Revision History

April 2011	Online only	New for Version 6.0 (Release 2011a)
September 2011	Online only	Revised for Version 6.1 (Release 2011b)
March 2012	Online only	Revised for Version 6.2 (Release 2012a)
September 2012	Online only	Revised for Version 6.3 (Release 2012b)
March 2013	Online only	Revised for Version 6.4 (Release 2013a)
September 2013	Online only	Revised for Version 6.5 (Release 2013b)
March 2014	Online only	Revised for Version 6.6 (Release 2014a)
October 2014	Online only	Revised for Version 6.7 (Release 2014b)
March 2015	Online only	Revised for Version 6.8 (Release 2015a)
September 2015	Online only	Revised for Version 6.9 (Release 2015b)
October 2015	Online only	Rereleased for Version 6.8.1 (Release 2015aSP1)
March 2016	Online only	Revised for Version 6.10 (Release 2016a)
September 2016	Online only	Revised for Version 6.11 (Release 2016b)
March 2017	Online only	Revised for Version 6.12 (Release 2017a)
September 2017	Online only	Revised for Version 6.13 (Release 2017b)
March 2018	Online only	Revised for Version 7.0 (Release 2018a)
September 2018	Online only	Revised for Version 7.1 (Release 2018b)
March 2019	Online only	Revised for Version 7.2 (Release 2019a)

Check Bug Reports for Issues and Fixes

Software is inherently complex and is not free of errors. The output of a code generator might contain bugs, some of which are not detected by a compiler. MathWorks reports critical known bugs brought to its attention on its Bug Report system at www.mathworks.com/support/bugreports/. In the search bar, type the phrase "Incorrect Code Generation" to obtain a report of known bugs that produce code that might compile and execute, but still produce wrong answers. To save a search, click Save Search.

The bug reports are an integral part of the documentation for each release. Examine periodically all bug reports for a release, as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

In addition to reviewing bug reports, you should implement a verification and validation strategy to identify potential bugs in your design, code, and tools.

Model Architecture and Design

Modeling Environment for Embedded Coder

Design Models for Generated Embedded Code Deployment

When using Embedded Coder to generate code for an embedded system architecture, it is important to design your Simulink models with code generation in mind from the very beginning of the design process. Think about relevant design factors and issues such as:

In this section...
“Application Algorithms and Run-Time Environments” on page 1-2
“Software Execution Framework for Generated Code” on page 1-3
“Map Embedded System Architecture to Simulink Modeling Environment” on page 1-5
“Model Templates for Code Generation” on page 1-14

Application Algorithms and Run-Time Environments

Use Simulink to design models that represent application algorithms and run-time environments from which you intend to generate deployable code. Depending on your application, you might deploy code to an execution environment that consists of a combination of:

Execution Environment Components	Choices
Hardware	• Development computer • Rapid-prototyping board • Microprocessor • Microcontroller • FPGA • ASIC
Cores	• Single • Multiple
Operating system	• General-purpose • Real-time • None (bare metal)

Execution Environment Components	Choices
Scheduling	• Single-tasking • Multitasking • Interrupt driven • Concurrency • Provided by operating system • Generated from model
Application algorithm code	• Generated from model • External code

As you design models to generate C or C++ code for rapid prototyping or production deployment, keep in mind the execution environment. Generate code that meets implementation requirements and avoids potential design rework. As the preceding table reflects, the execution environment for code that you generate can range from relatively simple to complex. For example, a simple case is code that you generate from a single, single-tasking model that runs on a single-core microprocessor. A complex case is code that generate from a model partitioned to run as a distributed system on a multicore microprocessor and an FPGA.

Software Execution Framework for Generated Code

Part of an application execution environment is the software execution framework that is responsible for scheduling and running the generated code. That software can preexist, as in the case of an operating system and its scheduler, or you can code the software manually. The level of complexity varies depending on which of the following modeling and code generation scenarios applies:

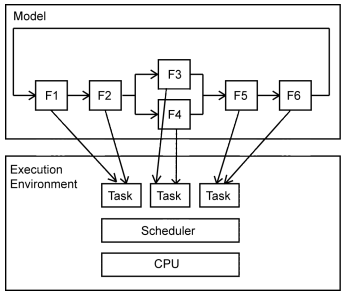
- Generate code from a single top model, which represents the algorithms intended to run in the execution environment.
- Generate code from a model, which represents part of an overall algorithm. You can mix the generated code with code written manually and code generated from other sources or releases of MathWorks® products.

Single Top Model

For a single top model, the software execution framework is responsible for running generated code the same way that Simulink simulates the model. Functions in the

generated code are highly coordinated and optimized because Simulink is aware of dependencies. The framework interfaces with code generated for the top model only. Code generated for a top model handles interfacing with code for referenced Model blocks.

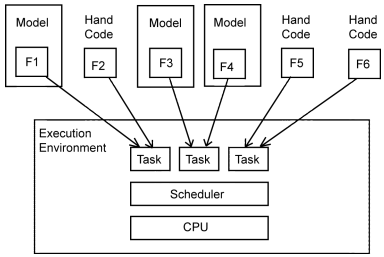
Consider the following example, where a single top model is mapped to tasks that run on a single-core CPU.



For this system, you map model clock rates to tasks that run on the hardware. You can choose for Simulink to map the rates implicitly or you can map them explicitly in your model. You can model latency effects resulting from how you map rates in a model to single-tasking or multitasking execution environments. Simulink schedules the tasks properly based on rates in the model and data dependencies between tasks. The code generator implements the same dependencies in the code that it generates. The software execution framework invokes generated entry-point functions at rates based on system timers and interrupts. The generated code executes in the same manner that Simulink simulates the model, and contains code dedicated to communicating data between functions running at different rates.

Multiple Top-Level Models

When you generate code from multiple top models separately and mix that code with code acquired in other ways, the execution environment of the application takes on more software execution framework responsibility. For this modeling scenario, you generate code for standalone, atomic reusable components.



With this scenario, Simulink is not aware of model dependencies. Functions in code generated from the different models are minimally coordinated and optimized. For example, the models might share generated utility functions. Potential optimizations that cross model boundaries are not possible. You must design the software execution framework taking into account dependencies between units of code, including execution order. For an application that requires concurrent execution across multiple cores, you must consider data latency effects across the cores.

The code generator helps you address software execution framework challenges, such as sharing global data and avoiding identifier conflicts. The code generated for a each model handles the interfacing for referenced Model blocks.

Map Embedded System Architecture to Simulink Modeling Environment

When mapping an embedded system architecture to the Simulink modeling environment, think about the model design.

“Modeling Algorithms” on page 1-6	Given initial state and input, a set of tasks or instructions that efficiently produce the results that you want.
“Modeling Interfaces” on page 1-7	Mechanisms that enable algorithm components to communicate and exchange information across component boundaries.
“Modeling Systems” on page 1-9	Collection of algorithm components that achieve a higher-level, domain-specific goal or result. Components often share resources.

"Modeling Run-Time Environments" on page 1-11	Framework that handles scheduling of system algorithm resources and execution.

Consider the following questions regarding an embedded system architecture with corresponding modeling capabilities and links to related information. Use the information as a guide for mapping your architecture details to the Simulink modeling environment. Designing a model architecture with your specific embedded system architecture in mind can help you avoid rework and future conversion and maintenance costs.

Kernel, operating system	• "Deploy Generated Standalone Executable Programs To Target Hardware" on page 63-2 • "Deploy Generated Component Software to Application Target Platforms" on page 63-33

Model Templates for Code Generation

The code generator provides a set of built-in templates to use as a starting point to create models for common application designs. Use the templates to create models that are preconfigured to generate code for rapid-prototyping or embedded system applications.

Template	Description
Code Generation System	Basic model consisting of an Inport block and Output block.
Exported functions	Model for generating code from function-call subsystems. You can export each function-call subsystem separately by right-clicking a subsystem, selecting **C/C++ Code > Export Functions**, and clicking **Build**.
Fixed-step, multirate	Fixed-step model that uses multiple rates and consists of Inport blocks, an Outport block, and a Sum block. The model is configured to use a fixed-step discrete solver and to use two rates with **Periodic sample time constraint** set to `Unconstrained` and the **Treat each discrete rate as a separate task** option selected. Simulink inserts a Rate Transition block to handle the two sample rates.
Fixed-step, single rate	Fixed-step model that uses a single rate and consists of Inport blocks, an Outport block, and a Sum block. The model is configured to use a fixed-step discrete solver.

To create a model from a template:

1. On the MATLAB® home tab, click **Simulink**.
2. In the Simulink start page, expand **Embedded Coder**.
3. Select a template.
4. Click **Create**. A new model that uses the template contents and settings appears in the Simulink Editor window.

For more information, for example to create and use a template as a reference design, see “Create a Template from a Model” (Simulink).

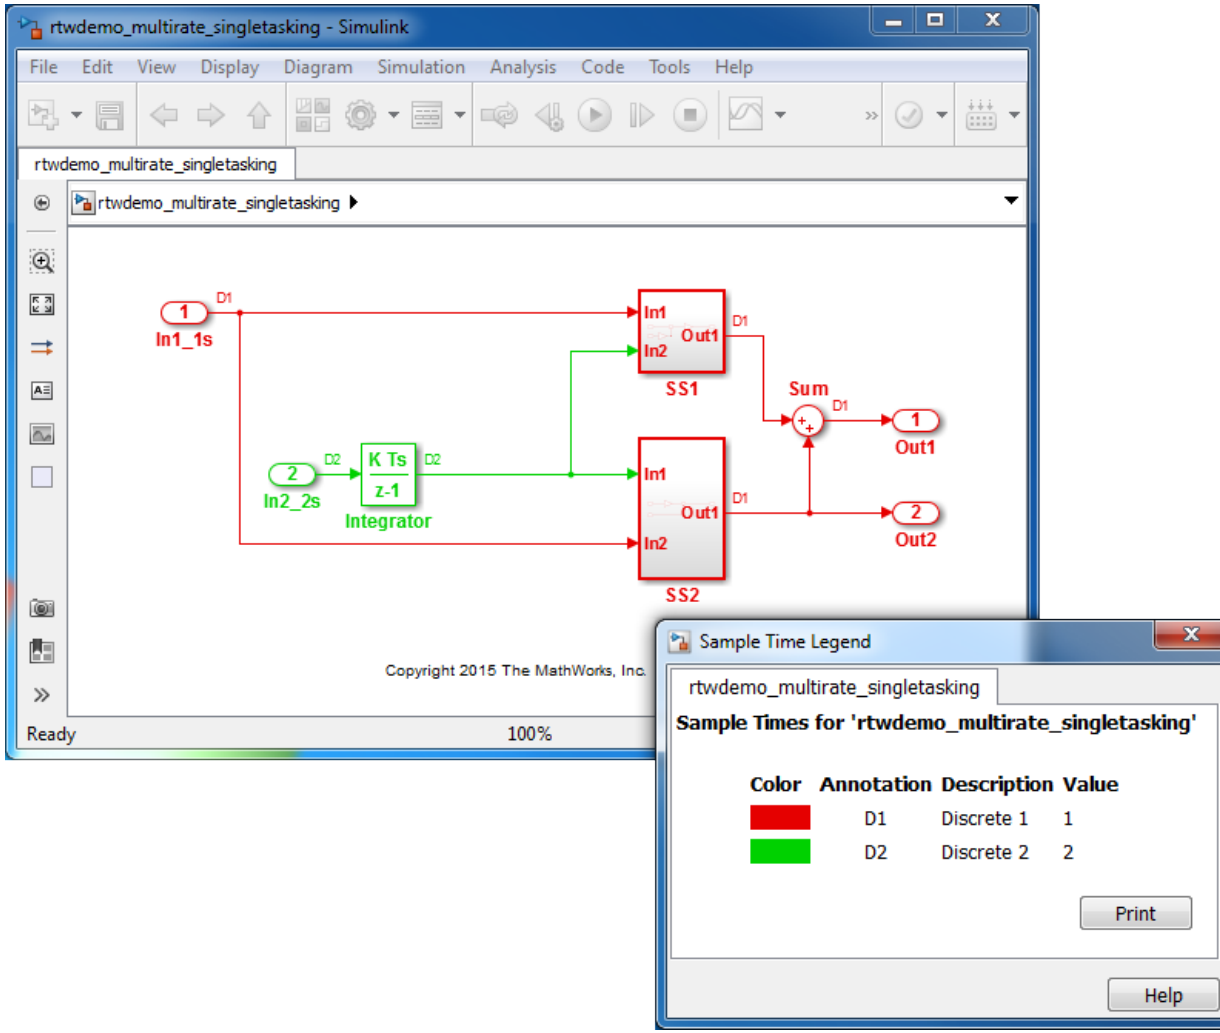
Model Single-Core, Single-Tasking Platform Execution

This example shows a model designed and configured for embedded system code generation intended to execute on a single-core, single-tasking platform. The application algorithm is captured in a single model hierarchy, making it possible to use Simulink® time-based, single-task scheduling to simulate the model and execute the generated code.

Periodic Multirate Model Set Up for Single-Tasking Execution

Open the example model rtwdemo_multirate_singletasking. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



- Sample times for Inport blocks `In1_1s` and `In2_2s` are set to 1 and 2 seconds, respectively.
- To provide clean partitioning of rates, sample times for subsystems `SS1` and `SS2` are set to 1.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block `In2_2s`, the green rate, is a subrate. The generated code properly transfers data between tasks running at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on single-tasking execution semantics.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_multirate_singletasking_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_multirate_singletasking.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_multirate_singletasking.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_multirate_singletasking.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of data type `real_T` with dimension of 1
- `rtU.In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_multirate_singletasking_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void rtwdemo_multirate_singletasking_step(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output ports:

- `rtY.Out1` of data type `real_T` with dimension of 1
- `rtY.Out2` of data type `real_T` with dimension of 1

More About

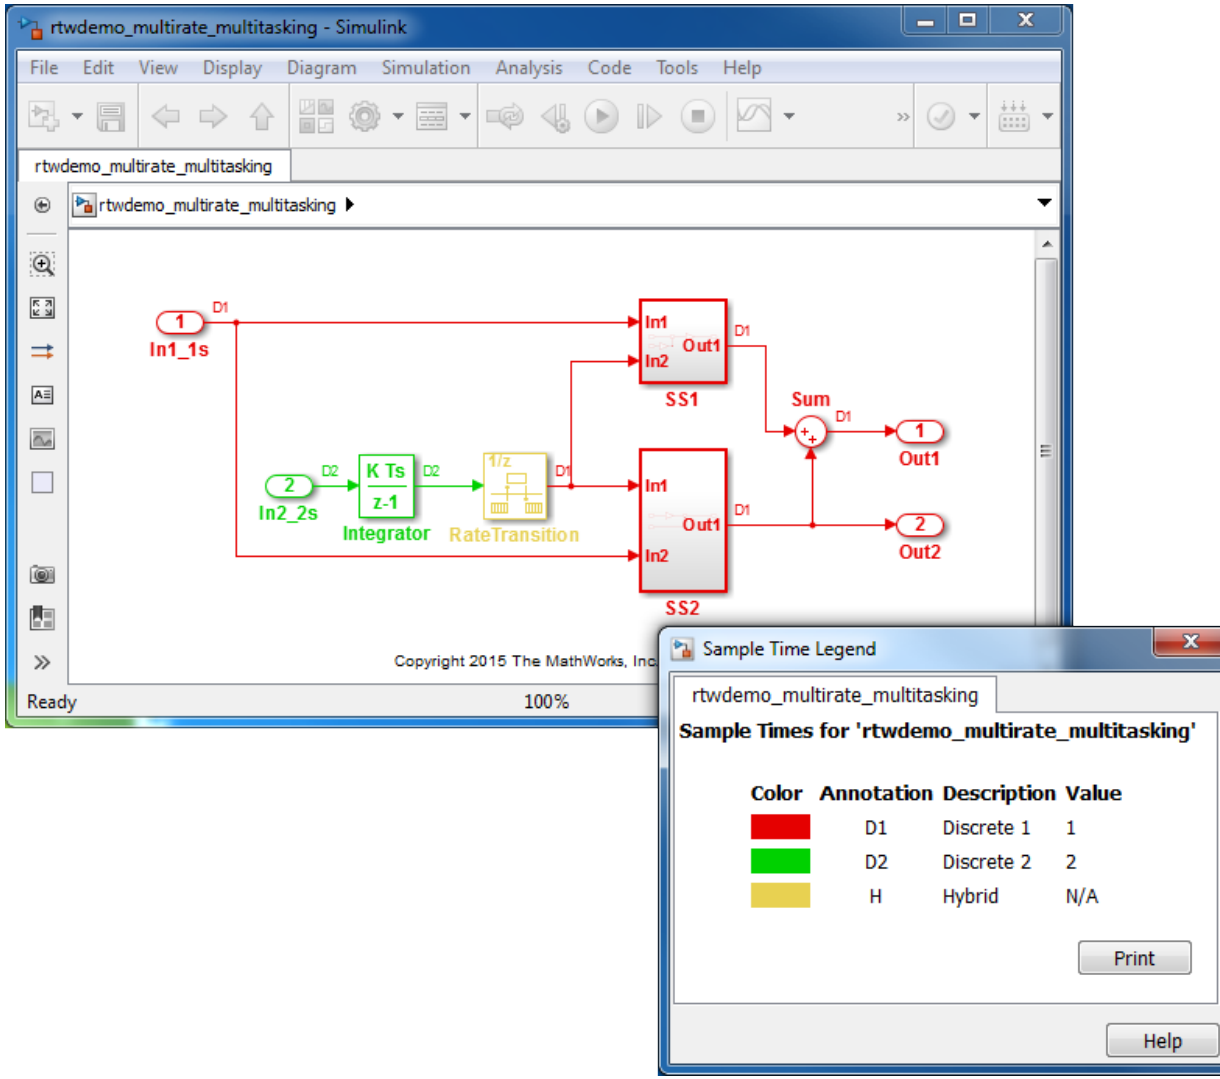
- “Modeling for Single-Tasking Execution” (Simulink Coder)
- “Deploy Generated Standalone Executable Programs To Target Hardware” on page 63-2
- “Customize Code Organization and Format” on page 50-59

Model Single-Core, Multitasking Platform Execution

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a single-core, multitasking platform. The model simulates and the generated code executes based on the model configuration and a rate monotonic scheduling algorithm.

Periodic Multirate Model Set Up for Multitasking Execution

Open the example model `rtwdemo_multirate_multitasking`. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



- Sample times for Inport blocks `In1_1s` and `In2_2s` are set to 1 and 2 seconds, respectively.
- To provide a clear partitioning of rates, sample times for subsystems `SS1` and `SS2` are set to 1.

- The Rate Transition block models an explicit rate transition. Alternatively, instruct Simulink to insert Rate Transition blocks for you by selecting model configuration parameter **Solver > Automatically handle rate transition for data transfer**.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** selected.

Scheduling

Simulink® simulates the model based on the model configuration. Code that this model generates implements the same execution semantics. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate. Yellow represents the mixture of the two rates.

The generated code schedules subrates in the model. In this example, the rate for Inport block `In2_2s`, the green rate, is a subrate. The generated code properly transfers data between tasks that run at the different rates.

Benefits of implicit rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within the model.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, the model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates based on multitasking execution semantics.

Simulink enforces data transfer constraints to achieve rate monotonic scheduling:

- Data transfers occur between a single read task and a single write task.
- When data transfers between two tasks, only one task can preempt the other task.

- For periodic tasks, a task with a faster rate has a higher priority than a task with a slower rate. In addition, a task with the faster rate, preempts a task with a slower rate.
- Tasks run on a single processor.
- Time slicing, use of a defined time period during which a task can run in a preemptive multitasking system, is not allowed.
- Processes do not crash or restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework communicates with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point functions `rtwdemo_multirate_multitasking_step0` and `rtwdemo_multirate_multitasking_step1`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_multirate_multitasking.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_multirate_multitasking.h` declares model data structures and a public interface to the model entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_multirate_singletasking.h`.

2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of data type `real_T` with dimension of 1
- `rtU.In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_multirate_multitasking_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void rtwdemo_multirate_multitasking_step0(void)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.
- Output and update entry-point function, `void rtwdemo_multirate_multitasking_step1(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds. To achieve real-time execution, attach this function to a timer.

Output ports:

- `rtY.Out1` of data type `real_T` with dimension of 1
- `rtY.Out2` of data type `real_T` with dimension of 1

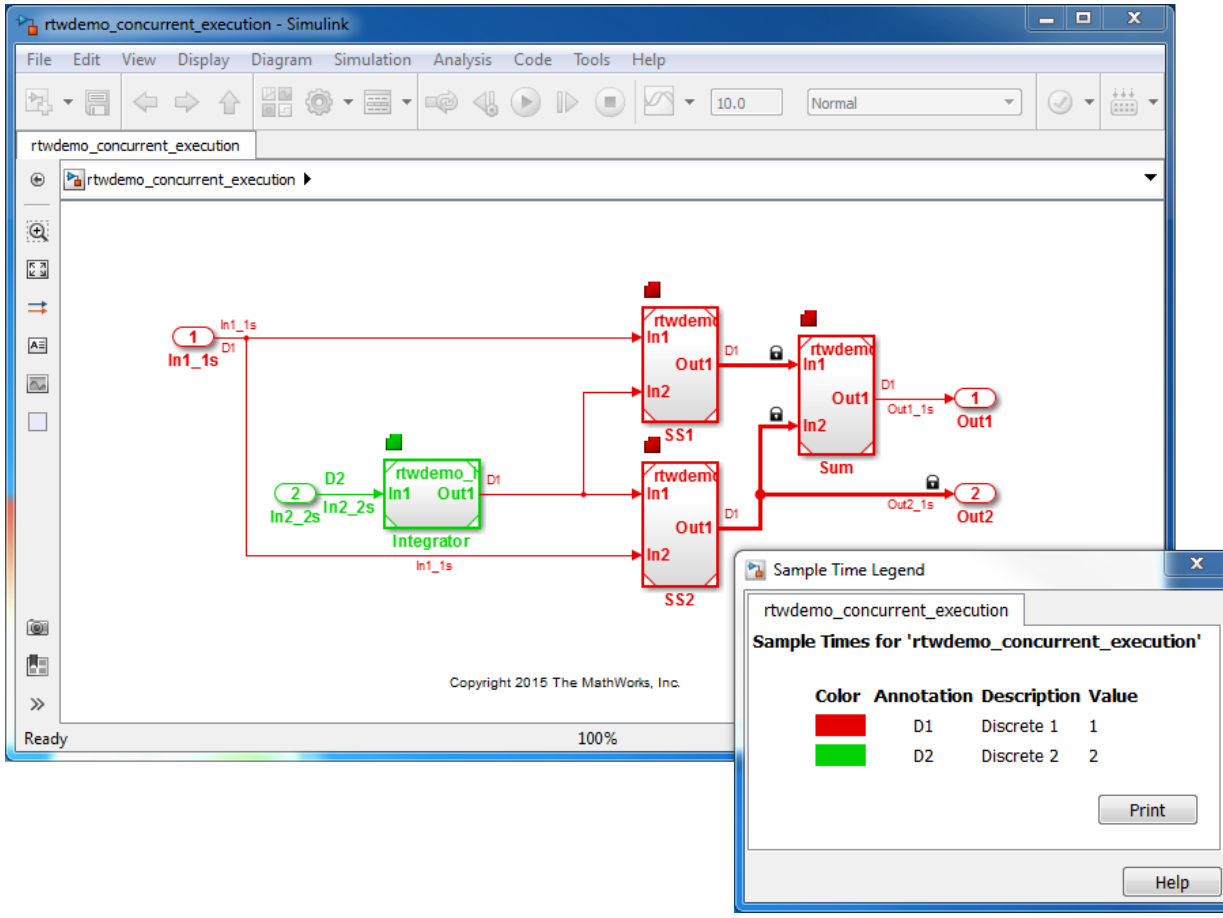
Model Concurrent Execution for Symmetric Multicore CPU Platforms

Use Simulink® time-based, multitask scheduling to simulate and generate code for an application algorithm captured in a single model hierarchy. The model is designed and configured for an embedded system intended to execute on a symmetric multicore, multitasking platform.

Periodic Multirate Model Set Up for Multitasking Concurrent Execution

Open the example model rtwdemo_concurrent_execution. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



Simulink supports simulating concurrent task execution by assigning partitions of a model to tasks that you designate to run concurrently on multicore hardware. Use an implicit or explicit approach to designating partitions.

Simulink implicit partitioning:

- Partitions the model based on sample times specified in the model.
- Assigns a task to each sample rate and designates that the tasks run concurrently.
- Controls the granularity of partitions. For example, you cannot split a sample rate into multiple tasks.

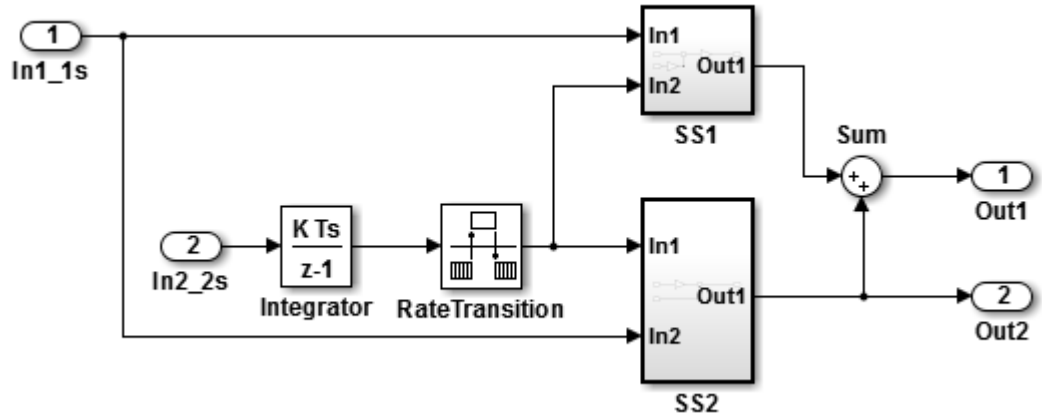
- Does not impose modeling constraints.
- Provides ready-to-use hardware solutions, such as solutions that the Simulink® Real-Time™ product produces.
- Is not relevant to standalone production code generation due to the lack of control over partition granularity.

Explicit partitioning:

- Use Model and Subsystem blocks to partition the model.
- Create an arbitrary number of tasks.
- Simulink assigns each partition to a task.
- Simulink imposes modeling constraints.
- Control the granularity of partitions.
- Split a sample rate into multiple tasks.
- Assign partitions to different processor cores.
- Is for standalone production code generation due to the level of control you have over granularity of partitions.

This example shows explicit partitioning.

Consider the following periodic multirate model that is set up for multitasking execution.



- Sample times for Inport blocks `In1_1s` and `In2_2s` are set to 1 and 2 seconds, respectively.
- To provide a clear partitioning of rates, sample times for models `SS1` and `SS2` are set to 1.
- The Rate Transition block explicitly models a rate transition.

To support concurrent execution of tasks in a multicore run-time environment, the preceding model was modified:

- The Integrator block is in a Model block configured with a fixed-step discrete solver and a step size of two seconds.
- Subsystems `SS1` and `SS2` were converted to Model blocks configured with a fixed-step discrete solver and a step size of one second.
- The Sum block is in a Model block configured with a fixed-step discrete solver and a step size of one second. Another option for the Sum block is to place it in `SS1` or `SS2` and compute its value coincident with the Model block. For concurrent execution of tasks, only connection blocks, Model blocks, and Subsystem blocks can be at the root level of a model.
- The Rate Transition block was removed.

Relevant Model Configuration Parameter Settings

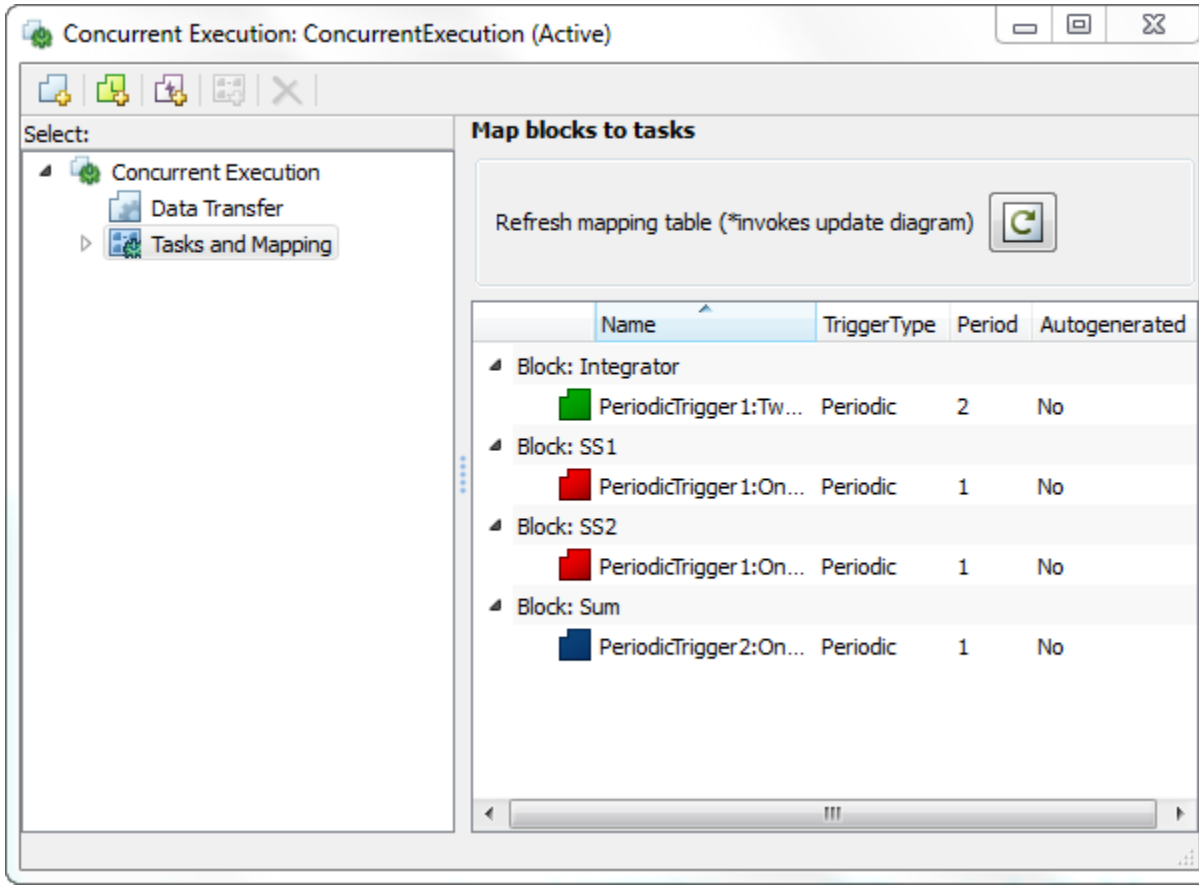
- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** selected.
- **Solver > Automatically handle rate transition for data transfer** selected. Necessary because Rate Transition block was removed.
- **Solver > Allow tasks to execute concurrently on target** selected.

Concurrent Execution Parameter Settings

Open the Concurrent Execution dialog box by clicking **Configure Tasks** on the Configuration Parameters **Solver** pane. Selecting **Allow tasks to execute concurrently on target** enables the **Configure Tasks** button.

When selected, the **Enable explicit model partitioning for concurrent behavior** parameter enables concurrent execution options for the top-level model.

Click **Tasks and Mapping** to review the tasks and mapping.



Simulink creates a default mapping for each partition (Model block) by assigning each partition to a separate task. Simulink designates that each partition executes concurrently and simulates latency effects that data communication between processor cores imposes. This dialog box displays a mapping consisting of partitions spread across two independent periodic triggers: `SS1`, `SS2`, and `Sum` mapped to periodic trigger 1 and `Integrator` mapped to periodic trigger 2.

Scheduling

Simulink® simulates the model based on the model configuration. Code generated from the model implements the same execution semantics. Simulink propagates and uses the

Inport block sample times to order block execution based on a multicore, multitasking execution platform.

For this model, the sample time legend shows an implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

The generated code schedules subrates in the model. In this example, the rate for Inport block `In2_2s`, the green rate, is a subrate. The generated code properly transfers data between the rates.

Benefits of implicit Simulink rate grouping:

- Simulink does not impose architectural constraints on the model. Create a model without imposing software architecture constraints within it.
- Your execution framework does not require details about underlying function scheduling and data transfers between rates. Therefore, model interface requirements are simplified. The execution framework uses generated interface code to write input, call the model step function, and read output.
- The code generator optimizes code across rates, based on multitasking execution semantics.

Simulink enforces data transfer constraints:

- Data transfers occur between a single read task and a single write task.
- Tasks run on a single processor.
- Processes do not stop or restart, especially during data transfers between tasks.
- Read and write operations on byte-sized variables are atomic.

Your execution framework can communicate with external devices for reading and writing model input. For example, model external devices by using Simulink S-Function blocks. Generate code for those blocks with the rest of the algorithm.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by indirectly calling entry-point functions `PeriodicTrigger1_OneSecond_step`, `PeriodicTrigger1_TwoSecond_step`, and `PeriodicTrigger2_OneSecond_step` with the function `rtwdemo_concurrent_execution_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_concurrent_execution.c` contains entry points for the code that implements the model algorithm. This file includes the rate and task scheduling code.
- `rtwdemo_concurrent_execution.h` declares model data structures and a public interface to the model entry points and data structures.
- `model_reference_types.h` contains type definitions for timing bridges. These type definitions are generated for a model reference target or a model containing Model blocks.
- `rtw_windows.h` declares mutex and semaphore function prototypes that the generated code uses for concurrent execution on Microsoft® Windows® platforms.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_concurrent_execution.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `In1_1s` of data type `real_T` with dimension of 1
- `In2_2s` of data type `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_concurrent_execution_initialize(void)`. At startup, call this function once.

- Output and update entry-point (step) function, `void PeriodicTrigger1_OneSecond_step(void)`. Call this function periodically for one of two tasks that require scheduling at the fastest rate in the model. For this model, call the function every second.
- Output and update entry-point function, `void PeriodicTrigger1_TwoSecond_step(void)`. Call this function periodically at the second fastest rate in the model. For this model, call the function every two seconds.
- Output and update entry-point function, `void PeriodicTrigger2_OneSecond_step(void)`. Call this function periodically for the second task that requires scheduling at the fastest rate in the model. For this model, call the function every second.

To achieve real-time execution, define a task or thread for each entry-point step function. Trigger execution of each function based on a timer that has the same rate as the given function. The operating system schedules the tasks across cores dynamically or based on your mapping of tasks to cores.

Output ports:

- `Out1_1s` of data type `real_T` with dimension 1
- `Out2_1s` of data type `real_T` with dimension 1

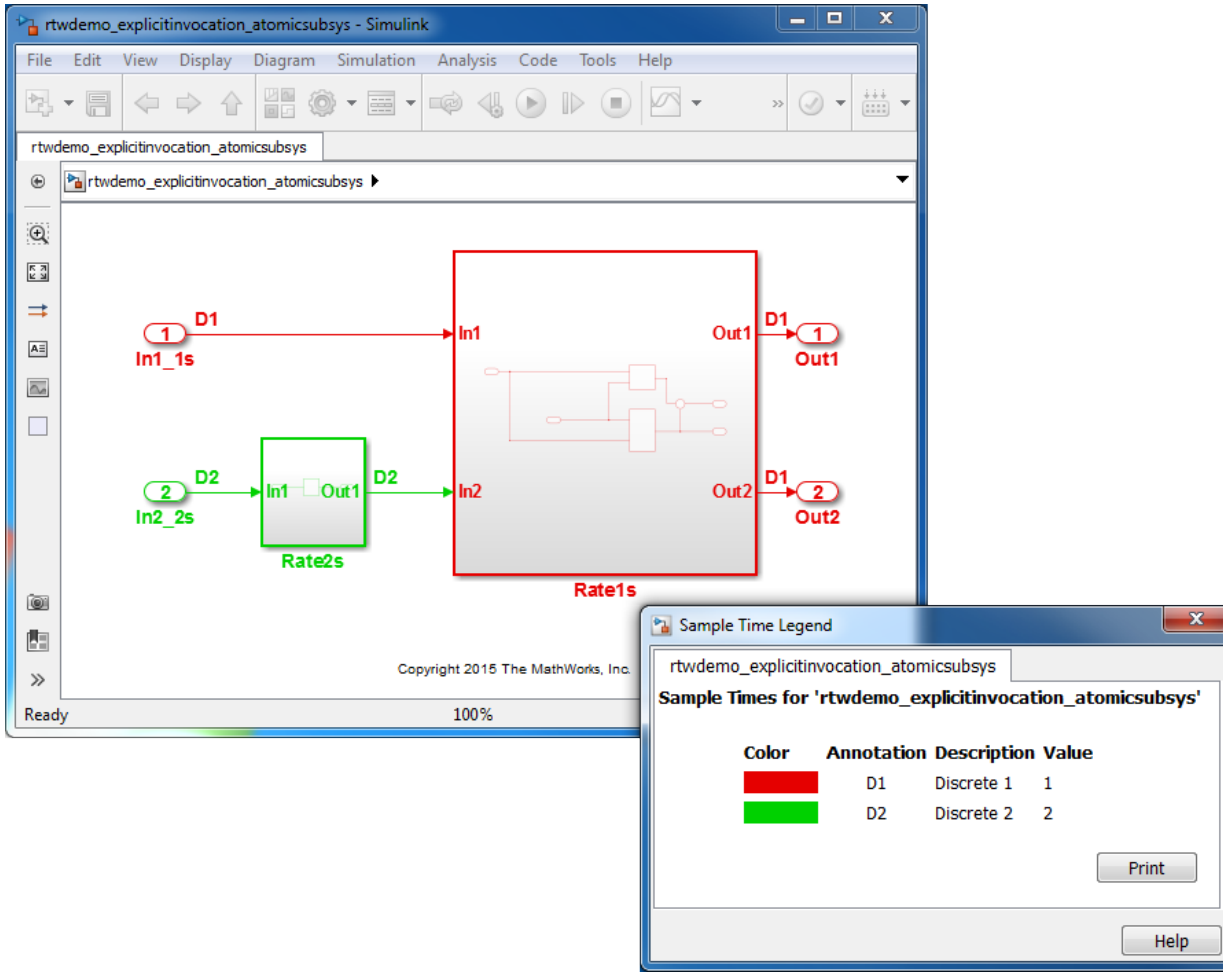
Model Explicit Function Invocation with Atomic Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into multiple atomic subsystems that you build separately.

Atomic Subsystem Model

Open the example model rtwdemo_explicitinvocation_atomicsubsys. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



This model partitions an algorithm into two atomic subsystems: `Rate1s` and `Rate2s`. Subsystem `Rate1s` is configured with a sample time of 1 second. Subsystem `Rate2s` is configured with a sample time of 2 seconds.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.

- **Solver > Treat each discrete rate as a separate task** cleared.

Scheduling

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, single-tasking execution platform.

For this example, the sample time legend shows implicit rate grouping. Red represents the fastest discrete rate. Green represents the second fastest discrete rate.

Based on ratemonotonic scheduling, your application code (execution framework) must transfer data between subsystems `Rate2s` and `Rate1s` at a frequency of 2 seconds with the priority of 1 second. That is, the generated function transfers data in the 1 second task every other time prior to executing code for subsystem `Rate1s`.

Your execution framework must schedule the generated function code and handle the data transfers between them. This is an advantage for multirate models because the generated code assumes no scheduling or data transfer semantics. However, the execution framework must handle data transfers explicitly.

Generate Code and Report

Generate a single callable function for each subsystem without connections between them. Multiple ways are available to generate code for a subsystem, including from the subsystem context menu. For example, right-click a subsystem block and click **C/C++ Code > Build This Subsystem**. In the Build code for Subsystem dialog box, click **Build**.

The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the subsystem. This code controls model code execution by calling entry-point function `Rate1s_step` or `Rate2s_step`. Use this file as a starting point for coding your execution framework.
- `Rate1s.c` and `Rate2s.c` contain entry points for the code that implements subsystem `Rate1s` and `Rate2s`, respectively. This file includes the rate and task scheduling code.

- `Rate1s.h` and `Rate2s.h` declare model data structures and a public interface to subsystem entry points and data structures.
- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header file by adding directive `#include rtwdemo_explicitinvocation_atomicsusys.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports, `Rate1s`:

- `rtU.In1` of type `real_T` with dimension of 1
- `rtU.In2` of type `real_T` with dimension of 1

Entry-point functions, `Rate1s`:

- Initialize entry-point function, `void Rate1s_initialize(void)`. At startup, call this function once.
- Output and update entry-point (step) function, `void Rate1s_step(void)`. Call this function periodically, every second.
- Termination function, `void Rate1s_terminate(void)`. Call this function once from your shutdown code.

Output ports, `Rate1s`:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

Input ports, `Rate2s`:

- `rtU.In1` of type `real_T` with dimension of 1

Entry-point functions, `Rate2s`:

- Initialize entry-point function, `void Rate2s_initialize(void)`. Call this function once at startup.
- Output and update entry-point (step), `void Rate2s_step(void)`. Call this function periodically, every 2 seconds.
- Termination function, `void Rate2s_terminate(void)`. Call this function once from your shutdown code.

Output ports, `Rate2s`:

- `rtY.Out1` of type `real_T` with dimension of 1

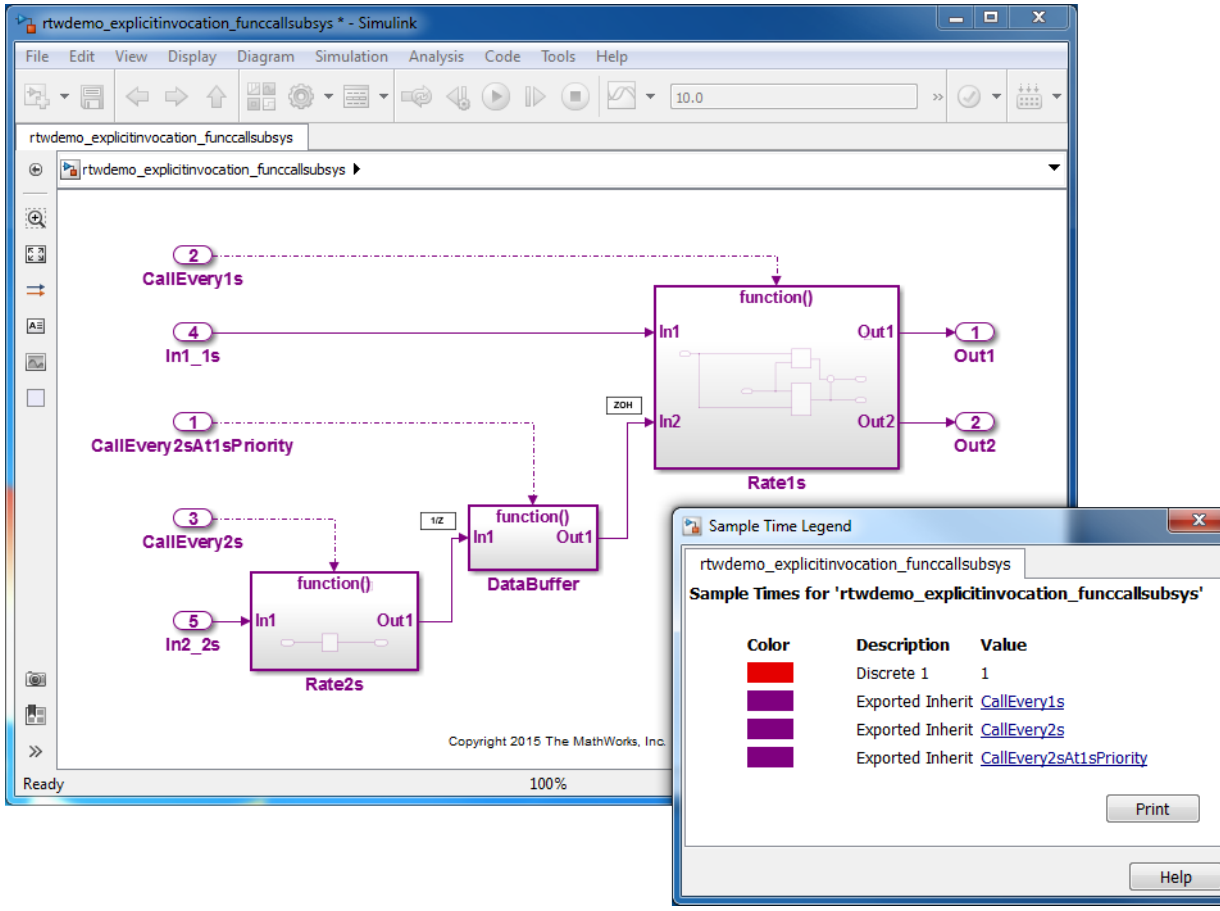
Model Explicit Function Invocation with Function-Call Subsystems

Deploy embedded system code from Simulink® models by partitioning a model into function-call subsystems that you build separately.

Function-Call Subsystem Model

Open the example model rtwdemo_explicitinvocation_funccallsubsys. The model is configured to display color-coded sample times with annotations. To see them, after opening the model, update the diagram by pressing **Ctrl+D**. To display the legend, press **Ctrl+J**.



This model partitions an algorithm into three function-call subsystems: `Rate1s`, `Rate2s`, and `DataBuffer`. Use function-call subsystems to model multirate systems explicitly.

Subsystems `Rate1s` and `DataBuffer` use a sample time of 1 second. Subsystem `Rate2s` uses a sample time of 2 seconds.

This model design is referred to as export function modeling. Simulink constrains the model to function-call subsystems at the root level. The driving Inport block specifies the function name.

Relevant Model Configuration Parameter Settings

- **Solver > Type** set to `Fixed-step`.
- **Solver > Solver** set to `discrete (no continuous states)`.
- **Solver > Treat each discrete rate as a separate task** selected. Simulink applies multitasking execution because the model uses multiple sample rates.

Scheduling

Simulink® simulates the model based on the model configuration. Simulink propagates and uses the Inport block sample times to order block execution based on a single-core, multitasking execution platform.

In the sample time legend, red identifies the fastest discrete rate. Magenta identifies rates inherited from exported functions, indicating their execution is outside the context of Simulink scheduling.

Your execution framework must schedule the generated function code and transfer data between functions.

Your execution framework needs to schedule the generated function code and handle data transfers between functions. The generated code is simple and you control the order of execution.

Generate Code and Report

Generate code and a code generation report. The example model generates a report.

Review Generated Code

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code shows how to call the exported functions. The code also shows how to initialize, execute, and terminate the generated code.
- `rtwdemo_explicitinvocation_funccallsubsys.c` calls the initialization function and exported functions for subsystems `Rate1s`, `Rate2s`, and `DataBuffer`.
- `rtwdemo_explicitinvocation_funccallsubsys.h` declares model data structures and a public interface to the exported entry point functions and data structures.

- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Code Interface

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework:

1. Include the generated header files by adding directives `#include Rate1s.h`, `#include DataBuffer.h`, and `#include Rate2s.h`.
2. Write input data to the generated code for model Inport blocks.
3. Call the generated entry-point functions.
4. Read data from the generated code for model Outport blocks.

Input ports:

- `rtU.In1_1s` of type `real_T` with dimension of 1
- `rtU.In2_2s` of type `real_T` with dimension of 1

Entry-point functions:

- Initialize entry-point function, `void rtwdemo_explicitinvocation_funccallsubsys_initialize(void)`. At startup, call this function once.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery1s(void)`. Call this function as needed.
- Exported function, `void CallEvery2sAt1sPriority(void)`. Call this function as needed.

Output ports:

- `rtY.Out1` of type `real_T` with dimension of 1
- `rtY.Out2` of type `real_T` with dimension of 1

More About

Modeling in Simulink Coder

Configure a Model for Code Generation

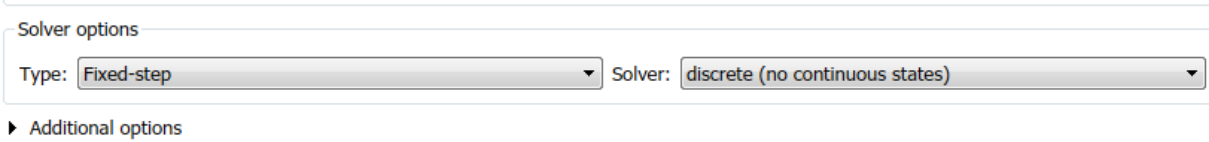
Model configuration parameters determine the method for generating the code and the resulting format.

1 Open `rtwdemo_throttlecntrl` and save a copy as `throttlecntrl` in a writable location on your MATLAB path.

Note This model uses Stateflow® software.

2 Open the Configuration Parameters dialog box **Solver** pane. To generate code for a model, you must configure the model to use a fixed-step solver. For this example, set the parameters as noted in the following table.

Parameter	Setting	Effect on Generated Code
Type	`Fixed-step`	Maintains a constant (fixed) step size, which is required for code generation
Solver	`discrete (no continuous states)`	Applies a fixed-step integration technique for computing the state derivative of the model
Fixed-step size	`.001`	Sets the base rate; must be the lowest common multiple of all rates in the system



3 Open the **Code Generation** pane and make sure that **System target file** is set to `grt.tlc`.

Note The GRT (Generic Real-Time Target) configuration requires a fixed-step solver. However, the `rsim.tlc` system target file supports variable step code generation.

The system target file (STF) defines a target, which is an environment for generating and building code for execution on a certain hardware or operating system platform. For example, one property of a target is code format. The grt configuration requires a fixed step solver and the rsim.tlc supports variable step code generation.

4. Open the **Code Generation > Custom Code** pane, and under **Additional build information**, select **Include directories**. In the **Include directories** text field, enter:

   ```
   "$matlabroot$\toolbox\rtw\rtwdemos\EmbeddedCoderOverview\"
   ```

   This directory includes files that are required to build an executable for the model.

5. Apply your changes and close the dialog box.

Blocks and Products Supported for Code Generation

In this section...

As you construct a model, to prevent issues later in the development process, determine whether the Simulink Coder and Embedded Coder code generators support the products and blocks that you want to use.

Related Products

The following table summarizes MathWorks products that extend and complement Simulink Coder software. For information about these products and how code generation supports them, refer to their product documentation at `www.mathworks.com`.

Product	Extends Code Generation Capabilities for ...
Aerospace Blockset™	Aircraft, spacecraft, rocket, propulsion systems, and unmanned airborne vehicles
Audio Toolbox™	Audio processing systems
Automated Driving Toolbox™	Designing, simulating, and testing ADAS and autonomous driving systems
AUTOSAR Blockset	Modeling and simulation of AUTOSAR Classic and Adaptive ECU software
Communications Toolbox™	Physical layer of communication systems
Computer Vision Toolbox™	Video processing, image processing, and computer vision systems
Control System Toolbox™	Linear control systems
DSP System Toolbox™	Signal processing systems
Embedded Coder	Embedded systems, rapid prototyping boards, and microprocessors in mass production

Product	Extends Code Generation Capabilities for ...
Fixed-Point Designer™	Fixed-point systems
Fuzzy Logic Toolbox™	System designs based on fuzzy logic
HDL Verifier™	Direct programming interface (DPI) component and transaction-level model (TLM) generation from Simulink
IEC Certification Kit	ISO 26262 and IEC 61508 certification
Model-Based Calibration Toolbox™	Developing processes for systematically identifying optimal balance of engine performance, emissions, and fuel economy, and reusing statistical models for control design, hardware-in-the-loop (HIL) testing, or powertrain simulation
Model Predictive Control Toolbox™	Controllers that optimize performance of multi-input and multi-output systems that are subject to input and output constraints
Deep Learning Toolbox™	Neural networks
Parallel Computing Toolbox™	Parallel builds for large Simulink models
Phased Array System Toolbox™	Sensor array systems in radar, sonar, wireless communications, and medical imaging applications
Polyspace® Bug Finder™	MISRA-C compliance and static analysis of generated code
Polyspace Code Prover™	Formal analysis of generated code
Powertrain Blockset™	Real-time testing of powertrain applications
Robotics System Toolbox™	Robot Operating System (ROS) node generation
Simscape™	Systems spanning mechanical, electrical, hydraulic, and other physical domains as physical networks
Simscape Driveline™	Driveline (drivetrain) systems
Simscape Electrical™	Electronic, electromechanical, and electrical power systems
Simscape Fluids™	Hydraulic power and control systems

Product	Extends Code Generation Capabilities for ...
Simscape Multibody™	Three-dimensional mechanical systems
Simulink 3D Animation™	Systems with 3D visualizations
Simulink Check™	Model standards compliance checking and metrics
Simulink Code Inspector™	Automated reviews of generated code
Simulink Control Design™	Autotuning of PID controllers
Simulink Coverage™	Model and code structural coverage analysis
Simulink Design Optimization™	Systems requiring maximum overall system performance
Simulink Desktop Real-Time™	Rapid prototyping or hardware-in-the-loop (HIL) simulation of control system and signal processing algorithms
Simulink Real-Time™	Rapid control prototyping, hardware-in-the-loop (HIL) simulation, and other real-time testing applications
Simulink Report Generator™	Automatically generating project documentation in a standard format
Simulink Requirements™	Authoring and tracing requirements to design and code
Simulink Test™	Software-in-the-loop (SIL), processor-in-the-loop (PIL), and real-time hardware-in-the-loop (HIL) testing of generated code
SoC Blockset™	Designing, evaluating, and implementing SoC hardware and software architectures
Stateflow	State machines and flow charts
System Identification Toolbox™	Systems constructed from measured input-output data
Vehicle Dynamics Blockset™	Modeling and simulation of vehicle dynamics in 3D environment
Vehicle Network Toolbox™	CAN blocks for Accelerator and Rapid Accelerator simulations and code deployment on Windows®

Simulink Built-In Blocks That Support Code Generation

The following tables summarize code generator support for Simulink blocks. There is a table for each block library. For more detail, including data types each block supports, in the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages. For some blocks, the generated code might rely on `memcpy` or `memset` (`string.h`).

In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Decrement Stored Integer	
Decrement Time To Zero	Supports code generation.
Decrement To Zero	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Increment Real World	
Increment Stored Integer	

Continuous

Block	Support Notes
Derivative	Not recommended for production-quality code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. The code generated can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. In general, consider using the Simulink Model Discretizer to map continuous blocks into discrete equivalents that support production code generation. To start the Model Discretizer, select **Analysis > Control Design > Model Discretizer**. One exception is the Second-Order Integrator block because, for this block, the Model Discretizer produces an approximate discretization.

Block	Support Notes
Trigonometric Function	Functions `asinh`, `acosh`, and `atanh` are not supported by all compilers. If you use a compiler that does not support those functions, the software issues a warning for the block and the generated code fails to link.
Unary Minus	Support code generation.modeling Gui
Vector Concatenate, Matrix Concatenate	
Weighted Sample Time Math	

Model Verification

Block	Support Notes
Assertion	Supports code generation.
Check Discrete Gradient	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Check Dynamic Gap	Support code generation.
Check Dynamic Lower Bound	
Check Dynamic Range	
Check Dynamic Upper Bound	
Check Input Resolution	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Check Static Gap	
Check Static Lower Bound	
Check Static Range	
Check Static Upper Bound	

Model-Wide Utilities

Block	Support Notes
Block Support Table	Ignored during code generation.
DocBlock	Uses the template symbol you specify for the **Embedded Coder Flag** block parameter to add comments to generated code. Requires an Embedded Coder license. For more information, see “Use a Simulink DocBlock to Add a Comment” on page 50-10.
Model Info	Ignored during code generation.

Sinks

Block	Support Notes
Display	Ignored for code generation.
Floating Scope and Scope Viewer	
Outport (Out1)	Supports code generation.
Scope	Ignored for code generation.
Stop Simulation	• Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable. • Generated code stops executing when the stop condition is true.
Terminator	Supports code generation.
To File	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
To Workspace	Ignored for code generation.
XY Graph	

Sources

Block	Support Notes
Band-Limited White Noise	Cannot use inside a triggered subsystem hierarchy.
Chirp Signal	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Clock	
Constant	Supports code generation.
Counter Free-Running	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Counter Limited	• The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option. • Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. Block	Support Notes
Digital Clock	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Enumerated Constant	Supports code generation.
From File	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
From Spreadsheet	
From Workspace	Ignored for code generation.
Ground	Support code generation.
Inport (In1)	
Pulse Generator	Cannot use inside a triggered subsystem hierarchy. Does not refer to absolute time when configured for sample-based operation. Depends on absolute time when in time-based operation.
Ramp	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Random Number	Supports code generation.

Block	Support Notes
Repeating Sequence	• Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable. • Consider using the Repeating Sequence Stair or Repeating Sequence Interpolated block instead.
Repeating Sequence Interpolated	• The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option. • Cannot use inside a triggered subsystem hierarchy.
Repeating Sequence Stair	The code generator does not explicitly group primitive blocks that constitute a nonatomic masked subsystem block in the generated code. This flexibility allows for more efficient code generation. In certain cases, you can achieve grouping by configuring the masked subsystem block to execute as an atomic unit by selecting the **Treat as atomic unit** option.
Signal Builder	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Signal Generator	

Block	Support Notes
Sine Wave	• Depends on absolute time when used inside a triggered subsystem hierarchy. • Does not refer to absolute time when configured for sample-based operation. Depends on absolute time when in time-based operation.
Step	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.
Uniform Random Number	Supports code generation.
Waveform Generator	Not recommended for production code. Relates to resource limits and restrictions on speed and memory often found in embedded systems. Generated code can contain dynamic allocation and freeing of memory, recursion, additional memory overhead, and widely-varying execution times. While the code is functionally valid and generally acceptable in resource-rich environments, smaller embedded targets often cannot support such code. Usually, blocks evolve toward being suitable for production code. Thus, blocks suitable for production code remain suitable.

User-Defined

Block	Support Notes
Fcn	Support code generation.
Function Caller	
Initialize Function	
Interpreted MATLAB Function	Consider using the MATLAB Function block instead.
Level-2 MATLAB S-Function	If a corresponding TLC file is available, the Level-2 MATLAB S-Function block uses the TLC file to generate code, otherwise code generation throws an error.
MATLAB Function	Support code generation.
MATLAB System	
S-Function	S-functions that call into MATLAB are not supported for code generation.
S-Function Builder	
Simulink Function	Support code generation.
Terminate Function	

Simulink Block Data Type Support Table

The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, in the MATLAB Command Window, type `showblockdatatypetable`, or consult the block reference pages.

Block Set Support for Code Generation

Several products that include blocks are available for you to consider for code generation. However, before using the blocks for one of these products, consult the documentation for that product to confirm which blocks support code generation.

Modeling Semantic Considerations

In this section...

Data Propagation

The first stage of code generation is compilation of the block diagram. This stage is analogous to that of a C or C++ program. The compiler carries out type checking and preprocessing. Similarly, the Simulink engine verifies that input/output data types of block ports are consistent, line widths between blocks are of expected thickness, and the sample times of connecting blocks are consistent.

The Simulink engine propagates data from one block to the next along signal lines. The data propagated consists of

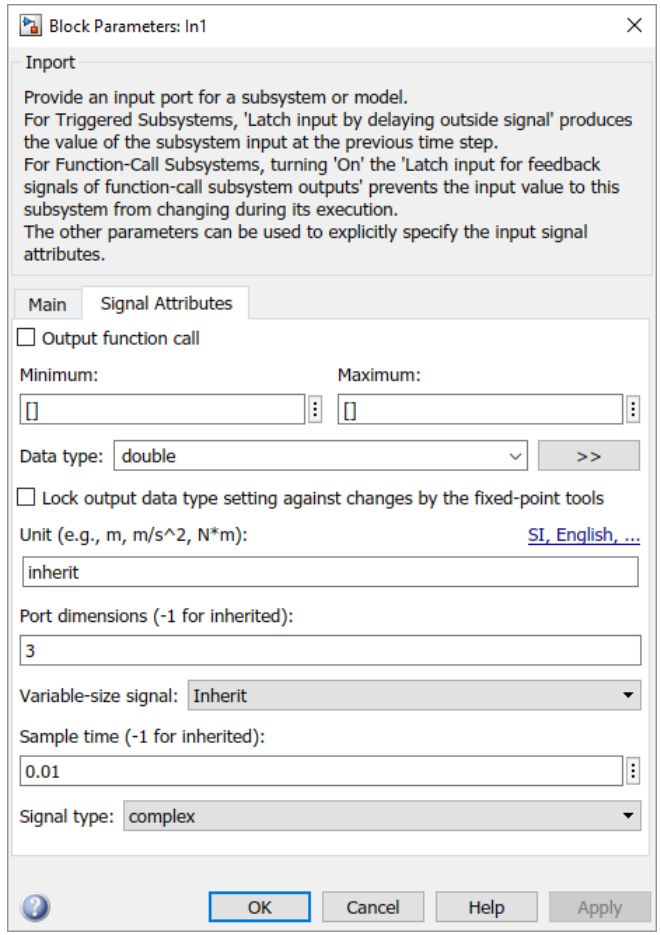
- Data type
- Line widths
- Sample times

You can verify what data types a Simulink block supports by typing

```
showblockdatatypetable
```

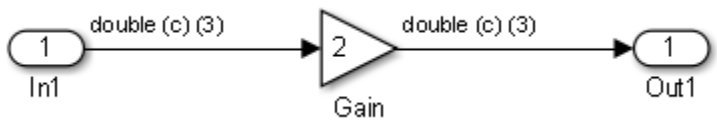
at the MATLAB prompt, or (from the Help browser) clicking the command above.

The Simulink engine typically derives signal attributes from a source block. For example, the Inport block's parameters dialog box specifies the signal attributes for the block.



In this example, the Inport block has a port width of 3, a sample time of .01 seconds, the data type is double, and the signal is complex.

This figure shows the propagation of the signal attributes associated with the Inport block through a simple block diagram.



In this example, the Gain and Outport blocks inherit the attributes specified for the Inport block.

Sample Time Propagation

Inherited sample times in source blocks (for example, a root inport) can sometimes lead to unexpected and unintended sample time assignments. Since a block may specify an inherited sample time, information available at the outset is often insufficient to compile a block diagram completely.

In such cases, the Simulink engine propagates the known or assigned sample times to those blocks that have inherited sample times but that have not yet been assigned a sample time. Thus, the engine continues to fill in the blanks (the unknown sample times) until sample times have been assigned to as many blocks as possible. Blocks that still do not have a sample time are assigned a default sample time.

For a completely deterministic model (one where no sample times are set using the above rules), you should explicitly specify the sample times of your source blocks. Source blocks include root inport blocks and blocks without input ports. You do not have to set subsystem input port sample times. You might want to do so, however, when creating modular systems.

An unconnected input implicitly connects to ground. For ground blocks and ground connections, the sample time is always constant (`inf`).

All blocks have an inherited sample time (T_s = -1). They are assigned a sample time of (T_f - T_i)/50.

Blocks Whose Outputs Have Constant Values

When you display sample time colors, by default, Constant blocks appear magenta in color to indicate that the block outputs have constant values during simulation. Downstream blocks whose output values are also constant during simulation, such as Gain blocks, similarly appear magenta if they use an inherited sample time. The code generated for these blocks depends in part on the tunability of the block parameters.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to `Inlined`, the block parameters are not tunable in the generated code. Because the block outputs are constant, the code generator eliminates the block code due to constant folding. If the code generator cannot fold the code, or if you select settings to disable constant folding, the block code appears in the model initialization function. The

generated code is more efficient because it does not compute the outputs of these blocks during execution.

However, if you configure a block or model so that the block parameters appear in the generated code as tunable variables, the code generator represents the blocks in a different way. Block parameters are tunable if, for example:

- You set **Default parameter behavior** to `Tunable`. By default, numeric block parameters appear as tunable fields of a global parameter structure.
- You use a tunable parameter, such as a `Simulink.Parameter` object that uses a storage class other than `Auto`, as the value of one or more numeric block parameters. These block parameters are tunable regardless of the setting that you choose for **Default parameter behavior**.

If a block parameter is tunable, the generated code must compute the block outputs during execution. Therefore, the block code appears in the model `step` function. If the model uses multiple discrete rates, the block code appears in the output function for the fastest downstream rate that uses the block outputs.

Latches for Subsystem Blocks

When an Inport block is the signal source for a triggered or function-call subsystem, you can use latch options to preserve input values while the subsystem executes. The Inport block latch options include:

For	Use
Triggered subsystems	**Latch input by delaying outside signal**
Function-call subsystems	**Latch input for feedback signals of function-call subsystem outputs**

When you use **Latch input for feedback signals of function-call subsystem outputs** for a function-call subsystem, the code generator

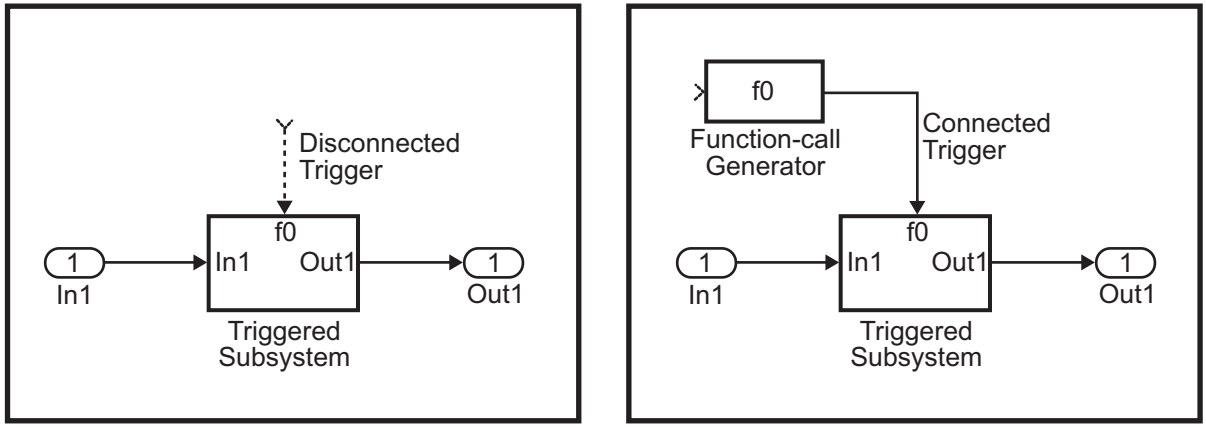
- Preserves latches in generated code regardless of optimizations that might be set
- Places the code for latches at the start of a subsystem's output/update function

For more information on these options, see the block description of Inport.

Block Execution Order

Once the Simulink engine compiles the block diagram, it creates a *`model`*`.rtw` file (analogous to an object file generated from a C or C++ file). The *`model`*`.rtw` file contains the connection information of the model, as well as the signal attributes. Thus, the timing engine in can determine when blocks with different rates should be executed.

You cannot override this execution order by directly calling a block (in handwritten code) in a model. For example, in the next figure the `disconnected_trigger` model on the left has its trigger port connected to ground, which can lead to the blocks inheriting a constant sample time. Calling the trigger function, `f()`, directly from user code does not work. Instead, you should use a function-call generator to specify the rate at which `f()` should be executed, as shown in the `connected_trigger` model on the right.



Instead of the function-call generator, you could use another block that can drive the trigger port. Then, you should call the model's main entry point to execute the trigger function.

For multirate models, a common use of the code generator is to generate code for individual models separately and then manually code the I/O between the generated code modules. This approach places the burden of data consistency between models on the developer of the models. Another approach is to let Simulink and the code generator maintain data consistency between rates and generate multirate code for use in a multitasking environment. The Rate Transition block is able to interface periodic and asynchronous signals. For a description of the Simulink Coder block libraries, see

"Asynchronous Events" (Simulink Coder). For more information on multirate code generation, see "Modeling for Multitasking Execution" (Simulink Coder).

Algebraic Loops

Algebraic loops are circular dependencies between variables. This prevents the straightforward direct computation of their values. For example, in the case of a system of equations

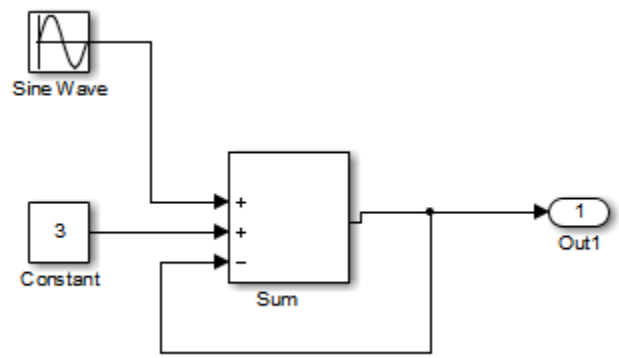
- `x = y + 2`
- `y = -x`

the values of `x` and `y` cannot be directly computed.

To solve this, either repeatedly try potential solutions for `x` and `y` (in an intelligent manner, for example, using gradient based search) or "solve" the system of equations. In the previous example, solving the system into an explicit form leads to

- `2x = 2`
- `y = -x`
- `x = 1`
- `y = -1`

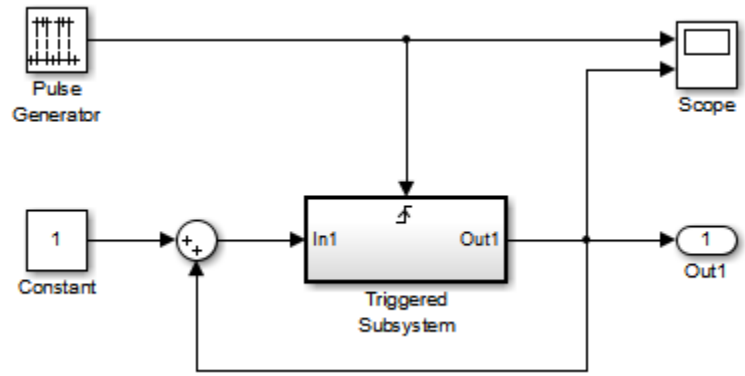
An algebraic loop exists whenever the output of a block having direct feedthrough (such as Gain, Sum, Product, and Transfer Fcn) is fed back as an input to the same block. The Simulink engine is often able to solve models that contain algebraic loops, such as the next diagram.



The code generator does not produce code that solves algebraic loops. This restriction includes models that use Algebraic Constraint blocks in feedback paths. However, the Simulink engine can often eliminate algebraic loops that arise, by grouping equations in certain ways in models that contain them. It does this by separating the update and output functions to avoid circular dependencies. For details, see “Algebraic Loop Concepts” (Simulink).

Algebraic Loops in Triggered Subsystems

While the Simulink engine can minimize algebraic loops involving atomic and enabled subsystems, a special consideration applies to some triggered subsystems. An example for which code can be generated is shown in the following model and triggered subsystem.



The default Simulink behavior is to combine output and update methods for the subsystem, which creates an apparent algebraic loop, even though the Unit Delay block in the subsystem has no direct feedthrough.

You can allow the Simulink engine to solve the problem by splitting the output and update methods of triggered and enabled-triggered subsystems when feasible. If you want the code generator to take advantage of this feature, select the **Minimize algebraic loop occurrences** check box in the Subsystem Parameters dialog box. Select this option to avoid algebraic loop warnings in triggered subsystems involved in loops.

Note If you check this box, the generated code for the subsystem might contain split output and update methods, even if the subsystem is not actually involved in a loop. Also, if a direct feedthrough block (such as a Gain block) is connected to the inport in the above

triggered subsystem, the Simulink engine cannot solve the problem, and the code generator is unable to generate code.

A similar **Minimize algebraic loop occurrences** option appears on the **Model Referencing** pane of the Configuration Parameters dialog box. Selecting it enables the Simulink Coder software to generate code for models containing Model blocks that are involved in algebraic loops.

Modeling Guidelines for Blocks

Code generation modeling guidelines include recommended model settings, block usage, and block parameters. When you develop models for code generation, use these guidelines.

Code Generation Modeling Guidelines	“cgsl_0101: Zero-based indexing” (Simulink) “cgsl_0102: Evenly spaced breakpoints in lookup tables” (Simulink) “cgsl_0103: Precalculated signals and parameters” (Simulink) “cgsl_0104: Modeling global shared memory using data stores” (Simulink) “cgsl_0105: Modeling local shared memory using data stores” (Simulink) “cgsl_0201: Redundant Unit Delay and Memory blocks” (Simulink)

Subsystems in Simulink Coder

Control Generation of Functions for Subsystems

What is a Subsystem Function?

A subsystem function is a function that the code generator produces for a subsystem in a model. The function interface and how the code generator packages the code depends on whether the subsystem is a virtual or atomic (nonvirtual) subsystem and how you configure the subsystem block parameters. For more information, see Subsystem, Atomic Subsystem, CodeReuse Subsystem.

Options for Controlling Generation of Subsystem Function Code

You can design and configure a model in a way that controls how the code generator produces code from subsystems.

To	See
Generate inlined code from a selected subsystem.	“Inline Subsystem Code” on page 3-8
Generate code for only a subsystem.	“Generate Code and Executables for Individual Subsystems” on page 3-4
Generate separate functions without arguments, and optionally place the subsystem code in a separate file.	“Generate Subsystem Code as Separate Function and Files” on page 3-11
Generate a single reentrant function for a subsystem that is included in multiple places within a model.	“Generate Reentrant Code from Subsystems” on page 6-43
Generate a single reentrant function for a subsystem that is included in multiple places in a model reference hierarchy.	“Generate Reusable Code from Library Subsystems Shared Across Models” on page 6-51
Generate code for a reusable library subsystem that contains multiple function interfaces.	“Library-Based Code Generation for Reusable Library Subsystems” on page 7-2

Subsystem Function Dependence

Code generated from subsystems can be completely independent of code generated for a model. When generating code for a subsystem, the code can reference global data structures of the model, even if the subsystem function code is in a separate file. Each subsystem code file contains `include` directives and comments describing the dependencies. The code generator checks for cyclic file dependencies and warns about them at build time. For descriptions of how the code generator packages code, see "Manage Build Process File Dependencies" (Simulink Coder).

To generate subsystem function code that is independent of the code generated for the parent model, place the subsystem in a library and configure it as a reusable subsystem, as explained in "Generate Reusable Code from Library Subsystems Shared Across Models" on page 6-51.

If you have an Embedded Coder license, you can generate code for library consisting of reusable subsystems that have different function interfaces. For more information, see "Library-Based Code Generation for Reusable Library Subsystems" on page 7-2.

Generate Code and Executables for Individual Subsystems

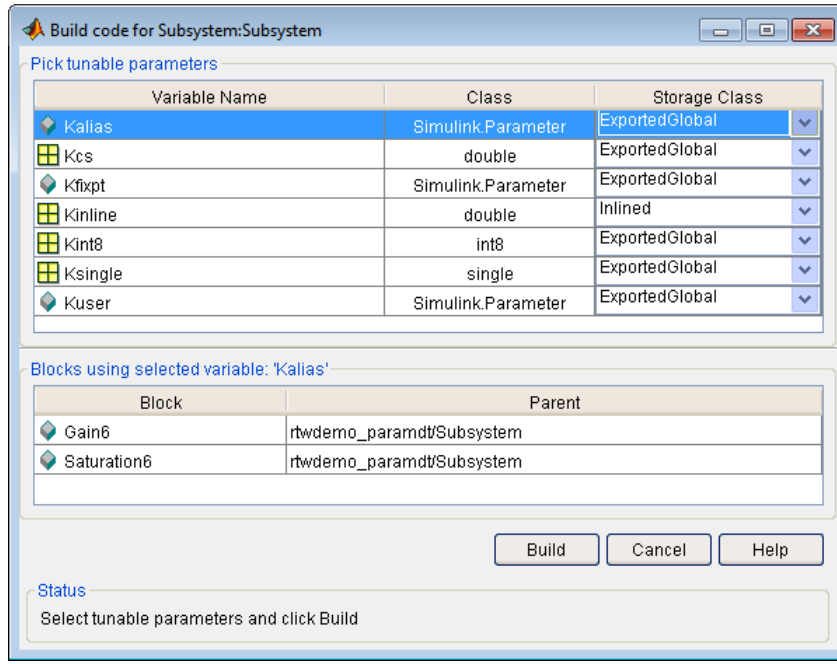
You can generate code and build an executable for a subsystem within a model. The code generation and build process uses the code generation and build parameters of the root model.

1. In the Configuration Parameters dialog box, set up the code generation and build parameters, similar to setting up the code generation for a model.
2. Right-click the Subsystem block. From the context menu, select **C/C++ Code > Build This Subsystem** from the context menu.

   Alternatively, in the current model, click a subsystem and then from the **Code** menu, select **C/C++ Code > Build Selected Subsystem**.

   Note When you select **Build This Subsystem**, if the model is operating in external mode, the build process automatically turns off external mode for the duration of the build. The code generator restores external mode upon completion of the build process.
3. The **Build code for Subsystem** window displays a list of the subsystem parameters. The upper pane displays the name, class, and storage class of each variable (or data object) that is referenced as a block parameter in the subsystem. When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter and the parent system of each block.

   The **Storage Class** column contains a menu for each row. The menu options set the storage class or inline the parameter. To declare a parameter to be tunable, set the **Storage Class** to a value other than **Inlined**.



For more information on tunable and inlined parameters and storage classes, see “Create Tunable Calibration Parameter in the Generated Code” on page 32-121.

4. After selecting tunable parameters, **Build** to initiate the code generation and build process.

5. The build process displays status messages in the MATLAB Command Window. When the build is complete, the generated executable is in your working folder. The name of the generated executable is *`subsystem`*`.exe` (on PC platforms) or *`subsystem`* (on The Open Group UNIX® platforms). *`subsystem`* is the name of the source subsystem block.

   The generated code is in a build subfolder, named *`subsystem_target`*`_rtw`. *`subsystem`* is the name of the source subsystem block and *`target`* is the name of the target configuration.

When you generate code for a subsystem, you can generate an S-function by selecting **Code > C/C++ Code> Generate S-Function**, or you right-click the subsystem block and select **C/C++ Code > Build This Subsystem** from the context menu. For more information on S-functions, see “Generate S-Function from Subsystem” (Simulink Coder).

Subsystem Build Limitations

The following limitations apply to building subsystems:

- Subsystem build does not support a subsystem that has a function-call trigger input or a function-call output.
- When you right-click a subsystem block and select **C/C++ Code > Build This Subsystem** from the context menu to build a subsystem that includes an Outport block for which the **Data type** parameter specifies a bus object, you must address errors that result from setting signal labels. To configure the software to display these errors, in the Configuration Parameters dialog box for the parent model, on the **Diagnostics > Connectivity** pane, set the **Signal label mismatch** parameter to `error`.
- When a subsystem is in a triggered or function-call subsystem, the right-click build process might fail if the subsystem code is not sample-time independent. To find out whether a subsystem is sample-time independent:

  1. Copy all blocks in the subsystem to an empty model.
  2. In the Configuration Parameters dialog box, on the **Solver** pane, set:
     a. **Type** to `Fixed-step`.
     b. **Periodic sample time constraint** to `Ensure sample time independent`.
     c. Click **Apply**.
  3. Update the model. If the model is sample-time dependent, Simulink generates an error in the process of updating the diagram.

- When you use the right-click build process for a subsystem, the code generator attempts to use the subsystem name for generated code files. In some cases, there can be a conflict with the name that you specify when you set, for example, **File name options** to `Use function name` or **Function name options** to `Use subsystem name`. You see an error:

  ```
  The subsystem 'model/subsys'
  is trying to generate code to an reserved file (subsys) for
  the model 'subsys'...
  ```

  To resolve the error, modify one of the conflicting file names so that the names are unique.

- In a subsystem build warning, the subsystem block path hyperlink that is created references a temporary model block path instead of the actual model block path. In the Diagnostic Viewer, clicking the subsystem hyperlink does not take you to the block. In the Command Window, you see a message:

  ```
  ...
  No system or file called 'subsystemName' found.
  ...
  ```

Inline Subsystem Code

You can configure a nonvirtual subsystem to inline the subsystem code with the model code. In the Subsystem Parameters dialog box, setting the **Function packaging** parameter to `Auto` or `Inline` inlines the generated code of the subsystem.

The `Auto` option is the default. When there is only one instance of a subsystem in the model, the `Auto` option inlines the subsystem code. When multiple instances of a subsystem exist, the `Auto` option results in a single copy of the function (as a reusable function). For function-call subsystems with multiple callers, the subsystem code is generated as if you specified `Nonreusable function`.

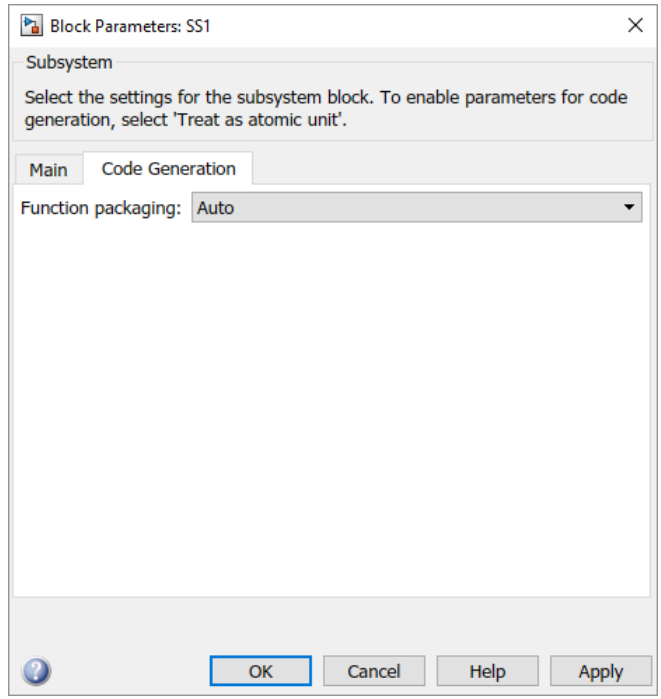
To inline subsystem code, select `Inline`. The `Inline` option explicitly directs the code generator to inline the subsystem unconditionally.

Configure Subsystem to Inline Code

To configure your subsystem for inlining:

1. Right-click the Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. This option makes the subsystem nonvirtual. On the **Code Generation** tab, the **Function packaging** option is now available.

   If the system is already nonvirtual, the **Function packaging** option is already selected.
3. Click the **Code Generation** tab and select `Auto` or `Inline` from the **Function packaging** parameter.



4 Click **Apply** and close the dialog box.

The border of the subsystem thickens, indicating that it is nonvirtual.

When you generate code from your model, the code generator inlines subsystem code within *`model`*`.c` or *`model`*`.cpp` (or in its parent system's source file). You can identify this code by system/block identification tags, such as:

```
/* Atomic SubSystem Block: <Root>/AtomicSubsys1 */
```

Exceptions to Inlining

There are certain cases in which the code generator does not inline a nonvirtual subsystem, even though the **Inline** option is selected.

- If the subsystem is a function-call subsystem that is called by a noninlined S-function, the **Inline** option is ignored. Noninlined S-functions make calls by using function pointers. Therefore, the function-call subsystem must generate a function with all arguments present.

- In a feedback loop involving function-call subsystems, the code generator forces one of the subsystems to be generated as a function instead of inlining it. Based on the order in which the subsystems are sorted internally, the software selects the subsystem to be generated as a function.
- If a subsystem is called from an S-function block that sets the option `SS_OPTION_FORCE_NONINLINED_FCNCALL` to `TRUE`, it is not inlined. When user-defined Async Interrupt blocks or Task Sync blocks are present, this result might occur. Such blocks must be generated as functions. These blocks are located in the `vxlib1` block library and use the `SS_OPTION_FORCE_NONINLINED_FCNCALL` option. This library demonstrates integration with an example RTOS (VxWorks®).[1]

Note You can use the blocks in the `vxlib1` (Simulink Coder) library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for your target environment.

1. VxWorks is a registered trademark of Wind River® Systems, Inc.

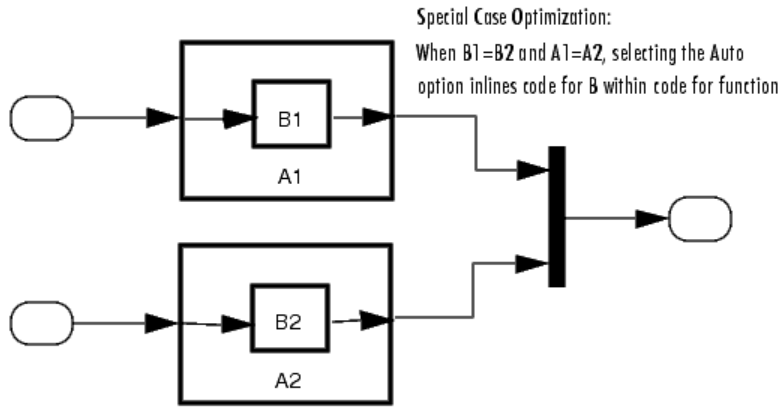
Generate Subsystem Code as Separate Function and Files

To generate a separate subsystem function and a separate file for a subsystem in a model:

1. Right-click a Subsystem block. From the context menu, select **Block Parameters (Subsystem)**.
2. In the Subsystem Parameters dialog box, if the subsystem is virtual, select **Treat as atomic unit**. On the **Code Generation** tab, the **Function packaging** parameter is now available.
3. Click the **Code Generation** tab and select `Nonreusable function` from the **Function packaging** parameter. The `Nonreusable function` option enables two parameters:
   - The “Function name options” (Simulink) parameter controls the naming of the generated function.
   - The “File name options” (Simulink) parameter controls the naming of the generated file.
4. Set the **Function name options** parameter.
5. Set the **File name options** parameter to a value other than `Auto`. If you are generating a reusable function for your subsystem, see “Generate Reentrant Code from Subsystems” on page 6-43 or “Generate Reusable Code from Library Subsystems Shared Across Models” on page 6-51.
6. Click **Apply** and close the dialog box.

Optimize Code for Identical Nested Subsystems

The **Function packaging** parameter `Auto` option can optimize code in situations in which identical subsystems contain other identical subsystems, by both reusing and inlining generated code. Suppose a model, such as the one shown in “Reuse of Identical Nested Subsystems” on page 3-12, contains identical subsystems `A1` and `A2`. `A1` contains subsystem `B1`, and `A2` contains subsystem `B2`, which are identical. In such cases, the `Auto` option causes one function to be generated which is called for both `A1` and `A2`. This function contains one piece of inlined code to execute `B1` and `B2`. This optimization generates less code which improves execution speed.



Reuse of Identical Nested Subsystems

Code Generation of Constant Parameters

The code generator attempts to generate constant parameters to the shared utilities folder first. If constant parameters are not generated to the shared utilities folder, they are defined in the top model in a global constant parameter structure. The declaration of the structure, `ConstParam_`*`model`*, is in *`model`*`.h`:

```
/* Constant parameters (auto storage) */
typedef struct {
   /* Expression: [1 2 3 4 5 6 7]
    * Referenced by: '<Root>/Constant'
    */
   real_T Constant_Value[7];

   /* Expression: [7 6 5 4 3 2 1]
    * Referenced by: '<Root>/Gain'
    */
   real_T Gain_Gain[7];
 } ConstParam_model;
```

The definition of the constant parameters, *`model`*`_constP`, is in:

```
/* Constant parameters (auto storage) */
const ConstParam_model model_ConstP = {
   /* Expression: [1 2 3 4 5 6 7]
    * Referenced by: '<Root>/Constant'
    */
   { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 },

   /* Expression: [7 6 5 4 3 2 1]
    * Referenced by: '<Root>/Gain'
    */
   { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 }
};
```

The *`model`*`_constP` is passed as an argument to referenced models.

Referenced Models in Simulink Coder

Code Generation of Referenced Models

This section describes model referencing considerations that apply specifically to code generation by the Simulink Coder. This section assumes that you understand referenced models and related terminology and requirements, as described in “Model Reference Basics” (Simulink) and associated topics.

When generating code for a referenced model hierarchy, the code generator produces a stand-alone executable for the top model, and a library module called a model reference target for each referenced model. When the code executes, the top executable invokes the model reference targets to compute the referenced model outputs. Model reference targets are sometimes called *Simulink Coder targets*.

Be careful not to confuse a model reference target (Simulink Coder target) with other types of targets:

- Target hardware — A platform for which the Simulink Coder software generates code
- System target — A file that tells the Simulink Coder software how to generate code for particular purpose
- Rapid Simulation target (RSim) — A system target file supplied with the Simulink Coder product
- Simulation target — A MEX-file that implements a referenced model that executes with Simulink Accelerator™ software

The code generator places the code for the top model of a hierarchy in the code generation folder (Simulink) and places the code for referenced models in an `slprj` folder in the code generation folder (Simulink). Subfolders in `slprj` provide separate places for different types of files. For folder information, see “Manage Build Process Folders” (Simulink Coder).

By default, the product uses *incremental code generation*. When generating code, it compares structural checksums of referenced model files with the generated code files to determine whether to regenerate model reference targets. To control when rebuilds occur, use the configuration parameter **Model Referencing > Rebuild**. For details, see “Rebuild” (Simulink).

In addition to incremental code generation, the Simulink Coder software uses *incremental loading*. The code for a referenced model is not loaded into memory until the code for its parent model executes and needs the outputs of the referenced model. The product then

loads the referenced model target and executes. Once loaded, the target remains in memory until it is no longer used.

Most code generation considerations are the same whether or not a model includes referenced models: the code generator handles the details automatically insofar as possible. This chapter describes topics that you may need to consider when generating code for a model reference hierarchy.

If you have a Embedded Coder license, custom targets must declare themselves to be model reference compliant if they need to support Model blocks. For more information, see “Support Model Referencing” on page 85-82.

Generate Code for Referenced Models

In this section...

About Generating Code for Referenced Models

To generate code for referenced models, you

1. Create a subsystem in an existing model.
2. Convert the subsystem to a referenced model (Model block).
3. Call the referenced model from the top model.
4. Generate code for the top model and referenced model.
5. Explore the generated code and the code generation folder.

You can accomplish some of these tasks automatically with a function called `Simulink.Subsystem.convertToModelReference`.

Create and Configure the Subsystem

In the first part of this example, you define a subsystem for the `vdp` example model, set configuration parameters for the model, and use the `Simulink.Subsystem.convertToModelReference` function to convert it into two new models — the top model (`vdptop`) and a referenced model `vdpmultRM` containing a subsystem you created (`vdpmult`).

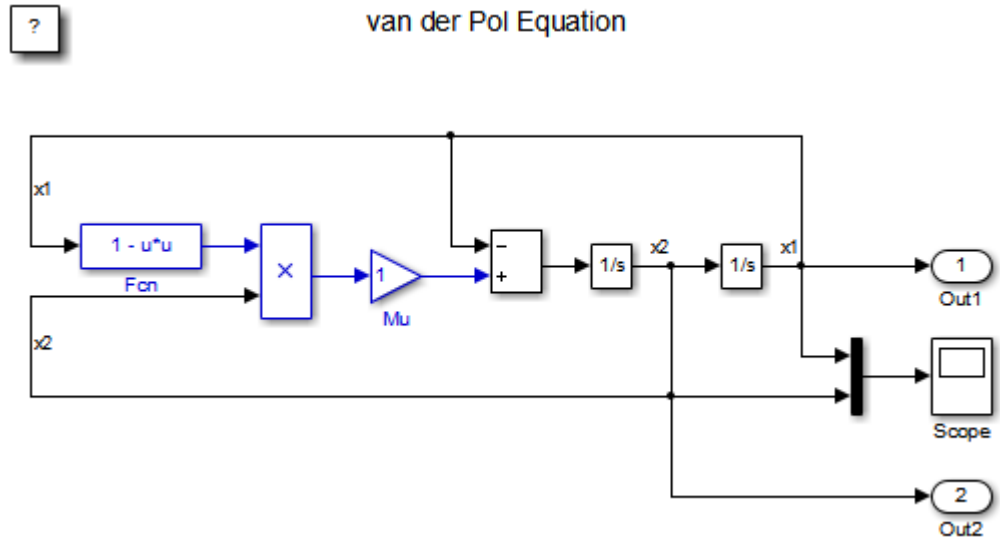
1. In the MATLAB Command Window, create a new working folder wherever you want to work and `cd` into it:

   ```
   mkdir mrexample
   cd mrexample
   ```

2. Open the `vdp` example model by typing:

`vdp`

3 Drag a box around the three blocks outlined in blue below:



4 Choose **Create Subsystem from Selection** from the **Diagram > Subsystem & Model Reference** menu.

A subsystem block replaces the selected blocks.

5 If the new subsystem block is not where you want it, move it to a preferred location.

6 Rename the block `vdpmult`.

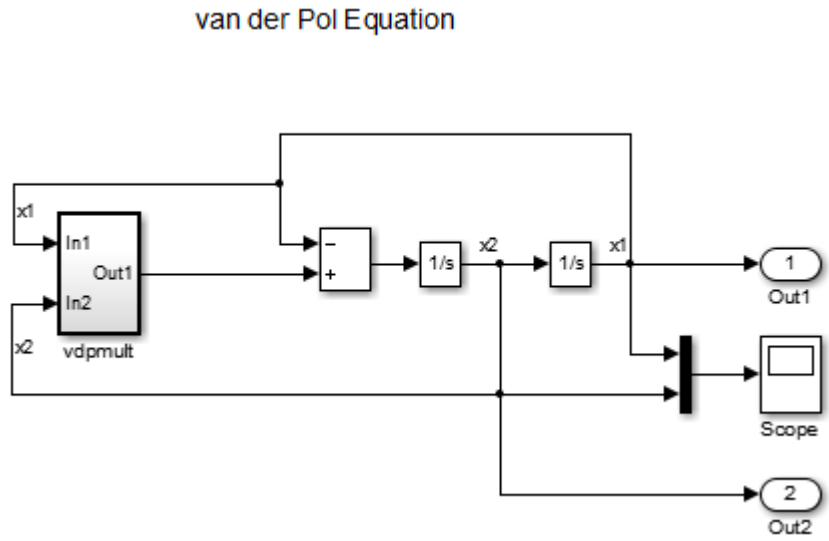
7 Right-click the `vdpmult` block and select **Block Parameters (Subsystem)**.

The **Function Block Parameters** dialog box appears.

8 In the **Function Block Parameters** dialog box, select **Treat as atomic unit**, then click **OK**.

The border of the `vdpmult` subsystem thickens to indicate that it is now atomic. An atomic subsystem executes as a unit relative to the parent model: subsystem block execution does not interleave with parent block execution. This property makes it possible to extract subsystems for use as stand-alone models and as functions in generated code.

The block diagram appears.



You must set several properties before you can extract a subsystem for use as a referenced model. To set the properties:

1. Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
2. In the **Model Hierarchy** pane, expand the model to reveal its components.
3. Select the Configurations node.
4. In the **Contents** pane, right-click **Configuration (Active)** and click **Open** in the context menu to open the Configuration Parameters dialog box.
5. In the left pane of the Configuration Parameters dialog box, select **Solver**.
6. Change the **Type** to `Fixed-step`, then click **Apply**. You must use fixed-step solvers when generating code, although referenced models can use different solvers than top models.
7. In the left pane, click the symbol preceding **Diagnostics**. In the left pane below **Diagnostics**, select **Data Validity**. In the **Signals** area, set **Signal resolution** to `Explicit only`. Alternatively, if you do not want to use `Simulink.Signal` objects, set **Signal resolution** to `None`.
8. Click **Apply**.

   The model now has the properties that model referencing requires.

9 In the left pane, click **Model Referencing**. In the **Options for all referenced models** section, set **Rebuild** to `If any changes in known dependencies detected`. Click **OK**. This setting prevents code regeneration when it is not required.

10 In the `vdp` model window, choose **File** > **Save as**. Save the model as `vdptop` in your working folder. Leave the model open.

Convert Model to Use Model Referencing

In this portion of the example, you use the conversion function `Simulink.SubSystem.convertToModelReference` to extract the subsystem `vdpmult` from `vdptop` and convert `vdpmult` into a referenced model named `vdpmultRM`. To see the complete syntax of the conversion function, type at the MATLAB prompt:

```
help Simulink.SubSystem.convertToModelReference
```

For additional information, type:

```
doc Simulink.SubSystem.convertToModelReference
```

If you want to see an example of `Simulink.SubSystem.convertToModelReference` before using it yourself, type:

```
sldemo_mdlref_conversion
```

Simulink also provides a menu command, **Subsystem & Model Reference** > **Convert Subsystem to** > **Referenced Model**, that you can use to convert a subsystem to a referenced model. The command calls `Simulink.SubSystem.convertToModelReference` with default arguments. For more information, see “Convert Subsystems to Referenced Models” (Simulink).

Extract the Subsystem to a Referenced Model

To use `Simulink.SubSystem.convertToModelReference` to extract `vdpmult` and convert it to a referenced model, type:

```
Simulink.SubSystem.convertToModelReference...
('vdptop/vdpmult', 'vdpmultRM',...
'ReplaceSubsystem', true, 'BuildTarget', 'Sim')
```

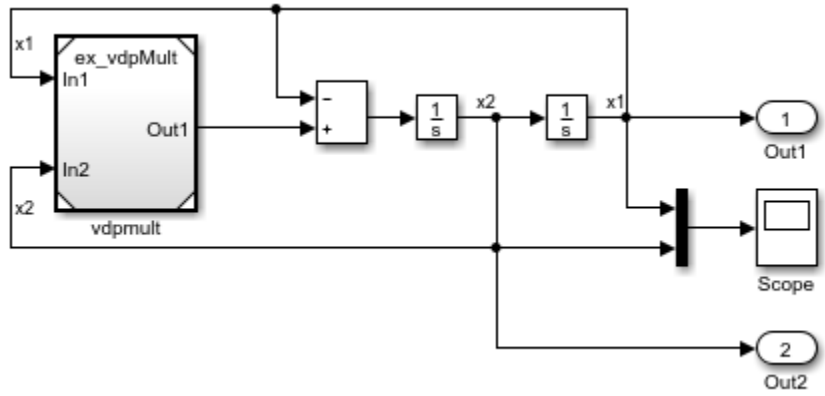
This command:

1. Extracts the subsystem `vdpmult` from `vdptop`.
2. Converts the extracted subsystem to a separate model named `vdpmultRM` and saves the model to the working folder.
3. In `vdptop`, replaces the extracted subsystem with a Model block that references `vdpmultRM`.
4. Creates a simulation target for `vdptop` and `vdpmultRM`.

The converter prints progress messages and terminates with

```
ans =
     1
```

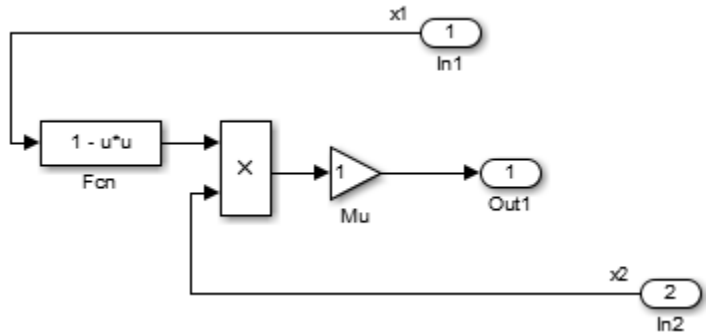
The parent model `vdptop` now looks like this:



Note the changes in the appearance of the block `vdpmult`. These changes indicate that it is now a Model block rather than a subsystem. As a Model block, it does not have contents of its own: the previous contents now exist in the referenced model `vdpmultRM`, whose name appears at the top of the Model block. Widen the Model block to expose the complete name of the referenced model.

If the parent model `vdptop` had been closed at the time of conversion, the converter would have opened it. Extracting a subsystem to a referenced model does *not* automatically create or change a saved copy of the parent model. To preserve the changes to the parent model, save `vdptop`.

Right-click the Model block `vdpmultRM` and choose **Open** to open the referenced model. The model looks like this:



Files Created and Changed by the Converter

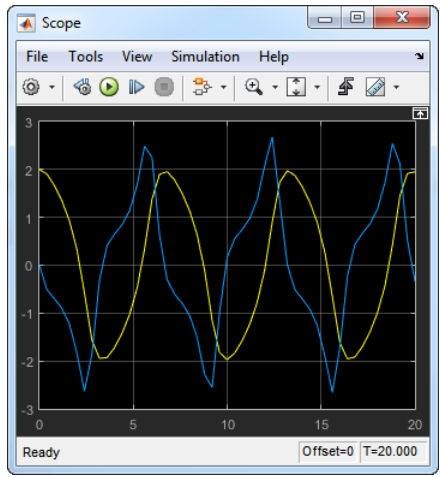
The files in your working folder now consist of the following (not in this order).

File	Description
`vdptop` model file	Top model that contains a Model block where the `vdpmult` subsystem was
`vdpmultRM` model file	Referenced model created for the `vdpmult` subsystem
`vdpmultRM_msf.mexw64`	Static library file (Microsoft® Windows platforms only). The file extension is system-dependent and may differ. This file executes when the `vdptop` model calls the Model block `vdpmult`. When called, `vdpmult` in turn calls the referenced model `vdpmultRM`.
`/slprj`	Folder for generated model reference code

Code for model reference simulation targets is placed in the `slprj/sim` subfolder. Generated code for GRT, ERT, and other Simulink Coder targets is placed in `slprj` subfolders named for those targets. You will inspect some model reference code later in this example. For more information on code generation folders, see “Work with Code Generation Folders” on page 4-12.

Run the Converted Model

Open the Scope block in `vdptop` if it is not visible. In the `vdptop` window, click the **Run** tool or choose **Run** from the **Simulation** menu. The model calls the `vdpmultRM_msf` simulation target to simulate. The output looks like this:



Generate Model Reference Code for a GRT Target

The function `Simulink.SubSystem.convertToModelReference` created the model and the simulation target files for the referenced model `vdpmultRM`. In this part of the example, you generate code for that model and the `vdptop` model, and run the executable you create:

1. Verify that you are still working in the `mrexample` folder.
2. If the model `vdptop` is not open, open it. Make sure it is the active window.
3. Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
4. In the **Model Hierarchy** pane, click the symbol preceding the `vdptop` model to reveal its components.
5. Select the Configurations node below the model node.
6. In the **Contents** pane, right-click **Configuration (Active)** and click **Open** in the context menu to open the Configuration Parameters dialog box.
7. In the left pane, select **Data Import/Export**.

8. In the **Save to workspace or file** section, select **Time** and **Output** and *clear* **Data stores**. Click **Apply**.

   These settings instruct the model `vdptop` (and later its executable) to log time and output data to MAT-files for each time step.

9. Generate GRT code (the default) and an executable for the top model and the referenced model. For example, in the model, press **Ctrl+B**.

The Simulink Coder build process generates and compiles code. The current folder now contains a new file and a new folder.

File	Description
`vdptop.exe`	The executable created by the build process
`vdptop_grt_rtw/`	The build folder, containing generated code for the top model

The build process also generated GRT code for the referenced model and placed it in the `slprj` folder.

To view a model's generated code in the **Model Explorer**, the model must be open. To use the **Model Explorer** to inspect the newly created build folder, `vdptop_grt_rtw`:

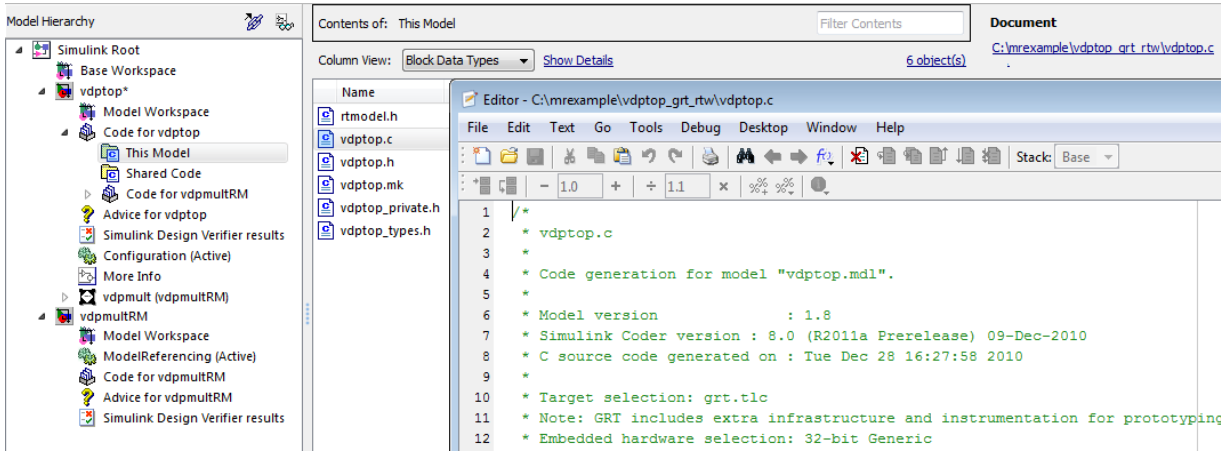
1. Open Model Explorer by selecting **Model Explorer** from the model's **View** menu.
2. In the **Model Hierarchy** pane, expand the model name to reveal its components.
3. Expand `Code for vdptop` to reveal its components.
4. Click `This Model`.

   A list of generated code files for `vdptop` appears in the **Contents** pane:

   ```
   rtmodel.h
   vdptop.c
   vdptop.h
   vdptop.mk
   vdptop_private.h
   vdptop_types.h
   ```

   You can browse code by selecting a file of interest in the **Contents** pane.

   To open a file in a text editor, click a filename, and then click the hyperlink that appears in the gray area at the top of the **Document** pane. This figure shows viewing code for `vdptop.c` in a text editor. Your code may differ.



To view the generated code in the HTML code generation report, see “Generate a Code Generation Report” (Simulink Coder).

Work with Code Generation Folders

Model reference code is generated in your code generation folder (Simulink) and simulation target code is generated in your simulation cache folder (Simulink). Because of this process, there are constraints on:

- When and where model reference targets are built.
- How the model reference targets are accessed.

The models referenced by Model blocks can be stored anywhere on the MATLAB path. A given top model can include models stored on different file systems or in different folders. The same is not true for the simulation targets and generated code derived from these models. Under most circumstances, to allow code reuse, models referenced by a given top model must be set up to simulate and generate model reference target code in a single code generation folder.

This means that, if you reference the same model from several top models, each stored in a different folder, you must choose one of these approaches:

- Always work with the same code generation folder and be sure that the models are on your path.

- Allow separate code generation folders, simulation targets, and Simulink Coder targets to be generated in each folder in which you work.

The second approach requires maintenance of several instances of the model reference code and it is possible for generated code to become redundant. For example, when you make changes to the referenced model. Therefore, to minimize code regeneration of referenced models, choose a specific code generation folder for all sessions.

Configure Referenced Models

Minimize occurrences of algebraic loops by selecting the **Minimize algebraic loop occurrences** parameter on the **Model Reference** pane. The setting of this option affects only generation of code from the model. For information on how this option affects code generation, see “Configure Run-Time Environment Options” (Simulink Coder). For more information about direct feed through, see “Algebraic Loop Concepts” (Simulink).

Use the **Integer rounding mode** parameter on your model's blocks to simulate the rounding behavior of the C compiler that you intend to use to compile code generated from the model. This setting appears on the **Signal Attributes** pane of the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product and n-D Lookup Table blocks.

For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the Simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see “Precision” (Fixed-Point Designer).

When models contain Model blocks, models that they reference must be configured to use identical hardware settings. For information on the **Model Referencing** pane options, see “Model Configuration Parameters: Model Referencing” (Simulink) and “Set Configuration Parameters for Model Referencing” (Simulink).

Note There are some configuration parameter setting limitations for code generation. See “Code Generation Model Referencing Limitations” (Simulink Coder).

Build Model Reference Targets

By default, the Simulink engine rebuilds simulation targets before the Simulink Coder software generates model reference targets. You can change the rebuild criteria or specify when the engine rebuilds targets. For more information, see “Rebuild” (Simulink).

The Simulink Coder software generates a model reference target directly from the Simulink model. The product automatically generates or regenerates model reference targets, for example, when they require an update.

You can command the Simulink and Simulink Coder products to generate a simulation target for an Accelerator mode referenced model, and a model reference target for a referenced model, by executing the `slbuild` command with arguments in the MATLAB Command Window.

The code generator produces only one model reference target for the instances of a referenced model. See “Generate Reentrant Code from Subsystems” (Simulink Coder) for details.

Reduce Change Checking Time

You can reduce the time that the Simulink and Simulink Coder products spend checking whether simulation targets and model reference targets need to be rebuilt by setting configuration parameter values as follows:

- In the top model, consider setting the model configuration parameter **Model Referencing** > **Rebuild** to `If any changes in known dependencies detected`. (See “Rebuild” (Simulink).)
- In the referenced models throughout the hierarchy, set the configuration parameter **Diagnostics** > **Data Validity** > **Signal resolution** to `Explicit only` or `None`. (See “Signal resolution” (Simulink).)

These parameter values exist in a referenced model's configuration set, not in the individual Model block. Setting either value for an instance of a referenced model, sets it for the instances of that model.

Simulink Coder Model Referencing Requirements

A model reference hierarchy must satisfy various Simulink Coder requirements, as described in this section. In addition to these requirements, a model referencing hierarchy to be processed by the Simulink Coder software must satisfy:

- The Simulink requirements listed in:
  - “Configuration Requirements for All Referenced Model Simulation” (Simulink)
  - “Model Reference Interface” (Simulink)
- The Simulink limitations listed in “Signal Requirements and Limitations” (Simulink)
- The Simulink Coder limitations listed in “Code Generation Model Referencing Limitations” on page 4-28

Configuration Parameter Requirements

A referenced model uses a configuration set in the same way a top model does, as described in “Manage a Configuration Set” (Simulink). By default, every model in a hierarchy has its own configuration set, which it uses in the same way that it would if the model executed independently.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model referencing. The response of the Simulink Coder software to an inconsistent or unusable configuration parameter depends on the parameter:

- Where an inconsistency has no significance, the product ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists, the product resolves the conflict silently; resolves it with a warning; or generates an error.
- If an acceptable resolution is not possible, the product generates an error. You must then change parameter values to eliminate the problem.

When a model reference hierarchy contains many referenced models that have incompatible parameter values, or a changed parameter value must propagate to many referenced models, manually eliminating configuration parameter incompatibilities can be tedious. You can control or eliminate such overhead by using configuration references to assign an externally-stored configuration set to multiple models. See “Manage a Configuration Reference” (Simulink) for details.

The following tables list configuration parameters that can cause problems if set in certain ways, or if set differently in a referenced model than in a parent model. Where possible, the Simulink Coder software resolves violations of these requirements automatically, but most cases require changes to parameters in your models.

Configuration Requirements for Model Referencing with All System Target Files

Dialog Box Pane	Option	Requirement
Solver	**Start time**	Some system target files require the start time of models to be zero.
Hardware Implementation	All options	Values must be the same for top and referenced models.
Code Generation	**System target file**	Must be the same for top and referenced models.
	Language	Must be the same for top and referenced models.
	Generate code only	Must be the same for top and referenced models.
Symbols	**Maximum identifier length**	Cannot be longer for a referenced model than for its parent model.
Interface	**Code replacement library**	Must be the same for top and referenced models.
	C API options	The C API check boxes must be the same for top and referenced models.
	ASAP2 interface	Can be `on` or `off` in a top model, but must be `off` in a referenced model. If it is not, the Simulink Coder software temporarily sets it to `off` during code generation.

Configuration Requirements for Model Referencing with ERT System Target Files (Requires Embedded Coder License)

Dialog Box Pane	Option	Requirement
Comments > Advanced parameters	**Ignore custom storage classes**	Must be the same for top and referenced models.
Symbols	**Global variables** **Global types** **Subsystem methods** **Local temporary variables** **Constant macros**	$R token must appear.
	Signal naming	Must be the same for top and referenced models.
	M-function	If specified, must be the same for top and referenced models.
	Parameter naming	Must be the same for top and referenced models.
	#define naming	Must be the same for top and referenced models.
Interface	**Support floating-point numbers**	Must be the same for both top and referenced models
	Support non-finite numbers	If `off` for top model, must be `off` for referenced models.
	Support complex numbers	If `off` for top model, must be `off` for referenced models.
	Suppress error status in real-time model	If `on` for top model, must be `on` for referenced models.
Code Placement	**Use owner from data object for data definition placement**	Must be the same for top and referenced models.

Dialog Box Pane	Option	Requirement
	Signal display level	Must be the same for top and referenced models.
	Parameter tune level	Must be the same for top and referenced models.

Configuration Parameters Changed During Code Generation

For referenced models, if these **Configuration Parameters > Code Generation > Symbols** parameters have settings that do not contain a $R token (which represents the name of the reference model), code generation prepends the $R token to the identifier format:

- **Global variables** (`CustomSymbolStrGlobalVar`)
- **Global types** (`CustomSymbolStrType`)
- **Subsystem methods** (`CustomSymbolStrFcn`)
- **Constant macros** (`CustomSymbolStrMacro`)

You can use the Model Advisor to identify models in a model referencing hierarchy for which code generation changes configuration parameter settings.

1. In the Simulink Editor, select **Analysis > Model Advisor**.
2. Select **By Task**.
3. Run the **Check code generation identifier formats used for model reference** check.

If a script that operates on generated code uses identifier formats that code generation changes, then update the script to use the updated identifier format (which includes an appended $R token).

For more information about identifiers, see “Identifier Format Control” on page 50-24.

Naming Requirements

Within a model that uses model referencing, names of the constituent models cannot collide. When you generate code from a model that uses model referencing, the **Maximum identifier length** parameter must be large enough to accommodate the root

model name and the name-mangling text. A code generation error occurs if **Maximum identifier length** is not large enough.

When a name conflict occurs between a symbol within the scope of a higher-level model and a symbol within the scope of a referenced model, the symbol from the referenced model is preserved. Name mangling is performed on the symbol from the higher-level model.

Embedded Coder Naming Requirements

The Embedded Coder product lets you control the formatting of generated symbols in much greater detail. When generating code with an ERT target from a model that uses model referencing:

- The `$R` token must be included in the **Identifier format control** parameter specifications (in addition to the `$M` token) except for **Shared utilities identifier format**.
- The **Maximum identifier length** must be large enough to accommodate full expansions of the `$R` and `$M` tokens.

See “Model Configuration Parameters: Code Generation Symbols” (Simulink Coder) for more information.

Custom Target Requirements

If you have an Embedded Coder license, a custom target must meet various requirements to support model referencing. For details, see “Support Model Referencing” on page 85-82.

Storage Classes for Signals Used with Model Blocks

Models containing Model blocks can use signals of storage class `Auto` without restriction. However, when you declare signals to be global, you must be aware of how the signal data will be handled.

A global signal is a signal with a storage class other than `Auto`:

- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`
- `Custom`

The above are distinct from signals that use the storage class `Model default` when you set the default storage class of the corresponding data category to `Default` in the Code Mapping Editor, which are treated as test points with `Auto` storage class.

Global signals are declared, defined, and used as follows:

- An `extern` declaration is generated for models that use a given global signal.

  As a result, if a signal crosses a Model block boundary, the top model and the referenced model both generate `extern` declarations for the signal.
- For an exported signal, the top model is responsible for defining (allocating memory for) the signal, whether or not the top model itself uses the signal.
- Global signals used by a referenced model are accessed directly (as global memory). They are not passed as arguments to the functions that are generated for the referenced models.

Custom storage classes also follow the above rules. However, certain custom storage classes are not currently supported for use with model reference. For details, see “Storage Class Limitations” (Simulink Coder).

Storage Classes for Parameters Used with Model Blocks

Storage classes are supported for simulation and code generation. Storage classes, with the exception of `Auto`, are tunable. The supported storage classes thus include

- `Model default`

- `ExportedGlobal`
- `ImportedExtern`
- `ImportedExternPointer`
- `Custom`

Note the following restrictions on parameters in referenced models:

- Tunable parameters are not supported for noninlined S-functions.
- Tunable parameters set using the Model Parameter Configuration dialog box are ignored.

Note the following considerations concerning how global tunable parameters are declared, defined, and used in code generated for targets:

- A global tunable parameter is a parameter in the base workspace with a storage class other than `Auto`.
- An `extern` declaration is generated by for models that use a given parameter.
- If a parameter is exported, the top model is responsible for defining (allocating memory for) the parameter (whether it uses the parameter or not).
- Global parameters are accessed directly (as global memory). They are not passed as arguments to the functions that are generated for the referenced models.
- In a referenced model that sets the default storage class for a category of parameter data to `Default` in the Code Mapping Editor, symbols for `Model default` parameters are generated using unstructured variables (`rtP_xxx`) instead of being written into the *`model`*`_P` structure. This is so that each referenced model can be compiled independently.

Certain custom storage classes for parameters are not currently supported for model reference. For details, see “Storage Class Limitations” (Simulink Coder).

Parameters used as Model block arguments must be defined in the referenced model's workspace. For details, see “Parameterize Instances of a Reusable Referenced Model” (Simulink).

Signal Name Mismatches Across Model Reference Boundary

Within a parent model, the name and storage class for a signal entering or leaving a Model block might not match those of the signal attached to the root inport or outport

within that referenced model. Because referenced models are compiled independently without regard to a parent model, they cannot adapt to the possible variations in how parent models label and store signals.

The code generator accepts cases where input and output signals in a referenced model have `Auto` storage class. When such signals are test pointed or are global, as described above, certain restrictions apply. The following table describes how mismatches in signal labels and storage classes between parent and referenced models are handled:

Relationships of Signals and Storage Classes Across Model Reference Boundary

Referenced Model	Parent Model	Signal Passing Method	Signal Mismatch Checking
`Auto`	Any storage class	Function argument	None
`Model default` (when Code Mapping Editor specifies `Default` storage class) or resolved to Signal Object	Any storage class	Function argument	**Signal label mismatch**
`Global`	Auto or `Model default` (when Code Mapping Editor specifies `Default` storage class)	Global variable	**Signal label mismatch**
`Global`	`Global`	Global variable	Labels and storage classes must be identical (else error)

To summarize, the following signal resolution rules apply to code generation:

- If the storage class of a root input or output signal in a referenced model is `Auto` (or is `Model default` when you set the storage class of the corresponding data category to `Default` in the Code Mapping Editor), the signal is passed as a function argument.
  - When such a signal is `Model default` or resolves to a `Simulink.Signal` object, the **Signal label mismatch** diagnostic is applied.
- If a root input or output signal in a referenced model is global, it is communicated by using direct memory access (global variable). In addition,

- If the corresponding signal in the parent model is also global, the names and storage classes must match exactly.
- If the corresponding signal in the parent model is not global, the **Signal label mismatch** diagnostic is applied.

You can set the **Signal label mismatch** diagnostic to `error`, `warning`, or `none` in the **Diagnostics > Connectivity** pane of the Configuration Parameters dialog box.

Inherited Sample Time for Referenced Models

For information about Model block sample time inheritance, see “Referenced Model Sample Times” (Simulink). In generated code, you can control inheriting sample time by using `ssSetModelReferenceSampleTimeInheritanceRule` in different ways:

- An S-function that precludes inheritance: If the sample time is used in the S-function's run-time algorithm, then the S-function precludes a model from inheriting a sample time. For example, consider the following `mdlOutputs` code:

  ```
  static void mdlOutputs(SimStruct *S, int_T tid)
  {
      const real_T *u = (const real_T*)
      ssGetInputPortSignal(S,0);
      real_T       *y = ssGetOutputPortSignal(S,0);
      y[0] = ssGetSampleTime(S,tid) * u[0];
  }
  ```

  This `mdlOutputs` code uses the sample time in its algorithm, and the S-function therefore should specify

  ```
  ssSetModelReferenceSampleTimeInheritanceRule
  (S, DISALLOW_SAMPLE_TIME_INHERITANCE);
  ```

- An S-function that does not preclude Inheritance: If the sample time is only used for determining whether the S-function has a sample hit, then it does not preclude the model from inheriting a sample time. For example, consider the `mdlOutputs` code from the S-function example `sfun_multirate.c`:

  ```
  static void mdlOutputs(SimStruct *S, int_T tid)
  {
      InputRealPtrsType enablePtrs;
      int               *enabled = ssGetIWork(S);

      if (ssGetInputPortSampleTime
      (S,ENABLE_IPORT)==CONTINUOUS_SAMPLE_TIME &&
      ssGetInputPortOffsetTime(S,ENABLE_IPORT)==0.0) {
          if (ssIsMajorTimeStep(S) &&
          ssIsContinuousTask(S,tid)) {
              enablePtrs =
              ssGetInputPortRealSignalPtrs(S,ENABLE_IPORT);
              *enabled = (*enablePtrs[0] > 0.0);
          }
      } else {
  ```

```
            int enableTid =
            ssGetInputPortSampleTimeIndex(S,ENABLE_IPORT);
            if (ssIsSampleHit(S, enableTid, tid)) {
                enablePtrs =
                ssGetInputPortRealSignalPtrs(S,ENABLE_IPORT);
                *enabled = (*enablePtrs[0] > 0.0);
            }
        }

        if (*enabled) {
            InputRealPtrsType uPtrs  =
            ssGetInputPortRealSignalPtrs(S,SIGNAL_IPORT);
            real_T            signal = *uPtrs[0];
            int               i;

            for (i = 0; i < NOUTPUTS; i++) {
                if (ssIsSampleHit(S,
                ssGetOutputPortSampleTimeIndex(S,i), tid)) {
                    real_T *y = ssGetOutputPortRealSignal(S,i);
                    *y = signal;
                }
            }
        }
    } /* end mdlOutputs */
```

The above code uses the sample times of the block, but only for determining whether there is a hit. Therefore, this S-function should set

```
ssSetModelReferenceSampleTimeInheritanceRule
(S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE);
```

Customize Library File Suffix and File Type

You can control the library file suffix and file type extension that the Simulink Coder code generator uses to name generated model reference libraries. Use the model configuration parameter `TargetLibSuffix` to specify the scheme for the suffix and extension. The scheme must include a period (.). If you do not set this parameter, the Simulink Coder software names the libraries as follows:

- On Windows systems, *`model`*`_rtwlib.lib`
- On UNIX or Linux® systems, *`model`*`_rtwlib.a`

The `TargetLibSuffix` parameter does not apply for model builds that use the toolchain approach. For more information, see “Identify Library File Type for Toolchain Approach” (Simulink Coder).

Code Generation Model Referencing Limitations

The following Simulink Coder limitations apply to model referencing. In addition to these limitations, a model reference hierarchy used for code generation must satisfy:

- The Simulink requirements listed in:
  - "Configuration Requirements for All Referenced Model Simulation" (Simulink)
  - "Model Reference Interface" (Simulink)
- The Simulink limitations listed in "Model Reference Requirements and Limitations" (Simulink).
- The Simulink Coder requirements applicable to the code generation target, as listed in "Configuration Parameter Requirements" on page 4-16.

Customization Limitations

- The code generator ignores custom code settings in the Configuration Parameters dialog box and custom code blocks when generating code for a referenced model.
- Data type replacement is not supported for simulation target code generation of referenced models.
- Simulation targets do not include Stateflow target custom code.
- If you have an Embedded Coder license, some restrictions exist on grouped custom storage classes in referenced models. For details, see "Storage Class Limitations" (Simulink Coder).

Data Logging Limitations

- To Workspace blocks, Scope blocks, and types of runtime display, such as the display of port values and signal values, are ignored when the Simulink Coder software generates code for a referenced model. The resulting code is the same as if the constructs did not exist.
- Code generated for referenced models cannot log data to MAT-files. If data logging is enabled for a referenced model, the Simulink Coder software disables the option before code generation and re-enables it afterwards.
- If you log states for a model that contains referenced models, the ordering of the states in the output is determined by block sorted order, and might not match between simulation output and generated code MAT-file logging output.

State Initialization Limitation

When a top model uses the **Data Import/Export > Initial state** parameter in the Configuration Parameters dialog box to specify initial conditions, the Simulink Coder software does not initialize the discrete states of the referenced models during code generation.

Reuse Limitations

If a referenced model used for code generation has at least one of the following characteristics, the model must specify the configuration parameter **Model Referencing > Total number of instances allowed per top model** as `One`. Other instances of the model can exist in the hierarchy. If you do not set the parameter to `One`, or more than one instance of the model exists in the hierarchy, an error occurs. The characteristics are:

- The model references another model that has been set to single instance.
- The model contains an internal signal or state with a storage class that is not supported for multi-instance models. Internal signals and states must have the storage class set to `Auto` or `Model default`. The default storage class for internal data must be a multi-instance storage class.
- The model uses at least one of these Stateflow constructs:
  - Machine-parented data
  - Machine-parented events
  - Stateflow graphical functions
- The model contains a subsystem that is marked as a function
- The model contains an S-function that is:
  - Inlined but has not set the option `SS_OPTION_WORKS_WITH_CODE_REUSE`
  - Not inlined
- The model contains a function-call subsystem that:
  - The Simulink engine forces to be a function
  - Is called by a wide signal

For more information about **Total number of instances allowed per top model**, see "Total number of instances allowed per top model" (Simulink).

S-Function Limitations

- If a referenced model contains an S-function that should be inlined using a Target Language Compiler file, the S-function must use the `ssSetOptions` macro to set the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option in its `mdlInitializeSizes` method. The simulation target will not inline the S-function unless this flag is set.
- A referenced model cannot use noninlined S-functions generated by the Simulink Coder software.
- The Simulink Coder S-function target does not support model referencing.

For additional information, see “S-Functions in Referenced Models” (Simulink).

Simulink Tool Limitations

- Simulink tools that require access to model internal data or configuration (including the Model Coverage tool, the Simulink Report Generator product, the Simulink debugger, and the Simulink profiler) have no effect on code generated by the Simulink Coder software for a referenced model, or on the execution of that code. Specifications made and actions taken by such tools are ignored and effectively do not exist.

Subsystem Limitations

- If a subsystem contains Model blocks, you cannot build a subsystem module by right-clicking the subsystem (or by using **Code > C/C++ Code > Build Selected Subsystem**) unless the model is configured to use an ERT target.
- If you generate code for an atomic subsystem as a reusable function, inputs or outputs that connect the subsystem to a referenced model might prevent code reuse, as described in “Generate Reentrant Code from Subsystems” (Simulink Coder).

Target Limitations

- The Simulink Coder S-function target does not support model referencing.

Other Limitations

- Errors or unexpected behavior can occur if a Model block is part of a cycle, the Model block is a direct feedthrough block, and an algebraic loop results. For details, see “Algebraic Loop Concepts” (Simulink).

- The **External mode** option is not supported. If it is enabled, it is ignored during code generation.
- When a model contains a trigger or enable port, you cannot generate standalone Simulink Coder code or PIL code.

Configuration Parameters Changed During Accelerated Simulation and Code Generation

During model referencing simulation in accelerator and rapid accelerator mode, Simulink temporarily sets several **Configuration Parameters > Diagnostics > Data Validity** parameter settings to `None`, if they are set to `Warning` or `Error`. You can use the Model Advisor to check for parameters that change. For details, see “Accelerated Simulation and Code Generation Changes Settings” (Simulink).

If the **Configuration Parameters > Code Generation > Symbols** parameters hold identifier information about the name of a referenced model and do not use a `$R` token, code generation prepends the `$R` token to the name of the model. You can use the Model Advisor to check for changed model names. See “Configuration Parameters Changed During Code Generation” (Simulink Coder).

Combined Models in Simulink Coder

Combine Code Generated for Multiple Models

Techniques

Techniques that you can use to combine code, which the code generator produces for multiple models or multiple instances of a model, into one executable program include:

- Referenced models. See “Model Reference Basics” (Simulink) and “Generate Code for Referenced Models” on page 4-4.
- If you have Embedded Coder software, interface the code for multiple models to a common harness program. From the harness program, call the entry-point functions generated for each model. The `ert.tlc` system target file has restrictions, relating to embedded processing, that could be incompatible with your application.
- Generate reusable, multi-instance code that is reentrant. See “Combine Code Generated for Multiple Models or Multiple Instances of a Model” on page 5-3.

The S-function system target (`rtwsfcn.tlc`) does not support combining code generated for multiple models.

Consider using model referencing to combine models for simulation and code generation. Model referencing helps with:

- Symbol naming consistency
- Required scheduling of the overall algorithm
- Model configuration consistency

If you combine code generated for different models (that is, without using referenced models), consider:

- Data is global. Symbol (name) clashes can result.
- Configuration parameter settings for the models must match, including settings such as hardware word sizes.
- Reuse and sharing of code can be suboptimal (for example, duplicate code for shared utility functions, scheduling, and solvers).
- Scheduling can be more complex (for example, models can have periodic sample times that are not multiples of each other, making scheduling from a common timer interrupt more complicated)

- For plant models that use continuous time and state, the continuous time signals connecting models are not handled by a single solver like continuous time signals within a model. This can lead to subtle numeric differences.

Control Ownership of Data

If you have Embedded Coder software, you can specify an owner for individual data items such as signals, parameters, and states. The owner of a data item generates the definition (memory allocation and initialization) for the data item. For example, if you apply a custom storage class to a `Simulink.Signal` object so that it appears as a global variable in the generated code, specify one of the combined models as the owner of the object. The code generated for that model defines the variable.

If you use model referencing, you can modularize the generated code and establish clear ownership of data when you work in a team.

If you do not use model referencing, you can prevent generation of duplicate definitions for a data item. For example, suppose you store a `Simulink.Parameter` object in the base workspace and apply the storage class `ExportedGlobal`. If you generate code from two separate models that use the object, each model generates a definition for the corresponding global variable. Instead, you can specify an owner for the object so that only the owner generates a definition.

To specify an owner for a data item:

1. Apply a custom storage class to the data item. See “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28.
2. Configure the owner of the data item by specifying the **Owner** custom attribute.
3. Select the model configuration parameter **Use owner from data object for data definition placement**.

For more information about controlling ownership and file placement of data definitions and declarations, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 33-2.

Combine Code Generated for Multiple Models or Multiple Instances of a Model

For each model for which you are combining code, generate the code.

1. Set the system target file to a GRT- or ERT-based system target file. The system target file for the models you combine, must be the same.
2. If you intend to have multiple instances of that model in the application, set the model configuration parameter **Code Generation > Interface > Code interface packaging** to `Reusable function`. If you specified an ERT-based system target file, optionally, you can set the model configuration parameter **Use dynamic memory allocation for model initialization**, depending on whether you want to statically or dynamically allocate the memory for each instance of the model.
3. Generate source code. The code generator includes an allocation function in the generated file *`model`*`.c`. The allocation function dynamically allocates model data for each instance of the model.

After generating source code for each model:

1. Compile the code for each model that you are combining.
2. Combine the makefiles generated for the models into one makefile.
3. Create a combined simulation engine by modifying a main program, such as `rt_malloc_main.c`. The main program initializes and calls the code generated for each model.
4. Run the makefile. The makefile links the object files and the main program into an executable program.

Share Data Across Models

Use unidirectional signal connections between models. This affects the order in which models are called. For example, if you use an output signal from `modelA` as input to `modelB`, the `modelA` output computation should be called first.

Timing Issues

When combining code generated for multiple models or multiple instances of a model:

- Configure the models with the same solver mode (single-tasking or multitasking).
- If the models use continuous states, configure the models with the same solver.

If the base rates for the models differ, the main program (such as `rt_malloc_main.c`) must set up the timer interrupt to occur at the greatest common divisor rate of the models. The main program calls each model at a time interval.

Data Logging and External Mode Support

A multiple-model program can log data to separate MAT-files for each model.

Only one of the models in a multiple-model program can use external mode.

Function Reuse in Generated Code

This example shows how to configure an atomic subsystem for code generation. To specify that a subsystem's code executes as an atomic unit, select the **Treat as atomic unit** parameter on the block parameters dialog box. This parameter enables the **Function Packaging** parameter of the **Code Generation** tab. The **Function Packaging** parameter has these four settings:

- `Inline`: Inline the subsystem code
- `Nonreusable function`: Function with I/O passed as global data
- `Reusable function`: Function with I/O passed as function arguments
- `Auto`: Let Simulink Coder optimize based on context

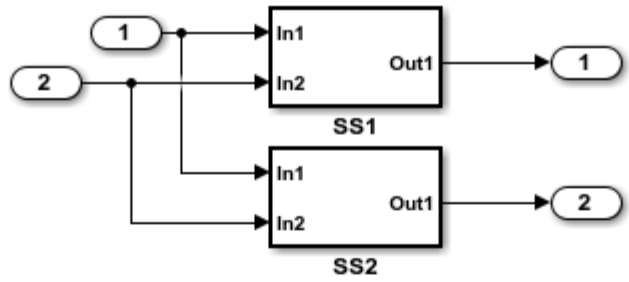
The `Reusable function` and `Auto` settings permit the code generator to reuse subsystem code. The `Reusable function` and `Nonreusable function` settings enable the **Function name options**, **Function name**, and **File name options** parameters.

If you have an Embedded Coder license, you can configure a nonreusable subsystem to accept arguments.

Example Model

The `rtwdemo_ssreuse` model contains two identical subsystems, `SS1` and `SS2`. For these subsystems, the **Function packaging** parameter is set to `Reusable function`, and the **Function name** parameter is `myfun`. The subsystems are parameterized masked subsystems. To see the contents of the masked subsystems, right-click the subsystem blocks and select **Mask > Look Under Mask**.

```
model = 'rtwdemo_ssreuse';
open_system(model);
```



Description
This model shows how to configure a subsystem for reuse of generated code. By selecting the Subsystem Parameters option "Treat as atomic unit," you specify that the code for that subsystem executes as an atomic unit. Once a system is marked atomic, you can specify how the subsystem is represented in code via the Subsystem Parameters option "Code Generation Function Packaging."

- Inline: An inlined function
- Nonreusable Function: Function with I/O passed as global data
- Reusable Function: Function with I/O passed as function arguments
- Auto: Let Simulink Coder optimize based on context

The last two options permit Simulink to reuse the subsystem in the generated code. The function name is controlled with the "Code Generation Function name" option. Here, SS2 is simply a copy of SS1, which is configured as a "Reusable Function" with function name "myfun". Notice that the system is a parameterized masked subsystem. Parameters of a mask become arguments to the function. This example uses parameters: T1Break, T1Data, T2Break, and T2Data.

Instructions
To see the subsystem parameters, right-click the subsystem block and select "SubSystem Parameters."
To see the content of the masked subsystem, right-click the subsystem block and select "Look Under Mask."

Generate Code Using Simulink Coder (double-click)

Generate Code Using Embedded Coder (double-click)

Generate Code

Create a temporary folder for the build and inspection process.

```
currentDir=pwd;
[~,cgDir]=rtwdemodir();
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_ssreuse
### Successful completion of build procedure for model: rtwdemo_ssreuse
```

```
cfile=fullfile(cgDir, 'rtwdemo_ssreuse_grt_rtw', 'rtwdemo_ssreuse.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_ssreuse_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/SS1' */

  /* Inport: '<Root>/In1' incorporates:
   *  Inport: '<Root>/In2'
   */
  myfun(rtwdemo_ssreuse_U.In1, rtwdemo_ssreuse_U.In2, &rtwdemo_ssreuse_B.SS1,
        rtwdemo_ssreuse_P.T1Data, rtwdemo_ssreuse_P.T1Break);

  /* End of Outputs for SubSystem: '<Root>/SS1' */

  /* Outport: '<Root>/Out1' */
  rtwdemo_ssreuse_Y.Out1 = rtwdemo_ssreuse_B.SS1.LookupTable;

  /* Outputs for Atomic SubSystem: '<Root>/SS2' */

  /* Inport: '<Root>/In1' incorporates:
   *  Inport: '<Root>/In2'
   */
  myfun(rtwdemo_ssreuse_U.In1, rtwdemo_ssreuse_U.In2, &rtwdemo_ssreuse_B.SS2,
        rtwdemo_ssreuse_P.T2Data, rtwdemo_ssreuse_P.T2Break);

  /* End of Outputs for SubSystem: '<Root>/SS2' */

  /* Outport: '<Root>/Out2' */
```

```
  rtwdemo_ssreuse_Y.Out2 = rtwdemo_ssreuse_B.SS2.LookupTable;
}
```

In the model step function, there are two calls to the reusable function, `myfun`. The mask parameters, `T1Break`, `T1Data`, `T2Break`, and `T2Data`, are function arguments.

Change the **Function Packaging** parameter to `Inline`.

```
set_param('rtwdemo_ssreuse/SS1','RTWSystemCode','Inline')
set_param('rtwdemo_ssreuse/SS2','RTWSystemCode','Inline')
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_ssreuse
### Successful completion of build procedure for model: rtwdemo_ssreuse
```

```
cfile=fullfile(cgDir, 'rtwdemo_ssreuse_grt_rtw', 'rtwdemo_ssreuse.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_ssreuse_step(void)
{
  real_T Out1_tmp;

  /* Outputs for Atomic SubSystem: '<Root>/SS2' */
  /* Outputs for Atomic SubSystem: '<Root>/SS1' */
  /* Sum: '<S1>/Sum' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   *  Sum: '<S2>/Sum'
   */
  Out1_tmp = rtwdemo_ssreuse_U.In1 + rtwdemo_ssreuse_U.In2;

  /* End of Outputs for SubSystem: '<Root>/SS2' */

  /* Outport: '<Root>/Out1' incorporates:
   *  Lookup_n-D: '<S1>/Lookup Table'
   *  Sum: '<S1>/Sum'
   */
  rtwdemo_ssreuse_Y.Out1 = look1_binlx(Out1_tmp, rtwdemo_ssreuse_P.T1Break,
    rtwdemo_ssreuse_P.T1Data, 10U);
```

```
  /* End of Outputs for SubSystem: '<Root>/SS1' */

  /* Outputs for Atomic SubSystem: '<Root>/SS2' */
  /* Outport: '<Root>/Out2' incorporates:
   *  Lookup_n-D: '<S2>/Lookup Table'
   */
  rtwdemo_ssreuse_Y.Out2 = look1_binlx(Out1_tmp, rtwdemo_ssreuse_P.T2Break,
    rtwdemo_ssreuse_P.T2Data, 10U);

  /* End of Outputs for SubSystem: '<Root>/SS2' */
}
```

In the model step function, the subsystem code is inline.

Change the **Function Packaging** parameter to `Nonreusable function`. For `SS2` , change the **Function name** parameter to `myfun2`.

```
set_param('rtwdemo_ssreuse/SS1','RTWSystemCode','Nonreusable function')
set_param('rtwdemo_ssreuse/SS2','RTWSystemCode','Nonreusable function')
set_param('rtwdemo_ssreuse/SS2','RTWFcnName','myfun2')
```

Build the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_ssreuse
### Successful completion of build procedure for model: rtwdemo_ssreuse
```

```
cfile=fullfile(cgDir, 'rtwdemo_ssreuse_grt_rtw', 'rtwdemo_ssreuse.c');
rtwdemodbtype(cfile, '/* Model step', '/* Model initialize', 1, 0);
```

```

/* Model step function */
void rtwdemo_ssreuse_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/SS1' */
  myfun();

  /* End of Outputs for SubSystem: '<Root>/SS1' */

  /* Outputs for Atomic SubSystem: '<Root>/SS2' */
  myfun2();

  /* End of Outputs for SubSystem: '<Root>/SS2' */
}
```

The model step function contains calls to the functions `myfun` and `myfun2`. These functions have a void-void interface.

Change the **Function Packaging** parameter to `Auto`.

```
set_param('rtwdemo_ssreuse/SS1','RTWSystemCode','Auto')
set_param('rtwdemo_ssreuse/SS2','RTWSystemCode','Auto')
```

For the `auto` setting, Simulink Coder chooses the optimal format. For this model, the optimal format is a reusable function.

Close the model and clean up.

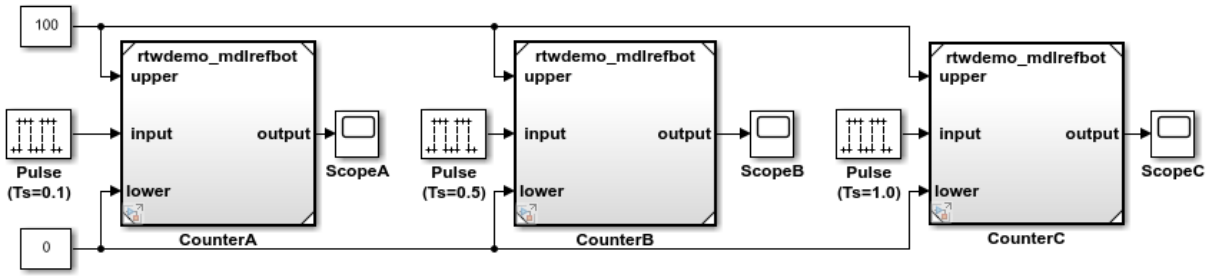
```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

File Packaging for Models (Code and Data)

This example shows how referenced models provide system interface encapsulation and incremental code generation. You can reference one model from another model (one or more times), and all aspects of the referenced model are fixed: input/output signal types, parameter types, and sample times. Therefore, you can modularize your design and perform incremental code generation with Simulink Coder.

The data and functions of a referenced model are partitioned into its own set of files, independent of its parent model. In this example, the referenced model `rtwdemo_mdlrefbot` is referenced three times. For simulation and code generation, the model is incrementally generated, which means `rtwdemo_mdlrefbot` builds the first time, but not on subsequent builds (until you change `rtwdemo_mdlrefbot`).

```
open_system('rtwdemo_mdlreftop')
```



```
bdclose('rtwdemo_mdlreftop');
```

Code Reuse for Simulink Coder

What Is Code Reuse?

Code reuse is a programming technique that reduces time and resources to develop software. When you develop code for reuse, the code serves multiple purposes. The technique involves modularization, which enables multiple individuals to develop code for various system components independently and in parallel. The technique also simplifies software distribution.

A software library is an example of code reuse. A library can contain code for several functions, each having specific behavior. To use a library, you need to know only the interface, which is the specification for calling the library functions.

Reusable code can be reentrant. You can invoke, interrupt, and reinvoke reentrant code. Reentrant code resides in shared memory. Instances of data associated with each use of the code are unique and preserved. Multiple calls to a reusable, reentrant function, for example, can access the function code with each call maintaining a unique data set.

Applications of code reuse include:

- Team-based development.
- Switching between implementations of a function.
- Intellectual property protection.
- Overriding library behavior with a custom implementation.
- Implementing a library that is based on standard library functions.
- Unit testing.
- Execution speed improvement.

The code generator supports code reuse and reentrancy. You can use key Simulink componentization techniques to partition a model into design components that you simulate, generate code for, and verify independently. You can save individual components as subsystems, libraries, referenced models, or combinations of these elements from which you can generate code. For example, the code generator produces reusable function code from library subsystems and export-function models.

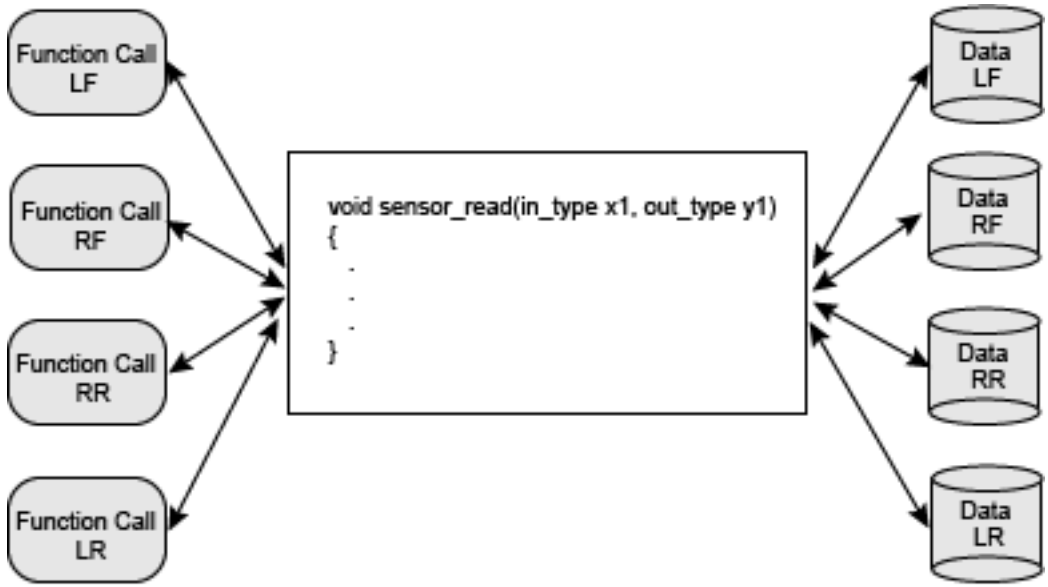
More About

- “What Is Reentrant Code?” on page 6-4
- “Choose a Componentization Technique for Code Reuse” on page 6-6

What Is Reentrant Code?

Reentrant (multi-instance) code is a reusable routine that multiple programs can invoke, interrupt, and reinvoke simultaneously. When you want to reuse code, but associate each instance of the shared code with unique, preserved data, use reentrant code. For example, consider this figure that shows four instances of function `sensor_read`. Although the function algorithm is the same in each case, the data associated with each instance varies and is relative to the sensor position.



To make generated code for a model component reentrant, you configure the component such that model entry-point functions receive root-level input and output data as arguments. How you configure the component depends on the modeling style or technique that you apply.

- “Choose a Componentization Technique for Code Reuse” on page 6-6

Choose a Componentization Technique for Code Reuse

Key componentization techniques that you can use with Simulink and the code generator to produce reusable code include:

- Referenced models
- Subsystems
- Library subsystems
- Combinations of models, subsystems, and library subsystems

Choose componentization techniques based on your code reuse goals.

Goal	Referenced Model	Subsystem in Model	Subsystem in Library
Design for explicit code reuse.	√	√	√
Facilitate parallel team development.	√	√	√
Reuse function within a model or across models.	√		
Reduce build time by generating reusable code incrementally.	√		
Verify reusable code with SIL or PIL simulation.	√		
Optimize generated code by configuring code generator to detect opportunities for code reuse.	√	√	√

Goal	Referenced Model	Subsystem in Model	Subsystem in Library
Maximize reuse with context-dependent behavior.		√	√
Develop a frequently used, and infrequently changed, utility function.			√

Simulink Function Blocks and Code Generation

Why Generate Code from Simulink Function Blocks and Function Callers?

Simulink Function blocks provide a mechanism for generating C or C++ code for modeling components that represent shared resources. You define the logic as a resource in a Simulink Function block, which separates the function interface (name and arguments) from the implementation of the logic. Function callers (Function Caller blocks, MATLAB Function blocks, and Stateflow charts) can then reuse the function logic at different levels of the model hierarchy.

Simulink Function blocks provide an alternative to reusable subsystems. For example, a consideration for using a Simulink Function block instead of a subsystem block is that a Simulink Function block shares states between function callers. The code generator produces one function. If the Simulink Function block contains blocks that have states, such as a delay or memory, the states persistent between function callers. The order of the function calls is an important consideration.

Reusable functions that the code generator produces from subsystems do not share states. The code generator produces one function for multiple instances of the subsystem as an optimization. If that subsystem contains blocks that have states, the code generator produces one function, but passes a different state variable to each instance. The instances do not share states.

Other uses of Simulink Function blocks and callers include:

- Nesting calls to a function.
- Calling a function defined in one modeling component from another modeling component.
- Generating functions that are globally accessible or scoped.
- Producing code for a client and server application.

Implementation Options

Choose how to implement Simulink functions and function callers based on your code generation requirements. Considerations include:

- How you represent a function and function callers in a model
- Scope of a function
- Whether to export a function from a model (requires Embedded Coder)
- Function code interface customizations (requires Embedded Coder)
- Code generation requirements
- Code generation limitations

Choose a Modeling Pattern

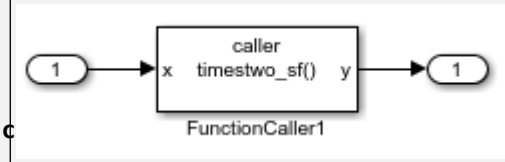
This table shows C code for a function that multiplies an input value times two and a Simulink Function block that can represent that function in a Simulink model.

Function Definition	Modeling Element

codegen-folder/*subsystem*.c
 	
`#include "timestwo_sf.h"`
 	
`#include "ex_slfunc_comp_sf.h"`
`#include "ex_slfunc_comp_sf_private.h"`
 	
`void timestwo_sf(real_T rtu_x, real_T *rty_`
`{`
`  *rty_y = 2.0 * rtu_x;`
`}`
	Simulink Function block
	
	 

A Simulink function caller invokes a function defined with a Simulink Function block. From anywhere in a model or chart hierarchy, you can call a function defined with a Simulink Function block by using one of these modeling elements:

Function Call	Modeling Element

codegen-folder/*model*.c
 	
`void ex_slfunc_comp_sf_step(void)`
`{`
`  real_T rtb_FunctionCaller1;`
 	
`timestwo_sf(ex_slfunc_comp_sf_U.In1, &rtb_Func`
 	
`ex_slfunc_comp_sf_Y.Out1 = rtb_FunctionCaller1;`
`.`
`.`
`.`
	Function Caller block
	
	 


codegen-folder/*model*.c
 	
`void ex_slfunc_comp_gf_step(void)`
`{`
`  real_T rtb_y1_l;`
 	
`  timestwo_gf(ex_slfunc_comp_gf_U.In4, &rtb_y1`
 	
`  ex_slfunc_comp_gf_Y.Out4 = rtb_y1_l;`
`  .`
`  .`
`  .`
	Stateflow chart transition
	
	 

codegen-folder/*model*.c
 	
`void ex_slfunc_comp_mf_step(void)`
`{`
`  real_T rtb_y;`
 	
`  timestwo_mf(ex_slfunc_comp_mf_U.In3, &rtb_y)`
 	
`  ex_slfunc_comp_mf_Y.Out3 = rtb_y;`
`  .`
`  .`
`  .`
	MATLAB Function block
	
	 

For more information about modeling choices, see “Simulink Functions Overview” (Simulink).

Specify Function Scope

A function that you define with a Simulink Function block can be global or scoped.

- Global---The code generator places code for a global function in source and header files that are separate from model code files (for example, *`function`*`.c` and *`function`*`.h`) . The separate files make the function code available for sharing between function callers.
- Scoped---The code generator places code for a scoped function in model code files (*`model`*`.c` and *`model`*`.h`). To call a scoped function in the context of a model, the function caller must be at the same level as the function in the model hierarchy, or one or more levels below.

  To create a library of functions that are accessible from anywhere in the generated model code, set up each function as a scoped Simulink Function block. Place each scoped function within a virtual subsystem at the root level of a model.

For more information, see and “Scoped and Global Simulink Function Blocks Overview” (Simulink).

Decide Whether to Generate Export Function Code

Although you can use Simulink Function blocks in a single top-model design, function code is more reusable when you generate it as standalone, atomic components. You do that by designing the functions in the context of export-function models.

For information, see “Generate Component Source Code for Export to External Code Base” on page 53-64 and “Export-Function Models” (Simulink).

Specify Function Code Interface Customizations

With Embedded Coder, simplify integration of generated code with external code by customizing generated function code interfaces for Simulink Function and Function Caller blocks. You can customize the function interfaces for:

- Global Simulink Function blocks
- Scoped Simulink Function blocks that are at the root level of a model

For more information, see “Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-24.

Uncalled Simulink Function Blocks

If you use a scoped Simulink Function block in a rate-based model and do not call that function, the code generator treats the Simulink Function block as a constant and does not produce function code. For example, this can occur during model development when you are ready to define a function, but are not ready to identify a caller.

To identify such blocks in a rate-based model, display sample time colors during simulation. By default, Constant blocks appear magenta. Because the code generator considers uncalled Simulink Function blocks constants during simulation, they appear magenta.

Requirements

- Within a model hierarchy, function names are unique. If the code generator finds multiple functions with the same name, it issues an error. Change the name of one of the functions and delete the `slprj` folder.
- The signature (for example, the arguments and argument data types) for a function and function callers must match.
  - If the code generator finds the function first and the signature of a function caller does not match, the code generator issues an error. Change the function caller signature to match the signature of the Simulink Function block or delete the `slprj` folder.
  - If the code generator finds a function caller first and the signature of the function does not match, the code generator issues a warning message. Change the signature of the function or function caller so that the signatures match.
- In a Simulink Function block definition, do not define input and output signals for Argument Inport and Argument Outport blocks with a storage class.
- Do not specify Argument Inport and Argument Outport blocks as test points.
- If you specify the data type of input and output signals for Argument Inport and Argument Outport blocks as a `Simulink.IntEnumType`, `Simulink.AliasType`, or `Simulink.Bus`, set the `DataScope` property to `Imported` or `Exported`.
- A function interface and function callers must agree in data type, complexity, dimension, and number of arguments.

Limitations

- To generate code from a model that includes scoped Simulink functions, the model must be an export-function model. The code generator does not support rate-based models that include scoped Simulink functions.
- You can use a Simulink Function block to define a scoped function in a referenced model. However, you cannot generate code for an export-function model that uses a Function Caller block in an atomic subsystem to invoke that function.
- You can invoke a C++ function that the code generator produces from a Simulink Function block with code generated from a Stateflow chart. Due to current scope limitations for generated C++ functions, you must invoke those functions with code generated from a Function Caller block.
- Simulink functions and function callers do not honor the `MaxStackSize` parameter.
- Code generation for a C++ class interface supports scoped Simulink functions only.

Generate and Call Reusable Function Code

This example shows how to use the Simulink Function and Function Caller blocks to generate reusable function code. The code generator produces a global function, which complies with code requirements so that existing external code can call the function and a local function. The code generator also produces calls to global and local functions. The call to the global function shows that the global function is reused (shared).

Code requirements for the global function are:

- Function names start with prefix `func_`.
- Names of input arguments are of the form `x`*n*, where *n* is a unique integer value.
- Names of output arguments are of the form `y`*n*, where *n* is a unique integer value.
- Input and output arguments are integers (`int`) and are passed by reference. The native integer size of the target hardware is 32 bits.

You create a function that calls the generated reusable function code. Then, you construct and configure a model to match the code requirements.

Some of the features used in this example, such as data type aliasing and replacement, require Embedded Coder software.

Inspect External Code That Calls Reusable Function

In your code generation root folder, create the files `call_times2.h` and `call_times2.c`. If you prefer, you can copy the files from `matlabroot\help\toolbox\ecoder\examples`.

`call_times2.h`

```
typedef int my_int;
```

`call_times2.c`

```
#include "call_times2.h"

void call_times2(void)
{
  int times2result;

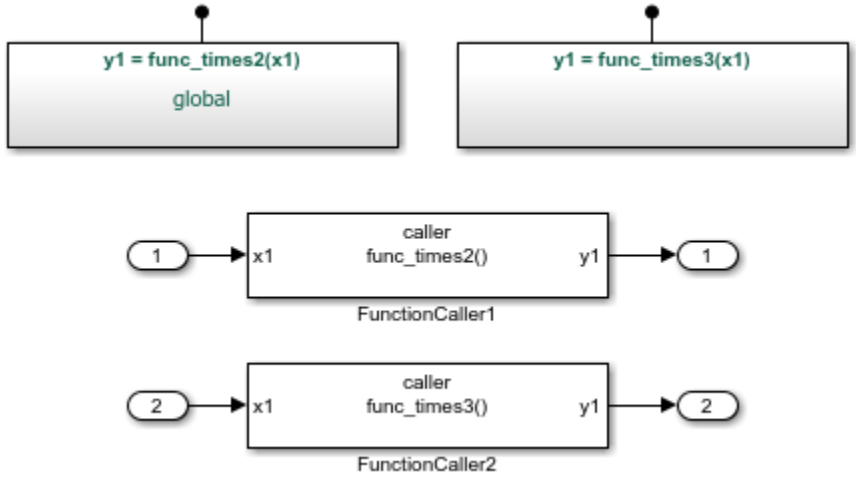
  func_times2(x1, &y1);

  printf('Times 2 Value:', y1);
}
```

This C code calls reusable function `func_times2`. The function multiplies an integer input value `x1` by 2 and returns the result as `y1`.

Create Model

Open the example model `ex_slfunc_comp`, which is available in the folder `matlabroot\help\toolbox\ecoder\examples`. The model includes two Simulink functions modeled as Simulink Function blocks, `func_times2` and `func_times3`, and a call to each function. As indicated in the model, the visibility of the Simulink Function block for `func_times2` is set to `global`. That visibility setting makes the function code accessible to other code, including external code that you want to integrate with the generated code. The visibility for `func_times3` is set to `scoped`.



If you configure the model with the GRT system target file or the ERT system target file with **File packaging format** set to `Modular`, the code generator produces function code for the model.

For more information, see “Generate Code for a Simulink Function and Function Caller” on page 6-21.

Configure Generated Code to Reuse Custom Data Type

The example assumes that the generated code runs on target hardware with a native integer size of 32 bits. The external code represents integers with data type `my_int`, which is an alias of `int`. Configure the code generator to use `my_int` in place of the data type that the code generator uses by default, which is `int32_T`.

1 Create a Simulink.AliasType object to represent the custom data type `my_int`.

```
my_int = Simulink.AliasType

my_int =

  AliasType with properties:

    Description: ''
      DataScope: 'Auto'
     HeaderFile: ''
       BaseType: 'double'
```

2 Set the alias type properties. Enter a description, set the scope to `Imported`, specify the header file that includes the type definition, and associate the alias type with the Simulink base type `int32`.

```
my_int.Description='Custom 32-bit int representation';
my_int.DataScope='Imported';
my_int.HeaderFile='call_times2.h';
my_int.BaseType='int32';

my_int
  AliasType with properties:

    Description: 'Custom 32-bit int representation'
      DataScope: 'Imported'
     HeaderFile: 'call_times2.h'
       BaseType: 'int32'
```

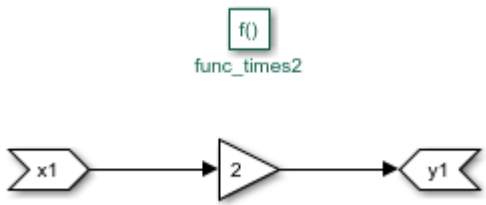
3 Configure the code generator to replace instances of type `int32_T` with `my_int`. In the Configuration Parameters dialog box, open the **Code GenerationData Type Replacement** pane.

- Select **Replace data type names in the generated code**.
- In the **Data type names** table, enter `my_int` for the replacement name for `int32`.

Configure Reusable, Global Function

For external code to call a global function, configure the corresponding Simulink Function block to have global visibility and an interface that matches what is expected by the external callers.

1 Open the block that represents the `times2` function.



2. Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
   - Set **Function name** to `func_times2`.
   - Set **Function visibility** to `global`.
3. Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form `x`*n* and `y`*n*. The requirements also specify that arguments be type `my_int`.
   - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
   - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `myint`.
4. Configure the Simulink Function block code interface. At the top level of the model, right-click the global function `func_times2`. From the menu, select **C/C++ CodeConfigure C/C++ Function Interface**.
   - Set **C/C++ function name** to `func_times2`.
   - Set **C/C++ return argument** to `void`.
   - Set **C/C++ Identifier Name** for argument `x1` to `x1`.
   - Set **C/C++ Identifier Name** for argument `y1` to `y1`.

   If the dialog box lists output argument `y1` before input argument `x1`, reorder the arguments by dragging the row for `x1` above the row for `y1`.

Configure Local Function

Configure a Simulink Function block that represents a local function with scoped visibility. Based on code requirements, you might also have to configure the function name, input and output argument names and types, and the function interface.

1. Open the block that represents the `times3` function.
2. Configure the function name and visibility by setting Trigger Port block parameters. For example, the code requirements specify that the function name start with the prefix `func_`.
   - Set **Function name** to `func_times3`.

- Set **Function visibility** to `scoped`.

3. Configure the function input and output arguments by setting Argument Inport and Argument Outport block parameters. For example, the code requirements specify that argument names be of the form `x`*n* and `y`*n*. The requirements also specify that arguments be type `my_int`.

   - On the **Main** tab, set **Argument name** to `x1` (input) and `y1` (output).
   - On the **Signal Attributes** tab, set **Data type** to `int32`. With the data type replacement that you specified previously, `int32` appears in the generated code as `my_int`.

4. Configure the Simulink Function block code interface. At the top level of the model, right-click the scoped function `func_times3`. From the menu, select **C/C++ CodeConfigure C/C++ Function Interface**. In this case, the code generator controls naming the function and arguments. The function name combines the name of the root model and the function name that you specify for the trigger port of the Simulink Function block. In this example, the name is `ex_slfunc_comp_func_times3`.

   You can set **C/C++ return argument** to the argument name that you specify for the Argument Outport block or `void`. For this example, set it to `void`.

   For arguments, the code generator prepends `rtu_` (input) or `rty_` (output) to the argument name that you specify for the Argument Inport block.

   If the dialog box lists output argument `y1` before input argument `x1`, reorder the arguments by dragging the row for `x1` above the row for `y1`.

Configure Function Callers

For each function caller, configure Function Caller block parameters:

- Set **Function prototype** to `y1 = func_times2(x1)`.
- Set **Input argument specifications** to `int32(1)`.
- Set **Output argument specifications** to `int32(1)`.

Generate and Inspect Code

Generate code for the model.

- Global function code

Source code for the global, reusable function `func_times2` is in the build folder in subsystem file, `func_times2.c`.

```
#include "func_times2.h"

/* Include model header file for global data */
#include "ex_slfunc_comp.h"
#include "ex_slfunc_comp_private.h"

void func_times2(my_int x1, my_int *y1)
{
  *y1 = x1 << 1;
}
```

- Local function code

  The code generator places the definition for the local (scoped) function `func_times3` in file build folder in file `ex_slfunc_comp.c`.

  ```
  void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1)
  {
    *rty_y1 = 3 * rtu_x1;
  }
  ```

- Calls to generated functions

  The model execution (step) function, in model file `ex_slfunc_comp.c`, calls the two Simulink functions: global function `func_times2` and local function `ex_slfunc_comp_func_times3`. The name `ex_slfunc_comp_func_times3` reflects the scope of the local function by combining the name of the model and the name of the function.

  ```
  void ex_slfunc_comp_step(void)
  {
    my_int rtb_FunctionCaller2;

    func_times2(ex_slfunc_comp_U.In1, &rtb_FunctionCaller2);

    ex_slfunc_comp_Y.Out1 = rtb_FunctionCaller2;

    ex_slfunc_comp_func_times3(ex_slfunc_comp_U.In2, &rtb_FunctionCaller2);

    ex_slfunc_comp_Y.Out2 = rtb_functionCaller2;
    .
    .
    .
  ```

- Entry-point declaration for local function

The model header file `ex_slfunc_comp.h` includes an `extern` declaration for function `ex_slfunc_comp_func_times3`. That statement declares the function entry point.

```
extern void ex_slfunc_comp_func_times3(my_int rtu_x1, my_int *rty_y1);
```

- Include statements for global function

  The model header file `ex_slfunc_comp.h` lists include statements for the global function`func_times2`.

  ```
  #include "func_times2_private.h"
  #include "func_times2.h"
  ```

- Local macros and data for global function

  The subsystem header file `func_times2_private.h` defines macros and includes header files that declare data and functions for the global function, `func_times2`.

  ```
  #ifndef RTW_HEADER_func_times2_private_h_
  #define RTW_HEADER_func_times2_private_h_
  #ifndef ex_slfunc_comp_COMMON_INCLUDES_
  #define ex_slfunc_comp_COMMON_INCLUDES_
  #include "rtwtypes.h"
  #endif
  #endif
  ```

- Entry-point declaration for global function

  The shared header file `func_times2.h`, in the shared utilities folder `slprj/`*`stf`*`/_sharedutils`, lists shared type includes for `rtwtypes.h`. The file also includes an `extern` declaration for the global function, `func_times2`. That statement declares the function entry point.

  ```
  #ifndef RTW_HEADER_func_times2_
  #define RTW_HEADER_func_times2_

  #include "rtwtypes.h"

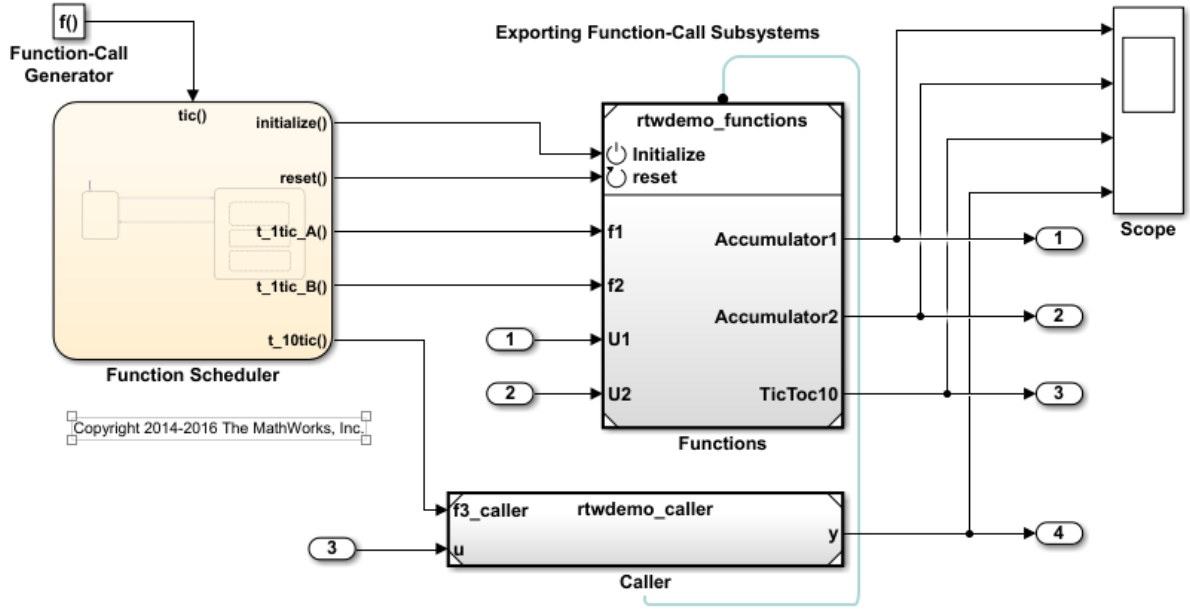
  extern void func_times2(my_int rtu_x1, my_int *rty_y1);

  #endif
  ```

Generate Code for a Simulink Function and Function Caller

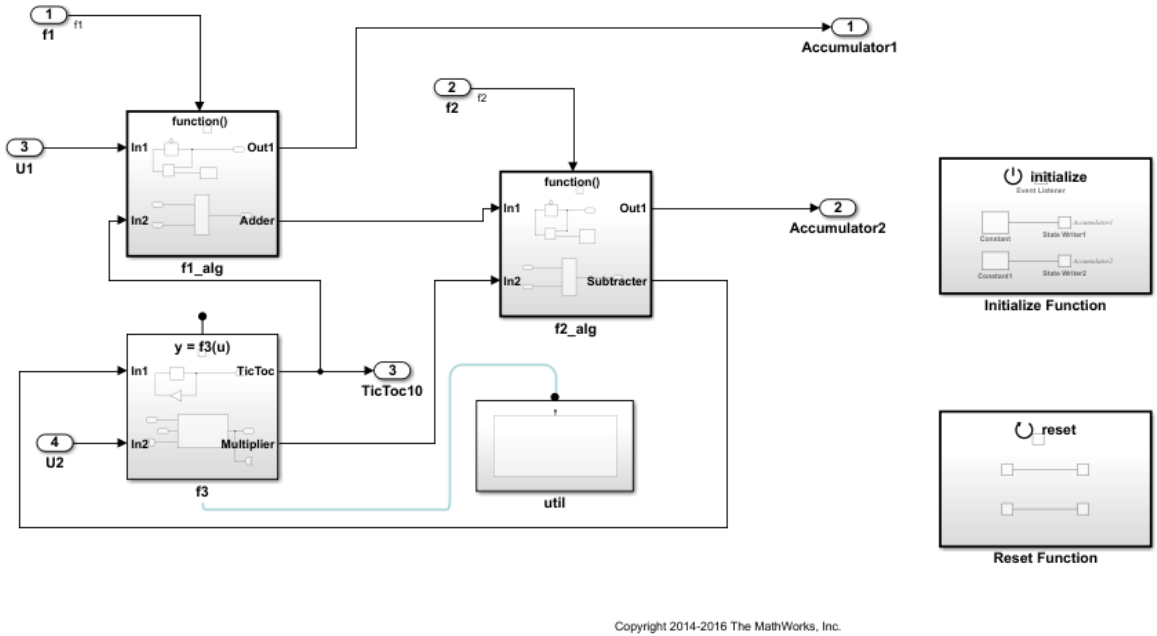
This example shows how to generate C code for Simulink Function and Function Caller blocks and displays the relevant generated code.

Open the example model `rtwdemo_export_functions`. The model uses Stateflow software, but this example reviews only the code generated from the referenced models.



Generate Code for Function Definition

1 To view the contents of the subsystem, double-click `rtwdemo_functions`. The Simulink Function block is the `f3` subsystem defined as `y = f3(u)`.



2 Generate code.

The code generator creates `rtwdemo_functions.c`. This file contains the function definition and function initialization code.

- Initialization code for function `f3`:

```
void f3_Init(void)
{
  rtDWork.Delay_DSTATE = 1;
}
```

- Code for function `f3`:

```
void f3(real_T rtu_u, real_T *rty_y)
{
  rtY.TicToc10 = rtDWork.Delay_DSTATE;

  rtDWork.Delay_DSTATE = (int8_T)(int32_T)-(int32_T)rtY.TicToc10;

  adder_h(rtB.Subtract, rtU.U2, rtu_u, rtB.FunctionCaller);
```

```
  *rty_y = rtB.FunctionCaller;
}

void adder_h(real_T rtu_u1,
             real_T rtu_u2,
             real_T rtu_u3,
             real_T *rty_y)
{
  *rty_y = (rtu_u1 + rtu_u2) + rtu_u3;
}
```

- The shared header file `f3.h` contains the entry point declaration for function `f3`.

```
#include "rtwtypes.h"

extern void f3(real_T rtu_u, real_T *rty_y);
```

Generate Code for Function Caller

1. In the `rtwdemo_export_functions` model, double-click `rtwdemo_caller` to view the contents of the caller subsystem.
2. Generate code.

The code generator creates the files `rtwdemo_caller.h` and `rtwdemo_caller.c` in the folder `rtwdemo_caller_ert_rtw`.

`rtwdemo_caller.h` includes the shared header file, `f3.h`, which contains the function entry-point declaration.

`rtwdemo_caller.c` calls function `f3`.

```
void rtwdemo_caller_t_10tic(const real_T *rtu_u,
                            real_T *rty_y)
{
  f3(*rtu_u, rty_y);
}
```

- “Scoped Simulink Function Blocks in Models” (Simulink)
- “Simulink Function Blocks in Referenced Models” (Simulink)

Generate Reentrant Code from Top Models

By default, for top models, the code generator produces code that is not reentrant. Entry-point functions have a void-void interface. Code communicates with other code by sharing access to global data structures that reside in shared memory.

For applications that can benefit from reuse and require that each use or instance of the code maintains its own unique data, configure a model such that the code generator produces reentrant code. To generate reentrant code, set the model configuration parameter "Code interface packaging" (Simulink Coder) to `Reusable function`. If you are using Embedded Coder and generating C++ code, alternatively, you can set the parameter to `C++ class`. In both cases, the code generator:

- Packages model data, such as block I/O, DWork vectors, and parameters, in the real-time model data structure (`rtModel`) .
- Passes the real-time model data structure as an input argument, by reference, to generated model entry-point functions.
- Passes root-level input and output arguments to generated model entry-point functions as individual arguments.
- Allocates memory for model data structures statically.
- Exports the real-time model data structure in the generated header file *`model`*`.h`.

Apply additional diagnostic and code generation control by setting these model configuration parameters:

- To select the severity level for diagnostic messages that the code generator displays when a model does not meet requirements for multi-instance code, set parameter "Multi-instance code error diagnostic" (Simulink Coder) to `None`, `Warning`, or `Error`. Set the parameter to `Error` unless you need to alter the severity level for diagnostics displayed when a model violates requirements for generating multi-instance code.
- To control how the generated code passes root-level model input and output to the reusable execution (step) function (requires Embedded Coder), set parameter "Pass root-level I/O as" (Simulink Coder) to `Individual arguments`, `Structure reference`, or `Part of model data structure`.

  When you set "Code interface packaging" (Simulink Coder) to `Reusable function`, the code generator packages model data (such as block I/O, Dwork, and parameters) into the real-time model data structure, and passes the model structure to generated model entry-point functions. If you set "Pass root-level I/O as" (Simulink Coder) to

`Part of model data structure`, the code generator packages root-level model input and output into the real-time model data structure also.

- To reduce memory usage by omitting the error status field from the real-time model data structure (requires Embedded Coder), select parameter **Remove error status field in real-time model data structure**.
- To include a function in the generated file *`model`*`.c` that uses `malloc` to dynamically allocate memory for model instance data (requires Embedded Coder), select **Use dynamic memory allocation for model initialization**. If you do not select this parameter, the generated code statically allocates memory for model data structures.

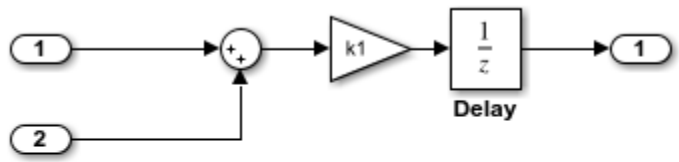
Generate Reentrant, Multi-Instance Code

This example shows you how to configure a model for reentrant, multi-instance code generation. Multiple programs can use reentrant code simultaneously. When you configure a model for reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures. After examining the configuration settings, generate and review the generated code.

Open the Model

Open the model `rtwdemo_reusable`. The model contains two root Inport blocks and a root Outport block.

```
model='rtwdemo_reusable';
open_system(model);
```



In your working folder, create a temporary folder for generating and reviewing the code.

```
currentDir=pwd;
[~,cgDir] = rtwdemodir();
```

Examine Relevant Model Configuration Settings

1. Open the Model Configuration Parameters dialog box.

2. **System target file** is set to `ert.tlc`. Although you can generate reentrant code for a model configured with the **System target file** set to `grt.tlc`, ERT and ERT-based system target files provide more control over how the code passes root-level I/O.

3. Open the **Code Generation > Interface** pane and explore relevant parameter settings.

- **Code interface packaging** is set to `Reusable function`. This parameter setting instructs the code generator to produce reusable, multi-instance code.
- The `Reusable function` parameter setting also displays the **Multi-instance code error diagnostic** parameter. That parameter is set to `Error`, indicating that the code generator abort if the model violates requirements for generating multi-instance code.
- **Pass root-level I/O as** is set to `Part of model data structure`. This setting packages root-level model input and output into the real-time model data structure (`rtModel`), which is an optimized data structure that replaces `SimStruct` as the top-level data structure for a model.
- **Remove error status field in real-time model data structure** is selected. This parameter setting reduces memory usage by omitting the error status field from the generated real-time model data structure.

Generate and Review Code

```
rtwbuild(model);
```

```
### Starting build procedure for model: rtwdemo_reusable
### Successful completion of build procedure for model: rtwdemo_reusable
```

From the code generation report, review the generated code.

- `ert_main.c` is an example main program (execution framework) for the model. This code controls model code execution by calling the entry-point function `rtwdemo_reusable_step`. Use this file as a starting point for coding your execution framework.
- `rtwdemo_reusable.c` contains entry points for the code that implements the model algorithm. This file includes the rate scheduling code.
- `rtwdemo_reusable.h` declare model data structures and a public interface to the model entry points and data structures.

- `rtwtypes.h` defines data types, structures, and macros that the generated code requires.

Open and review the Code Interface Report. Use the information in that report to write the interface code for your execution framework.

1. Include the generated header file by adding directive `#include rtwdemo_reusable.h`.

2. Write input data to the generated code for model Inport blocks.

3. Call the generated entry-point functions.

4. Read data from the generated code for the model Outport block.

Input ports:

- `<Root>/In1` of data `real_T` with dimension of 1
- `<Root>/In2` of data `real_T` with dimension of 1

Entry-point functions:

- Initialization entry-point function, `void rtwdemo_reusable_initialize(RT_MODEL *const rtM)`. At startup, call this function once.
- Output and update (step) entry-point function, `void rtwdemo_reusable_step(RT_MODEL *const rtM)`. Call this function periodically at the fastest rate in the model. For this model, call the function every second. To achieve real-time execution, attach this function to a timer.

Output port:

- `<Root>/Out1` of data type `real_T` with dimension of 1

```
Examine the |rtwdemo_reusable_step| function code in |rtwdemo_reusable.c|.

cfile = fullfile(cgDir,'rtwdemo_reusable_ert_rtw','rtwdemo_reusable.c');
rtwdemodbtype(cfile,'/* Model step function', '/* Model initialize function ', 1, 0);

/* Model step function */
void rtwdemo_reusable_step(RT_MODEL *const rtM)
{
```

```
  D_Work *rtDWork = ((D_Work *) rtM->dwork);
  ExternalInputs *rtU = (ExternalInputs *) rtM->inputs;
  ExternalOutputs *rtY = (ExternalOutputs *) rtM->outputs;

  /* Outport: '<Root>/Out1' incorporates:
   *  UnitDelay: '<Root>/Delay'
   */
  rtY->Out1 = rtDWork->Delay_DSTATE;

  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In1'
   *  Inport: '<Root>/In2'
   *  Sum: '<Root>/Sum'
   *  UnitDelay: '<Root>/Delay'
   */
  rtDWork->Delay_DSTATE = (rtU->In1 + rtU->In2) * rtP.k1;
}
```

The code generator passes model data to the `rtwdemo_reusable_step` function as part of the real-time model data structure. Try different settings for the **Code interface packaging** and **Pass root-level I/O** parameters and regenerate code. Observe how the function signature for the `rtwdemo_reusable_step` function changes.

Close the model and the code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Share Data Between Instances

When your code calls a reentrant model entry-point function multiple times, each call represents an instance of the model. By default, the code generator generates code that assumes each instance reads from and writes to a separate copy of the signals, block states, and parameters in the model.

- To share a piece of parameter data between the instances (for example, to share a setpoint for a reusable PID control algorithm), use a parameter object, such as `Simulink.Parameter`. Then, configure the parameter with a storage class other than `Auto` or in the Code Mappings editor, set the default storage class for the corresponding category of parameter data `Default` (the default setting) to `Model default`. The parameter object appears in the code as a global symbol, such as a global variable, that the function accesses directly. For more information, see “Apply

Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

- To share a piece of nonparameter data between the instances (for example, to share a fault indication or an accumulator), use a data store. You can configure the data store to appear in the code as a global symbol, such as a global variable, that the function accesses directly. Create a global data store by using a `Simulink.Signal` object or use a Data Store Memory block and select the **Share across model instances** parameter. For more information, see “Model Global Data by Creating Data Stores” (Simulink) and Data Store Memory.

Generate Reentrant Code from Simulink Function Blocks

If you are using Embedded Coder, you can generate reusable, reentrant code by representing an algorithm as a scoped Simulink Function block. Examples of when to generate reentrant code from Simulink Function blocks are when a function shares state between function callers within a model or for client/server applications. You can generate code that is highly modularized by using multiple instances of a shared Simulink Function block in an export-function model. The code generator produces function code and associates each use or call to the function with instance-specific data. The scope of the function depends on whether you place the function at the root level of model or in a subsystem.

The code generator produces reentrant function code when you configure a:

- Top model with model configuration parameter “Code interface packaging” (Simulink Coder) set to `Reusable function` or `C++ class` (C++ only).
- Referenced model with “Total number of instances allowed per top model” (Simulink) set to `Multiple`.

Call a function represented by a scoped Simulink Function block from one level above, at the same level, or from a level below the level of the function definition. You can scope a function in an atomic or nonvirtual subsystem, but function call accessibility is limited to the same level or below of the hierarchy. The function name does not have to be unique.

Identify Requirements

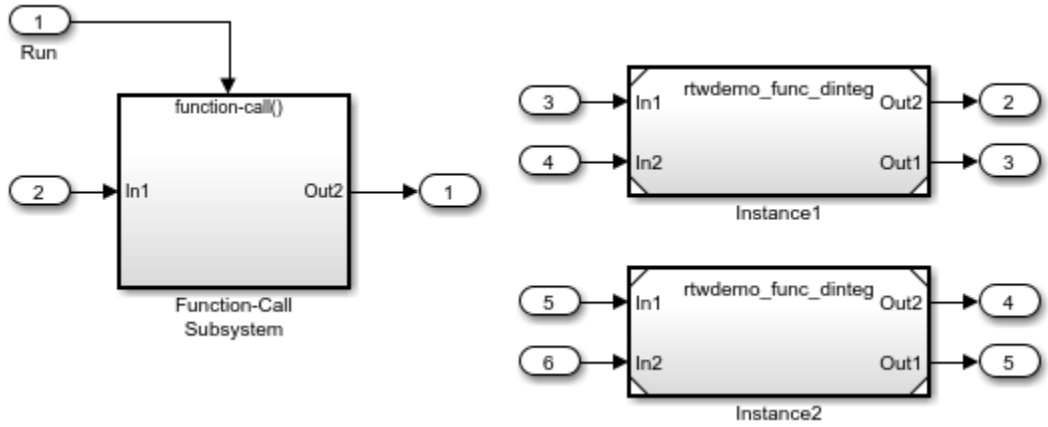
Before and while you design your model, consider:

- How many instances of each function are required?
- Do you need to restrict call sites for a function to the model containing the function definition?
- Do you need for a function to interface with signals in the local environment, but keep those signals hidden from callers?
- Do functions need to communicate directly with each other?
- Do functions need to connect to external I/O?
- Do you need to log function output?

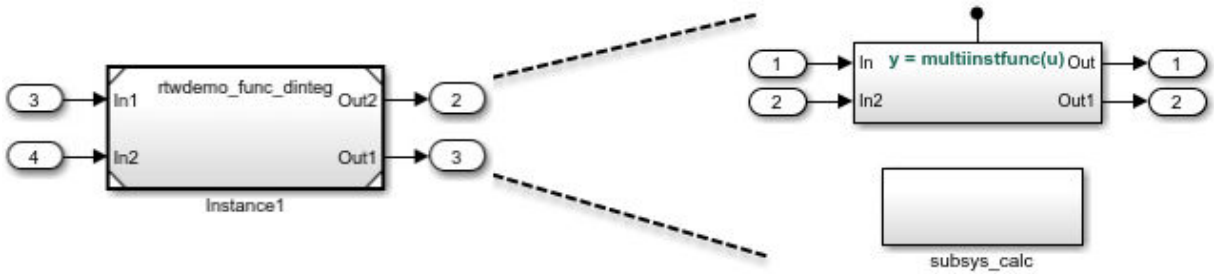
Create Model

Use the example model component `rtwdemo_comp` to see how to use Simulink Function blocks to generate reentrant C code. Use example model `rtwdemo_comp_cpp` if you prefer to generate C++ code. Open the model and examine the model hierarchy.

The top level of the model includes a function-call subsystem and two instances of a referenced model.

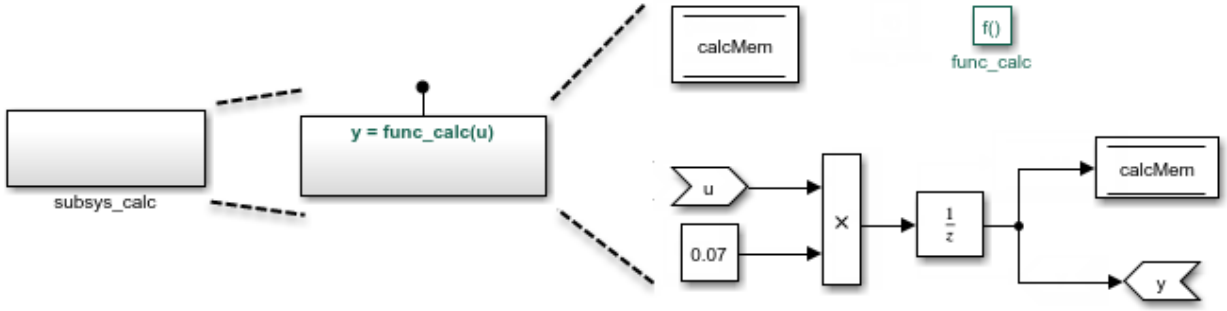


The referenced model, `rtwdemo_func_dinteg`, consists of a Simulink Function block that defines function `multiinstfunc` and subsystem `subsys_calc`.

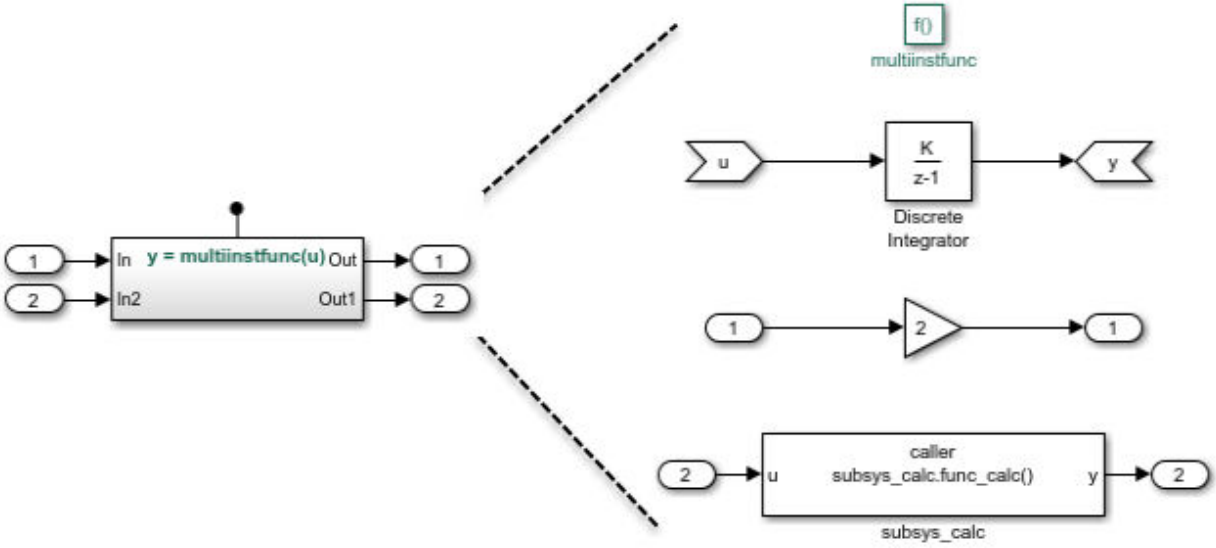


The subsystem consists of a Simulink Function block. This use of a Simulink Function block shows how you can limit the scope of the function that the block defines to the model that contains the subsystem. The code generator produces function code for

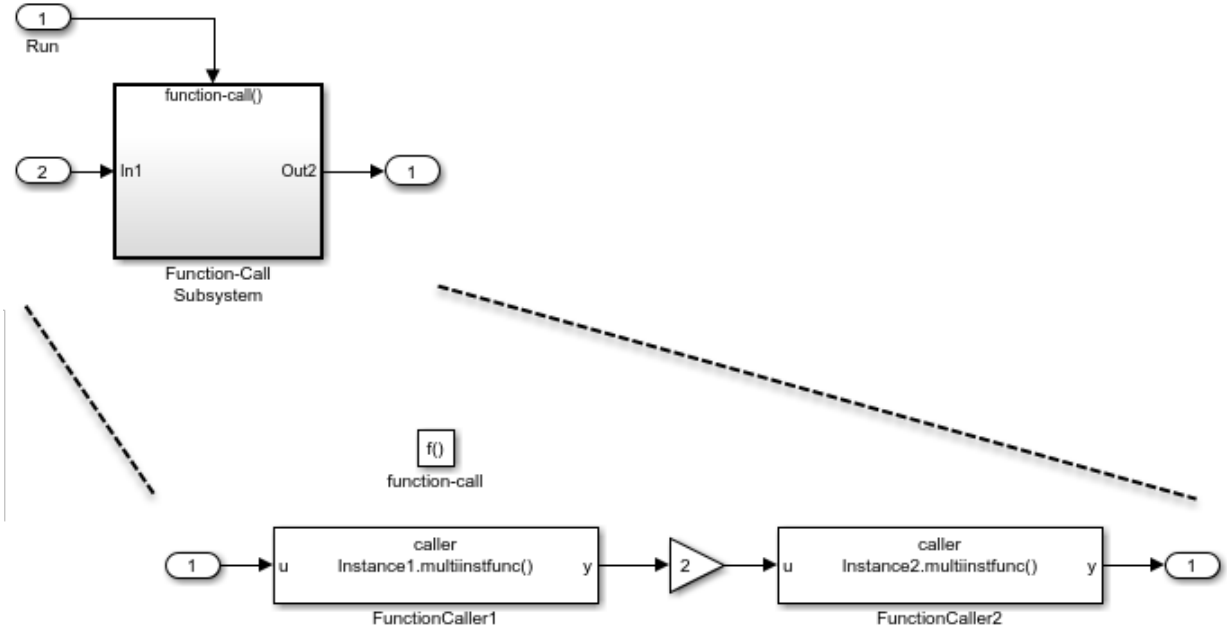
`func_calc` and associates each call to the function with instance-specific data. The data includes states, such as data stored in memory.



The Simulink Function block that defines function `multiinstfunc` uses a Function Caller block to invoke function `func_calc`. That Simulink Function block also shows that it can interface to signals in the local environment of the block through Inport and Outport blocks.



At the top level of model `rtwdemo_comp`, the function-call subsystem uses Function Caller blocks to invoke the two instances of function `multiinstfunc`. The code generator produces function code and associates each call with instance-specific data.



Configure Model and Model Elements

Configure Simulink Function Blocks

Configure the Simulink Function blocks by setting parameters for the function Trigger Port block. For the code generator to produce reentrant code from Simulink Function blocks:

- Configure block instances with the same function name.
- Set **Function visibility** to `scoped`.

In the example, the function name for the Simulink Function blocks in the two instances of the referenced model `rtwdemo_func_dinteg` is specified as `multiinstfunc`.

Configure Function Caller Blocks

Configure the Function Caller blocks. For each of the blocks, set the **Function prototype** block parameter. Start typing a prototype. For example, type `y`. Prototype options, based on function definitions in the model, appear in a selection list. Select the prototype that corresponds to each function call.

For this example, the prototypes are configured as follows:

- In the function-call subsystem, the prototypes for the function callers are configured as `y = Instance1.multiinstfunc(u)` and `y = Instance2.multiinstfunc(u)`. The `Instance`*n* prefix identifies each function invocation uniquely and associates the invocation with its own data set.
- The function caller in function `multiinstfunc` is configured with the prototype `y = subsys_calc.func_calc(u)`. The prefix `subsys_calc` identifies the subsystem that contains the function definition.

For the example, the input and output argument specifications and sample time retain default settings.

Subsystem Configuration

Configuration changes are not required for the subsystem in the example model. When you include a Simulink Function block in a subsystem, the code generator

- Scopes the function to the model that includes the subsystem.
- Treats the subsystem as an atomic unit.

Configure Referenced Model

Configure the referenced model that includes a Simulink Function block:

- In the Block Parameters dialog box, set **Model name** to the referenced model file name. For this example, the model name is `rtwdemo_func_dinteg.slx`.
- Set **Number of model instances allowed** to `Multiple`.
- To generate a C++ class interface for the reference model, set **Language** to `C++` and **Code interface packaging** to `C++ class`.

Optionally, you can customize model entry-point function interfaces. You can specify entry-point function names. For the execution (step) entry-point function you can configure the function name and arguments. Custom entry-point function interfaces can minimize changes to existing external code that you integrate with the generated code. The example uses the default function interfaces. See “Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-24.

Configure Top Model

Configure the top model for a model component. If you want the model component (that is, the top model) to be reusable, set **Code interface packaging** to `Reusable`

`function`. If you are generating C++ code, you can set this parameter to `C++ class`. In either case, also:

- Set **Multi-instance code error diagnostic** to `Error`.
- Set **Pass root-level I/O as** to `Part of model data structure`.

Optionally, you can customize model entry-point function interfaces. You can specify entry-point function names. For the execution (step) entry-point function you can configure the function name and arguments. Custom entry-point function interfaces can minimize changes to existing external code that you integrate with the generated code. The example uses the default function interfaces. See “Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks” on page 39-24.

Generate and Inspect C Code

Generate C code for the model.

- Function code for multi-instance Simulink Function block

  When you place a scoped Simulink Function block in a referenced model that you use multiple times in another model, the code generator places the function code in the *`model`*`.c` file for the referenced model. For this example, the code generator places function code for `multiinstfunc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```
real_T rtwdemo_func_dinteg_multiinstfunc(RT_MODEL_rtwdemo_func_dinteg_T * const
  rtwdemo_func_dinteg_M, const real_T rtu_u)
{
  real_T rtb_TmpLatchAtInOutport1;
  real_T rtb_TmpLatchAtIn2Outport1;
  real_T rty_y_0;

  rtb_TmpLatchAtInOutport1 =
    *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In1;

  rtb_TmpLatchAtIn2Outport1 =
    *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In2;

  *rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutport.rty_Out2 = 2.0 *
    rtb_TmpLatchAtInOutport1;

  rtwdemo_func_dinteg_func_calc(rtwdemo_func_dinteg_M, rtb_TmpLatchAtIn2Outport1,
    rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutport.rty_Out1);

  rty_y_0 = rtwdemo_func_dinteg_M->dwork.DiscreteIntegrator_DSTATE;

  rtwdemo_func_dinteg_M->dwork.DiscreteIntegrator_DSTATE += 0.1 * rtu_u;
```

```
  return rty_y_0;
}
```

- Function code for a Simulink Function block defined in a subsystem

  The code generator places the function code for a Simulink Function block that you define in a subsystem in the *`model`*`.c` file for the model that contains the subsystem. For this example, the code generator places the function code for `func_calc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```
void rtwdemo_func_dinteg_func_calc(RT_MODEL_rtwdemo_func_dinteg_T * const
  rtwdemo_func_dinteg_M, real_T rtu_u, real_T *rty_y)
{
  rtwdemo_func_dinteg_M->dwork.calcMem =
    rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE;

  *rty_y = rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE;

  rtwdemo_func_dinteg_M->dwork.UnitDelay_DSTATE = rtu_u * 0.07;
}
```

- Structure that stores multi-instance data for reusable functions

  The code generator uses a structure similar to the real-time model (`RT_MODEL`) data structure to store the multi-instance data associated with a reusable function. The code generator defines the structure in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.h`.

```
typedef struct rtwdemo_func_dinteg_tag_RTM RT_MODEL_rtwdemo_func_dinteg_T;
```

- Initialization code for multi-instance referenced model

  For each instance of a referenced model that includes the same scoped Simulink Function block, the code generator produces initialization and startup function code. A single copy of the initialization code is defined in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.c`.

```
void rtwdemo_func_dinteg_Start(RT_MODEL_rtwdemo_func_dinteg_T *const
  rtwdemo_func_dinteg_M, const real_T *rtu_In1, const real_T *rtu_In2, real_T
  *rty_Out2, real_T *rty_Out1)
{
  rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In1 = rtu_In1;
  rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextInport.rtu_In2 = rtu_In2;
  rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutport.rty_Out2 = rty_Out2;
  rtwdemo_func_dinteg_M->rtwdemo_func_dintegrtextOutport.rty_Out1 = rty_Out1;
}

void rtwdemo_func_dinteg_initialize(const char_T **rt_errorStatus,
  RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M)
{
  {
    rtmSetErrorStatusPointer(rtwdemo_func_dinteg_M, rt_errorStatus);
```

```
  }
}
```

The initialization code is called for each instance of a referenced model that contains the same Simulink Function block. That code is in file `rtwdemo_comp.c` in the build folder.

```
.
.
.
rtwdemo_func_dinteg_initialize(rtmGetErrorStatusPointer(rtwdemo_comp_M),
  (&(rtwdemo_comp_M->Instance1)));

rtwdemo_func_dinteg_initialize(rtmGetErrorStatusPointer(rtwdemo_comp_M),
  (&(rtwdemo_comp_M->Instance2)));

rtwdemo_func_dinteg_Start((&(rtwdemo_comp_M->Instance1)), &rtU->In2, &rtU->In3,
  &rtY->Out2, &rtY->Out3);

rtwdemo_func_dinteg_Start((&(rtwdemo_comp_M->Instance2)), &rtU->In4, &rtU->In5,
  &rtY->Out4, &rtY->Out5);
}
```

- Top model entry-point function declarations

  The model header file `rtwdemo_comp.h` includes `extern` declarations for top model initialize, terminate, and execution (run) entry-point functions.

  ```
  extern void rtwdemo_comp_initialize(RT_MODEL_rtwdemo_comp_T *const
    rtwdemo_comp_M);

  extern void Run(RT_MODEL_rtwdemo_comp_T *const rtwdemo_comp_M);
  ```

- Reference model entry-point function declarations

  Header file `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg.h` includes `extern` declarations for reference model entry-point functions.

  ```
  extern void rtwdemo_func_dinteg_initialize(const char_T **rt_errorStatus,
    RT_MODEL_rtwdemo_func_dinteg_T *const rtwdemo_func_dinteg_M);
  extern real_T rtwdemo_func_dinteg_multiinstfunc(RT_MODEL_rtwdemo_func_dinteg_T *
    const rtwdemo_func_dinteg_M, const real_T rtu_u);
  extern void rtwdemo_func_dinteg_Start(RT_MODEL_rtwdemo_func_dinteg_T *const
    rtwdemo_func_dinteg_M, const real_T *rtu_In1, const real_T *rtu_In2, real_T
    *rty_Out2, real_T *rty_Out1);
  ```

Generate and Inspect C++ Code

Generate C++ code for the model.

