index value in DS_A and an index value in DS_B. These indices point to a different data structure, DS_C, that contains the actual data type value. The next figure shows this scheme with more detail.



The figure shows three signals. `signal1` and `signal2` share the same data type, `double`. Instead of specifying this data type value in each signal data structure, the interface provides only an index value, 0, in the structure. `"double"` is described by entry 0 in the `rtDataTypeMap` array, which is referenced by both signals. Additionally, property values can be shared between signals, states, root-level inputs/outputs, and

parameters, so states, root-level inputs/outputs, and parameters also might reference the `double` entry in the `rtDataTypeMap` array. This reuse of information reduces the memory size of the generated interface.

Structure Arrays Generated in C API Files

As with data type, the interface maps other common properties (such as address, dimension, fixed-point scaling, and sample time) into separate structures and provides an index in the structure for the data item. For a complete list of structure definitions, refer to the file *`matlabroot`*`/rtw/c/src/rtw_capi.h`. This file also describes each member in a structure. The structure arrays generated in the *`model`*`_capi.c` (or `.cpp`) file are of structure types defined in the `rtw_capi.h` file. Here is a brief description of the structure arrays generated in *`model`*`_capi.c` (or `.cpp`):

- **`rtBlockSignals`** is an array of structures that contains information about global block output signals in the model. Each element in the array is of type `struct rtwCAPI_Signals`. The members of this structure provide the signal name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **`rtBlockParameters`** is an array of structures that contains information about the tunable block parameters in the model by block name and parameter name. Each element in the array is of type `struct rtwCAPI_BlockParameters`. The members of this structure provide the parameter name, block path, address, and indices to data type, dimension, and fixed-point structure arrays.
- **`rtBlockStates`** is an array of structures that contains information about discrete and continuous states in the model. Each element in the array is of type `struct rtwCAPI_States`. The members of this structure provide the state name, block path, type (continuous or discrete), and indices to the address, data type, dimension, fixed-point, and sample-time structure arrays.
- **`rtRootInputs`** is an array of structures that contains information about root-level inputs in the model. Each element in the array is of type `struct rtwCAPI_Signals`. The members of this structure provide the root-level input name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.
- **`rtRootOutputs`** is an array of structures that contains information about root-level outputs in the model. Each element in the array is of type `struct rtwCAPI_Signals`. The members of this structure provide the root-level output name, block path, block port number, address, and indices to the data type, dimension, fixed-point, and sample-time structure arrays.

- **`rtModelParameters`** is an array of structures that contains information about workplace variables that one or more blocks or Stateflow charts in the model reference as block parameters. Each element in the array is of data type `rtwCAPI_ModelParameters`. The members of this structure provide the variable name, address, and indices to data type, dimension, and fixed-point structure arrays.
- **`rtDataAddrMap`** is an array of base addresses of signals, states, root-level inputs/outputs, and parameters that appear in the `rtBlockSignals`, `rtBlockParameters`, `rtBlockStates`, and `rtModelParameters` arrays. Each element of the `rtDataAddrMap` array is a pointer to `void (void*)`.
- **`rtDataTypeMap`** is an array of structures that contains information about the various data types in the model. Each element of this array is of type `struct rtwCAPI_DataTypeMap`. The members of this structure provide the data type name, size of the data type, and information on whether or not the data is complex.
- **`rtDimensionMap`** is an array of structures that contains information about the various data dimensions in the model. Each element of this array is of type `struct rtwCAPI_DimensionMap`. The members of this structure provide information on the number of dimensions in the data, the orientation of the data (whether it is scalar, vector, or a matrix), and the actual dimensions of the data.
- **`rtFixPtMap`** is an array of structures that contains fixed-point information about the signals, states, root-level inputs/outputs, and parameters. Each element of this array is of type `struct rtwCAPI_FixPtMap`. The members of this structure provide information about the data scaling, bias, exponent, and whether or not the fixed-point data is signed. If the model does not have fixed-point data (signal, state, root-level input/output, or parameter), the Simulink Coder software assigns `NULL` or zero values to the elements of the `rtFixPtMap` array.
- **`rtSampleTimeMap`** is an array of structures that contains sampling information about the global signals, states, and root-level inputs/outputs in the model. (This array does not contain information about parameters.) Each element of this array is of type `struct rtwCAPI_SampleTimeMap`. The members of this structure provide information about the sample period, offset, and whether or not the data is frame-based or sample-based.

Generate Example C API Files

Subtopics “C API Signals” on page 57-11, “C API States” on page 57-14, “C API Root-Level Inputs and Outputs” on page 57-15, and “C API Parameters” on page 57-16 discuss generated C API structures using the example model `rtwdemo_capi`. To generate code from the example model, do the following:

1. Open the model by clicking the `rtwdemo_capi` link above or by typing `rtwdemo_capi` on the MATLAB command line.
2. If you want to generate C API structures for root-level inputs/outputs in `rtwdemo_capi`, open the Configuration Parameters dialog box, go to the **Code Generation** > **Interface** pane, and select **Generate C API for: root-level I/O**.

   Note The setting of **Generate C API for: root-level I/O** must match between the top model and the referenced model. If you modify the option, save the top model and the referenced model to the same writable work folder.
3. Generate code for the model by double-clicking **Generate Code Using Simulink Coder**.

Note The C API code examples in the next subtopics are generated with C as the target language.

This model has three global block output signals that will appear in C API generated code:

- `top_sig1`, which is a test point at the output of the Gain1 block in the top model
- `sig2_eg`, which appears in the top model and is defined in the base workspace as a `Simulink.Signal` object having storage class `ExportedGlobal`
- `bot_sig1`, which appears in the referenced model `rtwdemo_capi_bot` and is defined as a `Simulink.Signal` object having storage class `Model default`

The model also has two discrete states that will appear in the C API generated code:

- `top_state`, which is defined for the Delay1 block in the top model
- `bot_state`, which is defined for the Discrete Filter block in the referenced model

The model has root-level inputs/outputs that will appear in the C API generated code if you select the option **Generate C API for: root-level I/O**:

- Four root-level inputs, `In1` through `In4`
- Six root-level outputs, `Out1` through `Out6`

Additionally, the model has five global block parameters that will appear in C API generated code:

- `Kp` (top model `Gain1` block and referenced model `Gain2` block share)
- `Ki` (referenced model `Gain3` block)
- `p1` (lookup table `lu1d`)
- `p2` (lookup table `lu2d`)
- `p3` (lookup table `lu3d`)

C API Signals

The `rtwCAPI_Signals` structure captures signal information including the signal name, address, block path, output port number, data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API signals for the top model in `rtwdemo_capi`:

```
/* Block output signal information */
static const rtwCAPI_Signals rtBlockSignals[] = {
  /* addrMapIndex, sysNum, blockPath,
   * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
   */
  { 0, 0, "rtwdemo_capi/Gain1",
    "top_sig1", 0, 0, 0, 0, 0 },

  { 1, 0, "rtwdemo_capi/lu2d",
    "sig2_eg", 0, 0, 1, 0, 0 },

  {
    0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
  }
};
```

Note To better understand the code, read the comments in the file. For example, notice the comment that begins on the third line in the preceding code. This comment lists the members of the `rtwCAPI_Signals` structure, in order. This tells you the order in which the assigned values for each member appear for a signal. In this example, the comment tells you that `signalName` is the fourth member of the structure. The following lines describe the first signal:

```
  { 0, 0, "rtwdemo_capi/Gain1",
    "top_sig1", 0, 0, 0, 0, 0 },
```

From these lines you infer that the name of the first signal is `top_sig1`.

Each array element, except the last, describes one output port for a block signal. The final array element is a sentinel, with all elements set to null values. For example, examine the second signal, described by the following code:

```
  { 1, 0, "rtwdemo_capi/lu2d",
    "sig2_eg", 0, 0, 1, 0, 0 },
```

This signal, named `sig2_eg`, is the output signal of the first port of the block `rtwdemo_capi/lu2d`. (This port is the first port because the zero-based index for `portNumber` displayed on the second line is assigned the value `0`.)

The address of this signal is given by `addrMapIndex`, which, in this example, is displayed on the first line as `1`. This provides an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`:

```
/* Declare Data Addresses statically */
static void* rtDataAddrMap[] = {
  &rtwdemo_capi_B.top_sig1,            /* 0: Signal */
  &sig2_eg[0],                         /* 1: Signal */
  &rtwdemo_capi_DWork.top_state,       /* 2: Discrete State */
  &rtP_Ki,                             /* 3: Model Parameter */
  &rtP_Kp,                             /* 4: Model Parameter */
  &rtP_p1[0],                          /* 5: Model Parameter */
  &rtP_p2[0],                          /* 6: Model Parameter */
  &rtP_p3[0],                          /* 7: Model Parameter */
};
```

The index of `1` points to the second element in the `rtDataAddrMap` array. From the `rtDataAddrMap` array, you can infer that the address of this signal is `&sig2_eg[0]`.

This level of indirection supports multiple code instances of the same model. For multiple instances, the signal information remains constant, except for the address. In this case, the model is a single instance. Therefore, the `rtDataAddrMap` is declared statically. If you choose to generate reusable code, an initialize function is generated that initializes the addresses dynamically per instance. For details on generating reusable code, see "Configure Code Generation for Model Entry-Point Functions" (Simulink Coder) and see "Configure Code Reuse Support" on page 44-15.

The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the signal:

```
/* Data Type Map - use dataTypeMapIndex to access this structure */
static const rtwCAPI_DataTypeMap rtDataTypeMap[] = {
  /* cName, mwName, numElements, elemMapIndex, dataSize, slDataId, *
   * isComplex, isPointer */
  { "double", "real_T", 0, 0, sizeof(real_T), SS_DOUBLE, 0, 0 }
};
```

Because the index is `0` for `sig2_eg`, the index points to the first structure element in the array. You can infer that the data type of the signal is `double`. The value of `isComplex` is `0`, indicating that the signal is not complex. Rather than providing the data type information directly in the `rtwCAPI_Signals` structure, a level of indirection is introduced. The indirection allows multiple signals that share the same data type to point to one map structure, saving memory for each signal.

The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`, indicating the dimensions of the signal. Because this index is `1` for `sig2_eg`, the index points to the second element in the `rtDimensionMap` array:

```
/* Dimension Map - use dimensionMapIndex to access elements of ths structure*/
static const rtwCAPI_DimensionMap rtDimensionMap[] = {
  /* dataOrientation, dimArrayIndex, numDims, vardimsIndex */
  { rtwCAPI_SCALAR, 0, 2, 0 },

  { rtwCAPI_VECTOR, 2, 2, 0 },
...
};
```

From this structure, you can infer that this is a nonscalar signal having a dimension of `2`. The `dimArrayIndex` value, 2, provides an index into `rtDimensionArray`, found later in `rtwdemo_capi_capi.c`:

```
/* Dimension Array- use dimArrayIndex to access elements of this array */
static const uint_T rtDimensionArray[] = {
  1,                                   /* 0 */
  1,                                   /* 1 */
  2,                                   /* 2 */
...
};
```

The `fxpIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the signal. Your code can use the scaling information to compute the real-world value of the signal, using the equation `V=SQ+B`, where V is “real-world” (that is, base-10) value, S is user-specified slope, Q is “quantized fixed-point value” or “stored integer,” and B is user-specified bias. For details, see “Scaling” (Fixed-Point Designer).

Because this index is `0` for `sig2_eg`, the signal does not have fixed-point information. A fixed-point map index of zero means that the signal does not have fixed-point information.

The `sTimeIndex` (sample-time index) provides the index to the `rtSampleTimeMap` array, found later in `rtwdemo_capi_capi.c`, indicating task information about the signal. If you log multirate signals or conditionally executed signals, the sampling information can be useful.

Note *model*_capi.c (or .cpp) includes rtw_capi.h. A source file that references the rtBlockSignals array also must include rtw_capi.h.

C API States

The rtwCAPI_States structure captures state information including the state name, address, block path, type (continuous or discrete), data type information, dimensions information, fixed-point information, and sample-time information.

Here is the section of code in rtwdemo_capi_capi.c that provides information on C API states for the top model in rtwdemo_capi:

```
/* Block states information */
static const rtwCAPI_States rtBlockStates[] = {
  /* addrMapIndex, contStateStartIndex, blockPath,
   * stateName, pathAlias, dWorkIndex, dataTypeIndex, dimIndex,
   * fixPtIdx, sTimeIndex, isContinuous
   */
  { 2, -1, "rtwdemo_capi/Delay1",
    "top_state", "", 0, 0, 0, 0, 0, 0 },

  {
    0, -1, (NULL), (NULL), (NULL), 0, 0, 0, 0, 0, 0
  }
};
```

Each array element, except the last, describes a state in the model. The final array element is a sentinel, with all elements set to null values. In this example, the C API code for the top model displays one state:

```
  { 2, -1, "rtwdemo_capi/Delay1",
    "top_state", "", 0, 0, 0, 0, 0, 0 },
```

This state, named top_state, is defined for the block rtwdemo_capi/Delay1. The value of isContinuous is zero, indicating that the state is discrete rather than continuous. The other fields correspond to the like-named signal equivalents described in “C API Signals” on page 57-11, as follows:

- The address of the signal is given by addrMapIndex, which, in this example, is 2. This is an index into the rtDataAddrMap array, found later in rtwdemo_capi_capi.c. Because the index is zero based, 2 corresponds to the third element in rtDataAddrMap, which is &rtwdemo_capi_DWork.top_state.
- The dataTypeIndex provides an index into the rtDataTypeMap array, found later in rtwdemo_capi_capi.c, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.

- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 0 corresponds to the first entry, which is `{ rtwCAPI_SCALAR, 0, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

C API Root-Level Inputs and Outputs

The `rtwCAPI_Signals` structure captures root-level input/output information including the input/output name, address, block path, port number, data type information, dimensions information, fixed-point information, and sample-time information. (This structure also is used for block output signals, as previously described in “C API Signals” on page 57-11.)

Here is the section of code in `rtwdemo_capi_capi.c` that provides information on C API root-level inputs/outputs for the top model in `rtwdemo_capi`:

```
/* Root Inputs information */
static const rtwCAPI_Signals rtRootInputs[] = {
  /* addrMapIndex, sysNum, blockPath,
   * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
   */
  { 3, 0, "rtwdemo_capi/In1",
    "", 1, 0, 0, 0, 0 },

  { 4, 0, "rtwdemo_capi/In2",
    "", 2, 0, 0, 0, 0 },

  { 5, 0, "rtwdemo_capi/In3",
    "", 3, 0, 0, 0, 0 },

  { 6, 0, "rtwdemo_capi/In4",
    "", 4, 0, 0, 0, 0 },

  {
    0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
  }
};

/* Root Outputs information */
static const rtwCAPI_Signals rtRootOutputs[] = {
  /* addrMapIndex, sysNum, blockPath,
   * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
   */
  { 7, 0, "rtwdemo_capi/Out1",
    "", 1, 0, 0, 0, 0 },
```

```
  { 8, 0, "rtwdemo_capi/Out2",
    "", 2, 0, 0, 0, 0 },

  { 9, 0, "rtwdemo_capi/Out3",
    "", 3, 0, 0, 0, 0 },

  { 10, 0, "rtwdemo_capi/Out4",
    "", 4, 0, 0, 0, 0 },

  { 11, 0, "rtwdemo_capi/Out5",
    "sig2_eg", 5, 0, 1, 0, 0 },

  { 12, 0, "rtwdemo_capi/Out6",
    "", 6, 0, 1, 0, 0 },

  {
    0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
  }
};
```

For information about interpreting the values in the `rtwCAPI_Signals` structure, see the previous section “C API Signals” on page 57-11.

C API Parameters

The `rtwCAPI_BlockParameters` and `rtwCAPI_ModelParameters` structures capture parameter information including the parameter name, block path (for block parameters), address, data type information, dimensions information, and fixed-point information.

The `rtModelParameters` array contains entries for workspace variables that are referenced as tunable Simulink block parameters or Stateflow data of machine scope. For example, tunable parameters include `Simulink.Parameter` objects that use a storage class other than `Auto`. The Simulink Coder software assigns its elements only `NULL` or zero values in the absence of such data.

The setting that you select for the model configuration parameter **Default parameter behavior** determines how information is generated into the `rtBlockParameters` array in *`model`*`_capi.c` (or `.cpp`).

- If you set **Default parameter behavior** to `Tunable`, the `rtBlockParameters` array contains an entry for every modifiable parameter of every block in the model. However, if you use a MATLAB variable or a tunable parameter to specify a block parameter, the block parameter does not appear in `rtBlockParameters`. Instead, the variable or tunable parameter appears in `rtModelParameters`.
- If you set **Default parameter behavior** to `Inlined`, the `rtBlockParameters` array is empty. The Simulink Coder software assigns its elements only `NULL` or zero values.

The last member of each array is a sentinel, with all elements set to null values.

Here is the `rtBlockParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```
/* Individual block tuning is not valid when inline parameters is *
 * selected. An empty map is produced to provide a consistent     *
 * interface independent  of inlining parameters.                 *
 */
static const rtwCAPI_BlockParameters rtBlockParameters[] = {
  /* addrMapIndex, blockPath,
   * paramName, dataTypeIndex, dimIndex, fixPtIdx
   */
  {
    0, (NULL), (NULL), 0, 0, 0
  }
};
```

In this example, only the final, sentinel array element is generated, with all members of the structure `rtwCAPI_BlockParameters` set to `NULL` and zero values. This is because **Default parameter behavior** is set to `Inlined` by default for the `rtwdemo_capi` example model. If you set **Default parameter behavior** to `Tunable`, the block parameters are generated in the `rtwCAPI_BlockParameters` structure. However, MATLAB variables and tunable parameters appear in the `rtwCAPI_ModelParameters` structure.

Here is the `rtModelParameters` array that is generated by default in `rtwdemo_capi_capi.c`:

```
/* Tunable variable parameters */
static const rtwCAPI_ModelParameters rtModelParameters[] = {
  /* addrMapIndex, varName, dataTypeIndex, dimIndex, fixPtIndex */
  { 2, TARGET_STRING("Ki"), 0, 0, 0 },

  { 3, TARGET_STRING("Kp"), 0, 0, 0 },

  { 4, TARGET_STRING("p1"), 0, 2, 0 },

  { 5, TARGET_STRING("p2"), 0, 3, 0 },

  { 6, TARGET_STRING("p3"), 0, 4, 0 },

  { 0, (NULL), 0, 0, 0 }
};
```

In this example, the `rtModelParameters` array contains entries for each variable that is referenced as a tunable Simulink block parameter.

For example, the `varName` (variable name) of the fourth parameter is `p2`. The other fields correspond to the like-named signal equivalents described in “C API Signals” on page 57-11, as follows:

- The address of the fourth parameter is given by `addrMapIndex`, which, in this example, is `5`. This is an index into the `rtDataAddrMap` array, found later in `rtwdemo_capi_capi.c`. Because the index is zero based, `5` corresponds to the sixth element in `rtDataAddrMap`, which is `rtP_p2`.
- The `dataTypeIndex` provides an index into the `rtDataTypeMap` array, found later in `rtwdemo_capi_capi.c`, indicating the data type of the parameter. The value 0 corresponds to a double, noncomplex parameter.
- The `dimIndex` (dimensions index) provides an index into the `rtDimensionMap` array, found later in `rtwdemo_capi_capi.c`. The value 3 corresponds to the fourth entry, which is `{ rtwCAPI_MATRIX_COL_MAJOR, 6, 2, 0 }`.
- The `fixPtIndex` (fixed-point index) provides an index into the `rtFixPtMap` array, found later in `rtwdemo_capi_capi.c`, indicating fixed-point information about the parameter. As with the corresponding signal attribute, a fixed-point map index of zero means that the parameter does not have fixed-point information.

For more information about tunable parameter storage in the generated code, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50.

Map C API Data Structures to rtModel

The real-time model data structure encapsulates model data and associated information that describes the model fully. When you select the C API feature and generate code, the Simulink Coder code generator adds another member to the real-time model data structure generated in *`model`*`.h`:

```
/*
 * DataMapInfo:
 * The following substructure contains information regarding
 * structures generated in the model's C API.
 */
struct {
  rtwCAPI_ModelMappingInfo mmi;
} DataMapInfo;
```

This member defines `mmi` (for model mapping information) of type `struct rtwCAPI_ModelMappingInfo`. The structure is located in *`matlabroot`*`/rtw/c/src/rtw_modelmap.h`. The `mmi` substructure defines the interface between the model and the

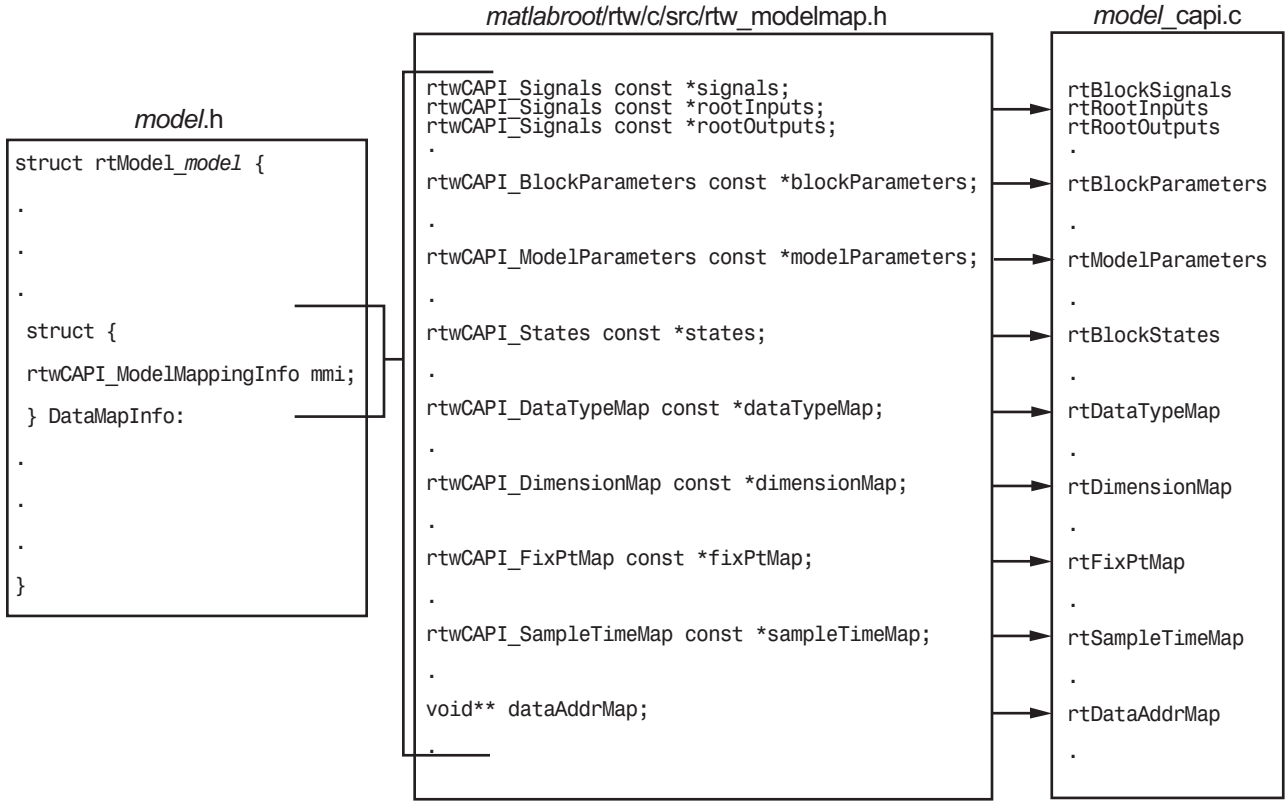
C API files. More specifically, members of `mmi` map the real-time model data structure to the structures in *`model`*`_capi.c` (or `.cpp`).

Initializing values of `mmi` members to the arrays accomplishes the mapping, as shown in “Map Model to C API Arrays of Structures” on page 57-20. Each member points to one of the arrays of structures in the generated C API file. For example, the address of the `rtBlockSignals` array of structures is allocated to the first member of the `mmi` substructure in *`model`*`.c` (or `.cpp`), using the following code in the `rtw_modelmap.h` file:

```
/* signals */
struct {
    rtwCAPI_Signals const *signals;     /* Signals Array */
    uint_T                numSignals;   /* Num Signals   */
    rtwCAPI_Signals const *rootInputs;  /* Root Inputs array */
    uint_T               numRootInputs; /* Num Root Inputs  */
    rtwCAPI_Signals const *rootOutputs; /* Root Outputs array */
    uint_T               numRootOutputs;/* Num Root Outputs  */
} Signals;
```

The model initialize function in *`model`*`.c` (or `.cpp`) performs the initializing by calling the C API initialize function. For example, the following code is generated in the model initialize function for example model `rtwdemo_capi`:

```
/* Initialize DataMapInfo substructure containing ModelMap for C API */
rtwdemo_capi_InitializeDataMapInfo(rtwdemo_capi_M);
```



Map Model to C API Arrays of Structures

Note This figure lists the arrays in the order that their structures appear in `rtw_modelmap.h`, which differs slightly from their generated order in *`model`*`_capi.c`.

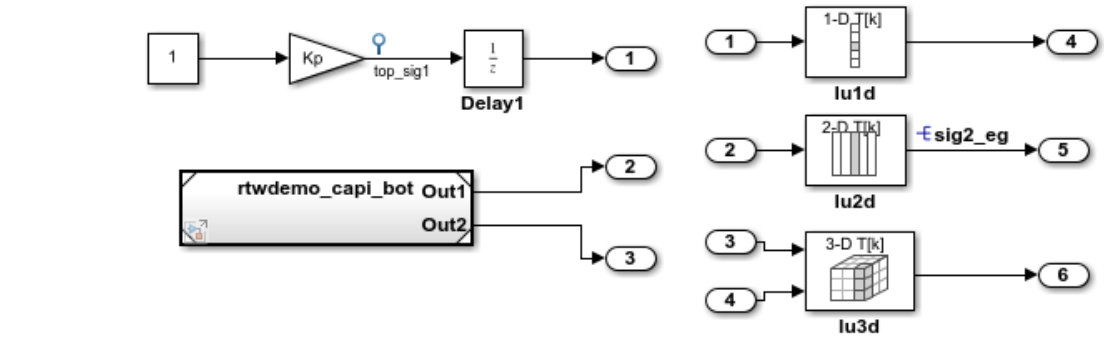
Generate C API Data Definition File for Exchanging Data with a Target System

This model illustrates the target-based C API for interfacing signals, parameters, and states in the generated code.

Open Example Model

Open the example model `rtwdemo_capi`.

```
open_system('rtwdemo_capi');
```



The C API is useful for real-time interaction with application data, without having to stop execution or recompile the generated code. Typically, a client/server protocol is set up from a host to a target using serial, TCP/IP, or dual-port memory connection. The purpose

of this example is not the client/server protocol. Rather, this model shows the necessary data interface required by the C client/server programs.

You enable the C API by selecting one or more C API options on the **Code Generation > Interface** pane of the Configuration Parameters dialog box. Any signal or parameter or state with an addressable storage class is placed in the C API data structure in *model*`_capi.c`. Note that signals, states, and parameters in the referenced model can be accessed using C API. So make sure that C API is enabled for the referenced model.

C API Limitations

The C API feature has the following limitations.

- The C API does not support the following values for the `CodeFormat` TLC variable:
  - `S-Function`
  - `Accelerator_S-Function` (for accelerated simulation)
- For ERT-based targets, the C API requires that support for floating-point code be enabled.
- Local block output signals are not supported.
- Local Stateflow parameters are not supported.
- The following custom storage class objects are not supported:
  - Objects without the package `csc_registration` file
  - Grouped custom storage classes
  - Objects defined by using macros
  - `BitField` objects
  - `FileScope` objects
- Customized data placement is disabled when you are using the C API. The interface looks for global data declaration in *model*`.h` and *model*`_private.h`. Declarations placed in any other file by customized data placement result in code that does not compile.

Note Custom Storage Class objects work in code generation, only if you use the ERT system target file and clear the model configuration parameter **Ignore custom storage classes**.

Use C API to Access Model Signals and States

This example helps you get started writing application code to interact with model signals and states. To get started writing application code to interact with model parameters, see “Use C API to Access Model Parameters” on page 57-30.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with the Simulink Coder generated code into an executable. The target-based application code accesses the C API structure arrays in *model*_capi.c (or .cpp). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files rtw_modelmap.h and rtw_capi.h, located in *matlabroot*/rtw/c/src (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that logs global signals and states in a model to a text file. This code is intended as a starting point for accessing signal and state addresses. You can extend the code to perform signal logging and monitoring, state logging and monitoring, or both.

This example uses the following macro and function interfaces:

- rtmGetDataMapInfo macro

  Accesses the model mapping information (MMI) substructure of the real-time model structure. In the following macro call, rtM is the pointer to the real-time model structure in *model*.c (or .cpp):

  ```
  rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
  ```

- rtmGetTPtr macro

  Accesses the absolute time information for the base rate from the timing substructure of the real-time model structure. In the following macro call, rtM is the pointer to the real-time model structure in *model*.c (or .cpp):

  ```
  rtmGetTPtr(rtM)
  ```

- Custom functions capi_StartLogging, capi_UpdateLogging, and capi_TerminateLogging, provided via the files rtwdemo_capi_datalog.h and rtwdemo_capi_datalog.c. These files are located in *matlabroot*/toolbox/rtw/rtwdemos (open).

- `capi_StartLogging` initializes signal and state logging.
- `capi_UpdateLogging` logs a signal and state value at each time step.
- `capi_TerminateLogging` terminates signal and state logging and writes the logged values to a text file.

You can integrate these custom functions into generated model code using one or more of the following methods:

- **Code Generation > Custom Code** pane of the Configuration Parameters dialog box
- Custom Code library blocks
- TLC custom code functions

This tutorial uses the **Code Generation > Custom Code** pane and the System Outputs block from the Custom Code library to insert calls to the custom functions into *`model`*`.c` (or `.cpp`), as follows:

- `capi_StartLogging` is called in the *`model`*`_initialize` function.
- `capi_UpdateLogging` is called in the *`model`*`_step` function.
- `capi_TerminateLogging` is called in the *`model`*`_terminate` function.

The following excerpts of generated code from *`model`*`.c` (rearranged to reflect their order of execution) show how the function interfaces are used.

```
void rtwdemo_capi_initialize(void)
{
...
  /* user code (Initialize function Body) */

  /* C API Custom Logging Function: Start Signal and State logging via C API.
   * capi_StartLogging: Function prototype in rtwdemo_capi_datalog.h
   */
  {
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
    printf("** Started state/signal logging via C API **\n");
    capi_StartLogging(MMI, MAX_DATA_POINTS);
  }
...
}
...
/* Model step function */
void rtwdemo_capi_step(void)
{
...
  /* user code (Output function Trailer) */

  /* System '<Root>' */
```

```
  /* C API Custom Logging Function: Update Signal and State logging buffers.
   * capi_UpdateLogging: Function prototype in rtwdemo_capi_datalog.h
   */
  {
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
    capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
  }
...
}
...
/* Model terminate function */
void rtwdemo_capi_terminate(void)
{
  /* user code (Terminate function Body) */

  /* C API Custom Logging Function: Dump Signal and State buffers into a text file.
   * capi_TerminateLogging: Function prototype in rtwdemo_capi_datalog.h
   */
  {
    capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
    printf("** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
  }
}
```

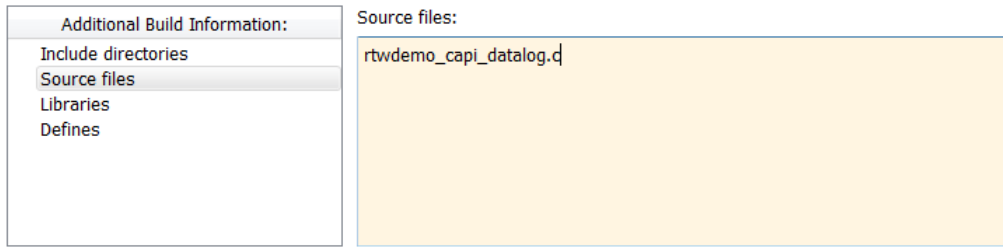
The following procedure illustrates how you can use the C API macro and function interfaces to log global signals and states in a model to a text file.

1. At the MATLAB command line, enter `rtwdemo_capi` to open the example model.
2. Save the top model `rtwdemo_capi` and the referenced model `rtwdemo_capi_bot` to the same writable work folder.
3. Open the Configuration Parameters dialog box.
4. If you are licensed for Embedded Coder software and you want to use the `ert.tlc` system target file instead of the default `grt.tlc`, go to the **Code Generation** pane and use the **System target file** parameter to select an `ert.tlc` system target tile. Make sure that you also select `ert.tlc` for the referenced model `rtwdemo_capi_bot`.
5. In the top model, go to the **Code Generation** > **Interface** pane. Confirm these model configuration parameter settings:
    a. Select **Generate C API for signals**, **Generate C API for states**, and **Generate C API for parameters**.
    b. If you are using the `ert.tlc` system target file, select **Support complex numbers**
    c. Select **MAT-file logging**.
    d. Click **Apply**.
    e. Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.

6 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane, and then click **Include directories**. The **Include directories** input field is displayed.

7 In the **Include directories** field, type *`matlabroot`*`/toolbox/rtw/rtwdemos`, where *`matlabroot`* represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)

8 In the **Additional Build Information** subpane, click **Source files**, and type `rtwdemo_capi_datalog.c`.



9 In the **Include custom C code in generated** subpane, click **Source file**, and type or copy and paste the following include statement:

```
#include "rtwdemo_capi_datalog.h"
```

10 In the **Initialize function** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Start Signal and State logging via C API.
 * capi_StartLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
  rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
  printf("** Started state/signal logging via C API **\n");
  capi_StartLogging(MMI, MAX_DATA_POINTS);
}
```

Note If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

11 In the **Terminate function** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Dump Signal and State buffers into a text file.
 * capi_TerminateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
```

```
capi_TerminateLogging("rtwdemo_capi_ModelLog.txt");
printf("** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **\n");
  }
```

Click **Apply**.

12 In the MATLAB Command Window, enter `custcode` to open the Simulink Coder Custom Code library. At the top level of the `rtwdemo_capi` model, add a System Outputs block.

13 Double-click the System Outputs block to open the System Outputs Function Custom Code dialog box. In the **System Outputs Function Exit Code** field, type or copy and paste the following application code:

```
/* C API Custom Logging Function: Update Signal and State logging buffers.
 * capi_UpdateLogging: Function prototype in rtwdemo_capi_datalog.h
 */
{
  rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);
  capi_UpdateLogging(MMI, rtmGetTPtr(rtwdemo_capi_M));
}
```

Note If you renamed the top model `rtwdemo_capi`, update two instances of the name `rtwdemo_capi_M` in the application code to reflect the new model name.

Click **OK**.

14 On the **Code Generation** pane, verify that the **Generate code only** check box is *cleared*.

Build the model and generate an executable program. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

15 In the MATLAB Command Window, enter the command `!rtwdemo_capi` to run the executable file. During execution, signals and states are logged using the C API and then written to the text file `rtwdemo_capi_ModelLog.txt` in your current working folder.

```
>> !rtwdemo_capi

** starting the model **
** Started state/signal logging via C API **
** Logging 2 signal(s) and 1 state(s). In this demo, only scalar named
 signals/states are logged **
** Finished state/signal logging. Created rtwdemo_capi_ModelLog.txt **
```

16 Examine the text file in the MATLAB editor or other text editor. Here is an excerpt of the signal and state logging output.

```
******** Signal Log File ********

Number of Signals Logged: 2
Number of points (time steps) logged: 51

Time           bot_sig1 (Referenced Model)            top_sig1

Use C API to Access Model Parameters

This example helps you get started writing application code to interact with model parameters. To get started writing application code to interact with model signals and states, see “Use C API to Access Model Signals and States” on page 57-24.

The C API provides you with the flexibility of writing your own application code to interact with model signals, states, root-level inputs/outputs, and parameters. Your target-based application code is compiled with generated code into an executable program. The target-based application code accesses the C API structure arrays in *`model`*`_capi.c` (or `.cpp`). You might have host-based code that interacts with your target-based application code. Or, you might have other target-based code that interacts with your target-based application code. The files `rtw_modelmap.h` and `rtw_capi.h`, located in *`matlabroot`*`/rtw/c/src` (open), provide macros for accessing the structures in these arrays and their members.

Here is an example application that prints the parameter values of tunable parameters in a model to the standard output. This code is intended as a starting point for accessing parameter addresses. You can extend the code to perform parameter tuning. The application:

- Uses the `rtmGetDataMapInfo` macro to access the mapping information in the `mmi` substructure of the real-time model structure

  ```
  rtwCAPI_ModelMappingInfo* mmi = &(rtmGetDataMapInfo(rtM).mmi);
  ```

  where `rtM` is the pointer to the real-time model structure in *`model`*`.c` (or `.cpp`).
- Uses `rtwCAPI_GetNumModelParameters` to get the number of model parameters in mapped C API:

  ```
  uint_T nModelParams = rtwCAPI_GetNumModelParameters(mmi);
  ```
- Uses `rtwCAPI_GetModelParameters` to access the array of model parameter structures mapped in C API:

  ```
  rtwCAPI_ModelParameters* capiModelParams = \
   rtwCAPI_GetModelParameters(mmi);
  ```
- Loops over the `capiModelParams` array to access individual parameter structures. A call to the function `capi_PrintModelParameter` displays the value of the parameter.

The example application code is provided below:

```
{
/* Get CAPI Mapping structure from Real-Time Model structure */
rtwCAPI_ModelMappingInfo* capiMap = \
&(rtmGetDataMapInfo(rtwdemo_capi_M).mmi);

/* Get number of Model Parameters from capiMap */
uint_T nModelParams = rtwCAPI_GetNumModelParameters(capiMap);
printf("Number of Model Parameters: %d\n", nModelParams);

/* If the model has Model Parameters, print them using the
application capi_PrintModelParameter */
if (nModelParams == 0) {
   printf("No Tunable Model Parameters in the model \n");
}
else {
   unsigned int idx;

   for (idx=0; idx < nModelParams; idx++) {
      /* call print utility function */
      capi_PrintModelParameter(capiMap, idx);
   }
}
}
```

The print utility function is located in *matlabroot*`/rtw/c/src/rtw_capi_examples.c`. This file contains utility functions for accessing the C API structures.

To become familiar with the example code, try building a model that displays the tunable block parameters and MATLAB variables. You can use `rtwdemo_capi`, the C API example model. The following steps apply to both `grt.tlc` and `ert.tlc` system target files, unless otherwise indicated.

1. At the MATLAB command line, enter `rtwdemo_capi` to open the example model.
2. Save the top model `rtwdemo_capi` and the referenced model `rtwdemo_capi_bot` to the same writable work folder.
3. If you are licensed for Embedded Coder software and you want to use the `ert.tlc` system target tile instead of the default `grt.tlc`, go to the **Code Generation** pane of the Configuration Parameters dialog box and use the **System target file** parameter to select an `ert.tlc` system target file. Make sure that you also select `ert.tlc` for the referenced model `rtwdemo_capi_bot`.
4. Confirm these model configuration parameter settings:

a Select **Generate C API for parameters**.

b If you are using the `ert.tlc` system target file, select **Support complex numbers**.

c Select **MAT-file logging**.

d Click **Apply**.

e Update configuration parameter settings in the referenced model, `rtwdemo_capi_bot`, to match changes you made in the top model.

5 Use the **Custom Code** pane to embed your custom application code in the generated code. Select the **Custom Code** pane, and then click **Initialize function**. The **Initialize function** input field is displayed.

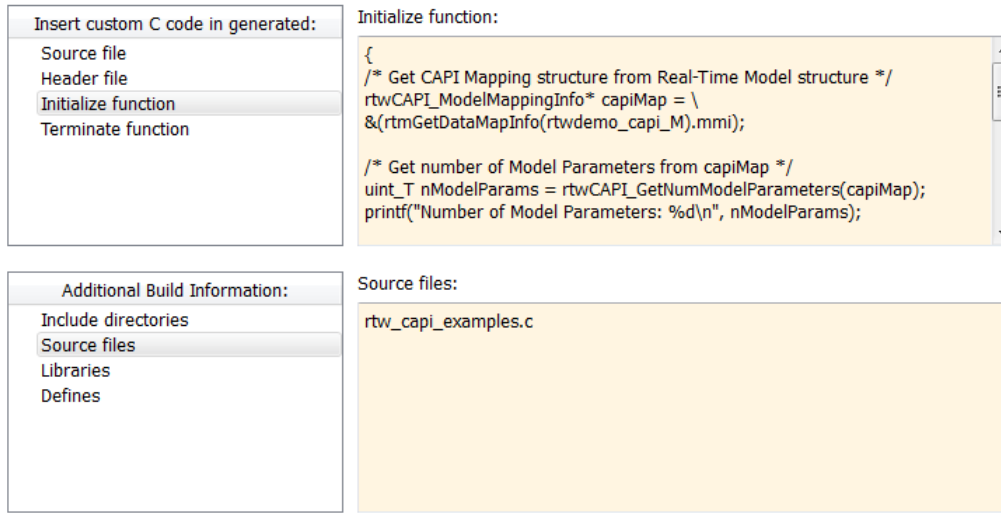
6 In the **Initialize function** input field, type or copy and paste the example application code shown above step 1. This embeds the application code in the *`model`*`_initialize` function.

Note If you renamed the top model `rtwdemo_capi`, update the name `rtwdemo_capi_M` in the application code to reflect the new model name.

---

7 Click **Include directories**, and type *`matlabroot`*`/rtw/c/src`, where *`matlabroot`* represents the root of your MATLAB installation folder. (If you are specifying a Windows path that contains a space, place the text inside double quotes.)

8 In the **Additional Build Information** subpane, click **Source files**, and type `rtw_capi_examples.c`.



Click **Apply**.

9 On the **Code Generation** pane, verify that the **Generate code only** check box is *cleared*.

Build the model and generate an executable program. For example, on a Windows system, the build generates the executable file `rtwdemo_capi.exe` in your current working folder.

10 In the MATLAB Command Window, enter `!rtwdemo_capi` to run the executable file. Running the program displays parameter information in the Command Window.

```
>> !rtwdemo_capi

** starting the model **
Number of Model Parameters: 5
Ki =
     7
Kp =
     4
p1 =
    0.15
    0.36
    0.81
p2 =
    0.09    0.75    0.57
```

```
    0.13    0.96    0.059
p3 =
ans(:,:,1) =
    0.23    0.82    0.04    0.64
    0.35    0.01    0.16    0.73

ans(:,:,2) =
    0.64    0.54    0.74    0.68
    0.45    0.29    0.18    0.18
```

ASAP2 Data Measurement and Calibration in Simulink Coder

Export ASAP2 File for Data Measurement and Calibration

The ASAM MCD-2 MC standard, also known as ASAP2, is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM). ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostic systems. For more information on ASAM and the ASAM MCD-2 MC (ASAP2) standard, see the ASAM Web site at `https://www.asam.net`.

The code generator lets you export an ASAP2 file containing information about your model during the code generation process.