- Function code for multi-instance Simulink Function block

  When you place a scoped Simulink Function block in a referenced model that you use multiple times in another model, the code generator places the function code in the *model*`.cpp` file for the referenced model. For this example, the code generator places function code for `multiinstfunc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
real_T rtwdemo_func_dintegModelClass::multiinstfunc(const real_T rtu_u)
{
  real_T rtb_TmpLatchAtInOutport1;
  real_T rtb_TmpLatchAtIn2Outport1;
  real_T rty_y_0;

  rtb_TmpLatchAtInOutport1 = *rtwdemo_func_dinteg_cprtrtu_In1;

  rtb_TmpLatchAtIn2Outport1 = *rtwdemo_func_dinteg_cprtrtu_In2;

  *rtwdemo_func_dinteg_crtrty_Out2 = 2.0 * rtb_TmpLatchAtInOutport1;

  rtwdemo_func_dinteg_c_func_calc(rtb_TmpLatchAtIn2Outport1,
    rtwdemo_func_dinteg_crtrty_Out1);

  rty_y_0 = rtwdemo_func_dinteg_cpprtDW.DiscreteIntegrator_DSTATE;

  rtwdemo_func_dinteg_cpprtDW.DiscreteIntegrator_DSTATE += 0.1 * rtu_u;
  return rty_y_0;
}
```

- Function code for a Simulink Function block defined in a subsystem

  The code generator places the function code for a Simulink Function block that you define in a subsystem in *model*`.cpp` for the model that contains the subsystem. For this example, the code generator places the function code for `func_calc` in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
void rtwdemo_func_dintegModelClass::rtwdemo_func_dinteg_c_func_calc(real_T rtu_u,
  real_T *rty_y)
{
  rtwdemo_func_dinteg_cpprtDW.calcMem =
    rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE;

  *rty_y = rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE;

  rtwdemo_func_dinteg_cpprtDW.UnitDelay_DSTATE = rtu_u * 0.07;
}
```

- Structure that stores multi-instance data for reusable functions

  The code generator uses a structure similar to the real-time model (`RT_MODEL`) data structure to store the multi-instance data associated with a `Reusable function`. The

code generator defines the structure in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.h`.

```
typedef struct rtwdemo_func_dinteg_cpp_tag_RTM rtwdemo_func_dinteg_cp_RT_MODEL;
```

- Initialization code for multi-instance referenced model

  For each instance of a referenced model that includes the same scoped Simulink Function block, the code generator produces initialization and startup function code. A single copy of the initialization code is defined in `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.cpp`.

```
void rtwdemo_func_dintegModelClass::start(real_T *rtu_In1, real_T *rtu_In2,
  real_T *rty_Out2, real_T *rty_Out1)
{
  rtwdemo_func_dinteg_cprtrtu_In1 = rtu_In1;
  rtwdemo_func_dinteg_cprtrtu_In2 = rtu_In2;
  rtwdemo_func_dinteg_crtrty_Out2 = rty_Out2;
  rtwdemo_func_dinteg_crtrty_Out1 = rty_Out1;
}
.
.
.
void rtwdemo_func_dintegModelClass::initializeRTM()
{
  (void) memset((void *)((&rtwdemo_func_dinteg_cpprtM)), 0,
                sizeof(rtwdemo_func_dinteg_cp_RT_MODEL));
}
```

  The initialization code is called for each instance of a referenced model that contains the same Simulink Function block. That code is in file `rtwdemo_comp_cpp.cpp` in the build folder.

```
.
.
.

Instance1MDLOBJ0.initializeRTM();

Instance1MDLOBJ0.setErrorStatusPointer(rtmGetErrorStatusPointer((&rtM)));
Instance1MDLOBJ0.initialize();

Instance2MDLOBJ1.initializeRTM();

Instance2MDLOBJ1.setErrorStatusPointer(rtmGetErrorStatusPointer((&rtM)));

Instance1MDLOBJ0.start(&rtU.In2, &rtU.In3, &rtY.Out2, &rtY.Out3);

Instance2MDLOBJ1.start(&rtwU.In4, &rtwU.In5, &rtY.Out4, &rtY.Out5);
}
```

- Top model class declaration

The model header file `rtwdemo_comp_cpp.h` includes the class declaration for the top model.

```
class rtwdemo_compModelClass {
 public:
  ExtU rtU;

  ExtY rtY;

  void initialize();

  void Run();

  rtwdemo_compModelClass();

  ~rtwdemo_compModelClass();

  RT_MODEL * getRTM();

 private:
  RT_MODEL rtM;

  rtwdemo_func_dintegModelClass Instance1MDLOBJ0;

  rtwdemo_func_dintegModelClass Instance2MDLOBJ1;
};
```

- Reference model class declaration

  Header file `slprj/ert/rtwdemo_func_dinteg/rtwdemo_func_dinteg_cpp.h` includes the class declaration for the reference model.

```
class rtwdemo_func_dintegModelClass {
 public:
  real_T multiinstfunc(const real_T rtu_u);

  void start(real_T *rtu_In1, real_T *rtu_In2, real_T *rty_Out2, real_T
               *rty_Out1);

  rtwdemo_func_dintegModelClass();

  ~rtwdemo_func_dintegModelClass();

  rtwdemo_func_dinteg_cp_RT_MODEL * getRTM();

  void initializeRTM();

  const real_T *rtwdemo_func_dinteg_cprtrtu_In2;
  real_T *rtwdemo_func_dinteg_crtrty_Out2;
```

```
  real_T *rtwdemo_func_dinteg_crtrty_Out1;

  rtwdemo_func_dinteg_cp_RT_MODEL rtwdemo_func_dinteg_cpprtM;

  void rtwdemo_func_dinteg_c_func_calc(real_T rtu_u, real_T *rty_y);
};
```

Limitations

These code generation limitations apply to export-function models that include multiple instances of a Simulink Function block.

- You must set the model configuration parameter **Pass root-level I/O as** to `Part of model data structure`.
- Generated code is compatible with single-threaded execution only. To avoid race conditions for shared signal data, invoke instances of the function code from the same execution thread.
- You cannot:
  - Generate code if the export-function model includes model variants.
  - Call the generated code from a Stateflow chart.
  - Enable the external mode data exchange interface.

Generate Reentrant Code from Subsystems

You can reduce the amount of code that the code generator produces for identical atomic subsystems by configuring the subsystems as reusable functions that pass data as arguments (for example, `rtB_*` for block input and output, `rtDW_*` for continuous states, and `rtP_*` for parameters) . By default, the code generator produces subsystem code that communicates with other code by sharing access to global data structures that reside in shared memory. By passing data as arguments, the code can be reentrant. Each instance of the code maintains its own unique data.

To configure subsystems for reusability and reentrancy, configure mask and block parameters of the identical subsystems the same way. The code generator performs a checksum to determine whether subsystems are identical and whether the code is reusable. If the code is reusable, the code generator produces a single instance of reusable, reentrant function code.

To configure the subsystem block parameters:

1. If a subsystem is virtual, select “Treat as atomic unit” (Simulink) to enable function packaging parameters.
2. On the **Code Generation** tab, set “Function packaging” (Simulink) to `Reusable function`. The code generator produces a separate function with arguments for each subsystem. Selecting `Reusable function` also enables additional parameters that you can use to control the names of the function and file that the code generator produces for the subsystem code.
3. Set “Function name options” (Simulink). To generate reusable, reentrant code, specify the same setting for identical subsystems.

   - To let the code generator determine the function name, select `Auto`.
   - To use the subsystem name or, for a library block, the name of the library block, select `Use subsystem name`.
   - To display the “Function name” (Simulink) parameter and enter a unique, valid C/C++ function name, select `User specified`.

   If multiple instances of an identical subsystem exist within a model reference hierarchy, select `Auto`.

   If you are using Embedded Coder, you can use identifier format controls. See “Identifier Format Control” on page 50-24.

4 Set “File name options” (Simulink). To generate reusable, reentrant code, specify the same setting for identical subsystems.

- To let the code generator determine file naming select `Auto`.
- To use the subsystem name or, for a library block, the name of the library block select `Use subsystem name`.
- To use the function name, as specified by **Function name options** select `Use function name`.
- To display the “File name (no extension)” (Simulink) parameter and enter a file name, excluding the extension (for example, `.c` or `.cpp`) select `User specified`.

Other considerations:

- If multiple instances of an identical subsystem exist within a model reference hierarchy, select `Auto`.
- If the code generator does not generate a separate file for a subsystem, the function code is placed in the file generated from the subsystem's parent system. If the parent is the model itself, the code generator places the function code in *`model`*`.c` or *`model`*`.cpp`.
- If your generated code is under source control, specify a value other than `Auto`. This specification prevents the generated file name from changing when you modify and rebuild the model.
- If you select `Use subsystem name`, the code generator mangles the subsystem file name if the model contains Model blocks, or if a model reference target is being generated for the model. In these situations, the code generator uses the file name *`modelsubsystem`*`.c`.

If subsystem A has mask parameter `b` and `K` and subsystem B has mask parameters `c` and `K`, code reuse is not possible. The code generator produces separate functions for subsystems A and B. If you set block parameters for subsystems A and B differently, code reuse is not possible.

Limitations

- The code generator uses a checksum to determine whether subsystems are identical and reusable. Subsystem code is not reused if:

- In blocks and data objects, you use symbols to specify dimensions.
- A port has different sample times, data types, complexity, frame status, or dimensions across subsystems.
- The output of a subsystem is marked as a global signal.
- Subsystems contain identical blocks with different names or parameter settings.
- The output of a subsystem is connected to a Merge block, and the output of the Merge block is configured with a custom storage class that is implemented in the C code as nonaddressable memory (for example, `BitField`).
- The input of a subsystem is nonscalar and is configured with a custom storage class that is implemented in the C code as nonaddressable memory.
- A masked subsystem has a parameter that is nonscalar and is configured with a custom storage class that is implemented in the C code as nonaddressable memory.
- A function-call subsystem uses mask parameters when you set the model configuration parameter “Default parameter behavior” (Simulink Coder) to `Tunable`. To reuse the masked function-call subsystem, place it inside a new atomic subsystem without a mask. Then move the Trigger block from the masked subsystem into the atomic subsystem.
- A block in a subsystem uses a partially tunable expression. Some partially tunable expressions disable code reuse.

  Partially tunable expressions are expressions that contain one or more tunable variables and an expression that is not tunable. For example, suppose that you create the tunable variable `K` with value `15.23` and the tunable variable `P` with value `[5;7;9]`. The expression `K+P'` is a partially tunable expression because the expression `P'` is not tunable. For more information about tunable expression limitations, see “Tunable Expression Limitations” (Simulink Coder).

- For subsystems that contain S-function blocks that are reusable, the blocks must meet the requirements listed in “S-Functions That Support Code Reuse” on page 12-99.
- If you select `Reusable function`, and the code generator determines that you cannot reuse the code for a subsystem, it generates a separate function that is not reused. The code generation report might show that the separate function is reusable, even if only one subsystem uses it. If you prefer that the code generator inline subsystem code in such cases (rather than deployed as functions), set “Function packaging” (Simulink) to `Auto`.
- If a reusable subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.

- Use of these blocks in a subsystem can prevent the subsystem code from being reused:
  - Scope blocks (with data logging enabled)
  - S-Function blocks that fail to meet certain criteria (see “S-Functions That Support Code Reuse” on page 12-99)
  - To File blocks (with data logging enabled)
  - To Workspace blocks (with data logging enabled)
- For reusable library subsystems (subsystems shared across reference models), the code generator uses a checksum to determine whether subsystems are identical. The code generator places the reusable library subsystem code in the shared utilities folder, and the reusable code is independent of the generated code of the top model or the reference model. For example, the reusable library subsystem code does not include *`model`*`.h` or *`model`*`_types.h`.

  Reusable code that the code generator places in the shared utilities folder and is dependent on the model code does not compile. If the code generator determines that the reusable library subsystem code is dependent on the model code, the reusable subsystem code is not placed in the shared utilities folder. The code generator produces code that is dependent on the model code when the reusable library subsystem:

  - Contains a block that uses time-related functionality, such as a Step block, or continuous time or multirate blocks.
  - Contains one or more Model blocks.
  - Contains a subsystem that is not inlined or a reusable library subsystem.
  - Contains a signal that is not configured with storage class `Auto`. The code generator places variables that are configured with a non-`Auto` storage class in *`model`*`.h`.
  - Contains a parameter that is not configure with storage class `Auto`.
  - Contains a user-defined storage class like Enumeration, Simulink.Signal, Simulink.Parameter, etc. where **Data Scope** is not set to `Exported`. The code generator might place the type definition in *`model`*`_types.h`.
  - Is a variant subsystem that generates preprocessor conditionals. The code generator places preprocessor directives that define the variant objects in *`model`*`_types.h`

The above limitations also apply for library-based code generation. For more information, see “Library-Based Code Generation for Reusable Library Subsystems” on page 7-2.

Generate Reusable Code From Referenced Models

Considerations for Subsystems that Contain Referenced Models

You can generate reusable code for subsystems that contain referenced models by using the same procedures and options described in “Control Generation of Functions for Subsystems” on page 3-2. However, consider these restrictions:

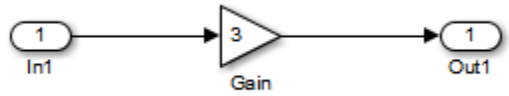
- A top model that uses single-tasking mode and includes a referenced model that uses multi-tasking mode executes for blocks with different rates that are not connected. however, you get an error if the blocks with different rates are connected by a Rate Transition block (inserted manually or by Simulink).
- S-functions that you generate with the Embedded Coder **Code > C/C++ Code > Generate S-function** menu option do not support subsystems that contain a continuous sample time.
- The S-function system target file is not supported.
- The code generator ignores tunable parameters settings that you configure from the Model Parameter Configuration dialog box. To configure parameters to be tunable, define them as Simulink parameter objects in the base workspace.
- The code generator inlines parameters that are not tunable in the generated code and S-function.

Note If you select the S-function system target file, the subsystem block menu options **C/C++ Code > Build This System** and **Code > C/C++ Code > Build Selected Subsystem** behave like **Code > C/C++ Code > Generate S-Function** (see “Generate S-Function from Subsystem” on page 12-74).

Code Reuse and Model Blocks with Root Inport or Outport Blocks

A reusable subsystem function with input or output connected to the root Inport or Outport block of a referenced model can impact code reuse. This can prevent you from reusing atomic subsystems in a reference model context the same way you might reuse the subsystems in a standalone model.

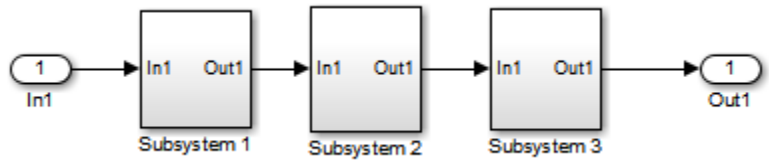
For example, consider this subsystem:



Suppose that you make the following changes to the subsystem block parameters:

- Select “Treat as atomic unit” (Simulink).
- On the **Code Generation** tab, set “Function packaging” (Simulink) to `Reusable function`.

Then, suppose you create this model, which includes three instances of the preceding subsystem.



With the model configuration parameter “Default parameter behavior” (Simulink Coder) set to `Inlined`, the code generator optimizes the code by generating one copy of the function for the reused subsystem.

```
void reuse_subsys1_Subsystem(real_T rtu_In1, B_Subsystem_reuse_subsys1_T *localB)
{
  localB->Gain = 3.0 * rtu_In1;
}
```

If you move the three subsystems into a Model block, you must modify your model and model configuration.

1. Add a Signal Conversion block or a Bias block between Subsystem3 and the Outport block. If the subsystem has a Merge block with initial conditions, do not add a Signal Conversion block. Instead, add a Bias block to obtain a reusable function.
2. Select the model configuration parameter “Pass fixed-size scalar root inputs by value for code generation” (Simulink).

The result is a single reusable function:

```
void reuse_subsys1_Subsystem(real_T rtu_In1, B_Subsystem_reuse_subsys1_T *localB)
{
  localB->Gain = 3.0 * rtu_In1;
}
```

Generate Reusable Code from Library Subsystems Shared Across Models

What Is a Reusable Library Subsystem?

A reusable library subsystem is a subsystem included in a library that is configured for reuse. You must define a subsystem in a library and configure it for reuse to reuse the subsystem across models.

To reuse common functionality, you can include multiple instances of a subsystem:

- Within a single model, which is a top model or part of model reference hierarchy
- Across multiple referenced models in a model reference hierarchy
- Across multiple top models that contain Model blocks
- Across multiple top models that do not include Model blocks

The code generator uses checksums to determine reusability. There are cases when the code generator cannot reuse subsystem code.

For incremental code generation, if the reusable library subsystem changes, a rebuild of itself and its parents occurs. During the build, if a matching function is not found, a new instance of the reusable function is generated into the shared utilities folder. If a different matching function is found from previous builds, that function is used, and a new reusable function is not emitted.

For subsequent builds, unused files are not replaced or deleted from your folder. During development of a model, when many obsolete shared functions exist in the shared utilities folder, you can delete the folder and regenerate the code. If all instances of a reusable library subsystem are removed from a model reference hierarchy and you regenerate the code, the obsolete shared functions remain in the shared utilities folder until you delete them.

If a model changes such that the change might cause different generated code for the subsystem, a new reusable function is generated. For example, model configuration parameters that modify code comments might cause different generated code for the subsystem even if the reusable library subsystem did not change.

Embedded Coder users can generate code from a library that contains subsystems are configured for reuse. For more information, see “Library-Based Code Generation for Reusable Library Subsystems” on page 7-2.

Reusable Library Subsystem Code Placement and Naming

The generated code of a reusable library subsystem is independent of the generated code of the model. Code for the reusable library subsystem is generated to the shared utility folder, `slprj/target/_sharedutils`, instead of the model reference hierarchy folders. The generated code for the supporting types, which are generated to the `.h` file, are also in the shared utilities folder.

For unique naming, reusable function names have a checksum appended to the reusable library subsystem name. For example, the code and files for a subsystem, `SS1`, which links to a reusable library subsystem, `RLS`, might be:

- Function name: `RLS_mgdjlngd`
- File name: `RLS_mgdjlnd.c` and `RLS_mgdjlnd.h`

Configure Reusable Library Subsystem

Set the Subsystem parameters as listed here:

- Select **Treat as an atomic unit**.
- On the **Code Generation** tab:
  - Set **Function packaging** to `Reusable function`.
  - Set the **Function name options**

    and **File name options** parameters to one of the following combinations:

    - Set **Function name options** and **File name options** to `Auto`.
    - Set **Function name options** to `Use subsystem name` and **File name options** to `Use function name`.
    - Set **Function name options** to `User specified` and **File name options** to `Auto` or `Use function name`.
    - Set **Function name options** to `User specified` and **File name options** to `User specified`. Set the same value for the **Function name** and **File name** parameters.

In a model reference hierarchy, if an instance of the reusable library subsystem is in the top model, then on the **Model Referencing** pane of the Configuration Parameters dialog box, you must select the **Pass fixed-size scalar root input by value for code generation** parameter. If you do not select the parameter, a separate shared function is generated for the reusable library subsystem instance in the top model, and a reusable function is generated for instances in the referenced models.

If a reusable library subsystem is connected to the root outport, reuse does not happen with identical subsystems that are not connected to the root outport. However, you can set **Pass reusable system outputs as** to `Individual arguments` on the **Optimizations** pane to make sure that reuse occurs between these subsystems. This parameter requires an Embedded Coder license.

For more information on creating a library, see “Libraries” (Simulink). For an example of creating a reusable library subsystem, see “Generate Reusable Code for Subsystems Shared Across Models” (Simulink Coder).

Configure Models That Include Reusable Library Subsystems

For a model to use a reusable library subsystem, you must configure the model differently depending on whether the model is a reference model or top model. If the subsystem is in a referenced model hierarchy, set the configuration parameter, “Shared code placement” (Simulink Coder) to `Auto`. Otherwise, for each model that uses the subsystem, set the model configuration parameter **Shared code placement** to `Shared location`.

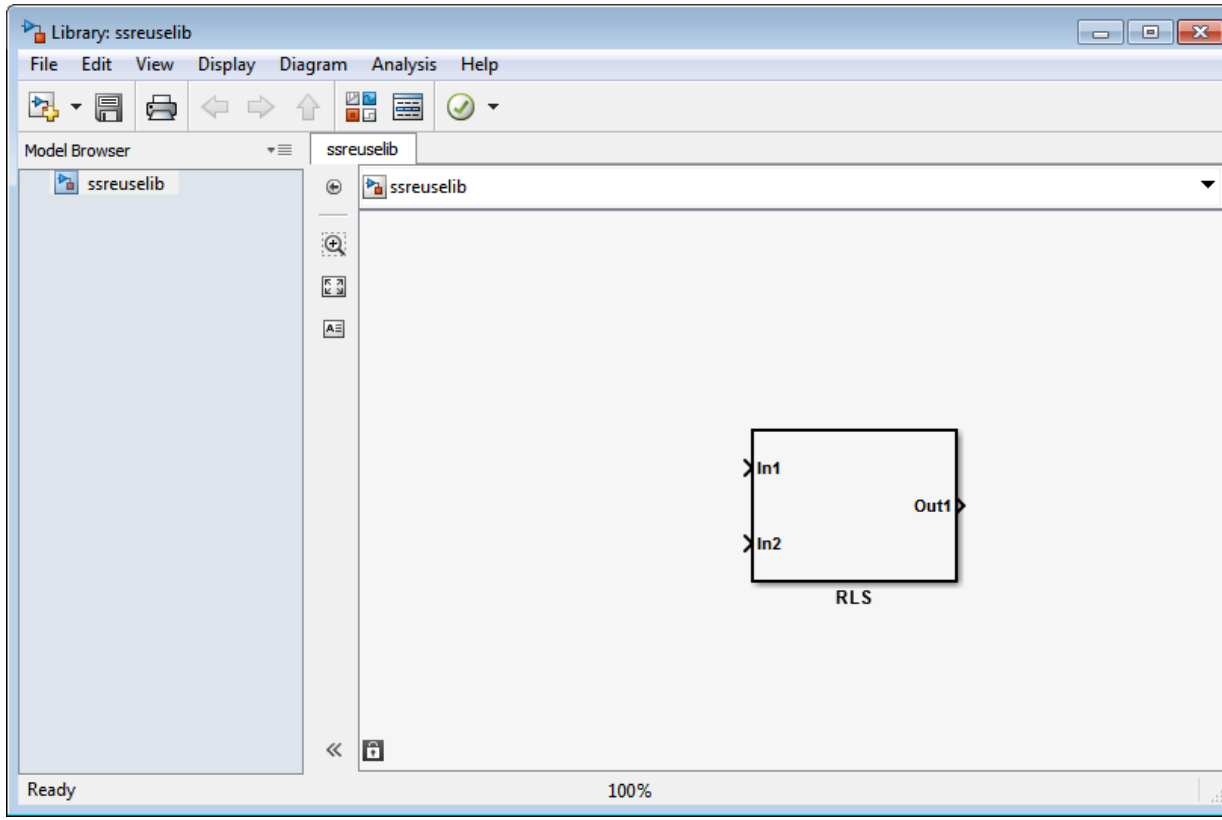
If a reusable library subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.

Generate Reusable Code for Subsystems Shared Across Models

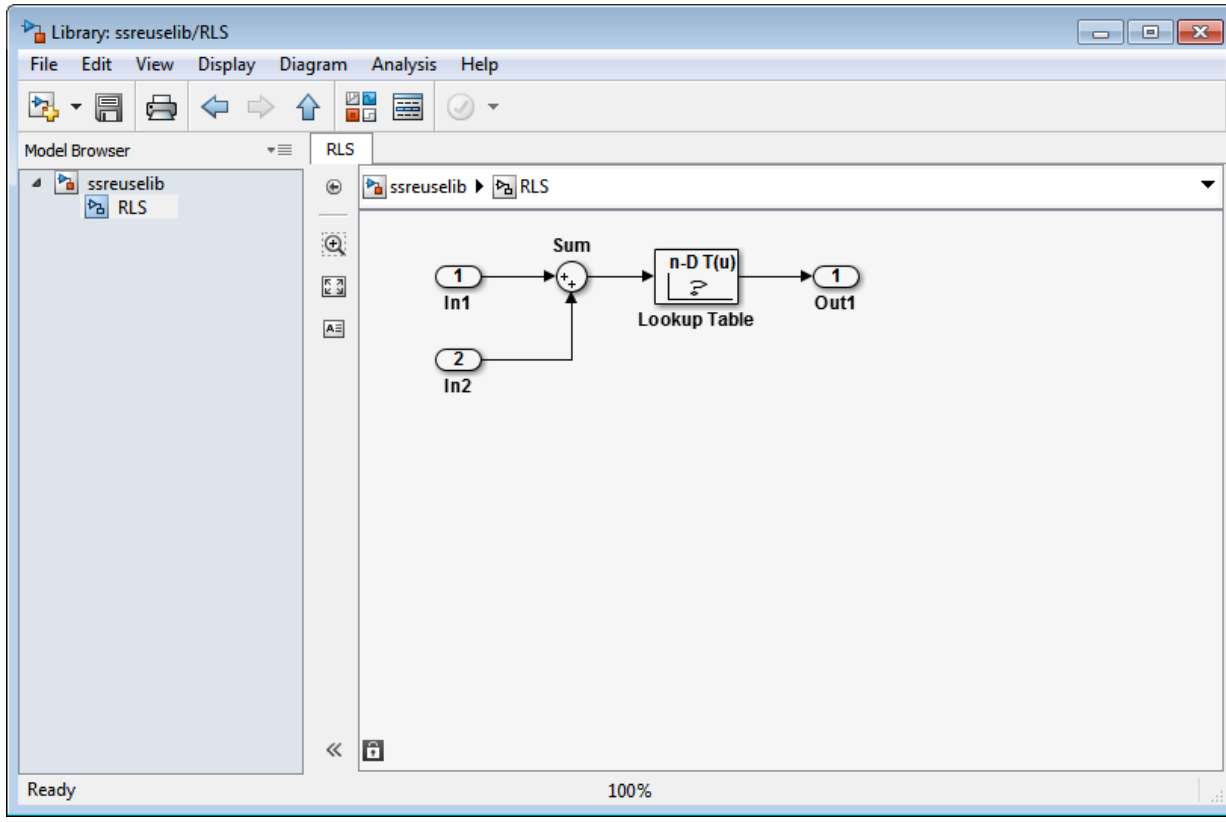
This example shows how to configure a reusable library subsystem and generate a reusable function for a subsystem shared across referenced models. The result is reusable code for the subsystem, which is generated to the shared utility folder (`slprj/`*`target`*`/_sharedutils`).

Create a reusable library subsystem.

1 In the Simulink Editor, select **File > New > Library**. Open `rtwdemo_ssreuse` to copy and paste subsystem `SS1` into the Library Editor. This action loads the variables for `SS1` into the base workspace. Rename the subsystem block to `RLS`.



2 Click the Subsystem block and press **Ctrl+U** to view the contents of subsystem `RLS`.



3 To configure the subsystem, in the Library editor, right-click RLS. In the context menu, select **Block Parameters(Subsystem)**. In the Subsystem Parameters dialog box, choose the following options:

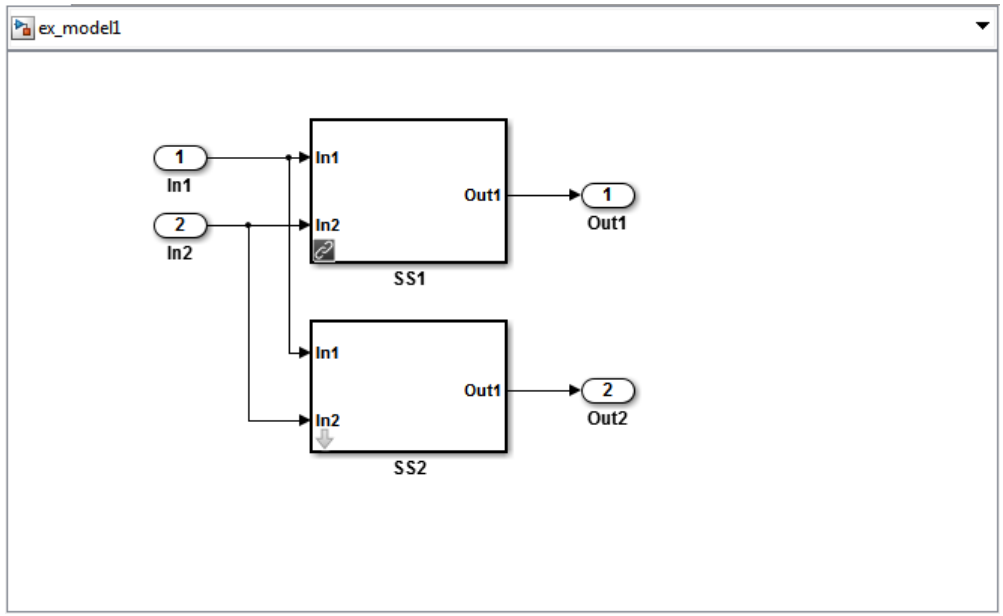
- Select **Treat as an atomic unit**.
- On the **Code Generation** tab:
  - Set **Function packaging** to `Reusable function`.
  - Set **Function name options** to `User specified` and verify that the **Function name** is set to `myfun`.
  - Set **File name options** to `Auto`.

4 Click **Apply** and **OK**.

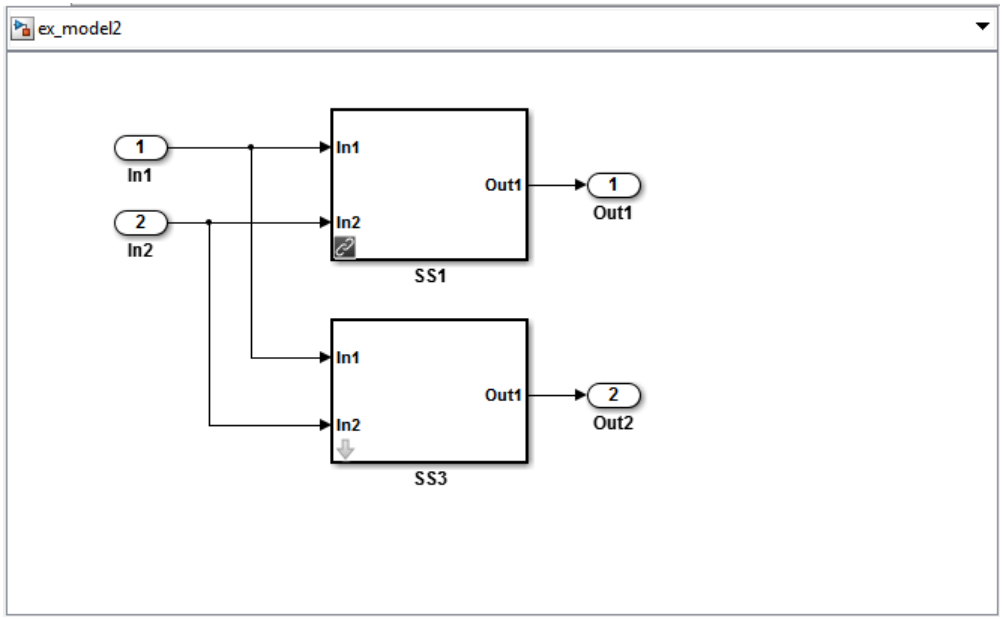
5 Save the reusable library subsystem as `ssreuselib`, which creates a file, `ssreuselib.slx`.

Create the example model.

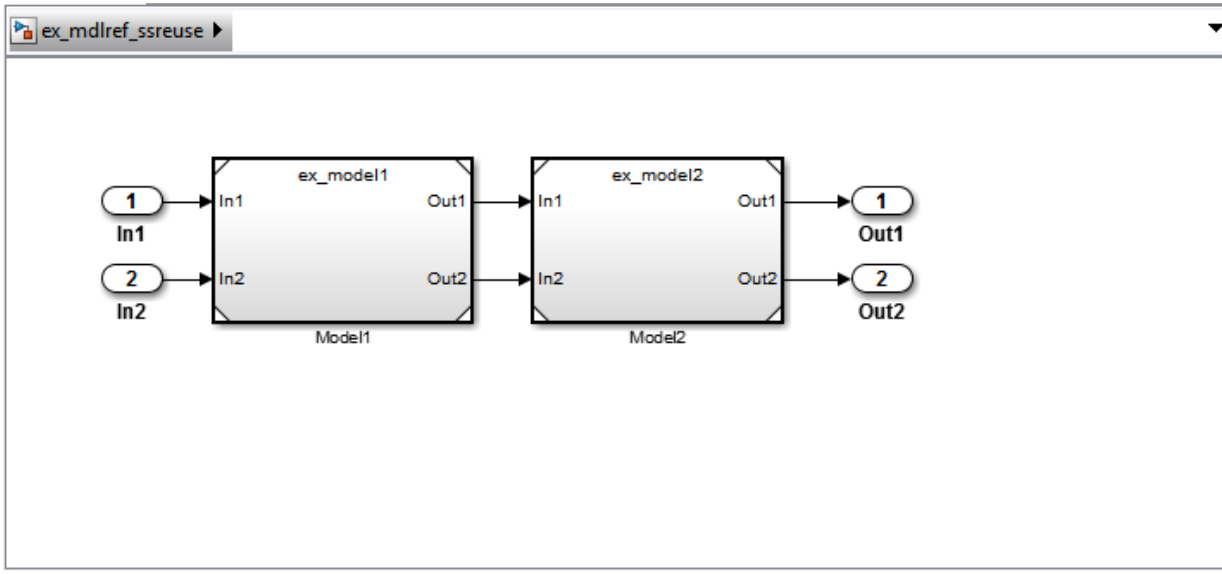
1 Create a model which includes one instance of RLS from `ssreuselib`. Name this subsystem SS1. Add another subsystem and name it SS2. Name the model `ex_model1`.



2 Create another model which includes one instance of RLS from `ssreuselib`. Name this subsystem SS1. Add another subsystem and name it SS3. Name the model `ex_model2`.



3 Create a top model with two model blocks that reference `ex_model1` and `ex_model2`. Save the top model as `ex_mdlref_ssreuse`.



Set configuration parameters of the top model.

1. With model `ex_mdlref_ssreuse` open in the Simulink Editor, select **Simulation > Model Configuration Parameters** to open the Configuration Parameters dialog box.
2. On the **Solver** pane, specify the **Type** as `Fixed-step`.
3. On the **Model Referencing** pane, select **Pass fixed-size scalar root inputs by value for code generation**.
4. On the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.
5. On the **Code Generation > Interface** pane, set the "Shared code placement" (Simulink Coder) to `Shared location`.
6. On the **Code Generation > Symbols** pane, set the **Maximum identifier length** to `256`. This step is optional.
7. Click **Apply** and **OK**.

Create and propagate a configuration reference.

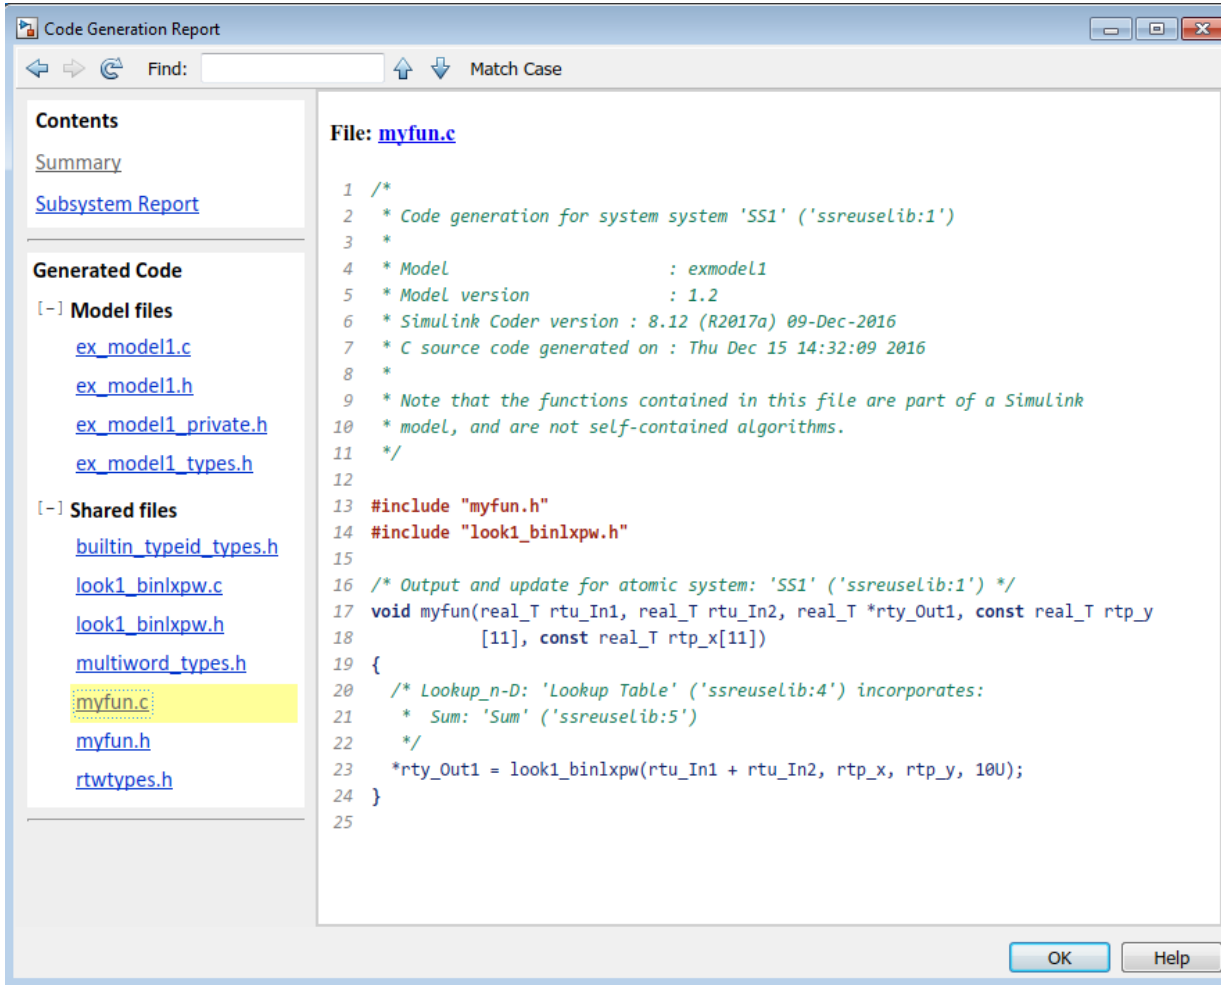
1. In the Simulink Editor, select **View > Model Explorer** to open the Model Explorer. In the left navigation column of the Model Explorer, expand the `ex_mdlref_ssreuse` node.

2. Select the Configurations node below the `ex_mdlref_ssreuse` node. In the **Contents** pane, right-click **Configuration** and select `Convert to Configuration Reference`.
3. In the Convert Active Configuration to Reference dialog box, click **OK**. This action converts the model configuration set to a configuration reference, `Simulink.ConfigSetRef`, and creates the configuration reference object, `configSetObj`, in the base workspace.
4. In the left navigation column, right-click **Reference (Active)** and select `Propagate to Referenced Models`.
5. In the Configuration Reference Propagation to Referenced Models dialog box, select the referenced models in the list. Click **Propagate**.

Now, the top model and referenced models use the same configuration reference, `Reference (Active)`, which points to a model configuration reference object, `configSetObj`, in the base workspace. When you save your model, you also need to export the `configSetObj` to a MAT-file.

Generate and view the code.

1. To generate code, in the Simulink Editor, press **Ctrl+B**. After the code is generated, the code generation report opens.
2. To view the code generation report for a referenced model, in the left navigation pane, in the **Referenced Models** section, select `ex_model1`. The code generation report displays the generated files for `ex_model1`.
3. In the left navigation pane, expand the **Shared files**. The code generator uses the reusable library subsystem name. The code for subsystem `SS1` is in `myfun.c` and `myfun.h`.



4 Click **Back** and navigate to the `ex_model2` code generation report. `ex_model2` uses the same source code, `myfun.c` and `myfun.h`, as the code for `ex_model1`. Your subsystem function and file names will be different.

Generate Reusable Code from Stateflow Atomic Subcharts

Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

1. Open the library model that contains your atomic subchart.
2. Unlock the library.
3. Right-click the library chart and select **Block Parameters**.
4. In the dialog box, specify the following parameters:
   a. On the **Main** tab, select **Treat as atomic unit**.
   b. On the **Code Generation** tab, set **Function packaging** to `Reusable function`.
   c. Set **File name options** to `User specified`.
   d. For **File name**, enter the name of the file without an extension.
   e. Click **OK** to apply the changes.
5. (OPTIONAL) Customize the generated function names for atomic subcharts:
   a. Set model configuration parameter **System target file** to `ert.tlc`.
   b. For model configuration parameter **Subsystem methods**, specify the format of the function names using a combination of the following naming rule tokens:
      - `$R` — root model name
      - `$F` — type of interface function for the atomic subchart
      - `$N` — block name
      - `$H` — subsystem index
      - `$M` — name-mangling text
   c. Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.

Generate Reusable Code for Unlinked Atomic Subcharts

To specify code generation parameters for an unlinked atomic subchart:

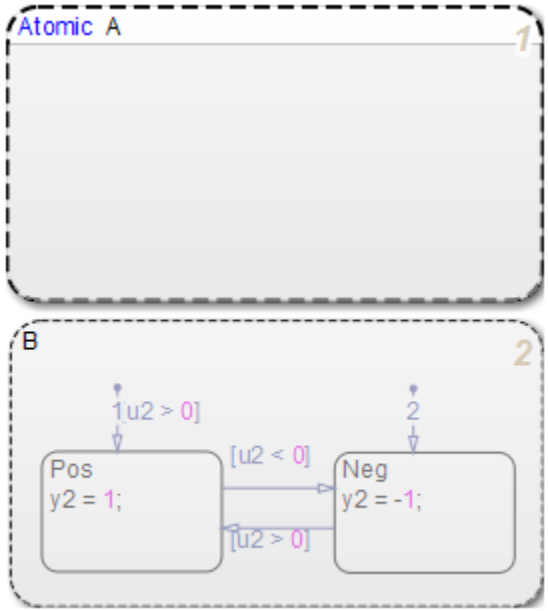
1. In your chart, right-click the atomic subchart and select **Properties**.
2. In the dialog box, specify the following parameters:
   a. Set **Code generation function packaging** to `Reusable function`.
   b. Set **Code generation file name options** to `User specified`.
   c. For **Code generation file name**, enter the name of the file without extension.
   d. Click **OK** to apply the changes.
3. (OPTIONAL) Customize the generated function names for atomic subcharts:
   a. Set model configuration parameter **System target file** to `ert.tlc`.
   b. For model configuration parameter **Subsystem methods**, specify the format of the function names using a combination of the following naming rule tokens:
      - `$R` — root model name
      - `$F` — type of interface function for the atomic subchart
      - `$N` — block name
      - `$H` — subsystem index
      - `$M` — name-mangling text
   c. Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for the atomic subchart. For more information, see “Generate Reusable Code for Unit Testing” on page 11-8.

Generate Reusable Code for Unit Testing

Convert a State to an Atomic Subchart

To convert state A to an atomic subchart, right-click the state and select **Group & Subchart > Atomic Subchart**. State A changes to an atomic subchart:



Set Up a Standalone C File for the Atomic Subchart

1. Open the properties dialog box for A.
2. Set **Code generation function packaging** to `Reusable function`.
3. Set **Code generation file name options** to `User specified`.
4. For **Code generation file name**, enter `saturator` as the name of the file.
5. Click **OK**.

Set Up the Code Generation Report

1. Open the Model Configuration Parameters dialog box.
2. In the **Code Generation** pane, set **System target file** to `ert.tlc`.
3. In the **Code Generation** > **Report** pane, select **Create code generation report**.

   This step automatically selects **Open report automatically** and **Code-to-model**.
4. Select **Model-to-code**.
5. Click **Apply**.

Customize the Generated Function Names

1. In the Model Configuration Parameters dialog box, go to the **Code Generation** > **Symbols** pane.
2. Set **Subsystem methods** to the format scheme `$R$N$M$F`, where:

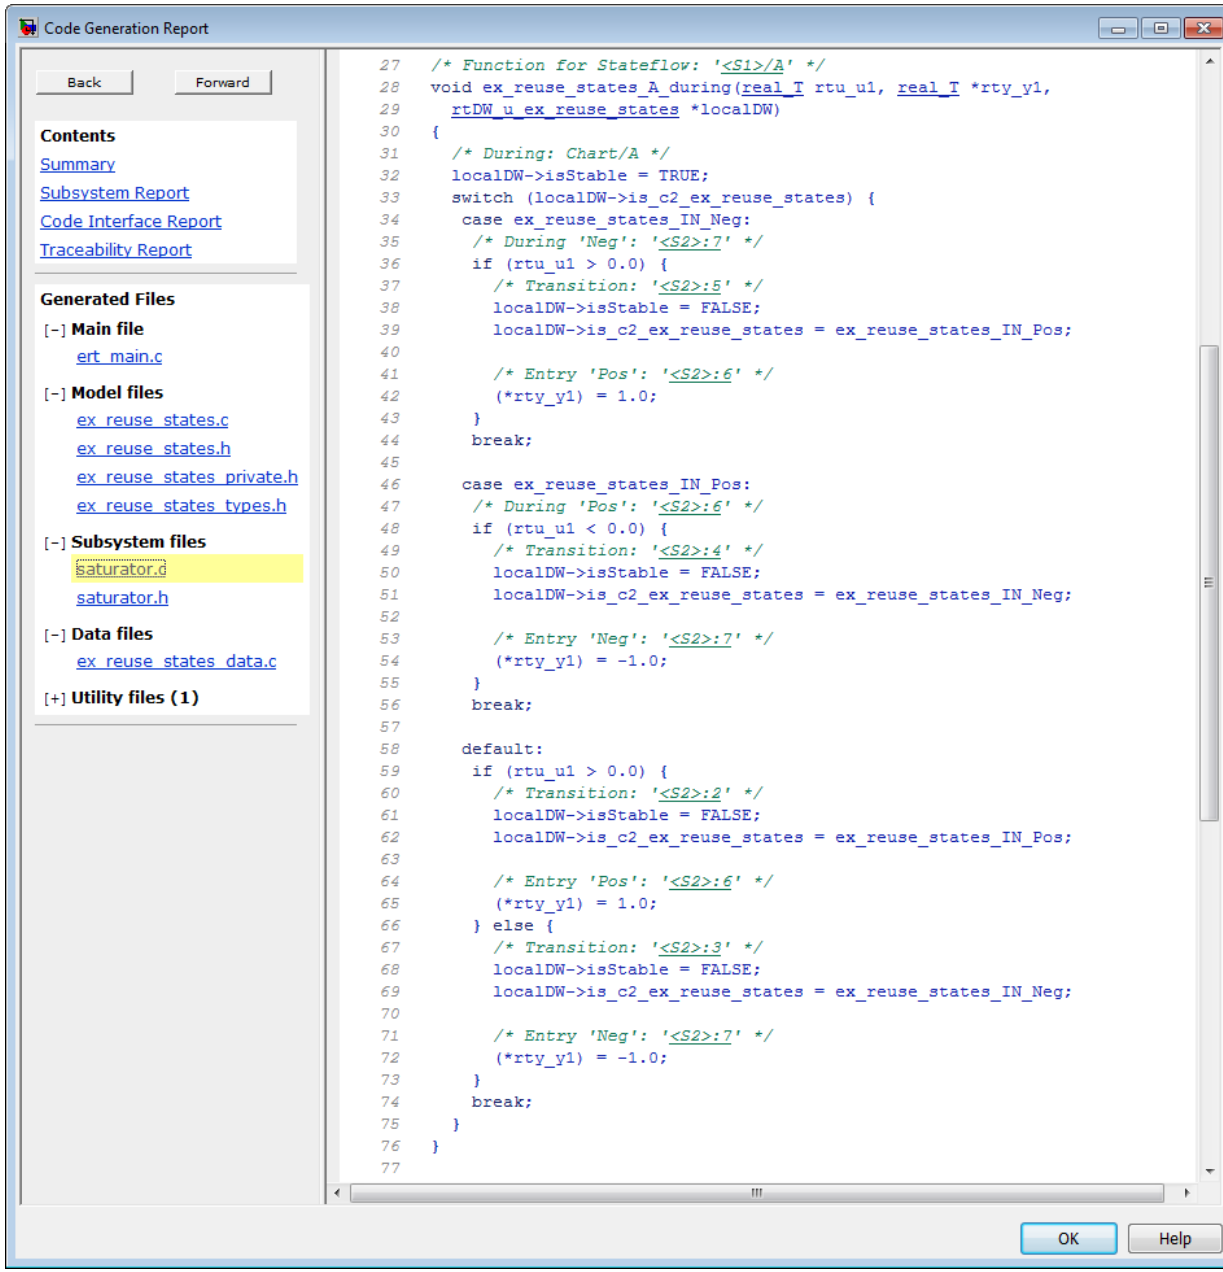
   - `$R` is the root model name.
   - `$N` is the block name.
   - `$M` is the mangle token.
   - `$F` is the type of interface function for the atomic subchart.

   For more information, see “Subsystem methods” (Simulink Coder).
3. Click **Apply**.

Generate Code for Only the Atomic Subchart

To generate code for your model, press **Ctrl+B**. In the code generation report that appears, you see a separate file that contains the generated code for the atomic subchart.

To inspect the code for `saturator.c`, click the hyperlink in the report to see the following code:



```
27  /* Function for Stateflow: '<S1>/A' */
28  void ex_reuse_states_A_during(real_T rtu_u1, real_T *rty_y1,
29    rtDW_u_ex_reuse_states *localDW)
30  {
31    /* During: Chart/A */
32    localDW->isStable = TRUE;
33    switch (localDW->is_c2_ex_reuse_states) {
34     case ex_reuse_states_IN_Neg:
35      /* During 'Neg': '<S2>:7' */
36      if (rtu_u1 > 0.0) {
37        /* Transition: '<S2>:5' */
38        localDW->isStable = FALSE;
39        localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Pos;
40
41        /* Entry 'Pos': '<S2>:6' */
42        (*rty_y1) = 1.0;
43      }
44      break;
45
46     case ex_reuse_states_IN_Pos:
47      /* During 'Pos': '<S2>:6' */
48      if (rtu_u1 < 0.0) {
49        /* Transition: '<S2>:4' */
50        localDW->isStable = FALSE;
51        localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Neg;
52
53        /* Entry 'Neg': '<S2>:7' */
54        (*rty_y1) = -1.0;
55      }
56      break;
57
58     default:
59      if (rtu_u1 > 0.0) {
60        /* Transition: '<S2>:2' */
61        localDW->isStable = FALSE;
62        localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Pos;
63
64        /* Entry 'Pos': '<S2>:6' */
65        (*rty_y1) = 1.0;
66      } else {
67        /* Transition: '<S2>:3' */
68        localDW->isStable = FALSE;
69        localDW->is_c2_ex_reuse_states = ex_reuse_states_IN_Neg;
70
71        /* Entry 'Neg': '<S2>:7' */
72        (*rty_y1) = -1.0;
73      }
74      break;
75    }
76  }
77
```

Line 28 shows that the `during` function generated for the atomic subchart has the name `ex_reuse_states_A_during`. This name follows the format scheme `$R$N$M$F` specified for **Subsystem methods**:

- `$R` is the root model name, `ex_reuse_states`.
- `$N` is the block name, `A`.
- `$M` is the mangle token, which is empty.
- `$F` is the type of interface function for the atomic subchart, `during`.

Note The line numbers shown can differ from the numbers that appear in your code generation report.

Generate Shared Utility Code

When to Generate Shared Utility Code

Blocks in a model can require common functionality to implement their algorithms. Consider modularizing this functionality into standalone support or helper functions. This approach can be more efficient than inlining the code for the functionality for each block instance. To decide about using a library or a shared utility, consider:

- Packaging functions that can have multiple callers into a library when the functions are defined statically. That is, before you use the code generator to produce code for your model, the function source code exists in a file.
- Packaging functions that can have multiple callers as shared utilities (produced during code generation) when the functions cannot be defined statically. For example, several model- and block-specific properties specify which functions are used and their behavior. Also, these properties determine type definitions (for example, `typedef`) in shared utility header files. The number of possible combinations of properties that determine unique behavior make it impractical to define statically the possible function files before code generation.

Configure Naming of Generated Functions

Configure a default naming rule for generated shared utility functions by using one of these methods.

Configuration	Action
A new model or an existing model for which you have mapped default customization settings by using the **Code Mapping Editor** or code default mapping programming interface	In the **Embedded Coder Dictionary**, define a function customization template that specifies a custom function naming rule. Then, in the **Code Mapping Editor** or by using the code default mapping programming interface, map the **Shared utility** function category to that template. For more information, see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7.

Configuration	Action
A model created in a release earlier than R2018a and that has not been configured with the **Code Mapping Editor** or default mapping programming interface	Set the model configuration parameter **Shared utilities identifier format** (`CustomSymbolsStrUtil`) to a custom function naming rule. For more information, see “Identifier Format Control” on page 50-24.

Once you use the **Code Mapping Editor** or default mapping programming interface to configure a model, setting the **Shared utilities identifier format** parameter does not impact code generation.

The naming rule for shared utility functions must include the conditional checksum token `$C`. To customize the length of the checksum that the code generator produces, use the **Shared checksum length** (`SharedChecksumLength`) parameter. Increasing the length of the checksum reduces the probability of clashes.

This example shows the customization of shared utility function names.

1. Open the example model `rtwdemo_crlmath`.
2. Set model configuration parameter **Shared code placement** to `Shared location`.
3. Set parameter **Shared utilities identifier format** as `mymodel_$N$C`. You can customize this format with a string. However, you must include token `$C`.
4. Set parameter **Shared checksum length** to 5.
5. Generate code and a code generation report.
6. In the left navigation pane of the report, review the list generated files for shared utilities under **Shared files**.

Control Placement of Shared Utility Code

Control placement of shared utility code with the model configuration parameter **Shared code placement**. The default option value is `Auto`. For this setting, the code generator places required code for fixed-point and other utilities in the *`model`*`.c` file, the *`model`*`.cpp` file, or a separate file in the build folder (for example, `vdp_grt_rtw`) if a model does not contain existing shared utility code or one of these blocks:

- Model blocks

- Simulink Function blocks
- Function Caller blocks
- Calls to Simulink Functions from Stateflow or MATLAB Function blocks
- Stateflow graphical functions when you select the **Export Chart Level Functions** parameter

If a model contains one or more of the preceding blocks, the code generator creates and uses a shared utilities folder within `slprj`. The naming convention for shared utility folders is `slprj/`*`target`*`/_sharedutils`. *`target`* is `sim` for simulations with Model blocks or the name of the system target file for code generation.

```
slprj/sim/_sharedutils      % folder used with simulation
slprj/grt/_sharedutils      % folder used with grt.tlc STF
slprj/ert/_sharedutils      % folder used with ert.tlc STF
slprj/mytarget/_sharedutils % folder used with mytarget.tlc STF
```

To force a model build to use the `slprj` folder for shared utility generation, even when the current model does not contain existing shared utility code or one of the preceding blocks, set parameter **Shared code placement** to `Shared location`. The code generator places utilities under the `slprj` folder rather than in the normal build folder. This setting is useful when you are manually combining code from several models, because it prevents symbol collisions between the models.

Control Placement of rtwtypes.h for Shared Utility Code

The generated `rtwtypes.h` header file provides fundamental type definitions, `#define` statements, and enumerations. For more information, see “rtwtypes.h” on page 47-50.

Control placement of rtwtypes.h file by selecting whether the build process uses the shared utilities folder. If the model build uses a shared utilities folder, the build process places `rtwtypes.h` in `slprj/`*`target`*`/_sharedutils`. Otherwise, the software places `rtwtypes.h` in *`model_target`*`_rtw`.

Adding a model to a model hierarchy or changing an existing model in the hierarchy can result in updates to the shared `rtwtypes.h` file during code generation. If updates occur, recompile and, depending on your development process, reverify previously generated code. To minimize updates to the `rtwtypes.h` file, make the following changes in the Configuration Parameters dialog box:

- Select **Support: complex numbers** even if the model does not currently use complex data types. Selecting this parameter protects against a future requirement to add support for complex data types when integrating code.

- Clear the **Support non-inlined S-functions** parameter. If you use noninlined S-functions in the model, this option generates an error.
- Clear the **Classic call interface** parameter. This parameter setting disables use of the GRT system target file.

Avoid Duplicate Header Files for Exported Data

Exported header files appear in the shared utility folder when:

- You control the file placement of declarations for signals, parameters, and states by defining and applying storage classes.
- The code generator places utility code in a shared location.

For example, you can specify a header file for a piece of data through:

- A storage class that you define in the **Embedded Coder Dictionary** and map to categories of model data in the **Code Mapping Editor**.
- The **Code Generation** tab in a Signal Properties dialog box.
- The `HeaderFile` property of a data object. Data objects are objects of the classes `Simulink.Signal` and `Simulink.Parameter`.

If you want the declaration to appear in the file *`model`*`.h`, it is a best practice to leave the header file name unspecified. By default, the code generator places data declarations in *`model`*`.h`.

If you specify *`model`*`.h` as the header file name, and if the code generator places utility code in a shared location, you cannot generate code from the model. The code generator cannot create the file *`model`*`.h` in both the model build folder and the shared utility folder.

Reduce Shared Utility Code Generation with Incremental Builds

You can specify that the model build generates C source files in a shared utilities folder. See “Generate Shared Utility Code” (Simulink Coder). These files include C source files that contain function definitions and header files that contain macro definitions. For this discussion, the term functions means functions and macros.

Blocks within the same model and blocks in different models can use a shared function when you use model reference or when you build multiple standalone models from the

same start build folder. The code generator produces the code for a given function only once for the block that first triggers code generation. As the product determines the requirement to generate function code for subsequent blocks, it performs a file existence check. If the file exists, the model build does not regenerate the function. The shared utility code mechanism requires that a given function and file name represent the same functional behavior regardless of which block or model generates the function. To satisfy this requirement:

- Model properties that determine function behavior contribute to the shared utility checksum or determine the function and file name.
- Block properties that determine the function behavior also determine the function and file name.

During compilation, makefile rules for the shared utilities folder select compilation of only new C files and incrementally archive the object file into the shared utility library, `rtwshared.lib`, or `rtwshared.a`. Incremental compilation also occurs.

Manage the Shared Utility Code Checksum

When you set the model configuration parameter **Shared code placement** to `Shared location` or when the model contains Model blocks, the code generator places shared code in the shared utilities folder. The build process generates a shared utilities checksum of the code generation configuration for the shared code.

During subsequent code generation, if the checksum file `slprj/`*`target`*`/_sharedutils/checksummap.mat` exists relative to the current folder, the code generator reads that file. The code generator verifies that the current model that you are building has configuration properties that match the checksum of properties from the shared utility model. If mismatches occur between the properties defined in `checksummap.mat` and the current model properties, you see an error. Use the error message to manage the checksum (for example, diagnose and resolve the configuration issues with the current model).

View the Shared Utility Checksum Hash Table

It is helpful to view the property values that contribute to the checksum. This example uses the `rtwdemo_lct_start_term.slx` model. To load the `checksum.mat` file into MATLAB and view the `targetInfoStruct` that defines the checksum-related properties:

1 Open the `rtwdemo_lct_start_term.slx` model. In the Command Window, type:

```
rtwdemo_lct_start_term
```

2. Create and move to a new working folder.

```
mkdir C:\Temp\demo
cd C:\Temp\demo
```

3. Save a copy of the model in the folder.
4. Build the model. This model is already set up to produce shared utilities.
5. Move to the `_sharedutils` folder created by the build process.

```
cd C:\Temp\demo\slprj\grt\_sharedutils
```

6. Load the `checksummap.mat` file into MATLAB.

```
load checksummap
```

7. Display the contents of `hashTbl.targetInfoStruct` and examine the checksum-related property values.

```
hashTbl.targetInfoStruct
```

For this example, the Command Window displays `hashTbl.targetInfoStruct` for the shared utilities that you generated from the model:

```
>> hashTbl.targetInfoStruct

ans =

  struct with fields:

                  ShiftRightIntArith: 'on'
              ProdShiftRightIntArith: 'on'
                           Endianess: 'LittleEndian'
                       ProdEndianess: 'LittleEndian'

Relate the Shared Utility Checksum to Configuration Parameters

Examine the `targetInfoStruct` hash table from the shared utility model. Some key-value pairs relate directly to a model property. Other pairs relate to groups of properties.

The following table describes the key-value pairs.

Key Names	Model Properties
`ShiftRightIntArith`	`TargetShiftRightIntArith`
`ProdShiftRightIntArith`	`ProdShiftRightIntArith`
`Endianess`	`TargetEndianess`
`ProdEndianess`	`ProdEndianess`

Key Names	Model Properties
wordlengths	TargetBitPerChar, TargetBitPerShort, TargetBitPerInt, TargetBitPerLong, TargetBitPerLongLong, TargetBitPerFloat, TargetBitPerDouble, TargetBitPerPointer
Prodwordlengths	ProdBitPerChar, ProdBitPerShort, ProdBitPerInt, ProdBitPerLong, ProdBitPerLongLong, ProdBitPerFloat, ProdBitPerDouble, ProdBitPerPointer
TargetWordSize	TargetWordSize
ProdWordSize	ProdWordSize
TargetHWDeviceType	TargetHWDeviceType
ProdHWDeviceType	ProdHWDeviceType
TargetIntDivRoundTo	TargetIntDivRoundTo
ProdIntDivRoundTo	ProdIntDivRoundTo
UseDivisionForNetSlopeComputation	UseDivisionForNetSlopeComputation
PurelyIntegerCode	PurelyIntegerCode
PortableWordSizes	PortableWordSizes
SupportNonInlinedSFcns	SupportNonInlinedSFcns
RTWReplacementTypes	EnableUserReplacementTypes, ReplacementTypes
MaxIdInt8	MaxIdInt8
MinIdInt8	MinIdInt8
MaxIdUint8	MaxIdUint8
MaxIdInt16	MaxIdInt16
MinIdInt16	MinIdInt16
MaxIdUint16	MaxIdUint16
MaxIdInt32	MaxIdInt32

Key Names	Model Properties
MinIdInt32	MinIdInt32
MaxIdUint32	MaxIdUint32
MaxIdInt64	MaxIdInt64
MinIdInt64	MinIdInt64
MaxIdUint64	MaxIdUint64
BooleanTrueId	BooleanTrueId
BooleanFalseId	BooleanFalseId
TypeLimitIdReplacementHeaderFile	TypeLimitIdReplacementHeaderFile
SharedCodeRepository	Reserved (internal use only)
TargetLang	TargetLang
PreserveExternInFcnDecls	PreserveExternInFcnDecls
EnableSignedRightShifts	EnableSignedRightShifts
EnableSignedLeftShifts	EnableSignedLeftShifts
TflName	CodeReplacementLibrary
TflCheckSum	Reserved (internal use only)
UtilMemSecName	MemSecFuncSharedUtil, MemSecPackage
CodeCoverageChecksum	Reserved (internal use only)
TargetLargestAtomicInteger	TargetLargestAtomicInteger
TargetLargestAtomicFloat	TargetLargestAtomicFloat
ProdLargestAtomicInteger	ProdLargestAtomicInteger
ProdLargestAtomicFloat	ProdLargestAtomicFloat
LongLongMode	TargetLongLongMode
ProdLongLongMode	ProdLongLongMode
CollapseNonTrivialExpressions	Reserved (internal use only)

Key Names	Model Properties
`toolchainOrTMF`	Name of: • Toolchain if build process uses either a toolchain (`Toolchain`) or a template makefile that is associated with a toolchain. • Template makefile if build process uses template makefile (`TemplateMakefile`).

Generate Shared Utility Code for Fixed-Point Functions

An important set of generated functions that the model build places in the shared utility folder are the fixed-point support functions. Based on model and block properties, there are many possible versions of fixed-point utilities functions that make it impractical to provide a complete set as static files. Generating only the required fixed-point utility functions during the code generation process is an efficient alternative.

The shared utility checksum mechanism makes sure that several critical properties are identical for models that use the shared utilities. For the fixed-point functions, there are additional properties that determine function behavior. The mechanism codes these properties into the functions and file names to maintain requirements. The additional properties include:

Category	Function/Property
Block properties	• Fixed-point operation that the block performs • Fixed-point data type and scaling (`Slope`, `Bias`) of function inputs and outputs • Overflow handling mode (`Saturation`, `Wrap`) • Rounding Mode (`Floor`, `Ceil`, `Zero`)
Model properties	`get_param(bdroot, 'NoFixptDivByZeroProtection')`

The property-based naming convention for the fixed-point utilities is as follows:

```
operation + [zero protection] + output data type + output bits +
[input1 data] + input1 bits + [input2 data type + input2 bits] +
[shift direction] + [saturate mode] + [round mode]
```

The file names shown are examples of generated fixed-point utility files. The function or macro names in the file are identical to the file name without the extension.

```
FIX2FIX_U12_U16.c
FIX2FIX_S9_S9_SR99.c
ACCUM_POS_S30_S30.h
MUL_S30_S30_S16.h
div_nzp_s16s32_floor.c
div_s32_sat_floor.c
```

For these examples, the table shows how the respective fields correspond.

The `ACCUM_POS` example uses the output variable as one of the input variables. So, the file and macro name only contain the output and second input.

The second `div` example has identical data type and bits for both inputs and the output. So, the file and function name only include the output.

Operation	FIX2FIX	FIX2FIX	ACCUM_POS	MUL	div	div
Zero protection	NULL	NULL	NULL	NULL	_nzp	NULL
Output data type	_U	_S	_S	_S	_s	_s
Output bits	12	9	30	30	16	32
Input data type	_U	_S	_S	_S [and _S]	s	NULL
Input bits	16	9	30	30 [and 16]	32	NULL
Shift direction	NULL	SR99	NULL	NULL	NULL	NULL
Saturate mode	NULL	NULL	NULL	NULL	NULL	_sat
Round mode	NULL	NULL	NULL	NULL	_floor	_floor

Generate Shared Utility Code for Custom Data Types

By default, if a model employs a custom data type (such as a `Simulink.AliasType` object or an enumeration class), the code generator places the corresponding type definition (`typedef`) in the *`model`*`_types.h` file. When you generate code from multiple models, each model duplicates the type definition. These duplicate definitions can prevent you from compiling the bodies of generated code together.

However, you can configure the code generator to place a single type definition in a header file in the `_sharedutils` folder. Then, when you generate code from a model, if the type definition already exists in the `_sharedutils` folder, the code generator does not duplicate the definition, but instead reuses it through inclusion (`#include`).

Through this mechanism, you can share:

- Simulink data type objects that you instantiate from the classes `Simulink.AliasType`, `Simulink.Bus`, and `Simulink.NumericType`. For basic information about creating and using these objects, see “Control Data Type Names in Generated Code” on page 34-2 and `Simulink.Bus`.
- Enumerations that you define, for example, by authoring an `enum` class in a script file or by using the function `Simulink.defineIntEnumType`. For basic information about defining enumerations in Simulink, see “Use Enumerated Data in Simulink Models” (Simulink).

To share a custom data type across multiple models:

1. Define the data type. For example, create the `Simulink.AliasType` object.
2. Set data scope and header file properties to specific values that enable sharing.

   For a data type object, set the `DataScope` property to `'Exported'` and, optionally, specify the header file name through the `HeaderFile` property.

   For an enumeration that you define as an `enum` class in a script file, implement the `getDataScope` method (with return value `'Exported'`) and, optionally, implement the `getHeaderFile` method.

   For an enumeration that you define by using the `Simulink.defineIntEnumType` function, set the `'DataScope'` pair argument to `'Exported'` and, optionally, specify the `'HeaderFile'` pair argument
3. Use the data type in the models.

4. Before generating code from each model, set the model configuration parameter **Shared code placement** to `Shared location`.
5. Generate code from the models.

Note You can configure the definition of the custom data type to appear in a header file in the `_sharedutils` folder. The shared utility functions that the model build generates into the `_sharedutils` folder do not use the custom data type name. Only model code located in code folders for each model uses the custom data type name.

Shared Constant Parameters for Code Reuse

You can share the generated code for constant parameters across models if either of the following conditions applies:

- Constant parameters are shared in a model reference hierarchy.
- The model configuration parameter “Shared code placement” (Simulink Coder) is set to `Shared location`.

If you do not want to generate shared constants, and **Shared code placement** is set to `Shared location`, set the parameter `GenerateSharedConstants` to `off`. For example, to turn off shared constants for the current model, in the Command Window, type the following.

```
set_param(gcs,'GenerateSharedConstants','off');
```

The code generator produces shared constant parameters individually and places them in the file `const_params.c`. The code generator places that file in the shared utilities folder `slprj/`*`target`*`/_sharedutils`.

For example, if a constant has multiple uses within a model reference hierarchy where the top model is named `topmod`, the code for the shared constant is as follows:

- In the shared utility folder, `slprj/grt/_sharedutils`, the constant parameters are defined in `const_params.c` and named `rtCP_pooled_` appended to a unique checksum:

  ```
  extern const real_T rtCP_pooled_lfcjjmohiecj[7];
  const real_T rtCP_pooled_lfcjjmohiecj[7] = { 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0 };

  extern const real_T rtCP_pooled_ppphohdbfcba[7];
  const real_T rtCP_pooled_ppphohdbfcba[7] = { 7.0, 6.0, 5.0, 4.0, 3.0, 2.0, 1.0 };
  ```

- In *`top_model`*`_private.h` or in a referenced model, *`ref_model`*`_private.h`, for better readability, the constants are renamed as follows:

  ```
  extern const real_T rtCP_pooled_lfcjjmohiecj[7];
  extern const real_T rtCP_pooled_ppphohdbfcba[7];

  #define rtCP_Constant_Value   rtCP_pooled_lfcjjmohiecj  /* Expression: [1 2 3 4 5 6 7]
                                                           * Referenced by: '<Root>/Constant'*/
  #define rtCP_Gain_Gain        rtCP_pooled_ppphohdbfcba  /* Expression: [7 6 5 4 3 2 1]
                                                           * Referenced by: '<Root>/Gain' */
  ```

- In `topmod.c` or `refmod.c`, the call site might be:

  ```
  for (i = 0; i < 7; i++) {
     topmod_Y.Out1[i] = (topmod_U.In1 + rtCP_Constant_Value[i]) * rtCP_Gain_Gain[i];
  }
  ```

The code generator attempts to generate constants as individual constants to the `const_params.c` file in the shared utilities folder. Otherwise, constants are generated as described in “Code Generation of Constant Parameters” on page 3-13.

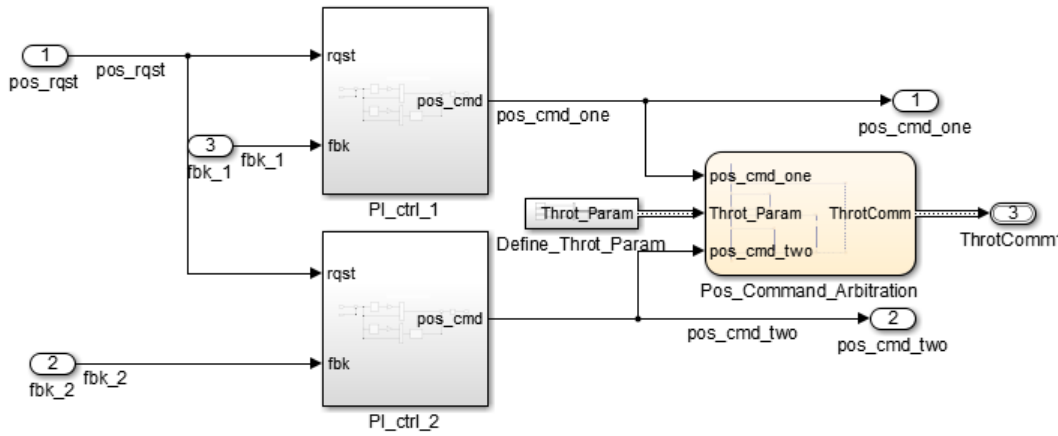
Suppress Shared Constants in the Generated Code

You can choose whether the code generator produces shared constants and shared functions. You might want to be able to keep the code and data separate between subsystems, or you might find that sharing constants results in a memory shortage during code generation.

You can change this setting programmatically by using the parameter `GenerateSharedConstants` with `set_param` and `get_param`.

In the following example, when `GenerateSharedConstants` is set to `on`, the code generator defines the constant values in the `_sharedutils` folder in the `const_params.c` file. When `GenerateSharedConstants` is set to `off`, the code generator defines the constant values in a nonshared area, in the `model_ert_rtw` file in the `model_data.c` file.

Open the model `rtwdemo_throttlecntrl`:



In the Configuration parameters dialog box, on the **Code Generation** > **Interface** pane, verify that “Shared code placement” (Simulink Coder) is set to `Shared location`. If

Shared code placement is set to `Auto`, the `GenerateSharedConstants` setting is ignored. If you try to set the parameter value, an error message appears. The default value of `GenerateSharedConstants` is `on`.

In the Command Window, set `GenerateSharedConstants` to `on`:

```
>> set_param('rtwdemo_throttlecntrl','GenerateSharedConstants','on')
```

You see the shared constant definitions in the folder `slprj/grt/_sharedutils`, in the file `const_params.c`:

```
extern const real_T rtCP_pooled_H4eTKtECwveN[9];
const real_T rtCP_pooled_H4eTKtECwveN[9] = { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6,
  0.75, 1.0 } ;

extern const real_T rtCP_pooled_SghuHxKVKGHD[9];
const real_T rtCP_pooled_SghuHxKVKGHD[9] = { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05,
  0.25, 0.5, 1.0 } ;

extern const real_T rtCP_pooled_WqWb2t17NA2R[7];
const real_T rtCP_pooled_WqWb2t17NA2R[7] = { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25,
  1.0 } ;

extern const real_T rtCP_pooled_Ygnal0wM3c14[7];
const real_T rtCP_pooled_Ygnal0wM3c14[7] = { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0
} ;
```

In the Command Window, set `GenerateSharedConstants` to `off`:

```
>> set_param('rtwdemo_throttlecntrl','GenerateSharedConstants','off')
```

You can see the unshared constants in the folder `rtwdemo_throttlecntrl_grt_rtw`, in the file `rtwdemo_throttlecntrl_data.c`:

```
/* Constant parameters (auto storage) */
const ConstP_rtwdemo_throttlecntrl_T rtwdemo_throttlecntrl_ConstP = {
  /* Pooled Parameter (Expression: P_OutMap)
   * Referenced by:
   *   '<S2>/Proportional  Gain Shape'
   *   '<S3>/Proportional  Gain Shape'
   */
  { 1.0, 0.25, 0.0, 0.0, 0.0, 0.25, 1.0 },

  /* Pooled Parameter (Expression: P_InErrMap)
   * Referenced by:
   *   '<S2>/Proportional  Gain Shape'
   *   '<S3>/Proportional  Gain Shape'
   */
  { -1.0, -0.25, -0.01, 0.0, 0.01, 0.25, 1.0 },

  /* Pooled Parameter (Expression: I_OutMap)
   * Referenced by:
```

```
   *   '<S2>/Integral  Gain Shape'
   *   '<S3>/Integral  Gain Shape'
   */
  { 1.0, 0.75, 0.6, 0.0, 0.0, 0.0, 0.6, 0.75, 1.0 },

  /* Pooled Parameter (Expression: I_InErrMap)
   * Referenced by:
   *   '<S2>/Integral  Gain Shape'
   *   '<S3>/Integral  Gain Shape'
   */
  { -1.0, -0.5, -0.25, -0.05, 0.0, 0.05, 0.25, 0.5, 1.0 }
};
```

Shared constant Parameters Limitations

The code generator does not produce shared constants or shared functions for a model when:

- The model has a code replacement library (CRL) that is specified for data alignment.
- The model is specified to replace data type names in the generated code.
- The **Memory Section** for constants is `MemVolatile` or `MemConstVolatile`.
- The parameter `GenerateSharedConstants` is set to `off`.

Individual constants are not shared, if:

- A constant is referenced by a non-inlined S-function.
- A constant has a user-defined type where **Data Scope** is not set to `Exported`.

More About

- “Generate Reentrant Code from Subsystems” on page 6-43
- “Generate Reusable Code from Library Subsystems Shared Across Models” (Simulink Coder)

Determine Why Subsystem Code Is Not Reused

Due to the limitations described in “Generate Reentrant Code from Subsystems” (Simulink Coder), the code generator might not reuse generated code as you expect. To determine why code generated for a subsystem is not reused:

1. Review the Subsystems section of the code generation report.
2. Compare subsystem checksum data.

Review Subsystems Section of HTML Code Generation Report

If the code generator does not generate code for a subsystem as reusable code, and you configured the subsystem as reusable, examine the Subsystems section of the code generation report (see “Generate a Code Generation Report” (Simulink Coder)). The Subsystems section contains:

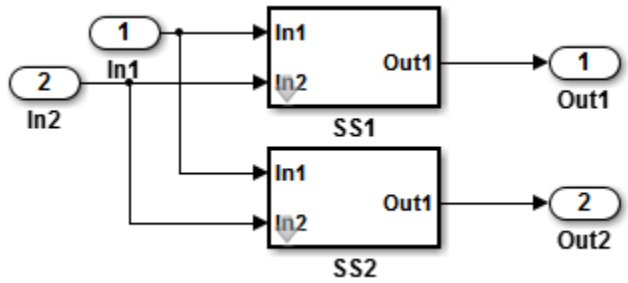
- A table that summarizes how nonvirtual subsystems were converted to generated code.
- Diagnostic information that describes why subsystems were not generated as reusable code.

The Subsystems section also maps noninlined subsystems in the model to functions or reused functions in the generated code. For an example, open and build the `rtwdemo_atomic` model.

Compare Subsystem Checksum Data

You can determine why subsystem code is not reused by comparing subsystem checksum data. The code generator determines whether subsystems are identical by comparing subsystem checksums, as noted in “Limitations” (Simulink Coder). For subsystem reuse across referenced models, this procedure might not flag every difference.

Consider the model, `rtwdemo_ssreuse`. `SS1` and `SS2` are instances of the same subsystem. In both instances the subsystem parameter **Function packaging** is set to `Reusable function`.



Use the method `Simulink.SubSystem.getChecksum` to get the checksum for a subsystem. Review the results to determine why code is not reused.

1. Open the model `rtwdemo_ssreuse`. Save a copy of the model in a folder where you have write access.
2. Associate the subsystems `SS1` and `SS2` with `gcb`. For each of the subsystems , in the model window, select the subsystem. While the subsystem is selected, in the Command Window, enter:

   ```
   SS1 = gcb;

   SS2 = gcb;
   ```
3. Use the method `Simulink.SubSystem.getChecksum` to get the checksum for each subsystem. This method returns two output values: the checksum value and details on the input used to compute the checksum.

   ```
   [chksum1, chksum1_details] = ...
   Simulink.SubSystem.getChecksum(SS1);
   [chksum2, chksum2_details] = ...
   Simulink.SubSystem.getChecksum(SS2);
   ```
4. Compare the two checksum values. The values should be equal based on the subsystem configurations.

   ```
   isequal(chksum1, chksum2)
   ans =
        1
   ```
5. To use `Simulink.SubSystem.getChecksum` to determine why the checksums of two subsystems differ, change the data type mode of the output port of SS1 so that it differs from that of SS2.

a. Look under the mask of `SS1`. Right-click the subsystem. In the context menu, select **MaskLook Under Mask**.

b. In the block diagram of the subsystem, double-click the Lookup Table block to open the Subsystem Parameters dialog box.

c. Click **Data Types**.

d. Select **Saturate on integer overflow** and click **OK**.

6. Get the checksum for `SS1`. Compare the checksums for the two subsystems. This time, the checksums are not equal.

```
[chksum1, chksum1_details] = ...
Simulink.SubSystem.getChecksum(SS1);
isequal(chksum1, chksum2)
ans =
     0
```

7. After you determine that the checksums are different, find out why. The Simulink engine uses information, such as signal data types, some block parameter values, and block connectivity information, to compute the checksums. To determine why checksums are different, compare the data that computes the checksum values. You can get this information from the second value returned by `Simulink.SubSystem.getChecksum`, which is a structure array with four fields.

   Look at the structure `chksum1_details`.

```
chksum1_details

chksum1_details =
          ContentsChecksum: [1x1 struct]
        InterfaceChecksum: [1x1 struct]
     ContentsChecksumItems: [287x1 struct]
    InterfaceChecksumItems: [53x1 struct]
```

   `ContentsChecksum` and `InterfaceChecksum` are component checksums of the subsystem checksum. The remaining two fields, `ContentsChecksumItems` and `InterfaceChecksumItems`, contain the checksum details.

8. Determine whether a difference exists in the subsystem contents, interface, or both. For example:

```
isequal(chksum1_details.ContentsChecksum.Value,...
        chksum2_details.ContentsChecksum.Value)
ans =
     0
```

```
isequal(chksum1_details.InterfaceChecksum.Value,...
        chksum2_details.InterfaceChecksum.Value)
ans =
     1
```

In this case, differences exist in the content.

9 Write a script like this script to find the differences.

```
idxForCDiffs=[];
for idx = 1:length(chksum1_details.ContentsChecksumItems)
    if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Identifier, ...
                chksum2_details.ContentsChecksumItems(idx).Identifier))
            disp(['Identifiers different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
    end
    if (ischar(chksum1_details.ContentsChecksumItems(idx).Value))
            if (~strcmp(chksum1_details.ContentsChecksumItems(idx).Value, ...
                        chksum2_details.ContentsChecksumItems(idx).Value))
            disp(['Character vector values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
            end
    end
    if (isnumeric(chksum1_details.ContentsChecksumItems(idx).Value))
            if (chksum1_details.ContentsChecksumItems(idx).Value ~= ...
                        chksum2_details.ContentsChecksumItems(idx).Value)
            disp(['Numeric values different for contents item ', num2str(idx)]);
            idxForCDiffs=[idxForCDiffs, idx];
            end
    end
end
```

10 Run the script. The example assumes that you named the script `check_details`.

```
check_details
Character vector values different for contents item 202
```

The results indicate that differences exist for index item 202 in the subsystem contents.

11 Use the returned index values to get the handle, identifier, and value details for each difference found.

```
chksum1_details.ContentsChecksumItems(202)

ans =

        Handle: 'rtwdemo_ssreuse/SS1/Lookup Table'
    Identifier: 'SaturateOnIntegerOverflow'
         Value: 'on'
```

The details identify the Lookup Table block parameter **Saturate on integer overflow** as the focus for debugging a subsystem reuse issue.

7

Library-Based Code Generation

Library-Based Code Generation for Reusable Library Subsystems

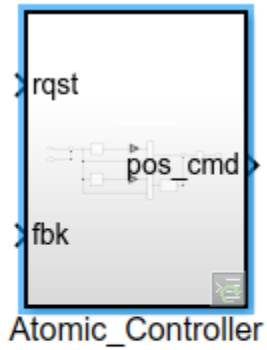
Library-based code generation provides a way of generating code for a set of reusable components that models can share. For each top-level reusable library subsystem, you specify a set of function interfaces that lock down the subsystem interface. A function interface consists of the subsystem input and output block parameter settings and the model configuration parameter settings.

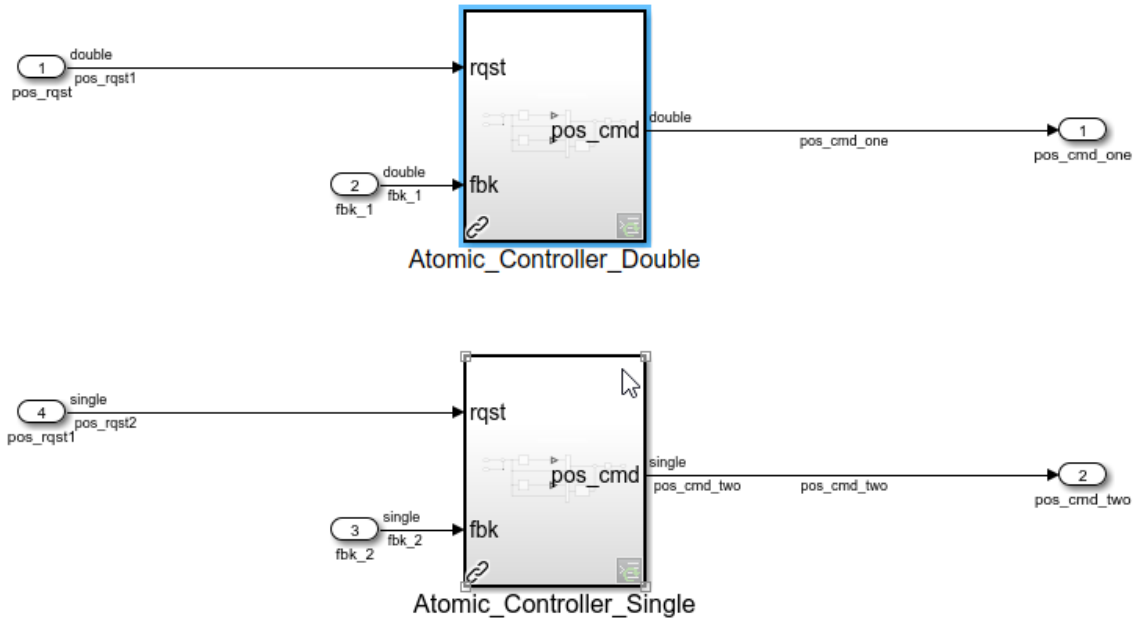
Function interfaces are independent models that you save with an accompanying library. Before generating code for a model containing instances of the reusable library subsystem, you generate code for the library. Library-based code generation makes the library the owner of the code. To make the individual models the owner of the code, you can generate code for reusable library subsystems to the shared utilities folder. For more information, see “Generate Reusable Code from Library Subsystems Shared Across Models” on page 6-51.

Example Model and Library

To show how to use function interfaces and library-based code generation, this example uses the model `rtwdemo_libcodegen_mdl` and library `rtwdemo_libcodegen_lib`. The model contains two instances of the reusable library subsystem `Atomic_Controller`. For `Atomic_Controller_Single`, the input signal data type is `single`. For `Atomic_Controller_Double`, the input signal data type is `double`. To open the model and library files, at the MATLAB command prompt, enter:

```
rtwdemo_libcodegen_mdl
rtwdemo_libcodegen_lib
```





Configure Reusable Library Subsystems

To perform library-based code generation, you must configure the library subsystem as reusable.

1. In the Subsystem block parameters dialog box, select “Treat as atomic unit” (Simulink).
2. In the Subsystem block parameters dialog box, on the **Code Generation** tab, set the “Function packaging” (Simulink) parameter to `Reusable function`.

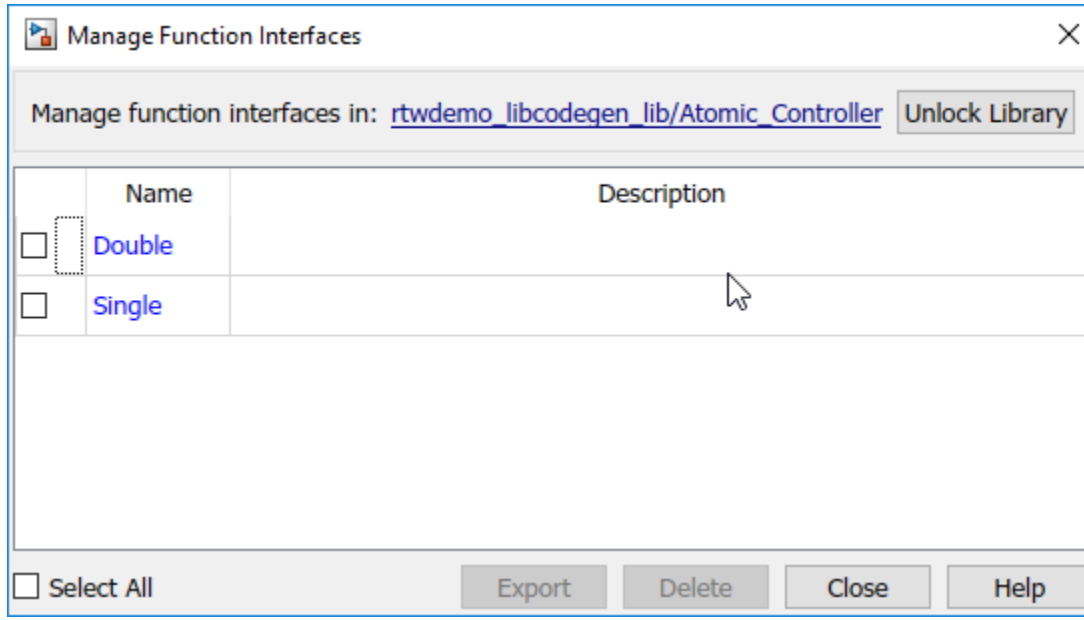
Specify Unique Function Interface Names

Each function interface corresponding to the same reusable library subsystem must have a unique name. To specify a unique name, follow these steps:

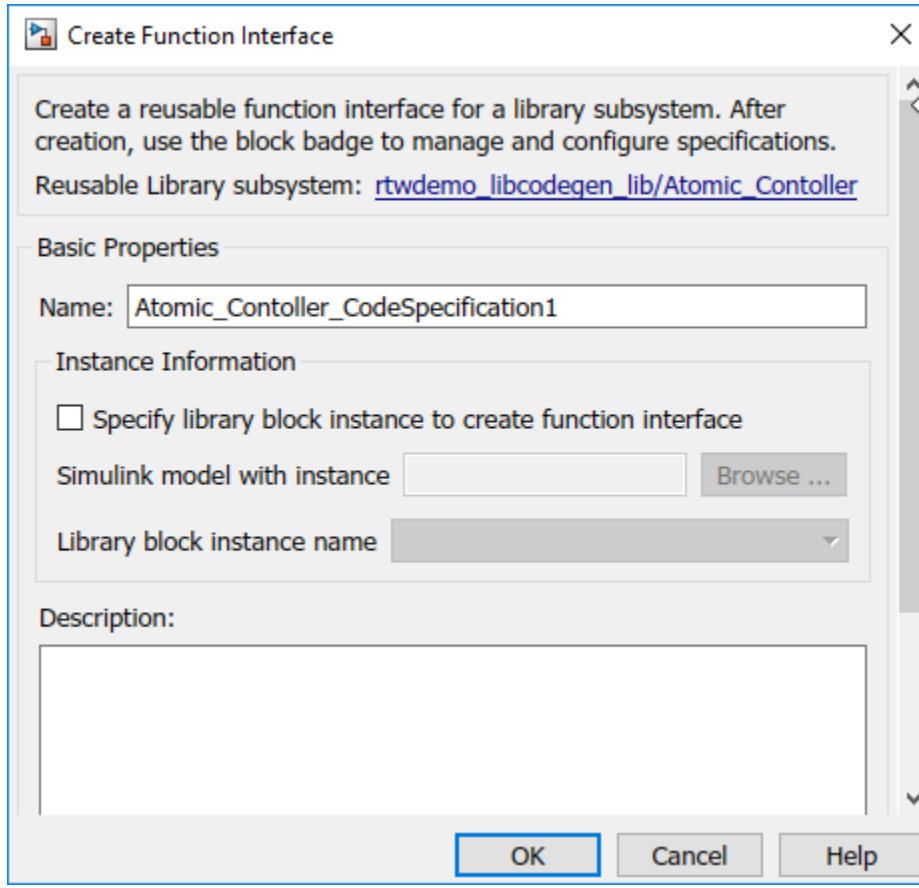
1. In the Subsystem block parameters dialog box, on the **Code Generation** tab, set the **Function name options** parameter to `User specified`.
2. For the **Function name** parameter, specify the `$R` and `$N` tokens. The `$R` token represents the function interface name. The `$N` token represents the subsystem name.
3. In the **Create Function Interface** dialog box, for the **Name** parameter, specify a name that describes the context.
4. Set the **File name option** parameter to `Auto` or `Use function name`.

Configure and Manage Function Interfaces

The model `rtwdemo_libcodegen_mdl` contains two instances of the reusable library subsystem `Atomic_Controller`. Each instance represents a function interface. In the library `rtwdemo_libcodegen_lib`, right-click the badge at the lower rightmost side of the reusable library subsystem `Atomic_Controller`. Select **Manage Function Interfaces**. The two function interfaces have the names `Single` and `Double` because `Atomic_Controller` takes `single` and `double` data types.



To create function interfaces, in a library, right-click a subsystem and select **C/C++ Function Interfaces > Create Function Interface**. Specify a function interface **Name**.



Then, to configure the function interfaces, choose one of the following methods.

Specify a Function Interface from Model

To create function interfaces from linked instances of the reusable library subsystem:

1. In the library, right-click the badge at the lower rightmost side of the reusable library subsystem and select **Create Function Interface**. In the dialog box, select the **Specify library block instance to create function interface** parameter.
2. For the **Simulink model with instance** parameter, select the model that contains the subsystem.

3. For the **Library block instance name** parameter, select the subsystem.
4. Click **OK** and close the **Create Function Interface** dialog box.
5. For each function interface, repeat the preceding steps.

Note You can create a function interface from within a model that contains an instance of a linked reusable library subsystem. You must be in the Code perspective. To open the Code perspective, select **Code > C/C++ Code > Configure Code Perspective**. If the subsystem has function interfaces, a badge appears at the lower-right corner of the subsystem. Right-click the badge and select **Create Function Interface**. If the subsystem does not have function interfaces, right-click the subsystem, and select **C/C++ Function Interfaces > Create Function Interface**.

Export and Configure an Existing Function Interface

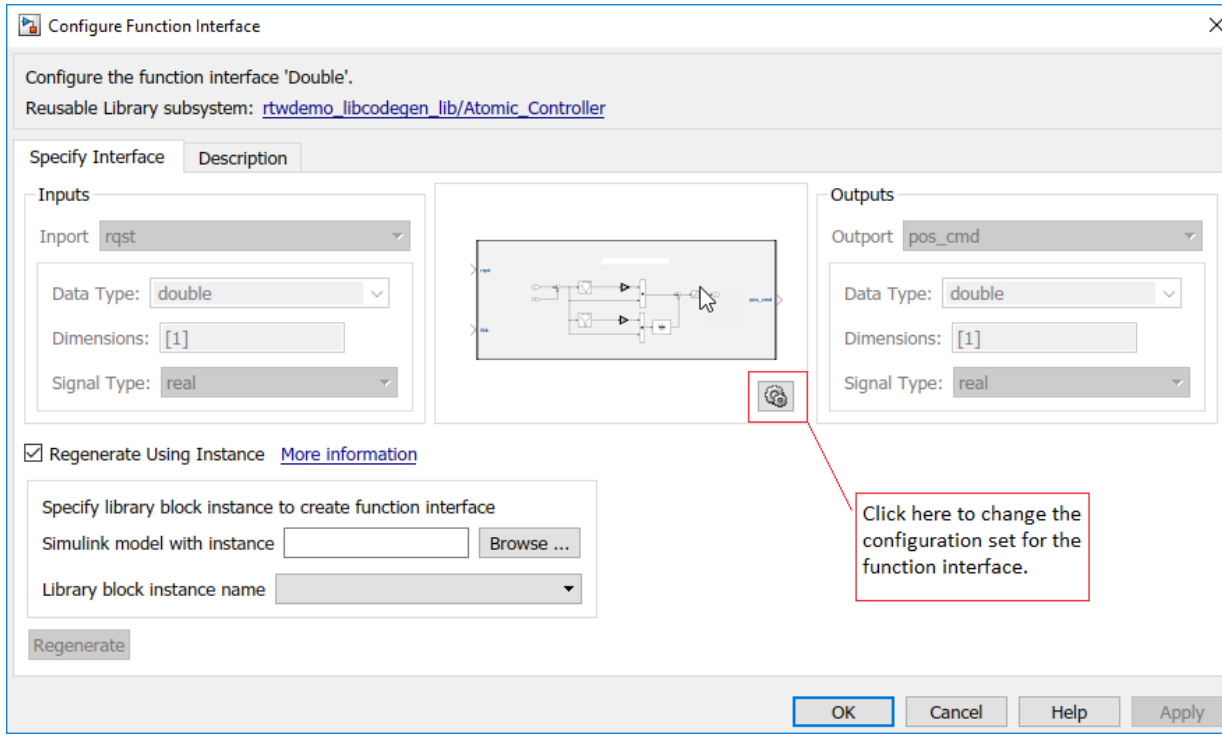
To export and configure the function interface as an independent model:

1. In the library, right-click the badge at the lower rightmost side of the reusable library subsystem and select **Manage Function Interfaces**.
2. Select the function interfaces that you want to modify.
3. Click **Export**.
4. In the **Save As** window, specify the current working folder. An exported function interface is a .slx file that has the function interface name plus the appendix `_export`.
5. Open the exported model. Make your changes to the subsystem input and output block parameter settings and model configuration parameter settings. Save the model.
6. In the library, right-click the reusable library subsystem and select **C/C++ Function Interfaces > Create Function Interface**. Specify a function interface **Name**.
7. For the **Simulink model with instance** parameter, select the exported model that is in the current working folder.
8. For the **Library block instance name** parameter, select the subsystem.
9. Click **OK** and close the **Create Function Interface** dialog box.

Configure Function Interfaces from Within a Library

1. In the library, right-click the badge at the lower rightmost side of the subsystem and select **Configure Function Interface**.

2 In the **Configure Function Interface** dialog box, for the subsystem inputs and outputs, specify values for the **Data Type**, **Dimensions**, and **Signal Type** parameters. To modify other subsystem input and output parameter settings, follow the export method in the preceding section.



3 To modify the model configuration parameters, click the gear button and make the changes. Click **Apply**. Close the Model Configuration Parameters dialog box.

4 To replace a function interface with an existing one from an instance model, select **Regenerate Using Instance**.

5 Specify values for the **Simulink model with instance** and **Library block instance name** parameters. Click **Regenerate**.

6 Click **Apply** and close the **Configure Function Interface** dialog box.

Build the Library

After you specify function interfaces for the subsystems in your library, to generate code, click **Build Library**. Before generating code for your model, you must generate code for the library. The code generator packages the library code as a separate C library. The generated code for the library is in a folder corresponding to your hardware settings (for example, IntelWin64). The library code folder has the same name as the library and must be at the same hierarchical level as the library.

When you generate code for the `rtwdemo_libcodegen_lib` library, the `rtwdemo_libcodegen_lib` folder contains these `.c` and `.h` files:

- `Atomic_Controller_Single.h`
- `Atomic_Controller_Single.c`
- `Atomic_Controller_Double.h`
- `Atomic_Controller_Double.c`

These functions names are representative of the `$N$R` specification for the **Function name options** and **Function name** parameters on the Subsystem block parameters dialog box.

A `_shared` folder contains code for shared utilities (for example, fixed-point utilities and Lookup Table and MATLAB function blocks), supplementary files, and exported parameters and types.

When you generate code for a model that contains an instance of a reusable library subsystem that can use the pregenerated library code, the model links to the library code. The code generator uses a checksum to determine reusability. The generated code for the model must be in the same folder as the library. At the MATLAB command line, enter:

```
Simulink.fileGenControl('set', 'CodeGenFolderStructure',...
 Simulink.filegen.CodeGenFolderStructure.TargetEnvironmentSubfolder);
```

For more information, see `Simulink.fileGenControl`.

If the model is unable to use the library code, you can specify whether or not Embedded Coder produces a warning or an error during code generation. In the Model Configuration Parameters dialog box, set the Behavior when pregenerated library subsystem code is missing diagnostic parameter setting.

You can generate code for a library but not execute a makefile by entering these commands:

```
library='rtwdemo_libcodegen_lib'
set_param(library, 'GenCodeOnly', 'on')
rtwbuild(library)
```

Note You can generate code for a library consisting of reusable subsystems that contain S-functions. To avoid uncompilable code, in the TLC function corresponding to the S-function, avoid directing the code generator to interact with model files, such as *`model`*`.c`, *`model`*`.h`, and *`model_types`*`.h`.

Generate Code from Model Containing a Reusable Library Subsystem Instance

To generate code from a model that contains an instance of a reusable library subsystem for which you want to use the library code:

1. Set the model configuration parameter **Shared code placement** to `Shared location`.
2. Specify a setting for the "Behavior when pregenerated library subsystem code is missing" (Simulink) parameter or leave the default setting, which is warning.
3. In the Model Configuration Parameters dialog box, the parameter settings on the **Code Generation** panes must all be identical to each other. If the settings are different, you might get a warning, error, or neither depending on the setting of the **Behavior when pregenerated library subsystem code is missing** parameter.
4. If a reusable library subsystem uses a shared local data store and you configure default mapping for model data elements, leave the default storage class mapping for category **Shared local data stores** set to **Default**.

Here is the generated C code for `rtwdemo_libcodegen_mdl`.

```
/* Model step function */
void rtwdemo_libcodegen_mdl_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/Atomic_Controller_Double' */

  /* Inport: '<Root>/pos_rqst' incorporates:
   *  Inport: '<Root>/fbk_1'
   *  Outport: '<Root>/pos_cmd_one'
   */
  Atomic_Controller_Double(pos_rqst1, rtU.fbk_1, &rtY.pos_cmd_one,
```

```
    &rtDW.Atomic_Controller_Double);

  /* End of Outputs for SubSystem: '<Root>/Atomic_Controller_Double' */

  /* Outputs for Atomic SubSystem: '<Root>/Atomic_Controller_Single' */

  /* Inport: '<Root>/pos_rqst1' incorporates:
   *  Inport: '<Root>/fbk_2'
   *  Outport: '<Root>/pos_cmd_two'
   */
  Atomic_Controller_Single(pos_rqst2, rtU.fbk_2, &rtY.pos_cmd_two,
    &rtDW.Atomic_Controller_Single);

  /* End of Outputs for SubSystem: '<Root>/Atomic_Controller_Single' */
}
```

The code contains calls to the `Atomic_Controller_Single` and `Atomic_Controller_Double` functions. The generated code pulls the function definitions from the pregenerated library code.

Limitations

Because the code generator uses a checksum to determine reusability, the same limitations that apply to generating code for models that share reusable library subsystems apply to library-based code generation. See “Limitations” on page 6-44. These limitations also apply:

- You cannot specify a function interface on a reusable library subsystem that is within another reusable library subsystem.
- Only ERT and ERT-derived system target files support library-based code generation.
- Each function interface that corresponds to the same reusable library subsystem must be unique.
- Only top-level subsystems can reuse library code.
- On Windows platform, avoid naming the library `lib.slx` as doing so may interfere with the static library compilation process.

Configure Model Parameters for Simulink Coder

Configure Run-Time Environment Options

When you use Simulink software to create and execute a model and use the code generator to produce C or C++ code, consider your configuration for up to three run-time environments:

- The MATLAB development computer run-time environment that runs MathWorks software during application development.
- The production hardware run-time environment in which you deploy an application when it is put into production.
- The test hardware run-time environment in which you test an application under development before deployment.

One run-time environment can serve in multiple capacities, but the run-time environments remain conceptually distinct. Often, the MATLAB development computer is the test hardware. Typically, the production hardware is different from, and less powerful than, the MATLAB development or the test hardware. Many types of production hardware can do little more than run a downloaded executable file.

Provide information about the production hardware board and the compiler that you use with it when:

- You use Simulink software to simulate a model for which you later generate code
- You use the code generator to produce code for deployment on *production* hardware

The software uses the board and compiler information to get bit-true agreement for the results of integer and fixed-point operations performed in simulation and in code generated for the production hardware. The code generator uses the information to create code that executes with maximum efficiency.

When you generate code for testing on *test* hardware, provide information about the test hardware board and the compiler that you use. The code generator uses this information to create code that provides bit-true agreement between results from:

- Integer and fixed-point operations performed in simulation
- Generated code run on the production hardware
- Generated code run on the test hardware

You can achieve bit-true agreement for results even if the production and test hardware are different. Where the C standard does not completely define behavior, the compilers for the two types of hardware can use different defaults.

Configure Production and Test Hardware

You can specify model simulation or code generation for a specific hardware board and its device type. For example, you can set the data size, byte ordering, and compiler behavior, such as integer rounding. You can configure:

- The production hardware and the compiler that you use with it. This information affects simulation and code generation. See “Example Production Hardware Setting That Affects Normal Mode Simulation” on page 8-14.
- The test hardware and the compiler that you use with it. This information affects only code generation.

Configure production hardware by selecting **Configuration Parameters > Hardware Implementation**. By default, the Hardware Implementation pane lists **Hardware board**, **Device vendor**, and **Device type** parameter fields only. Unless you have installed hardware support packages, **Hardware board** lists values `None` or `Determine by Code Generation system target file`, and `Get Hardware Support Packages`. After installing a hardware support package, the list also includes the corresponding hardware board name. If you select a hardware board name, parameters for that board appear. To set device details, such as data size and byte ordering, click **Device details**.

Configure test hardware on the **Configuration Parameters > Hardware Implementation > Advanced parameters** pane. To enable parameters for configuring test hardware details, disable the **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware is the same as production hardware** parameter. Code generated for test hardware executes in the environment specified by the test hardware parameters. The code behaves as if it were executing in the environment specified for the production hardware. For more information, see “Test Hardware Considerations” on page 8-14.

Default values and properties appear as initial values in the **Hardware Implementation** pane when:

- You specify a **System target file** in the **Code Generation** pane.
- The system target file specifies a default microprocessor and its hardware properties.

You cannot change parameters that have only one possible value. Parameters that have more than one possible value provide a list of valid values. If you specify hardware properties manually in **Hardware Implementation** pane, verify that these values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Hardware implementation parameters describe hardware and compiler properties to MATLAB software. The code generator uses the information to produce code for the run-time environment that runs as efficiently as possible. The generated code gives bit-true agreement for the results of integer and fixed-point operations in simulation, production code, and test code.

For details about specific parameters, see “Hardware Implementation Pane” (Simulink). To see an example of **Hardware Implementation** pane capabilities, see the `rtwdemo_targetsettings` example model. For details related to configuring a hardware implementation, see:

Specify Hardware Board

Specify the hardware board that runs the code generated from your model. Select a value for **Configuration Parameters > Hardware Implementation > Hardware board**.

The Hardware Implementation pane identifies the system target file selected on **Configuration Parameters > Code Generation**.

To configure test hardware, use the **Configuration Parameters > Hardware Implementation > Advanced parameters** pane.

To enable parameters for configuring test hardware details, set `ProdEqTarget` to `off`.

Ways to Specify the Hardware Board

If	Select
The menu *includes* the name of the hardware board that you want to use.	The name of that hardware board. If you select a hardware board name, parameters for that board appear.
The menu *does not include* the name of the hardware board that you want to use.	`Get Hardware Support Packages`. That value opens the Support Package Installer. Install the support package that you want. After you install the support package, the menu includes relevant hardware board names.
The model configuration *uses* system target file `ert.tlc`, `realtime.tlc`, or `autosar.tlc`.	`None`. No hardware board is specified for the hardware implementation.
The model configuration *does not use* system target file `ert.tlc`, `realtime.tlc`, or `autosar.tlc`.	`Determine by Code Generation system target file`. The code generator uses the specified system target file to determine the hardware implementation.

Specify Device Vendor

To specify the vendor of the microprocessor of the hardware device, use the **Device vendor** parameter. Your selection determines the available microprocessors in the **Device type** menu. If the vendor name does not appear, select `Custom Processor`. Then, use the **Device type** parameter to specify the microprocessor.

- For complete lists of **Device vendor** and **Device type** values, see “Device vendor” (Simulink) and “Device type” (Simulink).
- To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, see “Register More Device Vendor and Device Type Values” on page 8-6.

Specify the Device Type

To specify the microprocessor name from the supported devices listed for your **Device vendor** selection, use the **Device type** parameter. If the microprocessor does not appear

in the menu, change **Device vendor** to `Custom Processor`. Then, specify device details for your custom device.

If you select a device type for which the system target file specifies default hardware properties, the properties appear as initial values. You cannot change the value of parameters with only one possible selection. Parameters that have more than one possible value provide a menu. Select values for your hardware.

Register More Device Vendor and Device Type Values

To add **Device vendor** and **Device type** values to the default set that is displayed on the **Hardware Implementation** pane, you can use a hardware device registration API provided by the code generator.

To use this API, you create an `sl_customization.m` file, on your MATLAB path, that invokes the `registerTargetInfo` function and fills in a hardware device registry entry with device information. The device information is registered with Simulink software for each subsequent Simulink session. (To register your device information without restarting MATLAB, issue the MATLAB command `sl_refresh_customizations`.)

For example, the following `sl_customization.m` file adds device vendor `MyDevVendor` and device type `MyDevType` to the Simulink device lists.

```
function sl_customization(cm)
  cm.registerTargetInfo(@loc_register_device);
end

function thisDev = loc_register_device
  thisDev = RTW.HWDeviceRegistry;
  thisDev.Vendor = 'MyDevVendor';
  thisDev.Type = 'MyDevType';
  thisDev.Alias = {};
  thisDev.Platform = {'Prod', 'Target'};
  thisDev.setWordSizes([8 16 32 32 32]);
  thisDev.LargestAtomicInteger = 'Char';
  thisDev.LargestAtomicFloat = 'None';
  thisDev.Endianess = 'Unspecified';
  thisDev.IntDivRoundTo = 'Undefined';
  thisDev.ShiftRightIntArith = true;
  thisDev.setEnabled({'IntDivRoundTo'});
end
```

After device registration, you can select the device in the **Hardware Implementation** pane.

To register multiple devices, specify an array of `RTW.HWDeviceRegistry` objects in your `sl_customization.m` file. For example:

```
function sl_customization(cm)
  cm.registerTargetInfo(@loc_register_device);
end

function thisDev = loc_register_device

  thisDev(1) = RTW.HWDeviceRegistry;
  thisDev(1).Vendor = 'MyDevVendor';
  thisDev(1).Type = 'MyDevType1';
  ...

  thisDev(4) = RTW.HWDeviceRegistry;
  thisDev(4).Vendor = 'MyDevVendor';
  thisDev(4).Type = 'MyDevType4';
  ...

end
```

You can specify various `RTW.HWDeviceRegistry` properties in the `registerTargetInfo` function call in your `sl_customization.m` file.

Properties for `registerTargetInfo` Function Call

Property	Description
`Vendor`	Character vector specifying the **Device vendor** value for your hardware device.
`Type`	Character vector specifying the **Device type** value for your hardware device.
`Alias`	Cell array of character vectors specifying aliases or legacy names that can resolve to this device. Specify each alias or legacy name in the format `'Vendor->Type'`. Embedded Coder software provides the utility functions `RTW.isHWDeviceTypeEq` and `RTW.resolveHWDeviceType`. These functions detect and resolve alias values or legacy values when testing user-specified values for the hardware device type.
`Platform`	Cell array of enumerated character vector values specifying whether this device can be listed in the **Production hardware** subpane (`{'Prod'}`), the **Test hardware** subpane (`{'Target'}`), or both (`{'Prod', 'Target'}`).
`setWordSizes`	Array of integer sizes to associate with the **Number of bits** parameters **char**, **short**, **int**, **long**, and **native word size**, respectively.
`LargestAtomicInteger`	Character vector specifying an enumerated value for the **Largest atomic size: integer** parameter: `'Char'`, `'Short'`,`'Int'`, or `'Long'`.
`LargestAtomicFloat`	Character vector specifying an enumerated value for the **Largest atomic size: floating-point** parameter: `'Float'`, `'Double'`, or `'None'`.
`Endianess`	Character vector specifying an enumerated value for the **Byte ordering** parameter: `'Unspecified'`, `'Little'` for little Endian, or `'Big'` for big Endian.
`IntDivRoundTo`	Character vector specifying an enumerated value for the **Signed integer division rounds to** parameter: `'Zero'`, `'Floor'`, or `'Undefined'`.

Property	Description
`ShiftRightIntArith`	Boolean value specifying whether your compiler implements a signed integer right shift as an arithmetic right shift (`true`) or not (`false`).
`setEnabled`	Cell array of character vectors specifying which device properties you can modify in the **Hardware Implementation** pane when you select this device type. This property applies for the `'Endianess'`, `'IntDivRoundTo'`, and `'ShiftRightIntArith'` properties. You can apply this property to individual **Number of bits** parameters by using the property names `'BitPerChar'`, `'BitPerShort'`, `'BitPerInt'`, `'BitPerLong'`, and `'NativeWordSize'`.

Set Bit Lengths for Device Data Types

The **Number of bits** parameters describe the **native word size** of the microprocessor and the bit lengths of **char**, **short**, **int**, and **long** data. For code generation to succeed:

- The bit lengths must be such that **char** <= **short** <= **int** <= **long**.
- Bit lengths must be multiples of 8, with a maximum of 32.
- The bit length for **long** data must not be less than 32.

The `rtwtypes.h` file defines integer type names. The values that you provide must be consistent with the word sizes as defined in the compiler `limits.h` header file. The code generator maps its integer type names to the corresponding Simulink integer type names.

If no ANSI® C type with a matching word size is available, but a larger ANSI C type is available, the code generator uses the larger type for `int8_T`, `uint8_T`, `int16_T`, `uint16_T`, `int32_T`, and `uint32_T`. When the code generator uses a larger type, the resulting logged values (for example, MAT-file logging) can have different data types than logged values for simulation.

An application can use an integer data of length from 1 (unsigned) or 2 (signed) bits up 32 bits. If the integer length matches the length of an available type, the code generator uses that type. If a matching type is not available, the code generator uses the smallest available type that can hold the data, generating code that does not use unnecessary higher-order bits. For example, on hardware that supports 8-bit, 16-bit, and 32-bit

integers, for a signal specified as 24 bits, the code generator implements the data as an `int32_T` or `uint32_T`.

Code that uses emulated integer data is not maximally efficient. This code can be useful during application development for emulating integer lengths that are available only on production hardware. Emulation does not affect the results of execution.

During code generation, the software checks the compatibility of model data types with the data types that you specify for production hardware.

- If none of the lengths that you specify for production hardware integers is 32 bits, the software generates an error.
- If the lengths of data types that the model uses are smaller than the available production hardware integer lengths, the software generates a warning.

Mapping of Integer Types from Code Generator to Simulink

Code Generator Integer Type	Simulink Integer Type
`boolean_T`	`boolean`
`int8_T`	`int8`
`uint8_T`	`uint8`
`int16_T`	`int16`
`uint16_T`	`uint16`
`int32_T`	`int32`
`uint32_T`	`uint32`

Set Byte Ordering for Device

The **Byte ordering** parameter specifies whether the hardware uses `Big Endian` (most significant byte first) or `Little Endian` (least significant byte first) byte ordering. If left as `Unspecified`, the code generator produces code that determines the endianness of the hardware. This setting is the least efficient.

Set Quotient Rounding Behavior for Signed Integer Division

ANSI C does not completely define the quotient rounding technique for compilers to use when dividing one signed integer by another. So, the behavior is implementation-dependent. If both integers are positive, or both are negative, the quotient must round

down. If either integer is positive and the other is negative, the quotient can round up or down.

The **Signed integer division rounds to** parameter instructs the code generator about how the compiler rounds the result of signed integer division. Providing this information does not change the operation of the compiler. It only describes that behavior to the code generator, which uses the information to optimize code generated for signed integer division. The parameter values are:

- `Zero` — If the quotient is between two integers, the compiler chooses the integer that is closer to zero as the result.
- `Floor` — If the quotient is between two integers, the compiler chooses the integer that is closer to negative infinity.
- `Undefined` — If `Zero` or `Floor` do not describe the compiler behavior or if that behavior is unknown, choose this value.

Avoid selecting `Undefined`. When the code generator does not know the signed integer division rounding behavior of the compiler, the model build generates extra code.

The compiler quotient rounding behavior varies according to these values.

You can obtain the compiler implementation for signed integer division rounding from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

Example Quotient Rounding for Zero, Floor, and Undefined

N	D	Ideal N/D	Zero	Floor	Undefined
33	4	8.25	8	8	8
-33	4	-8.25	-8	-9	-8 or -9
33	-4	-8.25	-8	-9	-8 or -9
-33	-4	8.25	8	8	8 or 9

Set Arithmetic Right Shift Behavior for Signed Integers

ANSI C does not define the behavior of right shifts on negative integers for compilers. So, the behavior is implementation-dependent. The **Shift right on a signed integer as arithmetic shift** option instructs the code generator about how the compiler implements right shifts on negative integers. Providing this information does not change the operation

of the compiler. It only describes that behavior to the code generator, which uses the information to optimize the code generated for arithmetic right shifts.

If the C compiler implements a signed integer right shift as an arithmetic right shift, select the option. Otherwise, clear the option. An arithmetic right shift fills bits vacated by the right shift with the value of the most significant bit, which indicates the sign of the number in two's-complement notation. The option is selected by default. If your compiler handles right shifts as arithmetic shifts, this setting is preferred.

- When you select the option, the code generator produces efficient code whenever the Simulink model performs arithmetic shifts on signed integers.
- When the option is cleared, the code generator produces fully portable but less efficient code to implement right arithmetic shifts.

You can obtain the compiler implementation for arithmetic right shifts from the compiler documentation. If documentation is not available, you can determine this behavior by experiment.

Update Release 14 Hardware Configuration

If your model was created before Release 14 and you have not updated the model, the **Configure current execution hardware device** parameter (`TargetUnknown`) value is `'on'` by default.

To update your model, clear the box for **Configuration Parameters** > **Hardware Implementation** > **Advanced parameters** > **Test hardware** > **Configure test hardware**.Or in the Command Window, type:

```
cs = getActiveConfigSet('your_model_name');
set_param(cs,'TargetUnknown','off');
```

This update to your model:

- Enables the **Test Hardware is the same as production hardware** parameter (`ProdEqTarget`), setting the parameter to `'on'`.
- Copies the **Production device vendor and type** parameter (`ProdHWDeviceType`) value to the **Test device vendor and type** parameter (`TargetHWDeviceType`).

To complete the update:

1. Clear the box for **Configuration Parameters** > **Hardware Implementation** > **Advanced parameters** > **Test hardware** > **Test Hardware is the same as**

production hardware. Apply this step only if your production and test hardware are different.

2. Set the parameters in **Configuration Parameters** > **Hardware implementation** > **Advanced parameters** to match your production and test systems.
3. Save the model.

Production Hardware Considerations

When you configure production hardware, consider these points:

- Production hardware can have word sizes and other hardware characteristics that differ from the MATLAB development computer. You can prototype code on hardware that is different from the production hardware or the MATLAB development computer. When producing code, the code generator accounts for these differences.
- The Simulink product uses some of the information in the production hardware configuration. That information enables simulations without code generation to give the same results as executing generated code. For example, the results can detect error conditions that arise on the production hardware, such as hardware overflow.
- The code generator produces code that provides bit-true agreement with Simulink results for integer and fixed-point operations. Generated code that emulates unavailable data lengths runs less efficiently than without emulation. The emulation does not affect bit-true agreement with Simulink for integer and fixed-point results.
- If you change run-time environments during application development, before generating or regenerating code, reconfigure the hardware implementation parameters for the new run-time environment. When code executes on hardware for which it was not generated, bit-true agreement is not always achieved for results of integer and fixed-point operations in simulation, production code, and test code.
- To compile code generated from the model, use the **Integer rounding mode** parameter on model blocks to simulate the rounding behavior of the C compiler that you intend. This setting appears on the **Signal Attributes** pane in the parameter dialog boxes of blocks that can perform signed integer arithmetic, such as the Product and n-D Lookup Table blocks.
- For most blocks, the value of **Integer rounding mode** completely defines rounding behavior. For blocks that support fixed-point data and the simplest rounding mode, the value of **Signed integer division rounds to** also affects rounding. For details, see “Precision” (Fixed-Point Designer).
- When models contain Model blocks, configure models that they reference to use identical hardware settings.

Test Hardware Considerations

By default, the test hardware configuration is the same as the configuration for the production hardware. You can use the generated code for testing in an environment that is identical to the production environment.

If the test and production environments differ, you can generate code that runs on test hardware as if it were running on production hardware:

1. To enable test hardware parameters, clear the box for **Configuration Parameters > Hardware Implementation > Advanced parameters > Test hardware > Test hardware is the same as production hardware**. Or, in the Command Window type:

   ```
   cs = getActiveConfigSet('your_model_name');
   set_param(cs,'ProdEqTarget','off');
   ```

2. Specify device type details through the test hardware (`Target*`) parameters.

If you select a system target file that specifies a default microprocessor and its hardware properties, these default values and properties appear as initial values.

Parameters with only one possible value cannot be changed. If you modify hardware properties, check that their values are consistent with the system target file. Otherwise, the generated code can fail to compile or execute, or can execute but produce incorrect results.

Example Production Hardware Setting That Affects Normal Mode Simulation

Changing some production hardware settings, for example, `ProdLongLongMode` and `ProdIntDivRoundTo`, can affect normal mode simulation results. The following example simulates an adder with four inputs. In the first simulation, `ProdLongLongMode` is disabled. In the second simulation, `ProdLongLongMode` is enabled. In the plot of simulation outputs, you observe small differences between output values in the time step range 125–175.

```
model = 'hwSettingEffect';
new_system(model)
open_system(model)

% Create adder
pos = [140   140   200   340];
add_block('simulink/Math Operations/Add', ...
          [model '/sum_int32'], ...
```

```
          'Inputs','++++', ...
          'SaturateOnIntegerOverflow', ...
          'on', ...
          'Position', ...
          pos)

pos = [75   155   105   175];
add_block('built-in/Inport',[model '/In1'],'Position',pos)
set_param([model '/In1'], 'OutDataTypeStr', ...
          'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In1/1','sum_int32/1')

pos = [75   205   105   225];
add_block('built-in/Inport',[model '/In2'],'Position',pos)
set_param([model '/In2'], 'OutDataTypeStr', ...
           'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In2/1','sum_int32/2')

pos = [75   255   105   275];
add_block('built-in/Inport',[model '/In3'],'Position',pos)
set_param([model '/In3'], 'OutDataTypeStr', ...
          'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In3/1','sum_int32/3')

pos = [75   305   105   325];
add_block('built-in/Inport',[model '/In4'],'Position',pos)
set_param([model '/In4'], 'OutDataTypeStr', ...
           'int32','PortDimensions','1','SampleTime','1');
add_line(model, 'In4/1','sum_int32/4')

pos = [275   230   305   250];
add_block('built-in/Outport',[model '/Out1'],'Position',pos)
add_line(model, 'sum_int32/1','Out1/1')

% Specify input data
t = 0:200;
peakValue = 1.5e9;
in1 = peakValue * sin(t*2*pi/100);
in2 = peakValue * cos(t*2*pi/70);
in3 = -peakValue * sin(t*2*pi/40);
in4 = -peakValue * cos(t*2*pi/30);
set = Simulink.SimulationData.Dataset;
set = set.addElement(1, timeseries(int32(in1),t,'Name','sig1'));
set = set.addElement(2, timeseries(int32(in2),t,'Name','sig2'));
set = set.addElement(3, timeseries(int32(in3),t,'Name','sig3'));
set = set.addElement(4, timeseries(int32(in4),t,'Name','sig4'));

set_param(model, 'LoadExternalInput', 'on');
set_param(model, 'ExternalInput', 'set');

set_param(model, 'StopTime', '50');

% Disable production hardware setting and run first simulation
set_param(model, 'ProdLongLongMode', 'off');
[~, ~, y1] = sim(model, 200);
```

```
% Enable production hardware setting and run second simulation
set_param(model, 'ProdLongLongMode', 'on');
[~, ~, y2] = sim(model, 200);

plot([y1 y2]);
figure(gcf);
```

The difference in behavior is due to the accumulator data type in the Sum block. The **Accumulator data type** block parameter is set to `Inherit: Inherit via internal rule`. For this example, the resulting accumulator data type is 64 bits wide if the use of the C `long long` data type is enabled. Otherwise, it is 32 bits wide. Depending on the input values for the sum block, the 32-bit accumulator can saturate when the 64-bit accumulator does not. Therefore, normal mode behavior can depend on the `ProdLongLongMode` setting. In both cases, the normal mode behavior and production hardware behavior matches bitwise.

Register New Hardware Devices

On the **Hardware Implementation** pane, you can specify parameters that describe target hardware and compiler properties for MATLAB software, which enables you to:

- Observe target hardware during model simulations.
- Generate optimized code for production or test hardware.
- Directly test or deploy generated code on target hardware.

The **Hardware Implementation** pane supports a range of target hardware. To extend the range, register new hardware devices by using the `target.Processor` and `target.LanguageImplementation` classes.

Specify Hardware Implementation for New Device

To register a new hardware device:

1. Create a `target.Processor` object for the new hardware device.

```
myProc = target.create('Processor', ...
                       'Name', 'MyProcessor', ...
                       'Manufacturer', 'MyManufacturer');
```

2. Create a `target.LanguageImplementation` object for language implementation details.

```
myLanguageImplementation = target.create('LanguageImplementation', ...
                                         'Name', 'MyProcessorImplementation');
```

3. Specify language implementation details.

```
myLanguageImplementation.Endianess = target.Endianess.Little;

myLanguageImplementation.AtomicIntegerSize = 64;
myLanguageImplementation.AtomicFloatSize = 64;
myLanguageImplementation.WordSize = 64;

myLanguageImplementation.DataTypes.Char.Size = 8;
myLanguageImplementation.DataTypes.Short.Size = 16;
myLanguageImplementation.DataTypes.Int.Size = 32;
myLanguageImplementation.DataTypes.Long.Size = 64;
myLanguageImplementation.DataTypes.LongLong.IsSupported = true;
myLanguageImplementation.DataTypes.LongLong.Size = 64;
myLanguageImplementation.DataTypes.Float.Size = 32;
```

```
myLanguageImplementation.DataTypes.Double.Size = 64;

myLanguageImplementation.DataTypes.Pointer.Size = 32;

myLanguageImplementation.DataTypes.SizeT.Size = 64;
myLanguageImplementation.DataTypes.PtrDiffT.Size = 64;
```

4 Associate the language implementation with the hardware device.

```
myProc.LanguageImplementations = myLanguageImplementation;
```

5 Save the `target.Processor` object to MATLAB memory.

```
target.add(myProc);
```

On the **Hardware Implementation** pane, you can now set **Device vendor** and **Device type** to `MyManufacturer` and `MyProcessor` respectively.

Create New Hardware Implementation By Modifying Existing Implementation

If an existing hardware implementation contains most of the values you want in a new hardware implementation, you can quickly create the new implementation by creating and modifying a copy of the existing implementation.

1 Create a `target.Processor` object for the new hardware device.

```
myProc = target.create('Processor', ...
                       'Name', 'MyProcessor', ...
                       'Manufacturer', 'MyManufacturer');
```

2 Create a `target.LanguageImplementation` object that copies an existing language implementation.

```
myCopiedImplementation = target.create('LanguageImplementation', ...
                                       'Name', 'MyCopiedImplementation', ...
                                       'Copy', 'Atmel-AVR');
```

3 Specify the required language implementation details. For example, byte ordering.

```
myCopiedImplementation.Endianess = target.Endianess.Big;
```

4 Associate the language implementation with the hardware device.

```
myProc.LanguageImplementations = myCopiedImplementation;
```

5 Save the `target.Processor` object to MATLAB memory.

```
target.add(myProc);
```

Create New Hardware Implementation By Reusing Existing Implementation

If your hardware device requires the same hardware implementation as an existing implementation, you can reuse the existing implementation.

1. Create a `target.Processor` object for the new hardware device.

```
myProc = target.create('Processor', ...
                       'Name', 'MyProcessor', ...
                       'Manufacturer', 'MyManufacturer');
```

2. Retrieve the existing implementation by using the identifier for the device vendor and type, for example, `'ARM Compatible-ARM Cortex'`.

```
existingImplementation = target.get('LanguageImplementation', ...
                                    'ARM Compatible-ARM Cortex');
```

3. Associate the language implementation with the hardware device.

```
myProc.LanguageImplementations = existingImplementation;
```

4. Save the `target.Processor` object to MATLAB memory.

```
target.add(myProc);
```

Create Alternative Identifier for Target Feature Object

To create alternative identifiers for target feature objects, use the `target.Alias` class.

For example, if a `target.Processor` object has a long class identifier, you can create a `target.Alias` object that provides a short identifier for the `target.Processor` object.

1. Retrieve the `target.Processor` object.

```
proccesorObj = target.get('Processor', ...
                          'Analog Devices-ADSP-CM40x (ARM Cortex-M)');
```

2. Use the `target.create` function to create a `target.Alias` object.

```
aliasProcessorObj = target.create('Alias');
```

3. Use `target.Alias` object properties to specify the alternative identifier and original target feature object.

```
aliasProcessorObj.Name = 'myShortName';
aliasProcessorObj.For = proccesorObj;
```

4. Save the `target.Alias` object to MATLAB memory.

```
target.add(aliasProcessorObj);
```

5. To retrieve the original `target.Processor` object, run:

```
target.get('Processor', 'myShortName');
```

Model Protection in Simulink Coder

Protect Models to Conceal Contents

When you want to share a model with a third-party without revealing intellectual property, protect the model. When you create a protected model, you conceal the implementation details of the original model by compiling it into a model reference. The protected model includes derived files to support the optional functionalities that you specify.

When you protect a model, you can allow the user of the protected model to:

- Open a read-only web view of the model, including model contents and block parameters.
- Simulate the model in accelerator (default), rapid accelerator, and normal modes.
- Generate code for a model that includes the protected model.
- Generate HDL code for a model that includes the protected model. To learn about creating protected models with HDL code generation support, see “Create Protected Models to Conceal Contents and Generate HDL Code” (HDL Coder).
- Generate code for the protected model through the standalone interface, if you have Embedded Coder and specify an ERT-based system target file for the model.

You can optionally password-protect each option. If you choose-password protection for one of these options, the software protects the supporting files by using AES-256 encryption.

When you create a protected model:

- By default, Simulink creates and stores a protected version of the model in the current working folder. The protected model has the same name as the source model, with an `.slxp` extension.
- The original model file, with the `.slx` extension, does not change. If you protect the model through a Model block, that Model block does not change.
- The protected model file consists of the model itself and supporting files, depending on the options that you select when you create the protected model.

Create a protected model by using one of these options:

- The Model block context menu.
- The `Simulink.ModelReference.protect` function.

- The Simulink Editor menu bar. To create a protected model from the current model, select **File > Export Model To > Protected Model**.

If your protected model requires supporting files, such as base workspace definitions or a data dictionary, include these files with the model when you share it. For more information, see “Package and Share Protected Models” on page 9-16.

This example shows how to create a protected model for read-only viewing, simulation, or code generation by using the Model block context menu.

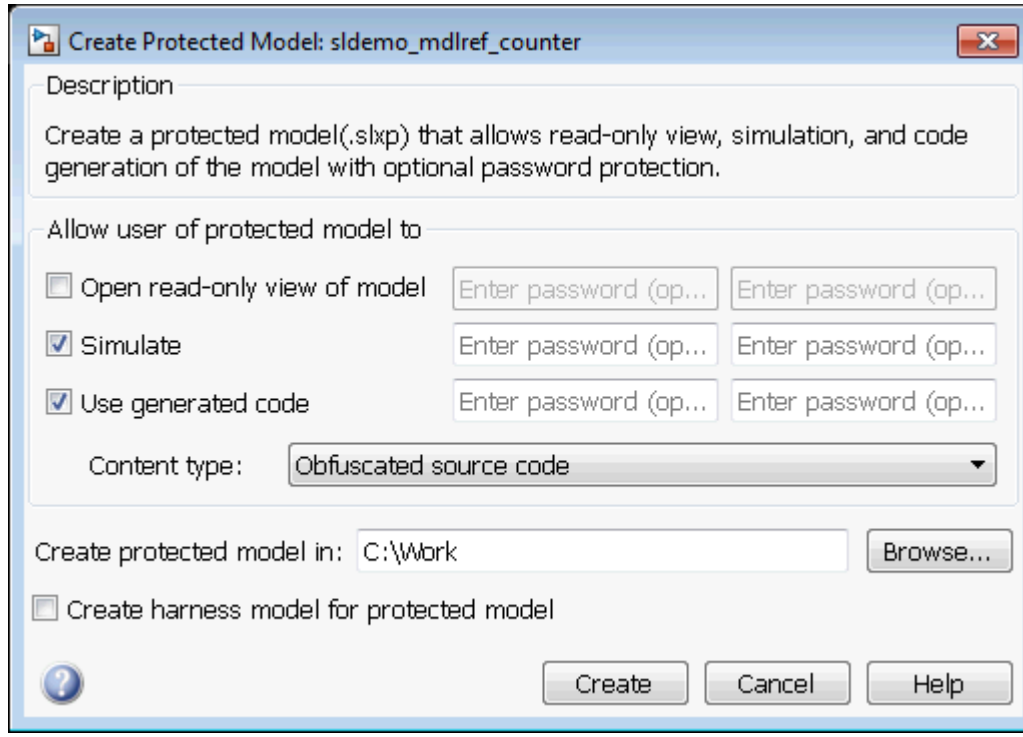
Prepare the Parent Model

Configure the Model blocks in the parent model to refer to the original referenced model. This step prevents the Model blocks from becoming protected references when you create the protected model.

1. Open the parent model that references the model you want to protect. For this example, open the model `sldemo_mdlref_basic`.
2. To run the workflow, create a local copy of the model `sldemo_mdlref_counter` that you want to protect. You can then create a local copy of the parent model `sldemo_mdlref_basic`. You must save the parent model in the same folder as the referenced model.
3. Open the `sldemo_mdlref_basic` model that you saved locally. Make sure that the Model blocks `CounterA`, `CounterB`, and `CounterC` reference the `sldemo_mdlref_counter` model that you saved locally.
4. For each Model block, open the Block Parameters dialog box and specify the extension `.slx` in the **Model name** field. When both the model and the protected model exist in the same folder, `.slxp` takes precedence over `.slx`. If you do not specify an extension, then the original Model block in the model refers to the protected model instead of the original model. Click **OK**.

Protect the Referenced Model

1. Right-click any of the three Model blocks. From the context menu, select **Subsystem & Model Reference > Create Protected Model for Selected Model Block**.



2 In the Create Protected Model dialog box, select the **Simulate** and **Use generated code** check boxes. These options allow the protected model user to simulate and generate code for a model that references the protected model. If you want to password-protect the functionality of the protected model, enter a password with a minimum of four characters. Each option can have a unique password.

3 If you have Embedded Coder and specify an ERT-based system target file (for example, `ert.tlc`) for the model, the **Code interface** field is visible.

In this example, `sldemo_mdlref_basic` does not specify an ERT-based system target file, therefore the **Code interface** options are not available in the Create Protected Model dialog box.

From the **Code interface** drop-down list, select one of these options:

- `Model reference` — Specifies code access through the model reference code interface, which allows use of the protected model within a model reference hierarchy. Users of the protected model can generate code from a parent model

that contains the protected model. Users can run Model block SIL/PIL simulations with the protected model.

- `Top model` — Specifies code access through the standalone interface. Users of the protected model can run Model block SIL/PIL simulations with the protected model.

4 From the **Content type** list, select `Obfuscated source code` to conceal the source code purpose and logic of the protected model. For more information on the model protection options, see “Content type” (Simulink Coder).

5 If you have HDL Coder™, you can select the **Use generated HDL code** check box to generate HDL code for a model that references the protected model. If you want to password-protect this functionality of the protected model, you must specify a minimum of eight characters. You cannot obfuscate the HDL source code for a protected model.

In this example, the referenced model `sldemo_mdlref_counter` uses `double` data types. In the **HDL Code Generation > Floating Point** tab, set **Library** to `Native Floating Point` and **Latency Strategy** to `ZERO`. See also “Create Protected Models to Conceal Contents and Generate HDL Code” (HDL Coder).

6 In the **Create protected model in** field, specify the folder path for the protected model. The default value is the current working folder.

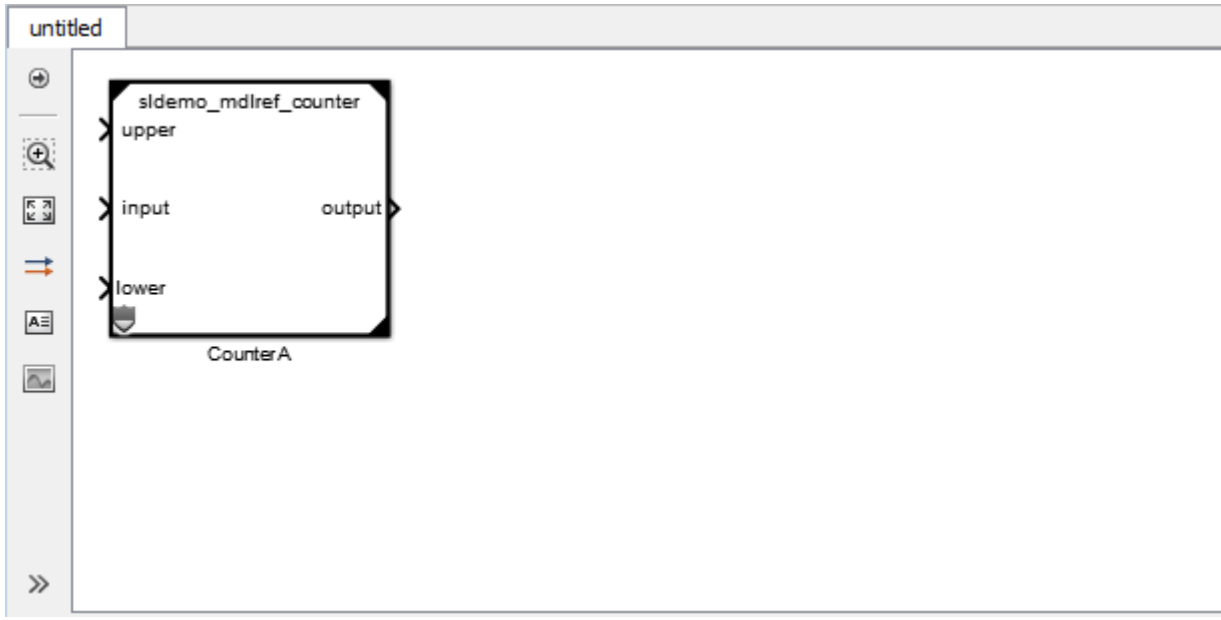
7 To create a harness model for the protected model, select the **Create harness model for protected model** check box. When you create the protected model, the harness model opens as a new, untitled model that contains only a Model block that references the protected model. To use the protected model, reference it through a Model block such as the one included in the harness model. For more information, see “Reference Protected Models from Third Parties” (Simulink).

8 To further customize your protected model, you can:

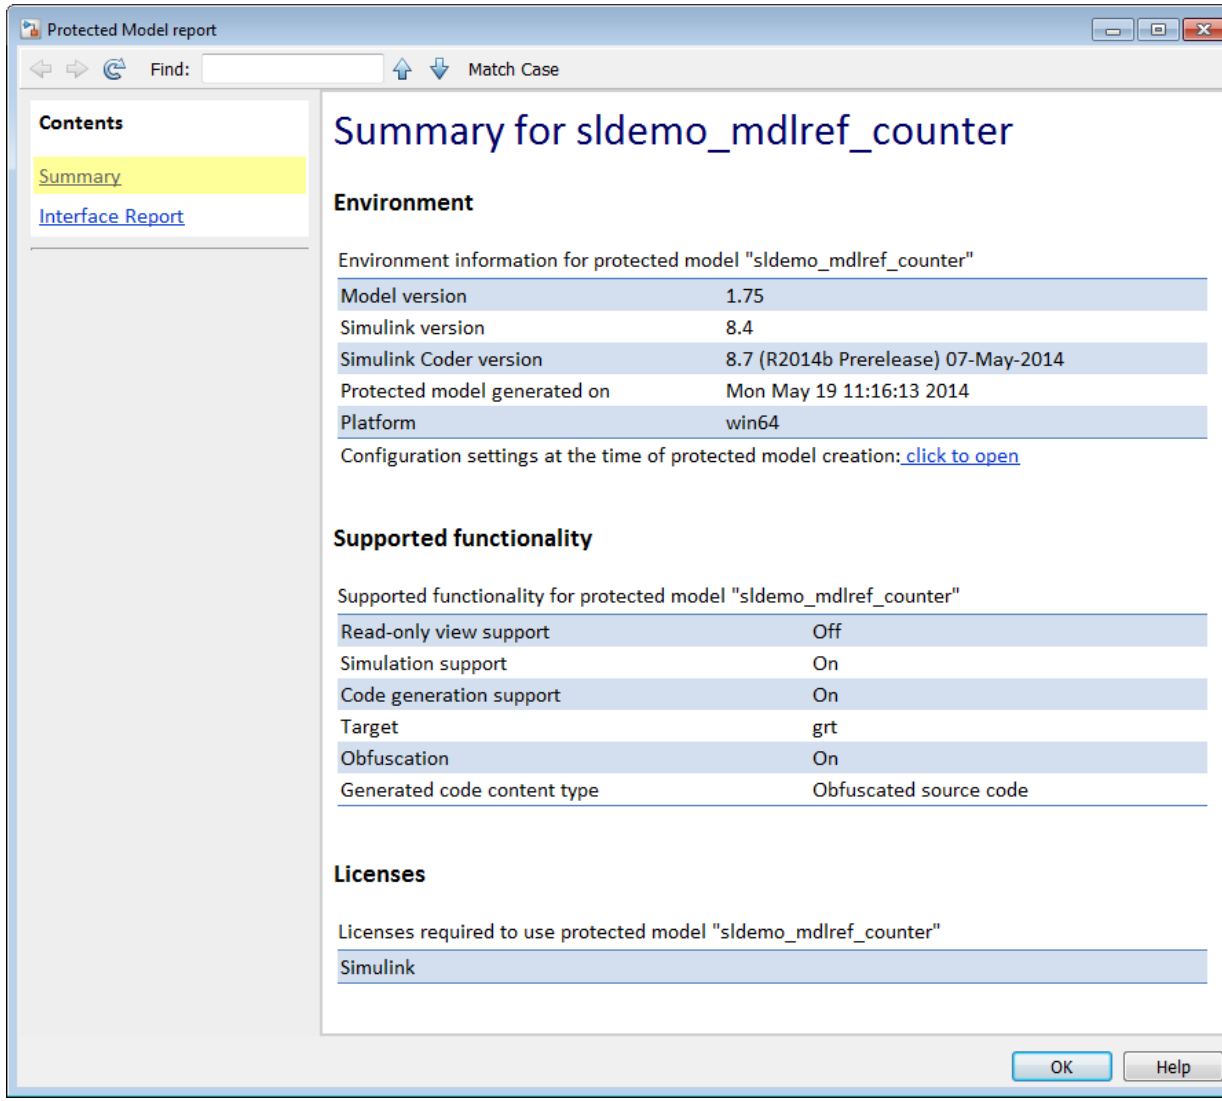
- Specify a custom obfuscator for code obfuscation. See “Specify Custom Obfuscators for Protected Models” on page 9-21.
- Specify multiple code generation targets. See “Create Protected Models with Multiple Targets” on page 9-12.
- Define callbacks for the protected model. See “Define Callbacks for Protected Models” on page 9-23.

9 Click **Create**. An untitled harness model opens. You can package the harness model with the protected model to share with a third-party. They can copy the Model block from the harness model to another model, where it is an interface to the protected

model. The **Simulation mode** for the Model block is set to `Accelerator`. You cannot change the mode.



10 When you create the protected model from the Simulink Editor, a protected model report is generated and included as part of the protected model. For this example, to view the protected model report, double-click the protected model or right-click the protected-model badge icon on the block in the harness model and select **Display Report**.



The report contains:

- A **Summary**, including the following tables:

    - **Environment**, providing the Simulink version and other product versions, and the platform used to create the protected model.
    - **Supported functionality**, reporting `On`, `Off`, or `On with password protection` for each possible functionality that the protected model supports. If you configure your protected model for multiple targets, this table includes a list of supported targets.
    - **Licenses**, listing licenses required to run the protected model.
  - An **Interface Report**, including model interface information such as input and output specifications, exported function information, interface parameters, and data stores.

  To generate a report when using the `Simulink.ModelReference.protect` function, set the '`Report`' option to `true`.

11. You can test the protected model to compare it to the original model. For more information, see "Test Protected Models" on page 9-14.

Protected Model Requirements and Limitations

When you create a protected model, consider these following requirements:

- You must have a Simulink Coder to create a protected model. You can also create a protected model if you have a HDL Coder license.
- The model must be available on the MATLAB path.
- The model cannot have unsaved changes.
- The model cannot use a noninlined S-function directly or indirectly.
- The model uses the configuration that is active during protection. You cannot change the configuration of a protected model.
- If the model contains variants, the protected model includes only the variant that is active during protection.
- The model protection process does not preserve callbacks. For more information on creating callbacks for use with a protected model, see "Define Callbacks for Protected Models" on page 9-23
- Do not rename the protected model or change its suffix. If you do so, the model is unusable until you restore its original name and suffix.
- Use a unique name for the model and for models that it references. If a protected model references a model that shares a name with either a different protected model

or a different model within the hierarchy of another protected model, there are limitations for using the protected models. If a top model references two protected models that have such a naming conflict, you cannot protect the top model, generate code for the top model, or simulate the top model in software-in-the-loop (SIL), processor-in-the-loop (PIL), or rapid accelerator modes.

The model must also meet the requirements listed in “Model Reference Requirements and Limitations” (Simulink).

Code Generation Requirements and Limitations

To create a protected model that supports code generation, your model must meet these requirements:

- The protected model must use normal, accelerator, software-in-the-loop (SIL), or processor-in-the-loop (PIL) modes and a single target.
- Do not select the **Code Generation > Verification > Measure function execution time** check box. If you have this option selected when you protect your model, the software turns off the parameter and displays a warning.
- Protected referenced models must support code generation without password protection.
- The protected model must be compatible with the **Content type** of each protected referenced model. This table provides compatibility information.

Code Generation Content Type Compatibility

Protected Parent Model Content Type	Compatible Protected Referenced Model Content Types
`Binaries`	• `Binaries` • `Obfuscated source code`
`Binaries` with `'ObfuscateCode'` set to `'false'`	• `Binaries` • `Binaries` with `'ObfuscateCode'` set to `'false'` • `Obfuscated source code` • `Readable source code`
`Obfuscated source code`	• `Obfuscated source code`
`Readable source code`	• `Obfuscated source code` • `Readable source code`

When the **Content type** of the protected parent model and protected referenced models do not match, code generation applies the **Content type** that provides the higher level of protection. For example, a protected parent model set for `Binaries` generates `Binaries` for protected referenced models that are set to `Obfuscated source code`. A protected parent model set for `Readable source code` generates `Obfuscated source code` for protected referenced models that are set to `Obfuscated source code`.

To avoid an error during code generation of a model that includes the protected model:

- The protected model name must be unique from other model names in the same model reference hierarchy.
- The interfaces must match.
- The parameters must be compatible.

Nested Protected Model Requirements and Limitations

If your protected model is referenced by another model that is protected, your model must:

- Support accelerator mode. You must select **Simulate** in the Create Protected Model dialog box or set `'Mode'` to `'Accelerator'` or `'CodeGeneration'` by using the `Simulink.ModelReference.protect` function.
- Use the default `'CodeInterface'` setting: `'Model reference'`.
- Not use password-protection for simulation.
- Not have callbacks.
- Support the operations that the protected parent model supports without password-protection.
- Use a **Content type** that is compatible with the **Content type** of the protected parent model if the protected parent model will support code generation. For a list of compatible **Content type** options, see the table in the preceding section.
- Not reference a model that shares a name with either a different protected model or a different model within the hierarchy of another protected model.

If the model that you want to protect references a protected model, the protected referenced model must meet the preceding requirements.

Note A protected model that you create with the **Use generated HDL code** option selected allows encryption and support for simulation and HDL code generation from a model that references the protected model. You cannot obfuscate the HDL source code, have callbacks, or use nested protected models with this option. To learn more about HDL code generation limitations, see “Protected Model Restrictions for HDL Code Generation” (HDL Coder).

- “Create Protected Models with Multiple Targets” on page 9-12
- “Define Callbacks for Protected Models” on page 9-23

Create Protected Models with Multiple Targets

You can create a protected model that supports multiple code generation targets. This example shows how to use command-line functions to create a protected model that supports code generation for GRT and ERT targets.

1. Load a model and save a local copy. This model is configured for a GRT target.

```
sldemo_mdlref_counter
save_system('sldemo_mdlref_counter','mdlref_counter.slx');
```

2. Add a required password for modifying a protected model. If you do not add a password, you are prompted to set a password when you create a modifiable, protected model.

```
Simulink.ModelReference.ProtectedModel.setPasswordForModify(...
'mdlref_counter','password');
```

3. Create a modifiable, protected model with support for code generation.

```
Simulink.ModelReference.protect('mdlref_counter','Mode',...
'CodeGeneration', 'Modifiable',true, 'Report',true);
```

4. Get a list of targets that the protected model supports.

```
 st = Simulink.ProtectedModel.getSupportedTargets('mdlref_counter')
```

```
st =

    'grt'    'sim'
```

5. Configure the unprotected model to support an ERT target.

```
 set_param('mdlref_counter', 'SystemTargetFile', 'ert.tlc');
 save_system('mdlref_counter');
```

6. Add support to the protected model for the ERT target. You are prompted for the modification password.

```
 Simulink.ProtectedModel.addTarget('mdlref_counter');
```

7. Verify that the list of supported targets now includes the ERT target.

```
 st = Simulink.ProtectedModel.getSupportedTargets('mdlref_counter')
```

```
st =

    'ert'    'grt'    'sim'
```

Test Protected Models

To test a protected model that you created, compare the output of the protected model to the output of the original model. Because you supply the protected model from the original model, both the original and the protected model might exist on the MATLAB path. In the parent model, if the Model block **Model name** parameter names the model without providing a suffix, the protected model takes precedence over the unprotected model. To override this default when testing the output, in the Model block **Model name** parameter, specify the file name with the extension of the unprotected model, `.slx`.

To compare the unprotected and protected versions of a Model block, use the Simulation Data Inspector. This example uses `sldemo_mdlref_basic` and the protected model, `sldemo_mdlref_counter.slxp`, which is created in “Protect Models to Conceal Contents” on page 9-2.

1. If it is not already open, open `sldemo_mdlref_basic`.
2. Enable logging for the output signal of the Model block, `CounterA`. In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Signal logging** parameter. Click **Apply** and **OK**.
3. Right-click the output signal. From the context menu, select `Properties`. In the Signal Properties dialog box, select **Log signal data**. Click **Apply** and **OK**. For more information, see “Export Signal Data Using Signal Logging” (Simulink).
4. Right-click the `CounterA` block. From the context menu, select `Block Parameters (ModelReference)`. In the Block Parameters dialog box, specify the **Model name** parameter with the name of the unprotected model and the extension, `sldemo_mdlref_counter.slx`. Click **Apply** and **OK**. Repeat this step for `CounterB` block and `CounterC` block.
5. In the Simulink Editor, click the **Simulation Data Inspector** button arrow and select **Send Logged Workspace Data to Data Inspector** from the menu.
6. Simulate the model. When the simulation is complete, click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
7. In the Simulation Data Inspector, rename the run to indicate that it is for the unprotected model.
8. In the Simulink Editor, right-click the `CounterA` block. From the context menu, select `Block Parameters (ModelReference)`. In the Block Parameters dialog box, specify the **Model name** parameter with the name of the protected model, `sldemo_mdlref_counter.slxp`. A badge icon appears on the Model block. Repeat this step for `CounterB` block and `CounterC` block.

9 Simulate the model, which now refers to the protected model. When the simulation is complete, a new run appears in the Simulation Data Inspector.

10 In the Simulation Data Inspector, rename the new run to indicate that it is for the protected model.

11 In the Simulation Data Inspector, click the **Compare** tab. From the **Baseline** and **Compare To** lists, select the runs from the unprotected and protected model, respectively. To compare the runs, click **Compare Runs**. For more information about comparing runs, see “Compare Simulation Data” (Simulink).

More About

- “Protect Models to Conceal Contents” on page 9-2
- “Package and Share Protected Models” on page 9-16

Package and Share Protected Models

In addition to the protected model file (`.slxp`), you can include additional files in the protected model package. Some ways to deliver the protected model package are:

- Provide the `.slxp` file and other supporting files as separate files.
- Combine the files into a ZIP or other container file.
- Combine the files by using a manifest. For more information, see “Export Files in a Manifest” (Simulink).
- Provide the files in some other standard or proprietary format specified by the receiver.

Whichever approach you use to deliver a protected model, include information on how to retrieve the original files.

Harness Model

You can create a harness model when you create your protected model. The harness model contains a Model block that references the protected model. A third-party can use the Model block to reference your protected model.

MAT-File with Base Workspace Definitions

Referenced models can use object definitions or tunable parameters that are defined in the MATLAB base workspace. These variables are not saved with the model. When you protect a model, you must obtain the definitions of required base workspace entities and ship them with the model.

The following base workspace variables must be saved to a MAT-file:

- Global tunable parameter
- Global data store
- The following objects used by a signal that connects to a root-level model Inport or Outport:
  - `Simulink.Signal`
  - `Simulink.Bus`

- `Simulink.Alias`
- `Simulink.NumericType` that is an alias

To determine the required base workspace definitions and save them to a MAT-file, see "Protected Models for Model Reference" (Simulink). Before executing the protected model as a part of a third-party model, the receiver of the protected model must load the MAT-file.

Simulink Data Dictionary

Referenced models can use data definitions from a data dictionary, which are not saved with the model. When you protect a model that uses a data dictionary, package and ship the data dictionary with the protected model.

Protected Model File Contents

A protected model file (`.slxp`) consists of the derived files that support the options that you selected when you created the protected model. The derived files are unpacked when you or a third-party use the protected model in simulation. You do not need to package these derived files with the protected model.

If you created a protected model for simulation only and the referencing model is in `Normal` mode, after simulation, the *`model`*`.mexext` file is placed in the build folder. The derived files that are unpacked depends on the support that you enabled when creating the protected model.

Protected Model Derived Files

Supported Functionality	Derived Files
Created a protected model for simulation only and the referencing model is in `Normal` mode	The *`model`*`.mexext` file is placed in the build folder.
Created protected model for simulation only and referencing model is in `Accelerator` or `Rapid Accelerator` mode.	These files are unpacked in the `slprj/sim/` folder: • `slprj/sim/`*`model`*`/*.h` • `slprj/sim/`*`model`*`/`*`model`*`lib.a` (or *`model`*`lib.lib`) • `slprj/sim/`*`model`*`/tmwinternal/*` • `slprj/sim/_sharedutils/*` For the protected model report, these additional files are unpacked (but not in the build folder): • `slprj/sim/`*`model`*`/html/*` • `slprj/sim/`*`model`*`/buildinfo.mat`
Created protected model with code generation support.	These files are unpacked in the `slprj` folder after building your model (in addition to the preceding files): • `slprj/sim/`*`model`*`/*.h` • `slprj/sim/`*`model`*`/`*`model`*`lib.a` (or *`model`*`lib.lib`) • `slprj/sim/`*`model`*`/tmwinternal/*` • `slprj/sim/_sharedutils/*` • `slprj/`*`target`*`/`*`model`*`/*.h` • `slprj/`*`target`*`/`*`model`*`/`*`model`*`_rtwlib.a` (or *`model`*`_rtwlib.lib`) • `slprj/`*`target`*`/`*`model`*`/buildinfo.mat` • `slprj/`*`target`*`/`*`model`*`/codeinfo.mat` • `slprj/`*`target`*`/_sharedutils/*` • `slprj/`*`target`*`/`*`model`*`/tmwinternal/*`

Supported Functionality	Derived Files
Specified a `Top model` code interface (requires Embedded Coder license) and enabled code generation support when creating protected model.	These files are unpacked in the `slprj` folder after building your model (in addition to the preceding files): • `slprj/sim/`*`model`*`/*.h` • `slprj/sim/`*`model`*`/`*`model`*`lib.a` (or *`model`*`lib.lib`) • `slprj/sim/`*`model`*`/tmwinternal/*` • `slprj/sim/_sharedutils/*` • *`model_target_rtw`*`/*.h` • *`model_target_rtw`*`/*.objExt` • *`model_target_rtw`*`/buildinfo.mat` • *`model_target_rtw`*`/codeinfo.mat` • `slprj/`*`target`*`/_sharedutils/*` • `slprj/`*`target`*`/`*`model`*`/tmwinternal/*` For the protected model report, after building your model these files are unpacked (in addition to the preceding files): • `slprj/`*`target`*`/`*`model`*`/html/*` • `slprj/`*`target`*`/`*`model`*`/buildinfo.mat` • `slprj/`*`target`*`/_sharedutils/html/*`

Supported Functionality	Derived Files
Created protected model with HDL code generation support (requires HDL Coder license).	The files are unpacked in the `hdlsrc` folder: • `hdlsrc/model/model.vhd`(or `model.v` if you specified `Verilog` as the **Target language**). • `hdlsrc/model/Subsystem.vhd`(or `Subsystem.v` if you specified `Verilog` as the **Target language** of the model that you protected. The additional HDL files depend on how hierarchically the referenced model was designed). • `hdlsrc/model/model_pkg.vhd` (This file is not generated if you specified `Verilog` as the **Target language** of the model that you protected). • `hdlsrc/model/model_report.html` • `hdlsrc/model/gm_model.slxp` (This is a generated protected model).

Note The `slprj/sim/model/*` files are deleted after they are used.

Specify Custom Obfuscators for Protected Models

When creating a protected model, you can specify your own postprocessing function for files that the protected model creation process generates. Before packaging the protected model files, this function is called by the `Simulink.ModelReference.protect` function. You can use this functionality to run your own custom obfuscator on the generated files by following these steps:

1. Create your postprocessing function. Use this function to call your custom obfuscator. The function must be on the MATLAB path and accept a `Simulink.ModelReference.ProtectedModel.HookInfo` object as an input variable.
2. In your function, get the files and exported symbol information that your custom obfuscator requires to process the protected model files. To get the files and information, access the properties of your function input variable. The variable is a `Simulink.ModelReference.ProtectedModel.HookInfo` object with the following properties:
   - `SourceFiles`
   - `NonSourceFiles`
   - `ExportedSymbols`
3. Pass the protected model file information to your custom obfuscator. The following is an example of a postprocessing function for custom obfuscation:

```
function myHook(protectedModelInfo)

    % Get source file list information.
    srcFileList = protectedModelInfo.SourceFiles;
    disp('### Obfuscating...');
    for i=1:length(srcFileList)
        disp(['### Obfuscator: Processing ' srcFileList{i} '...']);
        % call to custom obfuscator
        customObfuscator(srcFileList{i});
    end
end
```

4. Specify your postprocessing function when creating the protected model:

```
Simulink.ModelReference.protect('myModel, ...
    'Mode', ...
    'CodeGeneration', ...
```

```
    'CustomPostProcessingHook', ...
    @(protectedModelInfo)myHook(protectedModelInfo))
```

The protected model creator can also enable obfuscation of simulation target code and generated code through the '`ObfuscateCode`' option of the `Simulink.ModelReference.protect` function. Your custom obfuscator runs only on the generated code and not on the simulation target code or the generated HDL code. If both obfuscators are in use, the custom obfuscator is the last to run on the generated code before the files are packaged.

Define Callbacks for Protected Models

When you create a protected model, you can customize its behavior by defining callbacks. Callbacks specify code that executes when you view, simulate, or generate code for the protected model. You cannot have protected model callbacks with HDL code generation support enabled for a protected model. To learn more about HDL code generation limitations, see “Protected Model Restrictions for HDL Code Generation” (HDL Coder).

A protected model user cannot view or modify a callback. If a model references a protected model with callbacks, you cannot protect the model.

To create a protected model with callbacks:

1. Define `Simulink.ProtectedModel.Callback` objects for each callback.
2. To create your protected model, call the `Simulink.ModelReference.protect` function. Use the `'Callbacks'` option to specify a cell array of callbacks to include in the protected model.

Creating Callbacks

To create and define a protected model callback, create a `Simulink.ProtectedModel.Callback` object. Callback objects specify:

- The code to execute for the callback. The code can be a character vector of MATLAB commands or a script on the MATLAB path.
- The event that triggers the callback. The event can be `'PreAccess'` or `'Build'`.
- The protected model functionality that the event applies to. The functionality can be `'CODEGEN'`, `'SIM'`, `'VIEW'`, or `'AUTO'`. If you select `'AUTO'`, and the event is `'PreAccess'`, the callback applies to each functionality. If you select `'AUTO'`, and the event is `'Build'`, the callback applies only to `'CODEGEN'` functionality. If you do not select a functionality, the default behavior is `'AUTO'`.
- The option to override the protected model build process. This option applies only to `'CODEGEN'` functionality.

You can create only one callback per event and per functionality.

Defining Callback Code

You can define the code for a callback by using either a character vector of MATLAB commands or a script on the MATLAB path. When you write callback code, follow these guidelines:

- Callbacks must use MATLAB code (`.m` or `.p`).
- The code can include protected model functions or a MATLAB command that does not require loading the model.
- Callback code must not call out to external utilities unless those utilities are available in the environment where the protected model is used.
- Callback code cannot reference the source protected model unless you are using protected model functions.

You can use the `Simulink.ProtectedModel.getCallbackInfo` function in callback code to get information on the protected model. The function returns a `Simulink.ProtectedModel.CallbackInfo` object that provides the protected model name and the names of submodels. If the callback is specified for `'CODEGEN'` functionality and `'Build'` event, the object provides the target identifier and model code interface type (`'Top model'` or `'Model reference'`).

Create a Protected Model with Callbacks

This example creates a protected model with a callback for code generation.

1. On the MATLAB path, create a callback script, `pm_callback.m`, containing:

```
s1 = 'Code interface is: ';
cbinfobj = Simulink.ProtectedModel.getCallbackInfo(...
'sldemo_mdlref_counter','Build','CODEGEN');
disp([s1 cbinfobj.CodeInterface]);
```

2. Create a callback that uses the script.

```
pmCallback = Simulink.ProtectedModel.Callback('Build',...
'CODEGEN', 'pm_callback.m');
```

3. Create the protected model and specify the code generation callback.

```
Simulink.ModelReference.protect('sldemo_mdlref_counter',...
'Mode', 'CodeGeneration','Callbacks',{pmCallback})
```

4 Build the protected model. Before the build, the callback displays the code interface.

```
rtwbuild('sldemo_mdlref_basic')
```

Component Initialization, Reset, and Termination in Simulink Coder

Generate Code That Responds to Initialize, Reset, and Terminate Events

To generate code from a modeling component that responds to initialize, reset, and terminate events during execution, use the blocks Initialize Function and Terminate Function. For information on how to use these blocks, see “Using Initialize, Reset, and Terminate Functions” (Simulink). You can use the blocks anywhere in a model hierarchy.

Examples of when to generate code that responds to initialize, reset, or terminate events include:

- Starting and stopping a component.
- Calculating initial conditions.
- Saving and restoring state from nonvolatile memory.
- Generating reset entry-point functions that respond to external events.

Each nonvirtual subsystem and referenced model can have its own set of initialize, reset, and terminate functions.

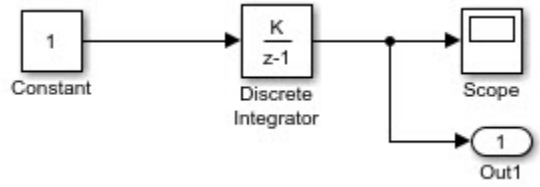
The code generator produces initialization and termination code differently than reset code. For initialization and termination code, the code generator includes your component initialization and termination code in the default entry-point functions, *model*`_initialize` and *model*`_terminate`. The code generator produces reset code only if you model reset behavior.

Generate Code for Initialize and Terminate Events

When you generate code for a component that includes Initialize Function and Terminate Function blocks, the code generator:

- Includes initialize event code with default initialize code in entry-point function *model*`_initialize`.
- Includes terminate event code with default terminate code in entry-point function *model*`_terminate`.

Consider the model rtwdemo_irt_base.



For this model, the code generator produces initialize and terminate entry-point functions that other code can interface with.

```
void rtwdemo_irt_base_initialize(void)
void rtwdemo_irt_base_terminate(void)
```

This code appears in the generated file `rtwdemo_irt_base.c`. The initialize function, `rtwdemo_irt_base_initialize`:

- Initializes an error status.
- Allocates memory for block I/O and state parameters.
- Sets the output value
- Sets the initial condition for the discrete integrator.

The terminate function, ,`rtwdemo_irt_base_terminate`, requires no code.

This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```
void rtwdemo_irt_base_initialize(void)
{
  rtmSetErrorStatus(rtwdemo_irt_base_M, (NULL));

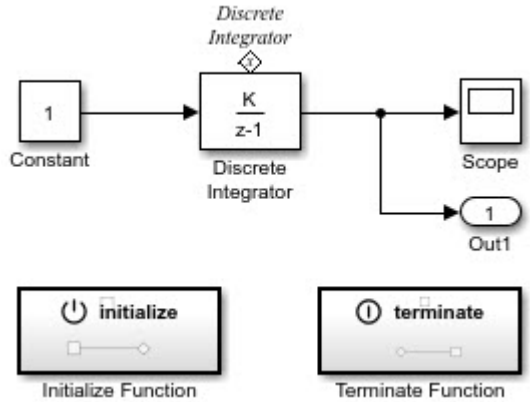
  (void) memset((void *)&rtwdemo_irt_base_DW, 0,
                sizeof(DW_rtwdemo_irt_base_T));

  rtwdemo_irt_base_Y.Out1 = 0.0;

  rtwdemo_irt_base_DW.DiscreteIntegrator_DSTATE = 0.0;
}

void rtwdemo_irt_base_terminate(void)
{
  /* (no terminate code required) */
}
```

Add Initialize Function and Terminate Function blocks to the model (see `rtwdemo_irt_initterm`). The Initialize Function block uses the State Writer block to set the initial condition of a Discrete Integrator block. The Terminate Function block includes a State Reader block, which reads the state of the Discrete Integrator block.



The **Event type** parameter of the Event Listener block for the initialize and terminate functions is set to `Initialize` and `Terminate`, respectively. The initialize function uses the State Writer block to initialize the input value for the Discrete Integrator block to 10. The terminate function uses the State Reader block to read the state of the Discrete Integrator block.

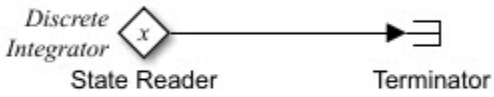
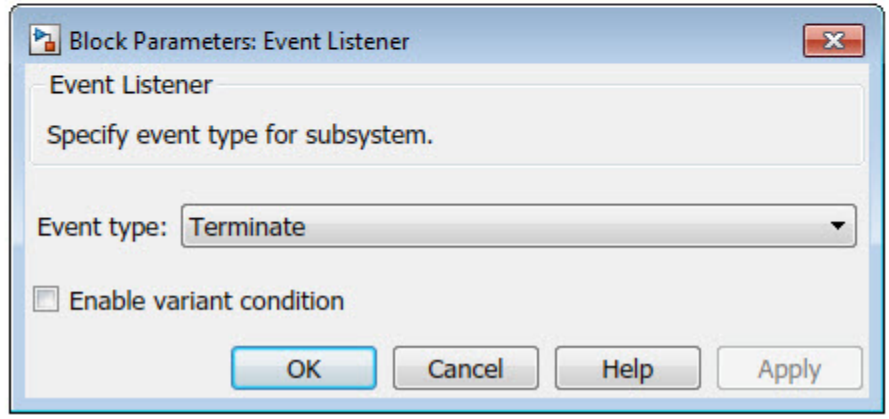
Help
Apply





The code generator includes the event code that it produces for the Initialize Function and Terminate Function blocks with standard initialize and terminate code in entry-point functions `rtwdemo_irt_initterm_initialize` and `rtwdemo_irt_initterm_terminate`. This code assumes that support for nonfinite numbers and MAT-file logging is disabled.

```
void rtwdemo_irt_initterm_initialize(void)
{
  rtmSetErrorStatus(rtwdemo_irt_initterm_M, (NULL));

  (void) memset((void *)&rtwdemo_irt__initterm_DW, 0,
                sizeof(DW_rtwdemo_irt__initterm_T));

  rtwdemo_irt_initterm_Y.Out1 = 0.0;
```

```
  rtwdemo_irt_initterm_DW.DiscreteIntegrator_DSTATE = 10.0;
}

void rtwdemo_irt__initterm_terminate(void)
{
  /* (no terminate code required) */
}
```

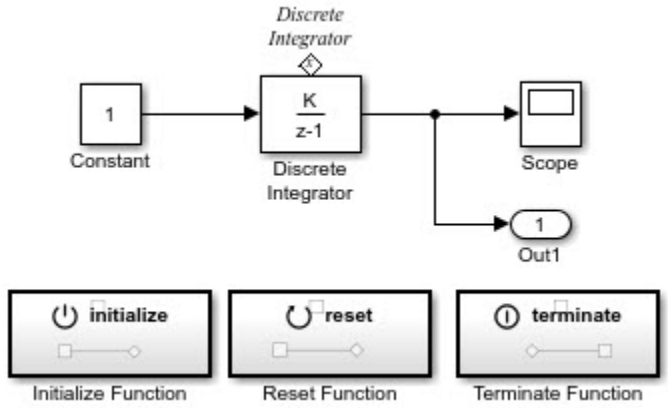
Generate Code for Reset Events

Generate code that responds to a reset event by including an Initialize Function or Terminate Function block in a modeling component. Configure the block for a reset by setting the **Event type** parameter of its Event Listener block to `Reset`. Also set the **Event name** parameter. The default name is `reset`.

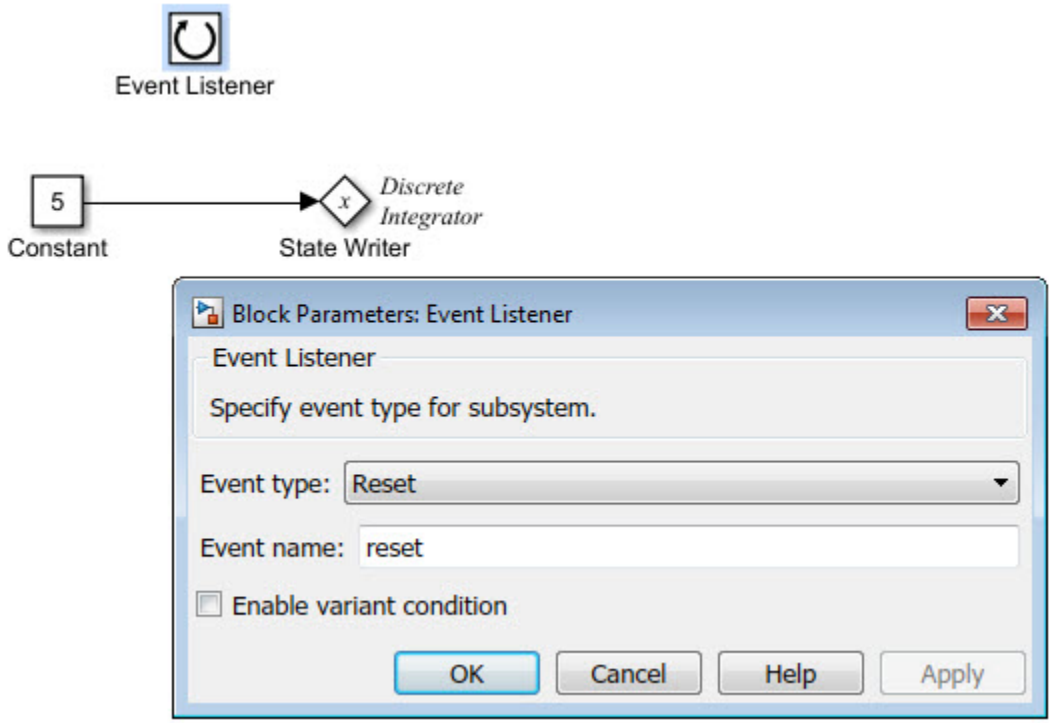
The code generator produces a reset entry-point function *only* if you model reset behavior. If a component contains multiple reset specifications, the code that the code generator produces depends on whether reset functions share an event name. For a given component hierarchy:

- For reset functions with unique event names, the code generator produces a separate entry-point function for each named event. The name of each function is the name of the corresponding event.
- For reset functions that share an event name, the code generator aggregates the reset code into one entry-point function. The code for the reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The name of the function is *`model`*`_reset`. For more information, see “Event Names and Code Aggregation” (Simulink Coder).

Consider the model `rtwdemo_irt_reset`, which includes a Reset Function block derived from an Initialize Function block.



The **Event type** and **Event name** parameters of the Event Listener block are set to `Reset` and `reset`, respectively. The function uses the State Writer block to reset the input value for the Discrete Integrator block to 5.



The code generator produces reset function `rtwdemo_irt_reset_reset`.

```
void rtwdemo_irt_reset_reset(void)

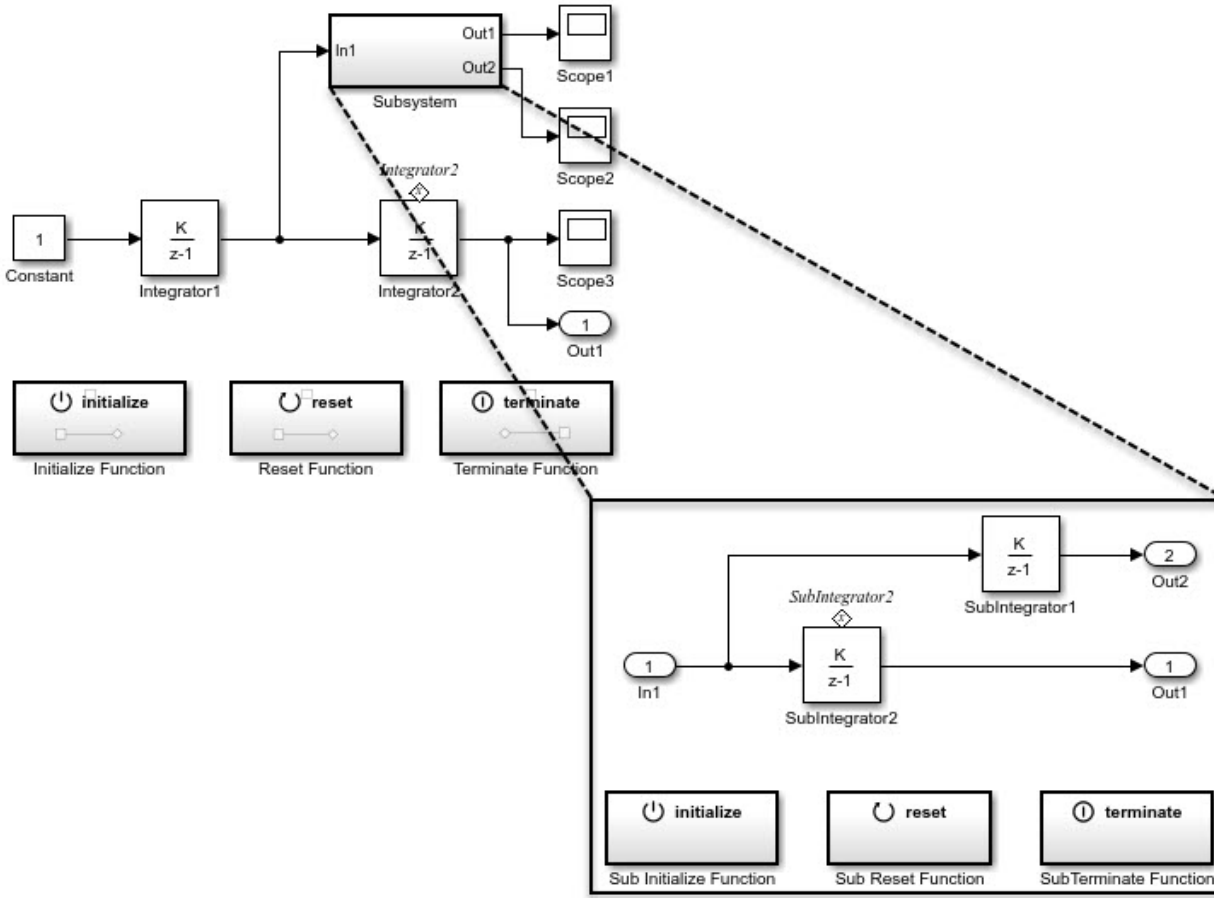
{
  rtwdemo_irt_reset_DW.DiscreteIntegrator_DSTATE = 5.0;
}
```

Event Names and Code Aggregation

Use the Initialize Function and Terminate Function blocks to define multiple initialize, reset, and terminate functions for a component hierarchy. Define only one initialize function and one terminate function per hierarchy level. You can define multiple reset functions for a hierarchy level. The event names that you configure for the functions at a given level must be unique.

When producing code, the code generator aggregates code for functions that have a given event name across the entire component hierarchy into one entry-point function. The code for reset functions appears in order, starting with the lowest level (innermost) of the component hierarchy and ending with the root (outermost). The code generator uses the event name to name the function.

For example, the model `rtwdemo_irt_shared` includes a subsystem that replicates the initialize, reset, and terminate functions that are in the parent model.



Although the model includes multiple copies of the initialize, reset, and terminate functions, the code generator produces one entry-point function for reset

(`rtwdemo_irt_shared_reset`), one for initialize (`rtwdemo_irt_shared_initialize`), and one for terminate (`rtwdemo_irt_shared_terminate`). Within each entry-point function, after listing code for blocks configured with an initial condition (*`model`*`_P.`*`block`*`_IC`), the code generator orders code for components, starting with the lowest level of the hierarchy and ending with the root.

```
.
.
.
void rtwdemo_irt_shared_reset(void)
{
  rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;

  rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}
.
.
.
void rtwdemo_irt_shared_initialize(void)
{
  rtmSetErrorStatus(rtwdemo_irt_shared_M, (NULL));

  (void) memset(((void *)&rtwdemo_irt_shared_DW), 0,
                sizeof(DW_rtwdemo_irt_shared_T));

  rtwdemo_irt_shared_Y.Out1 = 0.0;

  rtwdemo_irt_shared_DW.Integrator1_DSTATE = 0.0;

  rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 2.0;

  rtwdemo_irt_shared_DW.Integrator2_DSTATE = 10.0;
.
.
.
void rtwdemo_irt_shared_terminate(void)
{
   /* (no terminate code required) */
   }
```

If you rename the event configured for the subsystem reset function to `reset_02`, the code generator produces two reset entry-point functions, `rtwdemo_irt_shared_reset` and `rtwdemo_irt_shared_reset_02`.

```
void rtwdemo_irt_shared_reset(void)
{
      rtwdemo_irt_shared_DW.SubIntegrator2_DSTATE = 5.0;
}

void rtwdemo_irt_shared_reset_02(void)
{
   rtwdemo_irt_shared_DW.Integrator2_DSTATE = 5.0;
}
```

Limitation

You cannot generate code from a harness model—a root model that contains a Model block, which exposes initialize, reset, or terminate function ports.

Stateflow Blocks in Simulink Coder

Code Generation of Stateflow Blocks

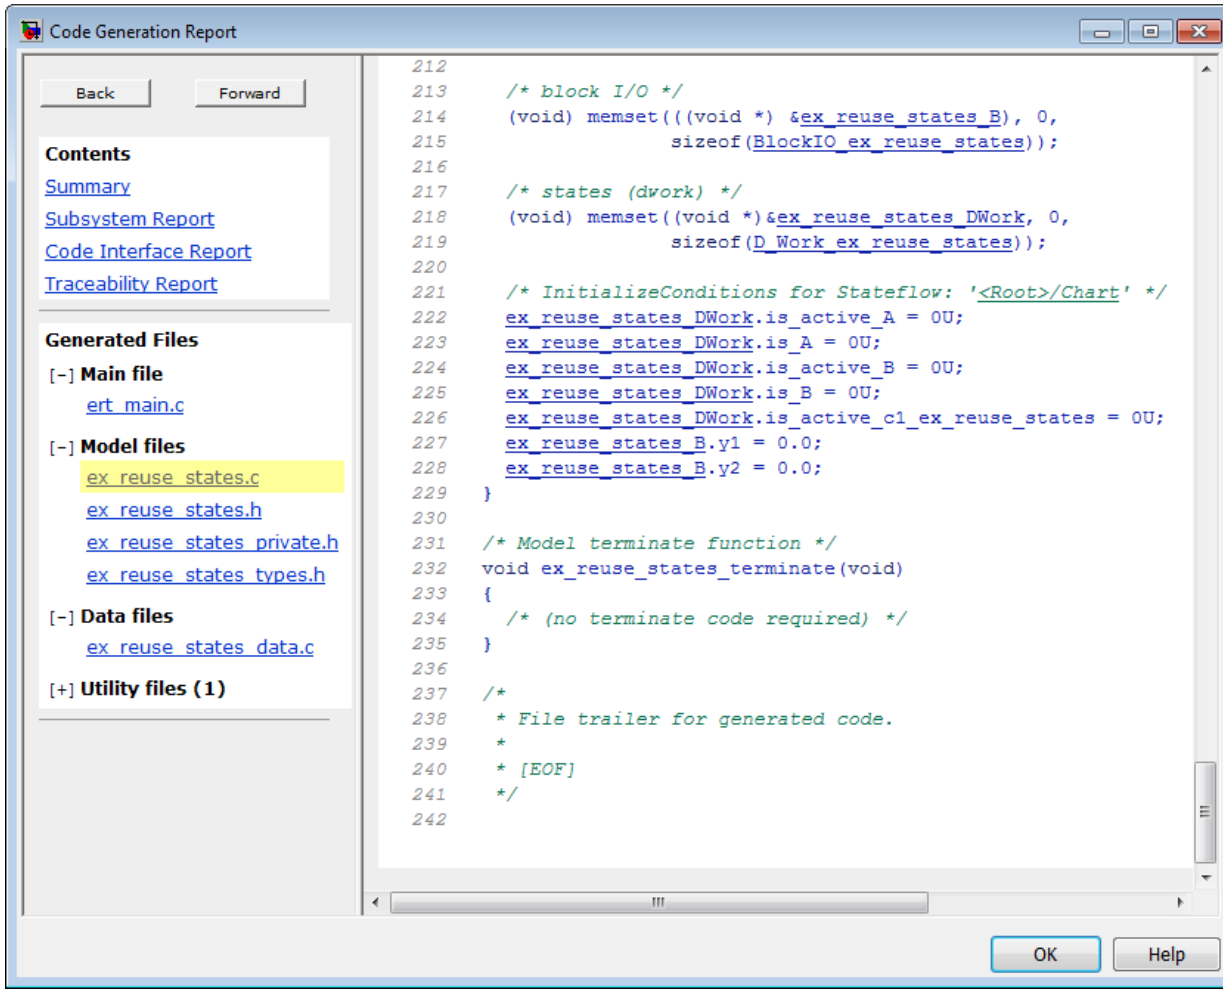
The code generator produces code for Stateflow blocks for rapid prototyping. If you have an Embedded Coder license, you can generate production code for Stateflow blocks.

Comparison of Code Generation Methods

The following sections compare two ways of generating code.

Code Generation Without Atomic Subcharts

You generate code for the entire model in one file and look through that entire file to find code for a specific part of the chart.



Code Generation With Atomic Subcharts

You specify code generation parameters so that code for an atomic subchart appears in a separate file. This method of code generation enables unit testing for a specific part of a chart. You can avoid searching through unrelated code and focus only on the part that interests you.

Generate Reusable Code for Atomic Subcharts

An atomic subchart is a graphical object that helps you to create standalone subcomponents in a Stateflow chart. Atomic subcharts are supported only in Stateflow charts in Simulink models. For more information, see “Create Reusable Subcomponents by Using Atomic Subcharts” (Stateflow).

How to Generate Reusable Code for Linked Atomic Subcharts

To specify code generation parameters for linked atomic subcharts from the same library:

1. Open the library model that contains your atomic subchart.
2. Unlock the library.
3. Right-click the library chart and select **Block Parameters**.
4. In the dialog box, specify the following parameters:
   a. On the **Main** tab, select **Treat as atomic unit**.
   b. On the **Code Generation** tab, set **Function packaging** to `Reusable function`.
   c. Set **File name options** to `User specified`.
   d. For **File name**, enter the name of the file with no extension.
   e. Click **OK** to apply the changes.
5. (OPTIONAL) Customize the generated function names for atomic subcharts:
   a. Open the Model Configuration Parameters dialog box.
   b. On the **Code Generation** pane, set **System target file** to `ert.tlc`.
   c. Navigate to the **Code Generation** > **Symbols** pane.
   d. For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:
      - `$R` — root model name
      - `$F` — type of interface function for the atomic subchart
      - `$N` — block name
      - `$H` — subsystem index
      - `$M` — name-mangling text

e Click **OK** to apply the changes.

When you generate code for your model, a separate file stores the code for linked atomic subcharts from the same library.

How to Generate Reusable Code for Unlinked Atomic Subcharts

To specify code generation parameters for an unlinked atomic subchart:

1. In your chart, right-click the atomic subchart and select **Properties**.
2. In the dialog box, specify the following parameters:
   a. Set **Code generation function packaging** to `Reusable function`.
   b. Set **Code generation file name options** to `User specified`.
   c. For **Code generation file name**, enter the name of the file with no extension.
   d. Click **OK** to apply the changes.
3. (OPTIONAL) Customize the generated function names for atomic subcharts:
   a. Open the Model Configuration Parameters dialog box.
   b. On the **Code Generation** pane, set **System target file** to `ert.tlc`.
   c. Navigate to the **Code Generation** > **Symbols** pane.
   d. For **Subsystem methods**, specify the format of the function names using a combination of the following tokens:
      - `$R` — root model name
      - `$F` — type of interface function for the atomic subchart
      - `$N` — block name
      - `$H` — subsystem index
      - `$M` — name-mangling text
   e. Click **OK** to apply the changes.

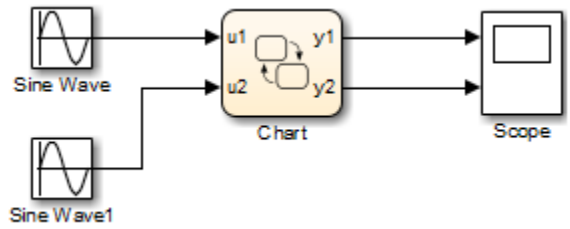
When you generate code for your model, a separate file stores the code for the atomic subchart. For more information, see “Generate Reusable Code for Unit Testing” on page 11-8.

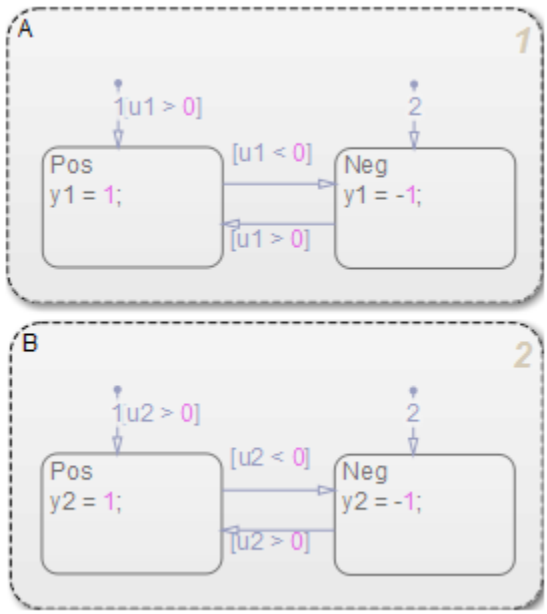
Generate Reusable Code for Unit Testing

An atomic subchart is a graphical object that helps you to create standalone subcomponents in a Stateflow chart. Atomic subcharts are supported only in Stateflow charts in Simulink models. For more information, see “Create Reusable Subcomponents by Using Atomic Subcharts” (Stateflow).

Goal of the Tutorial

Assume that you have the following model, and the chart has two states:

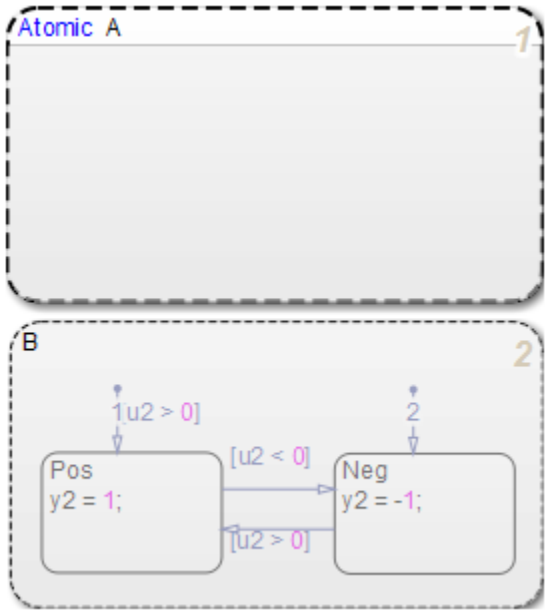




Suppose that you want to generate reusable code so that you can perform unit testing on state A. You can convert that part of the chart to an atomic subchart and then specify a separate file to store the generated code.

Convert a State to an Atomic Subchart

To convert state A to an atomic subchart, right-click the state and select **Group & Subchart > Atomic Subchart**. State A changes to an atomic subchart:



Specify Code Generation Parameters

Set Up a Standalone C File for the Atomic Subchart

1. Open the properties dialog box for A.
2. Set **Code generation function packaging** to `Reusable function`.
3. Set **Code generation file name options** to `User specified`.
4. For **Code generation file name**, enter `saturator` as the name of the file.

5 Click **OK**.

Set Up the Code Generation Report

1 Open the Model Configuration Parameters dialog box.
2 In the **Code Generation** pane, set **System target file** to `ert.tlc`.
3 In the **Code Generation** > **Report** pane, select **Create code generation report**.

   This step automatically selects **Open report automatically** and **Code-to-model**.
4 Select **Model-to-code**.
5 Click **Apply**.

Customize the Generated Function Names

1 In the Model Configuration Parameters dialog box, go to the **Code Generation** > **Symbols** pane.
2 Set **Subsystem methods** to the format scheme `$R$N$M$F`, where:

   - `$R` is the root model name.
   - `$N` is the block name.
   - `$M` is the mangle token.
   - `$F` is the type of interface function for the atomic subchart.

   For more information, see “Subsystem methods” (Simulink Coder).
3 Click **Apply**.

Generate Code for Only the Atomic Subchart

To generate code for your model, press **Ctrl+B**. In the code generation report that appears, you see a separate file that contains the generated code for the atomic subchart.

To inspect the code for `saturator.c`, click the hyperlink in the report to see the following code:

Help

Line 28 shows that the `during` function generated for the atomic subchart has the name `ex_reuse_states_A_during`. This name follows the format scheme `$R$N$M$F` specified for **Subsystem methods**:

- `$R` is the root model name, `ex_reuse_states`.
- `$N` is the block name, `A`.
- `$M` is the mangle token, which is empty.
- `$F` is the type of interface function for the atomic subchart, `during`.

Note The line numbers shown can differ from the numbers that appear in your code generation report.

Inline State Functions in Generated Code

In this section...

Inlined Generated Code for State Functions

By default, the code generator uses an internal heuristic to determine whether to inline generated code for state functions. The heuristic takes into consideration an inlining threshold. As code grows and shrinks in size, generated code for state functions can be unpredictable.

If your model includes Stateflow objects and you have rigorous requirements for traceability between generated code and the corresponding state functions, you can override the default behavior. Use the state property `Function Inline Option` to explicitly force or prevent inlining of state functions.

What Happens When You Force Inlining

If you force inlining for a state, the code generator inlines code for state actions into the parent function. The parent function contains code for executing the state actions, outer transitions, and flow charts. It does not include code for empty state actions.

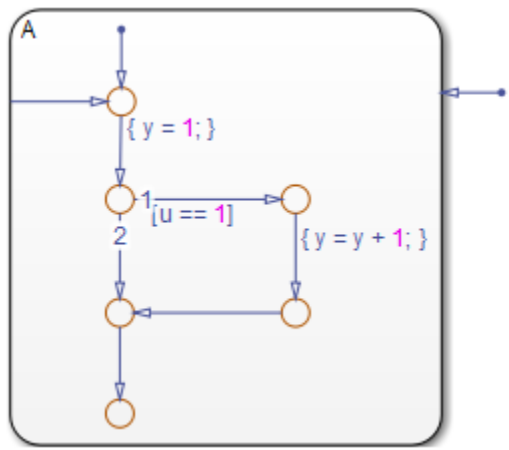
What Happens When You Prevent Inlining

If you prevent inlining for a state, the code generator produces these static functions for state *foo*.

Function	Description
`enter_atomic_`*`foo`*	Marks *`foo`* active and performs entry actions.
`enter_internal_`*`foo`*	Calls default paths.

Function	Description
`inner_default_`*`foo`*	Executes flow charts that originate when an inner transition and default transition reach the same junction inside a state. The code generator produces this function only when the flow chart is complex enough to exceed the inlining threshold. In generated code, Stateflow software calls this function from both the `enter_internal_`*`foo`* and *`foo`* functions.
`foo`	Checks for valid outer transitions and if none, performs during actions.
`exit_atomic_`*`foo`*	Performs exit actions and marks *`foo`* inactive.
`exit_internal_`*`foo`*	Performs exit actions of the child substates and then exits *`foo`*.

Suppose the following chart is in model `M`.



If you prevent inlining for state `A`, the code generator produces this code.

```
static void M_inner_default_A(void);
static void M_exit_atomic_A(void);
static void M_A(void);
static void M_enter_atomic_A(void);
static void M_enter_internal_A(void);
```

How to Set the State Function Inline Option

To set the function inlining property for a state:

1. Right-click inside the state and, from the context menu, select **Properties**.

   The State properties dialog box opens.

2. In the **Function Inline Option** field, select one of these options.

Option	Behavior
Inline	Forces inlining of state functions into the parent function, as long as the function is not part of a recursion. See “What Happens When You Force Inlining” on page 11-13.
Function	Prevents inlining of state functions. Generates up to six static functions for the state. See “What Happens When You Prevent Inlining” on page 11-13.
Auto	Uses internal heuristics to determine whether or not to inline the state functions.

3. Click **Apply**.

Best Practices for Controlling State Function Inlining

To	Set Function Inline Option Property To
Generate a separate function for each action of a state and a separate function for each action of its substates	**Function** for the state and each substate
Generate a separate function for each action of a state, but include code for the associated action of its substates	**Function** for the state and **Inline** for each substate

Air-Fuel Ratio Control System with Stateflow Charts

Generate code for an air-fuel ratio control system designed with Simulink® and Stateflow®.

Figures 1, 2, and 3 show relevant portions of the sldemo_fuelsys model, a closed-loop system containing a plant and controller. The plant validates the controller in simulation early in the design cycle. In this example, you generate code for the relevant controller subsystem, "fuel_rate_control". Figure 1 shows the top-level simulation model.

Open sldemo_fuelsys via rtwdemo_fuelsys and compile the diagram to see the signal data types.

```
rtwdemo_fuelsys
sldemo_fuelsys([],[],[],'compile');
sldemo_fuelsys([],[],[],'term');
```

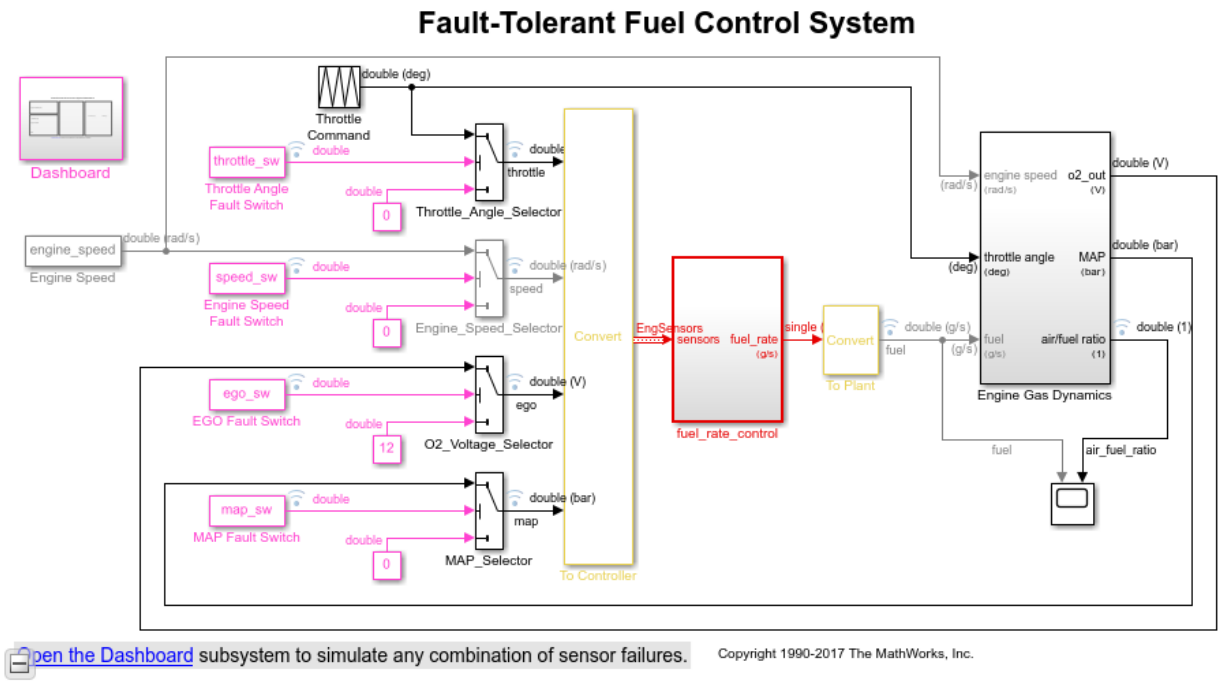


Figure 1: Top-level model of the plant and controller

The air-fuel ratio control system is comprised of Simulink® and Stateflow®. The control system is the portion of the model for which you generate code.

```
open_system('sldemo_fuelsys/fuel_rate_control');
```

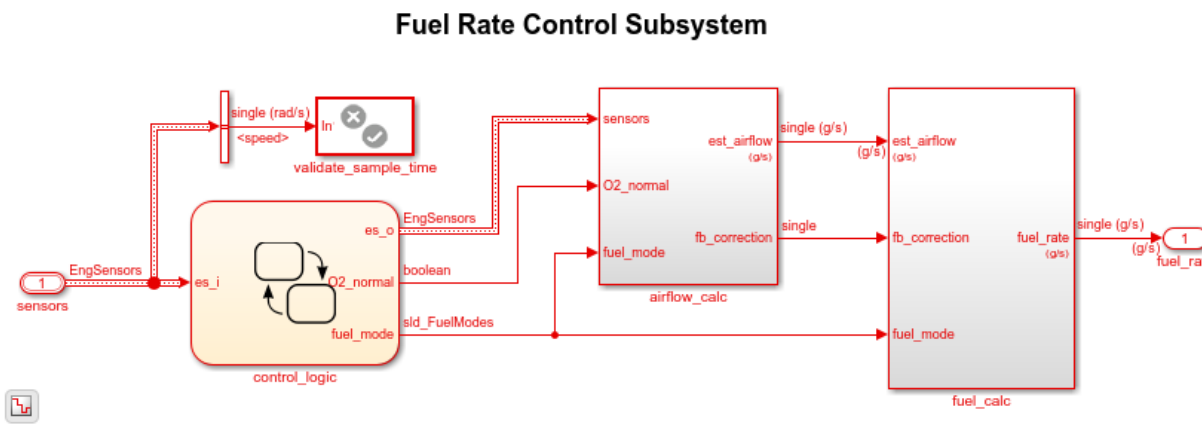

Figure 2: The air-fuel ratio controller subsystem

The control logic is a Stateflow® chart that specifies the different modes of operation.

```
open_system('sldemo_fuelsys/fuel_rate_control/control_logic');
```

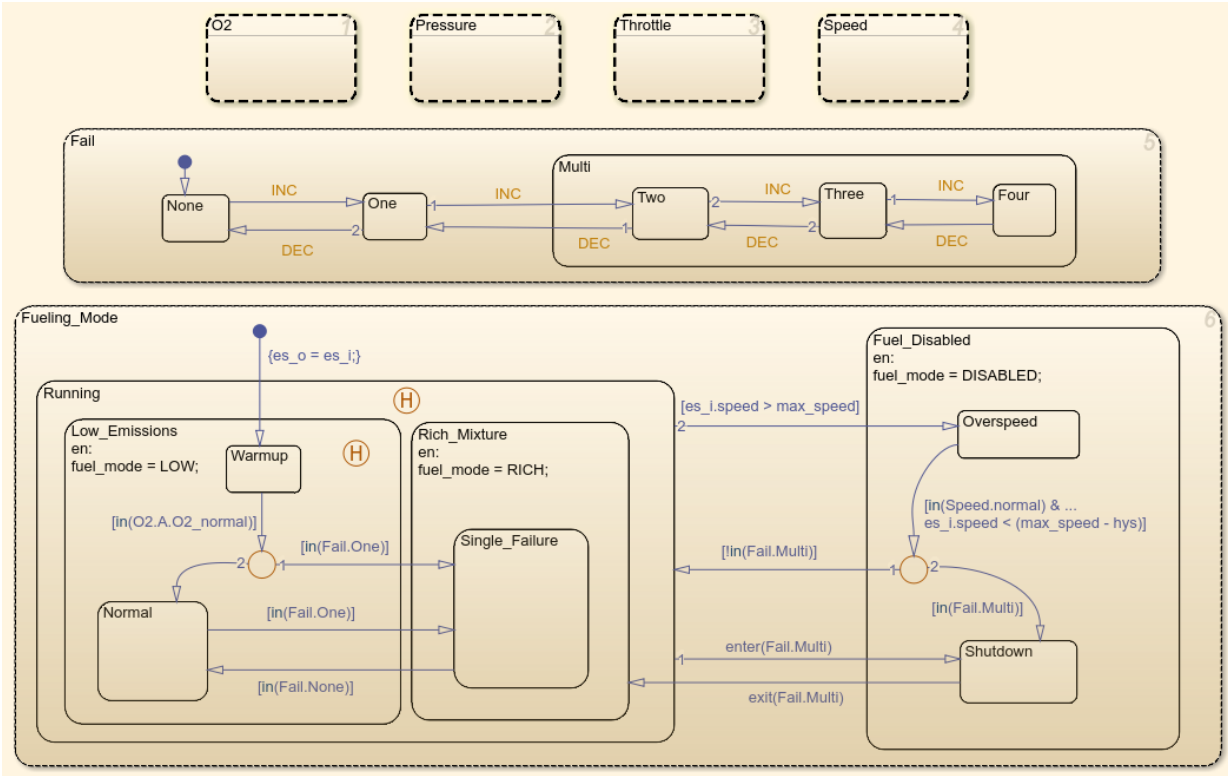

Figure 3: Air-fuel rate controller logic

Close these windows.

```
close_system('sldemo_fuelsys/fuel_rate_control/airflow_calc');
close_system('sldemo_fuelsys/fuel_rate_control/fuel_calc');
close_system('sldemo_fuelsys/fuel_rate_control/control_logic');
hDemo.rt=sfroot;hDemo.m=hDemo.rt.find('-isa','Simulink.BlockDiagram');
hDemo.c=hDemo.m.find('-isa','Stateflow.Chart','-and','Name','control_logic');
hDemo.c.visible=false;
close_system('sldemo_fuelsys/fuel_rate_control');
```

Configure and Build the Model with Simulink® Coder™

Simulink® Coder™ generates generic ANSI® C code for Simulink® and Stateflow® models via the Generic Real-Time (GRT) target. You can configure a model for code generation programmatically.

```
rtwconfiguredemo('sldemo_fuelsys','GRT');
```

For this example, build only the air-fuel ratio control system. Once the code generation process is complete, an HTML report detailing the generated code is displayed. The main body of the code is located in fuel_rate_control.c.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
```

```
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

Configure and Build the Model with Embedded Coder®

Embedded Coder® generates production ANSI® C/C++ code via the Embedded Real-Time (ERT) target. You can configure a model for code generation programmatically.

```
rtwconfiguredemo('sldemo_fuelsys','ERT');
```

Repeat the build process and inspect the generated code. In the Simulink® Coder™ Report, you can navigate to the relevant code segments interactively by using the **Previous** and **Next** buttons. From the chart context menu (right-click the Stateflow® block), select **Code Generation > Navigate to Code**. Programmatically, use the rtwtrace utility.

```
rtwbuild('sldemo_fuelsys/fuel_rate_control');
rtwtrace('sldemo_fuelsys/fuel_rate_control/control_logic')
```

```
### Starting build procedure for model: fuel_rate_control
### Successful completion of build procedure for model: fuel_rate_control
```

View the air-fuel ratio control logic in the generated code.

```
rtwdemodbtype('fuel_rate_control_ert_rtw/fuel_rate_control.c',...
    '/* Function for Chart:','case IN_Warmup:',1,0);
```

```
/* Function for Chart: '<S1>/control_logic' */
static void Fueling_Mode(const int32_T *sfEvent)
{
```

```
/* This state interprets the other states in the chart to directly control the fuelin
switch (rtDW.bitsForTID0.is_Fueling_Mode) {
 case IN_Fuel_Disabled:
  rtDW.fuel_mode = DISABLED;

  /* The fuel is completely shut off while in this state. */
  switch (rtDW.bitsForTID0.is_Fuel_Disabled) {
   case IN_Overspeed:
    /* Inport: '<Root>/sensors' */
    /* The speed is dangerously high, so shut off the fuel. */
    if ((rtDW.bitsForTID0.is_Speed == IN_normal) && (rtU.sensors.speed <
         603.0F)) {
      if (rtDW.bitsForTID0.is_Fail != IN_Multi) {
        rtDW.bitsForTID0.is_Fuel_Disabled = IN_NO_ACTIVE_CHILD;
        rtDW.bitsForTID0.is_Fueling_Mode = IN_Running;
        switch (rtDW.bitsForTID0.was_Running) {
         case IN_Low_Emissions:
          rtDW.bitsForTID0.is_Running = IN_Low_Emissions;
          rtDW.bitsForTID0.was_Running = IN_Low_Emissions;
          rtDW.fuel_mode = LOW;
          switch (rtDW.bitsForTID0.was_Low_Emissions) {
           case IN_Normal:
            rtDW.bitsForTID0.is_Low_Emissions = IN_Normal;
            rtDW.bitsForTID0.was_Low_Emissions = IN_Normal;
            break;
```

Close the model and code generation report.

```
clear hDemo;
rtwdemoclean;
close_system('sldemo_fuelsys',0);
```

Block Authoring and Code Generation for Simulink Coder

S-Functions and Code Generation

In this section...