You can run an interactive example of ASAP2 file generation. To open the example at the MATLAB command prompt, enter the following command:

```
rtwdemo_asap2
```

Note Simulink Coder support for ASAP2 file generation is version-neutral. By default, the software generates ASAP2 version 1.31 format, but the generated model information is generally compatible with all ASAP2 versions. ASAP2 file generation also is neutral with respect to the specific needs of ASAP2 measurement and calibration tools. The software provides customization APIs that you can use to customize ASAP2 file generation to generate an ASAP2 version and to meet the specific needs of your ASAP2 tools.

In this section...

What You Should Know

To make use of ASAP2 file generation, you should become familiar with the following topics:

- ASAM and the ASAP2 standard and terminology. See the ASAM Web site at `https://www.asam.net`.
- Simulink data objects. Data objects are used to supply information not contained in the model. For an overview, see "Data Objects" (Simulink).
- Storage and representation of signals and parameters in generated code. See "Data Access for Prototyping and Debugging" (Simulink Coder).
- If you are licensed for Embedded Coder, see also the Embedded Coder topic "Data Representation and Access".

Targets Supporting ASAP2

ASAP2 file generation is available to all code generator system target file configurations. For example,

- `Generic Real-Time Target` (`grt.tlc`) lets you generate an ASAP2 file as part of the code generation and build process.
- `Embedded Coder` (`ert.tlc`) system target file selections also let you generate an ASAP2 file as part of the code generation and build process.
- `ASAM-ASAP2 Data Definition Target` (`asap2.tlc`) lets you generate only an ASAP2 file, without building an executable program.

Procedures for generating ASAP2 files by using these target configurations are given in "Generate an ASAP2 File" on page 58-9.

Define ASAP2 Information

Define ASAP2 Information for Parameters and Signals

The ASAP2 file generation process requires information about parameters and signals in your model. Some of this information is contained in the model itself. You must supply the rest by using Simulink data objects in a workspace or data dictionary. In some cases, the use of workspace objects is optional.

You can use the Model Data Editor and built-in Simulink data objects to provide the information. For example, you can use `Simulink.Signal` objects to provide MEASUREMENT information and `Simulink.Parameter` objects to provide CHARACTERISTIC information. Also, you can use data objects from data classes that are derived from `Simulink.Signal` and `Simulink.Parameter` to provide the information. For information about data objects, see “Data Objects” (Simulink). For information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” (Simulink).

The following table contains the minimum set of data attributes required for ASAP2 file generation. Some data attributes are defined in the model; others are supplied in the properties of objects. For attributes that are defined in `Simulink.Signal` or `Simulink.Parameter` objects, the table gives the associated property name.

Data Attribute	Defined In	Property Name
Name (symbol)	Model and data object	Inherited from the handle of the data object to which parameter or signal name resolves
Description	Data object	`Description`
Data type	Model or data object	`DataType`
Scaling (if fixed-point data type)	Model or data object	`DataType`
Minimum allowable value	Model or data object	`Min`
Maximum allowable value	Model or data object	`Max`
Unit	Model or data object	`Unit`
Memory address (optional)	Model or data object	`MemoryAddress_ASAP2` (optional; see “Memory Address Attribute” on page 58-5.)

Memory Address Attribute

If the memory address attribute is unknown before code generation, the code generator inserts `ECU Address` placeholder text in the generated ASAP2 file. You can substitute an actual address for the placeholder by postprocessing the generated file. See the file *`matlabroot`*`/toolbox/rtw/targets/asap2/asap2/asap2post.m` for an example. `asap2post.m` parses through the linker map file that you provide and replaces the `ECU Address` placeholders in the ASAP2 file with the actual memory addresses. Since linker map files vary from compiler to compiler, you might need to modify the regular expression code in `asap2post.m` to match the format of the linker map you use.

Note If Embedded Coder is licensed and installed on your system, and if you are generating Executable and Linkable Format (ELF) or Program Database (PDB) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate ECU address replacement. For more information, see "Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)" on page 58-6.

If the memory address attribute is known before code generation, it can be defined in the data item or data object. By default, the `MemoryAddress_ASAP2` property does not exist in the `Simulink.Signal` or `Simulink.Parameter` data object classes. If you want to add the attribute, add a property called `MemoryAddress_ASAP2` to a custom class that is a subclass of the `Simulink` or `ASAP2` class. For information on subclassing Simulink data classes, see "Define Data Classes" (Simulink).

Note In previous releases, for ASAP2 file generation, you had to define objects explicitly as `ASAP2.Signal` and `ASAP2.Parameter`. This is no longer a limitation. As explained above, you can use built-in Simulink objects for generating an ASAP2 file. If you have been using an earlier release, you can continue to use the ASAP2 objects. If one of these ASAP2 objects was created in the previous release, and you use it in this release, the MATLAB Command Window displays a warning the first time the objects are loaded.

The following table indicates the Simulink object properties that have replaced the ASAP2 object properties of the previous release:

Differences Between ASAP2 and Simulink Parameter and Signal Object Properties

ASAP2 Object Properties (Previous)	Simulink Object Properties (Current)
LONGID_ASAP2	Description
PhysicalMin_ASAP2	Min
PhysicalMax_ASAP2	Max
Units_ASAP2	Unit

Automatic ECU Address Replacement for ASAP2 Files (Embedded Coder)

If Embedded Coder is licensed and installed on your system, and if you are generating Executable and Linkable Format (ELF) or Program Database (PDB) files for your embedded target, you can use the `rtw.asap2SetAddress` function to automate the replacement of `ECU Address` placeholder memory address values with actual addresses in the generated ASAP2 file.

If the memory address attribute is unknown before code generation, the code generator inserts `ECU Address` placeholder text in the generated ASAP2 file, as shown in the example below.

```
/begin CHARACTERISTIC
  /* Name            */ Ki
  /* Long Identifier */ ""
  /* Type            */ VALUE
  /* ECU Address     */ 0x0000 /* @ECU_Address@Ki@ */
```

To substitute actual addresses for the `ECU Address` placeholders, process the generated ASAP2 file using the `rtw.asap2SetAddress` function. The general syntax is as follows:

```
rtw.asap2SetAddress(ASAP2File,InfoFile)
```

The arguments are character vectors specifying the name of the generated ASAP2 file and the name of the generated executable ELF file, PDB file from Microsoft toolchain, or DWARF debug information files for the model. When called, `rtw.asap2SetAddress` extracts the actual ECU address from the specified ELF, PDB, or DWARF file and replaces the placeholder in the ASAP2 file with the actual address, for example:

```
/begin CHARACTERISTIC
  /* Name            */ Ki
  /* Long Identifier */ ""
```

```
/* Type            */ VALUE
/* ECU Address     */ 0x40009E60
```

Define ASAP2 Information for Lookup Tables

Simulink Coder software generates ASAP2 descriptions for lookup table data and its breakpoints. The software represents 1-D table data as `CURVE` information, 2-D table data as `MAP` information, and breakpoints as `AXIS_DESCR` and `AXIS_PTS` information. You can model lookup tables using one of the following Simulink Lookup Table blocks:

- Direct Lookup Table (n-D) — 1 and 2 dimensions
- Interpolation Using Prelookup — 1 and 2 dimensions
- 1–D Lookup Table
- 2–D Lookup Table
- n-D Lookup Table — 1 and 2 dimensions

The software supports the following types of lookup table breakpoints (axis points):

Breakpoint Type	Generates
Tunable and shared among multiple table axes (common axis)	`COM_AXIS`
Fixed and nontunable (fixed axis)	One of these variants of `FIX_AXIS`: • `FIX_AXIS_PAR` if breakpoints are integers with equidistant spacing and the equidistant spacing is a power of two • `FIX_AXIS_PAR_DIST` if breakpoints are integers with equidistant spacing • `FIX_AXIS_PAR_LIST` if breakpoints are integers with non-equidistant spacing
Tunable but not shared among multiple tables (standard axis)	`STD_AXIS`

When you configure the blocks for ASAP2 code generation:

- For table data, use a `Simulink.Parameter` data object with a non-`Auto` storage class.

- For tunable breakpoint data that is shared among multiple table axes (`COM_AXIS`), use a `Simulink.Parameter` data object with a non-`Auto` storage class.
- For fixed, nontunable breakpoint data (`FIX_AXIS`), use workspace variables or arrays specified in the block parameters dialog box. The breakpoints should be stored as integers in the code, so the data type should be a built-in integer type (`int8`, `int16`, `int32`, `uint8`, `uint16`, or `uint32`), a fixed-point data type, or an equivalent alias type.
- For tunable breakpoint data that is not shared among multiple tables (STD_AXIS):

  1. Create a `Simulink.Bus` object to define the `struct` packaging (names and order of the fields). The fields of the parameter structure must correspond to the lookup table data and each axis of the lookup table block. For example, in an n-D Lookup Table block with 2 dimensions, the structure must contain only three fields. This bus object describes the record layout for the lookup characteristic.
  2. Create a `Simulink.Parameter` object to represent a tunable parameter.
  3. Create table and axis values.
  4. Optionally, specify the **Units**, **Minimum**, and **Maximum** properties for the parameter object. The properties will be applied to table data only.

Here is an example of an n-D Lookup Table record generated into an ASAP2 file in Standard Axis format:

```
/begin CHARACTERISTIC
  /* Name */  STDAxisParam
  ...
  /* Record Layout */   Lookup1D_X_WORD_Y_FLOAT32_IEEE
  ...
  begin AXIS_DESCR
    /* Description of X-Axis Points */
    /* Axis Type */      STD_AXIS
    ...
  /end AXIS_DESCR
/end CHARACTERISTIC

/begin RECORD_LAYOUT Lookup1D_X_WORD_Y_FLOAT32_IEEE
  AXIS_PTS_X 1 WORD INDEX_INCR DIRECT
  FNC_VALUES 2 FLOAT32_IEEE COLUMN_DIR DIRECT
/end   RECORD_LAYOUT
```

Note The example model `rtwdemo_asap2` illustrates ASAP2 file generation for Lookup Table blocks, including both tunable (COM_AXIS) and fixed (FIX_AXIS) lookup table breakpoints.

Generate an ASAP2 File

About Generating ASAP2 Files

You can generate an ASAP2 file from your model in one of the following ways:

- Use the Generic Real-Time Target or a Embedded Coder target to generate an ASAP2 file as part of the code generation and build process.
- Use the ASAM-ASAP2 Data Definition Target to generate only an ASAP2 file, without building an executable.

This section discusses how to generate an ASAP2 file by using the targets that have built-in ASAP2 support. For an example, see the ASAP2 example model `rtwdemo_asap2`.

Use GRT or ERT System Target File

The procedure for generating the ASAP2 data definition for a model using the Generic Real-Time Target or Embedded Coder system target file is as follows:

1. Use the Model Data Editor (**View > Model Data Editor**) to apply storage classes to signals, block states, and block parameters as described in "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" on page 32-81. Use signal and state names to refer to corresponding MEASUREMENT records and parameter object names to refer to CHARACTERISTIC records.

   Use a storage class or custom storage class other than `Auto`, `FileScope`, or, if you set the default storage class of the corresponding data category to `Default` in the Code Mapping Editor (the default setting), `Model default`. For example, using `ExportedGlobal` configures the data item as an unstructured global variable in the generated code.

Note The data item is not represented in the ASAP2 file if one or more of the following conditions exist:

- You apply one of the storage classes `Auto`, `FileScope`, or `Default` (through `Model default`).
- You apply a custom storage class that causes the code generator to generate a macro or non-addressable variable.

2. Use the Model Data Editor to configure the remaining properties as desired for each data item.
3. On the **Code Generation** pane, click **Browse** to open the System Target File Browser. In the browser, select `grt.tlc` or an ERT based target file and click **OK**.
4. On the **Code Generation > Interface** pane, in the **Data exchange interface** subgroup, select **ASAP2 interface**.
5. Select the **Generate code only** check box on the **Code Generation** pane.
6. Click **Apply**.
7. Build the model.

   The code generator writes the ASAP2 file to the build folder. By default, the file is named *`model`*`.a2l`, where *`model`* is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see “Customize Generated ASAP2 File” on page 83-2.

Use the ASAM-ASAP2 Data Definition Target

The procedure for generating the ASAP2 data definition for a model using the ASAM-ASAP2 Data Definition Target is as follows:

1. Use the Model Data Editor (**View > Model Data Editor**) to apply storage classes to signals, block states, and block parameters as described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81. Use signal and state names to refer to corresponding MEASUREMENT records and parameter object names to refer to CHARACTERISTIC records.

   Use a storage class or custom storage class other than `Auto`, `FileScope`, or, if you set the default storage class of the corresponding data category to `Default` in the Code Mapping Editor (the default setting), `Model default`. For example, using `ExportedGlobal` configures the data item as an unstructured global variable in the generated code.

Note The data item is not represented in the ASAP2 file if one or more of the following conditions exist:

- You apply one of the storage classes `Auto`, `FileScope`, or `Default` (through `Model default`).
- You apply a custom storage class that causes the code generator to generate a macro or non-addressable variable.

2. Use the Model Data Editor to configure the remaining properties as desired for each data item.
3. On the **Code Generation** pane, click **Browse** to open the System Target File Browser. In the browser, select `asap2.tlc` and click **OK**.
4. Select the **Generate code only** check box on the **Code Generation** pane.
5. Click **Apply**.
6. Build the model.

   The Simulink Coder code generator writes the ASAP2 file to the build folder. By default, the file is named *`model`*`.a2l`, where *`model`* is the name of the model. The ASAP2 setup file controls the ASAP2 file name. For details, see “Customize Generated ASAP2 File” on page 83-2.

Generate ASAP2 Files for Referenced Models

The build process can generate an ASAP2 file for each referenced model in a model reference hierarchy. In the generated ASAP2 file, MEASUREMENT records represent signals and states inside the referenced model.

To generate ASAP2 files for referenced models, select ASAP2 file generation for the top model and for each referenced model in the reference hierarchy. For example, if you are using the Generic Real-Time Target or an Embedded Coder target, follow the procedure described in “Use GRT or ERT System Target File” on page 58-9 for the top model and each referenced model.

Merge ASAP2 Files for Top and Referenced Models

Use function `rtw.asap2MergeMdlRefs` to merge the ASAP2 files generated for top and referenced models. The function has the following syntax:

```
[status,info] = rtw.asap2MergeMdlRefs(topModelName,asap2FileName)
```

- `topModelName` is the name of the model containing one or more referenced models.
- `asap2FileName` is the name you specify for the merged ASAP2 file.
- *Optional:*: `status` returns false (logical 0) if the merge completes and true (logical 1) otherwise.
- *Optional:*: `info` returns additional information about merge failure if `status` is true. Otherwise, it returns an empty character vector.

Consider the following example.

```
[status,info] = rtw.asap2MergeMdlRefs('myTopMdl','merged.a2l')
```

This command merges the ASAP2 files generated for the top model `myTopMdl` and its referenced models in the file `merged.a2l`.

The example model `rtwdemo_asap2` includes an example of merging ASAP2 files.

Structure of the ASAP2 File

The following table outlines the basic structure of the ASAP2 file and describes the Target Language Compiler (TLC) functions and files used to create each part of the file:

- Static parts of the ASAP2 file are shown in **bold**.
- Function calls are indicated by `%<FunctionName()>`.

File Section	Contents of asap2main.tlc	TLC File Containing Function Definition
File header	%<ASAP2UserFcnWriteFileHead()>	asap2userlib.tlc
/begin PROJECT ""	**/begin PROJECT** "%<ASAP2ProjectName>"	asap2setup.tlc
/begin HEADER "" HEADER contents	**/begin HEADER**"%<ASAP2HeaderName>" %<ASAP2UserFcnWriteHeader()>	asap2setup.tlc asap2userlib.tlc
/end HEADER	**/end HEADER**	asap2userlib.tlc
/begin MODULE "" MODULE contents:	**/begin MODULE** "%<ASAP2ModuleName>"}	asap2setup.tlc asap2userlib.tlc
- A2ML - MOD_PAR - MOD_COMMON ...	%<ASAP2UserFcnWriteHardwareInterface()>	asap2userlib.tlc

File Section	Contents of asap2main.tlc	TLC File Containing Function Definition
Model-dependent `MODULE` contents:	`%<SLibASAP2WriteDynamicContents()>` Calls user-defined functions:	`asap2lib.tlc`

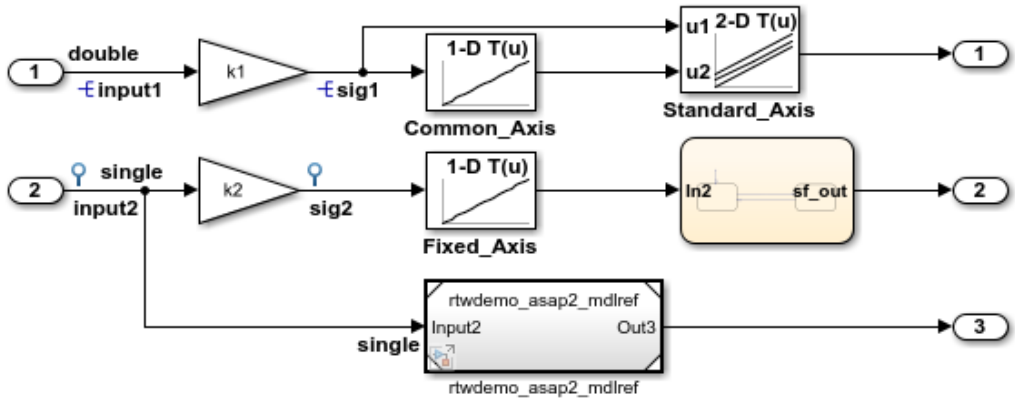
Create a Host-Based ASAM-ASAP2 Data Definition File for Data Measurement and Calibration

This model shows ASAP2 data export. ASAP2 is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM).

Open Example Model

Open the example model `rtwdemo_asap2`.

```
open_system('rtwdemo_asap2');
```



This model shows ASAP2 data export. ASAP2 is a data definition standard proposed by the Association for Standardization of Automation and Measuring Systems (ASAM). ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostics systems. For more information on ASAM and the ASAP2 standard, see the ASAM Web site: http://www.asam.de.

ASAP2 data definition is achieved with Simulink data objects and test point signals. Using the Target Language Compiler (TLC), you can create highly customized solutions for your application. See the Simulink Coder documentation for details on ASAP2 file generation.

You can configure ASAP2 file generation from "Code Generation > Interface > ASAP2 interface" in the Configuration Parameters dialog box.

Generate Code Using Simulink Coder (double-click) | **Generate Code Using Embedded Coder (double-click)** | **View Interface Configuration (double-click)** | **View Workspace Variables (double-click)**

ASAP2 is a non-object-oriented description of the data used for measurement, calibration, and diagnostics systems. For more information on ASAM and the ASAP2 standard, see the ASAM Web site: https://www.asam.de.

ASAP2 data definition is achieved with Simulink® data objects and test point signals. Using the Target Language Compiler (TLC), you can create highly customized solutions for your application. See the Simulink Coder® documentation for details on ASAP2 file generation.

You can configure ASAP2 file generation by selecting **ASAP2 interface** on the **Code Generation > Interface** pane of the Configuration Parameters dialog box.

Direct Memory Access to Generated Code for Simulink Coder

Access Memory in Generated Code Using Global Data Map

Simulink Coder provides a Target Language Compiler (TLC) function library that lets you create a global data map record. The global data map record, when generated, is added to the `CompiledModel` structure in the `model.rtw` file. The global data map record is a database containing information required for accessing memory in the generated code, including

- Signals (Block I/O)
- Parameters
- Data type work vectors (DWork)
- External inputs
- External outputs

Use of the global data map requires knowledge of the Target Language Compiler and of the structure of the `model.rtw` file. See “Target Language Compiler Overview” (Simulink Coder) for information on these topics.

The TLC functions that are required to generate and access the global data map record are contained in *`matlabroot`*`/rtw/c/tlc/mw/globalmaplib.tlc`. The comments in the source code fully document the global data map structures and the library functions.

The global data map structures and functions might be modified or enhanced in future releases.

Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File

After you create a model, you can use the rapid simulation (RSim) system target file to characterize model behavior. The executable program that results from the build process is for non-real-time execution on your development computer. The executable program is highly optimized for simulating models of hybrid dynamic systems, including models that use variable-step solvers and zero-crossing detection. The speed of the generated code makes the RSim system target file ideal for building programs for batch or Monte Carlo simulations.

About Rapid Simulation

Use the RSim target to generate an executable that runs fast, standalone simulations. You can repeat simulations with varying data sets, interactively or programmatically with scripts, without rebuilding the model. This can accelerate the characterization and tuning of model behavior and code generation testing.

Using command-line options:

- Define parameter values and input signals in one or more MAT-files that you can load and reload at the start of simulations without rebuilding your model.
- Redirect logging data to one or more MAT-files that you can then analyze and compare.
- Control simulation time.
- Specify external mode options.

Note To run an RSim executable, configure your computer to run MATLAB and have the MATLAB and Simulink installation folders accessible. To deploy a standalone host executable (i.e., without MATLAB and Simulink installed), consider using the Host-Based Shared Library target (ert_shrlib)."

Rapid Simulation Advantage

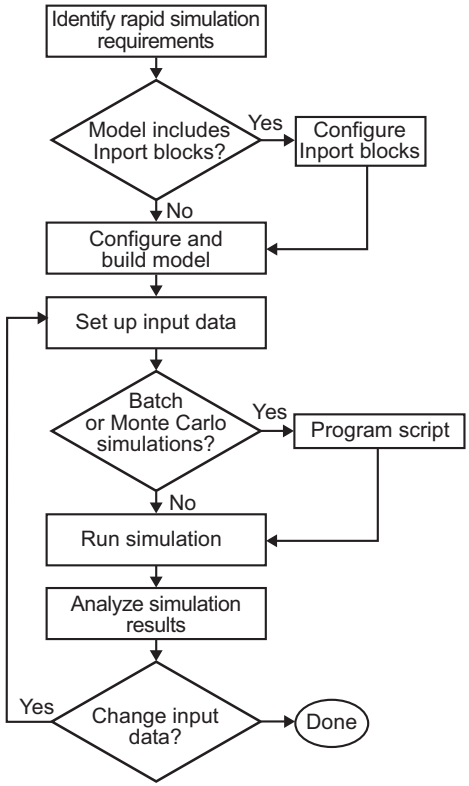
The advantage that you gain from rapid simulation varies. Larger simulations achieve speed improvements of up to 10 times faster than standard Simulink simulations. Some models might not show noticeable improvement in simulation speed. To determine the

speed difference for your model, time your standard Simulink simulation and compare the results with a rapid simulation. In addition, test the model simulation in Rapid Accelerator simulation mode.

General Rapid Simulation Workflow

Like other stages of Model-Based Design, characterization and tuning of model behavior is an iterative process, as shown in the general workflow diagram in the figure. Tasks in the workflow are:

1. Identify your rapid simulation requirements. on page 60-4
2. Configure Inport blocks on page 60-6 that provide input source data for rapid simulations.
3. Configure the model on page 60-6 for rapid simulation.
4. Set up simulation input data. on page 60-8
5. Run the rapid simulations. on page 60-19



Identify Rapid Simulation Requirements

The first step to setting up a rapid simulation is to identify your simulation requirements.

Question...	For More Information, See...
How long do you want simulations to run?	"Configure and Build Model for Rapid Simulation" on page 60-6
Are there solver requirements? Do you expect to use the same solver for which the model is configured for your rapid simulations?	"Configure and Build Model for Rapid Simulation" on page 60-6

Question...	For More Information, See...
Do your rapid simulations need to accommodate flexible custom code interfacing? Or, do your simulations need to retain storage class settings?	“Configure and Build Model for Rapid Simulation” on page 60-6
Will you be running simulations with multiple data sets?	“Set Up Rapid Simulation Input Data” on page 60-8
Will the input data consist of global parameters, signals, or both?	“Set Up Rapid Simulation Input Data” on page 60-8
What type of source blocks provide input data to the model — From File, Inport, From Workspace?	“Set Up Rapid Simulation Input Data” on page 60-8
Will the model's parameter vector (`model_P`) be used as input data?	“Create a MAT-File That Includes a Model Parameter Structure” on page 60-9
What is the data type of the input parameters and signals?	“Set Up Rapid Simulation Input Data” on page 60-8
Will the source data consist of one variable or multiple variables?	“Set Up Rapid Simulation Input Data” on page 60-8
Does the input data include tunable parameters?	“Create a MAT-File That Includes a Model Parameter Structure” on page 60-9
Do you need to gain access to tunable parameter information — model checksum and parameter data types, identifiers, and complexity?	“Create a MAT-File That Includes a Model Parameter Structure” on page 60-9
Will you have a need to vary the simulation stop time for simulation runs?	“Configure and Build Model for Rapid Simulation” on page 60-6 and“Override a Model Simulation Stop Time” on page 60-22
Do you want to set a time limit for the simulation? Consider setting a time limit if your model experiences frequent zero crossings and has a small minor step size.	“Set a Clock Time Limit for a Rapid Simulation” on page 60-22
Do you need to preserve the output of each simulation run?	“Specify a New Output File Name for a Simulation” on page 60-29 and “Specify New Output File Names for To File Blocks” on page 60-30

Question...	For More Information, See...
Do you expect to run the simulations interactively or in batch mode?	“Scripts for Batch and Monte Carlo Simulations” on page 60-19

Configure Inports to Provide Simulation Source Data

You can use Inport blocks as a source of input data for rapid simulations. To do so, configure the blocks so that they can import data from external MAT-files. By default, the Inport block inherits parameter settings from downstream blocks. In most cases, to import data from an external MAT-file, you must explicitly set the following parameters to match the source data in the MAT-file.

- **Main > Interpolate data**
- **Signal Attributes > Port dimensions**
- **Signal Attributes > Data type**
- **Signal Attributes > Signal type**

If you do not have control over the model content, you might need to modify the data in the MAT-file to conform to what the model expects for input. Input data characteristics and specifications of the Inport block that receives the data must match.

For details on adjusting these parameters and on creating a MAT-file for use with an Inport block, see “Create a MAT-File for an Inport Block” on page 60-14. For descriptions of the preceding block parameters, see the block description of Inport.

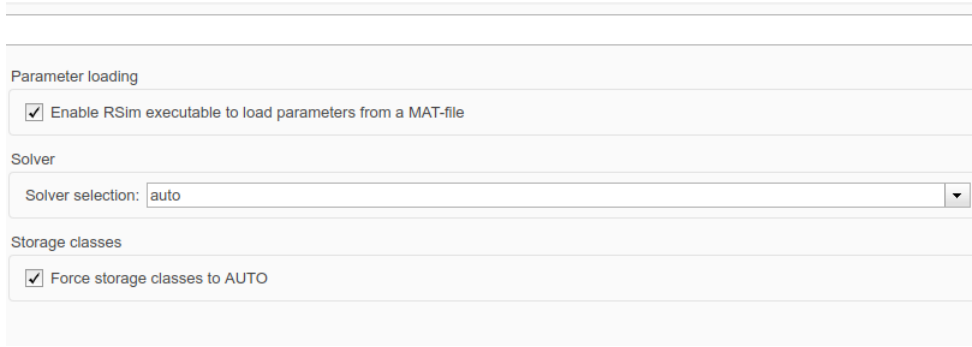
Configure and Build Model for Rapid Simulation

After you identify your rapid simulation requirements, configure the model for rapid simulation.

1. Open the Configuration Parameters dialog box.
2. Go to the **Code Generation** pane.
3. On the **Code Generation** pane, click **Browse**. The System Target File Browser opens.
4. Select `rsim.tlc` (Rapid Simulation Target) and click **OK**.

On the **Code Generation** pane, the code generator populates the **Make command** and "Template makefile" (Simulink Coder) fields with default settings and adds the **RSim Target** pane under **Code Generation**.

5 Click **RSim Target** to view the **RSim Target** pane.



6 Set the RSim target configuration parameters to your rapid simulation requirements.

If You Want to...	Then...
Generate code that allows the RSim executable to load parameters from a MAT-file	Select **Enable RSim executable to load parameters from a MAT-file** (default).
Let the target choose a solver based on the solver already configured for the model	Set **Solver selection** to `auto` (default). The code generator uses a built-in solver if a fixed-step solver is specified on the **Solver** pane or calls the Simulink solver module (a shared library) if a variable-step solver is specified.
Explicitly instruct the target to use a fixed-step solver	Set **Solver selection** to `Use fixed-step solvers`. In the Configuration Parameters dialog box, on the **Solver** pane, specify a fixed-step solver.
Explicitly instruct the target to use a variable-step solver	Set **Solver selection** to `Use Simulink solver module`. In the Configuration Parameters dialog box, on the **Solver** pane, specify a variable-step solver.
Force storage classes to `Auto` for flexible custom code interfacing	Select **Force storage classes to AUTO** (default).

If You Want to...	Then...
Retain storage class settings, such as `ExportedGlobal` or `ImportedExtern`, due to application requirements	Clear **Force storage classes to AUTO**.

7 Set up data import and export options. On the **Data Import/Export** pane, in the **Save to Workspace** section, select the **Time**, **States**, **Outputs**, and **Final States** options, as they apply. By default, the code generator saves simulation logging results to a file named *`model`*`.mat`. For more information, see “Export Simulation Data” (Simulink).

8 If you are using external mode communication, set up the interface, using the **Code Generation** > **Interface** pane. See “Host-Target Communication with External Mode Simulation” (Simulink Coder) for details.

9 Press **Ctrl+B**. The code generator builds a highly optimized executable program that you can run on your development computer with varying data, without rebuilding.

For more information on compilers that are compatible with the Simulink Coder product, see “Select and Configure C or C++ Compiler” on page 54-3 and “Template Makefiles and Make Options” on page 54-26 .

Set Up Rapid Simulation Input Data

About Rapid Simulation Data Setup

The format and setup of input data for a rapid simulation depends on your requirements.

If the Input Data Source Is...	Then...
The model's global parameter vector (*`model`*`_P`)	Use the `rsimgetrtp` function to get the vector content and then save it to a MAT-file.
The model's global parameter vector and you want a mapping between the vector and tunable parameters	Call the `rsimgetrtp` function to get the global parameter structure and then save it to a MAT-file.

If the Input Data Source Is...	Then...
Provided by a From File block	Create a MAT-file that a From File block can read.
Provided by an Inport block	Create a MAT-file that adheres to one of the three data file formats that the Inport block can read.
Provided by a From Workspace block	Create structure variables in the MATLAB workspace.

The RSim target requires that MAT-files used as input for From File and Inport blocks contain data. The `grt` target inserts MAT-file data directly into the generated code, which is then compiled and linked as an executable. In contrast, RSim allows you to replace data sets for each successive simulation. A MAT-file containing From File or Inport block data must be present if a From File block or Inport block exists in your model.

Create a MAT-File That Includes a Model Parameter Structure

To create a MAT-file that includes a model global parameter structure (*`model`*`_P`),

1. Get the structure by calling the function `rsimgetrtp`.
2. Save the parameter structure to a MAT-file.

If you want to run simulations over varying data sets, consider converting the parameter structure to a cell array and saving the parameter variations to a single MAT-file.

Get the Parameter Structure for a Model

Get the global parameter structure (*`model`*`_P`) for a model by calling the function `rsimgetrtp`.

```
param_struct = rsimgetrtp('model')
```

Argument	Description
`model`	The model for which you are running the rapid simulations.

The `rsimgetrtp` function forces an update diagram action for the specified model and returns a structure that contains the following fields.

Field	Description
`modelChecksum`	A four-element vector that encodes the structure of the model. The code generator uses the checksum to check whether the structure of the model has changed since the RSim executable was generated. If you delete or add a block, and then generate a new *`model`*`_P` vector, the new checksum does not match the original checksum anymore. The RSim executable detects this incompatibility in parameter vectors and exits to avoid returning incorrect simulation results. If the model structure changes, you must regenerate the code for the model.
`parameters`	A structure that contains the model's global parameters.

The parameter structure contains the following information.

Field	Description
`dataTypeName`	The name of the parameter data type, for example, `double`
`dataTypeID`	Internal data type identifier used by the code generator
`complex`	The value 0 if real; 1 if complex
dtTransIdx	Internal data index used by the code generator
values	A vector of the parameter values associated with this structure
map	This field contains the mapping information that correlates the 'values' to the tunable parameters of the model. This mapping information, in conjunction with `rsimsetrtpparam`, is useful for creating subsequent rtP structures without compiling the block diagram.

The code generator reports a tunable fixed-point parameter according to its stored value. For example, an `sfix(16)` parameter value of `1.4` with a scaling of `2^-8` has a value of `358` as an `int16`.

In the following example, `rsimgetrtp` returns the parameter structure for the example model `rtwdemo_rsimtf` to `param_struct`.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf')
```

```
param_struct =

    modelChecksum: [1.7165e+009 3.0726e+009 2.6061e+009 2.3064e+009]
       parameters: [1x1 struct]
```

Save the Parameter Structure to a MAT-File

After you issue a call to `rsimgetrtp`, save the return value of the function call to a MAT-file. Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

The following example saves the parameter structure returned for `rtwdemo_rsimtf` to the MAT-file `myrsimdemo.mat`.

```
save myrsimdemo.mat param_struct;
```

For information on using command-line options to specify required files, see “Run Rapid Simulations” on page 60-19.

Convert the Parameter Structure for Running Simulations on Varying Data Sets

To use rapid simulations to test changes to specific parameters, you can convert the model parameter structure to a cell array. You can then access a specific parameter set by using the @ operator to specify the index for a specific parameter set in the file.

To convert the structure to a cell array:

1. Use the function `rsimgetrtp` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

   ```
   param_struct = rsimgetrtp('rtwdemo_rsimtf');
   ```

   The `parameters` field of the structure is a substructure that contains parameter information. The `values` field of the `parameters` substructure contains the numeric values of the parameters that you can tune during execution of the simulation code.

2. Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

   ```
   param_struct = rsimsetrtpparam(param_struct,3);
   ```

   The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

3. Specify new values for the parameters in the second and third parameter sets.

```
param_struct.parameters{2}.values = [-150 -5000 0 4950];
param_struct.parameters{3}.values = [-170 -5500 0 5100];
```

4 Save the structure containing the parameter set information to a MAT-file.

```
save rtwdemo_rsimtf.mat param_struct;
```

Alternatively, you can modify the block parameters in the model, and use `rsimgetrtp` to create multiple parameter sets:

1 Use the function `rsimgetrtp` to get a structure containing parameter information for the example model `rtwdemo_rsimtf`. Store the structure in a variable `param_struct`.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
```

2 Use the function `rsimsetrtpparam` to expand the structure so that it contains more parameter sets. In this case, create two more parameter sets (for a total of three sets).

```
param_struct = rsimsetrtpparam(param_struct,3);
```

The function converts the `parameters` field to a cell array with three elements. Each element contains information for a single parameter set. By default, the function creates the second and third elements of the cell array by copying the first element. Therefore, all of the parameter sets use the same parameter values.

3 Change the values of block parameters or workspace variables. For example, change the value of the variable `w` from `70` to `72`.

```
w = 72;
```

4 Use `rimsgetrtp` to get another structure containing parameter information. Store the structure in a temporary variable `rtp_temp`.

```
rtp_temp = rsimgetrtp('rtwdemo_rsimtf');
```

5 Assign the value of the `parameters` field of `rtp_temp` to the structure `param_struct` as a second parameter set.

```
param_struct.parameters{2} = rtp_temp.parameters;
```

6 Change the value of the variable `w` from `72` to `75`.

```
w = 75;
```

7 Use `rimsgetrtp` to get another structure containing parameter information. Then, assign the value of the `parameters` field to `param_struct` as a third parameter set.

```
rtp_temp = rsimgetrtp('rtwdemo_rsimtf');
param_struct.parameters{3} = rtp_temp.parameters;
```

8 Save the structure containing the parameter set information to a MAT-file.

```
save rtwdemo_rsimtf.mat param_struct;
```

For more information on how to specify each parameter set when you run the simulations, see “Change Block Parameters for an RSim Simulation” on page 60-28.

Create a MAT-File for a From File Block

You can use a MAT-file as the input data source for a From File block. The format of the data in the MAT-file must match the data format expected by that block. For example, if you are using a matrix as an input for the MAT file, this cannot be different from the matrix size for the executable.

To create a MAT-file for a From File block:

1 For array format data, in the workspace create a matrix that consists of two or more rows. The first row must contain monotonically increasing time points. Other rows contain data points that correspond to the time point in that column. The time and data points must be data of type `double`.

For example:

```
t=[0:0.1:2*pi]';
Ina1=[2*sin(t) 2*cos(t)];
Ina2=sin(2*t);
Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix=[t Ina1 Ina2 Ina3]';
```

For other supported data types, such as `int16` or fixed-point, the time data points must be of type `double`, just as for array format data. However, the sample data can be of any dimension.

For more information on setting up the input data, see the block description of From File.

2 Save the matrix to a MAT-file.

The following example saves the matrix `var_matrix` to the MAT-file `myrsimdemo.mat` in Version 7.3 format.

```
save '-v7.3' myrsimdemo.mat var_matrix;
```

Using a command-line option, you can then specify that MAT-file as input for rapid simulations.

Create a MAT-File for an Inport Block

You can use a MAT-file as the input data source for an Inport block.

The format of the data in the MAT-file must adhere to one of the three column-based formats listed in the following table. The table lists the formats in order from least flexible to most flexible.

Format	Description
Single time/data matrix	• Least flexible. • One variable. • Two or more *columns*. Number of columns must equal the sum of the dimensions of all root Inport blocks plus 1. First column must contain monotonically increasing time points. Other columns contain data points that correspond to the time point in a given row. • Data of type `double`. For an example, see **Single time/data matrix** in the following procedure, step 4. For more information, see “Loading Data Arrays to Root-Level Inputs” (Simulink).

Format	Description
Signal-and-time structure	• More flexible than the single time/data matrix format. • One variable. • Must contain two top-level fields: `time` and `signals`. The `time` field contains a *column* vector of the simulation times. The `signals` field contains an array of substructures, each of which corresponds to an Inport block. The substructure index corresponds to the Inport block number. Each `signals` substructure must contain a field named `values`. The `values` field must contain an array of inputs for the corresponding Inport block, where each input corresponds to a time point specified by the `time` field. • If the `time` field is set to an empty value, clear the check box for the Inport block **Interpolate data** parameter. • Data type must match Inport block settings. For an example, see **Signal-and-time structure** in the following procedure, step 4. For more information on this format, see “Loading Data Structures to Root-Level Inputs” (Simulink).

Format	Description
Per-port structure	• Most flexible • Multiple variables. Number of variables must equal the number of Inport blocks. • Consists of a separate structure-with-time or structure-without-time for each Inport block. Each Inport block data structure has only one `signals` field. To use this format, in the **Input** text field, enter the names of the structures as a comma-separated list, `in1`, `in2`,..., `inN`, where `in1` is the data for your model's first port, `in2` for the second port, and so on. • Each variable can have a different time vector. • If the `time` field is set to an empty value, clear the check box for the Inport block **Interpolate data** parameter. • Data type must match Inport block settings. • To save multiple variables to the same data file, you must save them in the order expected by the model, using the `-append` option. For an example, see **Per-port structure** in the following procedure, step 4. For more information, see “Loading Data Structures to Root-Level Inputs” (Simulink).

The supported formats and the following procedure are illustrated in `rtwdemo_rsim_i`.

To create a MAT-file for an Inport block:

1. Choose one of the preceding data file formats.
2. Update Inport block parameter settings and specifications to match specifications of the data to be supplied by the MAT-file.

   By default, the Inport block inherits parameter settings from downstream blocks. To import data from an external MAT-file, explicitly set the following parameters to match the source data in the MAT-file.

   - **Main > Interpolate data**
   - **Signal Attributes > Port dimensions**
   - **Signal Attributes > Data type**
   - **Signal Attributes > Signal type**

If you choose to use a structure format for workspace variables and the `time` field is empty, you must clear **Interpolate data** or modify the field so that it is set to a nonempty value. Interpolation requires time data.

For descriptions of the preceding block parameters, see the block description of Inport.

3. Build an RSim executable program for the model. The build process creates and calculates a structural checksum for the model and embeds it in the generated executable. The RSim target uses the checksum to verify that data being passed into the model is consistent with what the model executable expects.
4. Create the MAT-file that provides the source data for the rapid simulations. You can create the MAT-file from a workspace variable. Using the specifications in the preceding format comparison table, create the workspace variables for your simulations.

   An example of each format follows:

   Single time/data matrix

   ```
   t=[0:0.1:2*pi]';
   Ina1=[2*sin(t) 2*cos(t)];
   Ina2=sin(2*t);
   Ina3=[0.5*sin(3*t) 0.5*cos(3*t)];
   var_matrix=[t Ina1 Ina2 Ina3];
   ```

   Signal-and-time structure

   ```
   t=[0:0.1:2*pi]';
   var_single_struct.time=t;
   var_single_struct.signals(1).values(:,1)=2*sin(t);
   var_single_struct.signals(1).values(:,2)=2*cos(t);
   var_single_struct.signals(2).values=sin(2*t);
   var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
   var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
   v=[var_single_struct.signals(1).values...
   var_single_struct.signals(2).values...
   var_single_struct.signals(3).values];
   ```

   Per-port structure

   ```
   t=[0:0.1:2*pi]';
   Inb1.time=t;
   Inb1.signals.values(:,1)=2*sin(t);
   ```

```
Inb1.signals.values(:,2)=2*cos(t);
t=[0:0.2:2*pi]';
Inb2.time=t;
Inb2.signals.values(:,1)=sin(2*t);
t=[0:0.1:2*pi]';
Inb3.time=t;
Inb3.signals.values(:,1)=0.5*sin(3*t);
Inb3.signals.values(:,2)=0.5*cos(3*t);
```

5 Save the workspace variables to a MAT-file.

Single time/data matrix

The following example saves the workspace variable `var_matrix` to the MAT-file `rsim_i_matrix.mat`.

```
save rsim_i_matrix.mat var_matrix;
```

Signal-and-time structure

The following example saves the workspace structure variable `var_single_struct` to the MAT-file `rsim_i_single_struct.mat`.

```
save rsim_i_single_struct.mat var_single_struct;
```

Per-port structure

To order data when saving per-port structure variables to a single MAT-file, use the `save` command's `-append` option. Be sure to append the data in the order that the model expects it.

The following example saves the workspace variables `Inb1`, `Inb2`, and `Inb3` to MAT-file `rsim_i_multi_struct.mat`.

```
save rsim_i_multi_struct.mat Inb1;
save rsim_i_multi_struct.mat Inb2 -append;
save rsim_i_multi_struct.mat Inb3 -append;
```

The `save` command does not preserve the order in which you specify your workspace variables in the command line when saving data to a MAT-file. For example, if you specify the variables `v1`, `v2`, and `v3`, in that order, the order of the variables in the MAT-file could be `v2 v1 v3`.

Using a command-line option, you can then specify the MAT-files as input for rapid simulations.

Scripts for Batch and Monte Carlo Simulations

The RSim target is for batch simulations in which parameters and input signals vary for multiple simulations. New output file names allow you to run new simulations without overwriting prior simulation results. You can set up a series of simulations to run by creating a `.bat` file for use on a Microsoft Windows platform.

Create a file for the Windows platform with a text editor and execute it by typing the file name, for example, `mybatch`, where the name of the text file is `mybatch.bat`.

```
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run1.mat -o results1.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run2.mat -o results2.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run3.mat -o results3.mat -tf 10.0
rtwdemo_rsimtf -f rtwdemo_rsimtf.mat=run4.mat -o results4.mat -tf 10.0
```

In this case, batch simulations run using four sets of input data in files `run1.mat`, `run2.mat`, and so on. The RSim executable saves the data to the files specified with the `-o` option.

The variable names containing simulation results in each of the files are identical. Therefore, loading consecutive sets of data without renaming the data once it is in the MATLAB workspace results in overwriting the prior workspace variable with new data. To avoid overwriting, you can copy the result to a new MATLAB variable before loading the next set of data.

You can also write MATLAB scripts to create new signals and new parameter structures, as well as to save data and perform batch runs using the bang command (`!`).

For details on running simulations and available command-line options, see “Run Rapid Simulations” on page 60-19. For an example of a rapid simulation batch script, see the example “Run Batch Simulations Without Recompiling Generated Code” (Simulink Coder).

Run Rapid Simulations

- “Specify New Signal Data File for a From File Block” on page 60-23
- “Specify Signal Data File for an Inport Block” on page 60-26
- “Change Block Parameters for an RSim Simulation” on page 60-28
- “Specify a New Output File Name for a Simulation” on page 60-29
- “Specify New Output File Names for To File Blocks” on page 60-30

Rapid Simulations

Using the RSim target, you can build a model once and run multiple simulations to study effects of varying parameter settings and input signals. You can run a simulation directly from your operating system command line, redirect the command from the MATLAB command line by using the bang (!) character, or execute commands from a script.

From the operating system command line, use

```
rtwdemo_rsimtf
```

From the MATLAB command line, use

```
!rtwdemo_rsimtf
```

The following table lists ways you can use RSim target command-line options to control a simulation.

To...	Use...
Read input data for a From File block from a MAT-file other than the MAT-file used for the previous simulation	*model* `-f` *oldfilename*`.mat=`*newfilename*`.mat`
Print a summary of the options for RSim executable targets	*executable filename* `-h`
Read input data for an Inport block from a MAT-file	*model* `-i` *filename*`.mat`
Time out after *n* clock time seconds, where *n* is a positive integer value	*model* `-L` *n*
Write MAT-file logging data to file *filename*`.mat`	*model* `-o` *filename*`.mat`
Read a parameter vector from file *filename*`.mat`	*model* `-p` *filename*`.mat`

To...	Use...
Override the default TCP port (17725) for external mode	*model* -port *TCPport*
Write MAT-file logging data to a MAT-file other than the MAT-file used for the previous simulation	*model* -t *oldfilename*.mat=*newfilename*.mat
Run the simulation until the time value *stoptime* is reached	*model* -tf *stoptime*
Run in verbose mode	*model* -v
Wait for the Simulink engine to start the model in external mode	*model* -w

The following sections use the `rtwdemo_rsimtf` example model in examples to illustrate some of these command-line options. In each case, the example assumes you have already done the following:

- Created or changed to a working folder.
- Opened the example model.
- Copied the data file *matlabroot*`/toolbox/rtw/rtwdemos/rsimdemos/rsim_tfdata.mat` to your working folder. You can perform this operation using the command:

```
copyfile(fullfile(matlabroot,'toolbox','rtw','rtwdemos',...
'rsimdemos','rsim_tfdata.mat'),pwd);
```

Requirements for Running Rapid Simulations

The following requirements apply to both fixed and variable step executables.

- You must run the RSim executable on a computer configured to run MATLAB. Also, the `RSim.exe` file must be able to access the MATLAB and Simulink installation folders on this machine. To obtain that access, your PATH environment variable must include /bin and /bin/($ARCH), where ($ARCH) represents your operating system architecture. For example, for a personal computer running on a Windows platform, ($ARCH) is “win64”, whereas for a Linux machine, ($ARCH) is “glnxa64”.
- On GNU Linux platforms, to run an RSim executable, define the LD_LIBRARY_PATH environment variable to provide the path to the MATLAB installation folder, as follows:

```
% setenv LD_LIBRARY_PATH /matlab/sys/os/glnx64:$LD_LIBRARY_PATH
```

- On the Apple Macintosh OS X platform, to run RSim target executables, you must define the environment variable `DYLD_LIBRARY_PATH` to include the folders `bin/mac` and `sys/os/mac` under the MATLAB installation folder. For example, if your MATLAB installation is under `/MATLAB`, add `/MATLAB/bin/mac` and `/MATLAB/sys/os/mac` to the definition for `DYLD_LIBRARY_PATH`.

Set a Clock Time Limit for a Rapid Simulation

If a model experiences frequent zero crossings and the model's minor step size is small, consider setting a time limit for a rapid simulation. To set a time limit, specify the `-L` option with a positive integer value. The simulation aborts after running for the specified amount of clock time (not simulation time). For example,

```
!rtwdemo_rsimtf -L 20
```

Based on your clock, after the executable runs for 20 seconds, the program terminates. You see a message similar to one of the following:

- On a Microsoft Windows platform,

  ```
  Exiting program, time limit exceeded
  Logging available data ...
  ```

- On The Open Group UNIX platform,

  ```
  ** Received SIGALRM (Alarm) signal @ Fri Jul 25 15:43:23 2003
  ** Exiting model  'vdp' @ Fri Jul 25 15:43:23 2003
  ```

You do not need to do anything to your model or to its configuration to use this option.

Override a Model Simulation Stop Time

By default, a rapid simulation runs until the simulation time reaches the time specified the Configuration Parameters dialog box, on the **Solver** pane. You can override the model simulation stop time by using the `-tf` option. For example, the following simulation runs until the time reaches 6.0 seconds.

```
!rtwdemo_rsimtf -tf 6.0
```

The RSim target stops and logs output data using MAT-file data logging rules.

If the model includes a From File block, the end of the simulation is regulated by the stop time setting specified in the Configuration Parameters dialog box, on the **Solver** pane, or with the RSim target option `-tf`. The values in the block's time vector are ignored.

However, if the simulation time exceeds the endpoints of the time and signal matrix (if the final time is greater than the final time value of the data matrix), the signal data is extrapolated to the final time value.

Read the Parameter Vector into a Rapid Simulation

To read the model parameter vector into a rapid simulation, you must first create a MAT-file that includes the parameter structure as described in “Create a MAT-File That Includes a Model Parameter Structure” on page 60-9. You can then specify the MAT-file in the command line with the `-p` option.

For example:

1. Build an RSim executable for the example model `rtwdemo_rsimtf`.
2. Modify parameters in your model and save the parameter structure.

   ```
   param_struct = rsimgetrtp('rtwdemo_rsimtf');
   save myrsimdata.mat param_struct
   ```

3. Run the executable with the new parameter set.

   ```
   !rtwdemo_rsimtf -p myrsimdata.mat

   ** Starting model 'rtwdemo_rsimtf' @ Tue Dec 27 12:30:16 2005
   ** created rtwdemo_rsimtf.mat **
   ```

4. Load workspace variables and plot the simulation results by entering the following commands:

   ```
   load myrsimdata.mat
   plot(rt_yout)
   ```

Specify New Signal Data File for a From File Block

If your model's input data source is a From File block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one simulation to the next. Each MAT-file must adhere to the format described in “Create a MAT-File for a From File Block” on page 60-13.

To change the MAT-file after an initial simulation, you specify the executable with the `-f` option and an *`oldfile`*`.mat=`*`newfile`*`.mat` parameter, as shown in the following example.

1. Set some parameters in the MATLAB workspace. For example:

```
w = 100;
theta = 0.5;
```

2 Build an RSim executable for the example model `rtwdemo_rsimtf`.

3 Run the executable.

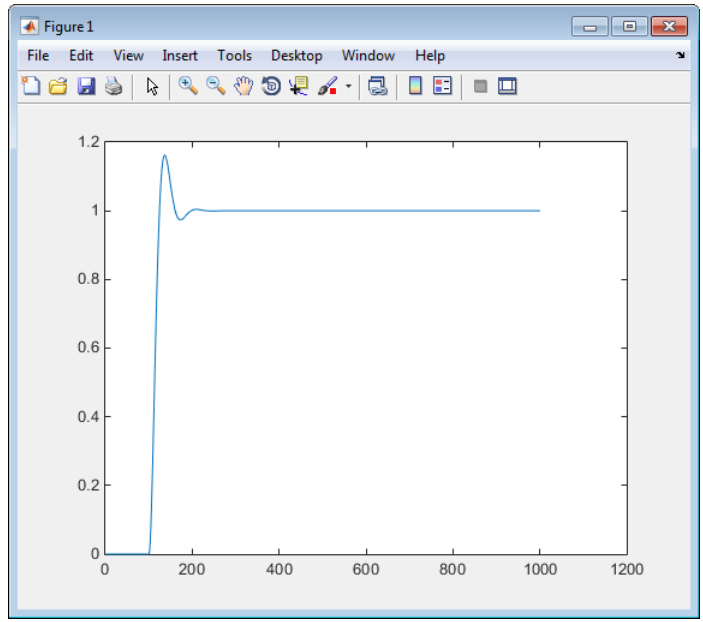
```
!rtwdemo_rsimtf
```

The RSim executable runs a set of simulations and creates output MAT-files containing the specific simulation result.

4 Load the workspace variables and plot the simulation results by entering the following commands:

```
load rtwdemo_rsimtf.mat
plot(rt_yout)
```

The resulting plot shows simulation results based on default input data.



5 Create a new data file, `newfrom.mat`, that includes the following data:

```
t=[0:.001:1];
u=sin(100*t.*t);
```

```
tu=[t;u];
save newfrom.mat tu;
```

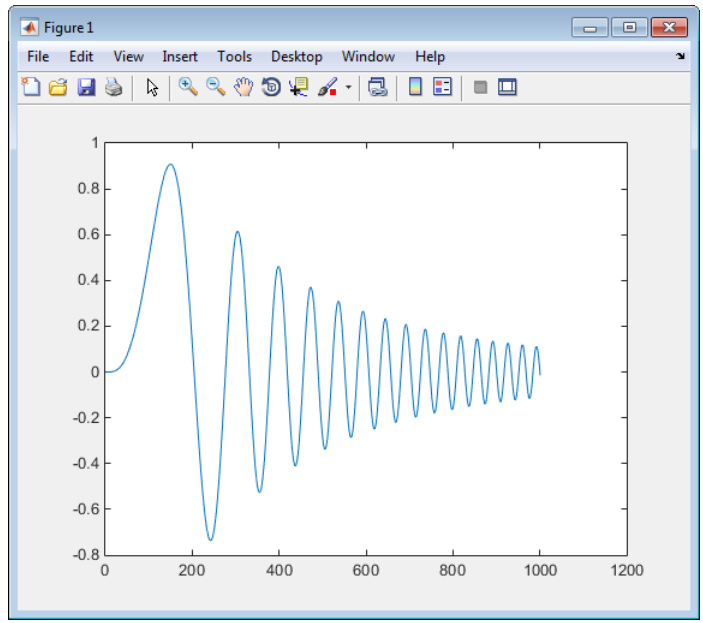
6 Run a rapid simulation with the new data by using the `-f` option to replace the original file, `rsim_tfdata.mat`, with `newfrom.mat`.

```
!rtwdemo_rsimtf -f rsim_tfdata.mat=newfrom.mat
```

7 Load the data and plot the new results by entering the following commands:

```
load rtwdemo_rsimtf.mat
plot(rt_yout)
```

The next figure shows the resulting plot.



From File blocks require input data of type `double`. If you need to import signal data of a data type other than `double`, use an Inport block (see “Create a MAT-File for an Inport Block” on page 60-14) or a From Workspace block with the data specified as a structure.

Workspace data must be in the format:

```
variable.time
variable.signals.values
```

If you have more than one signal, use the following format:

```
variable.time
variable.signals(1).values
variable.signals(2).values
```

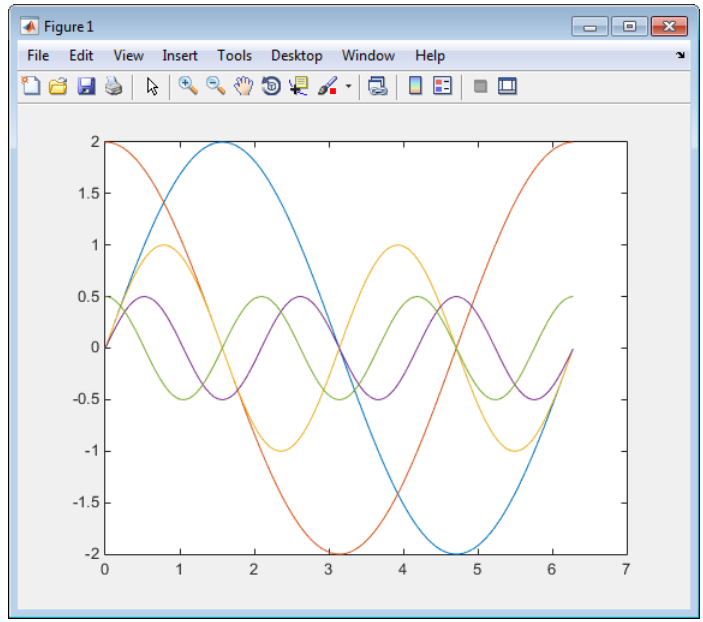
Specify Signal Data File for an Inport Block

If your model's input data source is an Inport block, you can feed the block with input data during simulation from a single MAT-file or you can change the MAT-file from one simulation to the next. Each MAT-file must adhere to one of the three formats described in “Create a MAT-File for an Inport Block” on page 60-14.

To specify the MAT-file after a simulation, you specify the executable with the `-i` option and the name of the MAT-file that contains the input data. For example:

1. Open the model `rtwdemo_rsim_i`.
2. Check the Inport block parameter settings. The following Inport block data parameter settings and specifications that you specify for the workspace variables must match settings in the MAT-file, as indicated in “Configure Inports to Provide Simulation Source Data” on page 60-6:
   - **Main > Interpolate data**
   - **Signal Attributes > Port dimensions**
   - **Signal Attributes > Data type**
   - **Signal Attributes > Signal type**
3. Build the model.
4. Set up the input signals. For example:

   ```
   t=[0:0.01:2*pi]';
   s1=[2*sin(t) 2*cos(t)];
   s2=sin(2*t);
   s3=[0.5*sin(3*t) 0.5*cos(3*t)];
   plot(t, [s1 s2 s3])
   ```



5 Prepare the MAT-file by using one of the three available file formats described in "Create a MAT-File for an Inport Block" on page 60-14. The following example defines a signal-and-time structure in the workspace and names it `var_single_struct`.

```
t=[0:0.1:2*pi]';
var_single_struct.time=t;
var_single_struct.signals(1).values(:,1)=2*sin(t);
var_single_struct.signals(1).values(:,2)=2*cos(t);
var_single_struct.signals(2).values=sin(2*t);
var_single_struct.signals(3).values(:,1)=0.5*sin(3*t);
var_single_struct.signals(3).values(:,2)=0.5*cos(3*t);
v=[var_single_struct.signals(1).values...
var_single_struct.signals(2).values...
var_single_struct.signals(3).values];
```

6 Save the workspace variable `var_single_struct` to MAT-file `rsim_i_single_struct`.

```
save rsim_i_single_struct.mat var_single_struct;
```

7 Run a rapid simulation with the input data by using the `-i` option. Load and plot the results.

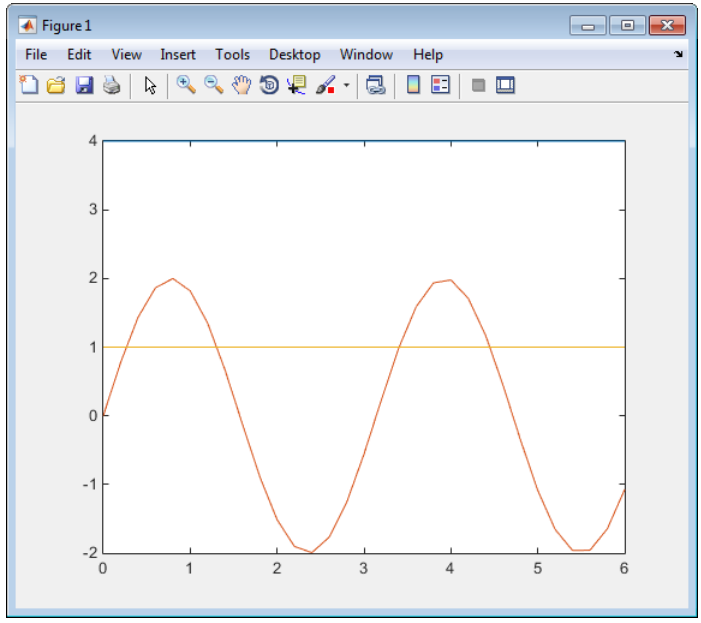
```
!rtwdemo_rsim_i -i rsim_i_single_struct.mat
```

```
** Starting model 'rtwdemo_rsim_i' @ Tue Aug 19 10:26:53 2014
 *** rsim_i_single_struct.mat is successfully loaded! ***
** created rtwdemo_rsim_i.mat **

** Execution time = 0.02024185130718954s
```

8 Load and plot the results.

```
load rtwdemo_rsim_i.mat
plot(rt_tout, rt_yout);
```



Change Block Parameters for an RSim Simulation

As described in “Create a MAT-File That Includes a Model Parameter Structure” on page 60-9, after you alter one or more parameters in a Simulink block diagram, you can extract the parameter vector, *model*_P, for the entire model. You can then save the parameter vector, along with a model checksum, to a MAT-file. This MAT-file can be read directly by the standalone RSim executable, allowing you to replace the entire parameter vector or individual parameter values, for running studies of variations of parameter values representing coefficients, new data for input signals, and so on.

RSim can read the MAT-file and replace the entire *model*_P structure whenever you change one or more parameters, without recompiling the entire model.

For example, assume that you changed one or more parameters in your model, generated the new *model*_P vector, and saved *model*_P to a new MAT-file called `mymatfile.mat`. To run the same `rtwdemo_rsimtf` model and use these new parameter values, use the `-p` option, as shown in the following example:

```
!rtwdemo_rsimtf -p mymatfile.mat
load rtwdemo_rsimtf
plot(rt_yout)
```

If you have converted the parameter structure to a cell array for running simulations on varying data sets, as described in “Convert the Parameter Structure for Running Simulations on Varying Data Sets” on page 60-11, you must add an @*n* suffix to the MAT-file specification. *n* is the element of the cell array that contains the specific input that you want to use for the simulation.

The following example converts `param_struct` to a cell array, changes parameter values, saves the changes to MAT-file `mymatfile.mat`, and then runs the executable using the parameter values in the second element of the cell array as input.

```
param_struct = rsimgetrtp('rtwdemo_rsimtf');
param_struct = rsimsetrtpparam(param_struct,2);
param_struct.parameters{1}

ans =

       dataTypeName: 'double'
         dataTypeId: 0
            complex: 0
         dtTransIdx: 0
             values: [-140 -4900 0 4900]
                map: []
    structParamInfo: []

param_struct.parameters{2}.values=[-150 -5000 0 4950];
save mymatfile.mat param_struct;
!rtwdemo_rsimtf -p mymatfile.mat@2 -o rsim2.mat
```

Specify a New Output File Name for a Simulation

If you have specified one or more of the **Save to Workspace** options — **Time**, **States**, **Outputs**, or **Final States** — in the Configuration Parameters dialog box, on the **Data Import/Export** pane, the default is to save simulation logging results to the file *model*`.mat`. For example, the example model `rtwdemo_rsimtf` normally saves data to `rtwdemo_rsimtf.mat`, as follows:

```
!rtwdemo_rsimtf
created rtwdemo_rsimtf.mat
```

You can specify a new output file name for data logging by using the `-o` option when you run an executable.

```
!rtwdemo_rsimtf -o rsim1.mat
```

In this case, the set of parameters provided at the time of code generation, including From File block data parameters, is run.

Specify New Output File Names for To File Blocks

In much the same way as you can specify a new system output file name, you can also provide new output file names for data saved from one or more To File blocks. To do this, specify the original file name at the time of code generation with a new name, as shown in the following example:

```
!rtwdemo_rsimtf -t rtwdemo_rsimtf_data.mat=mynewrsimdata.mat
```

In this case, assume that the original model wrote data to the output file `rtwdemo_rsimtf_data.mat`. Specifying a new file name forces RSim to write to the file `mynewrsimdata.mat`. With this technique, you can avoid overwriting an existing simulation run.

Tune Parameters Interactively During Rapid Simulation

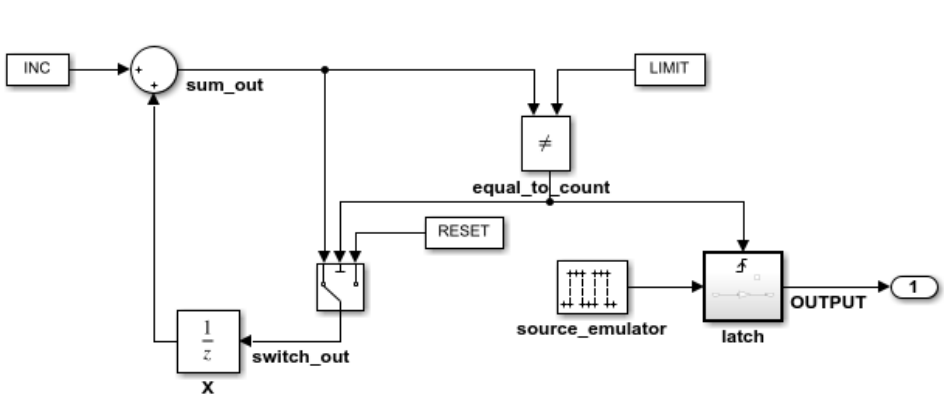
The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, whether you set **Default parameter behavior** to `Tunable` or to `Inlined`, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the file name to use for results.

For this example, **Default parameter behavior** is set to `Inlined`. The model declares workspace variables as tunable parameters. To use RSim with **Default parameter behavior** set to `Tunable`, and without explicitly declaring tunable parameters, see “Run Batch Simulations Without Recompiling Generated Code” (Simulink Coder).

Open Example Model

Open the example model `rtwdemo_rsim_param_tuning`.

```
open_system('rtwdemo_rsim_param_tuning');
```



The RSim target was designed to let you run batch simulations at the fastest possible speed. Using variable-step or fixed-step solvers with RSim combined with the use of a tunable parameter data structure, you can create multiple parameter sets to run with the RSim target's standalone executable file (.exe on Windows) generated using Simulink Coder. Each invocation of the executable allows specification of the filename to use for results.

This model uses the RSim target to allow a non-real-time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to easily get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

View MATLAB programs

Double-click the buttons at the upper right sequentially to run the example. To review the code used to create both the MATLAB GUI and standalone GUI, double-click the View MATLAB programs button.

For more information, you can also refer to the "Rapid Simulation Target" section in the Simulink Coder documentation.

This model uses the RSim target and the `rsimgetrtp` function to allow a non real time executable to be passed new data without the need to recompile the Simulink model. This feature allows you to get a map of the tunable parameters declared in a model and save it in a MAT-file. You can then create your own MATLAB GUI or a standalone GUI (independent of MATLAB) to read and write the MAT-file and rerun the executable to produce new output files.

Double-click the buttons at the upper right sequentially to run the example.

To review the code used to create both the MATLAB GUI and standalone GUI, double-click the View MATLAB programs button.

For more information, you can also refer to the "Rapid Simulation Target" section in the Simulink Coder documentation.

Rapid Simulation Target Limitations

The RSim target has the following limitations:

- Does not support algebraic loops.
- Does not support Interpreted MATLAB Function blocks.
- Does not support noninlined MATLAB language or Fortran S-functions.
- If an RSim build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In such cases, you must regenerate the code for the model.

Run Rapid Simulations Over Range of Parameter Values

This example shows how to use the RSim target to run simulations over a range of parameter values. The example uses the Van der Pol oscillator and performs a parameter sweep over a range of initial state values to obtain the phase diagram of a nonlinear system.

It is very easy to customize this example for your own application by modifying the MATLAB® script used to build this example. Click the link in the top left corner of this page to edit the MATLAB® script. Click the link in the top right corner to run this example from MATLAB®. When running this example, make sure you are in a writable directory. The example creates files that you may want to investigate later.

For this example, **Default parameter behavior** is set to `Inlined`. In the example, you create `Simulink.Parameter` objects as tunable parameters. To use RSim with **Default parameter behavior** set to `Tunable`, and without explicitly declaring tunable parameters, see “Run Batch Simulations Without Recompiling Generated Code” (Simulink Coder).

To quickly run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. For information about rapid accelerator, see “What Is Acceleration?” (Simulink). To sweep parameter values, see “Optimize, Estimate, and Sweep Block Parameter Values” (Simulink).

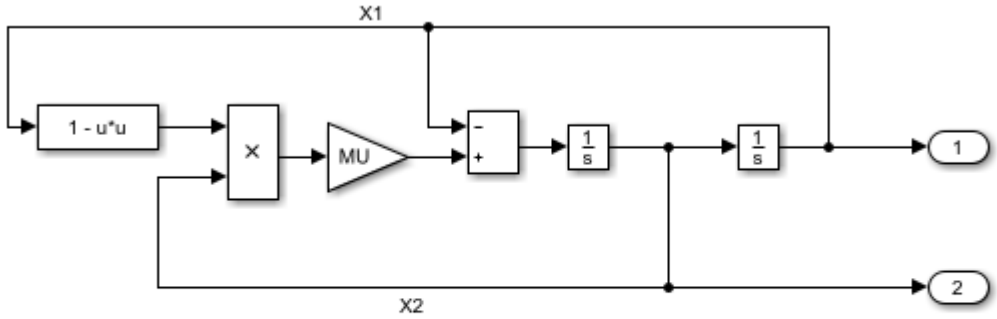
Step 1. Preparation

Make sure the current directory is writable because this example will be creating files.

```
[stat, fa] = fileattrib(pwd);
if ~fa.UserWrite
    disp('This script must be run in a writable directory');
    return
end
```

Open the model and configure it to use the RSim target. For more information on doing this graphically and setting up other RSim target related options, look here.

```
mdlName = 'rtwdemo_rsim_vdp';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc',[]);
```



Specify as Tunable the variables INIT_X1 (the initial condition for state x1), INIT_X2 (the initial condition for state x2), and MU (the gain value). To create tunable parameters, convert the variables to `Simulink.Parameter` objects, and use a storage class other than `Auto` for each object. In this example we will be investigating how the state trajectories evolve from different initial values for the states x1 and x2 in the model.

```
INIT_X1 = Simulink.Parameter(INIT_X1);
INIT_X1.StorageClass = 'Model default';

INIT_X2 = Simulink.Parameter(INIT_X2);
INIT_X2.StorageClass = 'Model default';

MU = Simulink.Parameter(MU);
MU.StorageClass = 'Model default';
```

Define the names of files that will be created during this example.

```
prmFileName = [mdlName, '_prm_sets.mat'];
logFileName = [mdlName, '_run_scr.log'];
batFileName = [mdlName, '_run_scr'];
exeFileName = mdlName;
if ispc
    exeFileName = [exeFileName, '.exe'];
    batFileName = [batFileName, '.bat'];
end
```

```
aggDataFile = [mdlName, '_results'];
startTime = cputime;
```

Step 2. Build the Model

Build the RSim executable for the model. During the build process, a structural checksum is calculated for the model and embedded into the generated executable. This checksum is used to check that a parameter set passed to the executable is compatible with it.

```
rtwbuild(mdlName);
```

```
### Starting build procedure for model: rtwdemo_rsim_vdp
### Successful completion of build procedure for model: rtwdemo_rsim_vdp
```

Step 3. Get the Default Parameter Set for the Model

Get the default rtP structure (parameter set) for the model. The modelChecksum field in the rtP structure is the structural checksum of the model. This must match the checksum embedded in the RSim executable (generated in step 2 above). If the two checksums do not match, the executable will generate an error. `rsimgetrtp` generates an rtP structure with entries for the named tunable variables INIT_X1, INIT_X2 and MU in the model.

```
rtp = rsimgetrtp(mdlName)
```

```
rtp =

  struct with fields:

         modelChecksum: [3.6535e+09 1.3537e+09 613731802 2.5612e+09]
            parameters: [1x1 struct]
    globalParameterInfo: [1x1 struct]
```

Step 4. Create Parameter Sets

Using the rtp structure from step 4, we build a structure array with different values for the tunable variables in the model. As mentioned earlier, in this example we want to see how the state trajectories evolve for different initial values for the states x1 and x2 in the model. Hence we generate different parameter sets with different values for INIT_X1 and INIT_X2 and leave the tunable variable MU at the default value.

```
INIT_X1_vals = -5:1:5;
INIT_X2_vals = -5:1:5;
```

```
MU_vals = 1;
nPrmSets = length(INIT_X1_vals)*length(INIT_X2_vals)*length(MU_vals)
```

```
nPrmSets =

   121
```

Note that in this example we have nPrmSets parameter sets, i.e., we need to run that many simulations. Initialize aggData, which is a structure array used to hold the parameter set and the corresponding results.

```
aggData = struct('tout', [], 'yout', [], ...
                 'prms', struct('INIT_X1',[],'INIT_X2',[], 'MU', []))
aggData = repmat(aggData, nPrmSets, 1);
```

```
aggData =

  struct with fields:

    tout: []
    yout: []
    prms: [1x1 struct]
```

The utility function rsimsetrtpparam is a convenient way to build the rtP structure by adding parameter sets one at a time with different parameters values.

```
idx = 1;
for iX1 = INIT_X1_vals
    for iX2 = INIT_X2_vals
        for iMU = MU_vals
            rtp = rsimsetrtpparam(rtp,idx,'INIT_X1',iX1,'INIT_X2',iX2,'MU',iMU);
            aggData(idx).prms.INIT_X1 = iX1;
            aggData(idx).prms.INIT_X2 = iX2;
            aggData(idx).prms.MU      = iMU;
            idx = idx + 1;
        end
    end
end
```

Save the rtP structure array with the parameter sets to a MAT-file.

```
save(prmFileName,'rtp');
```

Step 5. Create a Batch File

We create a batch/script file to run the RSim executable over the parameter sets. Each run reads the specified parameter set from the parameter MAT-file and writes the results to the specified output MAT-file. Note that we use the time out option so that if a particular run were to hang (because the model may have a singularity for that particular parameter set), we abort the run after the specified time limit is exceeded and proceed to the next run.

For example, the command (on Windows®)

```
  model.exe -p prm.mat@3 -o run3.mat -L 3600 2>&1>> run.log
```

specifies using the third parameter set from the rtP structure in prm.mat, writing the results to run3.mat, and aborting execution if a run takes longer than 3600 seconds of CPU time. In addition, messages from model.exe while it is running are piped to run.log. In case of problems, we can look at run.log to help debug.

```
fid = fopen(batFileName, 'w');
idx = 1;
for iX1 = INIT_X1_vals
    for iX2 = INIT_X2_vals
        for iMU = MU_vals
            outMatFile = [mdlName, '_run',num2str(idx),'.mat'];
            cmd = [exeFileName, ...
                   ' -p ', prmFileName, '@', int2str(idx), ...
                   ' -o ', outMatFile, ...
                   ' -L 3600'];
            if ispc
                cmd  = [cmd, ' 2>&1>> ', logFileName];
            else % (unix)
                cmd  = ['.' filesep cmd, ' 1> ', logFileName, ' 2>&1'];
            end
            fprintf(fid, ['echo "', cmd, '"\n']);
            fprintf(fid, [cmd, '\n']);
            idx = idx + 1;
        end
    end
end
if isunix,
    system(['touch ', logFileName]);
    system(['chmod +x ', batFileName]);
end
fclose(fid);
```

Creating a batch file to run the simulations enables us to call the system command once to run the simulations (or even run the batch script outside MATLAB®) instead of calling the system command in a loop for each simulation. This results in a performance improvement because the system command has significant overhead.

Step 6. Execute Batch File to Run Simulations

Run the batch/script file, which runs the RSim executable once for each parameter set and saves the results to a different MAT-file each time. Note that this batch file can be run from outside MATLAB®.

```
[stat, res] = system(['.' filesep batFileName]);
if stat ~= 0
    error(['Error running batch file ''', batFileName, ''' :', res]);
end
```

In this example we put the simulation runs into one batch file, ran the batch file to sequentially run 'n' simulations over 'n' parameter sets. For your application this script can be modified to generate multiple batch files, and these batch files are run in parallel by distributing them across multiple computers. Also the batch files can be run without launching MATLAB®.

Step 7. Load Output MAT-files and Collate the Results

Here we collect the simulation results from the output MAT-files into the aggData structure. If the output MAT-file corresponding to a particular run is not found, we set the results corresponding to that run to be NaN (not a number). This situation can occur if a simulation run with a particular set of parameters encounters singularities in the model.

```
idx = 1;
for iX1 = INIT_X1_vals
    for iX2 = INIT_X2_vals
        for iMU = MU_vals
            outMatFile = [mdlName, '_run',num2str(idx),'.mat'];
            if exist(outMatFile,'file')
                load(outMatFile);
                aggData(idx).tout = rt_tout;
                aggData(idx).yout = rt_yout;
            else
                aggData(idx).tout = nan;
                aggData(idx).yout = nan;
            end
            idx = idx + 1;
        end
```

```
    end
end
```

Save the aggData structure to the results MAT-file. At this point, you can delete the other MAT-files, as the aggData data structure contains the aggregation of input (parameters sets) and output data (simulation results).

```
save(aggDataFile,'aggData');
disp(['Took ', num2str(cputime-startTime), ...
      ' seconds to generate results from ', ...
      num2str(nPrmSets), ' simulation runs (Steps 2 to 7).']);
```

```
Took 16.3906 seconds to generate results from 121 simulation runs (Steps 2 to 7).
```

Step 8. Analyze Simulation Results

We now have data to plot the phase diagram (X2 versus X1) with different initial values for x1 and x2. The diagram shows that, irrespective of the initial condition, the Van der Pol oscillator converges to its natural oscillator mode.

```
colors = {'b','g','r','c','m','y','k'}; nColors = length(colors);
for idx = 1:nPrmSets
    col = colors{idx - nColors*floor(idx/nColors) + 1};
    plot(aggData(idx).prms.INIT_X1, aggData(idx).prms.INIT_X2, [col,'x'], ...
         aggData(idx).yout(:,1), aggData(idx).yout(:,2),col);
    hold on
end
grid on
xlabel('X1');
ylabel('X2');
axis('square');
title('Phase diagram for Van der Pol equation');
```

Run Batch Simulations Without Recompiling Generated Code

This example shows how to run batch simulations without recompiling the generated code. The example modifies input signal data and model parameters by reading data from a MAT-file. In the first part (steps 1-5), ten parameter sets are created from the Simulink® model by changing the transfer function damping factor. The ten parameter sets are saved to a MAT-file, and the RSim executable reads the specified parameter set from the file. In the second part (step 6-7) of this example, five sets of signal data chirps are created with increasingly high frequencies. In both parts, the RSim executable runs the set of simulations and creates output MAT-files containing the specific simulation result. Finally, a composite of runs appears in a MATLAB® figure.

To quickly run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. See “What Is Acceleration?” (Simulink).

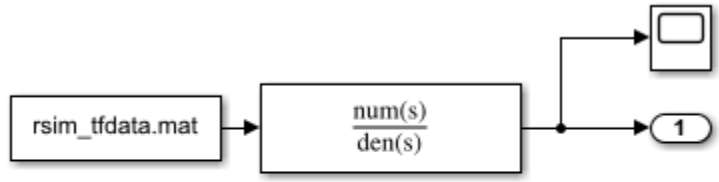
Step 1. Preparation

Make sure the current directory is writable because this example will be creating files.

```
[stat, fa] = fileattrib(pwd);
if ~fa.UserWrite
    disp('This script must be run in a writable directory');
    return;
end
```

Open the model and configure it to use the RSim target. For more information on doing this graphically and setting up other RSim target related options, look here.

```
mdlName = 'rtwdemo_rsimtf';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc',[]);
```



The MAT-file rsim_tfdata.mat is required in the local directory.

```
if ~isempty(dir('rsim_tfdata.mat')),
    delete('rsim_tfdata.mat');
end
str1 = fullfile(matlabroot,'toolbox','rtw','rtwdemos','rsimdemos','rsim_tfdata.mat');
str2 = ['copyfile(''', str1, ''','''rsim_tfdata.mat''','''writable''')'];
eval(str2);
```

Step 2. Build the Model

Build the RSim executable for the model. During the build process, a structural checksum is calculated for the model and embedded into the generated executable. This checksum is used to check that a parameter set passed to the executable is compatible with it.

```
evalin('base','w = 70;')
evalin('base','theta = 1.0;')
disp('Building compiled RSim simulation.')
rtwbuild(mdlName);
```

```
Building compiled RSim simulation.
### Starting build procedure for model: rtwdemo_rsimtf
### Successful completion of build procedure for model: rtwdemo_rsimtf
```

Step 3. Get the Default Parameter Set and Create 10 Parameters Sets

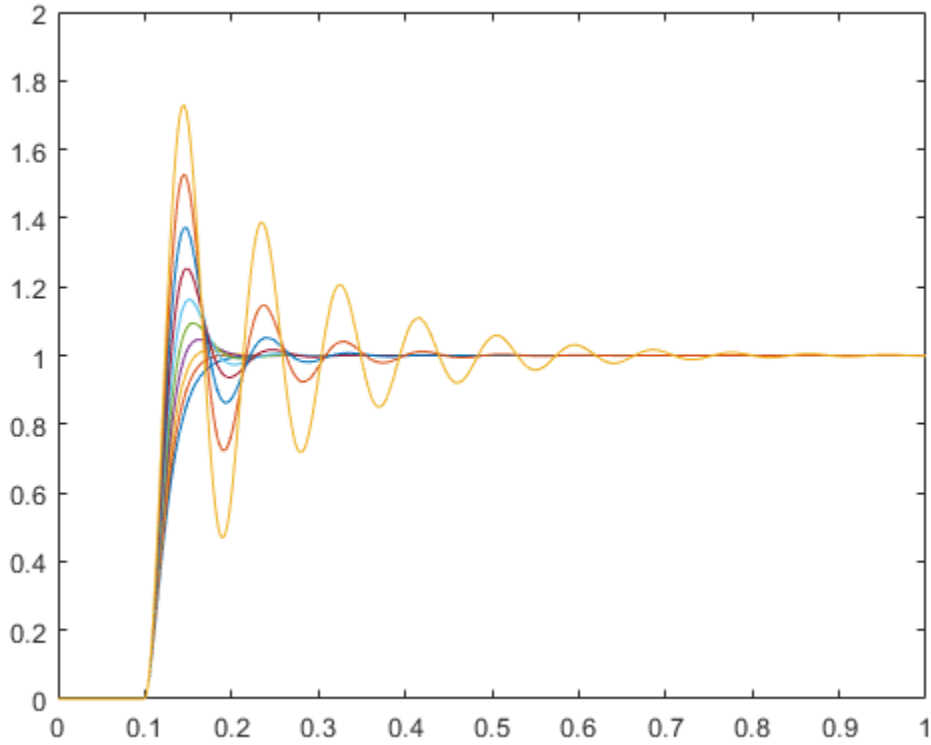
```
disp('Creating rtP data files')
for i=1:10
  % Extract current rtP structure using new damping factor.
  [rtpstruct]=evalin('base','rsimgetrtp(''rtwdemo_rsimtf'');');
  savestr = strcat('save params',num2str(i),'.mat rtpstruct');
```

```
  eval(savestr);
  evalin('base','theta = theta - .1;');
end
disp('Finished creating parameter data files.')
```

```
Creating rtP data files
Finished creating parameter data files.
```

Step 4. Run 10 RSim Simulations Using New Parameter Sets and Plot the Results

```
figure
for i=1:10
  % Bang out and run a simulation using new parameter data
  runstr = ['.', filesep, 'rtwdemo_rsimtf -p params',num2str(i),'.mat', ' -v'];
  [status, result] = system(runstr);
  if status ~= 0, error(result); end
  % Load simulation data into MATLAB for plotting.
  load rtwdemo_rsimtf.mat;
  axis([0 1 0 2]);
  plot(rt_tout, rt_yout)
  hold on
end
```



The plot shows 10 simulations, each using a different damping factor.

Step 5. Set Up a Time Vector and an Initial Frequency Vector

The time vector has 4096 points in the event we want to do windowing and spectral analysis on simulation results.

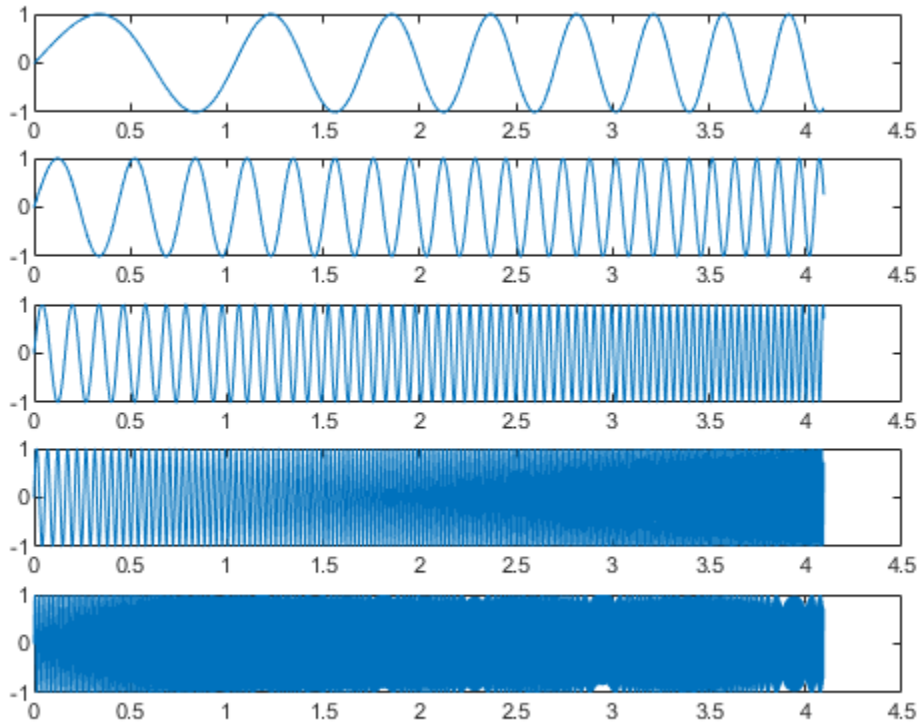
```
dt = .001;
nn = [0:1:4095];
t = dt*nn; [m,n] = size(t);
wlo = 1; whi = 4;
omega = [wlo:((whi-wlo)/n):whi - (whi-wlo)/n];
```

Step 6. Create 5 Sets of Signal Data in MAT Files

Creating .mat files with chirp data.

```
disp('This part of the example illustrates a sequence of 5 plots. Each')
disp('plot shows an input chirp signal of certain frequency range.')
for i = 1:5
  wlo = whi; whi = 3*whi; % keep increasing frequencies
  omega = [wlo:((whi-wlo)/n):whi - (whi-wlo)/n];
  % In a real application we recommend shaping the chirp using
  % a windowing function (hamming or hanning window, etc.)
  % This example does not use a windowing function.
  u      = sin(omega.*t);
  tudata = [t;u];
  % At each pass, save one more set of tudata to the next
  % .mat file.
  savestr = strcat('save sweep',num2str(i),'.mat tudata');
  eval(savestr);
  % Display each chirp. Note that this is only input data.
  % Simulations have not been run yet.
  plotstr = strcat('subplot(5,1,',num2str(i),');');
  eval(plotstr);
  plot(t,u)
  pause(0.3)
end
```

```
This part of the example illustrates a sequence of 5 plots. Each
plot shows an input chirp signal of certain frequency range.
```



Step 7. Run the RSim Compiled Simulation Using New Signal Data

Replace the original signal data (rsim_tfdata.mat) with the files sweep1.mat, sweep2.mat, and so on.

```
disp('Starting batch simulations.')
for i = 1:5
  % Bang out and run the next set of data with RSim
  runstr = ['.', filesep, 'rtwdemo_rsimtf -f rsim_tfdata.mat=sweep', ...
            num2str(i),'.mat -v -tf 4.096'];
  [status, result] = system(runstr);
  if status ~= 0, error(result); end
  % Load the data to MATLAB and plot the results.
  load rtwdemo_rsimtf.mat
```

```
  plotstr = strcat('subplot(5,1,',num2str(i),');');
  eval(plotstr);
  plot(rt_tout, rt_yout); axis([0 4.1 -3 3]);
end
zoom on
% cleanup
evalin('base','clear w theta')
disp('This part of the example illustrates a sequence of 5 plots. Each plot')
disp('shows the simulation results for the next frequency range. Using the')
disp('mouse, zoom in on each signal to observe signal amplitudes.')
close_system(mdlName, 0);
```

```
Starting batch simulations.
This part of the example illustrates a sequence of 5 plots. Each plot
shows the simulation results for the next frequency range. Using the
mouse, zoom in on each signal to observe signal amplitudes.
```

Use MAT-Files to Feed Data to Inport Blocks for Rapid Simulations

This example shows how the RSim -i option in Simulink® Coder™ lets you use a MAT-file as the input data source for Inport blocks for rapid simulations. The data in such a MAT-file can be presented in any of the following formats:

1. One variable that defines a time/input data matrix of double values.
2. One variable that defines a structure that uses a combination of Simulink® data types.
3. Multiple variables, each defining a structure that uses a combination of Simulink® data types.