You use S-functions to extend Simulink support for simulation and code generation. For example, you can use them to:

- Represent custom algorithms
- Interface existing external code with Simulink and the code generator
- Represent device drivers for interfacing with hardware
- Generate highly optimized code for embedded systems
- Verify code generated for a subsystem as part of a Simulink simulation

The application program interface (API) for writing S-functions allows you to implement generic algorithms in the Simulink environment with a great deal of flexibility. If you intend to use S-functions in a model for code generation, the level of flexibility can vary. For example, it is not possible to access the MATLAB workspace from an S-function that you use with the code generator. This topic explains conditions to be aware of for using S-functions. However, using the techniques presented in this topic, you can create S-functions for most applications that work with the generated code.

Although S-functions provide a generic and flexible solution for implementing complex algorithms in a model, the underlying API incurs overhead in terms of memory and computation resources. Most often the additional resources are acceptable for real-time rapid prototyping systems. Often, though, additional resources are unavailable in real-time embedded applications. You can minimize memory and computational requirements by using the Target Language Compiler technology provided with the code generator to inline your S-functions. If you are producing an S-function for existing external code, consider using the Legacy Code Tool to generate your S-function and relevant TLC file.

This content assumes that you understand the following concepts:

- Level 2 S-functions
- Target Language Compiler (TLC) scripting

- How the code generator produces and builds C/C++ code

Notes This information is for code generator users. Even if you do not currently use the code generator, follow these practices when writing S-functions, especially if you are creating general-purpose S-functions.

Types of S-Functions

Examples for which you might choose to implement an S-function for simulation and code generation include:

1. "I'm not concerned with efficiency. I want to write one version of my algorithm and have it work in the Simulink and code generator products automatically."
2. "I want to implement a highly optimized algorithm in the Simulink and code generator products that looks like a built-in block and generates efficient code."
3. "I have a lot of hand-written code that I need to interface. I want to call my function from the Simulink and code generator products efficiently."

Respectively, the preceding situations map to the following MathWorks terminology:

1. Noninlined S-function
2. Inlined S-function
3. Auto-generated S-function for external code

Noninlined S-Functions

A noninlined S-function is a C or C++ MEX S-function that is treated identically by the Simulink engine and generated code. In general, you implement your algorithm once according to the S-function API. The Simulink engine and generated code call the S-function routines (for example, `mdlOutputs`) during model execution.

Additional memory and computation resources are required for each instance of a noninlined S-Function block. However, this routine of incorporating algorithms into models and code generation applications is typical during the prototyping phase of a project where efficiency is not important. The advantage gained by forgoing efficiency is the ability to change model parameters and structures rapidly.

Writing a noninlined S-function does not involve TLC coding. Noninlined S-functions are the default case for the build process in the sense that once you build a MEX S-function in

your model, there is no additional preparation before pressing **Ctrl+B** to build your model.

Some restrictions exist concerning the names and locations of noninlined S-function files when generating makefiles. See “Write Noninlined S-Function” on page 12-107.

Inlined S-Functions

For S-functions to work in the Simulink environment, some overhead code is generated. When the code generator produces code from models that contain S-functions (without `sfunction.tlc` files), it embeds some of this overhead code in the generated code. If you want to optimize your real-time code and eliminate some of the overhead code, you must *inline* (or embed) your S-functions. This involves writing a TLC (`sfunction.tlc`) file that eliminates overhead code from the generated code. The Target Language Compiler processes `sfunction.tlc` files to define how to inline your S-function algorithm in the generated code.

Note Do not confuse the term *inline* with the C++ *inline* keyword. Inline means to specify text in place of the call to the general S-function API routines (for example, `mdlOutputs`). For example, when a TLC file is used to inline an S-function, the generated code contains the C/ C++ code that normally appears within the S-function routines and the S-function itself that has been removed from the build process.

A fully inlined S-function builds your algorithm (block) into generated code in a manner that is indistinguishable from a built-in block. Typically, a fully inlined S-function requires you to implement your algorithm twice: once for the Simulink model (C/C++ MEX S-function) and once for code generation (TLC file). The complexity of the TLC file depends on the complexity of your algorithm and the level of efficiency you try to achieve in the generated code. TLC files vary from simple to complex in structure. See “Inlining S-Functions” (Simulink Coder)

Auto-generated S-Functions for Legacy or Custom Code

If you need to invoke hand-written C/C++ code in your model, consider using the Simulink Legacy Code Tool. The Legacy Code Tool can automate the generation of a fully inlined S-function and a corresponding TLC file based on information that you register in a Legacy Code Tool data structure.

For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink) and see “Import Calls to External Code into Generated Code with Legacy Code Tool” on page 12-7.

Files Required for Implementing Noninlined and Inlined S-Functions

This topic briefly describes what files and functions you need to create noninlined and inlined S-functions.

- Noninlined S-functions require the C or C++ MEX S-function source code (*`sfunction`*`.c` or *`sfunction`*`.cpp`).
- Fully inlined S-functions require an *`sfunction`*`.tlc` file. Fully inlined S-functions produce the optimal code for a parameterized S-function. This is an S-function that operates in a specific mode dependent upon fixed S-function parameters that do not change during model execution. For a given operating mode, the *`sfunction`*`.tlc` file specifies the exact code that is generated to implement the algorithm for that mode. For example, the direct-index lookup table S-function in “Write Fully Inlined S-Functions with mdlRTW Routine” on page 12-121 contains two operating modes — one for evenly spaced `x-data` and one for unevenly spaced `x-data`.

  Note Fully inlined S-functions that are generated to invoke legacy or custom C/C++ code also require an *`sfunction`*`.tlc` file, which is generated by Legacy Code Tool.

Fully inlined S-functions might require the placement of the `mdlRTW` routine in your S-function MEX-file *`sfunction`*`.c` or *`sfunction`*`.cpp`. The `mdlRTW` routine lets you place information in *`model`*`.rtw`. *`model`*`.rtw` is the record file that specifies a model, and which the code generator invokes the Target Language Compiler to process before executing *`sfunction`*`.tlc` when generating code.

Including a `mdlRTW` routine is useful when you want to introduce non-tunable parameters into your TLC file. Such parameters are used to determine which operating mode is active in a given instance of the S-function. Based on this information, the TLC file for the S-function can generate highly efficient, optimal code for that operating mode.

Guidelines for Writing S-Functions that Support Code Generation

- You can use C/C++ MEX, MATLAB language, and Fortran MEX S-functions with code generation.
- You can inline S-functions for code generation by providing an inlining TLC file. See S-Function Inlining in “Target Language Compiler” (Simulink Coder). MATLAB and Fortran MEX S-functions must be inlined. C/C++ MEX S-functions can be inlined for code efficiency, or noninlined.
- To automatically generate a fully inlined C MEX S-function for invoking legacy or custom code, use the Legacy Code Tool. For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink) and see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder).
- If code efficiency is not an overriding consideration, for example, if you are rapid prototyping, you can choose not to inline a C/C++ MEX S-function. For more information, see “Write Noninlined S-Function” on page 12-107.

In this section...

Legacy Code Tool and Code Generation

You can use the Simulink Legacy Code Tool to generate fully inlined C MEX S-functions for legacy or custom code. The S-functions are optimized for embedded components, such as device drivers and lookup tables, and they call existing C or C++ functions.

Note The Legacy Code Tool can interface with C++ functions, but not C++ objects. To work around this issue so that the tool can interface with C++ objects, see “Legacy Code Tool Limitations” (Simulink).

You can use the tool to:

- Compile and build the generated S-function for simulation.
- Generate a masked S-Function block that is configured to call the existing external code.

If you want to include these types of S-functions in models for which you intend to generate code, use the tool to generate a TLC block file. The TLC block file specifies how the generated code for a model calls the existing C or C++ function.

If the S-function depends on files in folders other than the folder containing the S-function dynamically loadable executable file, use the tool to generate an

*sFunction*_makecfg.m or rtwmakecfg.m file for the S-function. Generating the file maintains those dependencies when you build a model that includes the S-function. For example, for some applications, such as custom targets, you might want to locate files in a target-specific location. The build process looks for *sFunction*_makecfg.m or rtwmakecfg.m in the same folder as the S-function dynamically loadable executable and calls the function in the file.

For more information, see “Integrate C Functions Using Legacy Code Tool” (Simulink).

Generate Inlined S-Function Files for Code Generation

Depending on the code generation requirements of your application, to generate code for a model that uses the S-function, do either of the following:

- Generate one .cpp file for the inlined S-function. In the Legacy Code Tool data structure, set the value of the Options.singleCPPMexFile field to true before generating the S-function source file from your existing C function. For example:

  ```
  def.Options.singleCPPMexFile = true;
  legacy_code('sfcn_cmex_generate', def);
  ```

- Generate a source file and a TLC block file for the inlined S-function. For example:

  ```
  def.Options.singleCPPMexFile = false;
  legacy_code('sfcn_cmex_generate', def);
  legacy_code('sfcn_tlc_generate', def);
  ```

singleCPPMexFile Limitations

You cannot set the singleCPPMexFile field to true if

- Options.language='C++'
- You use one of the following Simulink objects with the IsAlias property set to true:
  - Simulink.Bus
  - Simulink.AliasType
  - Simulink.NumericType
- The Legacy Code Tool function specification includes a void* or void** to represent scalar work data for a state argument
- HeaderFiles field of the Legacy Code Tool structure specifies multiple header files

Apply Code Style Settings to Legacy Functions

To apply the model configuration parameters for code style to a legacy function:

1. Initialize the Legacy Code Tool data structure. For example:

   ```
   def = legacy_code('initialize');
   ```

2. In the data structure, set the value of the `Options.singleCPPMexFile` field to `true`. For example:

   ```
   def.Options.singleCPPMexFile = true;
   ```

To check the setting, enter:

```
def.Options.singleCPPMexFile
```

singleCPPMexFile Limitations

You cannot set the `singleCPPMexFile` field to `true` if

- `Options.language='C++'`
- You use one of the following Simulink objects with the `IsAlias` property set to `true`:
  - `Simulink.Bus`
  - `Simulink.AliasType`
  - `Simulink.NumericType`
- The Legacy Code Tool function specification includes a `void*` or `void**` to represent scalar work data for a state argument
- `HeaderFiles` field of the Legacy Code Tool structure specifies multiple header files

Address Dependencies on Files in Different Locations

By default, the Legacy Code Tool assumes that files on which an S-function depends reside in the same folder as the dynamically loadable executable file for the S-function. If your S-function depends on files that reside elsewhere and you are using the template makefile build process, generate an *`sFunction`*`_makecfg.m` or `rtwmakecfg.m` file for the S-function. For example, you might generate this file if your Legacy Code Tool data structure defines compilation resources as path names.

To generate the *`sFunction`*`_makecfg.m` or `rtwmakecfg.m` file, call the `legacy_code` function with `'sfcn_makecfg_generate'` or `'rtwmakecfg_generate'` as the first

argument, and the name of the Legacy Code Tool data structure as the second argument. For example:

```
legacy_code('sfcn_makecfg_generate', lct_spec);
```

If you use multiple registration files in the same folder and generate an S-function for each file with a single call to `legacy_code`, the call to `legacy_code` that specifies `'sfcn_makecfg_generate'` or `'rtwmakecfg_generate'` must be common to all registration files. For more information, see “Handling Multiple Registration Files” (Simulink).

For example, if you define `defs` as an array of Legacy Code Tool structures, you call `legacy_code` with `'sfcn_makecfg_generate'` once.

```
defs = [defs1(:);defs2(:);defs3(:)];
legacy_code('sfcn_makecfg_generate', defs);
```

For more information, see “Build Support for S-Functions” (Simulink Coder).

Deploy S-Functions for Simulation and Code Generation

You can deploy the S-functions that you generate with the Legacy Code Tool so that other people can use them. To deploy an S-function for simulation and code generation, share the following files:

- Registration file
- Compiled dynamically loadable executable
- TLC block file
- *`sFunction`*`_makecfg.m` or `rtwmakecfg.m` file
- Header, source, and include files on which the generated S-function depends

When you use these deployed files:

- Before using the deployed files in a Simulink model, add the folder that contains the S-function files to the MATLAB path.
- If the Legacy Code Tool data structure registers required files as absolute paths and the location of the files changes, regenerate the *`sFunction`*`_makecfg.m` or `rtwmakecfg.m` file.

Integrate External C++ Object Methods

Integrate legacy C++ object methods by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C++ MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a block TLC file and optional rtwmakecfg.m file that calls the legacy code during code generation.

Provide the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The definition of the legacy C++ class in this example is:

```
class adder {
  private:
      int int_state;
  public:
      adder();
      int add_one(int increment);
      int get_val();
};
```

The legacy source code is in the files adder_cpp.h and adder_cpp.cpp.

```
% rtwdemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_adder_cpp';
def.StartFcnSpec  = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
def.HeaderFiles   = {'adder_cpp.h'};
def.SourceFiles   = {'adder_cpp.cpp'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

```
def.Options.language = 'C++';
def.Options.useTlcWithAccel = false;
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_adder_cpp.cpp.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_adder_cpp
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017'.
MEX completed successfully.
    mex('rtwdemo_sfun_adder_cpp.cpp', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2017'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_adder_cpp
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again. Set the first input to 'sfcn_tlc_generate' to generate a TLC block file that supports code generation through Simulink® Coder™. If the TLC block file is not created and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_adder_cpp.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

After you create the TLC block file, you can call the function legacy_code() again. Set the first input to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file that supports code

generation through Simulink® Coder™. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

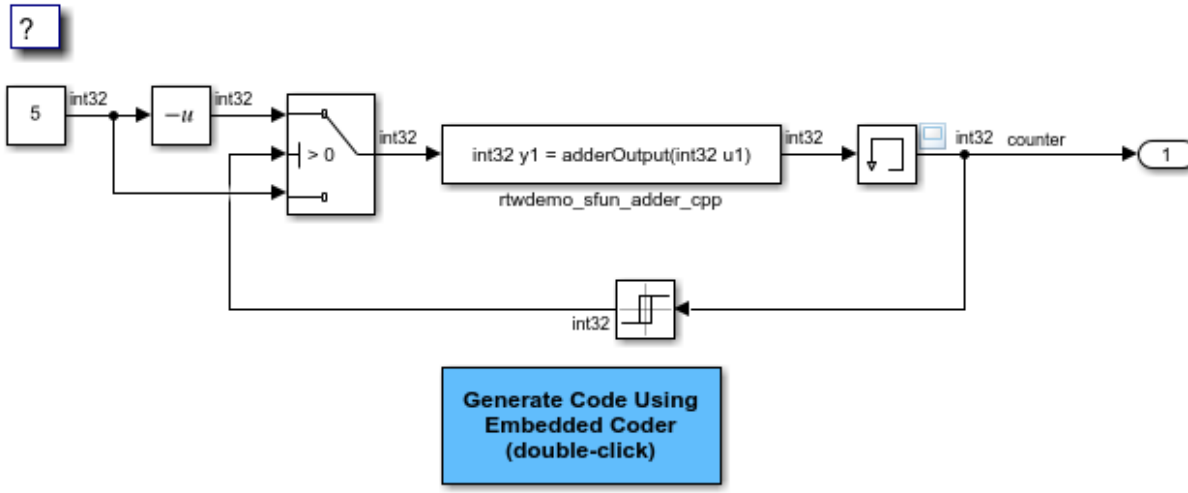
After you compile the C-MEX S-function source, you can call the function legacy_code() again. Set the first input to 'slblock_generate' to generate a masked S-function block that is configured to call that S-function. The software places the block in a new model. You can copy the block to an existing model.

```
% legacy_code('slblock_generate', def);
```

Show the Generated Integration with Legacy Code

The model rtwdemo_lct_cpp shows integration with the legacy code.

```
open_system('rtwdemo_lct_cpp')
sim('rtwdemo_lct_cpp')
```



Integrate External C++ Objects

The Legacy Code Tool can interface with C++ functions, but not C++ objects. Using the previous example as a starting point, here is an example of how you can work around this limitation.

- Modify the class definition for `adder` in a new file `adder_cpp.hpp`. Add three new macros that dynamically allocate a new `adder` object, invoke the method `add_one()`, and free the memory allocated. Each macro takes a pointer to an `adder` object. Because each function called by the Legacy Code Tool must have a C-like signature, the pointer is cached and passed as a `void*`. Then you must explicitly cast to `adder*` in the macro. The new class definition for `adder`:

```
#ifndef _ADDER_CPP_
#define _ADDER_CPP_

class adder {
private:
    int int_state;
public:
    adder(): int_state(0) {};
```

```
    int add_one(int increment);
    int get_val() {return int_state;};
};

// Method wrappers implemented as macros
#define createAdder(work1) \
    *(work1) = new adder

#define deleteAdder(work1) \
    delete(static_cast<adder*>(*(work1)))

#define adderOutput(work1, u1) \
    (static_cast<adder*> ((work1)))->add_one(u1)

#endif /* _ADDER_CPP_ */
```

- Update `adder_cpp.cpp`. With the class modification, instead of one global instance, each generated S-function manages its own `adder` object.

```
#include "adder_cpp.hpp"

int adder::add_one(int increment)
{
    int_state += increment;
    return int_state;
}
```

- Update `rtwdemo_sfun_adder_cpp.cpp` with the following changes:
  - `StartFcnSpec` calls the macro that allocates a new `adder` object and caches the pointer.

    ```
    def.StartFcnSpec  = 'createAdder(void **work1)';
    ```

  - `OutputFcnSpec` calls the macro that invokes the method `add_one()` and provides the S-function specific `adder` pointer object.

    ```
    def.OutputFcnSpec = 'int32 y1 = adderOutput(void *work1, int32 u1)';
    ```

  - `TerminateFcnSpec` calls the macro that frees the memory.

    ```
    def.TerminateFcnSpec = 'deleteAdder(void **work1)';
    ```

Legacy Code Tool Examples

Integrate External C Functions That Pass Input Arguments By Value Versus Address

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their input arguments by value versus address.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- FLT filterV1(const FLT signal, const FLT prevSignal, const FLT gain)
- FLT filterV2(const FLT* signal, const FLT prevSignal, const FLT gain)

FLT is a typedef to float. The legacy source code is in the files your_types.h, myfilter.h, filterV1.c, and filterV2.c.

Note the difference in the OutputFcnSpec defined in the two structures; the first case specifies that the first input argument is passed by value, while the second case specifies pass by pointer.

```
defs = [];

% rtwdemo_sfun_filterV1
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV1';
def.OutputFcnSpec = 'single y1 = filterV1(single u1, single u2, single p1)';
```

```
def.HeaderFiles   = {'myfilter.h'};
def.SourceFiles   = {'filterV1.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_filterV2
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_filterV2';
def.OutputFcnSpec = 'single y1 = filterV2(single u1[1], single u2, single p1)';
def.HeaderFiles   = {'myfilter.h'};
def.SourceFiles   = {'filterV2.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];
```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions in simulation. The source code for the S-functions is in the files rtwdemo_sfun_filterV1.c and rtwdemo_sfun_filterV2.c.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
### Start Compiling rtwdemo_sfun_filterV1
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_filterV1.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_filterV1
### Exit
```

```
### Start Compiling rtwdemo_sfun_filterV2
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_filterV2.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_filterV2
### Exit
```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are rtwdemo_sfun_filterV1.tlc and rtwdemo_sfun_filterV2.tlc.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an rtwmakecfg.m File for Code Generation

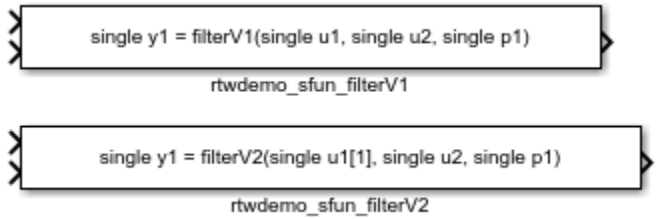
After you create the TLC block files, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

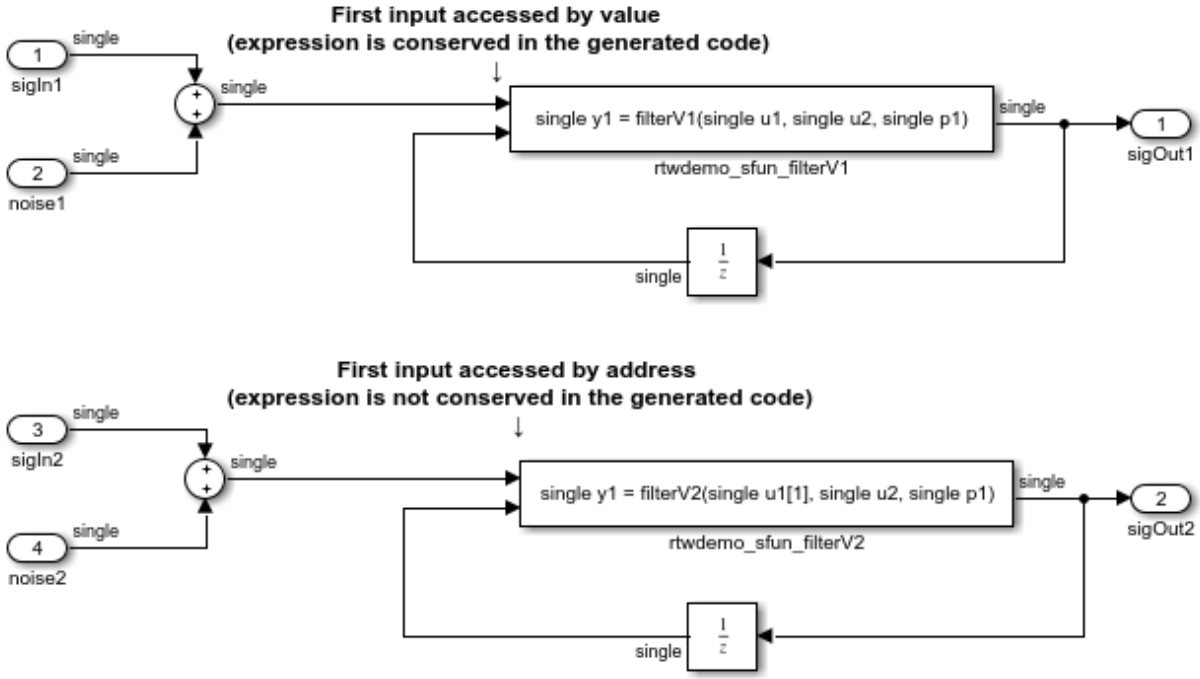
```
legacy_code('slblock_generate', defs);
```



Show the Generated Integration with Legacy Code

The model rtwdemo_lct_filter shows integration of the model with the legacy code. The subsystem TestFilter serves as a harness for the calls to the legacy C functions via the generate S-functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_filter')
open_system('rtwdemo_lct_filter/TestFilter')
sim('rtwdemo_lct_filter')
```



Integrate External C Functions That Pass the Output Argument As a Return Argument

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their output as a return argument.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

FLT gainScalar(const FLT in, const FLT gain)

FLT is a typedef to float. The legacy source code is in the files your_types.h, gain.h, and gainScalar.c.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_gain_scalar';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles   = {'gain.h'};
def.SourceFiles   = {'gainScalar.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_gain_scalar.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_gain_scalar
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
```

```
MEX completed successfully.
    mex('rtwdemo_sfun_gain_scalar.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_gain_scalar
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_gain_scalar.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

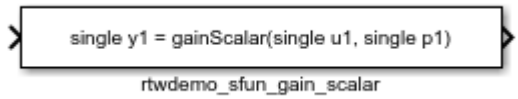
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

```
legacy_code('slblock_generate', def);
```



Show the Generated Integration with Legacy Code

The model rtwdemo_lct_gain shows integration of the model with the legacy code. The subsystem TestGain serves as a harness for the call to the legacy C function via the generate S-function.

```
open_system('rtwdemo_lct_gain')
open_system('rtwdemo_lct_gain/TestGain')
sim('rtwdemo_lct_gain')
```

Integrate External C Functions That Pass Input and Output Arguments as Signals with a Fixed-Point Data Type

This example shows how to use the Legacy Code Tool to integrate legacy C functions that pass their inputs and outputs by using parameters of fixed-point data type.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)

myFixpt is logically a fixed-point data type, which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files timesFixpt.h, and timesS16.c.

```
% rtwdemo_sfun_times_s16
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_times_s16';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt u2, uint8 p1)';
def.HeaderFiles   = {'timesFixpt.h'};
def.SourceFiles   = {'timesS16.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_times_s16.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_times_s16
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_times_s16.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
```

```
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_times_s16
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_times_s16.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

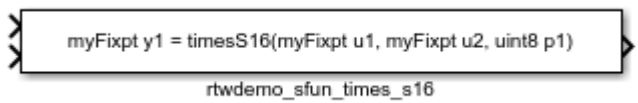
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

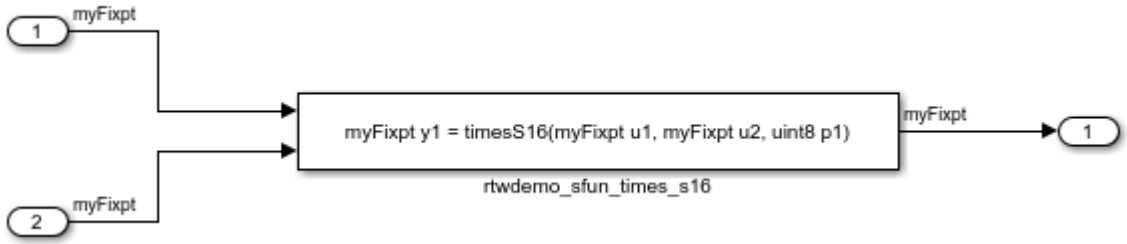
```
legacy_code('slblock_generate', def);
```



Show the Integration of the Model with Legacy Code

The model rtwdemo_lct_fixpt_signals shows integration of the model with the legacy code. The subsystem TestFixpt serves as a harness for the call to the legacy C function via the generated S-function.

```
open_system('rtwdemo_lct_fixpt_signals')
open_system('rtwdemo_lct_fixpt_signals/TestFixpt')
sim('rtwdemo_lct_fixpt_signals')
```



Integrate External C Functions with Instance-Specific Persistent Memory

Integrate legacy C functions that use instance-specific persistent memory by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

void memory_bus_init(COUNTERBUS *mem, int32_T upper_sat, int32_T lower_sat);

void memory_bus_step(COUNTERBUS *input, COUNTERBUS *mem, COUNTERBUS *output);

mem is an instance-specific persistent memory for applying a one integration step delay. COUNTERBUS is a struct typedef defined in counterbus.h and implemented with a Simulink.Bus object in the base workspace. The legacy source code is in the files memory_bus.h, and memory_bus.c.

```
evalin('base','load rtwdemo_lct_data.mat')

% rtwdemo_sfun_work
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_work';
def.InitializeConditionsFcnSpec = ...
    'void memory_bus_init(COUNTERBUS work1[1], int32 p1, int32 p2)';
def.OutputFcnSpec = ...
    'void memory_bus_step(COUNTERBUS u1[1], COUNTERBUS work1[1], COUNTERBUS y1[1])';
def.HeaderFiles   = {'memory_bus.h'};
def.SourceFiles   = {'memory_bus.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_work.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);

### Start Compiling rtwdemo_sfun_work
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
```

```
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_work.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-I(
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_work
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_work.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

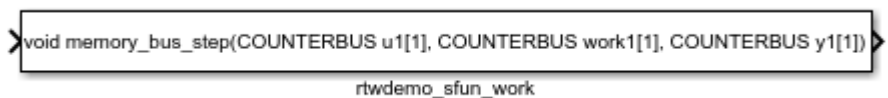
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

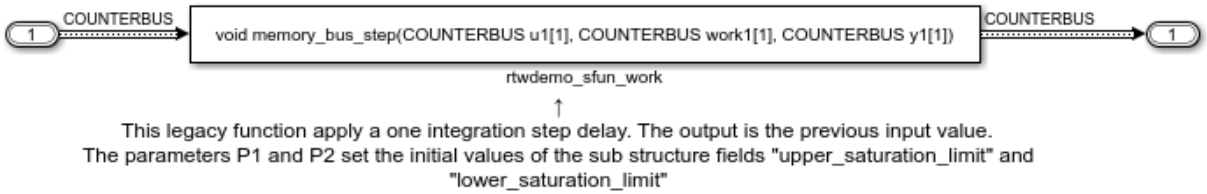
```
legacy_code('slblock_generate', def);
```



Show the Integration of the Model with Legacy Code

The model rtwdemo_lct_work shows integration of the model with the legacy code. The subsystem memory_bus serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_work')
open_system('rtwdemo_lct_work/memory_bus')
sim('rtwdemo_lct_work')
```



Integrate External C Functions That Use Structure Arguments

Integrate legacy C functions with structure arguments that use Simulink® buses with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

counterbusFcn(COUNTERBUS *u1, int32_T u2, COUNTERBUS *y1, int32_T *y2)

COUNTERBUS is a struct typedef defined in counterbus.h and implemented with a Simulink.Bus object in the base workspace. The legacy source code is in the files counterbus.h, and counterbus.c.

```
evalin('base','load rtwdemo_lct_data.mat')

% rtwdemo_sfun_counterbus
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_counterbus';
def.OutputFcnSpec = ...
    'void counterbusFcn(COUNTERBUS u1[1], int32 u2, COUNTERBUS y1[1], int32 y2[1])';
def.HeaderFiles   = {'counterbus.h'};
def.SourceFiles   = {'counterbus.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_counterbus.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_counterbus
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_counterbus.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_counterbus
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_counterbus.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

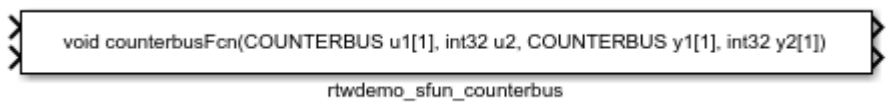
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

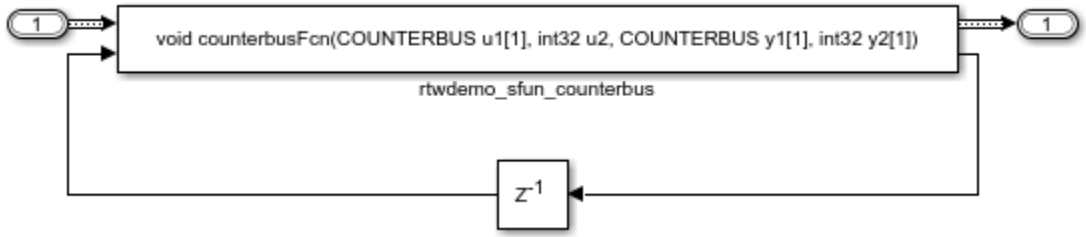
```
legacy_code('slblock_generate', def);
```



Show the Integration of the Model with Legacy Code

The model rtwdemo_lct_bus shows integration of the model with the legacy code. The subsystem TestCounter serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_bus')
open_system('rtwdemo_lct_bus/TestCounter')
sim('rtwdemo_lct_bus')
```



Integrate External C Functions That Pass Input and Output Arguments as Signals with Complex Data

Integrate legacy C functions using complex signals with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

void cplx_gain(creal_T *input, creal_T *gain, creal_T *output);

creal_T is the complex representation of a double. The legacy source code is in the files cplxgain.h, and cplxgain.c.

```
% rtwdemo_sfun_gain_scalar
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_cplx_gain';
def.OutputFcnSpec = ...
    ['void cplx_gain(complex<double> u1[1], '...
```

```
    'complex<double> p1[1], complex<double> y1[1])'];
def.HeaderFiles   = {'cplxgain.h'};
def.SourceFiles   = {'cplxgain.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_cplx_gain.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_cplx_gain
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_cplx_gain.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_cplx_gain
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_cplx_gain.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

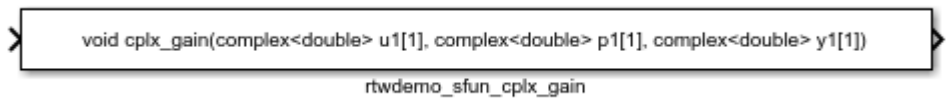
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

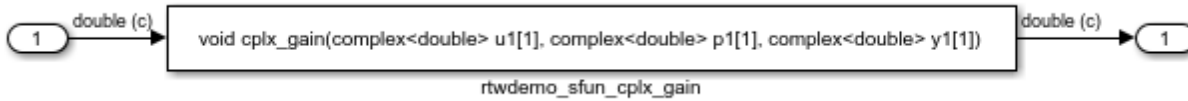
```
legacy_code('slblock_generate', def);
```



Show the Integration of the Model with Legacy Code

The model rtwdemo_lct_cplxgain shows integration of the model with the legacy code. The subsystem complex_gain serves as a harness for the call to the legacy C function via the generate S-function.

```
if isempty(find_system('SearchDepth',0,'Name','rtwdemo_lct_cplxgain'))
    open_system('rtwdemo_lct_cplxgain')
    open_system('rtwdemo_lct_cplxgain/complex_gain')
    sim('rtwdemo_lct_cplxgain')
end
```



Integrate External C Functions That Pass Arguments That Have Inherited Dimensions

This example shows how to use the Legacy Code Tool to integrate legacy C functions whose arguments have inherited dimensions.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- void mat_add(real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, real_T *y1)
- void mat_mult(real_T *u1, real_T *u2, int32_T nbRows1, int32_T nbCols1, int32_T nbCols2, real_T *y1)

real_T is a typedef to double, and int32_T is a typedef to a 32-bit integer. The legacy source code is in the files mat_ops.h, and mat_ops.c.

```
defs = [];

% rtwdemo_sfun_mat_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_add';
```

```
def.OutputFcnSpec = ['void mat_add(double u1[][], double u2[][], ' ...
                     'int32 u3, int32 u4, double y1[size(u1,1)][size(u1,2)])'];
def.HeaderFiles   = {'mat_ops.h'};
def.SourceFiles   = {'mat_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_mat_mult
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_mat_mult';
def.OutputFcnSpec =  ['void mat_mult(double u1[p1][p2], double u2[p2][p3], '...
                     'int32 p1, int32 p2, int32 p3, double y1[p1][p3])'];
def.HeaderFiles   = {'mat_ops.h'};
def.SourceFiles   = {'mat_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];
```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions during simulation. The source code for the S-function is in the files rtwdemo_sfun_mat_add.c and rtwdemo_sfun_mat_mult.c.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
### Start Compiling rtwdemo_sfun_mat_add
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_mat_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
```

```
### Finish Compiling rtwdemo_sfun_mat_add
### Exit

### Start Compiling rtwdemo_sfun_mat_mult
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_mat_mult.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src',
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_mat_mult
### Exit
```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are rtwdemo_sfun_mat_add.tlc and rtwdemo_sfun_mat_mult.tlc.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an rtwmakecfg.m File for Code Generation

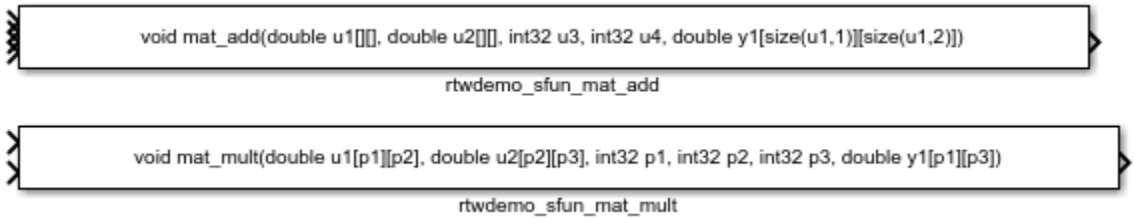
After you create the TLC block files, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model

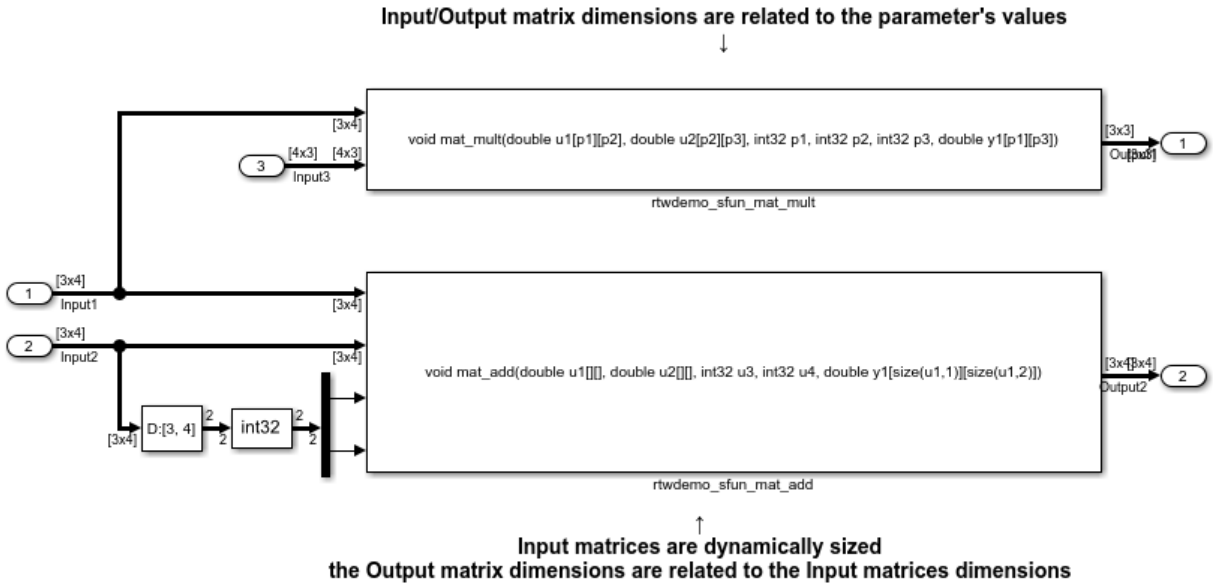
```
legacy_code('slblock_generate', defs);
```



Show the Generated Integration with Legacy Code

The model rtwdemo_lct_inherit_dims shows integration of the model with the legacy code. The subsystem TestMatOps serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_inherit_dims')
open_system('rtwdemo_lct_inherit_dims/TestMatOps')
sim('rtwdemo_lct_inherit_dims')
```



Integrate External C Functions That Implement Start and Terminate Actions

Integrate legacy C functions that have start and terminate actions by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties,

call legacy_code('help'). The prototypes of the legacy functions being called in this example are:

- void initFaultCounter(unsigned int *counter)
- void openLogFile(void **fid)
- void incAndLogFaultCounter(void *fid, unsigned int *counter, double time)
- void closeLogFile(void **fid)

The legacy source code is in the files your_types.h, fault.h, and fault.c.

```
% rtwdemo_sfun_fault
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_fault';
def.InitializeConditionsFcnSpec  = 'initFaultCounter(uint32 work2[1])';
def.StartFcnSpec                 = 'openLogFile(void **work1)';
def.OutputFcnSpec                = ...
    'incAndLogFaultCounter(void *work1, uint32 work2[1], double u1)';
def.TerminateFcnSpec             = 'closeLogFile(void **work1)';
def.HeaderFiles                  = {'fault.h'};
def.SourceFiles                  = {'fault.c'};
def.IncPaths                     = {'rtwdemo_lct_src'};
def.SrcPaths                     = {'rtwdemo_lct_src'};
def.Options.useTlcWithAccel      = false;
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_fault.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);

### Start Compiling rtwdemo_sfun_fault
```

```
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('rtwdemo_sfun_fault.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-I
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_fault
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_fault.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

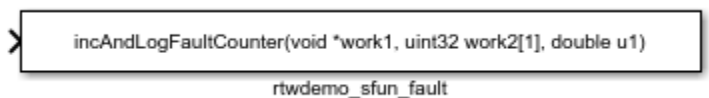
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

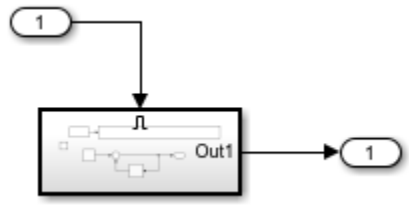
```
legacy_code('slblock_generate', def);
```



Showing the Generated Integration with Legacy Code

The model rtwdemo_lct_start_term shows integration of the model with the legacy code. The subsystem TestFixpt serves as a harness for the call to the legacy C function, and the scope compares the output of the function with the output of the built-in Simulink® product block; the results should be identical.

```
open_system('rtwdemo_lct_start_term')
open_system('rtwdemo_lct_start_term/TestFault')
sim('rtwdemo_lct_start_term')
```



Integrate External C Functions That Pass Arguments as Multi-Dimensional Signals

This example shows how to use the Legacy Code Tool to integrate legacy C functions with multi-dimensional Signals.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

void array3d_add(real_T *y1, real_T *u1, real_T *u2, int32_T nbRows, int32_T nbCols, int32_T nbPages);

real_T is a typedef to double, and int32_T is a typedef to a 32-bit integer. The legacy source code is in the files ndarray_ops.h, and ndarray_ops.c.

```
% rtwdemo_sfun_ndarray_add
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_ndarray_add';
def.OutputFcnSpec =...
    ['void array3d_add(double y1[size(u1,1)][size(u1,2)][size(u1,3)], ',...
    'double u1[][][], double u2[][][], ' ...
    'int32 size(u1,1), int32 size(u1,2), int32 size(u1,3))'];
def.HeaderFiles   = {'ndarray_ops.h'};
def.SourceFiles   = {'ndarray_ops.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

y1 is a 3-D output signal of same dimensions as the 3-D input signal u1. Note that the last 3 arguments passed to the legacy function correspond to the number of element in each dimension of the 3-D input signal u1.

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_ndarray_add.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_ndarray_add
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
```

```
    mex('rtwdemo_sfun_ndarray_add.c', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_ndarray_add
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate a TLC block file. The block file specifies how the generated code for a model calls the legacy code. If you do not generate a TLC block file and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_ndarray_add.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

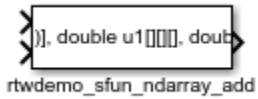
After you create the TLC block file, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate a masked S-function block that calls that S-function. The software places the block in a new model. From there you can copy it to an existing model.

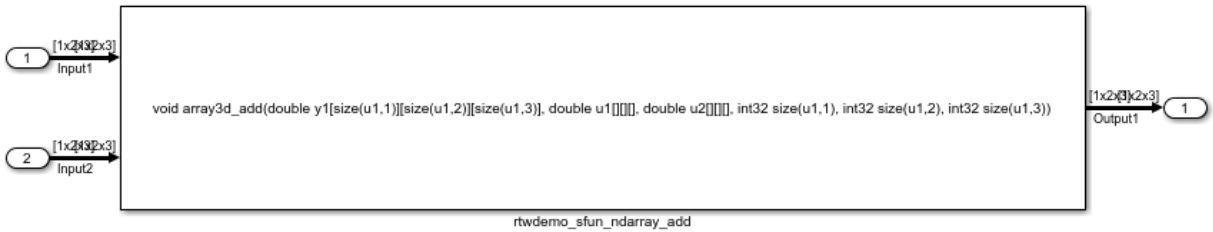
```
legacy_code('slblock_generate', def);
```



Showing the Generated Integration with Legacy Code

The model rtwdemo_lct_ndarray shows integration of the model with the legacy code. The subsystem ndarray_add serves as a harness for the call to the legacy C function.

```
open_system('rtwdemo_lct_ndarray')
open_system('rtwdemo_lct_ndarray/ndarray_add')
sim('rtwdemo_lct_ndarray')
```



Integrate External C Functions with a Block Sample Time Specified, Inherited, and Parameterized

This example shows how to use the Legacy Code Tool to integrate legacy C functions with the block's sample time specified, inherited and parameterized.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values

corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

FLT gainScalar(const FLT in, const FLT gain)

FLT is a typedef to float. The legacy source code is in the files your_types.h, gain.h, and gainScalar.c.

```
defs = [];

% rtwdemo_sfun_st_inherited
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_inherited';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles   = {'gain.h'};
def.SourceFiles   = {'gainScalar.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
defs = [defs; def];

% rtwdemo_sfun_st_fixed
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_fixed';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles   = {'gain.h'};
def.SourceFiles   = {'gainScalar.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
def.SampleTime    = [2 1];
defs = [defs; def];

% rtwdemo_sfun_st_parameterized
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_st_parameterized';
def.OutputFcnSpec = 'single y1 = gainScalar(single u1, single p1)';
def.HeaderFiles   = {'gain.h'};
def.SourceFiles   = {'gainScalar.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
def.SampleTime    = 'parameterized';
defs = [defs; def];
```

Generate S-Functions for Simulation

To generate C-MEX S-functions according to the description provided by the input argument 'defs', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-functions call the legacy functions during simulation. The source code for the S-functions is in the files rtwdemo_sfun_st_inherited.c and rtwdemo_sfun_st_fixed.c. rtwdemo_sfun_st_parameterized.c.

```
legacy_code('sfcn_cmex_generate', defs);
```

Compile the Generated S-Functions for Simulation

After you generate the C-MEX S-function source files, to compile the S-functions for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', defs);
```

```
### Start Compiling rtwdemo_sfun_st_inherited

```

Generate TLC Block Files for Code Generation

After you compile the S-functions and use them in simulation, you can call the function legacy_code() again with the first input set to 'sfcn_tlc_generate' to generate TLC block files. Block files specify how the generated code for a model calls the legacy code. If you do not generate TLC block files and you try to generate code for a model that includes the S-functions, code generation fails. The TLC block files for the S-functions are rtwdemo_sfun_st_inherited.tlc and rtwdemo_sfun_st_fixed.tlc. rtwdemo_sfun_st_parameterized.tlc.

```
legacy_code('sfcn_tlc_generate', defs);
```

Generate an rtwmakecfg.m File for Code Generation

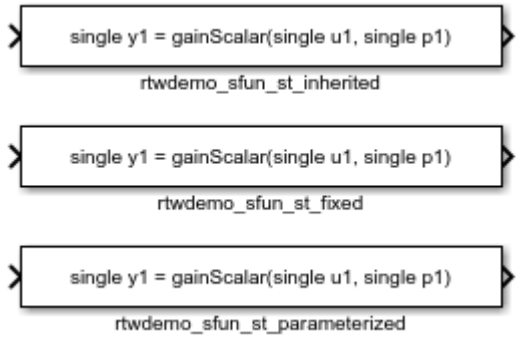
After you create the TLC block files, you can call the function legacy_code() again with the first input set to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file to support code generation. If the required source and header files for the S-functions are not in the same folder as the S-functions, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', defs);
```

Generate Masked S-Function Blocks for Calling the Generated S-Functions

After you compile the C-MEX S-function source, you can call the function legacy_code() again with the first input set to 'slblock_generate' to generate masked S-function blocks that call the S-functions. The software places the blocks in a new model. From there you can copy them to an existing model.

```
legacy_code('slblock_generate', defs);
```



Show the Generated Integration with Legacy Code

The model rtwdemo_lct_sampletime shows integration of the model with the legacy code. The subsystem sample_time serves as a harness for the calls to the legacy C functions, with unit delays serving to store the previous output values.

```
open_system('rtwdemo_lct_sampletime')
open_system('rtwdemo_lct_sampletime/sample_time')
sim('rtwdemo_lct_sampletime')
```

- “Call External C Code from Model and Generated Code”

Integrate External C Functions That Pass Input and Output Arguments as Parameters with a Fixed-Point Data Type

Integrate legacy C functions that pass their inputs and outputs by using parameters of a fixed-point data type with the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C-MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a TLC block file and optional rtwmakecfg.m file that specifies how the generated code for a model calls the legacy code.

Provide the Legacy Function Specification

Legacy Code Tool functions take a specific data structure or array of structures as the argument. You can initialize the data structure by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The prototype of the legacy functions being called in this example is:

myFixpt timesS16(const myFixpt in1, const myFixpt in2, const uint8_T fracLength)

myFixpt is logically a fixed point data type, which is physically a typedef to a 16-bit integer:

```
myFixpt = Simulink.NumericType;
myFixpt.DataTypeMode = 'Fixed-point: binary point scaling';
myFixpt.Signed = true;
myFixpt.WordLength = 16;
myFixpt.FractionLength = 10;
myFixpt.IsAlias = true;
myFixpt.HeaderFile = 'timesFixpt.h';
```

The legacy source code is in the files timesFixpt.h, and timesS16.c.

```
% rtwdemo_sfun_gain_fixpt
def = legacy_code('initialize');
```

```
def.SFunctionName = 'rtwdemo_sfun_gain_fixpt';
def.OutputFcnSpec = 'myFixpt y1 = timesS16(myFixpt u1, myFixpt p1, uint8 p2)';
def.HeaderFiles   = {'timesFixpt.h'};
def.SourceFiles   = {'timesS16.c'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_gain_fixpt.c.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

Integrate External C++ Object Methods

Integrate legacy C++ object methods by using the Legacy Code Tool.

With the Legacy Code Tool, you can:

- Provide the legacy function specification.
- Generate a C++ MEX S-function that calls the legacy code during simulation.
- Compile and build the generated S-function for simulation.
- Generate a block TLC file and optional rtwmakecfg.m file that calls the legacy code during code generation.

Provide the Legacy Function Specification

Functions provided with the Legacy Code Tool take a specific data structure or array of structures as the argument. The data structure is initialized by calling the function legacy_code() using 'initialize' as the first input. After initializing the structure, assign its properties to values corresponding to the legacy code being integrated. For detailed help on the properties, call legacy_code('help'). The definition of the legacy C++ class in this example is:

```
class adder {
  private:
      int int_state;
  public:
      adder();
      int add_one(int increment);
      int get_val();
};
```

The legacy source code is in the files adder_cpp.h and adder_cpp.cpp.

```
% rtwdemo_sfun_adder_cpp
def = legacy_code('initialize');
def.SFunctionName = 'rtwdemo_sfun_adder_cpp';
def.StartFcnSpec  = 'createAdder()';
def.OutputFcnSpec = 'int32 y1 = adderOutput(int32 u1)';
def.TerminateFcnSpec = 'deleteAdder()';
def.HeaderFiles   = {'adder_cpp.h'};
def.SourceFiles   = {'adder_cpp.cpp'};
def.IncPaths      = {'rtwdemo_lct_src'};
def.SrcPaths      = {'rtwdemo_lct_src'};
```

```
def.Options.language = 'C++';
def.Options.useTlcWithAccel = false;
```

Generate an S-Function for Simulation

To generate a C-MEX S-function according to the description provided by the input argument 'def', call the function legacy_code() again with the first input set to 'sfcn_cmex_generate'. The S-function calls the legacy functions during simulation. The source code for the S-function is in the file rtwdemo_sfun_adder_cpp.cpp.

```
legacy_code('sfcn_cmex_generate', def);
```

Compile the Generated S-Function for Simulation

After you generate the C-MEX S-function source file, to compile the S-function for simulation with Simulink®, call the function legacy_code() again with the first input set to 'compile'.

```
legacy_code('compile', def);
```

```
### Start Compiling rtwdemo_sfun_adder_cpp
    mex('-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src', '-IC:\TEMP\Bdoc19a_1067994_
Building with 'Microsoft Visual C++ 2017'.
MEX completed successfully.
    mex('rtwdemo_sfun_adder_cpp.cpp', '-IB:\matlab\toolbox\rtw\rtwdemos\rtwdemo_lct_src
Building with 'Microsoft Visual C++ 2017'.
MEX completed successfully.
### Finish Compiling rtwdemo_sfun_adder_cpp
### Exit
```

Generate a TLC Block File for Code Generation

After you compile the S-function and use it in simulation, you can call the function legacy_code() again. Set the first input to 'sfcn_tlc_generate' to generate a TLC block file that supports code generation through Simulink® Coder™. If the TLC block file is not created and you try to generate code for a model that includes the S-function, code generation fails. The TLC block file for the S-function is: rtwdemo_sfun_adder_cpp.tlc.

```
legacy_code('sfcn_tlc_generate', def);
```

Generate an rtwmakecfg.m File for Code Generation

After you create the TLC block file, you can call the function legacy_code() again. Set the first input to 'rtwmakecfg_generate' to generate an rtwmakecfg.m file that supports code

generation through Simulink® Coder™. If the required source and header files for the S-function are not in the same folder as the S-function, and you want to add these dependencies in the makefile produced during code generation, generate the rtwmakecfg.m file.

```
legacy_code('rtwmakecfg_generate', def);
```

Generate a Masked S-Function Block for Calling the Generated S-Function

After you compile the C-MEX S-function source, you can call the function legacy_code() again. Set the first input to 'slblock_generate' to generate a masked S-function block that is configured to call that S-function. The software places the block in a new model. You can copy the block to an existing model.

```
% legacy_code('slblock_generate', def);
```

Show the Generated Integration with Legacy Code

The model rtwdemo_lct_cpp shows integration with the legacy code.

```
open_system('rtwdemo_lct_cpp')
sim('rtwdemo_lct_cpp')
```

External Code Integration Examples

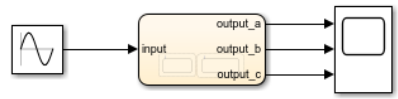
This topic shows various scenarios of external code integration.

Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

Open Model

```
model='rtwdemo_sfcustom';
open_system(model);
```



Integrating c-code into model

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the simulation target and enter the following:

Include Code - Header that defines functions, structures, and data to be accessible by Stateflow.
Include Path - Path to this include file.
Source Files - c-files that define the functions and data accessible by Stateflow.

▶ **Open simulation custom code settings**

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

Calling c-code from Stateflow

Functions
Custom c-code functions can be called from Stateflow using the same syntax as graphical function calls. The statement takes the form:

result = my_custom_function(in_args);

Structures
Variables of structure type can be accessed in Stateflow via the "dot" notation. The expression takes the form:

result = my_var.my_field;

To view the custom source for this examplenstration double click the links below.

▶ **Open my_header.h**

▶ **Open my_function.c**

Calling C++ code from Stateflow

Custom C++ code can also be integrated into Stateflow and Simulink Coder. Double-click below for a example.

▶ **Open rtwdemo_sfcpp**

Additional documentation

Additional documentation is available for integrating C and C++ code in your modelby double-clicking the link below.

▶ **C-Code integration**

▶ **C++-Code integration**

Integrate Code

1. The example includes the custom header file `my_header.c` and the custom source file `my_function.c`.

```
%Open files my_header.h and my_function.c
eval('edit my_header.h')
eval('edit my_function.c')
```

2. On the Configuration Parameters dialog box **Simulation Target** pane, enter the custom source file and header file. Also enter additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Simulation Target** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Simulation Target');
```

3. If you generate code with Simulink Coder®, on the Configuration Parameters dialog box **Code Generation > Custom Code** pane, enter the same custom source file and header file. Also enter the same additional include directories and source files.

In this example, the custom header file `my_header.c` and source file `my_function.c` are entered on the **Code Generation > Custom Code** pane.

```
%Open Configuration Parameters dialog box
slCfgPrmDlg(model,'Open');
slCfgPrmDlg(bdroot,'TurnToPage','Code Generation/Custom Code');
```

Generate Code

```
rtwbuild('rtwdemo_sfcustom')
```

```
### Starting build procedure for model: rtwdemo_sfcustom
### Successful completion of build procedure for model: rtwdemo_sfcustom
```

Call C Code from Stateflow

To call custom C code functions from Stateflow, use the same syntax as graphical function calls: `result = my_custom_function(in_args);`

To call variables of structure type, use the dot notation: `result = my_var.my_field;`

```

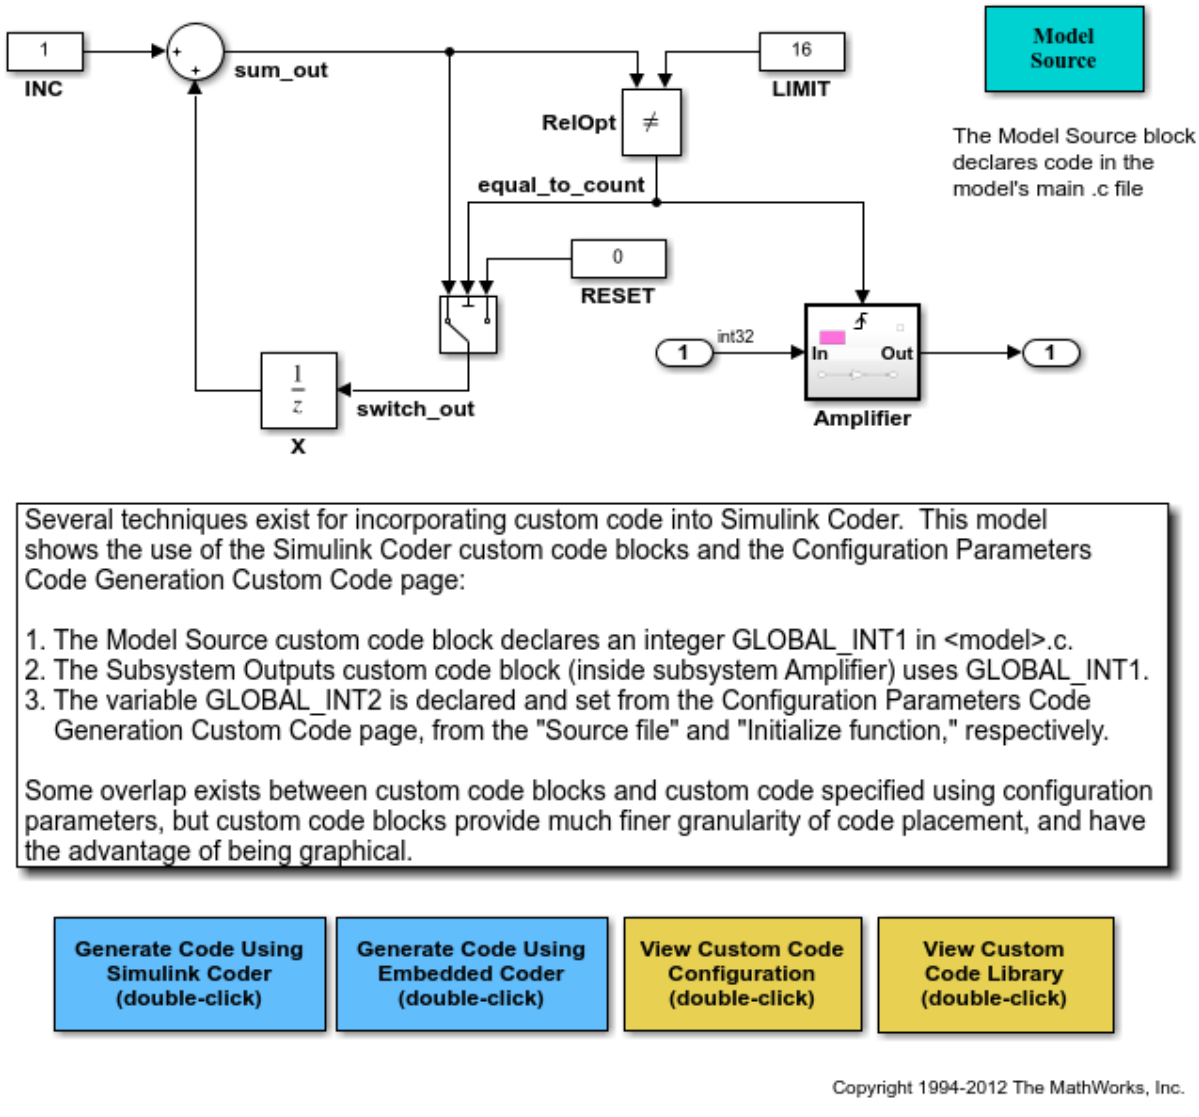
Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```



2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

3. Examine the settings for parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
- **Initialize function** initializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem `Amplifier`. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the `Amplifier` subsystem. The external code:

- Declares the pointer variable `*intPtr` and initializes it with the value of variable `GLOBAL_INT1`.
- Sets the pointer variable to -1 during execution.
- Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;

int_T GLOBAL_INT1 = 0;
```

The Output function for the `Amplifier` subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the `Amplifier` subsystem.

```
int_T *intPtr = &GLOBAL_INT1;

*intPtr = -1;

rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
```

```
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

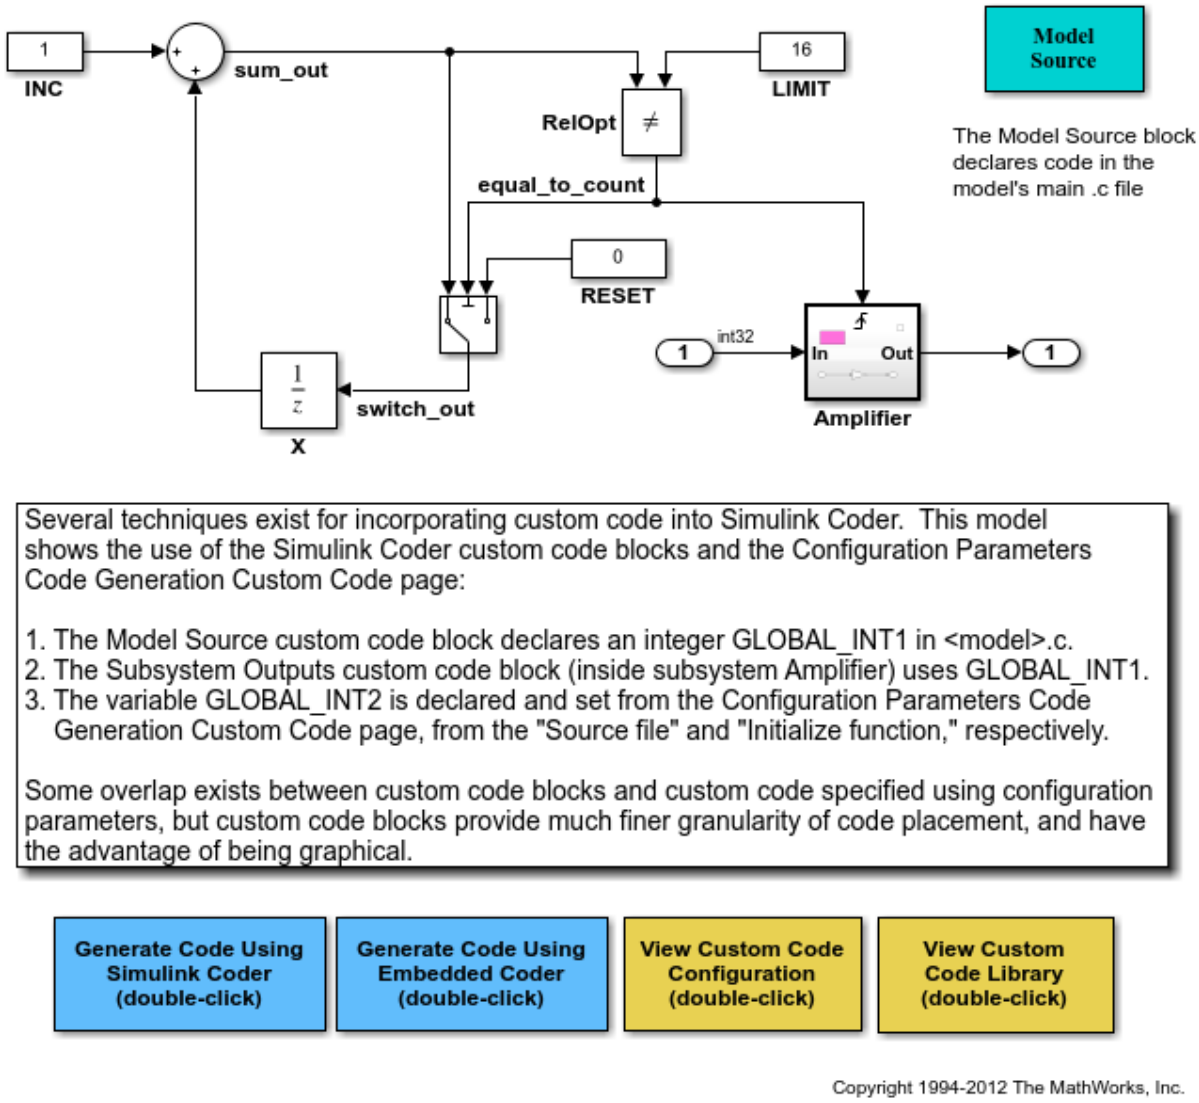
```
GLOBAL_INT2 = 1;
```

Integrate External C Code Into Generated Code By Using Custom Code Blocks and Model Configuration Parameters

This example shows how to place external code in generated code by using custom code blocks and model configuration parameters.

1. Open the model `rtwdemo_slcustcode`.

```
open_system('rtwdemo_slcustcode')
```



2. Open the Model Configuration Parameters dialog box and navigate to the **Custom Code** pane.

3. Examine the settings for parameters **Source file** and **Initialize function**.

- **Source file** specifies a comment and sets the variable `GLOBAL_INT2` to -1.
- **Initialize function** initializes the variable `GLOBAL_INT2` to 1.

4. Close the dialog box.

5. Double-click the Model Source block. The **Top of Model Source** field specifies that the code generator declare the variable `GLOBAL_INT1` and set it to 0 at the top of the generated file `rtwdemo_slcustcode.c`.

6. Open the triggered subsystem `Amplifier`. The subsystem includes the System Outputs block. The code generator places code that you specify in that block in the generated code for the nearest parent atomic subsystem. In this case, the code generator places the external code in the generated code for the `Amplifier` subsystem. The external code:

- Declares the pointer variable `*intPtr` and initializes it with the value of variable `GLOBAL_INT1`.
- Sets the pointer variable to -1 during execution.
- Resets the pointer variable to 0 before exiting.

7. Generate code and a code generation report.

8. Examine the code in the generated source file `rtwdemo_slcustcode.c`. At the top of the file, after the `#include` statements, you find the following declaration code. The example specifies the first declaration with the **Source file** configuration parameter and the second declaration with the Model Source block.

```
int_T GLOBAL_INT2 = -1;

int_T GLOBAL_INT1 = 0;
```

The Output function for the `Amplifier` subsystem includes the following code, which shows the external code integrated with generated code that applies the gain. The example specifies the three lines of code for the pointer variable with the System Outputs block in the `Amplifier` subsystem.

```
int_T *intPtr = &GLOBAL_INT1;

*intPtr = -1;

rtwdemo_slcustcode_Y.Output = rtwdemo_slcustcode_U.Input << 1;
```

```
*intPtr = 0;
```

The following assignment appears in the model initialize entry-point function. The example specifies this assignment with the **Initialize function** configuration parameter.

```
GLOBAL_INT2 = 1;
```

Insert External C and C++ Code Into Stateflow Charts for Code Generation

This example shows how to use Stateflow® to integrate external code into a model.

Open Model

model='rtwdemo_sfcustom';
open_system(model);
```

Integrating c-code into model

Custom written c-files can be easily integrated into Stateflow models. This code can be used to augment Stateflow's capabilities or to take advantage of legacy code.

To add custom c-files open the simulation target and enter the following:

Include Code - Header that defines functions, structures, and data to be accessible by Stateflow.
Include Path - Path to this include file.
Source Files - c-files that define the functions and data accessible by Stateflow.

Open simulation custom code settings

If generating code via Simulink Coder, these same settings must also be added to the Model's configuration parameters custom code settings.

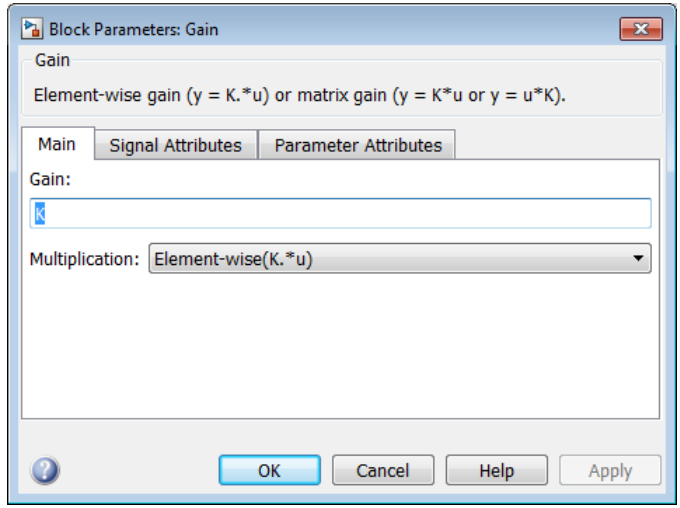
Generate S-Function from Subsystem

The **Generate S-function** feature automates the process of generating an S-function from a subsystem. In addition, the **Generate S-function** feature presents a display of parameters used within the subsystem, and lets you declare selected parameters tunable.

As an example, consider `SourceSubsys`, the same subsystem illustrated in the example "Create S-Function Blocks from a Subsystem" on page 60-62. The objective is to automatically extract `SourceSubsys` from the model and build an S-Function block from it, as in the previous example. In addition, the workspace variable `K` , which is the gain factor of the Gain block within `SourceSubsys` (as shown in the following Gain block parameter dialog box), is declared and generated as a tunable variable.



To auto-generate an S-function from `SourceSubsys` with tunable parameter `K`,

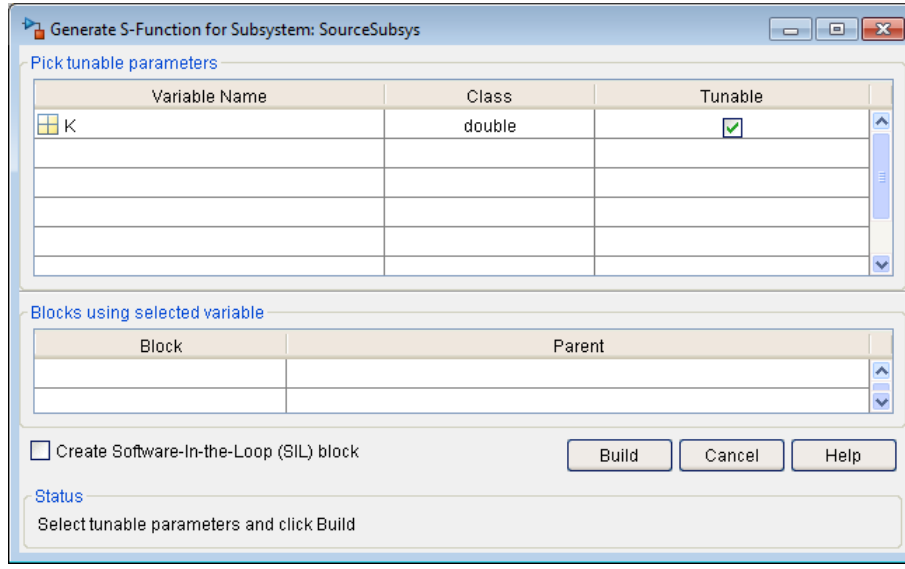
1. With the `SourceSubsys` model open, click the subsystem to select it.
2. From the **Code** menu, select **C/C++ Code** > **Generate S-Function**. This menu item is enabled when a subsystem is selected in the current model.

   Alternatively, you can right-click the subsystem and select **C/C++ Code** > **Generate S-Function** from the subsystem block's context menu.
3. The **Generate S-Function** window is displayed (see the next figure). This window shows variables (or data objects) that are referenced as block parameters in the subsystem, and lets you declare them as tunable.

The upper pane of the window displays three columns:

- **Variable Name**: name of the parameter.
- **Class**: If the parameter is a workspace variable, its data type is shown. If the parameter is a data object, its name and class is shown
- **Tunable**: Lets you select tunable parameters. To declare a parameter tunable, select the check box. In the next figure, the parameter K is declared tunable.

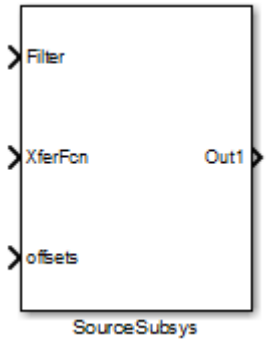
When you select a parameter in the upper pane, the lower pane shows the blocks that reference the parameter, and the parent system of each such block.



Generate S-Function Window

4 After selecting tunable parameters, click the **Build** button. This initiates code generation and compilation of the S-function, using the S-function target. The **Create New Model** option is automatically enabled.

5 The build process displays status messages in the MATLAB Command Window. When the build completes, the tunable parameters window closes, and a new untitled model window opens.



6 The model window contains an S-Function block with the same name as the subsystem from which the block was generated (in this example, `SourceSubsys`). Optionally, you can save the generated model containing the generated block.

7 The generated code for the S-Function block is stored in the current working folder. The following files are written to the top-level folder:

- *`subsys`*`_sf.c` or `.cpp`, where *`subsys`* is the subsystem name (for example, `SourceSubsys_sf.c`)
- *`subsys`*`_sf.h`
- *`subsys`*`_sf.`*`mexext`*, where *`mexext`* is a platform-dependent MEX-file extension (for example, `SourceSubsys_sf.mexw64`)

The source code for the S-function is written to the subfolder *`subsys`*`_sfcn_rtw`. The top level `.c` or `.cpp` file is a stub file that simply contains an include directive that you can use to interface other C/C++ code to the generated code.

Note For a list of files required to deploy your S-Function block for simulation or code generation, see “Required Files for S-Function Deployment” on page 60-60.

8 The generated S-Function block has inports and outports whose widths and sample times correspond to those of the original model.

The following code, from the `mdlOutputs` routine of the generated S-function code (in `SourceSubsys_sf.c`), shows how the tunable variable `K` is referenced by using calls to the MEX API.

```
static void mdlOutputs(SimStruct *S, int_T tid)
...
```

```
/* Gain: '<S1>/Gain' incorporates:
     *  Sum: '<S1>/Sum'
     */
    rtb_Gain_n[0] = (rtb_Product_p + (*(((const
      real_T**)ssGetInputPortSignalPtrs(S, 2))[0]))) * (*(real_T
      *)(mxGetData(K(S))));
    rtb_Gain_n[1] = (rtb_Product_p + (*(((const
      real_T**)ssGetInputPortSignalPtrs(S, 2))[1]))) * (*(real_T
      *)(mxGetData(K(S))));
```

- In automatic S-function generation, the **Use Value for Tunable Parameters** option is cleared or at the command line is set to `'off'`.
- Use a MEX S-function wrapper only in the MATLAB version in which the wrapper is created.

If you specify paths and files with absolute

Macro Parameters

Suppose that you apply a custom storage class such as `Define` to a `Simulink.Parameter` object so that the parameter appears as a macro in the generated code. If you use the parameter object inside a subsystem from which you generate an ERT S-function, you cannot select the parameter object as a tunable parameter. Instead, the S-function code generator applies the custom storage class to the parameter object. This generation of macros in the S-function code allows you to generate S-functions from subsystems that contain variant elements, such as Variant Subsystem blocks, that you configure to produce preprocessor conditionals in the generated code. However, you cannot change the value of the parameter during simulation of the S-function.

To select the parameter object as a tunable parameter, apply a different storage class or custom storage class. Custom storage classes that treat parameters as macros include `Define`, `ImportedDefine`, `CompilerFlag`, and custom storage classes that you create by setting **Data initialization** to `Macro` in the Custom Storage Class Designer. If you use a non-macro storage class or custom storage class, you cannot use the parameter object as a variant control variable and generate preprocessor conditionals.

If you apply a custom storage class that treats the parameter object as an imported macro, provide the macro definition before you generate the ERT S-function. For example, suppose that you apply the custom storage class `ImportedDefine` to a `Simulink.Parameter` object, and use the parameter object as a variant control variable in the subsystem. If you set the custom attribute `HeaderFile` to `'myHdr.h'`, when you generate the S-function, place the custom header file `myHdr.h` in the current folder. The

generated S-function uses the macro value from your header file instead of the value from the `Value` property of the parameter object.

To use a macro that you define through a compiler option, for example by applying the custom storage class `CompilerFlag`, use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** to specify the compiler option. For more information, see Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).

S-Functions That Support Expression Folding

Use expression folding to increase the efficiency of code generated by your own inlined S-Function blocks, by calling macros provided in the S-Function API.

The S-Function API lets you specify whether a given S-Function block should nominally accept expressions at a given input port. A block should not always accept expressions. For example, if the address of the signal at the input is used, expressions should not be accepted at that input, because it is not possible to take the address of an expression.

The S-Function API also lets you specify whether an expression can represent the computations associated with a given output port. When you request an expression at a block's input or output port, the Simulink engine determines whether or not it can honor that request, given the block's context. For example, the engine might deny a block's request to output an expression if the destination block does not accept expressions at its input, if the destination block has an update function, or if multiple output destinations exist.

The decision to honor or deny a request to output an expression can also depend on the category of output expression the block uses.

To take advantage of expression folding in your S-functions, you should understand when to request acceptance and generation of expressions for specific blocks. You do not have to understand the algorithm by which the Simulink engine chooses to accept or deny these requests. However, if you want to trace between the model and the generated code, it is helpful to understand some of the more common situations that lead to denial of a request.

Categories of Output Expressions

When you implement a C MEX S-function, you can specify whether the code corresponding to a block's output is to be generated as an expression. If the block generates an expression, you must specify that the expression is *constant*, *trivial*, or *generic*.

A *constant* output expression is a direct access to one of the block's parameters. For example, the output of a Constant block is defined as a constant expression because the output expression is simply a direct access to the block's `Value` parameter.

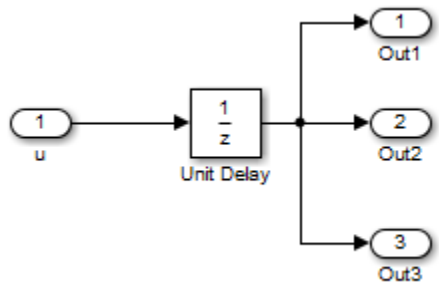
A *trivial* output expression is an expression that can be repeated, without a performance penalty, when the output port has multiple output destinations. For example, the output of

a Unit Delay block is defined as a trivial expression because the output expression is simply a direct access to the block's state. Because the output expression does not have computations, it can be repeated more than once without degrading the performance of the generated code.

A *generic* output expression is an expression that should be assumed to have a performance penalty if repeated. As such, a generic output expression is not suitable for repeating when the output port has multiple output destinations. For instance, the output of a Sum block is a generic rather than a trivial expression because it is costly to recompute a Sum block output expression as an input to multiple blocks.

Examples of Trivial and Generic Output Expressions

Consider this block diagram. The Delay block has multiple destinations, yet its output is designated as a trivial output expression, so that it can be used more than once without degrading the efficiency of the code.



This code excerpt shows the code generated from the Unit Delay block in this block diagram. The three root outputs are directly assigned from the state of the Unit Delay block, which is stored in a field of the global data structure `rtDWork`. Since the assignment is direct, without expressions, there is no performance penalty associated with using the trivial expression for multiple destinations.

```
void MdlOutputs(int_T tid)
{
   ...
  /* Outport: <Root>/Out1 incorporates:

   *   UnitDelay: <Root>/Unit Delay */
  rtY.Out1 = rtDWork.Unit_Delay_DSTATE;

  /* Outport: <Root>/Out2 incorporates:
   *   UnitDelay: <Root>/Unit Delay */
```

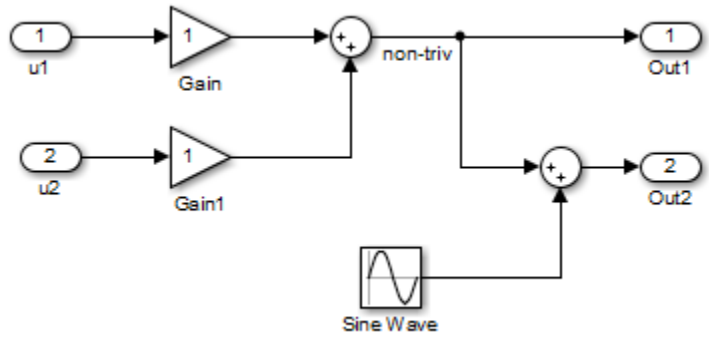
```
  rtY.Out2 = rtDWork.Unit_Delay_DSTATE;

  /* Outport: <Root>/Out3 incorporates:
   *   UnitDelay: <Root>/Unit Delay */
  rtY.Out3 = rtDWork.Unit_Delay_DSTATE;

   ...
}
```

The code generated shows how code is generated for Sum blocks with single and multiple destinations.

On the other hand, consider the Sum blocks in this model:



The upper Sum block in the model generates the signal labeled `non_triv`. Computation of this output signal involves two multiplications and an addition. If the Sum block's output were permitted to generate an expression even when the block had multiple destinations, the block's operations would be duplicated in the generated code. In this case, the generated expressions would proliferate to four multiplications and two additions. This would degrade the efficiency of the program. Accordingly the output of the Sum block is not allowed to be an expression because it has multiple destinations.

The Simulink engine does not permit the output of the upper Sum block to be an expression because the signal `non_triv` is routed to two output destinations. Instead, the result of the multiplication and addition operations is stored in a temporary variable (`rtb_non_triv`) that is referenced twice in the statements that follow, as seen in the code excerpt below.

In contrast, the lower Sum block, which has only a single output destination (`Out2`), does generate an expression.

```
void MdlOutputs(int_T tid)
{
  /* local block i/o variables */
  real_T rtb_non_triv;
  real_T rtb_Sine_Wave;

  /* Sum: <Root>/Sum incorporates:
   *   Gain: <Root>/Gain
   *   Inport: <Root>/u1
   *   Gain: <Root>/Gain1
   *   Inport: <Root>/u2
   *
   * Regarding <Root>/Gain:
   *   Gain value: rtP.Gain_Gain
   *
   * Regarding <Root>/Gain1:
   *   Gain value: rtP.Gain1_Gain
   */
  rtb_non_triv = (rtP.Gain_Gain * rtU.u1) + (rtP.Gain1_Gain *
rtU.u2);

  /* Outport: <Root>/Out1 */
  rtY.Out1 = rtb_non_triv;

  /* Sin Block: <Root>/Sine Wave */

  rtb_Sine_Wave = rtP.Sine_Wave_Amp *
    sin(rtP.Sine_Wave_Freq * rtmGetT(rtM_model) +
    rtP.Sine_Wave_Phase) + rtP.Sine_Wave_Bias;

  /* Outport: <Root>/Out2 incorporates:
   *   Sum: <Root>/Sum1
   */
  rtY.Out2 = (rtb_non_triv + rtb_Sine_Wave);
}
```

Specify the Category of an Output Expression

The S-Function API provides macros that let you declare whether an output of a block should be an expression, and if so, to specify the category of the expression. This table specifies when to declare a block output to be a constant, trivial, or generic output expression.

Types of Output Expressions

Category of Expression	When to Use
Constant	Use only if block output is a direct memory access to a block parameter.
Trivial	Use only if block output is an expression that can appear multiple times in the code without reducing efficiency (for example, a direct memory access to a field of the `DWork` vector, or a literal).
Generic	Use if output is an expression, but not constant or trivial.

You must declare outputs as expressions in the `mdlSetWorkWidths` function using macros defined in the S-Function API. The macros have the following arguments:

- `SimStruct *S`: pointer to the block's `SimStruct`.
- `int idx:` zero-based index of the output port.
- `bool value:` pass in TRUE if the port generates output expressions.

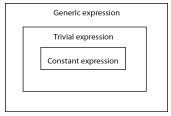
The following macros are available for setting an output to be a constant, trivial, or generic expression:

- `void ssSetOutputPortConstOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx, bool value)`
- `void ssSetOutputPortOutputExprInRTW(SimStruct *S, int idx, bool value)`

The following macros are available for querying the status set by prior calls to the macros above:

- `bool ssGetOutputPortConstOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortTrivialOutputExprInRTW(SimStruct *S, int idx)`
- `bool ssGetOutputPortOutputExprInRTW(SimStruct *S, int idx)`

The set of generic expressions is a superset of the set of trivial expressions, and the set of trivial expressions is a superset of the set of constant expressions.



Therefore, when you query an output that has been set to be a constant expression with `ssGetOutputPortTrivialOutputExprInRTW`, it returns `True`. A constant expression is considered a trivial expression because it is a direct memory access that can be repeated without degrading the efficiency of the generated code.

Similarly, an output that has been configured to be a constant or trivial expression returns `True` when queried for its status as a generic expression.

Acceptance or Denial of Requests for Input Expressions

A block can request that its output be represented in code as an expression. Such a request can be denied if the destination block cannot accept expressions at its input port. Furthermore, conditions independent of the requesting block and its destination blocks can prevent acceptance of expressions.

A block should not be configured to accept expressions at its input port under the following conditions:

- The block must take the address of its input data. It is not possible to take the address of most types of input expressions.
- The code generated for the block references the input more than once (for example, the Abs or Max blocks). This would lead to duplication of a potentially complex expression and a subsequent degradation of code efficiency.

If a block refuses to accept expressions at an input port, then a block that is connected to that input port is not permitted to output a generic or trivial expression.

A request to output a constant expression is not denied, because there is no performance penalty for a constant expression, and the software can take the parameter's address.

S-Function API to Specify Input Expression Acceptance

The S-Function API provides macros that let you:

- Specify whether a block input should accept nonconstant expressions (that is, trivial or generic expressions).

- Query whether a block input accepts nonconstant expressions.

By default, block inputs do not accept nonconstant expressions.

You should call the macros in your `mdlSetWorkWidths` function. The macros have these arguments:

- `SimStruct *S`: pointer to the block's SimStruct.
- `int idx:` zero-based index of the input port.
- `bool value:` pass in TRUE if the port accepts input expressions; otherwise pass in FALSE.

The macro available for specifying whether or not a block input should accept a nonconstant expression is:

```
void ssSetInputPortAcceptExprInRTW(SimStruct *S, int portIdx, bool value)
```

The corresponding macro available for querying the status set by any prior calls to `ssSetInputPortAcceptExprInRTW` is:

```
bool ssGetInputPortAcceptExprInRTW(SimStruct *S, int portIdx)
```

Denial of Block Requests to Output Expressions

Even after a specific block requests that it be allowed to generate an output expression, that request can be denied for generic reasons. These reasons include, but are not limited to:

- The output expression is nontrivial, and the output has multiple destinations.
- The output expression is nonconstant, and the output is connected to at least one destination that does not accept expressions at its input port.
- The output is a test point.
- The output has been assigned an external storage class.
- The output must be stored using global data (for example is an input to a merge block or a block with states).
- The output signal is complex.

You do not need to consider these generic factors when deciding whether or not to utilize expression folding for a particular block. However, these rules can be helpful when you are examining generated code and analyzing cases where the expression folding optimization is suppressed.

Expression Folding in a TLC Block Implementation

To take advantage of expression folding, modify the TLC block implementation of an inlined S-Function such that it informs the Simulink engine whether it generates or accepts expressions at its

- Input ports, as explained in “S-Function API to Specify Input Expression Acceptance” on page 12-84.
- Output ports, as explained in “Categories of Output Expressions” on page 12-79.

This topic discusses required modifications to the TLC implementation.

Expression Folding Compliance

In the `BlockInstanceSetup` function of your S-function, register your block to be compliant with expression folding. Otherwise, expression folding requested or allowed at the block's outputs or inputs will be disabled, and temporary variables will be used.

To register expression folding compliance, call the TLC library function `LibBlockSetIsExpressionCompliant(block)`, which is defined in *`matlabroot`*`/rtw/c/tlc/lib/utillib.tlc`. For example:

```
%% Function: BlockInstanceSetup ===========================================
%%
%function BlockInstanceSetup(block, system) void
  %%
  %<LibBlockSetIsExpressionCompliant(block)>
  %%
%endfunction
```

You can conditionally disable expression folding at the inputs and outputs of a block by making the call to this function conditionally.

If you override one of the TLC block implementations provided by the code generator with your own implementation, you should not make the preceding call until you have updated your implementation.

Output Expressions

The `BlockOutputSignal` function is used to generate code for a scalar output expression or one element of a nonscalar output expression. If your block outputs an expression, you should add a `BlockOutputSignal` function. The prototype of the `BlockOutputSignal` is

```
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
```

The arguments to `BlockOutputSignal` are these:

- `block`: the record for the block for which an output expression is being generated
- `system`: the record for the system containing the block
- `portIdx`: zero-based index of the output port for which an expression is being generated
- `ucv`: user control variable defining the output element for which code is being generated
- `lcv`: loop control variable defining the output element for which code is being generated
- `idx`: signal index defining the output element for which code is being generated
- `retType`: character vector defining the type of signal access desired:

  `"Signal"` specifies the contents or address of the output signal

  `"SignalAddr"` specifies the address of the output signal

The `BlockOutputSignal` function returns a character vector for the output signal or address. The character vector should enforce the precedence of the expression by using opening and terminating parentheses, unless the expression consists of a function call. The address of an expression can only be returned for a constant expression; it is the address of the parameter whose memory is being accessed. The code implementing the `BlockOutputSignal` function for the Constant block is:

```
%% Function: BlockOutputSignal ================================================
%% Abstract:
%%      Return the reference to the parameter.  This function *may*
%%      be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
  %switch retType
    %case "Signal"
      %return LibBlockParameter(Value,ucv,lcv,idx)
    %case "SignalAddr"
      %return LibBlockParameterAddr(Value,ucv,lcv,idx)
    %default
      %assign errTxt = "Unsupported return type: %<retType>"
      %<LibBlockReportError(block,errTxt)>
  %endswitch
%endfunction
```

The code implementing the `BlockOutputSignal` function for the Relational Operator block is:

```
%% Function: BlockOutputSignal ================================================
%% Abstract:
```

```
%%      Return an output expression.  This function *may*
%%      be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
%switch retType
%case "Signal"
%assign logicOperator = ParamSettings.Operator
 %if ISEQUAL(logicOperator, "~=")
 %assign op = "!="
elseif ISEQUAL(logicOperator, "==") %assign op = "=="
  %else
%assign op = logicOperator
%endif
 %assign u0 = LibBlockInputSignal(0, ucv, lcv, idx)
%assign u1 = LibBlockInputSignal(1, ucv, lcv, idx)
  %return "(%<u0> %<op> %<u1>)"
 %default
 %assign errTxt = "Unsupported return type: %<retType>"
 %<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
```

Expression Folding for Blocks with Multiple Outputs

When a block has a single output, the `Outputs` function in the block's TLC file is called only if the output port is not an expression. Otherwise, the `BlockOutputSignal` function is called.

If a block has multiple outputs, the `Outputs` function is called if any output port is not an expression. The `Outputs` function should guard against generating code for output ports that are expressions. This is achieved by guarding sections of code corresponding to individual output ports with calls to `LibBlockOutputSignalIsExpr()`.

For example, consider an S-Function with two inputs and two outputs, where

- The first output, y0, is equal to two times the first input.
- The second output, y1, is equal to four times the second input.

The `Outputs` and `BlockOutputSignal` functions for the S-function are shown in this code excerpt:

```
%% Function: BlockOutputSignal ================================================
%% Abstract:
%%      Return an output expression.  This function *may*
%%      be used by Simulink when optimizing the Block IO data structure.
%%
%function BlockOutputSignal(block,system,portIdx,ucv,lcv,idx,retType) void
%switch retType
%case "Signal"
   %assign u = LibBlockInputSignal(portIdx, ucv, lcv, idx)
```

```
 %case "Signal"
 %if portIdx == 0
  %return "(2 * %<u>)"
%elseif portIdx == 1
 %return "(4 * %<u>)"
%endif
%default
%assign errTxt = "Unsupported return type: %<retType>"
 %<LibBlockReportError(block,errTxt)>
%endswitch
%endfunction
%%
%% Function: Outputs ================================================
%% Abstract:
%%      Compute output signals of block
%%
%function Outputs(block,system) Output
%assign rollVars = ["U", "Y"]
%roll sigIdx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
%assign u0 = LibBlockInputSignal(0, "", lcv, sigIdx)
 %assign u1 = LibBlockInputSignal(1, "", lcv, sigIdx)
 %assign y0 = LibBlockOutputSignal(0, "", lcv, sigIdx)
 %assign y1 = LibBlockOutputSignal(1, "", lcv, sigIdx)
%if !LibBlockOutputSignalIsExpr(0)
%<y0> = 2 * %<u0>;
%endif
%if !LibBlockOutputSignalIsExpr(1)
 %<y1> = 4 * %<u1>;
%endif
%endroll
%endfunction
```

Comments for Blocks That Are Expression-Folding-Compliant

In the past, blocks preceded their outputs code with comments of the form

```
/* %<Type> Block: %<Name> */
```

When a block is expression-folding-compliant, the initial line shown above is generated automatically. Do not include the comment as part of the block's TLC implementation. Register additional information by using the `LibCacheBlockComment` function.

The `LibCacheBlockComment` function takes a character vector as an input, defining the body of the comment, except for the opening header, the final newline of a single or multiline comment, and the closing trailer.

The following TLC code illustrates registering a block comment. Note the use of the function `LibBlockParameterForComment`, which returns a character vector, suitable for a block comment, specifying the value of the block parameter.

```
%openfile commentBuf
  $c(*) Gain value: %<LibBlockParameterForComment(Gain)>
```

```
%closefile commentBuf
%<LibCacheBlockComment(block, commentBuf)>
```

S-Functions That Specify Port Scope and Reusability

You can use the following `SimStruct` macros in the `mdlInitializeSizes` method to specify the scope and reusability of the memory used for your S-function's input and output ports:

- `ssSetInputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function input port.
- `ssSetOutputPortOptimOpts`: Specify the scope and reusability of the memory allocated to an S-function output port.
- `ssSetInputPortOverWritable`: Specify whether one of your S-function's input ports can be overwritten by one of its output ports.
- `ssSetOutputPortOverwritesInputPort`: Specify whether an output port can share its memory buffer with an input port.

You declare an input or output as local or global, and indicate its reusability, by passing one of the following four options to the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros:

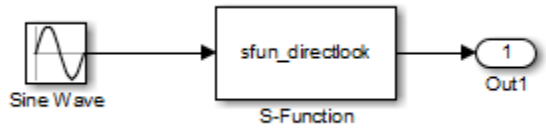
- `SS_NOT_REUSABLE_AND_GLOBAL`: Indicates that the input and output ports are stored in separate memory locations in the global block input and output structure.
- `SS_NOT_REUSABLE_AND_LOCAL`: Indicates that the code generator can declare individual local variables for the input and output ports.
- `SS_REUSABLE_AND_LOCAL`: Indicates that the code generator can reuse a single local variable for these input and output ports.
- `SS_REUSABLE_AND_GLOBAL`: Indicates that these input and output ports are stored in a single element in the global block input and output structure.

Note Marking an input or output port as a local variable does not imply that the code generator uses a local variable in the generated code. If your S-function accesses the inputs and outputs only in its `mdlOutputs` routine, the code generator declares the inputs and outputs as local variables. However, if the inputs and outputs are used elsewhere in the S-function, the code generator includes them in the global block input and output structure.

The reusability setting indicates if the memory associated with an input or output port can be overwritten. To reuse input and output port memory:

1. Indicate the ports are reusable using either the `SS_REUSABLE_AND_LOCAL` or `SS_REUSABLE_AND_GLOBAL` option in the `ssSetInputPortOptimOpts` and `ssSetOutputPortOptimOpts` macros.
2. Indicate the input port memory is overwritable using `ssSetInputPortOverWritable`.
3. If your S-function has multiple input and output ports, use `ssSetOutputPortOverwritesInputPort` to indicate which output and input ports share memory.

The following example shows how different scope and reusability settings affect the generated code. The following model contains an S-function block pointing to the C MEX S-function *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/src/sfun_directlook.c`, which models a direct 1-D lookup table.



The S-function's `mdlInitializeSizes` method declares the input port as reusable, local, and overwritable and the output port as reusable and local, as follows:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* snip */
    ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);
    ssSetInputPortOverWritable(S, 0, TRUE);

/* snip */
    ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);

/* snip */
}
```

The generated code for this model stores the input and output signals in a single local variable `rtb_SFunction`, as shown in the following output function:

```
static void sl_directlook_output(int_T tid)
{
  /* local block i/o variables */
  real_T rtb_SFunction[2];

  /* Sin: '<Root>/Sine Wave' */
  rtb_SFunction[0] = sin(((real_T)sl_directlook_DWork.counter[0] +
    sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
```

```
    sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[0] +
    sl_directlook_P.SineWave_Bias;
  rtb_SFunction[1] = sin(((real_T)sl_directlook_DWork.counter[1] +
    sl_directlook_P.SineWave_Offset) * 2.0 * 3.1415926535897931E+000 /
    sl_directlook_P.SineWave_NumSamp) * sl_directlook_P.SineWave_Amp[1] +
    sl_directlook_P.SineWave_Bias;

  /* S-Function Block: <Root>/S-Function */
  {
    const real_T *xData = &sl_directlook_P.SFunction_XData[0];
    const real_T *yData = &sl_directlook_P.SFunction_YData [0];
    real_T spacing = xData[1] - xData[0];
    if (rtb_SFunction[0] <= xData[0] ) {
      rtb_SFunction[0] = yData[0];
    } else if (rtb_SFunction[0] >= yData[20] ) {
      rtb_SFunction[0] = yData[20];
    } else {
      int_T idx = (int_T)( ( rtb_SFunction[0] - xData[0] ) / spacing );
      rtb_SFunction[0] = yData[idx];
    }

    if (rtb_SFunction[1] <= xData[0] ) {
      rtb_SFunction[1] = yData[0];
    } else if (rtb_SFunction[1] >= yData[20] ) {
      rtb_SFunction[1] = yData[20];
    } else {
      int_T idx = (int_T)( ( rtb_SFunction[1] - xData[0] ) / spacing );
      rtb_SFunction[1] = yData[idx];
    }
  }

  /* Outport: '<Root>/Out1' */
  sl_directlook_Y.Out1[0] = rtb_SFunction[0];
  sl_directlook_Y.Out1[1] = rtb_SFunction[1];
  UNUSED_PARAMETER(tid);
}
```

This table shows variations of the code generated for this model when using the generic real-time target (GRT). Each row explains a different setting for the scope and reusability of the S-function's input and output ports.

Scope and reusability	S-function `mdlInitializeSizes` code	Generated code

Inputs: Local, reusable, overwritable
 	
Outputs: Local, reusable
	`ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);`
	
	`ssSetInputPortOverWritable(S, 0, TRUE);`
	
	`ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_LOCAL);`
		The *`model`*`.c` file declares a local variable in the output function.
		
		`/* local block i/o variables */`
		`  real_T rtb_SFunction[2];`

Scope and reusability	S-function `mdlInitializeSizes` code	Generated code

Inputs: Global, reusable, overwritable
 	
Outputs: Global, reusable
	`ssSetInputPortOptimOpts(S, 0, SS_REUSABLE_AND_GLOBAL);`
	
	`ssSetInputPortOverWritable(S, 0, TRUE);`
	
	`ssSetOutputPortOptimOpts(S, 0, SS_REUSABLE_AND_GLOBAL);`
		The *model*.h file defines a block signals structure with a single element to store the S-function's input and output.
		
		`/* Block signals (auto storage) */`
		`typedef struct {`
		`  real_T SFunction[2];`
		`} BlockIO_sl_directlook;`
		
		The *model*.c file uses this element of the structure in calculations of the S-function's input and output signals.
		
		`/* Sin: '<Root>/Sine Wave' */`
		`sl_directlook_B.SFunction[0] = sin ...`
		`/* snip */`
		`/*S-Function Block:<Root>/S-Function*/`
		`{`
		`const real_T *xData =`
		`  &sl_directlook_P.SFunction_XData[0]`

Inputs: Local, not reusable
 	
Outputs: Local, not reusable
	`ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_LOCAL);`
	
	`ssSetInputPortOverWritable(S, 0, FALSE);`
	
	`ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_LOCAL);`
		The *model*.c file declares local variables for the S-function's input and output in the output function
		
		`/* local block i/o variables */`
		`  real_T rtb_SineWave[2];`
		`  real_T rtb_SFunction[2];`

Scope and reusability	S-function `mdlInitializeSizes` code	Generated code

Inputs: Global, not reusable
 	
Outputs: Global, not reusable
	`ssSetInputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);`
	
	`ssSetInputPortOverWritable(S, 0, FALSE);`
	
	`ssSetOutputPortOptimOpts(S, 0, SS_NOT_REUSABLE_AND_GLOBAL);`
		The *`model`*`.h` file defines a block signal structure with individual elements to store the S-function's input and output.
		`/* Block signals (auto storage) */`

S-Functions That Specify Sample Time Inheritance Rules

For the Simulink engine to determine whether a model can inherit a sample time, the S-functions in the model need to specify how they use sample times. You can specify this information by calling the macro `ssSetModelReferenceSampleTimeInheritanceRule` from `mdlInitializeSizes` or `mdlSetWorkWidths`. To use this macro:

1. Check whether the S-function calls any of these macros:
   - `ssGetSampleTime`
   - `ssGetInputPortSampleTime`
   - `ssGetOutputPortSampleTime`
   - `ssGetInputPortOffsetTime`
   - `ssGetOutputPortOffsetTime`
   - `ssGetSampleTimePtr`
   - `ssGetInputPortSampleTimeIndex`
   - `ssGetOutputPortSampleTimeIndex`
   - `ssGetSampleTimeTaskID`
   - `ssGetSampleTimeTaskIDPtr`
2. Check for these in your S-function TLC code:
   - `LibBlockSampleTime`
   - `CompiledModel.SampleTime`
   - `LibBlockInputSignalSampleTime`
   - `LibBlockInputSignalOffsetTime`
   - `LibBlockOutputSignalSampleTime`
   - `LibBlockOutputSignalOffsetTime`
3. Depending on your search results, use `ssSetModelReferenceSampleTimeInheritanceRule` as indicated in this table.

If...	Use...
None of the macros or functions are present, the S-function does not preclude the model from inheriting a sample time.	`ssSetModelReferenceSampleTimeInheritanceRule (S, USE_DEFAULT_FOR_DISCRETE_INHERITANCE)`
Any of the macros or functions are used for: • Throwing errors if sample time is inherited, continuous, or constant • Checking `ssIsSampleHit` • Checking whether sample time is inherited in either `mdlSetInputPortSampleTime` or `mdlSetOutputPortSampleTime` before setting	`ssSetModelReferenceSampleTimeInheritanceRule... (S,USE_DEFAULT_FOR_DISCRETE_INHERITANCE)`
The S-function uses its sample time for computing parameters, outputs, and so on.	`ssSetModelReferenceSampleTimeInheritanceRule (S, DISALLOW_SAMPLE_TIME_INHERITANCE)`

Note If an S-function does not set the `ssSetModelReferenceSampleTimeInheritanceRule` macro, by default the Simulink engine assumes that the S-function does not preclude the model containing that S-function from inheriting a sample time. However, the engine issues a warning indicating that the model includes S-functions for which this macro is not set.

You can use settings in the Configuration Parameters on the **Diagnostics > Sample Time** pane to control how the Simulink engine responds when it encounters S-functions that have unspecified sample time inheritance rules. Toggle the **Unspecified inheritability of sample time** (Simulink) diagnostic to `none`, `warning`, or `error`. The default is `warning`.

S-Functions That Support Code Reuse

You can reuse the generated code for identical subsystems that occur in multiple instances within a model and across referenced models. For more information about code generation of subsystems for code reuse, see “Control Generation of Functions for Subsystems” (Simulink Coder). If you want your S-function to support code reuse for a subsystem, the S-function must meet these requirements:

- The S-function must be inlined.
- Code generated from the S-function must not use static variables.
- The S-function must initialize its pointer work vector in `mdlStart` and not before.
- The S-function must not be a sink that logs data to the workspace.
- The S-function must register its parameters as run-time parameters in `mdlSetWorkWidths`. (It must not use `ssWriteRTWParameters` in its `mdlRTW` function for this purpose.)
- The S-function must not be a device driver.

In addition to meeting the preceding requirements, your S-function must set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag in the `ssSetOptions` function. This flag indicates that your S-function meets the requirements for subsystem code reuse.

S-Functions for Multirate Multitasking Environments

In this section...

About S-Functions for Multirate Multitasking Environments

S-functions can be used in models with multiple sample rates and deployed in multitasking target environments. Likewise, S-functions themselves can have multiple rates at which they operate. The code generator produces code for multirate multitasking models using an approach called *rate grouping*. In code generated for ERT-based targets, rate grouping generates separate `model_step` functions for the base rate task and each subrate task in the model. Although rate grouping is a code generation feature found in ERT targets only, your S-functions can use it in other contexts when you code them as explained below.

Rate Grouping Support in S-Functions

To take advantage of rate grouping, you must inline your multirate S-functions if you have not done so. You need to follow certain Target Language Compiler protocols to exploit rate grouping. Coding TLC to exploit rate grouping does not prevent your inlined S-functions from functioning properly in GRT. Likewise, your inlined S-functions will still generate valid ERT code even if you do not make them rate-grouping-compliant. If you do so, however, they will generate more efficient code for multirate models.

For instructions and examples of Target Language Compiler code illustrating how to create and upgrade S-functions to generate rate-grouping-compliant code, see "Rate Grouping Compliance and Compatibility Issues" on page 63-17.

For each multirate S-function that is not rate grouping-compliant, the code generator issues the following warning when you build:

```
Warning:  Simulink Coder: Code of output function for multirate block
'<Root>/S-Function' is guarded by sample hit checks rather than being rate
grouped. This will generate the same code for all rates used by the block,
possibly generating dead code. To avoid dead code, you must update the TLC
file for the block.
```

You will also find a comment such as the following in code generated for each noncompliant S-function:

```
/* Because the output function of multirate block
   <Root>/S-Function is not rate grouped,
   the following code might contain unreachable blocks of code.
   To avoid this, you must update your block TLC file. */
```

The words “update function” are substituted for “output function” in these warnings.

Create Multitasking, Multirate, Port-Based Sample Time S-Functions

The following instructions show how to support both data determinism and data integrity in multirate S-functions. They do not cover cases where there is no determinism nor integrity. Support for frame-based processing does not affect the requirements.

Note The slow rates must be multiples of the fastest rate. The instructions do not apply when two rates being interfaced are not multiples or when the rates are not periodic.

Rules for Properly Handling Fast-to-Slow Transitions

The rules that multirate S-functions should observe for inputs are

- The input should only be read at the rate that is associated with the input port sample time.
- Generally, the input data is written to `DWork`, and the `DWork` can then be accessed at the slower (downstream) rate.

The input can be read at every sample hit of the input rate and written into `DWork` memory, but this `DWork` memory cannot then be directly accessed by the slower rate. `DWork` memory that will be read by the slow rate must only be written by the fast rate when there is a *special sample hit*. A special sample hit occurs when both this input port rate and rate to which it is interfacing have a hit. Depending on their requirements and design, algorithms can process the data in several locations.

The rules that multirate S-functions should observe for outputs are

- The output should not be written by a rate other than the rate assigned to the output port, except in the optimized case described below.

- The output should always be written when the sample rate of the output port has a hit.

If these conditions are met, the S-Function block can specify that the input port and output port can both be made local and reusable.

You can include an optimization when little or no processing needs to be done on the data. In such cases, the input rate code can directly write to the output (instead of by using DWork) when there is a special sample hit. If you do this, however, you must declare the outport port to be *global* and *not reusable*. This optimization results in one less `memcpy` but does introduce nonuniform processing requirements on the faster rate.

Whether you use this optimization or not, the most recent input data, as seen by the slower rate, is the value when both the faster and slower rate had their hits (and possible earlier input data as well, depending on the algorithm). Subsequent steps by the faster rate and the associated input data updates are not seen by the slower rate until the next hit for the slow rate occurs.

Pseudocode Examples of Fast-to-Slow Rate Transition

The pseudocode below abstracts how you should write your C MEX code to handle fast-to-slow transitions, illustrating with an input rate of 0.1 second driving an output rate of one second. A similar approach can be taken when inlining the code. The block has following characteristics:

- File: `sfun_multirate_zoh.c`, Equation: `y = u(tslow)`
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

```
OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSepcialSampleHit("1")) {
        DWork = u;
    }
}
if (ssIsSampleHit("1")) {
    y = DWork;
}
```

An alternative, slightly optimized approach for simple algorithms:

- Input: local and reusable
- Output: global and not reusable because it needs to persist between special sample hits

- DirectFeedthrough: yes

```
OutputFcn
if (ssIsSampleHit(".1")) {
    if (ssIsSpecialSampleHit("1")) {
        y = u;
    }
}
```

Example adding a simple algorithm:

- File: `sfun_multirate_avg.c`; Equation: `y = average(u)`
- Input: local and reusable
- Output: local and reusable
- DirectFeedthrough: yes

  (Assume `DWork[0:10]` and `DWork[mycounter]` are initialized to zero)

```
OutputFcn
if (ssIsSampleHit(".1")) {
    /* In general, processing on 'u' could be done here,
        it runs on every hit of the fast rate. */
    DWork[DWork[mycounter]++] = u;
    if (ssIsSpecialSampleHit("1")) {
    /* In general, processing on DWork[0:10] can be done
       here, but it does cause the faster rate to have
       nonuniform processing requirements (every 10th hit,
       more code needs to be run).*/
        DWork[10] = sum(DWork[0:9])/10;
        DWork[mycounter] = 0;
    }
}
if (ssIsSampleHit("1")) {
    /* Processing on DWork[10] can be done here before
       outputing. This code runs on every hit of the
       slower task. */
    y = DWork[10];
}
```

Rules for Properly Handling Slow-to-Fast Transitions

When output rates are faster than input rates, input should only be read at the rate that is associated with the input port sample time, observing the following rules:

- Always read input from the update function.
- Use no special sample hit checks when reading input.
- Write the input to a DWork.

- When there is a special sample hit between the rates, copy the DWork into a second DWork in the output function.
- Write the second DWork to the output at every hit of the output sample rate.

The block can request that the input port be made local but it cannot be set to reusable. The output port can be set to local and reusable.

As in the fast-to-slow transition case, the input should not be read by a rate other than the one assigned to the input port. Similarly, the output should not be written to at a rate other than the rate assigned to the output port.

An optimization can be made when the algorithm being implemented is only required to run at the slow rate. In such cases, you use only one DWork. The input still writes to the DWork in the update function. When there is a special sample hit between the rates, the output function copies the same DWork directly to the output. You must set the output port to be global and not reusable in this case. This optimization results in one less `memcpy` operation per special sample hit.

In either case, the data that the fast rate computations operate on is always delayed, that is, the data is from the previous step of the slow rate code.

Pseudocode Examples of Slow-to-Fast Rate Transition

The pseudocode below abstracts what your S-function needs to do to handle slow-to-fast transitions, illustrating with an input rate of one second driving an output rate of 0.1 second. The block has following characteristics:

- File: `sfun_multirate_delay.c`, Equation: `y = u(tslow-1)`
- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1") {
    if (ssIsSpecialSampleHit("1") {
        DWork[1] = DWork[0];
    }
    y = DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
```

```
    DWork[0] = u;
}
```

An alternative, optimized approach can be used by some algorithms:

- Input: Set to local, will be local if output/update are combined (ERT) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: global and not reusable because it needs to persist between special sample hits.
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1") {
    if (ssIsSpecialSampleHit("1") {
        y = DWork;
    }
}
UpdateFcn
if (ssIsSampleHit("1")) {
    DWork = u;
}
```

Example adding a simple algorithm:

- File: `sfun_multirate_modulate.c`, Equation: `y = sin(tfast) + u(tslow-1)`
- Input: Set to local, will be local if output/update are combined (an ERT feature) otherwise will be global. Set to not reusable because input needs to be preserved until the update function runs.
- Output: local and reusable
- DirectFeedthrough: no

```
OutputFcn
if (ssIsSampleHit(".1") {
    if (ssIsSpecialSampleHit("1") {
    /* Processing not likely to be done here. It causes
     * the faster rate to have nonuniform processing
     * requirements (every 10th hit, more code needs to
     * be run).*/
        DWork[1] = DWork[0];
    }
    /* Processing done at fast rate */
    y = sin(ssGetTaskTime(".1")) + DWork[1];
}
UpdateFcn
if (ssIsSampleHit("1")) {
    /* Processing on 'u' can be done here. There is a delay of
```

```
   one slow rate period before the fast rate sees it.*/
DWork[0] = u;}
```

Write Noninlined S-Function

A noninlined S-function is a C or C++ MEX S-function that is treated identically by the Simulink engine and by the generated code. You implement your algorithm once according to the S-function API. The Simulink engine and generated code call the S-function routines (for example, `mdlOutputs`) during model execution.

Noninlined S-functions are identified by the absence of an *`sfunction`*`.tlc` file for your S-function. The file name varies depending on your platform. For example, on a 64-bit Microsoft Windows system, the file name is *`sfunction.mexw64`*. In the MATLAB Command Window, type `mexext` to see which extension your system uses.

Guidelines for Writing Noninlined S-Functions

- The MEX-file cannot call MATLAB functions.
- If the MEX-file uses functions in the MATLAB External Interface libraries, include the header file `cg_sfun.h` instead of `mex.h` or `simulink.c`. For the header file `cg_sfun.h`, at the end of your S-function, include these lines:

```
#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c"  /* MEX-file interface mechanism */
#else
#include "cg_sfun.h"   /* Code generation registration function */
#endif
```

- Use only the MATLAB API function that the code generator supports. The supported API functions are:
  - `mxGetEps`
  - `mxGetInf`
  - `mxGetM`
  - `mxGetN`
  - `mxGetNaN`
  - `mxGetPr`
  - `mxGetScalar`
  - `mxGetString`
  - `mxIsEmpty`
  - `mxIsFinite`

  - `mxIsInf`
- MEX library calls are not supported in generated code. To use such calls in the MEX-file and not in the generated code, add the following condition:

  ```
  #ifdef MATLAB_MEX_FILE
  #endif
  ```
- Use only full matrices that contain only real data.
- Do not specify a return value for calls to `mxGetString`. If you do specify a return value, the MEX-file does not compile. Instead, use the second input argument of the function, which returns a pointer to a character vector.
- Use the correct `#define` *`s-function_name`* statement. The S-function name that you specify must match the S-function file name.
- If possible, use the data types `real_T` and `int_T` instead of `double` and `int`. The data types `real_T` and `int_T` are more generic and can be used in multiple environments.
- Provide the build process with the names of the modules used to build the S-function. Use a template make file, the `set_param` function, or the `S-function modules` field of the S-Function block parameters dialog box. For example, suppose that you build your S-function with this command:

  ```
  mex sfun_main.c sfun_module1.c sfun_module2.c
  ```

  You can then use the following call to `set_param` to include the required modules:

  ```
  set_param(sfun_block, "SFunctionModules","sfun_module1 sfun_module2")
  ```

  When you are ready to generate code, force the code generator to rebuild the top model. For more information, see “Control Regeneration of Top Model Code” (Simulink Coder).

Noninlined S-Function Parameter Type Limitations

Parameters to noninlined S-functions can be of the following types only:

- Double precision
- Characters in scalars, vectors, or 2-D matrices

For more flexibility in the type of parameters that you can supply to S-functions or the operations in the S-function, inline your S-function and consider using an `mdlRTW` S-function routine.

Use of other functions from the MATLAB `matrix.h` API or other MATLAB APIs, such as `mex.h` and `mat.h`, are not supported. If you call unsupported APIs from an S-function source file, compiler errors occur. For details on supported MATLAB API functions, see the files *`matlabroot`*`/rtw/c/src/rt_matrx.h` and *`matlabroot`*`/rtw/c/src/rt_matrx.c`

If you use `mxGetPr` on an empty matrix, the function does not return `NULL`. It returns a random value. Therefore, you must protect calls to `mxGetPr` by using `mxIsEmpty`.

Write Wrapper S-Function and TLC Files

Create S-functions that work seamlessly with the Simulink and code generator products by using the wrapper concept. You can:

- Interface your algorithms in Simulink models by writing MEX S-function wrappers (*`sfunction`*`.mex`).
- Direct the code generator to insert your algorithm into the generated code by creating a TLC S-function wrapper (*`sfunction`*`.tlc`).

MEX S-Function Wrapper

Creating S-functions by using an S-function wrapper enables you to insert C/C++ code algorithms in Simulink models and the generated code with little or no change to your original C/C++ function. A MEX S-function wrapper is an S-function that calls code, which resides in another module.

Note Use a MEX S-function wrapper only in the MATLAB version in which you created the wrapper.

Suppose that you have an algorithm (that is, a C function) called `my_alg` that resides in the file `my_alg.c`. You can integrate `my_alg` into a Simulink model by creating a MEX S-function wrapper (for example, `wrapsfcn.c`). A Simulink model can then call `my_alg` from an S-Function block. The Simulink S-function contains a set of empty functions that the Simulink engine requires for various API related purposes. For example, although only `mdlOutputs` calls `my_alg`, the engine calls `mdlTerminate`, even though this S-function routine performs no action.

You can embed the call to `my_alg` in the generated code by creating a TLC S-function wrapper (for example, `wrapsfcn.tlc`). You can eliminate the empty function calls. You can avoid the overhead of executing the `mdlOutputs` function and you can then eliminate the `my_alg` function.

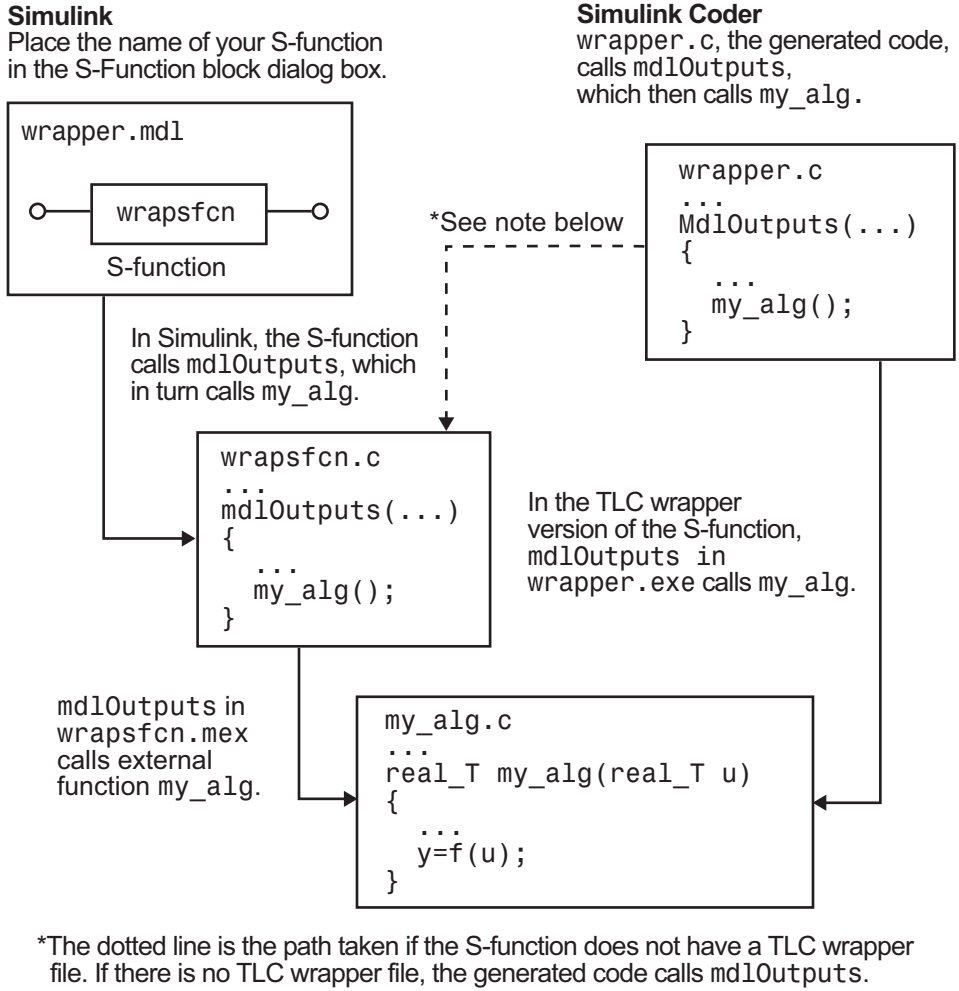
Wrapper S-functions are useful when you are creating algorithms that are procedural or when you are integrating legacy code into a Simulink model. If you want to create code that is:

- Interpretive in nature (that is, highly parameterized by operating modes)

• Heavily optimized (that is, no extra tests to decide what mode the code is operating in)

then you must create a fully inlined TLC file for your S-function.

The next figure shows the wrapper S-function concept.

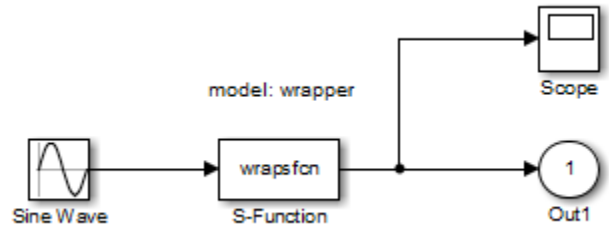


*The dotted line is the path taken if the S-function does not have a TLC wrapper file. If there is no TLC wrapper file, the generated code calls `mdlOutputs`.

Using an S-function wrapper to import algorithms into your Simulink model means that the S-function serves as an interface that calls your C/C++ algorithms from `mdlOutputs`.

You can quickly integrate large standalone C/C++ programs into your model without having to change the code.

This sample model includes an S-function wrapper.



Two files are associated with the `wrapsfcn` block: the S-function wrapper and the C/C++ code that contains the algorithm. The first three statements:

1. Define the name of the S-function (what you enter in the Simulink S-Function block dialog box).
2. Specify that the S-function is using the level 2 format.
3. Provide access to the `SimStruct` data structure. `SimStruct` contains pointers to data used during simulation and code generation and defines macros that store data in and retrieve data from the `SimStruct`.

```
#define S_FUNCTION_NAME wrapsfcn
#define S_FUNCTION_LEVEL 2
#include "simstruc.h"

extern real_T my_alg(real_T u);  /* Declare my_alg as extern */

/*
 * mdlInitializeSizes - initialize the sizes array
 */
static void mdlInitializeSizes(SimStruct *S)
{

    ssSetNumSFcnParams( S, 0); /*number of input arguments*/

    if (!ssSetNumInputPorts(S, 1)) return;
    ssSetInputPortWidth(S, 0, 1);
    ssSetInputPortDirectFeedThrough(S, 0, 1);

    if (!ssSetNumOutputPorts(S,1)) return;
    ssSetOutputPortWidth(S, 0, 1);

    ssSetNumSampleTimes( S, 1);
```

```
}

/*
 * mdlInitializeSampleTimes - indicate that this S-function runs
 * at the rate of the source (driving block)
 */
static void mdlInitializeSampleTimes(SimStruct *S)
{
    ssSetSampleTime(S, 0, INHERITED_SAMPLE_TIME);
    ssSetOffsetTime(S, 0, 0.0);
}

/*
 * mdlOutputs - compute the outputs by calling my_alg, which
 * resides in another module, my_alg.c
 */
static void mdlOutputs(SimStruct *S, int_T tid)
{
    InputRealPtrsType uPtrs = ssGetInputPortRealSignalPtrs(S,0);
    real_T            *y    = ssGetOutputPortRealSignal(S,0);
    *y = my_alg(*uPtrs[0]); /* Call my_alg in mdlOutputs */
 }
/*
 * mdlTerminate - called when the simulation is terminated.
 */
static void mdlTerminate(SimStruct *S)
{
}

#ifdef MATLAB_MEX_FILE /* Is this file being compiled as a MEX-file? */
#include "simulink.c" /* MEX-file interface mechanism */
#else
#include "cg_sfun.h" /* Code generation registration function */
#endif
```

For more information, see “Templates for C S-Functions” (Simulink).

The S-function routine `mdlOutputs` contains a function call to `my_alg`, which is the C function containing the algorithm that the S-function performs. For `my_alg.c`, the code is:

```
#ifdef MATLAB_MEX_FILE
#include "tmwtypes.h"
#else
#include "rtwtypes.h"
#endif
real_T my_alg(real_T u)
{
return(u * 2.0);
}
```

For more information, see “Manage Build Process File Dependencies” (Simulink Coder).

The wrapper S-function `wrapsfcn` calls `my_alg`, which computes `u * 2.0`. To build `wrapsfcn.mex`, use this command:

```
mex wrapsfcn.c my_alg.c
```

TLC S-Function Wrapper

A TLC S-function wrapper is a TLC file that specifies how the code generator calls your code. For example, you can inline the call to `my_alg` in the `mdlOutputs` section of the generated code. In the “MEX S-Function Wrapper” (Simulink Coder) example, the call to `my_alg` is embedded in the `mdlOutputs` section as:

```
*y = my_alg(*uPtrs[0]);
```

When you are creating a TLC S-function wrapper, the goal is to embed the same type of call in the generated code.

Look at how the code generator executes S-functions that are not inlined. A noninlined S-function is identified by the absence of the file *`sfunction`*`.tlc` and the existence of *`sfunction`*`.mex`. When generating code for a noninlined S-function, the code generator produces a call to `mdlOutputs` through a function pointer that, in this example, then calls `my_alg`.

The wrapper example contains one S-function, `wrapsfcn.mex`. You must compile and link an additional module, `my_alg`, with the generated code. At the MATLAB command prompt, enter:

```
set_param('wrapper/S-Function','SFunctionModules','my_alg')
```

Code Overhead for Noninlined S-Functions

The code generated when using `grt.tlc` as the system target file *without* `wrapsfcn.tlc` is:

```
<Generated code comments for wrapper model with noninlined wrapsfcn S-function>

#include <math.h>
#include <string.h>
#include "wrapper.h"
#include "wrapper.prm"

/* Start the model */
void mdlStart(void)
{
  /* (start code not required) */
```

```
}

/* Compute block outputs */
void mdlOutputs(int_T tid)
{
  /* Sin Block: <Root>/Sin */
  rtB.Sin = rtP.Sin.Amplitude *
    sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

  /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
  {
    /* Noninlined S-functions create a SimStruct object and
     * generate a call to S-function routine mdlOutputs
     */
    SimStruct *rts = ssGetSFunction(rtS, 0);
    sfcnOutputs(rts, tid);
  }

  /* Outport Block: <Root>/Out */
  rtY.Out = rtB.S_Function;
}

/* Perform model update */
void mdlUpdate(int_T tid)
{
  /* (update code not required) */
}

/* Terminate function */
void mdlTerminate(void)
{
  /* Level2 S-Function Block: <Root>/S-Function (wrapsfcn) */
  {
/* Noninlined S-functions require a SimStruct object and
     * the call to S-function routine mdlTerminate
     */
    SimStruct *rts = ssGetSFunction(rtS, 0);
    sfcnTerminate(rts);
  }
}

#include "wrapper.reg"

/* [EOF] wrapper.c */
```

The `wrapper.reg` generated file contains the initialization of the `SimStruct` for the wrapper S-Function block. There is one child `SimStruct` for each S-Function block in your model. You can significantly reduce this overhead by creating a TLC wrapper for the S-function.

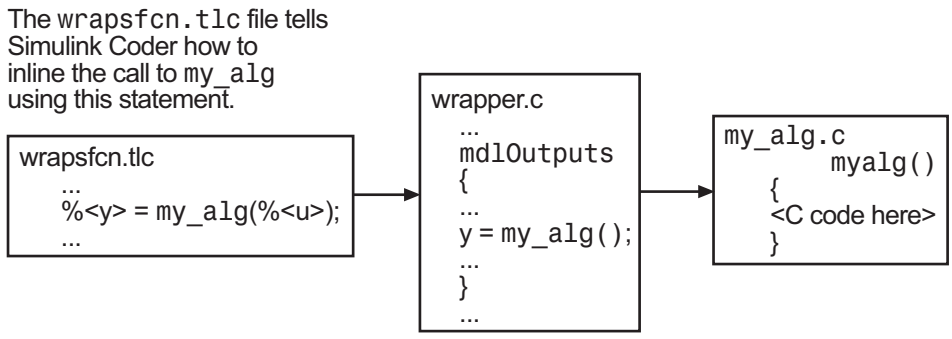
Inline a Wrapper S-Function

The generated code makes the call to your S-function, `wrapsfcn.c`, in `mdlOutputs` by using this code:

```
SimStruct *rts = ssGetSFunction(rtS, 0);
sfcnOutputs(rts, tid);
```

This call has computational overhead associated with it. The Simulink engine creates a `SimStruct` data structure for the S-Function block. The code generator constructs a call through a function pointer to execute `mdlOutputs`, then `mdlOutputs` calls `my_alg`. By inlining the call to your C/C++ algorithm, `my_alg`, you can eliminate both the `SimStruct` and the extra function call, thereby improving the efficiency and reducing the size of the generated code.

Inlining a wrapper S-function requires an *`sfunction`*`.tlc` file for the S-function. The TLC file must contain the function call to `my_alg`. The figure shows the relationships between the algorithm, the wrapper S-function, and the *`sfunction`*`.tlc` file.



To inline the call to `my_alg`, place your function call in an *`sfunction`*`.tlc` file with the same name as the S-function (in this example, `wrapsfcn.tlc`). The Target Language Compiler overrides the default method of placing calls to your S-function in the generated code.

This code is the TLC file `wrapsfcn.tlc` that inlines `wrapsfcn.c`:

```
%% File    : wrapsfcn.tlc
%% Abstract:
%%      Example inlined tlc file for S-function wrapsfcn.c
%%
```

```
%implements "wrapsfcn" "C"

%% Function: BlockTypeSetup ===================================================
%% Abstract:
%%      Create function prototype in model.h as:
%%      "extern real_T my_alg(real_T u);"
%%
%function BlockTypeSetup(block, system) void
  %openfile buffer
    extern real_T my_alg(real_T u); /* This line is placed in wrapper.h */
  %closefile buffer
  %<LibCacheFunctionPrototype(buffer)>
%endfunction %% BlockTypeSetup

%% Function: Outputs ==========================================================
%% Abstract:
%%      y = my_alg( u );
%%
%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %assign u = LibBlockInputSignal(0, "", "", 0)
  %assign y = LibBlockOutputSignal(0, "", "", 0)
  %% PROVIDE THE CALLING STATEMENT FOR "algorithm"
  %% The following line is expanded and placed in mdlOutputs within wrapper.c
  %<y> = my_alg(%<u>);

%endfunction %% Outputs
```

The first section of this code inlines the `wrapsfcn` S-Function block and generates the code in C:

```
%implements "wrapsfcn" "C"
```

The next task is to inform the code generator that the routine `my_alg` must be declared as external in the generated `wrapper.h` file for any `wrapsfcn` S-Function blocks in the model. Do this declaration once for all `wrapsfcn` S-Function blocks by using the `BlockTypeSetup` function. In this function, you direct the Target Language Compiler to create a buffer and cache the `my_alg` as `extern` in the `wrapper.h` generated header file.

The final step is the inlining of the call to the function `my_alg`. The `Outputs` function inlines the call. In this function, you access the block input and output and place a direct call to `my_alg`. The call is embedded in `wrapper.c`.

The Inlined Code

The code generated when you inline your wrapper S-function is similar to the default generated code. The `mdlTerminate` function does not contain a call to an empty function and the `mdlOutputs` function now directly calls `my_alg`.

```
void mdlOutputs(int_T tid)
{
  /* Sin Block: <Root>/Sin */
  rtB.Sin = rtP.Sin.Amplitude *
    sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

  /* S-Function Block: <Root>/S-Function */
  rtB.S_Function = my_alg(rtB.Sin); /* Inlined call to my_alg */

  /* Outport Block: <Root>/Out */
  rtY.Out = rtB.S_Function;
}
```

`wrapper.reg` does not create a child `SimStruct` for the S-function because the generated code is calling `my_alg` directly, eliminating over 1 KB of memory usage.

Related Examples

- “Write Noninlined S-Function” (Simulink Coder)
- “Write Fully Inlined S-Functions” (Simulink Coder)

Write Fully Inlined S-Functions

A fully inlined S-function builds your algorithm (block) into generated code that you cannot distinguish from a built-in block. Typically, a fully inlined S-function requires you to implement your algorithm twice: once for the Simulink model (C/C++ MEX S-function) and once for code generation (TLC file).

Using the example in “Write Wrapper S-Function and TLC Files” (Simulink Coder), you can eliminate the call to `my_alg` entirely by specifying the explicit code (that is, `2.0 * u`) in `wrapsfcn.tlc`. While this can improve performance, if you are working with a large amount of C/C++ code, the task can be lengthy. You also have to maintain your algorithm in two places, the C/C++ S-function itself and the corresponding TLC file. Consider whether the performance gains might outweigh the disadvantages. To inline the algorithm used in this example, in the `Outputs` section of your `wrapsfcn.tlc` file, instead of writing:

```
%<y> = my_alg(%<u>);
```

Use:

```
%<y> = 2.0 * %<u>;
```

This code is the code produced in `mdlOutputs`:

```
void mdlOutputs(int_T tid)
{
  /* Sin Block: <Root>/Sin */
  rtB.Sin = rtP.Sin.Amplitude *
    sin(rtP.Sin.Frequency * ssGetT(rtS) + rtP.Sin.Phase);

  /* S-Function Block: <Root>/S-Function */
  rtB.S_Function = 2.0 * rtB.Sin; /* Explicit embedding of algorithm */

  /* Outport Block: <Root>/Out */
  rtY.Out = rtB.S_Function;
}
```

The Target Language Compiler replaces the call to `my_alg` with the algorithm itself.

Multiport S-Function

A more advanced multiport inlined S-function example is `sfun_multiport.c` and `sfun_multiport.tlc`. This S-function illustrates how to create a fully inlined TLC file for an S-function that contains multiple ports.

Guidelines for Writing Inlined S-Functions

- Consider using the block property `RTWdata` (see “S-Function RTWdata” (Simulink Coder)). This property is a structure of character vectors that you can associate with a block. The code generator saves the structure with the model in the *`model`*`.rtw` file and makes the `.rtw` file more readable. For example in the MATLAB Command Window, suppose you enter these commands:

  ```
  mydata.field1 = 'information for field1';
  mydata.field2 = 'information for field2';
  set_param(sfun_block, 'RTWdata', mydata);
  ```

  The `.rtw` file that the code generator produces for the block includes the comments specified in the structure `mydata`.
- Consider using the `mdlRTW` function to inline your C MEX S-function in the generated code for:
  - Renaming tunable parameters in the generated code.
  - Introducing non-tunable parameters into a TLC file.

See Also

Related Examples

- “Write Fully Inlined S-Functions with mdlRTW Routine” (Simulink Coder)

Write Fully Inlined S-Functions with mdlRTW Routine

You can inline more complex S-functions by using the S-function `mdlRTW` routine. The `mdlRTW` routine provides the code generation process with more information about how the S-function is to be inlined by creating a parameter record of a non-tunable parameter for use with a TLC file. The `mdlRTW` routine places information in the *`model`*`.rtw` file. The `mdlRTW` function is described in the text file *`matlabroot`*`/simulink/src/sfuntmpl_doc.c`.

To use the `mdlRTW` function, take steps to create a direct-index lookup S-function. Lookup tables are collections of ordered data points of a function. Typically, these tables use some interpolation scheme to approximate values of the associated function between known data points. To incorporate the example lookup table algorithm into a Simulink model, the first step is to write an S-function that executes the algorithm in `mdlOutputs`. To produce the most efficient code, the next step is to create a corresponding TLC file to eliminate computational overhead and improve the speed of the lookup computations.

The Simulink product provides support for two general-purpose lookup 1-D and 2-D algorithms. You can use these algorithms as they are or create a custom lookup table S-function to fit your requirements. You can create a 1-D lookup S-function, `sfun_directlook.c`, and its corresponding inlined `sfun_directlook.tlc` file (see “Target Language Compiler” (Simulink Coder) for more details). You can:

- Error check of S-function parameters.
- Cache information for the S-function that does not change during model execution.
- Use the `mdlRTW` function to customize the code generator to produce the optimal code for a given set of block parameters.
- Create a `TLC` file for an S-function that either fully inlines the lookup table code or calls a wrapper function for the lookup table algorithm.

S-Function RTWdata

`RTWdata` is a property of blocks, which can be used by the Target Language Compiler when inlining an S-function. `RTWdata` is a structure of character vectors that you can attach to a block. `RTWdata` is saved with the model and placed in the *`model`*`.rtw` file when you generate code. For example, this set of MATLAB commands:

```
mydata.field1 = 'information for field1';
mydata.field2 = 'information for field2';
set_param(gcb,'RTWdata',mydata)
get_param(gcb,'RTWdata')
```

produces this result:

```
ans =

    field1: 'information for field1'
    field2: 'information for field2'
```

The information for the associated S-Function block inside the *model*`.rtw` file is:

```
Block {
  Type                    "S-Function"
  RTWdata {
    field1                  "information for field1"
    field2                  "information for field2"
  }
```

Note `RTWdata` is saved in the model file for S-functions that are not linked to a library. However, `RTWdata` is **not persistent** for S-Function blocks that are linked to a library.

Direct-Index Lookup Table Algorithm

The 1-D lookup table block provided in the Simulink library uses interpolation or extrapolation when computing outputs. In this example, you create a lookup table that directly indexes the output vector (*y*-data vector) based on the current input (*x*-data) point.

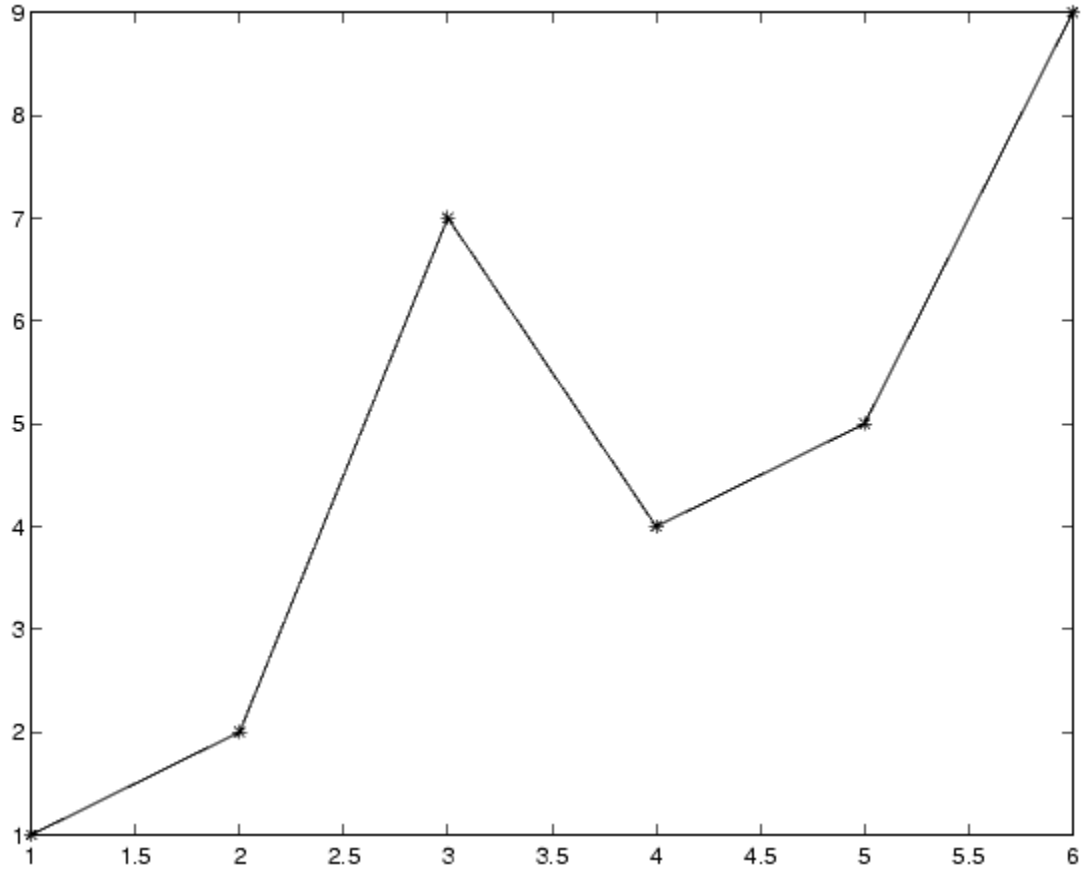
This direct 1-D lookup example computes an approximate solution *p(x)*to a partially known function *f(x)* at *x=x0*, given data point pairs *(x,y)* in the form of an *x*-data vector and a *y*-data vector. For a given data pair (for example, the *i'th* pair), *y_i = f(x_i)*. It is assumed that the *x*-data values are monotonically increasing. If *x0* is outside the range of the *x*-data vector, the first or last point is returned.

The parameters to the S-function are:

```
XData, YData, XEvenlySpaced
```

`XData` and `YData` are double vectors of equal length representing the values of the unknown function. `XDataEvenlySpaced` is a scalar, `0.0` for false and `1.0` for true. If the `XData` vector is evenly spaced, `XDataEvenlySpaced` is `1.0` and more efficient code is generated.

The graph shows how the parameters `XData=[1:6]`and `YData=[1,2,7,4,5,9]` are handled. For example, if the input (*x*-value) to the S-Function block is 3, the output (*y*-value) is 7.



Direct-Index Lookup Table Example

Improve the lookup table by inlining a direct-index S-function with a TLC file. This direct-index lookup table S-function does not require a TLC file. The example uses a TLC file for the direct-index lookup table S-function to reduce the code size and increase efficiency of the generated code.

Implementation of the direct-index algorithm with an inlined TLC file requires the S-function main module, `sfun_directlook.c` and a corresponding `lookup_index.c` module. The `lookup_index.c` module contains the `GetDirectLookupIndex` function

that is used to locate the index in the `XData` for the current `x` input value when the `XData` is unevenly spaced. The `GetDirectLookupIndex` routine is called from the S-function and the generated code. The example uses the wrapper concept for sharing C/C++ code between Simulink MEX-files and the generated code.

If the `XData` is evenly spaced, then both the S-function main module and the generated code contain the lookup algorithm to compute the *y*-value of a given *x*-value because the algorithm is short.

The inlined TLC file is `sfun_directlook.tlc`, which is used to either perform a wrapper call or embed the optimal C/C++ code for the S-function. (See the example in "mdlRTW Usage" (Simulink Coder)).

Error Handling

In `sfun_directlook.tlc`, the `mdlCheckParameters` routine verifies that:

- The new parameter settings are valid.
- `XData` and `YData` are vectors of the same length containing real, finite numbers.
- `XDataEvenlySpaced` is a scalar.
- The `XData` vector is a monotonically increasing vector and evenly spaced.

The `mdlInitializeSizes` function explicitly calls `mdlCheckParameters` after it verifies the number of parameters passed to the S-function. After the Simulink engine calls `mdlInitializeSizes`, it then calls `mdlCheckParameters` whenever you change the parameters or reevaluate them.

User Data Caching

In `sfun_directlook.tlc`, the `mdlStart` routine shows how to cache information that does not change during the simulation or while the generated code is executing. The example caches the value of the `XDataEvenlySpaced` parameter in `UserData`, a field of the `SimStruct`. The following line in `mdlInitializeSizes` instructs the Simulink engine to disallow changes to `XDataEvenlySpaced`.

```
ssSetSFcnParamTunable(S, iParam, SS_PRM_NOT_TUNABLE);
```

During execution, `mdlOutputs` accesses the value of `XDataEvenlySpaced` from `UserData` rather than calling the `mxGetPr` MATLAB API function.

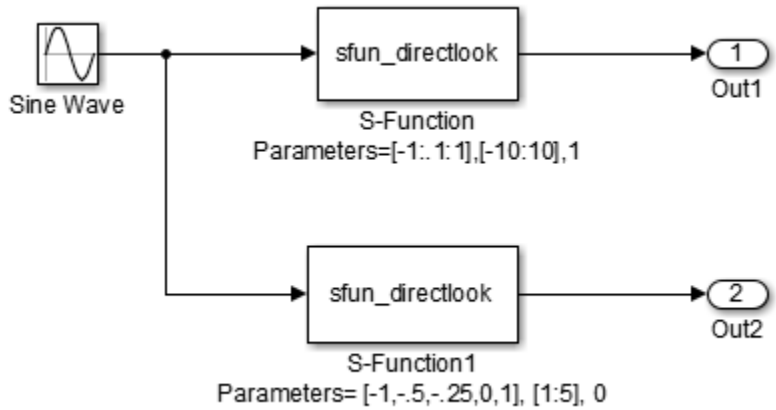
mdlRTW Usage

The code generator calls the `mdlRTW` routine while generating the *`model`*`.rtw` file. To produce optimal code for your Simulink model, you can add information to the *`model`*`.rtw` file about the mode in which your S-Function block is operating.

The example adds parameter settings to the *`model`*`.rtw` file. The parameter settings do not change during execution. In this case, the `XDataEvenlySpaced` S-function parameter cannot change during execution (`ssSetSFcnParamTunable` was specified as false (`0`) for it in `mdlInitializeSizes`). The parameter setting (`XSpacing`) uses the function `ssWriteRTWParamSettings`.

Because `xData` and `yData` are registered as run-time parameters in `mdlSetWorkWidths`, the code generator writes to the *`model`*`.rtw` file automatically.

Before examining the S-function and the inlined TLC file, consider the generated code for this model.



The model uses evenly spaced `XData` in the top S-Function block and unevenly spaced `XData` in the bottom S-Function block. When creating this model, specify the following commands for each S-Function block.

```
set_param('sfun_directlook_ex/S-Function','SFunctionModules','lookup_index')
set_param('sfun_directlook_ex/S-Function1','SFunctionModules','lookup_index')
```

The build process uses the module `lookup_index.c` when creating the executable.

When generating code for this model, the code generator uses the S-function `mdlRTW` method to generate a *`model`*`.rtw` file with the value `EvenlySpaced` for the `XSpacing` parameter for the top S-Function block and the value `UnEvenlySpaced` for the `XSpacing` parameter for the bottom S-Function block. The TLC-file uses the value of `XSpacing` to determine what algorithm to include in the generated code. The generated code contains the lookup algorithm when the `XData` is evenly spaced, but calls the `GetDirectLookupIndex` routine when the `XData` is unevenly spaced. The generated *`model`*`.c` or *`model`*`.cpp` code for the lookup table example model is similar to this code:

```
/*
 * sfun_directlook_ex.c
 *
 * Code generation for Simulink model
 * "sfun_directlook_ex.slx".
 *
...
 */

#include "sfun_directlook_ex.h"
#include "sfun_directlook_ex_private.h"

/* External outputs (root outports fed by signals with auto storage) */
ExtY_sfun_directlook_ex_T sfun_directlook_ex_Y;

/* Real-time model */
RT_MODEL_sfun_directlook_ex_T sfun_directlook_ex_M_;
RT_MODEL_sfun_directlook_ex_T *const sfun_directlook_ex_M =
  &sfun_directlook_ex_M_;

/* Model output function */
void sfun_directlook_ex_output(void)
{
  /* local block i/o variables */
  real_T rtb_SFunction;
  real_T rtb_SFunction1;

  /* Sin: '<Root>/Sine Wave' */
  rtb_SFunction1 = sin(sfun_directlook_ex_M->Timing.t[0]);

/* Code that is inlined for the top S-function block in the
   * sfun_directlook_ex model
   */
  /* S-Function (sfun_directlook): '<Root>/S-Function' */
  {
    const real_T *xData = sfun_directlook_ex_ConstP.SFunction_XData;
    const real_T *yData = sfun_directlook_ex_ConstP.SFunction_YData;
    real_T spacing = xData[1] - xData[0];
    if (rtb_SFunction1 <= xData[0] ) {
      rtb_SFunction = yData[0];
    } else if (rtb_SFunction1 >= yData[20] ) {
      rtb_SFunction = yData[20];
    } else {
      int_T idx = (int_T)( ( rtb_SFunction1 - xData[0] ) / spacing );
```

```
      rtb_SFunction = yData[idx];
    }
  }

  /* Outport: '<Root>/Out1' */
  sfun_directlook_ex_Y.Out1 = rtb_SFunction;

/* Code that is inlined for the bottom S-function block in the
   * sfun_directlook_ex model
   */
  /* S-Function (sfun_directlook): '<Root>/S-Function1' */
  {
    const real_T *xData = sfun_directlook_ex_ConstP.SFunction1_XData;
    const real_T *yData = sfun_directlook_ex_ConstP.SFunction1_YData;
    int_T idx;
    idx = GetDirectLookupIndex(xData, 5, rtb_SFunction1);
    rtb_SFunction1 = yData[idx];
  }

  /* Outport: '<Root>/Out2' */
  sfun_directlook_ex_Y.Out2 = rtb_SFunction1;
}

/* Model update function */
void sfun_directlook_ex_update(void)
{
  /* signal main to stop simulation */
  {                                    /* Sample time: [0.0s, 0.0s] */
    if ((rtmGetTFinal(sfun_directlook_ex_M)!=-1) &&
        !((rtmGetTFinal(sfun_directlook_ex_M)-sfun_directlook_ex_M->Timing.t[0])
          > sfun_directlook_ex_M->Timing.t[0] * (DBL_EPSILON))) {
      rtmSetErrorStatus(sfun_directlook_ex_M, "Simulation finished");
    }
  }

  /* Update absolute time for base rate */
  /* The "clockTick0" counts the number of times the code of this task has
   * been executed. The absolute time is the multiplication of "clockTick0"
   * and "Timing.stepSize0". Size of "clockTick0" ensures timer will not
   * overflow during the application lifespan selected.
   * Timer of this task consists of two 32 bit unsigned integers.
   * The two integers represent the low bits Timing.clockTick0 and the high bits
   * Timing.clockTickH0. When the low bit overflows to 0, the high bits increment.
   */
  if (!(++sfun_directlook_ex_M->Timing.clockTick0)) {
    ++sfun_directlook_ex_M->Timing.clockTickH0;
  }

  sfun_directlook_ex_M->Timing.t[0] = sfun_directlook_ex_M->Timing.clockTick0 *
    sfun_directlook_ex_M->Timing.stepSize0 +
    sfun_directlook_ex_M->Timing.clockTickH0 *
    sfun_directlook_ex_M->Timing.stepSize0 * 4294967296.0;
}
...

What is the Target Language Compiler?

Target Language Compiler Basics

In this section...

Target Language Compiler Overview

Target Language Compiler (TLC) is an integral part of the code generator. It enables you to customize generated code. Through customization, you can produce platform-specific code, or you can incorporate your own algorithmic changes for performance, code size, or compatibility with existing methods.

The TLC includes:

- Files corresponding to a subset of the provided Simulink blocks.
- Files for model-wide information that specify header and parameter information.

The TLC files are ASCII files that explicitly control the way that code is generated. By editing a TLC file, you can alter the way that the code is generated.

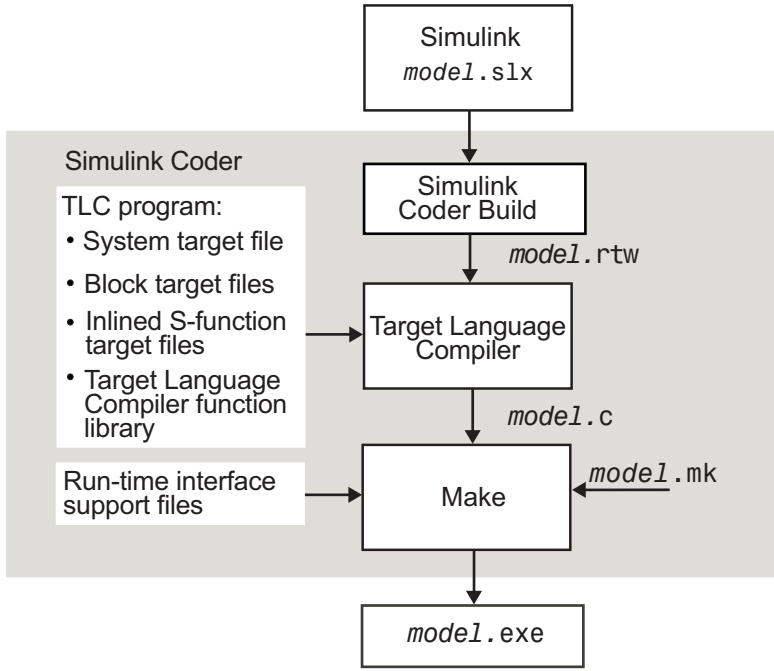
The Target Language Compiler provides a complete set of ready-to-use TLC files for generating ANSI C or C++ code. You can view the TLC files and make minor or extensive changes to them. This open environment provides tremendous flexibility for customizing the generated code.

For more information, see “Implement C/C++ S-Functions” (Simulink), which describes how to write wrapped and fully inlined S-functions, with emphasis on the `mdlRTW()` function.

Note Do not customize TLC files in the folder *`matlabroot`*`/rtw/c/tlc`, even though the capability exists. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results.

Overview of the TLC Process

This top-level diagram shows how the Target Language Compiler fits in with the code generation process.



The Target Language Compiler (TLC) is designed to convert the model description file *model*`.rtw` (or similar files) into target-specific code or text.

The Target Language Compiler transforms a representation of a Simulink block diagram, called *model*`.rtw`, into C or C++ code. The *model*`.rtw` file contains a partial representation of the model. The representation describes the execution semantics of the block diagram in a high-level language. For more information, see “model.rtw File and Scopes” on page 17-2.

After reading the *model*`.rtw` file, the Target Language Compiler generates its code based on target files, which specify particular code for each block, and model-wide files, which specify the overall code style. The TLC uses the target files and the *model*`.rtw` file to generate ANSI C or C++ code.

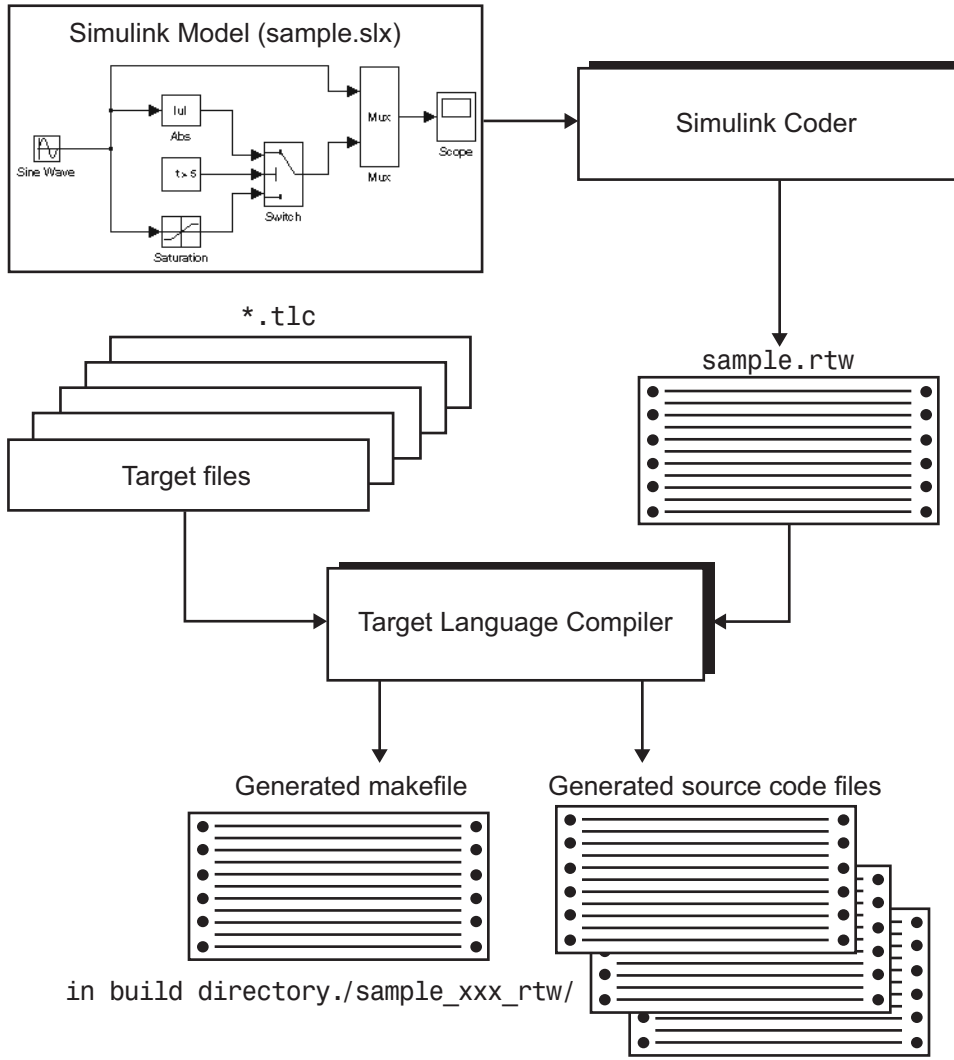
To create a target-specific application, the code generator requires a template makefile that specifies a C or C++ compiler and compiler options for the build process. The code generator transforms the template makefile into a target makefile (*model*.mk) by performing token expansion specific to a given model. The target makefile is a modified version of the generic `rt_main` file (or `grt_main`). You must modify `grt_main` to conform to the target's specific requirements, such as interrupt service routines. See "Template Makefiles and Make Options" (Simulink Coder) and "Customize Template Makefiles" (Simulink Coder).

The Target Language Compiler has similarities with HTML, Perl, and MATLAB. It has markup syntax similar to HTML, the power and flexibility of Perl and other scripting languages, and the data handling power of MATLAB (TLC can invoke MATLAB functions). The code that TLC generated is highly optimized and fully commented. With TLC, you can generate code from linear, nonlinear, continuous, discrete, or hybrid Simulink models. The models can include Simulink blocks that are automatically converted to code. Exceptions are MATLAB function blocks and S-function blocks that invoke MATLAB files. The Target Language Compiler uses block target files to transform each block in the *model*.rtw file and a model-wide target file for global customization of the code.

You can incorporate C MEX S-functions, with the generated code into the program executable. You can write a target file for your C MEX S-function to inline the S-function (see "Inline C MEX S-Functions" on page 20-10), to improve performance by eliminating function calls to the S-function itself and the memory overhead of the`SimStruct` of the S-function. Inlining an S-function incorporates the S-function block code into the generated code for the model. When a TLC target file is not present for the S-function, it's C or C++ code file is invoked through a function call. See "Inline S-Functions" on page 20-2. You can also write target files for MATLAB language files or Fortran S-functions.

Overview of the Code Generation Process

The Target Language Compiler works with its target files and the code generator output to produce code.



When generating code from a Simulink model, the first step in the automated process is to generate a *`model`*`.rtw` file. The *`model`*`.rtw` file includes the model-specific information required for generating code from the Simulink model. *`model`*`.rtw` is passed to the Target Language Compiler, which uses it in combination with a set of included system target files and block target files to generate the code.

Only the final executable file is written directly to the current folder. For other files created during code generation, including the *model*.rtw file, a build folder is used. This folder is created in the current folder and is named *model*_*target*_rtw. *target* is the abbreviation for the target environment grt that is a generic real-time target.

Files placed in the build folder include:

- The body for the generated C or C++ source code (*model*.c or *model*.cpp)
- Header files (*model*.h)
- Header file *model*_private.h defining parameters and data structures private to the generated code
- A makefile, *model*.mk, for building the application
- Additional files, described in “Manage Build Process Files” (Simulink Coder)

Why Use the Target Language Compiler?

If you simply need to produce ANSI C or C++ code from Simulink models, you do not need to know how to prepare files for the Target Language Compiler. If you need to customize the output, you must run the Target Language Compiler. With the Target Language Compiler, you can:

- Customize the set of options specified by your system target file.
- Inline the code for S-Function blocks.
- Generate additional or different types of files.

The MATLAB Function block and the Embedded Coder product facilitate code customization in a variety of ways. You might be able to accomplish what you need with them, without the need to write TLC files. However, you do need to prepare TLC files if you intend to inline S-functions.

See the following sections.

In this section...
“Customizing Output” on page 13-7
“Inlining S-Functions” on page 13-8
“Defining Advanced Custom Storage Classes” on page 13-8

Customizing Output

To produce customized output using the Target Language Compiler, it helps if you understand how blocks perform their functions, what data types are being manipulated, the structure of the *`model`*`.rtw` file, and how to modify target files to produce the desired output. Directives and Built-In Functions topics on “Target Language Compiler” (Simulink Coder), describe the target language directives and their associated constructs. You will use the Target Language Compiler directives and constructs to modify existing target files or create new ones, depending on your needs. See “TLC Files” on page 16-13 for more information about target files.

Note You should not customize TLC files in the folder *`matlabroot`*`/rtw/c/tlc` even though the capability exists to do so. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results.

Inlining S-Functions

The Target Language Compiler provides a great deal of freedom for altering, optimizing, and enhancing the generated code. One of the most important TLC features is that it lets you inline S-functions that you write to add your own algorithms, device drivers, and custom blocks to a Simulink model.

To create an S-function, you write code following a well-defined application program interface (API). By default, the Target Language Compiler will generate noninlined code for S-functions that invokes them using this same API. This generalized interface incurs a fair amount of overhead due to the presence of a large data structure called the `SimStruct` for each instance of each S-Function block in your model. In addition, extra run-time overhead is involved whenever methods (functions) within your S-function are called. You can eliminate this overhead by using the Target Language Compiler to inline the S-function, by creating a TLC file named *`sfunction_name`*`.tlc` that generates source code for the S-function as if it were a built-in block. Inlining an S-function improves the efficiency of the generated code and reduces memory usage.

Defining Advanced Custom Storage Classes

Certain data layouts, such as nested structures, cannot be generated using the standard `Unstructured` and `FlatStructure` custom storage class types. You can define an *advanced custom storage class* if you want to generate other types of data. Creating advanced CSCs requires understanding TLC programming and using a special advanced mode of the Custom Storage Class Designer. For more information, see “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 36-48. Note that this support requires an Embedded Coder license.

The Advantages of Inlining S-Functions

The goals of generated code usually include compactness and speed. On the other hand, S-functions are run-time-loadable extension modules for adding block-level functionality to Simulink. As such, the S-function interface is optimized for flexibility in configuring and using blocks in a simulation environment with capability to allow run-time changes to a block's operation via parameters. These changes typically take the form of algorithm selection and numerical constants for the block algorithms.

While switching algorithms is a desirable feature in the design phase of a system, when the time comes to generate code, this type of flexibility is often dropped in favor of optimal calculation speed and code size. The Target Language Compiler is designed to allow the generation of code that is compact and fast by selectively generating only the code you need for one instance of a block's parameter set.

When To Avoid Inlining

You might decide not to inline C MEX S-functions that have:

- Few or no numerical parameters.
- One algorithm that is already fixed in capability. For example, it has no optional modes or alternate algorithms.
- Support for only one data type.
- A significant or large code size in the `mdlOutputs()` function.
- Multiple instances of S-Function block in your models.

Whenever you encounter this situation, the effort of inlining the block might not improve execution speed and could actually increase the size of the generated code. The tradeoff is in the size of the block's body code generated for each instance versus the size of the child SimStruct created for each instance of a noninlined S-function in the generated code.

Alternatively, you can use a hybrid inlining method known as a C MEX wrapped S-function, where the block target file simply generates a call to a custom code function that the S-function itself also calls. This approach might be the optimal solution for code generation in the case of a large piece of existing code. See "Write Wrapper S-Function and TLC Files" (Simulink Coder) for the procedure and an example of a wrapped S-function.

Inlining Process

The strategy for improving code from blocks centers on determining what part of a block's operations are active and used in the generated code and what parts can be predetermined or left out.

In practice, this means the TLC code in the block target file will select an algorithm that is a subset of the algorithms contained in the S-function itself and then selectively hard-code numerical parameters that are not to be changed at run time. This reduces code memory size and results in code that is often much faster than its S-function counterpart when mode selection is a significant part of S-function processing. Additionally, function-call overhead is eliminated for inlined S-functions, as the code is generated directly in the body of the code unless there is an explicit call to a library function in the generated code.

The algorithm selections and parameters for each block are output in the initial phase of the code generation process from the registered S-function parameter set or the `mdlRTW()` function (if present), which results in entries in the model's `.rtw` file for that block at code generation time. A file written in the target language for the block is then called to read the entries in the *`model`*`.rtw` file and compute the generated code for this instance of the block. This TLC code is contained in the block target file.

One special case for inlined S-functions is for the case of I/O blocks and drivers such as A/D converters or communications ports. For simulation, the I/O driver is typically coded in the S-function as a pure source, a pass-through, or a pure sink. In the generated code, however, an actual interface to the I/O device must be made, typically through direct coding with the common `_in()`, `_out()` functions, inlined assembly code, or a specific set of I/O library calls unique to the device and target environment.

Search Algorithm for Locating TLC Files

The Target Language Compiler uses the following search order to locate TLC files:

1. Current folder.
2. Locations specified by `%addincludepath` directives. The compiler evaluates multiple `%addincludepath` directives from the *bottom up*.
3. Locations specified by `-I` options. The compiler evaluates multiple `-I` options from *right to left*.

For inlined S-function TLC files, the build process supports the following locations:

- The folder where the S-function executable (MEX or MATLAB) file is located.
- S-function folder subfolder `./tlc_c` (for C or C++ language targets).
- The current folder when the build process is initiated.

Note Note: Placing the inlined S-function TLC file elsewhere is not supported, even if the location is in the TLC include path.

The first target file encountered with the required name that implements the specified language is used in processing the S-function *`model`*`.rtw` file entry.

Note The compiler does *not* search the MATLAB path, and will not find a file that is available only on that path. The compiler searches only the locations described above.

Availability for Inlining and Noninlining

S-functions can be written in MATLAB language, Fortran, C, and C++. TLC inlining of S-functions is available as indicated in this table.

Inline TLC Support by S-Function Type

S-Function Type	Noninlining Supported	Inlining Supported
MATLAB language	No	Yes
Fortran MEX	No	Yes
C	Yes	Yes
C++	Yes	Yes

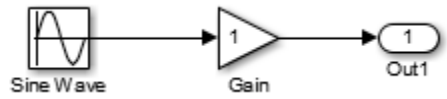
Getting Started

Code Architecture

Before investigating the specific code generation pieces of the Target Language Compiler (TLC), consider how Target Language Compiler generates code for a simple model. From the next figure, you see that blocks place code into `Mdl` routines. This shows `MdlOutputs`.



```
static void simple_output(int_T tid)
{

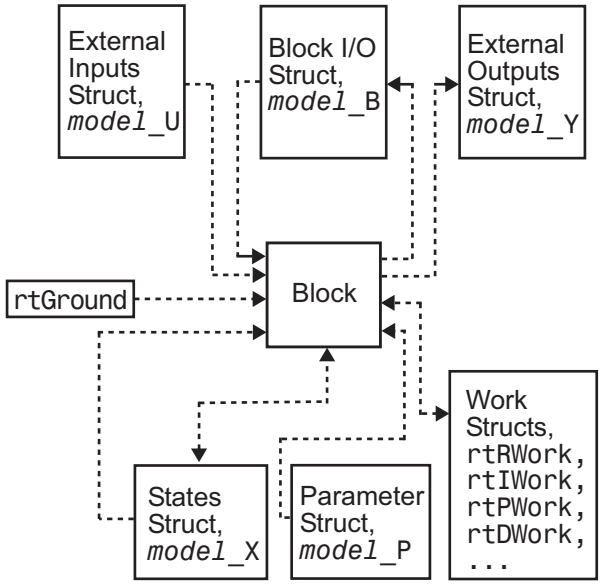
  /* Sin Block: '<Root>/Sine Wave' */

  simple_B.SineWave_d = simple_P.SineWave_Amp *
    sin(simple_P.SineWave_Freq * simple_M->Timing.t[0] +
    simple_P.SineWave_Phase) + simple_P.SineWave_Bias;

  /* Gain: '<Root>/Gain' */
  simple_B.Gain_d = simple_B.SineWave_d * simple_P.Gain_Gain;

  /* Outport: '<Root>/Out1' */
  simple_Y.Out1 = simple_B.Gain_d;
}
```

Blocks have inputs, outputs, parameters, states, plus other general properties. For example, block inputs and outputs are generally written to a block I/O structure (generated with identifiers of the type *`model`*`_B`, where *`model`* is the model name). Block inputs can also come from the external input structure (*`model`*`_U`) or the state structure when connected to a state port of an integrator (*`model`*`_X`), or ground (`rtGround`) if unconnected or grounded. Block outputs can also go to the external output structure, (*`model`*`_Y`). The following diagram shows the general block data mappings.



This discussion should give you a general sense of what the block object looks like. Now, you can look at specific pieces of the code generation process that are specific to the Target Language Compiler.

Code Generation Process

The code generator invokes the Target Language Compiler after a model is compiled into a partial representation of the model (*model*`.rtw`) suitable for code generation. To generate code, the Target Language Compiler uses its library of functions to transform two classes of target files:

- System target files
- Block target files

System target files are used to specify the overall structure of the generated code, tailoring for specific target environments. Block target files are used to implement the functionality of Simulink blocks, including user-defined S-function blocks.

You can create block target files for C MEX, Fortran, and MATLAB language S-functions to fully inline block functionality into the body of the generated code. C MEX S-functions

can be noninlined, wrapper-inlined, or fully inlined. Fortran S-functions must be wrapper-inlined or fully inlined.

How TLC Determines S-Function Inlining Status

Whenever the Target Language Compiler encounters an entry for an S-function block in the *model*`.rtw` file, it must decide whether to generate a call to the S-function or to inline it.

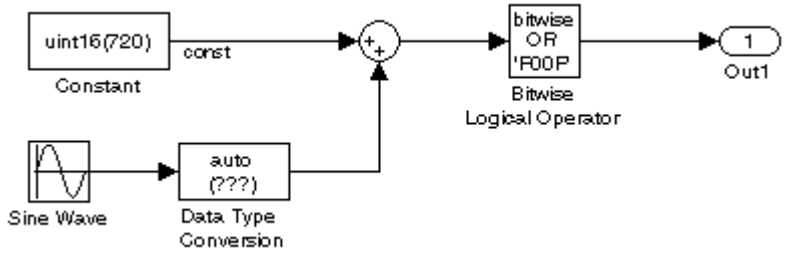
Because they cannot use `SimStructs`, Fortran and MATLAB language S-functions must be inlined. This inlining can either be in the form of a full block target file or a one-line block target file that refers to a substitute C MEX S-function source file.

The Target Language Compiler selects a C MEX S-function for inlining if an explicit `mdlRTW()` function exists in the S-function code or if a target file for the current target language for the current block is in the TLC file search path. If a C MEX S-function has an explicit `mdlRTW()` function, there must be a corresponding target file or an error condition results.

The target file for an S-function must have the same root name as the S-function and must have the extension `.tlc`. For example, the target file for a C MEX S-function named `sfix_bitop` has the filename `sfix_bitop.tlc`.

Inlined and Noninlined S-Function Code

This example focuses on a C MEX S-function named `sfix_bitop`. The code generation options are set to allow reuse of signal memory for signal lines that were not set as tunable signals.



The code generated for the bit-wise operator block reuses a temporary variable that is set up for the output of the sum block to save memory. This results in one very efficient line of code, as seen here.

```
/* Bitwise Logic Block: <Root>/Bitwise Logical Operator */
/* [input] OR 'F00F' */
rtb_temp2 |= 0xF00F;
```

Initialization or setup code is not required for this inlined block.

If this block were not inlined, the source code for the S-function itself with its various options would be added to the generated code base, memory would be allocated in the generated code for the block's `SimStruct` data, and calls to the S-function methods would be generated to initialize, run, and terminate the S-function code. To execute the `mdlOutputs` function of the S-function, code would be generated like this:

```
/* Level2 S-Function Block: <Root>/Bitwise Logical Operator (sfix_bitop) */
  {
    SimStruct *rts = ssGetSFunction(rtS, 0);
    sfcnOutputs(rts, tid);
  }
```

The entire `mdlOutputs` function is called and runs just as it does during simulation. That's not everything, though. There is also registration, initialization, and termination code for the noninlined S-function. The initialization and termination calls are similar to the fragment above. Then, the registration code for an S-function with just one inport and one outport is 72 lines of C code generated as part of file *`model`*`_reg.h`.

```
/*Level2 S-Function Block: <Root>/Bitwise Logical Operator (sfix_bitop) */
    {
      extern void untitled_sf(SimStruct *rts);
      SimStruct *rts = ssGetSFunction(rtS, 0);

      /* timing info */
      static time_T sfcnPeriod[1];
      static time_T sfcnOffset[1];
      static int_T sfcnTsMap[1];

      {
        int_T i;

        for(i = 0; i < 1; i++) {
          sfcnPeriod[i] = sfcnOffset[i] = 0.0;
        }
      }
      ssSetSampleTimePtr(rts, &sfcnPeriod[0]);
      ssSetOffsetTimePtr(rts, &sfcnOffset[0]);
      ssSetSampleTimeTaskIDPtr(rts, sfcnTsMap);
      ssSetMdlInfoPtr(rts, ssGetMdlInfoPtr(rtS));
```

```
      /* inputs */
      {
        static struct _ssPortInputs inputPortInfo[1];

        _ssSetNumInputPorts(rts, 1);
        ssSetPortInfoForInputs(rts, &inputPortInfo[0]);

        /* port 0 */
        {

          static real_T const *sfcnUPtrs[1];
          sfcnUPtrs[0] = &rtU.In1;
          ssSetInputPortSignalPtrs(rts, 0, (InputPtrsType)&sfcnUPtrs[0]);
          _ssSetInputPortNumDimensions(rts, 0, 1);
          ssSetInputPortWidth(rts, 0, 1);
        }
      }
.
.
.
```

This continues until S-function sizes and methods are declared, allocated, and initialized. The amount of registration code generated is essentially proportional to the number and size of the input ports and output ports.

A noninlined S-function will typically have a significant impact on the size of the generated code, whereas an inlined S-function can be close to the handwritten size and performance of the generated code.

Target Language Compiler Process

To write TLC code for your S-function, you need to understand the Target Language Compiler process for code generation. As previously described, the Simulink software generates a *model*.rtw file that contains a partial representation of the execution semantics of the block diagram. The *model*.rtw file is an ASCII file that contains a data structure in the form of a nested set of TLC records. The records comprise property name/property value pairs. The Target Language Compiler reads the *model*.rtw file and converts it into an internal representation.

Next, the Target Language Compiler runs (interprets) the TLC files, starting first with the system target file, for example, grt.tlc. This is the entry point to the system TLC and block files, that is, other TLC files included in or generated from the TLC file passed to Target Language Compiler on its command line (grt.tlc). As the TLC code in the system and block target files is run, it uses, appends to, and modifies the existing property name/property value pairs and records initially loaded from the *model*.rtw file.

model.rtw Structure

The structure of the *model*.rtw file mirrors the block diagram's structure:

- For each nonvirtual system in the model, there is a corresponding system record in the *model*.rtw file.
- For each nonvirtual block within a nonvirtual system, there is a block record in the *model*.rtw file in the corresponding system.

The basic structure of *model*.rtw is

```
CompiledModel {
  System {
    Block {
      DataInputPort {
        ...
      }
      DataOutputPort{
        ...
      }
      ParamSettings {
        ...
      }
      Parameter {
```

```
        ...
      }
    }
  }
}
```

Operating Sequence

For each occurrence of a given block in the model, a corresponding block record exists in the *`model`*`.rtw` file. The system target file TLC code loops through block records and calls the functions in the corresponding block target file for that block type. For inlined S-functions, it calls the inlining TLC file.

There is a method for getting block-specific information (internal block information, as opposed to inputs, outputs, parameters, etc.) into the block record in the *`model`*`.rtw` file for a block by using the `mdlRTW` function in the C MEX function of the block.

Among other things, the `mdlRTW` function allows you to write out parameter settings (`ParamSettings`), that is, unique information pertaining to this block. For parameter settings in the block TLC file, direct accesses to these fields are made from the block TLC code and can be used to alter the generated code as desired.

Inlining S-Functions

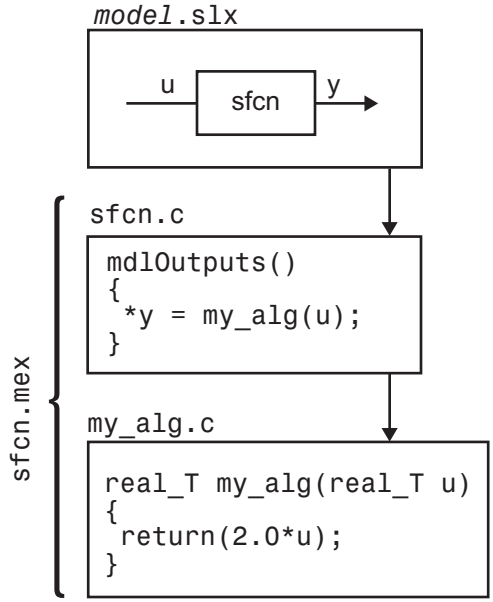
Inlining an S-function

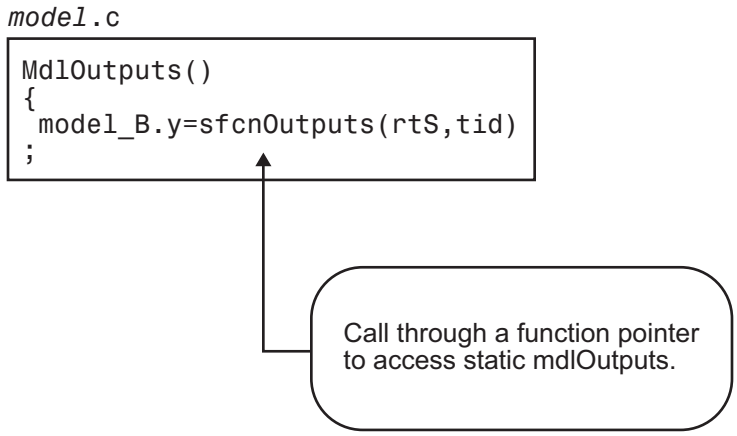
To inline an S-function means to provide a TLC file for an S-Function block that will replace the C, C++, Fortran, or MATLAB language version of the block that was used during simulation.

Noninlined S-Function

If an inlining TLC file is not provided, most targets support the block by recompiling the C MEX S-function for the block. As discussed earlier, there is overhead in memory usage and speed when using a C/C++ coded S-function and a limited subset of `mx*` API calls supported within the code generator context. If you want the most efficient generated code, you must inline S-functions by writing a TLC file for them.

When the simulation needs to execute one of the functions for an S-function block, it calls the MEX-file for that function. When the code generator executes a noninlined S-function, it does so in a similar manner, as this diagram illustrates.





Types of Inlining

It is helpful to define two categories of inlining:

- Fully inlined S-functions
- Wrapper inlined S-functions

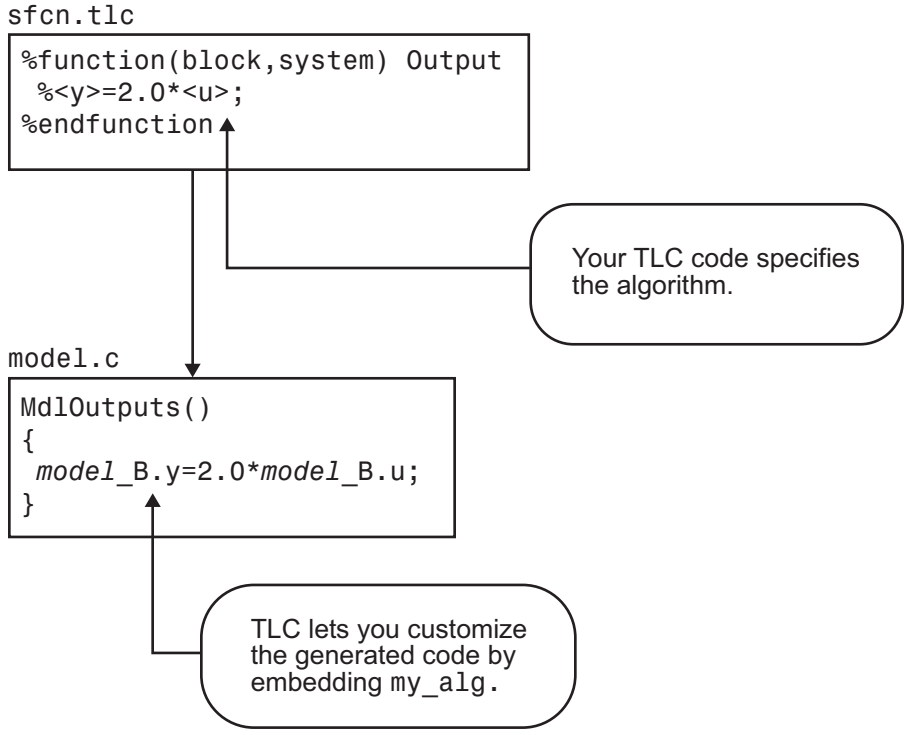
While both inline the S-function and remove the overhead of a noninlined S-function, the two approaches are different. The first example below, using `timestwo.tlc`, is considered a fully inlined TLC file, where the full implementation of the block is contained in the TLC file for the block.

The second example uses a wrapper TLC file. Instead of generating the algorithmic code in place, this example calls a C function that contains the body of code. There are several potential benefits for using the wrapper TLC file:

- It provides a way for the C MEX S-function and the generated code to share the C code. You do not need to write the code twice.
- The called C function is an optimized routine.
- Several of the blocks might exist in the model, and it is more efficient in terms of code size to have them call a function, as opposed to each creating identical algorithmic code.
- It provides a way to incorporate legacy C code seamlessly into generated code.

Fully Inlined S-Function Example

Inlining an S-function provides a mechanism to directly embed code for an S-function block into the generated code for a model. Instead of calling into a separate source file via function pointers and maintaining a separate data structure (`SimStruct`) for it, the code appears “inlined” as the next figure shows.



The S-function `timestwo.c` provides a simple example of a fully inlined S-function. This block multiplies its input by 2 and outputs it. The C MEX version of the block is in the file *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/src/timestwo.c`, and the inlining TLC file for the block is *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/tlc_c/timestwo.tlc`.

timestwo.tlc

```
%implements "timestwo" "C"
```

```
%% Function: Outputs =======================================
%%
%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %%
  /* Multiply input by two */
  %assign rollVars = ["U", "Y"]
  %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
    %<LibBlockOutputSignal(0, "", lcv, idx)> = \
    %<LibBlockInputSignal(0, "", lcv, idx)> * 2.0;
  %endroll
%endfunction
```

TLC Block Analysis

The `%implements` directive is required by TLC block files and is used by the Target Language Compiler to verify the block type and language supported by the block. The `%function` directive starts a function declaration and shows the name of the function, `Outputs`, and the arguments passed to it, `block` and `system`. These are the relevant records from the *`model`*`.rtw` file for this instance of the block.

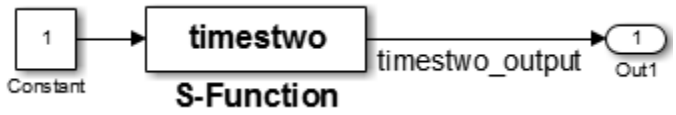
The last piece of the prototype is `Output`. This means that any line that is not a TLC directive is output by the function to the current file that is selected in TLC. So, nondirective lines in the `Outputs` function become generated code for the block.

The most complicated piece of this TLC block example is the `%roll` directive. TLC uses this directive to provide automatic generation of `for` loops, depending on input/output widths and whether the inputs are contiguous in memory. This example uses the typical form of accessing outputs and inputs from within the body of the roll, using `LibBlockOutputSignal` and `LibBlockInputSignal` to access the outputs and inputs and perform the multiplication and assignment. Note that this TLC file supports any valid signal width.

The only function used to implement this block is `Outputs`. For more complicated blocks, other functions are declared as well. You can find examples of more complicated inlining TLC files in the folders *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/tlc_c` (open) and *`matlabroot`*`/toolbox/simulink/blocks/tlc_c` (open), and by looking at the code for built-in blocks in the folder *`matlabroot/rtw/c/tlc/blocks`* (open).

The timestwo Model

This simple model uses the `timestwo` S-function and shows the `MdlOutputs` function from the generated *`model`*`.c` file, which contains the inlined S-function code.



Model Outputs Code

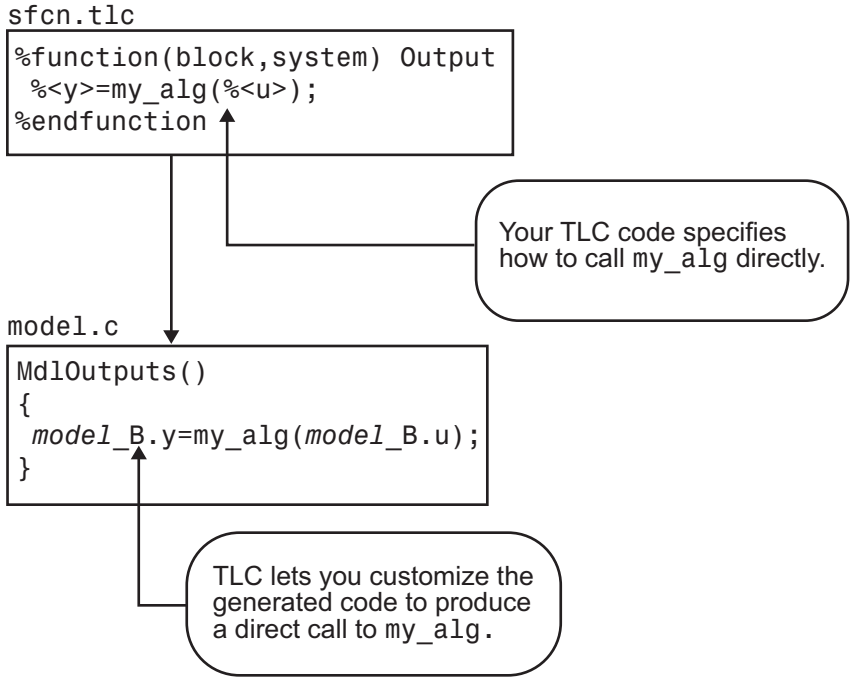
```
/* Model output function */
static void timestwo_ex_output(int_T tid)
{

  /* S-Function Block: <Root>/S-Function */
  /* Multiply input by two */
  timestwo_ex_B.timestwo_output = timestwo_ex_P.Constant_Value
     * 2.0;

  /* Outport: '<Root>/Out1' */
  timestwo_ex_Y.Out1 = timestwo_ex_B.timestwo_output;
}
```

Wrapper Inlined S-Function Example

The following diagram illustrates inlining an S-function as a wrapper. The algorithm is directly called from the generated model code, removing the S-function overhead but maintaining the user function.



This is the inlining TLC file for a wrapper version of the `timestwo` block.

```
%implements "timestwo" "C"

%% Function: BlockTypeSetup ===================================
%%
%function BlockTypeSetup(block, system) void
  %% Add function prototype to model's header file
  %<LibCacheFunctionPrototype...
   ("extern void mytimestwo(real_T* in,real_T* out,int_T els);")>
  %% Add file that contains "myfile" to list of files to be compiled
  %<LibAddToModelSources("myfile")>
%endfunction

%% Function: Outputs ==========================================
%%
%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %assign outPtr = LibBlockOutputSignalAddr(0, "", "", 0)
  %assign inPtr = LibBlockInputSignalAddr(0, "", "",0)
  %assign numEls = LibBlockOutputSignalWidth(0)
  /* Multiply input by two */
  mytimestwo(%<inPtr>,%<outPtr>,%<numEls>);
```

```
%endfunction
```

Analysis

The function `BlockTypeSetup` is called once for each type of block in a model; it doesn't produce output directly like the `Outputs` function. Use `BlockTypeSetup` to include a function prototype in the *`model`*`.h` file and to tell the build process to compile an additional file, `myfile.c`.

Instead of performing the multiplication directly, the `Outputs` function now calls the function `mytimestwo`. All instances of this block in the model call the same function to perform the multiplication. The resulting model function, `MdlOutputs`, then becomes

```
static void timestwo_ex_output(int_T tid)
{
  /* S-Function Block: <Root>/S-Function */
  /* Multiply input by two */
  mytimestwo(&model_B.Constant_Value,&model_B.S_Function,1);

  /* Outport Block: <Root>/Out1 */
model_Y.Out1 = model_B.S_Function;
}
```

Target Language Compiler Tutorials

Advice About TLC Tutorials

The fastest and easiest way to understand the Target Language Compiler (TLC) is to run it, paying attention to how TLC scripts transform compiled Simulink models (*model*.rtw files) into source code. The tutorials highlight the principal reasons for and techniques of using TLC. The tutorials provide a number of TLC exercises, each one organized as a major section.

The example models, S-functions, and TLC files for the exercises are located in the folder *matlabroot*/toolbox/rtw/rtwdemos/tlctutorial (open). In this chapter, this folder is referred to as tlctutorial. Each example is located in a separate subfolder within tlctutorial. Within that subfolder, you can find solutions to the problem in a solutions subfolder.

Note Before you begin the tutorial, copy the entire tlctutorial folder to a local working folder. The files are together, and if you make mistakes or want fresh examples to try again, you can recopy files from the original tlctutorial folder.

Each tutorial exercise is limited in scope, requiring just a small amount of experimentation. The tutorial explains details about TLC that will help customize and optimize code for code generation projects.

Note You should not customize TLC files in the folder *matlabroot*/rtw/c/tlc even though the capability exists to do so. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results.

The tutorials progress in difficulty from basic to more advanced. To get the most out of them, you should be familiar with

- Working in the MATLAB environment
- Building Simulink models
- Using the code generator to produce code for target systems
- High-level language concepts (for example, C or Fortran programming)

If you encounter terms in the tutorials that you do not understand, it may be helpful to read “Code Generation Concepts” on page 16-8 to acquaint yourself with the basic goals and methods of TLC programming. Similarly, if you see TLC keywords, built-in

functions, or directives that you would like to know more about, see the corresponding topics on “Target Language Compiler” (Simulink Coder).

The examples used in the tutorial are:

Example	Description
guide	Illustrative record file
timesN	An example C file S-function for multiplying an input by N
tlcdebug	An example using TLC Debugger
wrapper	Example TLC file for S-function `wrapsfcn.c`

Read Record Files with TLC

In this section...

Tutorial Overview

Objective: Understand the structure of record files and learn how to parse them with TLC directives.

Folder: *matlabroot*`/toolbox/rtw/rtwdemos/tlctutorial/guide` (open)

In this tutorial you interpret a simple file of structured records with a series of TLC scripts. You will learn how records are structured, and how TLC `%assign` and `%<>` token expansion directives are used to process them. In addition, the tutorial illustrates loops using `%foreach`, and scoping using `%with`.

The tutorial includes these steps, which you should follow sequentially:

1. **Structure of Record Files** — Some background and a simple example
2. **Interpret Records** — Presenting contents of the record file
3. **Anatomy of a TLC Script** — Deconstructing the presentation
4. **Modify `read-guide.tlc`** — Experiment with TLC
5. **Pass and Use a Parameter**— Pass parameters from the command line to TLC files
6. **Review**

Structure of Record Files

The code generator compiles models into a structured form called a record file, referred to as *`model`*`.rtw`. Such compiled model files are similar in syntax and organization to

source model files, in that they contain a series of hierarchically nested records of the form

```
recordName {itemName itemValue}
```

Item names are alphabetic. Item values can be strings or numbers. Numeric values can be scalars, vectors, or matrices. Curly braces set off the contents of each record, which may contain one or more items, delimited by space, tab, or return characters.

In a *`model`*`.rtw` file, the top-level (first) record's name is `CompiledModel`. Each block is represented by a subrecord within it, identified by the block's name. TLC can parse well-formed record files, as this exercise illustrates.

The following listing is a valid record file that TLC can parse, although not one for which it can generate code. Comments are indicated by a pound sign (`#`):

```
#
# File: guide.rtw    Illustrative record file, which can't be used by Simulink
#                                  Note: string values MUST be in quotes
Top {                             # Outermost Record, called Top
  Date         "21-Aug-2008"      # Name/Value pair named Top.Date
  Employee {                      # Nested record within the Top record
    FirstName  "Arthur"           #   Alpha field Top.Employee.FirstName
    LastName   "Dent"             #   Alpha field Top.Employee.LastName
    Overhead    1.78              #   Numeric field Top.Employee.Overhead
    PayRate     11.50             #   Numeric field Top.Employee.PayRate
    GrossRate   0.0               #   Numeric Field Top.Employee.GrossRate
  }                               # End of Employee record
  NumProject   3                  # Indicates length of following list
  Project {                       # First list item, called Top.Project[0]
    Name       "Tea"              #   Alpha field Name, Top.Project[0].Name
    Difficulty 3                  #   Numeric field Top.Project[0].Difficulty
  }                               # End of first list item
  Project {                       # Second list item, called Top.Project[1]
    Name       "Gillian"          #   Alpha field Name, Top.Project[1].Name
    Difficulty 8                  #   Numeric field Top.Project[1].Difficulty
  }                               # End of second list item
  Project {                       # Third list item, called Top.Project[2]
    Name       "Zaphod"           #   Alpha field Name, Top.Project[2].Name
    Difficulty 10                 #   Numeric field Top.Project[2].Difficulty
  }                               # End of third list item
}                                 # End of Top record and of file
```

As long as programmers know the names of records and fields, and their expected contents, they can compose TLC statements to read, parse, and manipulate record file data.

Interpret Records

Here is the output from a TLC program script that reads `guide.rtw`, interprets its records, manipulates field data, and formats descriptions, which are directed to the MATLAB Command Window:

```
Using TLC you can:
* Directly access a field's value, e.g.
  %<Top.Date> -- evaluates to:
  "21-Aug-2008"

* Assign contents of a field to a variable, e.g.
  "%assign worker = Top.Employee.FirstName"
  worker expands to Top.Employee.FirstName = "Arthur"

* Concatenate string values, e.g.
  "%assign worker = worker + " " + Top.Employee.LastName"
  worker expands to worker + " " + Top.Employee.LastName = "Arthur Dent"

* Perform arithmetic operations, e.g.
  "%assign wageCost = Top.Employee.PayRate * Top.Employee.Overhead"
  wageCost expands to Top.Employee.PayRate * Top.Employee.Overhead <- 11.5 * 1.78 = 20.47

* Put variables into a field, e.g.
  Top.Employee.GrossRate starts at 0.0
  "%assign Top.Employee.GrossRate = wageCost"
  Top.Employee.GrossRate expands to wageCost = 20.47

* Index lists of values, e.g.
  "%assign projects = Top.Project[0].Name + ", " + Top.Project[1].Name..."
  "+ ", " + Top.Project[2].Name"
  projects expands to Top.Project[0].Name + ", " + Top.Project[1].Name
  + ", " + Top.Project[2].Name = Tea, Gillian, Zaphod

* Traverse and manipulate list data via loops, e.g.
  - At top of Loop, Project = Tea; Difficulty = 3
  - Bottom of Loop, i = 0; diffSum = 3.0
  - At top of Loop, Project = Gillian; Difficulty = 8
  - Bottom of Loop, i = 1; diffSum = 11.0
  - At top of Loop, Project = Zaphod; Difficulty = 10
  - Bottom of Loop, i = 2; diffSum = 21.0
  Average Project Difficulty expands to diffSum / Top.NumProject = 21.0 / 3 = 7.0
```

This output from `guide.rtw` was produced by invoking TLC from the MATLAB Command Window, executing a script called `read-guide.tlc`. Do this yourself now, by following these steps:

1. In MATLAB, change folder (`cd`) to your copy of `tlctutorial/guide` within your working folder.
2. To produce the output just listed, process `guide.rtw` with the TLC script `read-guide.tlc` by typing the following command:

   ```
   tlc -v -r guide.rtw read-guide.tlc
   ```

Note command usage:

- The `-r` switch (for read) identifies the input data file, in this case `guide.rtw`.
- The TLC script handling the data file is specified by the last token typed.
- The `-v` switch (for verbose) directs output to the command window, unless the TLC file handles this itself.