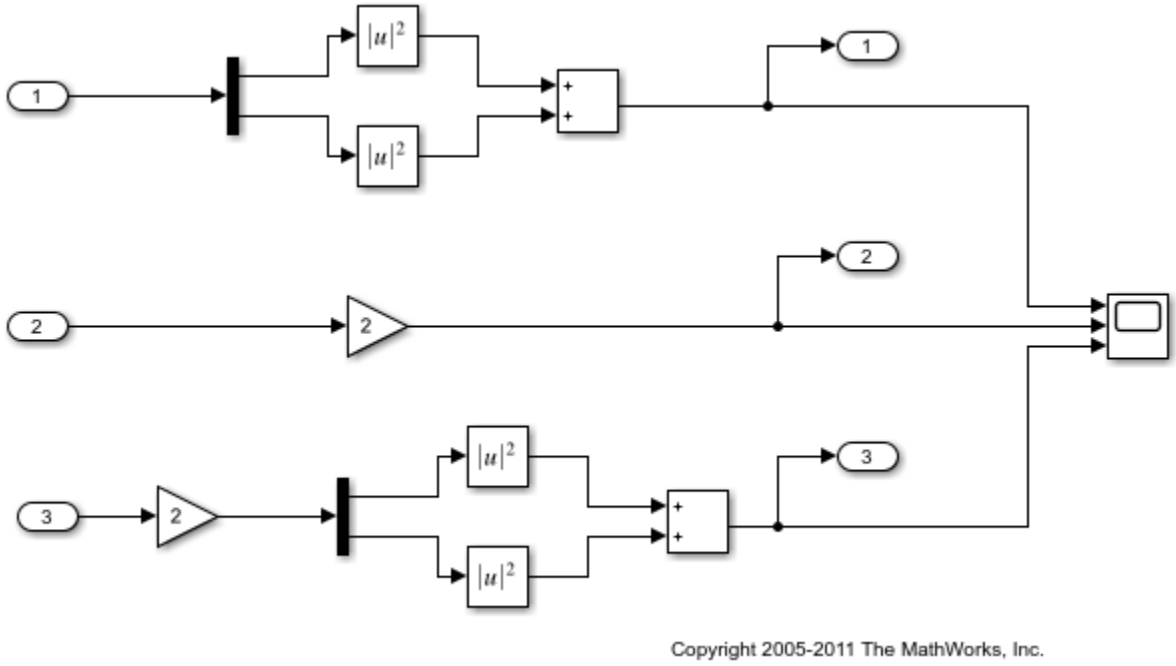
This flexibility lends itself well to applications for which you must run simulations over a range of input data stored in different data files. This example explains how to use this feature.

To quickly run multiple simulations in the Simulink environment, consider using rapid accelerator instead of RSim. See “What Is Acceleration?” (Simulink).

Step 1. Preparation

Open the model and configure it to use the Simulink® Coder™ RSim target. For more information on doing this graphically and setting up other RSim target related options, look here.

```
mdlName = 'rtwdemo_rsim_i';
open_system(mdlName);
cs = getActiveConfigSet(mdlName);
cs.switchTarget('rsim.tlc',[]);
```



Step 2. Configure the Inport Blocks

To use the RSim -i option, you must configure each Inport block properly. You can double-click an Inport block to view its properties. By default, Inport blocks inherit their properties from downstream blocks. Before you can import data from external MAT-files, you must set the parameters of each Inport block to match the data in the MAT file. In most cases, the following parameters of an Inport block must be set: Interpolate Data, Port Dimensions, Data Type, and Signal Type. For more information on these parameters, click the Help button. In this example model, three Inport blocks exist. We want Inport 1 and Inport 2 to interpolate between data, and Inport 3 to not interpolate. The dimension of the Inport blocks are 2, 1, and 2, respectively. Signals are real. The settings are as follows:

```
for i =1:3
    portName      =['/In', num2str(i)];
    Interp        = get_param(strcat(mdlName,portName),'Interpolate');
    PortDimension = get_param(strcat(mdlName,portName),'PortDimensions');
    DataType      = get_param(strcat(mdlName,portName),'OutDataTypeStr');
```

```
    SignalType    = get_param(strcat(mdlName,portName),'SignalType');
    s1= sprintf('For inport %s ', portName(2:4));
    disp('-----------------------------');
    disp(s1);
    s2= sprintf('The interpolation flag is %s', Interp);
    disp(s2);
    s3 = sprintf('    The port dimension is %s', PortDimension);
    disp(s3);
    s4 = sprintf('        The data type  is %s', DataType);
    disp(s4);
    s5 = sprintf('       The signal type is %s\n', SignalType);
    disp(s5);
end

-----------------------------
For inport In1
The interpolation flag is on
    The port dimension is 2
        The data type  is double
       The signal type is real

-----------------------------
For inport In2
The interpolation flag is on
    The port dimension is 1
        The data type  is double
       The signal type is real

-----------------------------
For inport In3
The interpolation flag is off
    The port dimension is 2
        The data type  is double
       The signal type is real
```

Step 3. Build the Model

Build the RSim executable for the model. During the build process, a structural checksum is calculated for the model and embedded into the generated executable. This checksum is used to check that a parameter set passed to the executable is compatible with it.

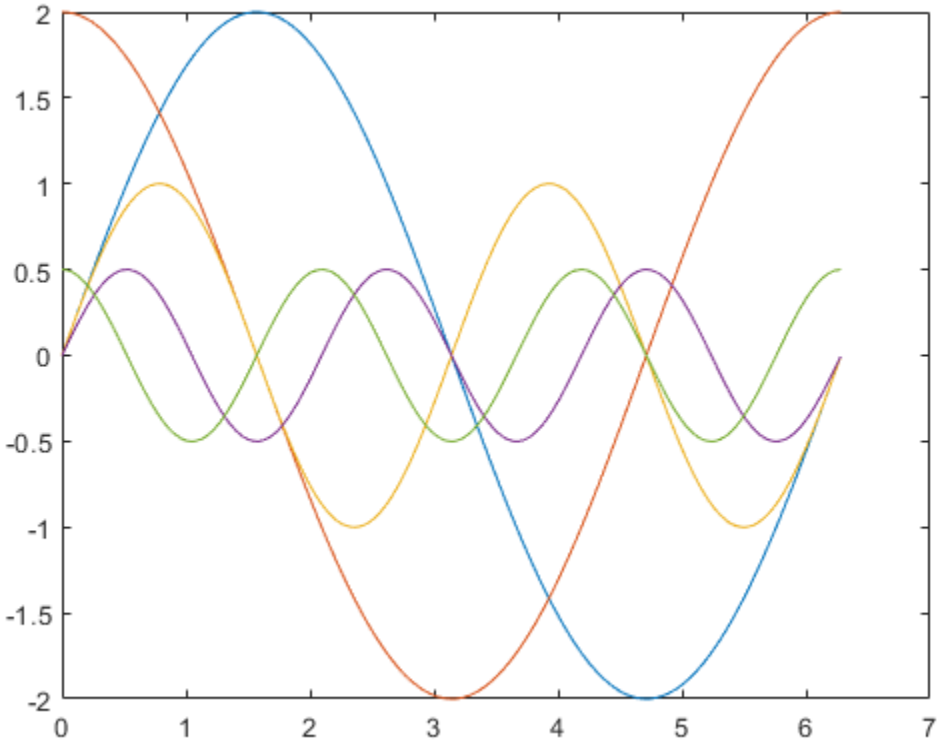
```
evalc('rtwbuild(mdlName)');
```

Step 4. The Input Signals

Once the Inport block is configured, the data file should be prepared based on the Inport blocks. The following figure shows the input signals to be used.

```
t=[0:0.01:2*pi]';
s1 = [2*sin(t) 2*cos(t)];
s2 = sin(2*t);
s3 = [0.5*sin(3*t) 0.5*cos(3*t)];
figure;
plot(t, [s1 s2 s3]);
disp('The following figure displays the input signals.');
```

```
The following figure displays the input signals.
```



Step 5. Prepare the MAT-File

Generally, the MAT-file can be created from a workspace variable. The RSim -i option supports three data file formats:

1) The MAT-file contains one variable in TU matrix format of doubles. For this format, the first column is the time vector and the remaining columns are input vectors. The number of columns in the TU matrix equals the sum of the dimensions of the root Inport blocks plus 1. The following MATLAB® code generates a MAT-file containing one variable var_matrix in TU matrix format. Note that you can use this format only if the input ports in your model have the same data type.

```
t=[0:0.1:2*pi]';
Ina1 = [2*sin(t) 2*cos(t)];
Ina2 = sin(2*t);
Ina3 = [0.5*sin(3*t) 0.5*cos(3*t)];
var_matrix = [ t Ina1 Ina2 Ina3];
save rsim_i_matrix.mat var_matrix;
disp('rsim_i_matrix.mat contains one variable var_matrix in TU matrix format.');
```

```
rsim_i_matrix.mat contains one variable var_matrix in TU matrix format.
```

2) The MAT-file contains one variable in structure format. For this format, the variable must contain two fields called time and signals. If one of the Inport block sets Interpolate Data to On, then the time field of the variable must not be an empty vector. Also, the width of the signals must equal the total width of the Inport blocks. The following code generates a MAT-file that contains one variable var_matrix in signal variable structure format. This format is more flexible than the TU matrix format because it can support input ports with different data types.

```
t= [0:0.1:2*pi]';
var_single_struct.time = t;
var_single_struct.signals(1).values(:,1) = 2*sin(t);
var_single_struct.signals(1).values(:,2) = 2*cos(t);
var_single_struct.signals(2).values = sin(2*t);
var_single_struct.signals(3).values(:,1) = 0.5*sin(3*t) ;
var_single_struct.signals(3).values(:,2) = 0.5*cos(3*t) ;
v=[var_single_struct.signals(1).values var_single_struct.signals(2).values ...
    var_single_struct.signals(3).values ];
save rsim_i_single_struct.mat var_single_struct;
disp('rsim_i_single_struct.mat contains one variable var_single_struct in')
disp('struct format.');
```

```
rsim_i_single_struct.mat contains one variable var_single_struct in
struct format.
```

3) The MAT-file contains multiple variables in structure format. For this format, the number of variables equals the number of Inport blocks. Different variables can have different time vectors. The following code generates a MAT-file that contains multiple variables, each in structure format. This is the most flexible format because it allows each Inport block to have its own time vector.

```
t= [0:0.1:2*pi]';
Inb1.time = t;
Inb1.signals.values(:,1) = 2*sin(t);
Inb1.signals.values(:,2) = 2*cos(t);
t= [0:0.2:2*pi]';
Inb2.time = t;
Inb2.signals.values(:,1) = sin(2*t);
t= [0:0.1:2*pi]';
Inb3.time =  t;
Inb3.signals.values(:,1) = 0.5*sin(3*t);
Inb3.signals.values(:,2) = 0.5*cos(3*t);
save rsim_i_multi_struct.mat Inb1;
save rsim_i_multi_struct.mat Inb2 -append;
save rsim_i_multi_struct.mat Inb3 -append;
disp('rsim_i_multi_struct.mat contains three variables Inb1\Inb2\Inb3');
disp('in struct format. Note that command save -append option must be');
disp('used to generate the MAT-file to preserve the order of the');
disp('variables in the MAT-file generated. The command:')
disp('save rsim_i_multi_struct.mat Inb1 Inb2 Inb3 might not preserve');
disp('the order of the variables in the MAT-file and you should not use it');
disp('to generate the MAT-file.');
```

```
rsim_i_multi_struct.mat contains three variables Inb1\Inb2\Inb3
in struct format. Note that command save -append option must be
used to generate the MAT-file to preserve the order of the
variables in the MAT-file generated. The command:
save rsim_i_multi_struct.mat Inb1 Inb2 Inb3 might not preserve
the order of the variables in the MAT-file and you should not use it
to generate the MAT-file.
```

Step 6. Run 3 RSim Simulations Using Different Files and Plot the Results

RSim -i options can also be used for batch mode simulation. Prepare different MAT-files and run the RSim target with them.

```
figure
fileName = ({'rsim_i_matrix', 'rsim_i_single_struct', 'rsim_i_multi_struct'});
for i=1:3
    % bang out and run a simulation using new parameter data
    name = fileName(i);
    runstr = ['.', filesep, 'rtwdemo_rsim_i -i ',char(name),'.mat', ' -v'];
    evalc('system(runstr)');
    pause(0.5);
    % load simulation data into MATLAB(R) for plotting.
    load rtwdemo_rsim_i.mat;
    subplot(3,1,i);
    axis([0,6, -5, 5]);
    plot(rt_tout, rt_yout);
    hold on
end

disp('This part of the example illustrates a sequence of 3 plots. Each plot');
disp('shows the simulation results by using input MAT-file with different');
disp('variable format. Notice that the model is compiled only once.');
close_system(mdlName, 0);
```

```
This part of the example illustrates a sequence of 3 plots. Each plot
shows the simulation results by using input MAT-file with different
variable format. Notice that the model is compiled only once.
```

Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target

S-functions are an important class of system target file for which the code generator can produce code. The ability to encapsulate a subsystem into an S-function allows you to increase its execution efficiency and facilitate code reuse.

The following sections describe the properties of S-function targets and illustrate how to generate them. For more details on the structure of S-functions, see “C/C++ S-Function Basics” (Simulink).

In this section...
“About the S-Function Target” on page 60-59
“Create S-Function Blocks from a Subsystem” on page 60-62
“Tunable Parameters in Generated S-Functions” on page 60-66
“System Target File” on page 60-68
“Checksums and the S-Function Target” on page 60-68
“Generated S-Function Compatibility” on page 60-69
“S-Function Target Limitations” on page 60-69

About the S-Function Target

Using the S-function target, you can build an S-function component and use it as an S-Function block in another model. The following sections describe deployment considerations for the S-function target.

- “Required Files for S-Function Deployment” on page 60-60
- “Sample Time Propagation in Generated S-Functions” on page 60-61
- “Choose a Solver Type” on page 60-61

The `'S-Function'` value for `CodeFormat` TLC variable used by the S-function target generates code that conforms to the Simulink C MEX S-function application programming interface (API). Applications of this format include

- Conversion of a model to a component. You can generate an S-Function block for a model, `m1`. Then, you can place the generated S-Function block in another model, `m2`. Regenerating code for `m2` does not require regenerating code for `m1`.

- Conversion of a subsystem to a component. By extracting a subsystem to a separate model and generating an S-Function block from that model, you can create a reusable component from the subsystem. See “Create S-Function Blocks from a Subsystem” on page 60-62 for an example of this procedure.
- Speeding up simulation. Often, an S-function generated from a model performs more efficiently than the original model.
- Code reuse. You can incorporate multiple instances of one model inside another without replicating the code for each instance. Each instance continues to maintain its own unique data.

You can place a generated S-function block into another model from which you can generate another S-function. This approach allows any level of nested S-functions. For limitations related to nesting, see “Limitations on Nesting S-Functions” on page 60-74.

Note While the S-function target provides a means to deploy an application component for reuse while shielding its internal logic from inspection and modification, the preferred solutions for protecting intellectual property in distributed components are:

- The protected model, a referenced model that hides all block and line information. For more information, see “Reference Protected Models from Third Parties” (Simulink).
- The shared library system target file, used to generate a shared library for a model or subsystem for use in a system simulation external to Simulink. For more information, see “Package Generated Code as Shared Libraries” on page 61-2.

Required Files for S-Function Deployment

There are different files required to deploy a generated S-Function block for simulation versus code generation.

To deploy your generated S-Function block for inclusion in other models *for simulation*, you need only provide the binary MEX-file object that was generated in the current working folder when the S-Function block was created. The required file is:

- `subsys_sf.mexext`

where `subsys` is the subsystem name and `mexext` is a platform-dependent MEX-file extension (see `mexext`). For example, `SourceSubsys_sf.mexw64`.

To deploy your generated S-Function block for inclusion in other models *for code generation*, you must provide all of the files that were generated in the current working folder when the S-Function block was created. The required files are:

- *subsys*`_sf.c` or `.cpp`, where *subsys* is the subsystem name (for example, `SourceSubsys_sf.c`)
- *subsys*`_sf.h`
- *subsys*`_sf.`*mexext*, where *mexext* is a platform-dependent MEX-file extension (see `mexext`)
- Subfolder *subsys*`_sfcn_rtw` and its contents

Note The generated S-function code uses **Configuration Parameters > Hardware Implementation** parameter values that match the host system on which the function was built. When you use the S-function in a model for code generation, make sure that these parameter values for the model match the parameter values of the S-function.

Sample Time Propagation in Generated S-Functions

A generated S-Function block can inherit its sample time from the model in which it is placed if certain criteria are met. Conditions that govern sample time propagation for both Model blocks and generated S-Function blocks are described in "Referenced Model Sample Times" (Simulink) and "Inherited Sample Time for Referenced Models" on page 4-25.

To generate an S-Function block that meets the criteria for inheriting sample time, you must constrain the solver for the model from which the S-Function block is generated. On the **Solver** configuration parameters dialog box pane, set **Type** to `Fixed-step` and **Periodic sample time constraint** to `Ensure sample time independent`. If the model is unable to inherit sample times, this setting causes the Simulink software to display an error message when building the model. For more information about this option, see "Periodic sample time constraint" (Simulink).

Choose a Solver Type

The table shows the possible combinations of top-level model solver types as these types relate to whether the model has discrete or continuous sample times and solver types for generated S-functions.

Top-Level Model Solver Options and Sample Times

	Model Configuration Parameters: Top-level model configuration	
Sample Times	**Solver Options, Type: Variable-step**	**Solver Options, Type: Fixed-step**
Discrete	Generated S-function requires a variable-step solver	Generated S-function can have a variable-step solver or a fixed-step solver
Continuous	Generated S-function requires a variable-step solver	Generated S-function requires a fixed-step solver

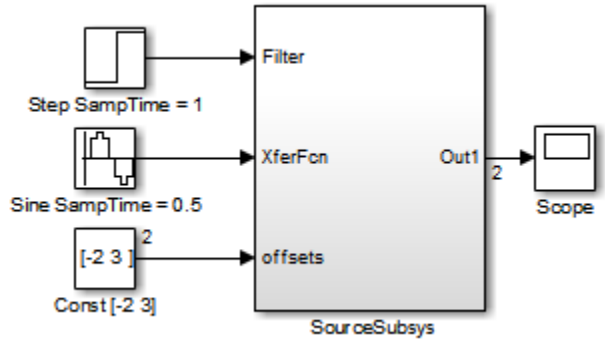
Note S-functions generated from a subsystem have parameters that are hardcoded into the block. Simulink calculates parameters such as sample time when it generates the block, not during simulation run time. It is important to verify whether the generated S-Function block works as expected in the destination model.

Create S-Function Blocks from a Subsystem

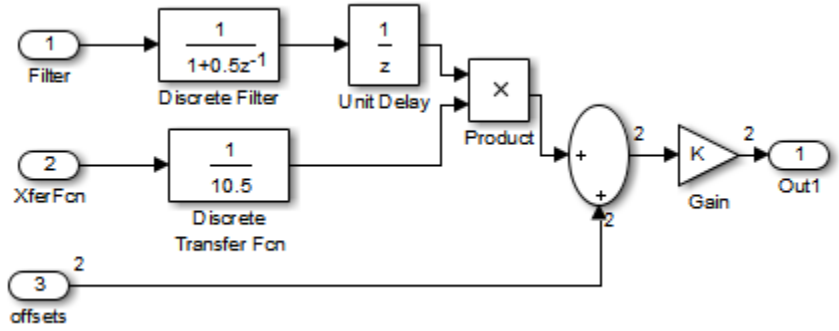
This section illustrates how to extract a subsystem from a model and generate a reusable S-function component from it.

The next figure shows `SourceModel`, a simple model that inputs signals to a subsystem. The subsequent figure shows the subsystem, `SourceSubsys`. The signals, which have different widths and sample times, are:

- A Step block with sample time 1
- A Sine Wave block with sample time 0.5
- A Constant block whose value is the vector [-2 3]



SourceModel



SourceSubsys

The objective is to extract `SourceSubsys` from the model and build an S-Function block from it, using the S-function target. The S-Function block must perform identically to the subsystem from which it was generated.

In this model, `SourceSubsys` inherits sample times and signal widths from its input signals. However, S-Function blocks created from a model using the S-function target has all signal attributes (such as signal widths or sample times) hard-wired. (The sole exception to this rule concerns sample times, as described in “Sample Time Propagation in Generated S-Functions” on page 60-61.)

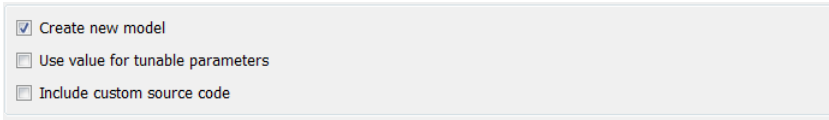
In this example, you want the S-Function block to retain the properties of `SourceSubsys` as it exists in `SourceModel`. Therefore, before you build the subsystem as a separate S-function component, you must set the inport sample times and widths explicitly. In addition, the solver parameters of the S-function component must be the same as those parameters of the original model. The generated S-function component operates identically to the original subsystem (see “Choose a Solver Type” on page 60-61 for more information).

To build `SourceSubsys` as an S-function component,

1. Create a new model and copy/paste the `SourceSubsys` block into the empty window.
2. Set the signal widths and sample times of inports inside `SourceSubsys` such that they match those of the signals in the original model. Inport 1, `Filter`, has a width of 1 and a sample time of 1. Inport 2, `Xferfcn`, has a width of 1 and a sample time of 0.5. Inport 3, `offsets`, has a width of 2 and a sample time of 0.5.
3. The generated S-Function block should have three inports and one outport. Connect inports and an outport to `SourceSubsys`, as shown in the next figure.

   The signal widths and sample times are propagated to these ports.
4. Set the solver type, mode, and other solver parameters such that they are identical to those of the source model. This is easiest to do if you use Model Explorer.
5. In the Configuration Parameters dialog box, go to the **Code Generation** pane.
6. Click **Browse** to open the System Target File Browser.
7. In the System Target File Browser, select the S-function target, `rtwsfcn.tlc`, and click **OK**.

8 Select the **S-Function Target** pane. Make sure that **Create new model** is selected, as shown in the next figure:



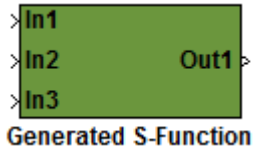
When this option is selected, the build process creates a new model after it builds the S-function component. The new model contains an S-Function block, linked to the S-function component.

Click **Apply**.

9 Save the new model containing your subsystem, for example as `SourceSubsys`.

10 Build the model.

11 The build process produces the S-function component in the working folder. After the build, a new model window is displayed.

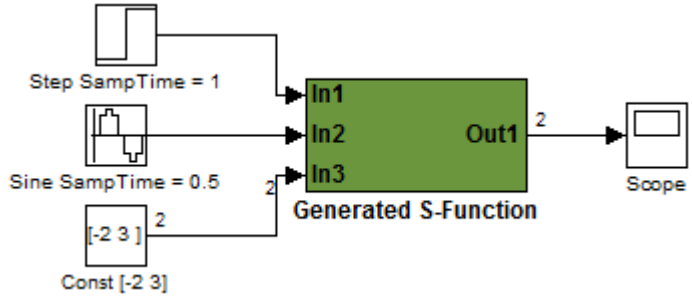


Optionally you can save the generated model, for example as `SourceSubsys_Sfunction`.

12 You can now copy the S-Function block generated from the new model and use it in other models or in a library.

Note For a list of files required to deploy your S-Function block for simulation or code generation, see “Required Files for S-Function Deployment” on page 60-60.

The next figure shows the S-Function block plugged into the original model. Given identical input signals, the S-Function block performs identically to the original subsystem.



Generated S-Function Configured Like SourceModel

The speed at which the S-Function block executes is typically faster than the original model. This difference in speed is more pronounced for larger and more complicated models. By using generated S-functions, you can increase the efficiency of your modeling process.

Tunable Parameters in Generated S-Functions

You can use tunable parameters in generated S-functions in two ways:

- Use the **Generate S-function** feature (see “Generate S-Function from Subsystem” on page 12-74).

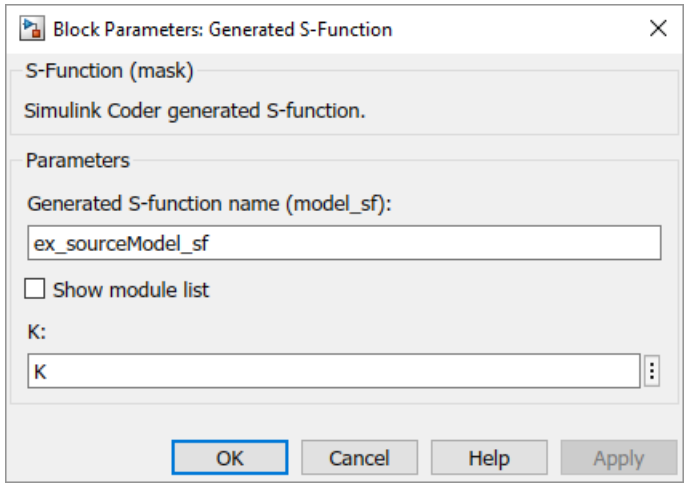
  or

- Use the Model Parameter Configuration dialog box (see “Declare Workspace Variables as Tunable Parameters Using the Model Parameter Configuration Dialog Box” (Simulink Coder)) to declare desired block parameters tunable.

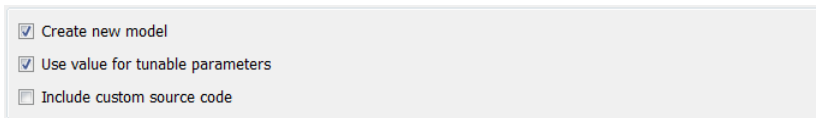
Block parameters that are declared tunable with the `auto` storage class in the source model become tunable parameters of the generated S-function. These parameters do not become part of a generated *`model`*`_P` (formerly `rtP`) parameter data structure, as they would in code generated from other targets. Instead, the generated code accesses these parameters by using MEX API calls such as `mxGetPr` or `mxGetData`. Your code should access these parameters in the same way.

For more information on MEX API calls, see “About C MEX S-Functions” (Simulink) and “Choosing a MATLAB API for Your Application” (MATLAB).

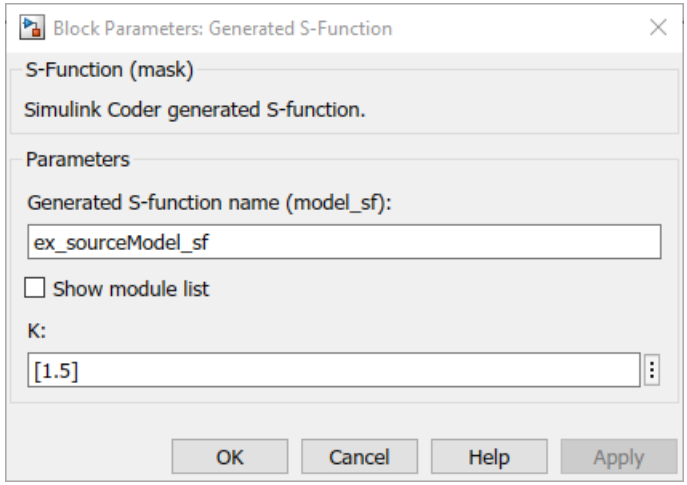
S-Function blocks created by using the S-function target are automatically masked. The mask displays each tunable parameter in an edit field. By default, the edit field displays the parameter by variable name, as in the following example.



You can choose to display the value of the parameter rather than its variable name by selecting **Use value for tunable parameters** on the **Code Generation > S-Function Target** pane of the Configuration Parameters dialog box.



When this option is chosen, the value of the variable (at code generation time) is displayed in the edit field, as in the following example.



System Target File

The `rtwsfcn.tlc` system target file is provided for use with the S-function target.

Checksums and the S-Function Target

The code generator creates a checksum for a model and uses the checksum during the build process for code reuse, model reference, and external mode features.

The code generator calculates a model checksum by

1. Calculating a checksum for each subsystem in the model. A subsystem's checksum is the combination of properties (data type, complexity, sample time, port dimensions, and so forth) of the subsystem's blocks.
2. Combining the subsystem checksums and other model-level information.

An S-function can add additional information, not captured during the block property analysis, to a checksum by calling the function `ssSetChecksumVal`. For the S-Function target, the value that gets added to the checksum is the checksum of the model or subsystem from which the S-function is generated.

The code generator applies the subsystem and model checksums as follows:

- Code reuse — If two subsystems in a model have the same checksum, the code generator produces code for one function only.
- Model reference — If the current model checksum matches the checksum when the model was built, the build process does not rebuild referenced models.
- External mode — If the current model checksum does not match the checksum of the code that is running on the target hardware, the build process generates an error.

Generated S-Function Compatibility

When you build a MEX S-function from your model, the code generator builds a level 2 noninlined S-function. Cross-release usage limitations on the generated code and binary MEX file (for example, `*.mexw64`) include:

- S-function target generated code from previous MATLAB release software is not compatible with newer releases. Do not recompile the generated code from a previous release with newer MATLAB release software. Use the same MATLAB release software to generate code for the S-function target and compile the code into a MEX file.
- You can use binary S-function MEX files generated from previous MATLAB release software with the same or newer releases with the same compatibility considerations as handwritten S-functions. For more information, see “S-Function Compatibility” (Simulink).
- The code generator can generate code and build an executable from a model that contains generated S-functions. This support requires that the S-functions are built with the same MATLAB release software that builds the model. It is not possible to incorporate a generated S-function MEX file from previous MATLAB release software into a model and build the model with newer releases.

S-Function Target Limitations

- “Limitations on Using Tunable Variables in Expressions” on page 60-70
- “Parameter Tuning” on page 60-70
- “Run-Time Parameters and S-Function Compatibility Diagnostics” on page 60-70
- “Limitations on Using Goto and From Block” on page 60-71
- “Limitations on Building and Updating S-Functions” on page 60-72
- “Unsupported Blocks” on page 60-73
- “SimState Not Supported for Code Generation” on page 60-73

Limitations on Using Tunable Variables in Expressions

Certain limitations apply to the use of tunable variables in expressions. When the code generator encounters an unsupported expression while producing code, a warning appears and the equivalent numeric value is generated in the code. For a list of the limitations, see “Tunable Expression Limitations” on page 32-135.

Parameter Tuning

The S-Function block does not support tuning of tunable parameters with:

- Complex values.
- Values or data types that are transformed to a constant (by setting the model configuration parameter **Optimization** > **Default parameter behavior** to `Inlined`).
- Data types that are not built-in.

If you select these tunable parameters (through the Generate S-Function for Subsystem dialog box):

- The software produces warnings during the build process.
- The generated S-Function block mask does not display these parameters.

Run-Time Parameters and S-Function Compatibility Diagnostics

If you set the **S-function upgrades needed** option on the **Diagnostics** > **Compatibility** pane of the Configuration Parameters dialog box to `warning` or `error`, the code generator instructs you to upgrade S-functions that you create with the **Generate S-function** feature. This is because the S-function system target file does not register run-time parameters. Run-time parameters are only supported for inlined S-Functions and the

generated S-Function supports features that prevent it from being inlined (for example, it can call or contain other noninlined S-functions).

You can work around this limitation by setting the **S-function upgrades needed** option to none.

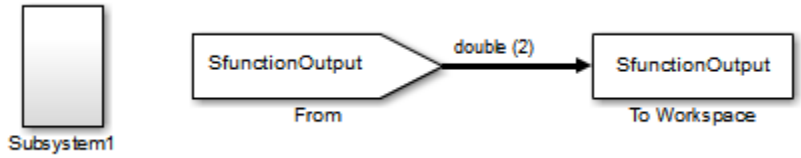
Limitations on Using Goto and From Block

When using the S-function system target file, the code generator restricts I/O to correspond to the root model Inport and Outport blocks (or the Inport and Outport blocks of the Subsystem block from which the S-function target was generated). No code is generated for Goto or From blocks.

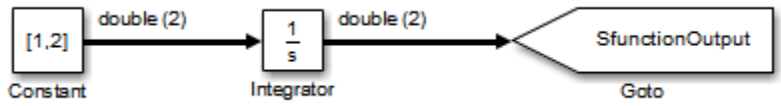
To work around this restriction, create your model and subsystem with the required Inport and Outport blocks, instead of using Goto and From blocks to pass data between the root model and subsystem. In the model that incorporates the generated S-function, you would then add Goto and From blocks.

Example Before Work Around

- Root model with a From block and subsystem, `Subsystem1`



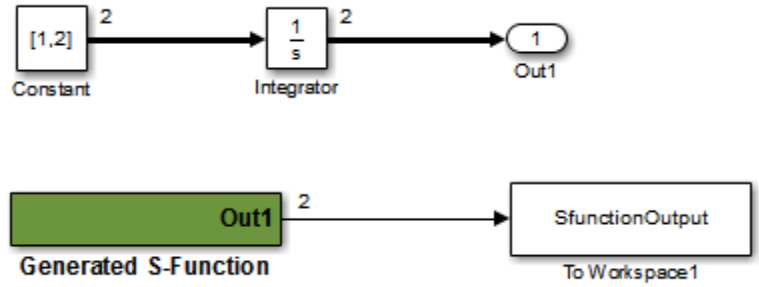
- `Subsystem1` with a Goto block, which has global visibility and passes its input to the From block in the root model



- `Subsystem1` replaced with an S-function generated with the S-Function target — a warning results when you run the model because the generated S-function does not implement the Goto block

Example After Work Around

An Outport block replaces the GoTo block in `Subsystem1`. When you plug the generated S-function into the root model, its output connects directly to the To Workspace block.



Limitations on Building and Updating S-Functions

The following limitations apply to building and updating S-functions using the S-function system target file:

- You cannot build models that contain Model blocks using the S-function system target file. This also means that you cannot build a subsystem module by right-clicking (or by using **Code > C/C++ Code > Build Selected Subsystem**) if the subsystem contains Model blocks. This restriction applies only to S-functions generated using the S-function target, not to ERT S-functions.
- If you modify the model that generated an S-Function block, the build process does not automatically rebuild models containing the generated S-Function block. This is in contrast to the practice of automatically rebuilding models referenced by Model blocks when they are modified (depending on the Model Reference **Rebuild** configuration setting).

- Handwritten S-functions without corresponding TLC files must contain exception-free code. For more information on exception-free code, see “Exception Free Code” (Simulink).

Unsupported Blocks

The S-function format does not support the following built-in blocks:

- Interpreted MATLAB Function block
- S-Function blocks containing any of the following:
  - MATLAB language S-functions (unless you supply a TLC file for C code generation)
  - Fortran S-functions (unless you supply a TLC file for C code generation)
  - C/C++ MEX S-functions that call into the MATLAB environment
- Scope block
- To Workspace block

The S-function format does not support blocks from the `embeddedtargetslib` block library.

SimState Not Supported for Code Generation

You can use `SimState` within C-MEX and Level-2 MATLAB language S-functions to save and restore the simulation state. See “S-Function Compliance with the ModelOperatingPoint” (Simulink). However, `SimState` is not supported for code generation, including with the S-function system target file.

Profiling Code Performance with TLC Hook Function Not Supported

Profiling the performance of generated code using the Target Language Compiler (TLC) hook function interface described in “Profile Code Execution Speed” (Simulink Coder) is not supported for the S-function target.

Note If you have an Embedded Coder license, see “Code Execution Profiling” for an alternative and simpler approach based on software-in-the-loop (SIL) or processor-in-the-loop (PIL) simulations.

Limitations on Nesting S-Functions

The following limitations apply to nesting a generated S-Function block in a model or subsystem from which you generate another S-function:

- The software does not support nonvirtual bus input and output signals for a nested S-function.
- You should avoid nesting an S-function in a model or subsystem having the same name as the S-function (possibly several levels apart). In such situations, the S-function can be called recursively. The software currently does not detect such loops in S-function dependency, which can result in aborting or hanging your MATLAB session. To prevent this from happening, be sure to name the subsystem or model to be generated as an S-function target uniquely, to avoid duplicating existing MEX filenames on the MATLAB path.

Limitations on User-Defined Data Types

The S-function system target file does not support the `HeaderFile` property that can be specified on user-defined data types, including those based on `Simulink.AliasType`, `Simulink.Bus`, and `Simulink.NumericType` objects. If a user-defined data type in your model uses the `HeaderFile` property to specify an associated header file, code generation with the S-function system target file disregards the value and does not generate a corresponding include statement.

Limitation on Right-Click Generation of an S-Function Target

If you generate an S-function target by right-clicking a Function-Call Subsystem block, the original subsystem and the generated S-function might not be consistent. An inconsistency occurs when the **States when enabling** parameter of the Trigger Port block inside the Function-Call Subsystem block is set to **inherit**. You must set the **States when enabling** parameter to **reset** or **held**, otherwise Simulink reports an error.

Limitation on S-Functions with Bus I/O Signals

If an S-function generated using the S-function target has bus input or output signals, the generated bus data structures might include padding to align fields of the bus elements with the Simulink representation used during simulation. However, if you insert the S-function in a model and generate code using a model target such as `grt.tlc`, the bus structure alignment generated for the model build might be incompatible with the padding generated for the S-function and might affect the numerical results of code execution. To make the structure alignment consistent between model simulation and

execution of the model code, for each `Simulink.Bus` object, you can modify the `HeaderFile` property to remove the unpadded bus structure header file. This will cause the bus typedefs generated for the S-function to be reused in the model code.

Limitation on Subsystems with Function-Call I/O Signals

The S-function target does not support creating an S-Function block from a subsystem that has a function-call trigger input or a function-call output.

Data Store Access

When an S-Function in your model accesses a data store during simulation, Simulink disables data store diagnostics.

- If you created the S-Function from a model, the diagnostic is disabled for global data stores as well.
- If you created the S-Function from a subsystem, the diagnostic is disabled for the following data stores:
  - Global data stores
  - Data stores placed outside the subsystem, but accessed by Data Store Read or Data Store Write blocks.

Cannot Specify Inport or Outport Block Parameters Through Subsystem Mask

You cannot specify any Inport or Outport block parameters through subsystem mask variables if you want to generate an S-Function block from the subsystem. The software produces an error when you try to run a simulation that uses the S-Function block, for example:

```
Invalid setting in 'testSystem/Subsystem/__OutputSSForSFun__/Out2'
for parameter 'PortDimensions'
...
```

Desktops in Embedded Coder

Package Generated Code as Shared Libraries

If you have an Embedded Coder license, you can package generated source code from a model component for easy distribution and shared use by building the code as a shared library—Windows dynamic link library (`.dll`), UNIX shared object (`.so`), or Macintosh OS X dynamic library (`.dylib`). You or others can integrate the shared library into an application that runs on a Windows, UNIX, or Macintosh OS X development computer. The generated `.dll`, `.so`, or `.dylib` file is shareable among different applications and upgradeable without having to recompile the applications that use it.

About Generated Shared Libraries

You build a shared library by configuring the code generator to use the system target file `ert_shrlib.tlc`. Code generation for that system target file exports:

- Variables and signals of type `ExportedGlobal` as data
- Real-time model structure (*`model`*`_M`) as data
- Functions essential to executing your model code

To view a list of symbols contained in a generated shared library:

- On Windows, use the Dependency Walker utility, downloadable from http://www.dependencywalker.com
- On UNIX, use `nm -D` *`model`*`.so`
- On Macintosh OS X , use `nm -g` *`model`*`.dylib`

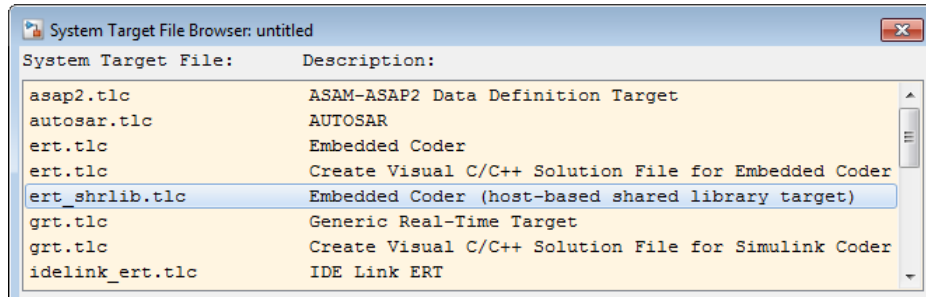
To generate and use a shared library:

1. Generate a shared library version of your model code
2. Create application code to load and use your shared library file

Generate Shared Library Version of Model Code

To generate a shared library version of your model code:

1. Open your model and configure it to use the `ert_shrlib.tlc` system target file.



Selecting the `ert_shrlib.tlc` system target file causes the build process to generate a shared library version of your model code into your current working folder. The selection does not change the code that the code generator produces for your model.

2. Build the model.
3. After the build completes, examine the generated code in the model subfolder and examine the `.dll`, `.so`, or `.dylib` file in your current folder.

Create Application Code to Use Shared Library

To illustrate how application code can load a shared library file and access its functions and data, MathWorks provides the model `rtwdemo_shrlib`.

Note Navigate to a writable working folder before running the `rtwdemo_shrlib` script.