Anatomy of a TLC Script

You now dissect the script you just ran. Each "paragraph" of output from `guide.tlc` is discussed in sequence in the following brief sections:

Coding Conventions

These are some basic TLC syntax and coding conventions:

`%% Comment`	TLC comment, which is not output
`/* comment */`	Comment, to be output
`%keyword`	TLC directive (keyword), start with "%"
`%<expr>`	TLC token operator
`.` (period)	Scoping operator, for example, `Top.Lev2.Lev3`
`...` (at end-of-line)	Statement continuation (line break is not output)
`\` (at end-of-line)	Statement continuation (line break is output)
`localvarIdentifier`	Local variables start in lowercase
`GlobalvarIdentifier`	Global variables start in uppercase

`RecordIdentifier`	Record identifiers start in uppercase
`EXISTS()`	TLC built-in functions are named in uppercase **Note:** TLC identifiers are case-sensitive.

For further information, see “TLC Coding Conventions” on page 20-22.

File Header

The file `read-guide.tlc` begins with:

```
%% File: read-guide.tlc   (This line is a TLC Comment, and will not print)
%%
%% To execute this file, type: tlc -v -r guide.rtw read-guide.tlc
%% Set format for displaying real values (default is "EXPONENTIAL")
%realformat "CONCISE"
```

- Lines 1 through 4 — Text on a line following the characters `%%` is treated as a comment (ignored, not interpreted or output).
- Line 5 — As explained in the text of the fourth line, is the TLC directive (keyword) `%realformat`, which controls how subsequent floating-point numbers are formatted when displayed in output. Here we want to minimize the digits displayed.

Token Expansion

The first section of output is produced by the script lines:

```
Using TLC you can:
* Directly access a field's value, e.g.
%assign td = "%" + "<Top.Date>"
  %<td> -- evaluates to:
  "%<Top.Date>"
```

- Lines 1 and 2 — (and lines that contain no TLC directives or tokens) are simply echoed to the output stream, including leading and trailing spaces.
- Line 3 — Creates a variable named `td` and assigns the string value `%<Top.Date>` to it. The `%assign` directive creates new and modifies existing variables. Its general syntax is:

  ```
  %assign ::variable = expression
  ```

  The optional double colon prefix specifies that the variable being assigned to is a global variable. In its absence, TLC creates or modifies a local variable in the current scope.

- Line 4 — Displays

  ```
  %<Top.Date> -- evaluates to:
  ```

  The preceding line enables TLC to print `%<Top.Date>` without expanding it. It constructs the string by pasting together two literals.

  ```
  %assign td = "%" + "<Top.Date>"
  ```

  As discussed in “String Processing Plus” on page 15-10, the plus operator concatenates strings as and adds numbers, vectors, matrices, and records.

- Line 5 — Evaluates (expands) the record `Top.Date`. More precisely, it evaluates the field `Date` which exists in scope `Top`. The syntax `%<expr>` causes expression `expr` (which can be a record, a variable, or a function) to be evaluated. This operation is sometimes referred to as an *eval*.

Note You cannot nest the `%<expr>` operator (that is, `%<foo%<bar>>` is not allowed).

Note When you use the `%<expr>` operator within quotation marks, for example, `"%<Top.Date>"`, TLC expands the expression and then encloses the result in quotation marks. However, placing `%assign` within quotation marks, for example, `"%assign foo = 3"`, simply echoes the statement enclosed in quotation marks to the output stream. No assignment results (the value of `foo` remains unchanged or undefined).

General Assignment

The second section of output is produced by the script lines:

```
* Assign contents of a field to a variable, e.g.
%assign worker = Top.Employee.FirstName
  "%assign worker = Top.Employee.FirstName"
  worker expands to Top.Employee.FirstName = %<worker>
```

- Line 1 — Echoed to output.
- Line 2 — An assignment of field `FirstName` in the `Top.Employee` record scope to a new local variable called `worker`.
- Line 3 — Repeats the previous statement, producing output by enclosing it in quotation marks.

- Line 4 — Explains the following assignment and illustrates the token expansion. The token `%<worker>` expands to `Arthur`.

String Processing Plus

The next section of the script illustrates string concatenation, one of the uses of the “+” operator:

```
* Concatenate string values, e.g.
%assign worker = worker + " " + Top.Employee.LastName
  "%assign worker = worker + " " + Top.Employee.LastName"
  worker expands to worker + " " + Top.Employee.LastName = "%<worker>"
```

- Line 1 — Echoed to output.
- Line 2 — Performs the concatenation.
- Line 3 — Echoes line 2 to the output.
- Line 4 — Describes the operation, in which a variable is concatenated to a field separated by a space character. An alternative way to do this, without using the + operator, is

  ```
  %assign worker = "%<Top.Employee.FirstName> %<Top.Employee.LastName>"
  ```

  The alternative method uses evals of fields and is equally efficient.

The + operator, which is associative, also works for numeric types, vectors, matrices, and records:

- Numeric Types — Add two expressions together; both operands must be numeric. For example:

  Output:

  ```
  * Numeric Type example, e.g.
    Top.Employee.PayRate = 11.5
    Top.Employee.Overhead = 1.78
    td = Top.Employee.PayRate + Top.Employee.Overhead
    td evaluates to 13.28
  ```

- Vectors — If the first argument is a vector and the second is a scalar value, TLC appends the scalar value to the vector. For example:

Output:

```
* Vector example, e.g.
  v1 is [0, 1, 2, 3]
  Top.Project[1].Difficulty is 8
  v2 = v1 + Top.Project[1].Difficulty
  v2 evaluates to: [0, 1, 2, 3, 8]
```

- Matrices — If the first argument is a matrix and the second is a vector of the same column-width as the matrix, TLC appends the vector as another row to the matrix. For example:

Output:

```
* Matrices example, e.g.
  mx1 is [ [4, 5, 6, 7]; [8, 9, 10, 11] ]
  v1 is [0, 1, 2, 3]
  mx = mx1 + v1
  mx evaluates to [ [4, 5, 6, 7]; [8, 9, 10, 11]; [0, 1, 2, 3] ]
```

- Records — If the first argument is a record, TLC adds the second argument as a parameter identifier (with its current value). For example:

Output:

```
* Record example, e.g.
  StartDate is August 28, 2008
  Top + StartDate
  Top.StartDate evaluates to August 28, 2008
```

Arithmetic Operations

TLC provides a full complement of arithmetic operators for numeric data. In the next portion of our TLC script, two numeric fields are multiplied:

```
* Perform arithmetic operations, e.g.
%assign wageCost = Top.Employee.PayRate * Top.Employee.Overhead
  "%assign wageCost = Top.Employee.PayRate * Top.Employee.Overhead"
  wageCost expands to Top.Employee.PayRate * Top.Employee.Overhead ...
 <- %<Top.Employee.PayRate> * %<Top.Employee.Overhead> = %<wageCost>
```

- Line 1 — Echoed to output.

- Line 2 — `%assign` statement that computes the value, which TLC stores in local variable `wageCost`.
- Line 3 — Echoes the operation in line 2.
- Lines 4 and 5 — Compose a single statement. The ellipsis (typed as three consecutive periods, for example, `...`) signals that a statement is continued on the following line, but if the statement has output, TLC does not insert a line break. To continue a statement and insert a line break, replace the ellipsis with a backslash (\).

Modify Records

Once read into memory, you can modify and manipulate records just like variables you create by assignment. The next segment of `read-guide.tlc` replaces the value of record field `Top.Employee.GrossRate`:

```
* Put variables into a field, e.g.
%assign Top.Employee.GrossRate = wageCost
  "%assign Top.Employee.GrossRate = wageCost"
  Top.Employee.GrossRate expands to wageCost = %<Top.Employee.GrossRate>
```

Such changes to records are nonpersistent (because record files are inputs to TLC; other file types, such as C source code, are outputs), but can be useful.

You can use several TLC directives besides `%assign` to modify records:

`%createrecord`	Creates new top-level records, and might also specify subrecords within them, including name/value pairs.
`%addtorecord`	Adds fields to an existing record. The new fields can be name/value pairs or aliases to existing records.
`%mergerecord`	Combines one or more records. The first record contains itself plus copies of the other records' contents specified by the command, in sequence.
`%copyrecord`	Creates a new record as `%createrecord` does, except the components of the record come from the existing record you specify.
`%undef var`	Removes (deletes) `var` (a variable or a record) from scope. If `var` is a field in a record, TLC removes the field from the record. If `var` is a record array (list), TLC removes the first element of the array; the remaining elements remain accessible. You can remove only records you create with `%createrecord` or `%copyrecord`.

See “Target Language Compiler Directives” on page 18-2 for details on these directives.

Index Lists

Record files can contain lists, or sequences of records having the same identifier. Our example contains a list of three records identified as `Project` within the `Top` scope. List references are indexed, numbered from 0, in the order in which they appear in the record file. Here is TLC code that compiles data from the `Name` field of the `Project` list:

```
* Index lists of values, e.g.
%assign projects = Top.Project[0].Name + ", " + Top.Project[1].Name...
+ ", " + Top.Project[2].Name
  "%assign projects = Top.Project[0].Name + ", " + Top.Project[1].Name..."
  "+ ", " + Top.Project[2].Name"
  projects expands to Top.Project[0].Name + ", " + Top.Project[1].Name
  + ", " + Top.Project[2].Name = %<projects>
```

The `Scope.Record[n].Field` syntax is similar to that used in C to reference elements in an array of structures.

While explicit indexing, such as the above, is perfectly acceptable, it is often preferable to use a loop construct when traversing entire lists, as shown in “Loop Over Lists” on page 15-13.

Loop Over Lists

By convention, the section of a record file that a list occupies is preceded by a record that indicates how many list elements are present. In *`model`*`.rtw` files, such parameters are declared as `Num`*`Ident`*, where *`Ident`* is the identifier used for records in the list that follows. In `guide.rtw`, the `Project` list looks like this:

```
  NumProject    3                 # Indicates length of following list
  Project {                       # First list item, called Top.Project[0]
    Name       "Tea"              #   Alpha field Name, Top.Project[0].Name
    Difficulty  3                 #   Numeric field Top.Project[0].Difficulty
  }                               # End of first list item
  Project {                       # Second list item, called Top.Project[1]
    Name       "Gillian"          #   Alpha field Name, Top.Project[1].Name
    Difficulty  8                 #   Numeric field Top.Project[1].Difficulty
  }                               # End of second list item
  Project {                       # Third list item, called Top.Project[2]
    Name       "Zaphod"           #   Alpha field Name, Top.Project[2].Name
    Difficulty  10                #   Numeric field Top.Project[2].Difficulty
  }                               # End of third list item
```

Thus, the value of `NumProject` describes how many `Project` records occur.

Note `model.rtw` files might also contain records that start with `Num` but are not list-size parameters. TLC does not require that list size parameters start with `Num`. Therefore you need to be cautious when interpreting `Num`*`Ident`* record identifiers. The built-in TLC function `SIZE()` can determine the number of records in a specified scope, hence the length of a list.

The last segment of `read-guide.tlc` uses a `%foreach` loop, controlled by the `NumProject` parameter, to iterate the `Project` list and manipulate its values.

```
* Traverse and manipulate list data via loops, e.g.
%assign diffSum = 0.0
%foreach i = Top.NumProject
  - At top of Loop, Project = %<Top.Project[i].Name>; Difficulty =...
 %<Top.Project[i].Difficulty>
  %assign diffSum = diffSum + Top.Project[i].Difficulty
  - Bottom of Loop, i = %<i>; diffSum = %<diffSum>
%endforeach
%assign avgDiff = diffSum / Top.NumProject
  Average Project Difficulty expands to diffSum / Top.NumProject = %<diffSum> ...
 / %<Top.NumProject> = %<avgDiff>
```

As you may recall, the TLC output looks like this:

```
* Traverse and manipulate list data via loops, e.g.
- At top of Loop, Project = Tea; Difficulty = 3
  - Bottom of Loop, i = 0; diffSum = 3.0
  - At top of Loop, Project = Gillian; Difficulty = 8
  - Bottom of Loop, i = 1; diffSum = 11.0
  - At top of Loop, Project = Zaphod; Difficulty = 10
  - Bottom of Loop, i = 2; diffSum = 21.0
Average Project Difficulty expands to diffSum / Top.NumProjects = 21.0 / 3 = 7.0
```

After initializing the summation variable `diffSum`, a `%foreach` loop is entered, with variable `i` declared as the loop counter, iterating up to `NumProject`. The scope of the loop is all statements encountered until the corresponding `%endforeach` is reached (`%foreach` loops may be nested).

Note Loop iterations implicitly start at zero and range to one less than the index that specifies the upper bound. The loop index is local to the loop body.

Modify read-guide.tlc

Now that you have studied `read-guide.tlc`, it is time to modify it. This exercise introduces two important TLC facilities, *file control* and *scoping control*. You implement both within the `read-guide.tlc` script.

File Control Basics

TLC scripts almost invariably produce output in the form of streams of characters. Output is normally directed to one or more buffers and files, collectively called *streams*. So far, you have directed output from `read-guide.tlc` to the MATLAB Command Window because you included the `-v` switch on the command line. Prove this by omitting `-v` when you run `read-guide.tlc`. Type

```
tlc -r guide.rtw read-guide.tlc
```

Nothing appears to happen. In fact, the script was executed, but output was directed to a null device (sometimes called the “bit bucket”).

There is one active output file, even if it is null. To specify, open, and close files, use the following TLC directives:

```
%openfile streamid ="filename" , "mode"
%closefile streamid
%selectfile streamid
```

If you do not give a filename, subsequent output flows to the memory buffer named by `streamid`. If you do not specify a mode, TLC opens the file for writing and deletes any existing content (subject to system-level file protection mechanisms). Valid mode identifiers are `a` (append) and `w` (write, the default). Enclose these characters in quotes.

The `%openfile` directive creates a file/buffer (in `w` mode), or opens an existing one (in `a` mode). Note the required equals sign for file specification. Multiple streams can be open for writing, but only one can be active at one time. To switch output streams, use the `%selectfile` directive. You do not need to close files until you are done with them.

The default output stream, which you can respecify with the stream ID `NULL_FILE`, is `null`. Another built-in stream is `STDOUT`. When activated using `%selectfile`, `STDOUT` directs output to the MATLAB Command Window.

Note The streams `NULL_FILE` and `STDOUT` are always open. Specifying them with `%openfile` generates errors. Use `%selectfile` to activate them.

The directive `%closefile` closes the current output file or buffer. Until an `%openfile` or a `%selectfile` directive is encountered, output goes to the previously opened stream (or, if none exists, to null). Use `%selectfile` to designate an open stream for reading or

writing. In practice, many TLC scripts write pieces of output data to separate buffers, which are then selected in a sequence and their contents spooled to one or more files.

Implement Output File Control

In your `tlctutorial/guide` folder, find the file `read-guide-file-src.tlc`. The supplied version of this file contains comments and three lines of text added. Edit this file to implement output file control, as follows:

1. Open `read-guide-file-src.tlc` in your text editor.
2. Save the file as `read-guide-file.tlc`.
3. Note five comment lines that begin with `%% ->`.

   Under each of these comments, insert a TLC directive as indicated.
4. Save the edited file as `read-guide-file.tlc`.
5. Execute `read-guide-file.tlc` with the following command:

   ```
   tlc -r guide.rtw read-guide-file.tlc
   ```

   If you succeeded, TLC creates the file `guidetext.txt` which contains the expected output, and the MATLAB Command Window displays

   ```
   *** Output being directed to file: guidetext.txt
   *** We're almost done . . .
   *** Processing completed.
   ```

If you did not see these messages, or if a text file was not produced, review the material and try again. If problems persist, inspect `read-guide-file.tlc` in the `guide/solutions` subfolder to see how you should specify file control.

Scope Basics

“Structure of Record Files” on page 15-4 explains the hierarchical organization of records. Each record exists within a scope defined by the records in which it is nested. The example file, `guide.rtw`, contains the following scopes:

```
Top
Top.Employee
Top.Project[0]
Top.Project[1]
Top.Project[2]
```

To refer to a field or a record, specify its scoping, even if no other context that contains the identifier exists. For example, in `guide.rtw`, the field `FirstName` exists only in the scope `Top.Employee`. You must refer to it as `Top.Employee.FirstName` whenever accessing it.

When models present scopes that are deeply nested, this can lead to extremely long identifiers that are tedious and error prone to type. For example:

```
CompiledModel.BlockOutputs.BlockOutput.ReusedBlockOutput
```

This identifier has a scope that is long and has similar item names that you could easily enter incorrectly.

The `%with/%endwith` directive eases the burden of coding TLC scripts and clarifies their flow of control. The syntax is

```
%with RecordName
  [TLC statements]
%endwith
```

Every `%with` is eventually followed by an `%endwith`, and these pairs might be nested (but not overlapping). If `RecordName` is below the top level, you need not include the top-level scope in its description. For example, to make the current scope of `guide.rtw` `Top.Employee`, you can specify

```
%with Employee
  [TLC statements]
%endwith
```

Naturally, `%with Top.Employee` is also valid syntax. Once bracketed by `%with/%endwith`, record identifiers in TLC statements do not require you to specify their outer scope. However, note the following conditions :

- You can access records outside of the current `%with` scope, but you must qualify them fully (for example, using record name and fields).
- Whenever you make assignments to records inside a `%with` directive, you must qualify them fully.

Change Scope Using %with

In the last segment of this exercise, you modify the TLC script by adding a `%with/%endwith` directive. You also need to edit record identifier names (but not those of local variables) to account for the changes of scope resulting from the `%with` directives.

1. Open the TLC script `read-guide-scope-src.tlc` in the text editor.
2. Save the file as `read-guide-scope.tlc`.
3. Note comment lines that commence with `%% ->`.

   Under each of these comments, insert a TLC directive or modify statements already present, as indicated.
4. Save the edited file as `read-guide-scope.tlc`.
5. Execute `read-guide-scope.tlc` with the following command:

   ```
   tlc -v -r guide.rtw read-guide-scope.tlc
   ```

The output should be exactly the same as from `read-guide.tlc`, except possibly for white space that you might have introduced by indenting sections of code inside `%with/ %endwith` or by eliminating blank lines.

Fully specifying a scope inside a `%with` context is not an error, it is simply unnecessary. However, failing to fully specify its scope when assigning it to a record (for example, `%assign GrossRate = wageCost`) is invalid.

If errors result from running the script, review the discussion of scoping above and edit `read-guide-scope.tlc` to eliminate them. As a last resort, inspect `read-guide-scope.tlc` in the `/solutions` subfolder to see how you should have handled scoping in this exercise.

For additional information, see “Scopes in the model.rtw File” on page 17-3 and “Variable Scoping” on page 18-53.

Pass and Use a Parameter

You can use the TLC commands and built-in functions to pass parameters from the command line to the TLC file being executed. The most general command switch is `-a`, which assigns arbitrary variables. For example:

```
tlc -r input.rtw -avar=1 -afoo="abc" vars.tlc
```

The result of passing this pair of strings via `-a` is the same as declaring and initializing local variables in the file being executed (here, `vars.tlc`). For example:

```
%assign var = 1
%assign foo = "abc"
```

You do not need to declare such variables in the TLC file, and they are available for use when set with `-a`. However, errors result if the code assigns undeclared variables that you do not specify with the `-a` switch when invoking the file. Also note that (in contrast to the `-r` switch) a space should not separate `-a` from the parameter you are declaring.

In the final section of this tutorial, you use the built-in function `GET_COMMAND_SWITCH()` to print the name of the record file being used in the TLC script, and provide a parameter to control whether or not the code is suppressed. By default the code is executed, but is suppressed if the command line contains `-alist=0`:

1. Open the TLC script `read-guide-param-src.tlc` in your text editor.
2. Save the file as `read-guide-param.tlc`.
3. To enable your program to access the input filename from the command line, do the following:

   a. Below the line `%selectfile STDOUT`, add the line:

   ```
   %assign inputfile = GET_COMMAND_SWITCH ("r")
   ```

   The `%assign` directive declares and sets variables. In this instance, it holds a string filename identifier. `GET_COMMAND_SWITCH()` returns whatever string argument follows a specified TLC command switch. You must use UPPERCASE for built-in function names.

   b. Change the line "`*** WORKING WITH RECORDFILE`" to read as follows:

   ```
   *** WORKING WITH RECORDFILE %<inputfile>
   ```

4. To control whether or not a section of TLC code is executed, do the following:

   a. Below the line "`%assign inputfile = GET_COMMAND_SWITCH ("r")`", add:

   ```
   %if (!EXISTS(list))
       %assign list = 1
   %endif
   ```

   The program checks whether a list parameter has been declared, via the intrinsic (built-in) function `EXISTS()`. If no list variable exists, the program assigns one. This defines `list` and by default its value is `TRUE`.

   b. Enclose lines of code within an `%if` block.

   ```
   %if (list)
       * Assign contents of a field to a variable, e.g.
         %assign worker = FirstName
   ```

```
        "%assign worker = FirstName"
        worker expands to FirstName = %<worker>
    %endif
```

Now the code to assign `worker` is sent to the output only when `list` is `TRUE`.

c Save `read-guide-param.tlc`.

5 Execute `read-guide-param.tlc` and examine the output, using the command

```
tlc -r guide.rtw read-guide-param.tlc
```

This yields

```
*** WORKING WITH RECORDFILE [guide.rtw]
* Assign contents of a field to a variable, e.g.
      "%assign worker = FirstName"
      worker expands to FirstName = Arthur
***END
```

6 Execute`read-guide-param.tlc` with the command:

```
tlc -r guide.rtw -alist=0 read-guide-param.tlc
```

With the `-alist=0` switch, the output displays only the information outside of the `if` statement.

```
*** WORKING WITH RECORDFILE [guide.rtw]
***END
```

Review

The preceding exercises examined the structure of record files, and expanded on how to use TLC directives. The following TLC directives are commonly used in TLC scripts (see “Target Language Compiler Directives” on page 18-2 for detailed descriptions):

`%addincludepath`	Enable TLC to find included files.
`%addtorecord`	Add fields to existing record. New fields can be name/value pairs or aliases to existing records.
`%assign`	Create or modify variables.

`%copyrecord`	Create new record and, if applicable, specify subrecords within them, including name/value pairs. The components of the record come from the existing record specified.
`%createrecord`	Create new top-level records and, if applicable, specify subrecords within them, including name/value pairs.
`%foreach/%endforeach`	Iterate loop variable from 0 to upper limit.
`%if/%endif`	Control whether code is executed, as in C.
`%include`	Insert one file into another, as in C.
`%mergerecord`	Combine one or more records. The first record contains itself plus copies of the other records contents specified by the command, in sequence.
`%selectfile`	Direct outputs to a stream or file.
`%undef var`	Remove (delete) `var` (a variable or a record) from scope. If `var` is a field in a record, TLC removes the field from the record. If `var` is a record array (list), TLC removes the first element of the array; the remaining elements remain accessible. Only records created via `%createrecord` or `%copyrecord` can be removed.
`%with/%endwith`	Add scope to simplify referencing blocks.

Inline S-Functions with TLC

In this section...

timesN Tutorial Overview

Objective: To understand how TLC works with an S-function.

Folder: *matlabroot*`/toolbox/rtw/rtwdemos/tlctutorial/timesN` (open)

In this tutorial, you generate versions of C code for existing S-function `timesN`.

The tutorial includes these steps:

1. **Noninlined Code Generation** — Via SimStructs and generic API
2. **Why Use TLC to Inline S-Functions?** — Benefits of inlining
3. **Create an Inlined S-Function** — Via custom TLC code

A later tutorial provides information and practice with “wrapping” S-functions.

Noninlined Code Generation

The tutorial folder `tlctutorial/timesN` in your working folder contains Simulink S-function `timesN.c`.

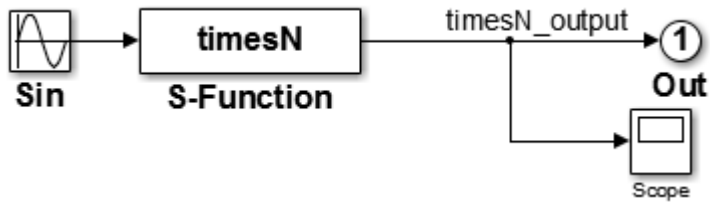
In this exercise, you generate noninlined code from the model `sfun_xN`.

1. Find the file `rename_timesN.tlc` in `tlctutorial/timesN`. Rename this file to `timesN.tlc`. This allows you to generate code.
2. In the MATLAB Command Window, create a MEX-file for the S-function:

   ```
   mex timesN.c
   ```

   This avoids picking up the version shipped with Simulink.

3 Open the model `sfun_xN`, which uses the `timesN` S-function. The block diagram looks like this.



4 Open the Configuration Parameters dialog box and select the **Solver** pane.

5 Set **Stop time** to `10.0`.

6 Set the **Solver Options**.

- **Type** to `Fixed-step`
- **Solver** to `Discrete (no continuous states)`
- **Fixed-step size** to `0.01`

7 Select the **Optimization** pane, and make sure that **Default parameter behavior** is set to `Tunable`.

8 Select the **Code Generation** > **Comments** pane, and notice that **Include comments** is checked by default.

9 Select the **Code Generation** pane and check **Generate code only**.

Click **Apply**.

10 Press **Ctrl+B** to generate C code for the model.

11 Open the resulting file `sfun_xN_grt_rtw/sfun_xN.c` and view the `sfun_xN_output` portion, shown below.

```
/* Model output function */
static void sfun_xN_output(int_T tid)
{
  /* Sin: '<Root>/Sin' */
  sfun_xN_B.Sin = sin(sfun_xN_M->Timing.t[0] * sfun_xN_P.Sin_Freq +
                      sfun_xN_P.Sin_Phase) * sfun_xN_P.Sin_Amp +
    sfun_xN_P.Sin_Bias;

  /* S-Function Block: <Root>/S-Function */
  /* Multiply input by 3.0 */
  sfun_xN_B.timesN_output = sfun_xN_B.Sin * 3.0;

  /* Outport: '<Root>/Out' */
```

```
  sfun_xN_Y.Out = sfun_xN_B.timesN_output;
  UNUSED_PARAMETER(tid);
}
```

Comments appear in the code because, in the **Code Generation > Comments** pane of the Configuration Parameters dialog box, **Include comments** is selected by default.

Why Use TLC to Inline S-Functions?

The code generator includes a generic API that you can use to invoke user-written algorithms and drivers. The API includes a variety of callback functions — for initialization, output, derivatives, termination, and so on — as well as data structures. Once coded, these are instantiated in memory and invoked during execution via indirect function calls. Each invocation involves stack frames and other overhead that adds to execution time.

In a real-time environment, especially when many solution steps are involved, generic API calls can be unacceptably slow. The code generator can speed up S-functions in standalone applications that it generates by embedding user-written algorithms within auto-generated functions, rather than indirectly calling S-functions via the generic API. This form of optimization is called inlining. TLC inlines S-functions, resulting in faster, optimized code.

You should understand that TLC is not a substitute for writing C code S-functions. To invoke custom blocks within Simulink, you still have to write S-functions in C (or as MATLAB files), since simulations do not make use of TLC files. You can, however, prepare TLC files that inline specified S-functions to make your target code much more efficient.

Create an Inlined S-Function

TLC creates an inlined S-function whenever it detects a `.tlc` file with the same name as an S-function. Assuming the `.tlc` file has the expected form, it directs construction of code that functionally duplicates the external S-function without incurring API overhead. See how this process works by completing the following steps:

1. If you have not done so already, find the file `rename_timesN.tlc` in `tlctutorial/timesN`. Rename this file to `timesN.tlc`, so you can use it to generate code. The executable portion of the file is

   ```
   %implements "timesN" "C"

   %% Function: Outputs ============================================================
   ```

```
%%
%function Outputs(block, system) Output
  %assign gain =SFcnParamSettings.myGain
  /* %<Type> Block: %<Name> */
  %%
  /* Multiply input by %<gain> */
  %assign rollVars = ["U", "Y"]
  %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
    %<LibBlockOutputSignal(0, "", lcv, idx)> = \
    %<LibBlockInputSignal(0, "", lcv, idx)> * %<gain>;
  %endroll

%endfunction
```

2. Create the inline version of the S-function.

   a. On the **Optimization** pane of the Configuration Parameters dialog box, set **Default parameter behavior** to `Inlined`, and click **Apply**.

   b. Change the diagram's label from `model: sfun_xN` to `model: sfun_xN_ilp`.

   c. Save the model as `sfun_x2_ilp`.

   d. Press **Ctrl+B**. Source files are created in a new subfolder called `sfun_xN_ilp_grt_rtw`.

   e. Inspect the code in generated file `sfun_xN_ilp.c`:

```
/* Model output function */
static void sfun_xN_ilp_output(int_T tid)
{
  /* Sin: '<Root>/Sin' */
  sfun_xN_ilp_B.Sin = sin(sfun_xN_ilp_M->Timing.t[0]);

  /* S-Function Block: <Root>/S-Function */
  /* Multiply input by 3.0 */
  sfun_xN_ilp_B.timesN_output = sfun_xN_ilp_B.Sin * 3.0;

  /* Outport: '<Root>/Out' */
  sfun_xN_ilp_Y.Out = sfun_xN_ilp_B.timesN_output;
  UNUSED_PARAMETER(tid);
}
```

   Note When the code generator produces code and builds executables, it creates or uses a specific subfolder (called the build folder) to hold source, object, and make files. By default, the build folder is named *`model`*`_grt_rtw`.

Notice that setting **Default parameter behavior** to `Inlined` did not change the code. This is because TLC inlines S-functions.

3. Continue the exercise by creating a standalone simulation.

   a. In the **Code Generation** pane of the Configuration Parameters dialog box, clear **Generate code only** and click **Apply**.

   b. In the **Data Import/Export** pane of the Configuration Parameters dialog box, check **Output**.

      This specification causes the model's output data to be logged in your MATLAB workspace.

   c. Press **Ctrl+B** to generate code, compile, and link the model into an executable, named `sfun_xN_ilp.exe` (or, on UNIX systems, `sfun_xN_ilp`).

   d. Confirm that the `timesN.tlc` file produces expected output by running the standalone executable. To run it, in the MATLAB Command Window, type

      ```
      !sfun_xN_ilp
      ```

      The following response appears:

      ```
      ** starting the model **
      ** created sfun_xN_ilp.mat **
      ```

   e. View or plot the contents of the `sfun_xN_ilp.mat` file to verify that the standalone model generated sine output ranging from -3 to +3. In the MATLAB Command Window, type

      ```
      load sfun_xN_ilp.mat
      plot (rt_yout)
      ```

Tip For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see "Run External Commands, Scripts, and Programs" (MATLAB).

Explore Variable Names and Loop Rolling

In this section...

timesN Looping Tutorial Overview

Objective: This example shows how you can influence looping behavior of generated code.

Folder: *`matlabroot`*`/toolbox/rtw/rtwdemos/tlctutorial/timesN` (open)

Work with the model `sfun_xN` in `tlctutorial/timesN`. It has one source (a Sine Wave generator block), a times N gain block, an Out block, and a Scope block.

The tutorial guides you through following steps:

1. **Getting Started** — Set up the exercise and run the model
2. **Modify the Model** — Change the input width and see the results
3. **Change the Loop Rolling Threshold** — Change the threshold and see the results
4. **More About TLC Loop Rolling** — Parameterize loop behavior

Getting Started

1. Make `tlctutorial/timesN` your current folder, so that you can use the files provided.

   Note You must use or create a working folder outside of *`matlabroot`* for Simulink models you make. You cannot build models in source folders.

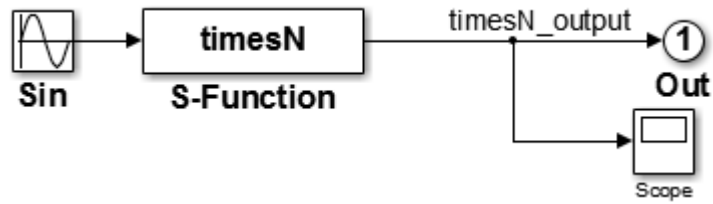
2. In the MATLAB Command Window, create a MEX-file for the S-function:

   ```
   mex timesN.c
   ```

This avoids picking up the version shipped with Simulink.

Note An error might occur if you have not previously run `mex -setup`.

3 Open the model file `sfun_xN`.



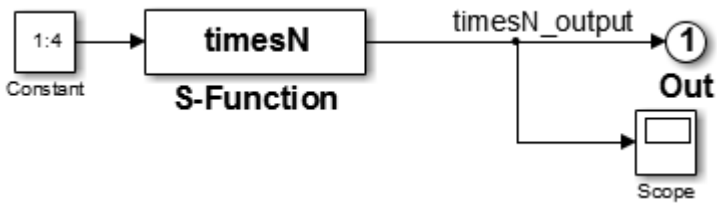
4 View the previously generated code in `sfun_xN_grt_rtw/sfun_xN.c`. Note that no loops exist in the code. This is because the input and output signals are scalar.

Modify the Model

1 Replace the Sine Wave block with a Constant block.

2 Set the parameter for the Constant block to 1:4, and change the top label, `model: sfun_xN`, to `model: sfun_vec`.

3 Save the edited model as `sfun_vec` (in `tlctutorial/timesN`). The model now looks like this.



4 Because the Constant block generates a vector of values, this is a vectorized model. Generate code for the model and view the `/*Model output function */` section of `sfun_vec.c` in your editor to observe how variables and `for` loops are handled. This function appears as follows:

```
/* Model output function */
static void sfun_vec_output(int_T tid)
{
  /* S-Function Block: <Root>/S-Function */
```

```
  /* Multiply input by 3.0 */
  sfun_vec_B.timesN_output[0] = sfun_vec_P.Constant_Value[0] * 3.0;
  sfun_vec_B.timesN_output[1] = sfun_vec_P.Constant_Value[1] * 3.0;
  sfun_vec_B.timesN_output[2] = sfun_vec_P.Constant_Value[2] * 3.0;
  sfun_vec_B.timesN_output[3] = sfun_vec_P.Constant_Value[3] * 3.0;

  /* Outport: '<Root>/Out' */
  sfun_vec_Y.Out[0] = sfun_vec_B.timesN_output[0];
  sfun_vec_Y.Out[1] = sfun_vec_B.timesN_output[1];
  sfun_vec_Y.Out[2] = sfun_vec_B.timesN_output[2];
  sfun_vec_Y.Out[3] = sfun_vec_B.timesN_output[3];
  UNUSED_PARAMETER(tid);
}
```

Notice that there are four instances of the code that generates model outputs, corresponding to four iterations.

5. Set the parameter for the Constant block to 1:10, and save the model.
6. Generate code for the model and view the `/*Model output function */` section of `sfun_vec.c` in your editor to observe how variables and `for` loops are handled. This function appears as follows:

```
/* Model output function */
static void sfun_vec_output(int_T tid)
{
  /* S-Function Block: <Root>/S-Function */
  /* Multiply input by 3.0 */
  {
    int_T i1;
    const real_T *u0 = &sfun_vec_P.Constant_Value[0];
    real_T *y0 = sfun_vec_B.timesN_output;
    for (i1=0; i1 < 10; i1++) {
      y0[i1] = u0[i1] * 3.0;
    }
  }

  {
    int32_T i;
    for (i = 0; i < 10; i++) {
      /* Outport: '<Root>/Out' */
      sfun_vec_Y.Out[i] = sfun_vec_B.timesN_output[i];
    }
  }

  UNUSED_PARAMETER(tid);
}
```

Notice that:

- The code that generates model outputs gets “rolled” into a loop. This occurs by default when the number of iterations exceeds 5.

- Loop index `i1` runs from 0 to 9.
- Pointer `*y0` is used and initialized to the output signal array.

Change the Loop Rolling Threshold

The code generator creates iterations or loops depending on the current value of the **Loop unrolling threshold** parameter.

The default value of **Loop unrolling threshold** is 5. To change looping behavior for blocks in a model:

1. On the **Optimization** pane of the Configuration Parameters dialog box, set **Loop unrolling threshold** to 12 and click `Apply`.

   The parameter `RollThreshold` is now 12. Loops will be generated only when the width of signals passing through a block exceeds 12.

   Note You cannot modify `RollThreshold` for specific blocks from the Configuration Parameters dialog box.

2. Press **Ctrl+B** to regenerate the output.
3. Inspect `sfun_vec.c`. It will look like this:

```
/* Model output function */
static void sfun_vec_output(int_T tid)
{
  /* S-Function Block: <Root>/S-Function */
  /* Multiply input by 3.0 */
  sfun_vec_B.timesN_output[0] = sfun_vec_P.Constant_Value[0] * 3.0;
  sfun_vec_B.timesN_output[1] = sfun_vec_P.Constant_Value[1] * 3.0;
  sfun_vec_B.timesN_output[2] = sfun_vec_P.Constant_Value[2] * 3.0;
  sfun_vec_B.timesN_output[3] = sfun_vec_P.Constant_Value[3] * 3.0;
  sfun_vec_B.timesN_output[4] = sfun_vec_P.Constant_Value[4] * 3.0;
  sfun_vec_B.timesN_output[5] = sfun_vec_P.Constant_Value[5] * 3.0;
  sfun_vec_B.timesN_output[6] = sfun_vec_P.Constant_Value[6] * 3.0;
  sfun_vec_B.timesN_output[7] = sfun_vec_P.Constant_Value[7] * 3.0;
  sfun_vec_B.timesN_output[8] = sfun_vec_P.Constant_Value[8] * 3.0;
  sfun_vec_B.timesN_output[9] = sfun_vec_P.Constant_Value[9] * 3.0;

  /* Outport: '<Root>/Out' */
  sfun_vec_Y.Out[0] = sfun_vec_B.timesN_output[0];
  sfun_vec_Y.Out[1] = sfun_vec_B.timesN_output[1];
  sfun_vec_Y.Out[2] = sfun_vec_B.timesN_output[2];
  sfun_vec_Y.Out[3] = sfun_vec_B.timesN_output[3];
  sfun_vec_Y.Out[4] = sfun_vec_B.timesN_output[4];
  sfun_vec_Y.Out[5] = sfun_vec_B.timesN_output[5];
  sfun_vec_Y.Out[6] = sfun_vec_B.timesN_output[6];
```

```
    sfun_vec_Y.Out[7] = sfun_vec_B.timesN_output[7];
    sfun_vec_Y.Out[8] = sfun_vec_B.timesN_output[8];
    sfun_vec_Y.Out[9] = sfun_vec_B.timesN_output[9];
    UNUSED_PARAMETER(tid);
  }
```

4 To activate loop rolling again, change the **Loop unrolling threshold** to 10 (or less) on the **Optimization** pane.

Loop rolling is an important TLC capability for optimizing generated code. Take some time to study and explore its implications before generating code for production requirements.

More About TLC Loop Rolling

The following TLC `%roll` code is the `Outputs` function of `timesN.tlc`:

```
%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %%
  /* Multiply input by %<gain> */
  %assign rollVars = ["U", "Y"]
  %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
     %<LibBlockOutputSignal(0, "", lcv, idx)> = \
    %<LibBlockInputSignal(0, "", lcv, idx)> * %<gain>;
  %endroll
%endfunction %% Outputs
```

Arguments for %roll

The lines between `%roll` and `%endroll` may be either repeated or looped. The key to understanding the `%roll` directive is in its arguments:

```
%roll sigIdx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
```

Argument	Description
`sigIdx`	Specify the index into a (signal) vector that is used in the generated code. If the signal is scalar, when analyzing that block of the *`model`*`.rtw` file, TLC determines that only a single line of code is required. In this case, it sets `sigIdx` to `0` so as to access only the first element of a vector, and no loop is constructed.

Argument	Description
`lcv`	A control variable generally specified in the `%roll` directive as `lcv = RollThreshold`. `RollThreshold` is a global (model-wide) threshold with the default value of 5. Therefore, whenever a block contains more than five contiguous and rollable variables, TLC collapses the lines nested between `%roll` and `%endroll` into a loop. If fewer than five contiguous rollable variables exist, `%roll` does not create a loop and instead produces individual lines of code.
`block`	This tells TLC that it is operating on block objects. TLC code for S-functions use this argument.
`"Roller"`	This, specified in `rtw/c/tlc/roller.tlc`, formats the loop. Normally you pass this as is, but other loop control constructs are possible for advanced uses (see `LibBlockInputSignal` in “Input Signal Functions” on page 21-7).

`rollVars`	Tells TLC what types of items should be rolled: input signals, output signals, and/or parameters. You do not have to use all of them. In a previous line, `rollVars` is defined using `%assign`.
	`%assign rollVars = ["U", "Y"]`
	This list tells TLC that it is rolling through input signals (`U`) and output signals (`Y`). In cases where blocks specify an array of parameters instead of a scalar parameter, `rollvars` is specified as
	`%assign rollVars = ["U", "Y", "P"]`

Input Signals, Output Signals, and Parameters

Look at the lines that appear between `%roll` and `%endroll`:

```
%<LibBlockOutputSignal(0, "", lcv, idx)> = \
%<LibBlockInputSignal (0, "", lcv, idx)> * 2.0;
```

The TLC library functions `LibBlockInputSignal` and `LibBlockOutputSignal` expand to produce scalar or vector identifiers that are named and indexed. `LibBlockInputSignal`, `LibBlockOutputSignal`, and a number of related TLC functions are passed four canonical arguments:

Argument	Description
first argument — `0`	Corresponds to the input port index for a given block. The first input port has index 0. The second input port has index 1, and so on.
second argument — `" "`	An index variable reserved for advanced use. For now, specify the second argument as an empty string. In advanced applications, you may define your own variable name to be used as an index with `%roll`. In such a case, TLC declares this variable as an integer in a location in the generated code.
third argument — `lcv`	As described previously, `lcv = RollThreshold` is set in `%roll` to indicate that a loop be constructed whenever `RollThreshold` (default value of 5) is exceeded.
fourth argument — `sigIdx`	Enables TLC to handle special cases. In the event that the `RollThreshold` is *not* exceeded (for example, if the block is only connected to a scalar input signal) TLC does not roll it into a loop. Instead, TLC provides an integer value for the index variable in a corresponding line of "inline" code. Whenever the `RollThreshold` is exceeded, TLC creates a `for` loop and uses an index variable to access inputs, outputs and parameters within the loop.

Debug Your TLC Code

In this section...

tlcdebug Tutorial Overview

Objective: Introduces the TLC debugger. You will learn how to set breakpoints and familiarize yourself with TLC debugger commands.

Folder: *`matlabroot`*`/toolbox/rtw/rtwdemos/tlctutorial/tlcdebug` (open)

You can cause the TLC debugger to be invoked whenever the build process is invoked. In this tutorial, you use it to detect a bug in a `.tlc` file for a model called `simple_log`. The bug causes the generated code output from the standalone version of the model to differ from its simulation output. The tutorial guides you through following steps:

1. **Getting Started** — Run the model and inspect output
2. **Generate and Run Code from the Model** — Compare compiled results to original output
3. **Start the Debugger and Use Its Commands** — Things you can do with the debugger
4. **Debug `timesN.tlc`** — Find out what went wrong
5. **Fix the Bug and Verify** — Easy ways to fix bugs and verify fixes

Getting Started

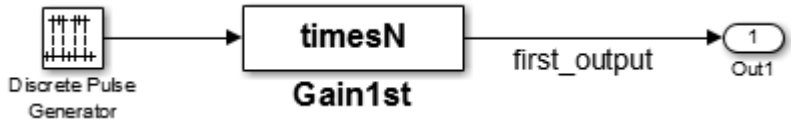
1. Copy the files from `tlctutorial/tlcdebug` to your current working directory.
2. In the MATLAB Command Window, create a MEX-file for the S-function:

   ```
   mex timesN.c
   ```

This avoids picking up the version shipped with your Simulink software.

Note An error might occur if you have not previously run `mex -setup`.

3 Open the model `simple_log`. The model looks like this.



4 In the **Data Import/Export** pane of the Configuration Parameters dialog box, check **Time** and **Output**. This causes model variables to be logged to the MATLAB workspace.

5 Run the model by selecting **Run** from the **Simulation** menu. Variables `tout` and `yout` appear in your MATLAB workspace.

6 Double-click `yout` in the **Workspace** pane of the MATLAB Command Window. The Variable Editor displays the 6x1 array output from `simple_log`. The display looks like this:

yout <6x1 double>

	1	2	3	4	5	6
1	3					
2	0					
3	3					
4	0					
5	3					
6	0					

Column 1 contains discrete pulse output for six time steps (3s and 0s), collected at port `out1`.

Next, you generate a standalone version of `simple_log`. You execute it and compare its results to the output from Simulink displayed above.

Note For the purpose of this exercise, the TLC file provided, `timesN.tlc`, contains a bug. This version must be in the same folder as the model that uses it.

Generate and Run Code from the Model

1 Press **Ctrl+B**.

The code generator produces, compiles, and links C source code. The MATLAB Command Window shows the progress of the build, which ends with these messages:

```
### Created executable: simple_log.exe
### Successful completion of build procedure
    for model: simple_log
```

2 Run the standalone model just created by typing

```
!simple_log
```

This results in the messages

```
** starting the model **
** created simple_log.mat **
```

3 Inspect results by placing the variables in your workspace. In the **Current Folder** pane, double-click `simple_log.mat`, then double-click `rt_yout` (the standalone version of variable `yout`) in the **Workspace** pane.

Compare `rt_yout` with `yout`. Do you notice differences? Can you surmise what caused values in `rt_yout` to change?

A look at the generated C code that TLC placed in your build folder (`simple_log_grt_rtw`) helps to identify the problem.

4 Edit `simple_log.c` and look at its `MdlOutputs` function, which should appear as shown below:

```
/* Model output function */
static void simple_log_output(void)
{
  /* DiscretePulseGenerator: '<Root>/Discrete Pulse Generator' */
  simple_log_B.DiscretePulseGenerator = (simple_log_DW.clockTickCounter < 1.0) &&
    (simple_log_DW.clockTickCounter >= 0) ? 1.0 : 0.0;
  if (simple_log_DW.clockTickCounter >= 2.0 - 1.0) {
    simple_log_DW.clockTickCounter = 0;
  } else {
    simple_log_DW.clockTickCounter++;
  }

  /* End of DiscretePulseGenerator: '<Root>/Discrete Pulse Generator' */

  /* S-Function (timesN): '<Root>/Gain1st' incorporates:
   *  Outport: '<Root>/Out1'
```

```
     */
    /* S-Function Block: <Root>/Gain1st */
    /* Multiply input by 3.0 */
    simple_log_Y.Out1 = simple_log_B.DiscretePulseGenerator * 1;
}
```

Note the line near the end:

```
simple_log_B.first_output = simple_log_B.DiscretePulseGenerator * 1;
```

How did the incorrect product get assigned to the output when it was supposed to receive a variable that alternates between 3.0 and 0.0? Use the debugger to find out.

Start the Debugger and Use Its Commands

You use the TLC debugger to monitor the code generation process. As it is not invoked by default, you need to request the debugger explicitly.

1. Set up the TLC debugging environment and start to build the application:
   a. Select the **Configuration Parameters > Code Generation** pane, and select the options **Retain .rtw file** and **Start TLC debugger when generating code**. Click **OK**.
   b. Build the model.

      The MATLAB Command Window describes the building process. The build stops at the `timesN.tlc` file and displays the command prompt:

      ```
      TLC-DEBUG>
      ```
2. Type `help` to list the TLC debugger commands. Here are some things you can do in the debugger.
   - View and query various entities in the TLC scope.

     ```
     TLC-DEBUG> whos CompiledModel
     TLC-DEBUG> print CompiledModel.NumSystems
     TLC-DEBUG> print TYPE(CompiledModel.NumSystems)
     ```
   - Examine the statements in your current context.

     ```
     TLC-DEBUG> list
     TLC-DEBUG> list 10,40
     ```
   - Move to the next line of code.

     ```
     TLC-DEBUG> next
     ```

- Step into a function.

  ```
  TLC-DEBUG> step
  ```

- Assign a constant value to a variable, such as the input signal `%<u>`.

  ```
  TLC-DEBUG> assign u = 5.0
  ```

- Set a breakpoint where you are or in some other part of the code.

  ```
  TLC-DEBUG> break timesN.tlc:10
  ```

- Execute until the next breakpoint.

  ```
  TLC-DEBUG> continue
  ```

- Clear breakpoints you have established.

  ```
  TLC-DEBUG> clear 1
  TLC-DEBUG> clear all
  ```

3 If you have tried the TLC debugger commands, execute the remaining code to finish the build process, then build `simple_log` again. The build stops at the `timesN.tlc` file and displays the command prompt:

```
TLC-DEBUG>
```

Debug timesN.tlc

Now look around to find out what is wrong with the code:

1 Set a breakpoint on line 20 of `timesN.tlc`.

```
TLC-DEBUG> break timesN.tlc:20
```

2 Instruct the TLC debugger to advance to your breakpoint.

```
TLC-DEBUG> continue
```

TLC processes input, reports its progress, advances to line 20 in `timesN.tlc`, displays the line, and pauses.

```
### Loading TLC function libraries
...
### Initial pass through model to cache user defined code
.
### Caching model source code
.
Breakpoint 1
00020:   %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
```

3. Use the `whos` command to see the variables in the current scope.

```
TLC-DEBUG> whos
Variables within: <BLOCK_LOCAL>
gain                            Real
rollVars                        Vector
block                           Resolved
system                          Resolved
```

4. Inspect the variables using the print command (names are case sensitive).

```
TLC-DEBUG> print gain
3.0

TLC-DEBUG> print rollVars
[U, Y]
```

5. Execute one step.

```
TLC-DEBUG> step
00021:     %<LibBlockOutputSignal(0, "", lcv, idx)> = \
```

6. Because it is a built-in function, advance via the `next` command.

```
TLC-DEBUG> next
.
00022:     %<LibBlockInputSignal(0, "", lcv, idx)> * 1;
```

   This is the origin of the C statement responsible for the erroneous constant output, `simple_log_B.first_output = simple_log_B.DiscretePulseGenerator * 1;`.

7. Abandon the build by quitting the TLC debugger. Type

```
TLC-DEBUG> quit
```

   An error message is displayed showing that you stopped the build by using the TLC debugger `quit` command. Close the error window.

Fix the Bug and Verify

The problem you identified is caused by evaluating a constant rather than a variable inside the TLC function `FcnEliminateUnnecessaryParams()`. This is a typical coding error and is easily repaired. Here is the code you need to fix.

```
%function Outputs(block, system) Output
   %assign gain =SFcnParamSettings.myGain
  /* %<Type> Block: %<Name> */
  %%
  /* Multiply input by %<gain> */
  %assign rollVars = ["U", "Y"]
  %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
```

```
    %<LibBlockOutputSignal(0, "", lcv, idx)> = \
    %<LibBlockInputSignal(0, "", lcv, idx)> * 1;
  %endroll

%endfunction

%% [EOF] timesN.tlc
```

1. To fix the coding error, edit `timesN.tlc`. The line

   ```
   %<LibBlockInputSignal(0, "", lcv, idx)> * 1;
   ```

   multiplies the evaluated input by 1. Change the line to

   ```
   %<LibBlockInputSignal(0, "", lcv, idx)> * %<gain>;
   ```

   Save `timesN.tlc`.
2. Build the standalone model again. Complete the build by typing `continue` at each `TLC-DEBUG>` prompt.
3. Execute the standalone model by typing

   ```
   !simple_log
   ```

   A new version of `simple_log.mat` is created containing its output.
4. Load `simple_log.mat` and compare the workspace variable `rt_yout` with `yout`, as you did before. The values in the first column should now correspond.

TLC Code Coverage to Aid Debugging

In this section...

tlcdebug Execute Tutorial Overview

Objective: Learn to use TLC coverage statistics to help identify bugs in TLC code.

Folder: *matlabroot*`/toolbox/rtw/rtwdemos/tlctutorial/tlcdebug` (open)

This tutorial teaches you how to determine whether your TLC code is being executed as expected. Here it uses the same model as for the previous tutorial. As you focus on understanding flow of control in processing TLC files, you don’t need to compile and execute a standalone model, only to look at code. The tutorial proceeds as follows:

1. **Getting Started** — Why and how to analyze TLC coverage
2. **Open the Model and Generate Code** — Read a coverage log file

Getting Started

The **Code Generation > Debug** pane provides the option **Start TLC coverage when generating code**. Selecting it results in a listing that documents how many times each line in your TLC source file was executed during code generation. The listing, *name*`.log` (where *name* is the filename of the TLC file being analyzed), is placed in your build folder.

Note A log file for every `.tlc` file invoked or included is generated in the build folder. Focus on `timesN.log`.

Open the Model and Generate Code

1. Copy the folder `tlctutorial/tlcdebug/` to your working folder and `cd` to it. *Do this even though you already have copied it*, to be sure you have the version of `timesN.tlc` that has the bug.

2. In the MATLAB Command Window, create a MEX-file for the S-function.

   ```
   mex timesN.c
   ```

   This avoids picking up the version shipped with your Simulink software.

3. Open the model `simple_log`.

4. In the **Code Generation** pane of the Configuration Parameters dialog box, check **Generate code only**.

5. In the **Code Generation** > **Debug** pane of the Configuration Parameters dialog box, select **Start TLC coverage when generating code**. (Do not select **Start TLC debugger when generating code**. Invoking the debugger is unnecessary.) Click **Apply**.

6. Press **Ctrl+B**. The usual messages appear in the MATLAB Command Window, and a build folder (`simple_log_grt_rtw`) is created in your working folder.

7. Enter the build folder. Find the file `timesN.log`, and copy it to your working folder, renaming it to `timesN_ilp.log` to prevent it from being overwritten.

8. Open the log file `timesN_ilp.log` in your editor. It looks almost like `timesN.tlc`, except for a number followed by a colon at the beginning of each line. This number represents the number of times TLC executed the line in generating code. The code for `Outputs()` should look like this:

   ```
   0: %% Function: Outputs ================================================================
        0: %%
        1: %function Outputs(block, system) Output
        1:   %assign gain =SFcnParamSettings.myGain
        1:   /* %<Type> Block: %<Name> */
        0:   %%
        1:   /* Multiply input by %<gain> */
        1:   %assign rollVars = ["U", "Y"]
        1:   %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
        1:     %<LibBlockOutputSignal(0, "", lcv, idx)> = \
        1:     %<LibBlockInputSignal(0, "", lcv, idx)> * 1;
        0:   %endroll
        1:
        0: %endfunction
   ```

   Notice that comments were not executed. TLC statements were reached, which means they output to the generated C code as many times as the number prefixed to those lines.

Changing code generation options can cause a latent issue in generated source code. Systematically changing options and observing the resulting differences in TLC coverage can facilitate the process of discovering faulty code.

Wrap User Code with TLC

In this section...

wrapper Tutorial Overview

Objective: Learn the architecture of wrapper S-functions and how to create an inlined wrapper S-function using TLC.

Folder: *matlabroot*`/toolbox/rtw/rtwdemos/tlctutorial/wrapper` (open)

Wrapper S-functions enable you to use existing C functions without fully rewriting them in the context of Simulink S-functions. Each wrapper you provide is an S-function “shell” that merely calls one or more existing, external functions. This tutorial explains and illustrates wrappers as follows:

- **Why Wrap User Code?** — Reason for building TLC wrapper functions
- **Getting Started** — Set up the wrapper exercise
- **Generate Code Without a Wrapper** — How the code generator handles external functions by default
- **Generate Code Using a Wrapper** — Bypass the API overhead

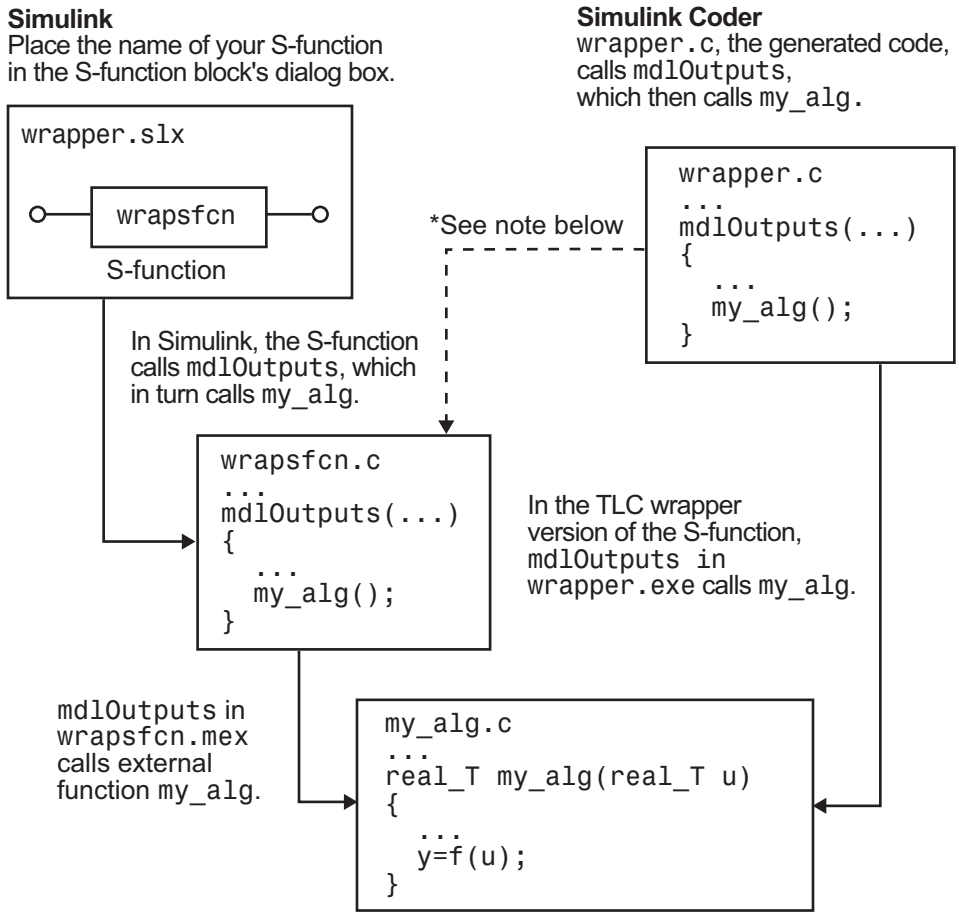
Why Wrap User Code?

Many Simulink users want to build models incorporating algorithms that they have already coded, implemented, and tested in a high-level language. Typically, such code is brought into Simulink as S-functions. To generate an external application that integrates user code, you can take several approaches:

- You can construct an S-function from user code that hooks it to the Simulink generic API. This is the simplest approach, but sacrifices efficiency for standalone applications.

- You can inline the S-function, reimplementing it as a TLC file. This improves efficiency, but takes time and effort, can introduce errors into working code, and leads to two sets of code to maintain for each algorithm, unless you use the Legacy Code Tool (see “Import Calls to External Code into Generated Code with Legacy Code Tool” (Simulink Coder)).
- You can inline the S-function via a TLC wrapper function. By doing so, you need to create only a small amount of TLC code, and the algorithm can remain coded in its existing form.

The next figure illustrates how S-function wrappers operate.



*The dotted line is the path taken if the S-function does not have a TLC wrapper file. If there is no TLC wrapper file, the generated code calls `mdlOutputs`.

Wrapping a function eliminates the need to recode it, requiring only a bit of extra TLC code to integrate it. Wrappers also enable object modules or libraries to be used in S-functions. This may be the only way to deploy functions for which source code is unavailable, and also allows users to distribute models to others without divulging implementation details that may be proprietary.

For example, you might have an existing object file compiled for a processor on which Simulink does not run. You can write a dummy C S-function and use a TLC wrapper that

calls the external function, despite not having its source code. You could similarly access functions in a library of algorithms optimized for the target processor. Accomplishing this requires making changes to a template makefile, or otherwise providing a means to link against the library.

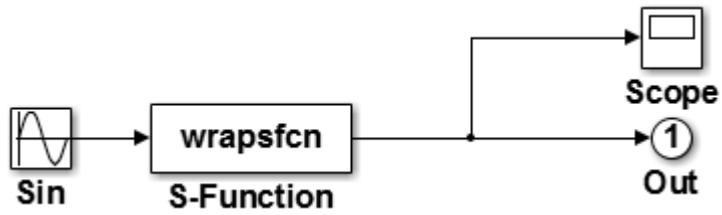
Note Object files that lack source code and are created with Microsoft Visual C and Microsoft Visual C++® Compiler (MSVC) work only with MSVC.

The only restriction on S-function wrappers is for the number of block inputs and outputs match number of inputs and outputs of the wrapped external function. Wrapper code may include computations, but usually these are limited to transforming values (for example, scaling or reformatting) passed to and from the wrapped external functions.

Getting Started

In the example folder, the “external function” is found in the file `my_alg.c`. You are also provided with a C S-function called `wrapsfcn.c` that integrates `my_alg.c` into Simulink. Set up the exercise as follows:

1. Make `tlctutorial/wrapper` your current folder.
2. In MATLAB, open the model `externalcode` from your working folder. The block diagram looks like this:



3. Activate the Scope block by double-clicking it.
4. Run the model (from the **Simulation** menu, or type **Ctrl+T**). You will get an error telling you that `wrapsfcn` does not exist. Can you figure out why?
5. The error occurs because a `mex` file does not exist for `wrapsfcn`. To rectify this, in the MATLAB Command Window type

```
mex wrapsfcn.c
```

Note An error might occur if you have not previously run `mex -setup`.

6 Run the simulation again with the S-function present.

The S-Function block multiplies its input by two. Looking at the Scope block, you see a sine wave that oscillates between -2.0 and 2.0. The variable `yout` that is created in your MATLAB workspace steps through these values.

In the remainder of the exercise, you build and run a standalone version of the model, then write some TLC code that allows the code generator to build a standalone executable that calls the S-function `my_alg.c` directly.

Generate Code Without a Wrapper

Before creating a wrapper, generate code that uses the Simulink generic API. The first step is to build a standalone model.

1 Choose **Code > C/C++ Code > Build Model**.

The code generator creates the standalone program in your working folder and places the source and object files in your build folder. The file will be called `externalcode.exe` on Microsoft Windows platforms or `externalcode` on UNIX platforms.

As it generates the program, the code generator reports its progress in the MATLAB Command Window. The final lines are:

```
### Created executable: externalcode.exe
### Successful completion of build procedure
for model: externalcode
```

2 Run the standalone program to see that it behaves the same as the Simulink version. There should not be differences.

```
!externalcode

** starting the model **
** created externalcode.mat **
```

3 Notice this line in `wrapsfcn.c`:

```
#include "my_alg.c"
```

This pulls in the external function. That function consists entirely of

```
/*
 * Copyright 1994-2002 The MathWorks, Inc.
 */

double my_alg(double u)
{
    return(u * 2.0);
}
```

Inspect the `mdlOutputs()` function of the code in `wrapsfcn.c` to see how the external function is called.

```
static void mdlOutputs(SimStruct *S, int tid)
{
    int_T             i;
    InputRealPtrsType uPtrs = ssGetInputPortRealSignalPtrs(S,0);
    real_T            *y    = ssGetOutputPortRealSignal(S,0);
    int_T             width = ssGetOutputPortWidth(S,0);

    *y = my_alg(*uPtrs[0]);
}
```

Tip For UNIX platforms, run the executable in the Command Window with the syntax `!./executable_name`. If preferred, run the executable from an OS shell with the syntax `./executable_name`. For more information, see "Run External Commands, Scripts, and Programs" (MATLAB).

Generally, functions to be wrapped are either included in the wrapper, as above, or, when object modules are being wrapped, resolved at link time.

Generate Code Using a Wrapper

To create a wrapper for the external function `my_alg.c`, you need to construct a TLC file that embodies its calling function, `wrapsfcn.c`. The TLC file must generate C code that provides:

- A function prototype for the external function that returns a double, and passes the input `double u`.
- A function call to `my_alg()` in the outputs section of the code.

To create a wrapper for `my_alg()`, do the following:

1. Open the file `change_wrapsfcn.tlc` in your editor, and add lines of code where comments indicate to create a workable wrapper.
2. Save the edited file as `wrapsfcn.tlc`. It must have the same name as the S-function block that uses it or TLC is not called to inline code.
3. In MATLAB, open the model `externalcode` from your working folder. Activate the Scope block by double-clicking it, and run the model (from the **Simulation** menu, or type **Ctrl+T**). This gives you a baseline result.
4. Inform Simulink that your code has an external reference to be resolved. To update the model's parameters, in the MATLAB Command Window, do one of the following:

   - Type

     ```
     set_param('externalcode/S-Function','SFunctionModules','my_alg')
     ```

   - In the S-Function block parameters dialog box, in the `S-function modules` field, specify `'my_alg'`.
5. Create the standalone application, by entering one of the following commands in the Command Window:

   ```
   rtwbuild('my_alg','ForceTopModelBuild',true)
   ```

   ```
   slbuild('my_alg', 'StandaloneCoderTarget','ForceTopModelBuild',true)
   ```

   These commands force the code generator to rebuild the top model, which is required when you make changes associated with external or custom code.

   Alternatively, you can force regeneration of top model code by deleting folders in the code generation folder (Simulink), such as `slprj` or the generated model code folder.

   For more information, see "Control Regeneration of Top Model Code" (Simulink Coder).
6. Run the new standalone application and verify that it yields identical results as in the scope window.

   ```
   !externalcode
   ```

If you had problems building the application:

- Find the error messages and try to determine what files are at fault, paying attention to which step (code generation, compiling, linking) failed.
- Be sure you issued the `set_param()` command as specified above.

- Chances are that problems can be traced to your TLC file. It may be helpful to use TLC debugger to step through `wrapsfcn.tlc`.
- As a last resort, look at `wrapsfcn.tlc` in the `solutions/tlc_solution` folder, also listed below:

```
%% File    : wrapsfcn.tlc
%% Abstract:
%%      Example tlc file for S-function wrapsfcn.c
%%
%% Copyright 1994-2002 The MathWorks, Inc.
%%
%%

%implements "wrapsfcn" "C"

%% Function: BlockTypeSetup ================================
%% Abstract:
%%      Create function prototype in model.h as:
%%        "extern double my_alg(double u);"
%%
%function BlockTypeSetup(block, system) void
  %openfile buffer
  %% ASSIGNMENT: PROVIDE A LINE OF CODE AS A FUNCTION PROTOTYPE
  %% FOR "my_alg" AS DESCRIBED IN THE WRAPPER TLC ASSIGNMENT
  extern double my_alg(double u);

  %closefile buffer
  %<LibCacheFunctionPrototype(buffer)>
%endfunction %% BlockTypeSetup

%% Function: Outputs =======================================
%% Abstract:
%%      y = my_alg( u );
%%
%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %assign u = LibBlockInputSignal(0, "", "", 0)
  %assign y = LibBlockOutputSignal(0, "", "", 0)
  %% PROVIDE THE CALLING STATEMENT FOR "wrapfcn"
  %<y> = my_alg( %<u> );
%endfunction %% Outputs
```

Look at the highlighted lines. Did you declare `my_alg()` as `extern double`? Did you call `my_alg()` with the expected input and output? Fix mistakes and rebuild the model.

Code Generation Architecture

Build Process

Build Process Overview

TLC compiles files written in the target language. The target language is an interpreted language and the compiler operates on source files every time it executes. You can change a target file and watch the effects of your change the next time you build a model. You do not need to recompile TLC binary or other large binary to see the changes.

Because the target language is an interpreted language, some statements might not be compiled or executed (and hence not checked by the compiler). For example:

```
%if 1
   Hello
%else
   %<Invalid_function_call()>
%endif
```

In this example, the `Invalid_function_call` statement is not executed. This example emphasizes that you should test TLC code with test cases that execute every line.

Create and Use Target Language File

This example creates a target language file that generates specific text from a model. It shows the sequence of steps that you should follow in creating and using your own target language files.

Process

To begin, create the Simulink model shown in the next figure.

1. Save the new model in a working folder as `basic`.
2. Display the Configuration Parameters dialog box.
3. Select the **Solver** pane.
4. In the **Solver** pane:

   a. Select `Fixed-step` in the **Type** field.
   b. Select `discrete (no continuous states)` in the **Solver** field.
   c. Under **Additional options**, specify `0.1` in the **Fixed-step size** field. (Otherwise, the code generator posts a warning and supplies a value when you generate code.)
5. Click **Apply**.
6. Select the **Code Generation** pane.
7. Select **Retain .rtw file**, then click **Apply**. This step lets you inspect the contents of the *`model`*`.rtw` file after the build finishes.
8. Select **Generate code only**, then click **OK**.
9. Build the model.

The build process generates code in the `basic_grt_rtw` folder. You can see the progress in the MATLAB Command Window. When code generation is complete, following message is displayed:

```
### Successful completion of code generation for model: basic
```

The slbuild Command

Invoke `slbuild` by pressing **Ctrl+B** in the model window. However, some circumstances require you to execute `slbuild` directly from the MATLAB prompt.

To generate a *`model`*`.rtw` file from the MATLAB prompt, type:

```
slbuild('model')
```

You can specify other options to `slbuild` that build or rebuild model reference simulation targets or a stand-alone executable. For more information, type:

```
help slbuild
```

at the MATLAB prompt or see `slbuild` in the Simulink documentation.

Viewing the basic.rtw File

A *`model`*`.rtw` file contains a hierarchy of labeled records and fields. Each record is delimited by brackets, and contains subordinate records and/or fields. The labels state the purpose of each record and field. The records and fields in the *`model`*`.rtw` file created for a model describe various details of the model and the Configuration Parameter settings that specify its context.

Open the file `./basic_grt_rtw/basic.rtw`, in MATLAB or a text editor.

Create the Target File

Note The following exercise is provided to give a conceptual overview of how the `.rtw` file is used in the build process. The code generator does not support manually invoking TLC with a `.rtw` file created from an earlier build. Also, the contents of the `.rtw` file are undocumented and subject to change. The `basic.tlc` file shows how information is provided in a `.rtw` file that can be accessed by the TLC files and executed as part of the build process.

Next, create a `basic.tlc` file to act as a target file for this model. Instead of generating code, simply display some information about the model using this file. The concept is the same as used in code generation.

Create a file called `basic.tlc` in the folder containing `basic`. This file should contain the following lines:

```
%with CompiledModel

My model is called %<Name>.
It was generated on %<GeneratedOn>.
It has %<NumModelOutputs> output(s) and %<NumContStates> continuous state(s).

%endwith
```

Note In the build process, the `.tlc` file specified on the command line when TLC is invoked (for example, `grt.tlc`) is referred to as the System Target File (STF). It can be selected via the **System target file** browser option in the **Code Generation** pane of the Configuration Parameters dialog box.

In this example, you generate the `.rtw` file as part of the build process and then manually run TLC using the file `basic.tlc` as an example STF. `basic.tlc` illustrates (in a limited capacity) how `.rtw` file information is used to generate an example output. To do this, enter at the MATLAB prompt:

```
slbuild('basic')
tlc -r basic_grt_rtw/basic.rtw basic.tlc -v
```

The first line generates the `.rtw` file in the build folder `'basic_grt_rtw'`. This step is unnecessary because the file has already been generated in the previous step. However, it is useful if the model is changed and the operation has to be repeated.

The second line runs TLC on the file `basic.tlc`. The `-r` option tells TLC that it should use the file `basic.rtw` as the `.rtw` file. Note that a space must separate `-r` and the input filename. The `-v` option tells TLC to be verbose in reporting its activity.

The output of this pair of commands is (date will differ):

```
My model is called basic.
It was generated on Wed Jun 22 20:51:11 2005.
It has 1 output(s) and 0 continuous state(s).
```

You can also try changing the model (for instance, by using `rand(2,2)` as the value for the constant block) and then repeating the process to see how the output of TLC changes.

Configure TLC

In this section...

Set Command-Line Arguments

You can enter TLC command-line arguments from the MATLAB command line using the `set_param` command, the model parameter `TLCOptions`, and the TLC option `-a`. For example, to enter the TLC command-line string `-amyConfigVariable=1`, use the following MATLAB command:

```
set_param(modelName,'TLCOptions','-amyConfigVariable=1');
```

Using `-amyConfigVariable=1` is equivalent to coding the following in your target file:

```
%assign myConfigVariable = 1
```

Alternatively, you can configure the TLC code generation process by using the `-a` option on the TLC command line. That is, you must give the TLC command interactively.

You can repeatedly use the `-a` option.

For an example of how this process works, consider the following TLC code fragment:

```
%if !EXISTS(myConfigVariable)
  %assign myConfigVariable = 0
%endif
  %if (myConfigVariable == 1)
      code fragment 1
  %else
      code fragment 2
  %endif
```

If you specify `-amyConfigVariable=1` in the command line, `code fragment 1` is generated; otherwise `code fragment 2` is generated. The `if` block starting with

```
%if !EXISTS(myConfigVariable)
```

serves to set the default value of `myConfigVariable` to 0, so that TLC does not generate an error if you forget to add `-amyConfigVariable` to the command line.

If you use the `-a` option to input a string variable, the variable must be enclosed in double quotation marks:

```
-aMyStringVariable="hello"
```

However, if the string contains white space, enclose the string within apostrophes and double quotation marks:

```
-aMyStringVariable="'hello world'"
```

Do this if apostrophes exist within the string, whether or not white space is included, and the apostrophes must be escaped (doubled):

```
-aMyStringVariable="'can''t'"
```

Configure for TLC Debugging

To configure TLC for debugging via the Configuration Parameters dialog box, search for the option **Start TLC debugger when generating code**. To activate TLC debugger, select **Start TLC debugger when generating code**. For more information, see “Using the TLC Debugger” on page 19-2 and the debugging topics in “Target Language Compiler” (Simulink Coder).

Code Generation Concepts

TLC interprets a target language, which is a general programming language, and you can use it as such. It is important, however, to remember that TLC was designed for one purpose: to convert a *`model`*`.rtw` file to generated code. Thus, the target language provides many features that are useful for this task but does not provide some of the features that other languages like C and C++ provide.

You might find some of the following general programming examples useful to familiarize yourself with the basic constructs used within TLC.

Output Streams

The typical “Hello World” example is rather simple in the target language. Type the following in a file named `hello.tlc`:

```
%selectfile STDOUT
Hello, World
```

To run this TLC program, type

```
tlc hello.tlc
```

at the MATLAB prompt.

This simple script illustrates some important concepts underlying the purpose (and hence the design) of TLC. Since the primary purpose of TLC is to generate code, it is output (or stream) oriented. It makes it easy to handle buffers of text and output them easily. In the above script, the `%selectfile` directive tells TLC to send any following text that it generates or does not recognize to the standard output device. Syntax that TLC recognizes begins with the `%` character. Because `Hello, World` is not recognized, it is sent directly to the output. You could easily change the output destination to be a file. Do not open the `STDOUT` stream, but select to write to the Command Window.

```
%openfile foo = "foo.txt"
%openfile bar = "bar.txt"
%selectfile foo
This line is in foo.
%selectfile STDOUT
Line has been output to foo.
%selectfile bar
This line is in bar.
```

```
%selectfile NULL_FILE
This line will not show up anywhere.
%selectfile STDOUT
About to close bar.
%closefile bar
%closefile foo
```

You can switch between buffers to display status messages. The semantics of the three directives `%openfile`, `%selectfile`, and `%closefile` are given in “Target Language Compiler Directives” on page 18-2.

Variable Types

The absence of explicit type declarations for variables is another feature of TLC. See “Target Language Compiler” (Simulink Coder) for more information on the implicit data types of variables.

Records

One of the constructs most relevant to generating code from the *`model`*`.rtw` file is a record. A record is similar to a structure in C or a record in Pascal. The syntax of a record declaration is

```
%createrecord recVar { ...
   field1        value1  ...
   field2        value2 ...
      ...
  fieldN        valueN ...
}
```

where `recVar` is the name of the record being declared, `fieldi` is a string, and `valuei` is the corresponding TLC value.

Records can have nested records, or subrecords, within them. The *`model`*`.rtw` file is essentially one large record, named `CompiledModel`, containing levels of subrecords.

Unlike MATLAB, TLC requires that you explicitly load function definitions not located in the same target file. In MATLAB, the line `A = myfunc(B)` causes MATLAB to automatically search for and load a MATLAB file or MEX-file named `myfunc`. TLC requires that you specifically include the file that defines the function using the `%addincludepath` directive.

TLC provides a `%with` directive that facilitates using records. See “Target Language Compiler Directives” on page 18-2.

Note The format and structure of the *`model`*`.rtw` file are subject to change from one release of the code generator to another.

A record read in from a file is changeable, like other records that you declare in a program. The record `CompiledModel` is modified many times during code generation. `CompiledModel` is the global record in the *`model`*`.rtw` file. It contains variables used for code generation, such as `NumNonvirtSubsystems`, `NumBlocks`. It is also appended during code generation with many new variables, options, and subrecords.

Functions such as `LibGetFormattedBlockPath` are provided in TLC libraries located in *`matlabroot`*`/rtw/c/tlc/lib/*.tlc` (open). For a complete list of available functions, refer to TLC Function Library Reference on “Target Language Compiler” (Simulink Coder).

Assign Values to Fields of Records

To assign a value to a field of a record, you must use a qualified variable expression. A qualified variable expression references a variable in one of the following forms:

- An identifier
- A qualified variable followed by “`.`” followed by an identifier, such as

  ```
  var[2].b
  ```
- A qualified variable followed by a bracketed expression such as

  ```
  var[expr]
  ```

Record Aliases

In TLC, it is possible to create what is called an alias to a record. Aliases are similar to pointers to structures in C. You can create multiple aliases to a single record. Modifications to the aliased record are visible to every place that holds an alias.

The following code fragment illustrates the use of aliases:

```
%createrecord foo { field 1 }
%createrecord a { }
```

```
%createrecord b { }
%createrecord c { }

%addtorecord a foo foo
%addtorecord b foo foo
%addtorecord c foo { field 1 }

%% notice we are not changing field through a or b.
%assign foo.field  = 2

ISALIAS(a.foo) = %<ISALIAS(a.foo)>
ISALIAS(b.foo) = %<ISALIAS(b.foo)>
ISALIAS(c.foo) = %<ISALIAS(c.foo)>

a.foo.field = %<a.foo.field>
b.foo.field = %<b.foo.field>
c.foo.field = %<c.foo.field>
%% note that c.foo.field is unchanged
```

Saving this script as `record_alias.tlc` and invoking it with

```
tlc -v record_alias.tlc
```

produces the output

```
ISALIAS(a.foo) = 1
ISALIAS(b.foo) = 1
ISALIAS(c.foo) = 0

a.foo.field = 2
b.foo.field = 2
c.foo.field = 1
```

When inside a function, it is possible to create an alias to a locally created record that is within the function. If the alias is returned from the function, it remains valid even after exiting the function, as in the following example:

```
%function func(value) Output
  %createrecord foo { field value }
  %createrecord a { foo foo }
ISALIAS(a.foo) = %<ISALIAS(a.foo)>
   %return a.foo
 %endfunction

 %assign x = func(2)
```

```
ISALIAS(x) = %<ISALIAS(x)>
x = %<x>
x.field = %<x.field>
```

Saving this script as `alias_func.tlc` and invoking it with

```
tlc -v alias_func.tlc
```

produces the output

```
ISALIAS(a.foo) = 1
ISALIAS(x) = 1
x = { field 2 }
x.field = 2
```

As long as there is some reference to a record through an alias, that record is not deleted. This allows records to be used as return values from functions.

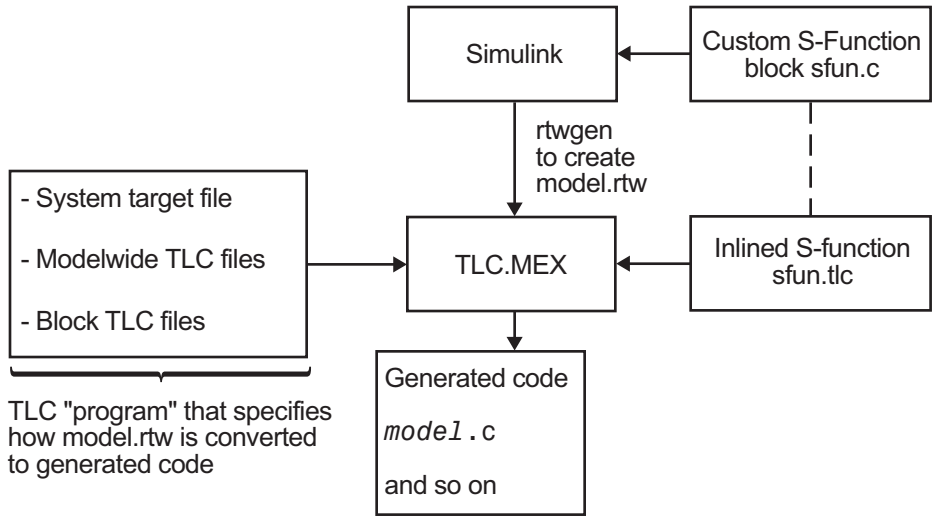
TLC Files

In this section...

TLC Program

Target Language Compiler (TLC) works with the Simulink software to generate code.



A TLC program is a collection of ASCII files called scripts. Because TLC is an interpreted language, there are no object files. The single target file that calls (with the `%include` directive) other target files used for the program is called the entry point.

Available Target Files

TLC interprets the set of target files to transform the partial representation of the Simulink model (*`model`*`.rtw`) into target-specific code.

Target files provide you with the flexibility to customize the code generated by the compiler. For example, if you use the available system target files, you produce generic C or C++ code from your Simulink model. This executable code is not platform-specific.

Note Do not customize TLC files even though the capability exists to do so. Such TLC customizations might not be applied during the code generation process and can lead to unpredictable results. Customize only the TLC files that you create.

The parameters in the target files are read from the *`model`*`.rtw` file and looked up by using block scoping rules. You can define additional parameters within the target files by using the `%assign` statement.

Use target language directives to write target files. “Target Language Compiler Directives” on page 18-2 provide complete descriptions of the block scope rules and the target language directives.

“model.rtw File and Scopes” on page 17-2 describes `model.rtw` file, which is useful for creating and modifying target files.

In the context of code generation, there are two types of target files:

- System target files

  System target files determine the overall framework of code generation. They determine when blocks are executed, how data is logged, and so on.
- Block target files

  Each block has a target file that determines what code should be generated for the block. The code can vary depending on the exact parameters of the block or the types of connections to it (e.g., wide vs. scalar input). For more information, see “Block Target File Methods” on page 20-27

Model-Wide Target Files and System Target Files

You use model-wide target files on a model-wide basis. Model-wide target files provide basic information to TLC, which transforms the *`model`*`.rtw` file into target-specific code.

The system target file is the entry point for TLC. It is analogous to the `main()` routine of a C program. System target files oversee the entire code generation process. For example, the system target file `grt.tlc` sets up some variables for `codegenentry.tlc`,

which is the entry point into the system target files. For a complete list of available system target files, see “Compare System Target File Support Across Products” (Simulink Coder).

Target File Usage

Use the target files to:

- Inline an S-function

  Inlining an S-function means writing a block target file that instructs TLC how to generate code for that S-Function block. The compiler can generate code for noninlined C MEX S-functions. If you inline a C MEX S-function, the compiler can generate more efficient code. Noninlined C MEX S-functions execute by using the S-function application program interface (API) and can be inefficient. You can inline a MATLAB file or Fortran S-function. TLC can generate code for the S-function in both cases.
- Customize the code generated for all models

  You might want to instrument the generated code for profiling or make other changes to overall code generation for all models. To accomplish such changes, modify some of the system target files.

System Target Files

The entire code generation process starts with the single system target file that you specify in the Configuration Parameters dialog box, on the **Code Generation** pane. Click the **Browse** button to activate the system target file browser for this purpose. A close examination of a system target file reveals how code generation occurs. This listing is a listing of the non-comment lines in `grt.tlc`, the target file to generate code for a generic real-time executable.

```
%selectfile NULL_FILE
%assign TargetType = "RT"
%assign Language   = "C"
%assign MatFileLogging = 1
%include "codegenentry.tlc"
```

The three variables, `Language`, `TargetType`, and `MatFileLogging`, are global TLC variables that other functions use. Code generation is then initiated by the call to `codegenentry.tlc`, the main entry point for code generation.

If you want to modify overall code generation, you must change the system target file. After the initial setup, instead of calling `codegenentry.tlc`, you must call your own TLC files. This code shows an example system target file called `mygrt.tlc`.

```
%% Set up variables, etc.
%% Load my library functions
%% Note that mylib.tlc should %include funclib.tlc at the
%% beginning.
%include "mylib.tlc"
%include "commonsetup.tlc"

%% Next, you can include TLC files that you need for
%% preprocessing information about the model and to fill in
%% hooks. The following is an example of including a single
%% TLC file that contains custom hooks.
%include "myhooks.tlc"

%% Finally, call the code generator.
%include "commonentry.tlc"
```

Generated code is placed in a model or subsystem function. The relevant generated function names and their execution order are described in “Execution of Code Generated from a Model” (Simulink Coder) and “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder). During code generation, functions from each of the block target files are executed and the generated code is placed in model or subsystem functions.

Data Handling with TLC

In this section...

Matrix Parameters

MATLAB, Simulink, and the code generator use column-major ordering for array storage (1-D, 2-D, ...). The next element of an array in memory is accessed by incrementing the first index of the array. For example, these element pairs are stored sequentially in memory: `A(i)` and `A(i+1)`, `B(i,j)` and `B(i+1,j)`, `C(i,j,k)` and `C(i+1,j,k)`. For more information on the internal representation of MATLAB data, see “MATLAB Data” (MATLAB).

Code Generator Matrix Parameters

Simulink and code generator internal data storage formatting differs from MATLAB internal data storage formatting only in the storage of complex number arrays. In MATLAB, the real and imaginary parts are stored in separate arrays. In the Simulink and code generator products they are stored in an "interleaved" format, where the numbers in memory alternate real, imaginary, real, imaginary, and so forth. This convention allows efficient implementations of small signals on Simulink lines and for Mux blocks and other "virtual" signal manipulation blocks (that is, they do not actively copy their inputs, merely the references to them).

The compiled model file, *`model`*`.rtw`, represents matrices as strings in MATLAB syntax, with no implied storage format. This is so you can copy the string out of an `.rtw` file and paste it into MATLAB code and have it recognized by MATLAB.

TLC declares Simulink block matrix parameters as scalar or 1-D array variables

```
real_T scalar;
real_T mat[ nRows * nCols ];
```

where `real_T` can be an arbitrary data type supported by Simulink, and match the variable type given in the model file.

For example, the 3-by-3 matrix in the Look-Up Table (2-D) block

```
1   2   3
4   5   6
7   8   9
```

is stored in *model*.rtw as

```
Parameter {
      Name                "OutputValues"
      Value                Matrix(3,3)
[[1.0, 2.0, 3.0]; [4.0, 5.0, 6.0]; [7.0, 8.0, 9.0];]
   String                "t"
   StringType               "Variable"
   ASTNode {
        IsNonTerminal                      0
       Op                      SL_NOT_INLINED
        ModelParameterIdx                   3
   }
}
```

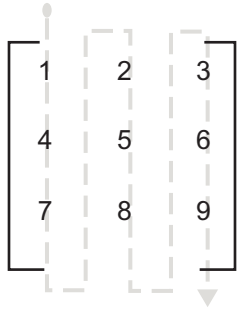
and results in this definition in *model*.h

```
typedef struct Parameters_tag {
  real_T s1_Look_Up_Table_2_D_Table[9];
                                /* Variable:s1_Look_Up_Table_2_D_Table
                                  * External Mode Tunable:yes
                                  * Referenced by block:
                                  * <S1>/Look-Up Table (2-D
                           */

  [ ... other parameter definitions ... ]

} Parameters;
```

The *model*.h file declares the actual storage for the matrix parameter and you can see that the format is column-major. That is, read down the columns, then across the rows.



```
Parameters model_P = {
  /* 3 x 3 matrix s1_Look_Up_Table_2_D_Table */
  { 1.0, 4.0, 7.0, 2.0, 5.0, 8.0, 3.0, 6.0, 9.0 },
  [ ... other parameter declarations ...]
};
```

TLC accesses matrix parameters via `LibBlockMatrixParameter` and `LibBlockMatrixParameterAddr`, where

`LibBlockMatrixParameter(OutputValues, "", "", 0, "", "", 1)` returns "*model*`_P.s1_Look_Up_Table_2_D_Table[`*nRows*`]`" (automatically optimized from "`[0+`*nRows*`*1]`") and

`LibBlockMatrixParameterAddr(OutputValues, "", "", 0, "", "", 1)` returns "`&`*model*`_P.s1_Look_Up_Table_2_D_Table[`*nRows*`]`" for both inlined and noninlined block TLC code.

Matrix parameters are like other TLC parameters. Only those parameters explicitly accessed by a TLC library function during code generation are placed in the parameters structure. So, following the example, `s1_Look_Up_Table_2_D_Table` is not declared unless `LibBlockParameter` or `LibBlockParameterAddr` explicitly access it.

model.rtw File and Authoring S-Functions and Data Objects

model.rtw File and Scopes

The code generation software creates a *model*.rtw file from your Simulink model. A *model*.rtw file is a partial representation of a model generated by the build process for use by the Target Language Compiler. It describes blocks, inputs, outputs, parameters, states, storage, and other model components and properties from the corresponding model file.

The generated *model*.rtw file is input to the Target Language Compiler. If you select **Retain .rtw file** from the **Configuration Parameters > Code Generation** pane, after building a model, you can view the *model*.rtw file that was generated.

A *model*.rtw file is implemented as an ASCII file of parameter-value pairs stored in a hierarchy of records. A parameter name/parameter value pair is specified as

```
ParameterName  value
```

where `ParameterName` (also called an identifier) is the name of the TLC identifier and `value` is a string, scalar, vector, or matrix. For example, in the parameter name/parameter value pair

```
     NumDataOutputPorts 1
```

`NumDataOutputPorts` is the identifier and 1 is its value.

A record is specified as

```
RecordName {
      .
      .
      .
}
```

A record contains parameter name/parameter value pairs and/or subrecords. For example, this record contains one parameter name/parameter value pair:

```
DataStores {
    NumDataStores        0
}
```

Note The structure of the *model*.rtw file is very likely to change between releases, which is a compelling reason to limit your access to *model*.rtw to the library functions

documented under TLC Function Library Reference: “Target Language Compiler” (Simulink Coder). For additional information, see “Exception to Using the Library Functions that Access model.rtw” on page 17-13.

Scopes in the model.rtw File

Each record creates a new scope. The *`model`*`.rtw` file uses curly braces `{` and `}` to open and close records (or scopes). Using scopes, you can access values within the *`model`*`.rtw` file.

The scope in this example begins with `CompiledModel`. Use periods (`.`) to access values within particular scopes. The format of *`model`*`.rtw` is

```
CompiledModel {
  Name   "modelname"           -- Example of a parameter-value
  ...                             pair (record field).
  System {                     -- There is one system for each
                                  nonvirtual subsystem.
    Block {                    -- Block records for each
      Type     "S-Function"       nonvirtual block in the
                                  system.
      Name     "<S3>/S-Function"
      ...
      Parameter {
       Name "P1"
       Value Matrix(1,2) [[1, 2];]
    }
    ...
    Block {
    }
  }
  ...
  System {                     -- The last system is for the
                                  root of your model.
}
```

For example, to access `Name` within `CompiledModel`, you would use

```
CompiledModel.Name
```

Multiple records of the same name form a list where the index of the first record starts at 0. To access the above S-function block record, you would use

```
CompiledModel.System[0].Block[0]
```

To access the name field of this block, you would use

```
CompiledModel.System[0].Block[0].Name
```

To simplify this process, you can use the `%with` directive, which changes the current scope. For example:

```
%with CompiledModel.System[0].Block[0]
%assign blockName = Name
%endwith
```

`blockName` will have the value `"<S3>/S-Function"`.

When inlining S-function blocks, your S-function block record is scoped as though the above `%with` directive was done. In an inlined `.tlc` file, you should access fields without a fully qualified path.

The following code shows a more detailed scoping example where the `Block` record has several parameter-value pairs (`Type`, `Name`, `Identifier`, and so on), and three subrecords, each called `Parameter`. `Block` is a subrecord of `System`, which is a subrecord of `CompiledModel`. Note that the parameter names in this file changes from release to release.

Data Object Information in model.rtw

In this section...

Data Object Overview

During the build process, the code generator writes information about Simulink signal and parameter data objects to the *`model`*`.rtw` file. An `Object` record with `CoderInfo` property information is written for each parameter or signal that meets certain conditions. These conditions are described in “Object Records for Parameters” on page 17-6 and “Object Records for Signals” on page 17-8.

The `Object` records contain the information corresponding to the associated data object. To access `Object` records, you must write Target Language Compiler code (see “Access Data Object Information via TLC” on page 17-9).

For some data, defining custom storage classes can be a helpful approach. For more information, see “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 36-48. Note that this support requires an Embedded Coder license.

Note The `Object` record examples in this section are generated from the example model `rtwdemo_advsc`, with model button **ExportedGlobal Storage Class** double-clicked and model option **Retain .rtw file** selected. (Do not use the example model buttons to build the model, as they modify model options, including **Retain .rtw file**.)

Object Records for Parameters

An `Object` record with `CoderInfo` property information is included in the `ModelParameters` section of the *`model`*`.rtw` file for each parameter that meets the following conditions:

- The parameter resolves to a `Simulink.Parameter` data object (or to a parameter data object that comes from a class derived from the `Simulink.Parameter` class).
- The parameter symbol is preserved in the generated code. The symbol is preserved when the `CoderInfo.StorageClass` property of the data object is not set to `Auto` or, if you set the default storage class for the corresponding category of data to `Default` in the Code Mapping Editor, `Model default`.

The following example shows part of an `Object` record for a parameter. A real record contains more fields than appear in the example.

```
ModelParameters {
  NumParameters     10
  ...
    Parameter {
      Identifier          "K1"
      LogicalSrc          P7
      WorkspaceVarName          "K1"
      Protected              no
      Tunable               yes
      StorageClass           "ExportedGlobal"
      Value               [2]
      OriginalDataTypeIdx     2
      CGTypeIdx              41
      ContainerCGTypeIdx      42
      ReferencedBy          Matrix(1,4)
[[1, -1, 4, 5];]
      GraphicalRef          Matrix(1,2)
[[0, 16];]
      GraphicalSource          [-1, -1]
      OwnerSysIdx           [1, -1]
      HasObject               1
      Object {
    Package            Simulink
    Class            Parameter
    ObjectProperties {
      Value              2.0
      CoderInfo {
        Object {
          Package              Simulink
          Class              CoderInfo
          ObjectProperties {
        StorageClass         "ExportedGlobal"
        TypeQualifier         ""
        Alias             ""
        Alignment         -1
        CSCPackageName         "Simulink"
        ParameterOrSignal    "Parameter"
        CustomStorageClass    "Default"
        CustomAttributes {
          Object {
            Package            SimulinkCSC
            Class            AttribClass_Simulink_Default
```

```
            ObjectProperties {
            }
          }
        }
          }
        }
      }
  ...
}
```

Object Records for Signals

An `Object` record with `CoderInfo` property information is included in either the `ExternalOutputs`, `ExternalInputs`, or `BlockOutputs` section of the *`model`*`.rtw` file for each signal (including root-level Inport and Outport blocks) whose symbol is preserved in the generated code. The symbol is preserved when the signal uses a storage class other than `Auto`. If the signal is configured to be an unstructured global variable in the generated code, its validity and uniqueness are enforced and its symbol is preserved.

The following example shows part of an `Object` record for a root-level Outport block. A real record contains more fields than appear in the example.

```
ExternalOutputs {
  ...
  NumExternalOutputs        1
  ...
    ExternalOutput {
      ArgSrc               Y0
      Block               [1,3]
      BlockName               "<Root>/Out1"
      Identifier           "output"
      OrigIdentifier           "output"
      StorageClass          "ExportedGlobal"
      ResolvedToSignalObject  embedded
      HasObject               1
      Object {
    Package            Simulink
    Class             Signal
    ObjectProperties {
      CoderInfo {
        Object {
          Package              Simulink
          Class               CoderInfo
          ObjectProperties {
        StorageClass         "ExportedGlobal"
        TypeQualifier         ""
        Alias              ""
        Alignment         -1
        CSCPackageName         "Simulink"
        ParameterOrSignal    "Signal"
        CustomStorageClass    "Default"
```

```
        CustomAttributes {
          Object {
            Package            SimulinkCSC
            Class            AttribClass_Simulink_Default
            ObjectProperties {
                  }
                }
              }
            }
          }
        }
  ...
}
```

Access Data Object Information via TLC

This section provides sample code to illustrate how to access data object information from the *`model`*`.rtw` file using TLC code.

Access Parameter Object Records

The following code fragment iterates over `Parameter` structures in the `ModelParameters` section of the *`model`*`.rtw` file and extracts information from parameter `Object` records encountered.

```
%with CompiledModel.ModelParameters
  %foreach modelParamIdx = NumParameters
    %assign thisModelParam = Parameter[modelParamIdx]
    %assign paramName = thisModelParam.Identifier
    %if EXISTS("thisModelParam.Object.ObjectProperties")
      %with thisModelParam.Object.ObjectProperties
        %assign valueInObject = Value
        %with CoderInfo.Object.ObjectProperties
          %assign storageClassInObject  = StorageClass
        %endwith
        %% ***********************************
        %% Access user-defined properties here
        %% ***********************************
        %if EXISTS("MY_PROPERTY_NAME")
          %assign userDefinedPropertyName = MY_PROPERTY_NAME
        %endif
        %% ***********************************
      %endwith
    %endif
  %endforeach
%endwith
```

Access Signal Object Records

The following code fragment iterates over `ExternalBlockOutput` structures in the `BlockOutputs` section of the *`model`*`.rtw` file and extracts information from signal `Object` records encountered.

```
%with CompiledModel.BlockOutputs
  %foreach blockOutputIdx = NumExternalBlockOutputs
    %assign thisBlockOutput = ExternalBlockOutput[blockOutputIdx]
    %assign signalName = thisBlockOutput.Identifier
    %if EXISTS("thisBlockOutput.Object.ObjectProperties")
      %with thisBlockOutput.Object.ObjectProperties
        %with CoderInfo.Object.ObjectProperties
          %assign storageClassInObject  = StorageClass
        %endwith \
        %% ***********************************\
        %% Access user-defined properties here\
        %% ***********************************
        %if EXISTS("MY_PROPERTY_NAME")
          %assign userDefinedPropertyName = MY_PROPERTY_NAME
        %endif
        %% ***********************************
      %endwith
    %endif
  %endforeach
%endwith
```

Data References in the model.rtw File

Data Reference Overview

Some records in a *model*.rtw file, such as those corresponding to parameters and constant block I/O, can have extremely large data value vectors embedded in them. Such a vector can cause significant memory overhead during code generation because the values must be maintained as text in memory during this process.

To avoid such overhead, by default the Simulink software does not write out the entire data value vector into *model*.rtw. Instead, it writes a key called a data reference that can be used during code generation to access the data directly from Simulink. If the data is not mutated during code generation, it is efficiently streamed to disk when the actual code containing the data values is written out.

A data reference has the format SLData(*index*), where *index* is a numeric value that tells Simulink which data is being referenced. TLC directives such as GENERATE_FORMATTED_VALUE store data references in unexpanded format in memory. When the generated code is written out to disk, the data values expand to the actual values.

Control the Data Reference Threshold

By default, Simulink writes a data reference to *model*.rtw in place of a data vector whose length is 10 or more. To change the maximum length of a vector that can appear literally in the file, use:

```
set_param(0, 'RTWDataReferencesMinSize', maxlen)
```

Simulink replaces a vector as long or longer than maxlen with a data reference when it creates *model*.rtw. Specify maxlen as an integer or as inf. Specifying inf disables data references. The complete value set of every vector, however long, then appears literally in *model*.rtw and occupies text memory during code generation.

Setting an explicit *maxlen* affects only the current MATLAB session. To set the value across sessions, include a set_param command in your startup.m file, or automate execution of the command when MATLAB launches.

Expand Data References

You can explicitly expand a data reference by using the `GENERATE_FORMATTED_VALUE` built-in function with the optional third `expand` argument. Commands such as `FEVAL` may cause a data reference to be expanded to the full form.

Avoid Data Reference Expansion

Either turning off data references completely or expanding select parameters in TLC can cause significant text memory overhead during the code generation process. During most common code generation tasks, it is unnecessary to have the expanded data vector in memory and pay the price of the additional overhead. Avoid expanded data vectors unless no alternative exists.

Restart Code Generation

A *`model`*`.rtw` file that contains data references cannot be used in isolation to restart a custom code generation process. The data references within it become stale once the code generation process is completed. Attempting to start a code generation process using only this file may result in unpredictable behavior and memory segmentation faults.

Related Examples

- “Data Object Information in model.rtw” on page 17-6
- “Exception to Using the Library Functions that Access model.rtw” on page 17-13

Exception to Using the Library Functions that Access model.rtw

There are several library functions that provide access to block inputs, outputs, parameters, sample times, and other information. It is recommended that you use these library functions to access many of the parameter name/parameter values pairs in the block record, as opposed to accessing the parameter name/parameter value pairs directly from your block TLC code. For more information about using these functions (recommended method for accessing *`model`*`.rtw`), see “Target Language Compiler Library Functions Overview” on page 21-2.

An exception to using these functions is when you access parameter settings for a block. Parameter settings can be written out using the `mdlRTW` function of a C MEX S-function. They can contain data in the form of strings, scalar values, vectors, and matrices. They can be used to pass fixed values and information that is used to alter the generated code for a block or directly as values in the resulting code of a block.

Example Exception to Using the Library Functions

The following example demonstrates accessing parameter settings for a block using the `mdlRTW` function of a C MEX S-function. For more details on using parameter settings, see “Inlining S-Functions” on page 14-9.

mdlRTW Function in C MEX S-Function Code

```
static void mdlRTW(SimStruct *S)
{
    if (!ssWriteRTWParamSettings( S, 1, SSWRITE_VALUE_QSTR, "Operator", "AND"))
    {
        ssSetErrorStatus(S,"Error writing parameter data to .rtw file");
        return;
    }
}
```

Resulting Block Record in model.rtw File

```
Block {
      Type    "S-Function"
      Name    "<Root>/S-Function"

      ...

      SFcnParamSettings {
        Operator    "AND"
```

```
      }
    }
```

TLC Code to Access the Parameter Settings

```
%function Outputs(block, system) Output
  %%
  %% Select Operator
  %switch(SFcnParamSettings.Operator)
    %case "AND"
      %assign LogicOp        = "&"
      %break
    ...
  %endswitch
%endfunction
```

Caution Against Directly Accessing Record Fields

When functions in the block target file are called, they are passed to the block and system records for this instance as arguments. The first argument, `block`, is in scope, which means that variable names inside this instance's block record are accessible by name. For example:

```
%assign fast = SFcnParamSetting.Fast
```

Block target files could generate code for a given block by directly using the fields in the Block record for the block. This process is *not* recommended, for two reasons:

- The contents of the *`model`*`.rtw` file can change from release to release. This can cause block TLC files that access the *`model`*`.rtw` file directly to stop working.
- TLC library functions are provided that substantially reduce the amount of TLC code for implementing a block while handling the various configurations (widths, data types, etc.) a block might have. These library functions are provided by the system target files to provide access to inputs, outputs, parameters, and so on. Using these functions in a block TLC script makes it flexible enough to generate code for multiple instances or configurations of the block, as well as across releases. Exceptions to this do occur, however, such as when you want to directly access a field in the block's record. This happens with parameter settings, as discussed in "TLC Code to Access the Parameter Settings" on page 17-14.

Directives and Built-In Functions

You control how code is generated from models largely through writing or modifying scripts that apply TLC directives and built-in functions. Use the following sections as your primary reference to the syntax and format of target language constructs, as well as the MATLAB `tlc` command itself.

Target Language Compiler Directives

In this section...

You control how code is generated from models largely through writing or modifying scripts that apply TLC directives and built-in functions. Use the following sections as your primary reference to the syntax and format of target language constructs, as well as the MATLAB `tlc` command itself.

A target language directive must be the first non-blank character on a line and begins with the `%` character. Lines beginning with `%%` are TLC comments, and are *not* passed to the output stream. Lines beginning with `/*` are C comments, and *are* passed to the output stream.

Syntax

A target language file consists of a series of statements of either form:

- `[text | %<expression>]*`

  The literal text is passed to the output stream unmodified, and expressions enclosed in `%< >` are evaluated before being written to output (stripped of `%< >`).

- `%keyword [argument1, argument2, ...]`

  The `%keyword` represents one of the directives of Target Language Compiler, and `[argument1, argument2, ...]` represents expressions that define required parameters. For example, the statement

  ```
  %assign sysNumber = sysIdx + 1
  ```

  uses the `%assign` directive to define or change the value of the `sysNumber` parameter.

Directives

The rest of this section shows the complete set of Target Language Compiler directives, and describes each directive in detail.

%% text

Single-line comment where `text` is the comment.

/% text%/

Single (or multiline) comment where `text` is the comment.

%matlab

Calls a MATLAB function that does not return a result. For example, `%matlab disp(2.718)`.

%<expr>

Target language expressions that are evaluated. For example, if you have a TLC variable that was created via `%assign varName = "foo"`, then `%<varName>` would expand to `foo`. Expressions can also be function calls, as in `%<FcnName(param1,param2)>`. On

directive lines, TLC expressions need not be placed within the %<> syntax. Doing so causes a double evaluation. For example, `%if %<x> == 3` is processed by creating a hidden variable for the evaluated value of the variable x. The `%if` statement then evaluates this hidden variable and compares it against 3. The efficient way to do this operation is to write `%if x == 3`. In MATLAB notation, this would equate to writing if `eval('x') == 3` as opposed to if `x = 3`. The exception to this is during an `%assign` for format control, as in

```
%assign str = "value is: %<var>"
```

Note: Nested evaluation expressions (e.g., `%<foo(%<expr>)>`) are not supported.

There is not a speed penalty for evaluations inside strings, such as

```
%assign x = "%<expr>"
```

Avoid evaluations outside strings, such as the following example.

```
%assign x = %<expr>
```

%if expr%elseif expr%else%endif

Conditional inclusion, where the constant expression *`expr`* must evaluate to an integer. For example, the following code checks whether a parameter, `k`, has the numeric value 0.0 by executing a TLC library function to check for equality.

```
%if ISEQUAL(k, 0.0)
  <text and directives to be processed if k is 0.0>
%endif
```

In this and other directives, you do not have to expand variables or expressions using the `%<expr>` notation unless `expr` appears within a string. For example,

`%if ISEQUAL(idx, "my_idx%<i>")`, where `idx` and `i` are both strings.

As in other languages, logical evaluations do short-circuit (are halted when the result is known).

%switch expr %case expr %break %default %break %endswitch

The `%switch` directive is similar to the C language `switch` statement. The expression `expr` should be of a type that can be compared for equality using the `== operator`. If the `%break` is not included after a `%case` statement, then it will fall through to the next statement.

%with %endwith

`%with recordName` is a scoping operator. Use it to bring the named record into the current scope, to remain until the matching `%endwith` is encountered (`%with` directives can be nested as desired).

Note that on the left side of `%assign` statements contained within a `%with` / `%endwith` block, references to fields of records must be fully qualified (see “Assign Values to Fields of Records” on page 16-10), as in the following example.

```
%with CompiledModel
     %assign oldName = name
     %assign CompiledModel.name = "newname"
     %endwith
```

%setcommandswitch string

Changes the value of a command-line switch as specified by the argument string. Only the following switches are supported:

```
v, m, p, O, d, r, I, a
```

The following example sets the verbosity level to 1.

```
%setcommandswitch "-v1"
```

See also “Command-Line Arguments” on page 18-66.

%assert expr

Tests a value of a Boolean expression. If the expression evaluates to false, TLC issues an error message, a stack trace and exit; otherwise, the execution continues normally. To enable the evaluation of assertions outside the code generator environment, use the command-line option `-da`. When building from within the code generator, this flag is ignored, as it is superseded by the **Enable TLC assertion** check box on the **TLC process** section of the **Code Generation** > **Debug** pane. To control assertion handling from the MATLAB Command Window, use

```
set_param(model, 'TLCAssertion', 'on|off')
```

to set this flag on or off. Default is Off. To see the current setting, use

```
get_param(model, 'TLCAssertion')
```

%error %warning %trace %exit

Flow control directives:

`%error` *`tokens`*

The *`tokens`* are expanded and displayed.

`%warning` *`tokens`*

The *`tokens`* are expanded and displayed.

`%trace` *`tokens`*

The *`tokens`* are expanded and displayed only when the verbose output command-line option `-v` or `-v1` is specified.

`%exit` *`tokens`*

The *`tokens`* are expanded, displayed, and TLC exits.

When reporting errors, use the following command if the error is produced by an incorrect configuration that the user needs to fix in the model.

```
%exit Error Message
```

If you are adding assert code (that is, code that should never be reached), use

```
%setcommandswitch "-v1" %% force TLC stack trace
%exit Assert message
```

%assign

Creates identifiers (variables). The general form is

```
%assign [::]variable = expression
```

The `::` specifies that the variable being created is a global variable; otherwise, it is a local variable in the current scope (i.e., a local variable in the function).

If you need to format the variable, say, within a string based upon other TLC variables, then you should perform a double evaluation, as in

```
%assign nameInfo = "The name of this is %<Name>"
```

or alternately

```
%assign nameInfo = "The name of this is " + Name
```

To assign a value to a field of a record, you must use a qualified variable expression. See “Assign Values to Fields of Records” on page 16-10.

%createrecord

Creates records in memory. This command accepts a list of one or more record specifications (e.g., `{ foo 27 }`). Each record specification contains a list of zero or more name-value pairs (e.g., `foo 27`) that become the members of the record being created. The values themselves can be record specifications, as the following illustrates.

```
%createrecord NEW_RECORD { foo 1 ; SUB_RECORD {foo 2} }
%assign x = NEW_RECORD.foo                  /* x = 1 */
%assign y = NEW_RECORD.SUB_RECORD.foo       /* y = 2 */
```

If more than one record specification follows a given record name, the set of record specifications constitutes an array of records.

```
%createrecord RECORD_ARRAY { foo 1 } ...
                                   { foo 2 } ...
                                   { bar 3 }
%assign x = RECORD_ARRAY[1].foo             /* x = 2 */
%assign y = RECORD_ARRAY[2].bar             /* y = 3 */
```

Note that you can create and index arrays of subrecords by specifying `%createrecord` with identically named subrecords, as follows:

```
%createrecord RECORD_ARRAY { SUB_RECORD { foo 1 } ...
                             SUB_RECORD { foo 2 } ...
                             SUB_RECORD { foo 3 } }
%assign x = RECORD_ARRAY.SUB_RECORD[1].foo  /* x = 2 */
%assign y = RECORD_ARRAY.SUB_RECORD[2].foo  /* y = 3 */
```

If the scope resolution operator (`::`) is the first token after the `%createrecord` token, the record is created in the global scope.

Note You should not create a record array by using `%createrecord` within a loop.

%addtorecord

Adds fields to an existing record. The new fields can be name-value pairs or aliases to already existing records.

```
%addtorecord OLD_RECORD foo 1
```

If the new field being added is a record, then `%addtorecord` makes an alias to that record instead of a deep copy. To make a deep copy, use `%copyrecord`.

```
%createrecord NEW_RECORD { foo 1 }
%addtorecord OLD_RECORD NEW_RECORD_ALIAS NEW_RECORD
```

%mergerecord

Adds (or merges) one or more records into another. The first record will contain the results of the merge of the first record plus the contents of the other records specified by the command. The contents of the second (and subsequent) records are deep copied into the first (i.e., they are not references).

```
%mergerecord OLD_RECORD NEW_RECORD
```

If duplicate fields exist in the records being merged, the original record's fields are not overwritten.

%copyrecord

Makes a deep copy of an existing record. It creates a new record in a similar fashion to `%createrecord` except the components of the record are deep copied from the existing record. Aliases are replaced by copies.

```
%copyrecord NEW_RECORD OLD_RECORD
```

%realformat

Specifies how to format real variables. To format in exponential notation with 16 digits of precision, use

```
%realformat "EXPONENTIAL"
```

To format without loss of precision and minimal number of characters, use

```
%realformat "CONCISE"
```

When inlining S-functions, the format is set to `concise`. You can switch to `exponential`, but should switch it back to `concise` when done.

%language

This must appear before the first `GENERATE` or `GENERATE_TYPE` function call. This specifies the name of the language as a string, which is being generated as in `%language "C"`. Generally, this is added to your system target file.

The only valid value is `C` which enables support for `C` and `C++` code generation as specified by the configuration parameter `TargetLang` (see “Language” (Simulink Coder) for more information).

%implements

Placed within the `.tlc` file for a specific record type, when mapped via `%generatefile`. The syntax is `%implements "Type" "Language"`. When inlining an S-function in C or C++, this should be the first noncomment line in the file, as in

```
%implements "s_function_name" "C"
```

The next noncomment lines will be `%function` directives specifying the functionality of the S-function.

See the `%language` and `GENERATE` function descriptions for further information.

%generatefile

Provides a mapping between a record `Type` and functions contained in a file. Each record can have functions of the same name but different contents mapped to it (i.e., polymorphism). Generally, this is used to map a `Block` record `Type` to the `.tlc` file that implements the functionality of the block, as in

```
%generatefile "Sin" "sin_wave.tlc"
```

%filescope

Limits the scope of variables to the file in which they are defined. A `%filescope` directive anywhere in a file declares that variables in the file are visible only within that file. Note that this limitation also applies to files inserted, via the `%include` directive, into the file containing the `%filescope` directive.

You should not use the `%filescope` directive within functions or `GENERATE` functions.

`%filescope` is useful in conserving memory. Variables whose scope is limited by `%filescope` go out of scope when execution of the file containing them completes. This frees memory allocated to such variables. By contrast, global variables persist in memory throughout execution of the program.

%include

Use `%include "file.tlc"`to insert the specified target file at the current point.

The `%include` directives behave as if they were in a global context. For example,

```
%addincludepath "./sub1"
%addincludepath "./sub2"
```

in a `.tlc` file enables either subfolder to be referenced implicitly:

```
%include "file_in_sub1.tlc"
%include "file_in_sub2.tlc"
```

Use forward slashes for folder names, as they work on both UNIX and PC systems. However, if you do use back slashes in PC folder names, be sure to escape them, e.g., `"C:\\mytlc"`. Alternatively, you can express a PC folder name as a literal using the L format specifier, as in `L"C:\mytlc"`.

%addincludepath

Use `%addincludepath "folder"` to add additional paths to be searched. Multiple `%addincludepath` directives can appear. The compiler evaluates multiple `%addincludepath` directives from the *bottom up*.

Using `%addincludepath` directives establishes a global context. For example,

```
%addincludepath "./sub1"
%addincludepath "./sub2"
```

in a `.tlc` file enables either subfolder to be referenced implicitly:

```
%include "file_in_sub1.tlc"
%include "file_in_sub2.tlc"
```

Use forward slashes for folder names, as they work on both UNIX and PC systems. However, if you do use back slashes in PC folder names, be sure to escape them, e.g., `"C:\\mytlc"`. Alternatively, you can express a PC folder name as a literal using the L format specifier, as in `L"C:\mytlc"`.

%roll %endroll

Multiple inclusion plus intrinsic loop rolling based upon a specified threshold. This directive can be used by most Simulink blocks that have the concept of an overall block width that is usually the width of the signal passing through the block.

This example of the `%roll` directive is for a gain operation, `y=u*k`:

```
%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %assign rollVars = ["U", "Y", "P"]
  %roll sigIdx = RollRegions, lcv = RollThreshold, block,...
        "Roller", rollVars
    %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
    %assign u = LibBlockInputSignal(0, "", lcv, sigIdx)
    %assign k = LibBlockParameter(Gain, "", lcv, sigIdx)
      %<y> = %<u> * %<k>;
  %endroll
%endfunction
```

The `%roll` directive is similar to `%foreach`, except that it iterates the identifier (`sigIdx` in this example) over roll regions. Roll regions are computed by looking at the input signals and generating regions where the inputs are contiguous. For blocks, the variable `RollRegions` is automatically computed and placed in the `Block` record. An example of a roll regions vector is `[0:19, 20:39]`, where there are two contiguous ranges of signals passing through the block. The first is `0:19` and the second is `20:39`. Each roll region is either placed in a loop body (e.g., the C language `for` statement) or inlined, depending upon whether or not the length of the region is less than the roll threshold.

Each time through the `%roll` loop, `sigIdx` is an integer for the start of the current roll region or an offset relative to the overall block width when the current roll region is less than the roll threshold. The TLC global variable `RollThreshold` is the general model-wide value used to decide when to place a given roll region in a loop. When the decision is made to place a given region in a loop, the loop control variable is a valid identifier (e.g., `"i"`); otherwise it is `""`.

The `block` parameter is the current block that is being rolled. The `"Roller"` parameter specifies the name for internal `GENERATE_TYPE` calls made by `%roll`. The default `%roll` handler is `"Roller"`, which is responsible for setting up the default block loop rolling structures (e.g., a C `for` loop).

The `rollVars` (roll variables) are passed to `"Roller"` functions to create roll structures. The defined loop variables relative to a block are

`"U"`

The inputs to the block. It assumes you use `LibBlockInputSignal(portIdx, "", lcv, sigIdx)` to access each input, where `portIdx` starts at 0 for the first input port.

`"u`*`i`*`"`

Similar to `"U"`, except only for specific input, *`i`*. The `"u"` must be lowercase or it will be interpreted as `"U"` above.

`"Y"`

The outputs of the block. It assumes you use `LibBlockOutputSignal(portIdx, "", lcv, sigIdx)` to access each output, where `portIdx` starts at 0 for the first output port.

`"y`*`i`*`"`

Similar to `"Y"`, except only for specific output, *`i`*. The `"y"` must be lowercase or it will be interpreted as `"Y"` above.

`"P"`

The parameters of the block. It assumes you use `LibBlockParameter(name, "", lcv, sigIdx)` to access them.

`"<param>/`*`name`*`"`

Similar to `"P"`, except specific for a specific *`name`*.

`rwork`

The `RWork` vectors of the block. It assumes you use `LibBlockRWork(name, "", lcv, sigIdx)` to access them.

`"<rwork>/`*`name`*`"`

Similar to `RWork`, except for a specific *`name`*.

`dwork`

The `DWork` vectors of the block. It assumes you use `LibBlockDWork(name, "", lcv, sigIdx)` to access them.

`"<dwork>/`*`name`*`"`

Similar to `DWork`, except for a specific *`name`*.

`iwork`

The `IWork` vectors of the block. It assumes you use `LibBlockIWork(name, "", lcv, sigIdx)` to access them.

`"<iwork>/`*`name`*`"`

Similar to `IWork`, except for a specific *`name`*.

`pwork`

The `PWork` vectors of the block. It assumes you use `LibBlockPWork(name, "", lcv, sigIdx)` to access them.

`"<pwork>/`*`name`*`"`

Similar to `PWork`, except for a specific *`name`*.

`"Mode"`

The mode vector. It assumes you use `LibBlockMode("",lcv,sigIdx)` to access it.

`"PZC"`

Previous zero-crossing state. It assumes you use `LibPrevZCState("",lcv, sigIdx)` to access it.

To roll your own vector based upon the block's roll regions, you need to walk a pointer to your vector. Assuming your vector is pointed to by the first `PWork`, called `name`,

```
datatype *buf = (datatype*)%<LibBlockPWork(name,"","",0)
%roll sigIdx = RollRegions, lcv = RollThreshold, block, ...
      "Roller", rollVars
  *buf++ = whatever;
%endroll
```

Note: In the above example, `sigIdx` and `lcv` are local to the body of the loop.

%breakpoint

Sets a breakpoint for the TLC debugger. See "%breakpoint Directive" on page 19-5.

%function %return %endfunction

A function that returns a value is defined as

```
%function name(optional-arguments)
    %return value
  %endfunction
```

A void function does not produce output and is not required to return a value. It is defined as

```
%function name(optional-arguments) void
  %endfunction
```

A function that produces outputs to the current stream and is not required to return a value is defined as

```
%function name(optional-arguments) Output
  %endfunction
```

For block target files, you can add to your inlined `.tlc` file the following functions that are called by the model-wide target files during code generation.

`%function` **`BlockInstanceSetup`**`(block,system) void`

Called for each instance of the block within the model.

`%function` **`BlockTypeSetup`**`(block,system) void`

Called once for each block type that exists in the model.

`%function` **`Enable`**`(block,system) Output`

Use this if the block is placed within an enabled subsystem and has to take specific actions when the subsystem is enabled. Place within a subsystem enable routine.

`%function` **`Disable`**`(block,system) Output`

Use this if the block is placed within a disabled subsystem and has to take specific actions when the subsystem is disabled. Place within a subsystem disable routine.

`%function` **`Start`**`(block,system) Output`

Include this function if your block has startup initialization code that needs to be placed within `MdlStart`.

`%function` **`InitializeConditions`**`(block,system) Output`

Use this function if your block has state that needs to be initialized at the start of execution and when an enabled subsystem resets states. Place in `MdlStart` and/or subsystem initialization routines.

`%function` **`Outputs`**`(block,system) Output`

The primary function of your block. Place in `MdlOutputs`.

`%function` **`Update`**`(block,system) Output`

Use this function if your block has actions to be performed once per simulation loop, such as updating discrete states. Place in `MdlUpdate`.

`%function` **`Derivatives`**`(block,system) Output`

Use this function if your block has derivatives.

`%function` **`ZeroCrossings`**`(block,system) Output`

Use this function if your block does zero-crossing detection and has actions to be performed in `MdlZeroCrossings`.

`%function` **`Terminate`**`(block,system) Output`

Use this function if your block has actions that need to be in `MdlTerminate`.

%foreach %endforeach

Multiple inclusion that iterates from `0` to the `upperLimit-1` constant integer expression. Each time through the loop, the `loopIdentifier`, (e.g., `x`) is assigned the current iteration value.

```
%foreach loopIdentifier = upperLimit
   %break -- use this to exit the loop
   %continue -- use this to skip the following code and
                continue to the next iteration
%endforeach
```

Note: The `upperLimit` expression is cast to a TLC integer value. The `loopIdentifier` is local to the loop body.

%for

Multiple inclusion directive with syntax

```
%for ident1 = const-exp1, const-exp2, ident2 = const-exp3
  %body
    %break
    %continue
  %endbody
%endfor
```

The first portion of the `%for` directive is identical to the `%foreach` statement. The `%break` and `%continue` directives act the same as they do in the `%foreach` directive. `const-exp2` is a Boolean expression that indicates whether the loop should be rolled (see `%roll` above).

If `const-exp2` evaluates to `TRUE`, `ident2` is assigned the value of `const-exp3`. Otherwise, `ident2` is assigned an empty string.

Note: `ident1` and `ident2` above are local to the loop body.

%openfile %selectfile %closefile

These are used to manage the files that are created. The syntax is

```
%openfile streamId="filename.ext" mode  {open for writing}
%selectfile streamId                    {select an open file}
%closefile streamId                     {close an open file}
```

Note that the "filename.ext" is optional. If a filename is not specified, a variable (string buffer) named streamId is created containing the output. The mode argument is optional. If specified, it can be "a" for appending or "w" for writing.

Note that the special string streamIdNULL_FILE specifies no output. The special string streamIdSTDOUT specifies output to the terminal.

To create a buffer of text, use

```
%openfile buffer
text to be placed in the 'buffer' variable.
%closefile buffer
```

Now buffer contains the expanded text specified between the %openfile and %closefile directives.

%generate

%generate blk fn is equivalent to GENERATE(*blk*,*fn*).

%generate blk fn type is equivalent to GENERATE(*blk*,*fn*,*type*).

See “GENERATE and GENERATE_TYPE Functions” on page 18-33.

%undef

%undef *var* removes the variable *var* from scope. If *var* is a field in a record, %undef removes that field from the record. If *var* is a record array, %undef removes the entire record array.

Comments

You can place comments anywhere within a target file. To include comments, use the /%...%/ or %% directives. For example:

```
/%
    Abstract:    Return the field with [width], if field is wide
%/
```

or

```
%endfunction %% Outputs function
```

Use the %% construct for line-based comments. Characters from %% to the end of the line become a comment.

Non-directive lines, that is, lines that do not have % as their first non-blank character, are copied into the output buffer verbatim. For example,

```
/* Initialize sysNumber */
int sysNumber = 3;
```

copies both lines to the output buffer.

To include comments on lines that do not begin with the % character, you can use the `/%...%/` or %% comment directives. In these cases, the comments are not copied to the output buffer.

Note If a non-directive line appears within a function, it is not copied to the output buffer unless the function is an output function or you specifically select an output file using the `%selectfile` directive. For more information about functions, see “Target Language Functions” on page 18-62.

Line Continuation

You can use the C language \ character or the MATLAB sequence `...` to continue a line. If a directive is too long to fit conveniently on one line, this allows you to split the directive onto multiple lines. For example:

```
%roll sigIdx = RollRegions, lcv = RollThreshold, block,\
      "Roller", rollVars
```

or

```
%roll sigIdx = RollRegions, lcv = RollThreshold, block,...
      "Roller", rollVars
```

Note Use \ to suppress line feeds to the output and the ellipsis `...` to indicate line continuation. Note that \ and the ellipsis `...` cannot be used inside strings.

Target Language Value Types

This table shows the types of values you can use within the context of expressions in your target language files. Expressions in the Target Language Compiler must use these types.

Value Type String	Example	Description
`"Boolean"`	`1==1`	Result of a comparison or other Boolean operator. The result will be `TLC_TRUE` or `TLC_FALSE`.
`"Complex"`	`3.0+5.0i`	64-bit double-precision complex number (`double` on the target machine).
`"Complex32"`	`3.0F+5.0Fi`	32-bit single-precision complex number (`float` on the target machine).
`"File"`	`%openfile x`	String buffer opened with `%openfile`.
`"File"`	`%openfile x = "out.c"`	File opened with `%openfile`.
`"Function"`	`%function foo...`	User-defined function and `TLC_FALSE` otherwise.
`"Gaussian"`	`3+5i`	32-bit integer imaginary number (`int` on the target machine).
`"Identifier"`	`abc`	Identifier values can appear only within the *`model`*`.rtw` file and cannot appear in expressions (within the context of an expression, identifiers are interpreted as values). To compare against an identifier value, use a string; the identifier will be converted to a string.
`"Matrix"`	`Matrix (3,2) [ [ 1, 2]; [3 , 4]; [ 5, 6] ]`	Matrices are simply lists of vectors. The individual elements of the matrix do not need to be the same type, and can be any supported type except vectors or matrices. The `Matrix (3,2)` text in the example is optional.
`"Number"`	`15`	Integer number (`int` on the target machine).
`"Range"`	`[1:5]`	Range of integers between 1 and 5, inclusive.
`"Real"`	`3.14159`	Floating-point number (`double` on the target machine), including exponential notation.

Value Type String	Example	Description
"Real32"	3.14159F	32-bit single-precision floating-point number (float on the target machine).
"Scope"	Block { ... }	Block record.
"Special"	FILE_EXISTS	Special built-in function, such as FILE_EXISTS.
"String"	"Hello, World"	ASCII character strings. In all contexts, two strings in a row are concatenated to form the final value, as in "Hello, " "World", which is combined to form "Hello, World". These strings include the ANSI C standard escape sequences such as \n, \r, \t, etc. Use of line continuation characters (i.e., \ and ...) inside strings is illegal.
"Subsystem"	<sub1>	Subsystem identifier. Within the context of an expansion, be careful to escape the delimiters on a subsystem identifier, as in %<x == <sub\>>.
"Unsigned"	15U	32-bit unsigned integer (unsigned int on the target machine).
"Unsigned Gaussian"	3U+5Ui	32-bit complex unsigned integer (unsigned int on the target machine).
"Vector"	[1, 2] or BR Vector(2) [1, 2]	Vectors are lists of values. The individual elements of a vector do not need to be the same type, and can be of any supported type except vectors or matrices.

Target Language Expressions

You can include an expression of the form %<*expression*> in a target file. The Target Language Compiler replaces %<*expression*> with a calculated replacement value based upon the type of the variables within the %<> operator. Integer constant expressions are folded and replaced with the resultant value; string constants are concatenated (e.g., two strings in a row "a" "b", are replaced with "ab").

```
%<expression>                /* Evaluates the expression.
  * Operators include most standard C
  * operations on scalars. Array indexing
```

```
  * is required for certain parameters that
  * are block-scoped within the .rtw file.*/
```

Within the context of an expression, each identifier must evaluate to an identifier or function argument currently in scope. You can use the `%< >` directive on a line to perform text substitution. To include the `>` character within a replacement, you must escape it with a `\` character. For example:

```
%<x \> 1 ? "ABC" : "123">
```

Operators that need the `>` character to be escaped are the following:

Operator	Description	Example
`>`	greater than	`y = %<x \> 2>;`
`>=`	greater than or equal to	`y = %<x \>= 3>;`
`>>`	right shift	`y = %<x \>\> 4>;`

The table Target Language Expressions lists the operators that are allowed in expressions. In this table, expressions are listed in order from highest to lowest precedence. The horizontal lines distinguish the order of operations.

As in C expressions, conditional operators are short-circuited. If the expression includes a function call with effects, the effects are noticed as if the entire expression was not fully evaluated. For example:

```
%if EXISTS(foo) && foo == 3
```

If the first term of the expression evaluates to a Boolean false (i.e., `foo` does not exist), the second term (`foo == 3`) is not evaluated.

In the upcoming table, note that *`numeric`* is one of the following:

- `Boolean`
- `Number`
- `Unsigned`
- `Real`
- `Real32`
- `Complex`
- `Complex32`

- `Gaussian`
- `UnsignedGaussian`

Also, note that *`integral`* is one of the following:

- `Number`
- `Unsigned`
- `Boolean`

See “TLC Data Promotions” on page 18-25 for information on the promotions that result when the Target Language Compiler operates on mixed types of expressions.

Target Language Expressions

Expression	Definition
`constant`	Constant parameter value. The value can be a vector or matrix.
`variable-name`	Valid in-scope variable name, including the local function scope, if any, and the global scope.
`::variable-name`	Used within a function to indicate that the function scope is ignored when the variable is looked up. This accesses the global scope.
`expr[expr]`	Index into an array parameter. Array indices range from `0` to `N-1`. This syntax is used to index into vectors, matrices, and repeated scope variables.
`expr([expr[,expr]...])`	Function call or macro expansion. The expression outside the parentheses is the function/macro name; the expressions inside are the arguments to the function or macro. **Note:** Macros are text-based; they cannot be used within the same expression as other operators.
`expr . expr`	The first expression must have a valid scope; the second expression is a parameter name within that scope.
`(expr)`	Use `()` to override the precedence of operations.
`!expr`	Logical negation (generates `TLC_TRUE` or `TLC_FALSE`). The argument must be numeric or Boolean.
`-expr`	Unary minus negates the expression. The argument must be numeric.
`+expr`	No effect; the operand must be numeric.
`~expr`	Bit-wise negation of the operand. The argument must be an integer.
`expr * expr`	Multiplies the two expressions; the operands must be numeric.

Expression	Definition
`expr / expr`	Divides the two expressions; the operands must be numeric.
`expr % expr`	Takes the integer modulo of the expressions; the operands must be integers.
`expr + expr`	Works on numeric types, strings, vectors, matrices, and records as follows: **Numeric types:** Add the two expressions; the operands must be numeric. **Strings:** The strings are concatenated. **Vectors:** If the first argument is a vector and the second is a scalar, the scalar is appended to the vector. **Matrices:** If the first argument is a matrix and the second is a vector of the same column width as the matrix, the vector is appended as another row in the matrix. **Records:** If the first argument is a record, the second argument is added as a parameter identifier (with its current value). Note that the addition operator is associative.
`expr - expr`	Subtracts the two expressions; the operands must be numeric.
`expr << expr`	Left-shifts the left operand by an amount equal to the right operand; the arguments must be integers.
`expr >> expr`	Right-shifts the left operand by an amount equal to the right operand; the arguments must be integers.
`expr > expr`	Tests whether the first expression is greater than the second expression; the arguments must be numeric.
`expr < expr`	Tests whether the first expression is less than the second expression; the arguments must be numeric.

Expression	Definition
`expr >= expr`	Tests whether the first expression is greater than or equal to the second expression; the arguments must be numeric.
`expr <= expr`	Tests whether the first expression is less than or equal to the second expression; the arguments must be numeric.
`expr == expr`	Tests whether the two expressions are equal.
`expr != expr`	Tests whether the two expressions are not equal.
`expr & expr`	Performs the bit-wise AND of the two arguments; the arguments must be integers.
`expr ^ expr`	Performs the bit-wise XOR of the two arguments; the arguments must be integers.
`expr | expr`	Performs the bit-wise OR of the two arguments; the arguments must be integers.
`expr && expr`	Performs the logical AND of the two arguments and returns `TLC_TRUE` or `TLC_FALSE`. This can be used on either numeric or Boolean arguments.
`expr || expr`	Performs the logical OR of the two arguments and returns `TLC_TRUE` or `TLC_FALSE`. This can be used on either numeric or Boolean arguments.
`expr ? expr : expr`	Tests the first expression for `TLC_TRUE`. If true, the first expression is returned; otherwise, the second expression is returned.
`expr , expr`	Returns the value of the second expression.

Note Relational operators (`<, =<, >, >=, !=, ==`) can be used with nonfinite values.

You do not have to place expressions in the `%< >eval` format when they appear on directive lines. Doing so causes a double evaluation.

TLC Data Promotions

When the Target Language Compiler operates on mixed types of expressions, it promotes the results to the common types indicated in the following table.

The table uses the following abbreviations:

`B`	Boolean
`N`	Number
`U`	Unsigned
`F`	Real32
`D`	Real
`G`	Gaussian
`UG`	UnsignedGaussian
`C32`	Complex32
`C`	Complex

The top row (in bold) and first column (in bold) show the types of expression used in the operation. The intersection of the row and column shows the resulting type of expressions.

For example, if the operation involves a Boolean expression (`B`) and an unsigned expression (`U`), the result will be an unsigned expression (`U`).

Data Types Resulting from Expressions of Mixed Type

	B	**N**	**U**	**F**	**D**	**G**	**UG**	**C32**	**C**

Formatting

By default, the Target Language Compiler outputs floating-point numbers in exponential notation with 16 digits of precision. To override the default, use the directive

```
%realformat string
```

If *`string`* is `"EXPONENTIAL"`, the standard exponential notation with 16 digits of precision is used. If *`string`* is `"CONCISE"`, the compiler uses internal heuristics to output the values in a more readable form while maintaining accuracy. The `%realformat` directive sets the default format for `Real` number output to the selected style for the remainder of processing or until it encounters another `%realformat` directive.

Conditional Inclusion

The conditional inclusion directives are

```
%if constant-expression
%else
%elseif constant-expression
%endif

%switch constant-expression
%case constant-expression
%break
```

```
%default
%endswitch
```

%if

The `constant-expression` must evaluate to an integer expression. It controls the inclusion of the following lines until it encounters an `%else`, `%elseif`, or `%endif` directive. If the `constant-expression` evaluates to `0`, the lines following the directive are not included. If the `constant-expression` evaluates to an integer value other than `0`, the lines following the `%if` directive are included until the `%endif`, `%elseif`, or `%else` directive.

When the compiler encounters an `%elseif` directive, and no prior `%if` or `%elseif` directive has evaluated to nonzero, the compiler evaluates the expression. If the value is 0, the lines following the `%elseif` directive are not included. If the value is nonzero, the lines following the `%elseif` directive are included until the subsequent `%else`, `%elseif`, or `%endif` directive.

The `%else` directive begins the inclusion of source text if the previous `%elseif` statements or the original `%if` statement evaluates to `0`; otherwise, it prevents the inclusion of subsequent lines up to and including the following `%endif`.

The `constant-expression` can contain any expression specified in “Target Language Expressions” on page 18-19.

%switch

The `%switch` statement evaluates the constant expression and compares it to expressions appearing on `%case` selectors. If a match is found, the body of the `%case` is included; otherwise the `%default` is included.

`%case ... %default` bodies flow together, as in C, and `%break` must be used to exit the switch statement. `%break` exits the nearest enclosing `%switch`, `%foreach`, or `%for` loop in which it appears. For example,

```
%switch(type)
%case x
    /* Matches variable x. */
    /* Note: Any valid TLC type is allowed. */
%case "Sin"
    /* Matches Sin or falls through from case x. */
   %break
    /* Exits the switch. */
```

```
%case "gain"
    /* Matches gain. */
   %break
%default
    /* Does not match x, "Sin," or "gain." */
%endswitch
```

In general, this is a more readable form for the `%if/%elseif/%else` construction.

Multiple Inclusion

%foreach

The syntax of the `%foreach` multiple inclusion directive is

```
%foreach identifier = constant-expression
   %break
   %continue
%endforeach
```

The `constant-expression` must evaluate to an integer expression, which then determines the number of times to execute the `foreach` loop. The `identifier` increments from `0` to one less than the specified number. Within the `foreach` loop, you can use `x`, where `x` is the identifier, to access the identifier variable. `%break` and `%continue` are optional directives that you can include in the `%foreach` directive:

- Use `%break` to exit the nearest enclosing `%for`, `%foreach`, or `%switch` statement.
- Use `%continue` to begin the next iteration of a loop.

%for

Note The `%for` directive is functional, but it is not recommended. Instead, use `%roll`, which provides the same capability in a more open way. The code generator does not use the `%for` construct.

The syntax of the `%for` multiple inclusion directive is

```
%for ident1 = const-exp1, const-exp2, ident2 = const-exp3
  %body
    %break
    %continue
```

```
  %endbody
%endfor
```

The first portion of the `%for` directive is identical to the `%foreach` statement in that it causes a loop to execute from `0` to `N-1` times over the body of the loop. In the normal case, it includes only the lines between `%body` and `%endbody`, and the lines between the `%for` and `%body`, and ignores the lines between `%endbody` and `%endfor`.

The `%break` and `%continue` directives act the same as they do in the `%foreach` directive.

`const-exp2` is a Boolean expression that indicates whether the loop should be rolled. If `const-exp2` is true, `ident2` receives the value of `const-exp3`; otherwise it receives the null string. When the loop is rolled, the lines between the `%for` and the `%endfor` are included in the output exactly one time. `ident2` specifies the identifier to be used for testing whether the loop was rolled within the body. For example,

```
%for Index = <NumNonVirtualSubsystems>3, rollvar="i"

    {
        int i;

        for (i=0; i< %<NumNonVirtualSubsystems>; i++)
        {
          %body
    x[%<rollvar>] = system_name[%<rollvar>];
          %endbody

        }
    }
%endfor
```

If the number of nonvirtual subsystems (`NumNonVirtualSubsystems`) is greater than or equal to 3, the loop is rolled, causing the code within the loop to be generated exactly once. In this case, `Index = 0`.

If the loop is not rolled, the text before and after the body of the loop is ignored and the body is generated `NumNonVirtualSubsystems` times.

This mechanism gives each individual loop control over whether or not it should be rolled.

%roll

The syntax of the `%roll` multiple inclusion directive is

```
%roll ident1 = roll-vector-exp, ident2 = threshold-exp, ...
               block-exp [, type-string [,exp-list] ]
  %break
  %continue
%endroll
```

This statement uses the `roll-vector-exp` to expand the body of the `%roll` statement multiple times as in the `%foreach` statement. If a range is provided in the `roll-vector-exp`and that range is larger than the `threshold-exp` expression, the loop will roll. When a loop rolls, the body of the loop is expanded once and the identifier (`ident2`) provided for the threshold expression is set to the name of the loop control variable. If no range is larger than the specified rolling threshold, this statement is identical to the `%foreach` statement. For example,

```
%roll Idx = [ 1 2 3:5, 6, 7:10 ], lcv = 10, ablock
%endroll
```

In this case, the body of the `%roll` statement expands 10 times, as in the `%foreach` statement, because there are no regions greater than or equal to 10. `Idx` counts from 1 to 10, and `lcv` is set to the null string, `""`.

When the Target Language Compiler determines that a given block will roll, it performs a `GENERATE_TYPE` function call to output the various pieces of the loop (other than the body). The default type used is `Roller`; you can override this type with a string that you specify. Extra arguments passed to the `%roll` statement are provided as arguments to these special-purpose functions. The called function is one of these four functions:

RollHeader(block, ...)

This function is called once on the first section of this roll vector that will actually roll. It should return a string that is assigned to the `lcv` within the body of the `%roll` statement.

LoopHeader(block, StartIdx, Niterations, Nrolled, ...)

This function is called once for each section that will roll prior to the body of the `%roll` statement.

LoopTrailer(block, Startidx, Niterations, Nrolled, ...)

This function is called once for each section that will roll after the body of the `%roll` statement.

RollTrailer(block, ...)

This function is called once at the end of the `%roll` statement if any of the ranges caused loop rolling.

These functions should output language-specific declarations, loop code, and so on as required to generate code for the loop.

An example of a `Roller.tlc` file is

```
%implements Roller "C"
%function RollHeader(block) Output
    {
        int i;
    %return ("i")
%endfunction
%function LoopHeader(block,StartIdx,Niterations,Nrolled) Output
     for (i = %<StartIdx>; i < %<Niterations+StartIdx>; i++)
    {
%endfunction
%function LoopTrailer(block,StartIdx,Niterations,Nrolled) Output
    }
%endfunction
%function RollTrailer(block) Output
    }
%endfunction
```

Note The Target Language Compiler function library provided with the code generator has the capability to extract references to the block I/O and other code generator vectors that vastly simplify the body of the `%roll` statement. These functions include `LibBlockInputSignal`, `LibBlockOutputSignal`, `LibBlockParameter`, `LibBlockRWork`, `LibBlockIWork`, `LibBlockPWork`, `LibDeclareRollVars`, `LibBlockMatrixParameter`, `LibBlockParameterAddr`, `LibBlockContinuousState`, and `LibBlockDiscreteState`. (See the function reference pages in “Input Signal Functions” on page 21-7, “Output Signal Functions” on page 21-20, “Parameter Functions” on page 21-27, and “Block State and Work Vector Functions” on page 21-35.) This library also includes a default implementation of `Roller.tlc` as a “flat” roller.

Extending the former example to a loop that rolls,

```
%language "C"
%assign ablock = BLOCK { Name "Hi" }
%roll Idx = [ 1:20, 21, 22, 23:25, 26:46], lcv = 10, ablock
    Block[%< lcv == "" ? Idx : lcv>] *= 3.0;
%endroll
```

This Target Language Compiler code produces this output:

```
{
    int             i;
    for (i = 1; i < 21; i++)
    {
        Block[i] *= 3.0;
    }
    Block[21] *= 3.0;
    Block[22] *= 3.0;
    Block[23] *= 3.0;
    Block[24] *= 3.0;
    Block[25] *= 3.0;
    for (i = 26; i < 47; i++)
    {
        Block[i] *= 3.0;
    }
}
```

Object-Oriented Facility for Generating Target Code

The Target Language Compiler provides a simple object-oriented facility. The language directives are

```
%language string
%generatefile
%implements
```

This facility was designed specifically for customizing the code for Simulink blocks, but can be used for other purposes as well.

%language

The `%language` directive specifies the target language being generated. It is required as a consistency check to verify the implementation files found for the language being generated. The `%language` directive must appear prior to the first `GENERATE` or `GENERATE_TYPE` built-in function call. `%language` specifies the language as a string. For example:

```
%language "C"
```

Simulink blocks have a `Type` parameter. This parameter is a string that specifies the type of the block, for example `"Sin"` or `"Gain"`. The object-oriented facility uses this type to search the path for a file that implements the block. By default the name of the file is the `Type` of the block with `.tlc` appended, so for example, if the `Type` is `"Sin"` the Compiler would search for `"Sin.tlc"` along the path. You can override this default filename using the `%generatefile` directive to specify the filename that you want to use to replace the default filename. For example,

```
%generatefile "Sin" "sin_wave.tlc"
```

The files that implement the block-specific code must contain an `%implements` directive indicating both the type and the language being implemented. The Target Language Compiler will produce an error if the `%implements` directive does not match as expected. For example,

```
%implements "Sin" "Pascal"
```

causes an error if the initial language choice was C.

You can use a single file to implement more than one target language by specifying the desired languages in a vector. For example,

```
%implements "Sin" "C"
```

Finally, you can implement several types using the wildcard (*) for the type field:

```
%implements * "C"
```

Note The use of the wildcard (*) is not recommended because it relaxes error checking for the `%implements` directive.

GENERATE and GENERATE_TYPE Functions

The Target Language Compiler has two built-in functions that dispatch object-oriented calls, `GENERATE` and `GENERATE_TYPE`. You can call a function appearing in an implementation file (from outside the specified file) only by using the `GENERATE` and `GENERATE_TYPE` special functions.

GENERATE

The GENERATE function takes two or more input arguments. The first argument must be a valid scope and the second a string containing the name of the function to call. The GENERATE function passes the first block argument and any additional arguments specified to the function being called. The return argument is the value, if any, returned from the function being called. Note that the compiler automatically "scopes" or adds the first argument to the list of scopes searched as if it appears on a `%with` directive line. (See "Variable Scoping" on page 18-53.) This scope is removed when the function returns.

GENERATE_TYPE

The GENERATE_TYPE function takes three or more input arguments. It handles the first two arguments identically to the GENERATE function call. The third argument is the type; the type specified in the Simulink block is ignored. This facility is used to handle S-function code generation by the build process. That is, the block type is `S-function`, but the Target Language Compiler generates it as the specific S-function specified by GENERATE_TYPE. For example,

```
GENERATE_TYPE(block, "Output", "dp_read")
```

specifies that S-function `block` is of type `dp_read`.

The `block` argument and any additional arguments are passed to the function being called. Like the GENERATE built-in function, the compiler automatically scopes the first argument before the GENERATE_TYPE function is entered and then removes the scope on return.

Within the file containing `%implements`, function calls are looked up first within the file and then in the global scope. This makes it possible to have hidden helper functions used exclusively by the current object.

Note It is not an error for the GENERATE and GENERATE_TYPE directives to find no matching functions. This is to prevent requiring empty specifications for all aspects of block code generation. Use the GENERATE_FUNCTION_EXISTS or GENERATE_TYPE_FUNCTION_EXISTS directives to determine whether the specified function actually exists.

Output File Control

The structure of the output file control construct is

```
%openfile string optional-equal-string optional-mode
%closefile id
%selectfile id
```

%openfile

The `%openfile` directive opens a file or buffer for writing; the required string variable becomes a variable of type `file`. For example,

```
%openfile x               /% Opens and selects x for writing. %/
%openfile out = "out.h"   /% Opens "out.h" for writing. %/
```

%selectfile

The `%selectfile` directive selects the file specified by the variable as the current output stream. Output goes to that file until another file is selected using `%selectfile`. For example,

```
%selectfile x               /% Select file x for output. %/
```

%closefile

The `%closefile` directive closes the specified file or buffer. If the closed entity is the currently selected output stream, `%closefile` invokes `%selectfile` to reselect the previously selected output stream.

There are two possible cases that `%closefile` must handle:

- If the stream is a file, the associated variable is removed as if by `%undef`.
- If the stream is a buffer, the associated variable receives the text that has been output to the stream. For example,

  ```
  %assign x = ""                /% Creates an empty string. %/
  %openfile x
  "hello, world"
  %closefile x         /% x = "hello, world\n"%/
  ```

If desired, you can append to an output file or string by using the optional mode, `a`, as in

```
%openfile "foo.c", "a"             %% Opens foo.c for appending.
```

Input File Control

The input file control directives are

```
%include string
%addincludepath string
```

%include

The `%include` directive searches the path for the target file specified by `string` and includes the contents of the file inline at the point where the `%include` statement appears.

%addincludepath

The `%addincludepath` directive adds an additional include path to be searched when the Target Language Compiler references `%include` or block target files. The syntax is

```
%addincludepath string
```

The `string` can be an absolute path or an explicit relative path. For example, to specify an absolute path, use

```
%addincludepath "C:\\folder1\\folder2"     (PC)
%addincludepath "/folder1/folder2"         (UNIX)
```

To specify a relative path, the path must explicitly start with `.`. For example,

```
%addincludepath ".\\folder2"                  (PC)
%addincludepath "./folder2"                   (UNIX)
```

Note that for PC, the backslashes must be escaped (doubled).

When an explicit relative path is specified, the folder that is added to the Target Language Compiler search path is created by concatenating the location of the target file that contains the `%addincludepath` directive and the explicit relative path.

The Target Language Compiler searches the folders in the following order for target or include files:

1. The current folder.
2. Include paths specified in `%addincludepath` directives. The compiler evaluates multiple `%addincludepath` directives from the *bottom up*.

3 Include paths specified at the command line via `-I` . The compiler evaluates multiple `-I` options from *right to left*.

Typically, `%addincludepath` directives should be specified in your system target file. Multiple `%addincludepath` directives will add multiple paths to the Target Language Compiler search path.

Note The compiler does *not* search the MATLAB path, and will not find a file that is available only on that path. The compiler searches only the locations described above.

Asserts, Errors, Warnings, and Debug Messages

The related assert, error, warning, and debug message directives are

```
%assert expression
%error tokens
%warning tokens
%trace tokens
%exit tokens
```

These directives produce error, warning, or trace messages whenever a target file detects an error condition, or tracing is desired. The tokens following the directive on a line become part of the generated error or warning message.

The Target Language Compiler places messages generated by `%trace` onto `stderr` if and only if you specify the verbose mode switch (`-v`) to the Target Language Compiler. See “Command-Line Arguments” on page 18-66 for additional information about switches.

The `%assert` directive evaluates the expression and produces a stack trace if the expression evaluates to a Boolean `false`.

Note In order for `%assert` directives to be evaluated, **Enable TLC assertion** must be selected in the **TLC process** section of the **Code Generation** > **Debug** pane. The default action is for `%assert` directives not to be evaluated.

The `%exit` directive reports an error and stops further compilation.

Built-In Functions and Values

The following table lists the built-in functions and values that are added to the list of parameters that appear in the *`model`*`.rtw` file. These Target Language Compiler functions and values are defined in uppercase so that they are visually distinct from other parameters in the *`model`*`.rtw` file, and, by convention, from user-defined parameters.

TLC Built-In Functions and Values

Built-In Function Name	Expansion
`CAST(expr, expr)`	The first expression must be a string that corresponds to one of the type names in the table “Target Language Value Types” on page 18-18, and the second expression will be cast to that type. A typical use might be to cast a variable to a real format as in `CAST("Real", variable-name)` An example of this is in working with parameter values for S-functions. To use them within C or C++ code, you need to typecast them to `real` so that a value such as `1` will be formatted as `1.0` (see also `%realformat`).
`EXISTS(var)`	If the `var` identifier is not currently in scope, the result is `TLC_FALSE`. If the identifier is in scope, the result is `TLC_TRUE`. `var` can be a single identifier or an expression involving the `.` and `[]` operators.

`FEVAL(matlab-command, TLC-expressions)`	Performs an evaluation in MATLAB. For example,
	`%assign result = FEVAL("sin",3.14159)`
	The `%matlab` directive can be used to call a MATLAB function that does not return a result. For example,
	`%matlab disp(2.718)`
	Note: If the MATLAB function returns more than one value, TLC receives the first value only.

`FILE_EXISTS(expr)`	`expr` must be a string. If a file by the name `expr` does not exist on the path, the result is `TLC_FALSE`. If a file by that name exists on the path, the result is `TLC_TRUE`.
`FORMAT(realvalue, format)`	The first expression is a `Real` value to format. The second expression is either `EXPONENTIAL` or `CONCISE`. Outputs the `Real` value in the designated format, where `EXPONENTIAL` uses exponential notation with 16 digits of precision, and `CONCISE` outputs the number in a more readable format while maintaining numerical accuracy.

Built-In Function Name	Expansion
`FIELDNAMES(record)`	Returns an array of strings containing the record field names associated with the record. Because it returns a sorted list of strings, the function is `O(n*log(n))`.
`GETFIELD(record, "fieldname")`	Returns the contents of the specified field name, if the field name is associated with the record. The function uses hash lookup, and therefore executes in constant time.
`GENERATE(record, function-name, ...)`	Executes function calls mapped to a specific record type (i.e., block record functions). For example, use this to execute the functions in the `.tlc` files for built-in blocks. Not that TLC automatically “scopes” or adds the first argument to the list of scopes searched as if it appears on a `%with` directive line.
`GENERATE_FILENAME(type)`	For the specified record type, does a `.tlc` file exist? Use this to see if the `GENERATE_TYPE` call will succeed.

Built-In Function Name	Expansion

`GENERATE_FORMATTED_VALUE (expr, string, expand)`	Returns a potentially multiline string that can be used to declare the value(s) of `expr` in the current target language. The second argument is a string that is used as the variable name in a descriptive comment on the first line of the return string. If the second argument is the empty string, `""`, then no descriptive comment is put into the output string. The third argument is a Boolean that when `TRUE` causes `expr` to be expanded into raw text before being output. `expand = TRUE` uses much more memory than the default (`FALSE`); set `expand = TRUE` only if the parameter text needs to be processed for some reason before being written to disk.
	
	For example,
	
	`static const unsigned char contents[] =`
	
	`%assign value = GENERATE_FORMATTED_VALUE(SFcnParamSettings.CONTENTS, "", TLC_FALSE)`
	
	`;`
	
	yields this C code:
	
	`static const unsigned char contents[] = { 0U, 1U, 2U, 3U, 4U };`

`GENERATE_FUNCTION_EXISTS (record, function-name)`	Determines whether a given block function exists. The first expression is the same as the first argument to `GENERATE`, namely a block scoped variable containing a `Type`. The second expression is a string that should match the function name.
`GENERATE_TYPE (record, function-name, type, ...)`	Similar to `GENERATE`, except that `type` overrides the `Type` field of the record. Use this when executing functions mapped to specific S-function block records based upon the S-function name (i.e., the name becomes the type).
`GENERATE_TYPE_FUNCTION_EXISTS (record, function-name, type)`	Same as `GENERATE_FUNCTION_EXISTS` except that it overrides the `Type` built into the record.

Built-In Function Name	Expansion
GET_COMMAND_SWITCH	Returns the values of command-line switches. Only the following switches are supported: v, m, p, O, d, dr, r, I, a See also “Command-Line Arguments” on page 18-66.
IDNUM(expr)	expr must be a string. The result is a vector where the first element is a leading string, if any, and the second element is a number appearing at the end of the input string. For example, IDNUM("ABC123") yields ["ABC", 123]
IMAG(expr)	Returns the imaginary part of a complex number.
INT8MAX	127
INT8MIN	-128
INT16MAX	32767
INT16MIN	-32768
INT32MAX	2147483647
INT32MIN	-2147483648
INTMIN	Minimum integer value on host machine.
INTMAX	Maximum integer value on host machine.
ISALIAS(record)	Returns TLC_TRUE if the record is a reference (symbolic link) to a different record, and TLC_FALSE otherwise.
ISEQUAL(expr1, expr2)	Where the data types of both expressions are numeric: returns TLC_TRUE if the first expression contains the same value as the second expression; returns TLC_FALSE otherwise. Where the data type of either expression is nonnumeric (e.g., string or record): returns TLC_TRUE if and only if both expressions have the same data type and contain the same value; returns TLC_FALSE otherwise.
ISEMPTY(expr)	Returns TLC_TRUE if the expression contains an empty string, vector, or record, and TLC_FALSE otherwise.
ISFIELD(record, "fieldname")	Returns TLC_TRUE if the field name is associated with the record, and TLC_FALSE otherwise.

Built-In Function Name	Expansion
ISINF(expr)	Returns TLC_TRUE if the value of the expression is inf, and TLC_FALSE otherwise.
ISNAN(expr)	Returns TLC_TRUE if the value of the expression is NAN, and TLC_FALSE otherwise.
ISFINITE(expr)	Returns TLC_TRUE if the value of the expression is not +/- inf or NAN, and TLC_FALSE otherwise.

ISSLPRMREF(param.value)	Returns a Boolean value indicating whether its argument is a reference to a Simulink parameter or not. This function supports parameter sharing with Simulink; using it can save memory and time during code generation. For example,
	`%if !ISSLPRMREF(param.Value)`
	`  assign param.Value = CAST("Real", param.Value)`
	`%endif`

NULL_FILE	A predefined file for no output that you can use as an argument to %selectfile to prevent output.
NUMTLCFILES	The number of target files used thus far in expansion.
OUTPUT_LINES	Returns the number of lines that have been written to the currently selected file or buffer. Does not work for STDOUT or NULL_FILE.
REAL(expr)	Returns the real part of a complex number.
REMOVEFIELD(record, "fieldname")	Removes the specified field from the contents of the record. Returns TLC_TRUE if the field was removed; otherwise returns TLC_FALSE.
ROLL_ITERATIONS()	Returns the number of times the current roll regions are looping or NULL if not inside a %roll construct.
SETFIELD(record, "fieldname", value)	Sets the contents of the field name associated with the record. Returns TLC_TRUE if the field was added; otherwise returns TLC_FALSE.

Built-In Function Name	Expansion
SIZE(expr[,expr])	Calculates the size of the first expression and generates a two-element row vector. If the second operand is specified, it is used as an integer index into this row vector; otherwise the entire row vector is returned. SIZE(x) applied to a scalar returns [1 1]. SIZE(x) applied to a scope returns the number of repeated entries of that scope type. For example, SIZE(Block) returns [1,<number of blocks>]
SPRINTF(format,var,...)	Formats the data in variable var (and in any additional variable arguments) under control of the specified format string, and returns a string variable containing the values. Operates like the C library sprintf(), except that output is the return value rather than contained in an argument to sprintf.
STDOUT	A predefined file for stdout output. You can use this as an argument to %selectfile to force output to stdout.
STRING(expr)	Expands the expression into a string; the characters \, \n, and " are escaped by preceding them with \ (backslash). The ANSI escape sequences are translated into string form. If %<> is in the expression, it is escaped so that the enclosed string is not subject to further TLC interpretation.
STRINGOF(expr)	Accepts a vector of ASCII values and returns a string that is constructed by treating each element as the ASCII code for a single character. Used primarily for S-function string parameters.

Built-In Function Name	Expansion
SYSNAME(expr)	Looks for specially formatted strings of the form <x>/y and returns x and y as a two-element string vector. This is used to resolve subsystem names. For example, %<sysname("<sub>/Gain")> returns ["sub","Gain"] In Block records, the name of the block is written <*sys*/blockname>, where *sys* is S# or Root. You can obtain the full path name by calling LibGetBlockPath(block); this will include newlines and other troublesome characters that cause display difficulties. To obtain a full path name suitable for one-line comments but not identical to the Simulink path name, use LibGetFormattedBlockPath(block).
TLCFILES	Returns a vector containing the names of the target files included thus far in the expansion. Absolute paths are used. See also NUMTLCFILES.
TLC_FALSE	Boolean constant that equals a negative evaluated Boolean expression.
TLC_TRUE	Boolean constant that equals a positive evaluated Boolean expression.
TLC_TIME	Date and time of compilation.
TLC_VERSION	Version and date of the Target Language Compiler.
TYPE(expr)	Evaluates expr and determines the result type. The result of this function is a string that corresponds to the type of the given expression. See the **Value Type String** column in the table "Target Language Value Types" on page 18-18 for possible values.
UINT8MAX	255U
UINT16MAX	65535U
UINT32MAX	4294967295U
UINTMAX	Maximum unsigned integer value on host machine.

Built-In Function Name	Expansion
`WHITE_SPACE(expr)`	Accepts a string and returns 1 if the string contains only white-space characters (, `\t`, `\n`, `\r`); returns 0 otherwise.
`WILL_ROLL(expr1, expr2)`	The first expression is a roll vector and the second expression is a roll threshold. This function returns `true` if the vector contains a range that will roll.

FEVAL Function

The `FEVAL` built-in function calls MATLAB file functions and MEX-functions. The structure is

```
%assign result = FEVAL( matlab-function-name, rhs1, rhs2, ...
    rhs3, ... );
```

Note

- Only a single left-side argument is allowed when you use `FEVAL`.
- If your MATLAB function evaluation leads to an error, the TLC compiler does not terminate but continues with the execution. The FEVAL directive returns an empty value to the TLC.

This table shows the conversions that are made when you use `FEVAL`.

MATLAB Conversions

TLC Type	MATLAB Type
`"Boolean"`	`Boolean` (scalar or matrix)
`"Number"`	`Double` (scalar or matrix)
`"Real"`	`Double` (scalar or matrix)
`"Real32"`	`Double` (scalar or matrix)
`"Unsigned"`	`Double` (scalar or matrix)
`"String"`	`String`
`"Vector"`	If the vector is homogeneous, it is converted to a MATLAB vector. If the vector is heterogeneous, it is converted to a MATLAB cell array.
`"Gaussian"`	`Complex` (scalar or matrix)
`"UnsignedGaussian"`	`Complex` (scalar or matrix)
`"Complex"`	`Complex` (scalar or matrix)
`"Complex32"`	`Complex` (scalar or matrix)
`"Identifier"`	`String`
`"Subsystem"`	`String`
`"Range"`	Expanded vector of `Doubles`
`"Idrange"`	Expanded vector of `Doubles`
`"Matrix"`	If the matrix is homogeneous, it is converted to a MATLAB matrix. If the matrix is heterogeneous, it is converted to a MATLAB cell array. (Cell arrays can be nested.)
`"Scope"` or `"Record"`	Structure with elements
`Scope` or `Record` alias	String containing fully qualified alias name
`Scope` or `Record` array	Cell array of structures
Other type not listed above	Conversion not supported

When values are returned from MATLAB, they are converted as shown in this table. Note that conversion of matrices with more than two dimensions is not supported, nor is conversion or downcast of 64-bit integer values.

More Conversions

MATLAB Type	TLC Type
`String`	`String`
`Vector of Strings`	Vector of Strings
`Boolean (scalar or matrix)`	`Boolean` (scalar or matrix)
`INT8,INT16,INT32 (scalar or matrix)`	`Number` (scalar or matrix)
`INT64`	Not supported
`UINT64`	Not supported
`Complex INT8,INT16,INT32 (scalar or matrix)`	Gaussian (scalar or matrix)
`UINT8,UINT16,UINT32 (scalar or matrix)`	`Unsigned` (scalar or matrix)
`Complex UINT8,UINT16,UINT32 (scalar or matrix)`	`UnsignedGaussian` (scalar or matrix)
`Single precision`	`Real32` (scalar or matrix)
`Complex single precision`	`Complex32` (scalar or matrix)
`Double precision`	`Real` (scalar or matrix)
`Complex double precision`	`Complex` (scalar or matrix)
`Sparse matrix`	Expanded to matrix of `Doubles`
`Cell array of structures`	Record array
`Cell array of non-structures`	Vector or matrix of types converted from the types of the elements
`Cell array of structures and non-structures`	Conversion not supported
`Structure`	`Record`
`Object`	Conversion not supported

Other value types are not currently supported.

As an example, this statement uses the `FEVAL` built-in function to call MATLAB to take the sine of the input argument.

```
%assign result = FEVAL( "sin", 3.14159 )
```

Variables (identifiers) can take on the following constant values. Note the suffix on the value .

Constant Form	TLC Type
`1.0`	`"Real"`
`1.0[F/f]`	`"Real32"`
`1`	`"Number"`
`1[U|u]`	`"Unsigned"`
1.0i	`"Complex"`
`1[Ui|ui]`	`"UnsignedGaussian"`
`1i`	`"Gaussian"`
`1.0[Fi|fi]`	`"Complex32"`

Note The suffix controls the Target Language Compiler type obtained from the constant.

This table shows Target Language Compiler constants and their equivalent MATLAB values.

TLC Constants	Equivalent MATLAB Value
`rtInf`, `Inf`, `inf`	`+inf`
`rtMinusInf`	`-inf`
`rtNan`, `NaN`, `nan`	`nan`
`rtInfi`, `Infi`, `infi`	`inf*i`
`rtMinusInfi`	`-inf*i`
`rtNaNi`, `NaNi`, `nani`	`nan*i`

TLC Reserved Constants

For double-precision values, the following are defined for infinite and not-a-number IEEE® values:

```
rtInf, inf, rtMinusInf, -inf, rtNaN, nan
```

For single-precision values, these constants apply:

```
rtInfF, InfF, rtMinusInfF, rtNaNF, NaNF
```

Their corresponding versions when complex are:

```
rtInfi, infi, rtMinusInfi, -infi, rtNaNi (for doubles)
rtInfFi, InfFi, rtMinusInfFi, rtNaNFi, NaNFi (for singles)
```

For integer values, the following are defined:

```
INT8MIN, INT8MAX, INT16MIN, INT16MAX, INT32MIN, INT32MAX,
UINT8MAX, UINT16MAX, UINT32MAX, INTMAX, INTMIN, UINTMAX
```

Identifier Definition

To define or change identifiers (TLC variables), use the directive

```
%assign [::]expression = constant-expression
```

This directive introduces new identifiers (variables) or changes the values of existing ones. The left side can be a qualified reference to a variable using the `.` and `[]` operators, or it can be a single element of a vector or matrix. In the case of the matrix, only the single element is changed by the assignment.

The `%assign` directive inserts new identifiers into the local function scope, file function scope, generate file scope, or into the global scope. Identifiers introduced into the function scope are not available within functions being called, and are removed upon return from the function. Identifiers inserted into the global scope are persistent. You can change existing identifiers by completely respecifying them. The constant expressions can include legal identifiers from the `.rtw` files. You can use `%undef` to delete identifiers in the same way that you use it to remove macros.

Within the scope of a function, variable assignments create new local variables unless you use the `::` scope resolution operator. In this example, the assignment creates a variable `foo`, local to the function, that will disappear when the function exits.

```
%function ...
...
%assign foo = 3
...
%endfunction
```

Note that `foo` is created even if a global `foo` already exists.

To create or change values in the global scope, you must use the scope resolution operator (`::`) to disambiguate, as in

```
%function ...
%assign foo = 3
%assign ::foo = foo
...
%endfunction
```

The scope resolution operator forces the compiler to assign the value of the local variable `foo`, 3, to the global variable `foo`.

Note It is an error to change a value from the code generator file without qualifying it with the scope. This example does not generate an error:

```
    %assign CompiledModel.name = "newname"    %% No error
```

This example generates an error:

```
%with CompiledModel
  %assign name = "newname"       %% Error     %endwith
```

Creating Records

Use the `%createrecord` directive to build new records in the current scope. For example, if you want to create a new record called `Rec` that contains two items (e.g., `Name "Name"` and `Type "t"`), use

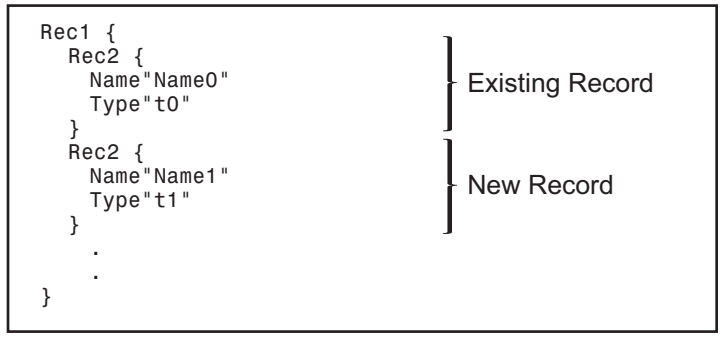
```
%createrecord Rec {  Name "Name"; Type "t" }
```

Adding Records

Use the `%addtorecord` directive to add new records to existing records. For example, if you have a record called `Rec1` that contains a record called `Rec2`, and you want to add an additional `Rec2` to it, use

```
%addtorecord Rec1 Rec2 {  Name "Name1"; Type "t1" }
```

This figure shows the result of adding the record to the existing one.



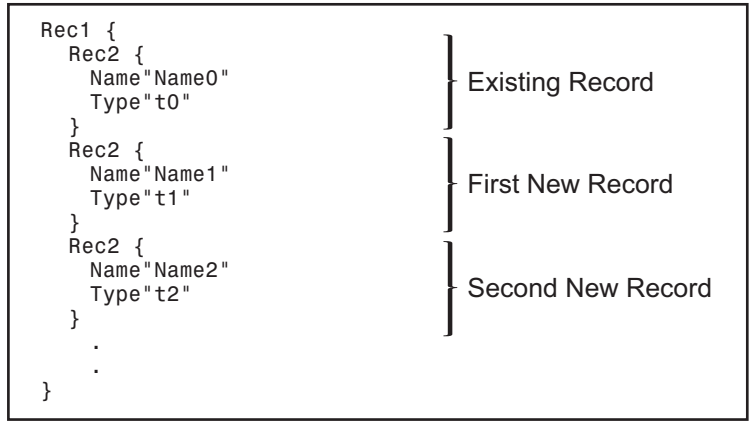
If you want to access the new record, you can use

```
%assign myname = Rec1.Rec2[1].Name
```

In this same example, if you want to add two records to the existing record, use

```
%addtorecord Rec1 Rec2 {  Name "Name1"; Type "t1" }
%addtorecord Rec1 Rec2 {  Name "Name2"; Type "t2" }
```

This produces

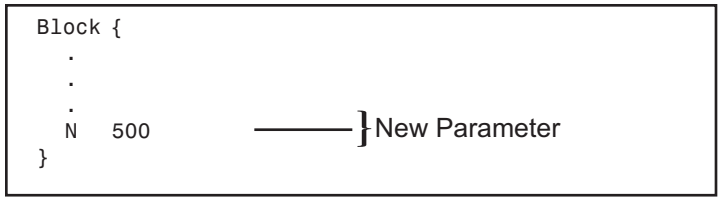


Adding Parameters to an Existing Record

You can use the `%assign` directive to add a new parameter to an existing record. For example,

```
%addtorecord Block[Idx] N 500 /% Adds N with value 500 to Block %/
%assign myn = Block[Idx].N    /% Gets the value 500 %/
```

adds a new parameter, `N`, at the end of an existing block with the name and current value of an existing variable, as shown in this figure. It returns the block value.



Variable Scoping

This section discusses how the Target Language Compiler resolves references to variables (including records).

Scope, in this document, has two related meanings. First, scope is an attribute of a variable that defines its visibility and persistence. For example, a variable defined within the body of a function is visible only within that function, and it persists only as long as that function is executing. Such a variable has function (or local) scope. Each TLC variable has one (and only one) of the scopes described in “Scopes” on page 18-53.

The term scope also refers to a collection, or pool, of variables that have the same scope. At a given point in the execution of a TLC program, several scopes can exist. For example, during execution of a function, a function scope (the pool of variables local to the function) exists. In all cases, a global scope (the pool of global variables) also exists.

To resolve variable references, TLC maintains a search list of current scopes and searches them in a well-defined sequence. The search sequence is described in “How TLC Resolves Variable References” on page 18-58.

Dynamic scoping refers to the process by which TLC creates and deallocates variables and the scopes in which they exist. For example, variables in a function scope exist only while the defining function executes.

Scopes

The following sections describe the possible scopes that a TLC variable can have.

Global Scope

By default, TLC variables have global scope. Global variables are visible to, and can be referenced by, code anywhere in a TLC program. Global variables persist throughout the execution of the TLC program. Global variables are said to belong to the global pool.

Note that the `CompiledModel` record of the *`model`*`.rtw` file has global scope. Therefore, you can access this structure from your TLC functions or files.

You can use the scope resolution operator (`::`) to explicitly reference or create global variables from within a function. See “The Scope Resolution Operator” on page 18-58 for examples.

Note that you can use the `%undef` directive to free memory used by global variables.

File Scope

Variables with file scope are visible only within the file in which they are created. To limit the scope of variables in this way, use the `%filescope` directive anywhere in the defining file.

In the following code fragment, the variables `fs1` and `fs2` have file scope. Note that the `%filescope` directive does not have to be positioned before the statements that create the variables.

```
%assign fs1 = 1
%filescope
%assign fs2 = 3
```

Variables whose scope is limited by `%filescope` go out of scope when execution of the file containing them completes. This lets you free memory allocated to such variables.

Function (Local) Scope

Variables defined within the body of a function have function scope. That is, they are visible within and local to the defining function. For example, in the following code fragment, the variable `localv` is local to the function `foo`. The variable `x` is global.

```
%assign x = 3

%function foo(arg)
   %assign localv = 1
   %return x + localv
%endfunction
```

A local variable can have the same name as a global variable. To refer, within a function, to identically named local and global variables, you must use the scope resolution operator (`::`) to disambiguate the variable references. See “The Scope Resolution Operator” on page 18-58 for examples.

Note Functions themselves (as opposed to the variables defined within functions) have global scope. There is one exception: functions defined in generate scope are local to that scope. See “Generate Scope” on page 18-55.

%with Scope

The `%with` directive adds a new scope, referred to as a *`%with scope`*, to the current list of scopes. This directive makes it easier to refer to block-scoped variables.

The structure of the `%with` directive is

```
%with expression
%endwith
```

For example, the directive

```
%with CompiledModel.System[sysidx]
   ...
%endwith
```

adds the `CompiledModel.System[sysidx]` scope to the search list. This scope is searched before anything else. You can then refer to the system name simply by

```
Name
```

instead of

```
CompiledModel.System[sysidx].Name
```

Generate Scope

Generate scope is a special scope used by certain built-in functions that are designed to support code generation. These functions dispatch function calls that are mapped to a specific record type. This capability supports a type of polymorphism in which different record types are associated with functions (analogous to methods) of the same name. Typically, this feature is used to map `Block` records to functions that implement the functionality of different block types.

Functions that employ generate scope include GENERATE, GENERATE_TYPE, GENERATE_FUNCTION_EXISTS, and GENERATE_TYPE_FUNCTION_EXISTS. See “GENERATE and GENERATE_TYPE Functions” on page 18-33. This section discusses generate scope using the GENERATE built-in function as an example.

The syntax of the GENERATE function is

```
GENERATE(blk,fn)
```

The first argument (blk) to GENERATE is a valid record name. The second argument (fn) is the name of a function to be dispatched. When a function is dispatched through a GENERATE call, TLC automatically adds blk to the list of scopes that is searched when variable references are resolved. Thus the record (blk) is visible to the dispatched function as if an implicit %with <blk>... %endwith directive existed in the dispatched function.

In this context, the record named blk is said to be in generate scope.

Three TLC files, illustrating the use of generate scope, are listed below. The file polymorph.tlc creates two records representing two hypothetical block types, MyBlock and YourBlock. Each record type has an associated function named aFunc. The block-specific implementations of aFunc are contained in the files MyBlock.tlc and YourBlock.tlc.

Using GENERATE calls, polymorph.tlc dispatches to a function for each block type. Notice that the aFunc implementations can refer to the fields of MyBlock and YourBlock, because these records are in generate scope.

- The following listing shows polymorph.tlc:

```
%% polymorph.tlc

%language "C"

%%create records used as scopes within dispatched functions

%createrecord MyRecord { Type "MyBlock"; data 123 }
%createrecord YourRecord { Type "YourBlock"; theStuff 666 }

%% dispatch the functions thru the GENERATE call.

%% dispatch to MyBlock implementation
%<GENERATE(MyRecord, "aFunc")>
```

```
%% dispatch to YourBlock implementation
%<GENERATE(YourRecord, "aFunc")>

%% end of polymorph.tlc
```

- The following listing shows `MyBlock.tlc`:

```
%%MyBlock.tlc

%implements "MyBlock" "C"

%% aFunc is invoked thru a GENERATE call in polymorph.tlc.
%% MyRecord is in generate scope in this function.
%% Therefore, fields of MyRecord can be referenced without
%% qualification

%function aFunc(r) Output
%selectfile STDOUT
The value of MyRecord.data is: %<data>
%closefile STDOUT
%endfunction

%%end of MyBlock.tlc
```

- The following listing shows `YourBlock.tlc`:

```
%%YourBlock.tlc

%implements "YourBlock" "C"

%% aFunc is invoked thru a GENERATE call in polymorph.tlc.
%% YourRecord is in generate scope in this function.
%% Therefore, fields of YourRecord can be referenced without
%% qualification

%function aFunc(r) Output
%selectfile STDOUT
The value of YourRecord.theStuff is: %<theStuff>
%closefile STDOUT
%endfunction

%%end of YourBlock.tlc
```

The invocation and output of `polymorph.tlc`, as displayed in the MATLAB Command Window, are shown below:

```
tlc -v polymorph.tlc

The value of MyRecord.data is: 123
The value of YourRecord.theStuff is: 666
```

Note Functions defined in generate scope are local to that scope. This is an exception to the general rule that functions have global scope. In the above example, for instance, neither of the `aFunc` implementations has global scope.

The Scope Resolution Operator

The scope resolution operator (`::`) is used to indicate that the global scope should be searched when a TLC function looks up a variable reference. The scope resolution operator is often used to change the value of global variables (or even create global variables) from within functions.

By using the scope resolution operator, you can resolve ambiguities that arise when a function references identically named local and global variables. In the following example, a global variable `foo` is created. In addition, the function `myfunc` creates and initializes a local variable named `foo`. The function `myfunc` explicitly references the global variable `foo` by using the scope resolution operator.

```
%assign foo = 3   %% this variable has global scope
.
.
.
%function myfunc(arg)
   %assign foo = 3   %% this variable has local scope
   %assign ::foo = arg   %% this changes the global variable foo
%endfunction
```

You can also use the scope resolution operator within a function to create global variables. The following function creates and initializes a global variable:

```
%function sideffect(arg)
   %assign ::theglobal = arg   %% this creates a global variable
%endfunction
```

How TLC Resolves Variable References

This section discusses how the Target Language Compiler searches the existing scopes to resolve variable references.

Global Scope

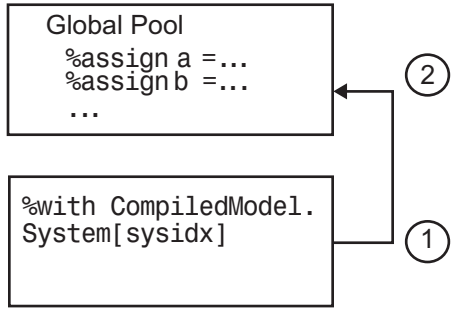
In the simplest case, the Target Language Compiler resolves a variable reference by searching the global pool (including the `CompiledModel` structure).

%with Scope

You can modify the search list and search sequence by using the `%with` directive. For example, when you add the following construct,

```
%with CompiledModel.System[sysidx]
   ...
%endwith
```

the `System[sysidx]` scope is added to the search list. This scope is searched first, as shown by this picture.



This technique makes it simpler to access embedded definitions. Using the `%with` construct (as in the previous example), you can refer to the system name simply by

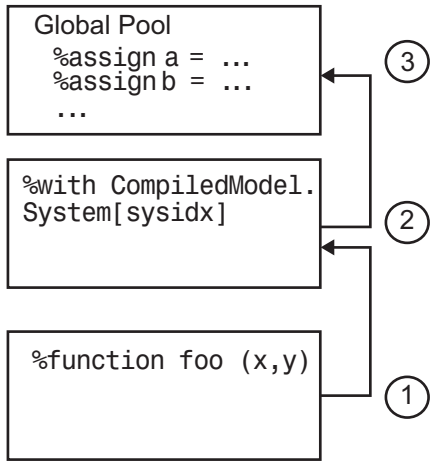
```
Name
```

instead of

```
CompiledModel.System[sysidx].Name
```

Function Scope

A function has its own scope. That scope is added to the previously described search list, as shown in this diagram.

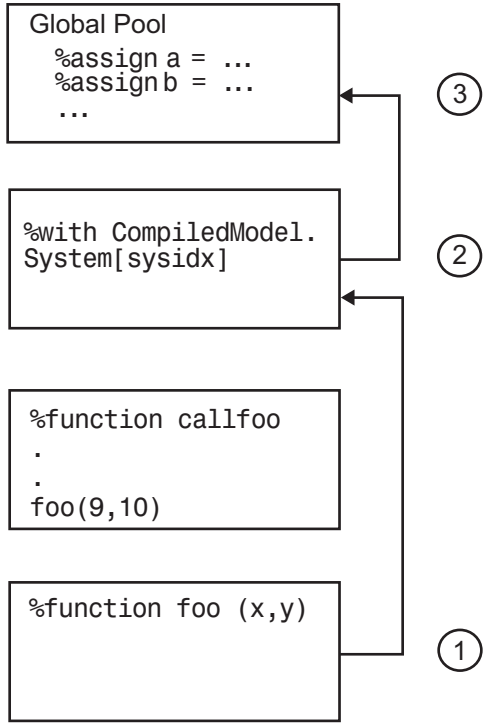


For example, in the following code fragment,

```
% with CompiledModel.System[sysidx]
...
   %assign a=foo(x,y)
...
%endwith
...
%function foo(a,b)
...
   assign myvar=Name
...
%endfunction
...
%<foo(1,2)>
```

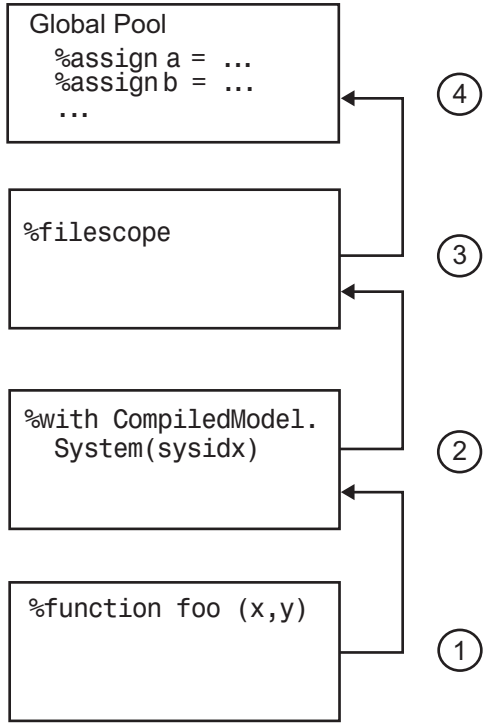
If `Name` is not defined in `foo`, the assignment uses the value of `Name` from the previous scope, `CompiledModel.System[SysIdx].Name`.

In a nested function, only the innermost function scope is searched, together with the enclosing `%with` and global scopes, as shown in the following diagram:



File Scope

File scopes are searched before the global scope, as shown in the following diagram.



The rule for nested file scopes is similar to that for nested function scopes. In the case of nested file scopes, only the innermost nested file scope is searched.

Target Language Functions

The target language function construct is

```
%function identifier ( optional-arguments ) [Output | void]
%return
%endfunction
```

Functions in the target language are recursive and have their own local variable space. Target language functions do not produce output unless they are output functions or explicitly use the `%openfile`, `%selectfile`, and `%closefile` directives.

A function optionally returns a value with the `%return` directive. The returned value can be a type defined in the table at “Target Language Value Types” on page 18-18.

In this example, a function, `name`, returns `x` if `x` and `y` are equal, or returns `z` if `x` and `y` are not equal:

```
%function name(x,y,z) void

%if x == y
   %return x
%else
   %return z
%endif

%endfunction
```

Function calls can appear in contexts where variables are allowed.

The `%with` statements that are in effect when a function is called are available to the function. Calls to other functions do not include the local scope of the function, but do include `%with` statements appearing within the function.

Assignments to variables within a function create new local variables and cannot change the value of global variables unless you use the scope resolution operator (`::`).

By default, a function returns a value and does not produce output. You can override this behavior by specifying the `Output` and `void` modifiers on the function declaration line, as in

```
%function foo() Output
...
%endfunction
```

In this case, the function continues to produce output to the currently open file, and is not required to return a value. You can use the `void` modifier to indicate that the function does not return a value and should not produce output, as in

```
%function foo() void
...
%endfunction
```

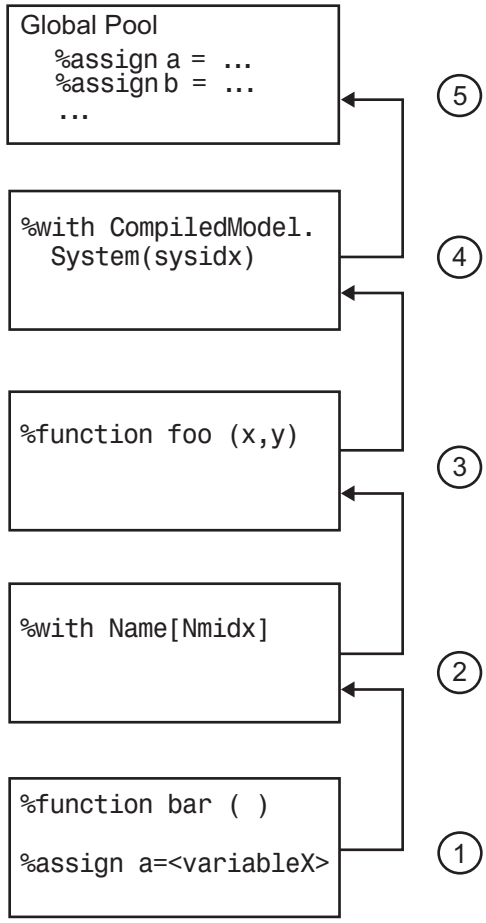
Variable Scoping Within Functions

Within a function, the left-hand member of an `%assign` statement defaults to creating a local variable. A new entry is created in the function's block within the scope chain; it does not affect the other entries. An example appears in "Function Scope" on page 18-59.

You can override this default behavior by using `%assign` with the scope resolution operator (`::`).

When you introduce new scopes within a function, using `%with`, these new scopes are used during nested function calls, but the local scope for the function is not searched.

If a `%with` is included within a function, its associated scope is carried with nested function calls, as shown in the next figure.



%return

The `%return` statement closes all `%with` statements appearing within the current function. In this example, the `%with` statement is automatically closed when the `%return` statement is encountered, removing the scope from the list of searched scopes:

```
%function foo(s)
    %with s
        %return(name)
    %endwith
%endfunction
```

The `%return` statement does not require a value. You can use `%return` to return from a function without a return value.

Command-Line Arguments

In this section...

Target Language Compiler Switches

To call the Target Language Compiler, use

```
tlc [switch1 expr1 switch2 expr2 ...] filename.tlc
```

This table lists the switches you can use with the Target Language Compiler. Order does not makes a difference. Note that if you specify a switch more than once, the last one takes precedence.

Target Language Compiler Switches

Switch	Meaning
`-r` *`filename`*	Reads a database file (such as an `.rtw` file). Repeat this option multiple times to load multiple database files into the Target Language Compiler. Omit this option for target language programs that do not depend on the database.
`-v[`*`number`*`]`	Sets the internal verbosity level to *`number`*. Omitting this option sets the verbosity level to `1`.
`-I`*`path`*	Adds the specified folder to the list of paths to be searched for TLC files.
`-O`*`path`*	Specifies that the output produced should be placed in the designated folder, including files opened with `%openfile` and `%closefile`, and `.log` files created in debug mode. To place files in the current folder, use `-O` (use the capital letter O, not zero).
`-m[`*`number`*`]`	The *`number`* specifies the maximum number of errors to report . Without `-m`, the default is to report the first five errors. If the *`number`* argument is omitted on this option, 1 is assumed.
`-x0`	Parse TLC file only (do not execute).
`-lint`	Performs some simple checks for performance and obsolete features.
`-p[`*`number`*`]`	Prints a dot (`.`) indicating progress for every *`number`* of TLC primitive operations executed.

Switch	Meaning
`-d[a|c|f|n|o]`	Invokes the TLC's debug mode. `-da` makes TLC execute `%assert` directives. However, when using the build process, this flag is ignored, because it is superseded by the **Enable TLC assertion** check box in the **TLC process** section of the **Code Generation** > **Debug** pane. `-dc` invokes the TLC command-line debugger. `-df` *`filename`* invokes the TLC debugger and runs the debugger script specified by *`filename`*. A debugger script is a text file containing valid debugger commands. TLC searches only the current working folder for the script file. `-dn` causes TLC to produce log files indicating which lines were and were not reached during compilation. `-do` disables the TLC debugging behavior.
`-dr`	Checks for cyclic records (records that reference each other, a source of memory leaks).
`-a[`*`ident`*`]=`*`expr`*	Specifies an initial value, *`expr`*, for the identifier, *`ident`*, for some parameters; equivalent to the `%assign` command.
`-shadow[0|1]`	Enables a warning when an identifier-value pair of a record overwrites a local variable. The warning is disabled by default. `-shadow0` disables the warning. `-shadow1` enables the warning.

As an example, the command line

```
tlc -r myModel.rtw -v grt.tlc
```

specifies that `myModel.rtw` should be read and used to process `grt.tlc` in verbose mode.

Filenames and Search Paths

Target files have the `.tlc` extension. By default, block-level files have the same name as the `Type` of the block in which they appear. You can override the search path for target files with your own local versions. The Target Language Compiler finds target files along this path. If you specify additional search paths with the `-I` switch of the `tlc` command or via the `%addincludepath` directive, the search order is:

1. Current folder.
2. Include paths specified in `%addincludepath` directives. The compiler evaluates multiple `%addincludepath` directives from the *bottom up*.
3. Include paths specified at the command line via `-I` . The compiler evaluates multiple `-I` options from *right to left*.

Note The compiler does *not* search the MATLAB path, and will not find a file that is available only on that path. The compiler searches only the locations described above.

Debugging TLC Files

The Target Language Compiler debugger is a command-line debugger that enables you to identify problems in executing TLC code. The following sections describe the facilities provided and provide examples of use.

Using the TLC Debugger

The TLC debugger helps you identify programming errors in your TLC code. Using the debugger, you can execute TLC code line-by-line, analyze and/or change variables in a specified block scope, and view the TLC call stack. The TLC debugger has a command-line interface that provides commands similar to standard debugging tools such as `dbx` or `gdb`.

Tips for Debugging TLC Code

Here are a few tips that will help you to debug your TLC code:

1. To see the full TLC call stack, place the following statement in your TLC code before the line that is pointed to by the error message. This will be helpful in narrowing down your problem.

   ```
   %setcommandswitch "-v1"
   ```

2. To trace the value of a variable in a function, place the following statement in your TLC file:

   ```
   %trace This is in my function %<variable>
   ```

   Your message will appear when the Target Language Compiler is run with the `-v` command switch, but not otherwise. You can use `%warning` instead of `%trace` to print variables, but you will need to remove or comment out such lines after you are through debugging.

3. Use the TLC coverage log files to identify parts of your code that have not been reached.

Invoking the Debugger

Use the TLC debugger to identify bugs and potential problems in your TLC files. To use the TLC debugger:

1. On the Configuration Parameters dialog box, select “Retain .rtw file” (Simulink Coder). This prevents the *`model`*`.rtw` file from being deleted after code generation.
2. Select “Start TLC debugger when generating code” (Simulink Coder) to invoke the TLC debugger when starting the code generation process.

Selecting **Start TLC debugger when generating code** is equivalent to specifying the TLC option `-dc` on the **Code Generation** pane of the Configuration Parameters dialog box.

3. Apply changes and start code generation by pressing **Ctrl+B**. This stops at the first line of executed TLC code, breaks into the TLC command-line debugger, and displays the following prompt:

   ```
   TLC_DEBUG>
   ```

You can now set breakpoints, explore the contents of code generator files, and explore variables in your TLC file using `print`, `which`, or `whos`.

An alternative way to invoke the TLC debugger is from the MATLAB prompt. (This assumes you retained the *`model`*`.rtw` file in the project folder.) To avoid making mistakes, copy the `tlc` command output of the build process to the MATLAB Command Window, and issue it after appending `-dc` to that command line.

A complete list of command-line switches for the TLC debugger is available in the table “Target Language Compiler Switches” on page 18-66.

TLC Debugger Command Summary

The table TLC Debugger Commands summarizes the TLC debugger commands.

To obtain more detailed help on individual commands, use the syntax

```
help command
```

from within the TLC debugger, as in this example:

```
TLC-DEBUG> help clear
```

You can abbreviate a TLC debugger command to its shortest unique form. For example,

```
TLC-DEBUG> break warning
```

can be abbreviated to

```
TLC-DEBUG> br warning
```

To view a complete list of TLC debugger commands, type `help` at the `TLC-DEBUG>` prompt.

TLC Debugger Commands

Command	Description
`assign variable=value`	Change a variable in the running program.
`break ["filename":]line|error|warning|trace|function`	Set a breakpoint. See also “%breakpoint Directive” on page 19-5.
`clear [breakpoint#|all]`	Remove a breakpoint.
`condition [breakpoint#] [expression]`	Attach a condition to a breakpoint.
`continue ["filename":]line|function`	Continue from a breakpoint.
`disable [breakpoint#]`	Disable a breakpoint.
`down [n]`	Move down the stack.
`enable [breakpoint#]`	Enable a breakpoint.
`finish`	Break after completing the current function.
`help [command]`	Obtain help for a command.
`ignore [breakpoint#]count`	Set the ignore count of a breakpoint.
`iostack`	Display contents of I/O stack.
`list start[,end]`	List lines from the file from start to end.
`loadstate "filename"`	Load debugger breakpoint state from a file.
`next`	Single step without going into functions.
`print expression`	Print the value of a TLC expression. To print a record, you must specify a fully qualified scope such as `CompiledModel.System[0].Block[0]`.
`quit`	Quit the TLC debugger. You can also exit the debugger by typing **Ctrl+C** at the prompt.
`run "filename"`	Run a batch file of command-line debugger commands.
`savestate "filename"`	Save debugger breakpoint state to a file.
`status`	Display a list of active breakpoints.
`step`	Step into.

Command	Description
`stop ["filename":]line|error| warning|trace| function`	Set a breakpoint (same as `break`).
`tbreak ["filename":]line|function`	Set a temporary breakpoint.
`thread [n]`	Change the active thread to thread `#n` (0 is the main program's thread number).
`threads`	List the currently active TLC execution threads.
`tstop ["filename":]line|function`	Set a temporary breakpoint.
`up [n]`	Move up the stack.
`where`	Show the currently active execution chains.
`which name`	Look up the name and display what scope it comes from.
`whos [::|expression]`	List the variables in the given scope.

%breakpoint Directive

As an alternative to the `break` command, you can embed breakpoints at locations in a TLC file by adding the directive

```
%breakpoint
```

Usage Notes

When using `break` or `stop`, use

- `error` to break or stop on error
- `warn` to break or stop on warning
- `trace` to break or stop on trace

For example, if you need to break on error, use

```
TLC_DEBUG> break error
```

When using `clear`, get the status of breakpoints using `status` and clear specific breakpoints. For example

```
TLC-DEBUG> break "foo.tlc":46
TLC-DEBUG> break "foo.tlc":25
```

```
TLC-DEBUG> status
Breakpoints:
[1] break File: foo.tlc Line: 46
[2] break File: foo.tlc Line: 25
TLC-DEBUG> clear 2
```

In this example, `clear 2` clears the second breakpoint.

TLC Coverage

Using the TLC Coverage Option

The example in “Using the TLC Debugger” on page 19-2 used the debugger to detect a problem in one section of the TLC file. Because a test model may not cover all possible cases, there is a technique that traces the untested cases, the TLC coverage option.

The TLC coverage option provides an easier way to ascertain that the different code parts (not paths) in your code are exercised. To specify TLC coverage tracking, on the Configuration Parameters dialog box, select “Start TLC coverage when generating code” (Simulink Coder).

When you initiate TLC coverage, the Target Language Compiler produces a `.log` file for every target file (`*.tlc`) used. These `.log` files are placed in project folder created for the model. Each `.log` file contains usage (count) information regarding how many times it encounters each line during execution. Each line begins with the number of times it is encountered, followed by a colon, followed by the code.

Example .log File

Here is a log file that results from generating code for the example model `sfcndemo_sdotproduct`, located in the folder *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures` (open). This model inlines the `sdotproduct` S-function in TLC. The TLC file that implements the S-function is located in the folder *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/tlc_c` (open). The `.log` file for `sdotproduct.tlc` is `sdotproduct.log`, which is placed in your build folder. The contents of `sdotproduct.log` are similar to:

```
Source: E:\matlab\toolbox\simulink\simdemos\simfeatures\tlc_c\sdotproduct.tlc
 0: %%
 0: %% File : sdotproduct.tlc generated from sdotproduct.ttlc revision 1.6

0:       %%
1:       %assign yre = LibBlockOutputSignal(0,"",lcv,"%<tRealPart>%<idx>")
1:       %assign yim = LibBlockOutputSignal(0,"",lcv,"%<tImagPart>%<idx>")
0:       %%
1:       %<FcnThriftedComplexConjMultiply(u0re, u0im, u1re, u1im, yre, yim, "+=")>\
0:     %endroll
0:   %endif
1:   %if outputOverWritesInput
0:     }
0:   %endif
1:
0: %endfunction
1:
0: %% [EOF] sdotproduct.tlc
```

Analyzing the Results

This structure makes it easy to identify branches not taken and to develop new tests that can exercise unused portions of the target files.

Looking at the `sdotproduct.log` file, you can see that the code has not been used to assign default values to parameters (e.g., the first part of the code for function `FcnThriftedComplexConjMultiply`). Using this log as a reference and creating models that exercise unexecuted lines, you can make sure that your code is more robust.

TLC Profiler

In this section...

Using the Profiler

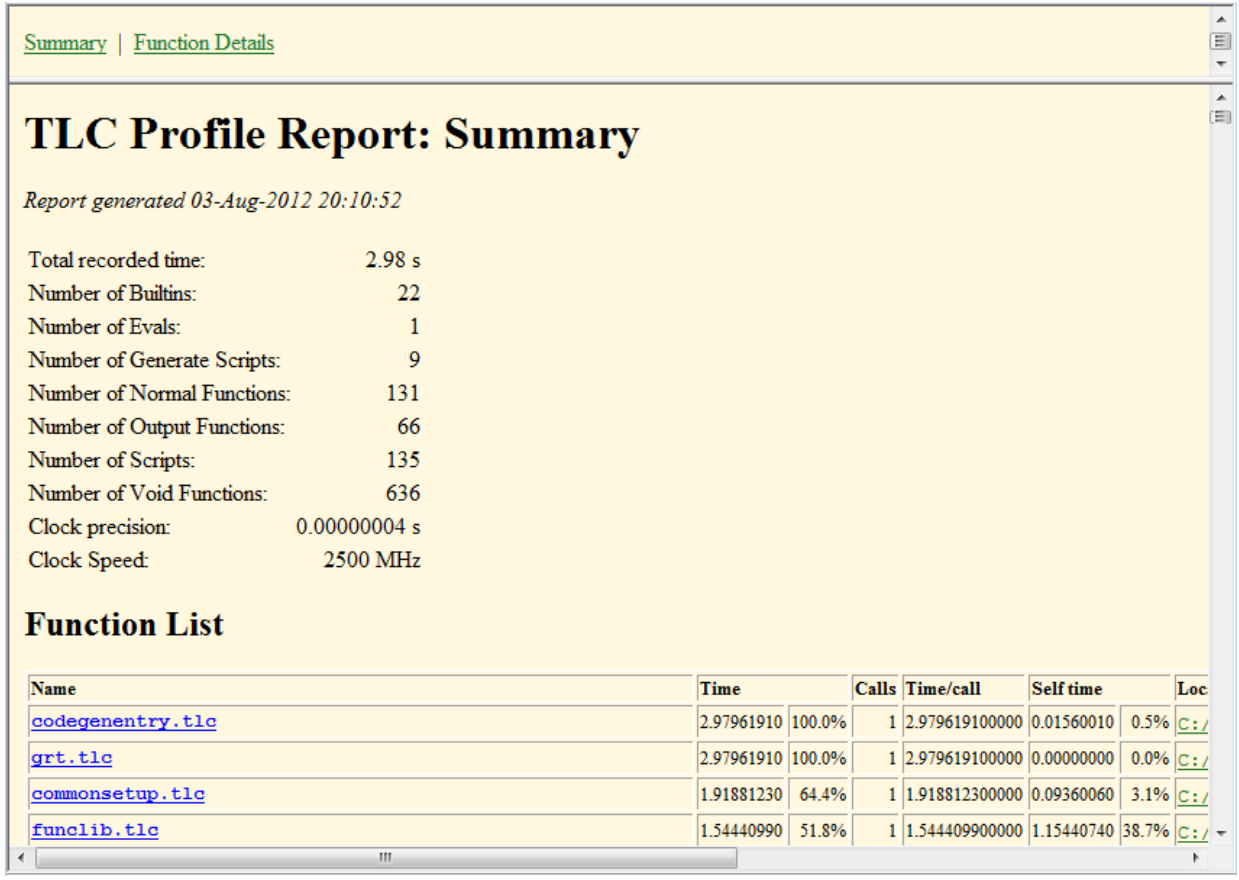
The TLC profiler collects timing statistics for TLC code. It collects execution time for functions, scripts, macros, and built-in functions. These results become the basis of HTML reports that are identical in format to MATLAB profiler reports. By analyzing the report, you can identify bottlenecks in your code that make code generation take longer.

On the Configuration Parameters dialog box, select “Profile TLC” (Simulink Coder). Apply your changes and press **Ctrl+B**.

At the end of the TLC process, the build process creates the HTML summary and related files.

Analyzing the Report

The profile report is generated into the build folder. To open the report, change folder (`cd`) to the build folder and open the file *`model`*`.html`, opening it in a browser window. Here is a sample of a TLC profiling report:



Summary | Function Details

TLC Profile Report: Summary

Report generated 03-Aug-2012 20:10:52

Total recorded time:	2.98 s
Number of Builtins:	22
Number of Evals:	1
Number of Generate Scripts:	9
Number of Normal Functions:	131
Number of Output Functions:	66
Number of Scripts:	135
Number of Void Functions:	636
Clock precision:	0.00000004 s
Clock Speed:	2500 MHz

Function List

Name	Time		Calls	Time/call	Self time		Loc
codegenentry.tlc	2.97961910	100.0%	1	2.979619100000	0.01560010	0.5%	C:/
grt.tlc	2.97961910	100.0%	1	2.979619100000	0.00000000	0.0%	C:/
commonsetup.tlc	1.91881230	64.4%	1	1.918812300000	0.09360060	3.1%	C:/
funclib.tlc	1.54440990	51.8%	1	1.544409900000	1.15440740	38.7%	C:/

The created report is fairly self-explanatory. Some points to note are

- Functions are sorted in descending order of their execution time.
- Self-time is the time spent in the function alone, not including the time spent in functions called by the function.
- Functions are hyperlinks that take you to the details related to that specific function.

The profiler report can be helpful when you have inlined S-functions in your model. You can use the profiler to compare time spent in specific user-written or `Lib` functions, and then modify your TLC code accordingly.

Nonexecutable Directives

TLC considers the following directives to be nonexecutable lines. Therefore, these directives are not counted in TLC Profiler reports:

- `%filescope`
- `%else`
- `%endif`
- `%endforeach`
- `%endfor`
- `%endroll`
- `%endwith`
- `%body`
- `%endbody`
- `%endfunction`
- `%endswitch`
- `%default`
- Comment (`%%` or `/% text %/`

Improving Performance

Analyzing the profiler results also gives you an overview of which functions are used more often or are more expensive. Then, you can either improve those functions, or try alternative methods to improve code generation speed. Two points to consider are

- Reduce usage of `EXISTS`. Performing an `EXISTS` on a field is more costly than comparing the field to a value. When possible, create an inert default value for a field. Then, instead of doing an `EXISTS` on the entity, compare it against the default value.
- Reduce the use of one-line functions. One-line functions might be a bottleneck for code generation speed. When readability is not an issue, consider expanding the function.

Inlining S-Functions

To wrap or to inline, that is the question. Once you have decided, the following sections explain how to go about it, using the `timestwo` S-function as a running example. Inlining works almost identically for C, C++, MATLAB file, and Fortran S-functions.

Inline S-Functions

Writing S-functions to be included in generated code involves requirements that go beyond writing S-functions used only for simulation. Before you proceed to inline an S-function make sure that it meets requirements and functions as you expect. For more information, see “S-Functions and Code Generation” (Simulink Coder). If your S-function is multirate, see “Time-Based Scheduling and Code Generation” (Simulink Coder) and “Modeling for Multitasking Execution” (Simulink Coder), and “Rate Grouping Compliance and Compatibility Issues” on page 63-17.

Inline S-Functions with Block Target Files

When to Inline S-Functions

With C MEX S-functions, non-ERT targets support calling the original C MEX code if the source code (`.c` file) is available when entering the build phase. For S-functions that are in Fortran or MATLAB language, you must inline them to have complete code generation for Simulink models that contain them. Additionally, once you have determined that you will inline an S-function, you must decide to make it either fully inlined or wrapped.

Fully Inlined S-Functions

The block target file for a fully inlined S-function is a self-contained definition of how to inline the block’s functionality directly into the various portions of the generated code — start code, output code, etc. This approach is most beneficial when there are many modes and data types supported for algorithms that are relatively small or when the code size is not significant.

Function-Based or Wrapped Code Generation

When the physical size of the code for a block becomes too large for inlining, the block target file is written to gather inputs, outputs, and parameters, and make a call to a function that you write to perform the block functionality. This has an advantage in generated code size when the code in the function is large or there are many instances of this block in a model. Of course, you should consider the overhead of the function call when weighing the option of fully inlining the block algorithm or generating function calls.

If you choose to go with function-based code generation, two more options need consideration:

- Write the functions once, put them in `.c` files, and have the TLC code's `BlockTypeSetup` method specify external references to your support functions. Use `LibAddToModelSources` for names of the modules containing the supporting functions. This approach is usually done using one function per file to get the smallest executable possible.
- Write a more sophisticated TLC file. In addition to methods such as `Start` and `Outputs`, conditionally generate customized versions of functions (data types, widths, algorithms, and so on), in separate code generation buffers, to be written to a separate `.c` file. The file should contain only functions used by this model, instead of all possible functions.

Either approach can produce optimal code. The first option can result in hundreds of files if your S-function supports many data types, signal widths, and algorithm choices. The second approach is more difficult to write, but results in a more maintainable code generation library, and the code can be every bit as tight as the first approach.

For further information on wrapping, see "Wrapper Inlined S-Function Example" on page 14-13.

Inline MATLAB File S-Functions

You can inline the functionality of MATLAB file S-functions in the generated code. The process for writing a block target file for a MATLAB file S-function is essentially identical to the process for writing a C MEX S-function.

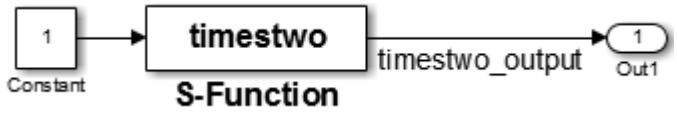
Note While you can fully inline a MATLAB file S-function to improve performance, Simulink Accelerator or the code generator does not include a C or C++ API for the MATLAB Math Library. You therefore cannot call MATLAB Math Library functions from a TLC file.

The following example illustrates the equivalence of C MEX and MATLAB file S-functions for code generation. The S-function MATLAB file `timestwo.m` is equivalent to the C MEX S-function `timestwo`. The TLC file for the C MEX S-function `timestwo` works for the S-function MATLAB file `timestwo.m`. TLC is independent of the type of S-function because TLC requires only the root name of the S-function and not its type. In the case of `timestwo`, one line determines how the code generator implements the TLC file:

```
%implements "timestwo" "C"
```

To try this yourself:

1. Create the following sample model:



2. Copy the file `timestwo.m` from the folder *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures` (open) to a temporary folder.
3. Copy the file `timestwo.tlc` from the folder *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/tlc_c` (open) to the same temporary folder.
4. In MATLAB, change folder (`cd`) to the temporary folder and make a Simulink model with an S-function block that calls `timestwo.`
5. On the **Signal Attributes** tab of the Inport Block Parameters dialog box, set the **Port dimensions** parameter to `5`.

Simulink uses the MATLAB file S-function for simulation because the MATLAB search path finds `timestwo.m` in the current folder before finding the C MEX S-function `timestwo` in the `matlabpath`. Verify which S-function the code generator uses by typing the MATLAB command:

```
which timestwo
```

The answer is the MATLAB file S-function `timestwo.m` in the temporary folder.

In the generated code, the `timestwo.tlc` file inlines the MATLAB file S-function.

```
/* S-Function (timestwo): '<Root>/MATLAB S-Function' */
  /* Multiply input by two */
  {
    int_T i1;
    const real_T *u0 = &times2_B.Gain[0];
    real_T *y0 = &times2_Y.Out1[0];
    for (i1=0; i1 < 5; i1++) {
      y0[i1] = u0[i1] * 2.0;
    }
  }
```

The output is the product of each input, `u0[i1]` times 2.0. The code generator uses this `Outputs` method from the block target file to generate code:

```
%function Outputs(block, system) Output
/* %<Type> Block: %<Name> */
```

```
  %%
  /* Multiply input by two */
  %assign rollVars = ["U", "Y"]
  %roll idx = RollRegions, lcv = RollThreshold, block, "Roller", rollVars
    %<LibBlockOutputSignal(0, "", lcv, idx)> = \
    %<LibBlockInputSignal(0, "", lcv, idx)> * 2.0;
  %endroll
%endfunction
```

Alter these temporary copies of the MATLAB file S-function and the TLC file to see how they interact. Start out by just changing the comments in the TLC file and see the changes that appear in the generated code. Then, work up to algorithmic changes.

For more information on inlining C MEX S-Functions, see “Inline C MEX S-Functions” on page 20-10.

Inline Fortran (F-MEX) S-Functions

The capabilities of Fortran MEX S-functions can be fully inlined using a TLC block target file. This interface can be illustrated with a Fortran MEX S-function that implements the `timestwo` function. Here is the sample Fortran S-function code:

```

      RETURN
      END

      SUBROUTINE SINGUL(T, X, U, SING)
      REAL*8           T, X(*), U(*), SING(*)
C --- Nothing to do.
      RETURN
      END
```

Copy the preceding code into file `ftimestwo.for` in a convenient working folder.

Putting this into an S-function block in a simple model will illustrate the interface for inlining the S-function. Once your Fortran MEX environment is set up, prepare the code for use by compiling the S-function in a working folder along with the file `simulink.for`

from the folder *matlabroot*/simulink/src (open). For more information about setting up your Fortran MEX environment, see “Create Level-2 Fortran S-Functions” (Simulink).

Compile the code with the mex command at the MATLAB command line:

```
mex ftimestwo.for simulink.for
```

Now reference this block from a simple model set with a fixed-step solver and the grt target.

The TLC code for inlining this block is a modified form of timestwo.tlc. In your working folder, create a file named ftimestwo.tlc and put this code into it.

```
%implements "ftimestwo" "C"

%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %%
  /* Multiply input by two */
  %assign rollVars = ["U", "Y"]
  %roll idx = RollRegions, lcv = RollThreshold, block, ...
"Roller", rollVars
    %<LibBlockOutputSignal(0, "", lcv, idx)> = \
    %<LibBlockInputSignal(0, "", lcv, idx)> * 2.0;
  %endroll
%endfunction
```

Now you can generate code for the ftimestwo Fortran MEX S-function. The resulting code fragment specific to ftimestwo is

```
/* S-Function Block: <Root>/F-MEX S-Function */
  /* Multiply input by two */
  rtB.F_MEX_S_Function = rtB.Gain * 2.0;
```

Inline C MEX S-Functions

In this section...

Inline S-Function Overview

When a Simulink model contains an S-function and a corresponding TLC block target file exists for that S-function, the code generator inlines the S-function. Inlining an S-function can produce more efficient code by eliminating the S-function API layer from the generated code.

For S-functions that can perform a variety of tasks, inlining them gives you the opportunity to generate code only for the current mode of operation set for each instance of the block. As an example of this, if an S-function accepts an arbitrary signal width and loops through each element of the signal, you would want to generate inlined code that has loops when the signal has two or more elements, but generates a simple nonlooped calculation when the signal has just one element.

Level 1 C MEX S-functions (written to an older form of the S-function API) that are not inlined will cause the generated code to make calls to all of these functions even if the routine is empty for the particular S-function.

Function	Purpose
`mdlInitializeSizes`	Initialize the sizes array
`mdlInitializeSampleTimes`	Initialize the sample times array
`mdlInitializeConditions`	Initialize the states
`mdlOutputs`	Compute the outputs
`mdlUpdate`	Update discrete states
`mdlDerivatives`	Compute the derivatives of continuous states
`mdlTerminate`	Clean up when the simulation terminates

Level 2 C MEX S-functions (i.e., those written to the current S-function API) that are not inlined make calls to the above functions, with the following exceptions:

- `mdlInitializeConditions` is called only if `MDL_INITIALIZE_CONDITIONS` is declared with `#define`.
- `mdlStart` is called only if `MDL_START` is declared with `#define`.
- `mdlUpdate` is called only if `MDL_UPDATE` is declared with `#define`.
- `mdlDerivatives` is called only if `MDL_DERIVATIVES` is declared with `#define`.

By inlining an S-function, you can eliminate the calls to these possibly empty functions in the simulation loop. This can greatly improve the efficiency of the generated code.

To inline an S-function called *`sfunc`*`_name`, you create a custom S-function block target file called *`sfunc`*`_name.tlc` and place it in the same folder as the S-function MEX-file. Then, at build time, the target file is executed instead of setting up function calls into the S-function `.c` file. The S-function target file “inlines” the S-function by directing the Target Language Compiler to insert only the statements defined in the target file.

In general, inlining an S-function is especially useful when

- The time required to execute the contents of the S-function is small in comparison to the overhead required to call the S-function.
- Certain S-function routines are empty (e.g., `mdlUpdate`).
- The behavior of the S-function changes between simulation and code generation. For example, device driver I/O S-functions might read from the MATLAB workspace during simulation, but read from an actual hardware address in the generated code.

S-Function Parameters

An S-function can write two different types of parameters into the *`model`*`.rtw` file for Target Language Compiler files to access:

- Parameter settings: These correspond to nontunable parameters (typically set from check boxes and menus on a masked S-function) that are written via the `mdlRTW` method of the S-function using `ssWriteRTWParamSettings`. The S-function TLC implementation file can then directly access the values of these parameter settings from the `SFcnParamSettings` record in the block.
- Tunable parameters: This class of parameters can be accessed when they are registered as run-time parameters within the S-function. Note that such tunable

parameters are automatically written out to the *model*`.rtw` file. Within the TLC file for the S-function, you can access run-time parameters and their attributes using the `LibBlockParameter` library function and its variants.

For more information on how to create and use run-time parameters, see “Create and Update S-Function Run-Time Parameters” (Simulink). Also see the example `sfcndemo_runtime` in the S-function examples for how to create and use the two classes of parameters. The example source files, which you can inspect and adapt, are

- `toolbox/simulink/simdemos/simfeatures/src/sfun_runtime1.c`
- `toolbox/simulink/simdemos/simfeatures/tlc_c/sfun_runtime1.tlc`
- `toolbox/simulink/simdemos/simfeatures/src/sfun_runtime2.c`
- `toolbox/simulink/simdemos/simfeatures/tlc_c/sfun_runtime2.tlc`
- `toolbox/simulink/simdemos/simfeatures/src/sfun_runtime3.c`
- `toolbox/simulink/simdemos/simfeatures/tlc_c/sfun_runtime3.tlc`

Sample Code for S-Function

Suppose you have a simple S-function that mimics the Gain block, with one input, one output, and a scalar gain. That is, `y = u * p`. If the Simulink block’s name is `foo` and the name of the Level 2 S-function is `foogain`, the C MEX S-function must contain this code:

```
#define S_FUNCTION_NAME foogain
#define S_FUNCTION_LEVEL 2
#include "simstruc.h"
#define GAIN mxGetPr(ssGetSFcnParam(S,0))[0]

static void mdlInitializeSizes(SimStruct *S)
{
  ssSetNumContStates        (S, 0);
  ssSetNumDiscStates        (S, 0);

  if (!ssSetNumInputPorts(S, 1)) return;
  ssSetInputPortWidth            (S, 0, 1);
  ssSetInputPortDirectFeedThrough(S, 0, 1);

  if (!ssSetNumOutputPorts(S, 1)) return;
  ssSetOutputPortWidth          (S, 0, 1);

  ssSetNumSFcnParams        (S, 1);
```

```
  ssSetNumSampleTimes        (S, 0);
  ssSetNumIWork        (S, 0);
  ssSetNumRWork        (S, 0);
  ssSetNumPWork        (S, 0);
}

static void
mdlOutputs(SimStruct *S, int_T tid)
{
  real_T *y = ssGetOutputPortRealSignal(S, 0);
  const InputRealPtrsType u = ssGetInputPortRealSignalPtrs(S, 0);

  y[0] = (*u)[0] * GAIN;
}

static void
mdlInitializeSampleTimes(SimStruct *S){}

static void
mdlTerminate(SimStruct *S) {}

#define MDL_RTW  /* Change to #undef to remove function */
#if defined(MDL_RTW)&&(defined(MATLAB_MEX_FILE)||defined(NRT))
static void
mdlRTW (SimStruct *S)
{
  if (!ssWriteRTWParameters(S, 1,SSWRITE_VALUE_VECT,"Gain","",
                            mxGetPr(ssGetSFcnParam(S,0)),1))
  {
    return;
  }
}
#endif

#ifdef  MATLAB_MEX_FILE
#include "simulink.c"
#else
#include "cg_sfun.h"
#endif
```

The following two sections show the difference in the generated code for *`model`*`.c` containing noninlined and inlined versions of S-function `foogain`. The model contains no other Simulink blocks.

For more information about these S-function related C library functions, see “Configure C/C++ S-Function Features” (Simulink). For information about how to generate code, see “Configure Model and Generate Code” (Simulink Coder) and “Choose Build Approach and Configure Build Process” (Simulink Coder).

Comparison of Noninlined and Inlined Versions of model.c

Without a TLC file to define the S-function specifics, the code generator must call the MEX-file S-function through the S-function API. The following code is the *model*.c file for the noninlined S-function (i.e., no corresponding TLC file exists).

Noninlined S-Function

```
/*
 * model.c
.
.
.
*/
real_T untitled_RGND = 0.0;             /* real_T ground */
/* Start the model */
void MdlStart(void)
{
  /* (no start code required) */
}
/* Compute block outputs */
void MdlOutputs(int_T tid)
{
  /* Level2 S-Function Block: <Root>/S-Function (foogain) */
  {
    SimStruct *rts = ssGetSFunction(rtS, 0);
    sfcnOutputs(rts, tid);
  }
}
/* Perform model update */
void MdlUpdate(int_T tid)
{
  /* (no update code required) */
}
/* Terminate function */
void MdlTerminate(void)
{
  /* Level2 S-Function Block: <Root>/S-Function (foogain) */
  {
```

```
    SimStruct *rts = ssGetSFunction(rtS, 0);
    sfcnTerminate(rts);
  }
}
#include "model_reg.h"
/* [EOF] model.c */
```

Inlined S-Function

This code is *model*`.c` with the `foogain` S-function fully inlined:

```
/*
 * model.c
.
.
.
*/
/* Start the model */
void MdlStart(void)
{
  /* (no start code required) */
}

/* Compute block outputs */
void MdlOutputs(int_T tid)

  /* S-Function block: <Root>/S-Function */
  /* NOTE: There are no calls to the S-function API in the inlined
     version of model.c. */
  rtB.S_Function = 0.0 * rtP.S_Function_Gain;
}

/* Perform model update */
void MdlUpdate(int_T tid)
{
  /* (no update code required) */
}

/* Terminate function */
void MdlTerminate(void)
{
  /* (no terminate code required) */
}

#include "model_reg.h"
```

```
/* [EOF] model.c */
```

If you include this target file for this S-function block, the resulting *model*`.c` code is

```
rtB.S_Function = 0.0 * rtP.S_Function_Gain;
```

Including a TLC file drastically decreased the code size and increased the execution efficiency of the generated code. These notes highlight some information about the TLC code and the generated output:

- The TLC directive `%implements` is required by block target files, and must be the first executable statement in the block target file. This directive prevents the Target Language Compiler from executing an inappropriate target file for S-function `foogain`.
- The input to `foo` is `rtGROUND` (a Simulink Coder global equal to 0.0) because `foo` is the only block in the model and its input is unconnected.
- Including a TLC file for `foogain` eliminates the need for an S-function registration segment for `foogain`. This significantly reduces code size.
- The TLC code inlines the `gain` parameter when the build process is configured to inline parameter values. For example, if the S-function parameter is specified as 2.5 in the S-function dialog box, the TLC `Outputs` function generates

  ```
  rtB.foo = input * 2.5;
  ```
- Use the `%generatefile` directive if your operating system has a filename size restriction and the name of the S-function is `foosfunction` (that exceeds the limit). In this case, you would include the following statement in the system target file (anywhere prior to a reference to this S-function block target file).

  ```
  %generatefile foosfunction "foosfunc.tlc"
  ```

  This statement tells the Target Language Compiler to open `foosfunc.tlc` instead of `foosfunction.tlc`.

Comparison of Noninlined and Inlined Versions of model_reg.h

Inlining a Level 2 S-function significantly reduces the size of the *model*`_reg.h` code. Model registration functions are lengthy; much of the code has been eliminated in this example. The code below highlights the difference between the noninlined and inlined versions of *model*`_reg.h`; inlining eliminates this code:

```
/*
 * model_reg.h
 *
*/
/* Normal model initialization code independent of
      S-functions  */

/* child S-Function registration */
  ssSetNumSFunctions(rtS, 1);

  /* register each child */
  {
    static SimStruct childSFunctions[1];
    static SimStruct *childSFunctionPtrs[1];

    (void)memset((char_T *)&childSFunctions[0], 0,
                 sizeof(childSFunctions));
    ssSetSFunctions(rtS, &childSFunctionPtrs[0]);
    {
      int_T i;

      for(i = 0; i < 1; i++) {
        ssSetSFunction(rtS, i, &childSFunctions[i]);
      }
    }

    /* Level2 S-Function Block: untitled/<Root>/S-Function
       (foogain) */
    {
      extern void foogain(SimStruct *rts);
      SimStruct *rts = ssGetSFunction(rtS, 0);

      /* timing info */
      static time_T sfcnPeriod[1];
      static time_T sfcnOffset[1];
      static int_T sfcnTsMap[1];

      {
        int_T i;

        for(i = 0; i < 1; i++) {
          sfcnPeriod[i] = sfcnOffset[i] = 0.0;
        }
      }
```

```
ssSetSampleTimePtr(rts, &sfcnPeriod[0]);
ssSetOffsetTimePtr(rts, &sfcnOffset[0]);
ssSetSampleTimeTaskIDPtr(rts, sfcnTsMap);
ssSetMdlInfoPtr(rts, ssGetMdlInfoPtr(rtS));

/* inputs */
{
  static struct _ssPortInputs inputPortInfo[1];

  _ssSetNumInputPorts(rts, 1);
  ssSetPortInfoForInputs(rts, &inputPortInfo[0]);

  /* port 0 */
  {
    static real_T const *sfcnUPtrs[1];

    sfcnUPtrs[0] = &untitled_RGND;
    ssSetInputPortWidth(rts, 0, 1);
    ssSetInputPortSignalPtrs(rts, 0,
        (InputPtrsType)&sfcnUPtrs[0]);
  }
}

/* outputs */
{
  static struct _ssPortOutputs outputPortInfo[1];
  _ssSetNumOutputPorts(rts, 1);
  ssSetPortInfoForOutputs(rts, &outputPortInfo[0]);
  ssSetOutputPortWidth(rts, 0, 1);
  ssSetOutputPortSignal(rts, 0, &rtB.S_Function);
}

/* path info */
ssSetModelName(rts, "S-Function");
ssSetPath(rts, "untitled/S-Function");
ssSetParentSS(rts, rtS);
ssSetRootSS(rts, ssGetRootSS(rtS));
ssSetVersion(rts, SIMSTRUCT_VERSION_LEVEL2);

/* parameters */
{
  static mxArray const *sfcnParams[1];

  ssSetSFcnParamsCount(rts, 1);
```

```
        ssSetSFcnParamsPtr(rts, &sfcnParams[0]);

        ssSetSFcnParam(rts, 0, &rtP.S_Function_P1Size[0]);
      }

      /* registration */
      foogain(rts);

      sfcnInitializeSizes(rts);
      sfcnInitializeSampleTimes(rts);

      /* adjust sample time */
      ssSetSampleTime(rts, 0, 0.2);
      ssSetOffsetTime(rts, 0, 0.0);
      sfcnTsMap[0] = 0;

      /* Update the InputPortReusable and BufferDstPort flags for
        each input port */
      ssSetInputPortReusable(rts, 0, 0);
      ssSetInputPortBufferDstPort(rts, 0, -1);

      /* Update the OutputPortReusable flag of each output port */
    }
  }
```

A TLC File to Inline S-Function foogain

To avoid unnecessary calls to the S-function and to generate the minimum code required for the S-function, the following TLC file, `foogain.tlc`, is provided as an example.

```
%implements "foogain" "C"

%function Outputs (block, system) Output
  /* %<Type> block: %<Name> */
  %%
  %assign y = LibBlockOutputSignal (0, "", "", 0)
  %assign u = LibBlockInputSignal (0, "", "", 0)
  %assign p = LibBlockParameter (Gain, "", "", 0)
  %<y> = %<u> * %<p>;
%endfunction
```

Managing Block Instance Data with an Eye Toward Code Generation

Instance data is extra data or working memory that is unique to each instance of a block in a Simulink model. This does not include parameter or state data (which is stored in the

model parameter and state vectors, respectively), but rather is used to cache intermediate results or derived representations of parameters and modes. One example of instance data is the buffer used by a transport delay block.

Allocating and using memory on an instance-by-instance basis can be done several ways in a Level 2 S-function: via `ssSetUserData`, work vectors (e.g., `ssSetRWorkValue`, `ssSetIWorkValue`), or data-typed work vectors known as `DWork` vectors. For the smallest effort in writing the S-function and block target file and for automatic conformance to both static and `malloc` instance data on targets such as `grt`, use data-typed work vectors when writing S-functions with instance data.

The advantages are twofold. In the first place, writing the S-function is more straightforward, in that memory allocations and frees are handled for you by Simulink. Secondly, the `DWork` vectors are written to the *`model`*`.rtw` file for you automatically, including the `DWork` name, data type, and size. This makes writing the block target file easier, because you do not have to write TLC code for allocating and freeing the `DWork` memory.

Additionally, if you want to bundle groups of `DWork` vectors into structures for passing to functions, you can populate the structure with pointers to `DWork` arrays in both your S-function `mdlStart` function and the block target file's `Start` method, achieving consistency between the S-function and the generated code's handling of data.

Finally, using a `DWork` makes it straightforward to create a specific version of code (data types, scalar vs. vectorized, etc.) for each block instance that matches the implementation in the S-function. Both implementations use `DWork` in the same way so that the inlined code can be used with the Simulink Accelerator software without changes to the C MEX S-function or the block target file.

Using Inlined Code with the Simulink Accelerator Software

By default, the Simulink Accelerator software calls your C MEX S-function as part of an accelerated model simulation. If you prefer to have the accelerator inline your S-function before running the accelerated model, tell the accelerator to use your block target file to inline the S-function with the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` flag in the call to `ssSetOptions()` in the `mdlInitializeSizes` function of that S-function.

Note that memory and work vector size and usage must be the same for the TLC generated code and the C MEX S-function, or the Simulink Accelerator software cannot execute the inlined code properly. This is because the C MEX S-function is called to initialize the block and its work vectors, calling the `mdlInitializeSizes`,

`mdlInitializeConditions`, `mdlCheckParameters`, `mdlProcessParameters`, and `mdlStart` functions. In the case of constant signal propagation, `mdlOutputs` is called from the C MEX S-function during the initialization phase of model execution.

During the time-stepping phase of accelerated model execution, the code generated by the `Output` and `Update` block TLC methods will execute, plus the `Derivatives` and zero-crossing methods if they exist. The `Start` method of the block target file is not used in generating code for an accelerated model.

TLC Coding Conventions

These guidelines can help you apply programming style in each target file consistently.

Begin Identifiers with Uppercase Letters

Identifiers in the file begin with an uppercase letter. For example,

```
NumModelInputs              1
NumModelOutputs             2
NumNonVirtBlocksInModel     42
DirectFeedthrough           yes
NumContStates               10
```

Because a `Name` identifier may be promoted into the parent scope, block records that contain a `Name` identifier should start the name with an uppercase letter. For example, a block might contain

```
Block {
   :
   :
RWork                   [4, 0]
   :
NumRWorkDefines         4
RWorkDefine {
    Name                "TimeStampA"
    Width               1
    StartIndex          0
  }
}
```

Because the `Name` identifier within the `RWorkDefine` record is promoted to `PrevT` in its parent scope, it must start with an uppercase letter. The promotion of the `Name` identifier into the parent block scope is currently done for the `Parameter`, `RWorkDefine`, `IWorkDefine`, and `PWorkDefine` block records.

The Target Language Compiler assignment directive (`%assign`) generates a warning if you assign a value to an “unqualified” code generator identifier. For example,

```
%assign TID = 1
```

produces an error because the `TID` identifier is not qualified by `Block`. However, a “qualified” assignment does not generate a warning. For example,

```
%assign Block.TID = 1
```

does not generate a warning because the assignment contains a qualifier. The Target Language Compiler therefore assumes that the programmer is intentionally modifying an identifier.

Begin Global Variable Assignments with Uppercase Letters

Global TLC variable assignments should start with uppercase letters. A global variable is a variable declared in a system target file (`grt.tlc`, `mdlwide.tlc`, `mdlhdr.tlc`, `mdlbody.tlc`, `mdlreg.tlc`, or `mdlparam.tlc`), or within a function that uses the operator. Global assignments have the same scope as code generator variables. An example of a global TLC variable defined in `mdlwide.tlc` is

```
%assign InlineParameters = 1
```

An example of a global reference in a function is

```
%function foo() void
  %assign ::GlobalIdx = ::GlobalIdx + 1
%endfunction
```

Begin Local Variable Assignments with Lowercase Letters

Local TLC variable assignments should start with lowercase letters. A local TLC variable is a variable assigned inside a function. For example,

```
%assign numBlockStates = ContStates[0]
```

Begin Functions Declared in block.tlc Files with Fcn

When you declare a function inside a `block.tlc` file, it should start with `Fcn`. For example,

```
%function FcnMyBlockFunc(...)
```

Note Functions declared inside a system file are global; functions declared inside a block file are local.

Do Not Hard-Code Variables Defined in commonsetup.tlc

Because the code generator tracks use of variables and generates code based on usage, you should use access routines instead of directly using a variable. For example, you should not use the following in your TLC file:

```
x = %<tInf>;
```

You should use

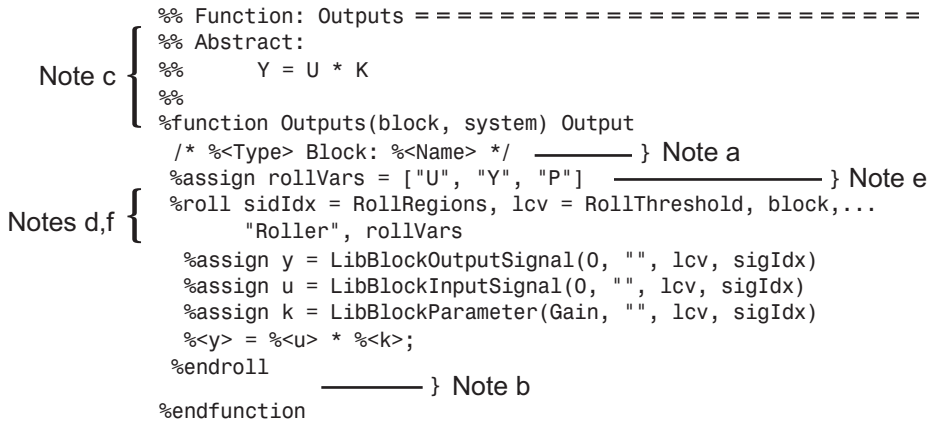
```
x = %<LibRealNonFinite(inf)>;
```

Similarly, instead of using `%<tTID>`, use `%<LibTID()>`. For a complete list of functions, see TLC Function Library Reference in “Target Language Compiler” (Simulink Coder).

Simulink Coder global variables start with `rt` and Simulink Coder global functions start with `rt_`.

Avoid naming global variables in modules that start with `rt` or `rt_` because they might conflict with Simulink Coder global variables and functions. These TLC variables are declared in `commonsetup.tlc`.

This convention creates consistent variables throughout the target files. For example, the Gain block contains the following `Outputs` function.



Notes about this TLC code

a. The code section for each block begins with a comment specifying the block type and name.

b. Include a blank line immediately after the end of the function to create consistent spacing between blocks in the output code.

c. Try to stay within 80 columns per line for the function banner. You might set up an 80 column comment line at the top of each function. As an example, see `constant.tlc`.

d. For consistency, use the variables `sysIdx` and `blkIdx` for system index and block index, respectively.

e. Use the variable `rollVars` when using the `%roll` construct.

f. When naming loop control variables, use `sigIdx` and `lcv` when looping over `RollRegions` and `xidx` and `xlcv` when looping over the states.

Example: Output function in gain.tlc

```
%roll sigIdx = RollRegions, lcv = RollThreshold, ...
       block, "Roller", rollVars
```

Example: InitializeConditions function in linblock.tlc

```
%roll xidx = [0:nStates-1], xlcv = RollThreshold,...
       block, "Roller", rollVars
```

Conditional Inclusion in Library Files

The Target Language Compiler function library files are conditionally included with guard code so you can reference them multiple times using `%include` without worrying if they have previously been included. Follow this practice for TLC library files that you create.

The convention is to use a variable with the same name as the base filename, uppercase and with underscores attached at both ends. So, a file named `customlib.tlc` should have the variable `_CUSTOMLIB_` guarding it.

As an example, the main Target Language Compiler function library, `funclib.tlc`, contains this TLC code to prevent multiple inclusion:

```
%if EXISTS("_FUNCLIB_") == 0
%assign _FUNCLIB_ = 1
  .
```

```
  .
  .
%endif  %% _FUNCLIB_
```

Code Defensively

As the code your TLC generates could be used in referenced models in unpredictable contexts, do not assume too much about name spaces. For example, when writing TLC code for a block and adding a `typedef`, guard it with `if/def`, as the following example illustrates:

```
%openfile tmpBuff
    #ifndef RESOLUTION_TYPEDEF

    typedef enum { LO_RES, HI_RES } Resolution;
    typedef struct { Resolution res; int8_T value; } Data;

    #define RESOLUTION_TYPEDEF
    #endif /* RESOLUTION_TYPEDEF */
  %closefile tmpBuff

  %<LibCacheTypedefs(tmpBuff)>;
```

Block Target File Methods

Block Functions Overview

Each block has a target file that determines what code should be generated for the block. The code can vary depending on the exact parameters of the block or the types of connections to it (e.g., wide vs. scalar input).

Within each block target file, block functions specify the code to be output for the block in the model's or subsystem's `start` function, `output` function, `update` function, and so on.

The functions declared inside each of the block target files are called by the system target files. In these tables, `block` refers to a Simulink block name (e.g., `gain` for the Gain block) and `system` refers to the subsystem in which the block resides. The first table lists the two functions that are used for preprocessing and setup. Neither of these functions outputs generated code.

- "BlockInstanceSetup(block, system)" on page 20-28
- "BlockTypeSetup(block, system)" on page 20-29

The following functions generate executable code that the code generator places appropriately:

- "Enable(block, system)" on page 20-30
- "Disable(block, system)" on page 20-30
- "Start(block, system)" on page 20-30
- "InitializeConditions(block, system)" on page 20-31
- "Outputs(block, system)" on page 20-32
- "Update(block, system)" on page 20-33
- "Derivatives(block, system)" on page 20-34
- "Terminate(block, system)" on page 20-34

In object-oriented programming terms, these functions are polymorphic in nature, because each block target file contains the same functions. The Target Language Compiler dynamically determines at run-time which block function to execute depending on the block's type. That is, the system file only specifies that the `Outputs` function, for

example, is to be executed. The particular `Outputs` function is determined by the Target Language Compiler depending on the block's type.

To write a block target file, use these polymorphic block functions combined with the Target Language Compiler library functions. For a complete list of the Target Language Compiler library functions, see TLC Function Library Reference on "Target Language Compiler" (Simulink Coder).

BlockInstanceSetup(block, system)

The `BlockInstanceSetup` function executes for the blocks that have this function defined in their target files in a model. For example, if a model includes 10 From Workspace blocks, then the `BlockInstanceSetup` function in `fromwks.tlc` executes 10 times, once for each From Workspace block instance. Use `BlockInstanceSetup` to generate code for each instance of a given block type.

See TLC Function Library Reference on "Target Language Compiler" (Simulink Coder) for available utility processing functions to call from inside this block function. See the file *`matlabroot`*`/rtw/c/tlc/blocks/lookup2d.tlc` for an example of the `BlockInstanceSetup` function.

Syntax

```
BlockInstanceSetup(block, system) void
block = Reference to a Simulink block
system = Reference to a nonvirtual Simulink subsystem
```

This example uses `BlockInstanceSetup`:

```
%function BlockInstanceSetup(block, system) void
%if (block.InMask == "yes")
    %assign blockName = LibParentMaskBlockName(block)
  %else
    %assign blockName = LibGetFormattedBlockPath(block)
  %endif
  %if (CodeFormat == "Embedded-C")
    %if !(ParamSettings.ColZeroTechnique == "NormalInterp" && ...
          ParamSettings.RowZeroTechnique == "NormalInterp")
      %selectfile STDOUT

Note: Removing repeated zero values from the X and Y axes will
produce more efficient code for block: %<blockName>.  To locate
this block, type
```

```
open_system('%<blockName>')

at the MATLAB command prompt.

      %selectfile NULL_FILE
    %endif
  %endif
%endfunction
```

BlockTypeSetup(block, system)

`BlockTypeSetup` executes once per block type before code generation begins. That is, if 10 Lookup Table blocks exist in the model, the `BlockTypeSetup` function in `look_up.tlc` is called only one time. Use this function to perform general work for multiple blocks of a given type.

See TLC Function Library Reference on "Target Language Compiler" (Simulink Coder) for a list of relevant functions to call from inside this block function. See `look_up.tlc` for an example of the `BlockTypeSetup` function.

Syntax

```
    BlockTypeSetup(block, system) void
    block = Reference to a Simulink block
    system = Reference to a nonvirtual Simulink subsystem
```

As an example, given the S-function `foo`, which requires a `#define` and two function declarations in the header file, you could define:

```
%function BlockTypeSetup(block, system) void

  %% Place a #define in the model's header file

  %openfile buffer
    #define A2D_CHANNEL 0
  %closefile buffer

  %<LibCacheDefine(buffer)>

  %% Place function prototypes in the model's header file

  %openfile buffer
```

```
    void start_a2d(void);
    void reset_a2d(void);
  %closefile buffer

  %<LibCacheFunctionPrototype(buffer)>
%endfunction
```

The remaining block functions execute once for each block in the model.

Enable(block, system)

The code generator creates `Enable` functions for nonvirtual subsystem whenever a Simulink subsystem contains a block with an `Enable` function. Including the `Enable` function in a block's target file places the block's specific enable code in this subsystem `Enable` function. For example:

```
%% Function: Enable ===========================================
%% Abstract:
%% Subsystem Enable code is required only for the discrete form
%% of the Sine Block. Setting the Boolean to TRUE causes the
%% Output function to resync its last values of cos(wt) and
%% sin(wt).
%%
%function Enable(block, system) Output
  %if LibIsDiscrete(TID)
    /* %<Type> Block: %<Name> */
    %<LibBlockIWork(SystemEnable, "", "", 0)> = (int_T) TRUE;

  %endif
%endfunction
```

Disable(block, system)

Nonvirtual subsystem `Disable` functions are created whenever a Simulink subsystem contains a block with a `Disable` function. Including the `Disable` function in a block's target file places the block's specific disable code into this subsystem `Disable` function.

Start(block, system)

Include a `Start` function to place code in the `Start` function. The code inside the `Start` function executes once and only once. Typically, you include a `Start` function to execute

code once at the beginning of the simulation (e.g., initialize values in the work vectors) or code that does not need to be re-executed when the subsystem in which it resides is enabled. See `constant.tlc` for an example of the `Start` function.

```
%% Function: Start ============================================
%% Abstract:
%% Set the output to the constant parameter value if the block
%% output is visible in the model's start function scope, i.e.,
%% it is in the global rtB structure.
%%
%function Start(block, system) Output
  %if  LibBlockOutputSignalIsInBlockIO(0)
    /* %<Type> Block: %<Name> */
    %assign rollVars = ["Y", "P"]
    %roll idx = RollRegions, lcv = RollThreshold, block, ...
      "Roller", rollVars
      %assign yr = LibBlockOutputSignal(0,"", lcv, ...
        "%<tRealPart>%<idx>")
      %assign pr = LibBlockParameter(Value, "", lcv, ...
        "%<tRealPart>%<idx>")
      %<yr> = %<pr>;
      %if LibBlockOutputSignalIsComplex(0)
        %assign yi = LibBlockOutputSignal(0, "", lcv, ...
          "%<tImagPart>%<idx>")
        %assign pi = LibBlockParameter(Value, "", lcv, ...
          "%<tImagPart>%<idx>")
        %<yi> = %<pi>;
      %endif
    %endroll
  %endif
%endfunction %% Start
```

InitializeConditions(block, system)

TLC code that is generated from the block's `InitializeConditions` function appears in one of two places. A nonvirtual subsystem contains an `Initialize` function when it is configured to reset states on enable. In this case, the TLC code generated by this block function is placed in the subsystem `Initialize` function, and the `start` function calls this subsystem `Initialize` function. If, however, the Simulink block resides in the root system or in a nonvirtual subsystem that does not require an `Initialize` function, the code generated from this block function is placed directly (inlined) into the `start` function.

There is a subtle difference between the block functions `Start` and `InitializeConditions`. Typically, you include a `Start` function to execute code that does not need to re-execute when the subsystem in which it resides is enabled. You include an `InitializeConditions` function to execute code that must re-execute when the subsystem in which it resides is enabled. For example:

```
%% Function: InitializeConditions ============================
%%
%% Abstract: Invalidate the stored output and input in
%% rwork[1 2*blockWidth] by setting the time stamp stored
%% in rwork[0]) to rtInf.
%%
%function InitializeConditions(block, system) Output
  /* %<Type> Block: %<Name> */
  %<LibBlockRWork(PrevT, "", "", 0)> = %<LibRealNonFinite(inf)>;
%endfunction
```

Outputs(block, system)

A block should generally include an `Outputs` function. The TLC code generated by a block's `Outputs` function is placed in one of two places. The code is placed directly in the model's `Outputs` function if the block does not reside in a nonvirtual subsystem, and in a subsystem's `Outputs` function if the block resides in a nonvirtual subsystem. For example:

```
%% Function: Outputs ========================================
%% Abstract:
%%      Y[i] = fabs(U[i]) if U[i] is real or
%%      Y[i] = sqrt(U[i].re^2 + U[i].im^2) if U[i] is complex.
%%
%function Outputs(block, system) Output
  /* %<Type> Block: %<Name> */
  %%
  %assign inputIsComplex = LibBlockInputSignalIsComplex(0)
  %assign RT_SQUARE = "RT_SQUARE"
  %%
  %assign rollVars = ["U", "Y"]
  %if inputIsComplex
    %roll sigIdx = RollRegions, lcv = RollThreshold, ...
      block, "Roller", rollVars
      %%
      %assign ur = LibBlockInputSignal( 0, "", lcv, ...
        "%<tRealPart>%<sigIdx>")
```

```
      %assign ui = LibBlockInputSignal( 0, "", lcv, ...
        "%<tImagPart>%<sigIdx>")
      %%
      %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
      %<y> = sqrt( %<RT_SQUARE>( %<ur> ) + %<RT_SQUARE>( %<ui> ) );
    %endroll
  %else
    %roll sigIdx = RollRegions, lcv = RollThreshold, ...
      block, "Roller", rollVars
      %assign u = LibBlockInputSignal (0, "", lcv, sigIdx)
      %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
      %<y> = fabs(%<u>);
    %endroll
  %endif
  %endfunction
```

Note Zero-crossing reset code is placed in the `Outputs` function.

If you write TLC code to generate inlined code from an S-function, and if the TLC code contains an `Outputs` function, you must modify the TLC code if all of these conditions are true:

- An output port uses or inherits constant sample time. The output port has a constant value.
- The S-function is a multirate S-function or uses port-based sample times.

In this case, the TLC code must generate code for the constant-valued output port by using the function `OutputsForTID` instead of the function `Outputs`. For more information, see “Specifying Constant Sample Time (Inf) for a Port” (Simulink).

Update(block, system)

Include an `Update` function if the block has code that needs to be updated at each major time step. Code generated from this function is placed in either the model’s or the subsystem’s `Update` function, depending on whether or not the block resides in a nonvirtual subsystem. For example:

```
%% Function: Update ============================================
%% Abstract:
%%      X[i] = U[i]
```

```
%%
%function Update(block, system) Output
  /* %<Type> Block: %<Name> */
  %assign rollVars = ["U", "Xd"]
  %roll idx = RollRegions, lcv = RollThreshold, block, ...
    "Roller", rollVars
    %assign u = LibBlockInputSignal(0, "", lcv, idx)
    %assign x = LibBlockDiscreteState("", lcv, idx)
    %<x> = %<u>;
  %endroll
%endfunction %% Update
```

Derivatives(block, system)

Include a `Derivatives` function when generating code to compute the block's continuous states. Code generated from this function is placed in either the model's or the subsystem's `Derivatives` function, depending on whether or not the block resides in a nonvirtual subsystem. See `integrat.tlc` for an example of the `Derivatives` function.

Terminate(block, system)

Include a `Terminate` function to place code in `MdlTerminate`. User-defined S-function target files can use this function to save data, free memory, reset hardware on the target, and so on. See `tofile.tlc` for an example of the `Terminate` function.

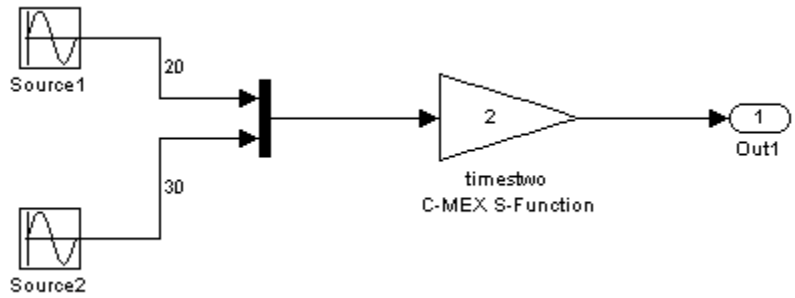
- "Loop Rolling" on page 20-35

Loop Rolling

One of the optimization features of the Target Language Compiler is the intrinsic support for loop rolling. Based on a specified threshold, code generation for looping operations can be unrolled or left as a loop (rolled).

Coupled with loop rolling is the concept of noncontiguous signals. Consider the following model:



The input to the `timestwo` S-function comes from two arrays located at two different memory locations, one for the output of `source1` and one for the output of block `source2`. This is because of an optimization that makes the Mux block virtual, meaning that code is not explicitly generated for the Mux block and thus processor cycles are not spent evaluating it (i.e., it becomes a pure graphical convenience for the block diagram). So this is represented in the *`model`*`.rtw` file in this case as

```
Block {
      Type              "S-Function"
      MaskType              "S-function: timestwo"
      BlockIdx              [0, 0, 2]
      SL_BlockIdx          2
      GrSrc               [0, 1]
      ExprCommentInfo {
    SysIdxList        []
    BlkIdxList        []
    PortIdxList        []
      }
      ExprCommentSrcIdx {
    SysIdx            -1
    BlkIdx            -1
```

```
    PortIdx            -1
      }
      Name              "<Root>/timestwo  C-MEX S-Function"
      SLName              "<Root>/timestwo \nC-MEX S-Function"
      Identifier          timestwoCMEXSFunction
      TID              0
      RollRegions           [0:19, 20:49]
      NumDataInputPorts          1
      DataInputPort {
    SignalSrc        [b0@20, b1@30]
    SignalOffset        [0:19, 0:29]
    Width            50
    RollRegions        [0:19, 20:49]
      }
      NumDataOutputPorts      1
      DataOutputPort {
    SignalSrc        [b2@50]
    SignalOffset        [0:49]
    Width            50
      }
      Connections {
    InputPortContiguous    [no]
    InputPortConnected    [yes]
    OutputPortConnected    [yes]
    OutputPortBeingMerged    [no]
    DirectSrcConn        [no]
    DirectDstConn        [yes]
    DataOutputPort {
      NumConnPoints          1
      ConnPoint {
        SrcSignal            [0, 50]
        DstBlockAndPortEl        [0, 4, 0, 0]
      }
    }
  }
.
.
.
```

From this fragment of the *`model`*`.rtw` file you can see that the block and input port `RollRegion` entries are not just one number, but two groups of numbers. This denotes two groupings in memory for the input signal. The generated code looks like this:

```
/* S-Function Block: <Root>/timestwo  C-MEX S-Function */
  /* Multiply input by two */
  {
    int_T i1;

    const real_T *u0 = &contig_sample_B.u[0];
    real_T *y0 = contig_sample_B.timestwoCMEXSFunction_m;

    for (i1=0; i1 < 20; i1++) {
      y0[i1] = u0[i1] * 2.0;
    }

    u0 = &contig_sample_B.u_o[0];
    y0 = &contig_sample_B.timestwoCMEXSFunction_m[20];

    for (i1=0; i1 < 30; i1++) {
      y0[i1] = u0[i1] * 2.0;
    }
}
```

Notice that two loops are generated and between them the input signal is redirected from the first base address, `&contig_sample_B.u[0]`, to the second base address of the signals, `&contig_sample_B.u_o[0]`. If you do not want to support this in your S-function or your generated code, you can use

```
ssSetInputPortRequiredContiguous(S, 1);
```

in the `mdlInitializeSizes` function to cause Simulink to implicitly generate code that performs a buffering operation. This option uses both extra memory and CPU cycles at run-time, but might be worth it if your algorithm performance increases enough to offset the overhead of the buffering.

Use the `%roll` directive to generate loops. See also “%roll” on page 18-29 for the reference entry for `%roll`, and “Input Signal Functions” on page 21-7 for a discussion on the behavior of `%roll`.

TLC Function Library Reference

This chapter provides a set of Target Language Compiler functions that are useful for inlining S-functions. The TLC files contain many other library functions, but you should use only the functions that are documented in these reference pages for development. Undocumented functions can change significantly from release to release. “Obsolete Functions” on page 21-95 includes a table of obsolete functions and their replacements.

Target Language Compiler Library Functions Overview

There are several library functions that provide access to block inputs, outputs, parameters, sample times, and other information. It is recommended that you use these library functions to access many of the parameter name/parameter values pairs in the block record, as opposed to accessing the parameter name/parameter value pairs directly from your block TLC code.

The library functions simplify block TLC code and provide support for loop rolling, data types, and complex data. The functions also provide a layer to protect against changes that can occur to the contents of the *`model`*`.rtw` file.

An exception to using these functions is when you access parameter settings for a block. Parameter settings can be written out using the `mdlRTW` function of a C MEX S-function. They can contain data in the form of strings, scalar values, vectors, and matrices. They can be used to pass fixed values and information that is used to alter the generated code for a block or directly as values in the resulting code of a block. For more information about this exception, see “Exception to Using the Library Functions that Access model.rtw” on page 17-13.

Target Language Compiler Function Conventions

In this section...

You can find examples using these functions in *`matlabroot`*`/toolbox/simulink/blocks/tlc_c` and *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/tlc_c`. The corresponding MEX S-function source code is located in *`matlabroot`*`/simulink/src` or *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures/src`. MATLAB file S-functions and the MEX-file executables (for example, *`sfunction`*`.mex*`) are located in *`matlabroot`*`/toolbox/simulink/blocks` or *`matlabroot`*`/toolbox/simulink/simdemos/simfeatures`.

Common Function Arguments

Several functions take similar or identical arguments. To simplify the reference pages, some of these arguments are documented in detail here instead of in the reference pages.

Argument	Description
`portIdx`	Refers to an input or output port index, starting at 0. For example, the first input port of an S-function is 0.
`ucv`	User control variable. This is an advanced feature that overrides the `lcv` and `sigIdx` parameters. When used within an inlined S-function, it should generally be specified as `""`.
`lcv`	Loop control variable. This is generally generated by the `%roll` directive via the second `%roll` argument (e.g., `lcv=RollThreshold`) and should be passed directly to the library function. It contains either `""`, indicating that the current pass through the `%roll` is being inlined, or it is the name of a loop control variable such as `"i"`, indicating that the current pass through the `%roll` is being placed in a loop. Outside the `%roll` directive, this is usually specified as `""`.

Argument	Description
`sigIdx`*or*`idx`	Signal index. Sometimes referred to as the signal element index. When accessing specific elements of an input or output signal directly, the call to the various library routines should have `ucv=""`, `lcv=""`, and `sigIdx` equal to the desired integer signal index starting at 0. For complex signals, `sigIdx` can be an overloaded integer index specifying both whether the real or imaginary part is being accessed and which element. When you access these items inside a `%roll`, use the `sigIdx` generated by the `%roll` directive. Most functions that take a `sigIdx` argument accept it in an overloaded form, where `sigIdx` can be • An integer, e.g., `3`. If the referenced signal is complex, then this refers to the identifier for the complex container. If the referenced signal is not complex, then this refers to the identifier. • An `id-num`, usually of the form (see “Overloading sigIdx” on page 21-5) **a** `"%<tRealPart>%<idx>"` (e.g., `"re3"`). The real part of the signal element. Usually `"%<tRealPart>%<sigIdx>"` when `sigIdx` is generated by the `%roll` directive. **b** `"%<tImagPart>%<idx>"` (e.g., `"im3"`). The imaginary part of the signal element or `""` if the signal is not complex. Usually `"%<tImagPart>%<sigIdx>"` when `sigIdx` is generated by the `%roll` directive. Use the `idx` name when referring to a state or work vector. Functions that accept the three arguments `ucv`, `lcv`, `sigIdx` (or `idx`) are called differently depending upon whether or not they are used within a `%roll` directive. If they are used within a `%roll` directive, `ucv` is generally specified as `""` and, `lcv` and `sigIdx` are the same as those specified in the `%roll` directive. If they are not used within a `%roll` directive, `ucv` and `lcv` are generally specified as `""`, and `sigIdx` specifies the index to access.
`paramIdx`	Parameter index. Sometimes referred to as the parameter element index. The handling of this parameter is very similar to `sigIdx` above: it can be `#`, `re#`, or `im#`.
`stateIdx`	State index. Sometimes referred to as the state vector element index. It must evaluate to an integer where the first element starts at `0`.

Overloading sigIdx

The signal index (`sigIdx` sometimes written as `idx`) can be overloaded when passed to most library functions. Suppose you are interested in element 3 of a signal, and `ucv=""`, `lcv=""`. The following table shows

- Values of `sigIdx`
- Whether the signal being referenced is complex
- What the function that uses `sigIdx` returns
- An example of a returned variable
- Data type of the returned variable

Note that “container” in the following table refers to the object that encapsulates both the real and imaginary parts of the number, e.g., `creal_T`, defined in `tmwtypes.h`.

sigIdx	Complex	Function Returns	Example	Data Type
`"re3"`	Yes	Real part of element 3	`u0[2].re`	`real_T`
`"im3"`	Yes	Imaginary part of element 3	`u0[2].im`	`real_T`
`"3"`	Yes	Complex container of element 3	`u0[2]`	`creal_T`
`3`	Yes	Complex container of element 3	`u0[2]`	`creal_T`
`"re3"`	No	Element 3	`u0[2]`	`real_T`
`"im3"`	No	`""`	N/A	N/A
`"3"`	No	Element 3	`u0[2]`	`real_T`
`3`	No	Element 3	`u0[2]`	`real_T`

Now suppose the following:

1. You are interested in element 3 of a signal.
2. (`ucv = "i"` AND `lcv == ""`) OR (`ucv = ""` AND `lcv = "i"`).

The following table shows values of `idx`, whether the signal is complex, and what the function that uses `idx` returns.

sigIdx	Complex	Function Returns
"re3"	Yes	Real part of element i
"im3"	Yes	Imaginary part of element ii
"3"	Yes	Complex container of element i
3	Yes	Complex container of element i
"re3"	No	Element i
"im3"	No	""
"3"	No	Element i
3	No	Element i

Notes

- The vector index is added only for wide signals.
- If ucv is not an empty string (""), then ucv is used instead of sigIdx in the above examples and both lcv and sigIdx are ignored.
- If ucv is empty but lcv is not empty, then the function returns "&y %<portIdx>[%<lcv>]" and sigIdx is ignored.
- It is assumed that the roller has declared and initialized the variables accessed inside the roller. The variables accessed inside the roller should be specified using rollVars as the argument to the %roll directive.

Input Signal Functions

In this section...

LibBlockInputPortIndexMode(block, pidx)

Purpose

Determines the index mode of a block's input port.

Arguments

`block` — Block record

`pidx` — Port index

Returns

"" for a nonindex port, and "Zero-based" or "One-based" otherwise.

Description

If an input port of a block is set as an index port and its indexing base is marked as zero-based or one-based, this information is written into the *model*.rtw file. LibBlockInputPortIndexMode queries the indexing base to branch to different code according to what the input port indexing base is.

Example

```
%if LibBlockInputPortIndexMode(block, pidx) == "Zero-based"
  ...
%elseif LibBlockInputPortIndexMode(block, pidx) == "One-based"
  ...
%else
  ...
%endif
```

See LibBlockInputPortIndexMode in blkiolib.tlc.

LibBlockInputSignal(portIdx, ucv, lcv, sigIdx)

Based on the input port number (portIdx), the user control variable (ucv), the loop control variable (lcv), the signal index (sigIdx), and where this input signal is coming from, LibBlockInputSignal returns the reference to a block input signal.

The returned string value is a valid rvalue (right-side value) for an expression. The block input signal can come from another block, a state vector, or an external input, or it can be a literal constant (e.g., 5.0).

Note Do not use LibBlockInputSignal to access the address of an input signal.

Because the returned value can be a literal constant, you should not use LibBlockInputSignal to access the address of an input signal. To access the address of an input signal, use LibBlockInputSignalAddr. Accessing the address of the signal via LibBlockInputSignal can result in a reference to a literal constant (e.g., 5.0).

For example, the following would *not* work.

```
%assign u = LibBlockInputSignal(0, "", lcv, sigIdx)
x = &%<u>;
```

If `%<u>` refers to an invariant signal with a value of `4.95`, the statement (after being processed by the preprocessor) would be generated as

```
x = &4.95;
```

or, if the input signal sources to ground, the statement could come out as

```
x = &0.0;
```

Neither of these would compile.

Avoid such situations by using `LibBlockInputSignalAddr`.

```
%assign uAddr = LibBlockInputSignalAddr(0, "", lcv, sigIdx)
x = %<uAddr>;
```

The code generator tracks signals and parameters accessed by their addresses and declares them in addressable memory.

Input Arguments

The following table summarizes the input arguments to `LibBlockInputSignal`.

LibBlockInputSignal Arguments

Argument	Description
`portIdx`	Integer specifying the input port index (zero-based). **Note:** For certain built-in blocks, `portIdx` can be a string identifying the port (such as `"enable"` or `"trigger"`).
`ucv`	User control variable. Must be a string, either an indexing expression or `""`.
`lcv`	Loop control variable. Must be a string, either an indexing expression or `""`.

`sigIdx`	Either an integer literal or a string of the form
	
	`%<tRealPart>Integer`
	`%<tImagPart>Integer`
	
	For example, the following signifies the real part of the signal and the imaginary part of the signal starting at 5:
	
	`"%<tRealPart>5"`
	`"%<tImagPart>5"`

General Usage

Uses of `LibBlockInputSignal` fall into the categories described below.

Direct indexing

If `ucv == ""` and `lcv == ""`, `LibBlockInputSignal` returns an indexing expression for the element specified by `sigIdx`.

Loop rolling/unrolling

In this case, `lcv` and `sigIdx` are generated by the `%roll` directive, and `ucv` must be `""`. A nonempty value for `lcv` is allowed only when generated by the `%roll` directive and when using the Roller TLC file (or a user supplied Roller TLC file that conforms to the same variable/signal offset handling). In addition, calls to `LibBlockInputSignal` with `lcv` should occur only when `"U"` or a specific input port (e.g., `"u0"`) is passed to the `%roll` directive via the roll variables argument.

The following example shows a single input/single output port S-function.

```
%assign rollVars  = ["U", "Y", "P"]
%roll sigIdx=RollRegions, lcv=RollThreshold, block, ...
    "Roller", rollVars
  %assign u = LibBlockInputSignal( 0, "", lcv, sigIdx)
  %assign y = LibBlockOutputSignal(0, "", lcv, sigIdx)
  %assign p = LibBlockParameter(   0, "", lcv, sigIdx)
  %<y> = %<p> * %<u>;
%endroll
```

With the `%roll` directive, `sigIdx` is the starting index of the current roll region and `lcv` is `""` or an indexing variable. The following are examples of valid values:

```
LibBlockInputSignal(0, "", lcv, sigIdx)    rtB.blockname[0]

LibBlockInputSignal(0, "", lcv, sigIdx)    u[i]
```

In the first example, `LibBlockInputSignal` returns `rtB.blockname[2]` when the input port is connected to the output of another block, and

- The loop control variable (`lcv`) generated by the `%roll` directive is empty, indicating that the current roll region is below the roll threshold, and `sigIdx` is `0`.
- The width of the input port is `1`, indicating that this port is being scalar expanded.

  If `sigIdx` is nonzero, then `rtB.blockname[sigIdx]` is returned. For example, if `sigIdx` is `3`, then `rtB.blockname[3]` is returned.

In the second example, `LibBlockInputSignal` returns `u[i]` when the current roll region is above the roll threshold and the input port width is nonscalar (wide). In this case, the Roller TLC file sets up a local variable, `u`, to point to the input signal, and the code in the current `%roll` directive is placed within a `for` loop.

For another example, consider a block with multiple input ports where each port has a width greater than or equal to 1 and at least one port has width equal to 1. The following code sets the output signal to the sum of the squares of the input signals.

```
%assign y = LibBlockOutputSignal(0, "", "", 0)
%<y> = 0;

%assign rollVars = ["U"]
%foreach port = block.NumDataInputPorts - 1
  %roll sigIdx=RollRegions, lcv = RollThreshold, block, ...
    "Roller", rollVars
  %assign u = LibBlockInputSignal(port, "", lcv, sigIdx)
```

```
  %<y> += %<u> * %<u>;
  %endroll
%endforeach
```

Because the first parameter of `LibBlockInputSignal` is `0` indexed, you must index the `foreach` loop to start from `0` and end at `NumDataInputPorts-1`.

User Control Variable (ucv) Handling

This is an advanced mode and generally not required by S-function authors.

If `ucv != ""`, `LibBlockInputSignal` returns an `rvalue` for the input signal using the user control variable indexing expression. The control variable indexing expression has the following form:

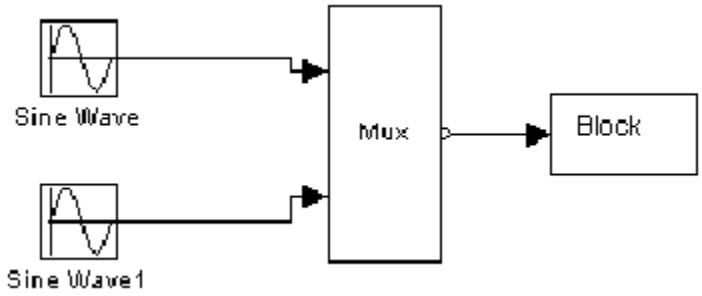
```
rvalue_id[%<ucv>]%<optional_real_or_imag_part>
```

To obtain `rvalue_id`, look at the integer part of `sigIdx`. You must specify `sigIdx` because the input to this block can be discontinuous, meaning that the input can come from several different memory areas (signal sources) and `sigIdx` is used to identify the area of interest for the `ucv`. You can also use `sigIdx` to determine whether the real or imaginary part of a signal is to be accessed.

You can obtain `optional_real_or_imag_part` from the string part of `sigIdx` (i.e., `"re"`, or `"im"`, or `""`).

Note that the value for `lcv` is ignored and `sigIdx` must point to the same element in the input signal to which the `ucv` initially points.

The handling of `ucv` with `LibBlockInputSignal` requires care. Consider a discontinuous input signal feeding an input port as in the following block diagram:



To use `ucv` in a robust manner, you must use the `%roll` directive with a roll threshold of `1` and a Roller TLC file that does not have loop header/trailer setup for this input signal. In addition, you need to use `ROLL_ITERATIONS` to determine the width of the current roll region, as in the following TLC code:

```
{
int i;

%assign rollVars  = [""]
%assign threshold = 1
  %roll sigIdx=RollRegions, lcv=threshold, block, ...
    "FlatRoller", rollVars
  %assign u = LibBlockInputSignal( 0, "i", "", sigIdx)
  %assign y = LibBlockOutputSignal(0, "i+%<sigIdx>", "", sigIdx)
  %assign p = LibBlockParameter( 0, "i+%<sigIdx>", "", sigIdx)
  for (i = 0; i < %<ROLL_ITERATIONS()>; i++) {
    %<y> = %<p> * %<u>;
  }
%endroll
}
```

Note that the `FlatRoller` does not have loop header/trailer setup (`rollVars` is ignored). Its purpose is to walk the `RollRegions` of the block. Alternatively, you can force a contiguous input signal to your block by specifying

```
ssSetInputPortRequiredContiguous(S, port, TRUE)
```

in your S-function.

In this case, the TLC code simplifies to

```
{
%assign u = LibBlockInputSignal( 0, "i", "", 0)
%assign y = LibBlockOutputSignal(0, "i", "", 0)
%assign p = LibBlockParameter(   0, "i", "", 0)

for (i = 0; i < %<LibBlockInputSignalWidth(0)>; i++) {
  %<y> = %<p> * %<u>;
  }
}
```

If you create your own roller and the indexing does not conform to the way the Roller TLC file provided by MathWorks operates, then must to use `ucv` instead of `lcv`.

Handling Input Arguments: ucv, lcv, and sigIdx

Consider the following cases:

Function (Case 1, 2, 3,4)	Example Return Value
`LibBlockInputSignal(0, "i", "", sigIdx)`	`rtB.blockname[i]`
`LibBlockInputSignal(0, "i", "", sigIdx)`	`rtU.signame[i]`
`LibBlockInputSignal(0, "", lcv, sigIdx)`	`u0[i1]`
`LibBlockInputSignal(0, "", lcv, sigIdx)`	`rtB.blockname[0]`

The value returned depends on what the input signal is connected to in the block diagram and how the function is invoked (e.g., in a `%roll` or directly). In the above example,

- Cases 1 and 2 occur when an explicit call is made with the `ucv` set to `"i"`.

  Case 1 occurs when `sigIdx` points to the block I/O vector, i.e., the first element that `"i"` starts with. For example, if you initialize `"i"` to be starting at offset `5`, then you should specify `sigIdx == 5`.

  Case 2 occurs when `sigIdx` points to the external input vector, i.e., the first element that `"i"` starts with. For example, if you initialize `"i"` to start at offset `20`, then you should specify `sigIdx == 20`.
- Cases 3 and 4 receive the same arguments, `lcv` and `sigIdx`; however, they produce different return values.

  Case 3 occurs when `LibBlockInputSignal` is called within a `%roll` directive and the current roll region is being rolled (`lcv != ""`).

  Case 4 occurs when `LibBlockInputSignal` is called within a `%roll` directive and the current roll region is not being rolled (`lcv == ""`).

When called within a`%roll` directive, `LibBlockInputSignal` looks at `ucv`, `lcv`, and `sigIdx`, the current roll region, and the current roll threshold to determine the return value. The variable `ucv` has highest precedence, `lcv` has the next highest precedence, and `sigIdx` has the lowest precedence. That is, if `ucv` is specified, it is used (thus, when called in a `%roll` directive it is usually `""`). If `ucv` is not specified, and if `lcv` and `sigIdx` are specified, the returned value depends on whether or not the current roll region is being placed in a `for` loop or being expanded. If the roll region is being placed in a loop, then `lcv` is used; otherwise, `sigIdx` is used.

A direct call to `LibBlockInputSignal` (inside or outside a `%roll` directive) uses `sigIdx` when `ucv` and `lcv` are specified as `""`.

For an example of `LibBlockInputSignal`, see `sfun_multiport.tlc`.

See also `blkiolib.tlc`.

LibBlockInputSignalAddr(portIdx, ucv, lcv, sigIdx)

Returns a string that provides the memory address of the specified block input port signal.

When you need an input signal address, you must use `LibBlockInputSignalAddr` instead of appending an "&" to the string returned by `LibBlockInputSignal`. For example, `LibBlockInputSignal` can return a literal constant, such as `5` (i.e., an invariant input signal). The code generator tracks when `LibBlockInputSignalAddr` is called on an invariant signal and declares the signal as `const` data (which is addressable), instead of being placed as a literal constant in the generated code (which is not addressable).

Note that the last input argument, `sigIdx`, is not overloaded, which it is in `LibBlockInputSignal`. Hence, if the input signal is complex, the address of the complex container is returned.

Example

To get the address of a wide input signal and pass it to a user function for processing, you could use

```
%assign uAddr = LibBlockInputSignalAddr(0, "", "", 0)
%assign y = LibBlockOutputSignal(0, "", "", 0)
%<y> = myfcn(%<uAddr>);
```

See `LibBlockInputSignalAddr` in `blkiolib.tlc`.

LibBlockInputSignalAliasedThruDataTypeName(portIdx, reim)

Returns the name of the aliased thru data type (e.g., `int_T, ... creal_T`) corresponding to the specified block input port. Specify the `reim` argument as `""` (empty) if you want the complete signal type name.

For example, if `reim == ""` and the first output port is real and complex, the data type name placed in `dtname` is `creal_T`.

```
%assign dtname = LibBlockInputSignalDataTypeName(0,"")
```

Specify `reim` as `tRealPart` if you want the raw element type name. For example, if `reim == tRealPart` and the first output port is real and complex, the data type name returned is `real_T`.

```
%assign dtname = LibBlockOutputSignalDataTypeName(0,tRealPart)
```

See `LibBlockInputSignalAliasedThruDataTypeName` in `blkiolib.tlc`.

LibBlockInputSignalConnected(portIdx)

Returns 1 if the specified input port is connected to a block other than the Ground block and 0 otherwise.

See `LibBlockInputSignalConnected` in `blkiolib.tlc`.

LibBlockInputSignalDataTypeId(portIdx)

Returns the numeric identifier (`id`) corresponding to the data type of the specified block input port.

If the input port signal is complex, `LibBlockInputSignalDataTypeId` returns the data type of the real part (or the imaginary part) of the signal.

See `LibBlockInputSignalDataTypeId` in `blkiolib.tlc`.

LibBlockInputSignalDataTypeName(portIdx, reim)

Returns the name of the data type (e.g., `int_T`, ... `creal_T`) corresponding to the specified block input port.

Specify the `reim` argument as `""` if you want the complete signal type name. For example, if `reim==""` and the first output port is real and complex, the data type name placed in `dtname` is `creal_T`.

```
%assign dtname = LibBlockInputSignalDataTypeName(0,"")
```

Specify the `reim` argument as `tRealPart` if you want the raw element type name. For example, if `reim==tRealPart` and the first output port is real and complex, the data type name returned is `real_T`.

```
%assign dtname = LibBlockInputSignalDataTypeName(0,tRealPart)
```

See `LibBlockInputSignalDataTypeName` in `blkiolib.tlc`.

LibBlockInputSignalDimensions(portIdx)

Returns the dimensions vector of the specified block input port, e.g., `[2,3]`.

See `LibBlockInputSignalDimensions` in `blkiolib.tlc`.

LibBlockInputSignalIsComplex(portIdx)

Returns 1 if the specified block input port is complex, 0 otherwise.

See `LibBlockInputSignalIsComplex` in `blkiolib.tlc`.

LibBlockInputSignalIsFrameData(portIdx)

Returns 1 if the specified block input port is frame based, 0 otherwise.

See `LibBlockInputSignalIsFrameData` in `blkiolib.tlc`.

LibBlockInputSignalLocalSampleTimeIndex(portIdx)

Returns the local sample time index corresponding to the specified block input port.

See `LibBlockInputSignalLocalSampleTimeIndex` in `blkiolib.tlc`.

LibBlockInputSignalNumDimensions(portIdx)

Returns the number of dimensions of the specified block input port.

See `LibBlockInputSignalNumDimensions` in `blkiolib.tlc`.

LibBlockInputSignalOffsetTime(portIdx)

Returns the offset time corresponding to the specified block input port.

See `LibBlockInputSignalOffsetTime` in `blkiolib.tlc`.

LibBlockInputSignalSampleTime(portIdx)

Returns the sample time corresponding to the specified block input port.

See `LibBlockInputSignalSampleTime` in `blkiolib.tlc`.

LibBlockInputSignalSampleTimeIndex(portIdx)

Returns the sample time index corresponding to the specified block input port.

See `LibBlockInputSignalSampleTimeIndex` in `blkiolib.tlc`.

LibBlockInputSignalSymbolicDimensions(portIdx)

Returns the number of dimensions of the specified block input port.

See `LibBlockInputSignalSymbolicDimensions(portIdx)` in `blkiolib.tlc`.

LibBlockInputSignalSymbolicWidth(portIdx)

Returns the symbolic width of the specified block input port.

See `LibBlockInputSignalSymbolicWidth(portIdx)` in `blkiolib.tlc`.

LibBlockInputSignalWidth(portIdx)

Returns the width of the specified block input port index.

See `LibBlockInputSignalWidth` in `blkiolib.tlc`.

LibBlockNumInputPorts(block)

Returns the number of data input ports of a block (excludes control ports).

See `LibBlockNumInputPorts` in `blocklib.tlc`.

Output Signal Functions

In this section...

LibBlockAssignOutputSignal(portIdx, ucv, lcv, sigIdx, rhs)

Based on the output port number (`portIdx`), the user control variable (`ucv`), the loop control variable (`lcv`), the signal index (`sigIdx`), and the output signal destination, `LibBlockAssignOutputSignal` assigns a block’s output to a specified right hand side value, (`rhs`).

See `LibBlockAssignOutputSignal` in `customstoragelib.tlc`.

LibBlockNumOutputPorts(block)

Returns the number of data output ports of a block (excludes control and state ports).

See `LibBlockNumOutputPorts` in `blocklib.tlc`.

LibBlockOutputPortIndexMode(block, pidx)

Purpose

Determines the index mode of a block's output port.

Description

If a block's output port is set as an index port and its indexing base is marked as zero-based or one-based, this information is written into the *`model`*`.rtw` file. `LibBlockOutputPortIndexMode` queries the indexing base to branch to different code according to what the output port indexing base is.

Example

```
%if LibBlockOutputPortIndexMode(block, idx) == "Zero-based"
  ...
%elseif LibBlockOutputPortIndexMode(block, idx) == "One-based"
  ...
%else
  ...
%endif
```

Arguments

`block` — Block record

`pidx` — Port index

Returns

`""` for a nonindex port, and `"Zero-based"` or `"One-based"` otherwise.

See `LibBlockOutputPortIndexMode` in `blkiolib.tlc`.

LibBlockOutputSignal(portIdx, ucv, lcv, sigIdx)

Based on the output port number (`portIdx`), the user control variable (`ucv`), the loop control variable (`lcv`), the signal index (`sigIdx`), and the output signal destination, `LibBlockOutputSignal` returns a reference to a block output signal.

The returned value is a valid `lvalue` (left-side value) for an expression. The block output destination can be a location in the block I/O vector (another block's input), the state vector, or an external output.

Note Do not use `LibBlockOutputSignal` to access the address of an output signal.

The code generator tracks when a variable (e.g., a signal or parameter) is accessed by its address. To access the address of an output signal, use `LibBlockOutputSignalAddr` as in the following example:

```
%assign yAddr = LibBlockOutputSignalAddr(0, "", lcv, sigIdx)
x = %<yAddr>;
```

See `LibBlockOutputSignal` in `blkiolib.tlc`.

LibBlockOutputSignalAddr(portIdx, ucv, lcv, sigIdx)

Returns a string that provides the memory address of the specified block output port signal.

When an output signal address is required, you must use `LibBlockOutputSignalAddr` instead of taking the address that is returned by `LibBlockOutputSignal`. For example, `LibBlockOutputSignal` can return a literal constant, such as 5 (i.e., an invariant output signal). When `LibBlockOutputSignalAddr` is called on an invariant signal, the signal is declared as a `const` instead of being placed as a literal constant in the generated code.

Note that unlike `LibBlockOutputSignal`, the last argument, `sigIdx`, is not overloaded. Hence, if the output signal is complex, the address of the complex container is returned.

Example

To get the address of a wide output signal and pass it to a user function for processing, you could use

```
%assign u = LibBlockOutputSignalAddr(0, "", "", 0)
%assign y = LibBlockOutputSignal(0, "", "", 0)
%<y> = myfcn (%<u>);
```

See `LibBlockOutputSignalAddr` in `blkiolib.tlc`.

LibBlockOutputSignalAliasedThruDataTypeName(portIdx, reim)

Returns the type name string (e.g., `int_T, ... creal_T`) of the aliased data type corresponding to the specified block output port.

Specify the `reim` argument as `""` if you want the complete signal type name. For example, if `reim == ""` and the first output port is real and complex, the data type placed in `dtname` is `creal_T`:

```
%assign dtname = LibBlockOutputSignalAliasedThroughDataTypeName(0x,"")
```

Specify the reim argument as `tRealPart` if you want the raw element type name. For example, if `reim == tRealPart` and the first output port is real and complex, the data type name returned is `real_T`.

```
%assign dtname = LibBlockOutputSignalAliasedThroughDataTypeName(0,tRealPart)
```

See `LibBlockOutputSignalAliasedThruDataTypeName` in `blkiolib.tlc`.

LibBlockOutputSignalBeingMerged(portIdx)

Returns whether the specified output port is connected to a Merge block.

See `LibBlockOutputSignalBeingMerged` in `blkiolib.tlc`.

LibBlockOutputSignalConnected(portIdx)

Returns 1 if the specified output port is connected to a block other than the Ground block and 0 otherwise.

See `LibBlockOutputSignalConnected` in `blkiolib.tlc`.

LibBlockOutputSignalDataTypeId(portIdx)

Returns the numeric ID corresponding to the data type of the specified block output port.

If the output port signal is complex, `LibBlockOutputSignalDataTypeId` returns the data type of the real (or the imaginary) part of the signal.

See `LibBlockOutputSignalDataTypeId` in `blkiolib.tlc`.

LibBlockOutputSignalDataTypeName(portIdx, reim)

Returns the type name string (e.g., `int_T`, ... `creal_T`) of the data type corresponding to the specified block output port.

Specify the `reim` argument as `""` if you want the complete signal type name. For example, if `reim==""` and the first output port is real and complex, the data type name placed in `dtname` is `creal_T`.

```
%assign dtname = LibBlockOutputSignalDataTypeName(0x,"")
```

Specify the `reim` argument as `tRealPart` if you want the raw element type name. For example, if `reim==tRealPart` and the first output port is real and complex, the data type name returned is `real_T`.

```
%assign dtname = LibBlockOutputSignalDataTypeName(0,tRealPart)
```

See `LibBlockOutputSignalDataTypeName` in `blkiolib.tlc`.

LibBlockOutputSignalDimensions(portIdx)

Returns the dimensions of the specified block output port.

See `LibBlockOutputSignalDimensions` in `blkiolib.tlc`.

LibBlockOutputSignalIsComplex(portIdx)

Returns 1 if the specified block output port is complex, 0 otherwise.

See `LibBlockOutputSignalIsComplex` in `blkiolib.tlc`.

LibBlockOutputSignalIsExpr(portIdx)

Returns 1 (true) if the output signal is an expression, and 0 (false) otherwise.

See `LibBlockOutputSignalIsExpr` in `blkiolib.tlc`.

LibBlockOutputSignalIsFrameData(portIdx)

Returns 1 if the specified block output port is frame based, 0 otherwise.

See `LibBlockOutputSignalIsFrameData` in `blkiolib.tlc`.

LibBlockOutputSignalLocalSampleTimeIndex(portIdx)

Returns the local sample time index corresponding to the specified block output port.

See `LibBlockOutputSignalLocalSampleTimeIndex` in `blkiolib.tlc`.

LibBlockOutputSignalNumDimensions(portIdx)

Returns the number of dimensions of the specified block output port.

See `LibBlockOutputSignalNumDimensions` in `blkiolib.tlc`.

LibBlockOutputSignalOffsetTime(portIdx)

Returns the offset time corresponding to the specified block output port.

See `LibBlockOutputSignalOffsetTime` in `blkiolib.tlc`.

LibBlockOutputSignalSampleTime(portIdx)

Returns the sample time corresponding to the specified block output port.

See `LibBlockOutputSignalSampleTime` in `blkiolib.tlc`.

LibBlockOutputSignalSymbolicDimensions(portIdx)

Returns the symbolic dimensions of specified block output port.

See `LibBlockOutputSignalSymbolicDimensions` in `blkiolib.tlc`.

LibBlockOutputSignalSymbolicWidth(portIdx)

Returns the symbolic width of specified block output port.

See `LibBlockOutputSignalSymbolicWidth` in `blkiolib.tlc`.

LibBlockOutputSignalSampleTimeIndex(portIdx)

Returns the sample time index corresponding to the specified block output port.

See `LibBlockOutputSignalSampleTimeIndex` in `blkiolib.tlc`.

LibBlockOutputSignalWidth(portIdx)

Returns the width of the specified block output port.

See `LibBlockOutputSignalWidth` in `blkiolib.tlc`.

- “Target Language Compiler Function Conventions” on page 21-3

Parameter Functions

In this section...

LibBlockMatrixParameter

`LibBlockMatrixParameter(param, rucv, rlcv, ridx, cucv, clcv, cidx)` returns a matrix parameter for a block, given the row and column user control variables (`rucv`, `cucv`), loop control variables (`rlcv`, `clcv`), and indices (`ridx`, `cidx`). Generally, blocks should use `LibBlockParameter`. If you have a matrix parameter, you should write it as a column-major vector and access it via `LibBlockParameter`.

Note Loop rolling is currently not supported, and will generate an error if requested (i.e., if either `rlcv` or `clcv` is not equal to `""`).

The row and column index arguments are similar to the arguments for `LibBlockParameter`. The column index (`cidx`) is overloaded to handle complex numbers.

See `LibBlockMatrixParameter` in `paramlib.tlc`.

LibBlockMatrixParameterAddr

`LibBlockMatrixParameterAddr(param, rucv, rlcv, ridx, cucv, clcv, cidx)` returns the address of a matrix parameter.

Note `LibBlockMatrixParameterAddr` returns the address of a matrix parameter. Loop rolling is not supported (i.e., `rlcv` and `clcv` should both be an empty string).

See `LibBlockMatrixParameterAddr` in `paramlib.tlc`.

LibBlockMatrixParameterBaseAddr

`LibBlockMatrixParameterBaseAddr(param)` returns the base address of a matrix parameter.

See `LibBlockMatrixParameterBaseAddr` in `paramlib.tlc`.

LibBlockParamSetting

`LibBlockParamSetting(bType, psType)` returns the string of a specified parameter setting for a specified block type. If you pass an empty block type into this function, the parameter setting will be assumed to be in the `ParamSettings` record of the block. If a nonempty block type is passed into the function, the parameter settings will be assumed to be in the `%<Btype>ParamSettings` record of that block.

See `LibBlockParamSetting` in `paramlib.tlc`.

LibBlockParameter

Based on the parameter reference (`param`), the user control variable (`ucv`), the loop control variable (`lcv`), the signal index (`sigIdx`), and the state of parameter inlining, `LibBlockParameter(param, ucv, lcv, sigIdx)` returns a reference to a block parameter. The returned value is a valid `rvalue` (right-side value for an expression). For example,

Case	Function Call	Can Produce
1	`LibBlockParameter(Gain, "i", lcv, sigIdx)`	`rtP.blockname[i]`
2	`LibBlockParameter(Gain, "i", lcv, sigIdx)`	`rtP.blockname`
3	`LibBlockParameter(Gain, "", lcv, sigIdx)`	`p_Gain[i]`
4	`LibBlockParameter(Gain, "", lcv, sigIdx)`	`p_Gain`
5	`LibBlockParameter(Gain, "", lcv, sigIdx)`	`4.55`
6	`LibBlockParameter(Gain, "", lcv, sigIdx)`	`rtP.blockname.re`
7	`LibBlockParameter(Gain, "", lcv, sigIdx)`	`rtP.blockname.im`

To illustrate the basic workings of `LibBlockParameter`, assume a noncomplex vector signal where `Gain[0]=4.55`:

```
LibBlockParameter(Gain, "", "i", 0)
```

Case	Rolling	Inline Parameter	Type	Result	Required in Memory
1	0	Yes	Scalar	4.55	No
2	1	Yes	Scalar	4.55	No
3	0	Yes	Vector	4.55	No
4	1	Yes	Vector	`p_Gain[i]`	Yes
5	0	No	Scalar	`rtP.blk.Gain`	No
6	0	No	Scalar	`rtP.blk.Gain`	No
7	0	No	Vector	`rtP.blk.prm[0]`	No
8	0	No	Vector	`p.Gain[i]`	Yes

Note Case 4. Even though Inline Parameter is Yes, the parameter must be placed in memory (RAM), because it is accessed inside a `for` loop.

Note `LibBlockParameter` also supports expressions when used with inlined parameters and parameter tuning.

For example, if the parameter field had the MATLAB expression `'2*a'`, `LibBlockParameter` would return the C expression `'(2*a)'`. The list of functions

supported by `LibBlockParameter` is determined by the functions `FcnConvertNodeToExpr` and `FcnConvertIdToFcn`. To enhance functionality, augment or update either of these functions.

Note that certain types of expressions are not supported, such as `x*y` where *both* `x` and `y` are nonscalar expressions.

See the documentation about tunable parameters for more details on the exact functions and syntax that are supported.

Warning

Do not use `LibBlockParameter` to access the address of a parameter, or you may might erroneously reference a number (i.e., `&4.55`) when the parameter is inlined. You can avoid this situation by using `LibBlockParameterAddr`.

See `LibBlockParameter` in `paramlib.tlc`.

LibBlockParameterAddr

`LibBlockParameterAddr(param, ucv, lcv, idx)` returns the address of a block parameter.

Using `LibBlockParameterAddr` to access a parameter when the global `InlineParams` variable is equal to 1 will cause the variable to be declared `const` in RAM instead of being inlined.

Accessing the address of an expression when the expression has multiple tunable/rolled variables in it will result in an error.

See `LibBlockParameterAddr` in `paramlib.tlc`.

LibBlockParameterBaseAddr

`LibBlockParameterBaseAddr(param)` returns the base address of a block parameter.

Using `LibBlockParameterBaseAddr` to access a parameter when the global `InlineParams` variable is equal to one will cause the variable to be declared `const` in RAM instead of being inlined.

Accessing the address of an expression when the expression has multiple tunable/rolled variables in it will result in an error.

See `LibBlockParameterBaseAddr` in `paramlib.tlc`.

LibBlockParameterDataTypeId

`LibBlockParameterDataTypeId(param)` returns the numeric ID corresponding to the data type of the specified block parameter.

See `LibBlockParameterDataTypeId` in `paramlib.tlc`.

LibBlockParameterDataTypeName

`LibBlockParameterDataTypeName(param, reim)` returns the name of the data type corresponding to the specified block parameter.

See `LibBlockParameterDataTypeName` in `paramlib.tlc`.

LibBlockParameterDimensions

`LibBlockParameterDimensions(param)` returns a row vector of length `N` (where `N >= 1`) giving the dimensions of the parameter data.

For example,

```
%assign dims  = LibBlockParameterDimensions("paramName")
%assign nDims = SIZE(dims,1)
%foreach i=nDims
   /* Dimension %<i+1> = %<dims[i]> */
%endforeach
```

`LibBlockParameterDimensions` differs from `LibBlockParameterSize` in that it returns the dimensions of the parameter data prior to collapsing the `Matrix` parameter to a column-major vector. The collapsing occurs for run-time parameters that have specified their `outputAsMatrix` field as `False`.

See `LibBlockParameterDimensions` in `paramlib.tlc`.

LibBlockParameterIsComplex

`LibBlockParameterIsComplex(param)` returns 1 if the specified block parameter is complex, 0 otherwise.

See `LibBlockParameterIsComplex` in `paramlib.tlc`.

LibBlockParameterSize

`LibBlockParameterSize(param)` returns a vector of size 2 in the format `[nRows, nCols]` where `nRows` is the number of rows and `nCols` is the number of columns.

See `LibBlockParameterSize` in `paramlib.tlc`.

LibBlockParameterString

Based on the block parameter reference (`param`), `LibBlockParameterString(param)` returns the specified block parameter interpreted as a string, for example, this function returns:

- `STRINGOF(param.Value[0])` if the parameter is a row matrix
- `STRINGOF(param.Value)` otherwise

Note It is an error to invoke this function with a matrix-valued parameter with more than one row.

If you are only accessing a parameter value using `LibBlockParameterValue` or `LibBlockParameterString`, consider converting the parameter from Tunable to Nontunable. Then, use `ssWriteRTWParamSettings` to write the value of the parameter to the *`model`*`.rtw` file. Inlining parameters reduces RAM usage because the code generator uses the numerical values of parameters, instead of their symbolic names, in the generated code.

See `LibBlockParameterString` in `paramlib.tlc`.

LibBlockParameterValue

Based on the block parameter reference (`param`) and the index element of the array (`elidx`), `LibBlockParameterValue(param, elIdx)` returns the numeric value of a parameter. You can use the `LibBlockParameterWidth(param)` function to get the

width of the array and then use `elidx` (valid values of `0` to `width-1`) to get a particular element of the array.

If you are only accessing a parameter value using `LibBlockParameterValue` or `LibBlockParameterString`, consider converting the parameter from Tunable to Nontunable. Then, use `ssWriteRTWParamSettings` to write the value of the parameter to the *`model`*`.rtw` file. Inlining parameters reduces RAM usage because the code generator uses the numerical values of parameters, instead of their symbolic names, in the generated code.

Example

If you want to generate code for a different integrator depending on a parameter for a block, you can use the following:

```
%assign mode = LibBlockParameterValue(Integrator, 0)
%switch (mode)
   %case 1
      %<CodeForIntegrator1>
      %break
   %case 2
      %<CodeForIntegrator2>
      %break
   %default
      Error: Unrecognized integrator value.
      %break
%endswitch
```

See `LibBlockParameterValue` in `paramlib.tlc`.

LibBlockParameterWidth

`LibBlockParameterWidth(param)` returns the number of elements (width) of a parameter.

See `LibBlockParameterWidth` in `paramlib.tlc`.

Block State and Work Vector Functions

In this section...

LibBlockAssignDWork(dwork, ucv, lcv, sigIdx, rhs)

Based on the block’s dwork index or record (`dwork`), the user control variable (`ucv`), the loop control variable (`lcv`), and the signal index (`sigIdx`), `LibBlockAssignDWork` assigns a block’s dwork to a specified right hand side value (`rhs`).

See `LibBlockAssignDWork` in `customstoragelib.tlc`.

LibBlockContinuousState(ucv, lcv, idx)

Returns a string corresponding to the specified block continuous state (`CSTATE`) element.

See `LibBlockContinuousState` in `blocklib.tlc`.

LibBlockContinuousStateDerivative(ucv, lcv, idx)

Returns a string corresponding to the specified block continuous state (`CSTATE`) element.

See also `LibBlockDiscreteState`.

See `LibBlockContinuousStateDerivative` in `blocklib.tlc`.

LibBlockContStateDisabled(ucv, lcv, idx)

Returns a string corresponding to the specified block continuous state (`CSTATE`) element.

See also `LibBlockDiscreteState`.

See `LibBlockContStateDisabled` in `blocklib.tlc`.

LibBlockDWork(dwork, ucv, lcv, idx)

Returns a string corresponding to the specified block `dwork` element. The last input argument is overloaded to handle complex `dworks`.

`idx = "re3"` — Returns the real part of element 3 if `dwork` is complex, otherwise returns element 3.

`idx = "im3"` — Returns the imaginary part of element 3 if `dwork` is complex, otherwise returns `""`.

`idx = "3"` — Returns the complex container of element 3 if `dwork` is complex, otherwise returns element 3.

If either `ucv` or `lcv` is specified (i.e., it is not equal to `""`) then the index part of the last input argument (`sigIdx`) is ignored.

See `LibBlockDWork` in `blocklib.tlc`.

LibBlockDWorkAddr(dwork, ucv, lcv, idx)

Returns a string corresponding to the address of the specified block `dwork` element.

See `LibBlockDWorkAddr` in `blocklib.tlc`.

LibBlockDWorkDataTypeId(dwork)

Returns the data type ID of the specified block `dwork`.

See `LibBlockDWorkDataTypeId` in `blocklib.tlc`.

LibBlockDWorkDataTypeName(dwork, reim)

Returns the data type name of the specified block `dwork`.

See `LibBlockDWorkDataTypeName` in `blocklib.tlc`.

LibBlockDWorkIsComplex(dwork)

Returns 1 if the specified block `dwork`is complex. Returns 0 otherwise.

See `LibBlockDWorkIsComplex` in `blocklib.tlc`.

LibBlockDWorkName(dwork)

Returns the name of the specified block `dwork`.

See `LibBlockDWorkName` in `blocklib.tlc`.

LibBlockDWorkStorageClass(dwork)

Returns the storage class of the specified block `dwork`.

See `LibBlockDWorkStorageClass` in `blocklib.tlc`.

LibBlockDWorkStorageTypeQualifier(dwork)

Returns the storage type qualifier of the specified block `dwork`.

See `LibBlockDWorkStorageTypeQualifier` in `blocklib.tlc`.

LibBlockDWorkUsedAsDiscreteState(dwork)

Returns 1 if the specified block `dwork` is used as a discrete state, returns 0 otherwise.

See `LibBlockDWorkUsedAsDiscreteState` in `blocklib.tlc`.

LibBlockDWorkWidth(dwork)

Returns the width of the specified block `dwork`.

See `LibBlockDWorkWidth` in `blocklib.tlc`.

LibBlockDiscreteState(ucv, lcv, idx)

Returns a string corresponding to the specified block discrete state (`DSTATE`) element.

See `LibBlockDiscreteState` in `blocklib.tlc`.

LibBlockIWork(definediwork, ucv, lcv, idx)

Returns a string corresponding to the specified block `IWORK` element. See `LibBlockRWork`.

See `LibBlockIWork` in `blocklib.tlc`.

LibBlockMode(ucv, lcv, idx)

Returns a string corresponding to the specified block `MODE` element.

See `LibBlockMode` in `blocklib.tlc`.

LibBlockNonSampledZC(ucv, lcv, NSZCIdx)

Returns a string corresponding to the specified block `NSZC`.

`LibBlockNonSampledZC` returns an element for the nonsampled zero-crossing state based on `ucv`, `lcv`, and `NSZCIdx`.

Arguments

`ucv` — User control variable string

`lcv` — Loop control variable string

`NSZCIdx` — Nonsampled zero-crossing index

See `LibBlockNonSampledZC` in `blocklib.tlc`.

LibBlockPWork(definedpwork, ucv, lcv, idx)

Returns a string corresponding to the specified block `PWORK` element. See `LibBlockRWork`.

See `LibBlockPWork` in `blocklib.tlc`.

LibBlockRWork(definedrwork, ucv, lcv, idx)

Returns a string corresponding to the specified block `RWORK` element. The first argument, `definedrwork`, is a symbol defined in the `mdlRTW` routine of the C MEX file with code like:

```
ssWriteRTWWorkVect([...], "RWork", [...], "MyRWorkName", [...])
```

Alternatively, if `RWork` defines have not been made, `definedrwork` is ignored and the raw `RWork` vector is accessed. In this case, uses in a loop rolling context are disallowed.

See `LibBlockRWork` in `blocklib.tlc`.

LibBlockZCSignalValue(ucv, lcv, zcsIdx, zcElIdx)

Purpose

Returns a string corresponding to the specified block `ZCSignalValue`

Arguments

`ucv`

User control variable string.

`lcv`

Loop control variable string.

`zcsIdx`

zc signal Idx

`zcElIdx`

Idx of zc signal element in the zc signal

Description

`LibBlockZCSignalValue` returns an element for the zero crossing state based on `ucv`, `lcv`, and `zcsIdx`.

See `LibBlockZCSignalValue` in `blocklib.tlc`.

Block Path and Error Reporting Functions

In this section...

LibBlockReportError(block, errorstring)

Use `LibBlockReportError` when reporting errors for a block. `LibBlockReportError` is designed to be used from block target files (e.g., the TLC file for an inlined S-function).

`LibBlockReportError` can be called with or without the block record scoped. To call the function without a block record scoped, pass the block record. To call the function when the block is scoped, pass `block = []`.

```
LibBlockReportError([],"error string")
  -- If block is scoped
LibBlockReportError(blockrecord,"error string")
  -- If block record is available
```

See `LibBlockReportError` in `utillib.tlc`.

LibBlockReportFatalError(block, errorstring)

Use `LibBlockReportFatalError` when reporting fatal (assert) errors for a block. Use `LibBlockReportFatalError` for defensive programming. Refer to “Generating Errors from TLC Files” on page A-8.

See `LibBlockReportFatalError` in `utillib.tlc`.

LibBlockReportWarning(block, warnstring)

Use `LibBlockReportWarning` when reporting warnings for a block. `LibBlockReportWarning` is designed to be used from block target files (e.g., the TLC file for an inlined S-function).

`LibBlockReportWarning` can be called with or without the block record scoped. To call this function without a block record scoped, pass the block record. To call this function when the block is scoped, pass `block = []`.

```
LibBlockReportWarning([],"warn string")
--    If block is scoped
LibBlockReportWarning(blockrecord,"warn string)
--    If block record is available
```

See `LibBlockReportWarning` in `utillib.tlc`.

LibGetBlockName(block)

`LibGetBlockName` returns the short block path name string for a block record, excluding carriage returns and other special characters that can be present in the name.

See `LibGetBlockName` in `utillib.tlc`.

LibGetBlockPath(block)

`LibGetBlockPath` returns the full block path name string for a block record, including carriage returns and other special characters that can be present in the name. Currently, the only other special string sequences defined are `'/*'` and `'*/'`.

The full block path name string is useful when you are accessing blocks from MATLAB. For example, you can use the full block name with `hilite_system` via `FEVAL` to match the Simulink path name exactly.

Use `LibGetFormattedBlockPath` to get a block path suitable for placing in a comment or error message.

See `LibGetBlockPath` in `utillib.tlc`.

LibGetFormattedBlockPath(block)

`LibGetFormattedBlockPath` returns the full path name string of a block without special characters. The string returned from `LibGetFormattedBlockPath` is suitable for placing the block name, in comments or generated code, on a single line.

Currently, the special characters are carriage returns, `'/*'`, and `'*/'`. A carriage return is converted to a space, `'/*'` is converted to `'/+'`, and `'*/'` is converted to `'+/'`. Note that a `'/'` in the name is automatically converted to a `'//'` to distinguish it from a path separator.

Use `LibGetBlockPath` to get the block path for MATLAB functions used in reference blocks in your model.

See `LibGetFormattedBlockPath` in `utillib.tlc`.

“LibGetDataTypeTransHdrBaseName()” on page 21-52
“LibGetModelDotCFile()” on page 21-53
“LibGetModelDotHFile()” on page 21-53

In this section...

LibAddSourceFileCustomSection(file, builtInSection, newSection)

Adds a custom section to a source file. You must associate a custom section with one of the built-in sections: Includes, Defines, Types, Enums, Definitions, Declarations, Functions, or Documentation. Nothing happens if the section already exists, except to report an error if a inconsistent built-in section association is attempted. `LibAddSourceFileCustomSection` is available only with the Embedded Coder product.

Arguments

`file` — Source file reference

`builtInSection` — Name of the associated built-in section

`newSection` — Name of the new (custom) section

See `LibAddSourceFileCustomSection` in `codetemplatelib.tlc`.

LibAddToCommonIncludes(incFileName)

Adds items to a list of `#include /package` specification items. Each member of the list is unique. Attempting to add a duplicate member does nothing.

`LibAddToCommonIncludes` should be called from block TLC methods to specify generation of `#include` statements in *`model`*`.h`. Specify the names of files on the include path inside angle brackets, e.g., `<sysinclude.h>`. Specify the names of local files without angle brackets, e.g., `myinclude.h`. Each call to `LibAddToCommonIncludes` adds the specified file to the list only if it is not already there. Filenames with and without angle brackets (e.g., `<math.h>` and `math.h`) are considered different. The `#include` statements are placed inside *`model`*`.h`.

Example

```
LibAddToCommonIncludes("tpu332lib.h")
```

See `LibAddToCommonIncludes` in `cachelib.tlc`.

LibAddToModelSources(newFile)

`LibAddToModelSources` serves two purposes:

- To notify the build process that it must build with the specified source file
- To update the `SOURCES: file1.c file2.c ...` comment in the generated code.

For inlined S-functions, `LibAddToModelSources` is generally called from `BlockTypeSetup`. `LibAddToModelSources` adds a filename to the list of sources for building this model. `LibAddToModelSources` returns `1` if the filename passed in was a duplicate (i.e., it was already in the sources list) and `0` if it was not a duplicate.

You can use the `LibAddToModelSources` function for other purposes in TLC aside from writing S-functions. If you write your own S-functions, use the `SFunctionModules` block parameter instead of `LibAddToModelSources`. See `LibAddToModelSources` in `utillib.tlc`.

LibCacheDefine(buffer)

Each call to `LibCacheDefine` appends your buffer to the existing cache buffer. For blocks, `LibCacheDefine` is generally called from `BlockTypeSetup`.

`LibCacheDefine` caches `#define` statements for inclusion in *`model`*`_private.h` or *`model`*`.c`. Call `LibCacheDefine` from inside `BlockTypeSetup` to cache a `#define` statement. Each call to `LibCacheDefine` appends your buffer to the existing cache buffer. The `#define` statements are placed inside *`model`*`_private.h` or *`model`*`.c`.

Example

```
%openfile buffer
#define INTERP(x,x1,x2,y1,y2) ( y1+((y2 - y1)/(x2 - x1))*(x-x1))
#define this that
%closefile buffer
%<LibCacheDefine(buffer)>
```

See `LibCacheDefine` in `cachelib.tlc`.

LibCacheExtern(buffer)

`LibCacheExtern` should be called from inside `BlockTypeSetup` to cache an `extern` statement. Each call to `LibCacheExtern` appends your buffer to the existing cache buffer. The `extern` statements are placed in *`model`*`_private.h`.

Example

```
%openfile buffer
 extern real_T mydata;
%closefile buffer
%<LibCacheExtern(buffer)>
```

See `LibCacheExtern` in `cachelib.tlc`.

LibCacheFunctionPrototype(buffer)

`LibCacheFunctionPrototype` should be called from inside `BlockTypeSetup` to cache a function prototype. Each call to `LibCacheFunctionPrototype` appends your buffer to the existing cache buffer. The prototypes are placed inside *`model`*`_private.h`.

Example

```
%openfile buffer
 extern int_T fun1(real_T x);
 extern real_T fun2(real_T y, int_T i);
%closefile buffer
%<LibCacheFunctionPrototype(buffer)>
```

See `LibCacheFunctionPrototype` in `cachelib.tlc`.

LibCacheTypedefs(buffer)

`LibCacheTypedefs` should be called from inside `BlockTypeSetup` to cache `typedef` declarations. Each call to `LibCacheTypedefs` appends your buffer to the existing cache buffer. The `typedef` statements are placed inside *`model`*`.h` (or *`model`*`_common.h`).

Example

```
%openfile buffer
typedef foo bar;
```

```
%closefile buffer
%<LibCacheTypedefs(buffer)>
```

See `LibCacheTypedefs` in `cachelib.tlc`.

LibCallModelInitialize()

Returns code for calling the model's initialize function (valid for ERT only).

See `LibCallModelInitialize` in `codetemplatelib.tlc`.

LibCallModelStep(tid)

Returns code for calling the model's step function (valid for ERT only).

See `LibCallModelStep` in `codetemplatelib.tlc`.

LibCallModelTerminate()

Returns code for calling the model's terminate function (valid for ERT only).

See `LibCallModelTerminate` in `codetemplatelib.tlc`.

LibCallSetEventForThisBaseStep(buffername)

Returns code for calling the model's set events function (valid for ERT only).

Argument

`buffername` — Name of the variable used to buffer the events. For the example `ert_main.c`, this is `eventFlags`.

See `LibCallSetEventForThisBaseStep` in `codetemplatelib.tlc`.

LibClearFileSectionContents(fileIdx, attrib)

Before writing file to disk, clear file sections with custom values.

Arguments

`fileIdx` (scope or number) — File index

`attrib` (string) — Name of model attribute

See `LibGetSourceFileAttribute` in `codetemplatelib.tlc`.

LibCreateSourceFile(type, creator, name)

Creates a new C or C++ file and returns its reference. If the file already exists, `LibCreateSourceFile` returns the existing file's reference.

Syntax

```
%assign fileH = LibCreateSourceFile
                ("Source", "Custom", "foofile")
```

Arguments

`type` (string) — Valid values are `"Source"` and `"Header"` for `.c` and `.h` files, respectively.

`creator` (string) — Who is creating the file? An error is reported if different creators attempt to create the same file.

`name` (string) — Base name of the file (i.e., without the extension). Note that files are not written to disk if they are empty.

Returns

Reference to the model file (scope).

See `LibCreateSourceFile` in `codetemplatelib.tlc`.

LibGetFileRecordName (file)

Returns model file name (including the path) without the file extension. To retrieve the file name (including the path) with the file extension, use `LibGetSourceFileSection`.

Arguments

`file` — Source file reference

See `LibGetFileRecordName` in `codetemplatelib.tlc`.

LibGetMdlPrvHdrBaseName()

Returns the base name of the model's private header file, for example, *`model`*`_private.h`.

See `LibGetMdlPrvHdrBaseName` in `codetemplatelib.tlc`.

LibGetMdlPubHdrBaseName()

Returns the base name of the model's public header file, for example, *`model`*`.h`.

See `LibGetMdlPubHdrBaseName` in `codetemplatelib.tlc`.

LibGetMdlSrcBaseName()

Returns the base name of the model's main source file, for example, *`model`*`.c`.

See `LibGetMdlSrcBaseName` in `codetemplatelib.tlc`.

LibGetMdlDataSrcBaseName()

Returns the base name of the model's data file, for example, *`model`*`_data.c`.

See `LibGetMdlDataSrcBaseName` in `codetemplatelib.tlc`.

LibGetMdlTypesHdrBaseName()

Returns the base name of the model types file, for example, *`model`*`_types.h`.

See `LibGetMdlTypesHdrBaseName` in `codetemplatelib.tlc`.

LibGetMdlCapiHdrBaseName()

Returns the base name of the model capi header file, for example, *model*_capi.h.

See LibGetMdlCapiHdrBaseName in codetemplatelib.tlc.

LibGetMdlCapiSrcBaseName()

Returns the base name of the model capi source file, for example, *model*_capi.c.

See LibGetMdlCapiSrcBaseName in codetemplatelib.tlc.

LibGetMdlCapiHostHdrBaseName()

Returns the base name of the model capi host header file, for example, *model*_host_capi.h.

See LibGetMdlCapiHostHdrBaseName in codetemplatelib.tlc.

LibGetMdlTestIfHdrBaseName()

Returns the base name of the model testinterface header file, for example, *model*_testinterface.h.

See LibGetMdlTestIfHdrBaseName in codetemplatelib.tlc.

LibGetMdlTestIfSrcBaseName()

Returns the base name of the model testinterface source file, for example, *model*_testinterface.c.

See LibGetMdlTestIfSrcBaseName in codetemplatelib.tlc.

LibGetDataTypeTransHdrBaseName()

Returns the base name of the data type transition file, for example, *model*_dt.h for code generation's Real-Time and Embedded-C code formats.

See LibGetDataTypeTransHdrBaseName in codetemplatelib.tlc.

LibGetModelDotCFile()

Returns a reference to the *model*`.c` or `.cpp` source file. You can then cache additional code using `LibSetSourceFileSection`.

Syntax

```
%assign srcFile = LibGetModelDotCFile()
%<LibSetSourceFileSection(srcFile, "Functions", mybuf)>
```

Returns

Returns a reference to the *model*`.c` or `.cpp` source file.

See `LibGetModelDotCFile` in `codetemplatelib.tlc`.

LibGetModelDotHFile()

Returns a reference to the *model*`.h` source file. You can then cache additional code using `LibSetSourceFileSection`.

Syntax

```
%assign hdrFile = LibGetModelDotHFile()
%<LibSetSourceFileSection(hdrFile, "Functions", mybuf)>
```

Returns

Returns a reference to the *model*`.h` source file.

See `LibGetModelDotHFile` in `codetemplatelib.tlc`.

LibGetModelName()

Returns the name of the model (without an extension).

See `LibGetModelName` in `codetemplatelib.tlc`.

LibGetNumSourceFiles()

Returns the number of source files (`.c` or `.cpp` and `.h`) that have been created.

Syntax

```
%assign numFiles = LibGetNumSourceFiles()
```

Returns

Returns the number of files (number).

See `LibGetNumSourceFiles` in `codetemplatelib.tlc`.

LibGetRTModelErrorStatus()

Returns the code required to get the model error status.

Syntax

```
%<LibGetRTModelErrorStatus()>;
```

See `LibGetRTModelErrorStatus` in `codetemplatelib.tlc`.

LibGetSourceFileAttribute(fileIdx, attrib)

Returns the specified attribute of a file. The table lists the valid attributes.

Attribute			
Name (with file extension)	SystemsInFile	IsEmpty	SharedType
BaseName	RequiredIncludes	Indent	CodeTemplate
Type	UtilityIncludes	WrittenToDisk	OutputDirectory
Creator	Filter	Shared	Group

Arguments

`fileIdx` (scope or number) — File index

`attrib` (string) — Name of model attribute

See `LibGetSourceFileAttribute` in `codetemplatelib.tlc`.

LibGetSourceFileFromIdx(fileIdx)

Returns a model file reference based on its index. This reference can be useful for a common operation on all files, for example, to set the leading file banner of all files.

Syntax

```
%assign fileH = LibGetSourceFileFromIdx(fileIdx)
```

Argument

`fileIdx` (number) — Index of model file

Returns

Reference (scope) to the model file.

See `LibGetSourceFileFromIdx` in `codetemplatelib.tlc`.

LibGetSourceFileSection(fileIdx, section)

Returns the contents of a file. See “LibSetSourceFileSection(fileH, section, value)” on page 21-60 for a list of valid sections.

Arguments

`fileIdx` (scope or number) — File index

`section` (string) — File section of interest

See `LibGetSourceFileSection` in `codetemplatelib.tlc`.

LibGetSourceFileTag(fileIdx)

Returns *`fileName`*`_h` and *`fileName`*`_c` for header and source files, respectively, where *`fileName`* is the name of the model file.

Syntax

```
%assign tag = LibGetSourceFileTag(fileIdx)
```

Argument

`fileIndex` (number) — File index

Returns

Returns the tag (string).

See `LibGetSourceFileTag` in `codetemplatelib.tlc`.

LibMdlRegCustomCode(buffer, location)

Places declaration statements and executable code inside the *`model`*`_initialize` function.

Arguments

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header
- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

See `LibMdlRegCustomCode` in `hookslib.tlc`.

LibMdlStartCustomCode(buffer, location)

Places declaration statements and executable code inside the start function. Start code is executed once, during the model initialization phase.

Syntax

```
LibMdlStartCustomCode(buffer, location)
```

Arguments

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header
- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

Description

`LibMdlStartCustomCode` places declaration statements and executable code inside the start function. This code is output into the following functions, depending on the current value for the `CodeFormat` TLC variable:

Function Name	Value of `CodeFormat` TLC variable
`model``_initialize`	`Embedded-C` (if not `ModelReferenceCoderTarget`)
`mdlStart`	`Embedded-C` (if `ModelReferenceCoderTarget`)
`mdlStart`	`S-Function`
`MdlStart`	`RealTime`

Each call to `LibMdlStartCustomCode` appends your buffer to the internal cache buffer.

See `LibMdlStartCustomCode` in `hookslib.tlc`.

LibMdlTerminateCustomCode(buffer, location)

Purpose

Places declaration statements and executable code inside the terminate function.

Syntax

```
LibMdlTerminateCustomCode(buffer, location)
```

Arguments

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header
- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

Description

`LibMdlTerminateCustomCode` places declaration statements and executable code inside the terminate function. This code is output into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of `CodeFormat` TLC variable
`model``_terminate`	`Embedded-C`
`mdlTerminate`	`S-Function`
`MdlTerminate`	`RealTime`

Each call to `LibMdlTerminateCustomCode` appends your buffer to the internal cache buffer.

See `LibMdlTerminateCustomCode` in `hookslib.tlc`.

LibSetRTModelErrorStatus(str)

Returns the code required to set the model error status.

Syntax

```
LibSetRTModelErrorStatus("\"Overrun\"")
```

Argument

`str` (string) — char * to a C string

See `LibSetRTModelErrorStatus` in `codetemplatelib.tlc`.

LibSetSourceFileCodeTemplate(opFile, name)

By default, `*.c` and `*.h` files are generated with the code templates specified in the **Code Generation > Templates** pane of the Configuration Parameters dialog box. `LibSetSourceFileCodeTemplate` allows you to change the template for a file.

Note Custom templates are a feature of the Embedded Coder product.

Syntax

```
%assign tag = LibSetSourceFileCodeTemplate(opFile,name)
```

Arguments

`opFile` (scope) — Reference to file

`name` (string) — Name of the desired template

Returns

Nothing

See `LibSetSourceFileCodeTemplate` in `codetemplatelib.tlc`.

LibSetSourceFileCustomSection(file, attrib, value)

Adds to the contents of a custom section previously created with `LibAddSourceFileCustomSection`. Available only with Embedded Coder software.

Arguments

`file` (scope or number) — Source file reference or index

`attrib` (string) — Name of custom section

`value` (string) — Value to be appended to section

See `LibSetSourceFileCustomSection` in `codetemplatelib.tlc`.

LibSetSourceFileOutputDirectory(opFile, name)

By default, `*.c` and `*.h` files are generated into a build folder at the current location. `LibSetSourceFileOutputDirectory` allows you to change the folder into which a specified source file is to be generated. Note that the caller is responsible for specifying a valid folder.

Syntax

```
%assign tag = LibSetSourceFileOutputDirectory(opFile,dirName)
```

Arguments

`opFile` (scope) — Reference to file

`dirName` (string) — Name of the desired output folder

Returns

Nothing

See `LibSetSourceFileOutputDirectory` in `codetemplatelib.tlc`.

LibSetSourceFileSection(fileH, section, value)

Adds to the contents of a specified section within a specified file. Valid file sections include

File Section	Description
`Banner`	Set the file banner (comment) at the top of the file.
`Includes`	Append to the `#include` section.
`Defines`	Append to the `#define` section.
`IntrinsicTypes`	Append to the intrinsic `typedef` section. Intrinsic types are those that depend only on intrinsic C types.

File Section	Description
`PrimitiveTypedefs`	Append to the primitive `typedef` section. Primitive `typedefs` are those that depend only on intrinsic C types and `typedefs` previously defined in the `IntrinsicTypes` section.
`UserTop`	Append to the User Top section.
`Typedefs`	Append to the `typedef` section. The `typedefs` can depend on a previously defined type.
`Enums`	Append to the enumerated types section.
`Definitions`	Append to the data definition section.
`ExternData`	(Reserved) Code generator `extern` data.
`ExternFcns`	(Reserved) Code generator `extern` functions.
`FcnPrototypes`	(Reserved) Code generator function prototypes.
`Declarations`	Append to the data declaration section.
`Functions`	Append to the C functions section.
`CompilerErrors`	Append to the `#error` section.
`CompilerWarnings`	Append to the `#warning` section.
`Documentation`	Append to the documentation (comment) section.
`UserBottom`	Append to the User Bottom section.

The code generator orders the code as listed above.

Syntax

Example (iterating over the files):

```
%openfile tmpBuf
  whatever
%closefile tmpBuf

%foreach fileIdx = LibGetNumSourceFiles()
  %assign fileH = LibGetSourceFileFromIdx(fileIdx)
  %<LibSetSourceFileSection(fileH,"SectionOfInterest",tmpBuf)>
%endforeach

%assign fileH = LibCreateSourceFile("Header","Custom","foofile")
%<LibSetSourceFileSection(fileH,"Defines","#define FOO 5.0\n")>
```

Arguments

`fileH` (scope or number) — Reference or index to a file

`section` (string) — File section of interest

`value` (string) — Value

See `LibSetSourceFileSection` in `codetemplatelib.tlc`.

LibSystemDerivativeCustomCode(system, buffer, location)

Purpose

Places declaration statements and executable code inside a subsystem's derivative function.

Syntax

```
LibSystemDerivativeCustomCode(system, buffer, location)
```

Arguments

`system` — Reference to the subsystem whose derivative function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header
- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

Description

`LibSystemDerivativeCustomCode` places declaration statements and executable code inside the derivative function for the subsystem specified by `system`. This code is output

into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of CodeFormat TLC variable
`mdlDerivatives`	`S-Function`
`model``_derivatives`	`RealTime`

`LibSystemDerivativeCustomCode` is not relevant when the value of the `CodeFormat` TLC variable is `Embedded-C`, because blocks with continuous states cannot be used.

Each call to `LibSystemDerivativeCustomCode` appends your buffer to the internal cache buffer. An error is generated if you attempt to add code to a subsystem that does not have continuous states.

See `LibSystemDerivativeCustomCode` in `hookslib.tlc`.

LibSystemDisableCustomCode(system, buffer, location)

Purpose

Places declaration statements and executable code inside a subsystem's disable function.

Syntax

```
LibSystemDisableCustomCode(system, buffer, location)
```

Arguments

`system` — Reference to the subsystem whose disable function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header
- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

Description

`LibSystemDisableCustomCode` places declaration statements and executable code inside the disable function for the subsystem specified by `system`. Each call to `LibSystemDisableCustomCode` appends your buffer to the internal cache buffer.

An error is generated if you attempt to add code to a subsystem that does not have a disable function.

See `LibSystemDisableCustomCode` in `hookslib.tlc`.

LibSystemEnableCustomCode(system, buffer, location)

Purpose

Places declaration statements and executable code inside a subsystem's enable function.

Syntax

```
LibSystemEnableCustomCode(system, buffer, location)
```

Arguments

`system` — Reference to the subsystem whose enable function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header
- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

Description

`LibSystemEnableCustomCode` places declaration statements and executable code inside the enable function for the subsystem specified by `system`. Each call to `LibSystemEnableCustomCode` appends your buffer to the internal cache buffer.

An error is generated if you attempt to add code to a subsystem that does not have an enable function.

See `LibSystemEnableCustomCode` in `hookslib.tlc`.

LibSystemInitializeCustomCode(system, buffer, location)

Purpose

Places declaration statements and executable code inside a subsystem's initialize function.

Syntax

```
LibSystemInitializeCustomCode(system, buffer, location)
```

Arguments

`system` — Reference to the subsystem whose initialize function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header
- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

Description

`LibSystemInitializeCustomCode` places declaration statements and executable code inside the initialize function for the subsystem specified by `system`. This code is output

into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of CodeFormat TLC variable
*model*_initialize	Embedded-C
mdlInitializeConditions	S-Function
MdlStart	RealTime

Code for a subsystem is output into the subsystem's initialization function. Each call to `LibSystemInitializeCustomCode` appends your buffer to the internal cache buffer.

Note Enable systems that are not configured to reset on enable are inlined into `MdlStart`. For this case, the subsystem's custom code is found in `MdlStart` above and below the enable subsystem's initialization code.

See `LibSystemInitializeCustomCode` in `hookslib.tlc`.

LibSystemOutputCustomCode(system, buffer, location)

Purpose

Places declaration statements and executable code inside a subsystem's output function.

Syntax

```
LibSystemOutputCustomCode(system, buffer, location)
```

Arguments

`system` — Reference to the subsystem whose output function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header

- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

Description

`LibSystemOutputCustomCode` places declaration statements and executable code inside the output function for the subsystem specified by `system`. This code is output into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of `CodeFormat` TLC variable
`model``_step`	`Embedded-C` (`CombineOutputUpdateFcns` is `1`)
`model``_output`	`Embedded-C` (`CombineOutputUpdateFcns` is `0`)
`mdlOutputs`	`S-Function`
`MdlOutputs`	`RealTime`

Each call to `LibSystemOutputCustomCode` appends your buffer to the internal cache buffer.

See `LibSystemOutputCustomCode` in `hookslib.tlc`.

LibSystemUpdateCustomCode(system, buffer, location)

Purpose

Places code inside a subsystem's update function.

Syntax

```
LibSystemUpdateCustomCode(system, buffer, location)
```

Arguments

`system` — Reference to the subsystem whose update function is to be modified.

`buffer` — String buffer containing text to append to the internal cache buffer.

`location` — String specifying where to place the buffer's contents. Possible values are

- `"header"` — Place buffer at top of function
- `"declaration"` — Place buffer at top of function
- `"execution"` — Place buffer at top of function, but after header
- `"trailer"` — Place buffer at bottom of function

Returns

Nothing

Description

`LibSystemUpdateCustomCode` places declaration statements and executable code inside the update function for the subsystem specified by `system`. This code is output into the following functions, depending on the current value of the `CodeFormat` TLC variable:

Function Name	Value of `CodeFormat` TLC variable
`model``_step`	`Embedded-C` (`CombineOutputUpdateFcns` is `1`)
`model``_update`	Embedded-C (`CombineOutputUpdateFcns` is `0`)
`mdlUpdate`	`S-Function`
`MdlUpdate`	RealTime

Each call to `LibSystemUpdateCustomCode` appends your buffer to the internal cache buffer.

See `LibSystemUpdateCustomCode` in `hookslib.tlc`.

LibWriteModelData()

Returns data for the model (valid for ERT only).

See `LibWriteModelData` in `codetemplatelib.tlc`.

LibWriteModelInput(tid, rollThreshold)

Returns the code for writing to a specified root input (that is, a model inport block). This function is valid for ERT only, and not valid for referenced models.

Arguments

`tid` (number) — Task identifier (`0` is fastest rate and `n` is the slowest)

`rollThreshold` — Width of signal before wrapping in a `for` loop.

See `LibWriteModelInput` in `codetemplatelib.tlc`.

LibWriteModelInputs()

Returns code that writes to all root inputs (that is, the model inport blocks). This function is valid for ERT only, and is not valid for referenced models.

See `LibWriteModelInputs` in `codetemplatelib.tlc`.

LibWriteModelOutput(tid, rollThreshold)

Returns code that writes to a specified root output (that is, a model outport block). This function is valid for ERT only, and not valid for referenced models.

Arguments

`tid` (number) — Task identifier (`0` is fastest rate and `n` is the slowest)

`rollThreshold` — Width of signal before wrapping in a `for` loop.

See `LibWriteModelOutput` in `codetemplatelib.tlc`.

LibWriteModelOutputs()

Returns code that writes to all root outputs (that is, the model outport blocks). This function is valid for ERT only, and not valid for referenced models.

See `LibWriteModelOutputs` in `codetemplatelib.tlc`.

In this section...

LibAsynchronousTriggeredTID(tid)

Returns whether this TID corresponds to a asynchronous triggered rate.

See `LibAsynchronousTriggeredTID` in `utillib.tlc`.

LibAsyncTaskAccessTimeInFcn(tid, fcnType)

Returns 1 if the specified asynchronous task identifier (TID) is given function type.

See `LibAsyncTaskAccessTimeInFcn` in `utillib.tlc`.

LibBlockSampleTime(block)

Returns the block's sample time. The returned value depends on the sample time classification of the block, as shown in the following table.

Block Classification	Returned Value
Discrete	The actual sample time of a block (real > `0`)
Continuous	`0.0`
Triggered	`-1.0`
Constant	`-2.0`

See `LibBlockSampleTime` in `blocklib.tlc`.

LibGetClockTick(tid)

Returns integer task time (current clock tick of the task timer). The resolution of the timer can be obtained from `LibGetClockTickStepSize(tid)`. The data type ID of the timer can be obtained from `LibGetClockTickDataTypeId(tid)`.

See `LibGetClockTick` in `utillib.tlc`.

LibGetClockTickDataTypeId(tid)

Returns clock tick data type ID.

See `LibGetClockTickDataTypeId` in `utillib.tlc`.

LibGetClockTickHigh(tid)

Returns high-order word of the integer task time. `LibGetClockTickHigh` is used when `uint32` pairs are used to store absolute time. The resolution of a clock tick can be obtained from `LibGetClockTickStepSize(tid)`.

See `LibGetClockTickHigh` in `utillib.tlc`.

LibGetClockTickStepSize(tid)

Returns clock tick step size, which is the resolution of the integer task time. `LibGetClockTickStepSize` cannot be used if the task does not have a timer.

See `LibGetClockTickStepSize` in `utillib.tlc`.

LibGetElapseTime(system)

Returns time elapsed since the last time the subsystem started to execute.

See `LibGetElapseTime` in `utillib.tlc`.

LibGetElapseTimeCounter(system)

Returns an integer elapsed time. This is the number of clock ticks elapsed since the last time the system started. To get real-world elapsed time, this integer elapsed time must be multiplied by the applicable resolution.

You can obtain the resolution by calling `LibGetElapseTimeResolution(system)`. You can obtain the data type ID of the integer elapsed time counter by calling `LibGetElapseTimeCounterDTypeId(system)`.

See `LibGetElapseTimeCounter` in `utillib.tlc`.

LibGetElapseTimeCounterDTypeId(system)

Returns the date type ID of the integer elapsed time returned by `LibGetElapseTimeCounter`.

See `LibGetElapseTimeCounterDTypeId` in `utillib.tlc`.

LibGetElapseTimeResolution(system)

Returns the resolution of the elapsed time returned by `LibGetElapseTimeCounter`.

See `LibGetElapseTimeResolution` in `utillib.tlc`.

LibGetGlobalTIDFromLocalSFcnTID(sfcnTID)

Returns the model task identifier (sample time index) corresponding to the specified local S-function task identifier or port sample time. `LibGetGlobalTIDFromLocalSFcnTID` allows you to use one function to determine a global TID, independent of port- or block-based sample times.

The input argument to `LibGetGlobalTIDFromLocalSFcnTID` should be one of the following:

- For block-based sample times (e.g., in S-function `mdlInitializeSizes`, `ssSetNumSampleTimes(S, N)` with `N > 1` was specified), `sfcnTID` is a nonnegative integer giving the corresponding local S-function sample time.
- For port-based sample times (e.g., in S-function `mdlInitializeSizes`, `ssSetNumSampleTimes(S, PORT_BASED_SAMPLE_TIMES)` was specified), `sfcnTID`

is a string of the form `"InputPortIdx`*I*`"` or `"OutputPortIdx`*I*`"`, where *I* is an integer ranging from 0 to the number of ports (e.g., `"InputPortIdx0"`.

Examples

Multirate block

```
%assign globalTID = LibGetGlobalTIDFromLocalSFcnTID(2)
```

or

```
%assign globalTID =
LibGetGlobalTIDFromLocalSFcnTID("InputPortIdx4")
%assign period =
CompiledModel.SampleTime[globalTID].PeriodAndOffset[0]
%assign offset =
CompiledModel.SampleTime[globalTID].PeriodAndOffset[1]
```

Inherited sample time block

```
%switch (LibGetSFcnTIDType(0))
  %case "discrete"
  %case "continuous"
    %assign globalTID = LibGetGlobalTIDFromLocalSFcnTID(2)
    %assign period = ...
      CompiledModel.SampleTime[globalTID].PeriodAndOffset[0]
    %assign offset = ...
      CompiledModel.SampleTime[globalTID].PeriodAndOffset[1]
    %break
  %case "triggered"
    %assign period = -1
    %assign offset = -1
    %break
  %case "constant"
    %assign period = rtInf
    %assign offset = 0
    %break
  %default
    %<LibBlockReportFatalError([],"Unknown tid type")>
%endswitch
```

See `LibGetGlobalTIDFromLocalSFcnTID` in `utillib.tlc`.

LibGetNumAsyncTasks()

Return the number of asynchronous tasks in generated code.

See `LibGetNumAsyncTasks` in `utillib.tlc`.

LibGetNumSFcnSampleTimes(block)

Returns the number of S-function sample times for a block.

See `LibGetNumSFcnSampleTimes` in `utillib.tlc`.

LibGetNumSyncPeriodicTasks()

Return the number of periodic tasks in generated code.

See `LibGetNumSyncPeriodicTasks` in `utillib.tlc`.

LibGetNumTasks()

Return the number of tasks in generated code.

See `LibGetNumTasks` in `utillib.tlc`.

LibGetSampleTimePeriodAndOffset(tid, idx)

Returns the sample time period value or offset value for a specified task.

Arguments

`tid` — Specify the identifier of the task for which to return information.

`idx` — Specify 0 to return the sample time period value or 1 to return the sample time offset value.

Examples

```
%% Get sample time period and offset for task 0
%assign sampleTime = LibGetSampleTimePeriodAndOffset(0,0)
%assign offsetTime = LibGetSampleTimePeriodAndOffset(0,1)
```

```
%% Get sample time periods for tasks 0 and 1
%assign periodTID0 = LibGetSampleTimePeriodAndOffset(0,0)
%assign periodTID1 = LibGetSampleTimePeriodAndOffset(1,0)
```

See `LibGetSampleTimePeriodAndOffset` in `codetemplatelib.tlc`.

LibGetSFcnTIDType(sfcnTID)

Returns the type of the specified S-function task identifier (`sfcnTID`). Possible values are:

- `"continuous"` — The specified `sfcnTID` is continuous.
- `"discrete"` — The specified `sfcnTID` is discrete.
- `"triggered"` — The specified `sfcnTID` is triggered.
- `"constant"` — The specified `sfcnTID` is constant.

The format of `sfcnTID` must be the same as for `LibIsSFcnSampleHit`.

Note This is useful primarily in the context of S-functions that specify an inherited sample time.

See `LibGetSFcnTIDType` in `utillib.tlc`.

LibGetTaskTime(tid)

Returns a string to access the absolute time of the task, which is a floating-point number. However, if you have configured the model for integer-only code generation (by deselecting **Support floating-point numbers**), the string represents an integer equal to the number of base rate ticks (the absolute time divided by the base sample time) rather than the absolute time. In integer-only code, the task time is an integer time value whose resolution is the model fundamental step size.

`LibGetTaskTime` is the TLC version of the SimStruct macro: `"ssGetTaskTime(S,tid)"`.

See `LibGetTaskTime` in `utillib.tlc`.

LibGetTaskTimeFromTID(block)

Returns a string to access the absolute time of the task associated with the block.

If the value of the `CodeFormat` TLC variable is not `Embedded-C`, `LibGetTaskTimeFromTID` returns the string `"RTMGet("T")"` if the block is constant or the system is single rate, and `"RTMGetTaskTimeForTID(tid)"` otherwise.

If the value for the `CodeFormat` TLC variable is `Embedded-C`, `LibGetTaskTimeFromTID` returns `"RTMGetTaskTimeForTID(tid)"`.

If the block is constant or the system is single rate, this is the TLC version of the SimStruct macro: `"ssGetT(S)"` and `"ssGetTaskTime(S, tid)"` otherwise.

In both cases, `S` is the name of the SimStruct.

See `LibGetTaskTimeFromTID` in `utillib.tlc`.

LibGetTID01EQ()

Returns the value of the TID01EQ flag — true (1) if sampling rates of the continuous task and the first discrete task are equal and false (0) otherwise.

When a model has continuous time and the flag TID01EQ is true, both continuous time and the fastest discrete time are treated as one rate in generated code. The code associated with the fastest discrete rate is guarded by a major time step check. When the model has only two rates, and TID01EQ is true, the generated code has a single-rate call interface.

Use `LibGetTID01EQ` to detect and account for the case where continuous time and the fastest discrete time are treated as one rate.

See `LibGetTID01EQ` in `codetemplatelib.tlc`, `bareboard_mrmain.tlc`, and `ertmainlib.tlc`.

LibIsContinuous(TID)

Returns 1 if the specified task identifier (`TID`) is continuous and 0 otherwise. Note that task identifiers equal to `"triggered"` or `"constant"` are not continuous.

See `LibIsContinuous` in `utillib.tlc`.

LibIsDiscrete(TID)

Returns 1 if the specified task identifier (`TID`) is discrete and 0 otherwise. Note that task identifiers equal to `"triggered"` or `"constant"` are not discrete.

See `LibIsDiscrete` in `utillib.tlc`.

LibIsSFcnSampleHit(sfcnTID)

Returns 1 if a sample hit occurs for the specified local S-function task identifier (`TID`) and 0 otherwise.

The input argument to `LibIsSFcnSampleHit` should be one of the following:

- `sfcnTID`: integer (e.g., 2)

  For block-based sample times (e.g., in S-function `mdlInitializeSizes`, `ssSetNumSampleTimes(S,N)` with N > 1 was specified), `sfcnTID` is an integer starting at 0 of the corresponding local S-function sample time.
- `sfcnTID`: `"InputPortIdx`*`I`*`"` or `"OutputPortIdx`*`I`*`"` (e.g., `"InputPortIdx0"`).

  For port-based sample times (e.g., in S-function `mdlInitializeSizes`, `ssSetNumSampleTimes(S,PORT_BASED_SAMPLE_TIMES)` was specified), `sfcnTID` is a string giving the input (or output) port index.

Examples

- Consider a multirate S-function block with four block sample times. The call `LibIsSFcnSampleHit(2)` returns the code to check for a sample hit on the third S-function block sample time.
- Consider a multirate S-function block with three input and eight output sample times. The call `LibIsSFcnSampleHit("InputPortIdx0")` returns the code to check for a sample hit on the first input port. The call `LibIsSFcnSampleHit("OutputPortIdx7")` returns the code to check for a sample hit on the eighth output port.

See `LibIsSFcnSampleHit` in `utillib.tlc`.

LibIsSFcnSingleRate(block)

Returns a Boolean value (1 or 0) indicating whether the S-function is single rate (one sample time) or multirate (multiple sample times).

See `LibIsSFcnSingleRate` in `utillib.tlc`.

LibIsSFcnSpecialSampleHit(sfcnSTI, sfcnTID)

Returns the Simulink macro to promote a slow task (`sfcnSTI`) into a faster task (`sfcnTID`).

This advanced function is specifically intended for use in rate transition blocks. `LibIsSFcnSpecialSampleHit` determines the global TID from the S-function TID

The input arguments to `LibIsSFcnSpecialSampleHit` are

- For multirate S-function blocks:

  `sfcnSTI`: local S-function sample time index (`sti`) of the slow task that is to be promoted

  `sfcnTID`: local S-function task ID (`tid`) of the fast task where the slow task is to run
- For single-rate S-function blocks using `SS_OPTION_RATE_TRANSITION`, `sfcnSTI` and `sfcnTID` are ignored and should be specified as `""`.

The format of `sfcnSTI` and `sfcnTID` must follow that of the argument to `LibIsSFcnSampleHit`.

Examples

- A rate transition S-function (one sample time with `SS_OPTION_RATE_TRANSITION`)

  ```
  if (%<LibIsSFcnSpecialSampleHit("","")>) {
  ```
- A multirate S-function with port-based sample times where the output rate is slower than the input rate (e.g., a zero-order hold operation)

  ```
  if (%<LibIsSFcnSpecialSampleHit("OutputPortIdx0","InputPortIdx0")>) {
  ```

See `LibIsSFcnSpecialSampleHit` in `utillib.tlc`.

LibIsSingleRateModel()

Returns `true` if model is single rate and `false` otherwise.

See `LibIsSingleRateModel` in `codetemplatelib.tlc`.

LibIsSingleTasking()

Returns `true` if the model is configured for single-tasking execution and `false` if the model is configured for multitasking execution.

See `LibIsSingleTasking` in `codetemplatelib.tlc`.

LibIsZOHContinuous(TID)

Returns 1 if the specified task identifier (TID) is zero order hold (ZOH) continuous and 0 otherwise. A TID equal to `triggered` or `constant` is not ZOH continuous.

See `LibIsZOHContinuous` in `utillib.tlc`.

LibNumAsynchronousSampleTimes()

Returns the number of asynchronous sample times in the model.

See `LibNumAsynchronousSampleTimes` in `codetemplatelib.tlc`.

LibNumDiscreteSampleTimes()

Returns the number of discrete sample times in the model.

See `LibNumDiscreteSampleTimes` in `codetemplatelib.tlc`.

LibNumSynchronousSampleTimes()

Returns the number of synchronous sample times in the model.

See `LibNumSynchronousSampleTimes` in `codetemplatelib.tlc`.

LibPortBasedSampleTimeBlockIsTriggered(block)

Determines whether the port-based S-function block is triggered.

See `LibPortBasedSampleTimeBlockIsTriggered` in `blocklib.tlc`.

LibSetVarNextHitTime(block, tNext)

Generates code to set the next variable hit time. Blocks with variable sample time must call `LibSetVarNextHitTime` in their output functions.

See `LibSetVarNextHitTime` in `blocklib.tlc`.

LibTriggeredTID(tid)

Returns whether this TID corresponds to a triggered rate.

See `LibTriggeredTID` in `utillib.tlc`.

- “Target Language Compiler Function Conventions” on page 21-3

Miscellaneous Functions

In this section...

In this section...

LibBlockExecuteFcnCall(block, callIdx)

For use by inlined S-functions with function-call outputs. Returns a string to call the function-call subsystem with required arguments or generates the subsystem's code in place (inlined).

Example

```
%foreach callIdx = NumSFcnSysOutputCalls
  %if LibIsEqual(SFcnSystemOutputCall[callIdx].BlockToCall,...
   "unconnected")
    %continue
  %endif
%% call the downstream system
  %<LibBlockExecuteFcnCall(block, callIdx)>\
%endforeach
```

See `LibBlockExecuteFcnCall` in `syslib.tlc`.

LibBlockExecuteFcnDisable(block, callIdx)

For use by inlined S-Functions to call the function-call system disable function. Returns a string to either call the function-call subsystem disable function with required arguments or to call the generated subsystem disable code (inlined).

Example

```
%foreach callIdx = NumSFcnSysOutputCallDsts
  %if LibIsEqual(SFcnSystemOutputCall[callIdx].BlockToCall, "unconnected")
   %continue
  %endif
%% call the downstream system
  %<LibBlockExecuteFcnDisable(block, callIdx)>\
%endforeach
```

See `LibBlockExecuteFcnDisable` in `syslib.tlc`.

LibBlockExecuteFcnEnable(block, callIdx)

For use by inlined S-Functions to call the function-call system enable function. Returns a string to call the function-call subsystem enable function with required arguments or the generated subsystem enable code (inlined).

Example

```
%foreach callIdx = NumSFcnSysOutputCallDsts
  %if LibIsEqual(SFcnSystemOutputCall[callIdx].BlockToCall, "unconnected")
   %continue
  %endif
%% call the downstream system
  %<LibBlockExecuteFcnEnable(block, callIdx)>\
%endforeach
```

See `LibBlockExecuteFcnEnable` in `syslib.tlc`.

LibBlockInputSignalAliasedThruDataTypeId(idx)

Return the data type ID the input signal is aliased thru to.

See LibBlockInputSignalAliasedThruDataTypeId in `dtypelib.tlc`.

LibBlockOutputSignalAliasedThruDataTypeId(idx)

Return the data type ID the output signal is aliased thru to.

See `LibBlockOutputSignalAliasedThruDataTypeId` in `dtypelib.tlc`

LibGenConstVectWithInit(data, typeId, varId)

Returns an initialized static constant variable string of form:

```
static const typeName varId[] = { data };
```

The `typeName` is generated from `typeId`, which can be one of

```
tSS_DOUBLE, tSS_SINGLE, tSS_BOOLEAN, tSS_INT8, tSS_UINT8,
tSS_INT16, tSS_UINT16, tSS_INT32, tSS_UINT32
```

The data input argument must be a numeric scalar or vector and must be finite (no `Inf`, `-Inf`, or `NaN` values).

See `LibGenConstVectWithInit` in `utillib.tlc`.

LibGetBlockAttribute(block, attr)

Get a field value inside a block record.

Syntax

```
%if LibIsEqual(LibGetBlockAttribute(ssBlock,"MaskType"), ...
  "Task Block")
  %assign isTaskBlock = 1
%endif
```

Returns

Returns the value of the attribute (field) or an empty string if it does not exist.

See `LibGetBlockAttribute` in `asynclib.tlc`.

LibGetCallerClockTickCounter(sfcnBlock)

For use by asynchronous S-functions with function call outputs. Asynchronous tasks can manage their own time. `LibGetCallerClockTickCounter` is used to access an upstream asynchronous task's time counter. This is preferred when being driven by another asynchronous rate (e.g., an Interrupt block driving a Task block) because the time the interrupt occurred is used, rather than the time the task is allowed to run.

Returns

Returns a string for the counter variable for the upstream asynchronous task.

See `LibGetCallerClockTickCounter` in `asynclib.tlc`.

LibGetCallerClockTickCounterHigh(sfcnBlock)

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks can manage their own time. `LibGetCallerClockTickCounterHigh` is used to access the high word of an upstream asynchronous task's time counter. This is preferred when being driven by another asynchronous rate (for example, an Interrupt block driving a Task block) because the time the interrupt occurred is used rather than the time the Task is allowed to run.

Returns

Returns a string for the high word of the counter variable for the upstream asynchronous task.

See `LibGetCallerClockTickCounterHigh` in `asynclib.tlc`.

LibGetDataTypeComplexNameFromId(id)

Returns the name of the complex data type corresponding to a data type ID. For example, if `id==tSS_DOUBLE` then `LibGetDataTypeComplexNameFromId` returns `"creal_T"`.

See `LibGetDataTypeComplexNameFromId` in `dtypelib.tlc`.

LibGetDataTypeEnumFromId(id)

Returns the data type `enum` corresponding to a data type ID. For example, if `id==tSS_DOUBLE`, then `enum` is `"SS_DOUBLE"`. If `id` does not correspond to a built-in data type, `LibGetDataTypeEnumFromId` returns `""`.

See `LibGetDataTypeEnumFromId` in `dtypelib.tlc`.

LibGetDataTypeIdAliasedThruToFromId(id)

Returns the data type `IdAliasedThruTo` that corresponds to a data type ID. For example, if `yourfloat` is an alias to `myfloat`, and `myfloat` is an alias to `double`, then the `IdAliasedThruTo` for both `yourfloat` and `myfloat` is 0 (because the ID for `double` is 0).

See `LibGetDataTypeIdAliasedThruToFromId` in `dtypelib.tlc`.

LibGetDataTypeIdAliasedToFromId(id)

Returns the data type `IdAliasedTo` that corresponds to a data type ID. For example, if `yourfloat` is an alias to `myfloat`, and `myfloat` is an alias to `double`, then the `IdAliasedTo` for `yourfloat` is the ID for `myfloat`, and the `IdAliasedTo` for `myfloat` is 0 (because the ID for `double` is 0).

See `LibGetDataTypeIdAliasedToFromId` in `dtypelib.tlc`.

LibGetDataTypeIdResolvesToFromId(id)

Returns the data type `IdResolvesTo` that corresponds to a data type ID.

See `LibGetDataTypeIdResolvesToFromId` in `dtypelib.tlc`.

LibGetDataTypeNameFromId(id)

Returns the data type name that corresponds to a data type `ID`.

See `LibGetDataTypeNameFromId` in `dtypelib.tlc`.

LibGetDataTypeSLSizeFromId(id)

Return the size (as Simulink knows it) corresponding to a data type ID.

See `LibGetDataTypeSLSizeFromId` in `dtypelib.tlc`.

LibGetDataTypeStorageIdFromId(id)

Returns the data type `StorageId` corresponding to a data type ID. For example, if the input ID is the ID for a 16-bit signed fixed-point data type, then the `StorageId` corresponds to `int16`.

See `LibGetDataTypeStorageIdFromId` in `dtypelib.tlc`.

LibGetFcnCallBlock(sfcnblock,callIdx)

Given an S-function block and call index, return the block record for the downstream function-call subsystem block.

Syntax

```
%assign ssBlock = LibGetFcnCallBlock(block,0)
```

Returns

The block record of the downstream function-call subsystem connected to that element (call index).

See `LibGetFcnCallBlock` in `asynclib.tlc`.

LibGetRecordDataTypeId(rec)

Returns the data type identifier of the specified record as an integer.

See `LibGetRecordDataTypeId` in `dtypelib.tlc`.

LibGetRecordDimensions(rec)

Returns the dimensions of the specified record as a vector of integers.

See `LibGetRecordDimensions` in `dtypelib.tlc`.

LibGetRecordIsComplex(rec)

Returns the value 1 if the specified record is complex, and zero otherwise.

See `LibGetRecordIsComplex` in `dtypelib.tlc`.

LibGetRecordWidth(rec)

Returns the width of the specified record as an integer.

See `LibGetRecordWidth` in `dtypelib.tlc`.

LibGetT()

Returns a string to access the absolute time, which is a floating-point number. However, if you have configured the model for integer-only code generation (by deselecting **Support floating-point numbers**), the string represents an integer equal to the number of base rate ticks (the absolute time divided by the base sample time) rather than the absolute time.

You should use `LibGetT` to access time only.

`LibGetT` is the TLC version of the SimStruct macro `ssGetT`.

See `LibGetT` in `utillib.tlc`.

LibIsComplex(arg)

Returns `1` if the argument passed in is complex, `0` otherwise.

See `LibIsComplex` in `utillib.tlc`.

LibIsFirstInitCond()

`LibIsFirstInitCond` returns generated code intended for placement in the initialization function. This code determines, during run-time, whether the initialization function is being called for the first time.

`LibIsFirstInitCond` also sets a flag that tells the code generator if it needs to declare and maintain the `first-initialize-condition` flag.

`LibIsFirstInitCond` is the TLC version of the SimStruct macro `ssIsFirstInitCond`.

See `LibIsFirstInitCond` in `syslib.tlc`.

LibIsMajorTimeStep()

Returns a string to access whether the current simulation step is a major time step.

`LibIsMajorTimeStep` is the TLC version of the SimStruct macro `ssIsMajorTimeStep`.

See `LibIsMajorTimeStep` in `utillib.tlc`.

LibIsMinorTimeStep()

Returns a string to access whether the current simulation step is a minor time step.

`LibIsMinorTimeStep` is the TLC version of the SimStruct macro `ssIsMinorTimeStep`.

See `LibIsMinorTimeStep` in `utillib.tlc`.

LibManageAsyncCounter(sfcnBlock, callIdx)

For use by asynchronous S-Functions with function-call outputs. Asynchronous tasks can manage their own time, and use `LibManageAsyncCounter` to determine whether a need exists for an asynchronous counter to manage its own timer.

Example

```
%if LibManageAsyncCounter(block,callIdx)
  %%      %<LibSetAsyncCounter(block,callIdx), CodeGetCounter)>
```

where `CodeGetCounter` is target specific code reading hardware timer.

Returns

Returns `TLC_TRUE` if an asynchronous counter is required to manage its own counter, otherwise `TLC_FALSE`.

See `LibManageAsyncCounter` in `asynclib.tlc`.

LibMaxIntValue(dtype)

For a built-in integer data type, `LibMaxIntValue` returns the formatted maximum value of that data type.

See `LibMaxIntValue` in `dtypelib.tlc`.

LibMinIntValue(dtype)

For a built-in integer data type, `LibMinIntValue` returns the formatted minimum value of that data type.

See `LibMinIntValue` in `dtypelib.tlc`.

LibNeedAsyncCounter(sfcnBlock, callIdx)

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks use `LibNeedAsyncCounter` to determine whether a need exists for an asynchronous counter.

Example

```
%if LibNeedAsyncCounter(block,0)
  %<LibSetAsyncCounter(block,0), "tickGet()")>
```

Returns

Returns `TLC_TRUE` if an asynchronous counter is required, otherwise `TLC_FALSE`.

See `LibNeedAsyncCounter` in `asynclib.tlc`.

LibSetAsyncClockTicks(sfcnBlock, callIdx, buf1, buf2)

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks can manage their own time. Use `LibSetAsyncClockTicks` to return code that sets `clockTick` counters that are to be maintained by the asynchronous task. If the data type of a `clockTick` counter maintained by the asynchronous task is `tSS_TIMER_UINT32_PAIR`, the low and high word of the `clockTick` counter are set.

Arguments

`buf1` — Code that reads the low word of the hardware counter

`buf2` — Code that reads the high word of the hardware counter. Leave `buf2` empty if hardware counter length is less than 32 bits.

Returns

Returns code that sets `clockTick` counters that are to be maintained by the asynchronous task.

Example

```
%if LibNeedAsyncCounter(block, callIdx)
%<LibSetAsyncCounter(block, 0, buf1, buf2)>
%endif
```

See `LibSetAsyncClockTicks` in `asynclib.tlc`.

LibSetAsyncCounter(sfcnBlock, callIdx, buf)

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks can manage their own time. Use `LibSetAsyncCounter` to return code that sets a counter variable that is to be maintained by the asynchronous task.

Returns

Returns code that sets the counter variable that is to be maintained by the asynchronous task.

Example

```
%if LibNeedAsyncCounter(block,0)
  %<LibSetAsyncCounter(block,0, "tickGet()")>
%endif
```

See `LibSetAsyncCounter` in `asynclib.tlc`.

LibSetAsyncCounterHigh(sfcnBlock, callIdx, buf)

For use by asynchronous S-functions with function-call outputs. Asynchronous tasks can manage their own time. Use `LibSetAsyncCounterHigh` to return code that sets the higher word of the counter variable that is to be maintained by the asynchronous task.

Returns

Returns code that sets the higher word of the counter variable that is to be maintained by the asynchronous task.

Example

```
%if LibNeedAsyncCounter(block,0)
%<LibSetAsyncCounterHigh(block,0, "hightTickGet()")>
%endif
```

See `LibSetAsyncCounterHigh` in `asynclib.tlc`.

LibTIDInSystem(system, fcnType)

Purpose

Returns a task identifier (TID) if it is in the scope of a subsystem function and can be called before or during TLC generating code.

Syntax

`LibTIDInSystem(`*`system`*`, `*`fcnType`*`)`

Arguments

`system`

A record within the global CompiledModel record.

`fcnType`

One of the following: `'Output'`, `'Update'`, `'Outputupdate'`.

Description

This function returns a TID if it is in the scope of a subsystem function and can be called before or during TLC generating code. It returns the TID argument name, if a TID is passed as argument in the system function scope. If TID is not passed as argument in the scope, this function returns:

- '0' if model is single tasking.
- The TID value of the subsystem if the subsystem is single rate.
- A local TID variable name, if the subsystem is multirate. A local TID variable is added to the subsystem code.

Note This function issue an error message if it is called for a reusable subsystem whose instances run at different rates.

See `LibTIDInSystem` in `syslib.tlc`.

LibIsRowMajor

Returns true when the current model uses the row-major array layout.

See `LibIsRowMajor` in `dtypelib.tlc`.

Obsolete Functions

The following table shows obsolete functions and the functions that have replaced them.

Obsolete Function	Equivalent Replacement Function
`LibBlockOutportLocation`	`LibBlockDstSignalLocation`
`LibCacheGlobalPrmData`	Use the block function `Start`
`LibCacheIncludes`	`LibAddToCommonIncludes`
`LibContinuousState`	`LibBlockContinuousState`
`LibControlPortInputSignal`	`LibBlockSrcSignalLocation`
`LibConvertZCDirection`	Function is not used in code generation.
`LibDataInputPortWidth`	`LibBlockInputSignalWidth`
`LibDataOutputPortWidth`	`LibBlockOutputSignalWidth`

`LibDefineIWork`
`LibDefinePWork`
`LibDefineRWork`
	`IWork` , `PWork`, and `RWork` names are now specified via the `mdlRTW` function in your C MEX S-function.

`LibDiscreteState`	`LibBlockDiscreteState`
`LibExportFileCustomCode`	`LibSetSourceFileSection`
`LibExternalResetSignal`	`LibBlockInputSignal`
`LibHeaderFileCustomCode`	`LibSetSourceFileSection`
`LibIsEqual`	Use built-in function `ISEQUAL`
`LibMapSignalSource`	`FcnMapDataTypedSignalSource`
`LibMaxBlockIOWidth`	Function is not used in Simulink Coder code generation.
`LibMaxDataInputPortWidth`	Function is not used in Simulink Coder code generation.
`LibMaxDataOutputPortWidth`	Function is not used in Simulink Coder code generation.
`LibPathName`	`LibGetBlockPath`, `LibGetFormattedBlockPath`

Obsolete Function	Equivalent Replacement Function
`LibPrevZCState`	`LibBlockPrevZCState`
`LibPrmFileCustomCode`	`LibSetSourceFileSection`
`LibRegFileCustomCode`	`LibSetSourceFileSection`
`LibRegisterGNUMathFcnPrototypes`	Function is not used in Simulink Coder code generation.
`LibRegisterISOCMathFcnPrototypes`	Function is not used in Simulink Coder code generation.
`LibRegisterMathFcnPrototype`	Function is not used in Simulink Coder code generation.
`LibRenameParameter`	Specifying parameter names is now supported via the `mdlRTW` function in your C MEX S-function.

Advanced Functions

In this section...

LibAppendToModelReferenceUserData(data)

Appends the given data object to the user data in the `binfo` file for the model currently being built. This function is only called during builds for model reference targets.

Note The data argument cannot be a vector or matrix. To work around this limitation, create a record with a field containing the vector or matrix data and pass this record into the function.

See `LibAppendToModelReferenceUserData` in `modelrefutil.tlc`.

LibBlockInputSignalBufferDstPort(portIdx)

Returns the output port corresponding to input port (`portIdx`) that share the same memory, otherwise (-1) is returned. You will need to use `LibBlockInputSignalBufferDstPort` when you specify `ssSetInputPortOverWritable(S,portIdx,TRUE)` in your S-function.

If an input port and some output port of a block are

- Not test points, and
- The input port is overwritable

then the output port might reuse the same buffer as the input port. In this case, `LibBlockInputSignalBufferDstPort` returns the index of the output port that reuses the specified input port's buffer. If none of the block's output ports reuse the specified input port buffer, then `LibBlockInputSignalBufferDstPort` returns `-1`.

`LibBlockInputSignalBufferDstPort` is the TLC version of the Simulink macro `ssGetInputPortBufferDstPort`.

Example

Assume you have a block that has two input ports, both of which receive a complex number in 2-wide vectors. The block outputs the product of the two complex numbers.

```
%assign u1r = LibBlockInputSignal (0, "", "", 0)
%assign u1i = LibBlockInputSignal (0, "", "", 1)
%assign u2r = LibBlockInputSignal (1, "", "", 0)
%assign u2i = LibBlockInputSignal (1, "", "", 1)
%assign yr  = LibBlockOutputSignal (0, "", "", 0)
%assign yi  = LibBlockOutputSignal (0, "", "", 1)
%if (LibBlockInputSignalBufferDstPort(0) != -1)
  %% The first input is going to be overwritten by yr so
  %% we need to save the real part in a temporary variable.
  {
  real_T tmpRe = %<u1r>;
%assign u1r = "tmpRe";
%endif
%<yr> = %<u1r> * %<u2r> - %<u1i> * %<u2i>;
%<yi> = %<u1r> * %<u2i> + %<u1i> * %<u2r>;
%if (LibBlockInputSignalBufferDstPort(0) != -1)
  }
%endif
```

Note that, because only one output port exists, this example could have used `(LibBlockInputSignalBufferDstPort(0) == 0)` as the Boolean condition for the `%if` statements.

See `LibBlockInputSignalBufferDstPort` in `blkiolib.tlc`.

LibBlockInputSignalStorageClass(portIdx, sigIdx)

Returns the storage class of the specified block input port signal. The storage class can be `"Auto"`, `"ExportedSignal"`, `"ImportedExtern"`, or `"ImportedExternPointer"`.

See `LibBlockInputSignalStorageClass` in `blkiolib.tlc`.

LibBlockInputSignalStorageTypeQualifier(portIdx, sigIdx)

Returns the storage type qualifier of the specified block input port signal. The type qualifier can be anything entered by the user, such as `const`. The default type qualifier is `"Auto"`, which means do the default action.

See `LibBlockInputSignalStorageTypeQualifier` in `blkiolib.tlc`.

LibBlockOutputSignalIsGlobal(portIdx)

Returns 1 if the specified block output port signal is declared in the global scope, otherwise returns `0`.

If `LibBlockOutputSignalIsGlobal` returns `1`, then the variable holding this signal is accessible from anywhere in generated code. For example, `LibBlockOutputSignalIsGlobal` returns `1` for signals that are test points, external, or invariant.

See `LibBlockOutputSignalIsGlobal` in `blkiolib.tlc`.

LibBlockOutputSignalIsInBlockIO(portIdx)

Returns 1 if the specified block output port exists in the global block I/O data structure. You might need to use this if you specify `ssSetOutputPortReusable(S,portIdx,TRUE)` in your S-function.

See `sfun_multiport.tlc`.

See `LibBlockOutputSignalIsInBlockIO` in `blkiolib.tlc`.

LibBlockOutputSignalIsValidLValue(portIdx)

Returns `1` if the specified block output port signal can be used as a valid left-side argument (`lvalue`) in an assignment expression, otherwise returns `0`. For example, `LibBlockOutputSignalIsValidLValue` returns `1` if the block output port signal is in read/write memory.

See `LibBlockOutputSignalIsValidLValue` in `blkiolib.tlc`.

LibBlockOutputSignalStorageClass(portIdx)

Returns the storage class of the block's specified output signal. The storage class can be `"Auto"`, `"ExportedSignal"`, `"ImportedExtern"`, or `"ImportedExternPointer"`.

See `LibBlockOutputSignalStorageClass` in `blkiolib.tlc`.

LibBlockOutputSignalStorageTypeQualifier(portIdx)

Returns the storage type qualifier of the block's specified output signal. The type qualifier can be anything entered by the user, such as `const`. The default type qualifier is `Auto`, which means do the default action.

See `LibBlockOutputSignalStorageType` in `blkiolib.tlc`.

LibBlockSrcSignalBlock(portIdx, sigIdx)

Returns a reference to the block that is the source of the specified block input port element. The return argument is one of the following:

`[systemIdx, blockIdx]`	If the block output or state is unique
`"ExternalInput"`	If external input (root inport)

`"Ground"`	If unconnected or connected to ground
`"FcnCall"`	If function-call output
`0`	If not unique (i.e., source for a Merge block or a signal reused because of block I/O optimization)

Example

The following code fragment finds the block that drives the second input on the first port of the current block, then assigns the input signal of this source block to the variable `y`:

```
%assign srcBlock = LibBlockSrcSignalBlock(0, 1)
%% Make sure that the source is a block
%if TYPE(srcBlock) == "Vector"
  %assign sys = srcBlock[0]
  %assign blk = srcBlock[1]
  %assign block = CompiledModel.System[sys].Block[blk]
  %with block
    %assign u = LibBlockInputSignal(0, "", "", 0)
    y = %<u>;
  %endwith
%endif
```

See `LibBlockSrcSignalBlock` in `blkiolib.tlc`.

LibBlockSrcSignalIsDiscrete(portIdx, sigIdx)

Returns 1 if the source signal corresponding to the specified block input port element is discrete, otherwise returns 0.

Note that `LibBlockSrcSignalIsDiscrete` also returns 0 if the driving block cannot be uniquely determined to be a merged or reused signal (i.e., the source is a Merge block or the signal has been reused because of optimization).

See `LibBlockSrcSignalIsDiscrete` in `blkiolib.tlc`.

LibBlockSrcSignalIsGlobalAndModifiable(portIdx, sigIdx)

`LibBlockSrcSignalIsGlobalAndModifiable` returns 1 if the source signal corresponding to the specified block input port element satisfies the following three conditions:

- It is readable everywhere in the generated code.
- It can be referenced by its address.
- Its value can change (i.e., it is not declared as a `const`).

Otherwise, `LibBlockSrcSignalIsGlobalAndModifiable` returns `0`.

See `LibBlockSrcSignalIsGlobalAndModifiable` in `blkiolib.tlc`.

LibBlockSrcSignalIsInvariant(portIdx, sigIdx)

Returns `1` if the source signal corresponding to the specified block input port element is invariant (i.e., the signal does not change).

For example, a source block with a constant `TID` (or equivalently, an infinite sample time) would output an invariant signal.

See `LibBlockSrcSignalIsInvariant` in `blkiolib.tlc`.

LibGetModelReferenceUserData(modelName)

Gets the user data for the given model. This returns a vector with one element for each time `LibAppendToUserData` is called in the given model. This function cannot be called during builds where the target type is SIM.

See `LibGetModelReferenceUserData` in `modelrefutil.tlc`.

LibGetReferencedModelNames()

Gets the names of the models referenced by the model that is currently being built. Returns the data as a structure with two fields:

- `NumReferencedModels`: an integer with the number of model names
- `ReferencedModel`: an array of structures, where each structure has a field –`Name`– containing the name of a referenced model

See `LibGetReferencedModelNames` in `modelrefutil.tlc`.

LibIsModelReferenceRTWTarget()

Returns true if the build process is generating code for model reference target.

See `LibIsModelReferenceRTWTarget` in `utillib.tlc`.

LibIsModelReferenceSimTarget()

Return true if we are generating code for model reference Simulation target.

See `LibIsModelReferenceSimTarget` in `utillib.tlc`.

LibIsModelReferenceTarget()

Return true if we are generating code for model reference target.

See `LibIsModelReferenceTarget` in `utillib.tlc`.

Error Reporting

You might need to detect and report error conditions in your TLC code. Error detection and reporting are used most often in library functions. While rare, it is also possible to encounter error conditions in block target file code if the S-function `mdlCheckParameters` function does not detect an unforeseen condition.

To report an error condition detected in your TLC code, use the `LibBlockReportError` or `LibBlockReportFatalError` utility functions. Here is an example of using `LibBlockReportError` in the `paramlib.tlc` function `LibBlockParameter` to report the condition of an improper use of that function:

```
%if TYPE(param.Value) == "Matrix"
    %% exit if the parameter is a true matrix,
    %% i.e., has more than one row or columns.
    %if nRows > 1
      %assign errTxt = "Must access parameter %<param.Name> using "...
        "LibBlockMatrixParameter."
      %<LibBlockReportError([], errTxt)>
    %endif
  %endif
```

Browse through the files in the folder *`matlabroot`*`/rtw/c/tlc` (open) for more examples of the use of `LibBlockReportError`.

Generating Errors from TLC Files

TLC Error Generation Overview

To generate errors from TLC files, you can use the `%exit` directive. Alternatively, you can use one of the library functions described below that calls `%exit` for you. The two types of errors are

Usage errors	These can be caused by incorrect models.

Fatal (internal) TLC coding errors	These *cannot* be caused by incorrect models.

Usage Errors

Usage errors are errors resulting from incorrect models or attributes defined on a model. For example, suppose you have an S-Function block and an inline TLC file for a specific D/A device. If a model can contain only one copy of this S-function, then an error needs to be generated for a model that contains two copies of this S-Function block.

Using Library Functions

To generate usage errors related to a specific block, use the library function

```
LibBlockReportError(block,"error string")
```

The `block` argument is the block record if it isn't scoped. If the block is currently scoped, then you can specify `block` as [ ].

To generate general usage errors that are not related to a specific block, use

```
LibReportError("error string")
```

These library functions prefix the string `Simulink Coder Error:` to the message you provide when reporting the error.

For a usage example of these functions, refer to `gensfun.tlc` for block errors and `commonsetup.tlc` for common errors. There are other files that use these functions in the TLC source folders within *`matlabroot`*`/rtw/c/tlc` (open.

Fatal (Internal) TLC Coding Errors

Suppose you have an S-function that has a local function that can accept only numerical numbers. You might want to add an assert requiring that the inputs be only numerical numbers. These asserts can indicate fatal coding errors for which the user does not have a way of building a model or specifying attributes that can cause the error to occur.

Using Library Functions

The two available library functions are

```
LibBlockReportFatalError(block,"fatal coding error message")
```

where *`block`* is the offending block record (or `[]` if the block is already scoped), and

```
LibReportFatalError("fatal coding error message")
```

for error messages that are not block specific. For example, to add assert code you could use

```
%if TYPE(argument) != "Number"
  %<LibBlockReportFatalError(block,"unexpected argument type")>
%endif
```

These library functions prefix the string `Simulink Coder Fatal:` to the message you provide and display the call stack when reporting the error.

For a usage example of these functions, refer to `gensfun.tlc` for block errors and `commonsetup.tlc` for common errors. There are other files that use these functions in the folder *`matlabroot`*`/rtw/c/tlc` (open).

Using %exit

You can call `%exit` to generate fatal error messages. However, MathWorks suggests that you use one of the library functions described above.

When generating fatal error messages directly with `%exit`, it is good practice to give a stack trace with the error message. This lets you see the call chain of functions that caused the error. To generate a stack trace, generate the message using the format:

```
%setcommandswitch "-v1"
%exit Simulink Coder Fatal: error string
```

Formatting Error Messages

If you want to display a formatted, multiple-line error message, create a local variable that contains the message text. For example:

```
%openfile message
My message text
with newlines
%closefile message
```

After formatting your error message, use one of the error reporting library functions described above, such as `LibReportError`, to report your error when it occurs. For example:

```
%<LibReportError(message)>
```

The error reporting library functions provide an error message prefix, such as `Simulink Coder Error:`.

Testing Error Messages

It is strongly suggested that you test your error messages before releasing your new TLC code. To test your error messages, copy the relevant code into a `test.tlc` file and run

```
tlc test.tlc
```

at the MATLAB prompt.

Using TLC Error Messages to Troubleshoot

This section lists and describes error messages generated by the Target Language Compiler. Use this reference to

- Confirm that an error has been reported
- Determine possible causes for an error
- Determine possible ways to fix an error

%closefile or %selectfile or %flushfile argument must be a valid open file

In `%closefile` or `%selectfile` or `%flushfile`, the argument must be a valid file variable opened with `%openfile`.

%define no longer supported, use %function instead

Macros are not supported. You must rewrite macros as functions or inline them in your code.

%error directive: text

Code containing the `%error` directive generates this message. It normally indicates some condition that the code was unable to handle and displays the text following the `%error` directive.

%exit directive: text

Code containing the `%exit` directive causes this message. It typically indicates some condition that the code was unable to handle and displays the text following the `%exit` directive. Note that this directive causes the Target Language Compiler to terminate regardless of the `-mnumber` command-line option.

%filescope has already been used in this file

The user attempted to use the `%filescope` directive more than once in a file.

%trace directive: text

The `%trace` directive produces this error message and displays the text following the `%trace` directive. Trace directives are reported only when the `-v` option (verbose mode) appears on the command line. Note that `%trace` directives are not considered errors and do not cause the Target Language Compiler to stop processing.

%warning directive: text

The `%warning` directive produces this error message and displays the text following the `%warning` directive. Note that `%warning` directives are not considered errors and do not cause the Target Language Compiler to stop processing.

A %implements directive must appear within a block template file and must match the %language and type specified

A block template file was found, but it did not contain an `%implements` directive. An `%implements` directive is required so that the expected language and type are implemented by this block template file. See “Object-Oriented Facility for Generating Target Code” on page 18-32 for more information.

A %switch statement can only have one %default

The user has written a `%switch` statement with multiple `%default` cases, as in the following example:

```
%switch expr
  %case 1
```

```
    code...
    %break
  %default

more code...
    %break
  %default          %% error
    even more code...
    %break
%endswitch
```

A language choice must be made using the %language directive prior to using GENERATE or GENERATE_TYPE

To use the `GENERATE` or `GENERATE_TYPE` built-in functions, the Target Language Compiler requires that you first specify the language being generated. This causes the block-level target file to implement the same language and type as specified in the `%language` directive.

A non-homogeneous vector was passed to GENERATE_FORMATTED_VALUE

The built-in `GENERATE_FORMATTED_VALUE` can process only vectors that have homogeneous elements (that is, vectors in which all the elements have the same type).

Ambiguous reference to identifier — must use array index to refer to one of multiple scopes

In a repeated scope identifier from a database file, you must specify an index to disambiguate the reference. For example

```
Database file:
block
{
    Name                "Abc2"
    Parameter {
        Name            "foo"
        Value            2
    }
}
```

```
block
{
    Name                "Abc3"
    Parameter {
        Name            "foo"
        Value            3
    }
}
TLC file:
%<GETFIELD(block, "Name")>
```

In the preceding example, the reference to `block` is ambiguous because multiple repeated scopes named `block` appear in the database file. Use an index to disambiguate the references, as in:

```
%<GETFIELD(block[0], "Name")>
```

An %if statement can only have one %else

The user has written an `%if` statement with multiple `%else` blocks, as in the following example:

```
%if expr
  code...
%else
  more code...
%else          %% error
  even mode code...
%endif
```

Argument to identifier must be a string

The following built-in functions expect a string and report this error if the argument passed is not a string.

CAST	GENERATE_FILENAME
EXISTS	GENERATE_FUNCTION_EXISTS
FEVAL	GENERATE_TYPE
FILE_EXISTS	GET_COMMAND _SWITCH
FORMAT	IDNUM

GENERATE	SYSNAME

Arguments to directive must be records

Arguments to `%mergerecord` and `%copyrecord` must be records. Also, the first argument to the following built-in functions must be a record:

- `ISALIAS`
- `REMOVEFIELD`
- `FIELDNAMES`
- `ISFIELD`
- `GETFIELD`
- `SETFIELD`

Arguments to TLC from the MATLAB command line must be strings

An attempt was made to invoke the Target Language Compiler from MATLAB, but some of the arguments that were passed were not strings.

Assertion failed

An expression in an `%assert` statement evaluated to false.

Assignment to scope identifier is only allowed when using the + operator to add members

Scope assignment must be `scope = scope + variable`.

Attempt to define a function identifier on top of an existing variable or function

A function cannot be defined twice. Make sure that you don't have the same function defined in separate TLC files.

Attempt to divide by zero

The Target Language Compiler does not allow division by zero.

Bad cast - unable to cast this expression to type

The Target Language Compiler cannot cast this expression from its current type to the specified type. For example, the Target Language Compiler cannot cast a string to a number, as in

```
%assign x = "1234"
%assign y = CAST("Number", x );
```

Bad directory (dirname) in O: filename

The `-O` option did not specify a valid folder.

builtin was expecting expression of type type, got one of type type

A built-in was passed an expression of incorrect type.

Cannot %undef any builtin functions or variables

User is not allowed to undefine a TLC built-in or variable. For example

```
%undef FORMAT  %% error
```

Cannot convert string your_string to a number

Cannot convert the string to a number.

Changing value of identifier from the RTW file

You have overwritten the value that appeared in the `.rtw` file.

Error opening filename

The Target Language Compiler could not open the file specified on the command line.

Error writing to file error

There was an error while writing to the current output stream; `error` contains the system specific error message.

Errors occurred — aborting

This error message is the last error to be reported. It occurs when either

- The number of error messages exceeds the error message threshold (5 by default).
- Processing completes and errors have occurred.

Expansion directives %<> cannot be nested

It is illegal to nest expansion directives. For example,

```
%<foo(%<expr>)>
```

Instead, do the following:

```
%assign tmp = %<expr>
%<foo(tmp)>
```

Expansion directives %<> cannot span multiple lines; use \ at end of line

An expansion directive cannot span multiple lines. To work around this restriction, use the \ line continuation character. The following is incorrect:

```
%<CompiledModel.System[Sysidx].Block[BlkIdx].Name +
"Hello">
```

Instead, use:

```
%<CompiledModel.System[Sysidx].Block[BlkIdx].Name + \
"Hello">
```

Extra arguments to the function-name built-in function were ignored (Warning)

The following built-in functions report this warning when too many arguments are passed to them:

CAST	NUMTLCFILES
EXISTS	OUTPUT_LINES
FILE_EXISTS	SIZE
FORMAT	STRING
GENERATE_FILENAME	STRINGOF
GENERATE_FUNCTION_EXISTS	SYSNAME
IDNUM	TLCFILES
ISFINITE	TYPE
ISINF	WHITE_SPACE
ISNAN	WILL_ROLL

File name too long (directory =dirname, name =filename)

The specified *`filename`* was too long. The default limits are 256 characters for *`filename`* and 1024 characters for *`dirname`*, but the limits can be larger, depending on the platform.

format is not a legal format value

The specified format was not legal for the `%realformat` directive. Valid format strings are `"EXPONENTIAL"` and `"CONCISE"`.

Function argument mismatch; function function_name expects number arguments

When calling a function, too many or too few arguments were passed to it.

Function reached the end and did not return a value

Functions that are not declared as `void` or `Output` must return a value. If a return value is not desired, declare the function as `void`, otherwise make it return a value.

Function values are not allowed

Attempt to use a TLC function as a variable.

Identifier identifier multiply defined. Second and succeeding definitions ignored.

The user is attempting to add the same field to a record more than once, as in the following code.

```
%createrecord err { foo 1; rec { val 2 } }
%addtorecord err foo 2             %% error
```

Identifier identifier used on a %foreach statement was already in scope (Warning)

The argument to a `%foreach` statement cannot be defined prior to entering the `%foreach`.

Illegal use of eval (i.e., %<...>)

It is illegal to use evals in `.rtw` files. There are also some places where evals are not allowed in directives. For example:

```
%function %<foo>(a, b, c) void  %% error
%endfunction
```

Indices may not be negative

An index used in a [ ] expression must be a nonnegative integer.

Indices must be constant integral numbers

An index used in a [ ] expression must be an integer number.

Invalid handle

An invalid handle was passed to the Target Language Compiler server mode.

Invalid identifier range, the leading strings string1 and string2 must match

In a range of signals, for example, `u1:u10`, the identifier in the first argument did not match the identifier in the second.

Invalid identifier range, the lower bound (bound) must be less than the upper bound (bound)

In a range of signals, for example, `u1:u10`, the lower bound was higher than the upper bound.

Invalid type for unary operator

Unary operators − and + require numeric types. Unary operator − requires an integral type. Unary operator `!` requires a numeric type.

Invalid type type

An invalid type was passed to a built-in function.

It is illegal to return a function from a function

A function value cannot be returned from a function call.

Named value identifier already exists within this scope-identifier; use %assign to change the value

You cannot use the block addition operator + to add a value that is already a member of the indicated block. Use `%assign` to change the value of an existing value. This example produces this error:

```
%assign x = BLK { a 1; b 2 }
%assign a = 3
%assign x = x + a
```

Use this instead:

```
%assign x.a = 3
```

No %case statement(s) seen yet, statement ignored

Statements that appear inside a `%switch` statement but precede `%case` statements are ignored, as in the following code:

```
%switch expr
%assign x = 2  %% this statement will be ignored
  %case 1
    code
    %break
%endswitch
```

Only double and character arrays can be converted from MATLAB to TLC. This can occur if the MATLAB function does not return a value (see %matlab)

Only double and character arrays can be converted from MATLAB to the Target Language Compiler. This error can occur if the MATLAB function does not return a value (see `%matlab`). For example,

```
%assign a = FEVAL("int8",3)
%matlab disp(a)
```

Only one output is allowed from the TLC

An attempt was made to receive multiple outputs from the MATLAB version of the Target Language Compiler.

Only strings of length 1 can be assigned using the [ ] notation

The right-hand side of a string assignment using the [ ] operator must be a string of length 1. You can replace only a single character using this notation.

Only strings or cells of strings may be used as the argument to Query and ExecString

A cell containing nonstring data was passed as the third argument to `Query` or `ExecString` in server mode.

Only vectors of the same length as the existing vector value can be assigned using the [ ] notation

In the [ ] notation to replace a row of a matrix, the row must be a vector of the same length as the existing rows.

Output file identifier opened with %openfile was not closed

Output files opened with `%openfile` must be closed with `%closefile`. The *`identifier`* is the name of the variable specified in the `%openfile` directive.

Note This might also occur a syntax error is present in a code section between an `openfile` and `closefile`, or if you try to assign the output of a function of type `void` or `Output` to a variable.

Ranges, identifier ranges, and repeat values cannot be repeated

You cannot repeat a range, identifier range, or repeat value. This prevents things like `[1@2@3]`.

String cannot modify the setting for the command line switch '-switch'

`%setcommandswitch` does not recognize the specified switch, or cannot modify it (e.g., `-r` cannot be modified).

string is not a recognized user defined property of this handle

The query performed on a TLC server mode handle is looking for an undefined property.

Syntax error

The indicated line contains a syntax error, for more information on syntax, see “Target Language Compiler Directives” on page 18-2.

The %break directive can only appear within a %foreach, %for, %roll, or %switch statement

The `%break` directive can be used only in a `%foreach`, `%for`, `%roll`, or `%switch` statement.

The %case and %default directives can only be used within the %switch statement

A `%case` or `%default` directive can appear only within a `%switch` statement.

The %continue directive can only appear within a %foreach, %for, or %roll statement

The `%continue` directive can be used only in a `%foreach`, `%for`, or `%roll` statement.

The %foreach statement expects a constant numeric argument

The argument of a `%foreach` must be a numeric type. For example:

```
%foreach Index = [1 2 3 4]
...
%endforeach
```

`%foreach` cannot accept a vector as input.

The %if statement expects a constant numeric argument

The argument of an `%if` statement must be a numeric type. For example,

```
%if [ 1 2 3 ]
...
%endif
```

`%if` cannot accept a vector as input.

The %implements directive expects a string or string vector as the list of languages

You can use the `%implements` directive to specify a string for the language being implemented, or to indicate that it implements multiple languages by using a vector of strings. You cannot specify any other argument type to the `%implements` directive.

The %implements directive specifies type as the type where type was expected

The type specified in the `%implements` directive must exactly match the type specified in the block or on the `GENERATE_TYPE` directive. If you want to specify that the block accept multiple input types, use the `%implements *` directive, as in

```
%implements * "C"   %% I accept any type and generate C code
```

The %implements language does not match the language currently being generated (language)

The language or languages specified in the `%implements` directive must exactly match the `%language` directive.

The %return statement can only appear within the body of a function

A `%return` statement can be only in the body of a function.

The == and != operators can only be used to compare values of the same type

The == and != operator arguments must be the same type. You can use the `CAST()` built-in function to change them into the same type.

The argument for %openfile must be a valid string

When you open an output file, the name specified for the file must be a valid string.

The argument for %with must be a valid scope

The argument to `%with` must be a valid scope identifier. For example,

```
%assign x = 1
%with x
...
%endwith
```

In this code, the `%with` statement argument is a number and produces this error message.

The argument for an [ ] operation must be a repeated scope symbol, a vector, or a matrix

When you use the [ ] operator to index, the expression on the left of the brackets must be a vector, matrix, string, numeric constant, or a repeated scope identifier. When you use array indexing on a scalar, the constant is automatically scalar expanded and the value of the scalar is returned. For example,

```
%openfile x
%assign y = x[0]
```

This example causes this error because `x` is a file and is not valid for indexing.

The argument to %addincludepath must be a valid string

The argument to `%addincludepath` must be a string.

The argument to %include must be a valid string

The argument to the input file control directive must be a valid string with the filename given in double quotation marks.

The begin directive must be in the same file as the corresponding end directive.

These Target Language Compiler `begin` directives must appear in the same file as their corresponding `end` directives: `%function`, `%switch`, `%foreach`, `%roll`, and `%for`. Place the construct entirely within one Target Language Compiler source file.

The begin directive on this line has no matching end directive

For block-scoped directives, this error is produced if a matching `end` directive is missing. This error can occur for the following block-scoped Target Language Compiler directives.

Begin Directive	End Directive	Description
`%if`	`%endif`	Conditional inclusion
`%for`	`%endfor`	Looping
`%foreach`	`%endforeach`	Looping
`%roll`	`%endroll`	Loop rolling
`%with`	`%endwith`	Scoping directive
`%switch`	`%endswitch`	Switch directive
`%function`	`%endfunction`	Function declaration directive
`{`	`}`	Record creation

The error is reported on the line that opens the scope and does not have matching `end` scope.

Note Nested scopes must be closed before their parent scopes. Failure to include an `end` for a nested scope often causes this error, as in

```
%if Block.Name == "Sin 3"
    %foreach idx = Block.Width %endif
%% Error reported here that the %foreach was not terminated
```

The construct %matlab function_name(...) construct is illegal in standalone tlc

You cannot call MATLAB from stand-alone TLC.

The FEVAL() function can accept only 2-dimensional arrays from MATLAB, not number dimensions

Return values from MATLAB can have at most two dimensions.

The FEVAL() function can accept vectors of numbers or strings only when calling MATLAB

Vectors passed to MATLAB can be numbers or strings. See “FEVAL Function” on page 18-46.

The FEVAL() function requires the name of a function to call

`FEVAL` requires a function to call. This error appears only inside MATLAB.

The final argument to %roll must be a valid block scope

When you use `%roll`, the final argument (prior to extra user-specified arguments) must be a valid block scope. See “%roll” on page 18-29 for a description of this command.

The first argument of a ? : operator must be a Boolean expression

The `? :` operator must have a Boolean expression as its first operand.

The first argument to GENERATE or GENERATE_TYPE must be a valid scope

When you call `GENERATE` or `GENERATE_TYPE`, the first argument must be a valid scope. See the “GENERATE and GENERATE_TYPE Functions” on page 18-33 for more information and examples.

The function name requires at least number arguments

User is passing too few arguments to a function, as in the following code:

```
%function foo(a, b, c)
  %return a + b + c
%endfunction

%<foo(1, 2)>  %% error
```

The GENERATE function requires at least 2 arguments

When you call the `GENERATE` built-in function, the first two arguments must be the block and the name of the function to call.

The GENERATE_TYPE function requires at least 3 arguments

When you call the `GENERATE_TYPE` built-in function, the first three arguments must be the block, the name of the function to call, and the type.

The ISINF(), ISNAN(), ISFINITE(), REAL(), and IMAG() functions expect a real or complex valued argument

These functions expect a `Real` or complex value as the input argument.

The language being implemented cannot be changed within a block template file

You cannot change the language using the `%language` directive within a block template file.

The language being implemented has changed from old-language to new-language (Warning)

The language being implemented should not be changed in midstream because `GENERATE` function calls that appear prior to the `%language` directive can cause `generate` functions to load for the prior language. Only one language directive should appear in a given file.

The left-hand side of a . operator must be a valid scope identifier

When you use the `.` operator, the left-hand side of the `.` operator must be a valid in-scope identifier. For example:

```
%assign x = 1
%assign y = x.y
```

In this code, the reference to `x.y` produces this error message because `x` is not defined as a scope.

The left-hand side of an assignment must be a simple expression comprised of ., [ ], and identifiers

Illegal left-hand side of assignment.

The number of columns specified (specified-columns) did not match the actual number of columns in the rows (actual-columns)

When you specify a Target Language Compiler matrix, the number of columns specified must match the actual number of columns in the matrix. For example,

```
%assign mat = Matrix(2,1) [[1,2];[2,3]]
```

In this case, the number of columns in the declaration of the matrix (1) did not match the number of columns seen in the matrix (2). Either change the number of columns in the matrix, or change the matrix declaration.

The number of rows specified (specified-rows) did not match the actual number of rows seen in the matrix (actual-rows)

When you specify a Target Language Compiler matrix, the number of rows must match the actual number of rows in the matrix. For example,

```
%assign mat = Matrix(1,2) [[1,2];[2,3]]
```

In this case, the number of rows in the declaration of the matrix (1) did not match the number of rows seen in the matrix (2). Either change the number of rows in the matrix or change the matrix declaration.

The operator_name operator only works on Boolean arguments

The && and || operators work only on Boolean values.

The operator_name operator only works on integral arguments

The &, ^, |, <<, >> and % operators work on numbers only.

The operator_name operator only works on numeric arguments

The arguments to the following operators both must be either numeric or real: <, <=, >, >=, -, *, /. This error can also occur when you use + as a unary operator. In addition, the `FORMAT` built-in function expects either a numeric or real argument.

The return value from the RollHeader function must be a string

When you use `%roll`, the `RollHeader()` function specified in `Roller.tlc` must return a string value. See “%roll” on page 18-29 for a complete discussion of the `%roll` construct.

The roll argument to %roll must be a nonempty vector of numbers or ranges

When you use `%roll`, the `roll` vector cannot be empty and must contain numbers or ranges of numbers. See “%roll” on page 18-29 for a complete discussion of the `%roll` construct.

The second value in a Range must be greater than the first value

In a range, for example, `1:10`, the lower bound was higher than the upper bound.

The specified index (index) was out of the range 0 - number-of-elements - 1

This error occurs when you index into a nonscalar beyond the end of the variable. For example:

```
%assign x = [1 2 3]
%assign y = x[3]
```

This example would cause this error. Remember, in the Target Language Compiler, array indices start at 0 and go to the number of elements minus 1.

The STRINGOF built-in function expects a vector of numbers as its argument

The `STRINGOF` function expects a vector of numbers. The function treats each number as the ASCII value of a valid character.

The SYSNAME built-in function expects an input string of the form xxx/yyy

The `SYSNAME` function takes a single string of the form `xxx/yyy` as it appears in the `.rtw` file and returns a vector of two strings, `xxx` and `yyy`. If the input argument does not match this format, `SYSNAME` returns this error.

The threshold on a %roll statement must be a single number

When you use `%roll`, the roll threshold specified must be a single number. See “%roll” on page 18-29 for a complete discussion of the `%roll` construct.

The use of feature is being deprecated and will not be supported in future versions of TLC. See the TLC manual for alternatives.

The `%define` and `%generate` directives are not recommended, as they are being replaced.

The WILL_ROLL built in function expects a range vector and an integer threshold

The `WILL_ROLL` function requires both arguments cited in the message.

There are no more free contexts. Use tlc('close', HANDLE) to free up a context

The global context table has filled up while the TLC server mode is in use.

There was no type associated with the given block for GENERATE

The scope specified to `GENERATE` must include a `Type` parameter that indicates which template file should be used to generate code for the specified scope. For example:

```
%assign scope = block { Name "foo" }
%<GENERATE( scope, "Output" )>
```

This example produces the error message because the scope does not include the parameter `Type`. See the “GENERATE and GENERATE_TYPE Functions” on page 18-33 for more information and examples.

This assignment would overwrite an identifier-value pair from the RTW file. To avoid this error either qualify the left-hand side, or choose another identifier.

The user is trying to modify a field of a record in a `%with` block without qualifying the left-hand side, as in this example:

```
  %createrecord foo { field 1 }
  %with foo
    %assign field = 2  %% error
  %endwith
```

Instead, use

```
%createrecord foo { field 1 }
  %with foo
    %assign foo.field = 2
  %endwith
```

TLC has leaked number symbols. You may have created a cyclic record. If this not the case then please report this leak to The MathWorks.

There has been a memory leak while running TLC. The most common cause of this is having cyclic records.

Unable to find identifier within the scope-identifier scope

The given identifier was not found in the scope specified. For example,

```
%assign scope = ascope { x 5 }
%assign y = scope.y
```

In this code, the reference to `scope.y` produces this error message.

Unable to open %include file filename

The file included in an `%include` directive was not found on the path. Either move the file to a location on the current path, or use the `-I` command-line option or the `%addincludepath` directive to specify the folder that contains the file.

Unable to open block template file filename from GENERATE or GENERATE_TYPE

You specified `GENERATE` but the given filename was not found on the Target Language Compiler path. You can

- Add the file to a folder on the path.
- Use the `%generatefile` directive to specify an alternative filename for this block type that is on the path.
- Add the folder in which this file appears to the search path using the `-I` command-line option or the `%addincludepath` directive.

Unable to open output file filename

The specified output file could not be opened. Either an invalid filename was specified or the file was read only.

Undefined identifier identifier_name

The identifier specified in this expression was undefined.

Unknown type type in CAST expression

When you call the `CAST` built-in function, the type must be a valid type from the “Target Language Value Types” on page 18-18 table.

Unrecognized command line switch passed to string: switch

You queried the current state of a switch, but the switch specified was not recognized.

Unrecognized directive directive-name seen

An illegal % directive was encountered. The valid directives are shown below.

`%addincludepath`	`%addtorecord`
`%assert`	`%assign`

`%break=`	`%case`
`%closefile`	`%continue`
`%copyrecord`	`%createrecord`
`%default`	`%define`
`%else`	`%elseif`
`%endbody`	`%endfor`
`%endforeach`	`%endfunction`
`%endif`	`%endroll`
`%endswitch`	`%endwith`
`%error`	`%exit`
`%filescope`	`%for`
`%foreach`	`%function`
`%generate`	`%generatefile`
`%if`	`%implements`
`%include`	`%language`
`%matlab`	`%mergerecord`
`%openfile`	`%realformat`
`%return`	`%roll`
`%selectfile`	`%setcommandswitch`
`%switch`	`%trace`
`%undef`	`%warning`
`%with`	

Unrecognized type output-type for function

The function type modifier was not `Output` or `void`. For functions that do not produce output, the default without a type modifier indicates that the function should not produce output.

Unterminated multiline comment.

A multiline comment (i.e., /% %/) does not have a terminator, as in the following code:

```
/% my comment

%assign x = 2
%assign y = x * 7
```

Unterminated string

A string must be closed prior to the end of an expansion directive or the end of a line.

Usage: tlc [options] file

A command-line problem has occurred. The error message contains a list of the available options.

Use of feature incurs a performance hit, please see TLC manual for possible workarounds.

The `%undef` and expansion (i.e., `%<expr>`) features can degrade performance.

Value of type type cannot be compared

Values of the specified *`type`* cannot be compared.

Values of specified_type type cannot be expanded

The specified type cannot be used on an expansion directive. Files and scopes cannot be expanded. This error can also occur when you expand a function without any arguments. If you use

```
%<Function>
```

call it with the required arguments.

Values of type Special, Macro Expansion, Function, File, Full Identifier, and Index cannot be converted to MATLAB variables

Values of the types listed in the message cannot converted to MATLAB variables.

When appending to a buffer stream, the variable must be a string

You can specify the `append` option for a buffer stream only if the variable currently exists as a string. Do not use the `append` option if the variable does not exist or is not a string. This example produces this error.

```
%assign x = 1
%openfile x , "a"
%closefile x
```

TLC Function Library Error Messages

The functions in the TLC function library can generate many error messages that are not documented. These messages are sufficiently self-descriptive so that they do not need additional explanation. However, if you encounter an error message that does not provide enough description to resolve your problem, contact our technical support staff.

Guidelines and Standards for Embedded Coder

Support for Standards and Guidelines

If your application has mission-critical development and certification goals, your models or subsystems and the code generated for them might need to comply with one or more of the standards and guidelines listed in the following table.

Standard or Guidelines	Organization	For More Information, See...
Guidelines: Use of MATLAB, Simulink, and Stateflow software for control algorithm modeling – MathWorks Automotive Advisory Board (MAAB) Guidelines	MAAB	• Control Algorithm Modeling Guidelines Using MATLAB, Simulink, and Stateflow Software: MathWorks Automotive Advisory Board (MAAB) Guidelines • Develop Models and Code that Comply with "MAAB Guidelines" on page 22-5
Guidelines: Use of the C Language in Critical Systems (MISRA C®[a])	Motor Industry Software Reliability Association (MISRA)	• MISRA C website • Develop Models and Code that Comply with "MISRA C Guidelines" on page 22-6
Standard: CERT® C Coding Standards [b]	CERT Division of the Software Engineering Institute (SEI)	• CERT C Coding Standards publication on the Software Engineering Institute website • Secure Coding on the Software Engineering Institute website • Develop Model and Code that Comply with "Secure Coding Standards" on page 22-8
Standard: Common Weakness Enumeration (CWE™[c])	The MITRE Corporation	• CWE list of software weaknesses types • Develop Model and Code that Comply with "Secure Coding Standards" on page 22-8

Standard or Guidelines	Organization	For More Information, See...
Standard: ISO/IEC TS 17961	International Organization for Standardization and International Electrotechnical Commission	• ISO/IEC TS 17961:2013 standards publication • Develop Model and Code that Comply with “Secure Coding Standards” on page 22-8
Standard: AUTomotive Open System ARchitecture (AUTOSAR)	AUTOSAR Development Partnership	• Publications and specifications available from the AUTOSAR website • AUTOSAR Support from Embedded Coder on the MathWorks website • “AUTOSAR Standard” on page 22-20 • “AUTOSAR Blockset” documentation
Standard: IEC 61508, Functional safety of electrical/ electronic/programmable electronic safety-related systems	International Electrotechnical Commission	• IEC functional safety zone website • IEC 61508 Support in MATLAB and Simulink • Develop Models and Code that Comply with “IEC 61508 Standard” on page 22-11
Standard: IEC 62304, Medical device software - Software life cycle processes	International Electrotechnical Commission	• Develop Models and Code that Comply with “IEC 62304 Standard” on page 22-13
Standard: ISO 26262, Road Vehicles - Functional Safety	International Organization for Standardization	• ISO 26262 Support in MATLAB and Simulink • Develop Models and Code that Comply with “ISO 26262 Standard” on page 22-14
Standard: EN 50128, Railway applications — Software for railway control and protection systems	European Committee for Electrotechnical Standardization	• Develop Models and Code that Comply with “EN 50128 Standard” on page 22-16

Standard or Guidelines	Organization	For More Information, See...
Standard: DO-178C, Software Considerations in Airborne Systems and Equipment Certification	Radio Technical Commission for Aeronautics (RTCA)	• Develop Models and Code that Comply with “DO-178C Standard” on page 22-18

b. CERT is registered in the U.S. Patent and Trademark Office by Carnegie Mellon University.
c. CWE is a trademark of The MITRE Corporation.

MAAB Guidelines

The MathWorks Automotive Advisory Board (MAAB) involves major automotive OEMs and suppliers in the process of evolving MathWorks controls, simulation, and code generation products, including Simulink, Stateflow, and Simulink Coder. An important result of the MAAB has been the “MAAB Control Algorithm Modeling” (Simulink) guidelines.

If you have a Simulink Check product license, you can check that your Simulink model or subsystem, and the code that you generate from it, complies with MAAB guidelines. To check your model or subsystem, open the Simulink Model Advisor (Simulink). Navigate to **By Product > Simulink Check > Modeling Standards > MathWorks Automotive Advisory Board Checks** and run the MathWorks Automotive Advisory Board checks (Simulink Check).

For more information on using the Model Advisor, see “Select and Run Model Advisor Checks” (Simulink).

MISRA C Guidelines

The Motor Industry Software Reliability Association (MISRA[2]) has established "Guidelines for the Use of the C Language in Critical Systems" (MISRA C).

For information about MISRA C, see `www.misra.org.uk`.

In 1998, MIRA Ltd. published MISRA C (MISRA C:1998) to provide a restricted subset of a standardized, structured language that met Safety Integrity Level (SIL) 2 and higher. A major update based on feedback was published in 2004 (MISRA C:2004), followed by a minor update in 2007 known as Technical Corrigendum (TC1).

In 2007, MIRA Ltd. published the MISRA AC AGC standard, "MISRA AC AGC: Guidelines for the Application of MISRA-C:2004 in the Context of Automatic Code Generation." MISRA AC AGC does not change MISRA C:2004 rules, rather it modifies the adherence recommendation.

In 2013, MIRA Ltd. published the MISRA C:2012 standard, "Guidelines for the use of the C language in critical systems." MISRA C:2012 provides improvements based on user feedback and includes guidance on automatic code generation.

Embedded Coder and Simulink offer capabilities to minimize the potential for MISRA C rule violations. Capabilities include:

- Code Generation Advisor, which helps you configure a model or subsystem so that the code generator is most likely to produce MISRA C:2012 compliant code. For more information, see "Configure Model for Code Generation Objectives by Using Code Generation Advisor" on page 43-2.
- Model Advisor (Simulink) checks, which you can use as you developed your model or subsystem to increase the likelihood of generating MISRA C:2012 compliant code. To execute the MISRA C:2012 compliance checks your model or subsystem:

  1. Open the Model Advisor.
  2. Navigate to **By Task > Modeling Guidelines for MISRA C:2012**.
  3. Run the checks in the folder.

  For more information on using the Model Advisor, see "Select and Run Model Advisor Checks" (Simulink).

2. MISRA and MISRA C are registered trademarks of MIRA Ltd., held on behalf of the MISRA Consortium.

When using MISRA C:2012 coding guidelines to evaluate the quality of your generated C code, you are required per section 5.3 of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document to prepare a compliance statement for the project being evaluated. To assist you in the development of this compliance statement, MathWorks evaluates the MISRA C:2012 guidelines against C code generated by using Embedded Coder. The results of the evaluation are published as:

- Compliance Summary Tables on page 23-7, which identify the method used to obtain compliance for each rule and directive.
- Deviations on page 23-32, which identify rules or directives that are not compliant.

For more information, see “Developing a MISRA C:2012 Compliance Statement” on page 23-2.

Secure Coding Standards

These coding standards are for software developers to use in the development of code in the C language:

- CERT® C — Published by the CERT Division of the Software Engineering Institute (SEI), these guidelines help eliminate constructs with undefined behavior that can lead to unexpected results at runtime and expose security weaknesses.
- Common Weakness Enumeration (CWE™) — Published by The MITRE Corporation, this list identifies common software weakness types that can occur in software architecture, design, code, or implementation. These weaknesses can lead to security vulnerabilities.
- ISO/IEC TS 19761:2013 — Published by International Organization for Standardization and International Electrotechnical Commission, these rules are designed so that they can be enforced by static analysis tools without excessive false positives.

If you have an Embedded Coder or Simulink Check product license, you can check that your Simulink model or subsystem, and the code that you generate from it, conforms to these secure coding standards. To check your model or subsystem:

1. Open the Model Advisor.
2. Navigate to **By Task > Modeling Guidelines for secure coding standards (CERT C, CWE, ISO/IEC TS 17961)** .
3. Run the checks in the folder.

For more information on using the Model Advisor, see “Select and Run Model Advisor Checks” (Simulink).

If you have a Polyspace Bug Finder product license, you can evaluate your code against these secure coding standards. For more information, see:

- “CWE Coding Standard and Polyspace Results” (Polyspace Bug Finder)
- “Check for Coding Standard Violations” (Polyspace Bug Finder)
- “Changes in Coding Standard Checking in R2019a” (Polyspace Bug Finder)

High-Integrity System Modeling Guidelines

The high-integrity system modeling guidelines provide model setting, block usage, and block parameter considerations for creating models that are complete, unambiguous, robust, and verifiable. Use these guidelines when you develop models and generate code for safety-critical systems, such as in projects that need to comply with the DO-178C / DO-331, IEC 61508, IEC 62304, ISO 26262, or EN 50128 safety standards.

For more information, see “High-Integrity System Modeling” (Simulink).

If you have a Simulink Check product license, you can use the Model Advisor to check for compliance with the high-integrity modeling guidelines. To check your model or subsystem, open the Model Advisor and execute the checks in these folders:

- **By Task > Modeling Standards for DO-178C/DO-331 > High-Integrity Systems**
- **By Task > Modeling Standards for IEC 61508 > High-Integrity Systems**
- **By Task > Modeling Standards for IEC 62304 > High-Integrity Systems**
- **By Task > Modeling Standards for EN 50128 > High-Integrity Systems**
- **By Task > Modeling Standards for ISO 26262 > High-Integrity Systems**

For more information on using the Model Advisor, see “Select and Run Model Advisor Checks” (Simulink).