In the model, click the blue button to run a script. The script:

1. Builds a shared library file from the model (for example, `rtwdemo_shrlib_win64.dll` on 64-bit Windows).
2. Compiles and links an example application, `rtwdemo_shrlib_app`, that loads and uses the shared library file.
3. Executes the example application.

Tip Explicit linking is preferred for portability. However, on Windows systems, the `ert_shrlib` system target file generates and retains the `.lib` file to support implicit linking.

To use implicit linking, the generated header file needs a small modification for you to use it with the generated C file. For example, if you are using Visual C++, declare `__declspec(dllimport)` in front of data to be imported implicitly from the shared library file.

The model uses the following example application files, which are located in the folder *`matlabroot`*`/toolbox/rtw/rtwdemos/shrlib_demo` (open).

File	Description
`rtwdemo_shrlib_app.h`	Example application header file
`rtwdemo_shrlib_app.c`	Example application that loads and uses the shared library file generated for the model
`run_rtwdemo_shrlib_app.m`	Script to compile, link, and execute the example application

You can view each of these files by clicking white buttons in the model window. Additionally, running the script places the relevant source and generated code files in your current folder. The files can be used as templates for writing application code for your own ERT shared library files.

The following sections present key excerpts of the example application files.

Example Application Header File

The example application header file `rtwdemo_shrlib_app.h` contains type declarations for the model's external input and output.

```
#ifndef _APP_MAIN_HEADER_
#define _APP_MAIN_HEADER_

typedef struct {
    int32_T Input;
} ExternalInputs_rtwdemo_shrlib;

typedef struct {
    int32_T Output;
} ExternalOutputs_rtwdemo_shrlib;

#endif /*_APP_MAIN_HEADER_*/
```

Example Application C Code

The example application `rtwdemo_shrlib_app.c` includes the following code for dynamically loading the shared library file. Notice that, depending on platform, the code invokes Windows or UNIX library commands.

```
#if (defined(_WIN32)||defined(_WIN64)) /* WINDOWS */
#include <windows.h>
#define GETSYMBOLADDR GetProcAddress
#define LOADLIB LoadLibrary
#define CLOSELIB FreeLibrary

#else /* UNIX */
#include <dlfcn.h>
#define GETSYMBOLADDR dlsym
#define LOADLIB dlopen
#define CLOSELIB dlclose

#endif

int main()
{
    void* handleLib;
...
#if defined(_WIN64)
    handleLib = LOADLIB("./rtwdemo_shrlib_win64.dll");
#else
#if defined(_WIN32)
    handleLib = LOADLIB("./rtwdemo_shrlib_win32.dll");
#else /* UNIX */
    handleLib = LOADLIB("./rtwdemo_shrlib.so", RTLD_LAZY);
#endif
#endif
...
    return(CLOSELIB(handleLib));
}
```

The following code excerpt shows how the C application accesses the model's exported data and functions. Notice the hooks for adding user-defined initialization, step, and termination code.

```
    int32_T i;
 ...
    void (*mdl_initialize)(boolean_T);
    void (*mdl_step)(void);
    void (*mdl_terminate)(void);

    ExternalInputs_rtwdemo_shrlib (*mdl_Uptr);
    ExternalOutputs_rtwdemo_shrlib (*mdl_Yptr);

    uint8_T (*sum_outptr);
...
#if (defined(LCCDLL)||defined(BORLANDCDLL))
```

```
    /* Exported symbols contain leading underscores when DLL is linked with
       LCC or BORLANDC */
    mdl_initialize =(void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_initialize");
    mdl_step       =(void(*)(void))GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_step");
    mdl_terminate  =(void(*)(void))GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_terminate");
    mdl_Uptr       =(ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_U");
    mdl_Yptr       =(ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
                      "_rtwdemo_shrlib_Y");
    sum_outptr     =(uint8_T*)GETSYMBOLADDR(handleLib , "_sum_out");
#else
    mdl_initialize =(void(*)(boolean_T))GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_initialize");
    mdl_step       =(void(*)(void))GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_step");
    mdl_terminate  =(void(*)(void))GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_terminate");
    mdl_Uptr       =(ExternalInputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_U");
    mdl_Yptr       =(ExternalOutputs_rtwdemo_shrlib*)GETSYMBOLADDR(handleLib ,
                      "rtwdemo_shrlib_Y");
    sum_outptr     =(uint8_T*)GETSYMBOLADDR(handleLib , "sum_out");
#endif

    if ((mdl_initialize && mdl_step && mdl_terminate && mdl_Uptr && mdl_Yptr &&
         sum_outptr)) {
        /* === user application initialization function === */
        mdl_initialize(1);
        /* insert other user defined application initialization code here */

        /* === user application step function === */
        for(i=0;i<=12;i++){
            mdl_Uptr->Input = i;
            mdl_step();
            printf("Counter out(sum_out): %d\tAmplifier in(Input): %d\tout(Output): %d\n",
                   *sum_outptr, i, mdl_Yptr->Output);
            /* insert other user defined application step function code here */
        }

        /* === user application terminate function === */
        mdl_terminate();
        /* insert other user defined application termination code here */
    }
    else {
        printf("Cannot locate the specified reference(s) in the shared library.\n");
        return(-1);
    }
```

Example Application Script

The application script `run_rtwdemo_shrlib_app` loads and rebuilds the model, and then compiles, links, and executes the model's shared library target file. You can view the script source file by opening `rtwdemo_shrlib` and clicking a white button to view source code. The script constructs platform-dependent command character vectors for compilation, linking, and execution that may apply to your development environment. To run the script, click the blue button.

Note To run the `run_rtwdemo_shrlib_app` script without first opening the `rtwdemo_shrlib` model, navigate to a writable working folder and issue the following MATLAB command:

```
addpath(fullfile(matlabroot,'toolbox','rtw','rtwdemos','shrlib_demo'))
```

Note It is invalid to invoke the terminate function twice in a row. The terminate function clears pointers and sets them to NULL. Invoking the function a second time dereferences null pointers and results in a program failure.

Shared Library Limitations

The following limitations apply to building shared libraries:

- Code generation for the `ert_shrlib.tlc` system target file exports the following as data:
  - Variables and signals of type `ExportedGlobal`
  - Real-time model structure (*`model`*`_M`)
- Code generation for the `ert_shrlib.tlc` system target file supports the C language only (not C++). When you select `ert_shrlib.tlc`, language selection is greyed out on the **Code Generation** pane of the Configuration Parameters dialog box.
- To reconstruct a model simulation using a generated shared library, the application author must maintain the timing between system and shared library function calls in the original application. The timing needs to be consistent so that you can compare the simulation and integration results. Additional simulation considerations apply if generating a shared library from a model that enables parameters **Support: continuous time** and **Single output/update function**. For more information, see “Single output/update function” (Simulink Coder) dependencies.

Real-Time Systems in Simulink Coder

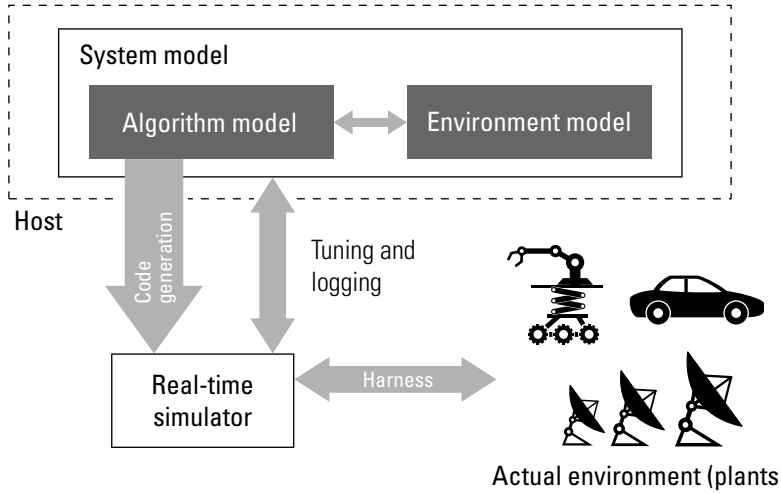
Deploy Algorithm Model for Real-Time Rapid Prototyping

Use the code generator to deploy algorithm models for real-time rapid prototyping.

About Real-Time Rapid Prototyping

Real-time rapid prototyping requires the use of a real-time simulator, potentially connected to system hardware (for example, physical plant or vehicle) being controlled. You generate, deploy, and tune code as it runs on the real-time simulator or embedded microprocessor. This design step is crucial for verifying whether a component can adequately control the system, and allows you to assess, interact with, and optimize code.

The following figure shows a typical approach for real-time rapid prototyping.



Goals of Real-Time Rapid Prototyping

Assuming that you have documented functional requirements, refined concept models, system hardware for the physical plant or vehicle being controlled, and access to target products you intend to use (for example, for example, the Simulink Real-Time or Simulink Desktop Real-Time product), you can use real-time prototyping to:

- Refine component and environment model designs by rapidly iterating between algorithm design and prototyping

- Validate whether a component can adequately control the physical system in real time
- Evaluate system performance before laying out hardware, coding production software, or committing to a fixed design
- Test hardware

Refine Code With Real-Time Rapid Prototyping

To perform real-time rapid prototyping:

1. Create or acquire a real-time system that runs in real time on rapid prototyping hardware. The Simulink Real-Time product facilitates real-time rapid prototyping. This product provides a real-time operating system that makes PCs run in real time. It also provides device driver blocks for numerous hardware I/O cards. You can then create a rapid prototyping system using inexpensive commercial-off-the-shelf (COTS) hardware. In addition, third-party vendors offer products based on the Simulink Real-Time product or other code generation technology that you can integrate into a development environment.
2. Use provided system target files to generate code that you can deploy onto a real-time simulator. See the following information.

Engineering Tasks	Related Product Information	Examples

Deploy Environment Model for Real-Time Hardware-In-the-Loop (HIL) Simulation

In this section...

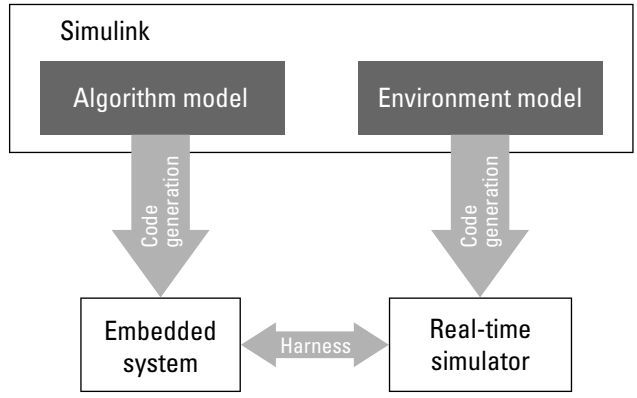
About Hardware-In-the-Loop Simulation

Hardware-in-the-loop (HIL) simulation tests and verifies an embedded system or control unit in the context of a software test platform. Examples of test platforms include real-time target systems and instruction set simulators (IISs). You use Simulink software to develop and verify a model that represents the test environment. Using the code generator, you produce, build, and download an executable program for the model to the HIL simulation platform. After you set up the environment, you can run the executable to validate the embedded system or control unit in real time.

During HIL simulation, you gradually replace parts of a system environment with hardware components as you refine and fabricate the components. HIL simulation offers an efficient design process that eliminates costly iterations of part fabrication.

The code that you build for the system simulator provides real-time system capabilities. For example, the code can include VxWorks from Wind River or another real-time operating system (RTOS).

The following figure shows a typical HIL setup.



The HIL platform available from MathWorks is the Simulink Real-Time product. Several third-party products are also available for use as HIL platforms. The Simulink Real-Time product offers hard real-time performance for PCs with Intel or AMD® 32-bit processors functioning as your real-time target. The Simulink Real-Time product enables you to add I/O interface blocks to your models and automatically generate code with code generation technology. The Simulink Real-Time product can download the code to a second PC running the Simulink Real-Time real-time kernel. System integrator solutions that are based on Simulink Real-Time are also available.

Set Up and Run HIL Simulations

To set up and run HIL simulations iterate through the following steps:

1. Develop a model that represents the environment or system under development.

   For more information, see “Compare System Target File Support Across Products” (Simulink Coder).
2. Generate an executable for the environment model.
3. Download the executable for the environment model to the HIL simulation platform.
4. Replace software representing a system component with corresponding hardware.
5. Test the hardware in the context of the HIL system.
6. Repeat steps 4 and 5 until you can simulate the system after including components that require testing.

Real-Time and Embedded Systems in Embedded Coder

Deploy Generated Standalone Executable Programs To Target Hardware

By default, the Embedded Coder software generates *standalone* executable programs that do not require an external real-time executive or operating system. A standalone program requires minimal modification to be adapted to the target hardware. The standalone program architecture supports execution of models with either single or multiple sample rates.

In this section...

Generate a Standalone Program

To generate a standalone program:

1. In the **Custom templates** section of the **Code Generation > Templates** pane of the Configuration Parameters dialog box, select the **Generate an example main program** option (which is on by default). This enables the **Target operating system** menu.
2. From the **Target operating system** menu, select `BareBoardExample` (the default selection).
3. Generate the code.

Different code is generated for multirate models depending on the following factors:

- Whether the model executes in single-tasking or multitasking mode.
- Whether or not reusable code is being generated.

These factors affect the scheduling algorithms used in generated code, and in some cases affect the API for the model entry point functions. The following sections discuss these variants.

Standalone Program Components

The core of a standalone program is the main loop. On each iteration, the main loop executes a background or null task and checks for a termination condition.

The main loop is periodically interrupted by a timer. The function `rt_OneStep` is either installed as a timer interrupt service routine (ISR), or called from a timer ISR at each clock step.

The execution driver, `rt_OneStep`, sequences calls to the *`model`*`_step` functions. The operation of `rt_OneStep` differs depending on whether the generating model is single-rate or multirate. In a single-rate model, `rt_OneStep` simply calls the *`model`*`_step` function. In a multirate model, `rt_OneStep` prioritizes and schedules execution of blocks according to the rates at which they run.

Main Program

Overview of Operation

The following pseudocode shows the execution of a main program.

```
main()
{
  Initialization (including installation of rt_OneStep as an
    interrupt service routine for a real-time clock)
  Initialize and start timer hardware
  Enable interrupts
  While(not Error) and (time < final time)
    Background task
  EndWhile
  Disable interrupts (Disable rt_OneStep from executing)
  Complete any background tasks
  Shutdown
}
```

The pseudocode is a design for a harness program to drive your model. The main program only partially implements this design. You must modify it according to your specifications.

Guidelines for Modifying the Main Program

This section describes the minimal modifications you should make in your production version of the main program module to implement your harness program.

1. Call *`model`*`_initialize`.
2. Initialize target-specific data structures and hardware, such as ADCs or DACs.
3. Install `rt_OneStep` as a timer ISR.
4. Initialize timer hardware.
5. Enable timer interrupts and start the timer.

   Note `rtModel` is not in a valid state until *`model`*`_initialize` has been called. Servicing of timer interrupts should not begin until *`model`*`_initialize` has been called.
6. Optionally, insert background task calls in the main loop.
7. On termination of the main loop (if applicable):

   - Disable timer interrupts.
   - Perform target-specific cleanup such as zeroing DACs.
   - Detect and handle errors. Note that even if your program is designed to run indefinitely, you may need to handle severe error conditions, such as timer interrupt overruns.

     You can use the macros `rtmGetErrorStatus` and `rtmSetErrorStatus` to detect and signal errors.

rt_OneStep and Scheduling Considerations

Overview of Operation

The operation of `rt_OneStep` depends upon

- Whether your model is single-rate or multirate. In a single-rate model, the sample times of all blocks in the model, and the model's fixed step size, are the same. A model in which the sample times and step size do not meet these conditions is termed multirate.
- Your model's solver mode (`SingleTasking` versus `MultiTasking`)

Permitted Solver Modes for Embedded Real-Time System Target Files summarizes the permitted solver modes for single-rate and multirate models. Note that for a single-rate model, only `SingleTasking` solver mode is allowed.

Permitted Solver Modes for Embedded Real-Time System Target Files

Mode	Single-Rate	Multirate
`SingleTasking`	Allowed	Allowed
`MultiTasking`	Disallowed	Allowed
`Auto`	Allowed (defaults to `SingleTasking`)	Allowed (defaults to `MultiTasking`)

The generated code for `rt_OneStep` (and associated timing data structures and support functions) is tailored to the number of rates in the model and to the solver mode. The following sections discuss each possible case.

Single-Rate Single-Tasking Operation

The only valid solver mode for a single-rate model is `SingleTasking`. Such models run in “single-rate” operation.

The following pseudocode shows the design of `rt_OneStep` in a single-rate program.

```
rt_OneStep()
{
  Check for interrupt overflow or other error
  Enable "rt_OneStep" (timer) interrupt
  Model_Step()  -- Time step combines output,logging,update
}
```

For the single-rate case, the generated *model*_step function is

```
void model_step(void)
```

Single-rate rt_OneStep is designed to execute *model*_step within a single clock period. To enforce this timing constraint, rt_OneStep maintains and checks a timer overrun flag. On entry, timer interrupts are disabled until the overrun flag and other error conditions have been checked. If the overrun flag is clear, rt_OneStep sets the flag, and proceeds with timer interrupts enabled.

The overrun flag is cleared only upon successful return from *model*_step. Therefore, if rt_OneStep is reinterrupted before completing *model*_step, the reinterruption is detected through the overrun flag.

Reinterruption of rt_OneStep by the timer is an error condition. If this condition is detected rt_OneStep signals an error and returns immediately. (Note that you can change this behavior if you want to handle the condition differently.)

Note that the design of rt_OneStep assumes that interrupts are disabled before rt_OneStep is called. rt_OneStep should be noninterruptible until the interrupt overflow flag has been checked.

Multirate Multitasking Operation

In a multirate multitasking system, code generation uses a prioritized, preemptive multitasking scheme to execute the different sample rates in your model.

The following pseudocode shows the design of rt_OneStep in a multirate multitasking program.

```
rt_OneStep()
{
  Check for base-rate interrupt overrun
  Enable "rt_OneStep" interrupt
  Determine which rates need to run this time step

  Model_Step0()        -- run base-rate time step code

  For N=1:NumTasks-1   -- iterate over sub-rate tasks
    If (sub-rate task N is scheduled)
    Check for sub-rate interrupt overrun
      Model_StepN()    -- run sub-rate time step code
    EndIf
```

```
  EndFor
}
```

Task Identifiers

The execution of blocks having different sample rates is broken into tasks. Each block that executes at a given sample rate is assigned a *task identifier* (`tid`), which associates it with a task that executes at that rate. Where there are `NumTasks` tasks in the system, the range of task identifiers is 0..`NumTasks`-1.

Prioritization of Base-Rate and Subrate Tasks

Tasks are prioritized, in descending order, by rate. The *base-rate* task is the task that runs at the fastest rate in the system (the hardware clock rate). The base-rate task has highest priority (`tid` 0). The next fastest task (`tid` 1) has the next highest priority, and so on down to the slowest, lowest priority task (`tid` `NumTasks`-1).

The slower tasks, running at multiples of the base rate, are called *subrate* tasks.

Rate Grouping and Rate-Specific model_step Functions

In a single-rate model, the block output computations are performed within a single function, *`model`*`_step`. For multirate, multitasking models, the code generator tries to use a different strategy. This strategy is called *rate grouping*. Rate grouping generates separate *`model`*`_step` functions for the base rate task and each subrate task in the model. The function naming convention for these functions is

`model``_step`*`N`*

where *`N`* is a task identifier. For example, for a model named `my_model` that has three rates, the following functions are generated:

```
void my_model_step0 (void);
void my_model_step1 (void);
void my_model_step2 (void);
```

Each *`model`*`_step`*`N`* function executes the blocks sharing `tid` *`N`*; in other words, the block code that executes within task *`N`* is grouped into the associated *`model`*`_step`*`N`* function.

Scheduling model_stepN Execution

On each clock tick, `rt_OneStep` maintains scheduling counters and *event flags* for each subrate task. The counters are implemented as `taskCounter` arrays indexed on `tid`. The event flags are implemented as arrays indexed on `tid`.

The scheduling counters and task flags for sub-rates are maintained by `rt_OneStep`. The scheduling counters are basically clock rate dividers that count up the sample period associated with each sub-rate task. A pair of tasks that exchanges data maintains an interaction flag at the faster rate. Task interaction flags indicate that both fast and slow tasks are scheduled to run.

The event flags indicate whether or not a given task is scheduled for execution. `rt_OneStep` maintains the event flags based on a task counter that is maintained by code in the main program module for the model. When a counter indicates that a task's sample period has elapsed, the main code sets the event flag for that task.

On each invocation, `rt_OneStep` updates its scheduling data structures and steps the base-rate task (`rt_OneStep` calls *`model`*`_step0` because the base-rate task must execute on every clock step). Then, `rt_OneStep` iterates over the scheduling flags in `tid` order, unconditionally calling *`model`*`_step`*`N`* for any task whose flag is set. The tasks are executed in order of priority.

Preemption

Note that the design of `rt_OneStep` assumes that interrupts are disabled before `rt_OneStep` is called. `rt_OneStep` should be noninterruptible until the base-rate interrupt overflow flag has been checked (see pseudocode above).

The event flag array and loop variables used by `rt_OneStep` are stored as local (stack) variables. Therefore, `rt_OneStep` is reentrant. If `rt_OneStep` is reinterrupted, higher priority tasks preempt lower priority tasks. Upon return from interrupt, lower priority tasks resume in the previously scheduled order.

Overrun Detection

Multirate `rt_OneStep` also maintains an array of timer overrun flags. `rt_OneStep` detects timer overrun, per task, by the same logic as single-rate `rt_OneStep`.

Note If you have developed multirate S-functions, or if you use a customized static main program module, see “Rate Grouping Compliance and Compatibility Issues” on page 63-17 for information about how to adapt your code for rate grouping compatibility. This adaptation lets your multirate, multitasking models generate more efficient code.

Multirate Single-Tasking Operation

In a multirate single-tasking program, by definition, sample times in the model must be an integer multiple of the model's fixed-step size.

In a multirate single-tasking program, blocks execute at different rates, but under the same task identifier. The operation of `rt_OneStep`, in this case, is a simplified version of multirate multitasking operation. Rate grouping is not used. The only task is the base-rate task. Therefore, only one *`model`*`_step` function is generated:

```
void model_step(void)
```

On each clock tick, `rt_OneStep` checks the overrun flag and calls *`model`*`_step`. The scheduling function for a multirate single-tasking program is `rate_scheduler` (rather than `rate_monotonic_scheduler`). The scheduler maintains scheduling counters on each clock tick. There is one counter for each sample rate in the model. The counters are implemented in an array (indexed on tid) within the `Timing` structure within `rtModel`.

The counters are clock rate dividers that count up the sample period associated with each subrate task. When a counter indicates that a sample period for a given rate has elapsed, `rate_scheduler` clears the counter. This condition indicates that blocks running at that rate should execute on the next call to *`model`*`_step`, which is responsible for checking the counters.

Guidelines for Modifying rt_OneStep

`rt_OneStep` does not require extensive modification. The only required modification is to reenable interrupts after the overrun flags and error conditions have been checked. If applicable, you should also

- Save and restore your FPU context on entry and exit to `rt_OneStep`.
- Set model inputs associated with the base rate before calling *`model`*`_step0`.
- Get model outputs associated with the base rate after calling *`model`*`_step0`.

Note If you modify `rt_OneStep` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline below.

- In a multirate, multitasking model, set model inputs associated with subrates before calling *`model`*`_step`*`N`* in the subrate loop.
- In a multirate, multitasking model, get model outputs associated with subrates after calling *`model`*`_step`*`N`* in the subrate loop.

Comments in `rt_OneStep` indicate the place to add your code.

In multirate `rt_OneStep`, you can improve performance by unrolling `for` and `while` loops.

In addition, you may choose to modify the overrun behavior to continue execution after error recovery is complete.

Also observe the following cautionary guidelines:

- You should not modify the way in which the counters, event flags, or other timing data structures are set in `rt_OneStep`, or in functions called from `rt_OneStep`. The `rt_OneStep` timing data structures (including `rtModel`) and logic are critical to the operation of the generated program.
- If you have customized the main program module to read model outputs after each base-rate model step, be aware that selecting model options **Support: continuous time** and **Single output/update function** together may cause output values read from `main` for a continuous output port to differ slightly from the corresponding output values in the model's logged data. This is because, while logged data is a snapshot of output at major time steps, output read from `main` after the base-rate model step potentially reflects intervening minor time steps. To eliminate the discrepancy, either separate the generated output and update functions (clear the **Single output/update function** option) or place a Zero-Order Hold block before the continuous output port.
- It is possible to observe a mismatch between results from simulation and logged MAT file results from generated code if you do not set model inputs before each time you call the model step function. In the generated example main program, the following comments show the locations for setting the inputs and stepping the model with your code:

  ```
  /* Set model inputs here */
  /* Step the model */
  ```

  If your model applies signal reuse and you are using `MatFileLogging` for comparing results from simulation against generated code, modify `rt_OneStep` to write model inputs in every time step as directed by these comments. Alternatively, you could “Choose a SIL or PIL Approach” on page 78-14 for verification.

Static Main Program Module

Overview

In most cases, the easiest strategy for deploying generated code is to use the **Generate an example main program option** to generate the `ert_main.c` or `.cpp` module (see "Generate a Standalone Program" on page 63-2).

However, if you turn the **Generate an example main program** option off, you can use a static main module as an example or template for developing your embedded applications. Static main modules provided by MathWorks include:

- *matlabroot*`/rtw/c/src/common/rt_main.c` — Supports `Nonreusable function` code interface packaging.
- *matlabroot*`/rtw/c/src/common/rt_malloc_main.c` — Supports `Reusable function` code interface packaging. The model option **Use dynamic memory allocation for model initialization** must be on and model parameter **Pass root-level I/O as** must be set to `Part of model data structure`.
- *matlabroot*`/rtw/c/src/common/rt_cppclass_main.cpp` — Supports `C++ class` code interface packaging.

The static main module is not part of the generated code; it is provided as a basis for your custom modifications, and for use in simulation. If your existing applications depend upon a static `ert_main.c` (developed in releases before R2012b), `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`, you may need to continue using a static main program module.

When developing applications using a static main module, you should copy the module to your working folder and rename it before making modifications. For example, you could rename `rt_main.c` to *`model`*`_rt_main.c`. Also, you must modify the template makefile or toolchain settings such that the build process creates a corresponding object file, such as *`model`*`_rt_main.obj` (on UNIX, *`model`*`_rt_main.o`), in the build folder.

The static main module contains

- `rt_OneStep`, a timer interrupt service routine (ISR). `rt_OneStep` calls *`model`*`_step` to execute processing for one clock period of the model.
- A skeletal `main` function. As provided, `main` is useful in simulation only. You must modify `main` for real-time interrupt-driven execution.

For single-rate models, the operation of `rt_OneStep` and the main function are essentially the same in the static main module as they are in the automatically generated version described in “Deploy Generated Standalone Executable Programs To Target Hardware” on page 63-2. For multirate, multitasking models, however, the static and generated code are slightly different. The next section describes this case.

Rate Grouping and the Static Main Program

Targets based on the ERT target sometimes use a static main module and disallow use of the **Generate an example main program** option. This is done because target-specific modifications have been added to the static main module, and these modifications would not be preserved if the main program were regenerated.

Your static main module may or may not use rate grouping compatible *`model`*`_step`*`N`* functions. If your main module is based on the static `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp` module, it does not use rate-specific *`model`*`_step`*`N`* function calls. It uses the old-style *`model`*`_step` function, passing in a task identifier:

```
void model_step(int_T tid);
```

By default, when the **Generate an example main program** option is off, the ERT target generates a *`model`*`_step` “wrapper” for multirate, multitasking models. The purpose of the wrapper is to interface the rate-specific *`model`*`_step`*`N`* functions to the old-style call. The wrapper code dispatches to the *`model`*`_step`*`N`* call with a `switch` statement, as in the following example:

```
void mymodel_step(int_T tid) /* Sample time:  */
{

  switch(tid) {
   case 0 :
    mymodel_step0();
    break;
   case 1 :
    mymodel_step1();
    break;
   case 2 :
```

```
    mymodel_step2();
    break;
   default :
    break;
  }
}
```

The following pseudocode shows how `rt_OneStep` calls *`model`*`_step` from the static main program in a multirate, multitasking model.

```
rt_OneStep()
{
  Check for base-rate interrupt overflow
  Enable "rt_OneStep" interrupt
  Determine which rates need to run this time step

  ModelStep(tid=0)     --base-rate time step

  For N=1:NumTasks-1  -- iterate over sub-rate tasks
    Check for sub-rate interrupt overflow
    If (sub-rate task N is scheduled)
      ModelStep(tid=N)    --sub-rate time step
    EndIf
  EndFor
}
```

You can use the TLC variable `RateBasedStepFcn` to specify that only the rate-based step functions are generated, without the wrapper function. If your target calls the rate grouping compatible *`model`*`_step`*`N`* function directly, set `RateBasedStepFcn` to `1`. In this case, the wrapper function is not generated.

You should set `RateBasedStepFcn` prior to the `%include "codegenentry.tlc"` statement in your system target file. Alternatively, you can set `RateBasedStepFcn` in your `target_settings.tlc` file.

Modify the Static Main Program

As with the generated `ert_main.c` or `.cpp`, you should make a few modifications to the main loop and `rt_OneStep`. See “Guidelines for Modifying the Main Program” on page 63-4 and “Guidelines for Modifying rt_OneStep” on page 63-9.

Also, you should replace the `rt_OneStep` call in the main loop with a background task call or null statement.

Other modifications you may need to make are

- If applicable, follow comments in the code regarding where to add code for reading/writing model I/O and saving/restoring FPU context.

  Note If you modify `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp` to read a value from a continuous output port after each base-rate model step, see the relevant cautionary guideline in "Guidelines for Modifying rt_OneStep" on page 63-9.

- When the **Generate an example main program** option is off, `rtmodel.h` is generated to provide an interface between the main module and generated model code. If you create your own static main program module, you would normally include `rtmodel.h`.

  Alternatively, you can suppress generation of `rtmodel.h`, and include *`model`*`.h` directly in your main module. To suppress generation of `rtmodel.h`, use the following statement in your system target file:

  ```
  %assign AutoBuildProcedure = 0
  ```

- If you have cleared the **Terminate function required** option, remove or comment out the following in your production version of `rt_main.c`, `rt_malloc_main.c`, or `rt_cppclass_main.cpp`:

  - The `#if TERMFCN...` compile-time error check
  - The call to `MODEL_TERMINATE`

- For `rt_main.c` (not applicable to `rt_cppclass_main.cpp`): If you do *not* want to combine output and update functions, clear the **Single output/update function** option and make the following changes in your production version of `rt_main.c`:

  - Replace calls to `MODEL_STEP` with calls to `MODEL_OUTPUT` and `MODEL_UPDATE`.
  - Remove the `#if ONESTEPFCN...` error check.

- The static `rt_main.c` module does not support `Reusable function` code interface packaging. The following error check raises a compile-time error if `Reusable function` code interface packaging is used illegally.

  ```
  #if MULTI_INSTANCE_CODE==1
  ```

Modify Static Main to Allocate and Access Model Instance Data

If you are using a static main program module, and your model is configured for `Reusable function` code interface packaging, but the model option **Use dynamic**

memory allocation for model initialization is not selected, model instance data must be allocated either statically or dynamically by the calling main code. Pointers to the individual model data structures (such as Block IO, DWork, and Parameters) must be set up in the top-level real-time model data structure.

To support main modifications, the build process generates a subset of the following real-time model (RTM) macros, based on the data requirements of your model, into *`model`*`.h`.

RTM Macro Syntax	Description
`rtmGetBlockIO(rtm)`	Get the block I/O data structure
`rtmSetBlockIO(rtm,val)`	Set the block I/O data structure
`rtmGetContStates(rtm)`	Get the continuous states data structure
`rtmSetContStates(rtm,val)`	Set the continuous states data structure
`rtmGetDefaultParam(rtm)`	Get the default parameters data structure
`rtmSetDefaultParam(rtm,val)`	Set the default parameters data structure
`rtmGetPrevZCSigState(rtm)`	Get the previous zero-crossing signal state data structure
`rtmSetPrevZCSigState(rtm,val)`	Set the previous zero-crossing signal state data structure
`rtmGetRootDWork(rtm)`	Get the DWork data structure
`rtmSetRootDWork(rtm,val)`	Set the DWork data structure
`rtmGetU(rtm)`	Get the root inputs data structure (when root inputs are passed as part of the model data structure)
`rtmSetU(rtm,val)`	Set the root inputs data structure (when root inputs are passed as part of the model data structure)
`rtmGetY(rtm)`	Get the root outputs data structure (when root outputs are passed as part of the model data structure)
`rtmSetY(rtm,val)`	Set the root outputs data structure (when root outputs are passed as part of the model data structure)

Use these macros in your static main program to access individual model data structures within the RTM data structure. For example, suppose that the example model `rtwdemo_reusable` is configured with `Reusable function` code interface packaging,

Use dynamic memory allocation for model initialization cleared, **Pass root-level I/O as** set to `Individual arguments`, and **Optimization** pane option **Remove root level I/O zero initialization** cleared. Building the model generates the following model data structures and model entry-points into `rtwdemo_reusable.h`:

```
/* Block states (auto storage) for system '<Root>' */
typedef struct {
  real_T Delay_DSTATE;                 /* '<Root>/Delay' */
} D_Work;

/* Parameters (auto storage) */
struct Parameters_ {
  real_T k1;                           /* Variable: k1
                                        * Referenced by: '<Root>/Gain'
                                        */
};

/* Model entry point functions */
extern void rtwdemo_reusable_initialize(RT_MODEL *const rtM, real_T *rtU_In1,
  real_T *rtU_In2, real_T *rtY_Out1);
extern void rtwdemo_reusable_step(RT_MODEL *const rtM, real_T rtU_In1, real_T
  rtU_In2, real_T *rtY_Out1);
```

Additionally, if **Generate an example main program** is not selected for the model, `rtwdemo_reusable.h` contains definitions for the RTM macros `rtmGetDefaultParam`, `rtmsetDefaultParam`, `rtmGetRootDWork`, and `rtmSetRootDWork`.

Also, for reference, the generated `rtmodel.h` file contains an example parameter definition with initial values (non-executing code):

```
#if 0

/* Example parameter data definition with initial values */
static Parameters rtP = {
  2.0                                  /* Variable: k1
                                        * Referenced by: '<Root>/Gain'
                                        */
};                                     /* Modifiable parameters */

#endif
```

In the definitions section of your static main file, you could use the following code to statically allocate the real-time model data structures and arguments for the `rtwdemo_reusable` model:

```
static RT_MODEL rtM_;
static RT_MODEL *const rtM = &rtM_;    /* Real-time model */
static Parameters rtP = {
  2.0                                  /* Variable: k1
                                        * Referenced by: '<Root>/Gain'
                                        */
```

```
};                                     /* Modifiable parameters */

static D_Work rtDWork;                 /* Observable states */

/* '<Root>/In1' */
static real_T rtU_In1;

/* '<Root>/In2' */
static real_T rtU_In2;

/* '<Root>/Out1' */
static real_T rtY_Out1;
```

In the body of your main function, you could use the following RTM macro calls to set up the model parameters and DWork data in the real-time model data structure:

```
int_T main(int_T argc, const char *argv[])
{
...
/* Pack model data into RTM */

rtmSetDefaultParam(rtM, &rtP);
rtmSetRootDWork(rtM, &rtDWork);

/* Initialize model */
rtwdemo_reusable_initialize(rtM, &rtU_In1, &rtU_In2, &rtY_Out1);
...
}
```

Follow a similar approach to set up multiple instances of model data, where the real-time model data structure for each instance has its own data. In particular, the parameter structure (`rtP`) should be initialized, for each instance, to the desired values, either statically as part of the `rtP` data definition or at run time.

Rate Grouping Compliance and Compatibility Issues

Main Program Compatibility

When the **Generate an example main program** option is off, code generation produces slightly different rate grouping code, for compatibility with the older static `ert_main.c` module. See “Rate Grouping and the Static Main Program” on page 63-12 for details.

Make Your S-Functions Rate Grouping Compliant

Built-in Simulink blocks, as well as DSP System Toolbox blocks, are compliant with the requirements for generating rate grouping code. However, user-written multirate inlined

S-functions may not be rate grouping compliant. Noncompliant blocks generate less efficient code, but are otherwise compatible with rate grouping. To take full advantage of the efficiency of rate grouping, your multirate inlined S-functions must be upgraded to be fully rate grouping compliant. You should upgrade your TLC S-function implementations, as described in this section.

Use of noncompliant multirate blocks to generate rate-grouping code generates dead code. This can cause two problems:

- Reduced code efficiency.
- Warning messages issued at compile time. Such warnings are caused when dead code references temporary variables before initialization. Since the dead code does not run, this problem does not affect the run-time behavior of the generated code.

To make your S-functions rate grouping compliant, you can use the following TLC functions to generate `ModelOutputs` and `ModelUpdate` code, respectively:

```
OutputsForTID(block, system, tid)
UpdateForTID(block, system, tid)
```

The code listings below illustrate generation of output computations without rate grouping (Listing 1) and with rate grouping (Listing 2). Note the following:

- The `tid` argument is a task identifier (`0..NumTasks-1`).
- Only code guarded by the `tid` passed in to `OutputsForTID` is generated. The `if (%<LibIsSFcnSampleHit(portName)>)` test is not used in `OutputsForTID`.
- When generating rate grouping code, `OutputsForTID` and/or `UpdateForTID` is called during code generation. When generating non-rate-grouping code, `Outputs` and/or `Update` is called.
- In rate grouping compliant code, the top-level `Outputs` and/or `Update` functions call `OutputsForTID` and/or `UpdateForTID` functions for each rate (`tid`) involved in the block. The code returned by `OutputsForTID` and/or `UpdateForTID` must be guarded by the corresponding `tid` guard:

  ```
  if (%<LibIsSFcnSampleHit(portName)>)
  ```

  as in Listing 2.

%% [EOF] sfun_multirate.tlc
```

Generate Code That Dereferences Data from a Literal Memory Address

This example shows how to generate code that reads the value of a signal by dereferencing a memory address that you specify. With this technique, you can generate a control algorithm that interacts with memory that your hardware populates (for example, memory that stores the output of an analog-to-digital converter in a microcontroller).

In this example, you generate an algorithm that acquires input data from a 16-bit block of memory at address `0x8675309`. Assume that a hardware device asynchronously populates only the lower 10 bits of the address. The algorithm must treat the address as read-only (`const`), volatile (`volatile`) data, and ignore the upper 6 bits of the address.

The generated code can access the data by defining a macro that dereferences `0x8675309` and masks the unnecessary bits:

```
#define A2D_INPUT ((*(volatile const uint16_T *)0x8675309)&0x03FF)
```

To configure a model to generate code that defines and uses this macro, you must create an advanced custom storage class and write Target Language Compiler (TLC) code. For an example that shows how to use the Custom Storage Class Designer without writing TLC code, see “Create and Apply a Custom Storage Class” on page 36-35.

As an alternative to writing TLC code, you can use memory sections to generate code that includes pragmas. Depending on your build toolchain, you can use pragmas to specify a literal memory address for storing a global variable. For more information about memory sections, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2.

Derivation of Macro Syntax

In this example, you configure the generated code to define and use the dereferencing macro. To determine the correct syntax for the macro, start by recording the target address.

```
0x8675309
```

Cast the address as a pointer to a 16-bit integer. Use the Simulink Coder data type name `uint16_T`.

```
(uint16_T *)0x8675309
```

Add the storage type qualifier `const` because the generated code must not write to the address. Add `volatile` because the hardware can populate the address at an arbitrary time.

```
(volatile const uint16_T *)0x8675309
```

Dereference the address.

```
*(volatile const uint16_T *)0x8675309
```

After the dereference operation, apply a mask to retain only the 10 bits that the hardware populates. Use explicit parentheses to control the order of operations.

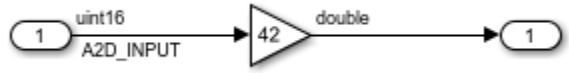
```
(*(volatile const uint16_T *)0x8675309)&0x03FF
```

As a safe coding practice, wrap the entire construct in another layer of parentheses.

```
((*(volatile const uint16_T *)0x8675309)&0x03FF)
```

Create Example Model

Create the example model `ex_memmap_simple`.



For the Inport block, set the output data type to `uint16`. Name the signal as `A2D_INPUT`. The Inport block and the signal line represent the data that the hardware populates.

For the Gain block, set the output data type to `double`.

Create Package to Contain Definitions of Data Class and Custom Storage Class

In your current folder, create a folder named `+MemoryMap`. The folder defines a package named `MemoryMap`.

To make the package available for use outside of your current folder, you can add the folder containing the `+MemoryMap` folder to the MATLAB path.

Create Custom Storage Class

To generate code that defines and reads `A2D_INPUT` as a macro, you must create a custom storage class that you can apply to the signal line in the model. Later, you write TLC code that complements the custom storage class.

Open the Custom Storage Class designer in advanced mode. To design a custom storage class that operates through custom TLC code, you must use the advanced mode.

```
cscdesigner('MemoryMap','-advanced');
```

In the Custom Storage Class Designer, click **New**. A new custom storage class, `NewCSC_1`, appears in the list of custom storage class definitions.

Rename the new custom storage class `MemoryMappedAddress`.

For `MemoryMappedAddress`, on the **General** tab, set:

- **Type** to `Other`. The custom storage class can operate through custom TLC code that you write later.
- **Data scope** to `Exported`. For data items that use this custom storage class, Simulink Coder generates the definition (for example, the `#define` statement that defines a macro).
- **Data initialization** to `None`. Simulink Coder does not generate code that initializes the data item. Use this setting because this custom storage class represents read-only data. You do not select `Macro` because the Custom Storage Class Designer does not allow you to use `Macro` for signal data.
- **Definition file** to `Specify` (leave the text box empty). For data items that consume memory in the generated code, **Definition file** specifies the `.c` source file that allocates the memory. However, this custom storage class yields a macro, which does not require memory. Typically, header files (`.h`), not `.c` files, define macros. Setting

Definition file to `Specify` instead of `Instance specific` prevents users of the custom storage class from unnecessarily specifying a definition file.

- **Header file** to `Instance specific`. To control the file placement of the macro definition, the user of the custom storage class must specify a header file for each data item that uses this custom storage class.
- **Owner** to `Specify` (leave the text box empty). **Owner** applies only to data items that consume memory.

After you finish selecting the settings, click **Apply** and **Save**.

Now, when you apply the custom storage class to a data item, such as the `A2D_INPUT` signal line, you can specify a header file to contain the generated macro definition. However, you cannot yet specify a memory address for the data item. To enable specification of a memory address, create a custom attributes class that you can associate with the `MemoryMappedAddress` custom storage class.

Define Class to Store Custom Attributes for Custom Storage Class

Define a MATLAB class to store additional information for data items that use the custom storage class. In this case, the additional information is the memory address.

In the `MemoryMap` package (the `+MemoryMap` folder), create a folder named `@MemoryMapAttribs`.

In the `@MemoryMapAttribs` folder, create a file named `MemoryMapAttribs`. The file defines a class that derives from the built-in class `Simulink.CustomStorageClassAttributes`.