Modeling Guidelines for Code Generation

Use the code generation guidelines when you develop models and generate code for embedded systems using Model-Based Design with MathWorks products. The guidelines provide model setting, block usage, and block parameter considerations that impact code generation.

The code generation guidelines for blocks include:

- “cgsl_0101: Zero-based indexing” (Simulink)
- “cgsl_0102: Evenly spaced breakpoints in lookup tables” (Simulink)
- “cgsl_0103: Precalculated signals and parameters” (Simulink)
- “cgsl_0104: Modeling global shared memory using data stores” (Simulink)
- “cgsl_0105: Modeling local shared memory using data stores” (Simulink)

The code generation guidelines for modeling patterns include:

- “cgsl_0201: Redundant Unit Delay and Memory blocks” (Simulink)
- “cgsl_0202: Usage of For, While, and For Each subsystems with vector signals” (Simulink)
- “cgsl_0204: Vector and bus signals crossing into atomic subsystems or Model blocks” (Simulink)
- “cgsl_0205: Signal handling for multirate models” (Simulink)
- “cgsl_0206: Data integrity and determinism in multitasking models” (Simulink)

The code generation guidelines for configuration parameters include:

- “cgsl_0301: Prioritization of code generation objectives for code efficiency” (Simulink)
- “cgsl_0302: Diagnostic settings for multirate and multitasking models” (Simulink)

IEC 61508 Standard

In this section...

Apply Simulink and Embedded Coder to the IEC 61508 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. IEC 61508, Functional safety of electrical/electronic/programmable electronic safety related systems, is such a standard. Because the standard was published when most software was coded by hand, the standard needs to be mapped to Model-Based Design technologies. For further information about MathWorks support for IEC 61508, see IEC 61508 Support in MATLAB and Simulink.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the IEC 61508 standard. For more information, see https://www.mathworks.com/products/iec-61508/.

Check for IEC 61508 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 61508 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for IEC 61508** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Select and Run Model Advisor Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Simulink Requirements) that is available if you have a Simulink Requirements license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 75-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 75-8 option when generating an HTML report during the code generation or build process.

IEC 62304 Standard

Apply Simulink and Embedded Coder to the IEC 62304 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. Standard: IEC 62304, Medical device software - Software life cycle processes, is such a standard.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the IEC 62304 standard. For more information, see https://www.mathworks.com/products/iec-61508/.

Check for IEC 62304 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the IEC 62304 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for IEC 62304** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Select and Run Model Advisor Checks” (Simulink).

ISO 26262 Standard

In this section...

Apply Simulink and Embedded Coder to the ISO 26262 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined functional safety standards. ISO 26262, Road Vehicles - Functional Safety, is such a standard. For further information about MathWorks support for ISO 26262, see ISO 26262 Support in MATLAB and Simulink.

MathWorks provides an IEC Certification Kit product that you can use to qualify MathWorks code generation and verification tools for projects based on the ISO 26262 standard. For more information, see https://www.mathworks.com/products/iso–26262/.

Check for ISO 26262 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the ISO 26262 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for ISO 26262** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Select and Run Model Advisor Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Simulink Requirements) that is available if you have a Simulink Requirements license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 75-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 75-8 option when generating an HTML report during the code generation or build process.

EN 50128 Standard

In this section...

Apply Simulink and Embedded Coder to the EN 50128 Standard

Applying Model-Based Design to a safety-critical system requires extra consideration and rigor so that the system adheres to defined safety standards. EN 50128, Railway applications — Software for railway control and protection systems, is such a standard.

MathWorks provides an IEC Certification Kit product that you can use to certify MathWorks code generation and verification tools for projects based on the EN 50128 standard. For more information, see https://www.mathworks.com/products/iec-61508/.

Check for EN 50128 Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the EN 50128 standard by running the Simulink Model Advisor (Simulink). Navigate to **By Task > Modeling Standards for EN 50128** and run the “IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks” (Simulink Check).

For more information on using the Model Advisor, see “Select and Run Model Advisor Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Simulink Requirements) that is available if you have a Simulink Requirements license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 75-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 75-8 option when generating an HTML report during the code generation or build process.

DO-178C Standard

In this section...

Apply Simulink and Embedded Coder to the DO-178C Standard

Applying Model-Based Design to a high-integrity system requires extra consideration and rigor so that the system adheres to defined safety standards. DO-178C Software Considerations in Airborne Systems and Equipment Certification is such a standard. A supplement to DO-178C, DO-331, provides guidance on the use of Model-Based Design technologies. MathWorks provides a DO Qualification Kit product that you can use to qualify MathWorks verification tools for projects based on the DO-178C, DO-331, and related standards. For more information, see https://www.mathworks.com/products/do-178/.

For information about Model-Based Design and MathWorks support of aerospace and defense industry standards, see https://www.mathworks.com/aerospace-defense/ .

Check for Standard Compliance Using the Model Advisor

If you have a Simulink Check product license, you can check that your Simulink model or subsystem and the code that you generate from it complies with selected aspects of the DO-178C standard by running the Simulink Model Advisor (Simulink). Navigate to **By Product > Simulink Check > Modeling Standards > DO-178C/DO-331 Checks** or **By Task > Modeling Standards for DO-178C/DO-331** and run the DO-178C/DO-331 checks (Simulink Check).

For more information on using the Model Advisor, see “Select and Run Model Advisor Checks” (Simulink).

Validate Traceability

Typically, applications that require certification require some level of traceability between requirements, models, and corresponding code.

To...	Use...
Associate requirements documents with objects in Simulink models	The “Requirements Management Interface Setup” (Simulink Requirements) that is available if you have a Simulink Requirements license.
Trace model blocks and subsystems to generated code	The “Model-to-Code Traceability” on page 75-10 option when generating an HTML report during the code generation or build process.
Trace generated code to model blocks and subsystems	The “Code-to-Model Traceability” on page 75-8 option when generating an HTML report during the code generation or build process.

AUTOSAR Standard

Simulink software supports *AUTomotive Open System ARchitecture* (AUTOSAR), an open and standardized automotive software architecture. Automobile manufacturers, suppliers, and tool developers jointly develop AUTOSAR components.

The AUTOSAR standard addresses:

- Architecture – Application, run-time environment, and service layers, which serve to decouple AUTOSAR software components from the execution platform. Standard interfaces between software components and the run-time environment allow reuse or relocation of components within the Electronic Control Unit (ECU) topology of a vehicle.

  The standard defines two AUTOSAR platforms:

  - Classic Platform (CP), with Application, Runtime Environment (RTE), and Basic Software (BSW) layers
  - Adaptive Platform (AP), with Application, AUTOSAR Runtime for Adaptive Applications (ARA), Services, and Basis layers
- Methodology – Specification of code formats and description file templates, for example.
- Foundation – Requirements and specifications shared between AUTOSAR platforms, supporting platform interoperability.
- Application Interfaces – Specification of interfaces for typical automotive applications.

For more information, see:

- `www.autosar.org` for details on the AUTOSAR standard.
- "AUTOSAR Blockset" for information on modeling and simulating AUTOSAR software, from which Embedded Coder can generate code.
- "AUTOSAR Code Generation" for information about generating AUTOSAR-compliant C/C++ code and XML software descriptions (requires AUTOSAR Blockset).
- `https://www.mathworks.com/automotive/standards/autosar.html` to learn about using MathWorks products and third-party tools for AUTOSAR.

Develop a Model that Complies with the IEC 61508 Standard

This example shows how to use Model Advisor checks for the IEC 61508 standard to develop a model and code that comply with the standard.

The IEC 61508 checks identify issues with a model that impede deployment in safety-related applications or limit traceability.

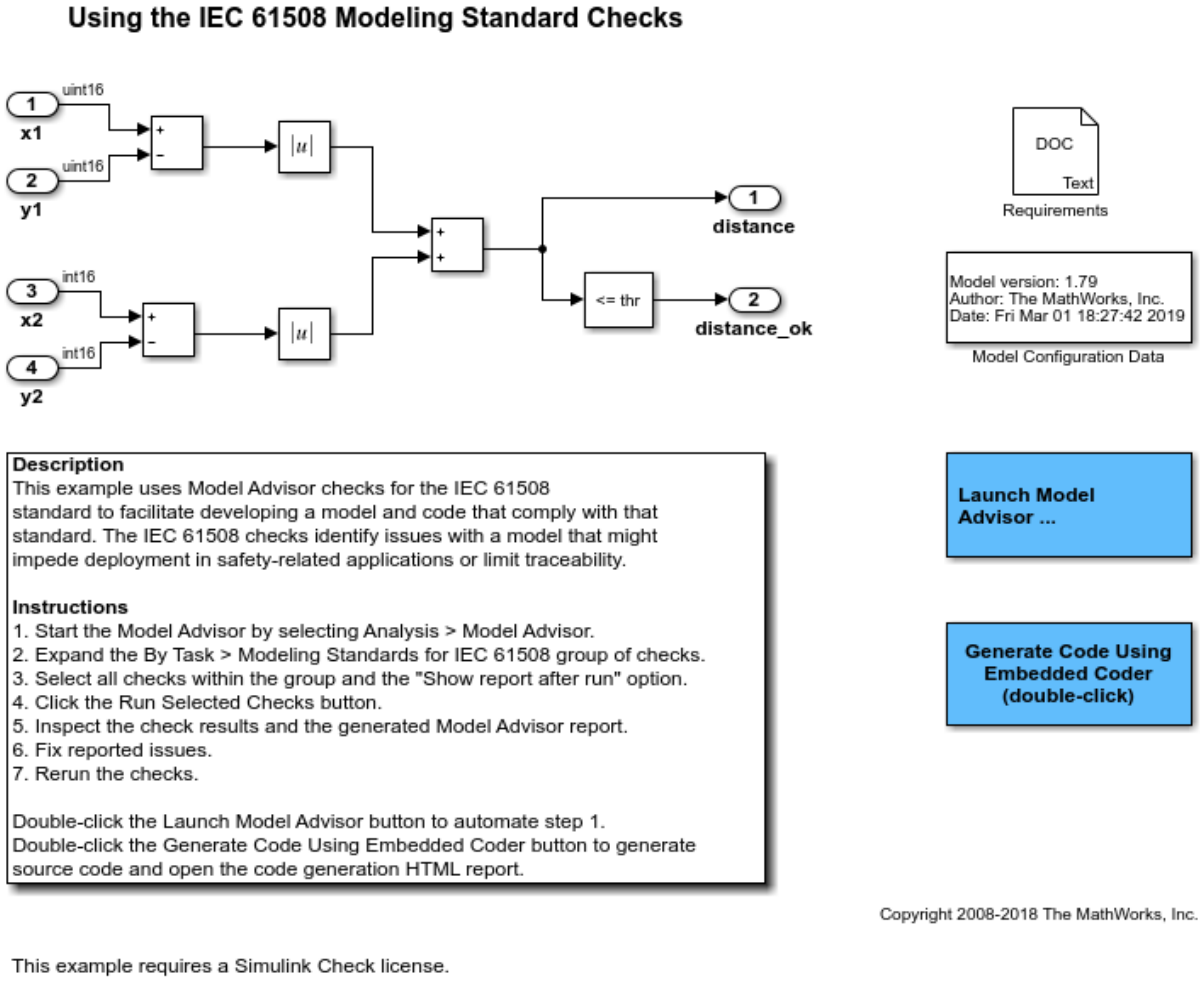
Understanding the Model

According to the functional requirements, a model shall be created that checks whether the 1-norm distance between points `(x1,x2)` and `(y1,y2)` is less than or equal to a given threshold `thr`. For two points `(x1,x2)` and `(y1,y2)`, the 1-norm distance is given as:

$$\sum_{i=1}^{2} |x_i - y_i|$$

The `rtwdemo_iec61508` model implements the preceding requirement. Open and get familiar with the model.

```
model='rtwdemo_iec61508';
open_system(model)
```



This example requires a Simulink Check license.

Apply the IEC 61508 Modeling Standard Checks

To deploy the model in a safety-related software component that must comply with the IEC 61508 safety standard, check the model for issues that might impede deployment in such an environment or limit traceability between the model and generated source code.

To identify possible compliance issues with the model:

1. Start the Model Advisor by selecting **Analysis > Model Advisor** or by entering `modeladvisor('rtwdemo_IEC61508')` at the MATLAB command line.
2. In the **Task Hierarchy**, expand **By Task > Modeling Standards for IEC 61508**.
3. Select the checks within the group.
4. Select **Show report after run** to generate an HTML report that shows the check results.
5. Click **Run Selected Checks**. Model Advisor processes the IEC 61508 checks and displays the results.

To review the check results and make changes:

1. Review the **Summary** in the **Report** section of the right pane.
2. In the **Task Hierarchy**, select a check that did not pass. Review the results that appear in the right pane for that check. For more information on the check and on how to resolve reported issues, with the check selected, click **Help**.
3. Click the **Generate Code Using Embedded Coder** button in the model to inspect the generated code and the traceability report.
4. Resolve the reported issues and rerun the checks.
5. Review the generated HTML report of the check results by clicking the link in the **Report** box.
6. Print the generated HTML report. You can use the report as evidence in the IEC 61508 compliance example process.

- For descriptions of the IEC 61508 checks, see IEC 61508, IEC 62304, ISO 26262, and EN 50128 Checks in the Simulink Check documentation.
- For more information on using Model Advisor, see Run Model Checks in the Simulink documentation.

Develop a Model that Complies with the AUTOSAR Standard

Generate AUTOSAR-compliant C code and export AUTOSAR XML (`arxml`) descriptions from a Simulink® model.

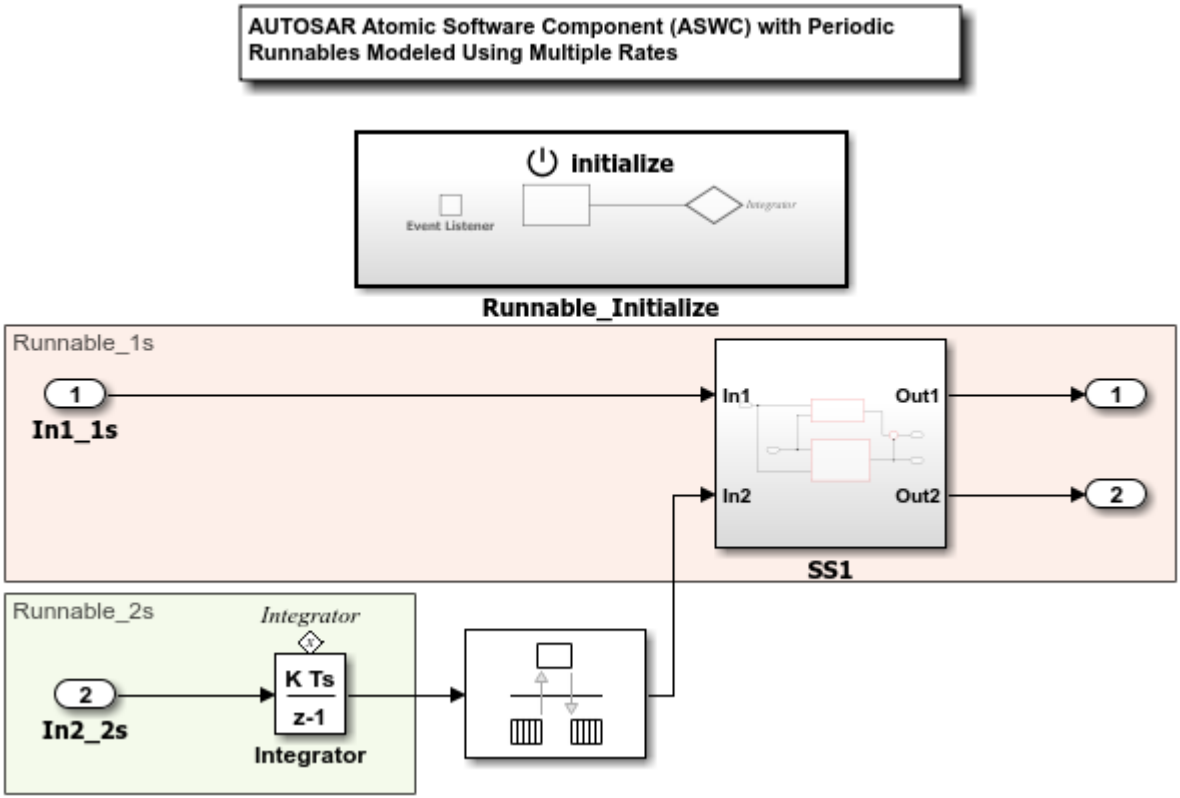
AUTOSAR Blockset software supports AUTomotive Open System ARchitecture (AUTOSAR), an open and standardized automotive software architecture. Automobile manufacturers, suppliers, and tool developers jointly develop AUTOSAR components. To develop AUTOSAR components in Simulink, follow this general workflow:

1. Create a Simulink representation of an AUTOSAR component.
2. Develop the component by refining the AUTOSAR configuration and creating algorithmic model content.
3. Generate `arxml` descriptions and algorithmic C code for testing in Simulink or integration into an AUTOSAR run-time environment. (AUTOSAR code generation requires Simulink Coder and Embedded Coder.)

Prepare Model for AUTOSAR Code Generation

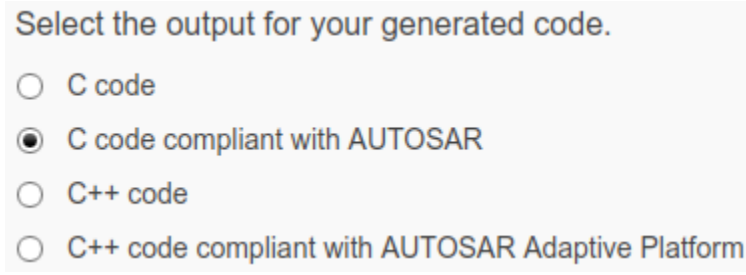
To see the steps for generating AUTOSAR-compliant C code and exporting `arxml` descriptions from an AUTOSAR model, open a model and prepare the model for AUTOSAR code generation.

Open a model from which you want to generate AUTOSAR code and descriptions. The model can be unconfigured or only partially configured for code generation. This example uses AUTOSAR example model `autosar_swc`.



To prepare the model for AUTOSAR code generation, use Embedded Coder Quick Start. In the model window, click **Code** > **C/C++ Code** > **Embedded Coder Quick Start**.

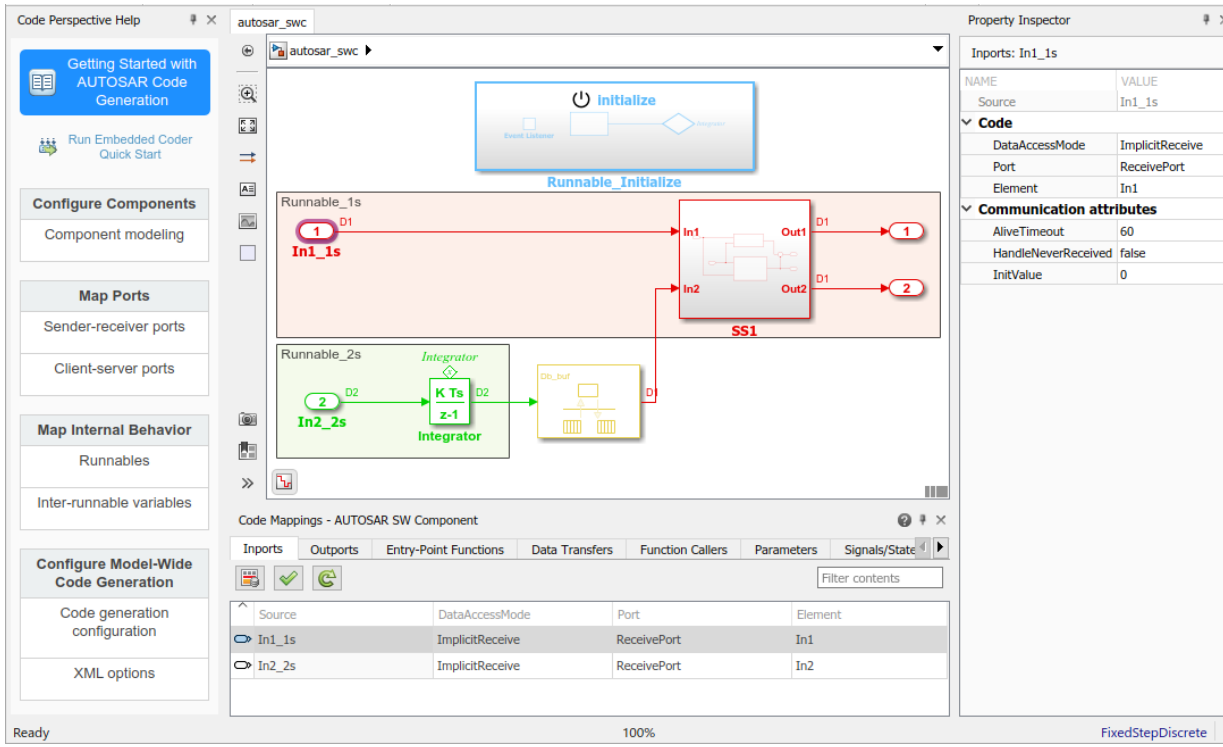
Work through the quick-start procedure. In the Output window, select output option **C code compliant with AUTOSAR**.



The quick-start software takes the following steps to configure an AUTOSAR software component model:

1. Configures code generation settings for the model. If the AUTOSAR target is not already selected, the software sets model configuration parameter **System target file** to `autosar.tlc` and **Generate XML for schema version** to a default schema value.
2. If no AUTOSAR mapping exists, creates a mapped AUTOSAR software component for the model.
3. Performs a model build.

In the last window, when you click **Finish**, your model opens in the AUTOSAR code perspective. AUTOSAR code perspective displays a help panel, a Property Inspector panel, and directly below the model, the Code Mappings editor.



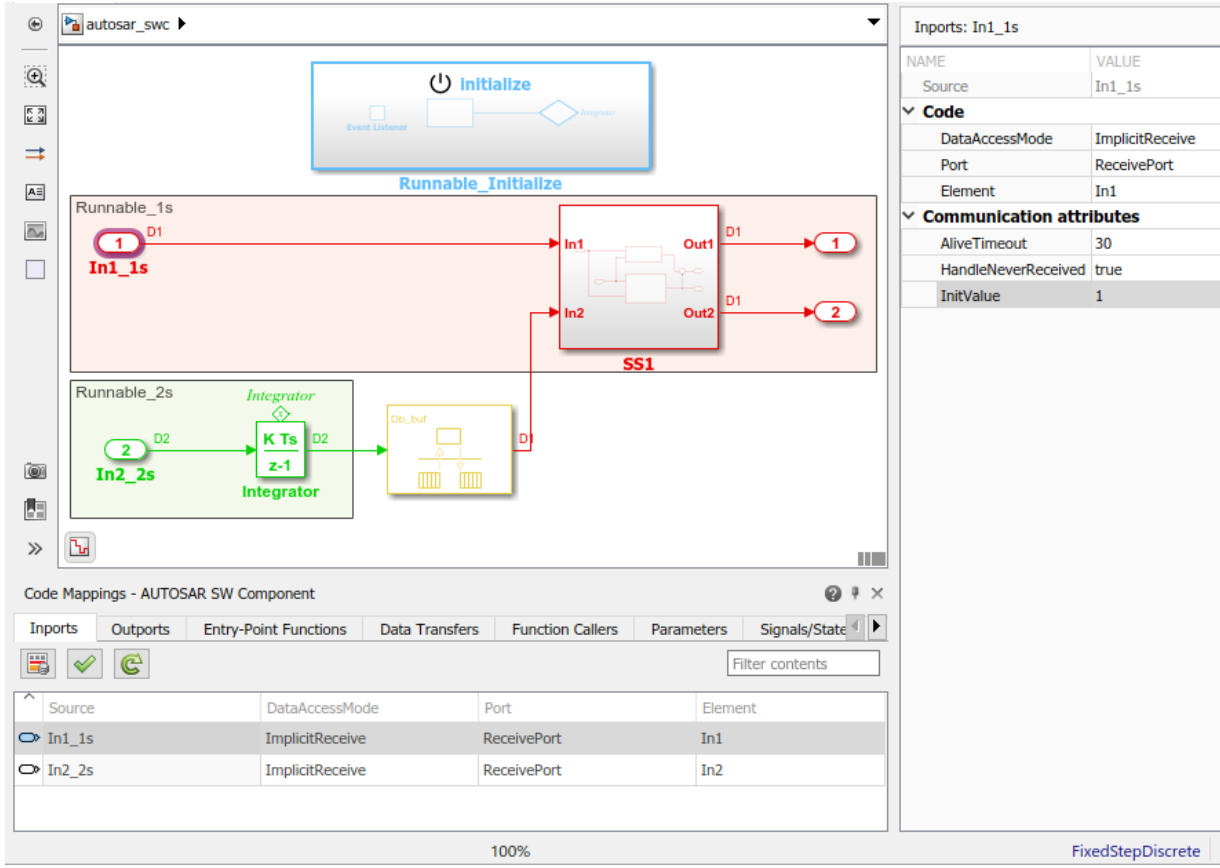
Develop Simulink Representation of AUTOSAR Software Component

After you create an AUTOSAR software component model in Simulink, use the Code Mappings editor and AUTOSAR Dictionary to further develop the AUTOSAR component. For more information, see “AUTOSAR Component Configuration” (AUTOSAR Blockset).

In a tabbed table format, the Code Mappings editor displays Simulink model elements, such as inports, outports, entry-point functions, and data transfers. Use the editor to map Simulink model elements to AUTOSAR component elements from a Simulink model perspective. AUTOSAR component elements are defined in the AUTOSAR standard, and include ports, runnable entities, and inter-runnable variables (IRVs).

In the AUTOSAR code perspective view of your model, select the Inports tab of the Code Mappings editor, and select a model inport. The attributes of the selected inport appear in the Property Inspector panel. This example selects Simulink inport `In1_1s`, which is mapped to AUTOSAR port `ReceivePort` and data element `In1` with data access mode `ImplicitReceive`. In each Code Mappings editor tab, you can select model elements and modify their AUTOSAR mapping and attributes. Your modifications are reflected in the generated `arxml` descriptions and C code.

If you are using AUTOSAR example model `autosar_swc` with this example, modify the communication attributes for the mapped Simulink inport `In1_1s`. In the Property Inspector, change the `AliveTimeout` attribute from 60 to 30, change `HandleNeverReceived` from `false` to `true`, and change `InitValue` from 0 to 1.

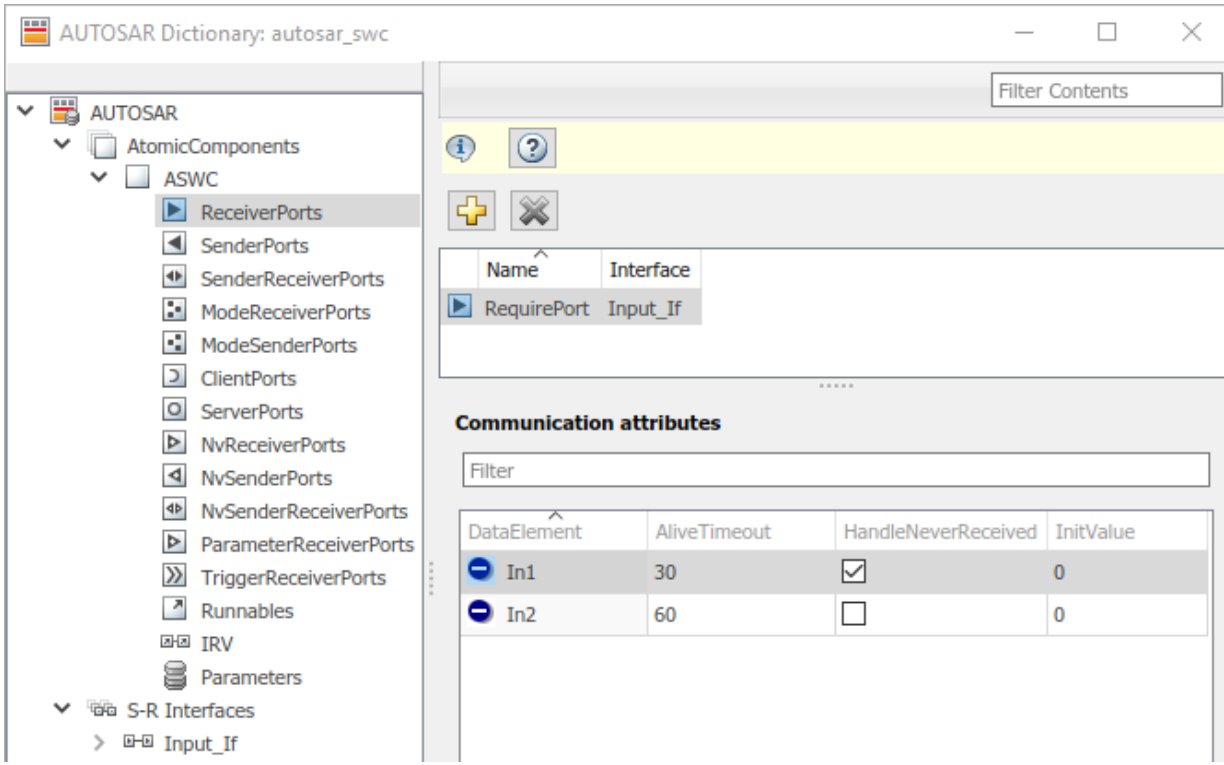


To configure the AUTOSAR properties of the mapped AUTOSAR software component, open AUTOSAR Dictionary. In Code Mappings editor, click the AUTOSAR Dictionary button, which is the leftmost button. AUTOSAR Dictionary opens in the AUTOSAR view that corresponds to the Simulink element that you last selected and mapped in Code Mappings editor. If you selected and mapped a Simulink inport, the dictionary opens in ReceiverPorts view and displays the AUTOSAR port to which you mapped the inport.

In a tree format, AUTOSAR Dictionary displays the mapped AUTOSAR component and its elements, communication interfaces, computation methods, software address methods, and XML options. Use the dictionary to configure AUTOSAR elements and properties from an AUTOSAR component perspective.

In the ReceiverPorts view, select the AUTOSAR receiver port to which the Simulink inport was mapped in the Code Mappings editor. If an AUTOSAR element has additional undisplayed attributes, selecting the element displays them. In each AUTOSAR element view, you can add or rename AUTOSAR elements and modify their displayed properties. Your modifications are reflected in the generated `arxml` descriptions and C code.

If you are using AUTOSAR example model `autosar_swc` with this example, rename the AUTOSAR receiver port from `ReceivePort` to `RequirePort`. To initiate the edit, click in the **Name** value field.

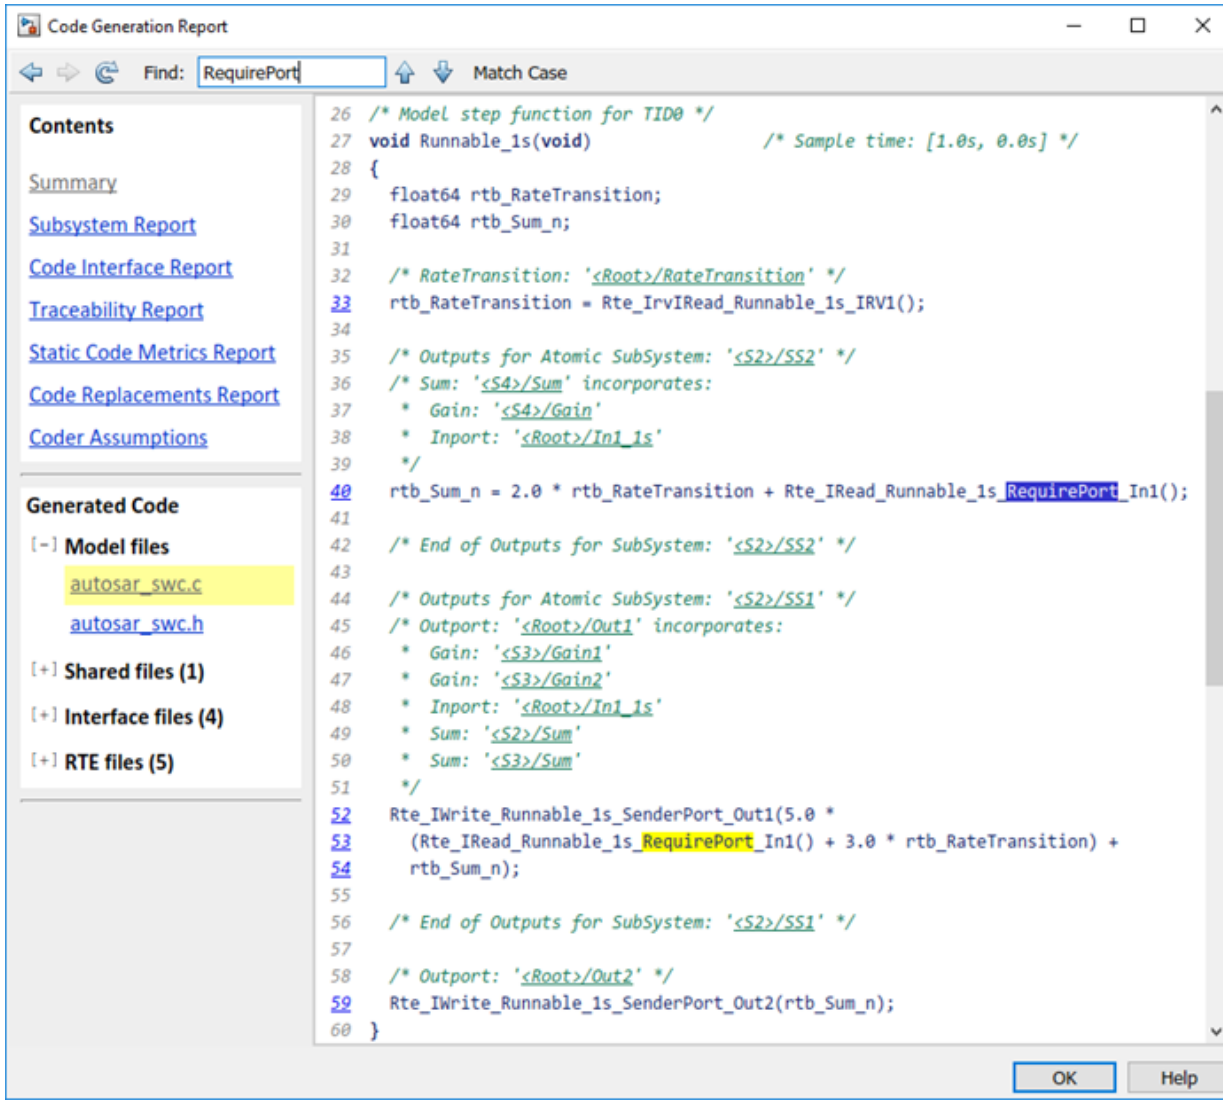


Generate C Code and ARXML Descriptions

If you are licensed for Simulink Coder and Embedded Coder, you can build the AUTOSAR model. Building the AUTOSAR model generates AUTOSAR-compliant C code and exports `arxml` descriptions. In the model window, press **Ctrl+B**, or click the **Code** menu and select **C/C++ Code** > **Build Model**.

When the build completes, a code generation report opens. Examine the report. Verify that your Code Mappings editor and AUTOSAR Dictionary changes are reflected in the C code and `arxml` descriptions. For example, use the **Find** field to search for the name of the AUTOSAR receiver port that you modified and renamed.

The generated C code encodes the AUTOSAR receiver port name in AUTOSAR run-time environment API read calls.



The generated `arxml` description of the AUTOSAR receiver port uses the modified port name and the modified values for port communication attributes `AliveTimeout`, `HandleNeverReceived`, and `InitValue`.

MISRA C:2012 Compliance and Deviations for Code Generated by Using Embedded Coder

Developing a MISRA C:2012 Compliance Statement

As part of the model development process, it is important that C code generated by Embedded Coder from Simulink and Stateflow complies with industry coding standards.

When using MISRA C:2012 coding guidelines to evaluate the quality of your generated C code, you are required per section 5.3 of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document to prepare a compliance statement for the project being evaluated. To assist you in the development of this compliance statement, MathWorks evaluates the MISRA C:2012 guidelines against C code generated by using Embedded Coder and provides the following information:

- Compliance Summary Tables on page 23-7, which identify the method used to obtain compliance for each rule and directive.
- Deviations on page 23-32, which identify rules or directives that are not compliant.

For information about the process MathWorks uses to evaluate generated C code against MISRA C:2012 guidelines, see “MathWorks Process for Identifying Violations of MISRA C:2012 Guidelines in Generated C Code” on page 23-2.

For additional information about the MISRA organization, their coding guidelines, and the MISRA publication timeline, see www.misra.org.uk .

Disclaimer While adhering to the recommendations in the MISRA C:2012 Compliance and Deviations for Code Generated using Embedded Coder documentation will reduce the risk that an error is introduced during development and not be detected, it is not a guarantee that the system being developed will be safe. Conversely, if some of the recommendations are not followed, it does not mean that the system being developed will be unsafe.

MathWorks Process for Identifying Violations of MISRA C:2012 Guidelines in Generated C Code

To determine any potential violations in the generated code, MathWorks maintains an extensive set of test models that cover the standard usage of compliant blocks. For each release, MathWorks uses these test models with the following products to evaluate the modeling, code generation, and analysis of generated code.

Product	Purpose
Simulink	Create/maintain models.
Stateflow	Create/maintain models.
Fixed-Point Designer	Create/maintain models.
Embedded Coder	Generate C code.
Simulink Check	Execute MISRA C:2012 Model Advisor checks.[a]
Polyspace Bug Finder	Identify bug/coding defects. Use the Polyspace Bug Finder MISRA C:2012 Checker (Polyspace Bug Finder) to analyze the generated code against the MISRA C:2012 Directives and Rules (Polyspace Bug Finder) and provide information about violations.
Polyspace Code Prover	Prove absence of run-time errors. Use the Polyspace Code Prover MISRA C:2012 checker (Polyspace Code Prover) to analyze the generated code against the MISRA C:2012 Directives and Rules (Polyspace Code Prover) and provide information about violations.

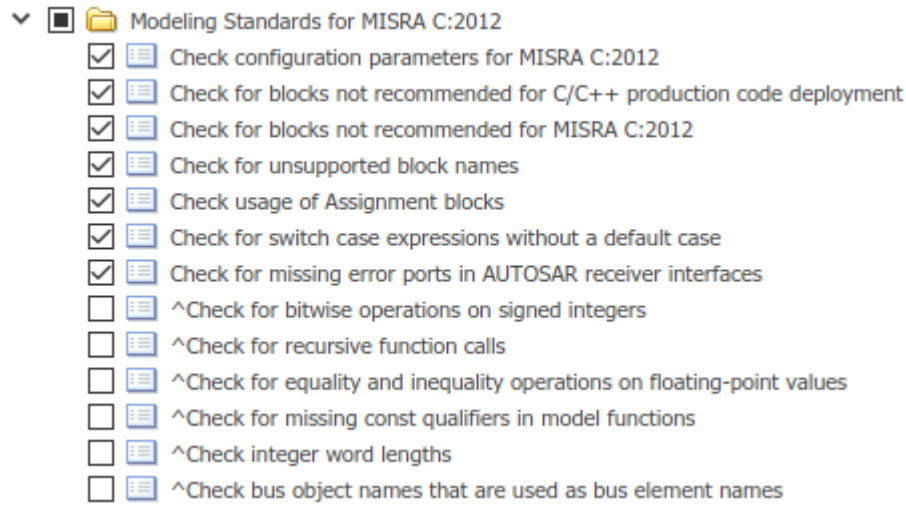
a. MISRA C:2012 checks are available only when you have an Simulink Check or Embedded Coder license.

Note The compliance analysis performed by the Polyspace MISRA C:2012 Checker assesses C code generated by Embedded Coder. No assessment is made of the Embedded Coder tool chain. Handwritten C code and third-party libraries that are used with code generated by Embedded Coder are not considered. Other MISRA C code analysis tools can yield different results.

Evaluate Your Generated Code for MISRA C:2012 Compliance

It is important to check that C code generated by Embedded Coder from Simulink and Stateflow complies with MISRA C:2012 coding standards. This workflow illustrates the process of evaluating your generated code for compliance to MISRA C:2012 guidelines.

1. Design your model in Simulink or Stateflow.
2. Open the Model Advisor (Simulink) and run the MISRA C:2012 checks (Simulink Check), which are available in **By Task > Modeling Standards for MISRA C:2012**.



3. If necessary, modify the model to adhere to the “Modeling Guidelines for MISRA C:2012 Compliance” on page 23-22.
4. After all MISRA C:2012 checks pass successfully, generate code by using Embedded Coder.

   To avoid possible name clashes, multiple functions definitions, and multiple data definitions, use one of these code generation approaches:

   - Single model: Generate code from a single model, including submodels, by using Model blocks.
   - Multiple models: Generate code from multiple models, including:

- A shared utility folder to synchronize functions
- Data ownership to control data definitions
- Hand integration to manage code generated from various models

5 Execute the Polyspace Bug Finder MISRA C:2012 Checker (Polyspace Bug Finder).

For more information about running a Polyspace analysis on your generated code, including analysis options and results, see:

- Analysis of Generated Code using Polyspace Bug Finder (Polyspace Bug Finder)
- Analysis of Generated Code using Polyspace Code Prover (Polyspace Code Prover)

6 Justify violations to the MISRA C:2012 coding standards using Polyspace annotations (Polyspace Bug Finder).

MISRA C:2012 Compliance Information Summary Tables

In this section...

Compliance Summary Tables

MathWorks evaluates C code generated by Embedded Coder from Simulink and Stateflow against the MISRA C:2012 coding standards. The results from this effort are available in these compliance summary tables. These tables identify:

- Methods used to obtain compliance:
  - Compliant: Compliance to the rule/directive is achieved through adherence to the code generation process, modeling guidelines, or Model Advisor checks. When applicable, there are explanatory notes that provide information relevant to compliance methods or actions that you can perform to satisfy the directive or rule.
  - Deviation: The rule or directive is not compliant.
- Whether the Polyspace MISRA C:2012 Checker supports the rule or directive.

You can use these tables when preparing the MISRA C:2012 compliance statement for your project as required per section 5.3 of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document. These tables align with the published MISRA C:2012 rule and directives tables.

"Implementation" MISRA C:2012 Directives

Directive	Category	Compliance	Polyspace Support?
1.1	Required	Compliant: • hisl_0060 • hisl_0016 • “Explanatory Note for Directive 1.1” on page 23-19	Yes, partially supported

"Compilation and Build" MISRA C:2012 Directives

Directive	Category	Compliance	Polyspace Support?
2.1	Required	Compliant	Yes

"Requirements Traceability" MISRA C:2012 Directives

Directive	Category	Compliance	Polyspace Support?
3.1	Required	Compliant: • “Explanatory Note for MISRA Directive 3.1” on page 23-20	No

"Code Design" MISRA C:2012 Directives

Directive	Category	Compliance	Polyspace Support?
4.1	Required	Compliant: • hisl_0001 • hisl_0002 • hisl_0004 • hisl_0005 • hisl_0006 • hisl_0053 • hisl_0054 • "Explanatory Note for Directive 4.1" on page 23-20	Yes
4.3	Required	Compliant: • "Explanatory Note for Directive 4.3" on page 23-20	No
4.6	Required	Not Applicable. See "Explanatory Note for Directive 4.6" on page 23-20	N/A
4.7	Required	Compliant: • Check for missing error ports for AUTOSAR receiver interfaces • Check for blocks not recommended for MISRA C:2012 Deviation: • Deviation for AUTOSAR target-based code generator - sender ports. See "MISRA C:2012 Directive 4.7 Deviation Rationale" on page 23-32	Yes[a]
4.10	Required	Compliant	Yes

Directive	Category	Compliance	Polyspace Support?
4.11	Required	Compliant: • "Explanatory Note for Directive 4.11" on page 23-20	Yes
4.12	Required	Compliant: • hisl_0060	No

a. The Polyspace MISRA C:2012 Checker might flag Directive 4.7 as a Rule 17.7 violation for user-defined functions when there is no knowledge about whether the return value contains error information.

"Standard C Environment" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
1.1	Required	Compliant	Yes
1.3	Required	Compliant	Yes

"Unused Code" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
2.1	Required	Compliant: • hisl_0053 • hisl_0101	Yes
2.2	Required	Compliant	Yes

"Comments" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
3.1	Required	Compliant: • Check for unsupported block names	Yes
3.2	Required	Compliant	Yes

"Character Sets and Lexical Conventions" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
4.1	Required	Compliant	Yes

"Identifiers" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
5.1	Required	Compliant: • hisl_0060 • hisl_0063 • “Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8” on page 23-21	Yes
5.2	Required	Compliant: • hisl_0060 • hisl_0063 • “Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8” on page 23-21	Yes
5.4	Required	Compliant: • hisl_0060 • hisl_0063 • “Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8” on page 23-21	Yes
5.5	Required	Compliant: • hisl_0060 • hisl_0063 • “Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8” on page 23-21	Yes
5.6	Required	Compliant: • hisl_0060 • “Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8” on page 23-21	Yes

Rule	Category	Compliance	Polyspace Support?
5.7	Required	Compliant: • hisl_0060 • "Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8" on page 23-21	Yes
5.8	Required	Compliant: • hisl_0060 • "Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8" on page 23-21	Yes

"Types" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
6.1	Required	Compliant: • hisl_0060	Yes
6.2	Required	Compliant: • hisl_0060	Yes

"Literals and Constants" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
7.4	Required	Compliant	Yes

"Declarations and Definitions" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
8.1	Required	Compliant	Yes
8.2	Required	Compliant	Yes
8.3	Required	Compliant	Yes
8.6	Required	Compliant	Yes
8.8	Required	Compliant	Yes
8.10	Required	Compliant	Yes
8.12	Required	Compliant: • “Explanatory Note for Rule 8.12” on page 23-21	Yes

"Initialization" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
9.1	Mandatory	Compliant: • hisl_0029 • Check usage of Assignment blocks	Yes
9.4	Required	Compliant	Yes

"Pointer Type Conversion" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
11.1	Required	Compliant	Yes
11.2	Required	Compliant	Yes
11.3	Required	Compliant: • hisl_0020	Yes
11.6	Required	Compliant	Yes
11.7	Required	Compliant	Yes
11.8	Required	Compliant: • hisl_0020	Yes

"Expressions" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
12.2	Required	Compliant	Yes

"Side Effects" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
13.1	Required	Compliant	Yes
13.2	Required	Compliant: • hisl_0062	Yes
13.5	Required	Compliant: • hisl_0062 Deviation: • “MISRA C:2012 Rule 13.5 Deviation Rationale” on page 23-36	Yes
13.6	Mandatory	Compliant	Yes

"Control Statement Expressions" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
14.3	Required	Compliant: • hisl_0101	Yes

"Control Flow" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
15.6	Required	Compliant	Yes

"Functions" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
17.1	Required	Compliant	Yes
17.2	Required	Compliant: • hisl_0060 • hisf_0004	Yes
17.3	Mandatory	Compliant	Yes
17.4	Mandatory	Compliant	Yes
17.6	Mandatory	Compliant	Yes

"Pointers and Arrays" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
18.1	Required	Compliant	Yes
18.2	Required	Compliant	Yes
18.3	Required	Compliant	Yes
18.6	Required	Compliant	Yes
18.7	Required	Compliant	Yes
18.8	Required	Compliant	Yes

"Overlapping Storage" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
19.1	Mandatory	Compliant	Yes

"Preprocessing Directives" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
20.2	Required	Compliant	Yes
20.3	Required	Compliant	Yes
20.4	Required	Compliant	Yes
20.6	Required	Compliant	Yes
20.7	Required	Compliant	Yes
20.9	Required	Compliant	Yes
20.11	Required	Compliant	Yes
20.12	Required	Compliant	Yes
20.13	Required	Compliant	Yes
20.14	Required	Compliant	Yes

"Standard Libraries" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
21.1	Required	Compliant	Yes
21.2	Required	Compliant: • hisl_0032	Yes
21.3	Required	Compliant: • hisl_0060	Yes
21.4	Required	Compliant	Yes
21.6	Required	Compliant: • hisl_0060 • Check for blocks not recommended for MISRA C:2012	Yes
21.7	Required	Compliant	Yes
21.8	Required	Compliant	Yes
21.9	Required	Compliant	Yes
21.10	Required	Compliant	Yes
21.11	Required	Compliant	Yes

"Resources" MISRA C:2012 Rules

Rule	Category	Compliance	Polyspace Support?
22.1	Required	Compliant	Yes
22.2	Mandatory	Compliant	Yes
22.3	Required	Compliant	Yes
22.4	Mandatory	Compliant	Yes
22.5	Mandatory	Compliant	Yes
22.6	Mandatory	Compliant	Yes

Explanatory Notes

These explanatory notes are referenced from the “MISRA C:2012 Compliance Information Summary Tables” on page 23-7.

Explanatory Note for Directive 1.1

Information about the implementation-defined behavior for Embedded Coder is available in “Configure Run-Time Environment Options” on page 8-2 . Compiler documentation is out of scope.

Character set encoding is managed by using the `SavedCharacterEncoding` model parameter. For additional information, including a list of supported character encodings, see `slCharacterEncoding`.

Configure the integer division method in the Model Configuration Parameters dialog box, on the **Hardware Implementation** pane. For additional information, see “Configure Run-Time Environment Options” on page 8-2

Embedded Coder generates `#pragma` when the user:

- Selects the use of memory sections (Simulink Coder)
- Creates a custom storage class with memory sections on page 36-35

In both instances, you are responsible for documenting the intended use of the `#pragma`. For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2.

To enable the generation of bitfields:

1. Select at least one of these model configuration parameters:
   - Pack Boolean data into bitfields. This parameter is available only for ERT-based system target files on page 44-2.
   - Use bitsets for storing state configuration.
   - Use bitsets for storing Boolean data.
2. Create a custom storage class with defined bitfields. See “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 36-35 for more information.

Explanatory Note for MISRA Directive 3.1

You can link requirements model elements. These links are included in the generated C code to provide traceability from a requirements document, to the model elements, and to the generated code. For additional information, see “View Linked Requirements in Models and Blocks” (Simulink) and “Link Blocks and Requirements” (Simulink Requirements).

Explanatory Note for Directive 4.1

You can use Polyspace Bug Finder to identify run-time errors and Polyspace Code Prover to prove the absence of run-time errors. For information, see:

- “Configure and Run Analysis” (Polyspace Code Prover)
- “Configure and Run Analysis” (Polyspace Bug Finder)

Simulink Design Verifier can be used to detect design errors at the model level. For more information, see “Run a Design Error Detection Analysis” (Simulink Design Verifier).

Explanatory Note for Directive 4.3

Embedded Coder does not directly call assembly language code. You can add calls to assembly language functions through S-functions, code replacement libraries, Stateflow, and in MATLAB blocks. These calls are documented as calls to “External C Functions” on page 24-62. In these cases, you are responsible for encapsulation.

For additional information, see:

- “External C Functions” on page 24-62
- “Code Replacement Customization”
- “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2

Explanatory Note for Directive 4.6

Embedded Coder replaces basic data types with typedefs types, which are compatible with Directive 4.6. A guideline is not required because this behavior is default behavior in Embedded Coder. For additional information, see “Replace and Rename Data Types to Conform to Coding Standards” on page 34-27 and Typedefs on page 24-73.

Explanatory Note for Directive 4.11

The requirements of this directive are satisfied by:

“Demonstrate statically that the input parameters can never take invalid values”.

You can use Polyspace Code Prover to analyze parameter ranges and prove the absence of run-time errors caused by out-of-range values. For additional information, see “Run Polyspace Analysis on Code Generated with Embedded Coder” (Polyspace Code Prover).

Explanatory Note for Rules 5.1, 5.2, 5.4, 5.5, 5.6, 5.7, and 5.8

Embedded Coder is configurable to limit the number of characters imposed by the implementation. For additional information, see Maximum identifier length.

To ensure unique names for different types of variables (local scope variables, global scope variables, macros, and so on), implement a naming convention. For additional information, see Model Configuration Parameters: Code Generation Symbols.

Explanatory Note for Rule 8.12

Embedded Coder supports the use of enumerated data. The file used to define the enumeration can be either manually or automatically generated. Files defining enumerations generated by Embedded Coder are compliant with MISRA C:2012 Rule 8.12 by design. If you manually create the definition file, you are responsible for ensuring compliance. For additional information, see “Use Enumerated Data in Simulink Models” (Simulink).

Explanatory Note for Rules 10.1 and 10.2

Embedded Coder does not directly create data of type char. Data of char type can be introduced by user-defined S-functions, code replacement libraries, and custom storage classes. In this case, limit the usage of plain char to:

- Plain char type for character values
- Signed and unsigned char type for numeric values

Modeling Guidelines for MISRA C:2012 Compliance

The “MISRA C:2012 Compliance Information Summary Tables” on page 23-7 identifies modeling guidelines that are relevant to the compliance of generated C code with MISRA C:2012 coding standards. For a list of these guidelines and their corresponding Model Advisor check, see “High-Integrity System Modeling Guidelines for MISRA C:2012 Compliance” on page 23-22. For information about the MISRA rationale for Model Advisor checks, see “MISRA C:2012 Rationale for Model Advisor Checks” on page 23-24.

High-Integrity System Modeling Guidelines for MISRA C:2012 Compliance

To augment the modeling guidelines developed by the MathWorks Automotive Advisory Board (MAAB), MathWorks has published a set of modeling guidelines that focus on high-integrity applications.

Many high-integrity modeling guidelines have Model Advisor checks that you can use to verify adherence of your model to the guideline. This table identifies the high-integrity modeling guidelines and provides the corresponding Model Advisor check. Not all modeling guidelines have a corresponding Model Advisor check.

High-Integrity Guideline	Model Advisor Check
hisl_0001: Usage of Abs block	Check usage of Abs blocks
hisl_0002: Usage of Math Function blocks (rem and reciprocal)	Check usage of Math Function blocks (rem and reciprocal functions)
hisl_0005: Usage of Product blocks	Not applicable
hisl_0006: Usage of While Iterator blocks	Check usage of While Iterator blocks
hisl_0008: Usage of For Iterator Blocks	Check usage of For Iterator blocks
hisl_0010: Usage of If blocks and If Action Subsystem blocks	Check usage of If blocks and If Action Subsystem blocks
hisl_0011: Usage of Switch Case blocks and Action Subsystem blocks	Check usage Switch Case blocks and Switch Case Action Subsystem blocks

High-Integrity Guideline	Model Advisor Check
hisl_0016: Usage of blocks that compute relational operators	Check for Relational Operator blocks that equate floating-point types
hisl_0017: Usage of blocks that compute relational operators (2)	Check usage of Relational Operator blocks
hisl_0018: Usage of Logical Operator block	Check usage of Logical Operator blocks
hisl_0019: Usage of Bitwise Operator block	Check usage of Bitwise Operator block
hisl_0020: Blocks not recommended for MISRA C:2012 compliance	Check for blocks not recommended for MISRA C:2012 Check for blocks not recommended for C/C++ production code deployment
hisl_0029: Usage of Assignment blocks	Check usage of Assignment blocks
hisl_0032: Model object names	Check model object names
hisl_0045: Configuration Parameters > Math and Data Types > Implement logic signals as Boolean data (vs. double)	Check safety-related optimization settings for logic signals
hisl_0053: Configuration Parameters > Code Generation > Optimization > Remove code from floating-point to integer conversions that wraps out-of-range values	Check safety-related optimization settings for data type conversions
hisl_0054: Configuration Parameters > Code Generation > Optimization > Remove code that protects against division arithmetic exceptions	Check safety-related optimization settings for division arithmetic exceptions
hisl_0314: Configuration Parameters > Diagnostics > Data Validity > Signals	Check safety-related diagnostic settings for signal data
hisl_0060: Configuration parameters that improve MISRA C:2012 compliance	Check configuration parameters for MISRA C:2012
hisl_0061: Unique identifiers for clarity	Check Stateflow charts for uniquely defined data objects

High-Integrity Guideline	Model Advisor Check
hisl_0062: Global variables in graphical functions	Check global variables in graphical functions
hisl_0063: Length of user-defined object names to improve MISRA C:2012 compliance	Check for length of user-defined object names
hisl_0101: Avoid invariant comparison operations to improve MISRA C:2012 compliance	Not applicable
hisl_0102: Data type of loop control variables to improve MISRA C:2012 compliance	Check data type of loop control variables
hisf_0003: Usage of bitwise operations	Check usage of bitwise operations in Stateflow charts
hisf_0004: Usage of recursive behavior	Not applicable
hisf_0064: Shift operations for Stateflow data to improve code compliance	Check usage of shift operations for Stateflow data
hisf_0065: Type cast operations in Stateflow to improve code compliance	Check assignment operations in Stateflow Charts
hisf_0211: Protect against use of unary operators in Stateflow Charts to improve code compliance	Check Stateflow charts for unary operators

MISRA C:2012 Rationale for Model Advisor Checks

This table provides MISRA C:2012 rationale for the Model Advisor checks.

Model Advisor Check		MISRA C:2012 Rule or Directive
Check configuration parameters for MISRA C:2012		
	Set **Use division for fixed-point net slope computation** to `On` or `Use division for reciprocals of integers only`.	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
	Set **Inf or NaN block output** to `warning` or `error`.	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized
	Set **Model Verification block enabling** to `Disable All`.	General recommendation for embedded systems.

Model Advisor Check		MISRA C:2012 Rule or Directive
	Set **Undirected event broadcasts** to `error`.	MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly
	Set configuration parameter **Wrap on overflow** to `warning` or `error`.	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized
	Set **Production hardware signed integer division rounds to** to `Zero` or `Floor`.	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
	Clear **Shift right on a signed integer as arithmetic shift** .	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
	Set **Compile-time recursion limit for MATLAB functions** to `0` .	MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly
	Clear **Dynamic memory allocation in MATLAB functions**.	MISRA C:2012 Directive 4.12: Dynamic memory allocation shall not be used. MISRA C:2012 Rule 21.3: The memory allocation and deallocation functions of <stdlib.h> shall not be used.
	Clear **Enable run-time recursion for MATLAB functions**.	MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly
	Set **Bitfield declarator type specifier** to `uint_T`.	MISRA C:2012 Rule 6.1: Bit-fields shall only be declared with an appropriate type MISRA C:2012 Rule 6.2: Single-bit named bit fields shall not be of a signed type
	Set **Casting Modes** to `Standards Compliant`.	MISRA C:2012 Rules 10.x: The essential type model
	Set **Code replacement library** to `None` or `AUTOSAR 4.0`	General recommendation for embedded systems.

Model Advisor Check		MISRA C:2012 Rule or Directive
	Clear **External mode**.	General recommendation for embedded systems. MISRA C:2012 Directive 4.12 Dynamic memory allocation shall not be used MISRA C:2012 Rule 21.3 The memory allocation and deallocation functions of <stdlib.h> shall not be used MISRA C:2012 Rule 21.6 The Standard Library input/output functions shall not be used
	Clear **Generate shared constants**.	MISRA Rule 8.5: An external object or function shall be declared once in one and only one file
	Clear **MAT-file logging**	General recommendation for embedded systems.
	Set **Maximum identifier length** to the implementation-dependent limit. The default is `31`.	MISRA C:2012 Rules 5.1-9: Identifiers
	Set **Parentheses level** to `Maximum (Specify precedence with parentheses)`.	MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit
	Select **Preserve static keyword in function declarations**.	MISRA Rule 8.7: Functions and objects should not be defined with external linkage if they are referenced in only one translation unit MISRA Rule 8.8: The static storage class specifier shall be used in all declarations of objects and functions that have internal linkage

Model Advisor Check		MISRA C:2012 Rule or Directive
	Clear **Replace multiplications by powers of two with signed bitwise shifts**.	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type
	Set **Shared code placement** to `Shared location`	Prerequisite of configuration parameter **Generate shared constants**
	Clear **Support continuous time**.	General recommendation for embedded systems.
	Clear **Support non-finite numbers**	MISRA C:2012 Directive 4.1: Run-time failures shall be minimized
	Clear **Support non-inlined S-functions**.	General recommendation for embedded systems.
	Set **System-generated identifiers** to `Shortened`.	MISRA C:2012 5.1: External identifiers shall be distinct MISRA C:2012 5.2: Identifiers declared in the same scope and name space shall be distinct MISRA C:2012 5.4: Macro identifiers shall be distinct MISRA C:2012 5.5: Identifiers shall be distinct from macro names
	Set **System target file** to an ERT-based target.	General recommendation for embedded systems.
	Clear **Use dynamic memory allocation for model initialization**. Select only when **Code Interface Packaging** is set to `Reusable Function`.	MISRA C:2012 Directive 4.12: Dynamic memory allocation shall not be used. MISRA C:2012 Rule 21.3: The memory allocation and deallocation functions of <stdlib.h> shall not be used.
	EnableSignedLeftShifts – off	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type

Model Advisor Check		MISRA C:2012 Rule or Directive
Check for blocks not recommended for C/C ++ production code deployment		General recommendation for embedded systems.
Check for blocks not recommended for MISRA C:2012		
	Lookup Table blocks using cubic spline interpolation or extrapolation methods. Specific blocks are: • 1-D Lookup Table • 2-D Lookup Table • n-D Lookup Table	MISRA C:2012 Rule 11.3: A cast shall not be performed between a pointer to object type and a pointer to a different object type. MISRA C:2012 Rule 11.5: A conversion should not be performed from pointer to void into pointer to object. MISRA C:2012 Rule 11.8: A cast shall not remove any const or volatile qualification from the type pointed to by a pointer. MISRA C:2012 Rule 11.9: The macro NULL shall be the only permitted form of integer null pointer constant. MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit.

Model Advisor Check		MISRA C:2012 Rule or Directive
	Deprecated Lookup Table blocks. Specific blocks are: • Lookup Table • Lookup Table (2-D)	MISRA C:2012 Rule 11.3: A cast shall not be performed between a pointer to object type and a pointer to a different object type. MISRA C:2012 Rule 11.5: A conversion should not be performed from pointer to void into pointer to object. MISRA C:2012 Rule 11.8: A cast shall not remove any const or volatile qualification from the type pointed to by a pointer. MISRA C:2012 Rule 11.9: The macro NULL shall be the only permitted form of integer null pointer constant. MISRA C:2012 Rule 12.1: The precedence of operators within expressions should be made explicit. MISRA C:2012 Rule 12.2: The right hand operand of a shift operator shall lie in the range zero to one less than the width in bits of the essential type of the left hand operand.
	S-Function Builder blocks	MISRA C:2012 Rule 8.4: A compatible declaration shall be visible when an object or function with external linkage is defined. MISRA C:2012 Rule 8.5: An external object or function shall be declared once in one and only one file.
	From Workspace blocks	MISRA C:2012 Rule 18.4: The +, -, += and -= operators should not be applied to an expression of pointer type.

Model Advisor Check		MISRA C:2012 Rule or Directive
	String blocks were found in the model or subsystem. Specific blocks are: • Compose String • Scan String • String to Single • String to Double • To String	MISRA C:2012 Directive 4.7: If a function returns error information, then that error information shall be tested MISRA C:2012 Rule 17.7: The value returned by a function having non-void return type shall be used MISRA C:2012 Rule 21.6: The Standard Library input/output functions shall not be used
Check for unsupported block names		MISRA C:2012 Rule 3.1: The character sequences /* and // shall not be used within a comment.
Check usage of Assignment blocks		MISRA C:2012 Rule 9.1: The value of an object with automatic storage duration shall not be read before it has been set.
Check for switch case expressions without a default case		MISRA C:2012 Rule 16.4: Every switch statement shall have a default label.
Check for missing error ports for AUTOSAR receiver interfaces		MISRA C:2012 Directive 4.7 If a function returns error information, then that error information shall be tested. MISRA C:2012 Rule 17.7: The value returned by a function having non-void return type shall be used.
Check for bitwise operations on signed integers		MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Check for recursive function calls		MISRA C:2012 Rule 17.2: Functions shall not call themselves, either directly or indirectly.
Check for equality and inequality operations on floating-point values		MISRA C:2012 Directive 1.1: Any implementation-defined behaviour on which the output of the program depends shall be documented and understood.

Model Advisor Check	MISRA C:2012 Rule or Directive
Check for missing const qualifiers in model functions	MISRA C:2012 Rule 8.13: A pointer should point to a const-qualified type whenever possible.
Check integer word length	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type.
Check bus object names that are used as element names	MISRA C:2012 Rule 10.1: Operands shall not be of an inappropriate essential type. MISRA C:2012 Rule 5.6: A typedef name shall be a unique identifier.

Deviations Rationale for MISRA C:2012 Compliance

Instances in which the generated code does not comply with the MISRA C:2012 guidelines are marked as deviations in the "MISRA C:2012 Compliance Information Summary Tables" on page 23-7. In accordance with Section 5.4 of the MISRA C:2012 guidelines,information about the deviations includes:

- The guideline being deviated
- The circumstances in which the deviation is permitted
- Justification for the deviation, including a risk assessment
- Demonstration of how safety is assured
- Potential consequences of non-conformance

Deviations to the MISRA C:2012 directives and rules include:

- "MISRA C:2012 Directive 4.7 Deviation Rationale" on page 23-32
- "MISRA C:2012 Rule 13.5 Deviation Rationale" on page 23-36

MISRA C:2012 Directive 4.7 Deviation Rationale

Directive Definition

If a function returns error information, then that error information shall be tested.

Rationale

Note This directive is violated only when an AUTOSAR-based code generation target is used.

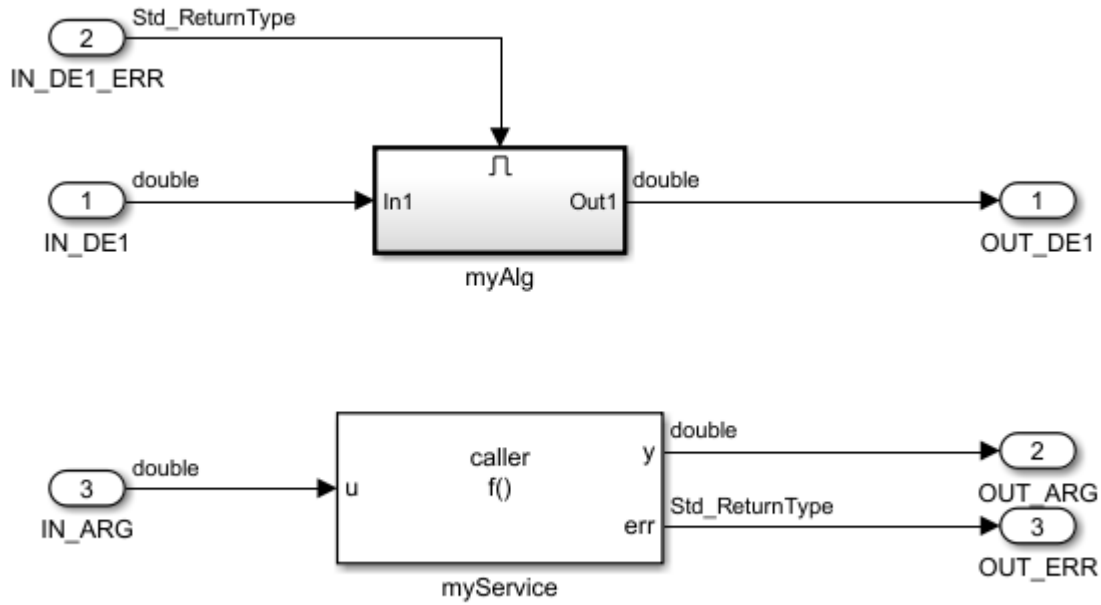
When a function call provides information that indicates an unsuccessful operation, the calling program has to check for the indication of an error when the function is returned. The function calls are not limited to calls in the standard library.

Description

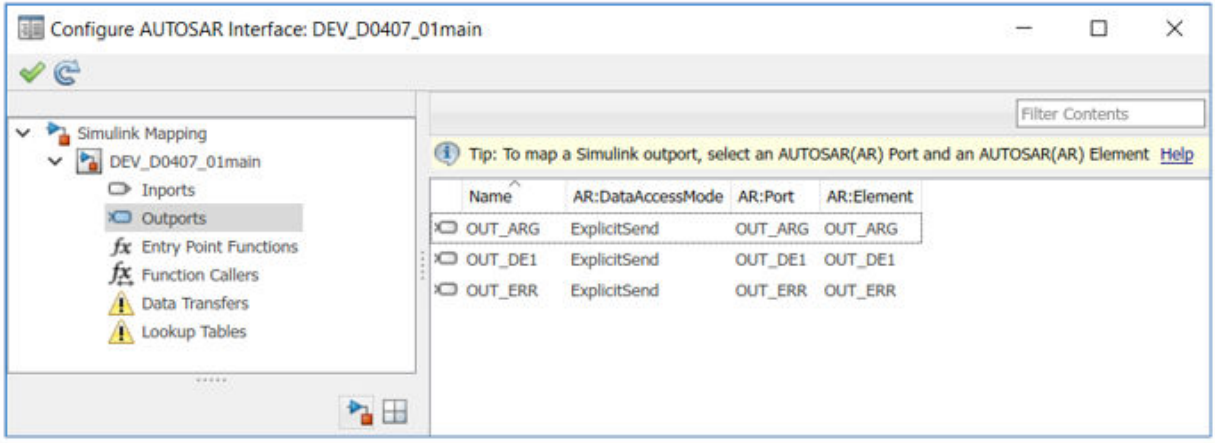
AUTOSAR sender interface function calls, such as `Rte_Write_...`, have return type `Std_ReturnType` that indicates if writing the value was successful. The matching

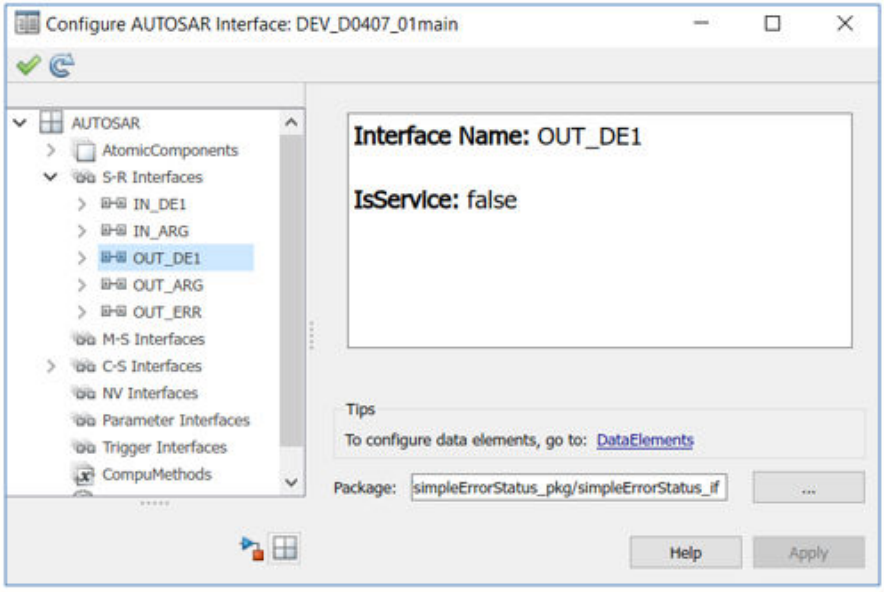
Simulink pattern is a top-level output port that is configured as an AUTOSAR Sender Interface.

Model Example



AUTOSAR Configuration





Generated Code Sample

In the sample code, note the use of AUTOSAR function call `Rte_Write_...` in **`Rte_Write_OUT_DE1_OUT_DE1`**`(rtb_TmpSignalConversionAtIN_DE1);`.

```
void Runnable_Step(void)
{
  /* local block i/o variables */
  real_T rtb_TmpSignalConversionAtIN_DE1;
  …
  rtb_TmpSignalConversionAtIN_D_l = Rte_Read_IN_DE1_IN_DE1
    (&rtb_TmpSignalConversionAtIN_DE1);
  …
  if (rtb_TmpSignalConversionAtIN_D_l > 0) {
    …
    Rte_Write_OUT_DE1_OUT_DE1(rtb_TmpSignalConversionAtIN_DE1);
  }
  …
}
```

Justification

Failures of `Rte_Write_...` function calls are typically handled on the receiver side because function call returns do not always include all potential errors.

Conditions Under Which the Deviation is Requested

The deviation is requested for all instances of AUTOSAR sender ports.

Consequences of Noncompliance

The calling program cannot react when the sender operation is unsuccessful.

Actions to Control Reporting

When a Polyspace analysis of your code finds known or acceptable coding rule violations, you can suppress the violations in subsequent analyses by adding code annotations (Polyspace Bug Finder) to the Outport block. In future analyses, Polyspace hides results justified through annotations in the **Results List** pane. To review the coding rule violations, see “Filter and Group Results” (Polyspace Bug Finder).

If you have already provided annotations for MISRA C:2004 violations, Polyspace imports these justifications when you check your code for MISRA C:2012 violations. For additional information, see “Import Existing MISRA C: 2004 Justifications to MISRA C: 2012 Results” (Polyspace Bug Finder).

For additional information, see:

- “Modeling Patterns for AUTOSAR Runnables” (AUTOSAR Blockset)
- “Develop a Model that Complies with the AUTOSAR Standard” on page 22-24
- “MISRA C:2012 Compliance Information Summary Tables” on page 23-7

MISRA C:2012 Rule 13.5 Deviation Rationale

Rule Definition

The right hand operand of a logical && or || operator shall not contain persistent side effects.

Rationale

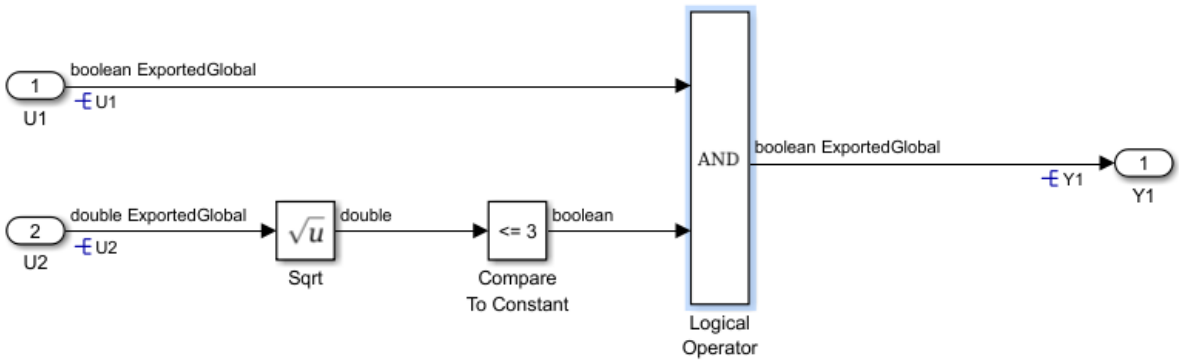
Persistent side effects of the right hand side operand of the && and || operators can occur depending on the left hand side operand, which is contrary to the expectations of the programmer.

Note The term *persistent side effect* is defined in "Appendix J: Glossary" of the *MISRA C:2012 Guidelines for the Use of C Language in Critical Systems* document.

Description

Using math operations as second input to Logical Operator blocks configured as AND or OR operation.

Model Example



Generated Code Sample

In the sample code, note the use of operand && in `Y1 = (U1 && (sqrt(U2) <= 3.0));`.

```
/* Exported block signals */
boolean_T U1;                 /* '<Root>/U1' */
real_T U2;                    /* '<Root>/U2' */
boolean_T Y1;                 /* '<Root>/Logical Operator' */

/* Model step function */
void DEV_R1305_01main_step(void)
{
  /* Logic: '<Root>/Logical Operator' incorporates:
   *  Constant: '<S1>/Constant'
   *  Inport: '<Root>/U1'
   *  Inport: '<Root>/U2'
   *  RelationalOperator: '<S1>/Compare'
   *  Sqrt: '<Root>/Sqrt'
   */
  Y1 = (U1 && (sqrt(U2) <= 3.0));
}
```

Justification

Some standard math functions have at least one persistent side effect of modifying the global `errno` variable, as defined in the C90 or C99 standard. Since the `errno` variable is not used by Embedded Coder, the second operand can be treated as not having persistent side effects.

Note Polyspace Bug Finder treats every function with no available source code as potentially having side effects.

Conditions Under Which the Deviation is Requested

This deviation is requested for all calls to standard math functions used as right hand side argument of && and || operators.

Consequences of Noncompliance

There are no consequences associated with noncompliance with MISRA C:2012 Rule 13.5 in the circumstances described in this deviation record. There are no additional verification and validation requirements resulting from this deviation.

Actions to Control Reporting

When a Polyspace analysis of your code finds known or acceptable coding rule violations, you can suppress the violations in subsequent analyses by adding code annotations (Polyspace Bug Finder) to the Logical Operator block. In future analyses, Polyspace hides results justified through annotations in the **Results List** pane. To review the coding rule violations, see “Filter and Group Results” (Polyspace Bug Finder).

If you have already provided annotations for MISRA C:2004 violations, Polyspace imports these justifications when you check your code for MISRA C:2012 violations. For additional information, see “Import Existing MISRA C: 2004 Justifications to MISRA C: 2012 Results” (Polyspace Bug Finder).

For additional information, see “MISRA C:2012 Compliance Information Summary Tables” on page 23-7.

Patterns for C Code in Embedded Coder

Prepare a Model for Code Generation

Several standard methods are available for setting up a model to generate specific C constructs in your code. For preparing your model for code generation, some of these methods include: configuring signals and ports, initializing states, and setting up configuration parameters for code generation. Depending on the components of your model, some of these methods are optional. Methods for configuring a model to generate specific C constructs are organized by category, for example, the Control Flow category includes constructs `if-else`, `switch`, `for`, and `while`. Refer to the name of a construct to see how you should configure blocks and parameters in your model. Different modeling methodologies are available, such as Simulink blocks, Stateflow charts, and MATLAB Function blocks, to implement a C construct.

Model examples in “Modeling Patterns for C Code” have the following naming conventions:

Model Components	Naming Convention
Inputs	`u1`, `u2`, `u3`, and so on
Outputs	`y1`, `y2`, `y3`, and so on
Parameters	`p1`, `p2`, `p3`, and so on
States	`x1`, `x2`, `x3`, and so on

Input ports are named to reflect the signal names that they propagate.

Configure Input Ports, Output Ports, and Arbitrary Signals

1. Create a model in Simulink. For more information, see “Interactive Model Editing” (Simulink).
2. In the model, select **View** > **Model Data Editor**.
3. In the Model Data Editor, on the **Inports/Outports** tab or the **Signals** tab, use the **Signal Name** column or the **Name** column to give the target signal a name.
4. Set the **Change view** drop-down list to `Code`.
5. Use the **Storage Class** column to apply a storage class to the signal.

   For example, apply the storage class `ExportedGlobal`, which makes the signal appear in the generated code as a separate global variable. The variable has the same name as the signal in the model.

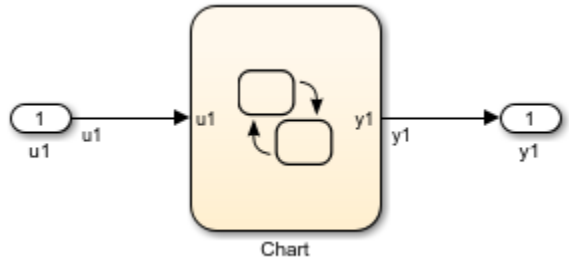
Initialize and Configure States

1. In the Model Data Editor, on the **States** tab, use the **Initial Value** column to specify initial values for a block state (such as the state of a Unit Delay block).
2. Set the **Change view** drop-down list to `Code`.
3. Use the **Name** column to give the state a name.
4. Use the **Storage Class** column to apply a storage class to the state.

Set Up Configuration Parameters for Code Generation

1. Open the Configuration Parameter dialog box by selecting **Simulation** > **Model Configuration parameters**. You can also use the keyboard shortcut `Ctrl+E`.
2. Open the **Solver** pane and select
   - **Solver type**: `Fixed-Step`
   - **Solver**: `discrete (no continuous states)`
3. Open the **Optimization** pane, and set **Default parameter behavior** to `Inlined`.
4. Open the **Code Generation** pane, and specify `ert.tlc` as the **System Target File**.
5. Clear **Generate makefile**.
6. Select **Generate code only**.
7. Enable the HTML report generation by opening the **Code Generation** > **Report** pane and selecting **Create code generation report** and **Open report automatically**. Click the horizontal ellipsis and, under **Advanced parameters**, select **Code-to-model**. Enabling the HTML report generation is optional.
8. Click **Apply** and then **OK** to exit.

Set Up an Example Model With a Stateflow Chart

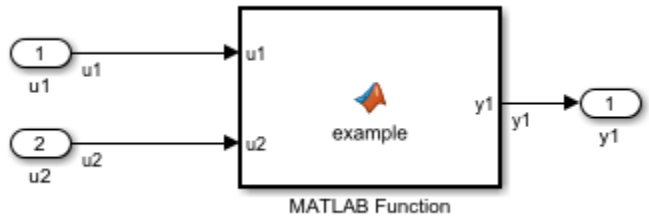


Follow this general procedure to create a simple model containing a Stateflow chart.

1. From the **Stateflow > Chart** library, add a Stateflow chart to your model .
2. Add Inport blocks and Outport blocks according to the example model.
3. Open the **Stateflow Editor** by performing one of the following:
   - Double-click the Stateflow chart.
   - Press **Ctrl+R**.
4. Select **Chart > Add Inputs & Outputs > Data Input from Simulink** to add the inputs to the chart. A Data dialog box opens for each input.
5. Specify the **Name** (`u1, u2, ...`) and the **Type** (`Inherit: Same as Simulink`) for each input, unless specified differently in the example. Click **OK**.

   Click **Apply** and close each dialog box.
6. Select **Chart > Add Inputs & Outputs > Data Output from Simulink** to add the outputs to the chart. A Data dialog opens for each output.
7. Specify the **Name** (`y1, y2, ...`) and **Type** (`Inherit: Same as Simulink`) for each output, unless specified differently in the example. Click **OK**.
8. Click **Apply** and close each dialog box.
9. In the **Stateflow Editor**, create the Stateflow diagram specific to the example.
10. The inputs and outputs appear on the chart in your model.
11. Connect the Inport and Outport blocks to the Stateflow Chart.
12. Configure the input and output signals; see “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 24-3.

Set Up an Example Model With a MATLAB Function Block



1. Add the number of Inport and Outport blocks according to a C construct example included in this chapter.
2. From the Simulink User-defined Functions library drag a MATLAB Function block into the model.
3. Double-click the block. The MATLAB Function Block Editor opens. Edit the function to implement your application.
4. Click **File > Save** and close the MATLAB Function Block Editor.
5. Connect the Inport and Outport blocks to the MATLAB Function block. See “Configure Input Ports, Output Ports, and Arbitrary Signals” on page 24-3.
6. Save your model.

Definition, Initialization, and Declaration of Parameter Data

This example shows how to export the definition, initialization, and declaration of a global variable that the generated code uses as a parameter.

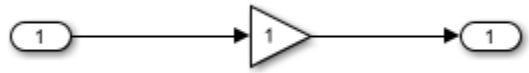
C Construct

```
int32 myParam = 3;

extern int32 myParam;
```

Procedure

1. Open the example model `ex_defn_decl`.



2. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the model, select the Gain block. In the Property Inspector, set the value of the **Gain** parameter to `myParam`.

4. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.

5. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(3)`. Click **Create**. `A Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter, in this case, 3.

6. In the Simulink.Parameter property dialog box, set **Data type** to `int32`.

7. Set **Storage class** to `ExportToFile`.

8. Set **Header File** to `myDecls.h`.

9. Set **Definition File** to `myDefns.c`. Click **OK**.

10. Generate code from the model.

Results

The generated header file `myDecls.h` declares the global variable `myParam` by using the `extern` keyword.

```
/* Declaration for custom storage class: ExportToFile */
extern int32_T myParam;
```

The generated source file `myDefns.c` defines and initializes `myParam`.

```
/* Definition for custom storage class: ExportToFile */
int32_T myParam = 3;
```

Definition and Declaration of Signal Data

This example shows how to export the definition and declaration of a global variable that the generated code uses as a signal.

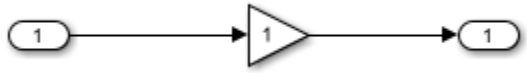
C Construct

```
float mySig;

extern float mySig;
```

Procedure

1. Open the example model `ex_defn_decl`.



2. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the Model Data Editor, open the **Inports/Outports** tab.

4. From the **Change view** drop-down list, select `Design`.

5. In the Model Data Editor, for the Inport block, set **Signal Name** to `mySig`.

6. Set **Data Type** to `single`.

7. From the **Change view** drop-down list, select `Code`.

8. For the Inport block, set **Storage class** to `ExportToFile`.

9. Set **Header File** to `myDecls.h`.

10. Set **Definition File** to `myDefns.c`. Click **OK**.

11. Generate code from the model.

Results

The generated header file `myDecls.h` declares the global variable `myParam` by using the `extern` keyword.

```
/* Declaration for custom storage class: ExportToFile */
extern real32_T mySig;
```

The generated source file `myDefns.c` defines and initializes `myParam`.

```
/* Definition for custom storage class: ExportToFile */
real32_T mySig;
```

Data Type Conversion

This example shows how to create a data type conversion by using a Data Type Conversion block, Stateflow Chart, or MATLAB Function block.

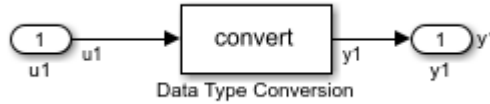
C Construct

```
y1 = (double)u1;
```

Modeling Pattern for Data Type Conversion — Simulink Block

To create a data type conversion, use a Data Type Conversion block from the **Simulink > Commonly Used Blocks library**.

1. Open example model `ex_data_type_SL`.



2. Click the Inport block. In the Property Inspector, under **Signal Attributes**, specify **Data type** as `int32`.

3. Click the Data Type Conversion block. In the Property Inspector, specify the **Output data type** parameter as `double`.

4. In the Configuration Parameters dialog box, set the **Casting modes** parameter to `Explicit`. By default, Simulink sets the **Casting modes** parameter to `Nominal` that generates minimal casting. For more details, see “Control Cast Expressions in Generated Code” on page 50-53.

5. To build the model and generate code, press **Ctrl+B** .

The generated code appears in `ex_data_type_SL.c`:

```
int32_T u1;                            /* '<Root>/u1' */
real_T y1;                             /* '<Root>/y1' */

/* Model step function */
void ex_data_type_SL_step(void)
```

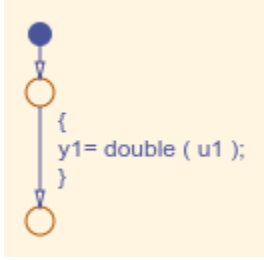
```
{
  /* Outport: '<Root>/y1' incorporates:
   *  DataTypeConversion: '<Root>/Data Type Conversion'
   *  Inport: '<Root>/u1'
   */
  y1 = (real_T)u1;
}
```

The code generator type definition for `double` is `real_T`.

Modeling Pattern for Data Type Conversion — Stateflow Chart

You can use a Stateflow® chart in place of a Data Type Conversion block, to create a data type conversion.

1. Open example model `ex_data_type_SF`.



2. Click the Inport block. In the Property Inspector, under **Signal Attributes**, specify **Data type** as `int32`.

3. In the Configuration Parameters dialog box, set the **Casting modes** parameter to `Explicit`.

4. To build the model and generate code, press **Ctrl+B** .

The generated code appears in `ex_data_type_SF.c`:

```
int32_T u1;                            /* '<Root>/u1' */
real_T y1;                             /* '<Root>/Type_Conversion' */

/* Model step function */
void ex_data_type_SF_step(void)
{
```

```
  /* Chart: '<Root>/Type_Conversion' incorporates:
   *  Inport: '<Root>/u1'
   */
  y1 = (real_T)u1;
}
```

Modeling Pattern for Data Type Conversion — MATLAB Function Block

1. Open example model `ex_data_type_ML`.

2. The MATLAB Function Block contains this function:

```
function y1 = typeconv(u1)
y1 = double(u1);
end
```

3. Click the Inport block. In the Property Inspector, under **Signal Attributes**, specify **Data type** as `int32`.

4. In the Configuration Parameters dialog box, set the **Casting modes** parameter to `Explicit`.

5. To build the model and generate code, press **Ctrl+B** .

The generated code appears in `ex_data_type_ML.c`:

```
int32_T u1;                            /* '<Root>/u1' */
real_T y1;                             /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_data_type_ML_step(void)
{
  /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
```

```
   *  Inport: '<Root>/u1'
   */
  y1 = (real_T)u1;
}
```

Other Type Conversions in Modeling

Type conversions can also occur on the output of blocks where the output variable is specified as a different data type. For example, in the Gain block, you can set the **Parameter data type** as `Inherit via internal rule` to control the output signal data type. Another example of type conversion can occur at the boundary of a Stateflow chart. You can specify the output variable as a different data type.

See Also

Data Type Conversion

Type Qualifiers

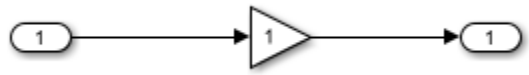
This example shows how to apply the `const` and `volatile` keywords to a global variable that represents parameter data.

C Construct

```
const volatile double myParam = 9.8;
```

Procedure

1. Open the example model `ex_const_volatile`.



2. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the model, select the Gain block. In the Property Inspector, set the value of the **Gain** parameter to `myParam`.

4. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.

5. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(9.8)`. Click **Create**. `A Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter, in this case, 9.8.

6. Set **Storage class** to `ConstVolatile`. Alternatively, to apply only one of the keywords, use the storage classes Const or Volatile.

7. Generate code from the model.

Results

The generated source file `ex_const_volatile.c` defines `myParam` by using the `const` and `volatile` keywords.

```
/* Definition for custom storage class: ConstVolatile */
const volatile real_T myParam = 9.8;
```

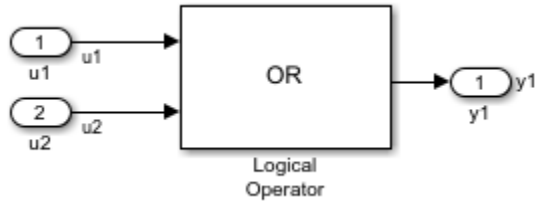
Relational and Logical Operators

This example shows how to implement relational and logical operators by using Simulink blocks, Stateflow Charts, and MATLAB Function blocks.

Modeling Pattern for Relational or Logical Operators — Simulink Blocks

To include a logical operation in your model, use the Logical Operator block from the **Logic and Bit Operations** library.

1. Open example model `ex_data_type_SL`.



The Logical Operator block performs an OR operation in the model. To change the operation, double-click the block and set the **Operator** field to any of the operations in the menu.

You can implement relational operators by replacing the Logical Operator block with a Relational Operator block.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the logical operator OR is in the `ex_logical_SL_step` function in `ex_logical_SL.c`.

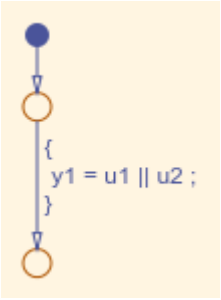
```
/* Exported block signals */
boolean_T u1;                          /* '<Root>/u1' */
boolean_T u2;                          /* '<Root>/u2' */
boolean_T y1;                          /* '<Root>/y1' */

/* Model step function */
void ex_logical_SL_step(void)
{
  /* Outport: '<Root>/y1' incorporates:
```

```
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   *  Logic: '<Root>/Logical Operator'
   */
  y1 = (u1 || u2);
}
```

Modeling Pattern for Relational and Logical Operators — Stateflow Chart

1. Open example model `ex_data_type_SF`.



In the Stateflow chart, the relational or logical operation actions are on the transition from one junction to another. Relational statements specify conditions to conditionally allow a transition. In that case, the statements are within square brackets.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the logical operator OR is in the `ex_logical_SF_step` function in `ex_logical_SF.c`.

```
/* Exported block signals */
boolean_T u1;                          /* '<Root>/u1' */
boolean_T u2;                          /* '<Root>/u2' */
boolean_T y1;                          /* '<Root>/Logical Operator' */

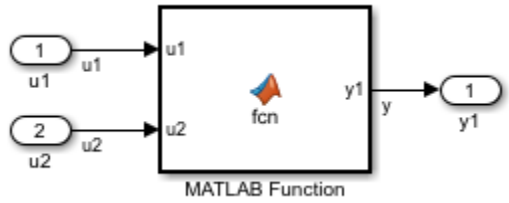
/* Model step function */
void ex_logical_SF_step(void)
{
  /* Chart: '<Root>/Logical Operator' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
```

```
  y1 = (u1 || u2);
}
```

Modeling Pattern for Relational and Logical Operators — MATLAB Function Block

This example shows the MATLAB Function block method for incorporating operators into the generated code by using a relational operator.

1. Open example model `ex_logical_ML`.



2. The MATLAB Function Block contains this function:

```
function y1 = fcn(u1, u2)
y1 = u1 > u2;
end
```

3. To build the model and generate code, press **Ctrl+B**.

The generated code appears in `ex_data_type_ML.c`:

```
/* Exported block signals */
real_T u1;                             /* '<Root>/u1' */
real_T u2;                             /* '<Root>/u2' */
boolean_T y;                           /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_logical_ML_step(void)
{
  /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
```

```
  y = (u1 > u2);
}
```

Logical Operator

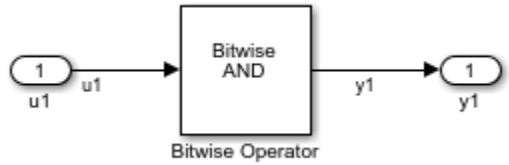
Bitwise Operations

This example shows how to implement bitwise operations by using Simulink blocks, Stateflow Charts, and MATLAB Function blocks.

Simulink Bitwise-Operator Block

To include a logical operation in your model, use the Bitwise Operator block from the **Logic and Bit Operations** library.

1. Open example model `ex_bit_logic_SL`.



The Logical Operator blocks perform an AND operation in the model. To change the operation, double-click the block and set the **Operator** field to any of the operations in the menu.

2. Double-click the block to open the Block Parameters dialog box.

3. To perform bitwise operations with a bit-mask, select **Use bit mask**.

If another input uses bitwise operations, clear the **Use bit mask** parameter and enter the number of input ports.

4. In the **Bit Mask** field, enter a decimal number. Use `bin2dec` or `hex2dec` to convert the input from binary or hexadecimal. In this example, enter `hex2dec('D9')`.

5. To build the model and generate code, press **Ctrl+B**.

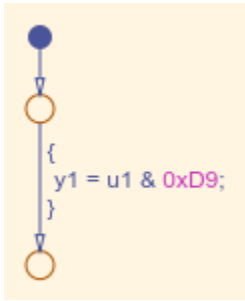
The code implementing the bitwise operator AND is in the `ex_bit_logic_SL_step` function in `ex_bit_logic_SL.c`:

```
/* Exported block signals */
uint8_T u1;                            /* '<Root>/u1' */
uint8_T y1;                            /* '<Root>/Bitwise Operator' */
```

```
/* Model step function */
void ex_bit_logic_SL_step(void)
{
  /* S-Function (sfix_bitop): '<Root>/Bitwise Operator' incorporates:
   *  Inport: '<Root>/u1'
   */
  y1 = (uint8_T)(u1 & 217);
}
```

Stateflow Chart

1. Open example model `ex_bit_logic_SF`.



2. Right-click the Stateflow chart to open the chart **Properties**.

3. Verify that the **Enable C-bit operations** check box is selected. For more information, see “Enable C-Bit Operations” (Stateflow).

4. To build the model and generate code, press **Ctrl+B**.

The code implementing the bitwise operator AND is in the `ex_bit_logic_SF_step` function in `ex_bit_logic_SF.c`:

```
/* Exported block signals */
uint8_T u1;                            /* '<Root>/u1' */
uint8_T y1;                            /* '<Root>/Bit_Logic' */

/* Model step function */
void ex_bit_logic_SF_step(void)
{
  /* Chart: '<Root>/Bit_Logic' incorporates:
```

```
   *  Inport: '<Root>/u1'
   */
  y1 = (uint8_T)(u1 & 0xD9);
}
```

MATLAB Function Block

In this example, to show the MATLAB Function block method for implementing bitwise logic into the generated code, use the bitwise OR, '|'.

1. Open example model `ex_bit_logic_ML`.

2. The MATLAB Function Block contains this function:

```
function y1 = fcn(u1, u2)
%#eml

y1 = bitor(u1, u2);
end
```

3. To build the model and generate code, press **Ctrl+B**.

The code implementing the bitwise operator OR is in the `ex_bit_logic_ML_step` function in `ex_bit_logic_ML.c`:

```
/* Exported block signals */
uint8_T u1;                            /* '<Root>/u1' */
uint8_T u2;                            /* '<Root>/u2' */
uint8_T y1;                            /* '<Root>/Bitwise OR' */

/* Model step function */
void ex_bit_logic_ML_step(void)
```

```
{
  /* MATLAB Function: '<Root>/Bitwise OR' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
  y1 = (uint8_T)(u1 | u2);
}
```

Bitwise Operator

Enumeration

To generate an enumerated data type, define an enumeration class in a MATLAB file. Then, use the enumeration class as the data type of signals, block parameters, and states in your model.

C Construct

```
typedef enum {
  Choice1 = 0,
  Choice2
} myEnumType;
```

Procedure

In your current folder, create the MATLAB file `ex_myEnumType.m`. The file defines an enumeration class `ex_myEnumType`.

```
classdef ex_myEnumType < Simulink.IntEnumType

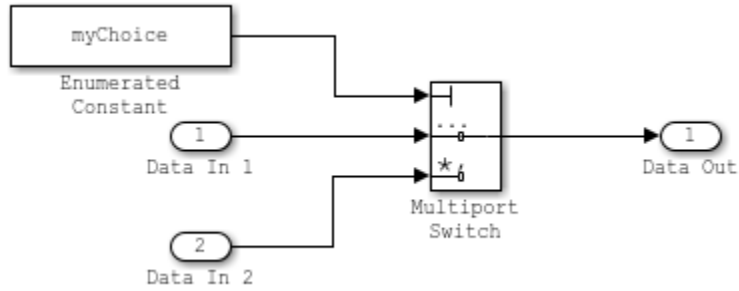
    enumeration
        Choice1(0)
        Choice2(1)
    end %enumeration

    methods (Static)
        function retVal = getHeaderFile()
            retVal = 'myEnumHdr.h';
        end %function

        function retVal = getDataScope()
            retVal = 'Exported';
        end %function
    end %methods

end %classdef
```

1. Open the model `ex_pattern_enum` that has an Enumerated Constant block and a Multiport Switch block.



2. The model opens in the Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the Model Data Editor, select the **Parameters** tab.

4. In the model, click the Enumerated Constant block.

5. In the Model Data Editor, use the **Value** column to set the constant value to `myChoice`. Next to `myChoice`, click the action button (with three vertical dots) and select **Create**.

6. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(ex_myEnumType.Choice1)` and click **Create**. A `Simulink.Parameter` object named `myChoice` appears in the base workspace. The object stores the enumerated value `Choice1` of the type `ex_myEnumType`.

7. In the property dialog box for `myChoice`, set **Storage Class** to `ExportedGlobal`. With this setting, the object appears in the generated code as a global variable.

8. In the Model Data Editor, select the **Signals** tab.

9. In the model, select the output signal of the Enumerated Constant block.

10. In the Model Data Editor, use the **Data Type** column to set the signal data type to `Enum: ex_myEnumType`.

11. In the model, select **View > Property Inspector**. Then, select the Multiport Switch block.

12. In the Property Inspector, set:

- **Data port order** to `Specify indices`.
- **Data port indices** to `enumeration('ex_myEnumType')`. This expression returns all of the enumeration members of `ex_myEnumType`.

13. Set **Configuration Parameters > File packaging format** to `Modular`. With this setting, in the generated code, the definition of `ex_myEnumType` can appear in the specified header file, `myEnumHdr.h`.

14. Generate code from the model.

Results

View the generated header file `myEnumHdr.h`. The file defines the enumerated data type.

```
typedef enum {
  Choice1 = 0,                         /* Default value */
  Choice2
} ex_myEnumType;
```

View the source file `ex_pattern_enum.c`. The file defines the variable `myChoice`. The algorithm in the `step` function uses `myChoice` to route one of the input signals to the output signal.

```
ex_myEnumType myChoice = Choice1;      /* Variable: myChoice

/* Model step function */
void ex_pattern_enum_step(void)
{
  /* MultiPortSwitch: '<Root>/Multiport Switch' incorporates:
   *  Constant: '<S1>/Constant'
   */
  if (myChoice == Choice1) {
    /* Outport: '<Root>/Data Out' incorporates:
     *  Inport: '<Root>/Data In 1'
     */
    rtY.DataOut = rtU.DataIn1;
  } else {
    /* Outport: '<Root>/Data Out' incorporates:
     *  Inport: '<Root>/Data In 2'
     */
    rtY.DataOut = rtU.DataIn2;
  }
```

```
  /* End of MultiPortSwitch: '<Root>/Multiport Switch' */
}
```

If-Else

This example shows how to implement an if-else construct by using Simulink blocks, Stateflow Charts, and MATLAB Function block.

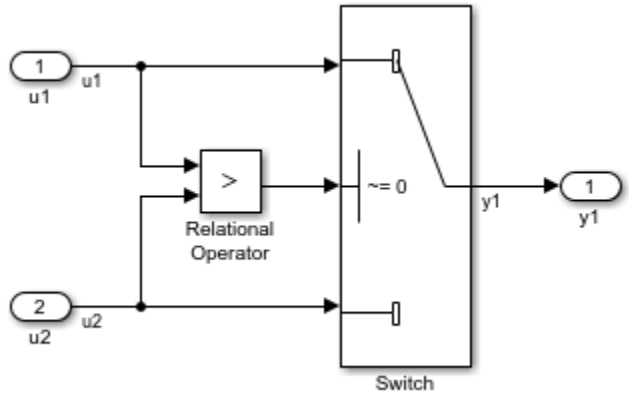
C Construct

```
if (u1 > u2)
{
    y1 = u1;
}
else
{
    y1 = u2;
}
```

Modeling Pattern for If-Else: Switch block

One method to create an `if-else` statement is to use a Switch block from the **Simulink > Signal Routing** library.

1. Open example model `ex_if_else_SL`.



The model contains the Switch block with the block parameter **Criteria for passing first input** of `u2~=0`. The software selects `u1` if `u2` is `TRUE`, otherwise `u2` passes.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `if-else` construct is in the `ex_if_else_SL_step` function in `ex_if_else_SL.c`:

```
/* External inputs (root inport signals with default storage) */
ExternalInputs U;

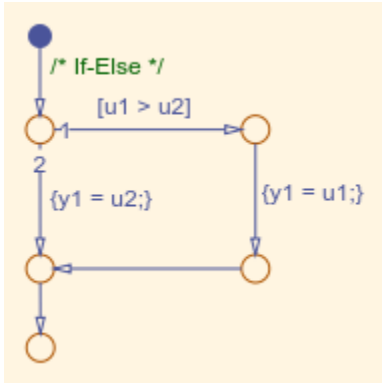
/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_SL_step(void)
{
  /* Switch: '<Root>/Switch' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   *  RelationalOperator: '<Root>/Relational Operator'
   */
  if (U.u1 > U.u2) {
    /* Outport: '<Root>/y1' */
    Y.y1 = U.u1;
  } else {
    /* Outport: '<Root>/y1' */
    Y.y1 = U.u2;
  }

  /* End of Switch: '<Root>/Switch' */
}
```

Modeling Pattern for If-Else: Stateflow Chart

1. Open example model `ex_if_else_SF`.



The model contains an `If-Else` decision pattern that you add by selecting **Chart** > **Add Pattern in Chart** > **Decision** > **If-Else**.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `if-else` construct is in the `ex_if_else_SF_step` function in `ex_if_else_SF.c`:

```
/* External inputs (root inport signals with default storage) */
ExternalInputs U;

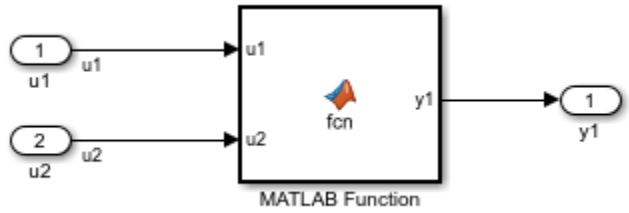
/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_SF_step(void)
{
  /* Chart: '<Root>/Chart' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
  /*  If-Else  */
  if (U.u1 > U.u2) {
    /* Outport: '<Root>/y1' */
    Y.y1 = U.u1;
  } else {
    /* Outport: '<Root>/y1' */
    Y.y1 = U.u2;
  }
```

```
  /* End of Chart: '<Root>/Chart' */
}
```

Modeling Pattern for If-Else: MATLAB Function Block

1. Open example model `ex_if_else_ML`.



2. The MATLAB Function Block contains this function:

```
function y1 = fcn(u1, u2)
if u1 > u2;
    y1 = u1;
else y1 = u2;
end
```

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `if-else` construct is in the `ex_if_else_ML_step` function in `ex_if_else_ML.c`:

```
/* External inputs (root inport signals with default storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_if_else_ML_step(void)
{
  /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
```

```
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
  if (U.u1 > U.u2) {
    /* Outport: '<Root>/y1' */
    Y.y1 = U.u1;
  } else {
    /* Outport: '<Root>/y1' */
    Y.y1 = U.u2;
  }

  /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

Switch

This example shows how to implement a `switch` construct by using Simulink blocks, Stateflow Charts, and MATLAB Function block.

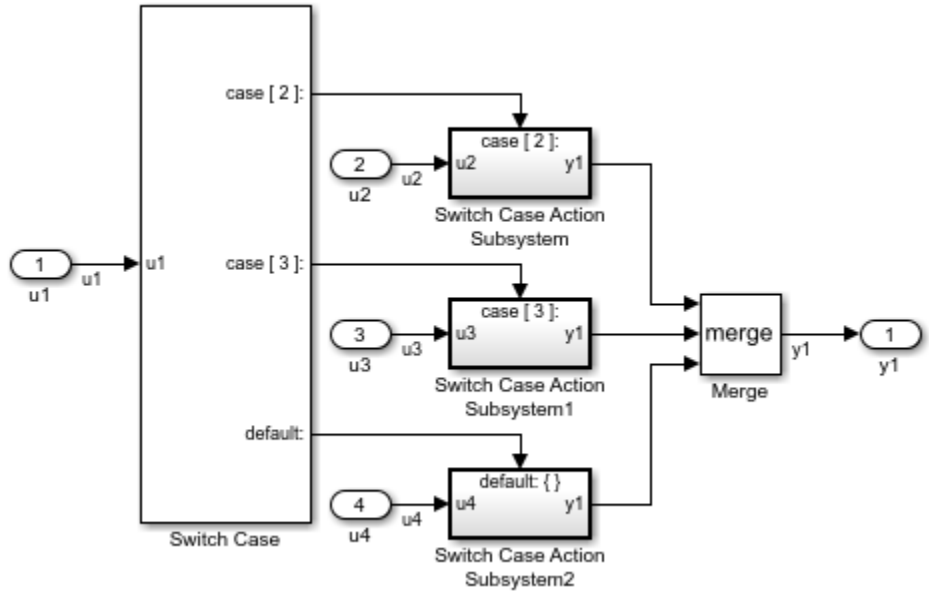
C Construct

```
switch (u1)
{
 case 2:
   y1 = u2;
   break;
 case 3:
   u3;
   break;
 default:
   y1 = u4;
   break;
}
```

Modeling Pattern for Switch: Switch Case block

One method to create a `switch` statement is to use a Switch Case block from the **Simulink > Signal Routing** library.

1. Open example model `ex_switch_SL`.



The model contains a Switch Case Action Subsystem. The Switch Case block takes an integer input, therefore, the input signal `u1` is type cast to `int32`.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `switch` construct is in the `ex_switch_SL_step` function in `ex_switch_SL.c`:

```
/* Exported block signals */
int32_T u1;                            /* '<Root>/u1' */

/* External inputs (root inport signals with default storage) */
ExternalInputs rtU;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs rtY;

/* Model step function */
void ex_switch_SL_step(void)
{
```

```
/* SwitchCase: '<Root>/Switch Case' incorporates:
 *  Inport: '<Root>/u1'
 */
switch (u1) {
 case 2:
  /* Outputs for IfAction SubSystem: '<Root>/Switch Case Action Subsystem' incorporat
   *  ActionPort: '<S1>/Action Port'
   */
  /* Outport: '<Root>/y1' incorporates:
   *  Inport: '<Root>/u2'
   *  Inport: '<S1>/u2'
   */
  rtY.y1 = rtU.u2;

  /* End of Outputs for SubSystem: '<Root>/Switch Case Action Subsystem' */
  break;

 case 3:
  /* Outputs for IfAction SubSystem: '<Root>/Switch Case Action Subsystem1' incorpora
   *  ActionPort: '<S2>/Action Port'
   */
  /* Outport: '<Root>/y1' incorporates:
   *  Inport: '<Root>/u3'
   *  Inport: '<S2>/u3'
   */
  rtY.y1 = rtU.u3;

  /* End of Outputs for SubSystem: '<Root>/Switch Case Action Subsystem1' */
  break;

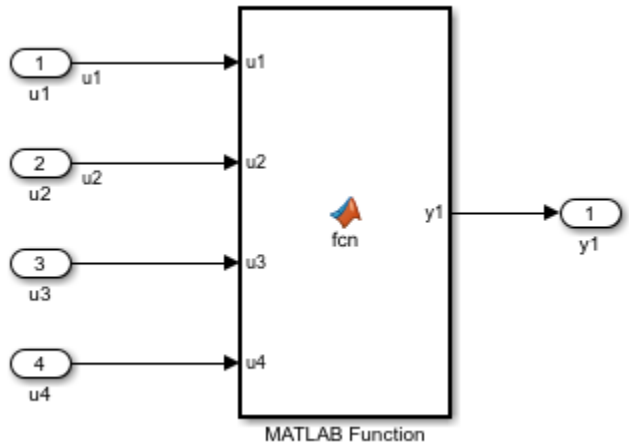
 default:
  /* Outputs for IfAction SubSystem: '<Root>/Switch Case Action Subsystem2' incorpora
   *  ActionPort: '<S3>/Action Port'
   */
  /* Outport: '<Root>/y1' incorporates:
   *  Inport: '<Root>/u4'
   *  Inport: '<S3>/u4'
   */
  rtY.y1 = rtU.u4;

  /* End of Outputs for SubSystem: '<Root>/Switch Case Action Subsystem2' */
  break;
}
```

```
  /* End of SwitchCase: '<Root>/Switch Case' */
}
```

Modeling Pattern for Switch: MATLAB Function Block

1. Open example model `ex_switch_ML`.



The MATLAB Function Block contains this function:

```
function y1 = fcn(u1, u2, u3, u4)

switch u1
    case 2
        y1 = u2;
    case 3
        y1 = u3;
    otherwise
        y1 = u4;
end
```

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `switch` construct is in the `ex_switch_ML_step` function in `ex_switch_ML.c`:

```
/* External inputs (root inport signals with default storage) */
ExternalInputs rtU;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs rtY;

/* Model step function */
void ex_switch_ML_step(void)
{
  /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
   *  Inport: '<Root>/u1'
   */
  switch (rtU.u1) {
   case 2:
    /* Outport: '<Root>/y1' incorporates:
     *  Inport: '<Root>/u2'
     */
    rtY.y1 = rtU.u2;
    break;

   case 3:
    /* Outport: '<Root>/y1' incorporates:
     *  Inport: '<Root>/u3'
     */
    rtY.y1 = rtU.u3;
    break;

   default:
    /* Outport: '<Root>/y1' incorporates:
     *  Inport: '<Root>/u4'
     */
    rtY.y1 = rtU.u4;
    break;
  }

  /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

Convert If-Elseif-Else to Switch statement

If a MATLAB Function block or a Stateflow chart uses `if-elseif-else` decision logic, you can convert the block or chart to a `switch` statement by using a configuration parameter. Select the **Configuration Parameters > Code Generation > Code Style > "Convert if-elseif-else patterns to switch-case statements"** parameter. For more information, see "Converting If-Elseif-Else Code to Switch-Case Statements" (Simulink). For more information on this conversion by using a Stateflow chart, see "Enhance Readability of Code for Flow Charts" on page 50-112.

For Loop

This example shows how to implement a `for` loop construct by using Simulink blocks, Stateflow Charts, and MATLAB Function blocks.

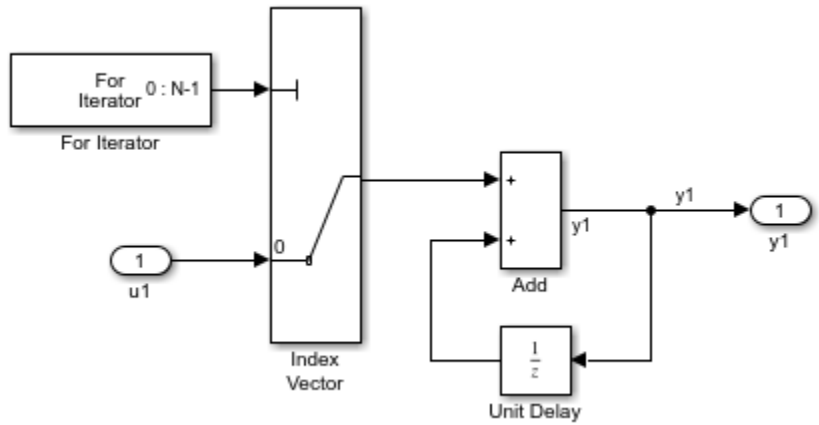
C Construct

```
y1 = 0;
for(inx = 0; inx <10; inx++)
{
    y1 = u1[inx] + y1;
}
```

Modeling Pattern for For Loop: For-Iterator Subsystem block

One method for creating a `for` loop is to use a For Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

1. Open example model `ex_for_loop_SL`.



The model contains a For Iterator Subsystem block that repeats execution of the contents of the subsystem during a simulation time step.

Observe the following settings in the model:

- Open the For Iterator block. In the Block Parameters dialog box, the **Index-mode** parameter is `Zero-based` and the **Iteration limit** parameter is 10.
- Open the Unit Delay block. In the Block Parameters dialog box, the **Initial Conditions** parameter is 0. This parameter initializes the state to zero.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `for` loop is in the `ex_for_loop_SL_step` function in `ex_for_loop_SL.c`:

```
/* External inputs (root inport signals with default storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

/* Model step function */
void ex_for_loop_SL_step(void)
{
  int32_T s1_iter;
  int32_T rtb_y1;

  /* Outputs for Iterator SubSystem: '<Root>/For Iterator Subsystem' incorporates:
   *  ForIterator: '<S1>/For Iterator'
   */
  for (s1_iter = 0; s1_iter < 10; s1_iter++) {
    /* Sum: '<S1>/Add' incorporates:
     *  Inport: '<Root>/u1'
     *  MultiPortSwitch: '<S1>/Index Vector'
     *  UnitDelay: '<S1>/Unit Delay'
     */
    rtb_y1 = U.u1[s1_iter] + DWork.UnitDelay_DSTATE;

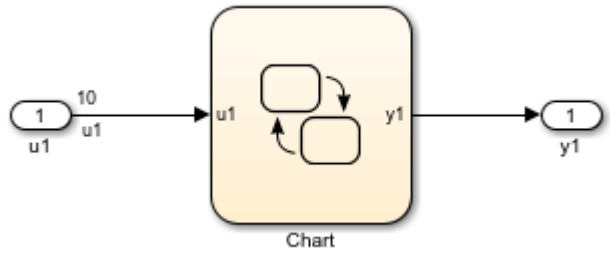
    /* Update for UnitDelay: '<S1>/Unit Delay' */
    DWork.UnitDelay_DSTATE = rtb_y1;
  }

  /* End of Outputs for SubSystem: '<Root>/For Iterator Subsystem' */

  /* Outport: '<Root>/y1' */
  Y.y1 = rtb_y1;
}
```

Modeling Pattern for For Loop: Stateflow Chart

1. Open example model `ex_for_loop_SF`.



The chart contains a `For` loop decision pattern that you add by selecting **Chart** > **Add Pattern in Chart** > **Loop** > **For**.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `for` loop is in the `ex_for_loop_SF_step` function in `ex_for_loop_SF.c`:

```
/* External inputs (root inport signals with default storage) */
ExternalInputs U;

/* External outputs (root outports fed by signals with default storage) */
ExternalOutputs Y;

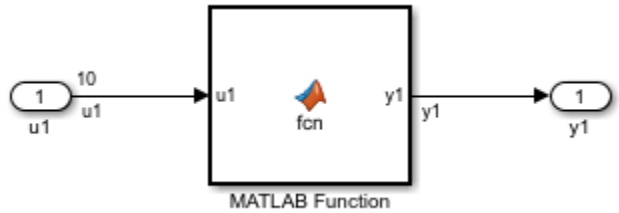
/* Model step function */
void ex_for_loop_SF_step(void)
{
  int32_T inx;

  /* Chart: '<Root>/Chart' */
  for (inx = 0; inx < 10; inx++) {
    /* Outport: '<Root>/y1' incorporates:
     *  Inport: '<Root>/u1'
     */
    Y.y1 += U.u1[inx];
  }
```

```
  /* End of Chart: '<Root>/Chart' */
}
```

Modeling Pattern for For Loop: MATLAB Function block

1. Open example model `ex_for_loop_ML`.



The MATLAB Function Block contains this function:

```
function y1 = fcn(u1)

y1 = 0;

for inx=1:10
    y1 = u1(inx) + y1 ;
end
```

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `for` loop is in the `ex_for_loop_ML_step` function in `ex_for_loop_ML.c`:

```
/* Exported block signals */
real_T u1[10];                         /* '<Root>/u1' */
real_T y1;                             /* '<Root>/MATLAB Function' */

/* Model step function */
void ex_for_loop_ML_step(void)
{
  int32_T inx;

  /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
```

```
   *  Inport: '<Root>/u1'
   */
  y1 = 0.0;
  for (inx = 0; inx < 10; inx++) {
    y1 += u1[inx];
  }

  /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

While Loop

This example shows how to implement a `while` loop construct by using Simulink blocks, Stateflow Charts, and MATLAB Function blocks.

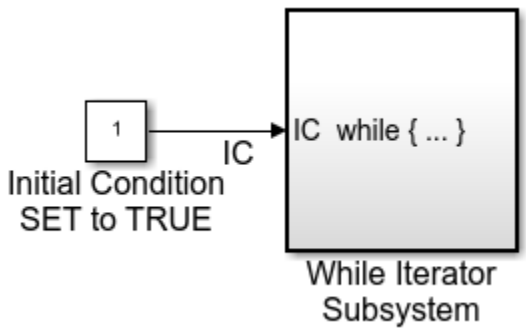
C Construct

```
while(flag && (num_iter <= 100)
{
    flag = func ();
    num_iter ++;
}
```

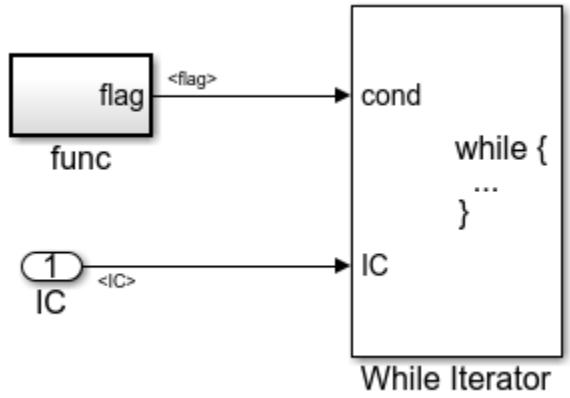
Modeling Pattern for While Loop: While Iterator Subsystem block

One method for creating a `while` loop is to use a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

1. Open example model `ex_while_loop_SL`.



The model contains a While Iterator Subsystem block that repeats execution of the contents of the subsystem during a simulation time step.



Observe the following settings in the model:

- The Constant block provides an initial condition to the While Iterator Subsystem. For the Constant block, the **Constant value** is `1` and the **Output data type** is `boolean`. The initial condition can be dependent on the input to the block.
- In the While Iterator Subsystem, the `func` subsystem block has an output `flag` of `0` or `1` depending on the result of the algorithm in `func( )`. `func()` is the **Function name** in `func` subsystem.
- In the While Iterator Subsystem, for the While Iterator block, the **Maximum number of iterations** is `100`.
- For the While Iterator block, the **While loop type** is `while`.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `while` loop is in the `ex_while_loop_SL_step` function in `ex_while_loop_SL.c`:

```
/* Model step function */
void ex_while_loop_SL_step(void)
{
  int32_T s1_iter;
  boolean_T loopCond;

  /* Outputs for Iterator SubSystem: '<Root>/While Iterator Subsystem' incorporates:
```

```
   *  WhileIterator: '<S1>/While Iterator'
   */
  s1_iter = 1;

  /* SystemReset for Atomic SubSystem: '<S1>/func' */
  func_Reset();

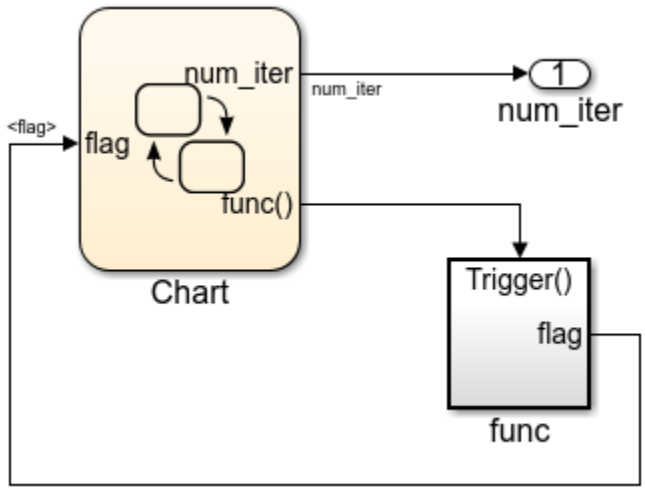
  /* End of SystemReset for SubSystem: '<S1>/func' */
  loopCond = true;
  while (loopCond && (s1_iter <= 100)) {
    /* Outputs for Atomic SubSystem: '<S1>/func' */
    func();

    /* End of Outputs for SubSystem: '<S1>/func' */
    loopCond = flag;
    s1_iter++;
  }

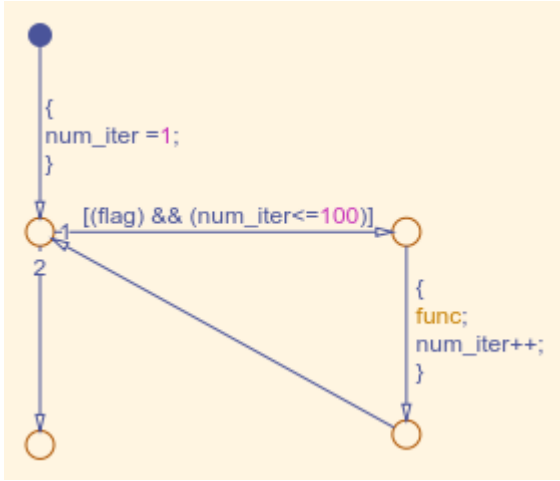
  /* End of Outputs for SubSystem: '<Root>/While Iterator Subsystem' */
}
```

Modeling Pattern for While Loop: Stateflow Chart

1. Open example model `ex_while_loop_SF`.



In the model, the `ex_while_loop_SF/Chart` executes the `while` loop.



The chart contains a `While` loop decision pattern that you add by selecting **Chart > Add Pattern in Chart > Loop > While**.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `while` loop is in the `ex_while_loop_SF_step` function in `ex_while_loop_SF.c`:

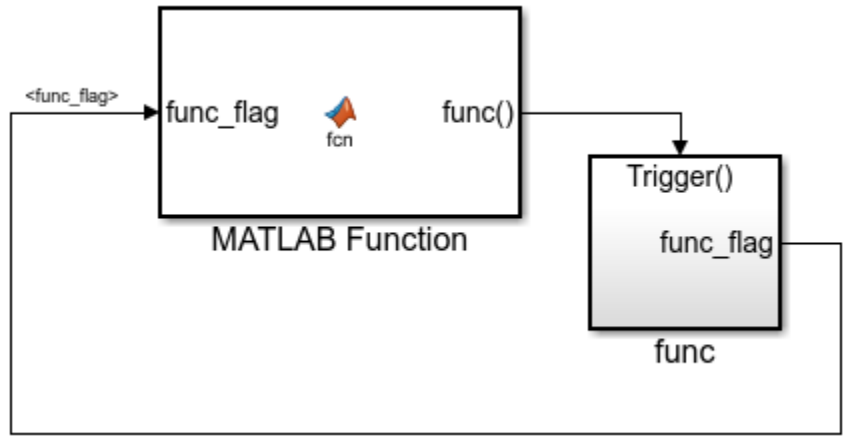
```
/* Model step function */
void ex_while_loop_SF_step(void)
{
  /* Chart: '<Root>/Chart' */
  num_iter = 1;
  while (flag && (num_iter <= 100)) {
    /* Outputs for Function Call SubSystem: '<Root>/func' */
    func();

    /* End of Outputs for SubSystem: '<Root>/func' */
    num_iter++;
  }

  /* End of Chart: '<Root>/Chart' */
}
```

Modeling Pattern for For Loop: MATLAB Function block

1. Open example model `ex_while_loop_ML`.



The MATLAB Function Block contains this function:

```
function fcn(func_flag)

flag = true;
num_iter = 1;

while(flag && (num_iter<=100))
    func;
    flag = func_flag;
    num_iter = num_iter + 1;
end
```

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `while` loop is in the `ex_while_loop_ML_step` function in `ex_while_loop_ML.c`:

```
/* Model step function */
void ex_while_loop_ML_step(void)
```

```
{
  boolean_T func_flag_0;
  boolean_T flag;
  int32_T num_iter;

  /* MATLAB Function: '<Root>/MATLAB Function' */
  func_flag_0 = func_flag;
  flag = true;
  num_iter = 1;
  while (flag && (num_iter <= 100)) {
    /* Outputs for Function Call SubSystem: '<Root>/func' */
    func();

    /* End of Outputs for SubSystem: '<Root>/func' */
    flag = func_flag_0;
    num_iter++;
  }

  /* End of MATLAB Function: '<Root>/MATLAB Function' */
}
```

More About

- “Implementing MATLAB Functions Using Blocks” (Simulink)

Do While Loop

This example shows how to implement a `do while` loop construct by using Simulink blocks and Stateflow Charts.

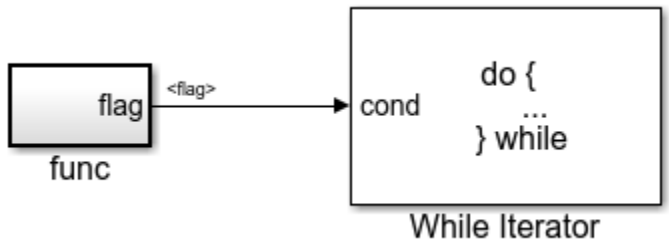
C Construct

```
num_iter = 1;
do {
   flag = func();
   num_iter++;
   }
while (flag && num_iter <= 100)
```

Modeling Pattern for Do While Loop: While Iterator Subsystem block

One method for creating a `do while` loop is to use a While Iterator Subsystem block from the **Simulink > Ports and Subsystems** library.

1. Open example model `ex_do_while_loop_SL`.



The model contains a While Iterator Subsystem block that repeats execution of the contents of the subsystem during a simulation time step.

Observe the following settings in the While Iterator Subsystem:

- The `func` subsystem block has an output `flag` of `0` or `1` depending on the result of the algorithm in `func( )`. `func()` is the **Function name** in `func` subsystem.
- For the While Iterator block, the **Maximum number of iterations** is `100`.

- For the While Iterator block, the **While loop type** is `do-while`.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `do while` loop is in the `ex_do_while_loop_SL_step` function in `ex_do_while_loop_SL.c`:

```
/* Model step function */
void ex_do_while_loop_SL_step(void)
{
  int32_T s1_iter;

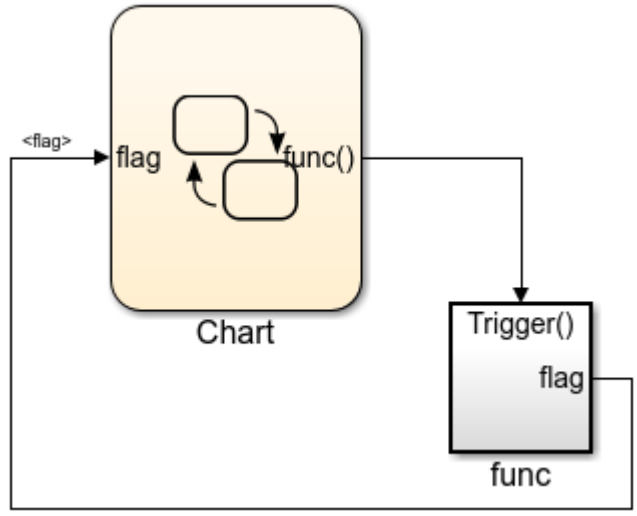
  /* Outputs for Iterator SubSystem: '<Root>/While Iterator Subsystem' incorporates:
   *  WhileIterator: '<S1>/While Iterator'
   */
  s1_iter = 1;

  /* SystemReset for Atomic SubSystem: '<S1>/func' */
  func_Reset();

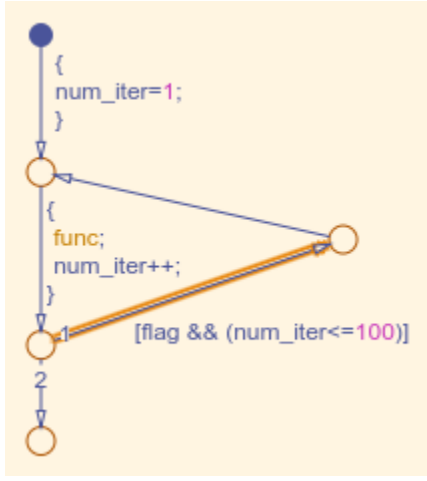
  /* End of SystemReset for SubSystem: '<S1>/func' */
  /* End of Outputs for SubSystem: '<Root>/While Iterator Subsystem' */
  do {
    func();
    s1_iter++;
  } while (flag && (s1_iter <= 100));
}
```

Modeling Pattern for Do While Loop: Stateflow Chart

1. Open example model `ex_do_while_loop_SF`.



In the model, the `ex_do_while_loop_SF/Chart` executes the `do while` loop.



The chart contains a `While` loop decision pattern that you add by selecting **Chart** > **Add Pattern in Chart** > **Loop** > **While**.

2. To build the model and generate code, press **Ctrl+B**.

The code implementing the `do while` loop is in the `ex_do_while_loop_SF_step` function in `ex_do_while_loop_SF.c`:

```
/* Model step function */
void ex_do_while_loop_SF_step(void)
{
  int32_T num_iter;

  /* Chart: '<Root>/Chart' */
  num_iter = 1;
  do {
    func();
    num_iter++;
  } while (flag && (num_iter <= 100));
}
```

While Iterator Subsystem

Related Examples

- “While Loop” on page 24-45
- “Create Flow Charts by Using Pattern Wizard” (Stateflow)

Function Call

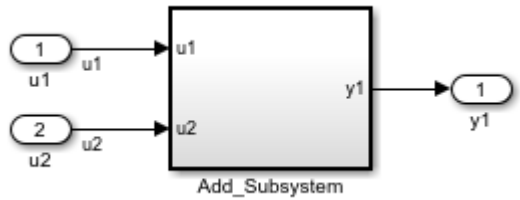
This example shows how to generate a function call by adding a subsystem, which implements the operations that you want.

C Construct

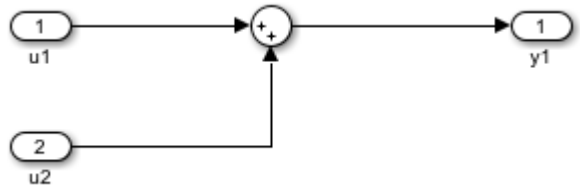
```
void add_function(void)
{
   y1 = u1 + u2;
}
```

Procedure

1. Open example model `ex_function_call`.



The subsystem has two inputs and returns one output.



Selecting the **Treat as atomic unit** parameter enables parameters on the **Code Generation** tab. The **Code Generation** tab provides these customizations:

- **Function packaging** set to `Nonreusable function`
- **Function name options** set to `User specified`

- **Function name** specified as `add_function`
- **File name options** set to `Use function name`

2. To build the model and generate code, press **Ctrl+B**.

Results

In `ex_function_call.c`, the function is called from `ex_function_call_step`:

```
/* Model step function */
void ex_function_call_step(void)
{
  /* Outputs for Atomic SubSystem: '<Root>/Add_Subsystem' */
  add_function();

  /* End of Outputs for SubSystem: '<Root>/Add_Subsystem' */
}
```

The function prototype is externally declared through the subsystem file, `add_function.h`:

```
extern void add_function(void);
```

The function definition is in the subsystem file `add_function.c`:

```
void add_function(void)
{
  /* Outport: '<Root>/y1' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   *  Sum: '<S1>/Sum'
   */
  rtY.y1 = u1 + u2;
}
```

Function Prototyping

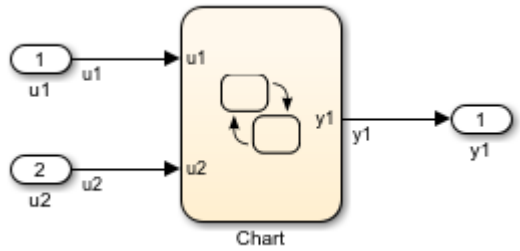
This example shows how to create and customize your function prototype.

C Construct

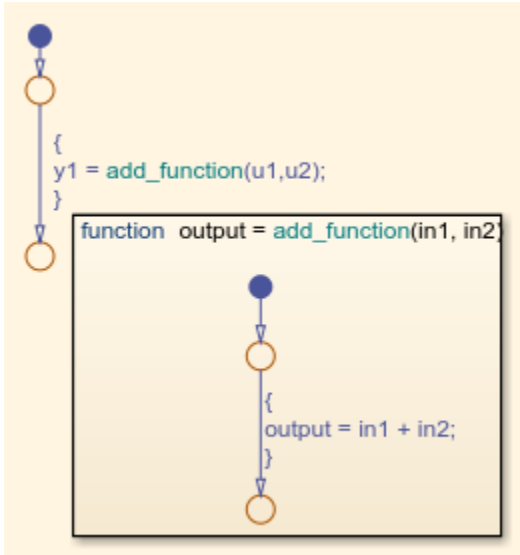
```
double add_function(double u1, double u2)
{
   return u1 + u2;
}
```

Function Call by Using Graphical Functions

1. Open example model `ex_func_SF`. This example model contains two Inport blocks and one Outport block.



The Stateflow chart contains a graphical function that you create by clicking the **fx** button and placing a graphical function into the Stateflow chart.



The graphical function contains this signature:

```
output = add_function(u1, u2)
```

In the Stateflow chart, there is an example of a simple transition that calls `add_function`.

2. Open the Model Explorer. From the Model Hierarchy tree, select **ex_func_SF > Chart > add_function**. On the right pane, make sure that the **Function Inline Option** is set as `Function`.

3. From the Model Hierarchy tree, click **Chart**. On the right pane make sure that the **Export Chart Level Functions** parameter is selected.

4. To build the model and generate code, press **Ctrl+B**.

`ex_func_SF.c` contains the generated code:

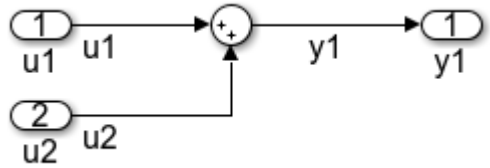
```
/* Function for Chart: '<Root>/Chart' */
void add_function(real_T in1, real_T in2, real_T *output)
{
  *output = in1 + in2;
```

```
}

/* Model step function */
void ex_func_SF_step(void)
{
  /* Chart: '<Root>/Chart' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
  add_function(u1, u2, &y1);
}
```

Control Function Prototype of the *model*_step Function

1. Open example model `ex_control_step_function`.



2. Open the Code perspective. In the Code Mappings editor, select the **Entry-Point Functions** tab.

3. In the step function row, under the **Function Preview** column, click the prototype hyperlink. The configuration dialog box used for customization opens. The first field in the dialog box, **C function prototype**, automatically updates to preview the changes to the step function as you make them.

4. Change the function name. If you do not specify a name, the code generator names the function based on a default naming rule. For this example, rename the function by setting **C Step Function Name** to `ex_control_run`. The function preview changes to reflect the new step function name.

5. Configure step function arguments. If an application requires a `void-void` interface, clear **Configure arguments for Step function prototype**. For this example, select that option.

6. Display current default settings for the entry-point function arguments by clicking **Get default**. An updated diagram appears.

7. Configure the function return argument by setting **C return argument** to `void` or one of the listed outport arguments. For this example, select `void`. Check your change in the preview.

8. Configure the function input and output arguments. For each root inport and outport, you can change the C type qualifier and argument name. For details, see “Override Default C Step Function Interface” on page 39-7.

For this example:

- For `u1`, set **C Type Qualifier** to `Value` and **C Identifier Name** to `arg_u1`.
- For `u2`, set **C Type Qualifier** to `Pointer to const` and **C Identifier Name** to `arg_u2`.
- For the outport, set **C Identifier Name** to `arg_y1`.

Review your changes in the preview.

9. To validate your changes, click **Validate**.

10. Apply your changes. Click **Apply**. Then, click **OK**.

11. To build the model and generate code, press **Ctrl+B**.

`ex_control_step_function.c` contains the generated code:

```
void ex_control_run(real_T arg_u1, const real_T *arg_u2, real_T *arg_y1)
```

External C Functions

This example shows several methods for integrating legacy C functions into generated code. These methods create an S-function or make a call to an external C function. For more information on S-functions, see “S-Functions and Code Generation” on page 12-2.

C Construct

```
extern double add(double, double);

#include "add.h"
double add(double u1, double u2)
{
   double y1;
   y1 = u1 + u2;
   return (y1);
}
```

Create S-Functions by Using Legacy Code Tool

Use the Legacy Code Tool to create an S-function and generate a TLC file. The code generation software uses the TLC file to generate code from this S-function. The advantage to using the Legacy Code Tool is that the generated code is fully inlined and does not need wrapper functions to access the custom code.

1. Create a C header file named `add.h` that contains the function signature:

```
extern double add(double, double);
```

2. Create a C source file named `add.c` that contains the function body:

```
double add(double u1, double u2)
{
   double y1;
   y1 = u1 + u2;
   return (y1);
}
```

3. To build an S-function for use in simulation and code generation, run the following script or execute each of these commands at the MATLAB command line:

```
%% Initialize legacy code tool data structure
def = legacy_code('initialize');

%% Specify Source File
def.SourceFiles = {'add.c'};

%% Specify Header File
def.HeaderFiles = {'add.h'};

%% Specify the Name of the generated S-function
def.SFunctionName = 'add_function';

%% Create a c-mex file for S-function
legacy_code('sfcn_cmex_generate', def);

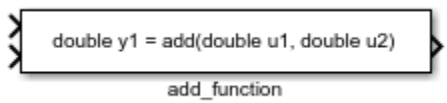
%% Define function signature and target the Output method
def.OutputFcnSpec = ['double y1 = add(double u1, double u2)'];

%% Compile/Mex and generate a block that can be used in simulation
legacy_code('generate_for_sim', def);

%% Create a TLC file for Code Generation
legacy_code('sfcn_tlc_generate', def);

%% Create a Masked S-function Block
legacy_code('slblock_generate', def);
```

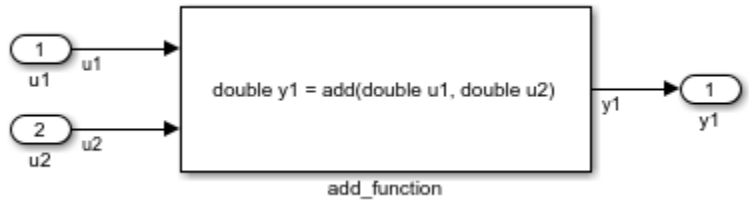
```
### Start Compiling add_function
    mex('-IC:\TEMP\Bdoc19a_1067994_6688\ib99EA80\28\tp19e605e4\ex61094511', '-c', '-out
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
    mex('add_function.c', '-IC:\TEMP\Bdoc19a_1067994_6688\ib99EA80\28\tp19e605e4\ex6109
Building with 'Microsoft Visual C++ 2017 (C)'.
MEX completed successfully.
### Finish Compiling add_function
### Exit
```



The output of this script produces:

- A new model containing the S-function block.
- A TLC file named `add_function.tlc`.
- A C source file named `add_function.c`.
- A mexw32 dll file named `add_function.mexw32`.

4. Add inport blocks and an outport block and make the connections, as shown in the model.



5. Name and save your model. In this example, the model is named `ex_function_call_lct`.

6. To build the model and generate code, press **Ctrl+B**.

This code is generated in `ex_function_call_lct.c`:

```
/* Exported block signals */
real_T u1;                             /* '<Root>/u1' */
real_T u2;                             /* '<Root>/u2' */
real_T y1;                             /* '<Root>/add_function' */

/* Model step function */
void ex_function_call_lct_step(void)
{
  /* S-Function (add_function): '<Root>/add_function' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
  y1 = add(u1, u2);
}
```

The user-specified header file `add.h` is included in `ex_function_call_lct.h`:

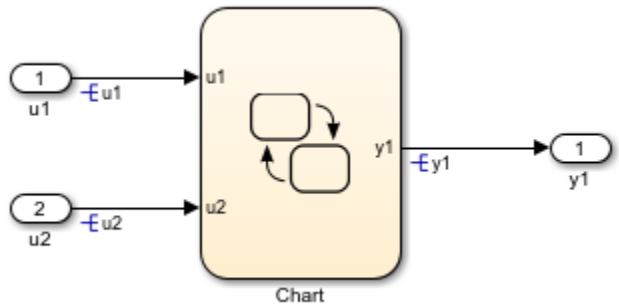
```
#include "add.h"
```

Call C Functions by Using a Stateflow Chart

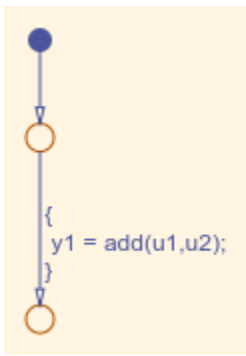
1. Create a C header file named `add.h` that contains the example function signature. Refer to the preceding example.

2. Create a C source file named `add.c` that contains the function body. Refer to the preceding example.

3. Add inport blocks and an outport block and make the connections, as shown in the model. In this example, the model is named `ex_function_call_SF`.



4. Double-click the Stateflow chart and edit the chart as shown. Place the call to the `add` function within a transition action.



5. Select the **Configuration Parameters > Simulation Target > Custom Code** pane. In the **Include custom C code in generated section**, on the left pane, select **Header file**. In the **Header file** field, enter the `#include` statement:

```
#include "add.h"
```

6. In the **Additional build information** section, select **Source files**. In the **Source files** field, enter:

```
add.c
```

7. Select the **Configuration Parameters > Simulation Target > Custom Code > Use the same custom code settings as Simulation Target** parameter.

8. To build the model and generate code, press **Ctrl+B**.

`ex_exfunction_call_SF.c` contains the following code in the step function:

```
/* Definition for custom storage class: Global */
real_T u1;
real_T u2;
real_T y1;

/* Model step function */
void ex_function_call_SF_step(void)
{
  /* Chart: '<Root>/Chart' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
  y1 = (real_T)add(u1, u2);
}
```

`ex_exfunction_call_SF.h` contains the include statement for `add.h`:

```
#include "add.h"
```

Use MATLAB Function Block to Call C Functions

1. Create a C header file named `add.h` that contains the example function signature. Refer to the preceding example.

2. Create a C source file named `add.c` that contains the function body. Refer to the preceding example.

3. In the Simulink Library Browser, click **Simulink > User Defined Functions**. Drag a MATLAB Function block into your model.

4. Double-click the MATLAB Function block. Edit the function to include:

```
function y1 = add_function(u1, u2)

% Set the class and size of output
y1 = u1;

% Call external C function
y1 = coder.ceval('add',u1,u2);

end
```

5. Select the **Configuration Parameters > Simulation Target > Custom Code** pane. In the **Include custom C code in generated section**, on the left pane, select **Header file**. In the **Header file** field, enter the `#include` statement:

```
#include "add.h"
```

6. In the **Additional build information** section, select **Source files**. In the **Source files** field, enter:

```
add.c
```

7. Add two Inport blocks and one Outport block to the model and connect it to the MATLAB Function block.

8. Save the model as `ex_function_call_ML`.

9. To build the model and generate code, press **Ctrl+B**.

`ex_exfunction_call_ML.c` contains the following code in the step function:

```
/* Definition for custom storage class: Global */
real_T u1;
real_T u2;
real_T y1;

/* Model step function */
void ex_function_call_ML_step(void)
{
  /* MATLAB Function: '<Root>/MATLAB Function' incorporates:
   *  Inport: '<Root>/u1'
   *  Inport: '<Root>/u2'
   */
  y1 = add(u1, u2);
}
```

`ex_exfunction_call_ML.h` contains the include statement for `add.h`:

```
#include "add.h"
```

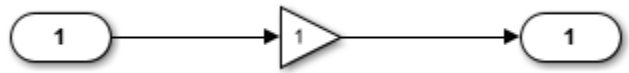
Macro Definitions (#define)

C Construct

```
#define myParam 9.8;
```

Export Generated Macro Definition

1. Open example model `ex_param_macro`.



2. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the model, select the Gain block. In the Property Inspector, set the value of the **Gain** parameter to `myParam`.

4. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.

5. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(9.8)`. Click **Create**. `A Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter, in this case, `9.8`.

6. In the `Simulink.Parameter` property dialog box, set **Storage class** to `Define`. Click **OK**.

7. Generate code from the model.

The generated header file `ex_param_macro.h` defines `myParam` as a macro.

```
/* Definition for custom storage class: Define */
#define myParam                        9.8
```

Reuse Macro from Handwritten Code

1. In the Model Data Editor, on the **Parameters** tab, click the **Show/refresh additional information** button.

2. Set the **Change view** drop-down list to `Code`.

3. Use the **Storage Class** column to change the storage class of `myParam` from `Define` to `ImportedDefine`.

4. For `myParam`, set **Header File** to `external_params.h`. The generated code imports the macro definition from a custom header file named `external_params.h`.

5. In your current folder, create the C header file `external_params.h`, which contains the `#define` statement.

```
#ifndef _EXTERNAL_PARAMS
#define _EXTERNAL_PARAMS

#define myParam 9.8

#endif

/* EOF */
```

7. Generate code from the model.

The generated header file `ex_param_macro.h` does not define the macro. Instead, the file includes (`#include`) the custom header file `external_params.h`.

```
/* Includes for objects with custom storage classes. */
#include "external_params.h"
```

The source file `ex_param_macro.c` contains a guard to check that a definition for `myParam` exists.

```
/*
 * Check that imported macros with storage class "ImportedDefine" are defined
 */
#ifndef myParam
#error The variable for the parameter "myParam" is not defined
```

```
#endif
```

Conditional Inclusions (#if / #endif)

You can generate preprocessor conditional directives in your code by implementing Variant Subsystem blocks in your model. In the generated code, preprocessor conditional directives select a section of code to execute at compile time. To implement variants in your model, see “Create a Simple Variant Model” (Simulink). To generate code for variants, see “Generate Preprocessor Conditionals for Variant Systems” on page 25-35.

Typedef

Create data type aliases by generating `typedef` statements.

C Construct

```
typedef float float_32;
```

Procedure

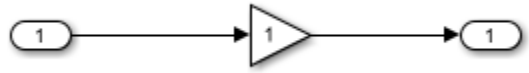
To create a data type alias in Simulink®, use a `Simulink.AliasType`. The code generator creates a `typedef` statement.

The built-in Simulink data type `single` corresponds to the C data type `float`.

1. At the command prompt, create a `Simulink.AliasType` object named `float_32` that represents an alias of `single`.

```
float_32 = Simulink.AliasType('single');
```

2. Open the example model `ex_typedef`.



3. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

4. In the Model Data Editor, open the **Inports/Outports** tab.

5. From the **Change View** drop-down list, select `Design`.

6. In the model, select the Inport block.

7. In the Model Data Editor, for the Inport block, set **Data Type** to `Refresh data types`.

8. In the Model Data Editor, for the Inport block, set **Data Type** to `float_32`.

9. From the **Change view** drop-down list, select `Code`.

10. For the Inport block, set **Signal Name** to `mySig`.

11. Set **Storage Class** to `ExportedGlobal`. The Inport block appears in the generated code as a separate global variable.

12. Generate code from the model.

Results

The generated header file `ex_typedef.h` defines the data type alias `float_32`.

```
#ifndef DEFINED_TYPEDEF_FOR_float_32_
#define DEFINED_TYPEDEF_FOR_float_32_

typedef real32_T float_32;

#endif
```

By default, the code generator also creates the alias `real32_T`, which corresponds to the C data type `float`. You can see the `typedef` statement in the generated header file `rtwtypes.h`.

```
typedef float real32_T;
```

The generated source file `ex_typedef.c` uses `float_32` to define the global variable mySig.

```
/* Exported block signals */
float_32 mySig;                        /* '<Root>/In1' */
```

`Simulink.AliasType`

Related Examples

- “Control Data Type Names in Generated Code” on page 34-2
- “Structures of Signals” on page 24-79

Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

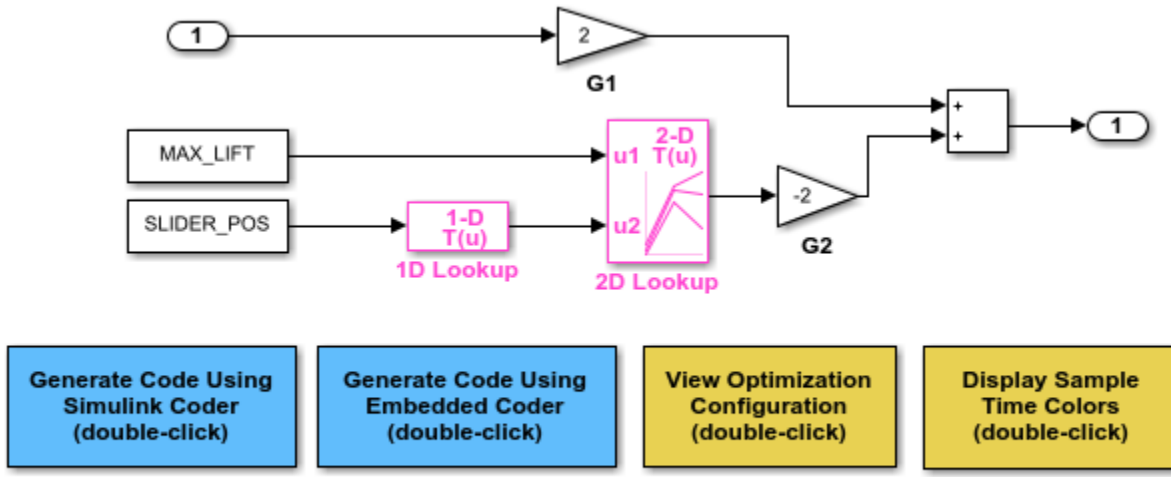
C Construct

```
typedef struct {
  double G1;
  double G2;
} myStructType;

myStructType myStruct = {
  2.0,
  -2.0
} ;
```

Procedure

1. Open the example model `rtwdemo_paraminline`.



2. Select **View > Model Data Editor**. In the Model Data Editor, select the **Parameters** tab.

3. In the model, click the Gain block labeled `G1`. In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `myStruct.G1`.

4. Set the value of the **Gain** parameter in the `G2` block to `myStruct.G2`.

5. Next to `myStruct.G2`, click the action button (with three vertical dots) and select **Create**.

6. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(struct)` and click **Create**. A `Simulink.Parameter` object named `myStruct` appears in the base workspace.

7. In the Simulink.Parameter property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.

8. Right-click the white space under the **Field** column and select **New**. Name the new structure field `G1`. Use the **Value** column to set the value of the field to `2`.

9. Add a field `G2` whose value is `-2`, and then close the Variable Editor.

10. In the Simulink.Parameter property dialog box, set **Storage class** to `ExportedGlobal`. The structure `myStruct` appears in the generated code as a global variable.

11. Generate code from the model.

Results

The generated header file `rtwdemo_paraminline_types.h` defines a structure type that has a random name a random name.

```
typedef struct {
  real_T G1;
  real_T G2;
} struct_6h72eH5WFuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```
/* Exported block parameters */
struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
  2.0,
  -2.0
} ;                                    /* Variable: myStruct
                                        * Referenced by:
                                        *   '<Root>/G1'
                                        *   '<Root>/G2'
                                        */
```

Specify Name of Structure Type

1. Optionally, specify a name to use for the structure type definition (`struct`). At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.

2. The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.

3. In the Model Data Editor, click the **Show/refresh additional information** button.

4. In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.

5. Generate code from the model.

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```
myStructType myStruct = {
  2.0,
```

```
  -2.0
} ;                                    /* Variable: myStruct
```

See Also

Related Examples

- “Organize Data into Structures in Generated Code” on page 32-181

Structures of Signals

This example shows how to create a structure of signal data in the generated code.

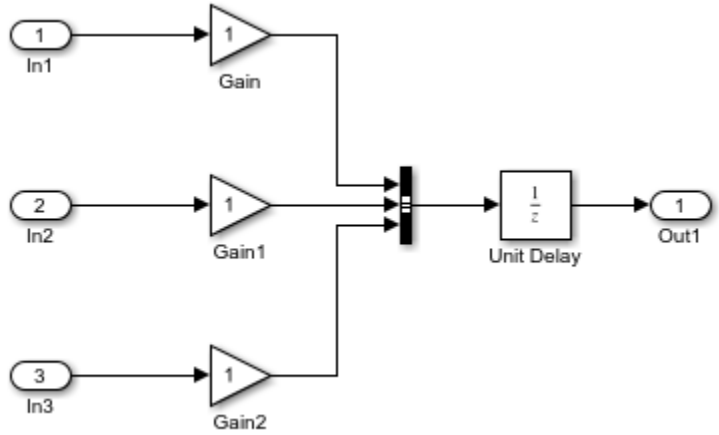
C Construct

```
typedef struct {
   double signal1;
   double signal2;
   double signal3;
} my_signals_type;
```

Procedure

1. To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

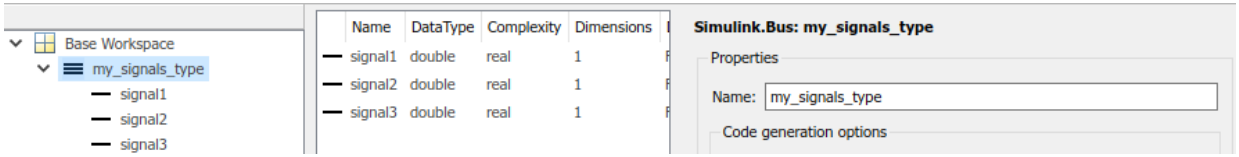
2. Create the `ex_signal_struct` model by using Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.



3. To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

4. In the model, select **Edit > Bus Editor**.

5. Use the Bus Editor to create a `Simulink.Bus` object named `my_signals_type` that contains three signal elements: `signal1`, `signal2`, and `signal3`. See “Create Bus Objects with the Bus Editor” (Simulink).



This bus object represents the structure type that you want the generated code to use.

6. In the Bus Creator block dialog box, set **Output data type** to `Bus: my_signals_type`.

7. Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

8. In the model, select **View > Model Data Editor**. In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select `Code`.

9. In the model, click the output signal of the Bus Creator block.

10. In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

11. Set **Storage Class** to `ExportedGlobal`. The output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

12. Generate code from the model.

Results

The generated header file `ex_signal_struct_types.h` defines the structure type `my_signals_type`.

```
typedef struct {
  real_T signal1;
  real_T signal2;
  real_T signal3;
} my_signals_type;
```

The source file `ex_signal_struct.c` allocates memory for the global variable `sig_struct_var`, which represents the output of the Bus Creator block.

```
/* Exported block signals */
my_signals_type sig_struct_var;        /* '<Root>/Bus Creator' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

Nested Structures of Signals

You can create nested structures of signal data in the generated code.

C Construct

```
typedef struct {
  double signal1;
  double signal2;
  double signal3;
} B_struct_type;

typedef struct {
  double signal1;
  double signal2;
} C_struct_type;

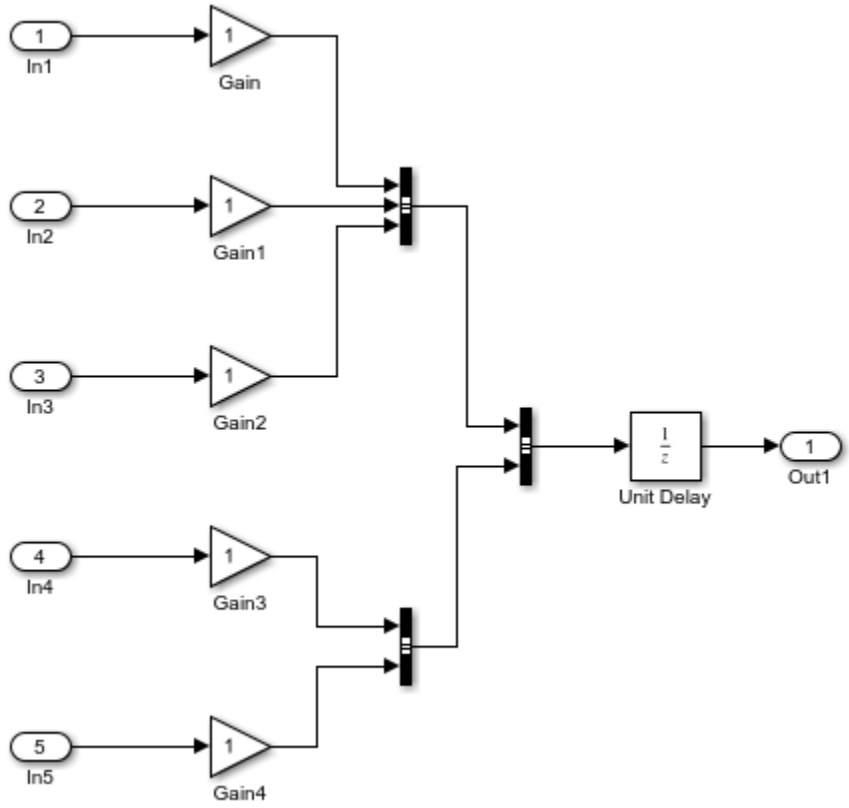
typedef struct {
  B_struct_type subStruct_B;
  C_struct_type subStruct_C;
} A_struct_type;
```

Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

To nest a structure inside another structure, use a bus object as the data type of a signal element in another bus object.

1. Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

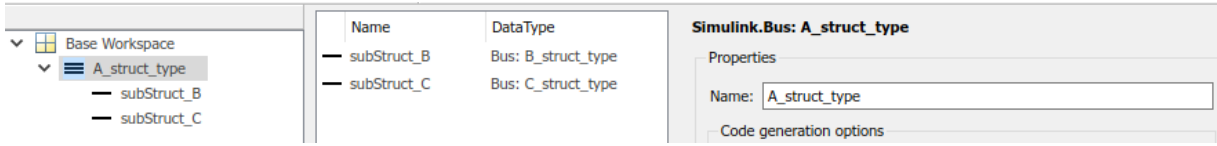


2. To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to `3`.

3. In the model, select **Edit > Bus Editor**.

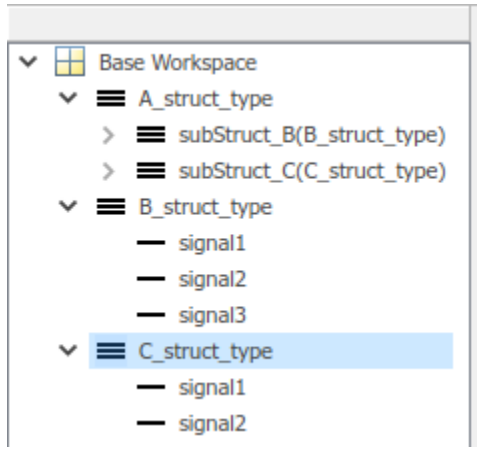
Use the Bus Editor to create a `Simulink.Bus` object named `A_struct_type` that contains two signal elements: `subStruct_B` and `subStruct_C`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink). This bus object represents the top-level structure type that you want the generated code to use.

4. For the `subStruct_B` element, set **DataType** to `Bus: B_struct_type`. Use a similar type name for `subStruct_C`.



Each signal element in `A_struct_type` uses another bus object as a data type. Now, these elements represent substructures.

5. Use the Bus Editor to create the `Simulink.Bus` objects `B_struct_type` (with three signal elements) and `C_struct_type` (with two signal elements).



6. In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to `Bus: B_struct_type`. Click **Apply**.

7. Select **Output as nonvirtual bus** and click **OK**.

8. In the dialog box of the other subordinate Bus Creator block, set **Output data type** to `Bus: C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

9. In the last Bus Creator block dialog box, set **Output data type** to `Bus: A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

10. In the model, select **View > Model Data Editor**.

11. In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select `Code`.

12. In the model, click the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block.

13. In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

14. Set **Storage Class** to `ExportedGlobal`. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

15. Generate code from the model.

Results

The generated header file `ex_signal_nested_struct_types.h` defines the structure types. Each structure type corresponds to a `Simulink.Bus` object.

```
typedef struct {
  real_T signal1;
  real_T signal2;
  real_T signal3;
} B_struct_type;

typedef struct {
  real_T signal1;
  real_T signal2;
} C_struct_type;

typedef struct {
  B_struct_type subStruct_B;
  C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is `Bus Creator2`.

```
/* Exported block signals */
A_struct_type sig_struct_var;          /* '<Root>/Bus Creator2' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

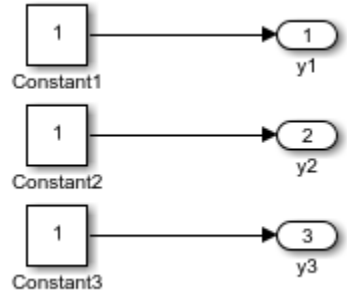
Bitfields

C Construct

```
typedef struct {
   unsigned int p1 : 1;
   unsigned int p2 : 1;
   unsigned int p3 : 1;
} my_struct_type
```

Procedure

1. Open example model `ex_struct_bitfield_CSC`. The model contains three Constant blocks and three Outport blocks.



2. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the Model Data Editor, on the **Parameters** tab, in the **Value** column, observe that the value of the first Constant block is `p1`. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.

4. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(false)`. Click **Create**. A `Simulink.Parameter` object, `p1`, appears in the base workspace. The object stores a Boolean value, `false`, and uses the data type `boolean`.

5. In the `Simulink.Parameter` property dialog box, click **OK**.

6. Use the Model Data Editor to configure the other Constant blocks to refer to new parameter objects named `p2` and `p3`.

7. In the Model Data Editor, click the **Show/refresh additional information** button.

8. Set the **Change view** drop-down list to `Code`.

9. Use the **Storage Class** column to apply the custom storage class `BitField` to all parameter objects.

10. Use the **Struct Name** column to configure each object to use the same structure type, `my_struct`.

11. Generate code from the model.

Results

The generated header file `ex_struct_bitfield_CSC.h` defines the structure type `my_struct_type`.

```
/* Type definition for custom storage class: BitField */
typedef struct myStruct_tag {
  uint_T p1 : 1;
  uint_T p2 : 1;
  uint_T p3 : 1;
} myStruct_type;
```

The generated source file `ex_struct_bitfield_CSC.c` defines and initializes the structure variable `my_struct`.

```
/* Definition for custom storage class: BitField */
myStruct_type myStruct = {
  /* p1 */
  0,

  /* p2 */
  0,

  /* p3 */
```

```
  0
};
```

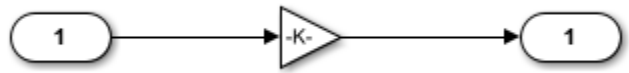
Arrays for Parameters

C Construct

```
float myParams[5]= {1.0F,2.0F,3.0F,4.0F,5.0F};
```

Procedure

1. Create the `ex_param_array` model by using a Gain block.



2. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the model, select the Gain block. In the Property Inspector, set the value of the **Gain** parameter to `myParam`.

4. Next to the parameter value, click the action button (the button with three vertical dots) and select **Create**.

5. In the Create New Data dialog box, set **Value** to `Simulink.Parameter ([1 2 3 4 5])`. Click **Create**. A `Simulink.Parameter` object, `myParam`, appears in the base workspace. The Gain block uses the object to set the value of the Gain parameter.

6. In the `Simulink.Parameter` property dialog box, set **Storage class** to `ExportedGlobal`. Click OK.

With this setting, `myParams` appears in the generated code as a separate global variable.

7. Set **Data type** to `single`. Click **OK**.

8. Generate code from the model.

Results

The generated source file `ex_param_array.c` defines and initializes the global variable `myParams`.

```
/* Exported block parameters */
```

```
real32_T myParam[5] = { 1.0F, 2.0F, 3.0F, 4.0F, 5.0F } ;/* Variable: myParam
                                                         * Referenced by: '<Root>/Gain
                                                         */
```

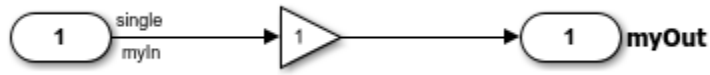
Arrays for Signals

C Construct

```
double myIn[5];
double myOut[5];
```

Procedure

1. Open example model `ex_signal_array`.



2. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the Model Data Editor, select the **Inports/Outports** tab.

4. From the **Change View** drop-down list, select `Design`.

Observe these settings:

- For the Inport block, the **Signal Name** is `myIn` and Dimensions is `[5 1]`.
- For the Outport block, the **Signal Name** is `myOut`.

5. From the **Change View** drop-down list, select `Code`.

6. For the Inport block and the Outport block, the **Storage Class** is `ExportedGlobal`. With this setting, the blocks appear in the generated code as separate global variables.

7. Generate code from the model.

Results

The generated source file `ex_signal_array.c` defines the global variables `myIn` and `myOut` as arrays with 5 elements each.

```
/* Exported block signals */
```

```
real32_T myIn[5];                      /* '<Root>/In1' */
real32_T myOut[5];                     /* '<Root>/Out1' */
```

Pointers

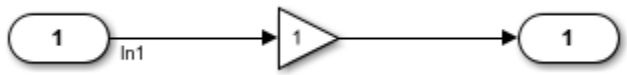
When your handwritten code allocates memory for signal, state, or parameter data, you can generate code that accesses that data through a pointer. Apply a storage class such as `ImportedExternPointer` to a data item in the model. Your handwritten code provides the pointer definition.

C Construct

```
extern double *myIn;
```

Procedure

1. Open example model `ex_pointer`.



2. The model opens in Simulink Editor code perspective mode. If it does not, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3. In the Model Data Editor, select the **Inports/Outports** tab.

4. From the **Change View** drop-down list, select `Code`.

For the Inport block, **Signal Name** is `In1` and **Storage Class** is `ImportedExternPointer`.

5. Generate code from the model.

Results

The generated header file `ex_pointer.h` declares the pointer.

```
/* Imported (extern) pointer block signals */
extern real_T *In1;                    /* '<Root>/In1' */
```

In the generated source file `ex_pointer.c`, in the model step function, the algorithm dereferences the pointer, `In1`.

```
/* Model step function */
void ex_pointer_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Inport: '<Root>/In1'
   */
  rtY.Out1 = *In1;
}
```

Variant Systems in Embedded Coder

Implement Dimension Variants for Array Sizes in Generated Code

Dimension Variants

Use symbolic dimensions to simulate various sets of dimension choices without regenerating code for every set. Set up your model with dimensions that you specify as symbols in blocks and data objects. These symbols propagate throughout the model during simulation, and then go into the generated code. Modeling constraints for symbols during simulation (for example, `C=A+B`) are output as preprocessor conditionals in either the `model.h` or the *`model`* `_types.h` file.

You can directly specify dimension information as a symbol or a numeric constant for these blocks and data objects:

- Inport
- Outport
- Signal Specification
- Data Store Memory
- Interpreted MATLAB Function
- `Simulink.Signal`
- `Simulink.Parameter`
- `Simulink.BusElement`
- `AUTOSAR.Parameter`

The Data Store Memory and Interpreted MATLAB Function blocks also support variable dimension signals. For these blocks, the symbolic dimensions control the maximum allowed size.

You must provide the code for `Simulink.Parameter` objects that contain symbolic dimensions. You can provide this code by using the `ImportedExtern` or `ImportedExternPointer` built-in storage classes.

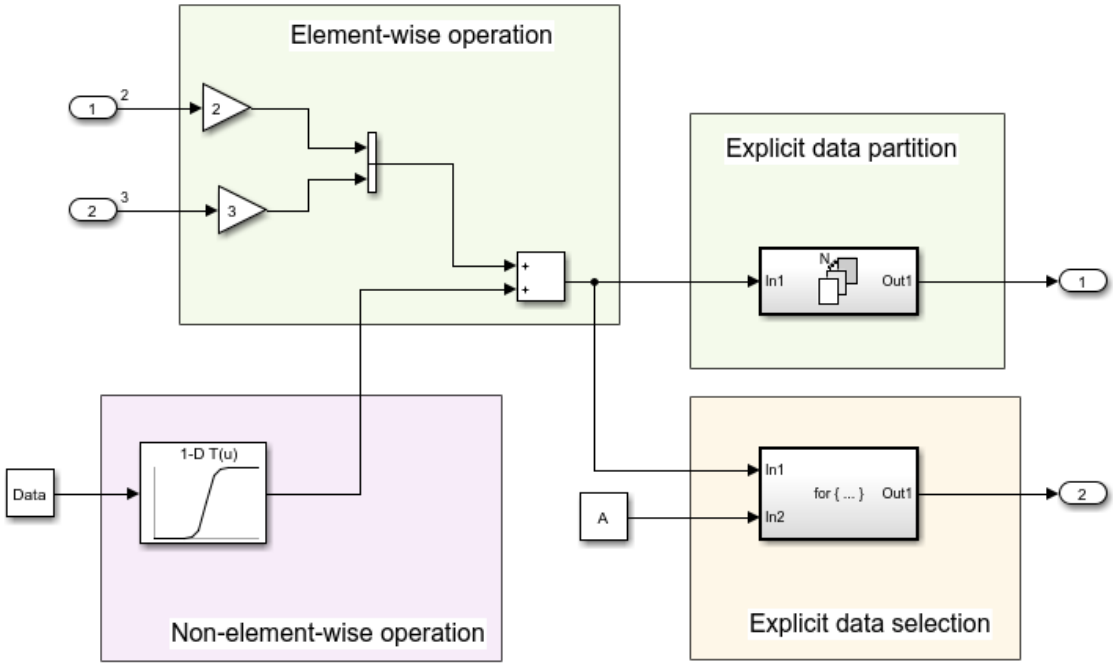
You use `Simulink.Parameter` objects to specify dimension information as symbols. For more information on signal dimensions, see “Signal Dimensions” (Simulink).

You must fix symbolic dimension values at compile-time. You can not resolve a symbolic dimension to another variable and then vary it during run-time because you define the behavior during simulation.

Note: The dimension variants feature is on by default. You can turn off this feature by clearing the “Allow symbolic dimension specification” (Simulink) parameter in the Configuration Parameters dialog box.

Define Symbolic Dimensions

This example uses the model `rtwdemo_dimension_variants` to show how to implement symbolic dimensions. This model has four modeling patterns involving vectors and matrices.



1. To show block names, on the **Display** menu, deselect **Hide Automatic Names**.
2. Open the Model Explorer. Select the base workspace pane.

3. In the base workspace, there are four `Simulink.Parameter` objects for specifying symbolic dimensions. These `Simulink.Parameter` objects have the names `A`, `B`, `C`, and `D`.
4. Select the `Simulink.Parameter` object `A`. Review the information in the Simulink.Parameter dialog box. `A` has a storage class of `CompilerFlag`.
5. Repeat Step 4 for each of the `Simulink.Parameter` objects `B`, `C`, and `D`.
6. For `Simulink.Parameter` objects with an `ImportedDefine` custom storage class, provide a header file on the MATLAB path. Insert the name of the header file in the **HeaderFile** field in the Simulink.Parameter dialog box.

To use a Simulink.Parameter object for dimension specification, it must be defined in the base workspace and have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- User-defined custom storage class that defines data as a macro in a specified header file

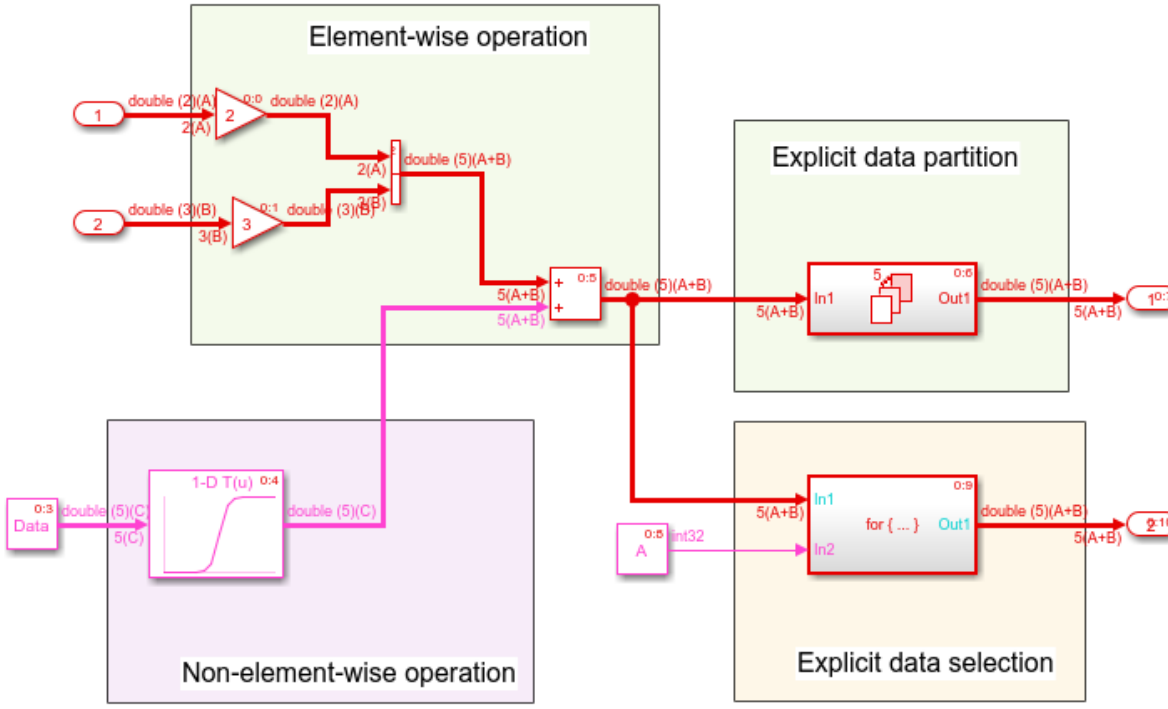
You can use MATLAB expressions to specify symbolic dimensions. For a list of supported MATLAB expressions, see the section Operators and Operands in Variant Condition Expressions in “Introduction to Variant Controls” (Simulink).

Specify Symbolic Dimensions for Blocks and Data Objects

1. Open the Source Block Parameters dialog box of Inport Block `In2`. In the **Signal Attributes** tab, the **Port Dimensions** field contains the `Simulink.Parameter` object `A`. For Inport blocks, you specify symbolic dimensions in the **Port Dimensions** field.
2. Open the Source Block Parameters dialog box of Inport block `In3`. In the **Signal Attributes** tab, the **Port Dimensions** field contains the `Simulink.Parameter` object `B`.
3. In the base workspace, select the `Simulink.Parameter` object `Data`. In the Simulink.Parameter dialog box for `Data`, the Dimension field has the character vector `'[1,C]'` , which is equivalent to `'[1,5]'` because `C` has a value of `5`. The **Value** field contains an array with `5` values, so the dimensions of `C` are consistent with the dimension of the `Data` object. The dimensions of the `Data` object must always be consistent with the value of the `Simulink.Parameter` object that is in the `Data` object **Dimensions** field. `Data` has a **Storage class** of `ImportedExtern`. A `Simulink.Parameter` object that uses a `Simulink.Parameter` for symbolic

dimension specification must have a storage class of either `ImportedExtern` or `ImportedExternPointer`.

4. Open the Block Parameters dialog box of the `1-D Lookup Table1` block. The **Table data** field contains the `Simulink.Parameter`, `PT`. The **Breakpoints 1** field contains the `Simulink.Parameter`, `PB`.
5. In the base workspace, view the information in the Simulink.Parameter dialog boxes for `PB` and `PT`. These parameters contain the character vector `'[1,D]'` in their **Dimensions** field and are arrays consisting of 15 values. The dimension of `D` are consistent with the dimension of the `PB` and `PT` parameters because `D` has a value of `15` .
6. Simulate the model. Simulink propagates the dimensions symbolically in the diagram. During propagation, Simulink establishes modeling constraints among symbols. Simulink then checks for consistency with these constraints based on current numerical assignments. One modeling constraint for `rtwdemo_dimension_variants` is that `C=A+B`. The **Diagnostic Viewer** produces a warning for any violations of constraints.
7. Change the dimension specification to a different configuration and simulate the model again.



Though not shown in this example, you can specify an n-D dimension expression with one or more of the dimensions being a symbol (for example, `'[A,B,C]'` or `'[1,A,3]'`).

Generate Code for a Model with Dimension Variants

Once you have verified dimension specifications through model simulation, generate code for `rtwdemo_dimension_variants`.

Create a temporary folder for the build and inspection process.

```
currentDir = pwd;
[~,cgDir] = rtwdemodir();
```

Build the model.

```
model='rtwdemo_dimension_variants';
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_dimension_variants
### Successful completion of build procedure for model: rtwdemo_dimension_variants
```

View the generated code. In the `rtwdemo_dimension_variants.h` file, symbolic dimensions are in data declarations.

```
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'/* External inputs', '/* Real-time', 1, 0);
```

```
/* External inputs (root inport signals with default storage) */
typedef struct {
  real_T In2[A];                       /* '<Root>/In2' */
  real_T In3[B];                       /* '<Root>/In3' */
} ExtU;

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
  real_T Out1[(A + B)];                /* '<Root>/Out1' */
  real_T Out2[(A + B)];                /* '<Root>/Out2' */
} ExtY;
```

The `rtwdemo_dimension_variants.h` file contains data definitions and preprocessor conditionals that define constraints established among the symbols during simulation. One of these constraints is that the value of a symbolic dimension must be greater than `1`. This file also includes the user-provided header file for any `Simulink.Parameter` objects with an `ImportedDefine` custom storage class.

```
hfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.h');
rtwdemodbtype(hfile,'#ifndef A', '/* Macros for accessing', 1, 0);
```

```
#ifndef A
#error The variable for the parameter "A" is not defined
#endif

#ifndef B
#error The variable for the parameter "B" is not defined
#endif

#ifndef C
#error The variable for the parameter "C" is not defined
#endif

#ifndef D
```

```
#error The variable for the parameter "D" is not defined
#endif

/*
 * Constraints for division operations in dimension variants
 */
#if (1 == 0) || (((A+B) % 1) != 0)
# error "The preprocessor definition '1' must not be equal to zero and     the divisio
#endif

/*
 * Registered constraints for dimension variants
 */
/* Constraint 'C == (A+B)' registered by:
 * '<Root>/1-D Lookup Table1'
 */
#if C != (A+B)
# error "The preprocessor definition 'C' must be equal to '(A+B)'"
#endif

#if A <= 1
# error "The preprocessor definition 'A' must be greater than '1'"
#endif

#if B <= 1
# error "The preprocessor definition 'B' must be greater than '1'"
#endif

/* Constraint 'D > 1' registered by:
 * '<Root>/1-D Lookup Table1'
 */
#if D <= 1
# error "The preprocessor definition 'D' must be greater than '1'"
#endif

/* Constraint 'C > 1' registered by:
 * '<S2>/Assignment'
 */
#if C <= 1
# error "The preprocessor definition 'C' must be greater than '1'"
#endif
```

In the `rtwdemo_dimension_variants.c` file, symbolic dimensions participate in loop bound calculations, array size and index offset calculations, and a parameterized utility function (for example, Lookup Table block) calculation.

```
cfile = fullfile(cgDir,'rtwdemo_dimension_variants_ert_rtw',...
    'rtwdemo_dimension_variants.c');
rtwdemodbtype(cfile,'/* Model step', '/* Model initialize', 1, 0);
```

```
/* Model step function */
void rtwdemo_dimension_variants_step(void)
{
  real_T rtb_VectorConcatenate[A + B];
  int32_T s2_iter;
  int32_T ForEach_itr;
  real_T rtb_VectorConcatenate_m;

  /* Gain: '<Root>/Gain' incorporates:
   *  Inport: '<Root>/In2'
   */
  for (ForEach_itr = 0; ForEach_itr <= (int32_T)(A - 1); ForEach_itr++) {
    rtb_VectorConcatenate[ForEach_itr] = 2.0 * rtU.In2[ForEach_itr];
  }

  /* End of Gain: '<Root>/Gain' */

  /* Gain: '<Root>/Gain1' incorporates:
   *  Inport: '<Root>/In3'
   */
  for (ForEach_itr = 0; ForEach_itr <= (int32_T)(B - 1); ForEach_itr++) {
    rtb_VectorConcatenate[(int32_T)(A + ForEach_itr)] = 3.0 *
      rtU.In3[ForEach_itr];
  }

  /* End of Gain: '<Root>/Gain1' */

  /* Outputs for Iterator SubSystem: '<Root>/For Each Subsystem' incorporates:
   *  ForEach: '<S1>/For Each'
   */
  for (ForEach_itr = 0; ForEach_itr <= (int32_T)((int32_T)(A + B) - 1);
       ForEach_itr++) {
    /* Sum: '<Root>/Add' incorporates:
     *  Constant: '<Root>/Constant'
     *  Lookup_n-D: '<Root>/1-D Lookup Table1'
     */
    rtb_VectorConcatenate_m = rtb_VectorConcatenate[ForEach_itr] + look1_binlx
```

```
      (Data[ForEach_itr], PB, PT, (uint32_T)((uint32_T)D - 1U));

    /* ForEachSliceAssignment: '<S1>/ImpAsg_InsertedFor_Out1_at_inport_0' incorporates
     *  MATLAB Function: '<S1>/MATLAB Function'
     */
    /* MATLAB Function 'For Each Subsystem/MATLAB Function': '<S3>:1' */
    /* '<S3>:1:4' y = 2*u; */
    rtY.Out1[ForEach_itr] = 2.0 * rtb_VectorConcatenate_m;

    /* Sum: '<Root>/Add' */
    rtb_VectorConcatenate[ForEach_itr] = rtb_VectorConcatenate_m;
  }

  /* End of Outputs for SubSystem: '<Root>/For Each Subsystem' */

  /* Outputs for Iterator SubSystem: '<Root>/For Iterator Subsystem' incorporates:
   *  ForIterator: '<S2>/For Iterator'
   */
  /* Constant: '<Root>/Constant1' */
  for (s2_iter = 0; s2_iter < ((int32_T)A); s2_iter++) {
    /* Assignment: '<S2>/Assignment' incorporates:
     *  Constant: '<S2>/Constant'
     *  Outport: '<Root>/Out2'
     *  Product: '<S2>/Product'
     *  Selector: '<S2>/Selector'
     */
    if (s2_iter == 0) {
      for (ForEach_itr = 0; ForEach_itr <= (int32_T)((int32_T)(A + B) - 1);
           ForEach_itr++) {
        rtY.Out2[ForEach_itr] = rtb_VectorConcatenate[ForEach_itr];
      }
    }

    rtY.Out2[s2_iter] = rtb_VectorConcatenate[s2_iter] * 2.0;

    /* End of Assignment: '<S2>/Assignment' */
  }

  /* End of Constant: '<Root>/Constant1' */
  /* End of Outputs for SubSystem: '<Root>/For Iterator Subsystem' */
}
```

Close the model and code generation report.

```
bdclose(model)
rtwdemoclean;
cd(currentDir)
```

Set Parameter Value Based on Variant Choice

When you specify the dimensions of a parameter in a model by using a symbol, you must make sure that the parameter value is consistent with the dimension value. To simulate different choices for the dimension value, you must manually correct the parameter value.

For example, in the `rtwdemo_dimension_variants` model , the `Simulink.Parameter` object `Data` stores a vector value, `[1 2 3 4 5]`, and uses a symbolic dimension `C` with initial value `5`. If you change the value of `C`, to simulate the model, you must make sure the number of elements in the vector value matches the new value of `C`.

To reduce the effort of maintenance when you change the value of `C`, you can set the value of `Data` to an expression involving `C`.

1. Open the model.

   ```
   rtwdemo_dimension_variants
   ```
2. At the command prompt, inspect the initial values of `Data` and `C`. The value of `Data` is a vector of integers from `1` to `C`.

   ```
   Data.Value
   ```

   ```
   ans =

        1     2     3     4     5
   ```

   ```
   C.Value
   ```

   ```
   ans =

        5
   ```
3. In MATLAB code syntax, the value of `Data` is `1:C`. To preserve this relationship between the parameter objects, set the value of `Data` by using the `slexpr` function.

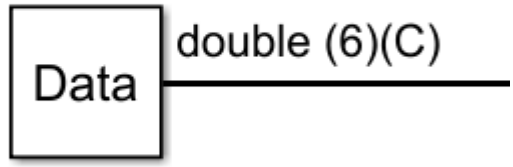
   ```
   Data.Value = slexpr('1:C');
   ```
4. To prevent data type propagation errors, set the data type of `Data` explicitly to `double`, which is the data type that the parameter acquired before you set the parameter value to an expression.

```
Data.DataType = 'double';
```

5 Set the value of `C` to a different number, such as `6`. Due to dimension constraints in the model, you must set the value of another dimension symbol, `A`, to `3`.

```
C.Value = 6;
A.Value = 3;
```

6 Simulate the model. The block diagram shows that the value of `Data` now has six elements.



For more complicated applications, you can write your own MATLAB function that returns parameter values based on dimension symbols. Set the value of the parameter data to an expression that calls your function.

For general information about using an expression to set the value of a `Simulink.Parameter` object, see “Set Variable Value by Using a Mathematical Expression” (Simulink).

Code Generation Optimization Considerations

When you create a model with symbolic dimensions, be aware of the following optimization considerations:

- The code generator reuses buffers only if dimension propagation establishes equivalence among buffers.
- Two loops with symbolic loop bound calculations are fused together only if they share equivalent symbolic expression.

- Optimizations do not eliminate a symbolic expression or condition check based on the current value of a symbolic dimension.

Backward Compatibility

If an existing model uses `Simulink.Parameter` objects to specify dimensions, it can be incompatible with dimension variants. Here are two common scenarios:

- Only a subset of blocks accepts symbolic dimension specifications. If a block is not compatible with symbolic dimensions, it causes an update diagram error.
- `Simulink.Parameter` objects that you use to define symbolic dimensions or have symbolic dimensions must have one of the storage classes described in this example. If these specifications are not met, the build procedure for the model fails during code generation.

You can address these backward compatibility issues by doing the following:

- Turn off dimension variants feature by clearing the **Allow symbolic dimension specification** parameter in the Configuration Parameters dialog box.
- Update `Simulink.Parameter` objects that define symbolic dimensions or have symbolic dimension specifications.
- Update the model so that only supported blocks have symbolic dimensions or propagate symbolic dimensions.

Supported Blocks

For a list of supported blocks, see the Block Support Table. To access the information in this table, enter `showblockdatatypetable` at the MATLAB command prompt. Unsupported blocks (for example, MATLAB Function) can still work in a model containing symbolic dimensions as long as these blocks do not directly interact with symbolic dimensions.

In the following cases, supported blocks do not propagate symbolic dimensions.

- For `Unit Delay` blocks, you specify a `Simulink.Signal` object that has symbolic dimensions for the **Block Parameters** > **State Attributes** > **State name** parameter.
- For Assignment and Selector blocks, you set the **Block Parameters** > **Index Option** parameter to `Index vector (dialog)`. For Selector and Assignment blocks, if you specify a symbolic dimension for the Index parameter, the code generator does not honor the symbolic dimension in the generated code.

- For the Sum block, you specify `|+` for the **Block Parameters > List of signs** parameter, and you set the **Block Parameters > Sum over** parameter to `Specified dimension`.
- For the Product block, you specify a value of `1` for the **Block Parameters > Number of inputs** parameter, and you set the **Multiply over** parameter to `Specified dimensions`.
- For the ForEach block, you specify a symbolic dimension for the **Partition Width** parameter.

Note that the following modeling patterns are among those modeling patterns that can cause Simulink to error out:

- For Switch blocks, an input signal or the **Threshold** parameter has symbolic dimensions, and you select **Allow different data input sizes (Results in variable-size output signal)**.
- A Data Store Read block selects elements of a `Simulink.Bus` signal that has symbolic dimensions.
- For Lookup Table blocks, on the **Block Parameters > Algorithm** tab, you select the parameter **Use one input port for all input data**.

Limitations

The following products and software capabilities support dimension variants in that they act on the numeric value of a symbolic dimension. These features do not support the propagation of symbolic dimensions during model simulation and the preservation of symbolic dimensions in the generated code.

- Code Replacement for Lookup Tables
- Software-in-the-Loop (SIL) and Processor-in-the-Loop (PIL) simulations
- Accelerator and rapid accelerator simulation modes
- Scope and simulation observation (for example, logging, SDI, and so on)
- Model coverage
- Simulink Design Verifier
- Fixed-Point Designer
- Data Dictionary
- Simulink PLC Coder

- HDL Coder

The following do not support dimension variants:

- System Object
- Stateflow
- Physical modeling
- Discrete-event simulation
- Frame data
- MATLAB functions

The following limitations also apply to models that utilize symbolic dimensions.

- For simulation, the size of a symbolic dimension can equal 1. For code generation, the size of a symbolic dimension must be greater than `1`.
- If a symbolic dimension is a MATLAB expression that contains an arithmetic expression and either a relational or logical expression, you must add `+0` after the relational or logical part of the MATLAB expression. If you do not add `+0`, the model errors out during simulation because you cannot mix a `boolean` data type with integer or `double` data types. Adding `+0` converts the data type of the relational or logical part of the expression from a `boolean` to a `double`.

  For example, suppose in the Inport block parameters dialog box, the **Port dimensions** parameter has the expression `[(C==8)*D+E,3]`. The **Data type** parameter is set to `double`. Since `C==8` is a relational expression, you must change the expression to `[((C==8)+0)*D+E,3]` to prevent the model from producing an error during simulation.
- Simulink propagates symbolic dimensions for an entire structure or matrix, but not for a part of a structure or matrix. For example, the `Simulink.Parameter` `P` is a `2x3` matrix with symbolic dimensions `[Dim,Dim1]`.

  ```
  p=Simulink.Parameter(struct('A',[1 2 3;4 5 6]))
  p.DataType='Bus:bo'
  bo=Simulink.Bus
  bo.Elements(1).Name='A'
  bo.Elements(1).Dimensions='[Dim,Dim1]'
  Dim=Simulink.Parameter(2)
  Dim1=Simulink.Parameter(3)
  p.CoderInfo.StorageClass='Custom'
  p.CoderInfo.CustomStorageClass='Define'
  ```

```
Dim.CoderInfo.StorageClass='Custom'
Dim.CoderInfo.CustomStorageClass='Define'
Dim1.CoderInfo.StorageClass='Custom'
Dim1.CoderInfo.CustomStorageClass='Define'
```

If you specify `p.A` for a dimensions parameter, Simulink propagates the symbolic dimensions `[Dim,Dim1]`. If you specify `p.A(1,:)`, Simulink propagates the numeric dimension `3` but not the symbolic dimension, `Dim1`.

- The MATLAB expression `A(:)` does not maintain symbolic dimension information. Use `A` instead.
- The MATLAB expression `P(2:A)` does not maintain symbolic dimension information. Use the Selector block instead.
- The MATLAB expression `P(2,:)` is not a tunable expression, so it does not maintain symbolic dimension information.
- Suppose that you set the value of a mask parameter, `myMaskParam`, by using a field of a structure or by using a subset of the structures in an array of structures. You store the structure or array of structures in a `Simulink.Parameter` object so that you can use a `Simulink.Bus` object to apply symbolic dimensions to the structure fields. Under the mask, you configure a block parameter to use one of the fields that have symbolic dimensions. The table shows some example cases.

Description	Value of mask parameter (`myMaskParam`)	Value of block parameter
`myStruct` is a structure with field `gains`, which uses symbolic dimensions.	`myStruct.gains`	`myMaskParam`
`myStruct` is a structure with field hierarchy `myStruct.subStruct.gains`. The field `gains` uses symbolic dimensions.	`myStruct.subStruct`	`myMaskParam.gains`
`myStructs` is an array of structures. Each structure has a field `gains`, which uses symbolic dimensions.	`myStructs(2)`	`myMaskParam.gains`

In these cases, you cannot generate code from the model. As a workaround, choose one of these techniques:

- Use the entire structure (`myStruct`) or array of structures (`myStructs`) as the value of the mask parameter. Under the mask, configure the block parameter to dereference the target field from the mask parameter by using an expression such as `myMaskParam.subStruct.gains`.
- Use literal dimensions instead of symbolic dimensions for the target field (`gains`).

This limitation also applies when you use a field of a structure or a subset of the structures in an array of structures as the value of a model argument in a Model block.

Code Generation for Variant Blocks

The code generator produces code from a Simulink model containing one or more Variant Subsystem, Variant Source, and Variant Sink blocks. To learn how to create a model containing variant blocks, see “Create a Simple Variant Model” (Simulink). To learn how to create a custom Model Advisor check that evaluates the generated code from active and inactive variant paths in a variant system model, see “Create Custom Check to Evaluate Active and Inactive Variant Paths from a Model” (Simulink Check).

Note During code generation, a warning related to 'Code generation function packaging' for the Variant block might be displayed. In the block parameters dialog of the Variant block, click **Code Generation** and then select `Reusable function` from the **Function packaging** drop-down list to solve this issue.

Code is generated for different variant choices, the active variant, and the default variant. To generate code for variants, set the following conditions in the Variant Subsystem, Variant Source, or Variant Sink block:

- Select `Expression` as **Variant Control mode** from the block parameters dialog.
- Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.

Code generated for Variant Subsystem blocks is surrounded by C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Code generated for Variant Source and Variant Sink blocks is surrounded by C preprocessor conditionals `#if` and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

To construct variant models and generate preprocessor directives in the generated code, see the example “Use Variant Models to Generate Code That Uses C Preprocessor Conditionals” on page 25-68.

To construct variant subsystems and generate preprocessor directives in the generated code, see the example “Use Variant Subsystem To Generate Code That Uses C Preprocessor Conditionals” on page 25-61.

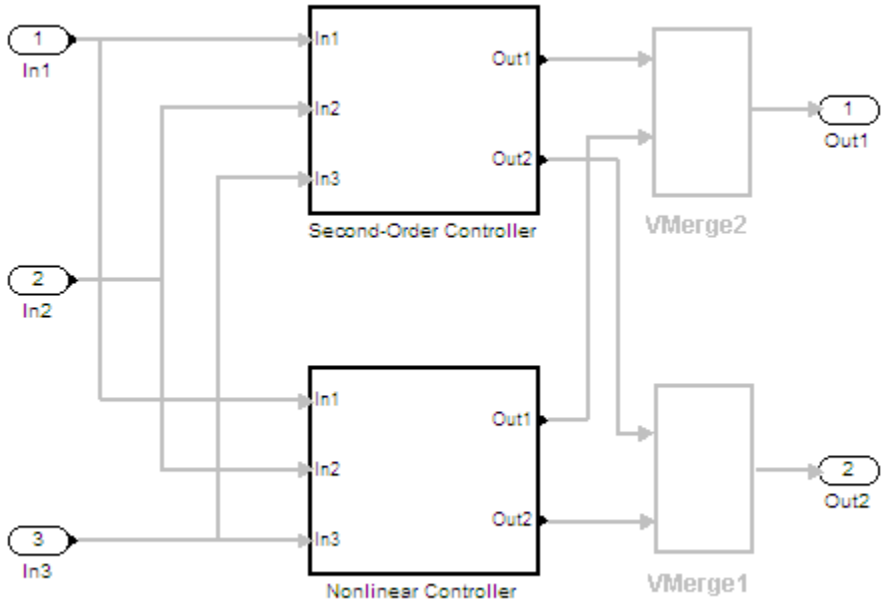
To construct models with variant sources and sinks and generate preprocessor directives in the generated code, see the example “Represent Variant Source and Sink Blocks in Generated Code” on page 25-42.

Restrictions on Variant Subsystem Code Generation

To generate preprocessor conditionals, the types of blocks that you can place within the child subsystems of a Variant Subsystem block are limited. Connections are not allowed in the Variant Subsystem block diagram. However, during the code generation process, one `VariantMerge` block is placed at the input of each Outport block within the Variant Subsystem block diagram. All of the child subsystems connect to each of the `VariantMerge` blocks.

In the figure below, the code generation process makes the following connections and adds `VariantMerge` blocks to the sldemo_variant_subsystems model.

When compared to a generic Merge block the `VariantMerge` block can have only one parameter which is the number of Inputs. The `VariantMerge` block is used for code generation in variant subsystems internally, and is not available externally to be used in models. The number of inputs for `VariantMerge` is determined and wired as shown in the figure below.



The child subsystems of the Variant Subsystem block must be atomic subsystems. Select **Treat as atomic unit** parameter in the Subsystem block parameters dialog, to make the subsystems atomic. The `VariantMerge` blocks are inserted at the outport of the subsystems if more than one child subsystems are present. If the source block of a `VariantMerge` block input is nonvirtual, an error message will be displayed during code generation. You must make the source block contiguous, by inserting Signal Conversion blocks inside the variant choices. The signals that enter a Variant Subsystem block must have the same signal properties (for example, signal dimensions, port width, and storage class). The `VariantMerge` block does not support different signal properties because the input ports and output ports share the same memory. You can use symbolic dimensions to generate code for a variant subsystem with child subsystems of different output signal dimensions.

Generated Code Components Not Compiled Conditionally

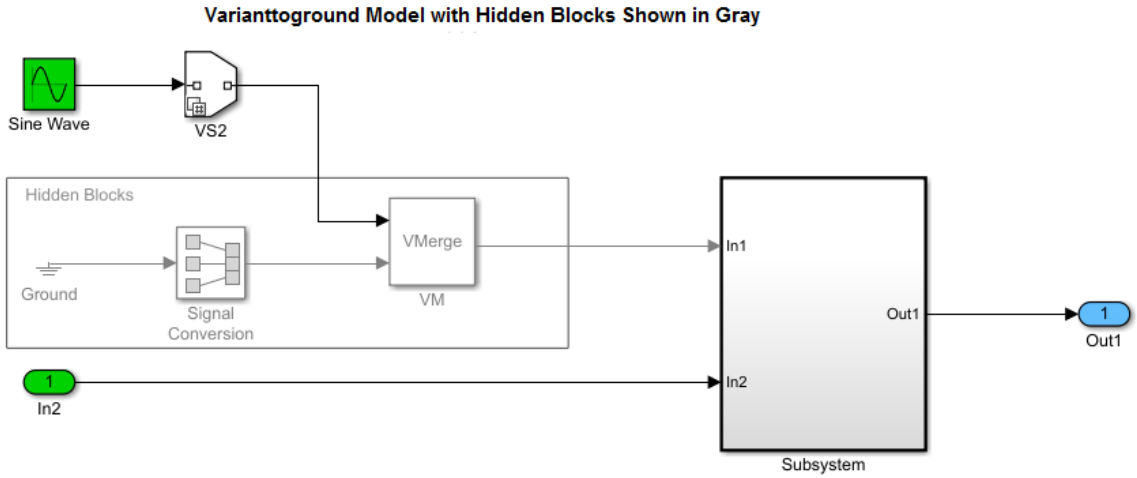
The following components are not conditionally compiled even if only code for variant subsystems or models that are conditionally compiled reference them.

- `rtModel` data structure fields
- `#include`'s of utility files
- Global constant parameter structure fields that are referenced by multiple subsystems activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are referenced by multiple subsystems that are activated by different variants
- Parameters that are configured to use an imported, exported, or custom code generation storage class, and are used by variant model blocks

Code Generation for Variant Blocks with One Variant Choice

For modeling patterns in which a Root Inport block connects to a Variant block with one variant choice, Simulink inserts a hidden block combination of a Ground block, Signal Conversion block, and a Variant Merge block. If the variant choice evaluates to false, this block combination produces an output of `0.0`.

For example, the model `Varianttoground` contains a Variant Source block with one variant choice. When the Variant Control `SYSCONST_A==6` evaluates to true, the input to `Subsystem` is a sine wave. When `SYSCONST_A==6` evaluates to false, the input to `Subsystem` is `0.0`.



The `varianttoground.c` file contains this code:

```
/* Sin: '<Root>/Sine Wave' */
#if SYSCONST_A == 6

  varianttoground_B.VM_Conditional_Signal_Subsystem_0_r64 = sin
    (varianttoground_M->Timing.t[0]);

#endif                                 /* SYSCONST_A == 6 */

  /* End of Sin: '<Root>/Sine Wave' */

  /* SignalConversion: '<Root>/VM_SignalConversion_Subsystem_0' */
#if SYSCONST_A != 6

  varianttoground_B.VM_Conditional_Signal_Subsystem_0_r64 = 0.0;

#endif                                 /* SYSCONST_A != 6 */

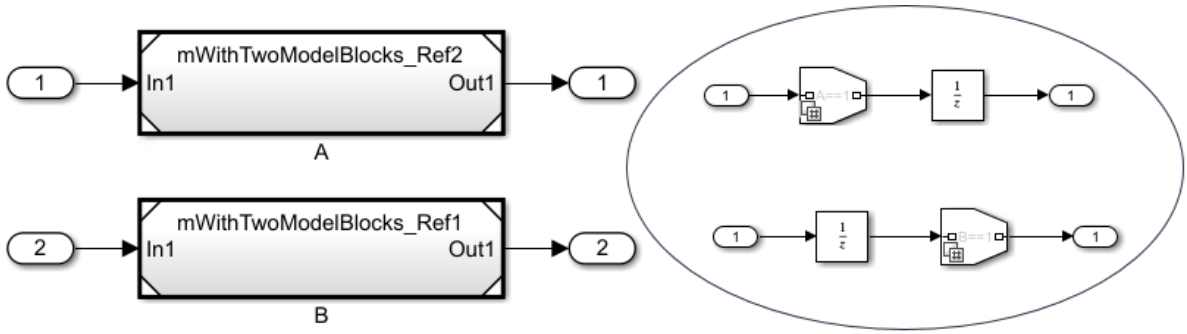
  /* End of SignalConversion: '<Root>/VM_SignalConversion_Subsystem_0' */
```

The comments in the generated code indicate the presence of the hidden signal conversion block. The code does not contain a comment for the Variant Merge block because this block does not have associated generated code. The Variant Merge block is used internally and is not in the Simulink library.

Guarding Reference Model Headers

When a model has Model Reference blocks that are conditional due to inline variants, the header file and the instances referring to the Model Reference blocks are guarded.

Consider this model with two Model References blocks that are conditional due to inline variants.



When you generate code for this model, the header file and instances referring to the Model Reference blocks are guarded as shown in the code below.