```
classdef MemoryMapAttribs < Simulink.CustomStorageClassAttributes
    properties( PropertyType = 'char' )
        MemoryAddress = '';
    end
end
```

Later, you associate this MATLAB class with the `MemoryMappedAddress` custom storage class. Then, when you apply the custom storage class to a data item, you can specify a memory address.

Write TLC Code That Emits Correct C Code

Write TLC code that uses the attributes of the custom storage class, such as `HeaderFile` and `MemoryAddress`, to generate correct C code for each data item.

In the `+MemoryMap` folder, create a folder named `tlc`.

Navigate to the new folder.

Inspect the built-in template TLC file, `TEMPLATE_v1.tlc`.

```
edit(fullfile(matlabroot,...
    'toolbox','rtw','targets','ecoder','csc_templates','TEMPLATE_v1.tlc'))
```

Save a copy of `TEMPLATE_v1.tlc` in the `tlc` folder. Rename the copy `memory_map_csc.tlc`.

In `memory_map_csc.tlc`, find the portion that controls the generation of C-code data declarations.

```
    %case "declare"

      %% LibDefaultCustomStorageDeclare is the default declare function to
      %% declares a global variable whose identifier is the name of the data.
      %return "extern %<LibDefaultCustomStorageDeclare(record)>"
      %%break

    %% ============================================================================
```

The `declare` case (`%case`) constructs a return value (`%return`), which the code generator emits into the header file that you specify for each data item. To control the C code that declares each data item, adjust the return value in the `declare` case.

Replace the existing `%case` content with this new code, which specifies a different return value:

```
%case "declare"

        %% In TLC code, a 'record' is a data item (for example, a signal line).
        %% 'LibGetRecordIdentifier' returns the name of the data item.
        %assign id = LibGetRecordIdentifier(record)
```

```
    %assign dt = LibGetRecordCompositeDataTypeName(record)

    %% The 'CoderInfo' property of a data item stores a
    %% 'Simulink.CoderInfo' object, which stores code generation settings
    %% such as the storage class or custom storage class that you specify
    %% for the item.
    %assign ci = record.Object.ObjectProperties.CoderInfo
    %% The 'ci' variable now stores the 'Simulink.CoderInfo' object.

    %% By default, the 'CustomAttributes' property of a 'Simulink.CoderInfo'
    %% object stores a 'Simulink.CustomStorageClassAttributes' object.
    %% This nested object stores specialized code generation settings
    %% such as the header file and definition file that you specify for
    %% the data item.
    %%
    %% The 'MemoryMap' package derives a new class,
    %% 'MemoryMapAttribs', from 'Simulink.CustomStorageClassAttributes'.
    %% The new class adds a property named 'MemoryAddress'.
    %% This TLC code determines the memory address of the data item by
    %% acquiring the value of the 'MemoryAddress' property.
    %assign ca = ci.Object.ObjectProperties.CustomAttributes
    %assign address = ca.Object.ObjectProperties.MemoryAddress

    %assign width = LibGetDataWidth(record)

    %% This TLC code constructs the full macro, with correct C syntax,
    %% based on the values of TLC variables such as 'address' and 'dt'.
    %% This TLC code also asserts that the data item must be a scalar.
    %if width == 1
            %assign macro = ...
                "#define %<id> ((*(volatile const %<dt>*)%<address>) & 0x03FF)"
    %else
            %error( "Non scalars are not supported yet." )
    %endif

    %return "%<macro>"
  %%break

%% ============================================================================
```

The new TLC code uses built-in, documented TLC functions, such as `LibGetRecordIdentifier`, and other TLC commands and operations to access information about the data item. Temporary variables such as `dt` and `address` store that

information. The TLC code constructs the full macro, with the correct C syntax, by expanding the variables, and stores the macro in the variable `macro`.

In the same file, find the portion that controls the generation of data definitions.

```
%case "define"

  %% LibDefaultCustomStorageDefine is the default define function to define
  %% a global variable whose identifier is the name of the data.  If the
  %% data is a parameter, the definition is also statically initialized to
  %% its nominal value (as set in MATLAB).
  %return "%<LibDefaultCustomStorageDefine(record)>"
  %%break

%% ============================================================================
```

The `define` case derives a return value that the code generator emits into a `.c` file, which defines data items that consume memory.

Replace the existing `%case` content with this new content:

```
%case "define"
  %return ""
  %%break

%% ============================================================================
```

`MemoryMappedAddress` yields a macro in the generated code, so you use the `declare` case instead of the `define` case to construct and emit the macro. To prevent the `define` case from emitting a duplicate macro definition, the new TLC code returns an empty string.

Find the portion that controls the generation of code that initializes data.

```
%case "initialize"

  %% LibDefaultCustomStorageInitialize is the default initialization
  %% function that initializes a scalar element of a global variable to 0.
  %return LibDefaultCustomStorageInitialize(record, idx, reim)
  %%break

%% ============================================================================
```

The `initialize` case generates code that initializes data items (for example, in the *`model`*`_initialize` function).

Replace the existing `%case` content with this new content:

```
%case "initialize"
  %return ""
  %%break

%% ============================================================================
```

`MemoryMappedAddress` yields a macro, so the generated code must not attempt to initialize the value of the macro. The new TLC code returns an empty string.

Complete the Definition of the Custom Storage Class

Your new MATLAB class, `MemoryMapAttribs`, can enable users of your new custom storage class, `MemoryMappedAddress`, to specify a memory address for each data item. To allow this specification, associate `MemoryMapAttribs` with `MemoryMappedAddress`. To generate correct C code based on the information that you specify for each data item, associate the customized TLC file, `memory_map_csc.tlc`, with `MemoryMappedAddress`.

Navigate to the folder that contains the `+MemoryMap` folder.

Open the Custom Storage Class Designer again.

```
cscdesigner('MemoryMap','-advanced');
```

For `MemoryMappedAddress`, on the **Other Attributes** tab, set:

- **TLC file name** to `memory_map_csc.tlc`.
- **CSC attributes class** to `MemoryMap.MemoryMapAttribs`.

Click **Apply** and **Save**.

Define Signal Data Class

To apply the custom storage class to a signal in a model, in the `MemoryMap` package, you must create a MATLAB class that derives from `Simulink.Signal`. When you configure the signal in the model, you select this new data class instead of the default class, `Simulink.Signal`.

In the `MemoryMap` package, create a folder named `@Signal`.

In the `@Signal` folder, create a file named `Signal.m`.

```
classdef Signal < Simulink.Signal
    methods
        function setupCoderInfo( this )
            useLocalCustomStorageClasses( this, 'MemoryMap' );
            return;
        end
    end
end
```

The file defines a class named `MemoryMap.Signal`. The class definition overrides the `setupCoderInfo` method, which the `Simulink.Signal` class already implements. The new implementation specifies that objects of the `MemoryMap.Signal` class use custom storage classes from the `MemoryMap` package (instead of custom storage classes from the `Simulink` package). When you configure a signal in a model by selecting the `MemoryMap.Signal` class, you can select the new custom storage class, `MemoryMappedAddress`.

Apply Custom Storage Class to Signal Line

Navigate to the folder that contains the example model and open the model.

In the model, select **View > Property Inspector**.

Click the signal named `A2D_INPUT`.

In the Property Inspector, under **Code Generation**, set **Signal object class** to `MemoryMap.Signal`. If you do not see `MemoryMap.Signal`, select `Customize class lists` and use the dialog box to enable the selection of `MemoryMap.Signal`.

In the Property Inspector, set **Storage class** to `MemoryMappedAddress`.

Set **Header file** to `memory_mapped_addresses.h`.

Set **MemoryAddress** to `0x8675309`.

Generate and Inspect Code

Generate code from the model.

```
### Starting build procedure for model: ex_memmap_simple
### Successful completion of build procedure for model: ex_memmap_simple
```

Inspect the generated header file `memory_mapped_addresses.h`. The file defines the macro `A2D_INPUT`, which corresponds to the signal line in the model.

```
/* Declaration of data with custom storage class MemoryMappedAddress */
#define A2D_INPUT                      ((*(volatile const uint16_T*)0x8675309) & 0x03FF
```

Inspect the generated file `ex_memmap_simple.c`. The generated algorithmic code (which corresponds to the Gain block) calculates the model output, `rtY.Out1`, by operating on `A2D_INPUT`.

```
/* Model step function */
void ex_memmap_simple_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain'
   *  Inport: '<Root>/In1'
   */
  rtY.Out1 = 42.0 * (real_T)A2D_INPUT;
}
```

Generate Main Program for Deployment to Bare Board Target (Without an Operating System)

This example shows how to configure a model such that the code generator produces an example `main` program that you can customize for deployment on bare-board target hardware (does not have an operating system). When you select the model configuration parameter **Generate an example main program**, the code generator produces the example file `ert_main.c` or `ert_main.cpp`. This file includes:

- `main()` function for the generated program
- Task scheduling code that determines how and when block computations execute on each time step of the model

Operation of the `main` program and the scheduling algorithm depend primarily on:

- Whether the model is a single-rate or multirate model
- Whether the model solver mode is set to single-tasking or multitasking

For more information, see “Deploy Generated Standalone Executable Programs To Target Hardware” on page 63-2.

Alternatively, you can configure a model to generate an example main program for deployment on target hardware that is running the VxWorks® operating system or threaded code that runs on your host operating system. The example file `ert_main.c` that the code generator produces, shows how to deploy the generated example code.

You can customize a generated main program by using a custom file processing (CFP) template. Consider using a template file to:

- Assemble generated code in buffers
- Call an API to obtain buffered code into specific sections of generated source and header files

For more information, see “File customization template”.

Open Example Model

Open the example model `rtwdemo_examplemain`.

```
open_system('rtwdemo_examplemain');
```

Configure Model

1. Select the model configuration parameter **Generate an example main program**. When you select this parameter, you enable the parameter **Target operating system**.
2. Set the parameter **Target operating system** to `BareBoardExample`, `VxWorksExample`, or `NativeThreadsExample`. For more information, see "Target operating system"
3. Consider whether you want to specify a custom file processing template. To configure a template, specify the file name and extension for your template TLC file as a string for the **File customization template** parameter.

Generate Code

Generate code for the model.

Add Hand-Coded Customizations

Augment the generated code with hand code as needed.

Deploy Generated Component Software to Application Target Platforms

The code generator supports integration of generated code with operating systems and processors. For details, see “Embedded Coder Supported Hardware” on page 82-2.

Interface to an Example Real-Time Operating System (VxWorks®)

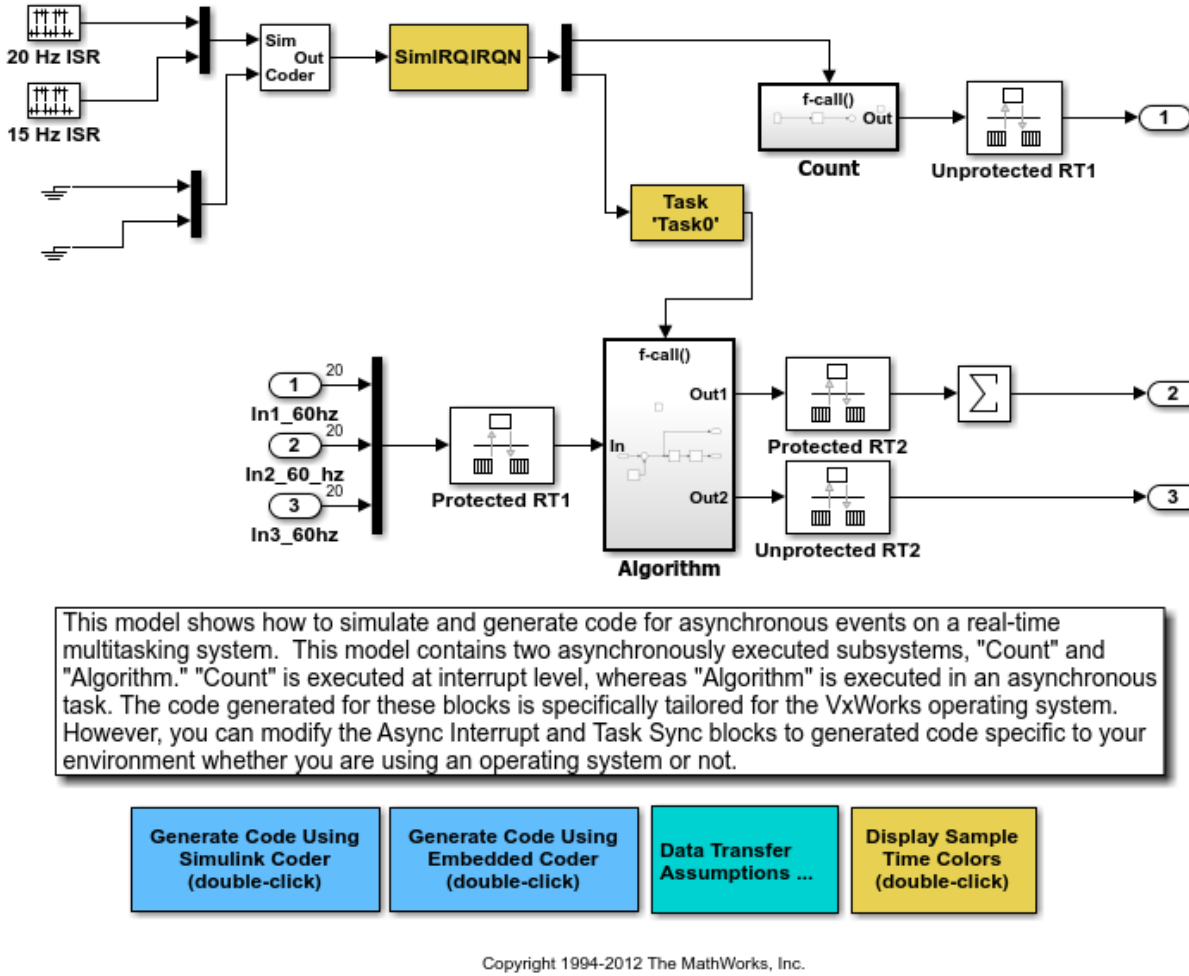
This example shows how to simulate and generate code for asynchronous events on an example RTOS (VxWorks).

The operating system integration techniques that are demonstrated in this example use one or more blocks the blocks in the `vxlib1` library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

Example Model

Open the `rtwdemo_vxworks` model.

```
model = 'rtwdemo_vxworks';
open_system(model);
%
```



Model Description

The example model contains two asynchronously executed subsystems, `Count` and `Algorithm`. `Count` executes at interrupt level. `Algorithm` executes in an asynchronous task. The generated code for these blocks is tailored for the VxWorks® operating system. However, you can modify the `Async Interrupt` and `Task Sync` blocks to generate code for your run-time environment whether you are using an operating system or not.

Multirate Modeling in Multitasking Mode (VxWorks® OS)

This example generates code for a multirate discrete-time model configured for a multitasking operating system target (VxWorks®). The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the **Periodic sample time constraint** solver configuration parameter setting. The solver is set for multitasking operation, which means a Rate Transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Simulink® and the code generator enforce proper rate transitions. This model specifies an explicit Rate Transition block. Alternatively, you can instruct Simulink® to insert this block for you by setting the model configuration parameter **Automatically handle rate transition for data transfer**.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the **Display Sample Time Colors** button to update the diagram and show sample-time colors.

Example Model

```
model = 'rtwdemo_mrmtos';
open_system(model);
```

Export Code Generated from Model to External Application in Embedded Coder

Control Generation of C++ Class Interfaces

Using the **Code interface packaging** (Simulink Coder) option `C++ class`, on the **Code Generation** > **Interface** pane of the Configuration Parameters dialog box, you can generate a C++ class interface to model code. The generated interface encapsulates required model data into C++ class attributes and model entry point functions into C++ class methods. The benefits of C++ class encapsulation include:

- Greater control over access to model data
- Ability to multiply instantiate model classes
- Easier integration of model code into C++ programming environments

C++ class encapsulation also works for right-click builds of nonvirtual subsystems. (For information on requirements that apply, see “Configure C++ Class Interfaces for Nonvirtual Subsystems” on page 39-54.)

The general procedure for generating C++ class interfaces to model code is as follows:

1. Configure your model to use an `ert.tlc` system target file provided by MathWorks.
2. Select the `C++` language for your model.
3. Select `C++ class` code interface packaging for your model.
4. Optionally, configure related C++ class interface settings for your model code, using either a graphical user interface (GUI) or application programming interface (API).
5. Generate model code and examine the results.

To get started with an example, see “Simple Use of C++ Class Control” on page 39-36. For more details about configuring C++ class interfaces for your model code, see “Customize C++ Class Interfaces Using Graphical Interfaces” on page 39-43 and “Customize C++ Class Interfaces Programmatically” on page 39-54. For limitations that apply, see “C++ Class Interface Control Limitations” on page 39-61.

Note For an example of C++ class code generation, see the example model `rtwdemo_cppclass`.

Code Replacement Customization for Simulink Models in Embedded Coder

What Is Code Replacement Customization?

Customize how and when the code generator replaces C/C++ code that it generates by default for functions and operators by developing a custom code replacement library. You can develop libraries interactively with the **Code Replacement Tool** or programmatically.

- Develop libraries tailored to specific application requirements
- Add identifiers to the list of reserved keywords the code generator considers during code replacement
- Customize the code generator's match and replacement process for functions

To get started, "Quick Start Code Replacement Library Development - Simulink®" on page 65-28.

Code Replacement Match and Replacement Process

When the code generator encounters a call site for a function or operator, it:

1. Creates and partially populates a code replacement entry object with the function or operator name or key and conceptual arguments.
2. Uses the entry object to query the configured code replacement library for a conceptual representation match. The code generator searches the tables in a code replacement library for a match in the order that the tables appear in the library. When searching for a match, the code generator takes into account:
   - Conceptual name or key
   - Arguments, including quantity, type, type qualifiers, and complexity
   - Algorithm (computation method)
   - Fixed-point saturation and rounding modes
   - Priority
3. When a match exists, the code generator returns a code replacement object, fully populated with the conceptual representation, implementation representation, and priority. If the code generator finds multiple matches within a table, the entry priority determines the match. The priority can range from 0 to 100. The highest priority is 0. The code generator uses a higher-priority entry over a similar entry with a lower priority.

4 Uses the C or C++ replacement function prototype in the code replacement object to generate code.

Code Replacement Customization Limitations

- Code replacement verification — It is possible that code replacement behaves differently than you expect. For example, data types that you observe in code generator input might not match what the code generator uses as intermediate data types during an operation. Verify code replacements by examining generated code. See “Verify Code Replacements” on page 65-80.
- Code replacement for matrices — Code replacement libraries do not support the replacement of functions that have variable-size inputs.
- Tokens in file paths—You can include tokens in file paths when specifying build information for a code replacement entry by using the programming interface only. The ability to include tokens is not available from the Code Replacement Tool. See “Specify Build Information for Replacement Code” on page 65-62.
- Addition and subtraction operation replacements—See“Addition and Subtraction Operator Code Replacement” on page 65-178 for relevant limitations.
- Data alignment—
  - Not supported for
    - Arguments associated with a built-in custom storage class with `DataScope` set to `Exported` or the imported built-in custom storage class `GetSet`
    - Software-in-the-loop (SIL)
    - Processor-in-the-loop (PIL)
    - Model reference parameters
    - Exported functions in Stateflow charts
    - Replaced functions that are generated with C function prototype control or C++ class I/O arguments step method and that use root-level I/O variables
    - Replaced functions that are generated with the AUTOSAR system target file and that use root-level I/O or AUTOSAR inter-runnable access functions
  - If the following conditions exist, the code generator includes data alignment directives for root-level I/O variables in the `ert_main.c` or `ert_main.cpp` file it produces:

- Compiler supports global variable alignment
- Generate an example main program (select **Configuration Parameters** > **Generate an example main program**)
- Generate a reusable function interface for the model (set **Configuration Parameters** > **Code Generation** > **Interface** > **Code interface packaging** to `Reusable function`)
- Function uses root-level I/O variables that are passed in as individual arguments (set **Configuration Parameters** > **Code Generation** > **Interface** > **Pass root-level I/O as**to `Individual arguments`)
- Replaced function uses a root-level I/O variable
- Replaced function imposes alignment requirements

If you discard the generated example main program, align used root-level I/O variables correctly.

If you choose not to generate an example main program in this case, the code generator does not replace the function.

- If a replacement imposes alignment requirements on the shared utility interface arguments, the code generator does not honor data alignment. Under these conditions, replacement does not occur. Replacement is allowed if the registered data alignment type specification supports alignment of local variables, and the replacement involves only local variables.
- For `Simulink.Bus`:
  - If user registered alignment specifications do not support structure field alignment, aligning `Simulink.Bus` objects is not supported unless the `Simulink.Bus` is imported.
  - When aligning a `Simulink.Bus` data object, the elements in the bus object are aligned on the same boundary. The boundary is the lowest common multiple of the alignment requirements for each individual bus element.
- When you specify alignment for functions that occur in a model reference hierarchy, and multiple models in the hierarchy operate on the same function data, the bottommost model dictates alignment for the rest of the hierarchy. If the alignment requirement for a function in a model higher in the hierarchy cannot be honored due to the alignment set by a model lower in the hierarchy, the replacement in the higher model does not occur. In some cases, an error message is generated. To work around this issue, if the shared data is represented by a bus

or signal object, manually set the alignment property on the shared data by setting the alignment property of the `Simulink.Bus` or `Simulink.Signal` object.

- It is your responsibility to honor the `Alignment` property setting for custom storage classes that you create.

See “Data Alignment for Code Replacement” on page 65-137.

- `coder.replace` function — See `coder.replace` for relevant limitations.

Code You Can Replace From Simulink Models

Code that the code generator replaces depends on the code replacement library (CRL) that you use. By default, the code generator does not apply a code replacement library. Your choice of libraries is dependent on product licensing and whether you have access to custom libraries.

For information on how to explore functions and operators that a code replacement library supports, see “Choose a Code Replacement Library” on page 52-8 license and want to develop a custom code replacement library, see Code Replacement Customization.

`sqrt`	Integer Floating point Fixed point	Scalar Vector Matrix	Real
`tan`	Floating point	Scalar Vector Matrix	Real Complex input/complex output Real input/complex output
`tand`[2]	Floating point	Scalar Vector Matrix	Real Complex
`tanh`	Floating point	Scalar Vector Matrix	Real Complex input/complex output Real input/complex output

[1] Wrap on integer overflow only. Clear block parameter **Saturate on integer overflow**.

[2] Only when used with the MATLAB Function block.

[3] Supports the CORDIC approximation method.

[4] Stateflow support only.

Math Functions – Stateflow Support

When generating C/C++ code from Stateflow charts, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following math functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`abs`[1]	Integer Floating point	Scalar	Real
`acos`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output
`acosd`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acot`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acotd`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acoth`[3,5]	Floating point	Scalar Vector Matrix	Real Complex
`acsc`[3]	Floating point	Scalar Vector Matrix	Real Complex
`acscd`[3]	Floating point	Scalar Vector Matrix	Real Complex

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`acsch`[3]	Floating point	Scalar Vector Matrix	Real Complex
`asec`[3]	Floating point	Scalar Vector Matrix	Real Complex
`asecd`[3]	Floating point	Scalar Vector Matrix	Real Complex
`asech`[3]	Floating point	Scalar Vector Matrix	Real Complex
`asin`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`tanh`[2]	Floating point	Scalar Vector Matrix	Real Complex Complex input/complex output Real input/complex output

[1] Wrap on integer overflow only.

[2] For models involving vectors or matrices, the code generator replaces only functions coded in the MATLAB action language.

[3] The code generator replaces only functions coded in the MATLAB action language.

Memory Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following memory functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`memcmp`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memcpy`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memset`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex
`memset2zero`	Void pointer (`void*`)	Scalar Vector Matrix	Real Complex

Some target processors provide optimized functions to set memory to zero. Use the code replacement library programming interface to replace the `memset2zero` function with more efficient target-specific functions.

Nonfinite Functions

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following nonfinite functions with application-specific implementations.

Function	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
`getInf`	Floating point	Scalar	Real
`getMinusInf`	Floating point	Scalar	Real
`getNaN`	Floating point	Scalar	Real
`rtIsInf`	Floating point	Scalar	Real Complex
`rtIsNaN`	Floating point	Scalar	Real Complex

Mutex and Semaphore Functions

Mutex and semaphore functions control access to resources shared by multiple processes in multicore target environments. MathWorks provides code replacement libraries that support mutex and semaphore replacement for Rate Transition and Task Transition blocks on Windows, Linux, Mac, and VxWorks platforms.

Generated mutex and semaphore code typically consists of:

- In model initialization code, an initialization function call to create a mutex or semaphore to control entry to a critical section of code.
- In model step code:
  - Before code for a data transfer between tasks enters the critical section, mutex lock or semaphore wait function calls to reserve a critical section of code.
  - After code for a data transfer between tasks finishes executing the critical section, mutex unlock or semaphore post function calls to release the critical section of code.

- In model termination code, an optional destroy function call to explicitly delete the mutex or semaphore.

Depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following mutex and semaphore functions with application-specific implementations.

Function	Key
Mutex Destroy	`RTW_MUTEX_DESTROY`
Mutex Init	`RTW_MUTEX_INIT`
Mutex Lock	`RTW_MUTEX_LOCK`
Mutex Unlock	`RTW_MUTEX_UNLOCK`
Semaphore Destroy	`RTW_SEM_DESTROY`
Semaphore Init	`RTW_SEM_INIT`
Semaphore Post	`RTW_SEM_POST`
Semaphore Wait	`RTW_SEM_WAIT`

Operators

When generating C/C++ code from a Simulink model, depending on code replacement libraries available in your development environment, you can configure the code generator to replace instances of the following operators with application-specific implementations.

Mixed data type support indicates that you can specify different data types for different inputs.

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Addition (+)[1]	`RTW_OP_ADD`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Subtraction (-)[1]	RTW_OP_MINUS	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Multiplication (*)[2]	RTW_OP_MUL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Division (/)	RTW_OP_DIV	Integer Floating point Fixed-point Mixed	Scalar	Real Complex
Data type conversion (cast)	RTW_OP_CAST	Integer Floating point[3] Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Shift left (<<)	RTW_OP_SL	Integer Fixed-point Mixed	Scalar Vector Matrix[4]	Real
Shift right arithmetic (>>)[5]	RTW_OP_SRA	Integer Fixed-point Mixed	Scalar Vector Matrix[4]	Real
Shift right logical (>>)	RTW_OP_SRL	Integer Fixed-point Mixed	Scalar Vector Matrix[4]	Real
Element-wise matrix multiplication (.*)[6]	RTW_OP_ELEM_MUL	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Matrix right division (`/`)	`RTW_OP_RDIV`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix left division (`\`)	`RTW_OP_LDIV`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Matrix inversion (`inv`)	`RTW_OP_INV`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Complex conjugation	`RTW_OP_CONJUGATE`	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Transposition (`.'`)	`RTW_OP_TRANS`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Hermitian (complex conjugate) transposition (`'`)	`RTW_OP_HERMITIAN`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with transposition[2]	`RTW_OP_TRMUL`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex
Multiplication with Hermitian transposition[2]	`RTW_OP_HMMUL`	Integer Floating point Fixed-point Mixed	Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
Multiplication followed by shift right arithmetic (u1*u2>>u3)[7]	RTW_OP_MUL_SRA	Integer Fixed-point	Scalar	Real
Multiplication followed by division (u1*u2/u3)[8]	RTW_OP_MULDIV	Integer Fixed-point	Scalar	Real
Greater than (>)	RTW_OP_GREATER_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Greater than or equal (>=)	RTW_OP_GREATER_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than (<)	RTW_OP_LESS_THAN	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Less than or equal (<=)	RTW_OP_LESS_THAN_OR_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Equal (==)	RTW_OP_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex
Not equal (!=)	RTW_OP_NOT_EQUAL	Integer Floating point Fixed-point Mixed	Scalar Vector Matrix	Real Complex

Operator	Key	Data Type Support	Scalar, Vector, Matrix Support	Real, Complex Support
[1] See “Addition and Subtraction Operator Code Replacement” on page 65-178 for details to consider when defining mappings for addition and subtraction code replacements. [2] Can map to Basic Linear Algebra Subroutine (BLAS) multiplication functions. [3] Scaled floating point is not supported. [4] Shift operator replacement with matrix data is supported for shift values that you specify with an input port. Replacement is not supported for shift values that you specify in a block parameter dialog. [5] The code generator converts some arithmetic shift rights to logical shift rights. To avoid unexpected results, when creating a code replacement library that includes a table entry for an arithmetic shift right implementation, also include an entry for a logical shift right implementation. [6] Use the multiplication (*) operator (`RTW_OP_MUL`) for scalar multiplication. [7] Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; shift operand is an unsigned integer; and net slope is equal to 1 (`U1_slope * U2_slope == Mul_output_slope` and `Mul_output_slope == output_slope_of_shift_operation`). [8] Requires scalar, real, or fixed-point data types with zero bias; output type of the multiplication operation to accommodate all possible output values; and net slope is equal to 1 (`U1_slope * U2_slope == Mul_output_slope == U3_slope * Div_output_slope`).

Develop a Code Replacement Library

Iterate through the following steps, as necessary, to develop a code replacement library:

1. “Identify Code Replacement Requirements” on page 65-39
2. “Prepare for Code Replacement Library Development” on page 65-42
3. “Define Code Replacement Mappings” on page 65-44
4. “Specify Build Information for Replacement Code” on page 65-62
5. “Register Code Replacement Mappings” on page 65-71
6. “Verify Code Replacements” on page 65-80
7. “Deploy Code Replacement Library” on page 65-97

To get started, see “Identify Code Replacement Requirements” on page 65-39.

To experiment with the process and tools, see “Quick Start Code Replacement Library Development - Simulink®” on page 65-28.

Quick Start Code Replacement Library Development - Simulink®

This example shows how to develop a code replacement library that includes an entry for generating replacement code for the math function `sin`. You use the Code Replacement Tool.

Prerequisites

To complete this example, install the following software:

- MATLAB®
- MATLAB Coder™
- Simulink®
- Simulink Coder™
- Embedded Coder®
- Compiler

For instructions on installing MathWorks® products, see the MATLAB installation documentation. If you have installed MATLAB and want to see what other MathWorks products are installed, in the Command Window, enter `ver`.

For a list of supported compilers, see `https://www.mathworks.com/support/compilers/current_release/`.

Open the Code Replacement Tool

1. Start a MATLAB session.

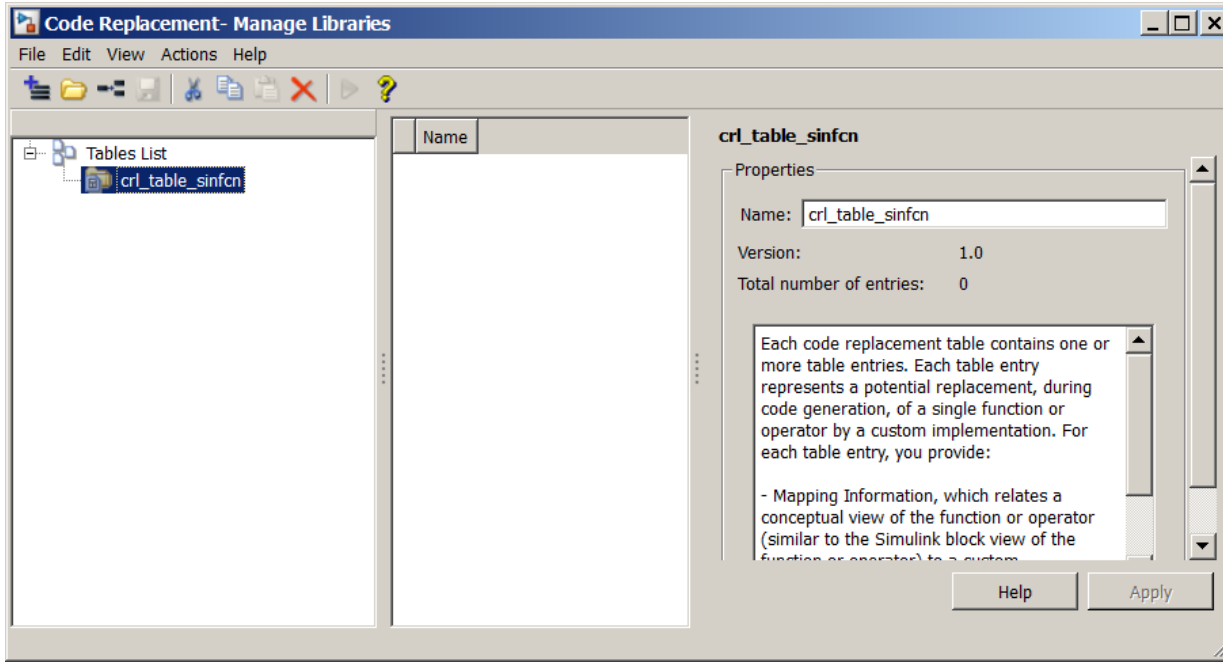
2. Create or navigate (`cd`) to an empty folder.

3. At the command prompt, enter the `crtool` command. The Code Replacement Tool window opens.

Create Code Replacement Table

1. In the Code Replacement Tool window, select **File > New table**

2. In the right pane, name the table `crl_table_sinfcn` and click **Apply**. When you save the table, the tool saves it with the file name `crl_table_sinfcn.m`.



Create Table Entry

Create a table entry that maps a `sin` function with `double` input and `double` output to a custom implementation function.

1. In the left pane, select table `crl_table_sinfcn`. Then, select **File > New entry > Function**. The entry appears in the middle pane, initially without a name.

2. In the middle pane, select the new entry.

3. In the right pane, on the **Mapping Information** tab, from the **Function** menu, select `sin`.

4. Leave **Algorithm** set to `Unspecified`, and leave parameters in the **Conceptual function** group set to default values.

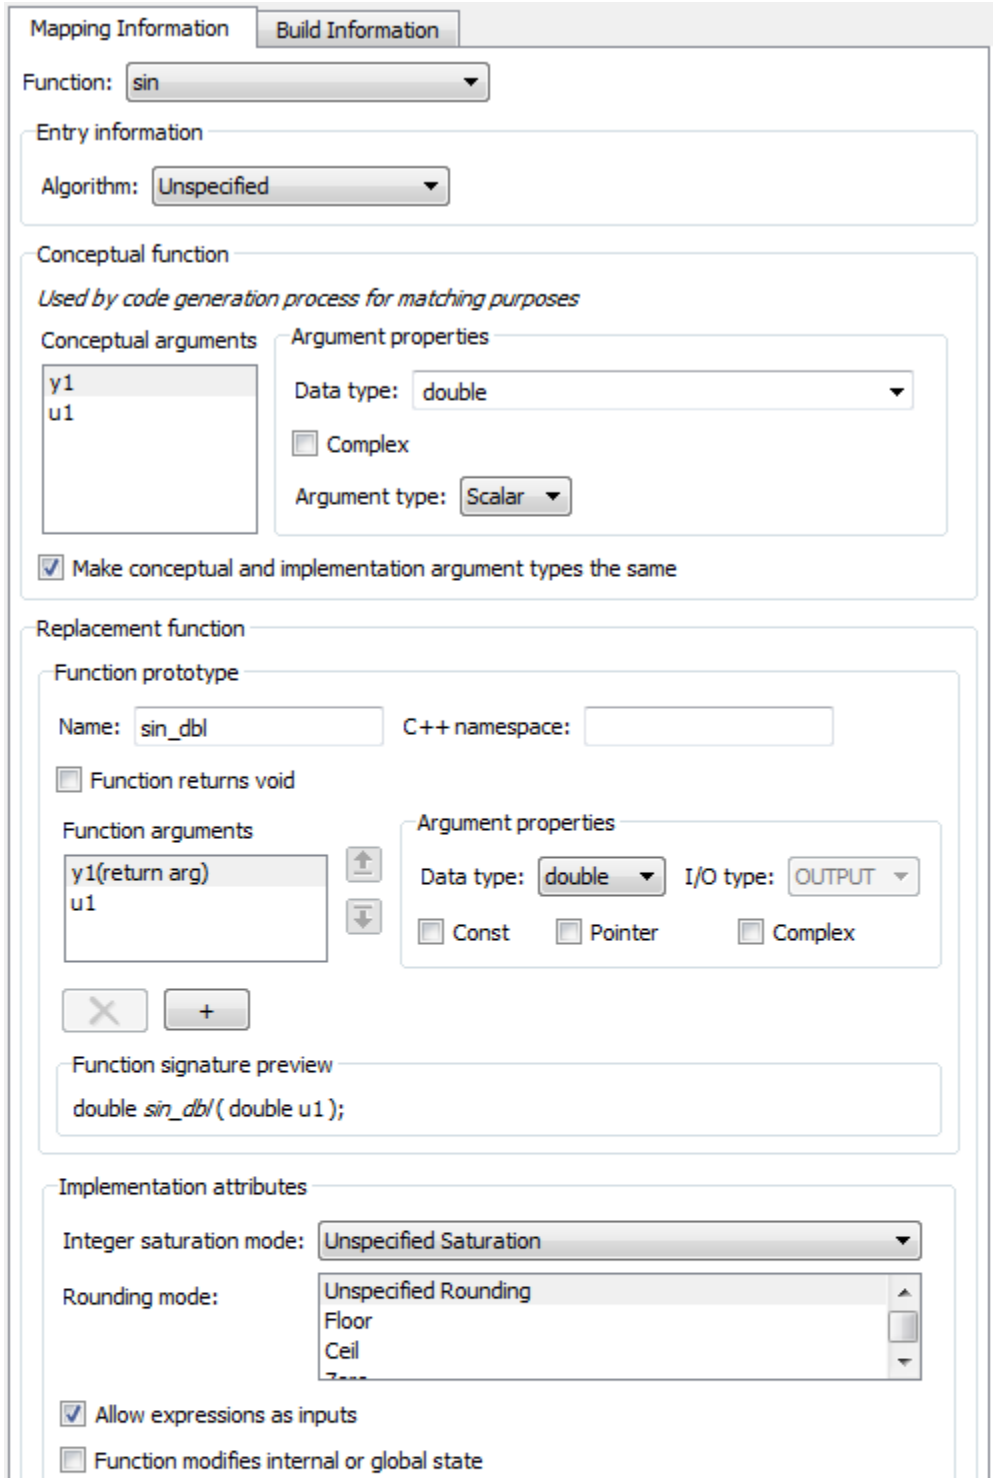
5. In the **Replacement function** group, name the replacement function `sin_dbl`.

6. Leave the remaining parameters in the **Replacement function** group set to default values.

7. Click **Apply**. The tool updates the **Function signature preview** to reflect the specified replacement function name.

8. Scroll to the bottom of the **Mapping Information** tab and click **Validate entry**. The tool validates your entry.

The following figure shows the completed mapping information.



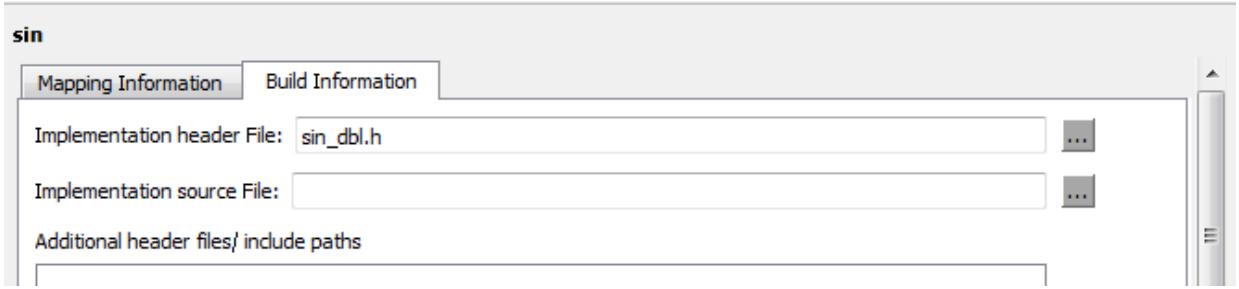
Mapping Information
Build Information
Function: sin
Entry information
Algorithm: Unspecified
Conceptual function
Used by code generation process for matching purposes
Conceptual arguments
y1
u1
Argument properties
Data type: double
Complex
Argument type: Scalar
Make conceptual and implementation argument types the same
Replacement function
Function prototype
Name: sin_dbl
C++ namespace:
Function returns void
Function arguments
y1(return arg)
u1
Argument properties
Data type: double
I/O type: OUTPUT
Const
Pointer
Complex
+
Function signature preview
double sin_dbl(double u1);
Implementation attributes
Integer saturation mode: Unspecified Saturation
Rounding mode: Unspecified Rounding
Floor
Ceil
Allow expressions as inputs
Function modifies internal or global state

Specify Build Information for Replacement Code

1. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_dbl.h`.

2. Leave the remaining parameters set to default values.

3. Click **Apply**.



4. Optionally, you can revalidate the entry. Return to the **Mapping Information** tab and click **Validate entry**.

Create Another Table Entry

Create an entry that maps a `sin` function with `single` input and `double` output to a custom implementation function named `sin_sgl`. Create the entry by copying and pasting the `sin_dbl` entry.

1. In the middle pane, select the `sin_dbl` entry.

2. Select **Edit > Copy**.

3. Select **Edit > Paste**.

4. On the **Mapping Information** tab, in the **Conceptual function** section, set the data type of input argument `u1` to `single`.

5. In the **Replacement function** section, name the function `sin_sgl`. Set the data type of input argument `u1` to `single`.

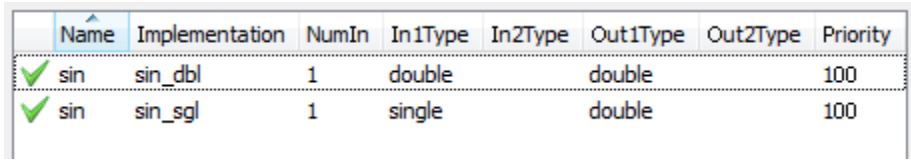
6. Click **Apply**. Note the changes that appear for the **Function signature preview**.

7. On the **Build Information** tab, for the **Implementation header file** parameter, enter `sin_sgl.h`. Leave the remaining parameters set to default values and click **Apply**.

Validate the Code Replacement Table

1. Select **Actions > Validate table**.

2. If the tool reports errors, fix them, and rerun the validation. Repeat fixing and validating errors until the tool does not report errors. The following figure shows a validation report.



Name	Implementation	NumIn	In1Type	In2Type	Out1Type	Out2Type	Priority
sin	sin_dbl	1	double		double		100
sin	sin_sgl	1	single		double		100

Save the Code Replacement Table

Save the code replacement table to a MATLAB file in your working folder. Select **File > Save table**. By default, the tool uses the table name to name the file. For this example, the tool saves the table in the file `crl_table_sinfcn.m`.

Review the Code Replacement Table Definition

Consider reviewing the MATLAB code for your code replacement table definition. After using the tool to create an initial version of a table definition file, you can update, enhance, or copy the file in a text editor.

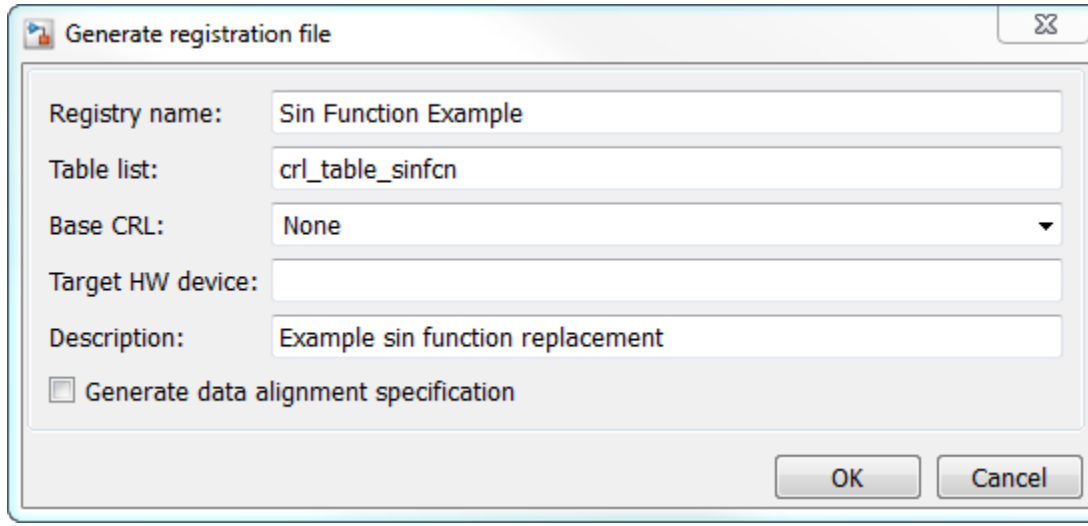
To review it, in MATLAB or another text editor, open the file `crl_table_sinfcn.m`.

Generate a Registration File

Before you can use your code replacement table, you must register it as part of a code replacement library. Use the Code Replacement Tool to generate a registration file.

1. In the Code Replacement Tool, select **File > Generate registration file**.

2. In the **Generate registration file** dialog box, edit the dialog box fields to match the following figure, and click **OK**.



3. In the **Select location to save the registration file** dialog box, specify a location for the registration file. The location must be on the MATLAB path or in the current working folder. Save the file. The tool saves the file as `rtwTargetInfo.m`.

Register the Code Replacement Table

At the command prompt, enter:

```
RTW.TargetRegistry.getInstance('reset');
```

Review and Test Code Replacements

Apply your code replacement library. Verify that the code generator makes code replacements that you expect.

1. Check for errors. At the command line, invoke the table definition file. For example:

|tbl = crl_table_sinfcn

tbl =

```
TflTable with properties:

                Version: '1.0'
       ReservedSymbols: []
```

```
   StringResolutionMap: []
            AllEntries: [2x1 RTW.TflCFunctionEntry]
          EnableTrace: 1|
```

If an error exists in the definition file, the invocation triggers a message. Fix the error and try again.

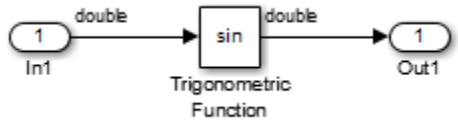
2. Use the Code Replacement Viewer to check your code replacement entries. For example:

```
crviewer('Sin Function Example')
```

In the viewer, select entries in your table and verify that the content is what you expect. The viewer can help you detect issues such as:

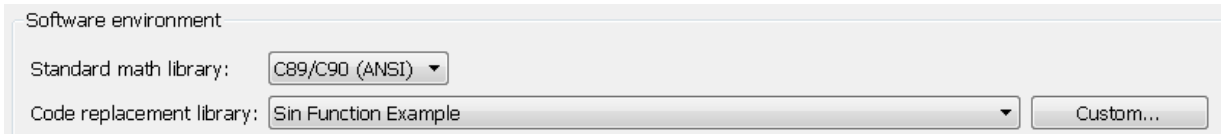
- Incorrect argument order.
- Conceptual argument names that do not match what the code generator expects.
- Incorrect priority settings.

3. Identify existing model or create a model that includes a Trigonometric block that is set to the `sin` function. For example:



4. Open the model and configure it for code generation with an Embedded Coder (ERT-based) target.

5. See whether your library is listed as an available option for the **Code Generation > Interface > Code replacement library** model configuration parameter. If it is, select it.



If it is not listed, open the registration file, `rtwTargetInfo.m`. See whether you entered the correct code replacement table name when you created the file. If you hover the

cursor over the selected library, a tool tip appears. This tip contains information derived from your code replacement library registration file, such as the library description and the list of tables it contains.

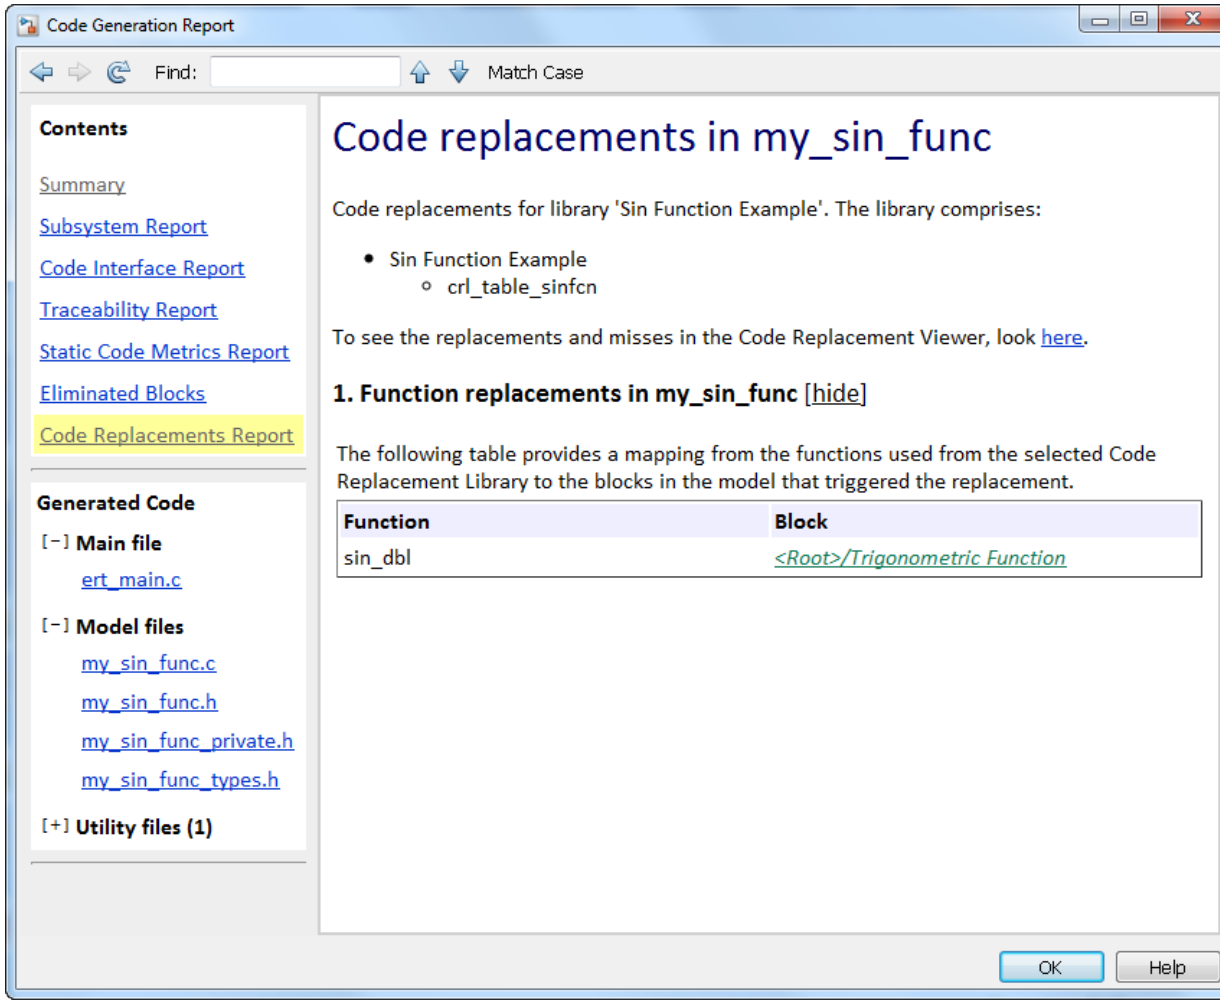
6. To find parameters quickly, in the Configuration Parameters dialog box **Search** field, type the parameter name. Configure the code generation report for code replacement analysis by selecting the following parameters:

- **Create code generation report**
- **Open report automatically**
- **Code-to-model**
- **Model-to-code**
- **Summarize which blocks triggered code replacements**
- **Include comments**
- **Simulink block comments**
- **Simulink block descriptions**

7. Configure the model to generate code only. Before you build an executable program, confirm that the code generator is replacing code as expected.

8. Generate code for the model.

9. Review code replacement results in the Code Replacement Report section of the code generation report.



The report indicates that the code generator found a match and applied the replacement code for the function `sin_dbl`.

10. Review the code replacements. In the model window, right-click the Trigonometric Function block. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report opens and highlights the code replacement in `my_sin_func.c`. In this case, the code generator replaced `sin` with `sin_dbl`.

Identify Code Replacement Requirements

The first step to developing a code replacement library is to consider the following types of requirements for the library.

Mapping Information Requirements

- Are you defining a code replacement mapping for the first time?
- Are you updating code replacement entries in an existing library? Or, are you creating a new library?
- Are you rapid prototyping code replacements?
- Can you base your mappings on existing mappings?
- What type of code do you want to replace? Options include:
  - Math operation
  - Function
  - BLAS operation
  - CBLAS operation
  - Net slope fixed-point operation
  - Semaphore or mutex functions
- Do you want to change the inline or nonfinite behavior for functions?
- What specific functions and operations do you want to replace?
- What input and output arguments does the function or operator that you are replacing take? For each argument, what is the data type, complexity, and dimensionality?
- What does the prototype for your replacement code look like?
  - What is the replacement function name?
  - What are the input and output arguments?
  - Are there return values?
  - What is the data type, complexity, and dimensionality of each argument and return value?

Build Information Requirements

- Does your replacement function implementation require a header file? If yes, specify the header file.
- If the replacement function implementation requires a header file, what is the path for that file?
- Is the source file for the replacement function in your working folder? If not, you can explicitly specify the source file name and extension. For example, if the file is required in the generated makefile or specified in a build information object, specify the source file.
- Does the replacement function use additional include files? If yes, what are they and what are the paths for those files?
- Does the replacement function use additional source files? If yes, what are they and what are the paths for those files?
- What compiler flags are required for compiling code that includes the replacement code?
- What linker flags are required for building an executable that includes the replacement code?
- Are the required header, source, and object files for building an executable that includes your replacement code in the working folder for your project? If not, before starting the build process, do you want the code generator to copy required files to the build folder?

Registration Information Requirements

- What do you want to name your code replacement library?
- What code replacement tables do you want to include in the library? What are the file names and paths for the tables?
- What is the purpose of the library? You can document the purpose as the library description.
- Does the library apply to specific hardware devices? If yes, what devices?
- Are you developing a hierarchy of code replacement libraries? Is the library that you are developing based (dependent) on another library? For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x` device library.

- Do you need to specify data alignment for the library? What data alignments are required? For each specification, what type of alignment is required and for what programming language?

Next, prepare for developing a library by reviewing a code replacement library development checklist.

- “Develop a Code Replacement Library” on page 65-27
- “Prepare for Code Replacement Library Development” on page 65-42
- “What Is Code Replacement Customization?” on page 65-3

Prepare for Code Replacement Library Development

After you identify your code replacement requirements, prepare for library development by reviewing this checklist:

- Get familiar with the library development process.
- Decide whether to define code replacement mappings and produce a registration file interactively with the **Code Replacement Tool** or programmatically.
- Identify or develop MATLAB code and Simulink models to test your code replacement library. Determine if you would like to use `coder.replace` in your programs to provide warning or error feedback when a code replacement library function cannot be found.
- Consider the hierarchy and organization of your library. A library can consist of multiple tables and each table can include multiple entries. How do you want to organize the library to optimize reuse of tables and entries? For example, a registration file can define code replacement tables organized in a hierarchy of code replacement libraries based on entries that increase in specificity:
  - Common entries
  - Entries for TI devices
  - Entries for TI C6xx devices
  - Entries specific to the TI C67x device
- If support files, such as header files, additional source files, and dynamically linked libraries are not in your current working folder, note their location. You need to specify the paths for such files.

Next, based on your requirements and preparation, define code replacement mappings.

- “Define Code Replacement Mappings” on page 65-44

- “Develop a Code Replacement Library” on page 65-27
- “What Is Code Replacement Customization?” on page 65-3

Define Code Replacement Mappings

After you prepare for library development, use your requirements to define code replacement mappings. A code replacement mapping associates a conceptual representation of a function or operator that is familiar to the code generator with a custom implementation representation that specifies a C or C++ replacement function prototype. You capture a mapping as an entry in a code replacement table:

- Interactively, by using the Code Replacement Tool.
- Programmatically, by using a MATLAB programming interface.

Choose an Approach for Defining Code Replacement Mappings

The following table lists situations to help you decide when to use the interactive or programmatic approach.

Situation	Approach
Defining mappings for the first time.	Code Replacement Tool.
Rapid prototyping mappings.	Code Replacement Tool to quickly generate, register, and test mappings.
Developing a mapping as a template or starting point for defining similar mappings.	Code Replacement Tool to generate definition code that you can copy and modify.
Modifying a registration file, including copying and pasting content.	MATLAB Editor to update the programming interface directly.
Defining mappings that specify attributes not available from the Code Replacement Tool (for example, sets of algorithm parameters).	Programming interface.
Reusing existing code for new mappings by copying, pasting, and editing existing mappings.	Programming interface.

Define Mappings Interactively with the Code Replacement Tool

This example shows how to use the Code Replacement Tool to develop code replacement mappings. The tool is ideal for getting started with developing mappings, rapid prototyping, and developing a mapping to use as a starting point for defining similar mappings.

Open the Code Replacement Tool

Do one of the following:

- In the Command Window, enter the command `crtool`.
- In the Configuration Parameters dialog box, navigate to **Code Generation** pane. In the **Advanced parameters** section, scroll down and click **Custom CRL...** button.

An Embedded Coder license is not required to create a custom code replacement library. However, you must have an Embedded Coder license to use a such a library.

By default, the tool displays, left to right, a root pane, a list pane, and a dialog pane. You can manipulate the display:

- Drag boundaries to widen, narrow, shorten, or lengthen panes, and to resize table columns.
- Select **View > Show dialog pane** to hide or display the right-most pane.
- Click a table column heading to sort the table based on contents of the selected column.
- Right-click a table column heading and select **Hide** to remove the column from the display. (You cannot hide the **Name** column.)

Create a Code Replacement Table

1. In the **Code Replacement Tool** window, select **File > New table**.
2. In the right pane, name the table and click **Apply**. Later, when you save the table, the tool uses the table name that you specify to name the file. For example, if you enter the name `my_sinfcn`, the tool names the file `my_sinfcn.m`.

Create Table Entries

Create one or more table entries. Each entry maps the conceptual representation of a function or operator to your implementation representation. The information that you enter depends on the type of entry you create. Enter the following information:

1. In the left pane, select the table to which you want to add the entry.
2. Select **File** > **New entry** > **entry-type**, where **entry-type** is one of:

   - Math Operation
   - Function
   - BLAS Operation
   - CBLAS Operation
   - Net Slope Fixed-Point Operation
   - Semaphore entry
   - Customization entry

   The new entry appears in the middle pane, initially without a name.
3. In the middle pane, select the new entry.
4. In the right pane, on the **Mapping Information** tab, from the **Function** or **Operation** menu, select the function or operation that you want the code generator to replace. Regardless of the entry type, make a selection from this menu. Your selection determines what other information you specify.

   Except for customization entries, you also specify information for your replacement function prototype. You can also specify implementation attributes, such as the rounding modes to apply.
5. If prompted, specify additional entry information that you want the code generator to use when searching for a match. For example, when you select an addition or subtraction operation, the tool prompts you to specify an algorithm (`Cast before operation` or `Cast after operation`).
6. Review the conceptual argument information that the tool populates for the function or operation. Conceptual input and output arguments represent arguments for the function or operator being replaced. Conceptual arguments observe naming conventions (`'y1'`, `'u1'`, `'u2'`, ...) and data types familiar to the code generator.

When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have `IOType` of `RTW_IO_INPUT`.

If you do not want the data types for your implementation to be the same as the conceptual argument types, clear the **Make the conceptual and implementation argument types the same** check box. For example, most ANSI-C functions operate on and return `double` data. Clear the check box if want to map a conceptual representation of the function to an implementation representation that specifies an argument and return value. For example, clear the check box to map the conceptual representation of the function `sin` to an implementation representation that specifies an argument and return value of type `single` (`single sin(single)`), of type `double` (`double sin(double)`. In this case, the code generator produces the following code:

```
y = (single) sin(u1);
```

If you select `Custom` for a function entry, specify only conceptual argument information.

7 Specify the name and argument information for your replacement function. As you enter the information and click **Apply**, the tool updates the **Function signature preview**.

When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type `RTW_IO_OUTPUT` requires a compatible implementation argument of type `RTW_IO_OUTPUT` or `RTW_IO_INPUT_OUTPUT`. The default I/O type is `RTW_IO_INPUT`.

8 Specify additional implementation attributes that apply. For example, depending on the type and name of the entry that you specify, the tool prompts you to specify:

- Integer saturation mode
- Rounding modes
- Whether to allow inputs that include expressions
- Whether a function modifies internal or global state

9 Click **Apply**.

Validate Tables and Entries

The Code Replacement Tool provides a way to validate the syntax of code replacement tables and table entries as you define them. If the tool finds validation errors, you can

address them and retry the validation. Repeat the process until the tool does not report errors.

To	Do
Validate table entries	Select an entry, scroll to the bottom of the **Mapping Information** tab, and click **Validate entry**. Alternatively, select one or more entries, right-click, and select **Validate entries**.
Validate a table	Select the table. Then, select **Actions** > **Validate table**.

Save a Table

When you save a table, the tool validates unvalidated content.

1. Select **File** > **Save table**.
2. In the Browse For Folder dialog box, specify a location and name for the file. Typically, you select a location on the MATLAB path. By default, the tool names the file using the name that you specify for the table with the extension `.m`.
3. Click **Save**.

Open and Modify Tables

After saving a code replacement table, to make changes in the table:

1. Select **File** > **Open table**.
2. In the Import file dialog box, browse to the MATLAB file that contains the table.

Repeat the sequence to open and work on multiple tables.

If you open multiple tables, you can manage the tables together. For example, use the tool to:

- Create new table entries.
- Delete entries.
- Copy and paste or cut and paste information between tables.

Define Mappings Programmatically

This example shows how to define a code replacement mapping programmatically. The programming interface for defining code replacement table mappings is ideal for

- Modifying tables that you create with the Code Replacement Tool.
- Defining mappings for specialized entries that you cannot create with the Code Replacement Tool.
- Replicating and modifying similar entries and tables.

Steps for defining a mapping programmatically are:

- “Create Code Replacement Table” on page 65-49
- “Create Table Entry” on page 65-49
- “Set Entry Parameters” on page 65-51
- “Create Conceptual Arguments” on page 65-53
- “Create Implementation Arguments” on page 65-55
- “Add Entry to Table” on page 65-59
- “Validate Entry” on page 65-59
- “Save Table” on page 65-60

Create Code Replacement Table

1. Create a table definition file that contains a function definition. For example:

   ```
   function hTable = crl_table_sinfcn()
   ```

2. Within the function body, create the table by calling the function `RTW.TflTable`.

   ```
   hTable = RTW.TflTable;
   ```

Create Table Entry

For each function or operator that you want the code generator to replace, map a conceptual representation of the function or operator to an implementation representation as a table entry.

1. Within the body of a table definition file, create a code replacement entry object. Call one of the following functions.

Entry Type	Function
Math operation	`RTW.TflCOperationEntry`
Function	`RTW.TflCFunctionEntry`
BLAS operation	`RTW.TflBlasEntryGenerator`

Entry Type	Function
CBLAS operation	`RTW.TflCBlasEntryGenerator`
Fixed-point addition and subtraction operations (support for `SlopesMustBeTheSame` and `MustHaveZeroNetBias` parameters)	`RTW.TflCOperationEntryGenerator`
Net slope fixed-point operation	`RTW.TflCOperationEntryGenerator_NetSlope`
Semaphore or mutex entry	`RTW.TflCSemaphoreEntry`
Custom function entry	*`MyCustomFunctionEntry`* (where *`MyCustomFunctionEntry`* is a class derived from `RTW.TflCFunctionEntryML`)
Custom operation entry	*`MyCustomOperationEntry`* (where *`MyCustomOperationEntry`* is a class derived from `RTW.TflCOperationEntryML`)

For example:

```
hEnt = RTW.TflCFunctionEntry;
```

You can combine steps of creating the entry, setting entry parameters, creating conceptual and implementation arguments, and adding the entry to a table with a single function call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` if you are creating an entry for a function and the function implementation meets the following criteria:

- Implementation argument names and order match the names and order of corresponding conceptual arguments.
- Input arguments are of the same type.
- The return and input argument names follow the code generator's default naming conventions:
  - Return argument is `y1`.
  - Input arguments are `u1`, `u2`, ..., `u`*`n`*.

For example:

```
registerCFunctionEntry(hTable, 100, 1, 'sin', 'double', ...
   'sin_dbl', 'double', 'sin_dbl.h','','');
```

As another alternative, you can significantly reduce the amount of code that you write by combining the steps of creating the entry and conceptual and implementation arguments with a call to the `createCRLEntry` function. In this case, specify the conceptual and implementation information as character vector or string scalar specifications.

For example:

```
hEnt = createCRLEntry(hTable, ...
    'double y1 = sin(double u1)', ...
    'mySin');
```

This approach does not support:

- C++ implementations
- Data alignment
- Operator replacement with net slope arguments
- Entry parameter specifications (for example, priority, algorithm, building information)
- Semaphore and mutex function replacements

Set Entry Parameters

Set entry parameters, such as the priority, algorithm information, and implementation (replacement) function name. Call the function listed in the following table for the entry type that you created.

Entry Type	Function
Math operation	`setTflCOperationEntryParameters`
Function	`setTflCFunctionEntryParameters`
BLAS operation	`setTflCOperationEntryParameters`
CBLAS operation	`setTflCOperationEntryParameters`

Entry Type	Function
Fixed-point addition and subtraction operations where there is a many-to-one mapping, such as a mapping for a range of fixed-point types to the same replacement function (support for `SlopesMustBeTheSame` and `MustHaveZeroNetBias` parameters)	`setTflCOperationEntryParameters`
Net slope fixed-point operation	`setTflCOperationEntryParameters`
Semaphore or mutex entry	`setTflCSemaphoreEntryParameters`
Custom function entry	`setTflCFunctionEntryParameters`
Custom operation entry	`setTflCOperationEntryParameters`

To see a list of the parameters that you can set, at the command line, create a new entry and omit the semicolon at the end of the command. For example:

```
hEnt = RTW.TflCFunctionEntry
```

```
hEnt =

  TflCFunctionEntry with properties:

             Implementation: [1x1 RTW.CImplementation]
         SlopesMustBeTheSame: 0
           BiasMustBeTheSame: 0
             AlgorithmParams: []
                    ImplType: 'FCN_IMPL_FUNCT'
       AdditionalHeaderFiles: {0x1 cell}
       AdditionalSourceFiles: {0x1 cell}
      AdditionalIncludePaths: {0x1 cell}
       AdditionalSourcePaths: {0x1 cell}
          AdditionalLinkObjs: {0x1 cell}
     AdditionalLinkObjsPaths: {0x1 cell}
         AdditionalLinkFlags: {0x1 cell}
      AdditionalCompileFlags: {0x1 cell}
                 SearchPaths: {0x1 cell}
                         Key: ''
                    Priority: 100
                 ArrayLayout: 'COLUMN_MAJOR'
               ConceptualArgs: [0x1 handle]
                    EntryInfo: []
```

```
                GenCallback: ''
                GenFileName: ''
             SaturationMode: 'RTW_SATURATE_UNSPECIFIED'
              RoundingModes: {'RTW_ROUND_UNSPECIFIED'}
          TypeConversionMode: 'RTW_EXPLICIT_CONVERSION'
             AcceptExprInput: 1
                 SideEffects: 0
                  UsageCount: 0
          RecordedUsageCount: 0
                 Description: ''
    StoreFcnReturnInLocalVar: 0
     AllowShapeAgnosticMatch: 0
                TraceManager: [1x1 RTW.TflTraceManager]
```

To see the implementation parameters, enter:

```
hEnt.Implementation
```

```
ans =

  CImplementation with properties:

            HeaderFile: ''
            SourceFile: ''
            HeaderPath: ''
            SourcePath: ''
                Return: []
        StructFieldMap: []
                  Name: ''
             Arguments: [0x1 RTW.Argument]
    ArgumentDescriptor: []
```

For example, to set entry parameters for the `sin` function and name your replacement function `sin_dbl`, use the following function call:

```
setTflCFunctionEntryParameters(hEnt, ...
          'Key', 'sin', ...
          'ImplementationName', 'sin_dbl');
```

Create Conceptual Arguments

Create conceptual arguments and add them to the entry's array of conceptual arguments.

- Specify output arguments before input arguments.

- Specify argument names that comply with code generator argument naming conventions:
  - `y1` for a return argument
  - `u1`, `u2`, ..., `u`*n* for input arguments
- Specify data types that are familiar to the code generator.
- The function signature, including argument naming, order, and attributes, must fulfill the signature match sought by function or operator callers.
- The code generator determines the size of the value for an argument with an unsized type, such as integer, based on hardware implementation configuration settings.

For each argument:

1. Identify whether the argument is for input or output, the name, and data type. If you do not know what arguments to specify for a supported function or operation, use the Code Replacement Tool to find them. For example, to find the conceptual arguments for the `sin` function, open the tool, create a table, create a function entry, and in the **Function** menu select `sin`.

   When validating the entry, the code generator validates that each conceptual argument has an I/O type that is compatible with the argument name. For example, an input must have `IOType` of `RTW_IO_INPUT`.

2. Create and add the conceptual argument to an entry. You can choose a method from the methods listed in this table.

If	Then

You want simpler code or want to explicitly specify whether the argument is scalar or nonscalar (vector or matrix).	Call the function `createAndAddConceptualArg`. For example:
	`createAndAddConceptualArg(hEnt, ...`
	`'RTW.TflArgNumeric', ...`
	`'Name', 'y1',...`
	`'IOType', 'RTW_IO_OUTPUT',...`
	`'DataTypeMode', 'double');`
	The second argument specifies whether the argument is scalar (`RTW.TflArgNumeric` or`RTW.TflArgMatrix`) .

If	Then

You want to create an argument based on a built-in argument definition (for example, scalar or nonscalar).	Call `getTflArgFromString` to create the argument. Then, call `addConceptualArg` to add the argument to the entry.
	
	`arg = getTflArgFromString(hEnt, 'y1','double');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`addConceptualArg(hEnt, arg);`

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.
	
	`hEnt = createCRLEntry(hTable, ...`
	`'double y1 = sin(double u1)', ...`
	`'mySin');`

The following code shows the second approach listed in the table for specifying the conceptual output and input argument definitions for the `sin` function.

```
% Conceptual Args

arg = getTflArgFromString(hEnt, 'y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
addConceptualArg(hEnt, arg);

arg = getTflArgFromString(hEnt, 'u1','double');
addConceptualArg(hEnt, arg);
```

Create Implementation Arguments

Create implementation arguments for the C or C++ replacement function and add them to the entry.

- When replacing code, the code generator uses the argument names to determine how it passes data to the implementation function.
- For function replacements, the order of implementation argument names must match the order of the conceptual argument names.

- For operator replacements, the order of implementation argument names do not have to match the order of the conceptual argument names. For example, for an operator replacement for addition, `y1=u1+u2`, the conceptual arguments are `y1`, `u1`, and `u2`, in that order. If the signature of your implementation function is `t myAdd(t u2, t u1)`, where `t` is a valid C type, based on the argument name matches, the code generator passes the value of the first conceptual argument, `u1`, to the second implementation argument of `myAdd`. The code generator passes the value of the second conceptual argument, `u2`, to the first implementation argument of `myAdd`.
- For operator replacements, you can remap operator output arguments to implementation function input arguments.

For each argument:

1. Identify whether the argument is for input or output, the name, and the data type.

   When validating the entry, the code generator validates that each implementation argument has an I/O type that is compatible with the conceptual argument to which it is mapped. For example, an conceptual argument of type `RTW_IO_OUTPUT` requires a compatible implementation argument of type `RTW_IO_OUTPUT` or `RTW_IO_INPUT_OUTPUT`. The default I/O type is `RTW_IO_INPUT`.
2. Create and add the implementation argument to an entry. You can choose a method from the methods listed in this table.

If	Then
You want to populate implementation arguments as copies of previously created matching conceptual arguments	Call the function `copyConceptualArgsToImplementation`. For example: `copyConceptualArgsToImplementation(hEnt);`

If	Then

You want to create and add implementation arguments individually, or vary argument attributes, while maintaining conceptual argument order	Call functions `createAndSetCImplementationReturn` and`createAndAddImplementationArg` . For example:
	
	`createAndSetCImplementationReturn(hEnt,`
	`'RTW.TflArgNumeric', ...`
	`'Name', 'y1', ...`
	`'IOType', 'RTW_IO_OUTPUT', ...`
	`'IsSigned', true, ...`
	`'WordLength', 32, ...`
	`'FractionLength', 0);`
	
	`createAndAddImplementationArg(op_entry,`
	`'RTW.TflArgNumeric',...`
	`'Name', 'u1', ...`
	`'IOType', 'RTW_IO_INPUT',...`
	`'IsSigned', true,...`
	`'WordLength', 32, ...`
	`'FractionLength', 0 );`

If	Then

You want to minimize the amount of code, or specify constant arguments to pass to the implementation function	Create the argument with a call to the function `getTflArgFromString`. Then, use the convenience method `setReturn` or `addArgument` to specify whether an argument is a return value or argument and to add the argument to the entry's array of implementation arguments. For example:
	
	`arg = getTflArgFromString(hEnt,...`
	`    'y1','double');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`hEnt.Implementation.setReturn(arg);`
	
	`arg = getTflArgFromString(hEnt,...`
	`    'u1','double');`
	`hEnt.Implementation.addArgument(arg);`
	
	The following call to `getTflArgFromString` passes the constant `0` to argument `u2`:
	
	`arg = getTflArgFromString(hEnt,...`
	`    'u2', 'int16', 0)`
	`hEnt.Implementation.addArgument(arg);`
	
	For semaphore and mutex entries, use the functions `getTflDWorkFromString` and `addDWorkArg` to create and add a DWork argument to the entry. Then create implementation arguments as shown above with `getTflArgFromString` and the convenience methods `setReturn` and `addArgument`. For example:
	
	`arg = getTflDWorkFromString(...`
	`    'd1', 'void*')`
	`hEnt.addDWorkArg(arg);`
	
	`arg = hEnt.getTflArgFromString(...`
	`    'y1', 'void');`
	`arg.IOType = 'RTW_IO_OUTPUT';`
	`hEnt.Implementation.setRetrurn(arg);`
	
	`arg = hEnt.getTflArgFromString(...`
	`    'u1', 'integer');`
	`hEnt.Implementation.addArgument(arg);`

If	Then

	`arg = hEnt.getTflArgFromString(...`
	`    'd1', 'void**');`
	`hEnt.Implementation.addArgument(arg);`

You need to define several similar mappings, you want to minimize the code to write, and the entries do not require data alignment, use net slope arguments, or involve semaphore or mutex replacements.	Call `createCRLEntry` to create the entry and specify conceptual and implementation arguments in a single function call.
	`hEnt = createCRLEntry(hTable, ...`
	`    'double y1 = sin(double u1)', ...`
	`    'mySin');`

The following code shows the third approach listed in the table for specifying the implementation output and input argument definitions for the `sin` function:

```
% Implementation Args

arg = hEnt.getTflArgFromString('y1','double');
arg.IOType = 'RTW_IO_OUTPUT';
hEnt.Implementation.setReturn(arg);

arg = hEnt.getTflArgFromString('u1','double');
hEnt.Implementation.addArgument(arg);
```

Add Entry to Table

Add an entry to a code replacement table by calling the function `addEntry`.

```
addEntry(hTable, hEnt);
```

Validate Entry

After you create or modify a code replacement table entry, validate it by invoking it at the MATLAB command line. For example:

```
hTbl = crl_table_sinfcn

hTbl =
```

```
RTW.TflTable
    Version: '1.0'
    AllEntries: [2x1 RTW.TflCFunctionEntry]
    ReservedSymbols: []
    StringResolutionMap: []
```

If the table includes errors, MATLAB reports them. The following examples shows how MATLAB reports a typo in a data type name:

```
hTbl = crl_table_sinfcn

??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Save Table

Save the table definition file. Use the name of the table definition function to name the file, for example, `crl_table_sinfcn.m`.

Next, from your requirements, determine whether you need to specify build information for your replacement code.

Specify Build Information for Replacement Code

After you define code replacement mappings, determine whether you need to specify build information for your replacement code. A code replacement table entry can specify build information for the code generator to use when replacing code for a match. For example, specify files for implementation replacement code if you are using a generated makefile and the code generation software compiles the code.

Add build information to an entry:

- Interactively, by using the **Build Information** tab in the **Code Replacement Tool**.
- Programmatically, by using a MATLAB programming interface.

Build Information

The build information can include:

- Paths and file names for header files
- Paths and file names for source files
- Paths and file names for object files
- Compile flags
- Link flags

Choose an Approach for Specifying Build Information

The following table lists situations to help you decide when to use an interactive or programmatic approach to specifying build information:

Situation	Approach
Creating code replacement entries for the first time.	Code Replacement Tool.
You used the Code Replacement Tool to create the entries for which the build information applies.	Code Replacement Tool to specify the build information quickly .

Situation	Approach
Rapid prototyping entries.	Code Replacement Tool to generate, register, and test entries quickly.
Developing an entry to use as a template or starting point for defining similar entries.	Code Replacement Tool to generate entry code that you can copy and modify.
Modifying existing mappings.	MATLAB Editor to update the programming interface directly.

- If an entry uses header, source, or object files, consider whether to make the files accessible to the code generator. You can copy files to the build folder or you can specify individual file names and paths explicitly.
- If you specify *additional* header files/include paths or source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files (an instance in the build folder and an instance in the original folder).
- If you choose to copy files to the build folder and you are using the `packNGo` function to relocate static and generated code files to another development environment:
  - In the call to `packNGo`, specify the property-value pair `'minimalHeaders' true` (the default). That setting instructs the function to include the minimal header files required to build the code in the zip file.
  - Do not collocate files that you copy with files that you do not copy. If the `packNGo` function finds multiple instances of the same file, the function returns an error.
- If you use the programming interface, paths that you specify can include tokens. A token is a variable defined as a character vector, cell array of character vectors, or string array in the MATLAB workspace that you enclose with dollar signs (`$`*`variable`*`$`). The code generator evaluates and replaces a token with the defined value. For example, consider the path `$myfolder$\folder1`, where `myfolder` is a character vector or string scalar variable defined in the MATLAB workspace as `'d:\work\source\module1'`. The code generator generates the custom path as `d:\work\source\module1\folder1`.

Specify Build Information Interactively with the Code Replacement Tool

The Code Replacement Tool provides a quick, easy way for you to specify build information for code replacement table entries. It is ideal for getting started with defining

a table entry, rapid prototyping, and developing table entries to use as a starting point for defining similar mappings.

1. Determine the information that you must specify.
2. Open the Code Replacement Tool.
3. Select the code replacement table entry for which you want to specify the build information. In the left pane, select the table that contains the entry. In the middle pane, select the entry that you want to modify.
4. In the right pane, select the **Build Information** tab.
5. On the **Build Information** tab, specify your build information.

Parameter	Specify
Implementation header file	File name and extension for the header file the code generator needs to generate the replacement code. For example, `sin_dbl.h`.
Implementation source file	File name and extension for the C or C++ source file the code generator needs to generate the replacement code. For example, `sin_dbl.c`.
Additional header files/ include paths	Paths and file names for additional header files the code generator needs to generate the replacement code. For example, `C:\libs\headerFiles` and `C:\libs\headerFiles\common.h`. This parameter adds `-I` to the compile line in the generated makefile.
Additional source files/ paths	Paths and file names for additional source files the code generator needs to generate the replacement code. For example, `C:\libs\srcFiles` and `C:\libs\srcFiles\common.c`. This parameter adds `-I` to the compile line in the generated makefile.
Additional object files/ paths	Paths and file names for additional object files the linker needs to build the replacement code. For example, `C:\libs\objFiles` and `C:\libs\objFiles\common.obj`.

Parameter	Specify
Additional link flags	Flags the linker needs to generate an executable file for the replacement code.
Additional compile flags	Flags the compiler needs to generate object code for the replacement code.
Copy files to build directory	Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation. If you specify files with **Additional header files/include paths** or **Additional source files/ paths** and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files.

6. Click **Apply**.
7. Select the **Mapping Information** tab. Scroll to the bottom of that table and click **Validate entry**. The tool validates the changes that you made to the entry.
8. Save the table that includes the entry that you just modified.

Specify Build Information Programmatically

The programming interface for specifying build information for a code replacement entry is ideal for:

- Modifying entries created with the Code Replacement Tool.
- Replicating and then modifying similar entries and tables.

The basic workflow for specifying build information programmatically is:

1. Identify or create the code replacement entry that you want to specify the build information.
2. Determine what information to specify.
3. Specify your build information.

Specify	Action

Implementation header file	Use one of the following:
	• Set properties `ImplementationHeaderFile` and `ImplementationHeaderPath` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.h', ...`
	`'ImplementationHeaderPath', 'D:/lib/headerFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl');`
	• Set argument `headerFile` in a call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry`

Implementation source file	Set properties `ImplementationSourceFile` and `ImplementationSourcePath` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.c', ...`
	`'ImplementationHeaderPath', 'D:/lib/sourceFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl');`

Additional header files/include paths	For each file, specify the file name and path in calls to the functions `addAdditionalHeaderFile` and `addAdditionalIncludePath`. For example:
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	`hEnt = RTW.TflCFunctionEntry;`
	`addAdditionalHeaderFile(hEnt, 'common.h');`
	`addAdditionalIncludePath(hEnt, fullfile(libdir, 'include'));`
	These functions add `-I` to the compile line in the generated makefile.

Specify	Action

Additional source files/paths	For each file, specify the file name and path in calls to the functions `addAdditionalSourceFile` and `addAdditionalSourcePath`. For example:
	
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`addAdditionalSourceFile(hEnt, 'common.c');`
	`addAdditionalSourcePath(hEnt, fullfile(libdir, 'src'));`
	
	These functions add `-I` to the compile line in the generated makefile.

Additional object files/paths	For each file, specify the file name and path in calls to the functions `addAdditionalLinkObj` and `addAdditionalLinkObjPath`. For example:
	
	`libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');`
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`addAdditionalLinkObj(hEnt, 'sin.o');`
	`addAdditionalLinkObjPath(hEnt, fullfile(libdir, 'bin'));`

Compile flags	Set the entry property `AdditionalCompileFlags` to a cell array of character vectors or string array representing the required compile flags. For example:
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`hEnt.AdditionalCompileFlags = {'-Zi -Wall', '-03'};`

Link flags	Set the entry property `AdditionalLinkFlags` to a cell array of character vectors or string array representing the required link flags. For example:
	
	`hEnt = RTW.TflCFunctionEntry;`
	
	`hEnt.AdditionalCompileFlags = {'-MD -Gy', '-T'};`

Specify	Action

Whether to copy header, source, or object files, which are required to generate replacement code, to the build folder before code generation	Use one of the following:
	• Set property `GenCallback` to `'RTW.copyFileToBuildDir'` in a call to `setTflCFunctionEntryParameters`, `setTflCOperationEntryParameters`, or `setTflCSemaphoreEntryParameters`. For example:
	`setTflCFunctionEntryParameters(hEnt, ...`
	`'ImplementationHeaderFile', 'sin_dbl.h', ...`
	`'ImplementationHeaderPath', 'D:/lib/headerFiles'`
	`'Key', 'sin', ...`
	`'ImplementationName', 'sin_dbl'`
	`'GenCallback', 'RTW.copyFileToBuildDir');`
	• Set argument `genCallback` in a call to `registerCFunctionEntry`, `registerCPPFunctionEntry`, or `registerCPromotableMacroEntry` to `'RTW.copyFileToBuildDir'`.
	If a match occurs for a table entry, a call to the function `RTW.copyFileToBuildDir` copies required files to the build folder.
	If you specify additional header files/include paths or additional source files/paths and you copy files, the compiler and utilities such as `packNGo` might find duplicate instances of files.

4 Save the table that includes the entry that you added or modified.

The following example defines a table entry for an optimized multiplication function that takes signed 32-bit integers and returns a signed 32-bit integer, taking saturation into account. Multiplications in the generated code are replaced with calls to the optimized function. The optimized function does not reside in the build folder. For the code generator to access the files, copy them into the build folder to be compiled and linked into the application.

The table entry specifies the source and header file names and paths. To request the copy operation, the table entry sets the `genCallback` property to `'RTW.copyFileToBuildDir'` in the call to the `setTflCOperationEntryParameters` function. In this example, the header file `s32_mul.h` contains an inlined function that invokes assembly functions contained in `s32_mul.s`. If a match occurs for the table entry,

the function `RTW.copyFileToBuildDir` copies the specified source and header files to the build folder for use during the remainder of the build process.

```
function hTable = make_my_crl_table

hTable = RTW.TflTable;

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                'Key',                      'RTW_OP_MUL', ...
                'Priority',                 100, ...
                'SaturationMode',           'RTW_SATURATE_ON_OVERFLOW', ...
                'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                'ImplementationName',       's32_mul_s32_s32_sat', ...
                'ImplementationHeaderFile', 's32_mul.h', ...
                'ImplementationSourceFile', 's32_mul.s', ...
                'ImplementationHeaderPath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
                'ImplementationSourcePath', {fullfile('$(MATLAB_ROOT)','crl')}, ...
                'GenCallback',              'RTW.copyFileToBuildDir');
.
.
.
addEntry(hTable, op_entry);
```

The following example uses the functions `addAdditionalHeaderFile`, `addAdditionalIncludePath`, `addAdditionalSourceFile`, `addAdditionalSourcePath`, `addAdditionalLinkObj`, and `addAdditionalLinkObjPath` in addition to the code generation callback function `RTW.copyFileToBuildDir`.

```
hTable = RTW.TflTable;

% Path to external source, header, and object files
libdir = fullfile('$(MATLAB_ROOT)','..', '..', 'lib');

op_entry = RTW.TflCOperationEntry;
setTflCOperationEntryParameters(op_entry, ...
                'Key',                      'RTW_OP_ADD', ...
                'Priority',                 90, ...
                'SaturationMode',           'RTW_SATURATE_UNSPECIFIED', ...
                'RoundingModes',            {'RTW_ROUND_UNSPECIFIED'}, ...
                'ImplementationName',       's32_add_s32_s32', ...
                'ImplementationHeaderFile', 's32_add_s32_s32.h', ...
                'ImplementationSourceFile', 's32_add_s32_s32.c'...
                'GenCallback',              'RTW.copyFileToBuildDir');

addAdditionalHeaderFile(op_entry, 'all_additions.h');
addAdditionalIncludePath(op_entry, fullfile(libdir, 'include'));
addAdditionalSourceFile(op_entry, 'all_additions.c');
addAdditionalSourcePath(op_entry, fullfile(libdir, 'src'));
addAdditionalLinkObj(op_entry, 'addition.o');
addAdditionalLinkObjPath(op_entry, fullfile(libdir, 'bin'));
.
```

```
.
.
addEntry(hTable, op_entry);
```

Next, include your code replacement table in a code replacement library and register the library with the code generator.