```
#include "mWithTwoModelBlocks_Top_types.h"
#include "multiword_types.h"

#if (A == 1) //Guarding
#define mWithTwoModelBlocks_Ref2_MDLREF_HIDE_CHILD_
#include "mWithTwoModelBlocks_Ref2.h"
#endif

#if (B == 1) //Guarding
#include "mWithTwoModelBlocks_Ref1.h"
#endif
```

Represent Subsystem and Variant Models in Generated Code

In this section...

Required products: Simulink, Embedded Coder, Simulink Coder

Using Simulink, you can create models that are based on a modular design platform that comprises a fixed common structure with a finite set of variable components. The variability helps you develop a single, fixed master design with variable components. For more information, see “What Are Variants and When to Use Them” (Simulink). When you implement variants in the generated code, you can:

- Reuse generated code from a set of application models that share functionality with minor variations.
- Share generated code with a third party that activates one of the variants in the code.
- Validate the supported variants for a model and then choose to activate one variant for a particular application, without regenerating and re-validating the code.
- Generate code for the default variant that is selected when an active variant does not exist.

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

This example shows how to represent variant choices in a Simulink model and then prepare the model so that those variant choices are represented in generated code.

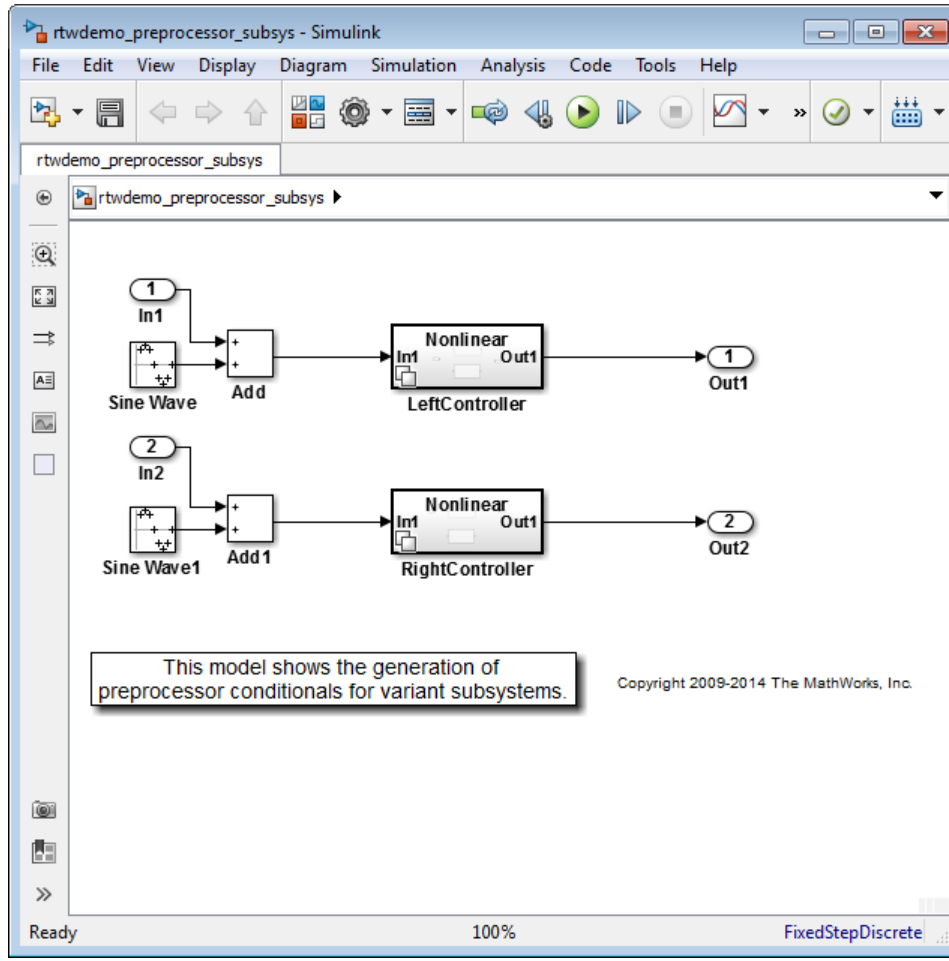
Step 1: Represent Variant Choices in Simulink

Variant choices are two or more configurations of a component in your model. This example uses the model `rtwdemo_preprocessor_subsys` to illustrate how to represent

variant choices inside Variant Subsystem blocks. For other ways to represent variant choices, see “Options for Representing Variants in Simulink” (Simulink).

1 Open the model `rtwdemo_preprocessor_subsys`.

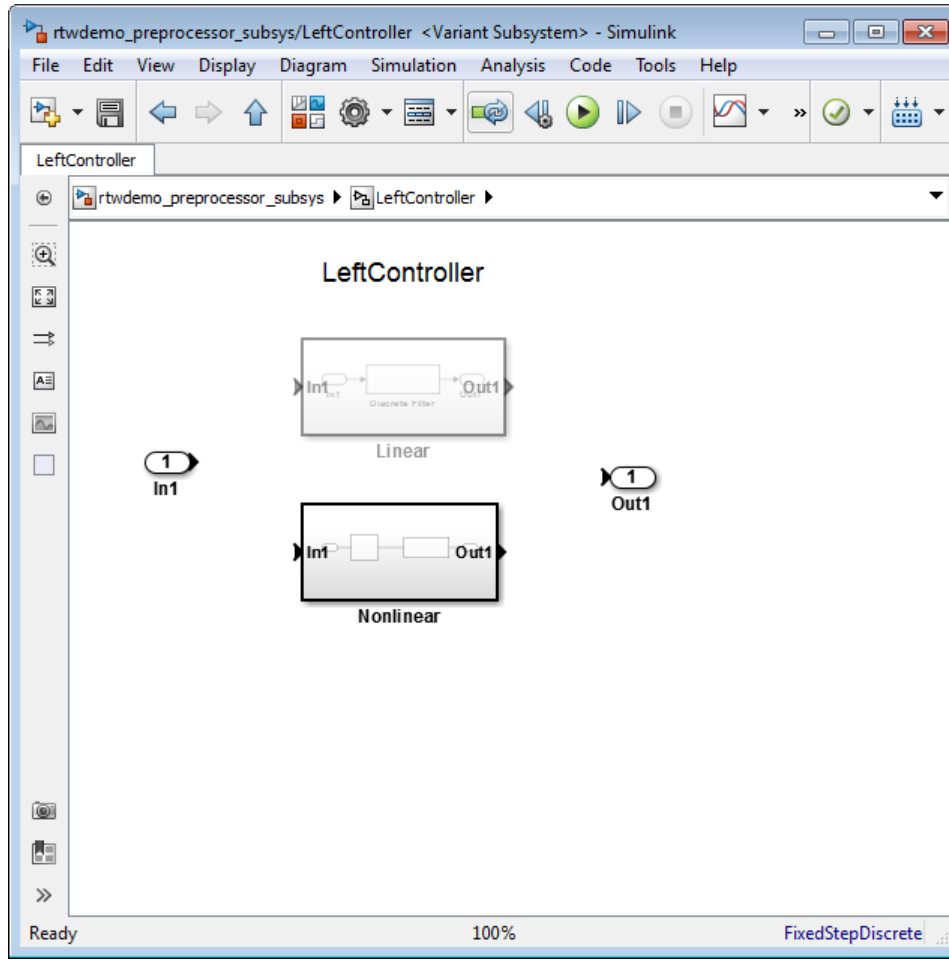
```
open_system('rtwdemo_preprocessor_subsys')
```



The model contains two Variant Subsystem blocks: **LeftController** and **RightController**.

Note You can only add Inport, Outport, Subsystem, and Model blocks inside a Variant Subsystem block.

2 Open the **LeftController** block.

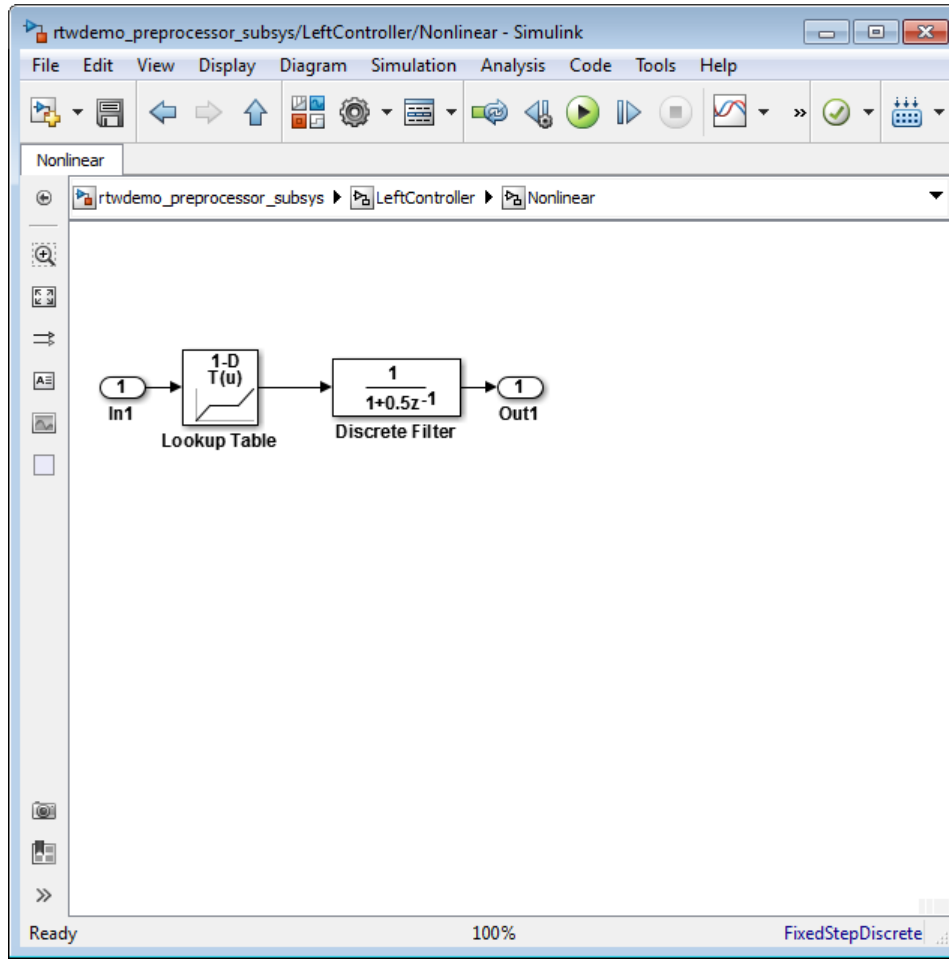


The **LeftController** block serves as the container for the variant choices. It contains two variant choices represented using Subsystem blocks **Nonlinear** and **Linear**. The nonlinear controller subsystems implement hysteresis, whereas the linear controller subsystems act as simple low-pass filters.

The Subsystem blocks have the same number of inports and outports as the containing Variant Subsystem block.

Variant choices can have different numbers of inports and outports. See “Mapping Inports and Outports of Variant Choices” (Simulink).

3 Open the **Nonlinear** block.



The **Nonlinear** block represents one variant choice that Simulink activates when a condition is satisfied. The **Linear** block represents another variant choice.

Tip When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside a Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

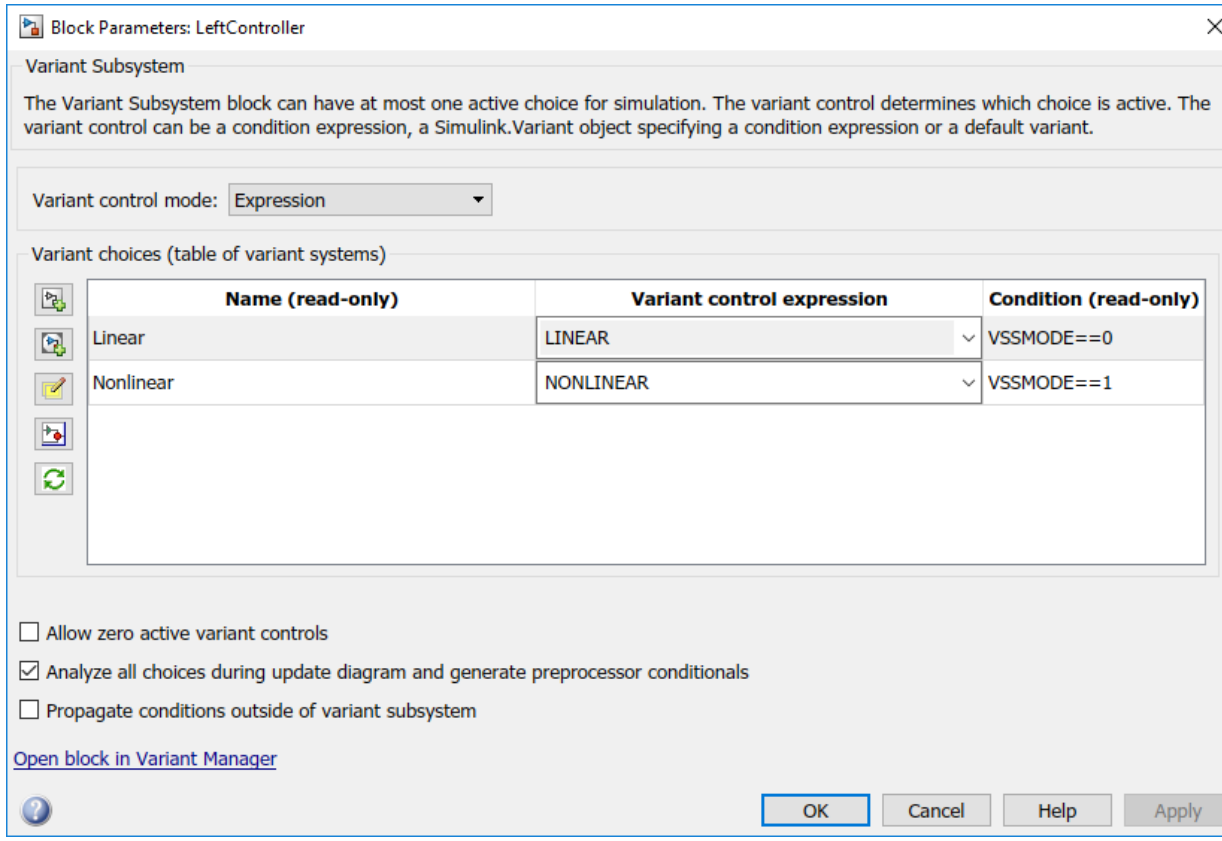
Step 2: Specify Conditions That Control Variant Choice Selection

You can switch between variant choices by constructing conditional expressions called variant controls for each variant choice represented in a Variant Subsystem block. Variant controls determine which variant choice is active, and changing the value of a variant control causes the active variant choice to switch.

A variant control is a Boolean expression that activates a specific variant choice when it evaluates to `true`.

For more information, see “Introduction to Variant Controls” (Simulink).

1 Right-click the **LeftController** block and select **Block Parameters (Subsystem)**.



The **Condition** column displays the Boolean expression that when `true` activates each variant choice. In this example, these conditions are specified using `Simulink.Variant` objects `LINEAR` and `NONLINEAR`.

2 Use these commands to specify a variant control using a `Simulink.Variant` object.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Here, `VSSMODE` is called a variant control variable that can be specified in one of the ways listed in “Approaches for Specifying Variant Controls” (Simulink).

3 Define the variant control variable `VSSMODE`.

You can define `VSSMODE` as a scalar variable or as a `Simulink.Parameter` object. In addition to enabling the specification of parameter value, `Simulink.Parameter` objects allow you to specify other attributes such as data type that are required for generating code.

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes.

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant (AUTOSAR)`
- Your own custom storage class that defines data as a macro

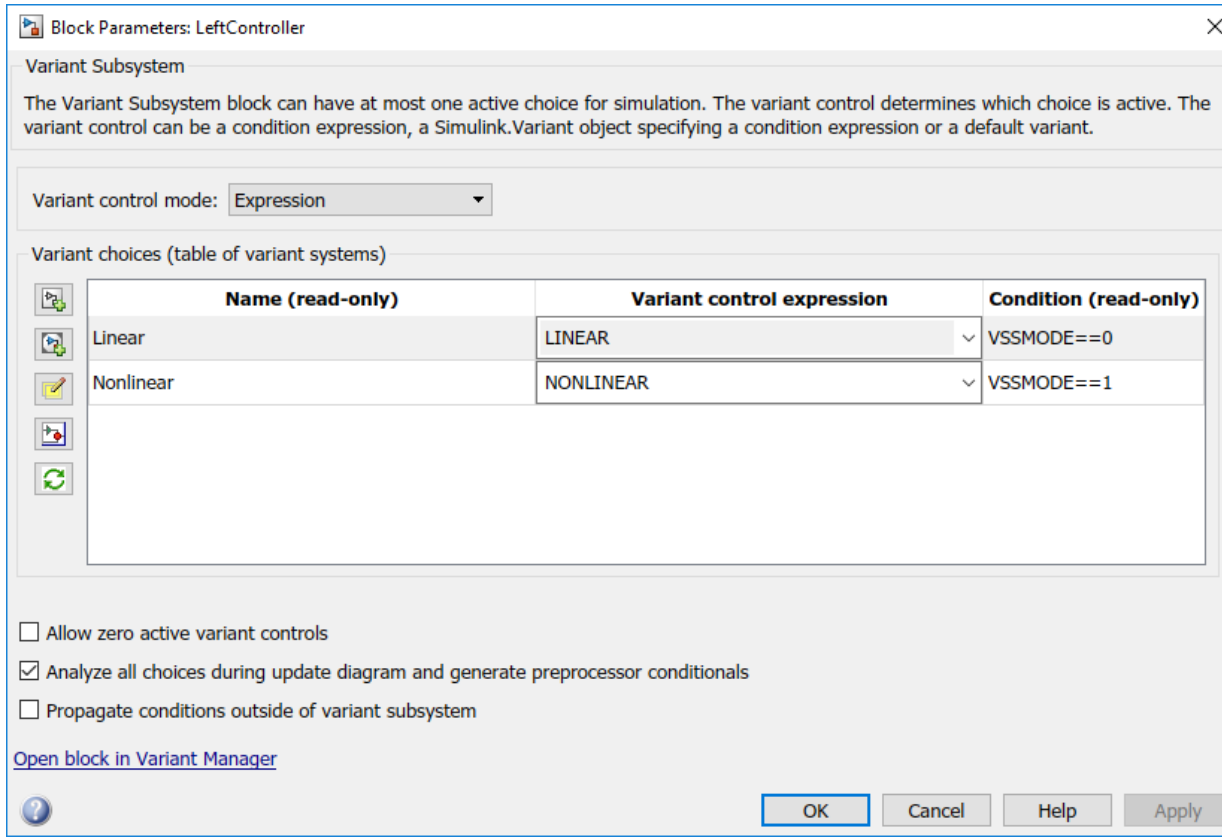
You can also convert a scalar variant control variable into a `Simulink.Parameter` object. See “Convert Variant Control Variables into Simulink.Parameter Objects” (Simulink).

Step 3: Configure Model for Generating Preprocessor Conditionals

Code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`. Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

1. In the Simulink editor, select **Simulation** > **Model Configuration Parameters**.
2. Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
3. In the **Report** pane, select **Create code generation report**.
4. In the Configuration Parameters dialog box, clear **Ignore custom storage classes** and click **Apply**.
5. In your model, right-click the **LeftController** block and select **Block Parameters (Subsystem)**.

6 Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.



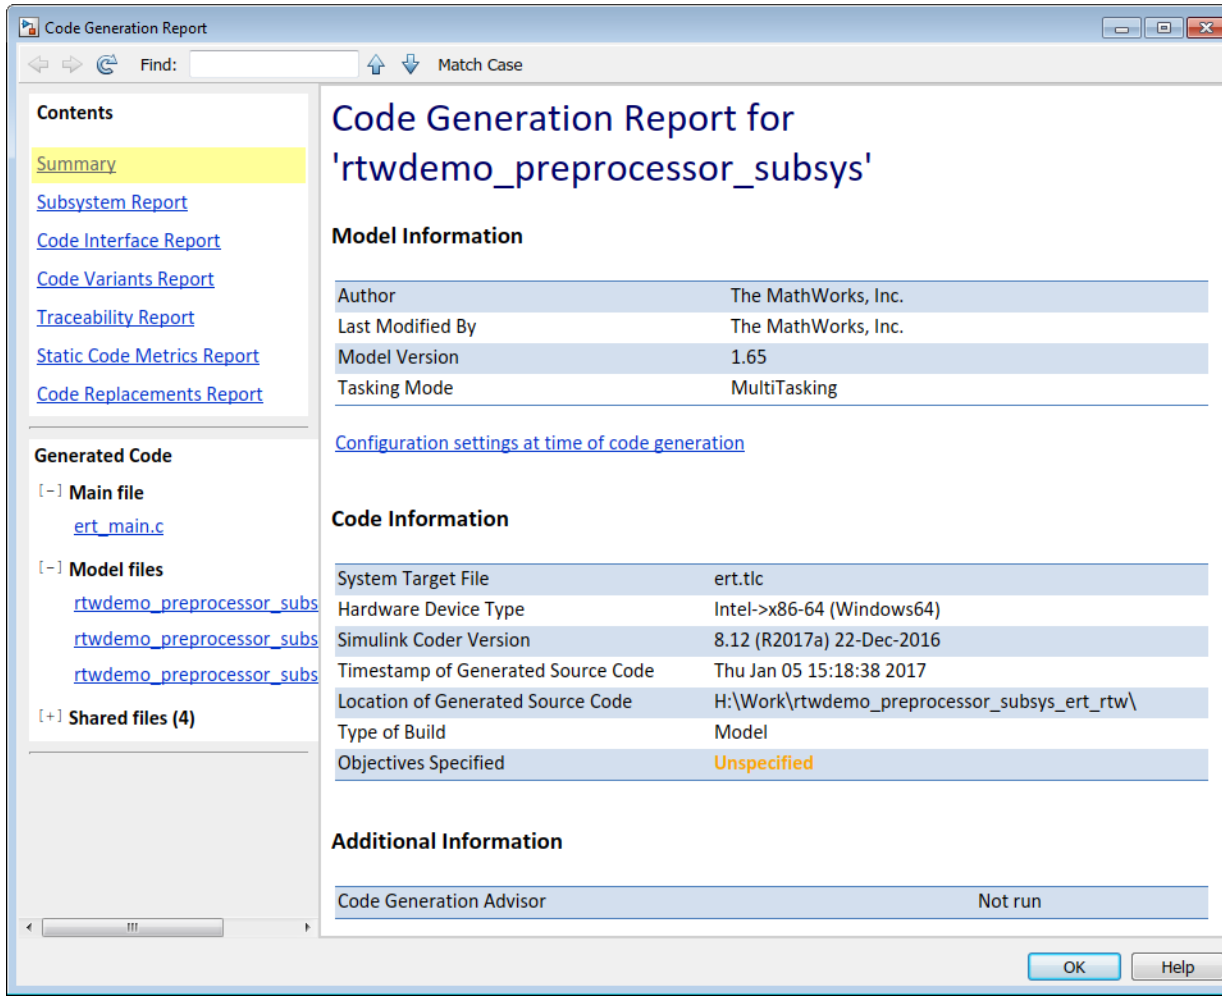
When you select this option, Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness of all variant choices.

7 Build the model.

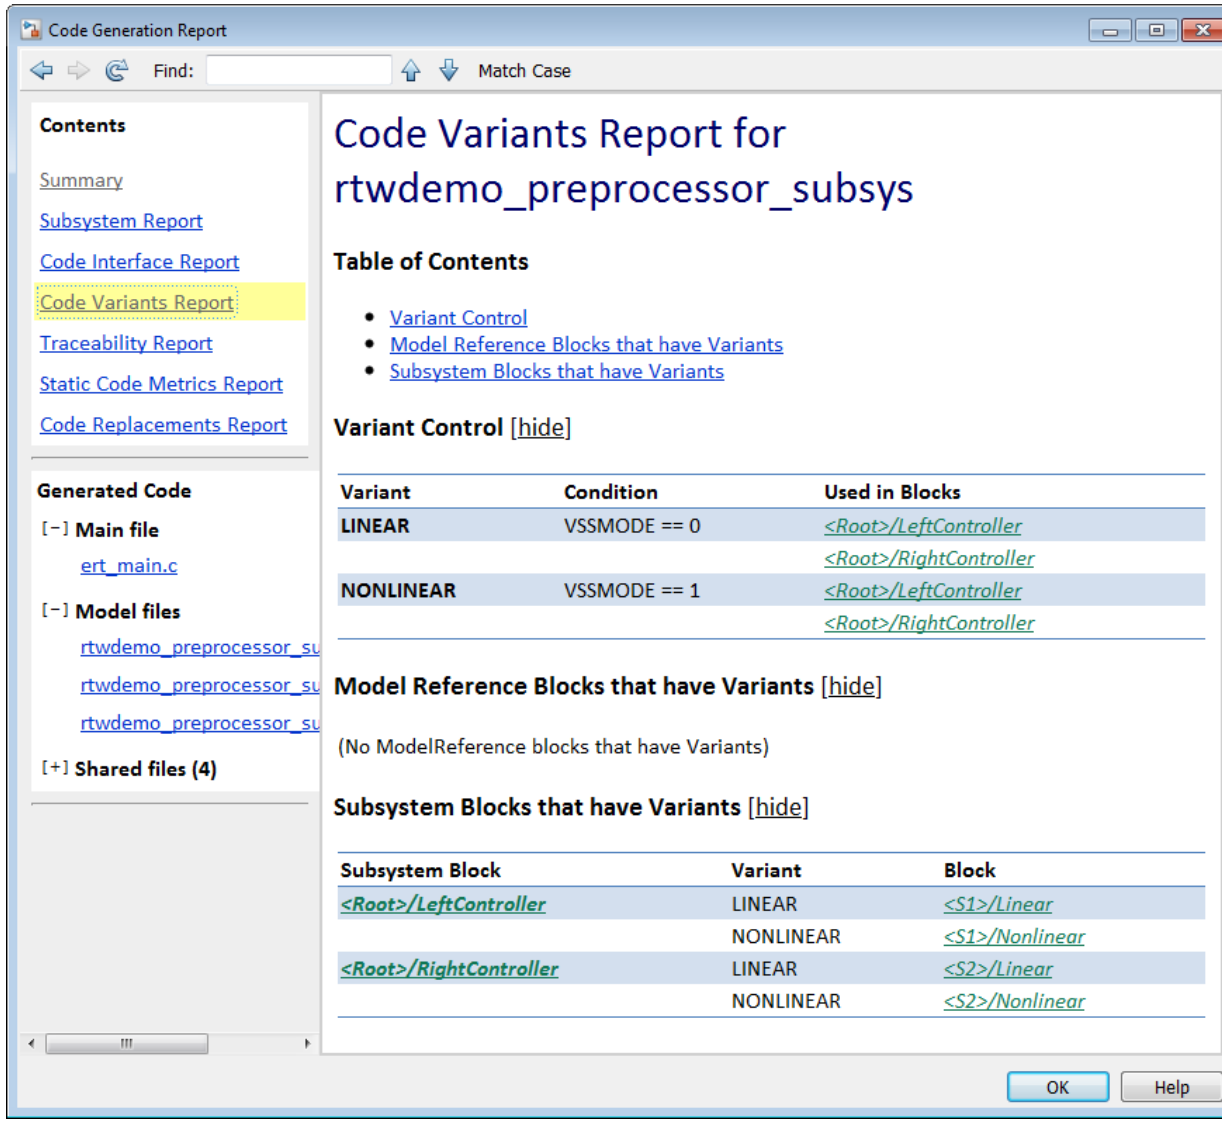
Step 4: Review Generated Code

The code generation report contains a section dedicated to the subsystems that have variants controlled by preprocessor conditionals.

1 To open the Code Generation Report click **Code > C/C++ Code > Code Generation Report > Open Model Report**.



2 Select the **Code Variant Report** from the left.



In this example, the generated code includes references to the `Simulink.Variant` objects `LINEAR` and `NONLINEAR`. The code also includes the definitions of macros corresponding to those variants. The definitions depend on the value of `VSSMODE`, which is supplied in an external header file `rtwdemo_importedmacros.h`. The

active variant is determined by using preprocessor conditionals (`#if`) on the macros (`#define`) `LINEAR` and `NONLINEAR`.

3. Select the `rtwdemo_preprocessor_subsys_types.h` file from the left.

   This file contains the definitions of macros `LINEAR` and `NONLINEAR`.

```
#ifndef LINEAR
    #define LINEAR      (VSSMODE == 0)
#endif

#ifndef NONLINEAR
    #define NONLINEAR   (VSSMODE == 1)
#endif
```

4. Select the `rtwdemo_preprocessor_subsys.c` file from the left.

   In this file, calls to the step and initialization functions of each variant are conditionally compiled.

```
    /* Outputs for Atomic SubSystem: '<Root>/LeftController' */
#if LINEAR
    /* Output and update for atomic system: '<S1>/Linear' */
    ...
#elif NONLINEAR
    /* Output and update for atomic system: '<S1>/Nonlinear' */
    ...
#endif
```

Limitations

- When you are generating code for Variant Subsystem blocks, the blocks cannot have:
  - Mass matrices
  - Function call ports
  - Outports with constant sample time
  - Simscape blocks
- The port numbers and names for each active child subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.

Generate Preprocessor Conditionals for Variant Systems

In this section...

Define Variant Controls

For variant systems, conditional expressions called variant controls determine which variant choice is active. You can specify a variant control as a condition expression, a `Simulink.Variant` object specifying a condition expression, a MATLAB variable, or a `Simulink.Parameter` object. This example shows how to define variant controls as `Simulink.Parameter` objects.

1. Open the Model Explorer. Select the **base workspace**.
2. In the Model Explorer, select **Add > Simulink Parameter**. Specify a name for the new parameter.
3. Use the function `Simulink.VariantManager.findVariantControlVars` to find and convert MATLAB variables used in variant control expressions into `Simulink.Parameter` objects. For an example, see "Convert Variant Control Variables into Simulink.Parameter Objects" (Simulink).
4. On the `Simulink.Parameter` property dialog box, specify the **Value** and **Data type**.
5. Select one of these **Storage class** values.
   - `Define`
   - `ImportedDefine(Custom)`
   - `CompilerFlag(Custom)`
   - A storage class created using the Custom Storage Class Designer. Your storage class must have the **Data initialization** parameter set to `Macro` and the **Data scope** parameter set to `Imported`. See "Control Data Representation by Configuring Custom Storage Class Properties" on page 36-40 for more information.
6. Specify the value of the variant control. If the storage class is `ImportedDefine(Custom)`, do the following:

a Specify the **Header File** parameter as an external header file in the Custom Attributes section of the `Simulink.Parameter` property dialog box.

b Enter the values of the variant controls in the external header file.

Note The generated code refers to a variant control as a user-defined macro. The generated code does not contain the value of the macro. The value of the variant control determines the active variant in the compiled code.

If the variant control is a `CompilerFlag` custom storage class, the value of the variant control is set at compile time. Use the **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines** parameter to add a list of variant controls (macro definitions) to the compiler command line. For example, for variant control `VSSMODE`, in the text field for the **Defines** parameter, enter:

```
-DVSSMODE=1
```

If you want to modify the value of the variant control after generating a makefile, use a makefile option when compiling your code. For example, at a command line outside of MATLAB, enter:

```
makecommand -f model.mk DEFINES_CUSTOM="-DVSSMODE=1"
```

Note You can define the variant controls using `Simulink.Parameter` object of enumerated type. This approach provides meaningful names and improves the readability of the conditions. The generated code includes preprocessor conditionals to check that the variant condition contains valid values of the enumerated type.

Configure Model for Generating Preprocessor Conditional Directives

1 Open the Configuration Parameters dialog box.

2 Select the **Code Generation** pane, and set **System target file** as `ert.tlc`.

3 In the **Report** pane, select **Create code generation report**.

4 In the Configuration Parameters dialog box, clear the “Ignore custom storage classes” (Simulink Coder) parameter. In order to generate preprocessor conditionals, you must use custom storage classes.

5. In the Variant Subsystem, Variant Source, or Variant Sink block parameter dialog boxes, select the **Analyze all choices during update diagram and generate preprocessor conditionals** option.
6. Generate code.

Special Considerations for Generating Preprocessor Conditionals

- The port numbers and names for each child variant subsystem must belong to a subset of the port numbers and names of the parent Variant Subsystem block.
- The code generation process checks that there is at least one active variant by using the variant control values stored in the base workspace. The variant control that evaluates to `true` becomes the active variant. If none of the variant controls evaluates to `true`, the default variant, if specified, becomes the active variant. The code generation process issues an error if an active variant does not exist.
- Implement the condition expressions of the variant objects such that only one evaluates to `true`. The generated code includes a test of the variant objects to determine that there is only one active variant. If this test fails, your code will not compile.
- If you comment out child subsystems listed in the **Variant Choices** table in the Variant Subsystem block parameter dialog box, the code generator does not generate code for the commented out subsystems.
- If the sample time for a default variant differs from that of the other variant choices, the `#else` preprocessor conditional is not generated for the default variant. Instead, an `#if !(`*`<variant conditions>`*`)` is generated.
- For Variant Subsystems, the `model_private.h` file contains conditional parameter definitions. For example, if the value of a Constant block is a `Simulink.Parameter` with an `ImportedDefine` custom storage class, and the Constant block is in a Variant Subsystem, the conditional definition of the `Simulink.Parameter` is in the `model_private.h` file.

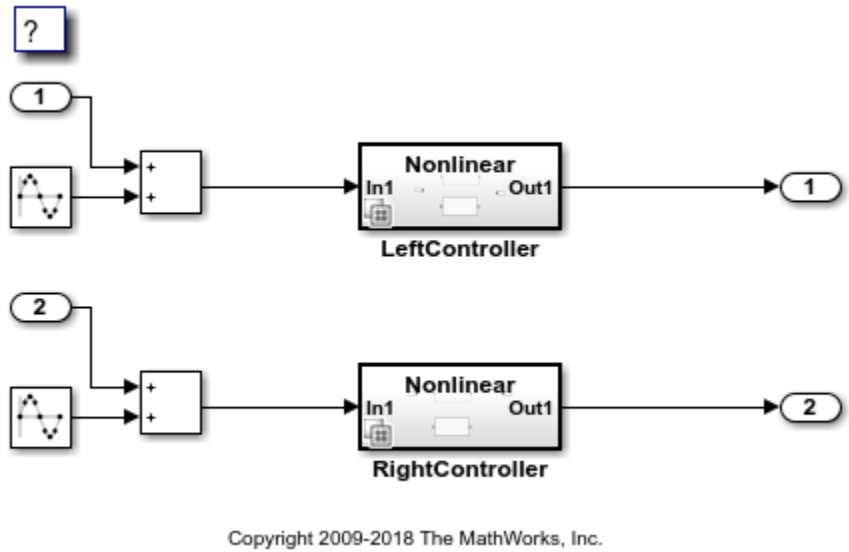
Generate Variant Control Macros in Same Header File

This example shows how to aggregate multiple variant control macros (`#define`) into the same generated header file. This aggregation makes it easier for you to manage the complexities inherent in a system with multiple interacting variant conditions.

Explore Example Model

Run the script `prepare_rtwdemo_preproc_subsys`, which opens the model `rtwdemo_preprocessor_subsys` and prepares it for this example.

```
run(fullfile(matlabroot,'examples','ecoder','main','prepare_rtwdemo_preproc_subsys'));
```



The model contains two Variant Subsystem blocks.

Navigate inside the variant subsystems. The subsystems each have a linear and a nonlinear algorithm variant.

At the root level of the model, open the block dialog box of the variant subsystem labeled `LeftController`. The algorithm variants in the subsystem activate based on the states of two `Simulink.Variant` objects, `LINEAR` and `NONLINEAR`, in the base workspace.

The state of each object depends on the values of two variant control variables, `MODE_A` and `MODE_B`, which are `Simulink.Parameter` objects in the base workspace. The parameter objects use the custom storage class `Define` and are configured to appear in the generated code as C-code macros in `macros.h`.

Change Name of Generated Header File Through Model Data Editor

In this example, change the name of the generated header file from `macros.h` to `variant_controls.h`. You must change the file name in each parameter object.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

Click the **Show/refresh additional information** button.

Set the **Change view** drop-down list to `Code`.

In the **Filter contents** box, enter `MODE`. The Model Data Editor shows two rows that correspond to the parameter objects.

Select both rows. Then, for one of the rows, use the **Header File** column to change the header file name from `macros.h` to `variant_controls.h`. The Model Data Editor applies the change to both rows.

Reduce Maintenance Effort by Creating Custom Storage Class

To change the name of the header file, you must change the configuration of each parameter object. You can use the Model Data Editor to perform batch editing, but when you add a new variant control variable (parameter object), you must remember to specify the name of the header file for that object. Also, the Model Data Editor can show the parameter objects used by only one model at a time.

Instead, you can create a custom storage class and specify the name of the header file only once: In the definition of the custom storage class.

Set your current folder to a writable location.

At the command prompt, copy the built-in `SimulinkDemos` package into your current folder as `myPackage`.

```
copyfile(fullfile(matlabroot,...
    'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
    '+myPackage','f')
```

Navigate inside the `+myPackage` folder to the file `Parameter.m` and open the file.

Uncomment the `methods` section that defines the method `setupCoderInfo`. In the call to the function `useLocalCustomStorageClasses`, replace `'packageName'` with `'myPackage'`. When you finish, the section appears as follows:

```
methods
  function setupCoderInfo(h)
    % Use custom storage classes from this package
    useLocalCustomStorageClasses(h, 'myPackage');
  end
end % methods
```

Save and close the file.

Set your current folder to the folder that contains the package `myPackage`.

Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

Select the custom storage class `Define`.

Click **Copy**. A new custom storage class, `Define_1`, appears. Select this new custom storage class.

Set **Name** to `VariantControlVar`.

Set **Header file** to `Specify`. In the text box, enter `variant_controls.h`.

Click **Apply**, **Save**, and **OK**.

At the command prompt, replace the `Simulink.Parameter` objects `MODE_A` and `MODE_B` with `myPackage.Parameter` objects. Apply the new custom storage class `VariantControlVar`.

```
MODE_A = myPackage.Parameter;
MODE_A.Value = 1;
MODE_A.DataType = 'int32';
MODE_A.CoderInfo.StorageClass = 'Custom';
MODE_A.CoderInfo.CustomStorageClass = 'VariantControlVar';

MODE_B = myPackage.Parameter;
```

```
MODE_B.Value = 1;
MODE_B.DataType = 'int32';
MODE_B.CoderInfo.StorageClass = 'Custom';
MODE_B.CoderInfo.CustomStorageClass = 'VariantControlVar';
```

Now, to indicate that a parameter object represents a variant control variable, you can apply the custom storage class `VariantControlVar`. To change the name of the header file, use the Custom Storage Class Designer.

Represent Variant Source and Sink Blocks in Generated Code

In this section...

You can use Variant Source and Variant Sink blocks to perceive multiple implementations of a model in a single, unified block diagram. Each implementation depends on conditions that you set for Variant Source and Variant Sink blocks. Simulink propagates these conditions to upstream and downstream blocks including root input and root output ports.

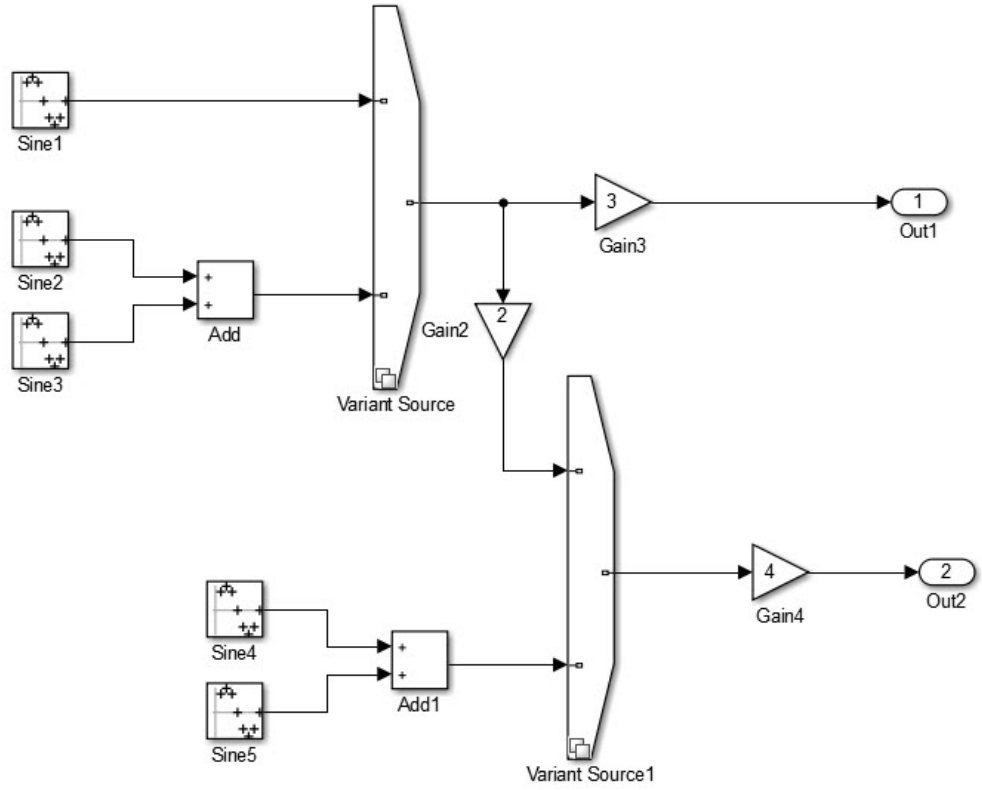
You can generate:

- Code from a Simulink model containing Variant Sink and Variant Source blocks.
- Code that contains preprocessor conditionals that control the activation of each variant choice.
- Preprocessor conditionals that allow for no active variant choice.

Represent Variant Source and Variant Sink blocks in Simulink

This example shows how Variant Source blocks make model elements conditional.

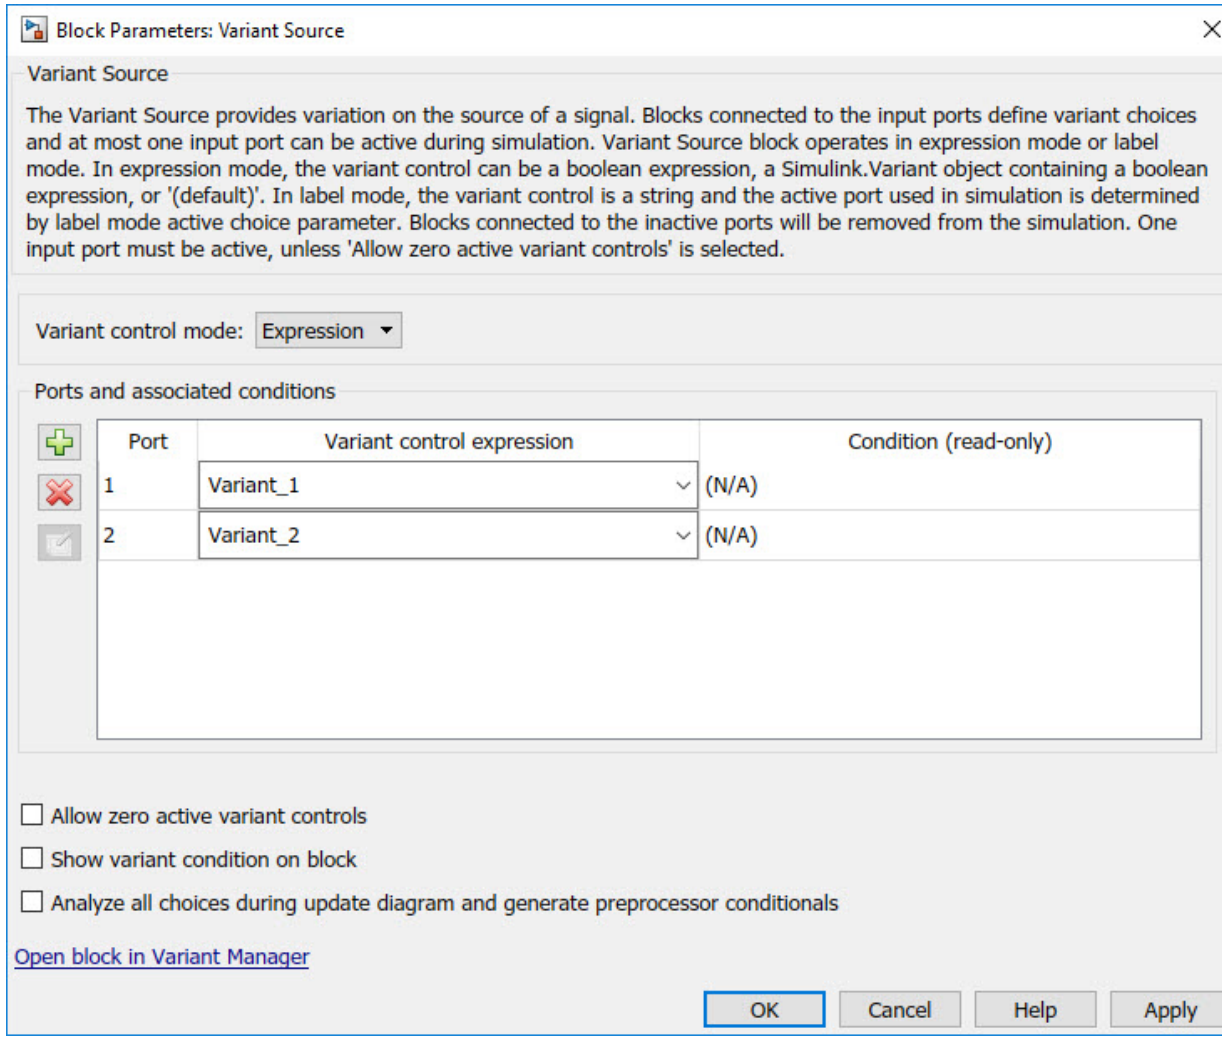
1. From the Simulink Block Library, add 1 Sine Wave Function block, two Add blocks, three Gain blocks, two Outports, and two Variant Source blocks into a new model.
2. Open the Sine Wave Function block. For the **Sine type** parameter, select `Sample based`. For the **Time (t)** parameter, select `Use simulation time`. For the **Sample time** parameter, insert a value of `0.2`.
3. Make four copies of the Sine Wave Function block.
4. Connect and name the blocks as shown.



5 Insert values of 2, 3, and 4 in the `Gain2`, `Gain3`, and `Gain4` blocks, respectively.

6 Give the model the name `inline_variants_example`.

7 Open the Block Parameters dialog box for `Variant Source`.



8 In the **Variant control** column, for Port 1, replace `Variant_1` with `V==1`. For Port 2, replace `Variant_2` with `V==2`.

9 Open the Block Parameters dialog box for `Variant Source1`.

10 In the **Variant control** column, replace `Variant_1` with `W==1`. For Port 2, replace `Variant_2` with `W==2`.

11 In the MATLAB Command Window, use these commands to define `V` and `W` as `Simulink.Parameter` objects.

```
V = Simulink.Parameter;
V.Value = 1;
V.DataType='int32';
V.CoderInfo.StorageClass = 'custom';
V.CoderInfo.CustomStorageClass = 'Define';
V.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'

W = Simulink.Parameter;
W.Value = 2;
W.DataType='int32';
W.CoderInfo.StorageClass = 'custom';
W.CoderInfo.CustomStorageClass = 'Define';
W.CoderInfo.CustomAttributes.HeaderFile='inline_importedmacro.h'
```

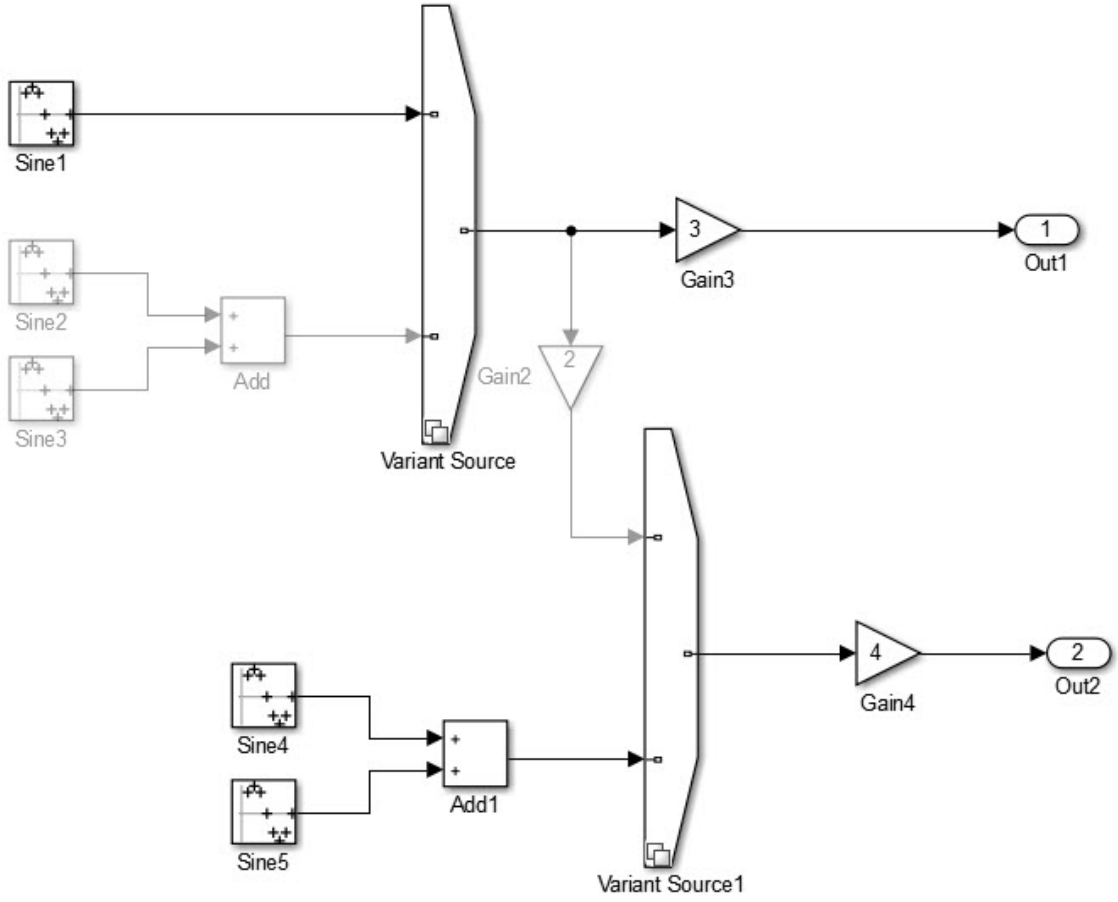
In this example, the variant control variables are `Simulink.Parameter` objects. For code generation, if you use `Simulink.Variant` objects to specify variant controls, use `Simulink.Parameter` objects or MATLAB variables to specify their conditions. .

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes:

- `Define` with header file specified
- `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant (AUTOSAR)`
- User-defined custom storage class that defines data as a macro in a specified header file

If you use scalar variant control variables to simulate the model, you can convert those variables into `Simulink.Parameter` objects. See “Convert Variant Control Variables into Simulink.Parameter Objects” (Simulink).

12 Simulate the model.



Input port 1 is the active choice for `Variant Source` because the value of variant control variable `V` is `1`. Input port 2 is the active choice for `Variant Source1` because the value of variant control variable `W` is 2. The inactive choices are removed from execution, and their paths are grayed-out in the diagram.

Specify Conditions That Control Variant Choice Selection

You can generate code in which each variant choice is enclosed within C preprocessor conditionals `#if` and `#endif`. The compiler chooses the active variant at compile time and the preprocessor conditionals determine which sections of the code to execute.

1. In the Simulink editor, select **Simulation** > **Model Configuration Parameters**.
2. Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
3. In the **Report** pane, select **Create code generation report**.
4. In your model, open the block parameters dialog box for `Variant Source`.
5. Select the **Analyze all choices during update diagram and generate preprocessor conditionals** parameter. During an update diagram or simulation, when you select this parameter, Simulink analyzes all variant choices. This analysis provides early validation of the code generation readiness of variant choices. During code generation, when you select this parameter, the code generator generates preprocessor conditionals that control the activation of each variant choice.
6. Clear the **Allow zero active variant controls** parameter.
7. Open the Block Parameters dialog box for `Variant Source 1`. Repeat steps 5 through 7.
8. Build the model. When code generation is complete, the Code Generation Report is displayed.

Review the Generated Code

1. In the code generation report, select the `inline_variants_example.c` file.
2. In the `inline_variants_example.c` file, calls to the `inline_variants_example_step` function and the `inline_variants_example_initialize` functions are conditionally compiled as shown:

```
/* Model step function */
void inline_variants_example_step(void)
{
  real_T rtb_Sine4;
  real_T rtb_VariantMerge_For_Variant_So;

  /* Sin: '<Root>/Sine1' */
#if V == 1
```

```
  rtb_Sine4 = sin((real_T)inline_variants_example_DW.counter * 2.0 *
                  3.1415926535897931 / 10.0);

#endif                                 /* V == 1 */

  /* End of Sin: '<Root>/Sine1' */

  /* Sin: '<Root>/Sine2' incorporates:
   *  Sin: '<Root>/Sine3'
   *  Sum: '<Root>/Add'
   */
#if V == 2

  rtb_Sine4 = sin((real_T)inline_variants_example_DW.counter_i * 2.0 *
                  3.1415926535897931 / 10.0) + sin((real_T)
    inline_variants_example_DW.counter_f * 2.0 * 3.1415926535897931 / 10.0);

#endif                                 /* V == 2 */

  /* End of Sin: '<Root>/Sine2' */

  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain3'
   */
  inline_variants_example_Y.Out1 = 3.0 * rtb_Sine4;

  /* Gain: '<Root>/Gain2' */
#if W == 1

  rtb_VariantMerge_For_Variant_So = 2.0 * rtb_Sine4;

#endif                                 /* W == 1 */

  /* End of Gain: '<Root>/Gain2' */

  /* Sin: '<Root>/Sine4' incorporates:
   *  Sin: '<Root>/Sine5'
   *  Sum: '<Root>/Add1'
   */
#if W == 2

  rtb_VariantMerge_For_Variant_So = sin((real_T)
    inline_variants_example_DW.counter_fe * 2.0 * 3.1415926535897931 / 10.0) *
```

```
    2.0 + sin((real_T)inline_variants_example_DW.counter_e * 2.0 *
              3.1415926535897931 / 10.0);

#endif                                 /* W == 2 */

  /* End of Sin: '<Root>/Sine4' */

/* Outport: '<Root>/Out2' incorporates:
   *  Gain: '<Root>/Gain4'
   */
  inline_variants_example_Y.Out2 = inline_variants_example_P.Gain4_Gain *
    rtb_VariantMerge_For_Variant_So;
...
}
```

The variables `rtb_Sine4` and `rtb_VariantMerge_For_Variant_So` hold the input values to the Variant Source blocks. Notice that the code for these variables is conditional. The variables `inline_variants_example_Y.Out1` and `inline_variants_example_Y.Out2` hold the output values of the Variant Source blocks. Notice that the code for these variables is not conditional.

Generate Code with Zero Active Variant Controls

You can generate code in which blocks connected to the input and the output of a Variant Source block are conditional.

1. For `Variant Source`, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.
2. For `Variant Source 1`, open the Block Parameters dialog box. Select the parameter **Allow zero active variant controls**.

When you select **Allow zero active variant controls** parameter, you can generate code for a model containing Variant Source and Variant Sink blocks even when you specify a value for a variant control variable that does not allow for an active variant. Choosing a value for a variant control variable that does not allow for an active variant and not selecting the **Allow zero active variant controls** parameter, produces an error.

Generate code for `inline_variants_example`. Notice in the `inline_variants_example.c` file, that the code for the variables `inline_variants_example_Y.Out1` and `inline_variants_example_Y.Out2` is conditional.

```
/* Model step function */
void inline_variants_example_step(void)
{
 ...
 #if V == 1 || V == 2

  inline_variants_example_Y.Out1 = 3.0 * rtb_Sine4;

#endif                                 /* V == 1 || V == 2 */

 ...
#if (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2

  inline_variants_example_Y.Out2 = 4.0 * rtb_VariantMerge_For_Variant_So;

#endif                      /* (V == 1 && W == 1) || (V == 2 && W == 1) || W == 2 */

 ...
```

Global Data Guarding Limitation

For external ports and most DWork vectors, signals, and states, preprocessor conditionals (`#if` and `#endif`) surround global data variable declarations. For models in which you enable C API code for global block output signals, global block parameters, and discrete and continuous states, preprocessor conditionals do not surround global data variable declarations. For information on the C API, see “Exchange Data Between Generated and External Code Using C API” (Simulink Coder).

State Logging Limitation

There are some rare cases in which preprocessor conditionals do not surround global data structures that contain state variable declarations. For models that contain Variant Source blocks or Variant Sink blocks and also contain blocks that maintain state information, such as Unit Delay blocks, the exclusion of preprocessor conditionals surrounding state variable declarations can lead to a mismatch between simulation and code generation results.

For example, suppose that a model has a Variant Source block with four variant choices. One of these choices contains blocks with state information. If you simulate the model with the active variant that is other than the variant choice that contains state information, there is no logged state data. In the *`model`*`.h` file, the generated code still

initializes these global state variables to `0` because `#if` and `#endif` guards do not surround the state variable declarations. If you create a *`model`*`.mat` file from a *`model`*`.exe` file, and compare it to the simulation output, the results do not match. For this example, the simulation output is empty because there is no logged state data. The *`model`*`.mat` file contains multiple values of `0`.

If the active variant is the variant choice containing state information, the results do match.

Configure Dimension Variants for S-Function Blocks

To configure symbolic dimensions for S-function blocks, you can use the following C/C++ functions. You can configure S-functions to support forward propagation, backward propagation, or forward and backward propagation of symbolic dimensions during simulation.

Many of these functions return the variable `SymbDimsId`. A `SymbDimsId` is a unique integer value. This value corresponds to each symbolic dimension specification that you create or is the result of a mathematical operation that you perform with symbolic dimensions.

C/C++ S-Functions	Purpose
`ssSetSymbolicDimsSupport`	Specify whether or not an S-function supports symbolic dimensions.
`mdlSetInputPortSymbolicDimensions`	Specify the symbolic dimensions of an input port and how those dimensions propagate forward.
`mdlSetOutputPortSymbolicDimensions`	Specify the symbolic dimensions of an output port and how those dimensions propagate backward.
`ssRegisterSymbolicDimsExpr`	Create a `SymbDimsId` from an expression string (`aExpr`). The expression string must form a valid syntax in C.
`ssRegisterSymbolicDims`	Create a `SymbDimsId` from a vector of `SymbDimsId`s.
`ssRegisterSymbolicDimsString`	Create a `SymbDimsId` from an identifier string (`aString`).
`ssRegisterSymbolicDimsIntValue`	Create a `SymbDimsId` from an integer value (`aIntValue`)
`ssRegisterSymbolicDimsPlus`	Create a `SymbDimsId` by adding two symbolic dimensions.
`ssRegisterSymbolicDimsMinus`	Create a `SymbDimsId` by subtracting two symbolic dimensions.

C/C++ S-Functions	Purpose
`ssRegisterSymbolicDimsMultiply`	Create a `SymbDimsId` by multiplying two symbolic dimensions.
`ssRegisterSymbolicDimsDivide`	Create a `SymbDimsId` by dividing two symbolic dimensions.
`ssGetNumSymbolicDims`	Get the number of dimensions for a `SymbDimsId`.
`ssGetSymbolicDim`	Get a `SymbDimsId` from a vector of `SymbDimsId`s.
`ssSetInputPortSymbolicDimsId`	Set the precompiled `SymbDimsId` of an input port. You can call this function from inside the `mdlInitializeSizes` function.
`ssGetCompInputPortSymbolicDimsId`	Get the compiled `SymbDimsId` of an input port.
`ssSetCompInputPortSymbolicDimsId`	Set the compiled `SymbDimsId` of an input port.
`ssSetOutputPortSymbolicDimsId`	Set the precompiled `SymbDimsId` of an output port. You can call this function from inside the `mdlInitializeSizes` function.
`ssGetCompOutputPortSymbolicDimsId`	Get the compiled `SymbDimsId` of an output port.
`ssSetCompOutputPortSymbolicDimsId`	Set the compiled `SymbDimsId` of an output port.
`ssSetCompDWorkSymbolicDimsId`	Set the compiled `SymbDimsId` of an index of a block's data type work (`DWork`) vector.

S-Function That Supports Forward Propagation of Symbolic Dimensions

This S-function subtracts the symbolic dimension `B` from a symbolic input dimension. It does not support backward propagation of symbolic dimensions because the compiled

symbolic dimensions of the input port are not set. Symbolic dimensions are set for the output port, so forward propagation occurs.

```
static void mdlInitializeSizes(SimStruct *S)
{
     // Enable symbolic dimensions for the s-function.
     ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
   int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
    // Set the compiled input symbolic dimension.
    ssSetCompInputPortSymbolicDimsId(S,  portIndex, symbDimsId);
    // Register "B" and get its symbolic dimensions id.
    const SymbDimsId symbolIdForB = ssRegisterSymbolicDimsString(S, "B");
   // Subtract "B" from the input symbolic dimension.
    const SymbDimsId outputDimsId =
        ssRegisterSymbolicDimsMinus(S, symbDimsId, symbolIdForB);
   //Set the resulting symbolic dimensions id as the output.
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, outputDimsId);
}
#endif

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_OUTPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetOutputPortSymbolicDimensions(SimStruct *S,
   int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
   // The input dimensions are not set, so this S-function only
    // supports forward propagation.
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, symbDimsId);
}
#endif
```

S-Function That Supports Forward and Backward Propagation of Symbolic Dimensions

This S-function transposes two symbolic dimensions. It supports forward and backward propagation of symbolic dimensions because the compiled symbolic dimension of both the input and output ports are set.

```
static void mdlInitializeSizes(SimStruct *S)
{
     // Enable symbolic dimensions for the s-function.
     ssSetSymbolicDimsSupport(S, true);
}

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_INPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetInputPortSymbolicDimensions(SimStruct* S,
   int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);

    ssSetCompInputPortSymbolicDimsId(S,  portIndex, symbDimsId);

    assert(2U == ssGetNumSymbolicDims(S, symbDimsId));

    if (SL_INHERIT ==
        ssGetCompOutputPortSymbolicDimsId(S, portIndex)) {

        const SymbDimsId idVec[] = {
            ssGetSymbolicDim(S, symbDimsId, 1),
            ssGetSymbolicDim(S, symbDimsId, 0)};
        // Register the transposed dimensions.
       // Set the output symbolic dimension to the resulting id.
  const SymbDimsId outputDimsId =
            ssRegisterSymbolicDims(S, idVec, 2U);

        ssSetCompOutputPortSymbolicDimsId(S, portIndex,
           outputDimsId);
    }
}
#endif

#if defined(MATLAB_MEX_FILE)
#define MDL_SET_OUTPUT_PORT_SYMBOLIC_DIMENSIONS
static void mdlSetOutputPortSymbolicDimensions(SimStruct *S,
```

```
    int_T portIndex, SymbDimsId symbDimsId)
{
    assert(0 == portIndex);
    ssSetCompOutputPortSymbolicDimsId(S, portIndex, symbDimsId);

    assert(2U == ssGetNumSymbolicDims(S, symbDimsId));

    if (SL_INHERIT ==
        ssGetCompInputPortSymbolicDimsId(S, portIndex)) {

        const SymbDimsId idVec[] = {
            ssGetSymbolicDim(S, symbDimsId, 1),
            ssGetSymbolicDim(S, symbDimsId, 0)};
        const SymbDimsId inputDimsId =
            ssRegisterSymbolicDims(S, idVec, 2U);
        // Register the transposed dimensions.
       // Set the input symbolic dimension to the resulting id.
        ssSetCompInputPortSymbolicDimsId(S, portIndex, inputDimsId);
    }
}
#endif
```

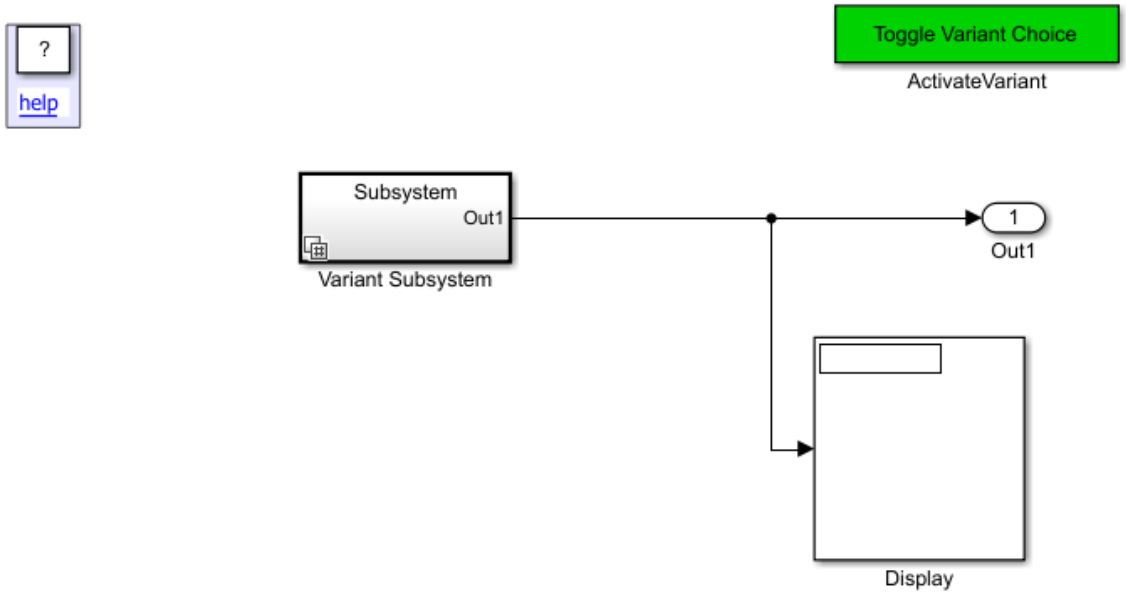
Generate Code for Variant Subsystem with Child Subsystems of Different Output Signal Dimensions

In this section...

This example shows how to use symbolic dimensions to generate code with preprocessor conditionals for a variant subsystem consisting of child subsystems of different output signal dimensions. The value of the variant control variable determines the active variant choice and the output signal dimensions. By changing the value of the variant control variable, you change the active variant and the output signal dimensions in the generated code.

Example Model

The model `slexVariantSymbolicDims` contains a Variant Subsystem consisting of the child subsystems `Subsystem` and `Subsystem1`. When the variant control variable `Var` has a value of `1`, `Subsystem` is the active variant. When `Var` has a value of `2`, `Subsystem1` is the active variant.



Simulate Model

To generate code with preprocessor conditionals, the output signal dimensions of the child subsystems must be the same during simulation. In this example, double-clicking the subsystem `Activate Variant Choice` changes the active variant and the output signal dimension. When `Var` equals `1`, the output signal dimension of each child subsystem is `5`. When `Var` equals `2`, the output signal dimension of each child subsystem is `6`.

1. Open the example model `slexVariantSymbolicDims`.
2. From the **Display** > **Signals & Ports** menu, select **Signal Dimensions**.
3. Open the Variant Subsystem Block Parameters dialog box. The **Analyze all choices during update diagram and generate preprocessor conditionals** parameter is selected.
4. Open `Subsystem`. In the Constant Block Parameters dialog box, the **Constant value** parameter is `P1`.
5. Open `Subsystem1`. In the Constant Block Parameters dialog box, the **Constant value** parameter is `P2`.

6. Open the base workspace. The `Simulink.Parameters` `P1` and `P2` are arrays with dimensions `'[1,A]'`. The `Simulink.Parameter` `A` has a value of `5`. `Var` has a value of `1`.
7. Simulate the model. `Subsystem` is the active variant with an output signal dimension of `5`.
8. Double-click the masked subsystem `ActivateVariant`.
9. In the base workspace, `Var` has a value of `2`. `P1` and `P2` have a dimension of `6`. `A` has a value of `6`.
10. Simulate the model. `Subsystem1` is the active variant with an output signal dimension of `6`.

In the base workspace, `A` has a **Storage class** of `ImportedDefine(Custom)`. To use a `Simulink.Parameter` object for dimension specification, it must have one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- User-defined custom storage class that defines data as a macro in a specified header file

In the base workspace, `P1` and `P2` have a storage class of `ImportedExtern`. A `Simulink.Parameter` object that uses a `Simulink.Parameter` for symbolic dimension specification must have a storage class of either `ImportedExtern` or `ImportedExternPointer`.

Generate Code

1. Open the header file `slexVariantSymbolicDims_variant_defines.h`. The definition of `A` is conditional upon the value of `Var`.

```
/* Copyright 2016 The MathWorks, Inc. */
// To select variant choice during compile, define Var at compile time,

#ifndef Var
#define Var 1
#endif

#if Var == 1
#define A 5
#elif Var == 2
```

```
#define A 6
#else
#error "Variant control variable, Var, must be defined as 1 or 2"
#endif
```

2. Generate code.
3. Open the `slexVariantSymbolicDims.h` file. The output dimension size is `A`.

```
/* External outputs (root outports fed by signals with auto storage) */
typedef struct {
  int32_T Out1[A];                     /* '<Root>/Out1' */
} ExternalOutputs_slexVariantSymb;
```

4. Open the `slexVariantSymbolicDims.c` file. If `Var` equals `1`, `P1` has five values. If `Var` equals `2`, `P2` has six values. In the Configuration Parameters dialog box, on the **Code Generation** > **Custom Code** pane, the **Source file** parameter contains this code.

```
/* user code (top of source file) */
#if Var == 1

int32_T P1[] = { 5, 5, 5, 5, 5 };

#elif Var == 2

int32_T P2[] = { 6, 6, 6, 6, 6, 6 };

#endif
```

Preprocessor conditionals control the size of `A` and which array, `P1` or `P2`, is active in the generated code. By changing the value of `Var`, you can change the size of `A` and the active array.

Use Variant Subsystem To Generate Code That Uses C Preprocessor Conditionals

This example shows how to use Simulink® variant subsystems to generate C preprocessor conditionals that control which child subsystem of the variant subsystem is active in the generated code produced by the Simulink® Coder™.

Overview of Variant Subsystems

A Variant Subsystem block contains two or more child subsystems where one child is active during model execution. The active child subsystem is referred to as the *active variant*. You can programmatically switch the active variant of the Variant Subsystem block by changing values of variables in the base workspace, or by manually overriding variant selection using the Variant Subsystem block dialog. The *active variant* is programmatically wired to the Inport and Outport blocks of the Variant Subsystem by Simulink® during model compilation.

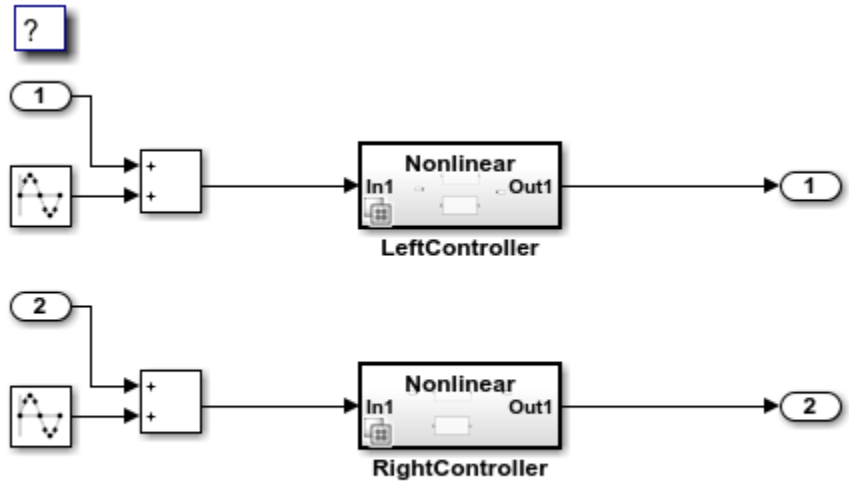
To programmatically control variant selection, a `Simulink.Variant` object is associated with each child subsystem in the Variant Subsystem block dialog. `Simulink.Variant` objects are created in the MATLAB® base workspace. These objects have a property named `Condition`, an expression, which evaluates to a Boolean value and is used to determine the active variant child subsystem.

When you generate code, you can only generate code for the active variant. You can also generate code for all variants of a Variant Subsystem block and defer the choice of active variant until it is time to compile the generated code.

Specifying Variants for a Subsystem Block

Opening the example model `rtwdemo_preprocessor_subsys` will run the **PostLoadFcn** defined in the "File: ModelProperties: Callbacks" dialog. This will populate the base workspace with the variables for the Variant Subsystem blocks.

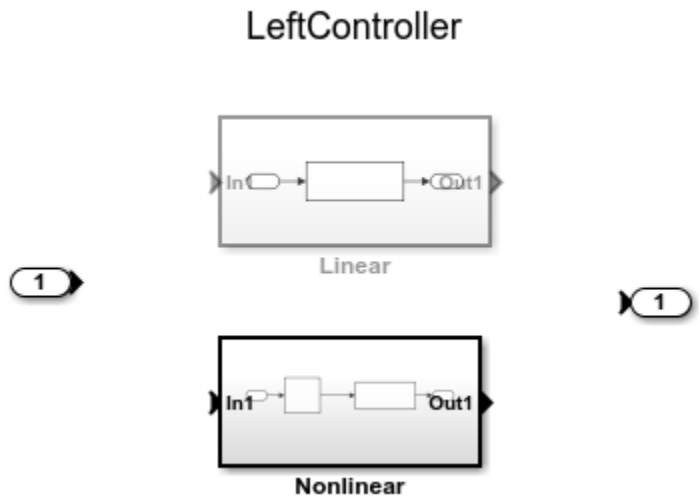
```
open_system('rtwdemo_preprocessor_subsys')
```



The LeftController variant subsystem contains two child subsystems: Linear and Nonlinear. The LeftController/Linear child subsystem executes when the Simulink.Variant object LINEAR evaluates to `true`, and the LeftController/Nonlinear child subsystem executes when the Simulink.Variant object NONLINEAR evaluates to `true`.

Simulink.Variant objects are specified for the LeftController subsystem by right-clicking the LeftController subsystem and selecting `Subsystem Parameters`, which will open the LeftController subsystem block dialog.

```
open_system('rtwdemo_preprocessor_subsys/LeftController');
```



The LeftController subsystem block dialog creates an association between the Linear and Nonlinear subsystems with the two Simulink.Variant objects, `LINEAR` and `NONLINEAR`, that exist in the base workspace. These objects have a property named `Condition`, an expression, which evaluates to a Boolean value and determines the active variant child subsystem (Linear or Nonlinear). The condition is also shown in the subsystem block dialog. In this example, the conditions of `LINEAR` and `NONLINEAR` are 'VSSMODE == 0' and 'VSSMODE == 1', respectively.

In this example, the Simulink.Variant objects are created in the base workspace.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Specifying a Variant Control Variable

Variant objects allow you to reuse arbitrarily complex conditions throughout a model. Multiple Variant Subsystem blocks can use the same Simulink.Variant objects, allowing you to toggle the activation of choices as a set. You can toggle the set prior to simulation by changing the value of `VSSMODE` in the MATLAB environment or when compiling the generated code, as explained in the next section. In this example, LeftController and RightController reference the same variant objects, so that you can toggle them simultaneously.

The nonlinear controller subsystems implement hysteresis, while the linear controller subsystems act as simple low-pass filters. Open the subsystem for the left channel. The subsystems for the right channel are similar.

The generated code accesses the variant control variable `VSSMODE` as a user-defined macro. In this example, `rtwdemo_importedmacros.h` supplies `VSSMODE`. Within the MATLAB environment, you specify `VSSMODE` using a `Simulink.Parameter` object. Its value will be ignored when generating code including preprocessor conditionals. However, the value is used for simulation. The legacy header file specifies the value of the macro to be used when compiling the generated code, which ultimately activates one of the two specified variants in the embedded executable.

Variant control variables can be defined as `Simulink.Parameter` objects with one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant (AUTOSAR)`
- User-defined custom storage class that defines data as a macro in a specified header file

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Simulating the Model with Different Variants

Because you set the value of `VSSMODE` to 1, the model uses the nonlinear controllers during simulation.

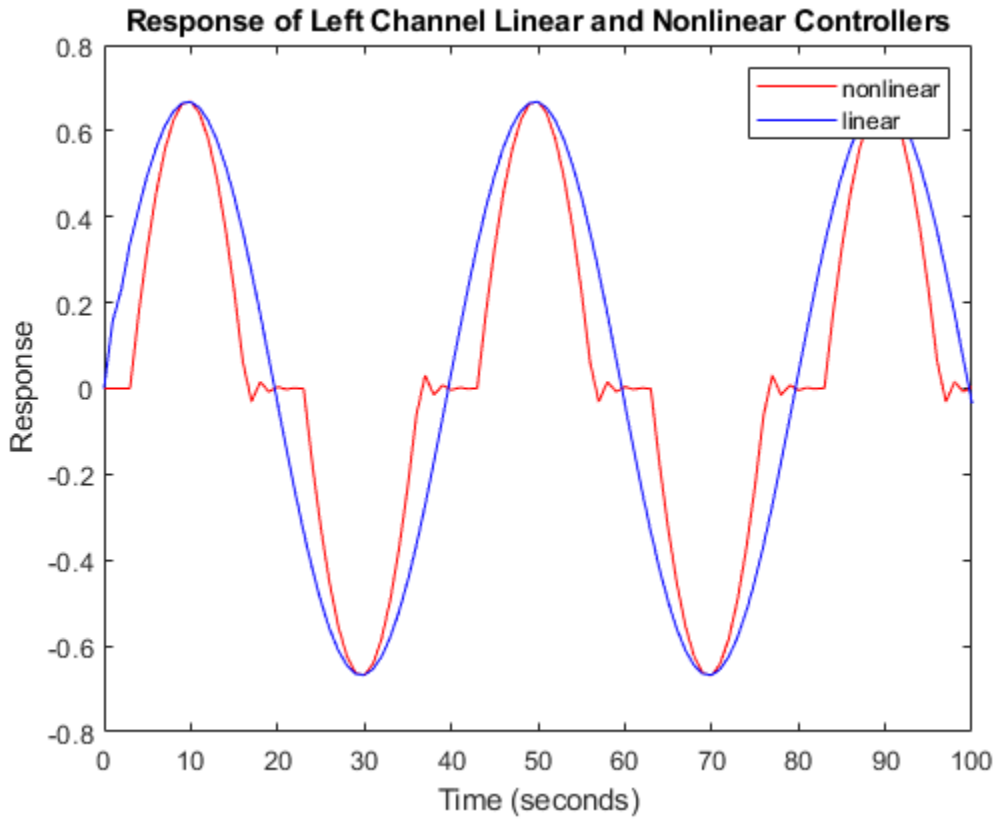
```
sim('rtwdemo_preprocessor_subsys')
youtnl = yout;
```

If you change the value of `VSSMODE` to 0, the model uses the linear controllers during simulation.

```
VSSMODE.Value = int32(0);
sim('rtwdemo_preprocessor_subsys')
youtl = yout;
```

You can plot and compare the response of the linear and nonlinear controllers:

```
figure('Tag','CloseMe');
plot(tout, youtnl.signals(1).values, 'r-', tout, youtl.signals(1).values, 'b-')
title('Response of Left Channel Linear and Nonlinear Controllers');
ylabel('Response');
xlabel('Time (seconds)');
legend('nonlinear','linear')
axis([0 100 -0.8 0.8]);
```



Using C Preprocessor Conditionals

This example model has been configured to generate C preprocessor conditionals. You can generate code for the model by selecting **Code > C/C++ Code > Build Model**.

To activate code generation of preprocessor conditionals, check whether the following conditions are true:

- Select an Embedded Coder® target in **Code Generation > System target file** in the Configuration Parameters dialog box
- In the Variant Subsystem block parameter dialog box, clear the option to **Override variant conditions and use following variant**
- In the Variant Subsystem block parameter dialog box, Select the option to **Analyze all choices during update diagram and generate preprocessor conditionals**.

The Simulink® Coder™ code generation report contains sections in the Code Variants report dedicated to the subsystems that have variants controlled by preprocessor conditionals.

In this example, the generated code includes references to the Simulink.Variant objects `LINEAR` and `NONLINEAR`, as well as the definitions of macros corresponding to those variants. Those definitions depend on the value of `VSSMODE`, which is supplied in an external header file `rtwdemo_importedmacros.h`. The active variant is determined by using preprocessor conditionals (#if) on the macros (#define) `LINEAR` and `NONLINEAR`.

The macros `LINEAR` and `NONLINEAR` are defined in the generated `rtwdemo_preprocessor_subsys_types.h`, header file:

```
#ifndef LINEAR
#define LINEAR      (VSSMODE == 0)
#endif

#ifndef NONLINEAR
#define NONLINEAR   (VSSMODE == 1)
#endif
```

In the generated code, the code related to the variants is guarded by C preprocessor conditionals. For example, in `rtwdemo_preprocessor_subsys.c`, the calls to the step and initialization functions of each variant are conditionally compiled:

```
/* Outputs for atomic SubSystem: '<Root>/LeftController' */
#if LINEAR
    /* Output and update for atomic system: '<S1>/Linear' */
#elif NONLINEAR
    /* Output and update for atomic system: '<S1>/Nonlinear' */
#endif
```

Close the model, figure, and workspace variables from the example.

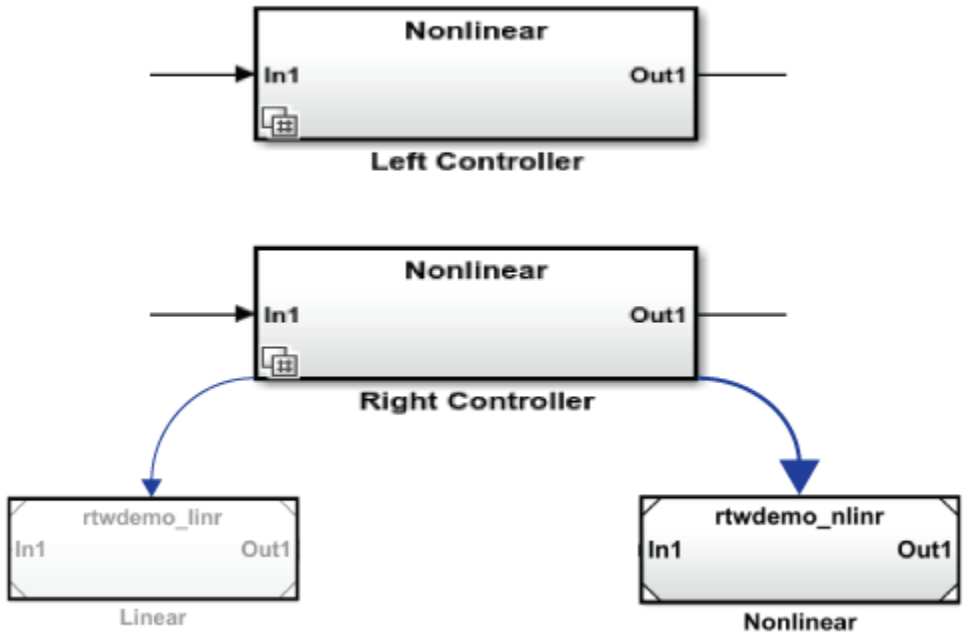
```
bdclose('rtwdemo_preprocessor_subsys')
close(findobj(0,'Tag','CloseMe'));
clear LINEAR NONLINEAR VSSMODE
clear tout yout youtl youtnl
```

Use Variant Models to Generate Code That Uses C Preprocessor Conditionals

This example shows you how to use variant models to generate code that uses preprocessor conditionals to control which code is linked into the embedded executable.

Overview of Variant Models

You can use a Model block to reference one Simulink® model (the *child model*) from another Simulink® model (the *parent model*). A Variant Subsystem block can have different *variants*. The variants can include a set of Model blocks, from which the Variant Subsystem block selects one. The figure below is a conceptual depiction of variant models. In this example the `Right Controller` model block can potentially select from two Model blocks. The models referenced by the Model blocks provide variations upon a nominal, prescribed functionality.

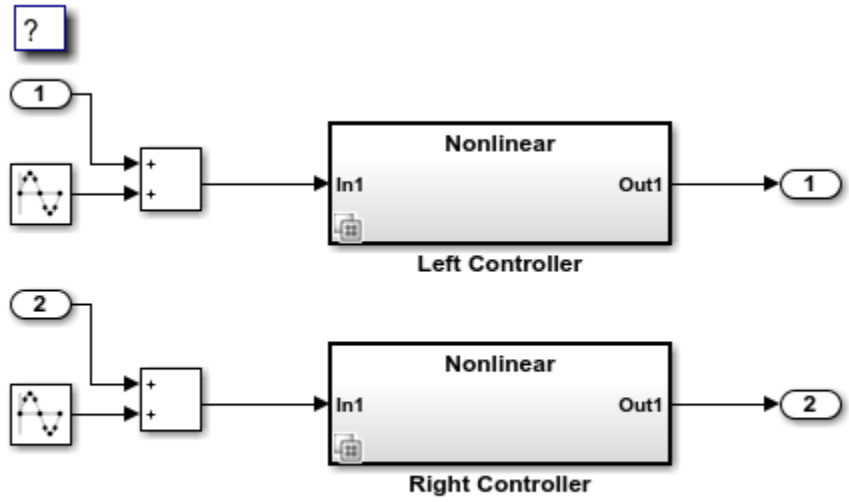


A Variant Subsystem block has only one variant active at a time. You can use the Variant Subsystem block dialog to select the active variant. Alternatively, you can parameterize the selection of the active variant, and make it dependent on the values of variables and objects in the base MATLAB® workspace. When you generate code, you can generate code for all variants and defer the choice of active variant until it is time to compile that code.

Specifying Variant Models

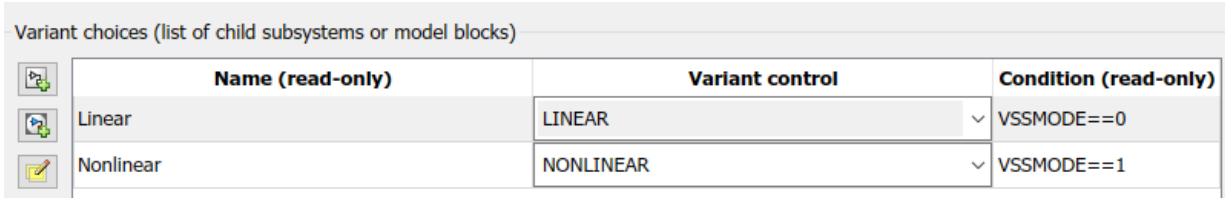
Opening the example model `rtwdemo_preprocessor` runs the **PostLoadFcn** defined in the "File: ModelProperties: Callbacks" dialog. This populates the base workspace with the control variables for the Variant Subsystem blocks.

```
open_system('rtwdemo_preprocessor')
```



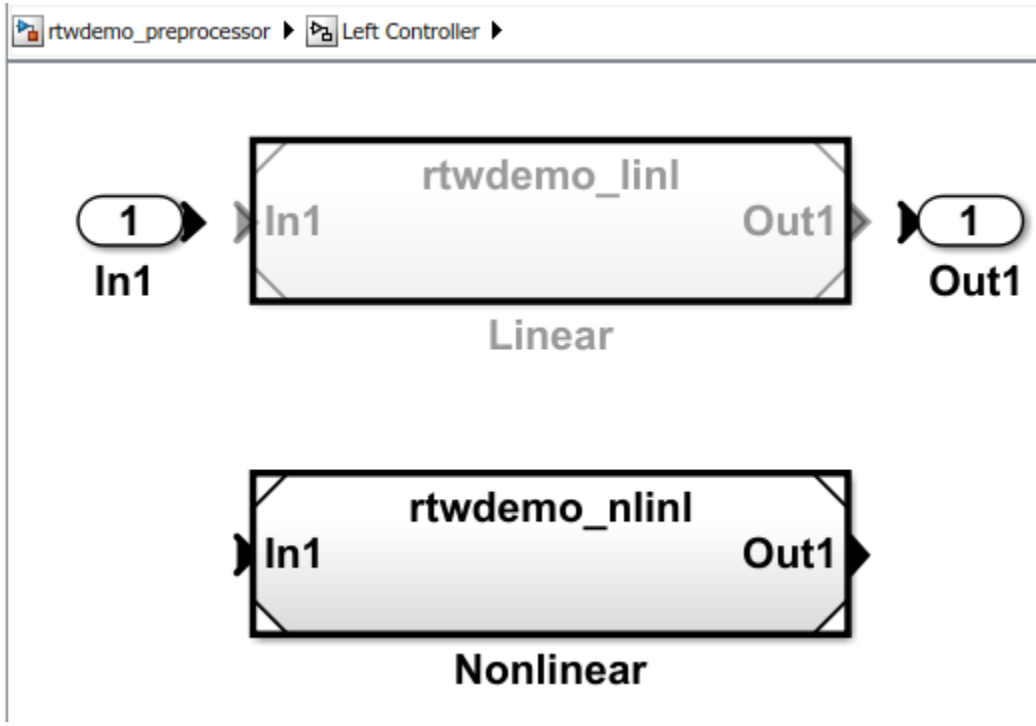
The `Left Controller` variant subsystem contains two child Model blocks: `Linear` and `Nonlinear`. The `Left Controller/Linear` child model executes when the `Simulink.Variant` object `LINEAR` evaluates to `true`, and the `Left Controller/Nonlinear` child model executes when the `Simulink.Variant` object `NONLINEAR` evaluates to `true`.

`Simulink.Variant` objects are specified for the `Left Controller` subsystem by right-clicking the `Left Controller` subsystem and selecting `Subsystem Parameters`, which opens the `Left Controller` Variant Subsystem block dialog box.



The `Left Controller` subsystem block dialog creates an association between the `Linear` and `Nonlinear` Model blocks with the two `Simulink.Variant` objects from the base workspace, `LINEAR` and `NONLINEAR`. These objects have a property named

`Condition`, which is an expression that evaluates to a Boolean value and determines the active variant model (`Linear` or `Nonlinear`). The condition is also shown in the subsystem block dialog. In this example, the conditions of `LINEAR` and `NONLINEAR` are `'VSSMODE == 0'` and `'VSSMODE == 1'`, respectively.



In this example, `Simulink.Variant` objects are created in the base workspace.

```
LINEAR = Simulink.Variant;
LINEAR.Condition = 'VSSMODE==0';
NONLINEAR = Simulink.Variant;
NONLINEAR.Condition = 'VSSMODE==1';
```

Specifying a Variant Control Variable

Variant objects allow you to reuse arbitrarily complex conditions throughout a model. Multiple Variant Subsystem blocks can use the same `Simulink.Variant` objects, allowing you to toggle the activation of variant models as a set. You can toggle the set prior to simulation by changing the value of `VSSMODE` in the MATLAB environment or

when compiling the generated code, as explained in the next section. In this example, `Left Controller` and `Right Controller` reference the same variant objects, so that you can toggle them simultaneously.

The nonlinear controller models implement hysteresis, while the linear controller models act as simple low-pass filters. Open the subsystem for the left channel. The models for the right channel are similar.

The generated code accesses the variant control variable `VSSMODE` as a user-defined macro. In this example, `rtwdemo_importedmacros.h` supplies `VSSMODE`. Within the MATLAB environment, you specify `VSSMODE` using a `Simulink.Parameter` object. Its value will be ignored when generating code including preprocessor conditionals. However, the value is used for simulation. The legacy header file specifies the value of the macro to be used when compiling the generated code, which ultimately activates one of the two specified variants in the embedded executable.

Variant control variables can be defined as `Simulink.Parameter` objects with one of these storage classes:

- `Define` or `ImportedDefine` with header file specified
- `CompilerFlag`
- `SystemConstant` (AUTOSAR)
- User-defined custom storage class that defines data as a macro in a specified header file

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = 'rtwdemo_importedmacros.h';
```

Simulating the Model with Different Variants

Because you set the value of `VSSMODE` to `1`, the model uses the nonlinear controllers during simulation.

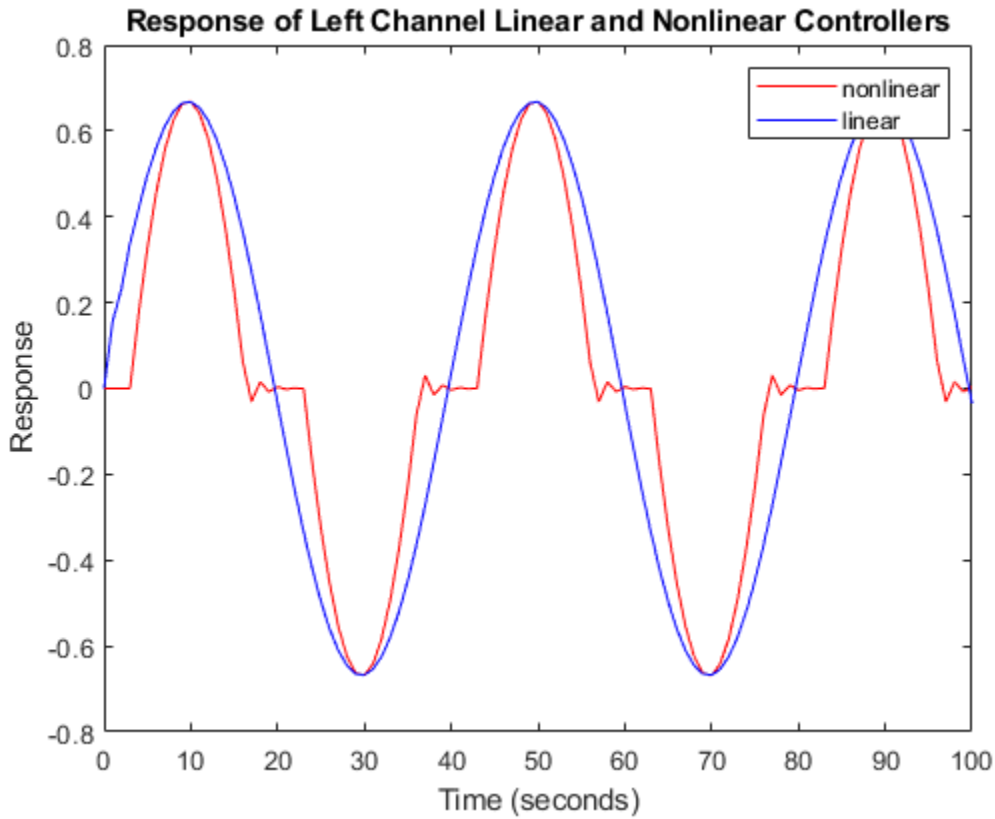
```
sim('rtwdemo_preprocessor')
youtnl = yout;
```

If you change the value of `VSSMODE` to `0`, the model uses the linear controllers during simulation.

```
VSSMODE.Value = int32(0);
sim('rtwdemo_preprocessor')
youtl = yout;
```

You can plot and compare the response of the linear and nonlinear controllers:

```
figure('Tag','CloseMe');
plot(tout, youtnl.signals(1).values, 'r-', tout, youtl.signals(1).values, 'b-')
title('Response of Left Channel Linear and Nonlinear Controllers');
ylabel('Response');
xlabel('Time (seconds)');
legend('nonlinear','linear')
axis([0 100 -0.8 0.8]);
```



Using C Preprocessor Conditionals

This example model has been configured to generate C preprocessor conditionals. You can generate code for the model by selecting **Code > C/C++ Code > Build Model**.

To activate code generation of preprocessor conditionals, check whether the following conditions are true:

- Select an Embedded Coder® target in **Code Generation > System target file** in the Configuration Parameters dialog box
- In the Variant Subsystem block parameter dialog box, clear the option to **Override variant conditions and use following variant**
- In the Variant Subsystem block parameter dialog box, Select the option to **Analyze all choices during update diagram and generate preprocessor conditionals**.

The Simulink® Coder™ code generation report contains sections in the **Code Variants** report dedicated to the subsystems that have variants controlled by preprocessor conditionals.

In this example, the generated code includes references to the `Simulink.Variant` objects `LINEAR` and `NONLINEAR`, as well as the definitions of macros corresponding to those variants. Those definitions depend on the value of `VSSMODE`, which is supplied in an external header file `rtwdemo_importedmacros.h`. The active variant is determined by using preprocessor conditionals (`#if`) on the macros (`#define`) `LINEAR` and `NONLINEAR`.

The macros `LINEAR` and `NONLINEAR` are defined in the generated `rtwdemo_preprocessor_types.h` header file:

```
|#ifndef LINEAR|
|#define LINEAR      (VSSMODE == 0)|
|#endif|

|#ifndef NONLINEAR|
|#define NONLINEAR   (VSSMODE == 1)|
|#endif|
```

In the generated code, the code related to the variants is guarded by C preprocessor conditionals. For example, in `rtwdemo_preprocessor.c`, the calls to the step and initialization functions of each variant are conditionally compiled:

```
  /* Outputs for Atomic SubSystem: '<Root>/Left Controller' */

  /* ModelReference: '<S1>/Linear' incorporates:
   *  ModelReference: '<S1>/Nonlinear'
   */
#if LINEAR

  rtwdemo_linl(&rtb_Add, &rtb_VariantMergeForOutportOut_h,
               &(rtwdemo_preprocessor_DWork.Linear_InstanceData_c.rtdw));

#elif NONLINEAR

  /* ModelReference: '<S1>/Nonlinear' */
  rtwdemo_nlinl(&rtb_Add, &rtb_VariantMergeForOutportOut_h,
                &(rtwdemo_preprocessor_DWork.Nonlinear_InstanceData_e.rtdw));

#endif                                 /* LINEAR */
```

Close the model, figure, and workspace variables from the example.

```
bdclose('rtwdemo_preprocessor')
close(findobj(0,'Tag','CloseMe'));
clear LINEAR NONLINEAR VSSMODE
clear tout yout youtl youtnl
```

Timers in Simulink Coder

Absolute and Elapsed Time Computation

In this section...

About Timers

Certain blocks require the value of either *absolute* time (that is, the time from the start of program execution to the present time) or *elapsed* time (for example, the time elapsed between two trigger events). Targets that support the real-time model (`rtModel`) data structure provide efficient time computation services to blocks that request absolute or elapsed time. Absolute and elapsed timer features include

- Timers are implemented as unsigned integers in generated code.
- In multirate models, at most one timer is allocated per rate. If no blocks executing at a given rate require a timer, a timer is not allocated to that rate. This minimizes memory allocated for timers and significantly reduces overhead involved in maintaining timers.
- Allocation of elapsed time counters for use of blocks within triggered subsystems is minimized, further reducing memory usage and overhead.
- S-function and TLC APIs let your S-functions access timers, in simulation and code generation.
- The word size of the timers is determined by a user-specified maximum counter value, **Application lifespan (days)** (Simulink). If you specify this value, timers will not overflow. For more information, see “Control Memory Allocation for Time Counters” (Simulink Coder).

See “Absolute Time Limitations” (Simulink Coder) for more information about absolute time and the restrictions that it imposes.

Timers for Periodic and Asynchronous Tasks

Timing services provided for blocks execute within *periodic* tasks (that is, tasks running at the model base rate or subrates).

The code generator also provides timer support for blocks whose execution is *asynchronous* with respect to the periodic timing source of the model. See the following topics:

- “Timers in Asynchronous Tasks” on page 28-42
- “Create a Customized Asynchronous Library” on page 28-45

Allocation of Timers

If you create or maintain an S-Function block that requires absolute or elapsed time data, it must register the requirement (see “Access Timers Programmatically” on page 26-5). In multirate models, timers are allocated on a per-rate basis. For example, consider a model structured as follows:

- There are three rates, A, B, and C, in the model.
- No blocks running at rate B require absolute or elapsed time.
- Two blocks running at rate C register a requirement for absolute time.
- One block running at rate A registers a requirement for absolute time.

In this case, two timers are generated, running at rates A and C respectively. The timing engine updates the timers as the tasks associated with rates A and C execute. Blocks executing at rates A and C obtain time data from the timers associated with rates A and C.

Integer Timers in Generated Code

In the generated code, timers for absolute and elapsed time are implemented as unsigned integers. The default size is 64 bits. This is the amount of memory allocated for a timer if you specify a value of `inf` for the **Application lifespan (days)** (Simulink) parameter. For an application with a sample rate of 1000 MHz, a 64-bit counter will not overflow for more than 500 years. See “Timers in Asynchronous Tasks” on page 28-42 and “Control Memory Allocation for Time Counters” on page 67-11 for more information.

Elapsed Time Counters in Triggered Subsystems

Some blocks, such as the Discrete-Time Integrator block, perform computations requiring the elapsed time (delta T) since the previous block execution. Blocks requiring elapsed time data must register the requirement (see “Access Timers Programmatically” on page 26-5). A triggered subsystem then allocates and maintains a single elapsed time counter if required. This timer functions at the subsystem level, not at the individual block level. The timer is generated if the triggered subsystem (or a unconditionally executed subsystem within the triggered subsystem) contains one or more blocks requiring elapsed time data.

Note If you are using simplified initialization mode, elapsed time is reset on first execution after becoming enabled, whether or not the subsystem is configured to reset on enable. For more information, see “Underspecified initialization detection” (Simulink).

Access Timers Programmatically

In this section...

About Timer APIs

This topic describes APIs that let your S-functions take advantage of the efficiencies offered by absolute and elapsed timers. SimStruct macros are provided for use in simulation, and TLC functions are provided for inlined code generation. Note that

- To generate and use the new timers as described above, your S-functions must register the need to use an absolute or elapsed timer by calling `ssSetNeedAbsoluteTime` or `ssSetNeedElapseTime` in `mdlInitializeSampleTime`.
- Existing S-functions that read absolute time but do not register by using these macros continue to operate as expected, but generate less efficient code.

C API for S-Functions

The SimStruct macros described in this topic provide access to absolute and elapsed timers for S-functions during simulation.

In the functions below, the `SimStruct *S` argument is a pointer to the `simstruct` of the calling S-function.

- `void ssSetNeedAbsoluteTime(SimStruct *S, boolean b)`: if `b` is `TRUE`, registers that the calling S-function requires absolute time data, and allocates an absolute time counter for the rate at which the S-function executes (if such a counter has not already been allocated).
- `int ssGetNeedAbsoluteTime(SimStruct *S)`: returns 1 if the S-function has registered that it requires absolute time.
- `double ssGetTaskTime(SimStruct *S, tid)`: read absolute time for a given task with task identifier `tid`. `ssGetTaskTime` operates transparently, regardless of whether or not you use the new timer features. `ssGetTaskTime` is documented in the SimStruct Functions chapter of the Simulink documentation.

- `void ssSetNeedElapseTime(SimStruct *S, boolean b)`: if `b` is `TRUE`, registers that the calling S-function requires elapsed time data, and allocates an elapsed time counter for the triggered subsystem in which the S-function executes (if such a counter has not already been allocated). See also “Elapsed Time Counters in Triggered Subsystems” on page 26-4.
- `int ssGetNeedElapseTime(SimStruct *S)`: returns 1 if the S-function has registered that it requires elapsed time.
- `void ssGetElapseTime(SimStruct *S, (double *)elapseTime)`: returns, to the location pointed to by `elapseTime`, the value (as a `double`) of the elapsed time counter associated with the S-function.
- `void ssGetElapseTimeCounterDtype(SimStruct *S, (int *)dtype)`: returns the data type of the elapsed time counter associated with the S-function to the location pointed to by `dtype`. This function is intended for use with the `ssGetElapseTimeCounter` function (see below).
- `void ssGetElapseResolution(SimStruct *S, (double *)resolution)`: returns the resolution (that is, the sample time) of the elapsed time counter associated with the S-function to the location pointed to by `resolution`. This function is intended for use with the `ssGetElapseTimeCounter` function (see below).
- `void ssGetElapseTimeCounter(SimStruct *S, (void *)elapseTime)`: This function is provided for the use of blocks that require the elapsed time values for fixed-point computations. `ssGetElapseTimeCounter` returns, to the location pointed to by `elapseTime`, the integer value of the elapsed time counter associated with the S-function. If the counter size is 64 bits, the value is returned as an array of two 32-bit words, with the low-order word stored at the lower address.

  To determine how to access the returned counter value, obtain the data type of the counter by calling `ssGetElapseTimeCounterDtype`, as in the following code:

```
int    *y_dtype;
ssGetElapseTimeCounterDtype(S, y_dtype);

 switch(*y_dtype) {
  case SS_DOUBLE_UINT32:
      {
          uint32_T dataPtr[2];
          ssGetElapseTimeCounter(S, dataPtr);
      }
      break;
  case SS_UINT32:
      {
```

```
        uint32_T dataPtr[1];
        ssGetElapseTimeCounter(S, dataPtr);
     }
      break;
  case SS_UINT16:
     {
         uint16_T dataPtr[1];
         ssGetElapseTimeCounter(S, dataPtr);
     }
      break;
  case SS_UINT8:
     {
        uint8_T dataPtr[1];
        ssGetElapseTimeCounter(S, dataPtr);
    }
     break;
  case SS_DOUBLE:
      {
        real_T dataPtr[1];
        ssGetElapseTimeCounter(S, dataPtr);
     }
      break;
  default:
    ssSetErrorStatus(S, "Invalid data type for elaspe time
        counter");
    break;
}
```

If you want to use the actual elapsed time, issue a call to the `ssGetElapseTime` function to access the elapsed time directly. You do not need to get the counter value and then calculate the elapsed time.

```
double *y_elapseTime;
.
.
.
ssGetElapseTime(S, elapseTime)
```

TLC API for Code Generation

The following TLC functions support elapsed time counters in generated code when you inline S-functions by writing TLC scripts for them.

- `LibGetTaskTimeFromTID(block)`: Generates code to read the absolute time for the task in which `block` executes.

  `LibGetTaskTimeFromTID` is documented with other sample time functions in the TLC Function Library Reference pages of the Target Language Compiler documentation.

  Note Do not use `LibGetT` for this purpose. `LibGetT` always reads the base rate (`tid 0`) timer. If `LibGetT` is called for a block executing at a subrate, the wrong timer is read, causing serious errors.

- `LibGetElapseTime(system)`: Generates code to read the elapsed time counter for `system`. (`system` is the parent system of the calling block.) See “Generate Code for an Elapsed Time Counter” on page 26-9 for an example of code generated by this function.
- `LibGetElapseTimeCounter(system)`: Generates code to read the integer value of the elapsed time counter for `system`. (`system` is the parent system of the calling block.) This function should be used in conjunction with `LibGetElapseTimeCounterDtypeId` and `LibGetElapseTimeResolution`. (See the discussion of `ssGetElapseTimeCounter` above.)
- `LibGetElapseTimeCounterDtypeId(system)`: Generates code that returns the data type of the elapsed time counter for `system`. (`system` is the parent system of the calling block.)
- `LibGetElapseTimeResolution(system)`: Generates code that returns the resolution of the elapsed time counter for `system`. (`system` is the parent system of the calling block.)

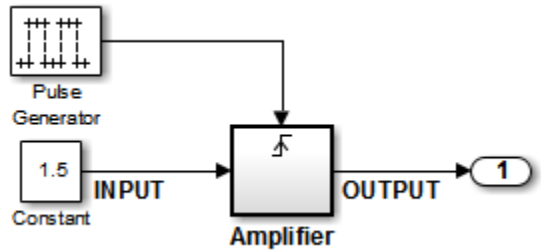
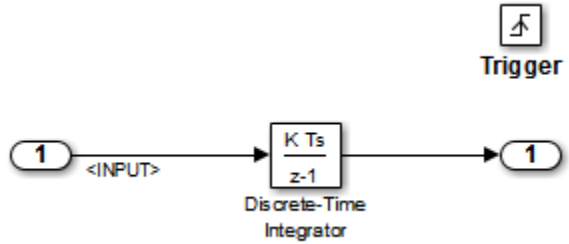
Generate Code for an Elapsed Time Counter

This example shows a model that includes a triggered subsystem, `Amplifier`, consisting of a Discrete-Time Integrator block that uses an elapsed time counter. The model `ex_elapseTime` is in the folder `matlab/help/toolbox/rtw/examples`.



ex_elapseTime Model



Amplifier Subsystem

Code in the generated header file `ex_elapseTime.h` for the model uses 64 bits to implement the timer for the base rate (`clockTick0` and `clockTickH0`).

```
/*
 * Timing:
 * The following substructure contains information regarding
 * the timing information for the model.
 */
struct {
  time_T taskTime0;
  uint32_T clockTick0;
```

```
  uint32_T clockTickH0;
  time_T stepSize0;
  time_T tFinal;
  boolean_T stopRequestedFlag;
} Timing;
```

The code generator allocates storage for the previous-time value and elapsed-time value of the `Amplifier` subsystem (`Amplifier_PREV_T`) in the `D_Work(states)` structure in `ex_elapsedTime.h`.

```
/* Block states (auto storage) for system '<Root>' */
typedef struct {
  real_T DiscreteTimeIntegrator_DSTATE;
    /* '<S1>/Discrete-Time Integrator' */
  int32_T clockTickCounter;
    /* '<Root>/Pulse Generator' */
  uint32_T Amplifier_ELAPS_T[2];
    /* '<Root>/Amplifier' */
  uint32_T Amplifier_PREV_T[2];
    /* '<Root>/Amplifier' */
    } DW_ex_elapseTime_T;
```

The elapsed time computation is performed as follows within the `ex_elapseTime_step` function:

```
/* ---
   Outputs for Triggered SubSystem:
      '<Root>/Amplifier' incorporates:
         TriggerPort: '<S1>/Trigger'
 --- */
 zcEvent = rt_ZCFcn(RISING_ZERO_CROSSING,
        &ex_elapseTime_PrevZCX.Amplifier_Trig_ZCE,
        ((real_T)rtb_PulseGenerator));
    if (zcEvent != NO_ZCEVENT) {
   elapseT_H = ex_elapseTime_M->Timing.clockTickH0 -
        ex_elapseTime_DW.Amplifier_PREV_T[1];
       if (ex_elapseTime_DW.Amplifier_PREV_T[0] >
        ex_elapseTime_M->Timing.clockTick0) {
     elapseT_H--;
       }

   ex_elapseTime_DW.Amplifier_ELAPS_T[0] =
      ex_elapseTime_M->Timing.clockTick0
      - ex_elapseTime_DW.Amplifier_PREV_T[0];
   ex_elapseTime_DW.Amplifier_PREV_T[0] =
```

```
      ex_elapseTime_M->Timing.clockTick0;
   ex_elapseTime_DW.Amplifier_ELAPS_T[1] =
      elapseT_H;
   ex_elapseTime_DW.Amplifier_PREV_T[1] =
      ex_elapseTime_M->Timing.clockTickH0;
```

As shown above, the elapsed time is maintained as a state of the triggered subsystem. The Discrete-Time Integrator block finally performs its output and update computations using the elapsed time.

```
/* ---
DiscreteIntegrator: '<S1>/Discrete-Time Integrator'
--- */
OUTPUT = ex_elapseTime_DW.DiscreteTimeIntegrator_DSTATE;

/* ---
Update for DiscreteIntegrator:
   '<S1>/Discrete-Time Integrator' incorporates:
      Constant: '<Root>/Constant'
--- */
   ex_elapseTime_DW.DiscreteTimeIntegrator_DSTATE += 0.3 * (real_T)
     ex_elapseTime_DW.Amplifier_ELAPS_T[0] * 1.5;
```

Absolute Time Limitations

Absolute time is the time that has elapsed from the beginning of program execution to the present time, as distinct from *elapsed time*, the interval between two events. See “Absolute and Elapsed Time Computation” on page 26-2 for more information.

When you design an application that is intended to run indefinitely, you must take care when logging time values, or using charts or blocks that depend on absolute time. If the value of time reaches the largest value that can be represented by the data type used by the timer to store time, the timer overflows and the logged time or block output is incorrect.

If your target uses `rtModel`, you can avoid timer overflow by specifying a value for the **Application life span** parameter. See “Integer Timers in Generated Code” on page 26-3 for more information.

The following limitations apply to absolute time:

- If you log time values by opening the Configuration Parameters dialog box and enabling **Data Import/Export > Time** parameter, your model uses absolute time.
- Every Stateflow chart that uses time is dependent on absolute time. The only way to eliminate the dependency is to change the Stateflow chart to not use time.
- The following Simulink blocks depend on absolute time:
  - Backlash
  - Chirp Signal
  - Clock
  - Derivative
  - Digital Clock
  - Discrete-Time Integrator (only when used in triggered subsystems)
  - From File
  - From Workspace
  - Pulse Generator
  - Ramp
  - Rate Limiter
  - Repeating Sequence

- Signal Generator
- Sine Wave (only when the **Sine type** parameter is set to `Time-based`)
- Step
- To File
- To Workspace (only when logging to `StructureWithTime` format)
- Transport Delay
- Variable Time Delay
- Variable Transport Delay

In addition to the Simulink blocks above, blocks in other blocksets may depend on absolute time. See the documentation for the blocksets that you use.

Time-Based Scheduling in Simulink Coder

Time-Based Scheduling and Code Generation

In this section...

Sample Time Considerations

Simulink models run at one or more sample times. The Simulink product provides considerable flexibility in building multirate systems, that is, systems with more than one sample time. However, this same flexibility also allows you to construct models for which the code generator cannot generate real-time code for execution in a multitasking environment. To make multirate models operate as expected in real time (that is, to give the right answers), you sometimes must modify your model or instruct the Simulink engine to modify the model for you. In general, the modifications involve placing Rate Transition blocks between blocks that have unequal sample times. The following sections discuss issues you must address to use a multirate model in a multitasking environment. For a comprehensive discussion of sample times, including rate transitions, see “What Is Sample Time?” (Simulink), “Sample Times in Subsystems” (Simulink), “Sample Times in Systems” (Simulink), “Resolve Rate Transitions” (Simulink), and associated topics.

Tasking Modes

There are two execution modes for a fixed-step Simulink model: single-tasking and multitasking. These modes are available only for fixed-step solvers. To select an execution mode, use the **Treat each discrete rate as a separate task** checkbox on the **Solver** pane of the Configuration Parameters dialog box. When this parameter is selected, multitasking execution is applied for a multirate model. When this option is cleared, single-tasking execution is applied.

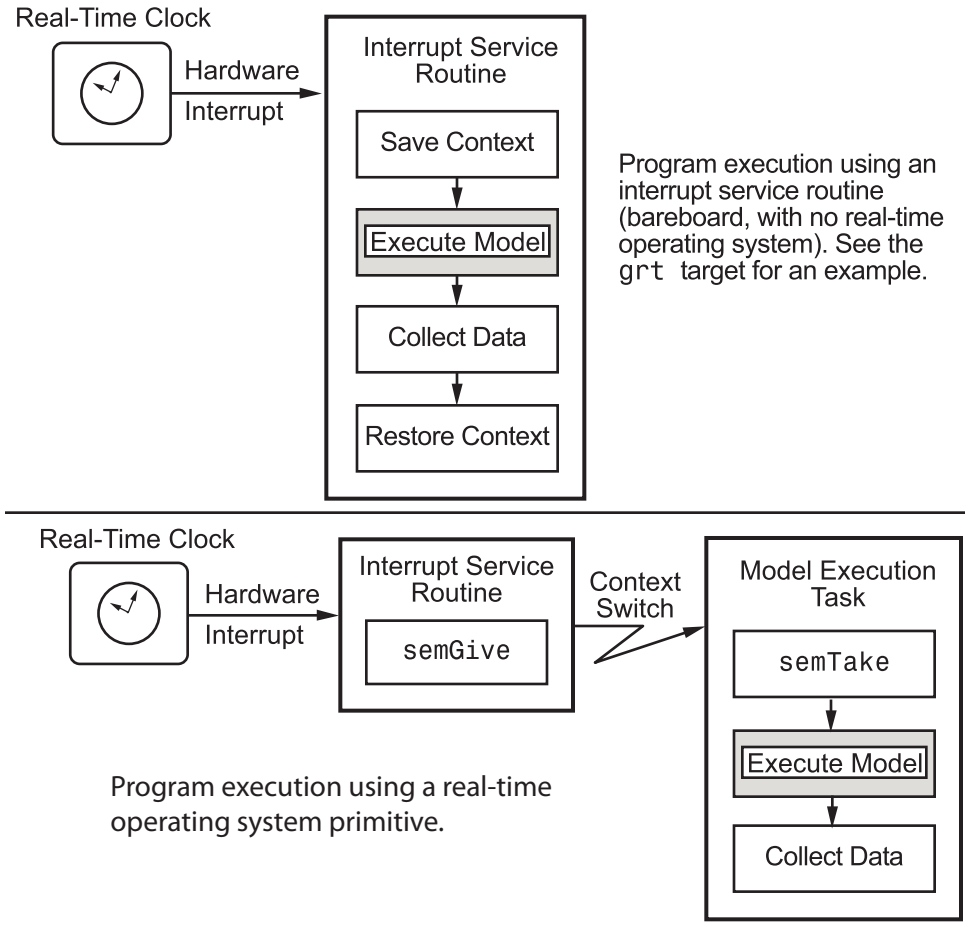
Note A model that is multirate and uses multitasking cannot reference a multirate model that uses single-tasking.

Execution of models in a real-time system can be done with the aid of a real-time operating system, or it can be done on *bare-metal* target hardware, where the model runs in the context of an interrupt service routine (ISR).

The fact that a system (such as The Open Group UNIX or Microsoft Windows systems) is multitasking does not imply that your program can execute in real time. This is because the program might not preempt other processes when required.

In operating systems (such as PC-DOS) where only one process can exist at a given time, an interrupt service routine (ISR) must perform the steps of saving the processor context, executing the model code, collecting data, and restoring the processor context.

Other operating systems, such as POSIX-compliant ones, provide automatic context switching and task scheduling. This simplifies the operations performed by the ISR. In this case, the ISR simply enables the model execution task, which is normally blocked. The next figure illustrates this difference.



Model Execution and Rate Transitions

To generate code that executes as expected in real time, you (or the Simulink engine) might need to identify and handle sample rate transitions within the model. In multitasking mode, by default the Simulink engine flags errors during simulation if the model contains invalid rate transitions, although you can use the **Multitask rate transition** diagnostic to alter this behavior. A similar diagnostic, called **Single task rate transition**, exists for single-tasking mode.

To avoid raising rate transition errors, insert Rate Transition blocks between tasks. You can request that the Simulink engine handle rate transitions automatically by inserting hidden Rate Transition blocks. See “Automatic Rate Transition” on page 27-26 for an explanation of this option.

To understand such problems, first consider how Simulink simulations differ from real-time programs.

Execution During Simulink Model Simulation

Before the Simulink engine simulates a model, it orders the blocks based upon their topological dependencies. This includes expanding virtual subsystems into the individual blocks they contain and flattening the entire model into a single list. Once this step is complete, each block is executed in order.

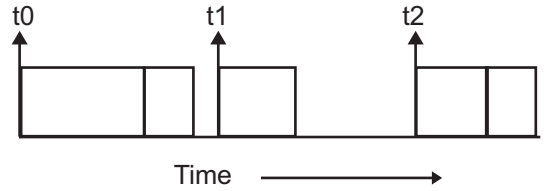
The key to this process is the ordering of blocks. A block whose output is directly dependent on its input (that is, a block with direct feedthrough) cannot execute until the block driving its input executes.

Some blocks set their outputs based on values acquired in a previous time step or from initial conditions specified as a block parameter. The output of such a block is determined by a value stored in memory, which can be updated independently of its input. During simulation, computations are performed prior to advancing the variable corresponding to time. This results in computations occurring instantaneously (that is, no computational delay).

Model Execution in Real Time

A real-time program differs from a Simulink simulation in that the program must execute the model code synchronously with real time. Every calculation results in some computational delay. This means the sample intervals cannot be shortened or lengthened (as they can be in a Simulink simulation), which leads to less efficient execution.

Consider the following timing figure.



Note the processing inefficiency in the sample interval `t1`. That interval cannot be compressed to increase execution speed because, by definition, sample times are clocked in real time.

You can circumvent this potential inefficiency by using the multitasking mode. The multitasking mode defines tasks with different priorities to execute parts of the model code that have different sample rates.

See “Multitasking and Pseudomultitasking Modes” on page 27-12 for a description of how this works. It is important to understand that section before proceeding here.

Single-Tasking Versus Multitasking Operation

Single-tasking programs require longer sample intervals, because all computations must be executed within each clock period. This can result in inefficient use of available CPU time, as shown in the previous figure.

Multitasking mode can improve the efficiency of your program if the model is large and has many blocks executing at each rate.

However, if your model is dominated by a single rate, and only a few blocks execute at a slower rate, multitasking can actually degrade performance. In such a model, the overhead incurred in task switching can be greater than the time required to execute the slower blocks. In this case, it is more efficient to execute all blocks at the dominant rate.

If you have a model that can benefit from multitasking execution, you might need to modify your model by adding Rate Transition blocks (or instruct the Simulink engine to do so) to generate expected results.

For more information about the two modes of execution and examples, see “Modeling for Single-Tasking Execution” on page 27-8 and “Modeling for Multitasking Execution” on page 27-12.

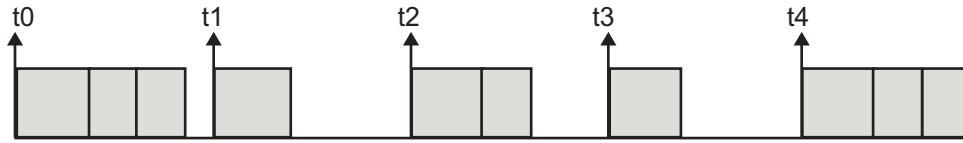
Modeling for Single-Tasking Execution

Single-Tasking Mode

You can execute model code in a strictly single-tasking manner. While this mode is less efficient with regard to execution speed, in certain situations, it can simplify your model.

In single-tasking mode, the base sample rate must define a time interval that is long enough to allow the execution of all blocks within that interval.

The next figure illustrates the inefficiency inherent in single-tasking execution.



Single-tasking system execution requires a base sample rate that is long enough to execute one step through the entire model.

Build a Program for Single-Tasking Execution

To use single-tasking execution, clear the **Treat each discrete rate as a separate task** checkbox on the **Solver** pane of the Configuration Parameters dialog box. If you select the checkbox, single-tasking mode is used in the following cases:

- If your model contains one sample time
- If your model contains a continuous and a discrete sample time and the fixed step size is equal to the discrete sample time

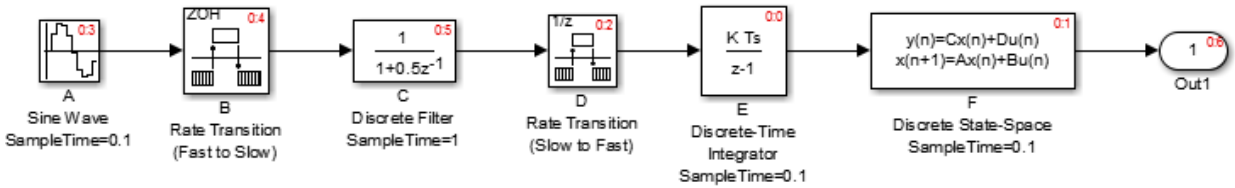
Single-Tasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting of the **Treat each discrete rate as a separate task** parameter on the **Solver** pane.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see “Simulation Phases in Dynamic Systems” (Simulink).

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.



Note The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected) mode, with the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options on.

This example considers the execution of the above model when the **Treat each discrete rate as a separate task** checkbox is cleared, which indicates the single-tasking mode.

In a single-tasking system, if the **Configuration Parameters > Optimization > Advanced parameters > Block reduction** option is selected, fast-to-slow Rate Transition blocks are optimized out of the model. The default case is shown (**Block reduction** selected), so block B does not appear in the timing diagrams in this section. For more information, see “Block reduction” (Simulink).

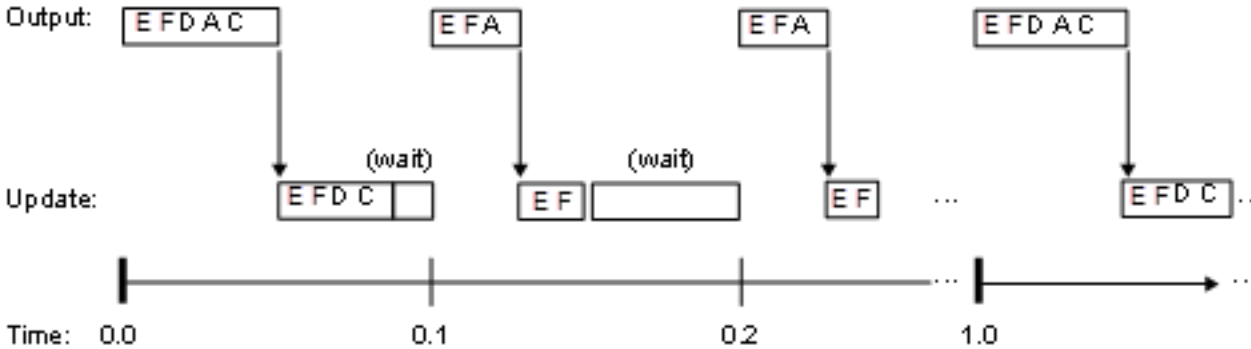
The following table shows, for each block in the model, the execution order, sample time, and whether the block has an output or update computation. Block A does not have discrete states, and accordingly does not have an update computation.

Execution Order and Sample Times (Single-Tasking)

Blocks (in Execution Order)	Sample Time (in Seconds)	Output	Update
E	0.1	Y	Y
F	0.1	Y	Y
D	1	Y	Y
A	0.1	Y	N
C	1	Y	Y

Real-Time Single-Tasking Execution

The next figure shows the scheduling of computations when the generated code is deployed in a real-time system. The generated program is shown running in real time, under control of interrupts from a 10 Hz timer.



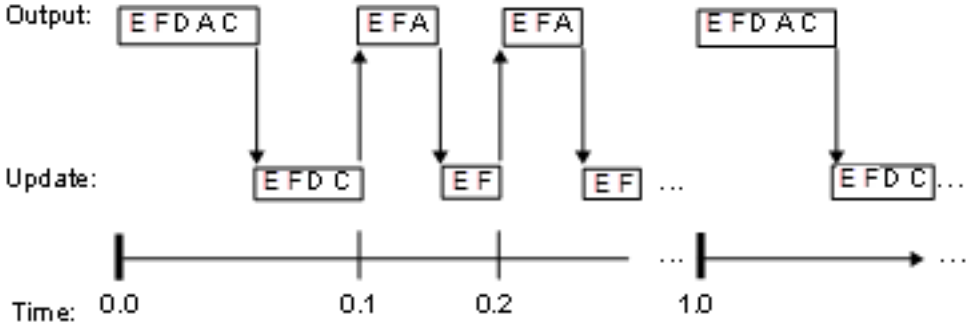
At time 0.0, 1.0, and every second thereafter, both the slow and fast blocks execute their output computations; this is followed by update computations for blocks that have states. Within a given time interval, output and update computations are sequenced in block execution order.

The fast blocks execute on every tick, at intervals of 0.1 second. Output computations are followed by update computations.

The system spends some portion of each time interval (labeled “wait”) idling. During the intervals when only the fast blocks execute, a larger portion of the interval is spent idling. This illustrates an inherent inefficiency of single-tasking mode.

Simulated Single-Tasking Execution

The next figure shows the execution of the model during the Simulink simulation loop.



Because time is simulated, the placement of ticks represents the iterations of the simulation loop. Blocks execute in exactly the same order as in the previous figure, but without the constraint of a real-time clock. Therefore there is no idle time between simulated sample periods.

Modeling for Multitasking Execution

Multitasking and Pseudomultitasking Modes

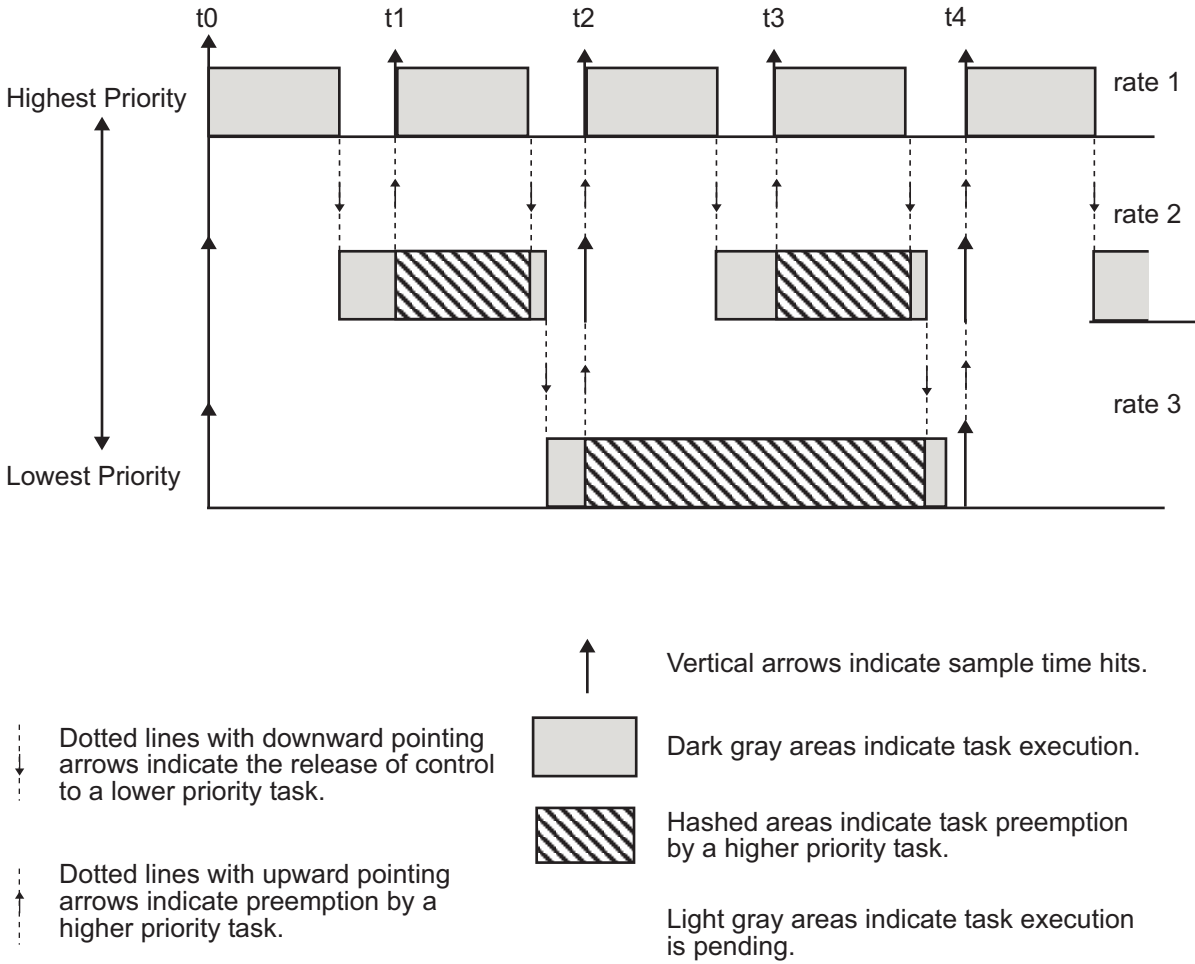
When periodic tasks execute in a multitasking mode, by default the blocks with the fastest sample rates are executed by the task with the highest priority, the next fastest blocks are executed by a task with the next higher priority, and so on. Time available in between the processing of high-priority tasks is used for processing lower priority tasks. This results in efficient program execution.

Where tasks are asynchronous rather than periodic, there may not necessarily be a relationship between sample rates and task priorities; the task with the highest priority need not have the fastest sample rate. You specify asynchronous task priorities using Async Interrupt and Task Sync blocks. You can switch the sense of what priority numbers mean by selecting or deselecting the Solver option **Higher priority value indicates higher task priority**.

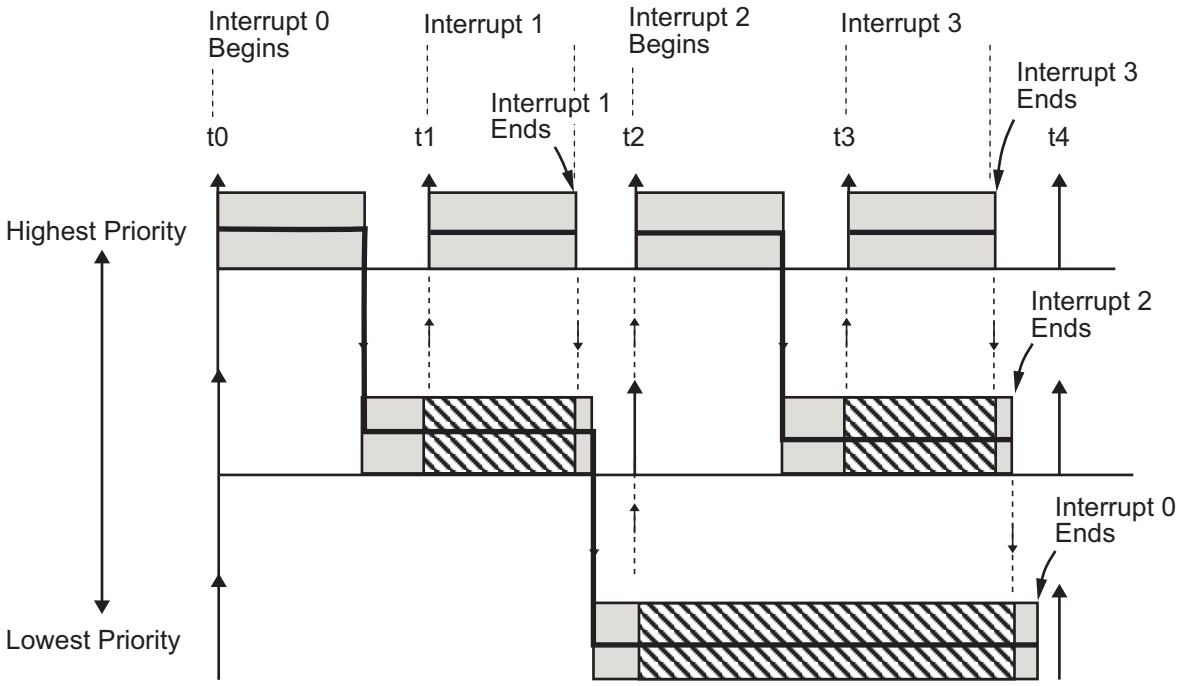
In multitasking environments (that is, under a real-time operating system), you can define separate tasks and assign them priorities. For bare-metal target hardware (that is, no real-time operating system present), you cannot create separate tasks. However, generated application modules implement what is effectively a multitasking execution scheme using overlapped interrupts, accompanied by programmatic context switching.

This means an interrupt can occur while another interrupt is currently in progress. When this happens, the current interrupt is preempted, the floating-point unit (FPU) context is saved, and the higher priority interrupt executes its higher priority (that is, faster sample rate) code. Once complete, control is returned to the preempted ISR.

The next figures illustrate how timing of tasks in multirate systems are handled by the code generator in multitasking, pseudomultitasking, and single-tasking environments.



The next figure shows how overlapped interrupts are used to implement pseudomultitasking. In this case, Interrupt 0 does not return until after Interrupts 1, 2, and 3.



Build a Program for Multitasking Execution

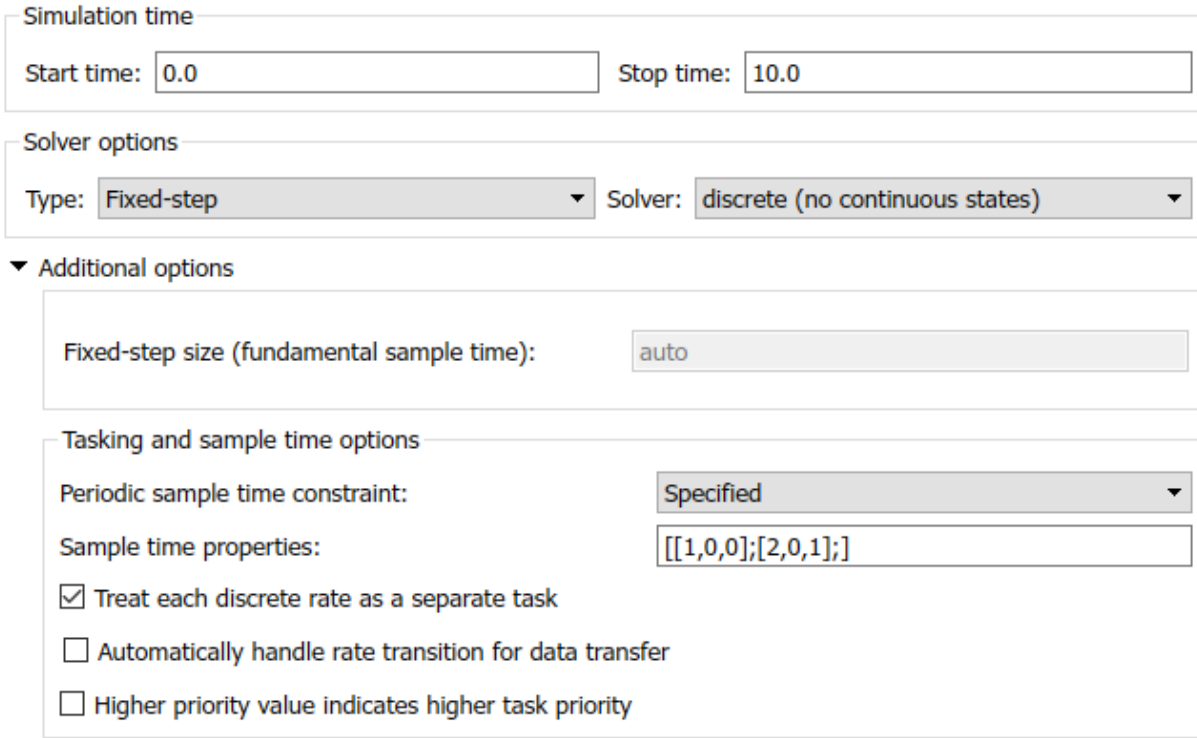
To use multitasking execution, select the **Treat each discrete rate as a separate task** check box on the **Solver** pane of the Configuration Parameters dialog box. This menu is active only if you select `Fixed-step` as the solver type. `Auto` mode results in a multitasking environment if your model has two or more different sample times. A model with a continuous and a discrete sample time runs in single-tasking mode if the fixed-step size is equal to the discrete sample time.

Execute Multitasking Models

In cases where the continuous part of a model executes at a rate that is different from the discrete part, or a model has blocks with different sample rates, the Simulink engine assigns each block a *task identifier* (`tid`) to associate the block with the task that executes at the block's sample rate.

You set sample rates and their constraints on the **Solver** pane of the Configuration Parameters dialog box. To generate code, select `Fixed-step` for the solver type. Certain restrictions apply to the sample rates that you can use:

- The sample rate of a block must be an integer multiple of the base (that is, the fastest) sample period.
- When **Periodic sample time constraint** is `unconstrained`, the base sample period is determined by the **Fixed step size** specified on the **Solvers** pane of the Configuration parameters dialog box.
- When **Periodic sample time constraint** is `Specified`, the base rate fixed-step size is the first element of the sample time matrix that you specify in the companion option **Sample time properties**. The **Solver** pane from the example model `rtwdemo_mrmtbb` shows an example.



- Continuous blocks execute by using an integration algorithm that runs at the base sample rate. The base sample period is the greatest common denominator of all rates in the model only when **Periodic sample time constraint** is set to `Unconstrained` and **Fixed step size** is `Auto`.
- The continuous and discrete parts of the model can execute at different rates only if the discrete part is executed at the same or a slower rate than the continuous part and is an integer multiple of the base sample rate.

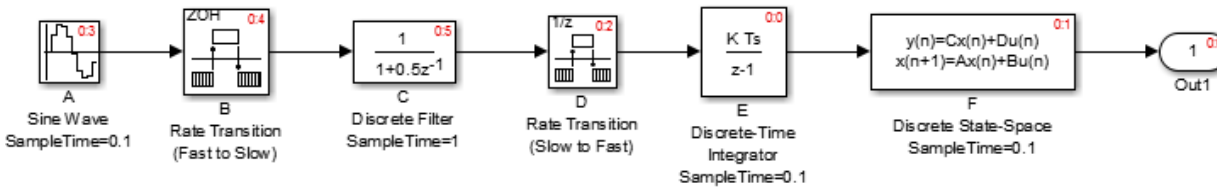
Multitasking Execution

This example examines how a simple multirate model executes in both real time and simulation, using a fixed-step solver. It considers operation in both single-tasking and multitasking modes, as determined by setting of the **Treat each discrete rate as a separate task** parameter on the **Solver** pane.

The example model is shown in the next figure. The discussion refers to the six blocks of the model as A through F, as labeled in the block diagram.

The execution order of the blocks (indicated in the upper right of each block) has been forced into the order shown by assigning higher priorities to blocks F, E, and D. The ordering shown is one possible valid execution ordering for this model. For more information, see “Simulation Phases in Dynamic Systems” (Simulink).

The execution order is determined by data dependencies between blocks. In a real-time system, the execution order determines the order in which blocks execute within a given time interval or task. This discussion treats the model's execution order as a given, because it is concerned with the allocation of block computations to tasks, and the scheduling of task execution.



Note The discussion and timing diagrams in this section are based on the assumption that the Rate Transition blocks are used in the default (protected) mode, with the **Ensure**

data integrity during data transfer and **Ensure deterministic data transfer (maximum delay)** options on.

This example considers the execution of the above model when the solver **Tasking mode** is `MultiTasking`. Block computations are executed under two tasks, prioritized by rate:

- The slower task, which gets the lower priority, is scheduled to run every second. This is called the *1 second task*.
- The faster task, which gets higher priority, is scheduled to run 10 times per second. This is called the *0.1 second task*. The 0.1 second task can preempt the 1 second task.

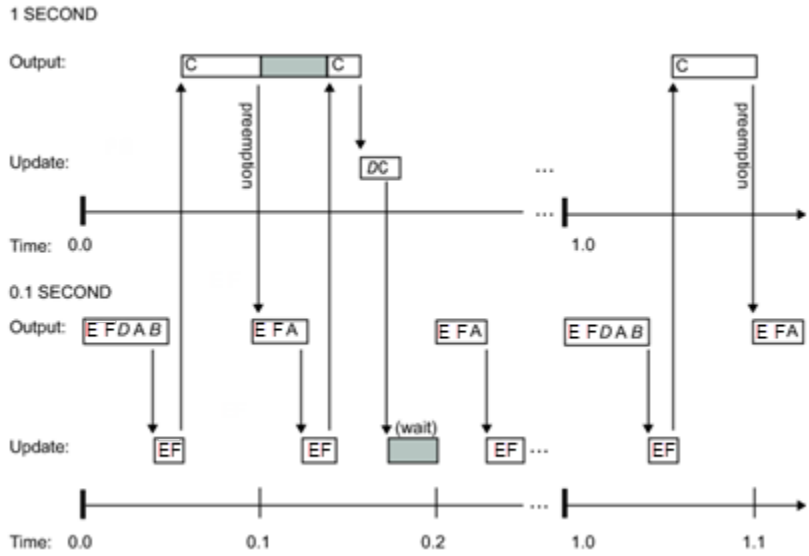
The following table shows, for each block in the model, the execution order, the task under which the block runs, and whether the block has an output or update computation. Blocks A and B do not have discrete states, and accordingly do not have an update computation.

Task Allocation of Blocks in Multitasking Execution

Blocks (in Execution Order)	Task	Output	Update
E	0.1 second task	Y	Y
F	0.1 second task	Y	Y
D	The Rate Transition block uses port-based sample times. Output runs at the output port sample time under 0.1 second task. Update runs at input port sample time under 1 second task. For more information on port-based sample times, see “Referenced Model Sample Times” (Simulink).	Y	Y
A	0.1 second task	Y	N
B	The Rate Transition block uses port-based sample times. Output runs at the output port sample time under 0.1 second task. For more information on port-based sample times, see “Referenced Model Sample Times” (Simulink).	Y	N
C	1 second task	Y	Y

Real-Time Multitasking Execution

The next figure shows the scheduling of computations in `MultiTasking` solver mode when the generated code is deployed in a real-time system. The generated program is shown running in real time, as two tasks under control of interrupts from a 10 Hz timer.



Simulated Multitasking Execution

The next figure shows the Simulink execution of the same model, in `MultiTasking` solver mode. In this case, the Simulink engine runs the blocks in one thread of execution, simulating multitasking. No preemption occurs.

Handle Rate Transitions

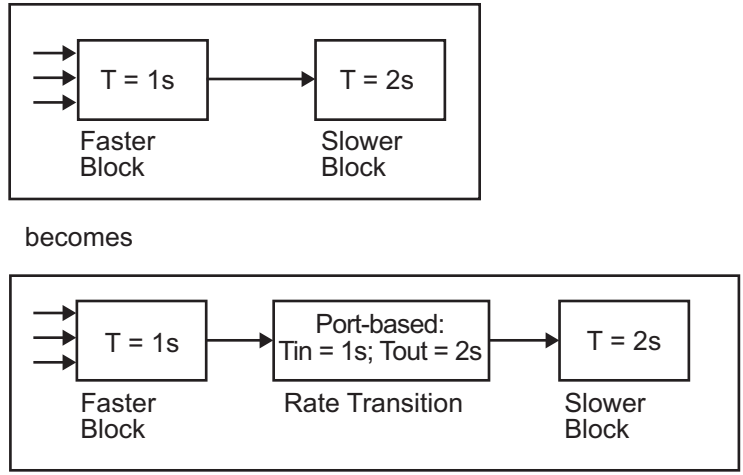
Rate Transitions

Two periodic sample rate transitions can exist within a model:

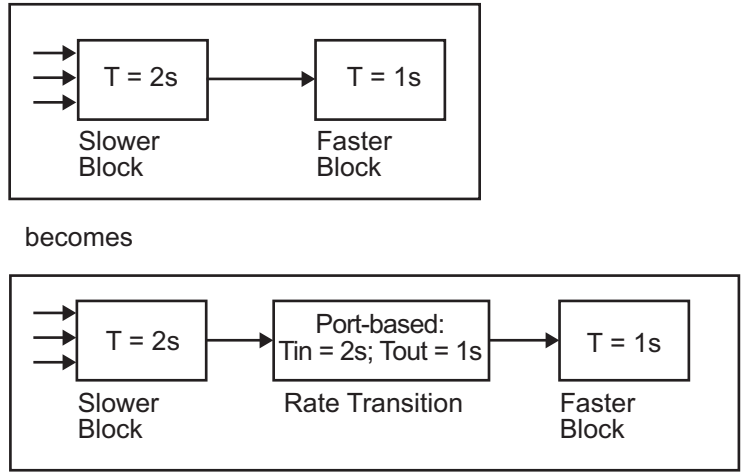
- A faster block driving a slower block
- A slower block driving a faster block

The following sections concern models with periodic sample times with zero offset only. Other considerations apply to multirate models that involve asynchronous tasks. For details on how to generate code for asynchronous multitasking, see “Asynchronous Support” (Simulink Coder).

In multitasking and pseudomultitasking systems, differing sample rates can cause blocks to be executed in the wrong order. To prevent possible errors in calculated data, you must control model execution at these transitions. When connecting faster and slower blocks, you or the Simulink engine must add Rate Transition blocks between them. Fast-to-slow transitions are illustrated in the next figure.



Slow-to-fast transitions are illustrated in the next figure.



Note Although the Rate Transition block offers a superset of the capabilities of the Unit Delay block (for slow-to-fast transitions) and the Zero-Order Hold block (for fast-to-slow transitions), you should use the Rate Transition block instead of these blocks.

Data Transfer Problems

Rate Transition blocks deal with issues of data integrity and determinism associated with data transfer between blocks running at different rates.

- *Data integrity*: A problem of data integrity exists when the input to a block changes during the execution of that block. Data integrity problems can be caused by preemption.

  Consider the following scenario:

  - A faster block supplies the input to a slower block.
  - The slower block reads an input value V_1 from the faster block and begins computations using that value.
  - The computations are preempted by another execution of the faster block, which computes a new output value V_2.
  - A data integrity problem now arises: when the slower block resumes execution, it continues its computations, now using the “new” input value V_2.

Such a data transfer is called *unprotected*. “Faster to Slower Transitions in Real Time” on page 27-30 shows an unprotected data transfer.

In a *protected* data transfer, the output V_1 of the faster block is held until the slower block finishes executing.

- *Deterministic* versus *nondeterministic* data transfer: In a *deterministic* data transfer, the timing of the data transfer is completely predictable, as determined by the sample rates of the blocks.

  The timing of a *nondeterministic* data transfer depends on the availability of data, the sample rates of the blocks, and the time at which the receiving block begins to execute relative to the driving block.

You can use the Rate Transition block to protect data transfers in your application and make them deterministic. These characteristics are considered desirable in most applications. However, the Rate Transition block supports flexible options that allow you to compromise data integrity and determinism in favor of lower latency. The next section summarizes these options.

Data Transfer Assumptions

When processing data transfers between tasks, the code generator makes these assumptions:

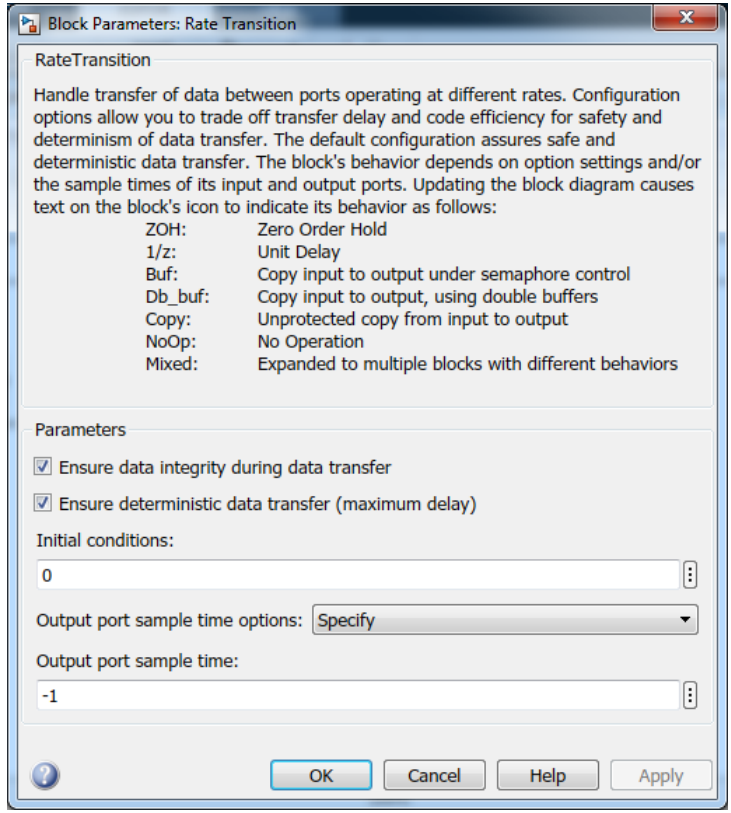
- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte-sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash or restart (especially while data is transferred between tasks).

Rate Transition Block Options

Several parameters of the Rate Transition block are relevant to its use in code generation for real-time execution, as discussed below. For a complete block description, see Rate Transition.

The Rate Transition block handles periodic (fast to slow and slow to fast) and asynchronous transitions. When inserted between two blocks of differing sample rates, the Rate Transition block automatically configures its input and output sample rates for the type of transition; you do not need to specify whether a transition is slow-to-fast or fast-to-slow (low-to-high or high-to-low priorities for asynchronous tasks).

The critical decision you must make in configuring a Rate Transition block is the choice of data transfer mechanism to be used between the two rates. Your choice is dictated by considerations of safety, memory usage, and performance. As the Rate Transition block parameter dialog box in the next figure shows, the data transfer mechanism is controlled by two options.



- **Ensure data integrity during data transfer**: When this option is on, data transferred between rates maintains its integrity (the data transfer is protected).

When this option is off, the data might not maintain its integrity (the data transfer is unprotected). By default, **Ensure data integrity during data transfer** is on.

- **Ensure deterministic data transfer (maximum delay)**: This option is supported for periodic tasks with an offset of zero and fast and slow rates that are multiples of each other. Enable this option for protected data transfers (when **Ensure data integrity during data transfer** is on). When this option is on, the Rate Transition block behaves like a Zero-Order Hold block (for fast to slow transitions) or a Unit Delay block (for slow to fast transitions). The Rate Transition block controls the timing of data transfer in a completely predictable way. When this option is off, the data transfer is nondeterministic. By default, **Ensure deterministic data transfer (maximum delay)** is on for transitions between periodic rates with an offset of zero; for asynchronous transitions, it cannot be selected.

Thus the Rate Transition block offers three modes of operation with respect to data transfer. In order of level of safety:

- **Protected/Deterministic (default):** This is the safest mode. The drawback of this mode is that it introduces deterministic latency into the system for the case of slow-to-fast periodic rate transitions. For that case, the latency introduced by the Rate Transition block is one sample period of the slower task. For the case of fast-to-slow periodic rate transitions, the Rate Transition block introduces does not introduce additional latency.
- **Protected/NonDeterministic:** In this mode, for slow-to-fast periodic rate transitions, data integrity is protected by double-buffering data transferred between rates. For fast-to-slow periodic rate transitions, a semaphore flag is used. The blocks downstream from the Rate Transition block use the latest available data from the block that drives the Rate Transition block. Maximum latency is less than or equal to one sample period of the faster task.

  The drawbacks of this mode are its nondeterministic timing. The advantage of this mode is its low latency.
- **Unprotected/NonDeterministic:** This mode is not recommended for mission-critical applications. The latency of this mode is the same as for Protected/NonDeterministic mode, but memory requirements are reduced since neither double-buffering nor semaphores are required. That is, the Rate Transition block does nothing in this mode other than to pass signals through; it simply exists to notify you that a rate transition exists (and can cause generated code to compute incorrect answers). Selecting this mode, however, generates the least amount of code.

Note In unprotected mode (**Ensure data integrity during data transfer** option off), the Rate Transition block does nothing other than allow the rate transition to exist in the model.

Rate Transition Blocks and Continuous Time

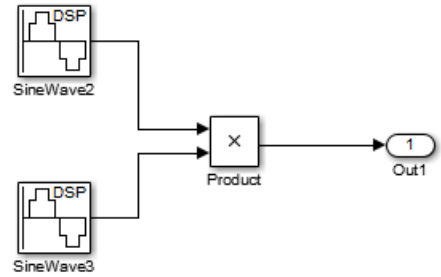
The sample time at the output port of a Rate Transition block can only be discrete or fixed in minor time step. This means that when a Rate Transition block inherits continuous sample time from its destination block, it treats the inherited sample time as Fixed in Minor Time Step. Therefore, the output function of the Rate Transition block runs only at major time steps. If the destination block sample time is continuous, Rate Transition block output sample time is the base rate sample time (if solver is fixed-step), or zero-order-hold-continuous sample time (if solver is variable-step).

Automatic Rate Transition

The Simulink engine can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, in the **Solver** pane of model configuration parameters, select **Automatically handle rate transition for data transfer**. The default setting for this option is off. When you select this option:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.
- The code generator produces code for the Rate Transition blocks that were automatically inserted. This code is identical to the code generated for Rate Transition blocks that were inserted manually.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by the **Deterministic data transfer** parameter in the **Solver** pane. The default setting is `Whenever possible`, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer” (Simulink). To use other modes, you must insert Rate Transition blocks and set their modes manually.

For example, in this model, SineWave2 has a sample time of 2, and SineWave3 has a sample time of 3.

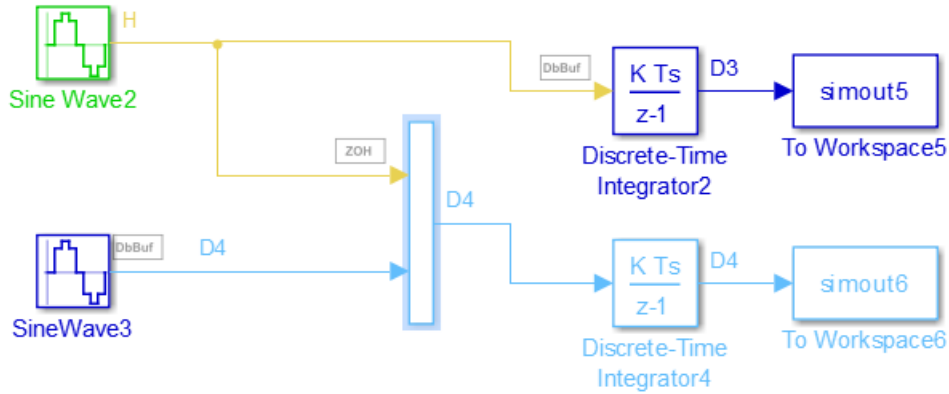


When you select **Automatically handle rate transition for data transfer**, Simulink inserts a Rate Transition block between each Sine Wave block and the Product block. The inserted blocks have the parameter values to reconcile the Sine Wave block sample times.

If the input port and output port data sample rates in a model are not multiples of each other, Simulink inserts a Rate Transition block whose sample rate is the greatest common divisor (GCD) of the two rates. If no other block in the model contains this new rate, an error occurs during simulation. In this case, you must insert a Rate Transition block manually.

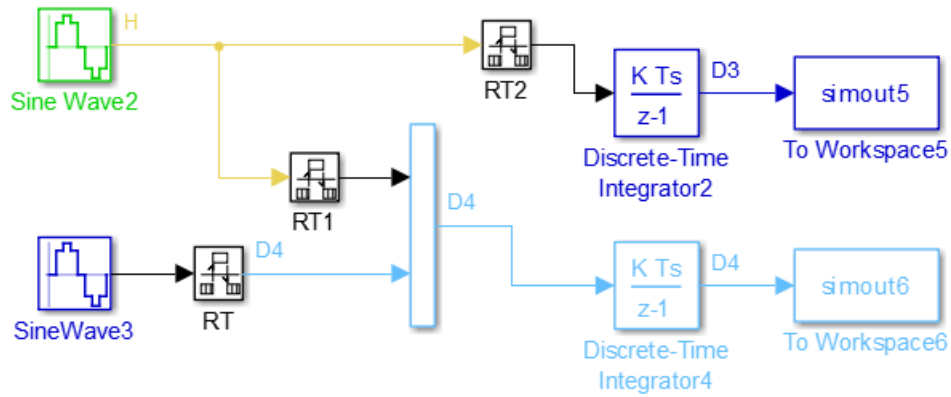
Visualize Inserted Rate Transition Blocks

When you select the **Automatically handle rate transition for data transfer** option, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.



You can show or hide badge labels using the **Display > Signals and Ports > Hidden Rate Transition Block Indicators** setting.

To configure the hidden Rate Transition blocks, right click on a badge label and click on **Insert rate transition block** to make the block visible.

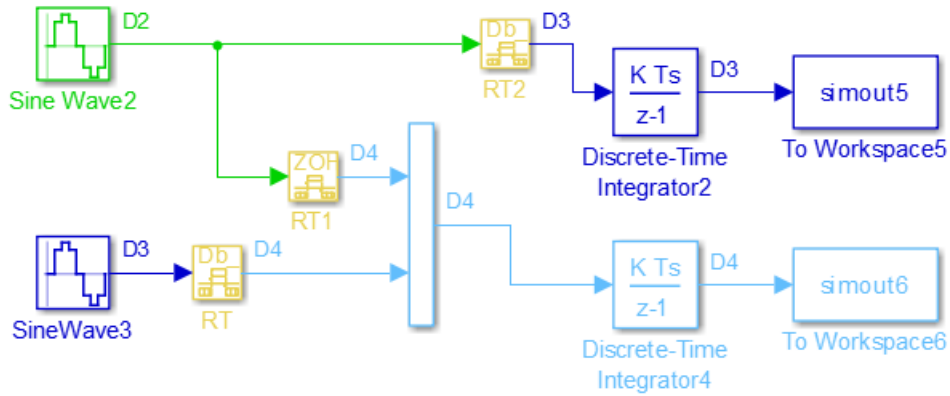


When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted as well as the location in the model.

- You can set the **Initial Conditions** of these blocks.
- You can change block parameters for rate transfer.

Validate the changes to your model by updating your diagram.



Displaying inserted Rate Transition blocks is not compatible with:

- Concurrent execution environment
- Export-function models

To learn more about the types of Rate Transition blocks, see Rate Transition.

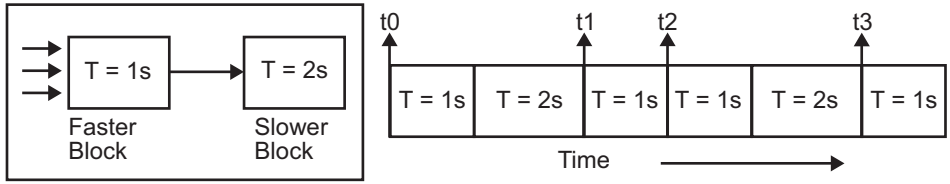
Periodic Sample Rate Transitions

These sections describe cases in which Rate Transition blocks are required for periodic sample rate transitions. The discussion and timing diagrams in these sections are based on the assumption that the Rate Transition block is used in its default (protected/deterministic) mode; that is, the **Ensure data integrity during data transfer** and **Ensure deterministic data transfer (maximum delay)** options are both on. These are the settings used for automatically inserted Rate Transition blocks.

Faster to Slower Transitions in a Simulink Model

In a model where a faster block drives a slower block having direct feedthrough, the outputs of the faster block are computed first. In simulation intervals where the slower

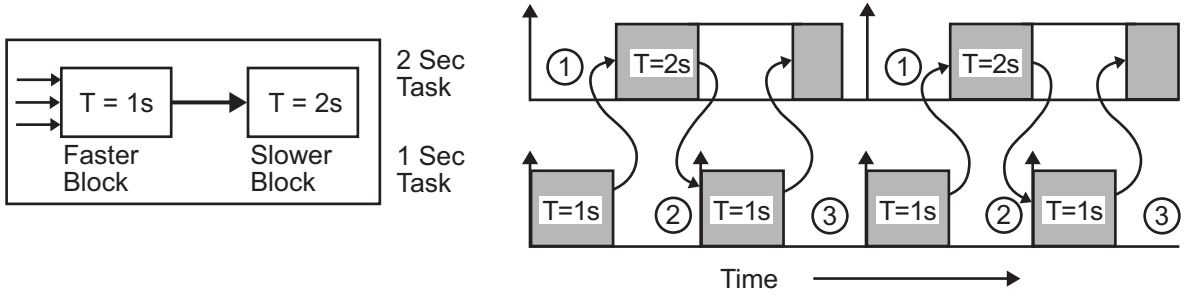
block does not execute, the simulation progresses more rapidly because there are fewer blocks to execute. The next figure illustrates this situation.



A Simulink simulation does not execute in real time, which means that it is not bound by real-time constraints. The simulation waits for, or moves ahead to, whatever tasks are required to complete simulation flow. The actual time interval between sample time steps can vary.

Faster to Slower Transitions in Real Time

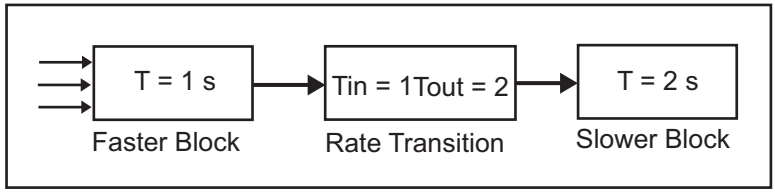
In models where a faster block drives a slower block, you must compensate for the fact that execution of the slower block might span more than one execution period of the faster block. This means that the outputs of the faster block can change before the slower block has finished computing its outputs. The next figure shows a situation in which this problem arises (T = sample time). Note that lower priority tasks are preempted by higher priority tasks before completion.



1. The faster task (T=1s) completes.
2. Higher priority preemption occurs.
3. The slower task (T=2s) resumes and its inputs have changed. This leads to unpredictable results.

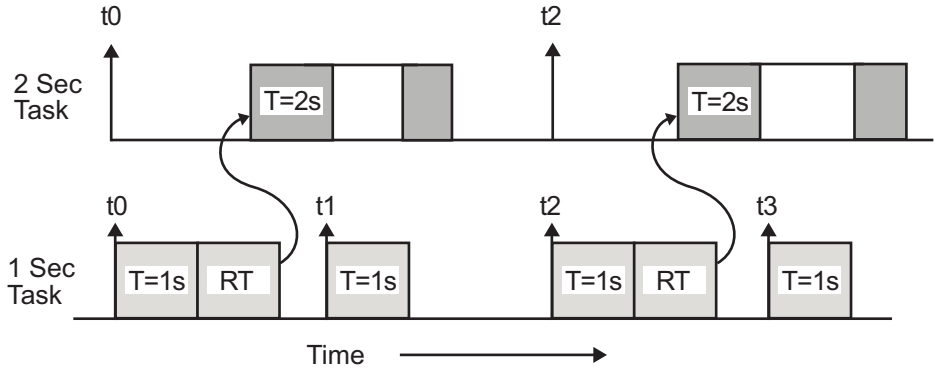
In the above figure, the faster block executes a second time before the slower block has completed execution. This can cause unpredictable results because the input data to the slow task is changing. Data might not maintain its integrity in this situation.

To avoid this situation, the Simulink engine must hold the outputs of the 1 second (faster) block until the 2 second (slower) block finishes executing. The way to accomplish this is by inserting a Rate Transition block between the 1 second and 2 second blocks. The input to the slower block does not change during its execution, maintaining data integrity.



It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The Rate Transition block executes at the sample rate of the slower block, but with the priority of the faster block.

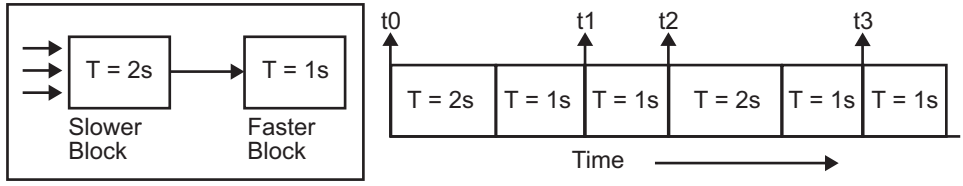


When you add a Rate Transition block, the block executes before the 2 second block (its priority is higher) and its output value is held constant while the 2 second block executes (it executes at the slower sample rate).

Slower to Faster Transitions in a Simulink Model

In a model where a slower block drives a faster block, the Simulink engine again computes the output of the driving block first. During sample intervals where only the faster block executes, the simulation progresses more rapidly.

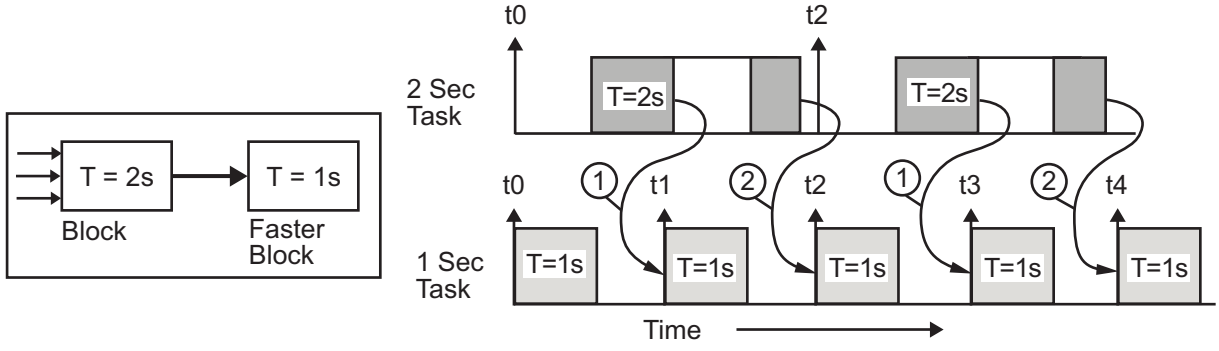
The next figure shows the execution sequence.



As you can see from the preceding figures, the Simulink engine can simulate models with multiple sample rates in an efficient manner. However, a Simulink simulation does not operate in real time.

Slower to Faster Transitions in Real Time

In models where a slower block drives a faster block, the generated code assigns the faster block a higher priority than the slower block. This means the faster block is executed before the slower block, which requires special care to avoid incorrect results.



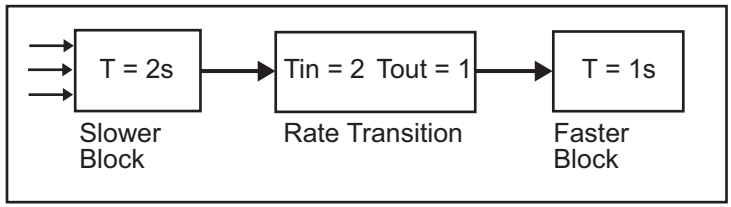
(1) The faster block executes a second time prior to the completion of the slower block.

(2) The faster block executes before the slower block.

This timing diagram illustrates two problems:

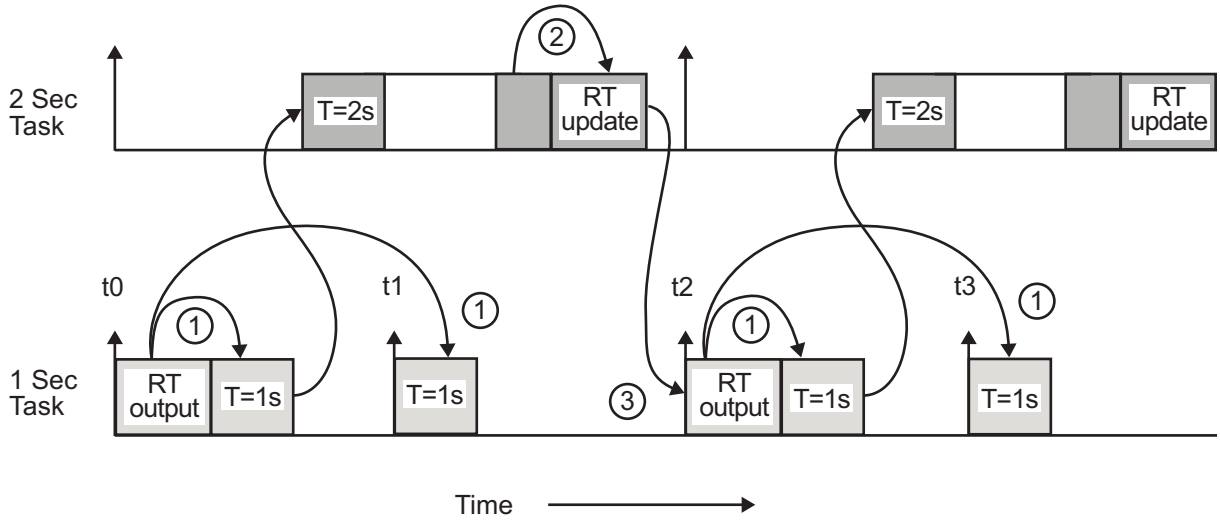
- Execution of the slower block is split over more than one faster block interval. In this case the faster task executes a second time before the slower task has completed execution. This means the inputs to the faster task can have incorrect values some of the time.
- The faster block executes before the slower block (which is backward from the way a Simulink simulation operates). In this case, the 1 second block executes first; but the inputs to the faster task have not been computed. This can cause unpredictable results.

To eliminate these problems, you must insert a Rate Transition block between the slower and faster blocks.



It is assumed that the Rate Transition block is used in its default (protected/deterministic) mode.

The next figure shows the timing sequence that results with the added Rate Transition block.



Three key points about transitions in this diagram (refer to circled numbers):

1 The Rate Transition block output runs in the 1 second task, but at a slower rate (2 seconds). The output of the Rate Transition block feeds the 1 second task blocks.

2 The Rate Transition update uses the output of the 2 second task to update its internal state.

3 The Rate Transition output in the 1 second task uses the state of the Rate Transition that was updated in the 2 second task.

The first problem is alleviated because the Rate Transition block is updating at a slower rate and at the priority of the slower block. The input to the Rate Transition block (which is the output of the slower block) is read after the slower block completes executing.

The second problem is alleviated because the Rate Transition block executes at a slower rate and its output does not change during the computation of the faster block it is driving. The output portion of a Rate Transition block is executed at the sample rate of the slower block, but with the priority of the faster block. Since the Rate Transition block drives the faster block and has effectively the same priority, it is executed before the faster block.

Note This use of the Rate Transition block changes the model. The output of the slower block is now delayed by one time step compared to the output without a Rate Transition block.

Protect Data Integrity with volatile Keyword

When you select **Ensure data integrity during data transfer**, the code generated for a Rate Transition block defines global buffers and semaphores and uses them to protect the integrity of the transferred data.

Particularly for a multitasking application, the tasks (rates) involved in a data transfer can write to the transferred data, buffers, and semaphores at times that your compiler cannot anticipate. To prevent your compiler from optimizing the assembly code in a manner that compromises the integrity of the transferred data, the code generator applies the keyword `volatile` to the buffers and semaphores. The code generator does not apply `volatile` to the global variable that represents the transferred data because the `volatile` buffers and semaphores typically offer enough protection.

With Embedded Coder, you can explicitly apply `volatile` to the transferred data by applying the built-in custom storage class `Volatile` to the input of the Rate Transition block. For example, you can use this technique to help protect the integrity of data that your external code shares with the generated code.

Alternatively, to protect data that your external code shares with the generated code, you can write your own C functions that read and write the data in a protected manner. Then, you can apply the custom storage class `GetSet` to the data in the model, which causes the generated code to call your functions instead of directly accessing the data.

For more information about applying `volatile`, see “Protect Global Data with const and volatile Type Qualifiers” on page 40-17. For more information about `GetSet`, see “Access Data Through Functions with Custom Storage Class GetSet” on page 36-51.

Separate Rate Transition Block Code and Data from Algorithm Code and Data

By default, Rate Transition block code is set inline with algorithm code and data. If you have Embedded Coder, you can separate the code and data, so that the generated code contains separate `get` and `set` functions that the *`model`*`_step` functions call and a dedicated structure for state data. The generated code also contains separate `start` and

`initialize` functions that the *`model`*`_initialize` function calls. To separate Rate Transition block code and data from algorithm code and data, in the Configuration Parameters dialog box, set the Rate Transition block code parameter to `Function`.

Separating Rate Transition block code and data from algorithm code and data enables you to analyze, optimize, and test Rate Transition block and algorithm code independently from each other.

Configure Time-Based Scheduling

For details about solver options, see “Solver Pane” (Simulink).

Configure Start and Stop Times

The **Stop time** (Simulink) must be greater than or equal to the **Start time** (Simulink). If the stop time is zero, or if the total simulation time (`Stop` minus `Start`) is less than zero, the generated program runs for one step. If the stop time is set to `inf`, the generated program runs indefinitely.

When using the GRT or ERT targets, you can override the stop time when running a generated program from the Microsoft Windows command prompt or UNIX[3] command line. To override the stop time that was set during code generation, use the `-tf` switch.

```
model -tf n
```

The program runs for `n` seconds. If `n = inf`, the program runs indefinitely.

Certain blocks have a dependency on absolute time. If you are designing a program that is intended to run indefinitely (**Stop time** = `inf`), and your generated code does not use the `rtModel` data structure (that is, it uses `simstructs` instead), you must not use these blocks. See “Absolute Time Limitations” on page 26-12 for a list of blocks that can potentially overflow timers.

If you know how long an application that depends on absolute time needs to run, you can prevent the timers from overflowing and force the use of optimal word sizes by specifying the **Application lifespan (days)** (Simulink) parameter on the **Math and Data Types** pane. See “Control Memory Allocation for Time Counters” on page 67-11 for details.

Configure the Solver Type

For code generation, you must configure a model to use a fixed-step solver for all targets except the S-function and RSim targets. You can configure the S-function and RSim targets with a fixed-step or variable-step solver.

3. UNIX is a registered trademark of The Open Group in the United States and other countries.

Configure the Tasking Mode

The code generator supports both single-tasking and multitasking modes for periodic sample times. See “Time-Based Scheduling and Code Generation” on page 27-2 for details.

Time-Based Scheduling Example Models

Optimize Memory Usage for Time Counters

This example shows how to optimize the amount of memory that the code generator allocates for time counters. The example optimizes the memory that stores elapsed time, the interval of time between two events.

The code generator represents time counters as unsigned integers. The word size of time counters is based on the setting of the model configuration parameter **Application lifespan (days)**, which specifies the expected maximum duration of time the application runs. You can use this parameter to prevent time counter overflows. The default size is 64 bits.

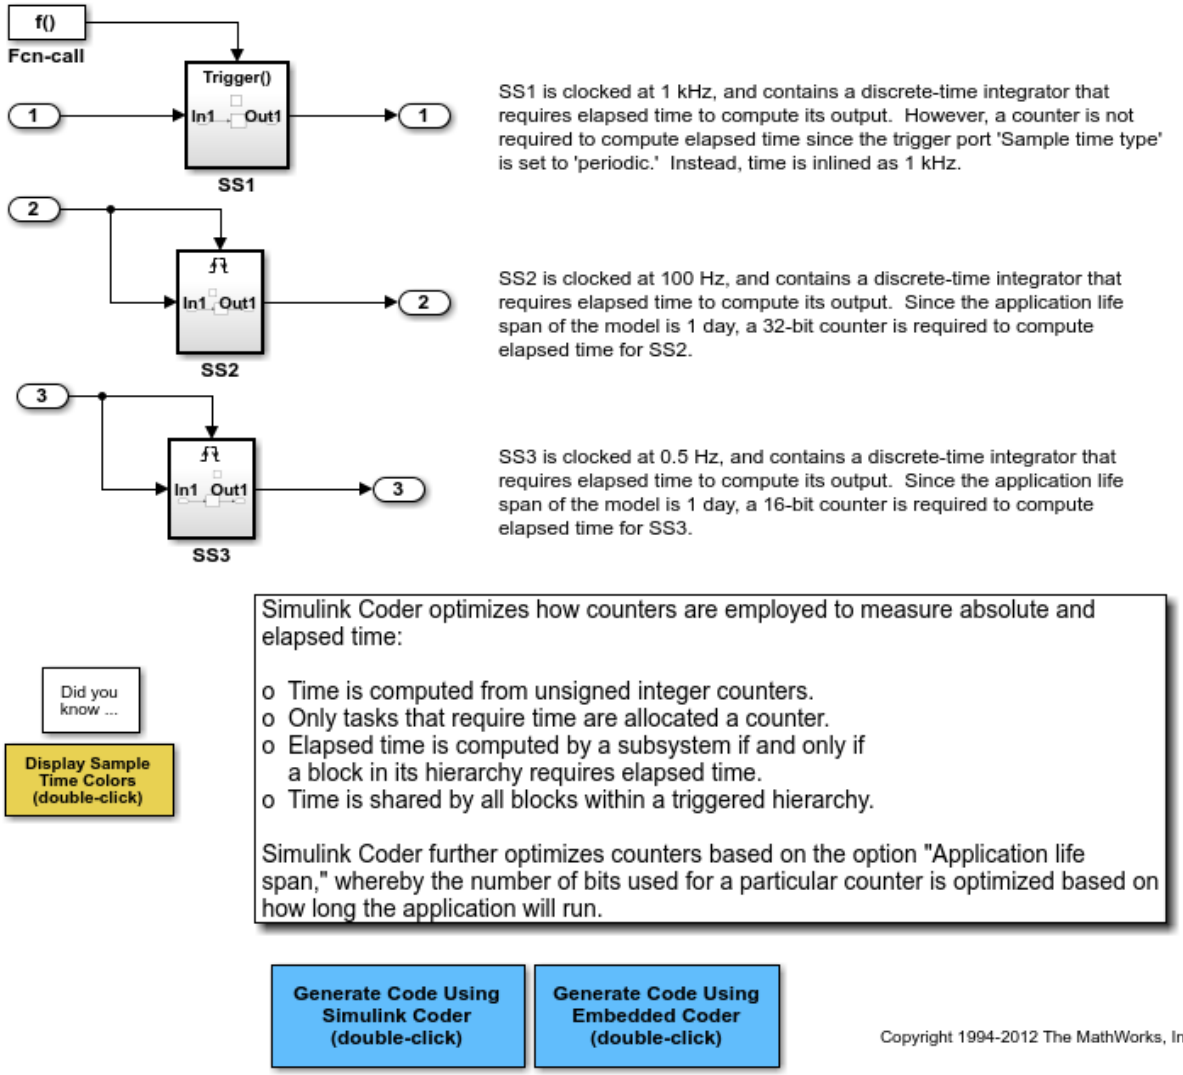
The number of bits that a time counter uses depends on the setting of the **Application lifespan (days)** parameter. For example, if a time counter increments at a rate of 1 kHz, to avoid an overflow, the counter has the following number of bits:

- Lifespan < 0.25 sec: 8 bits
- Lifespan < 1 min: 16 bits
- Lifespan < 49 days: 32 bits
- Lifespan > 50 days: 64 bits

A 64-bit time counter does not overflow for 590 million years.

Open Example Model

Open the example model `rtwdemo_abstime`.



The model consists of three subsystems `SS1`, `SS2`, and `SS3`. On the **Math and Data Types** pane, the **Application lifespan (days)** parameter is set to the default, which is `inf`.

The three subsystems contain a discrete-time integrator that requires elapsed time as input to compute its output value. The subsystems vary as follows:

- SS1 - Clocked at 1 kHz. Does not require a time counter. **Sample time type** parameter for trigger port is set to `periodic`. Elapsed time is inlined as 0.001.
- SS2 - Clocked at 100 Hz. Requires a time counter. Based on a lifespan of 1 day, a 32-bit counter stores the elapsed time.
- SS3 - Clocked at 0.5 Hz. Requires a time counter. Based on a lifespan of 1 day, a 16-bit counter stores the elapsed time.

Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for the three subsystems appear red, green, and blue. Triggered subsystems are blue-green.

Generate Code and Report

1. Create a temporary folder for the build and inspection process.

2. Configure the model for the code generator to use the GRT system target file and a lifespan of `inf` days.

3. Build the model.

```
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

Review Generated Code

Open the generated source file `rtwdemo_abstime.c`.

```
struct tag_RTM_rtwdemo_abstime_T {
  const char_T *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
```

```
    uint32_T clockTickH1;
    uint32_T clockTick2;
    uint32_T clockTickH2;
    struct {
      uint16_T TID[3];
      uint16_T cLimit[3];
    } TaskCounters;
  } Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;

/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model.  The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model.  For example,
 *
 * hilite_system('<S3>')    - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtwdemo_abstime'
 * '<S1>'   : 'rtwdemo_abstime/SS1'
 * '<S2>'   : 'rtwdemo_abstime/SS2'
```

```
 * '<S3>'   : 'rtwdemo_abstime/SS3'
 */
#endif                                 /* RTW_HEADER_rtwdemo_abstime_h_ */
```

Four 32-bit unsigned integers, `clockTick1` , `clockTickH1` , `clockTick2` , and `clockTickH2` are counters for storing the elapsed time of subsystems `SS2` and `SS3`.

Enable Optimization and Regenerate Code

1. Reconfigure the model to set the lifespan to 1 day.

2. Build the model.

```
### Starting build procedure for model: rtwdemo_abstime
### Successful completion of build procedure for model: rtwdemo_abstime
```

Review the Regenerated Code

```
struct tag_RTM_rtwdemo_abstime_T {
  const char_T *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
    uint16_T clockTick2;
    struct {
      uint16_T TID[3];
      uint16_T cLimit[3];
    } TaskCounters;
  } Timing;
};

/* Block states (default storage) */
extern DW_rtwdemo_abstime_T rtwdemo_abstime_DW;

/* External inputs (root inport signals with default storage) */
extern ExtU_rtwdemo_abstime_T rtwdemo_abstime_U;

/* External outputs (root outports fed by signals with default storage) */
extern ExtY_rtwdemo_abstime_T rtwdemo_abstime_Y;
```

```
/* Model entry point functions */
extern void rtwdemo_abstime_initialize(void);
extern void rtwdemo_abstime_step(int_T tid);
extern void rtwdemo_abstime_terminate(void);

/* Real-time Model object */
extern RT_MODEL_rtwdemo_abstime_T *const rtwdemo_abstime_M;

/*-
 * The generated code includes comments that allow you to trace directly
 * back to the appropriate location in the model.  The basic format
 * is <system>/block_name, where system is the system number (uniquely
 * assigned by Simulink) and block_name is the name of the block.
 *
 * Use the MATLAB hilite_system command to trace the generated code back
 * to the model.  For example,
 *
 * hilite_system('<S3>')    - opens system 3
 * hilite_system('<S3>/Kp') - opens and selects block Kp which resides in S3
 *
 * Here is the system hierarchy for this model
 *
 * '<Root>' : 'rtwdemo_abstime'
 * '<S1>'   : 'rtwdemo_abstime/SS1'
 * '<S2>'   : 'rtwdemo_abstime/SS2'
 * '<S3>'   : 'rtwdemo_abstime/SS3'
 */
#endif                                 /* RTW_HEADER_rtwdemo_abstime_h_ */
```

The new setting for the **Application lifespan (days)** parameter instructs the code generator to set aside less memory for the time counters. The regenerated code includes:

- 32-bit unsigned integer, `clockTick1`, for storing the elapsed time of the task for `SS2`
- 16-bit unsigned integer, `clockTick2`, for storing the elapsed time of the task for `SS3`

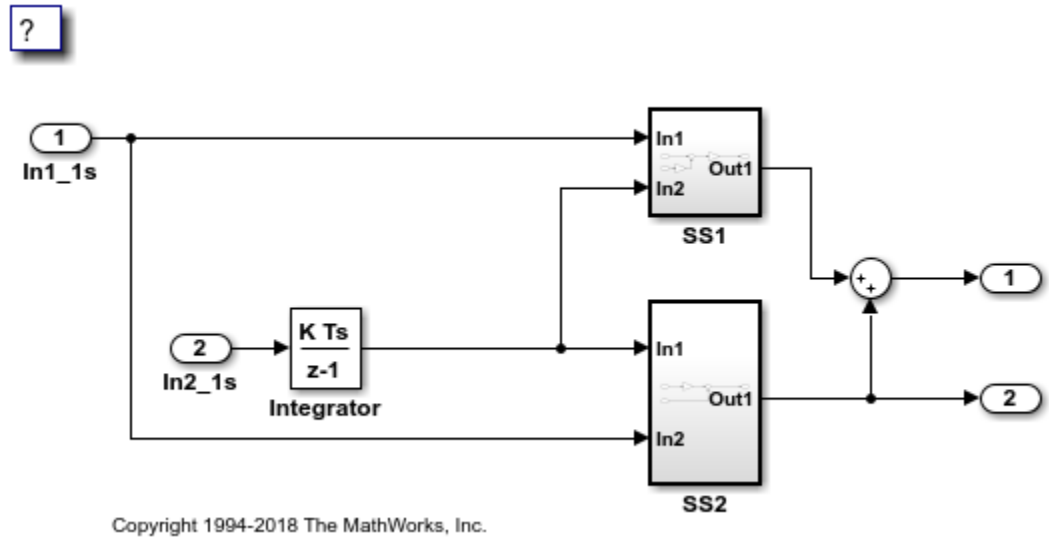
Single-Rate Modeling (Bare Board, No OS)

This model shows code generation for a single-rate discrete-time model configured for a bare-board target (one with no operating system).

Open Example Model

Open the example model `rtwdemo_srbb`.

```
open_system('rtwdemo_srbb')
```



The model uses one sample time and is configured to display sample-time colors when an update diagram occurs. Inport blocks In1_1s and In2_1s specify a 1-second sample time, which is enforced by the model configuration parameter **Periodic sample time constraint**. To view **Periodic sample time constraint** and related parameters on the Solver pane of the Model Configuration Parameters dialog box, double-click the yellow button labeled **View Solver Configuration**. To verify use of one sample time, double-click the yellow button labeled **Display Sample Time Colors**. Because the model is

configured with one sample time, the model appears red, which is the color that represents the fastest discrete sample time in the model.

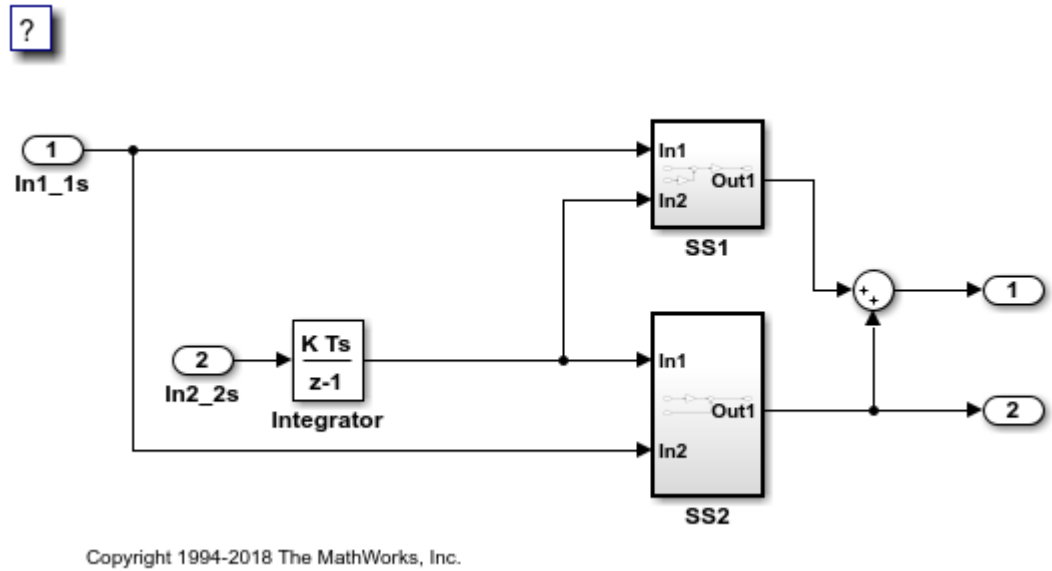
Multirate Modeling in Single-Tasking Mode (Bare Board, no OS)

This model shows the code generated for a multirate discrete-time model configured for single-tasking on a bare-board target (one with no operating system).

Open Example Model

Open the example model `rtwdemo_mrstbb`.

```
open_system('rtwdemo_mrstbb')
```



The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the **Periodic sample time constraint** option on the **Solver** configuration page. The solver is set for single-tasking operation. Rate transition blocks are, therefore, not necessary between blocks executing at different sample times because preemption will not occur.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Double-click the yellow button in the model to update the diagram and show sample-time colors.

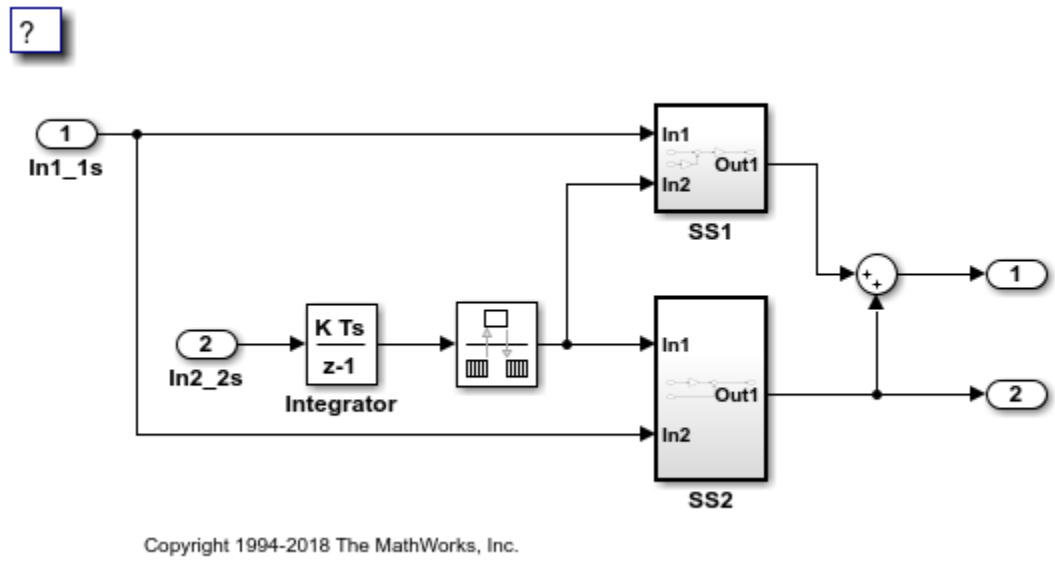
Multirate Modeling in Multitasking Mode (Bare Board, no OS)

This model shows the code generated for a multirate discrete-time model configured for a multitasking bare-board target (one with no operating system).

Open Example Model

Open the example model `rtwdemo_mrmtbb`.