Register Code Replacement Mappings

After you define code replacement entries and specify build information in a code replacement table, you can include the table in a code replacement library that you register with the code generator. When registered, a library appears in the list of available code replacement libraries that you can choose from when configuring the code generator.

Register a code replacement table as a code replacement library:

- Interactively, by using the Code Replacement Tool
- Programmatically, by using a MATLAB programming interface

Choose an Approach for Creating the Registration File

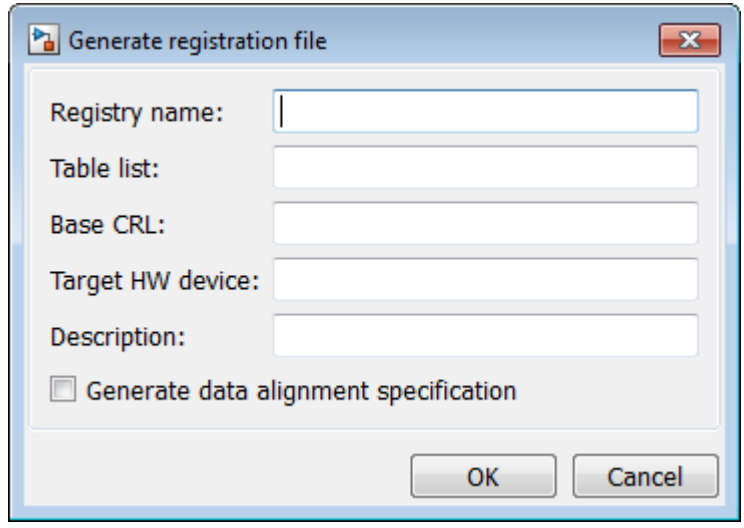
The following table lists situations to help you decide when to use an interactive or programmatic approach to creating a registration file:

If...	Then...
Registering a code replacement table for the first time	Use the Code Replacement Tool.
You used the Code Replacement Tool to create the table	Use the Code Replacement Tool to quickly register the table.
Rapid prototyping code replacement	Use the Code Replacement Tool to quickly generate, register, and test entries.
Creating registration file to use as a template or starting point for defining similar registration files	Use the Code Replacement Tool to generate code that you can copy and modify.
Modifying existing registration files	Use the MATLAB Editor to update the registration file.
Defining multiple code replacement libraries in one registration file	Use the MATLAB Editor to create a new or extend an existing registration file.
Defining code replacement library hierarchy in a registration file	Use the MATLAB Editor to create a new or extend an existing registration file.

Create Registration File Interactively with the Code Replacement Tool

The Code Replacement tool provides a quick, easy way for you to create a registration file for a code replacement table. It is ideal for getting started, rapid prototyping, and generating a registration file that you want to use as a starting point for similar registrations.

1 After you validate and save a code replacement table, select **File** > **Generate registration file** to open the **Generate registration file** dialog box.



2 Enter the registration information. Minimally, specify:

For...	Specify...
Registry name	Text naming the code replacement library. For example, `Sin Function Example`.

For...	Specify...
Table list	Text naming one or more code replacement tables to include in the library. Specify each table as one of the following: • Name of a table file on the MATLAB search path • Absolute path to a table file • Path to a table file relative to `$(MATLAB_ROOT)` You can specify multiple tables. If you do, separate the table specifications with a comma. For example: `crl_table_sinfcn, c:/work_crl/crl_table_muldiv` See “Registration Files That Define Multiple Code Replacement Libraries” on page 66-63 for examples of each type of table specification.

Optionally, you can specify:

For...	Specify...
Description	Text that describes the purpose and content of the library.
Target HW device	Text naming one or more hardware devices the code replacement library supports. Separate names with a comma. To support all device types, enter an asterisk (*). For example, `TI C28x, TI C62x`.
Base CRL	Text naming a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general `TI device library` as the base library for a more specific `TI C28x` device library.
Generate data alignment specification	Flag that enables data alignment specification.

Create Registration File Programmatically

The programming interface for creating a registration file for a code replacement table is ideal for:

- Modifying registration files created with the Code Replacement Tool
- Replicating and modifying similar registration files
- Defining multiple code replacement libraries in one registration file

The basic workflow for creating a registration file programmatically consists of the following steps:

1 Define an `rtwTargetInfo` function. The code generator recognizes this function as a customization file. The function definition must include at least the following content:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'crl-name';
this(1).TableList = {'table',...};
```

For...	Replace...
`this(1).Name = '`*`crl-name`*`';`	*`crl-name`* with text naming the code replacement library. For example, `Sin Function Example`.

For...	Replace...
`this(1).TableList = {'table',...};`	*`table`* with text that identifies the code replacement table that contains your code replacement entries. Specify a table as one of the following: • Name of a table file on the MATLAB search path • Absolute path to a table file • Path to a table file relative to `$(MATLAB_ROOT)` You can specify multiple tables. If you do, separate the table specifications with commas.

Optionally, you can specify:

For...	Replace...
`this(1).Description = 'text'`	*`text`* with text that describes the purpose and content of the library.
`this(1).TargetHWDeviceType = {'device-type',...}`	*`device-type`* with text that names a hardware device the code replacement library supports. You can specify multiple device types. Separate device types with a comma. For example, `TI C28x, TI C62x`. To support all device types, enter an asterisk (*).

For...	Replace...
`this(1).BaseTfl = '`*`base-lib`*`'`	*`base-lib`* with text that names a code replacement library that you want to serve as a base library for the library you are registering. Use this field to specify library hierarchies. For example, you can specify a general `TI device` library as the base library for a `TI C28x device` library. See “Registration Files That Define Code Replacement Library Hierarchies” on page 66-63 for an example.

For example:

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@loc_register_crl);

function this = loc_register_crl

this(1) = RTW.TflRegistry;
this(1).Name = 'Sin Function Example';
this(1).TableList = {'crl_table_sinfcn'};
this(1).TargetHWDeviceType = {'*'};
this(1).Description = 'Example - sin function replacement';
```

2. Save the file with the name `rtwTargetInfo.m`.
3. Place the file on the MATLAB path. When the file is on the MATLAB path, the code generator reads the file after starting and applies the customizations during the current MATLAB session.

Register a Code Replacement Library

Before you can use the code replacement tables defined in a registration file, refresh Simulink customizations within the current MATLAB session. To initiate a refresh, enter the following command:

```
sl_refresh_customizations
```

Register a Library that Includes Multiple Code Replacement Tables

Use the programming interface to create a registration file that defines a code replacement library that includes multiple code replacement tables. The following example defines a library that includes multiple tables. The `TableList` fields specify tables that reside at different locations. The tables reside on the MATLAB search path or at locations specified with a path.

```
function rtwTargetInfo(cm)

cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

  % Register a code replacement library for use with model: rtwdemo_crladdsub
  thisCrl(1) = RTW.TflRegistry;
  thisCrl(1).Name = 'Addition & Subtraction Examples';
  thisCrl(1).Description = 'Example of addition/subtraction op replacement';
  thisCrl(1).TableList = {'crl_table_addsub'};
  thisCrl(1).TargetHWDeviceType = {'*'};

  % Register a code replacement library for use with model: rtwdemo_crlmuldiv
  thisCrl(2) = RTW.TflRegistry;
  thisCrl(2).Name = 'Multiplication & Division Examples';
  thisCrl(2).Description = 'Example of mult/div op repl for built-in integers';
  thisCrl(2).TableList = {'c:/work_crl/crl_table_muldiv'};
  thisCrl(2).TargetHWDeviceType = {'*'};

  % Register a code replacement library for use with model: rtwdemo_crlfixpt
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'Fixed-Point Examples';
  thisCrl(3).Description = 'Example of fixed-point operator replacement';
  thisCrl(3).TableList = {fullfile('$(MATLAB_ROOT)', ...
     'toolbox','rtw','rtwdemos','crl_demo','crl_table_fixpt')};
  thisCrl(3).TargetHWDeviceType = {'*'};
```

Registration Files That Define Code Replacement Library Hierarchies

Using the programming interface, you can organize multiple code replacement libraries in a hierarchy. The following example shows a registration file that defines four code replacement tables organized in a hierarchy of four code replacement libraries. The tables include entries that increase in specificity: common entries, entries for TI devices, entries for TI C6xx devices, and entries specific to the TI C67x device.

```
function rtwTargetInfo(cm)
```

```
cm.registerTargetInfo(@locCrlRegFcn);

function thisCrl = locCrlRegFcn

  % Register a code replacement library that includes common entries
  thisCrl(1) = RTW.TflRegistry;
  thisCrl(1).Name = 'Common Replacements';
  thisCrl(1).Description = 'Common code replacement entries shared by other libraries';
  thisCrl(1).TableList = {'crl_table_general'};
  thisCrl(1).TargetHWDeviceType = {'*'};

  % Register a code replacement library for TI devices
  thisCrl(2) = RTW.TflRegistry;
  thisCrl(2).Name = 'TI Device Replacements';
  thisCrl(2).Description = 'Code replacement entries shared across TI devices';
  thisCrl(2).TableList = {'crl_table_TI_devices'};
  thisCrl(2).TargetHWDeviceType = {'TI C28x', 'TI C55x', 'TI C62x', 'TI C64x', 'TI 67x'};
  thisCrl(2).BaseTfl = 'Common Replacements';

  % Register a code replacement library for TI c6xx devices
  thisCrl(3) = RTW.TflRegistry;
  thisCrl(3).Name = 'TI c6xx Device Replacements';
  thisCrl(3).Description = 'Code replacement entries shared across TI C6xx devices';
  thisCrl(3).TableList = {'crl_table_TIC6xx_devices'};
  thisCrl(3).TargetHWDeviceType = {'TI C62x', 'TI C64x', 'TI 67x'};
  thisCrl(3).BaseTfl = 'TI Device Replacements';

  % Register a code replacement library for the TI c67x device
  thisCrl(4) = RTW.TflRegistry;
  thisCrl(4).Name = 'TI c67x Device Replacements';
  thisCrl(4).Description = 'Code replacement entries for the TI C67x device';
  thisCrl(4).TableList = {'crl_table_TIC67x_device'};
  thisCrl(4).TargetHWDeviceType = {'TI 67x'};
  thisCrl(4).BaseTfl = 'TI c6xx Device Replacements';
```

After registering your code replacement mappings, verify that code replacements occur.

Troubleshoot Code Replacement Library Registration

If a code replacement library is not listed as a configuration option or does not appear in the Code Replacement Viewer:

- Refresh the library registration information within the current MATLAB session (`RTW.TargetRegistry.getInstance('reset');` or for the Simulink environment,`sl_refresh_customizations`).
- See whether the registration file, `rtwTargetInfo.m`, contains an error.

More About

- “Register Code Replacement Mappings” on page 65-71

Verify Code Replacements

After you create or modify and register a code replacement table, use the following techniques to examine and verify the table and its entries.

- Invoke the table definition file at the command prompt.
- Use the Code Replacement Viewer to examine libraries, tables, and entries.
- Trace code replacements from the source where you applied the code replacement library.
- Examine code replacement hits and misses logged during code generation.

Code Replacement Hits and Misses

The code generator logs code replacement table entries for which it finds and does not find matches in the hit cache and miss cache, respectively. When a code replacement entry match fails and code is not replaced, the code generator logs the call site object (CSO) for the miss in the miss cache. When an entry match succeeds, the code generator logs the matched entry in the hit cache.

The code generator overwrites the hit and miss cache data each time it produces code. The cache data reflects hits and misses for only the last application component (MATLAB code or Simulink model) for which you generate code.

You can use the Code Replacement Viewer to review trace information based on logged hit and miss trace data. The hit cache provides trace information that helps to verify code replacements.

The miss cache and related miss data collected and stored in code replacement tables provide trace information for misses. Use this information for misses to troubleshoot expected code replacements that do not occur. Trace information for a miss:

- Identifies the call site object.
- Provides a link to the relevant source location for the miss.
- Includes information about the reason for the miss.

Validate Table Definition File

After you create or modify a code replacement table definition file, validate it. At the command prompt, specify the name of the table in a call to the `isvalid` function. For example:

```
isvalid(crl_table_sinfcn)

ans =

      1
```

MATLAB displays errors that occur. In the following example, MATLAB detects a typo in a data type name.

```
isvalid(crl_table_sinfcn)

??? RTW_CORE:tfl:TflTable: Unsupported data type, 'dooble'.

Error in ==> crl_table_sinfcn at 7
hTable.registerCFunctionEntry(100, 1, 'sin', 'dooble', 'sin_dbl', ...
```

Review Library Content

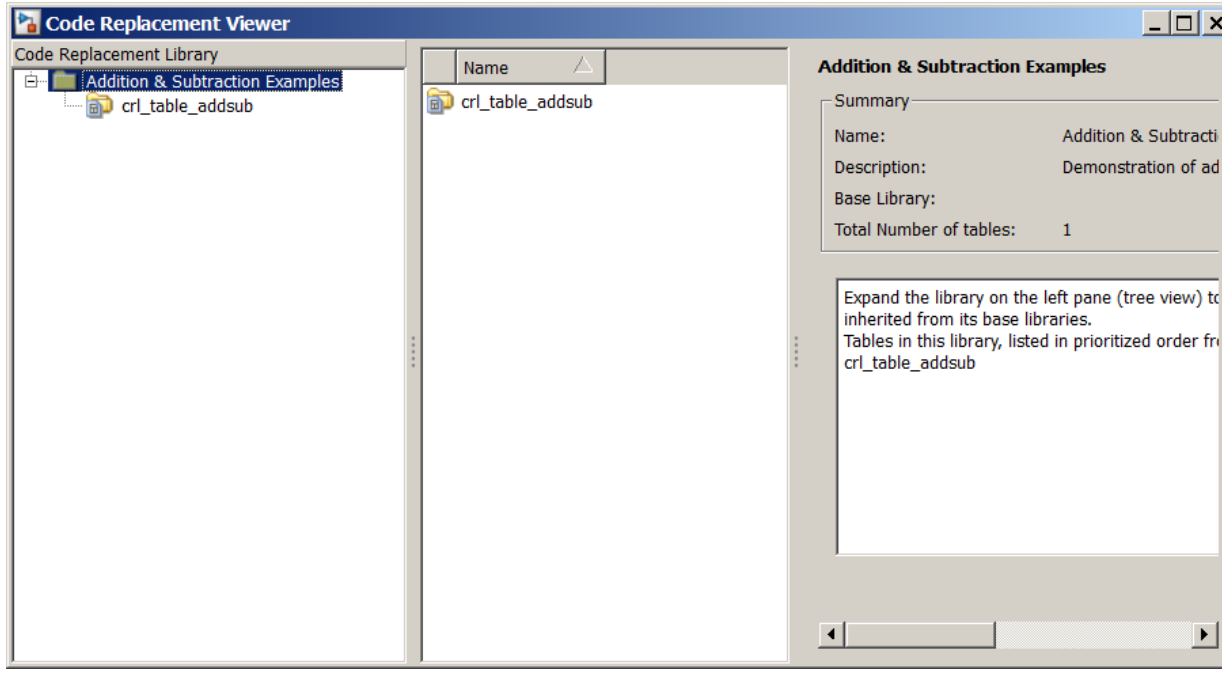
After you create or modify a code replacement library, use the **Code Replacement Viewer** to review and verify the list of tables in the library and the entries in each table.

1. Open the viewer to display the contents of your library. At the command prompt, enter the following command:

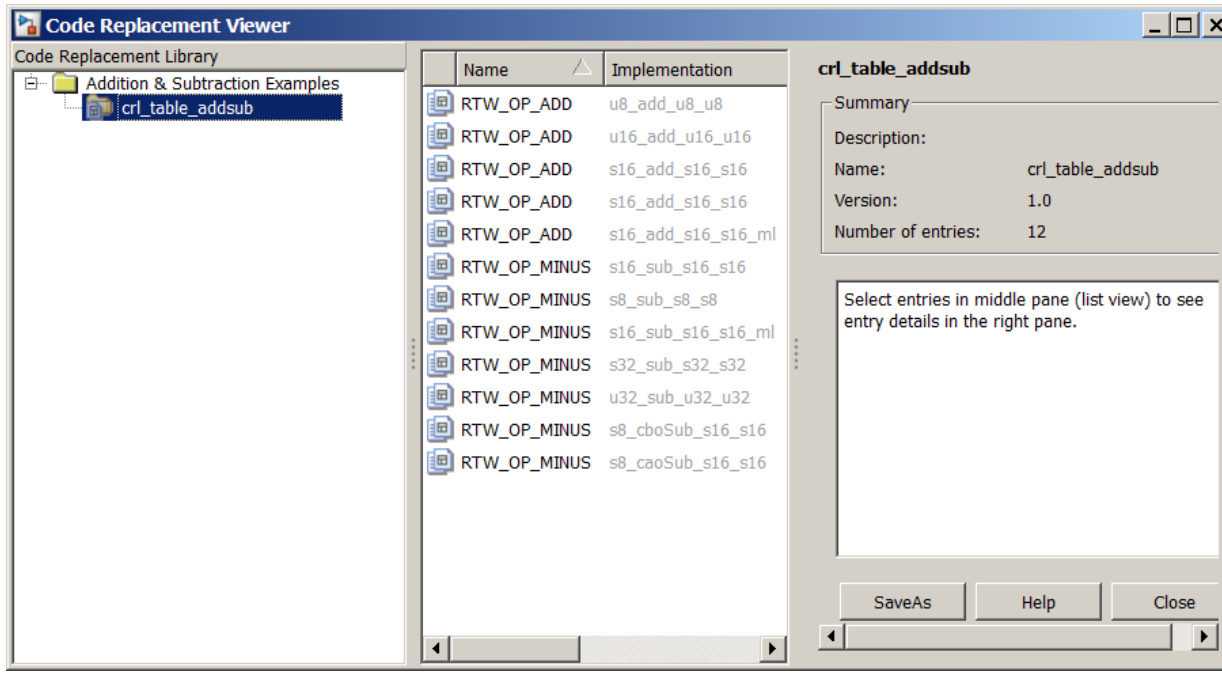
   ```
   crviewer('library')
   ```

   For example:

   ```
   crviewer('Addition & Subtraction Examples')
   ```



2. Review the list of tables in the left pane. Are tables missing? Are the tables listed in the correct relative order? By default, the viewer displays tables in search order.
3. In the left pane, click each table and review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries?



Review Table Content

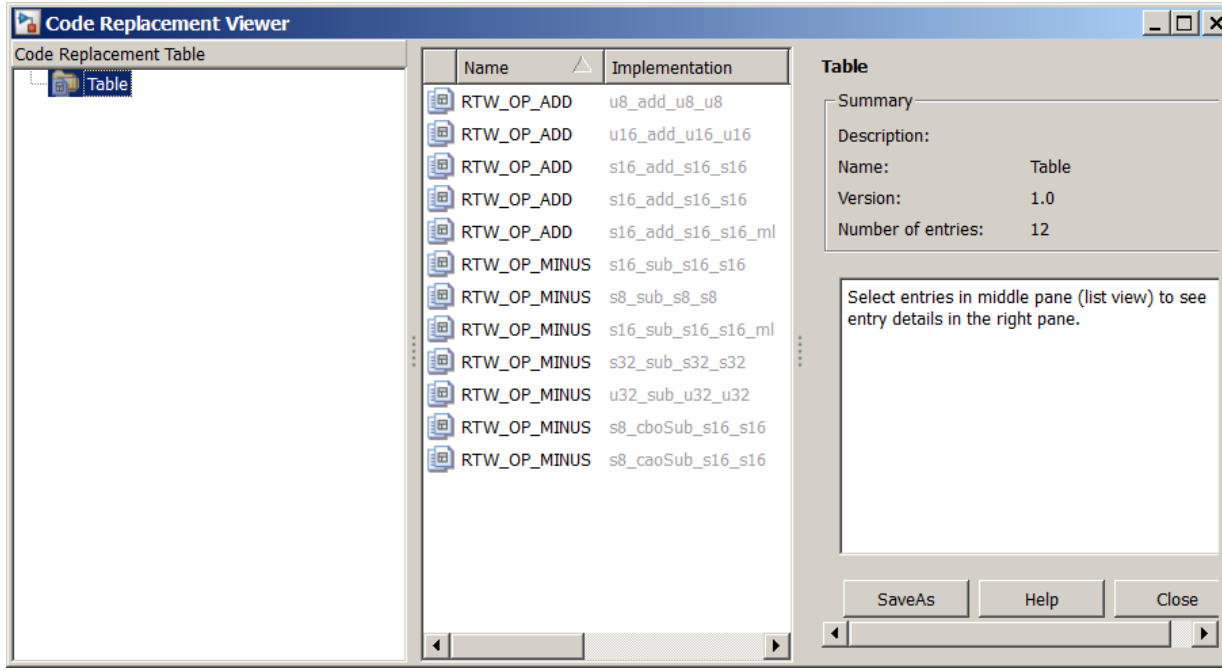
After you create or modify a code replacement table, use the **Code Replacement Viewer** to review and verify table entries.

1. Open the viewer to display the contents of your table. At the command prompt, enter the following command. *`table`* is a MATLAB file that defines code replacement tables. The file must be in the current folder or on the MATLAB path.

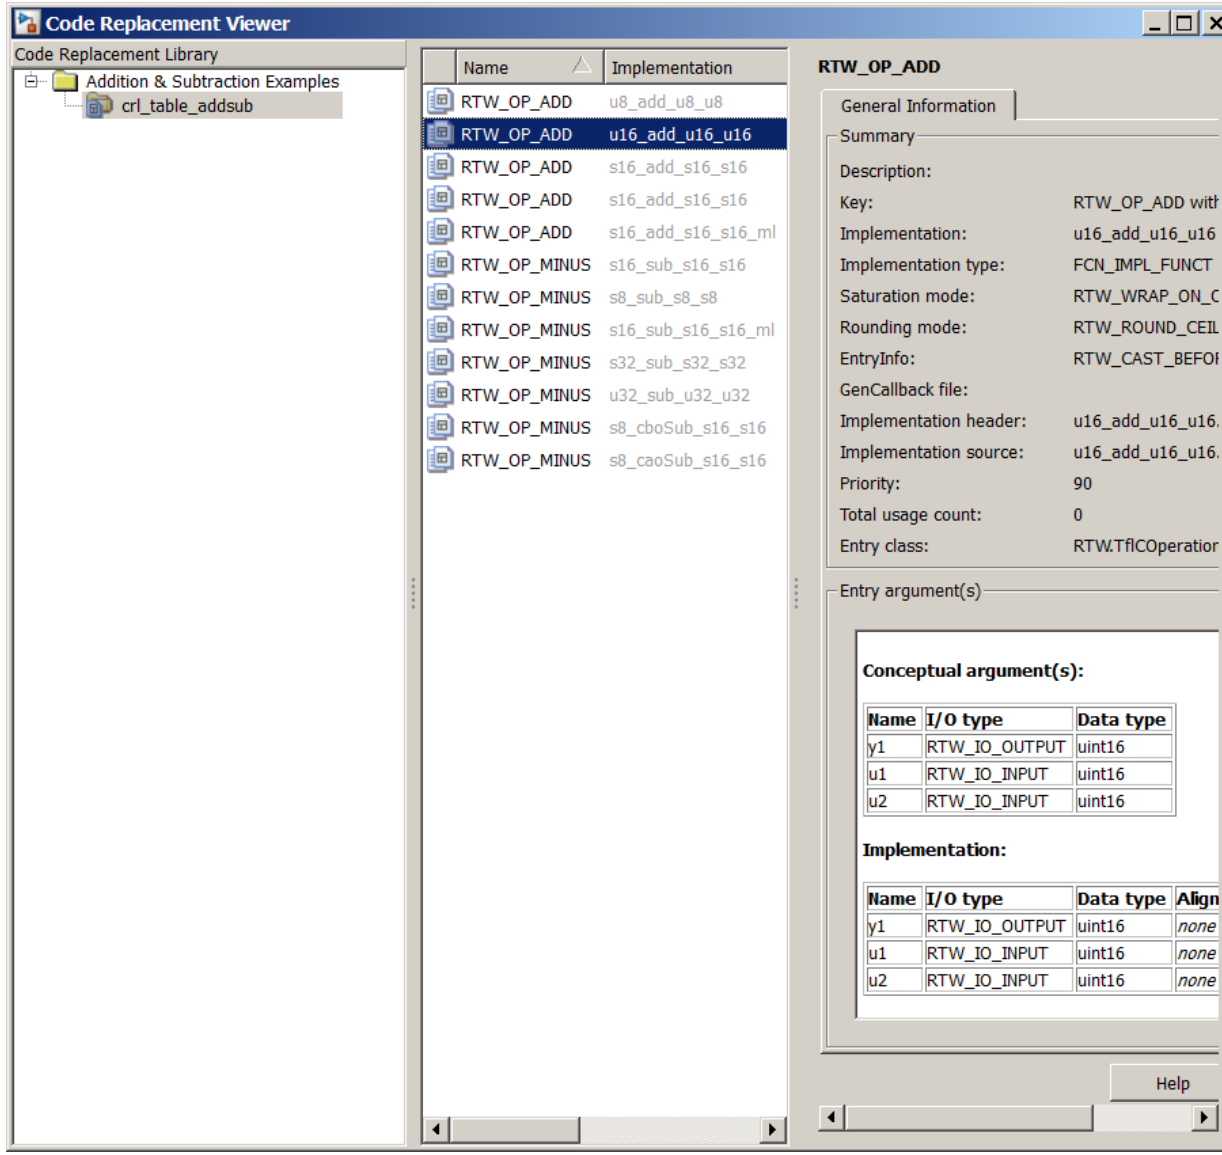
   ```
   crviewer(table)
   ```

   For example:

   ```
   crviewer(crl_table_addsub)
   ```



2. Review the list of entries in the center pane. Are entries missing? Does the list include extraneous or unexpected entries? By default, the viewer displays entries in search order.
3. In the center pane, click each entry and verify the entry information in the right pane.



- Argument order is correct.
- Conceptual argument names match code generator naming conventions.

- Implementation argument names are correct.
- Algorithm properties (for example, saturation and rounding mode) are set correctly.
- Header or source file specification is not missing.
- I/O types are correct.
- Relative priority of entries is correct.

Review Code Replacements

After you review the content of your code replacement library and tables, generate code and a code generation report. Verify that the code generator replaces code as you expect.

The Code Replacements Report details the code replacement library functions that the code generator uses for code replacements. The report provides a mapping between each replacement instance and the model element that triggered the replacement.

The following example illustrates two complementary approaches to reviewing code replacements:

- Check the Code Replacements Report section of the code generation report for expected replacements.
- Trace code replacements.

For models that consist of model hierarchies, repeat the following procedure for each model in the hierarchy. Generate code for and review the trace information of each referenced model separately. Logged cache hit and miss information captured in the Code Replacement Viewer is valid for the last model for which code was generated. As you generate code for each model in the hierarchy, the code generator overwrites logged information.

1. Open the model where you anticipate that a function or operator replacement occurs. This example uses the model `rtwdemo_crladdsub`.
2. Configure the code generator to use your code replacement library. For this example, set the library to `Addition & Subtraction Examples`.
3. Configure the code generation report to include the Code Replacements Report. On the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**. In the **Advanced parameters** section, select **Model-to-code** and **Summarize which blocks triggered code replacements**.

4 Configure comments for the generated code. On the **Code Generation > Comments** pane, select:

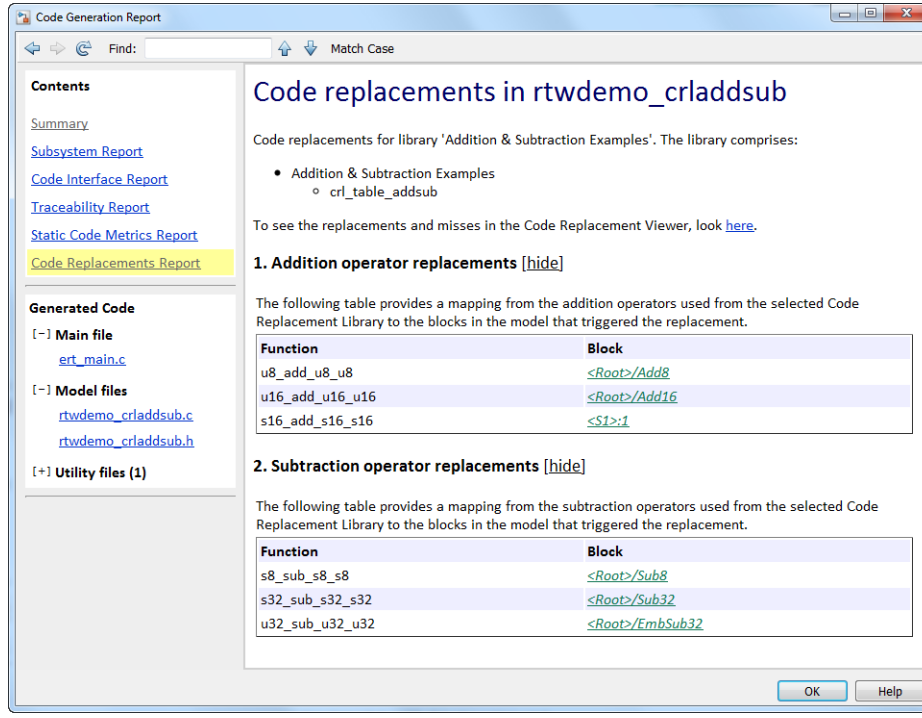
- **Include comments**
- Either or both of **Simulink block comments** and **Simulink block descriptions**

In the **Code Replacements Report**, these options include Simulink block information.

5 Configure the code generator to generate only code. Before you build an executable file, review your code replacements in the generated code.

6 Generate code and a report.

7 Open the **Code Replacements Report** section of the code generation report.



The report lists the replacement functions that the code generator used. It provides a mapping between each replacement instance and the Simulink block that triggered the replacement.

Review the report:

- Check whether expected function and operator code replacements occurred.
- In the replacements sections, click each block link to see the source that triggered the reported code replacement.

8 In the Simulink model window, use model-to-code highlighting to trace code replacements. Identify and right-click a block where you expected code replacement to occur. Select **C/C++ Code > Navigate to C/C++ Code**. The code generation report appears with the corresponding replacement code highlighted. In the example model `rtwdemo_crladdsub`, right-click the Add8 block and select **C/C++ Code > Navigate to C/C++ Code**.

```
24  /* Real-time model */
25  RT_MODEL rtM_;
26  RT_MODEL *const rtM = &rtM_;
27
28  /* Model step function */
29  void rtwdemo_crladdsub_step(void)
30  {
31    /* Outport: '<Root>/Out1' incorporates:
32     *  Inport: '<Root>/In1'
33     *  Inport: '<Root>/In2'
34     *  Sum: '<Root>/Add8'
35     */
36    rtY.Out1 = u8_add_u8_u8(rtU.In1, rtU.In2);
37
38    /* Outport: '<Root>/Out2' incorporates:
39     *  Inport: '<Root>/In3'
40     *  Inport: '<Root>/In4'
41     *  Sum: '<Root>/Add16'
42     */
43    rtY.Out2 = u16_add_u16_u16(rtU.In3, rtU.In4);
```

Inspect the generated code to see if the function or operator replacement occurred as you expected.

If a function or operator is not replaced as expected, the code generator used a higher-priority (lower-priority value) match or did not find a match.

To analyze and troubleshoot code replacement misses, use the trace information that the **Code Replacement Viewer** provides. See “Troubleshoot Code Replacement Misses” on page 65-90.

Next, deploy your code replacement library for others to use.

More About

- “Troubleshoot Code Replacement Misses” on page 65-90
- “Register Code Replacement Mappings” on page 65-71
- “Deploy Code Replacement Library” on page 65-97
- “What Is Code Replacement Customization?” on page 65-3

Troubleshoot Code Replacement Misses

Use miss reason messages that appear in the **Code Replacement Viewer** to analyze and correct code replacement misses.

Miss Reason Messages

The Code Replacement Viewer displays miss reason messages in trace information for code replacement misses. A legend listing each message that appears in the miss report precedes the report details. A message consists of:

- Numeric identifier, which identifies the message in the report details.
- Message text, which in some cases includes placeholders for names of arguments, call site object values, table entry values, and property names.

For example:

```
1. Mismatched data types (argument name, CSO value, table entry value)
```

The parenthetical information represents placeholders for actual values that appear in the report details.

In the **Miss Source Locations** table that lists the miss details, the **Reason** column includes:

- The message identifier, as listed in the legend.
- The placeholder values for that instance of the miss reason message.

The following **Reason** details indicate a data type mismatch because the call site object specifies data type `int8` for arguments `y1`, `u1`, and `u2`, while the code replacement table entry specifies `uint32`.

```
1. y1, int8, uint32
   u1, int8, uint32
   u2, int8, uint32
```

Depending on your situation and the reported miss reason, troubleshoot reported misses by looking for instances of the following:

- A typo in the code replacement table entry definition or a source parameter setting.

- Information missing from the code replacement table entry or a source parameter setting.
- Invalid or incorrect information in the code replacement table entry definition or a source parameter setting.
- Arguments incorrectly ordered in the code replacement table entry definition or the source being replaced with replacement code.
- Failed algorithm classification for an addition or subtraction operation due to:
  - An ideal accumulator not being calculated because the type of an input argument is not fixed-point or the slope adjustment factors of the input arguments are not equal.
  - Input or output casts with a floating-point cast type.
  - Input or output casts with cast types that have different slope adjustment factors or biases.
  - Output casts not being convertible to a single output cast.
  - Input casts resulting in loss of bits.

Analyze and Correct Code Replacement Misses

The following example shows how to use Code Replacement Viewer trace information to troubleshoot code replacement misses. You must have already reviewed and tested code replacements for your model.

1 Review the code generated for a model element, looking for expected code replacements. For this example, examine the code generated for block Sub32 in model `rtwdemo_crladdsub`. Right-click the block and select **C/C++ Code** > **Navigate to C/C++ Code**.

The Code Generation Report opens to the location of the generated code for that block.

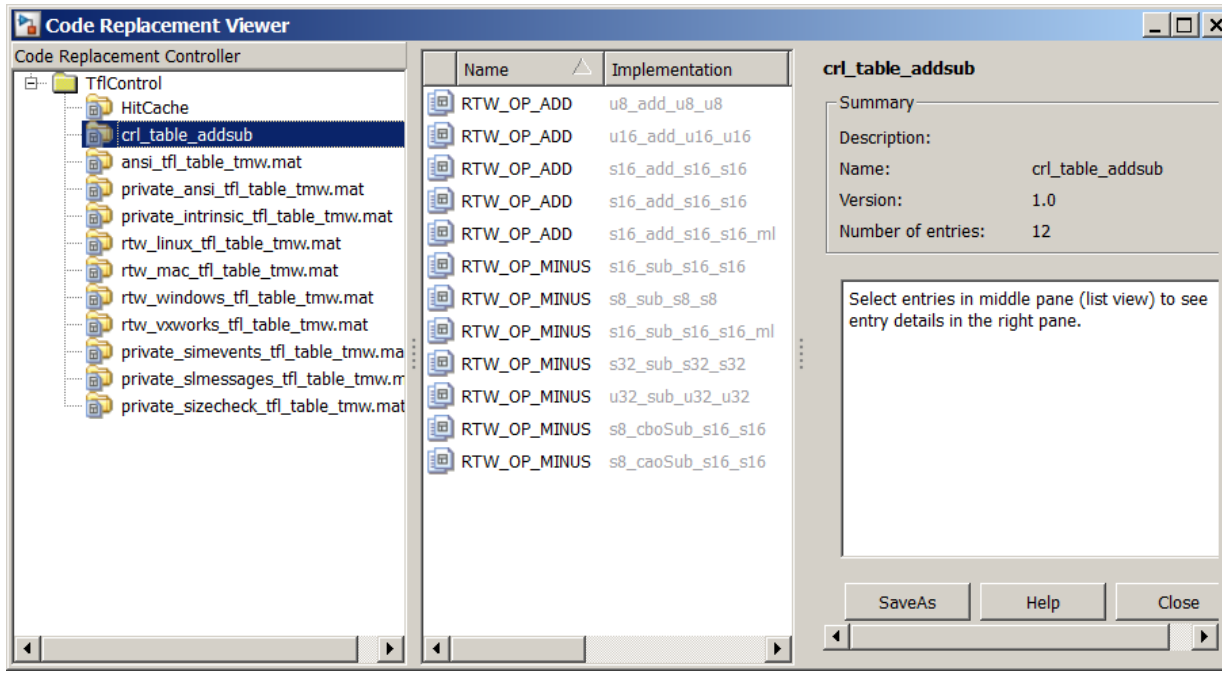
```
63   /* Outport: '<Root>/Out5' incorporates:
64    *  Inport: '<Root>/In10'
65    *  Inport: '<Root>/In9'
66    *  Sum: '<Root>/Sub32'
67    */
68   rtY.Out5 = s32_sub_s32_s32(rtU.In9, rtU.In10);
```

The code generator replaced code, but the replacement was for the signed version of the 32-bit subtraction operation. You expected an unsigned operation.

2 Regenerate or reopen the Code Replacements Report for your model. If you already generated the code generation report that includes the Code Replacements Report for model `rtwdemo_crladdsub`, open the file `rtwdemo_crladdsub_ert_rtw/html/rtwdemo_crladdsub_codegen_rpt.html`. For information on how to regenerate the report, see “Review Code Replacements” on page 65-86.

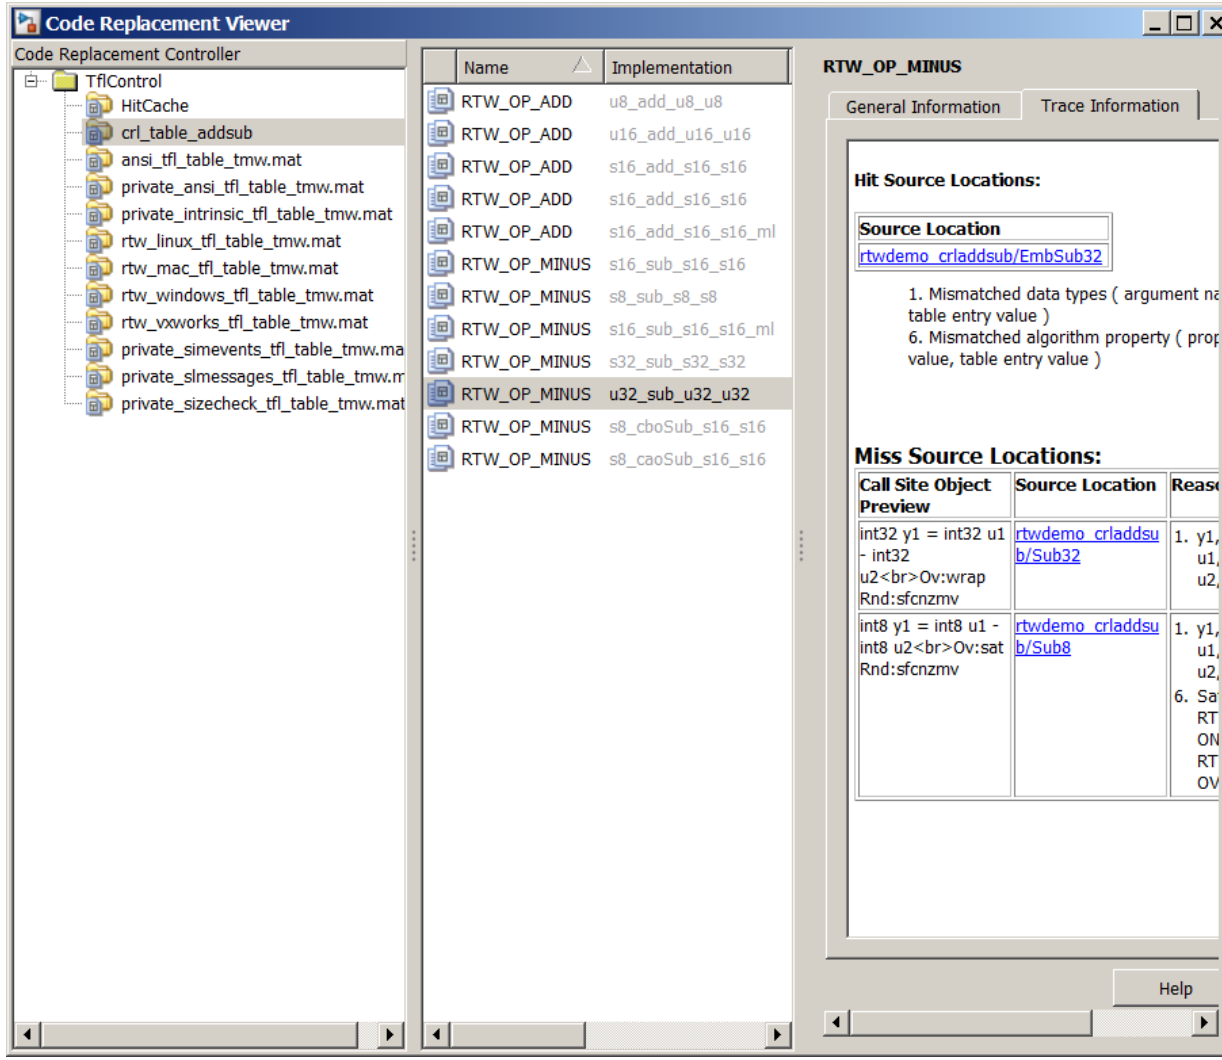
3 Click the link to open the Code Replacement Viewer.

4 In the viewer left pane, select your code replacement table. The following display shows entries for code replacement table `crl_table_addsub`.



5 In the middle pane, select table entry `RTW_OP_MINUS` with implementation function `u32_sub_u32_u32`.

6 In the right pane, select the **Trace Information** tab.



The **Trace Information** is a table that lists the following information for each miss:

- Call site object preview. The call site object is the conceptual representation of a subtraction operator. The code generator uses this object to query the code replacement library for a match.

- A link to the source location in the model for which the code generator considered replacing code.
- The reasons that the miss occurred. For the list of reasons that misses occur, see “Miss Reason Messages” on page 65-90.

For this example, the report shows misses for two blocks: Sub32 and Sub8.

7 Find that source in the trace information. Depending on your situation and the reported miss reason, consider looking for a condition such as a typo in the code replacement table entry definition or in a source parameter setting. “Miss Reason Messages” on page 65-90 lists conditions to consider.

For this example, determine why code for the Sub32 block was not replaced with code for an unsigned 32-bit subtraction operation. The miss reason for the Sub32 block indicates a data type mismatch. The data type in the call site object for the three arguments is a signed 32-bit integer. The code replacement entry specifies an unsigned 32-bit integer.

8 Correct the model or code replacement table entry. If the issue is in the model, use the source location link in the trace information to find the model element to correct. For this example, you expected an unsigned subtraction operation for the Sub32 block. Click the link in the trace report for the Sub32 block.

The model opens with the Sub32 block highlighted.