```
open_system('rtwdemo_mrmtbb')
```



Explore Example Model

The model contains two sample times. Inport block 1 and Inport block 2 specify 1-second and 2-second sample times, respectively, which are enforced by the **Periodic sample time constraint** option on the **Solver** configuration page. The solver is set for

multitasking operation, which means a rate transition block is required to ensure that data integrity is enforced when the 1-second task preempts the 2-second task. Proper rate transitions are always enforced by Simulink and Simulink Coder. This model specifies an explicit rate transition block. Alternatively, this block could be automatically inserted by Simulink using the model configuration parameter **Automatically handle rate transition for data transfer**.

The model is configured to display sample-time colors upon diagram update. Red represents the fastest discrete sample time in the model, green represents the second fastest, and yellow represents mixed sample times. Click the yellow button to the right to update the diagram and show sample-time colors.

Data Transfer Assumptions

Basis of operation for data transfers between tasks:

1. Data transitions occur between a single reading task and a single writing task.
2. A read or write of a byte sized variable is atomic.
3. When two tasks interact through a data transition, only one of them can preempt the other.
4. For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
5. All tasks run on a single processor. Time slicing is not allowed.
6. Processes do not crash/restart (especially while data is being transferred between tasks)

Trade Determinism and Data Integrity to Improve System Performance

This model shows the differences in the operation modes of the Rate Transition block when used in a multirate, multitasking model. The flexible options for the Rate Transition block allow you to select the mode that is best suited for your application. You can trade levels of determinism and data integrity to improve system performance.

Rate Transition Block Modes of Operation

Ensure data integrity and determinism (DetAndInteg) : Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. Additionally, it is ensured that the relative sample time (delay) from which the

data is transferred from one rate to another is always the same. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

Ensure integrity (IntegOnly) : Data is transferred such that all data bytes for the signal (including all elements of a wide signal) are from the same time step. However, from one transfer of data to the next, the relative sample time (delay) for which the data is transferred can vary. In this mode, the code to read/write the data is run more often than in the DetandInt mode. In the worst case, the delay is equivalent to the DetandInt mode, but the delay can be less which is important is some applications. Also, this mode support data transfers to/from asynchronous rates which the DetandInt mode cannot support. Only ANSI-C code is used, no target specific 'critical section' protection is needed.

No data consistency operations are performed (None) : For this case, the Rate Transition block does not generated code. This mode is acceptable in some application where atomic access of scalar data types is guaranteed and when the relative temporal values of the data is not important. This mode does not introduce any delay.

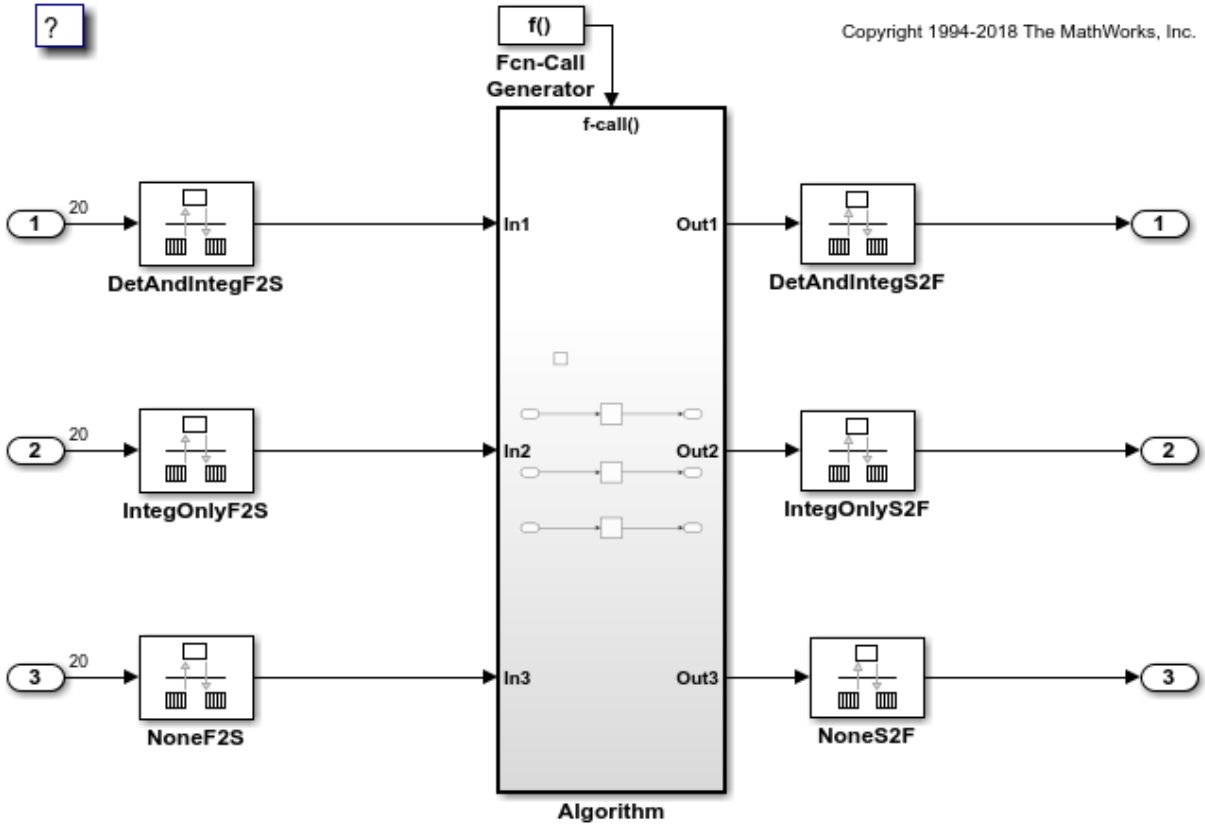
Data Transfer Assumptions

Basis of operation for data transfers between tasks:

- Data transitions occur between a single reading task and a single writing task.
- A read or write of a byte sized variable is atomic.
- When two tasks interact through a data transition, only one of them can preempt the other.
- For periodic tasks, the faster rate task has higher priority than the slower rate task; the faster rate task always preempts the slower rate task.
- All tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash/restart (especially while data is being transferred between tasks)

Model `rtwdemo_ratetrans`

```
open_system('rtwdemo_ratetrans')
```



Model `rtwdemo_ratetrans` shows the differences in the operation modes of the following Rate Transition blocks.

Rate Transition block `DetAndIntegF2S`

Determinism and data integrity (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to output at slower rate but done during the faster rate context
- Data as seen by the slower rate is always the value when both the faster and slower rate last executed. Any subsequent steps by the faster rate (and associated data updates) while the slower rate is running are not seen by the slower rate.

Rate Transition block `DetAndIntegS2F`

Determinism and data integrity (slow to fast transition):

- Uses two persistent data buffers, an internal buffer and the blocks output.
- The internal buffer is copied to the output at the slower rate but done during the faster rate context.
- The internal buffer is written at the slower rate and during the slower rate context.
- The data that Fast rate sees is always delayed, i.e. data is from the previous step of the slow rate code.

Rate Transition block `IntegOnlyF2S`

Data integrity only (fast to slow transition):

- The block output is used as a persistent data buffer.
- Data is written to buffer during the faster rate context if a flag indicates it not in the process of being read.
- The flag is set and data is copied from the buffer to output at the slow rate, the flag is then cleared. This is an additional copy as compared to the deterministic case.
- Data as seen by the slower rate can be from a more recent step of the faster rate than from when the slower rate and faster rate both executed.

Rate Transition block `IntegOnlyS2F`

Data integrity only (slow to fast transition):

- Uses two persistent data buffers, both are internal buffers.
- One of the 2 buffers is always copied to the output at faster rate.
- One of the 2 buffers is written at the slower rate and during the slower rate context, then the active buffer is switched.
- The data as seen by the faster rate can be more recent than for the deterministic case. Specifically, when both the slower and faster rate have their hits, the faster rate will see a previous value from the slower rate. But, subsequent steps for the faster rate may see an updated value (when the slower rate updates the non-active buffer and switches the active buffer flag.

Rate Transition block NoneF2S

No code is generated for the Rate Transition block when determinism and data integrity is waived.

Rate Transition block NoneS2F

No code is generated for the Rate Transition block when determinism and data integrity is waived.

```
bdclose('rtwdemo_ratetrans');
```

Event-Based Scheduling in Simulink Coder

Asynchronous Events

Asynchronous Support

Normally, you time models from which you plan to generate code from a *periodic* interrupt source (for example, a hardware timer). Blocks in a periodically clocked single-rate model run at a timer interrupt rate (the base rate of the model). Blocks in a periodically clocked multirate model run at the base rate or at multiples of that rate.

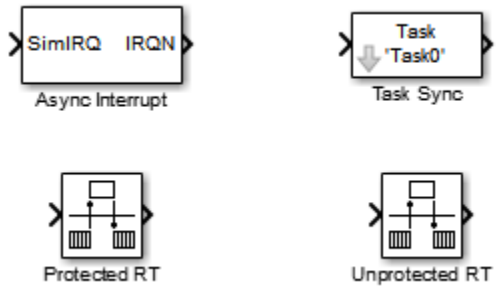
Many systems must also support execution of blocks in response to events that are *asynchronous* with respect to the periodic timing source of the system. For example, a peripheral device might signal completion of an input operation by generating an interrupt. The system must service such interrupts, for example, by acquiring data from the interrupting device.

This topic explains how to use blocks to model and generate code for asynchronous event handling, including servicing of hardware-generated interrupts, maintenance of timers, asynchronous read and write operations, and spawning of asynchronous tasks under a real-time operating system (RTOS). This block library demonstrates integration with an example RTOS (VxWorks). Although the blocks target an example RTOS, this chapter provides source code analysis and other information you can use to develop blocks that support asynchronous event handling for an alternative target RTOS.[4]

Block Library for Calls to an Example Real-Time Operating System

The next figure shows the blocks in the `vxlib1` block library.

4. VxWorks is a registered trademark of Wind River Systems, Inc.



The key blocks in the library are the Async Interrupt and Task Sync blocks. These blocks are targeted for an example RTOS (VxWorks). You can use them, with modification, to support your RTOS applications.

Note You can use the blocks in the `vxlib1` (Simulink Coder) library (Async Interrupt and Task Sync) for simulation and code generation. These blocks provide starting point examples to help you develop custom blocks for your target environment.

To implement asynchronous support for an RTOS other than the example RTOS, use the guidelines and example code are provided to help you adapt the `vxlib1` library blocks to target your RTOS. This topic is discussed in “Create a Customized Asynchronous Library” on page 28-45.

The `vxlib1` library includes blocks you can use to

- Generate interrupt-level code — Async Interrupt block
- Spawn an RTOS task that calls a function call subsystem — Task Sync block
- Enable data integrity when transferring data between blocks running as different tasks — Protected RT block
- Use an unprotected/nondeterministic mode when transferring data between blocks running as different tasks — Unprotected RT block

The use of protected and unprotected Rate Transition blocks in asynchronous contexts is discussed in “Rate Transitions and Asynchronous Blocks” on page 28-36. For general information on rate transitions, see “Time-Based Scheduling and Code Generation” on page 27-2.

Access the Block Library for RTOS Integration

To access the example RTOS (VxWorks) block library, enter the MATLAB command `vxlib1`.

Generate Code Using Library Blocks for RTOS Integration

To generate an example RTOS compatible application from a model containing `vxlib1` library blocks, use the following configuration parameter values for your model.

- Select system target file `ert.tlc` (requires an Embedded Coder license) from the browse menu for the **Code Generation > System target file** parameter (`SystemTargetFile`).
- Enable the **Configuration Parameters > Code Generation > Generate code only** parameter (`GenCodeOnly`).
- Enable the **Configuration Parameters > Code Generation > Templates > Custom templates > Generate an example main program** parameter (`GenerateSampleERTMain`).
- Select `VxWorksExample` from the menu for the **Configuration Parameters > Code Generation > Templates > Custom templates > Target operating system** parameter (`TargetOS`).

Examples and Additional Information

Additional information relevant to the topics in this chapter can be found in

- The `rtwdemo_async` model, which uses the `tornado.tlc` system target file and `vxlib1` block library. To open this example, type `rtwdemo_async` at the MATLAB command prompt.
- The `rtwdemo_async_mdlreftop` model, which uses the `tornado.tlc` system target file and `vxlib1` block library. To open this example, type `rtwdemo_async_mdlreftop` at the MATLAB command prompt.
- “Time-Based Scheduling and Code Generation” (Simulink Coder), discusses general multitasking and rate transition issues for periodic models.
- The Embedded Coder documentation discusses the `ert.tlc` system target file, including task execution and scheduling.

- For detailed information about the system calls to the example RTOS (VxWorks) mentioned in this chapter, see VxWorks system documentation on the Wind River website.

- “Asynchronous Support Limitations” (Simulink Coder)

Generate Interrupt Service Routines

To generate an interrupt service routine (ISR) associated with a specific VME interrupt level for the example RTOS (VxWorks), use the Async Interrupt block. The Async Interrupt block enables the specified interrupt level and installs an ISR that calls a connected function call subsystem.

You can also use the Async Interrupt block in a simulation. It provides an input port that can be enabled and connected to a simulated interrupt source.

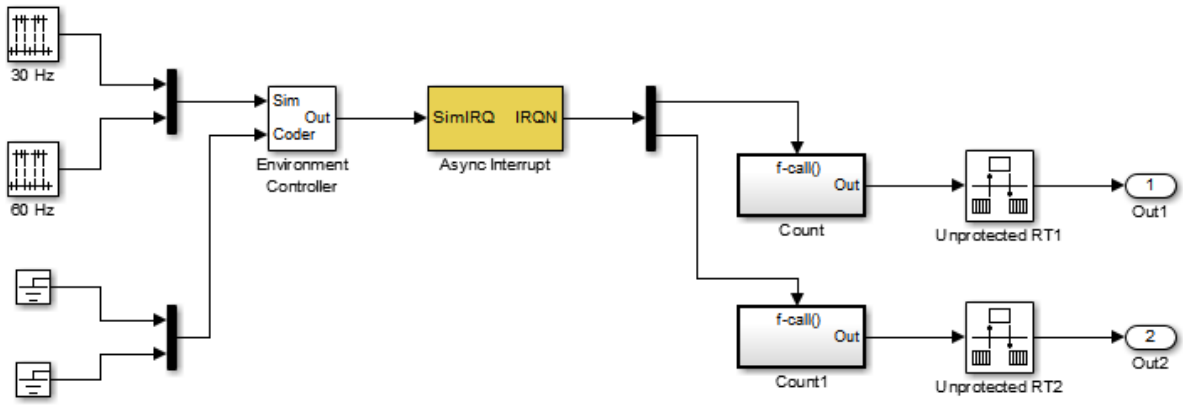
Note The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

Connecting the Async Interrupt Block

To generate an ISR, connect an output of the Async Interrupt block to the control input of

- A function call subsystem
- The input of a Task Sync block
- The input to a Stateflow chart configured for a function call input event

The next figure shows an Async Interrupt block configured to service two interrupt sources. The outputs (signal width 2) are connected to two function call subsystems.



Requirements and Restrictions

Note the following requirements and restrictions:

- The Async Interrupt block supports VME interrupts 1 through 7.
- The Async Interrupt block uses the following system calls to the example RTOS (VxWorks):
  - `sysIntEnable`
  - `sysIntDisable`
  - `intConnect`
  - `intLock`
  - `intUnlock`
  - `tickGet`

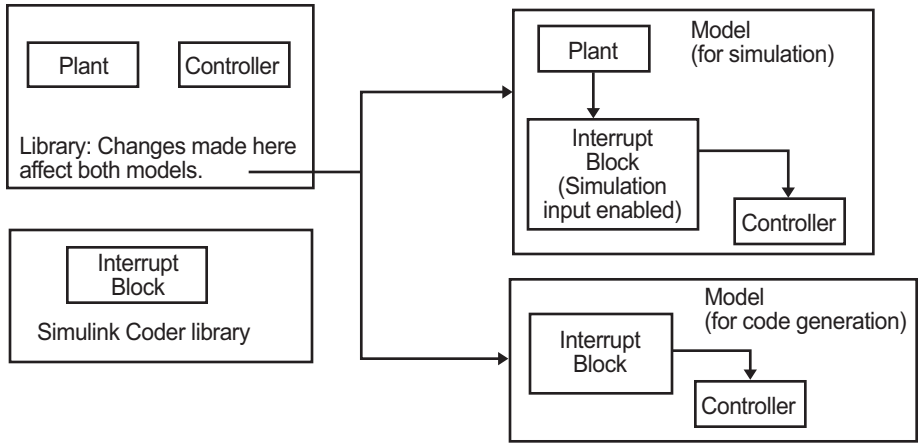
Performance Considerations

Execution of large subsystems at interrupt level can have a significant impact on interrupt response time for interrupts of equal and lower priority in the system. As a general rule, it is best to keep ISRs as short as possible. Connect only function call subsystems that contain a small number of blocks to an Async Interrupt block.

A better solution for large subsystems is to use the Task Sync block to synchronize the execution of the function call subsystem to a RTOS task. The Task Sync block is placed between the Async Interrupt block and the function call subsystem. The Async Interrupt block then installs the Task Sync block as the ISR. The ISR releases a synchronization semaphore (performs a `semGive`) to the task, and returns immediately from interrupt level. The task is then scheduled and run by the example RTOS (VxWorks). See “Spawn and Synchronize Execution of RTOS Task” on page 28-15 for more information.

Using the Async Interrupt Block in Simulation and Code Generation

This section describes a *dual-model* approach to the development and implementation of real-time systems that include ISRs. In this approach, you develop one model that includes a plant and a controller for simulation, and another model that only includes the controller for code generation. Using a Simulink library, you can implement changes to both models simultaneously. The next figure shows how changes made to the plant or controller, both of which are in a library, are propagated to the models.

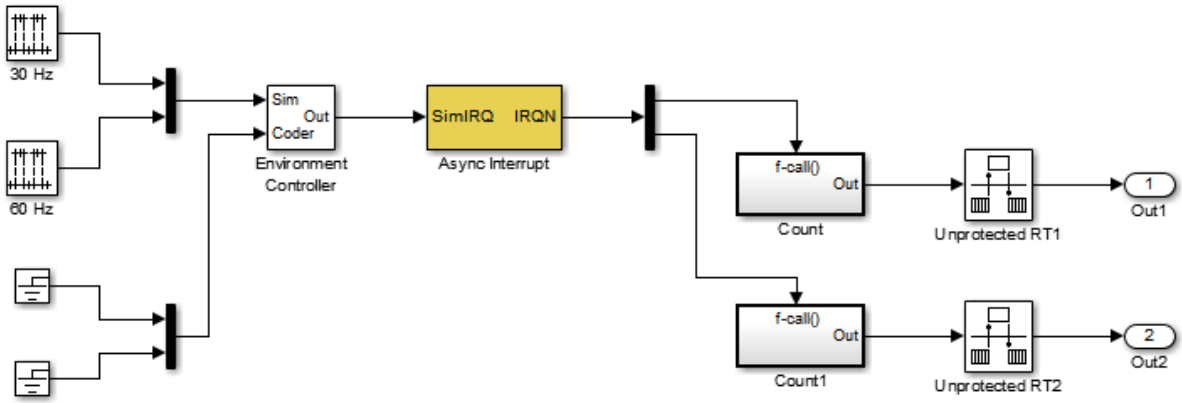


Dual-Model Use of Async Interrupt Block for Simulation and Code Generation

A *single-model* approach is also possible. In this approach, the Plant component of the model is active only in simulation. During code generation, the Plant components are effectively switched out of the system and code is generated only for the interrupt block and controller parts of the model. For an example of this approach, see the `rtwdemo_async` model.

Dual-Model Approach: Simulation

The following block diagram shows a simple model that illustrates the dual-model approach to modeling. During simulation, the Pulse Generator blocks provide simulated interrupt signals.



The simulated interrupt signals are routed through the Async Interrupt block's input port. Upon receiving a simulated interrupt, the block calls the connected subsystem.

During simulation, subsystems connected to Async Interrupt block outputs are executed in order of their priority in the example RTOS (VxWorks). In the event that two or more interrupt signals occur simultaneously, the Async Interrupt block executes the downstream systems in the order specified by their interrupt levels (level 7 gets the highest priority). The first input element maps to the first output element.

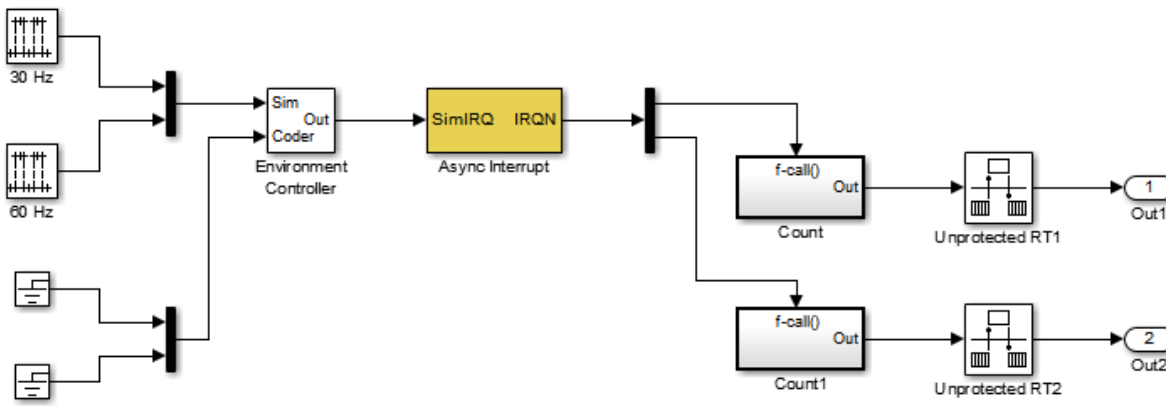
You can also use the Async Interrupt block in a simulation without enabling the simulation input. In such a case, the Async Interrupt block inherits the base rate of the model and calls the connected subsystems in order of their priorities in the RTOS. (In this case, the Async Interrupt block behaves as if all inputs received a 1 simultaneously.)

Dual-Model Approach: Code Generation

In the generated code for the sample model,

- Ground blocks provide input signals to the Environment Controller block
- The Async Interrupt block does not use its simulation input

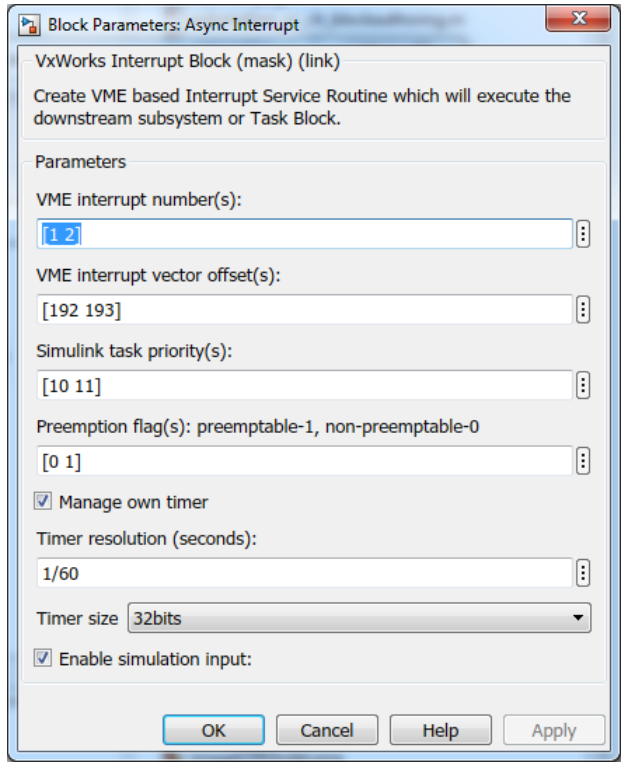
The Ground blocks drive control input of the Environment Controller block, so code is not generated for that signal path. The code generator does not produce code for blocks that drive the simulation control input to the Environment Controller block because that path is not selected during code generation. However, the sample times of driving blocks for the simulation input to the Environment Controller block contribute to the sample times supported in the generated code. To avoid including unnecessary sample times in the generated code, use the sample times of the blocks driving the simulation input in the model where generated code is intended.



Standalone functions are installed as ISRs and the interrupt vector table is as follows:

Offset	
192	`&isr_num1_vec192()`
193	`&isr_num2_vec193()`

Consider the code generated from this model, assuming that the Async Interrupt block parameters are configured as shown in the next figure.



Initialization Code

In the generated code, the Async Interrupt block installs the code in the Subsystem blocks as interrupt service routines. The interrupt vectors for `IRQ1` and `IRQ2` are stored at locations `192` and `193` relative to the base of the interrupt vector table, as specified by the **VME interrupt vector offset(s)** parameter.

Installing an ISR requires two RTOS (VxWorks) calls, `int_connect` and `sysInt_Enable`. The Async Interrupt block inserts these calls in the *`model`*`_initialize` function, as shown in the following code excerpt.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
    /* Connect and enable ISR function: isr_num1_vec192 */
    if( intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
      printf("intConnect failed for ISR 1.\n");
    }
    sysIntEnable(1);
```

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num2_vec193 */
if( intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK)
{
  printf("intConnect failed for ISR 2.\n");
}
sysIntEnable(2);
```

The hardware that generates the interrupt is not configured by the Async Interrupt block. Typically, the interrupt source is a VME I/O board, which generates interrupts for specific events (for example, end of A/D conversion). The VME interrupt level and vector are set up in registers or by using jumpers on the board. You can use the `mdlStart` routine of a user-written device driver (S-function) to set up the registers and enable interrupt generation on the board. You must match the interrupt level and vector specified in the Async Interrupt block dialog to the level and vector set up on the I/O board.

Generated ISR Code

The actual ISR generated for `IRQ1` in the RTOS (VxWorks) is listed below.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */

void isr_num1_vec192(void)
{
  int_T lock;
  FP_CONTEXT context;

   /* Use tickGet() as a portable tick counter example.
      A much higher resolution can be achieved with a
      hardware counter */
   Async_Code_M->Timing.clockTick2 = tickGet();

   /* disable interrupts (system is configured as non-ive) */
   lock = intLock();

   /* save floating point context */
   fppSave(&context);

   /* Call the system: <Root>/Subsystem A */
   Count(0, 0);

   /* restore floating point context */
   fppRestore(&context);

   /* re-enable interrupts */
```

```
   intUnlock(lock);
}
```

There are several features of the ISR that should be noted:

- Because of the setting of the **Preemption Flag(s)** parameter, this ISR is locked; that is, it cannot be preempted by a higher priority interrupt. The ISR is locked and unlocked in the example RTOS (VxWorks) by the `int_lock` and `int_unlock` functions.
- The connected subsystem, `Count`, is called from within the ISR.
- The `Count` function executes algorithmic (model) code. Therefore, the floating-point context is saved and restored across the call to `Count`.
- The ISR maintains its own absolute time counter, which is distinct from other periodic base rate or subrate counters in the system. Timing data is maintained for the use of any blocks executed within the ISR that require absolute or elapsed time.

  See “Timers in Asynchronous Tasks” on page 28-42 for details.

Model Termination Code

The model's termination function disables the interrupts in the RTOS (VxWorks):

```
/* Model terminate function */
void Async_Code_terminate(void)
{
   /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
   /* Disable interrupt for ISR system: isr_num1_vec192 */
   sysIntDisable(1);

   /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
   /* Disable interrupt for ISR system: isr_num2_vec193 */
   sysIntDisable(2);
}
```

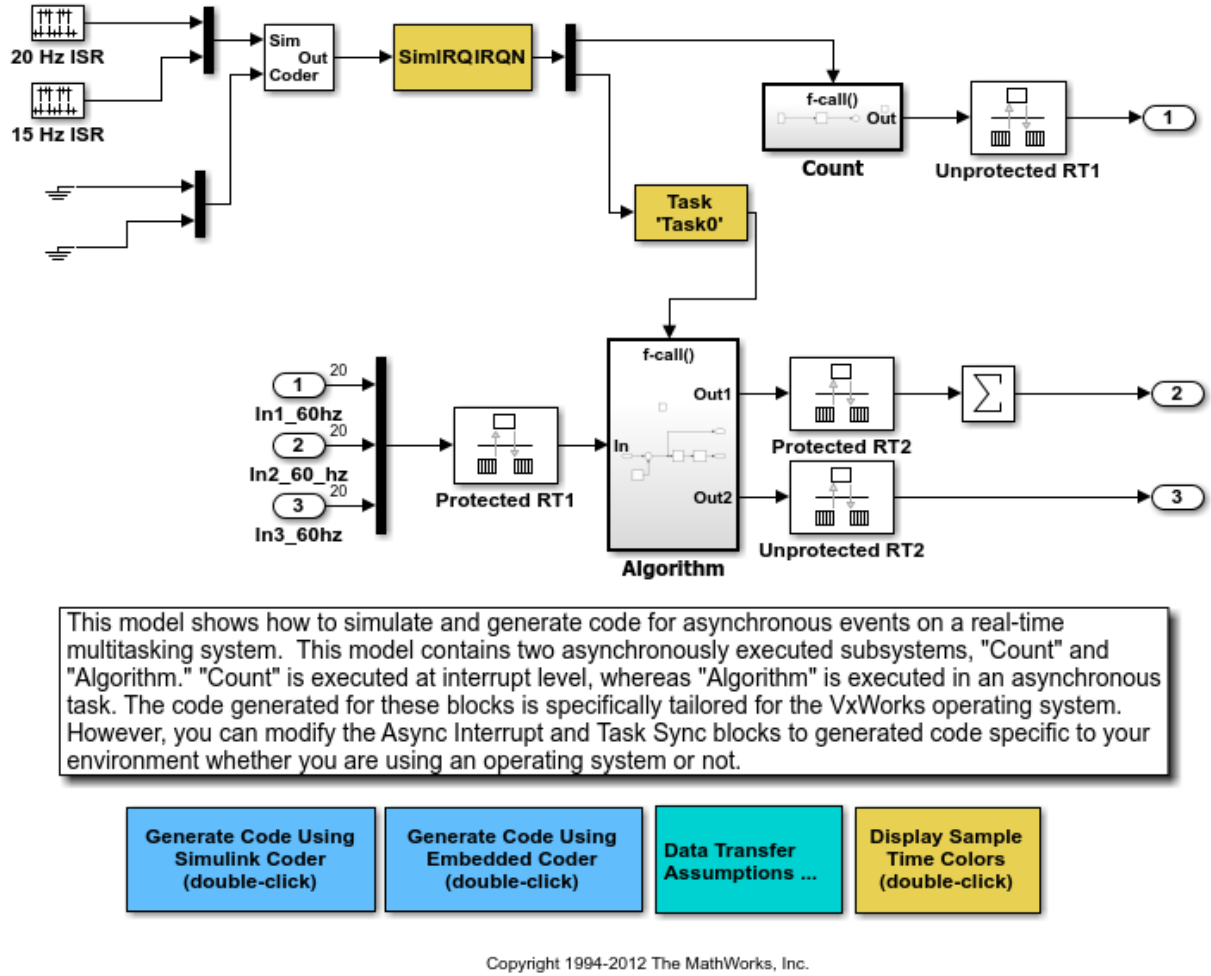
Spawn and Synchronize Execution of RTOS Task

This example shows how to simulate and generate code for asynchronous events on a multitasking real-time operating system (VxWorks®). The model shows different techniques for handling asynchronous events depending on the size of the triggered subsystems.

About the Example Model

Open the example model `rtwdemo_async`.



The model simulates an interrupt source and includes an Async Interrupt block, a Task Sync block, function-call subsystems `Count` and `Algorithm`, and Rate Transition blocks. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to subsystem `Count` and the Task Sync block. You can place an Async Interrupt block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event
- A referenced model with an Inport block that connects to one of the preceding model elements

The Async Interrupt and Task Sync blocks enable the subsystems to execute asynchronously.

`Count` represents a simple interrupt service routine (ISR) that executes at interrupt level. It is best to keep ISRs as simple as possible. This subsystem includes only a Discrete-Time Integrator block.

`Algorithm` includes more substance. It includes multiple blocks and produces two output values. Execution of larger subsystems at interrupt level can significantly impact response time for interrupts of equal and lower priority in the system. A better solution for larger subsystems is to use the Task Sync block to represent the ISR for the function-call subsystem.

The Async Interrupt block generates calls to ISRs. Place the block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event

For each specified interrupt level, the block generates a Versa Module Eurocard (VME) ISR that executes the connected subsystem, Task Sync block, or chart.

In the example model, the Async Interrupt block is configured for VME interrupts 1 and 2, by using interrupt vector offsets 192 and 193. Interrupt 1 connects directly to subsystem `Count`. Interrupt 2 connects to a Task Sync block, which serves as the ISR for `Algorithm`. Place a Task Sync block in one of the following locations:

- Between an Async Interrupt block and a function-call subsystem or Stateflow® chart.
- At the output port of a Stateflow® chart that has an event, `Output to Simulink`, that you configure as a function call.

In the example model, the Task Sync block is between the Async Interrupt block and function-call subsystem `Algorithm`. The Task Sync block is configured with the task

name `Task()`, a priority of 50, a stack size of 8192, and data transfers of the task synchronized with the caller task. The spawned task uses a semaphore to synchronize task execution. The Async Interrupt block triggers a release of the task semaphore.

Four Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, Protected Rate Transition blocks protect data transfers (prevent them from being preempted and corrupted). In the other two instances, Unprotected Rate Transition blocks introduce no special behavior. Their presence informs Simulink® of a rate transition.

The code generated for the Async Interrupt and Task Sync blocks is tailored for the example RTOS (VxWorks®). However, you can modify the blocks to generate code specific to your run-time environment.

Data Transfer Assumptions

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-size variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks with slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not stop and restart, especially while data is being transferred between tasks.

Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are reddish-blue. Asynchronous interrupts and tasks are purple. The Rate Transition Blocks, which are a hybrid rate (their input and output sample times can differ), are yellow.

Generate Code and Report

Generate code and a code generation report for the model. Generated code for the Async Interrupt and Task Sync blocks is for the example RTOS (VxWorks®). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.

2. Build the model.

```
### Starting build procedure for model: rtwdemo_async
Warning: Simulink Coder: The tornado.tlc target will be removed in a future
release.

### Successful completion of code generation for model: rtwdemo_async
```

Review Initialization Code

Open the generated source file `rtwdemo_async.c`. The initialization code:

1. Creates and initializes the synchronization semaphore `Task0_semaphore`.

```
*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID = semBCreate(SEM_Q_PRIORITY,
  SEM_EMPTY);
if (rtwdemo_async_DW.SFunction_PWORK.SemID == NULL) {
  printf("semBCreate call failed for block Task0.\n");
}
```

2. Spawns task `task0` and assigns the task priority 50.

```
rtwdemo_async_DW.SFunction_IWORK.TaskID = taskSpawn("Task0",
  50.0,
  VX_FP_TASK,
  8192.0,
  (FUNCPTR)Task0,
  0, 0, 0, 0, 0, 0, 0,0, 0, 0);
if (rtwdemo_async_DW.SFunction_IWORK.TaskID == ERROR) {
  printf("taskSpawn call failed for block Task0.\n");
}

/* End of Start for S-Function (vxtask1): '<S5>/S-Function' */

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
/* Connect and enable ISR function: isr_num1_vec192 */
if (intConnect(INUM_TO_IVEC(192), isr_num1_vec192, 0) != OK) {
  printf("intConnect failed for ISR 1.\n");
}

sysIntEnable(1);

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
```

```
/* Connect and enable ISR function: isr_num2_vec193 */
if (intConnect(INUM_TO_IVEC(193), isr_num2_vec193, 0) != OK) {
  printf("intConnect failed for ISR 2.\n");
}

sysIntEnable(2);
```

3. Connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

```
{
  int32_T i;

  /* InitializeConditions for RateTransition: '<Root>/Protected RT1' */
  for (i = 0; i < 60; i++) {
    rtwdemo_async_DW.ProtectedRT1_Buffer[i] = 0.0;
  }

  /* End of InitializeConditions for RateTransition: '<Root>/Protected RT1' */

  /* InitializeConditions for RateTransition: '<Root>/Protected RT2' */

The order of these operations is important. Before the code generator enables the interrupt that activates the task, it must spawn the task.

Review Task and Task Synchronization Code

In the generated source file `rtwdemo_async.c`, review the task and task synchronization code.

The code generator produces the code for function `Task0` from the Task Sync block. That function includes a small amount of interrupt-level code and runs as an RTOS task.

The task waits in an infinite `for` loop until the system releases a synchronization semaphore. If the system releases the semaphore, the function updates its task timer and calls the code generated for the `Algorithm` subsystem.

In the example model, the **Synchronize the data transfer of this task with the caller task** parameter for the Task Sync block is set. This parameter setting updates the timer associated with the Task Sync block (`rtM->Timing.clockTick2`) with the value of the timer that the Async Interrupt block (`rtM->Timing.clockTick3`) maintains. As a result, code for blocks within the `Algorithm` subsystem use timer values that are based on the time of the most recent interrupt, rather than the most recent activation of `Task0`.

```
{
  /* Wait for semaphore to be released by system: rtwdemo_async/Task Sync */
  for (;;) {
    if (semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID,NO_WAIT) !=
        ERROR) {
      logMsg("Rate for Task Task0() too fast.\n",0,0,0,0,0,0);

#if STOPONOVERRUN

      logMsg("Aborting real-time simulation.\n",0,0,0,0,0,0);
      semGive(stopSem);
      return(ERROR);

#endif

    } else {
      semTake(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID, WAIT_FOREVER);
    }
```

```
/* Use the upstream clock tick counter for this Task. */
rtwdemo_async_M->Timing.clockTick4 = rtwdemo_async_M->Timing.clockTick3;

/* Call the system: '<Root>/Algorithm' */
{
  {
    int32_T tmp;
    int32_T i;

    /* RateTransition: '<Root>/Protected RT1' */
    tmp = rtwdemo_async_DW.ProtectedRT1_ActiveBufIdx * 60;
    for (i = 0; i < 60; i++) {
      rtwdemo_async_B.ProtectedRT1[i] =
        rtwdemo_async_DW.ProtectedRT1_Buffer[i + tmp];
    }

          (rtwdemo_async_DW.ProtectedRT2_ActiveBufIdx == 0);

        /* End of Update for RateTransition: '<Root>/Protected RT2' */
      }
    }
  }
}
```

The code generator produces code for ISRs `isr_num1_vec192` and `isr_num2_vec293`. ISR `isr_num2_vec192`:

- Disables interrupts.

- Saves floating-point context.
- Calls the code generated for the subsystem that connects to the referenced model Inport block, which receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

```
void isr_num1_vec192(void)
{
  int_T lock;
  FP_CONTEXT context;

  /* Use tickGet()  as a portable tick
     counter example. A much higher resolution can
     be achieved with a hardware counter */
  rtwdemo_async_M->Timing.clockTick2 = tickGet();

  /* disable interrupts (system is configured as non-preemptive) */
  lock = intLock();

  /* save floating point context */
  fppSave(&context);

  /* Call the system: '<Root>/Count' */
  {
    /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

    /* Output and update for function-call system: '<Root>/Count' */
    {
      uint32_T Count_ELAPS_T_tmp;
      Count_ELAPS_T_tmp = rtwdemo_async_M->Timing.clockTick2;
      rtwdemo_async_DW.Count_ELAPS_T = Count_ELAPS_T_tmp -
        rtwdemo_async_DW.Count_PREV_T;
      rtwdemo_async_DW.Count_PREV_T = Count_ELAPS_T_tmp;

      /* Outport: '<Root>/Out1' incorporates:
       *  DiscreteIntegrator: '<S2>/Integrator'
       */
      rtwdemo_async_Y.Out1 = rtwdemo_async_DW.Integrator_DSTATE_l;

      /* Update for DiscreteIntegrator: '<S2>/Integrator' */
      rtwdemo_async_DW.Integrator_DSTATE_l += 0.016666666666666666 * (real_T)
        rtwdemo_async_DW.Count_ELAPS_T;
```

```
    }

    /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
  }

  /* restore floating point context */
  fppRestore(&context);

  /* re-enable interrupts */
  intUnlock(lock);
}

/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
```

ISR `isr_num2_vec293` maintains a timer that stores the tick count at the time that the interrupt occurs. After updating the timer, the ISR releases the semaphore that activates `Task0`.

```
void isr_num2_vec193(void)
{
  /* Use tickGet()  as a portable tick
     counter example. A much higher resolution can
     be achieved with a hardware counter */
  rtwdemo_async_M->Timing.clockTick3 = tickGet();

  /* Call the system: '<S4>/Subsystem' */
  {
    /* S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

    /* Output and update for function-call system: '<S4>/Subsystem' */

    /* S-Function (vxtask1): '<S5>/S-Function' */

    /* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
    /* Release semaphore for system task: Task0 */
    semGive(*(SEM_ID *)rtwdemo_async_DW.SFunction_PWORK.SemID);

    /* End of Outputs for S-Function (vxtask1): '<S5>/S-Function' */

    /* End of Outputs for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */
  }
}
```

```
/* VxWorks Task Block: '<S5>/S-Function' (vxtask1) */
```

Review Task Termination Code

The Task Sync block generates the following termination code.

```
static void rtwdemo_async_terminate(void)
{
  /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Disable interrupt for ISR system: isr_num1_vec192 */
  sysIntDisable(1);

  /* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
  /* Disable interrupt for ISR system: isr_num2_vec193 */
  sysIntDisable(2);

  /* End of Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' */

  /* Terminate for S-Function (vxinterrupt1): '<Root>/Async Interrupt' incorporates:
   *  SubSystem: '<S4>/Subsystem'
   */

  /* Termination for function-call system: '<S4>/Subsystem' */

Pass Asynchronous Events in RTOS as Input To a Referenced Model

This example shows how to simulate and generate code for a model that triggers asynchronous events in an example RTOS (VxWorks®) that get passed as input to a referenced model.

Open Example Model

Open the example model `rtwdemo_async_mdlreftop`.

The model simulates an interrupt source and includes an Async Interrupt block and referenced model. The Async Interrupt block creates two Versa Module Eurocard (VME) interrupt service routines (ISRs) that pass interrupt signals to Inport blocks 1 and 2 of the referenced model. You can place an Async Interrupt block between a simulated interrupt source and one of the following:

- Function call subsystem
- Task Sync block
- A Stateflow® chart configured for a function call input event
- A referenced model with a Inport block that connects to one of the preceding model elements

In this example model, the Async Interrupt block passes asynchronous events (function-call trigger signals), `Interrupt1` and `Interrupt2`, to the referenced model through Inport blocks 1 and 2.

The code generated for the Async Interrupt block is tailored for the example real-time operating system (VxWorks). However, you can modify the block to generate code specific to your run-time environment.

Open the referenced model.

The referenced model includes the two Inport blocks that receive the interrupts, each connected to an Asynchronous Task Specification block, function-call subsystems `Count` and `Algorithm`, and Rate Transition blocks. The Asynchronous Task Specification block, in combination with a root-level Inport block, allows a reference model to receive asynchronous function-call input. To use the block:

1. Connect the Asynchronous Task Specification block to the output port of a root-level Inport block that outputs a function-call trigger.
2. Select the **Output function call** parameter of the Inport block to specify that it accepts function-call signals.
3. On the Asynchronous Task Specification parameters dialog box, set the task priority for the asynchronous task associated with an Inport block. Specify an integer or []. If you specify an integer, it must match the priority of the interrupt initiated by the Async Interrupt block in the parent model. If you specify [], the priorities do not have to match.

The Asynchronous Task Specification block for the higher priority interrupt, `interrupt1`, connects to function-call subsystem `Count`. `Count` represents a simple interrupt service routine (ISR). The second Asynchronous Task Specification block connects to the subsystem `Algorithm`, which includes more substance. It includes multiple blocks and produces two output values. Both subsystems execute at interrupt level.

For each interrupt level specified for the Async Interrupt block in the parent model, the block generates a VME ISR that executes the connected subsystem, Task Sync block, or chart.

In the example top model, the Async Interrupt block is configured for VME interrupts 1 and 2, using interrupt vector offsets 192 and 193. Interrupt 1 is wired to trigger subsystem `Count`. Interrupt 2 is wired to trigger subsystem `Algorithm`.

The Rate Transition blocks handle data transfers between ports that operate at different rates. In two instances, the blocks protect data transfers (prevent them from being preempted and corrupted). In the other instance, no special behavior occurs.

Data Transfer Assumptions

- Data transfers occur between one reading task and one writing task.
- A read or write operation on a byte-sized variable is atomic.
- When two tasks interact, only one can preempt the other.
- For periodic tasks, the task with the faster rate has higher priority than the task with the slower rate. The task with the faster rate preempts the tasks with slower rates.
- Tasks run on a single processor. Time slicing is not allowed.
- Processes do not crash and restart, especially while data is being transferred between tasks.

Simulate the Model

Simulate the model. By default, the model is configured to show sample times in different colors. Discrete sample times for input and output appear red and green, respectively. Constants are magenta. Asynchronous interrupts are purple. The Rate Transition Blocks, which are hybrid (input and output sample times can differ), appear yellow.

Generate Code and Report

Generate code and a code generation report for the model. Async Interrupt block and Task Sync block generated code is for the example RTOS (VxWorks). However, you can modify the blocks to generate code for another run-time environment.

1. Create a temporary folder for the build and inspection process.

2. Build the model.

Review Initialization Code

Open the generated source file `rtwdemo_async_mdlreftop.c`. The initialization code connects and enables ISR `isr_num1_vec192` for interrupt 1 and ISR `isr_num2_vec193` for interrupt 2.

Review ISR Code

In the generated source file `rtwdemo_async_mdlreftop.c`, review the code for ISRs `isr_num1_vec192` and `isr_num2_vec293`. Each ISR:

- Disables interrupts.
- Saves floating-point context.
- Calls the code generated for the subsystem connected to the referenced model Inport block that receives the interrupt.
- Restores floating-point context.
- Reenables interrupts.

Review Task Termination Code

The Task Sync block generates the following termination code.

Rate Transitions and Asynchronous Blocks

Because an asynchronous function call subsystem can preempt or be preempted by other model code, an inconsistency arises when more than one signal element is connected to an asynchronous block. The issue is that signals passed to and from the function call subsystem can be in the process of being written to or read from when the preemption occurs. Thus, some old and some new data is used. This situation can also occur with scalar signals in some cases. For example, if a signal is a double (8 bytes), the read or write operation might require two machine instructions.

Note The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

About Rate Transitions and Asynchronous Blocks

The Simulink Rate Transition block is designed to deal with preemption problems that occur in data transfer between blocks running at different rates. These issues are discussed in “Time-Based Scheduling and Code Generation” (Simulink Coder).

You can handle rate transition issues automatically by selecting the **Automatically handle rate transition for data transfer** parameter on the **Solver** pane of the Configuration Parameters dialog box. This saves you from having to manually insert Rate Transition blocks to avoid invalid rate transitions, including invalid *asynchronous-to-periodic* and *asynchronous-to-asynchronous* rate transitions, in multirate models. For asynchronous tasks, the Simulink engine configures inserted blocks for data integrity but not determinism during data transfers.

For asynchronous rate transitions, the Rate Transition block provides data integrity, but cannot provide determinism. Therefore, when you insert Rate Transition blocks explicitly, you must clear the **Ensure data determinism** check box in the Block Parameters dialog box.

When you insert a Rate Transition block between two blocks to maintain data integrity and priorities are assigned to the tasks associated with the blocks, the code generator assumes that the higher priority task can preempt the lower priority task and the lower priority task cannot preempt the higher priority task. If the priority associated with task

for either block is not assigned or the priorities of the tasks for both blocks are the same, the code generator assumes that either task can preempt the other task.

Priorities of periodic tasks are assigned by the Simulink engine, in accordance with the options specified in the **Solver selection** section of the **Solver** pane of the Configuration Parameters dialog box. When the **Periodic sample time constraint** option field of **Solver selection** is set to `Unconstrained`, the model base rate priority is set to `40`. Priorities for subrates then increment or decrement by `1` from the base rate priority, depending on the setting of the **Higher priority value indicates higher task priority option**.

You can assign priorities manually by using the **Periodic sample time properties** field. The Simulink engine does not assign a priority to asynchronous blocks. For example, the priority of a function call subsystem that connects back to an Async Interrupt block is assigned by the Async Interrupt block.

The **Simulink task priority** field of the Async Interrupt block specifies a priority level (required) for every interrupt number entered in the **VME interrupt number(s)** field. The priority array sets the priorities of the subsystems connected to each interrupt.

For the Task Sync block, if the example RTOS (VxWorks) is the target, the **Higher priority value indicates higher task priority** option should be deselected. The **Simulink task priority** field specifies the block priority relative to connected blocks (in addition to assigning an RTOS priority to the generated task code).

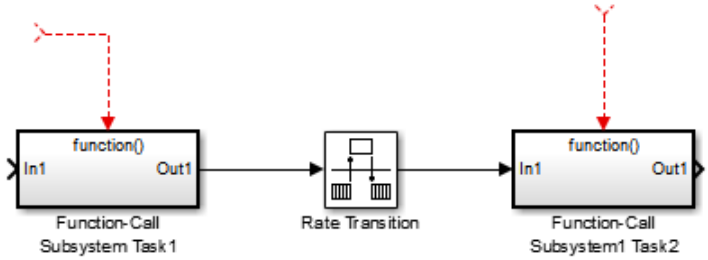
The `vxlib1` library provides two types of rate transition blocks as a convenience. These are simply preconfigured instances of the built-in Simulink Rate Transition block:

- Protected Rate Transition block: Rate Transition block that is configured with the **Ensure data integrity during data transfers** on and **Ensure deterministic data transfer** off.
- Unprotected Rate Transition block: Rate Transition block that is configured with the **Ensure data integrity during data transfers** option off.

Handle Rate Transitions for Asynchronous Tasks

For rate transitions that involve asynchronous tasks, you can maintain data integrity. However, you cannot achieve determinism. You have the option of using the Rate Transition block or target-specific rate transition blocks.

Consider the following model, which includes a Rate Transition block.



You can use the Rate Transition block in either of the following modes:

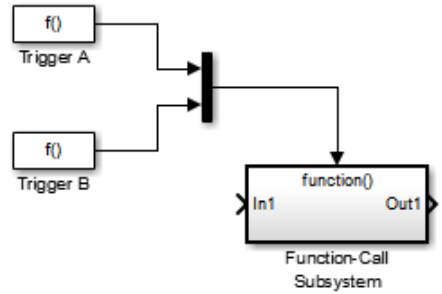
- Maintain data integrity, no determinism
- Unprotected

Alternatively, you can use target-specific rate transition blocks. The following blocks are available for the example RTOS (VxWorks):

- Protected Rate Transition block (reader)
- Protected Rate Transition block (writer)
- Unprotected Rate Transition block

Handle Multiple Asynchronous Interrupts

Consider the following model, in which two functions trigger the same subsystem.



The two tasks must have equal priorities. When priorities are the same, the outcome depends on whether they are firing periodically or asynchronously, and also on a diagnostic setting. The following table and notes describe these outcomes:

Supported Sample Time and Priority for Function Call Subsystem with Multiple Triggers

	Async Priority = 1	Async Priority = 2	Async Priority Unspecified	Periodic Priority = 1	Periodic Priority = 2
Async Priority = 1	Supported (1)				
Async Priority = 2		Supported (1)			
Async Priority Unspecified			Supported (2)		
Periodic Priority = 1				Supported	
Periodic Priority = 2					Supported

1. Control these outcomes using the **Tasks with equal priority** option in the **Diagnostics** pane of the Configuration Parameters dialog box; set this diagnostic to `none` if tasks of equal priority cannot preempt each other in the target system.
2. For this case, the following warning message is issued unconditionally:

   ```
   The function call subsystem <name> has multiple asynchronous
   triggers that do not specify priority. Data integrity will
   not be maintained if these triggers can preempt one another.
   ```

Empty cells in the above table represent multiple triggers with differing priorities, which are unsupported.

The code generator provides absolute time management for a function call subsystem connected to multiple interrupts in the case where timer settings for `TriggerA` and `TriggerB` (time source, resolution) are the same.

Assume that all of the following conditions are true for the model shown above:

- A function call subsystem is triggered by two asynchronous triggers (TriggerA and TriggerB) having identical priority settings.

- Each trigger sets the source of time and timer attributes by calling the functions `ssSetTimeSource` and `ssSetAsyncTimerAttributes`.
- The triggered subsystem contains a block that needs elapsed or absolute time (for example, a Discrete Time Integrator).

The asynchronous function call subsystem has one global variable, `clockTick#` (where `#` is the task ID associated with the subsystem). This variable stores absolute time for the asynchronous task. There are two ways timing can be handled:

- If the time source is set to `SS_TIMESOURCE_BASERATE`, the code generator produces timer code in the function call subsystem, updating the clock tick variable from the base rate clock tick. Data integrity is maintained if the same priority is assigned to TriggerA and TriggerB.
- If the time source is `SS_TIMESOURCE_SELF`, generated code for both TriggerA and TriggerB updates the same clock tick variable from the hardware clock.

The word size of the clock tick variable can be set directly or be established according to the **Application lifespan (days)** (Simulink) setting and the timer resolution set by the TriggerA and TriggerB S-functions (which must be the same). See “Timers in Asynchronous Tasks” on page 28-42 and “Control Memory Allocation for Time Counters” on page 67-11 for more information.

Protect Data Integrity with volatile Keyword

When you select **Ensure data integrity during data transfer**, the code generated for a Rate Transition block defines `volatile` global buffers and semaphores and uses them to protect the integrity of the transferred data. For additional protection, or for protection without a Rate Transition block, you can explicitly apply `volatile` to the transferred data. For more information, see “Protect Global Data with const and volatile Type Qualifiers” on page 40-17.

Timers in Asynchronous Tasks

An ISR can set a source for absolute time. This is done with the function `ssSetTimeSource`. The function `ssSetTimeSource` cannot be called before `ssSetOutputPortWidth` is called. If this occurs, the program will come to a halt and generate an error message. `ssSetTimeSource` has the following three options:

- `SS_TIMESOURCE_SELF`: Each generated ISR maintains its own absolute time counter, which is distinct from a periodic base rate or subrate counters in the system. The counter value and the timer resolution value (specified in the **Timer resolution (seconds)** parameter of the Async Interrupt block) are used by downstream blocks to determine absolute time values required by block computations.
- `SS_TIMESOURCE_CALLER`: The ISR reads time from a counter maintained by its caller. Time resolution is thus the same as its caller's resolution.
- `SS_TIMESOURCE_BASERATE`: The ISR can read absolute time from the model's periodic base rate. Time resolution is thus the same as its base rate resolution.

Note The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

By default, the counter is implemented as a 32-bit unsigned integer member of the `Timing` substructure of the real-time model structure. For a target that supports the `rtModel` data structure, when the time data type is not set by using `ssSetAsyncTimeDataType`, the counter word size is determined by the **Application lifespan (days)** (Simulink) model parameter. As an example (from ERT target code),

```
/* Real-time Model Data Structure */
struct _RT_MODEL_elapseTime_exp_Tag {
   const char *errorStatus;

  /*
   * Timing:
   * The following substructure contains information regarding
   * the timing information for the model.
   */
  struct {
    uint32_T clockTick1;
```

```
    uint32_T clockTick2;
  } Timing;
};
```

The example omits unused fields in the `Timing` data structure (a feature of ERT target code not found in GRT). For a target that supports the `rtModel` data structure, the counter word size is determined by the **Application lifespan (days)** (Simulink) model parameter.

By default, the `vxlib1` library blocks for the example RTOS (VxWorks) set the timer source to `SS_TIMESOURCE_SELF` and update their counters by using the system call `tickGet`. `tickGet` returns a timer value maintained by the RTOS kernel. The maximum word size for the timer is `UINT32`. The following example shows a generated call to `tickGet`.

```
/* VxWorks Interrupt Block: '<Root>/Async Interrupt' */
void isr_num2_vec193(void)
{

 /* Use tickGet() as a portable tick counter example. A much
    higher resolution can be achieved with a hardware counter */
 rtM->Timing.clockTick2 = tickGet();
. . .
```

The `tickGet` call is supplied only as an example. It can (and in many instances should) be replaced by a timing source that has better resolution. If you are implementing a custom asynchronous block for an RTOS other than the example RTOS (VxWorks), you should either generate an equivalent call to the target RTOS, or generate code to read a timer register on the target hardware.

The default **Timer resolution (seconds)** parameter of your Async Interrupt block implementation should be changed to match the resolution of your target's timing source.

The counter is updated at interrupt level. Its value represents the tick value of the timing source at the most recent execution of the ISR. The rate of this timing source is unrelated to sample rates in the model. In fact, typically it is faster than the model's base rate. Select the timer source and set its rate and resolution based on the expected rate of interrupts to be serviced by the Async Interrupt block.

For an example of timer code generation, see “Async Interrupt Block Implementation” on page 28-46.

Create a Customized Asynchronous Library

This topic describes how to implement asynchronous blocks for use with your target RTOS, using the Async Interrupt and Task Sync blocks as a starting point. Rate Transition blocks are target-independent, so you do not need to develop customized rate transition blocks.

Note The operating system integration techniques that are demonstrated in this section use one or more blocks the blocks in the `vxlib1` (Simulink Coder) library. These blocks provide starting point examples to help you develop custom blocks for your target environment.

About Implementing Asynchronous Blocks

You can customize the asynchronous library blocks by modifying the block implementation. These files are

- The block's underlying S-function MEX-file
- The TLC files that control code generation of the block

In addition, you need to modify the block masks to remove references specific to the example RTOS (VxWorks) and to incorporate parameters required by your target RTOS.

Custom block implementation is an advanced topic, requiring familiarity with the Simulink MEX S-function format and API, and with the Target Language Compiler (TLC). These topics are covered in the following documents:

- Simulink topics “What Is an S-Function?” (Simulink), “Use S-Functions in Models” (Simulink), “How S-Functions Work” (Simulink), and “Implementing S-Functions” (Simulink) describe MEX S-functions and the S-function API in general.
- The “Inlining S-Functions” (Simulink Coder), “Inline C MEX S-Functions” (Simulink Coder), and “S-Functions and Code Generation” (Simulink Coder) describe how to create a TLC block implementation for use in code generation.

The following sections discuss the C/C++ and TLC implementations of the asynchronous library blocks, including required `SimStruct` macros and functions in the TLC asynchronous support library (`asynclib.tlc`).

Async Interrupt Block Implementation

The source files for the Async Interrupt block are located in *matlabroot*/rtw/c/tornado/devices (open):

- vxinterrupt1.c: C MEX-file source code, for use in configuration and simulation
- vxinterrupt1.tlc: TLC implementation, for use in code generation
- asynclib.tlc: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in “asynclib.tlc Support Library” on page 28-52.

C MEX Block Implementation

Most of the code in vxinterrupt1.c performs ordinary functions that are not related to asynchronous support (for example, obtaining and validating parameters from the block mask, marking parameters nontunable, and passing parameter data to the *model*.rtw file).

The mdlInitializeSizes function uses special SimStruct macros and SS_OPTIONS settings that are required for asynchronous blocks, as described below.

Note that the following macros cannot be called before ssSetOutputPortWidth is called:

- ssSetTimeSource
- ssSetAsyncTimerAttributes
- ssSetAsyncTimerResolutionEl
- ssSetAsyncTimerDataType
- ssSetAsyncTimerDataTypeEl
- ssSetAsyncTaskPriorities
- ssSetAsyncTaskPrioritiesEl

If one of the above macros is called before ssSetOutputPortWidth, the following error message appears:

```
SL_SfcnMustSpecifyPortWidthBfCallSomeMacro {
S-function '%s' in '%<BLOCKFULLPATH>'
must set output port %d width using
ssSetOutputPortWidth before calling macro %s
 }
```

ssSetAsyncTimerAttributes

`ssSetAsyncTimerAttributes` declares that the block requires a timer, and sets the resolution of the timer as specified in the **Timer resolution (seconds)** parameter.

The function prototype is

```
ssSetAsyncTimerAttributes(SimStruct *S, double res)
```

where

- S is a Simstruct pointer.
- `res` is the **Timer resolution (seconds)** parameter value.

The following code excerpt shows the call to ssSetAsyncTimerAttributes.

```
/* Setup Async Timer attributes */
ssSetAsyncTimerAttributes(S,mxGetPr(TICK_RES)[0]);
```

ssSetAsyncTaskPriorities

`ssSetAsyncTaskPriorities` sets the Simulink task priority for blocks executing at each interrupt level, as specified in the block's **Simulink task priority** field.

The function prototype is

```
ssSetAsyncTaskPriorities(SimStruct *S, int numISRs,
                         int *priorityArray)
```

where

- S is a `SimStruct` pointer.
- `numISRs` is the number of interrupts specified in the **VME interrupt number(s)** parameter.
- `priorityarray` is an integer array containing the interrupt numbers specified in the **VME interrupt number(s)** parameter.

The following code excerpt shows the call to `ssSetAsyncTaskPriorities`:

```
/* Setup Async Task Priorities */
    priorityArray = malloc(numISRs*sizeof(int_T));
    for (i=0; i<numISRs; i++) {
        priorityArray[i] = (int_T)(mxGetPr(ISR_PRIORITIES)[i]);
```

```
    }
    ssSetAsyncTaskPriorities(S, numISRs, priorityArray);
    free(priorityArray);
    priorityArray = NULL;
}
```

SS_OPTION Settings

The code excerpt below shows the SS_OPTION settings for vxinterrupt1.c. SS_OPTION_ASYNCHRONOUS_INTERRUPT should be used when a function call subsystem is attached to an interrupt. For more information, see the documentation for SS_OPTION and SS_OPTION_ASYNCHRONOUS in *matlabroot*/simulink/include/simstruc.h.

```
ssSetOptions( S, (SS_OPTION_EXCEPTION_FREE_CODE |
              SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
              SS_OPTION_ASYNCHRONOUS_INTERRUPT |
```

If an S-function specifies the SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME option and inherits a sample time of Inf, the code generator determines how to produce code for the block based on whether the block is invariant. A block is invariant if its port signals are invariant. A signal is invariant if it has a constant value during the entire simulation. If you specify a Constant block sample time, do not assume that the port signals are invariant. For more information, see “Inline Invariant Signals” (Simulink Coder). If the block is not invariant, the code generator produces code only in the initialize entry-point function. If the block is invariant, the code generator does not produce code for the block.

TLC Implementation

This section discusses each function of vxinterrupt1.tlc, with an emphasis on target-specific features that you will need to change to generate code for your target RTOS.

Generate #include Directives

vxinterrupt1.tlc begins with the statement

```
%include "vxlib.tlc"
```

vxlib.tlc is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

BlockInstanceSetup Function

For each connected output of the Async Interrupt block, `BlockInstanceSetup` defines a function name for the corresponding ISR in the generated code. The functions names are of the form

`isr_`*`num`*`_vec_`*`offset`*

where *`num`* is the ISR number defined in the **VME interrupt number(s)** block parameter, and *`offset`* is an interrupt table offset defined in the **VME interrupt vector offset(s)** block parameter.

In a custom implementation, this naming convention is optional.

The function names are cached for use by the `Outputs` function, which generates the actual ISR code.

Outputs Function

`Outputs` iterates over the connected outputs of the Async Interrupt block. An ISR is generated for each such output.

The ISR code is cached in the `"Functions"` section of the generated code. Before generating the ISR, `Outputs` does the following:

- Generates a call to the downstream block (cached in a temporary buffer).
- Determines whether the ISR should be locked or not (as specified in the **Preemption Flag(s)** block parameter).
- Determines whether the block connected to the Async Interrupt block is a Task Sync block. (This information is obtained by using the `asynclib` calls `LibGetFcnCallBlock` and `LibGetBlockAttribute`.) If so,
  - The preemption flag for the ISR must be set to `1`. An error results otherwise.
  - The RTOS (VxWorks) calls to save and restore floating-point context are generated, unless the user has configured the model for integer-only code generation.

When generating the ISR code, `Outputs` calls the `asynclib` function `LibNeedAsyncCounter` to determine whether a timer is required by the connected subsystem. If so, and if the time source is set to be `SS_TIMESOURCE_SELF` by `ssSetTimeSource`, `LibSetAsyncCounter` is called to generate an RTOS (VxWorks) `tickGet` function call and update the counter. In your implementation, you should

generate either an equivalent call to the target RTOS, or generate code to read the a timer register on the target hardware.

Start Function

The `Start` function generates the required RTOS (VxWorks) calls (`int_connect` and `sysInt_Enable`) to connect and enable each ISR. You should replace this with calls to your target RTOS.

Terminate Function

The `Terminate` function generates the call `sysIntDisable` to disable each ISR. You should replace this with calls to your target RTOS.

Task Sync Block Implementation

The source files for the Task Sync block are located in *`matlabroot`*`/rtw/c/tornado/devices` (open). They are

- `vxtask1.cpp`: MEX-file source code, for use in configuration and simulation.
- `vxtask1.tlc`: TLC implementation, for use in code generation.
- `asynclib.tlc`: library of TLC support functions, called by the TLC implementation of the block. The library calls are summarized in “asynclib.tlc Support Library” on page 28-52.

C MEX Block Implementation

Like the Async Interrupt block, the Task Sync block sets up a timer, in this case with a fixed resolution. The priority of the task associated with the block is obtained from the **Simulink task priority** parameter. The `SS_OPTION` settings are the same as those used for the Async Interrupt block.

```
ssSetAsyncTimerAttributes(S, 0.01);

priority  = (int_T) (*(mxGetPr(PRIORITY)));
ssSetAsyncTaskPriorities(S,1,&priority);

ssSetOptions(S, (SS_OPTION_EXCEPTION_FREE_CODE |
                 SS_OPTION_ASYNCHRONOUS |
                 SS_OPTION_DISALLOW_CONSTANT_SAMPLE_TIME |
}
```

TLC Implementation

Generate #include Directives

`vxtask1.tlc` begins with the statement

```
%include "vxlib.tlc"
```

`vxlib.tlc` is a target-specific file that generates directives to include header files for the example RTOS (VxWorks). You should replace this with a file that generates includes for your target RTOS.

BlockInstanceSetup Function

The `BlockInstanceSetup` function derives the task name, block name, and other identifiers used later in code generation. It also checks for and warns about unconnected block conditions, and generates a storage declaration for a semaphore (`stopSem`) that is used in case of interrupt overflow conditions.

Start Function

The `Start` function generates the required RTOS (VxWorks) calls to define storage for the semaphore that is used in management of the task spawned by the Task Sync block. Depending on the value of the `CodeFormat` TLC variable of the target, either a static storage declaration or a dynamic memory allocation call is generated. This function also creates a semaphore (`semBCreate`) and spawns an RTOS task (`taskSpawn`). You should replace these with calls to your target RTOS.

Outputs Function

The `Outputs` function generates an example RTOS (VxWorks) task that waits for a semaphore. When it obtains the semaphore, it updates the block's tick timer and calls the downstream subsystem code, as described in “Spawn and Synchronize Execution of RTOS Task” on page 28-15. `Outputs` also generates code (called from interrupt level) that grants the semaphore.

Terminate Function

The `Terminate` function generates the example RTOS (VxWorks) call `taskDelete` to end execution of the task spawned by the block. You should replace this with calls to your target RTOS.

Note also that if the target RTOS has dynamically allocated memory associated with the task, the `Terminate` function should deallocate the memory.

asynclib.tlc Support Library

`asynclib.tlc` is a library of TLC functions that support the implementation of asynchronous blocks. Some functions are specifically designed for use in asynchronous blocks. For example, `LibSetAsyncCounter` generates a call to update a timer for an asynchronous block. Other functions are utilities that return information required by asynchronous blocks (for example, information about connected function call subsystems).

The following table summarizes the public calls in the library. For details, see the library source code and the `vxinterrupt1.tlc` and `vxtask1.tlc` files, which call the library functions.

Summary of asynclib.tlc Library Functions

Function	Description
`LibBlockExecuteFcnCall`	For use by inlined S-functions with function call outputs. Generates code to execute a function call subsystem.
`LibGetBlockAttribute`	Returns a field value from a block record.
`LibGetFcnCallBlock`	Given an S-Function block and call index, returns the block record for the downstream function call subsystem block.
`LibGetCallerClockTickCounter`	Provides access to the time counter of an upstream asynchronous task.
`LibGetCallerClockTickCounterHighWord`	Provides access to the high word of the time counter of an upstream asynchronous task.
`LibManageAsyncCounter`	Determines whether an asynchronous task needs a counter and manages its own timer.
`LibNeedAsyncCounter`	If the calling block requires an asynchronous counter, returns `TLC_TRUE`, otherwise returns `TLC_FALSE`.
`LibSetAsyncClockTicks`	Returns code that sets `clockTick` counters that are to be maintained by the asynchronous task.
`LibSetAsyncCounter`	Generates code to set the tick value of the block's asynchronous counter.
`LibSetAsyncCounterHighWord`	Generates code to set the tick value of the high word of the block's asynchronous counter

Import Asynchronous Event Data for Simulation

Capabilities

You can import asynchronous event data into a function-call subsystem via an Inport block. For standalone fixed-step simulations, you can specify:

- The time points at which each asynchronous event occurs
- The number of asynchronous events at each time point

Input Data Format

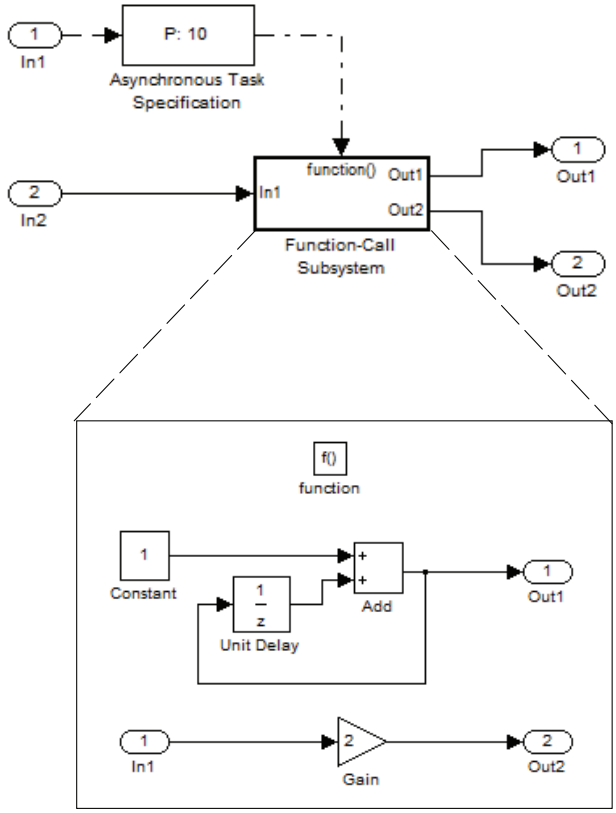
You can enter your asynchronous data at the MATLAB command line or on the **Data Import/Export** pane of the Configuration Parameters dialog box. In either case, a number of restrictions apply to the data format.

- The expression for the parameter **Data Import/Export > Input** must be a comma-separated list of tables.
- The table corresponding to the input port outputting asynchronous events must be a column vector containing time values for the asynchronous events.
  - The time vector of the asynchronous events must be of double data type and monotonically increasing.
  - All time data must be integer multiples of the model step size.
  - To specify multiple function calls at a given time step, you must repeat the time value accordingly. In other words, if you wish to specify three asynchronous events at $t = 1$ and two events at $t = 9$, then you must list `1` three times and `9` twice in your time vector. (`t = [1 1 1 9 9]'`)
- The table corresponding to normal data input port can be of any other supported format.

See “Load Data to Root-Level Input Ports” (Simulink) for more information.

Example

In this model, a function-call subsystem is used to track the total number of asynchronous events and to multiply a set of inputs by 2.



1 To input data via the Configuration Parameters dialog box,

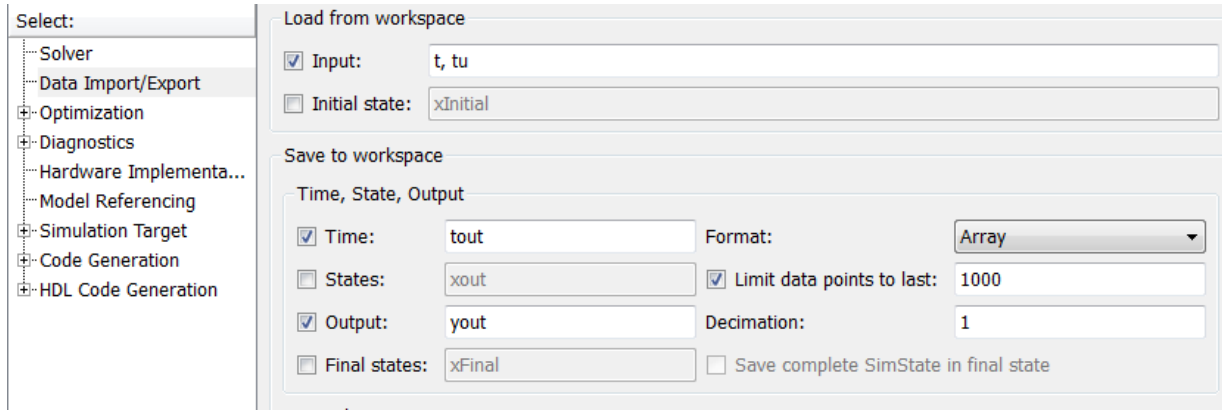
   a Select **Simulation > Configuration Parameters > Data Import/Export**.

   b Select the **Input** parameter.

   c For this example, enter the following command in the MATLAB window:

   ```
   >> t = [1 1 5 9 9 9]', u = [[0:10]' [0:10]']
   ```

   Alternatively, you can enter the data as *t, tu* in the Data Import/Export pane:



Here, *t* is a column vector containing the times of asynchronous events for Inport block In1 while *tu* is a table of input values versus time for Inport block In2.

2. By default, the **Time** and **Output** options are selected and the output variables are named *tout* and *yout*.
3. Simulate the model.
4. Display the output by entering `[tout yout]` at the MATLAB command line and obtain:

```
ans =

     0     0    -1
     1     2     2
     2     2     2
     3     2     2
     4     2     2
     5     3    10
     6     3    10
     7     3    10
     8     3    10
     9     6    18
    10     6    18
```

Here the first column contains the simulation times.

The second column represents the output of Out1 — the total number of asynchronous events. Since the function-call subsystem is triggered twice at $t = 1$, the output is 2. It is not called again until $t = 5$, and so does not increase to 3 until then. Finally, it is called three times at 9, so it increases to 6.

The third column contains the output of Out2 obtained by multiplying the input value at each asynchronous event time by 2. At any other time, the output is held at its previous value

Asynchronous Support Limitations

In this section...

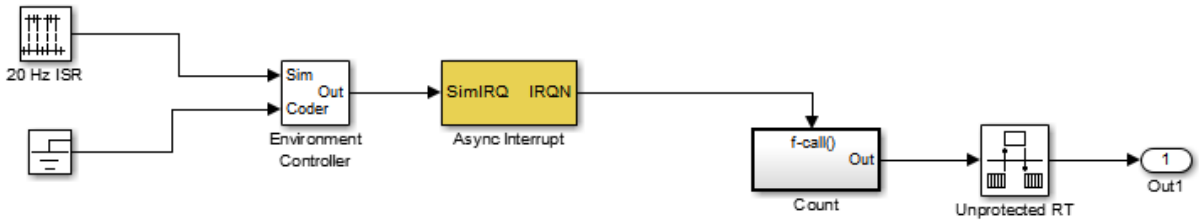
Asynchronous Task Priority

The Simulink product does not simulate asynchronous task behavior. Although you can specify a task priority for an asynchronous task represented in a model with the Task Sync block, the priority setting is for code generation purposes only and is not honored during simulation.

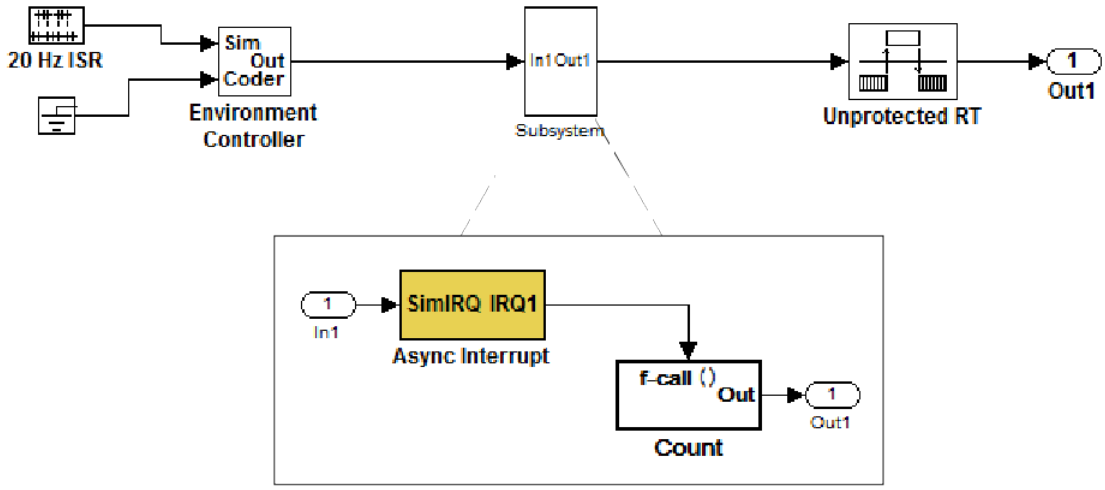
Convert an Asynchronous Subsystem into a Model Reference

You can use the Asynchronous Task Specification block to specify an asynchronous function-call input to a model reference. However, you must convert the Async Interrupt and Function-Call blocks into a subsystem and then convert the subsystem into a model reference.

Following is an example with step-by-step instructions for conversion.



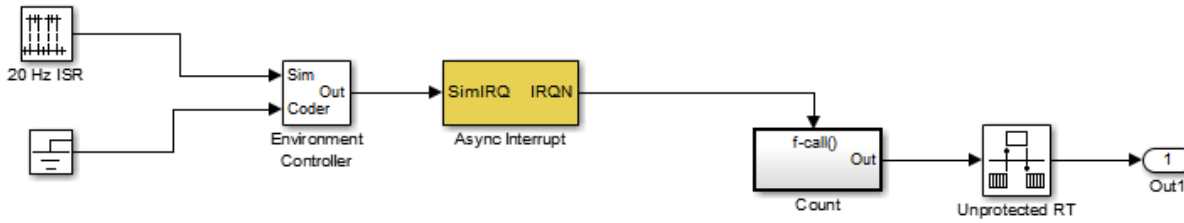
1. Convert the Async Interrupt and Count blocks into a subsystem. Select both blocks and right-click Count. From the menu, select **Subsystem & Model Reference** > **Create Subsystem from Selection**.

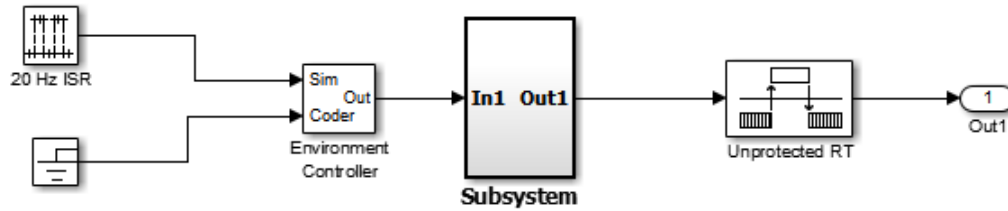


2. To prepare for converting the new subsystem to a Model block, set the following configuration parameters in the top model. Open the Configuration Parameters dialog box.

   - Under Diagnostics, navigate to the Sample Time pane. Then set **Multitask rate transition** to `error` and **Multitask conditionally executed subsystem** to `error`.
   - Under Diagnostics, navigate to the Connectivity pane. Set **Bus signal treated as vector**, and **Invalid function-call connection** to `error`. Also set **Context-dependent inputs** to `Enable All`.
   - Under Diagnostics, navigate to the Data Validity pane and set the **Multitask data store** option to `error`.
   - Set the **Configuration Parameters > Diagnostics > Data Validity > Advanced parameters > Underspecified initialization detection** parameter to `Simplified`.
   - If your model is large or complex, run the Model Advisor checks in the folder "Migrating to Simplified Initialization Mode Overview" (Simulink) and make the suggested changes.

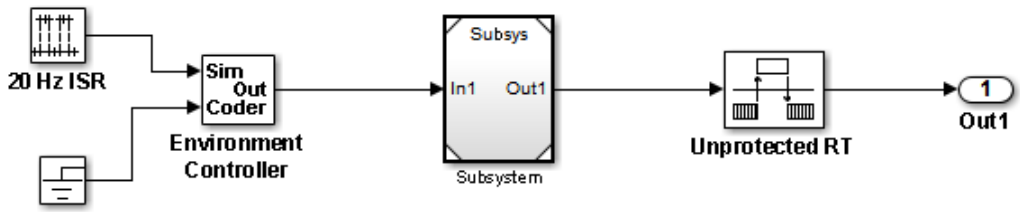
3. Convert the subsystem to an atomic subsystem. Select **Edit > Subsystem Parameters > Treat as atomic unit**.



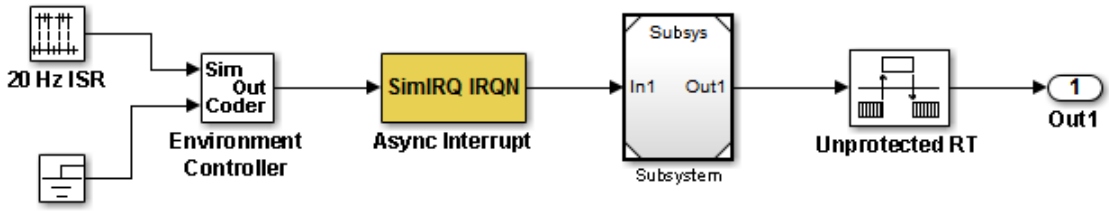


4 Convert the subsystem to a Model block. Right-click the subsystem and select **Subsystem & Model Reference > Convert Subsystem to > Referenced Model**. A window opens with a model reference block inside of it.

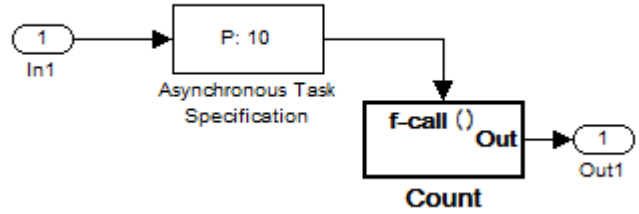
5 Replace the subsystem in the top model with the new model reference block.



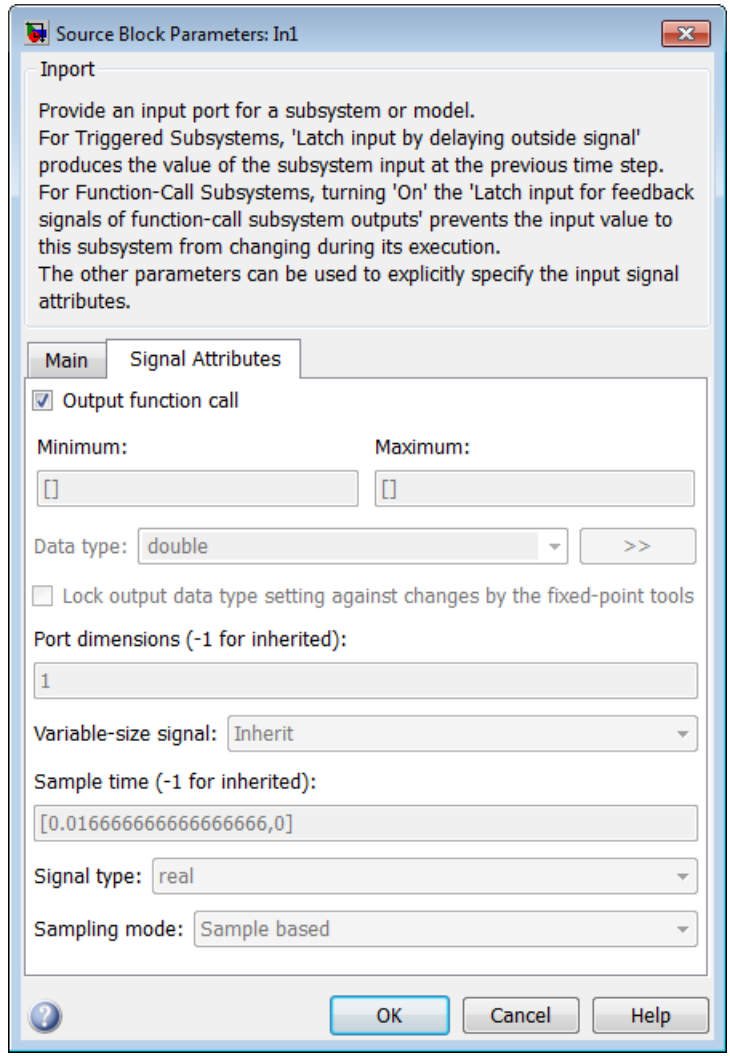
6 Move the Async Interrupt block from the model reference to the top model, before the model reference block.



7 Insert an Asynchronous Task Specification block in the model reference. Set the priority of the Asynchronous Task Specification block. (For more information on setting the priority, see Asynchronous Task Specification.)



8 In the model reference, double-click the input port to open its Source Block Parameters dialog box. Click the **Signal Attributes** tab and select the **Output function call** option. Click **OK**.



9 Save your model and then perform **Simulation > Update Diagram** to verify your settings.

Scheduling Considerations in Embedded Coder

Use Discrete and Continuous Time

In this section...

Support for Discrete and Continuous Time Blocks

The ERT target supports code generation for discrete and continuous time blocks. If the **Support: continuous time** option is selected on the **Code Generation > Interface** pane, you can use these blocks in your models, without restriction.

Note that use of certain blocks is not recommended for production code generation for embedded systems. The Simulink Block Data Type Support table summarizes characteristics of blocks in the Simulink and Fixed-Point Designer block libraries, including whether or not they are recommended for use in production code generation. To view this table, execute the following command and see the “Code Generation Support” column of the table that appears:

```
showblockdatatypetable
```

Support for Continuous Solvers

The ERT target supports continuous solvers. In the **Solver** options dialog, you can select an available solver in the **Solver** menu. (Note that the solver **Type** must be `fixed-step` for use with the ERT target.)

Note Custom targets must be modified to support continuous time. The required modifications are described in “Customize System Target Files” (Simulink Coder).

Support for Stop Time

The ERT target supports the stop time for a model. When generating host-based executables, the stop time value is honored if one of the following is true:

- **External mode** is selected on the **Code Generation > Interface** pane
- **MAT-file logging** is selected
- **Classic call interface** is selected

Otherwise, the executable runs indefinitely.

Note The ERT target provides both generated and static examples of the `ert_main.c` file. The `ert_main.c` file controls the overall model code execution by calling the *`model`*`_step` function and optionally checking the `ErrorStatus`/`StopRequested` flags to terminate execution. For a custom target, if you provide your own custom static `main.c`, you should consider including support for checking these flags.

Optimize Multirate Multitasking Execution for RTOS Run-Time Environments

Using the `rtmStepTask` macro, run-time environments that employ task management mechanisms of an real-time operating system (RTOS)—for example, VxWorks—can improve performance of generated code by eliminating redundant scheduling calls during the execution of tasks in a multirate, multitasking model, The following sections describe implementation details.

Use rtmStepTask

The `rtmStepTask` macro is defined in `model.h` and its syntax is as follows:

```
boolean task_ready = rtmStepTask(rtm, idx);
```

The arguments are:

- `rtm`: pointer to the real-time model structure (`rtM`)
- `idx`: task identifier (`tid`) of the task whose scheduling counter is to be tested

`rtmStepTask` returns `TRUE` if the task's scheduling counter equals zero, indicating that the task should be scheduled for execution on the current time step. Otherwise, it returns `FALSE`.

If your target supports the **Generate an example main program** parameter, you can generate calls to `rtmStepTask` using the TLC function `RTMTaskRunsThisBaseStep`.

Schedule Code for Real-time Model without an RTOS

To understand the optimization that is available for an RTOS target, consider how the ERT target schedules tasks for bareboard targets (where RTOS is not present). The ERT target maintains scheduling counters and event flags for each subrate task. The scheduling counters are implemented within the real-time model (rtM) data structure as arrays, indexed on task identifier (`tid`).

The scheduling counters are updated by the base-rate task. The counters are clock rate dividers that count up the sample period associated with each subrate task. When a given subrate counter reaches a value that indicates it has a hit, the sample period for that rate has elapsed and the counter is reset to zero. When this occurs, the subrate task must be scheduled for execution.

The event flags indicate whether or not a given task is scheduled for execution. For a multirate, multitasking model, the event flags are maintained by code in the main program for the model. For each task, the code maintains a task counter. When the counter reaches 0, indicating that the task's sample period has elapsed, the event flag for that task is set.

On each time step, the counters and event flags are updated and the base-rate task executes. Then, the scheduling flags are checked in `tid` order, and tasks whose event flag is set is executed. Therefore, tasks are executed in order of priority.

For bareboard targets that cannot rely on an external RTOS, the event flags are mandatory to allow overlapping task preemption. However, an RTOS target uses the operating system itself to manage overlapping task preemption, making the maintenance of the event flags redundant.

Schedule Code for Multirate Multitasking on an RTOS

The following task scheduling code, from `ertmainlib.tlc`, is designed for multirate multitasking operation on an example RTOS (VxWorks) target. The example uses the TLC function `RTMTaskRunsThisBaseStep` to generate calls to the `rtmStepTask` macro. A loop iterates over each subrate task, and `rtmStepTask` is called for each task. If `rtmStepTask` returns `TRUE`, the RTOS `semGive` function is called, and the RTOS schedules the task to run.

```
%assign ifarg = RTMTaskRunsThisBaseStep("i")
for (i = 1; i < %<FcnNumST>; i++) {
   if (%<ifarg>) {
     semGive(taskSemList[i]);
     if (semTake(taskSemList[i],NO_WAIT) != ERROR) {
       logMsg("Rate for SubRate task %d is too fast.\n",i,0,0,0,0,0);
       semGive(taskSemList[i]);
     }
   }
}
```

Suppress Redundant Scheduling Calls

Redundant scheduling calls are still generated by default for backward compatibility. To change this setting and suppress them, add the following TLC variable definition to your system target file before the `%include "codegenentry.tlc"` statement:

```
%assign SuppressSetEventsForThisBaseRateFcn = 1
```

Representing a Software Architecture by Creating Code Generation Definitions

Define Storage Classes, Memory Sections, and Function Templates for Software Architecture

In a team or large organization, to enable multiple users to generate code that conforms to a standard architecture, you can create and share code generation definitions, such as storage classes, with those users. When configuring code generation settings for different models, the users can apply the definitions to data and function elements in the models, generating standardized code.

Create Code Definitions for Use as Default Code Generation Settings

To control the default appearance of model elements in the generated code, you apply settings to categories of elements, such as data and functions, by using the Code Mappings editor. For more information, see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7.

To create definitions that you and other users can use in the Code Mappings editor, use an Embedded Coder Dictionary.

When you create definitions in an Embedded Coder Dictionary, you must decide where to store the definitions.

- If you want to use the definitions in only one model, create the definitions in the Embedded Coder Dictionary of the model.
- If you want to use the definitions in multiple models, including the models in a model reference hierarchy, store the definitions in the Embedded Coder Dictionary of a Simulink data dictionary. For general information about data dictionaries, see “What Is a Data Dictionary?” (Simulink).

To use an Embedded Coder Dictionary, and for limitations with respect to code generation definitions in an Embedded Coder Dictionary, see Embedded Coder Dictionary.

Create Code Definitions to Override Default Settings

To override the default settings that you specify in the Code Mappings editor, you apply code generation settings to individual model elements by using other tools such as the Model Data Editor and the Property Inspector. For general information, see “Environment for Configuring Model Data and Functions for Code Generation” on page 31-2.

To create code definitions that you can apply through these other tools, use the Custom Storage Class Designer. You can define storage classes and memory sections, which you can apply only to data elements. For more information, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 36-35 and “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2.

Constrain Use of Storage Class Code Mappings

When defining a storage class in the Embedded CoderEmbedded Coder Dictionary, you can specify whether users can map the storage class to parameters, signals, or parameters and signals. To constrain the use of a storage class, the **Data Initialization** property must be set to `None`. Then, in the Property Inspector, under **Allowed Usage**, select **Parameters**, **Signals**, or **Parameters** and **Signals**. For more information, see **Embedded Coder Dictionary**.

Avoid Maintaining Duplicate Definitions in Packages and Dictionaries

If you want to use the same code generation definition as a default setting and for direct application to individual model elements, you do not need to store one copy of the definition in an Embedded Coder Dictionary and another copy in a package. Instead, store the definition in a package (by using the Custom Storage Class Designer). Then, configure one or more Embedded Coder Dictionaries to refer to the definition in the package. With this technique, when you want to make changes to the definition, you make the changes in only one place, the package.

However, if you create a custom storage class by using the Custom Storage Class Designer and set **Type** to `FlatStructure`, as described in “Generate Structured Data” on page 36-42, or to `Other`, as described in “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 36-48, you cannot configure an Embedded Coder Dictionary to refer to the package. Therefore, you cannot use the storage class in the Code Mappings editor.

To create a code generation definition in a package by using the Custom Storage Class Designer, see “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 36-35. Then, to configure an Embedded Coder Dictionary to refer to the package, see “Refer to Code Generation Definitions in a Package”.

Deploy Code Generation Definitions to Users

In a large organization with multiple models and users, you can share code generation definitions by storing them in a mutually accessible location. The process of sharing code definitions is called deployment. For more information, see “Deploy Code Generation Definitions” on page 30-7.

Maintain Code Generation Definitions

In a model, you apply a code definition to a model element by selecting the name of the definition from a list, for example, in the Model Data Editor or in the Code Mappings editor. Also, you can associate a memory section with a storage class or function customization template by using a list in the Custom Storage Class Designer or in an Embedded Coder Dictionary.

Depending on the storage location of the code definition, changing or deleting the definition can break these usage points, requiring you to take action.

Package Definitions

If you create a code definition in a package, changing the name or deleting the definition can break usage points, which you must fix manually.

- To fix usage points for individual data elements in a model, optionally, you can write a script. See the interactive and programmatic examples in “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28.
- To fix usage points in a package (for example, when you change the name of a memory section that a storage class uses), use the Custom Storage Class Designer. You cannot write a script.

If you load a package into Embedded Coder Dictionaries (see “Refer to Code Generation Definitions in a Package”), when you make changes to the code definition (including to properties other than the name) or delete the definition:

1. Reload the package. In each dictionary, click the **Manage Packages** button to open the Manage Packages dialog box. From the **Select package** drop-down list, select the package. Use the buttons to unload, and then reload the package.

   Reloading the package breaks usage points in the Code Mappings editor for affected models, which you must fix manually.

2 Fix usage points in the Code Mappings editor for affected models. To write a script that fixes Code Mappings editor usage points, see “Configure Default Data and Function Code Generation Programmatically” on page 31-23.

Embedded Coder Dictionary Definitions

If you create a code definition in an Embedded Coder Dictionary:

- Changing the name of the code definition does not break usage points. Simulink propagates the new name to the usage points.
- Deleting a code definition breaks usage points in the Code Mappings editor for affected models. In the editor, lists display `Unresolved`. Fix these usage points manually. To fix them by writing a script, see “Configure Default Data and Function Code Generation Programmatically” on page 31-23.

Interact with Code Generation Definitions Programmatically

You cannot create code generation definitions programmatically. However, for Embedded Coder Dictionary definitions, you can delete, copy, and move code definitions between models and data dictionaries by using these functions:

- `coder.dictionary.copy`
- `coder.dictionary.move`
- `coder.dictionary.remove`

- “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2

- “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7

Deploy Code Generation Definitions

As described in “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2, you can create code generation definitions that you and other users can apply to model elements such as data and functions. The code definitions control the appearance of those elements in the generated code.

In a large organization with multiple models and users, you can share code generation definitions by storing them in a mutually accessible location. The process of sharing code definitions is called deployment.

Share Code Generation Definitions Between Multiple Models and Users

When you create custom code generation definitions, to share the definitions between models and other users:

- When you create definitions in a package by using the Custom Storage Class Designer, for each user, place the folder containing the package folder on the MATLAB path. For more information, see “What Is the MATLAB Search Path?” (MATLAB).
- When you create definitions in an Embedded Coder Dictionary, store the definitions in a Simulink data dictionary. Then, link each model to a separate data dictionary. Configure each separate dictionary to refer to the dictionary that contains the code generation definitions. For an example, see “Share Embedded Coder Dictionary Definition Between Models” on page 30-10.

Dictionary Usage for Models Created with Different Versions of Simulink

Simulink provides version handling for Embedded Coder Dictionaries. When these events occur, Simulink synchronizes data in a data dictionary, including the Embedded Coder Dictionaries, for use with a model regardless of the Simulink version used to create the model.

- You link a model to a data dictionary that was saved in a previous version of Simulink (for example, you link a model that you develop in R2018b with a dictionary saved in R2018a).
- You open a model, which has a local Embedded Coder Dictionary, in a version of Simulink that is older than the current version (for example, you developed a model

that uses a local dictionary in R2018a and you open that model in R2018b to continue development).

You also have the option to export (save) an Embedded Coder Dictionary for use with models created with a different version (previous or older) of the code generator.

For more information, see “Dictionary Usage for Models Created with Different Versions of Simulink” (Simulink).

Configure Default Code Mapping in a Shared Dictionary

While setting up an Embedded Coder Dictionary intended to be shared by multiple models, you can map default code definitions for categories of model data and functions. In this example, you map default code definitions for the Embedded Coder Dictionary in `exSharedCodeDefs.sldd`.

1. If not already defined, define code definitions (storage classes, function customization templates, and memory sections) in a data dictionary. For this example, you define code definitions in data dictionary `exSharedCodeDefs.sldd`. Place a copy of this file in a writeable location.
2. In **Current Folder** pane of the MATLAB Command Window, double-click the file name of your copy of `exSharedCodeDefs.sldd`.
3. In the **Model Hierarchy** pane of the Model Explorer, right-click the dictionary node and select **Show Empty Sections**. Model Explorer lists nodes for **Design Data**, **Configurations**, **Embedded Coder Dictionary**, and **Other data**.
4. Open the Embedded Coder Dictionary. In the **Model Hierarchy** pane, click **Embedded Coder Dictionary**. Then, in the right pane, click **Open Embedded Coder Dictionary**.
5. In the Embedded Coder Dictionary toolbar, click **Configure Defaults**.
6. In the Configure Dictionary Defaults dialog box, configure default code definitions for categories of data and functions.

    - On the **Data Defaults** tab, configure the storage class and, if applicable, a memory section, for these categories of data,

Model Element Category	Description
Inports	Root-level input ports of a model.

Model Element Category	Description
Outports	Root-level output ports of a model.
Global parameters	Parameters that are defined in the base workspace or in a data dictionary. Multiple models in an application can use these parameters.
Local parameters	Parameters that are defined within a model, such as parameters in the model workspace. Excludes model arguments.
Parameter arguments	Block parameters in the model workspace that are configured as model arguments. These parameters are exposed at the model block to allow each model instance to provide its own value. To specify a parameter as a model argument, select the **Argument** check box on the **Parameters** tab in the Model Data Editor.
Shared local data stores	Data Store Memory blocks with the block parameter **Share across model instances** set. These data stores are accessible only in the model where they are defined. The data store value is shared across instances of the model.
Global data stores	Data stores that are defined by a signal object in the base workspace or in a data dictionary. Multiple models in an application can use these data stores.
Internal data	Local data, such as data stores, discrete block states, block output signals, and zero-crossing signals.
Constants	Constant-value block output and constant parameters in a model.

- On the **Function Defaults** tab, configure the function customization template and, if applicable, a memory section, for these categories of functions:

Model Function Category	Description
Initialize/Terminate	Entry-point functions for initialization and termination
Execution	Entry-point functions for initiating execution and resets
Shared utility	Shared utility functions

The default mapping for a category applies to elements in a category throughout a model.

For this example, set the storage class for data categories **Inports**, **Outports**, and **Global data stores** to `ExportedGlobal`.

7. Apply your changes and close the dialog box. Click **Apply**. Then, click **OK**.
8. Close the Embedded Coder Dictionary and Model Explorer.

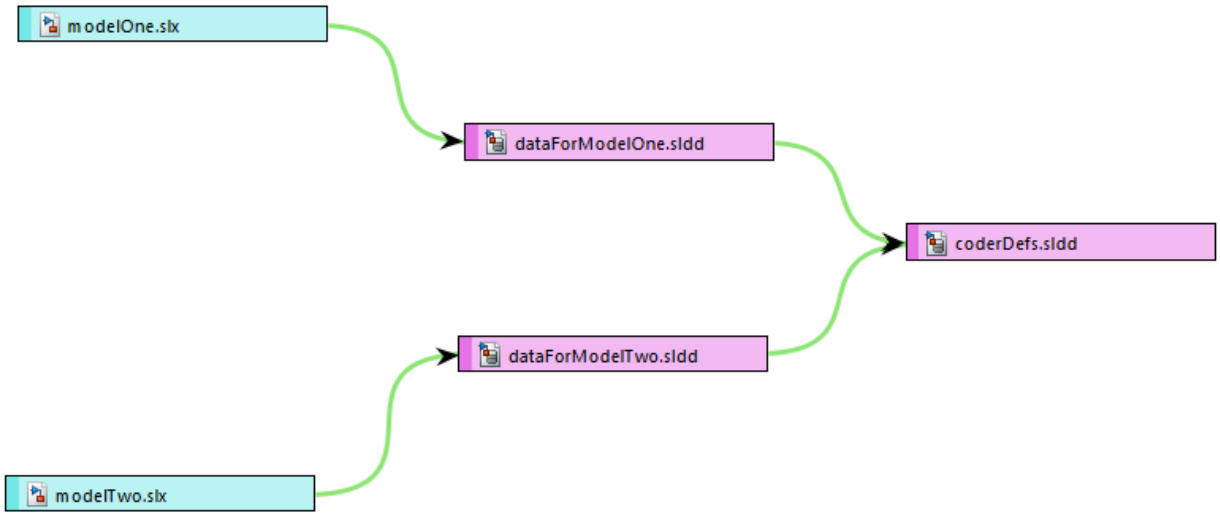
Share Embedded Coder Dictionary Definition Between Models

This example shows how to create a storage class that yields separate global variables in the generated code and share the storage class between two models, `rtwdemo_roll` and `rtwdemo_advsc`. Then, you configure each model to use the storage class as the default code generation setting for internal data, which includes block states.

It is a best practice to store shared code generation definitions in a standalone data dictionary, which means that no models are linked directly to the dictionary. Then, you can link the target models to one or more additional, intermediate dictionaries, which you configure to refer to the standalone dictionary. With this modular dictionary hierarchy, each model can store other data, such as design data, separately from the code generation definitions.

The figure shows an example dictionary hierarchy. In the figure:

- `modelOne.slx` and `modelTwo.slx` are different model files.
- `dataForModelOne.sldd` and `dataForModelTwo.sldd` are data dictionaries. Each dictionary stores design data, such as numeric MATLAB variables, for one of the models.
- `coderDefs.sldd` is a shared data dictionary that stores code generation definitions for both models. The other dictionaries reference `coderDefs.sldd`.



Create Code Generation Definition in Standalone Data Dictionary

Create a data dictionary. Then, create the storage class in the dictionary.

1. At the command prompt, open the Model Explorer.

   ```
   daexplr
   ```
2. In the Model Explorer, select **File** > **New** > **Data Dictionary**.
3. Name the dictionary `coderDefs.sldd`.
4. In the Model Explorer **Model Hierarchy** pane, right-click `coderDefs` and select **Show Empty Sections**.
5. In the **Model Hierarchy** pane, select the **Embedded Coder Dictionary** node.
6. In the Dialog pane (the right pane), click **Open Embedded Coder Dictionary**.
7. In the Embedded Coder Dictionary dialog box, click **Add**.
8. For the new storage class, in the **Property Inspector** pane, set **Name** to `internalsInFile`.
9. In the Model Explorer **Model Hierarchy** pane, right-click `coderDefs` and select **Save Changes**.

Link Models to Data Dictionaries

Link each model to a separate data dictionary. Configure each dictionary to refer to the standalone dictionary (`coderDefs.sldd`).

1. Open the models.

   ```
   rtwdemo_advsc
   rtwdemo_roll
   ```
2. In `rtwdemo_roll`, select **File** > **Model Properties** > **Link to Data Dictionary**.
3. In the Model Properties dialog box, click **New**.
4. Create a dictionary named `rtwdemo_roll_data.sldd` by using the Create a new Data Dictionary dialog box.
5. In the Model Properties dialog box, click **OK**.

   Simulink links the model to the new dictionary. The dictionary does not contain any data because the model does not use data in the base workspace.
6. In the lower-left corner of the model, click the data dictionary badge, which opens the dictionary in the Model Explorer.
7. In the Dialog pane, under **Referenced Dictionaries**, click **Add**.
8. In the Open Data Dictionary dialog box, double-click `coderDefs.sldd`.
9. Use the **Model Hierarchy** pane to save the changes you made to `rtwdemo_roll_data.sldd`.
10. Link `rtwdemo_advsc` to a dictionary named `rtwdemo_advsc_data.sldd`.

    `rtwdemo_advsc` uses a variable in the base workspace. To migrate the variable into the dictionary, in the Model Properties dialog box, click **Migrate data**. Then follow the instructions to link the model to the dictionary and copy the referenced variables.
11. Configure `rtwdemo_advsc_data.sldd` to refer to `coderDefs.sldd`.

Apply Code Generation Definition in Models

Confirm that the shared definition is available for use in the models by applying it as a default setting for internal data and inspecting the generated code.

1. In `rtwdemo_roll`, select **Code** > **C/C++ Code** > **Configure Model in Code Perspective**.
2. Under **Code Mappings** > **Data Defaults**, for the **Internal data** row, set **Storage Class** to `internalsInFile`.
3. In `rtwdemo_advsc`, use the Code perspective to set **Storage Class** to `internalsInFile` for the **Internal data** row.
4. Generate code from `rtwdemo_roll`.
5. In the **Code** view, inspect the generated file `rtwdemo_roll.c`. The file defines global variables that correspond to state data in the model, such as the state of the Integrator block in the `BasicRollMode` subsystem.

```
/* Storage class 'internalsInFile' */
real32_T rtwdemo__FixPtUnitDelay1_DSTATE;
real32_T rtwdemo_roll_Integrator_DSTATE;
int8_T rtwde_Integrator_PrevResetState;
```

6 Optionally, generate code from `rtwdemo_advsc` and confirm that the code appears as expected.

Migrate Definitions from Model File to Shared Data Dictionary

If you create code generation definitions in the Embedded Coder Dictionary of a model, the definitions are stored in the model file. If you want to share the definitions between models:

1 Create a shared data dictionary as shown in “Share Embedded Coder Dictionary Definition Between Models” on page 30-10. Before you proceed to the next step, make sure all of the target models have access to the shared dictionary.

2 Use the `coder.dictionary.move` function to migrate the definitions from the source model file to the shared data dictionary.

3 Optionally, copy Code Mappings editor settings from the source model to other models by using the programmatic interface of the Code Mappings editor (see “Configure Default Data and Function Code Generation Programmatically” on page 31-23).

In this example, you create a storage class in the Embedded Coder Dictionary of a model and use the storage class in the Code Mappings editor. Then, you convert a subsystem to a referenced model. To use the same Code Mappings editor settings for the first model and for the referenced model, you must extract the storage class into a shared data dictionary (`.sldd`).

Create and Apply Storage Class

1 Open the example model `rtwdemo_roll`.

```
rtwdemo_roll
```

2 In the model, select **Code > C/C++ Code > Configure Model in Code Perspective**.

3 Underneath the block diagram, in the Code Mappings editor, click the **Embedded Coder Dictionary** button  .

4 In the Embedded Coder Dictionary dialog box, on the **Storage Classes** tab, click **Add**.

5 For the new storage class, set these property values:

   - **Name** to `internalsInFile`.
   - **Header File** to `$R_internal.h`.
   - **Definition File** to `$R_internal.c`.

6 In the model, in the Code Mappings editor, for the **Data Defaults** > **Internal data** row, set **Storage Class** to `internalsInFile`.

Create Referenced Model

1 In the model, right-click the `BasicRollMode` subsystem and select **Subsystem & Model Reference** > **Convert to** > **Referenced Model**.
2 In the Model Reference Conversion Advisor, click **Convert**.

   The new referenced model, `BasicRollMode`, opens. The model file is in your current folder.

By default, the referenced model cannot access the code generation definitions in the Embedded Coder Dictionary of the parent model. Now, move the storage class out of the parent model and into a shared data dictionary.

Move Storage Class to Shared Data Dictionary

As a best practice, link each model to a separate data dictionary (`.sldd`), create a shared, standalone data dictionary to store the code generation definition (the storage class), and configure dictionary referencing so that all of the models can use the code generation definition.

To link the models to separate dictionaries:

1 In the `rtwdemo_roll` model, select **File** > **Model Properties** > **Link to Data Dictionary**.
2 In the Model Properties dialog box, click **New**.
3 Use the Create a new Data Dictionary dialog box to create a dictionary named `rtwdemo_roll_data.sldd`.
4 In the Model Properties dialog box, click **OK**.
5 In the Link Model to Data Dictionary dialog box, click **Change this model only**.
6 In the `BasicRollMode` model, use the Model Properties dialog box to link the model to a new data dictionary named `basicRollMode_data.sldd`.
7 Click, **OK**.

To create the shared, standalone dictionary and store the code generation definition in it:

1. In both models, at the lower-left corner of the block diagram, click the data dictionary badge to open each dictionary in the Model Explorer.
2. In the Model Explorer, select **File** > **New** > **Data Dictionary**.
3. Create a data dictionary named `coderDefs.sldd`.
4. In the Model Explorer **Model Hierarchy** pane, select the **rtwdemo_roll_data** node.
5. In the Dialog pane (the right pane), under **Referenced Dictionaries**, click **Add**.
6. Add a reference to `coderDefs.sldd`.
7. Configure `basicRollMode_data.sldd` to refer to `coderDefs.sldd`.
8. In the **Model Hierarchy** pane, right-click the **rtwdemo_roll_data** node and select **Save Changes**.
9. At the command prompt, move the code generation definitions from the `rtwdemo_roll` model file to the `coderDefs.sldd` data dictionary.

   ```
   coder.dictionary.move('rtwdemo_roll','coderDefs.sldd')
   ```

Now, both models have access to the storage class `internalsInFile`.

Copy Code Mappings Editor Settings from Parent Model to Referenced Model

By default, the new referenced model does not use the Code Mappings editor settings that the parent model uses. To copy the settings from the parent model to the referenced model, use the programmatic interface of the Code Mappings editor.

At the command prompt, copy the storage class setting for **Internal data** from `rtwdemo_roll` to `BasicRollMode`.

```
roll_sc = coder.mapping.defaults.get('rtwdemo_roll','InternalData','StorageClass');

coder.mapping.create('BasicRollMode');
coder.mapping.defaults.set('BasicRollMode','InternalData','StorageClass',roll_sc);
```

Now, both models use the same Code Mappings editor settings. For more information about the programmatic interface of the Code Mappings editor, see “Configure Default Data and Function Code Generation Programmatically” on page 31-23.

Make Shared Definitions in a Data Dictionary Available to New Models

A model that you create from the Simulink Start Page or by using the `new_system` function is not linked to a Simulink data dictionary. The new model cannot access code generation definitions that you store in a data dictionary.

To make code definitions available to a new model out of the box, write callbacks and other code that immediately links the model to a data dictionary.

- For a simple example that shows how to link a model to a data dictionary programmatically and for information about configuring dictionary referencing programmatically, see “Store Data in Dictionary Programmatically” (Simulink).
- If you use a project, consider creating a project shortcut that creates a model and immediately links the new model to a data dictionary. For information about projects and project shortcuts, see “What Are Projects?” (Simulink).

Use Data Dictionary to Store Code Definitions but Not Design Data

A Simulink data dictionary can store design data such as MATLAB variables and `Simulink.AliasType` objects (see “Global and Shared Data: Data Dictionary” (Simulink)). However, migrating the design data of a large model or of multiple models from the base workspace to a data dictionary can take time and careful planning.

If you want to store shared code generation definitions in a data dictionary but do not want to migrate the design data of a model, in the Model Properties dialog box, on the **Data** tab, select the **Enable access to base workspace** property. The model can use design data from the base workspace and code generation definitions from the dictionary or from a referenced dictionary. For more information, see “Continue to Use Shared Data in the Base Workspace” (Simulink).

Opening Code Perspective Generates Error

In a hierarchy of referenced data dictionaries (see “Dictionary Referencing” (Simulink)), only one dictionary can store code generation definitions in an Embedded Coder Dictionary. When you open the Code perspective in a model that has access to multiple Embedded Coder Dictionaries through referenced data dictionaries, Simulink generates an error. To resolve the error, use `coder.dictionary.move` and `coder.dictionary.remove` to transfer and delete Embedded Coder Dictionaries until only one exists in the dictionary hierarchy. If necessary, store the Embedded Coder Dictionary in a standalone, shared data dictionary as described in “Share Embedded Coder Dictionary Definition Between Models” on page 30-10.

- “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 36-35

Conform to Software Architecture by Sharing and Copying Default Code Generation Settings Between Models

You and other users can configure default code generation settings for categories of model data and functions by using the Code Mappings editor (see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7). You can also configure other model-wide code generation settings through configuration parameters. With these broad, general settings, you can make models generate code that conforms to a general software architecture by default.

As projects expand and you and other users create more models, manually configuring the default settings for each new model takes time. To reduce this manual data entry, you can write scripts and create templates that apply these default settings to new models.

You can copy settings between models, enabling each model to later change the settings independently of each other. Alternatively, you can share settings, enabling you to change the settings for multiple models at once with minimal effort.

Tools to Copy and Share Settings

Tool	Description and Considerations	Reference
Template models	You can create a template model with preconfigured settings such as configuration parameter settings and Code Mappings editor settings. However, when you create a model by instantiating a template, the new model is not linked to a data dictionary. If the preconfigured settings in the template model depend on shared data that you store in a data dictionary, you must configure dictionary linking and referencing for each new model.	“Create a Template from a Model” (Simulink)
Template projects	You can create a template project that contains models, data dictionaries, and other artifacts. You can also write project shortcuts that execute custom code to create models, copy settings, and share settings.	“What Are Projects?” (Simulink)
Programmatic interfaces	To copy settings between models, you can write scripts, callbacks, and shortcuts. Each kind of setting has a programmatic interface.	“Techniques to Copy Settings” on page 30-20

Tool	Description and Considerations	Reference
Configuration set objects	To share configuration parameter settings between models, you can create a configuration set object that each model can refer to.	“About Configuration References” (Simulink)
Data dictionaries	A Simulink data dictionary stores variables, objects, and other data for one or more models. You can create hierarchies of referenced dictionaries to share configuration parameter settings and to partition and organize the settings. It is a best practice to store shared settings in a standalone dictionary, which means that no models are linked to the dictionary. Then, you can link models to one or more additional, intermediate dictionaries, which you configure to refer to the standalone dictionary. With this modular dictionary hierarchy, each model can store other data, such as design data, separately from the shared settings.	For general information about data dictionaries, including how to access them programmatically, see “What Is a Data Dictionary?” (Simulink). For an example that shows how to store shared data for a model reference hierarchy in a standalone dictionary, see “Partition Data for Model Reference Hierarchy Using Data Dictionaries” (Simulink).

Techniques to Copy Settings

To copy settings, use one or more of the techniques described in the table.

Technique	Description
Create a template model.	To create a model, you and other users can instantiate the template. Each new model can later change the settings independently of other models.
Create a template project.	The template project can contain models and associated data dictionaries. Also, through custom project shortcuts and referenced projects, you can make shared data stored in a dictionary available to new models.
Write code by using programmatic interfaces.	You can execute this code in: • A script. • A model callback. For example, you can use the `PreLoadFcn` callback, which executes whenever you open a model. For information about model callbacks, see “Model Callbacks” (Simulink). • A project shortcut. The shortcut can create a model and copy settings into the model. For information about project shortcuts, see “What Can You Do With Project Shortcuts?” (Simulink). To copy settings programmatically, use the programmatic interface. • For configuration parameter settings, use the `set_param` and `get_param` functions. • For Code Mappings editor settings, see “Configure Default Data and Function Code Generation Programmatically” on page 31-23.

Techniques to Share Settings

- To share configuration parameter settings, create a configuration set object. Create a template model that refers to the object through a configuration reference.

  Consider storing the object in a data dictionary. Because you cannot create a template model that is linked to a data dictionary, you must configure dictionary linking and referencing for each new model.
- You cannot share default data and function settings that you specify in the Code Mappings editor.

Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mappings Editor

Starting in R2018a, for new models:

- To apply model-wide memory section settings, do not use the model configuration parameters under **Code Generation > Advanced parameters > Memory Sections**. Instead, use the Code Mappings editor. To define the memory sections, continue to use packages or you can use the Embedded Coder Dictionary.
- To set a naming rule for shared utility functions, do not use the model configuration parameter **Code Generation > Symbols > Advanced parameters > Shared utilities identifier format**. Instead, you use the Embedded Coder Dictionary to create a function customization template that specifies the naming rule, then apply the template by using the Code Mappings editor.

For general information about the Simulink Editor Code perspective mode, the Code Mappings editor, and the Embedded Coder Dictionary, see “Environment for Configuring Model Data and Functions for Code Generation” on page 31-2.

In a model that you created in a release before R2018a, when someone enables Code perspective mode, Simulink migrates memory section and shared utility settings from the configuration parameters to the Code Mappings editor of the model. If necessary, as part of this migration, Simulink configures the Embedded Coder Dictionary that the model uses:

- To refer to the package that defines the memory sections, as described in “Refer to Code Generation Definitions in a Package”.
- To contain a function customization template that specifies the naming rule and, if applicable, memory section settings that you specified for shared utilities.

Also, if you use the `coder.mapping.create` function on such a model, Simulink migrates memory section and shared utility settings in this manner.

Effects of Migration

- The migration process makes changes to the model file, which you must save. The changes include:
  - Translating the configuration parameter settings into Code Mappings editor settings.

    - If the model is not linked to a data dictionary, configuring the Embedded Coder Dictionary in the model file to refer to the memory section package and to contain a function customization template.
- If the model is linked to a data dictionary, the migration process makes changes to the dictionary, which you must save. The changes include:

    - If the configuration parameters are stored in the model file (the model does not refer to a `Simulink.ConfigSet` object), configuring the Embedded Coder Dictionary of the data dictionary to refer to the memory section package and to contain a function customization template.

      If the data dictionary references other dictionaries, the migration process configures the dictionary at the bottom of the reference hierarchy so other models and dictionaries in the hierarchy can use the memory section and function template definitions.
    - If the model refers to a `Simulink.ConfigSet` object, configuring the Embedded Coder Dictionary of the data dictionary that stores the object.

Considerations Before Migrating

- Typically, when you enable the Code perspective mode, Simulink executes the migration process without prompting you. Do not enable Code perspective mode unless you are ready to migrate memory section and shared utility naming settings.

  Code perspective mode prompts you to accept the migration if your model meets either of these conditions:

    - The model has multiple configuration sets (one active and one or more inactive).
    - The model refers to a `Simulink.ConfigSet` object.

  If you do not accept, you cannot use the Code perspective.
- If you use Simulink data dictionaries, before you or other users open the Code perspective in any models, consider creating and configuring the dictionaries first.

  In a hierarchy of referenced data dictionaries (for example, a dictionary hierarchy that parallels a model hierarchy), only one dictionary can contain an Embedded Coder Dictionary. Setting up data dictionaries before migrating associated models enables you to control where the Embedded Coder Dictionary resides in the dictionary hierarchy. Create or identify a data dictionary at the bottom of the hierarchy so that all

of the models can access the memory section and function template definitions. Then, when you initiate migration by enabling Code perspective for a model, Simulink configures that data dictionary.

For information about sharing an Embedded Coder Dictionary between models by using referenced dictionaries, see “Share Embedded Coder Dictionary Definition Between Models” on page 30-10.

- The migration process makes changes based on the active configuration set of the model (see “Manage a Configuration Set” (Simulink)) at the time that you enable Code perspective mode. Before you enable Code perspective, activate the configuration set whose settings you want the migration process to use.

  The process ignores settings in inactive configuration sets. If different configuration sets of the model specify different settings, you must choose one set to migrate.

Considerations After Migrating

- In a branching hierarchy of referenced models and referenced data dictionaries, after you or other users migrate referenced models in different branches, enabling Code perspective mode in a parent model can generate an error due to the presence of multiple Embedded Coder Dictionaries in the data dictionary hierarchy. To resolve these errors, use `coder.dictionary.move` and `coder.dictionary.remove` to transfer and delete Embedded Coder Dictionaries until only one dictionary remains. Place the remaining Embedded Coder Dictionary in a data dictionary at the bottom of the hierarchy so that all of the models can access the memory section and function template definitions.

  For information about sharing an Embedded Coder Dictionary between models by using referenced dictionaries, see “Share Embedded Coder Dictionary Definition Between Models” on page 30-10.

- After you migrate a model, Embedded Coder ignores memory section and shared utility settings in the configuration parameters. If you use `set_param` or `get_param` to access these configuration parameter settings programmatically, the functions generate warnings. To change or set these settings, use the Code Mappings editor or the equivalent programmatic interface as described in “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7.

  However, if a model contains atomic subsystems that have nondefault memory section settings, the model continues to depend on the **Package** setting in the configuration

parameters. See “Override Default Memory Placement for Subsystem Functions and Data” on page 40-12.

- If a model refers to a `Simulink.ConfigSet` object, after migration, the model no longer uses the memory section and shared utility settings in the object. If you used the object to set the configuration parameters of multiple models:
  - Changing memory section and shared utility settings in the object affects only models that you have not migrated.
  - Migrated models no longer acquire memory section and shared utility settings from a single location (the `Simulink.ConfigSet` object). To change these settings for these models, you must use the Code Mappings editor of each individual model.

Flexible Storage Class for Different Model Hierarchy Contexts

This example shows how to use one storage class throughout a model hierarchy to generate code that is unstructured for single-instance data and structured for multi-instance data. When a model hierarchy contains single-instance and multi-instance data, use a flexible storage class to specify the settings for the two contexts instead of creating two separate storage classes.

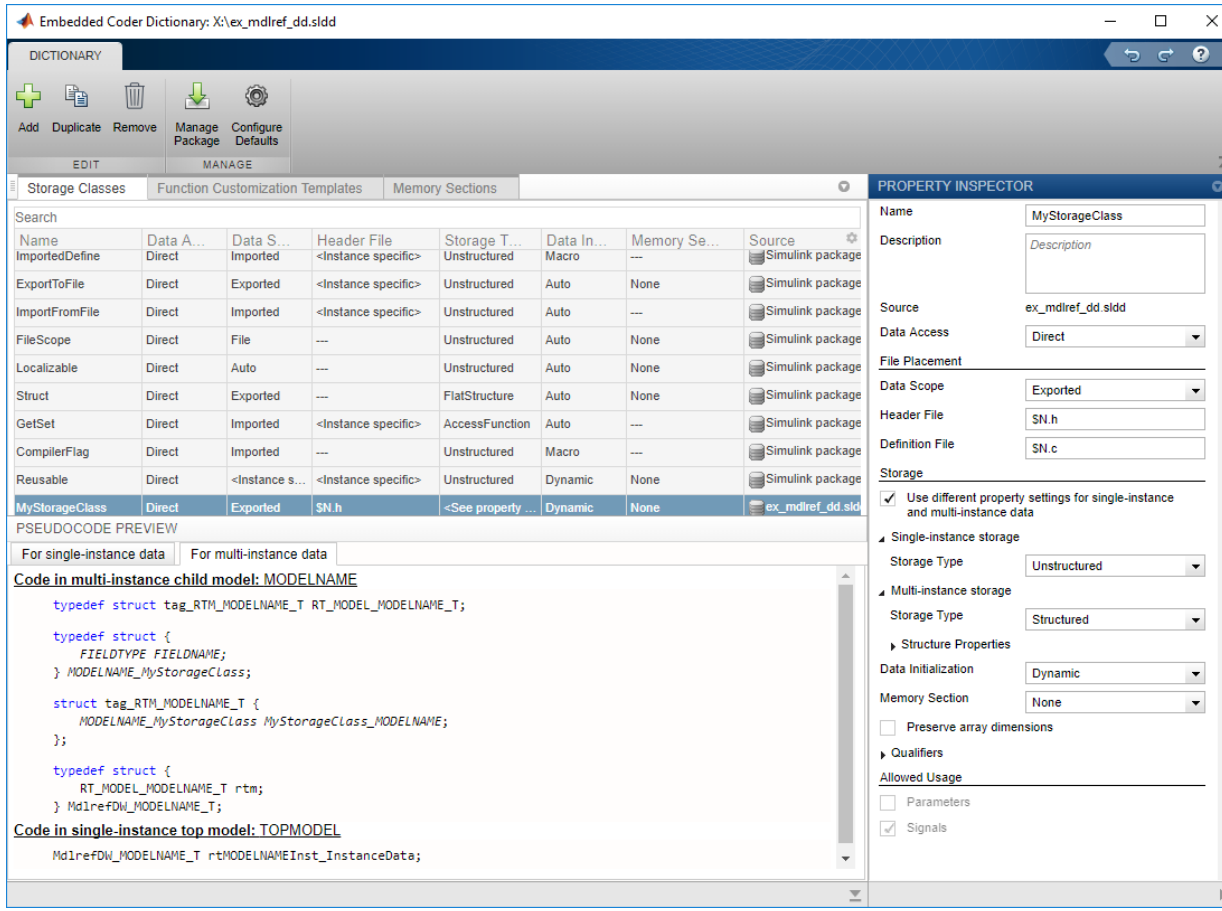
This example uses the single-instance top model `ex_mdlreftop_dd`, which references the multi-instance model `ex_mdlrefbot_dd` three times. Both models share the data dictionary `ex_mdlref_dd.sldd`. When you define the storage class in the shared data dictionary, you can apply the class to data items in both models.

1. Open the example model `ex_mdlreftop_dd`.

   ```
   addpath(fullfile(docroot,'toolbox','ecoder','examples'))
   ex_mdlreftop_dd
   ```

2. Open the shared data dictionary. In the lower-left corner of the model editor, click the Simulink data dictionary icon.
3. Open the shared Embedded Coder Dictionary. In the Model Explorer **Model Hierarchy** pane, expand the `ex_mdlref_dd` node and click **Embedded Coder Dictionary**. In the right pane, click **Open Embedded Coder Dictionary**.
4. To create a storage class, click **Add**.
5. For the new storage class, in the **Property Inspector** pane, set these property values:

   - **Name** to `MyStorageClass`.
   - Select **Use different property settings for single-instance and multi-instance data**.
   - **Single-instance storage** > **Storage Type** to `Unstructured`.
   - **Multi-instance storage** > **Storage Type** to `Structured`.



When you apply `MyStorageClass` to a data item, the Embedded Coder Dictionary implements the single-instance settings or the multi-instance settings depending on the type of data and the context of the model within the model reference hierarchy. Review the implementations for the different settings in the pseudocode preview.

6 Apply the storage class to internal data items by specifying it as a dictionary default. In the Embedded Coder Dictionary, click **Configure Defaults**. For the **Internal Data** row, set **Storage Class** to `MyStorageClass`. Click **OK**.

Because `ex_mdlreftop_dd` and `ex_mdlrefbot_dd` share the dictionary `ex_mdlref_dd.sldd`, both models use `MyStorageClass` as the default storage class for internal data.

7. Open the Code perspective. Select **Code** > **C/C++ Code** > **Configure Model in Code Perspective**.
8. Generate code for the model.
9. Review the generated code for the referenced model. To open the referenced model in the editor, double-click the Model block, CounterA. The reference model code appears in the Code view. In `ex_mdlrefbot_dd.h`, the reference model code defines the storage class structure in which it stores the internal data of the referenced model.

   ```
   /* Storage class 'MyStorageClass', for model 'ex_mdlrefbot_dd' */
   typedef struct {
     real_T PreviousOutput_DSTATE;        /* '<Root>/Previous Output' */
   } ex_mdlrefbot_dd_MyStorageClass;

   /* Real-time Model Data Structure */
   struct ex_mdlrefbot_dd_tag_RTM {
     const char_T **errorStatus;
     ex_mdlrefbot_dd_MyStorageClass *MyStorageClass_ex_mdlrefbot_dd;
   };
   ```

   Because the referenced model is multi-instance, the definition implements the multi-instance data settings of `MyStorageClass`. The reference model code stores the internal data in the structure `ex_mdlrefbot_dd_MyStorageClass`.
10. Navigate back to the top model and review the generated code. In `ex_mdlreftop_dd.c`, the top model code defines its internal data for each Model block by instantiating the storage class of the referenced model, `ex_mdlrefbot_dd_MyStorageClass`.

    ```
    /* Storage class 'MyStorageClass' */
    ex_mdlrefbot_dd_MdlrefDW ex_mdlreftop_dd_CounterA_InstanceData;
    ex_mdlrefbot_dd_MdlrefDW ex_mdlreftop_dd_CounterB_InstanceData;
    ex_mdlrefbot_dd_MdlrefDW ex_mdlreftop_dd_CounterC_InstanceData;

    /* Storage class 'MyStorageClass' */
    ex_mdlrefbot_dd_MyStorageClass MyStorageClass_CounterA;

    /* Storage class 'MyStorageClass' */
    ex_mdlrefbot_dd_MyStorageClass MyStorageClass_CounterB;

    /* Storage class 'MyStorageClass' */
    ex_mdlrefbot_dd_MyStorageClass MyStorageClass_CounterC;
    ```

Because the top model is single-instance, these definitions implement the single-instance data settings of `MyStorageClass`. The top model also packages its own internal data as standalone variables by using the single-instance data settings. The top model code does not contain a structure definition for internal data.

Data, Function, and File Definition

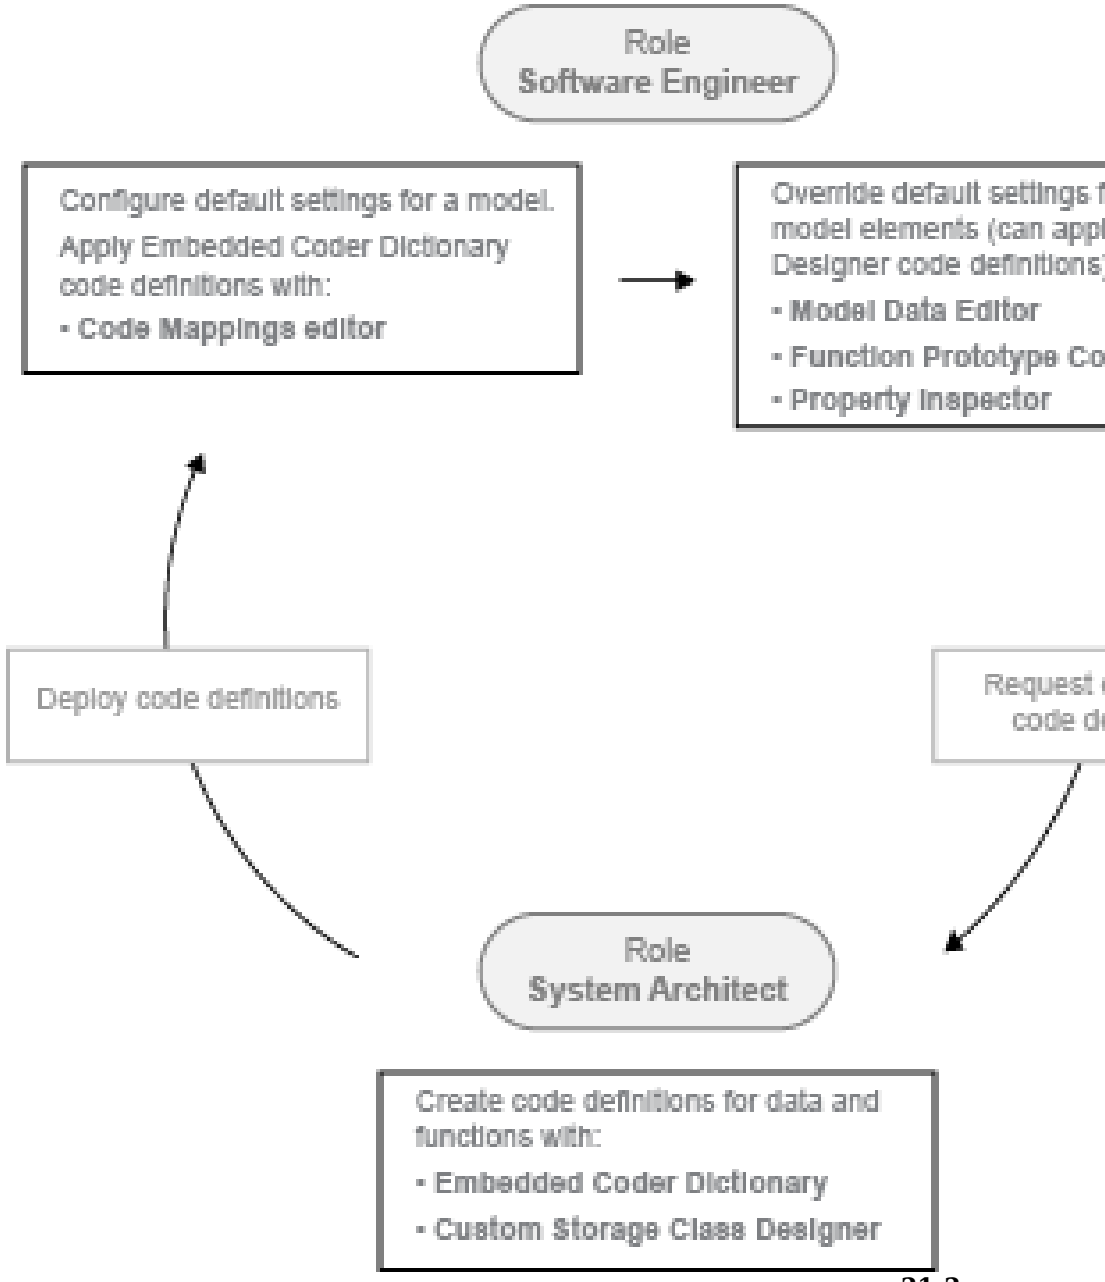
Configuring Data and Functions in the Generated Code

Environment for Configuring Model Data and Functions for Code Generation

When you generate code from a model, the code includes:

- Entry-point functions such as *`model`*`_step`, which your application code calls to execute the model algorithm.
- Data such as signals, states, and parameters, which your application code can read from and write to.

To control the names and representation of the data and functions in the code, follow the iterative paradigm shown in this diagram.



Role
Software Engineer
Configure default settings for a model.
Apply Embedded Coder Dictionary code definitions with:
• Code Mappings editor
Override default settings f
model elements (can appl
Designer code definitions)
• Model Data Editor
• Function Prototype Co
• Property Inspector
Deploy code definitions
Request
code d
Role
System Architect
Create code definitions for data and functions with:
• Embedded Coder Dictionary
• Custom Storage Class Designer

In this paradigm:

- A software engineer directly interacts with and generates code from production models.
- A system architect helps multiple engineers and multiple projects generate code that conforms to the standards of a department or organization. The architect achieves this standardization by customizing the Simulink development environment that engineers use.

To access tools such as the **Code Mappings editor**, use the Simulink Editor in Code perspective mode. To enable Code perspective mode, select **Code > C/C++ Code > Configure Model in Code Perspective**.

Software Engineer: Configure Default Settings

For each category of data and functions in a model, such as root-level input, parameters, and execution functions, you can specify default code generation settings. For example, you can configure the generated code to conform to these objectives by default:

- Read root-level input data from global variables defined by external code.
- Store state data in structures whose placement in memory you can control.
- Name functions according to a rule that you specify.

The default settings can help you to reduce manual data entry.

- As you add blocks and signals to a model, the new data elements and functions inherit the default settings.
- To change code generation settings for many data elements or functions at once, you make the changes in one place—the default settings.
- You can use naming rules and other parameterized, abstract schemes to avoid additional effort as you make changes elsewhere in the model.

For some categories of data, code generation optimizations can eliminate the data from the code. For your default settings to apply, you must identify individual data elements that you want to preserve against the optimizations. For more information, see “Elimination of Parameters and Other Internal Data by Optimizations” on page 31-33.

To configure default settings, use the **Code Mappings editor**.

Software Engineer: Override Default Settings

After using the **Code Mappings editor** to configure model-wide default settings, you can override the defaults for individual data elements and functions.

Override Defaults	Action
Data	Use the Model Data Editor `Code` view. Apply a setting in the **Storage Class** column. See "Configure Data Properties by Using the Model Data Editor" (Simulink).
Entry-point functions	In the Code Mappings editor, use the **Entry-Point Functions** tab. For an individual function, you can override the function customization template, function name, and memory section. For the base rate step (execution) function of a rate-based model and the step functions generated from Simulink Function blocks, you can override the default interface (name and arguments) through the Configure C Step Function Interface dialog box. See "Customize Generated C Function Interfaces" on page 39-2 and "Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks" on page 39-24.

System Architect: Create Code Generation Definitions

Using the Code Mappings editor and the Model Data Editor, application developers apply code generation definitions, such as the built-in storage class `ExportedGlobal`, to model data elements and functions. To standardize the code that you and your users generate from multiple models, you can create and share custom definitions with meaningful names. Creating custom definitions also enables you to achieve code generation objectives that built-in definitions cannot satisfy.

- To create definitions that you want to appear in the **Code Mappings editor**, use the **Embedded Coder Dictionary**. See Embedded Coder Dictionary.

  If you plan to use your Embedded Coder Dictionary definitions in one model, you can store the definitions in the model file. Alternatively, to share the definitions between models and projects, store the definitions in a Simulink data dictionary. With a data

dictionary, to modify a shared definition, you change a definition in one place—the dictionary.

- To create definitions that you want to appear in other tools, such as the Model Data Editor, use the Custom Storage Class Designer. See “Create Custom Storage Classes by Using the Custom Storage Class Designer” on page 36-35.

  For some definitions that you create by using the Custom Storage Class Designer, you can make the definitions appear in the Code Mappings editor by configuring an Embedded Coder Dictionary to refer to them.

- “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2

Configure Default C Code Generation for Categories of Model Data and Functions

Reduce the effort of preparing a model for C code generation by specifying default configurations for categories of data elements and functions across a model. Applying default configurations can save time and reduce the risk of introducing errors in code, especially for larger models and models from which you generate multi-instance code.

You can set a default code generation configuration for:

- Categories of model data. When producing code for the data, the code generator uses a storage class that you specify to determine properties, such as whether the data is structured, naming rules for definition and header files, and whether the data is stored in a memory section.
- Categories of functions. When producing code for the functions, the code generator uses a function customization template that you specify to determine properties, such as a function naming rule and whether the function code is stored in a memory section.

You can specify the default configurations interactively in the Simulink model editing environment from the **Code Mapping Editor** or programmatically.

Configure Default Data and Function Configurations in Model Editing Environment

To specify default code generation configurations for model data and functions interactively in Simulink model editing environment, use the **Code Mapping Editor** and Property Inspector. When you use the Simulink Editor in code perspective mode, the editor and inspector are accessible. After preparing the model for code generation, the Embedded Coder Quick Start tool places a model in code perspective mode. Alternatively, you can enable code perspective mode from the Simulink Editor by doing one of the following:

- Click the perspective control in the lower-right corner of the model editing pane and select **Code**.
- Select **Code > C/C++ Code > Configure Model in Code Perspective**.

The Code Mapping Editor appears below the model diagram. The editor display consists of three tabbed tables: **Entry-Point Functions**, **Data Defaults**, and **Function Defaults**.

Use the **Data Defaults** table to associate categories of model data elements with storage classes. Use the **Function Defaults** table to associate functions with function customization templates. When you select a row in one of the tables, the **Code** section of the Property Inspector shows the property settings for that data element or function category.

If you close the Code Mapping Editor, the Simulink Editor window remains in code perspective mode. To reopen the Code Mapping Editor, select **View > Code Mappings**.

After you enable code perspective mode or use the default mapping programmatic interface to configure one or more categories of data and functions for a model, setting memory section and **Shared utilities identifier format** model configuration parameters has no effect. Also, when you enable code perspective mode, Simulink migrates the model configuration parameter settings to the Code Mapping Editor. If necessary, as part of the migration, Simulink configures the Embedded Coder Dictionary that the model uses as described in “Migrate Memory Section and Shared Utility Settings from Configuration Parameters to Code Mappings Editor” on page 30-23.

Configure Default Code Generation for Data

You configure default code generation for categories of data elements in a model by associating the categories with storage classes and memory sections. Data elements are grouped into these categories.

Model Element Category	Description
Inports	Root-level input ports of a model.
Outports	Root-level output ports of a model.
Global parameters	Parameters that are defined in the base workspace or in a data dictionary. Multiple models in an application can use these parameters.
Local parameters	Parameters that are defined within a model, such as parameters in the model workspace. Excludes model arguments.

Model Element Category	Description
Parameter arguments	Block parameters in the model workspace that are configured as model arguments. These parameters are exposed at the model block to allow each model instance to provide its own value. To specify a parameter as a model argument, select the **Argument** check box on the **Parameters** tab in the Model Data Editor.
Shared local data stores	Data Store Memory blocks with the block parameter **Share across model instances** set. These data stores are accessible only in the model where they are defined. The data store value is shared across instances of the model.
Global data stores	Data stores that are defined by a signal object in the base workspace or in a data dictionary. Multiple models in an application can use these data stores.
Internal data	Local data, such as data stores, discrete block states, block output signals, and zero-crossing signals.
Constants	Constant-value block output and constant parameters in a model.

The **Code Mapping Editor** presents valid storage class options for a given category. The options can include:

- Unspecified storage class (`Default`). The code generator places the code for the category of data elements in standard structures, such as `B_`, `ExtY_`, `ExtU_`, `DW_`, and `P_`. See “Standard Data Structures in the Generated Code” on page 32-26.
- Relevant built-in storage class, such as `ExportedGlobal`.
- Relevant storage class in an available package, such as `ImportFromFile`.
- Storage class defined in an Embedded Coder Dictionary.

Before configuring default code generation settings for data, consider:

Consideration	See
What categories are relevant to your model?	The model element categories in the preceding table

Consideration	See
Does the model use several instances of data that are in a category? If the answer is yes, applying default mappings is beneficial. If the answer is no, consider configuring code generation for each data element individually by using the Model Data Editor.	"Configure Data Properties by Using the Model Data Editor" (Simulink), "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" on page 32-81, and "Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements" on page 36-28
Which storage class aligns with your code generation requirements for each category?	"Choose Storage Class for Controlling Data Representation in Generated Code" on page 32-69
Do you want the model data be structured? For example, if you configured the model for multi-instance code generation, structures can improve code efficiency and readability.	"Organize Data into Structures in Generated Code" on page 32-181
Do categories require the code generator to store data in specific areas of memory? For example, consider whether to store initialization data in slow memory and algorithmic or computational data in fast memory.	"Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 30-2 and "Control Data and Function Placement in Memory by Inserting Pragmas" on page 40-2
Do you want to prevent optimizations from eliminating specific data from the code?	"Elimination of Parameters and Other Internal Data by Optimizations" on page 31-33
Are there data elements for which you must override the default configuration settings?	Example below.
Do you need to define new storage classes that you can select in the Code Mapping Editor?	"Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 30-2 and "Create Custom Storage Classes by Using the Custom Storage Class Designer" on page 36-35

This example shows how to use the **Code Mapping Editor** to specify code generation requirements for model data. The model uses multiple execution rates and is configured for single-instance usage.

In this example, the code generation requirements for data:

- Use project type definition `DBL_FLOAT` defined in header file `exDblFloat.h`.
- Get data element `ex_input1` from header file `exInDataMem.h`. The data is used for computing a value stored in memory, and then used in an if-else condition of a Switch block.
- Get data elements `ex_input2`, `ex_input3`, and `ex_input4` from header file `exInDataLut.h`. The data is used in lookup tables `Table1` and `Table2`.
- Data imported into the model from header files `exInDataMem.h` and `exInDataLut.h` is of type `DBL_FLOAT`, a project standard.
- Parameter `K1` must be tunable to enable calibration.
- Data store `mode` defines data that is shared within the model. The Logical Operator block writes to the data store and a Rate Transition block reads from the data store.
- Data element `X` represents the delay for the Unit Delay block.
- Store data that is internal to the model, such as delay `X`, in a section of memory labeled `internalDataMem`.
- Export output data declarations to header file `exSysOut.h` and definitions to `exSysOut.c`.

To configure default code generation mappings for the model data, use the **Code Mapping Editor**. Although the model uses single instances of some data, the example configures default settings to demonstrate different types of mappings. As you add blocks to the model, new data elements acquire the default code generation mappings.

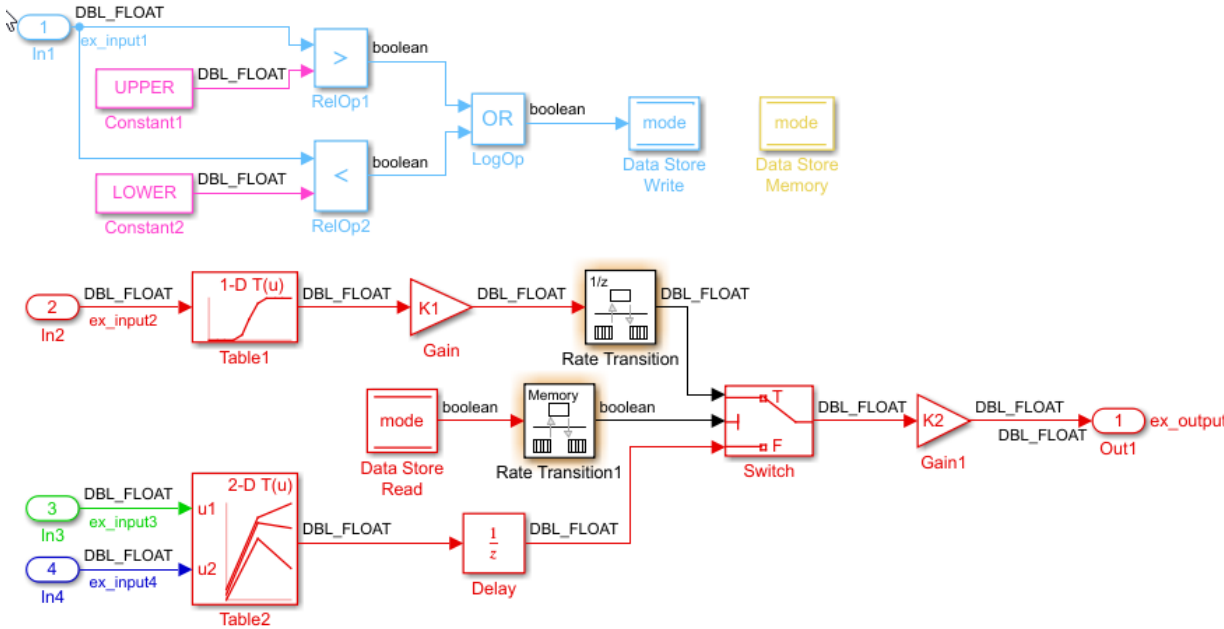
Set Up Example Environment

1 Copy these external source and header files from `matlabroot/toolbox/rtw/rtwdemos` to a writable working folder. These files define and declare the external data type and data that the generated code uses.

File	Description
`exDblFloat.h`	Defines the project data type alias for `double`, `DBL_FLOAT`. Simulink uses the `PreLoadFcn` callback specified for the model to parse this header file and create a corresponding `Simulink.AliasType` object.

File	Description
`exInDataMem.c`	Includes `exInDataMem.h` and defines variable `ex_input1`.
`exInDataMem.h`	Includes `exDbFloat.h` and declares variable `ex_input1`.
`exInDataLut.c`	`exInDataLut.c` includes `exInDataLut.h` and defines variables `ex_input2`, `ex_input3`, and `ex_input4`.
`exInDataLut.h`	Includes `exDbFloat.h` and declares variables `ex_input2`, `ex_input3`, and `ex_input4`.
`rtwdemo_configdefaults.slx`	Example model.

2 Open your copy of example model `rtwdemo_configdefaults`.



3 To gain access to the Code Mapping Editor, enable code perspective mode. Select **Code > C/C++ Code > Configure Model in Code Perspective**.

Configure Default Settings for Inport Data

Specify an external header file that declares input data. Three of the four root inports read input from variables declared in header file `exInDataLut.h`. Set that header file as the default.

1. Under **Code Mappings - C**, in the **Data Defaults** tab, select category **Inports**. Set the storage class to `ImportFromFile`.
2. In the Property Inspector, set **Header File** to `exInDataLut.h`.

   The default mappings for a model are stored as part of the model.

Override Default Settings for Inport In1

Override the default external header file setting for `In1`. That inport reads data from a variable declared in header file `exInDataMem.h`.

1. Open the Model Data Editor.
2. In the **Source** column, select **In1**.
3. Set the storage class for **In1** to `ImportFromFile`.
4. Set **Header File** to `inDataMem.h`.
5. Return to the Code Mappings Editor by clicking the **Code Mappings - C** tab.

Configure Default Settings for Local Parameters

Configure parameters `UPPER`, `LOWER`, `K1`, and `K2`. Those parameters are local parameters for which parameter objects are stored in the model workspace. Map category **Local parameters** to storage class `ExportedGlobal`, which makes the parameter objects appear in the generated code as tunable global variables.

Prevent Optimizations From Eliminating Parameter From Generated Code

Prevent code generator optimizations from eliminating `K1` from the generated code. The data requirements indicate that `K1` must be tunable. To prevent potential elimination of the variable from the generated code, in the **Code** view of the Model Data Editor, find the model workspace parameter for `K1`. Set the storage class to `Model default`. For more information, see “Elimination of Parameters and Other Internal Data by Optimizations” on page 31-33.

Define Memory Section for Internal Data

Define a memory section for storing the unit delay X, data that is internal to the model.

1. Return to the Code Mappings Editor.
2. Open the Embedded Coder Dictionary by clicking  .
3. Click the **Memory Sections** tab.
4. Click **Add**.
5. In the new row at the bottom of the table, name the new memory section `internalDataMem`. Also set:
   - **Pre Statement** to `#pragma start INTERNALDATA`
   - **Post Statement** to `#pragma end INTERNALDATA`
   - **Statements Surround** to `Group of variables`
6. Close the dictionary.

Configure Default Memory Section for Internal Data

In the Code Mapping Editor, configure the code generator to place internal data in memory section `internalDataMem`.

1. Select category **Internal data**.
2. In the Property Inspector, set **Memory Section** to `internalDataMem`.

Configure Default Settings for Outport Data

Specify the default external header and definition files for variables to which the generated code writes output.

1. Map category **Outports** to storage class `ExportToFile`.
2. In the Property Inspector, set **Header File** to `exSysOut.h` and **Definition File** to `exSysOut.c`.
3. Save the model.

Generate and Verify Code

In the **Code** view:

- Open the file `rtwdemo_configdefaults_private.h`. Use the **Search** field to find the `#include` statements that include the header files that declare external input data.

  ```
  #include "exInDataMem.h"
  #include "exInDataLut.h"
  ```

- Open the file `rtwdemo_configdefaults.c`. The code initializes the gain variable `K1` and uses the variable in the model step function `exFast_step1`.

  ```
  DBL_FLOAT K1 = 2.0;
  .
  .
  .
  void exFast_step1(void)
  {
    DBL_FLOAT rtb_Gain;

    rtb_Gain = K1 * look1_binlc(ex_input2, rtCP_Table1_bp01Data,
      rtCP_Table1_tableData, 10U);
    .
    .
    .
  }
  ```

- In the file `rtwdemo_configdefaults.c`, search for `#pragma` control lines. Find the `pragma` control lines that define memory sections for the local data store, unit delay, and constants.

  ```
  #pragma start INTERNALDATA
  BlockIO_rtwdemo_configdefaults B;
  #pragma end INTERNALDATA

  #pragma start INTERNALDATA
  D_Work_rtwdemo_configdefaults DWork;
  #pragma end INTERNALDATA

  #pragma start INTERNALDATA
  RT_MODEL_rtwdemo_configdefaults M_;
  #pragma end INTERNALDATA

  #pragma start INTERNALDATA
  RT_MODEL_rtwdemo_configdefaults *const M = &M_;
  #pragma end INTERNALDATA
  ```

- Open the file `exSysOut.c`. The file includes an exported data definition for `Out1`.

  ```
  #include "rtwtypes.h"
  #include "rtwdemo_dataconfig_types.h"

  DBL_FLOAT Out1;
  ```

- Open the shared file `exSysOut.h`. The file declares `Out1`. To gain access to `Out1`, external code can include this header file.

  ```
  extern DBL_FLOAT Out1;
  ```

Configure Default Code Generation for Functions

Configure default code generation for a category of functions by using the **Code Mapping Editor** to associate the category with a function customization template.

Model Function Category	Description
Initialize/Terminate	Initialization and termination function code, such as *`model`*`_initialize` and *`model`*`_terminate`.
Execution	Execution code for a model, such as *`model`*`_step` and *`model`*`_reset`.
Shared utility	Code for shared utility functions.

A function customization template defines how the code generator produces code for a category of functions. For a function category, you can define:

- A rule for naming functions
- A location in memory for function definitions (memory section)

By default, the code generator uses the identifier naming rule `$R$N` to name entry-point functions. `$R` is the name of the root model. `$N` is the default code generator name of the function, for example, `initialize`, `step`, and `terminate`. To integrate generated code with existing external code or to comply with naming standards or guidelines, you can adjust the default naming rule. Adjusting the default naming rule can save time, especially for multirate models for which the code generator produces a unique `step` function for each rate.

Unless someone has defined function customization templates for a model, the Code Mapping Editor presents `Default` as the only template option. To define a template, use the Embedded Coder Dictionary. You can open the dictionary by clicking  .

Before configuring default code generation settings for functions, consider these questions.

Consideration	See
What categories are relevant to your model?	"Configure Code Generation for Model Entry-Point Functions" on page 38-2
Do you have function naming requirements? If the answer is yes, what are they? To which categories do the requirements apply?	"Configure Code Generation for Model Entry-Point Functions" on page 38-2 and "Identifier Format Control" on page 50-24
Does the model use several instances of functions that are in a category? If the answer is yes, applying default mappings is beneficial. If the answer is no, consider configuring code generation for each function separately, as described in the cited topics.	"Customize Generated C Function Interfaces" on page 39-2 and "Customize Entry-Point Function Interfaces for Simulink Function and Function Caller Blocks" on page 39-24
Does your application require the code generator to store function code in a specific area of memory?	"Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 30-2 and "Control Data and Function Placement in Memory by Inserting Pragmas" on page 40-2
Do you need to define new function customization templates to include as options in the Code Mapping Editor?	"Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 30-2
What function customization template aligns with code generation requirements for each category?	"Define Function Customization Templates" on page 31-18 and **Embedded Coder Dictionary**

This example shows how to use the **Code Mapping Editor** to specify code generation requirements for model functions. The model uses multiple execution rates and is configured for single-instance usage. The code generator produces initialize, execution, and terminate entry-point functions. Because the model uses multiple rates, the code generator produces an execution function for each rate.

In this example, code generation requirements for entry-point functions:

- Store generated initialize and terminate functions in memory section `functionSlowMem` and execution functions in memory section `functionFastMem`.
- Use the naming rule `exSlow_$N` to name `initialize` and `terminate` entry-point functions. Use the naming rule `exFast_$N` to name execution functions.

To configure default code generation settings for the functions, use the **Embedded Coder Dictionary** and **Code Mapping Editor**.

Open Model

Open the copy of example model `rtwdemo_configdefaults` that you previously created.

Define Memory Sections

Define the two memory sections: `functionSlowMem` for initialize and terminate functions and `functionFastMem` for execution functions.

1. Open the Embedded Coder Dictionary by clicking **Code > C/C++ Code > Embedded Coder Dictionary**.
2. Click the **Memory Sections** tab.
3. Click **Add**.
4. In the new row at the bottom of the table, name the new memory section `functionFastMem`. Then, set:
   - **Pre Statement** to `#pragma start FASTMEM`
   - **Post Statement** to `#pragma end FASTMEM`
5. Click **Add** again. Name the memory section `functionSlowMem`. Then, set:
   - **Pre Statement** to `#pragma start SLOWMEM`
   - **Post Statement** to `#pragma end SLOWMEM`

Define Function Customization Templates

To configure categories of functions, define function customization templates. Unless you define templates in the Embedded Coder Dictionary that are associated with a model, the only available template is `Default`. Based on the requirements, in the dictionary, define two function customization templates: one to specify the naming rule and memory section for initialize and terminate functions and one to specify the naming rule and memory section for execution functions.

1. In the Embedded Coder Dictionary, click the **Function Customization Templates** tab.
2. Click **Add**.

3. In the new row of the table, name the new template `exFastFunction`. Then, set:
   - **Function Name** to `exFast_$N`. This naming rule applies the prefix `exFast_` to the name that identifies the default code generator name of the function (for example, `initialize` or `step`).
   - **Memory Section** to `functionFastMem`. This mapping associates the memory section that you defined in step 2 with the new template.
4. Click **Add** again. Name the template `exSlowFunction`. Then, set:
   - **Function Name** to `exSlow_$N`.
   - **Memory Section** to `functionSlowMem`.

Configure Default Settings for Functions

1. To access the Code Mapping Editor, enable code perspective mode.
2. In the Code Mapping Editor, click the **Function Defaults** tab.
3. Configure the initialize and terminate entry-point functions. For category **Initialize/Terminate**, select template `exSlowFunction`.
4. Configure the execution entry-point functions. For category **Execution**, select template `exFastFunction`.

The default mappings for a model are stored as part of the model.

Generate and Verify Code

In the **Code** view:

- Open the file `rtwdemo_configdefaults.c`. Click in the **Search** field. A menu lists the generated entry-point functions:
  - `exSlow_initialize`
  - `exFast_step` (called periodically, every 0.5 seconds)
  - `exFast_step1` (called periodically, every 1 second)
  - `exFast_step2` (called periodically, every 1.5 seconds)
  - `exSlow_terminate`
- To gain access to the entry-point function code in `rtwdemo_configdefaults.c`, clidk the function name. Verify the `pragma` control statements that surround the function code. For example:

```
.
.
.
#pragma start FASTMEM

void exFast_step2(void)                /* Sample time: [1.5s, 0.0s] */
{
   DWork.RateTransition1_Buffer0 = ((ex_input1 > 10.0) || (ex_input1 < -10.0));
}

#pragma end FASTMEM

#pragma start SLOWMEM

void exSlow_initialize(void)
{
   /* (no initialization code required) */
}

#pragma end SLOWMEM
.
.
.
```

- Open the file `rtwdemo_configdefaults.h`. Search for the `pragma` control statements. Verify the `pragma` control statements surround the declarations. For example:

```
.
.
.
#pragma start SLOWMEM
extern void exSlow_initialize(void);
#pragma end SLOWMEM

#pragma start FASTMEM
extern void exFast_step0(void);
#pragma end FASTMEM
.
.
.
```

Configure Default Data and Function Code Generation with Definitions Stored in Shared Data Dictionary

You have the option of configuring default data and function code generation with definitions that are set up in a Simulink data dictionary. A data dictionary enables sharing of code definitions between models. Using definitions in a data dictionary, configure default mappings:

1. If not already defined, define code definitions (storage classes, function customization templates, and memory sections) in a data dictionary. For this example, use definitions defined in the existing data dictionary `exSharedCodeDefs.sldd`. See “Share Code Generation Definitions Between Multiple Models and Users” on page 30-7.
2. Link the model to the data dictionary.
3. Map data and function default categories to code definitions in the dictionary.

This example shows how to link model `model rtwdemo_configdefaults` to data dictionary `exSharedCodeDefs.sldd`. That data dictionary includes Embedded Coder Dictionary definitions for:

- Memory section `internalDataMem` with **Pre Statement** set to `#pragma start INTERNALDATA` and **Post Statement** set to `#pragma end INTERNALDATA`.
- Memory section `functionFastMem` with **Pre Statement** set to `#pragma start FASTMEM` and **Post Statement** set to `#pragma end FASTMEM`.
- Memory section `functionSlowMem` with **Pre Statement** set to `#pragma start SLOWMEM` and **Post Statement** set to `#pragma end SLOWMEM`.
- Function customization template `exFastFunction` with function naming rule `exFast_$N` and memory section `functionFastMem`
- Function customization template `exSlowFunction` with function naming rule `exSlow_$N` and memory section `functionSlowMem`

Then, use the Code Mapping Editor to map data and function categories to code definitions in the data dictionary.

Link Model to Data Dictionary

1. Open model `rtwdemo_configdefaults`.
2. In the model window, select **File** > **Model Properties** > **Link to Data Dictionary**.
3. In the Model Properties dialog box, click **Browse**.
4. Open the dictionary `exSharedCodeDefs.sldd` through the Open Data Dictionary dialog box.
5. In the Model Properties dialog box, click **Apply**. The Link Model to Data Dictionary dialog box appears.
6. Click **Migrate data**.
7. In Migrate Data dialog box, click **Migrate**.

8. Click **OK**.
9. In the lower-left corner of the model, click the data dictionary badge. The dictionary opens in Model Explorer.
10. In the **Model Hierarchy** pane, under `exSharedCodeDefs`, select `Embedded Coder Dictionary`.
11. In the **Dialog** pane, click **Open Embedded Coder Dictionary**.
12. Verify that the dictionary includes the required code definitions.

Configure Default Categories for Code Generation

1. In the Simulink Editor, enable code perspective mode.
2. In the Code Mapping Editor, in the **Data Defaults** tab, select category **Internal data**.
3. In the Property Inspector, set **Memory Section** to `internalDataMem`.
4. In the **Function Defaults** tab, for the **Initialize/Terminate** category, select the function customization template `exSlowFunction`. For the **Execution** category, select template `exFastFunction`.
5. Save the model.
6. Generate and review code.

For more information about setting up an Embedded Coder Dictionary, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2.

Map Categories of Data and Functions to Shared Coder Dictionary Defaults

If you link a model to a Simulink data dictionary, which includes a coder dictionary that configures default code definitions for categories of data and functions, you can use the Code Mapping Editor to apply the dictionary defaults. In the Code Mapping Editor, on the **Data Defaults** or **Function Defaults** tab, select a category and set the storage class or function customization template to `Dictionary Default`. If someone makes a change to the default settings in the shared coder dictionary, the code generator applies the updated default settings when producing code for your model.

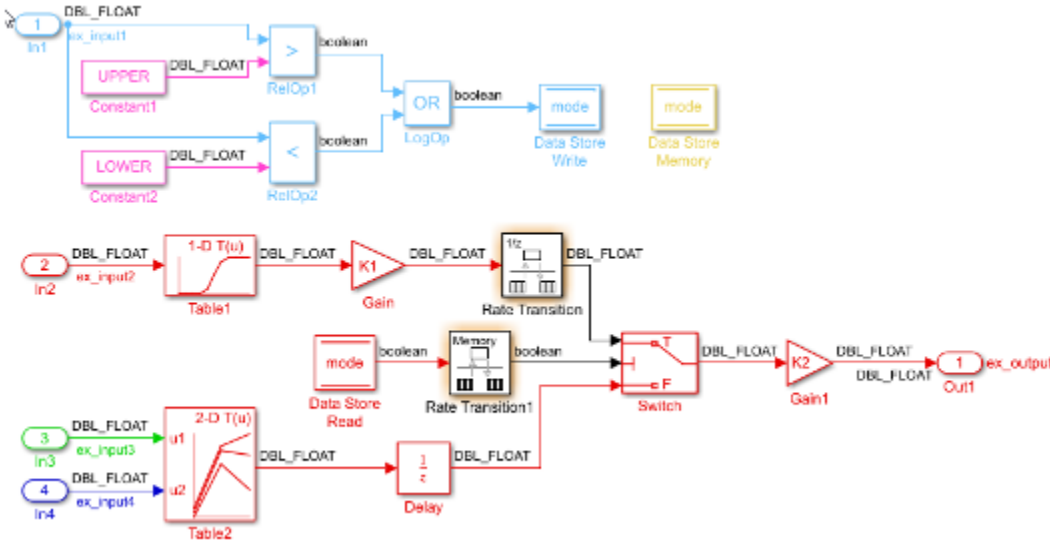
For more information, see “Configure Default Code Mapping in a Shared Dictionary” on page 30-8.

Configure Default Data and Function Code Generation Programmatically

This example shows how to configure default data and function code generation for example model `rtwdemo_configdefaults`.The example uses the default mapping programming interface to specify code generation requirements for model data and functions. Use that interface to automate the configuration, or if you prefer to configure models programmatically. For information about configuring the default data and function code generation by using the Code Mapping Editor, see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7.

Open the Model

The model `rtwdemo_configdefaults` uses multiple execution rates and is configured for single-instance usage.



```
open_system('rtwdemo_configdefaults')
```

Code Generation Requirements

For this example, the code generation requirements:

- Import project type definition for data of type `double`, DBL_FLOAT, from header file `exDblFloat.h`.
- Import signal `ex_input1` for computing a value stored in memory and used in an if-else condition in the Switch block. Import the signal data from header file`exInDataMem.h`.
- Import signals `ex_input2`, `ex_input3`, and `ex_input4` for lookup tables `Table1` and `Table2`. Import the signal data from header file `exInDataLut.h`.
- Data imported into the model from header files `exInDataMem.h` and `exInDataLut.h` is of type `DBL_FLOAT`, a project standard.
- Parameters `UPPER`, `LOWER`, `K1`, and `K2` are parameter objects stored in the model workspace. `K1` must be tunable to enable calibration.
- Data store `mode` defines data that is shared within the model.
- Data element `X` represents the delay for the Unit Delay block.
- Store data that is internal to the model in memory section `internalDataMem`.
- Store generated initialize and terminate functions in memory section `functionSlowMem` and execution functions in memory section `functionFastMem`.
- Use the identifier naming rule `exSlow_$N` to name `initialize` and `terminate` entry-point functions. Use the naming rule `exFast_$N` to name execution functions.
- Export output data declarations to header file `exSysOut.h` and definitions to `exSysOut.c`.

For this example someone, such as a system architect, has previously created these code definitions in an Embedded Coder Dictionary that is part of Simulink data dictionary `ex_configdefault.sldd`:

- Memory sections `internalDataMem`, `functionFastMem`, and `functionSlowMem`.
- Function customization templates `exFastFunction` and `exSlowFunction`.

Create Environment for Configuring Code Generation for Data and Functions

Create an environment for configuring code generation for data and functions associated with model `rtwdemo_configdefaults` by calling the function `coder.mapping.create`. You can skip this step if you previously opened the model in Code Perspective mode.

```
coder.mapping.create('rtwdemo_condigdefaults');
```

Identify Category, Property, and Value Combinations To Set As Data Defaults

Align the code generation requirements for data with available data categories. Each category has a set of properties that you can configure. Each property has a set of possible values. Use calls to `coder.mapping.defaults.dataCategories`, `coder.mapping.defaults.allowedProperties`, and `coder.mapping.defaults.allowedValues` to review the list of names for categories, properties, and values of interest.

For this example, you need to configure default settings for inports, outports, and parameter objects stored in the model workspace. Get a list of the available data categories by calling `coder.mapping.defaults.dataCategories`.

```
coder.mapping.defaults.dataCategories()
```

```
ans = 1x9 cell array
  Columns 1 through 4

    {'Inports'}    {'Outports'}    {'GlobalParameters'}    {'LocalParameters'}

  Columns 5 through 7

    {'ParameterArgum...'}    {'SharedLocalDat...'}    {'GlobalDataStores'}

  Columns 8 through 9

    {'InternalData'}    {'Constants'}
```

For data categories `Inports`, `Outports`, `LocalParameters`, and `InternalData` identify the properties that you can set with calls to `coder.mapping.defaults.allowedProperties`.

```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'Inports')
```

```
ans = 2x1 cell array
    {'StorageClass'}
    {'HeaderFile'  }
```

```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'Outports')
```

```
ans = 4x1 cell array
    {'StorageClass'  }
```

```
    {'HeaderFile'    }
    {'DefinitionFile'}
    {'Owner'         }
```

```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'LocalParameters')
```

```
ans = 1x1 cell array
    {'StorageClass'}
```

```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'InternalData')
```

```
ans = 2x1 cell array
    {'StorageClass' }
    {'MemorySection'}
```

For data category and property combinations that you want to set, identify possible values with calls to `coder.mapping.defaults.allowedValues`. Based on requirements and the results of step b, specify:

- `StorageClass` with categories `Inports`, `Outports`, `LocalParameters`, and `InternalData`
- `MemorySection` with `InternalData`

You do not need to determine values for properties `HeaderFile` (for `Inports` and `Outports`) and `DefinitionFile` (`Outports`). The values that you set for those properties are known strings.

```
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'Inports', 'StorageClass
```

```
ans = 9x1 cell array
    {'Default'              }
    {'ExportedGlobal'       }
    {'ImportedExtern'       }
    {'ImportedExternPointer'}
    {'Volatile'             }
    {'ExportToFile'         }
    {'ImportFromFile'       }
    {'AutoScope'            }
    {'GetSet'               }
```

```
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'Outports', 'StorageClas
```

```
ans = 9x1 cell array
    {'Default'              }
    {'ExportedGlobal'       }
    {'ImportedExtern'       }
    {'ImportedExternPointer'}
    {'Volatile'             }
    {'ExportToFile'         }
    {'ImportFromFile'       }
    {'AutoScope'            }
    {'GetSet'               }
```

```
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'LocalParameters', 'Sto
```

```
ans = 14x1 cell array
    {'Default'              }
    {'ExportedGlobal'       }
    {'ImportedExtern'       }
    {'ImportedExternPointer'}
    {'Const'                }
    {'Volatile'             }
    {'ConstVolatile'        }
    {'Define'               }
    {'ImportedDefine'       }
    {'ExportToFile'         }
    {'ImportFromFile'       }
    {'FileScope'            }
    {'GetSet'               }
    {'CompilerFlag'         }
```

```
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'InternalData', 'Storage
```

```
ans = 10x1 cell array
    {'Default'              }
    {'ExportedGlobal'       }
    {'ImportedExtern'       }
    {'ImportedExternPointer'}
    {'Volatile'             }
    {'ExportToFile'         }
    {'ImportFromFile'       }
    {'FileScope'            }
    {'AutoScope'            }
    {'GetSet'               }
```

```
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'InternalData', 'MemoryS

ans = 5x1 cell array
    {'None'           }
    {'MemVolatile'    }
    {'functionFastMem'}
    {'functionSlowMem'}
    {'internalDataMem'}
```

Identify Category, Property, and Value Combinations To Set As Function Defaults

Align the code generation requirements for functions with available function categories. For this example, you need to configure default settings for initialize, execution, and terminate functions. Get a list of the available function categories by calling `coder.mapping.defaults.functionCategories`.

```
coder.mapping.defaults.functionCategories()

ans = 1x3 cell array
    {'InitializeTermi...'}    {'Execution'}    {'SharedUtility'}
```

The categories that apply are `InitializeTerminate` and `Execution`.

For function categories `InitializeTerminate` and `Execution`, identify the properties that you can set with calls to `coder.mapping.defaults.allowedProperties`.

```
coder.mapping.defaults.allowedProperties('rtwdemo_configdefaults', 'InitializeTerminate

ans = 1x1 cell array
    {'FunctionCustomizationTemplate'}
```

You get the same output for category `Execution`.

For function category and property combinations that you want to set, identify possible values with calls to `coder.mapping.defaults.allowedValues`. Based on requirements and the results of calling `coder.mapping.defaults.allowedProperties`, specify `FunctionCustomizationTemplate` with categories `InitializeTerminate` and `Execution`.

```
coder.mapping.defaults.allowedValues('rtwdemo_configdefaults', 'InitializeTerminate',.
'FunctionCustomizationTemplate')
```

```
ans = 3x1 cell array
    {'Default'       }
    {'exSlowFunction'}
    {'exFastFunction'}
```

The list of templates is the same for `InitializeTerminate` and `Execution`.

Set Relevant Category, Property, and Value Combinations

Set relevant category, property, and value combinations with calls to `coder.mapping.defaults.set`.

```
coder.mapping.defaults.set('rtwdemo_configdefaults', 'Inports',...
  'Storageclass', 'ImportFromFile',...
  'HeaderFile', 'exInDataLut.h');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'Outports',...
  'Storageclass', 'ExportToFile',...
  'HeaderFile', 'exSysOut.h',...
  'DefinitionFile', 'exSysOut.c');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'LocalParameters',...
  'Storageclass', 'ExportedGlobal');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'InternalData',...
  'MemorySection', 'internalDataMem');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'InitializeTerminate',...
  'FunctionCustomizationTemplate', 'exSlowFunction');

coder.mapping.defaults.set('rtwdemo_configdefaults', 'Execution',...
  'FunctionCustomizationTemplate', 'exFastFunction');
```

Verify Default Mappings

Verify default mappings with calls to `coder.mapping.defaults.get`.

```
coder.mapping.defaults.get('rtwdemo_configdefaults', 'Inports', 'StorageClass')

ans =
'ImportFromFile'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Inports', 'HeaderFile')
```

```
ans =
'exInDataLut.h'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'StorageClass')

ans =
'ExportToFile'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'HeaderFile')

ans =
'exSysOut.h'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Outports', 'DefinitionFile')

ans =
'exSysOut.c'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'LocalParameters',...
    'StorageClass')

ans =
'ExportedGlobal'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'InternalData',...
    'MemorySection')

ans =
'internalDataMem'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'InitializeTerminate',...
    'FunctionCustomizationTemplate')

ans =
'exSlowFunction'

coder.mapping.defaults.get('rtwdemo_configdefaults', 'Execution',...
    'FunctionCustomizationTemplate')

ans =
'exFastFunction'
```

Override Header File Setting

Override the header file setting for input signal `ex_input1`. Previously, you set the default header file for data in the `Inports` category to `exInDataLut.h`. The

requirements specify that you import data for that signal from header file `exInDataMem.h`.

Create a handle to the output port of block In1.

```
portHandles = get_param('rtwdemo_configdefaults/In1', 'PortHandles');
outH = portHandles.Outport;
```

In the base workspace, create a temporary signal object.

```
temp_Obj = Simulink.Signal
```

```
temp_Obj =
  Signal with properties:

         CoderInfo: [1x1 Simulink.CoderInfo]
       Description: ''
          DataType: 'auto'
               Min: []
               Max: []
              Unit: ''
        Dimensions: -1
    DimensionsMode: 'auto'
        Complexity: 'auto'
        SampleTime: -1
      InitialValue: ''
```

In the nested `Simulink.CoderInfo` object, set the `StorageClass` property to `Custom`. Then, use the `CustomStorageClass` property to specify the storage class `ImportFromFile`.

```
temp_Obj.CoderInfo.StorageClass = 'Custom';
temp_Obj.CoderInfo.CustomStorageClass = 'ImportFromFile';
```

Define the instance-specific header file, `exDataInMem.h`, in the nested `Simulink.CoderInfo` object by using the `CustomAttributes` property.

```
temp_Obj.CoderInfo.CustomAttributes.HeaderFile='exInDataMem.h';
```

Embed the signal object in the target signal line by attaching a copy of the temporary workspace object.

```
set_param(outH, 'SignalObject', temp_Obj);
```

Clear the object from the base workspace. The signal now uses an embedded copy of the object.

```
clear temp_Obj
```

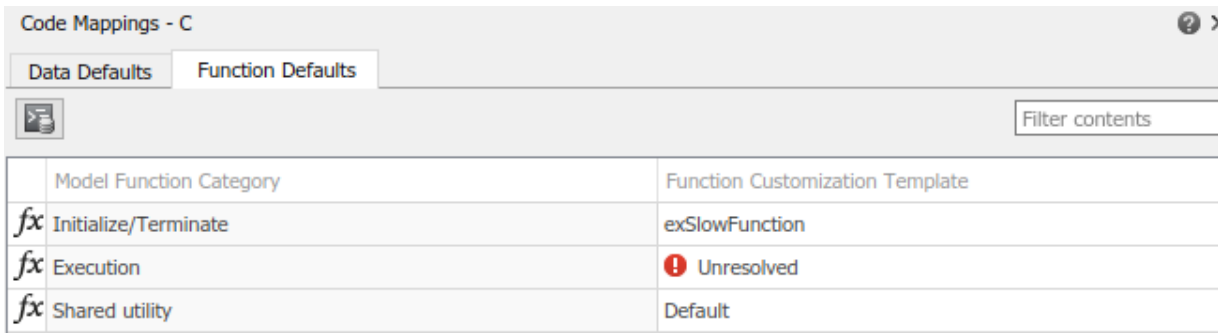
Unresolved Storage Classes, Function Customization Templates, and Memory Sections

If someone removes the definition for a storage class, function customization template, or memory section from the Embedded Coder Dictionary associated with a model, the **Code Mapping Editor** identifies the definition as `Unresolved`. For example, this figure shows that the function customization template for execution entry-point functions was removed from the dictionary associated with the model.



To fix the unresolved code definition, do one of the following:

- Select a different definition in the **Storage Classes**, **Function Customization Templates**, or **Memory Sections** column.
- Replace or add a definition to the Embedded Coder Dictionary. Then, update the mapping.
- Consult with someone else, such as the system architect for your project, about adding a definition to the Embedded Coder Dictionary. Then, update the mapping.

Elimination of Parameters and Other Internal Data by Optimizations

Code generation optimizations can eliminate data from the code, which means your application code cannot interact with the data. For general information about data elimination by optimizations, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50.

The optimizations can eliminate data in these categories:

- **Global parameters**
- **Local parameters**
- **Internal data**

The optimizations cannot eliminate:

- Data in other categories.
- Data that the code needs for numeric accuracy, including most block states, which are in the **Internal data** category.

After eliminating data with optimizations, the code generator applies the default code generation settings in the Code Mapping Editor to the remaining data. For parameters and signal lines, optimizations can eliminate data for an entire category. If this happens, default settings that you specify for that category do not apply to data.

To prevent optimizations from eliminating individual data elements, explicitly apply a storage class to the element by using the Model Data Editor. The storage class controls the appearance of the data in the generated code. To force a data element to use the default storage class that you specify in the Code Mapping Editor, explicitly apply the storage class `Model default`. See “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69.

Limitations

- For a referenced model, map data element categories **Inports** and **Outports** to `Default`, a built-in storage class, or a package storage class. You cannot map these data element categories to `ParamStruct` or `SignalStruct`, which are example storage classes that the Quick Start tool creates.
- For these categories, use the example storage class `SignalStruct` or create your own structured storage class in an Embedded Coder Dictionary.

  - **Inport**
  - **Outport**
  - **Internal data**
- For these categories, set up default mappings to a storage class defined with property **const** selected or property **Data Initialization** set to `Dynamic` or `None`:
  - **Inports**
  - **Outports**
  - Data store categories
  - **Internal data**
- Map parameter categories to storage classes defined with the **Data Initialization** property set to `Static` or `None`.
- Map categories **Inport**, **Outport**, and **Internal data**, where at least one data element in the category is specified with symbolic dimensions (see “Define Variable-Size Data for Code Generation” (Simulink)), to a storage class defined with the **Data Scope** property set to `Imported`.
- Map data element categories **Global parameters** and **Global data stores** to `Default`, a built-in storage class, or a package storage class. You cannot map these data element categories to example storage classes that the Quick Start tool creates, `ParamStruct` and `SignalStruct`.
- If a model includes a reusable subsystem (subsystem with block parameter **Function packaging** set to `Reusable function`) that contains a shared local data store, map the category **Shared local data stores** to a storage class that is defined in the Embedded Coder Dictionary for that model. For more information, see “Generate Reentrant Code from Subsystems” on page 6-43.
- For top and referenced models configured for multi-instance usage (see “Generate Reentrant Code from Top Models” on page 6-25 and “Generate Reentrant Code from Simulink Function Blocks” on page 6-31), map data element categories to storage classes that have the **Storage Type** property set to **Structured**.
- If a model uses data object alignment, do not configure default data mappings for the model. For more information, see `Simulink.CoderInfo`.
- If you configure a model with a code replacement library that includes a data alignment specification, you cannot configure default code mappings that involve storage classes defined in an Embedded Coder Dictionary. For more information, see “Data Alignment for Code Replacement” on page 65-137.

- When evaluating storage class settings for variant control variables, the code generator ignores default mappings. For more information, see “Represent Subsystem and Variant Models in Generated Code” on page 25-23.
- Default mappings for global data categories must be the same across model reference hierarchies.
- You cannot set up default mappings to:
  - Structure-based built-in storage classes, `Struct` and `BitField`
  - Package storage classes of type `FlatStructure` or `Other` (requires you to write TLC code) , which you create with the Custom Storage Class Designer

  .
- When a model is configured for compact file packaging, you cannot map a data element category to a storage class defined with the **Data Scope** property set to `Exported` and the **Header File** property set to a naming rule other than `$N.h`.
- Storage classes defined in an Embedded Coder Dictionary are not compatible with models that contain nonreusable subsystems with separate data or are configured to generate a C++ class interface.
- If a model contains a tunable, nonfinite parameter (for example, with a value of `inf`):
  - If you specify the nonfinite value directly in the model, without using a MATLAB variable or parameter object (such as `Simulink.Parameter`), in the generated code, the parameter appears as a field of the default parameter data structure (see “Standard Data Structures in the Generated Code” on page 32-26). The parameter does not use the storage class that you specify for the corresponding category of parameter data in the Code Mapping Editor.
  - If you store the nonfinite value in a variable or parameter object, for the corresponding category of parameter data in the Code Mapping Editor, you cannot use a storage class that you create in an Embedded Coder Dictionary. When you try to generate code, the model generates an error. Choose one of these workarounds:
    - Apply a storage class other than `Auto` or `Model default` directly to the nonfinite parameter as described in “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.
    - If only one block uses the variable or object, instead of using the variable or object, specify the nonfinite value directly in the model, in the block parameter.

Dimension Preservation of Multidimensional Arrays

Dimension Preservation in Generated Code

The code generator generates one-dimensional arrays in the C/C++ code for multidimensional model data. For example, consider matrix `matrixParam`.

```
matrixParam =
        1        2        3
        4        5        6
```

By default, MATLAB stores data in column-major format. The code generator defines matrix `matrixParam` in the generated code as:

```
/* const_params.c */
matrixParam[6] = {1, 4, 2, 5, 3, 6};
```

The code generator initializes matrix `matrixParam` in the generated code as:

```
/* model.c */
extern const real_T matrixParam[6];

for(int i = 0; i < 6; i++) {
    ... = matrixParamValue[i];
}
```

When you set the model configuration parameter **Array layout** (Simulink Coder) to `Row-major`, you can preserve dimensions of multidimensional arrays in the generated code. Preserving array dimensions in generated code enhances integration with external code.

For example, in row-major array layout, the code generator preserves the array dimensions in type definition in the generated code as:

```
/* const_params.c */
const real_T matrixParam[2][3] = {{1, 2, 3}, {4, 5, 6}};
```

The code for initializing the multidimensional data is nested as:

```
/* model.c */
extern const real_T matrixParam[2][3];

for(int i = 0; i < 2; i++) {
    for (int j = 0; j < 3; j++) {
```

```
            ... = matrixParam[i][j];
        }
    }
```

Difference in Dimension Preservation Between MATLAB and C

When you define a multidimensional array in the MATLAB Command Window, MATLAB stores the array in column-major format. For example:

```
>> matrixParam.Value = [1 2 3; 4 5 6];  % Data inilitialized in row-major

>> matrixParam.Value                    % Data displayed in row-major
ans =
     1     2     3
     4     5     6

>> matrixParam.Value(:)'                % Data stored in column-major
ans =
     1     4     2     5     3     6
```

Even if the data is initialized in row-major format in the MATLAB Command Window, MATLAB serializes data in memory in column-major format.

When Embedded Coder preserves dimensions, the generated code is:

```
real_T matrixParam[2][3] = { { 1.0, 2.0, 3.0 }, { 4.0, 5.0, 6.0 } } ;
```

For 2-D arrays, the index order and data definition are consistent with what you see in the MATLAB Command Window and the generated code.

For n-D arrays, when Embedded Coder generates row-major code and preserves array dimensions, the index order is consistent with MATLAB. The data definition of n-D arrays in the generated code is not consistent with the data displayed in the MATLAB Command Window. For example, consider that `matrixParam` is a `Simulink.Parameter`:

```
>> matrixParam.Value = reshape(1:24,[4 3 2])

>> matrixParam.Value
ans(:,:,1) =
     1     5     9
     2     6    10
     3     7    11
     4     8    12
ans(:,:,2) =
    13    17    21
    14    18    22
    15    19    23
    16    20    24

>> matrixParam.Value(:)'
ans =
```

```
  Columns 1 through 10

     1     2     3     4     5     6     7     8     9    10

  Columns 11 through 20

    11    12    13    14    15    16    17    18    19    20

  Columns 21 through 24

    21    22    23    24
```

In row-major array layout, the code generator preserves the array dimensions during type definition in the generated code as:

```
/* const_params.c */
const real_T matrixParam[4][3][2] = { { { 1.0, 13.0 }, { 5.0, 17.0 }, { 9.0, 21.0 } },
  { { 2.0, 14.0 }, { 6.0, 18.0 }, { 10.0, 22.0 } }, { { 3.0, 15.0 }, { 7.0, 19.0
    }, { 11.0, 23.0 } }, { { 4.0, 16.0 }, { 8.0, 20.0 }, { 12.0, 24.0 } } };
```

The code for initializing the multidimensional data is nested as:

```
/* model.c */
extern const real_T matrixParam[4][3][2];

for (i = 0; i < 3; i++) {
    for (i_1 = 0; i_1 < 4; i_1++) {
      for (i_0 = 0; i_0 < 2; i_0++) {
        ... = ... + matrixParam[i_1][i][i_0];
      }
    }
  }
```

Related Examples

- “Preserve Dimensions of Multidimensional Arrays in Generated Code” on page 31-40
- “Code Generation of Matrices and Arrays” on page 47-80
- “Select Array Layout for Matrices in Generated Code” (Stateflow)

Preserve Dimensions of Multidimensional Arrays in Generated Code

By default, the generated code contains one-dimensional arrays for multidimensional model data. In the Configuration Parameters dialog box, if you set **Array layout** (Simulink Coder) parameter to `Row-major`, you can preserve dimensions of multidimensional arrays in the generated code. Preserving array dimensions in the generated code enhances integration with external code.

MATLAB and C organizes multidimensional data in different ways. For more details, see “Dimension Preservation of Multidimensional Arrays” on page 31-37.

Preserve Dimensions for Custom Storage Classes

You can preserve dimensions of root-level inports and outports, parameters, and lookup tables in the generated code for these custom storage classes:

- `Const`
- `Volatile`
- `ConstVolatile`
- `ExportToFile`
- `ImportFromFile`
- `FileScope`

Select the **Preserve array dimensions** property when you select one of the preceding custom storage classes for these objects:

- `Simulink.Signal` object associated with a root-level Inport/Outport
- `Simulink.Parameter`
- `Simulink.LookupTable`

Preserve Dimensions for New Custom Storage Classes

To preserve dimensions when you design your own custom storage class, in the Embedded Coder Dictionary, select the **Preserve array dimensions** option in the Property Inspector. Selecting this property preserves dimensions for all instances of your

custom storage class. To change the default behavior for an instance of your custom storage class, use the Model Data Editor.

To preserve dimensions when you design your own custom storage class, use the new **Preserve array dimensions** property in the Custom Storage Class Designer. **Preserve array dimensions** has these options:

- `No`(default) — Flattens the multidimensional array to one dimension in the generated code.
- `Yes` — Preserves array dimensions for all parameters of the specified custom storage class.
- `Instance Specific` — If you want to preserve array dimensions for each instance of the custom storage class, enable the **Preserve array dimensions** property on the parameter object. For the Simulink package, this property setting is `Instance Specific` by default.

Preserve Dimensions for Stateflow Local Data

To preserve dimensions of Stateflow local data in the generated code, in the Configuration Parameters dialog box, select the **Preserve Stateflow local data array dimensions** (Simulink Coder) parameter.

You can preserve dimensions for all built-in storage classes and these custom storage classes:

- `Volatile`
- `ExportToFile`
- `ImportFromFile`
- `FileScope`
- `Localizable`

If a `Simulink.Signal` object is associated as local data with a Stateflow chart in the model, you can preserve dimensions of the `Simulink.Signal` object for all built-in storage classes and the preceding custom storage classes.

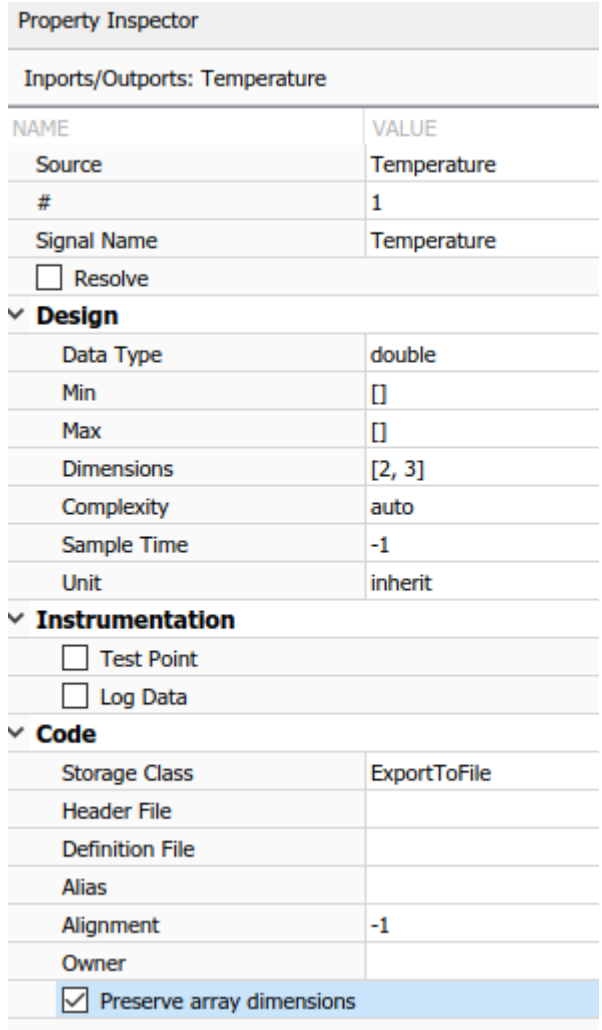
Preserve Dimensions of Root-Level Inports/Outports

1 Open the example model `rtwdemo_preservedimensions`.

2. In the Configuration Parameters dialog box, on the **Code Generation** > **Interface** pane, verify that **Array layout** (Simulink Coder) is set to `Row-major`.
3. Open the model in the Simulink Editor code perspective. Select **Code** > **C/C++ Code** > **Configure Model in Code Perspective**.
4. In the Model Data Editor, click the **Show/refresh additional information** button.

Preserve dimensions for root-level inports and outports by configuring the storage class for each block or by configuring the default settings.

1. In the Model Data Editor, select the **Inports/Outports** tab.
2. Set the **Change view** drop-down list to `Code`.
3. Select the source `Temperature` and set the **Storage Class** to `ExportToFile`.
4. In the Property Inspector, under the **Code** menu, select the **Preserve array dimensions** property.



5 Build the model and generate the code. The generated code preserves the dimensions.

```
real_T Temperature[2][3];
```

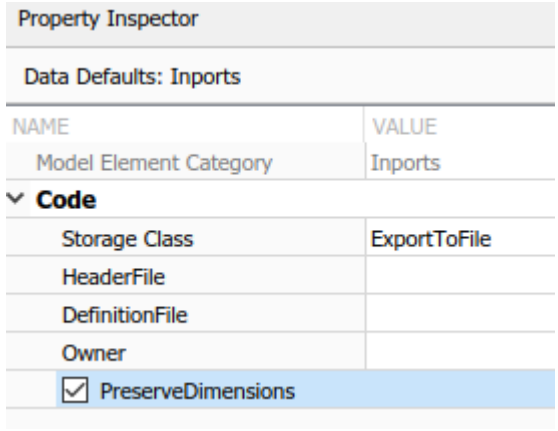
6 In the Model Data Editor, select these sources and update their **Storage Class**:

- `Pressure` to `Model default`

- `Target Volume` to `Auto`

7 In the Code Mappings editor, select the **Data Defaults** tab.

Select Inports in the Model Element Category. The **Storage Class** specified is `ExportToFile`. In the Property Inspector, under the **Code** menu, select the **PreserveDimensions** property.



When the **Storage Class** is either `Auto` or `Model default`, the settings in **Code Mappings > Data Defaults** are applied.

8 Build the model and generate the code. The generated code preserves the dimensions.

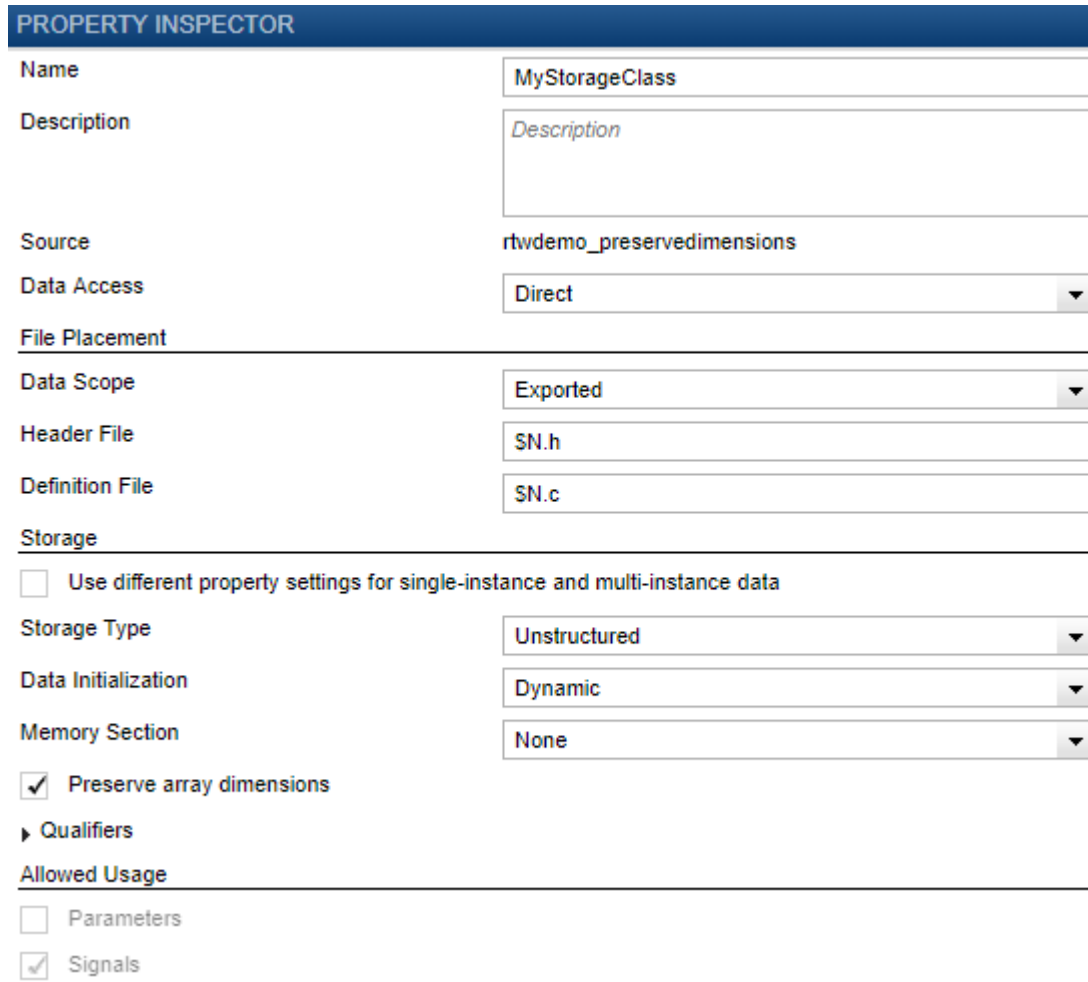
```
real_T Pressure[2][3];
...
real_T rtTargetVolume[2][3];
```

If a root-level inport and outport resolve to a `Simulink.Signal` object, you can preserve dimensions of the `Simulink.Signal` object.

When you create your own custom storage classes in the Embedded Coder Dictionary, you can select the **Preserve array dimensions** property.

1 Open Embedded Coder Dictionary. Select **Code > C/C++ Code > Embedded Coder Dictionary**.
2 To add a storage class, click the **Add** button.
3 In the Property Inspector, specify:

- **Name**: `MyStorageClass`
- Select **Preserve array dimensions** property.



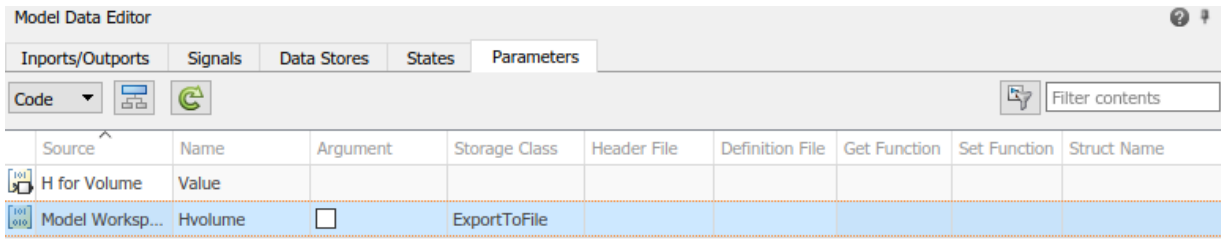
4 In the Code Mappings editor, select the **Data Defaults** tab.
5 Select Outports in the Model Element Category. Specify the **Storage Class** as `MyStorageClass`.
6 Build the model and generate the code. The generated code preserves the dimensions.

```
/* Storage class 'MyStorageClass' */
real_T rtVolume[2][3];
real_T rtActuatorCommand[2][3];
```

In **Code Mappings > Data Defaults**, you can preserve dimensions of **Global parameters** and **Local parameters** for supported custom storage classes.

Preserve Dimensions of Parameters, Lookup Tables, and Stateflow Local Data

1. Open the example model `rtwdemo_preservedimensions`.
2. Open the model in the Simulink Editor code perspective. Select **Code > C/C++ Code > Configure Model in Code Perspective**.
3. In the Model Data Editor, click the **Show/refresh additional information** button.
4. Select the **Parameters** tab and set the **Change view** drop-down list to `Code`.
5. Select the model workspace variable `Hvolume`. Make sure that the **Storage class** specified is supported to preserve dimensions and that the **Preserve array dimensions** property in the Property Inspector is selected. In this case, the **Storage class** is set to `ExportToFile`.



When you build the model, the generated code is:

```
/* Definition for custom storage class: ExportToFile */
real_T Hvolume[2][3] = { { 1.01, 0.98, 1.0 }, { 1.03, 0.99, 1.02 } } ;
```

6. Open the subsystem TP to Volume. The subsystem contains a Lookup Table.
7. In the Model Data Editor, select the **Parameters** tab. Make sure that the **Preserve array dimensions** property is selected for variable `tp2Lut`.

When you build the model, the generated code in the header file is:

```
typedef struct {
  real_T BP1[11];
```

```
  real_T BP2[9];
  real_T Table[11][9];
} t2pLut;
```

8 In this model, the Stateflow chart resolves the local data to the `Simulink.Signal` object. To preserve multidimensionality of Stateflow local data, on the **Configuration Parameters > Code Generation > Interface** pane, enable the **Preserve Stateflow local data array dimensions** (Simulink Coder) configuration parameter.

When you build the model, the generated code is:

```
/* Exported block states */
real_T LogSignal[11][9];              /* '<Root>/Log volume difference' */
```

Limitations

- Multidimensional arrays in Simulink buses are flattened in the generated code.
- You cannot preserve array dimensions for MPT parameter objects.
- The code generator does not preserve dimensions for signal objects when you:
  - Resolve Stateflow local data as the signal object.
  - Apply custom package to the signal object and rename the storage class that supports dimension preservation.
  - Select the configuration parameter **Preserve Stateflow local data array dimensions**.
  - Use the signal object for model elements except root-level inports or outports.

Configure Multi-Instance Code Generation

By default, for top models, the code generator produces code that is not reentrant. Entry-point functions have a `void-void` interface. Code communicates with other code by sharing access to global data structures that reside in shared memory.

For applications that can benefit from code reuse and require that each use or instance of the code maintains its own unique data, configure a model such that the code generator produces reentrant, multi-instantiable code. Multiple programs can use reentrant code simultaneously. When you configure a model for reentrancy, the execution (step) entry-point function uses root-level input and output arguments instead of global data structures.

Configure a Top Model for Multi-Instance Code Generation

Set model configuration parameter **Code interface packaging** to `Reusable function`.

Apply additional diagnostic and code generation control by setting these model configuration parameters:

- To select the severity level for diagnostic messages that the code generator displays when a model does not meet requirements for multi-instance code, set parameter **Multi-instance code error diagnostic** to `None`, `Warning`, or `Error`.
- To control how the generated code passes root-level model input and output to the reusable execution (step) function (requires Embedded Coder), set parameter **Pass root-level I/O as** to `Individual arguments`, `Structure reference`, or `Part of model data structure`.
- To reduce memory usage by omitting the error status field from the real-time model data structure (requires Embedded Coder), set parameter **Remove error status field in real-time model data structure** to `On`.
- To include a function in the generated file *`model`*`.c` that uses `malloc` to dynamically allocate memory for model data structures (requires Embedded Coder), set parameter **Use dynamic memory allocation for model initialization** to `On`.

For more information, see “Generate Reentrant Code from Top Models” on page 6-25.

Configure a Referenced Model for Multi-Instance Code Generation

Set model configuration parameter **Total number of instances allowed per top model** to `Multiple`. With this parameter setting, a model can be referenced more than once in a model hierarchy, if it contains not constructs that preclude multiple references. An error occurs if the model cannot be referenced multiple times, even if only one reference exists.

For more information, see “Generate Reentrant Code from Simulink Function Blocks” on page 6-31.

Configure Data Interfaces

Configure Default Code Generation for Data

1. In the Code Mapping Editor, click the **Data Defaults** tab.
2. In the **Data Defaults** table, select a row for a model data element category.
3. In the **Storage Class** column, select a storage class. If your model is linked to a Simulink data dictionary that includes a shared coder dictionary for which defaults are set up, you can select `Dictionary Default`. For help on choosing a storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69. For information on using dictionary defaults, see “Map Categories of Data and Functions to Shared Coder Dictionary Defaults” on page 31-22. If you need to define a new storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2.
4. In the Property Inspector, add values for unspecified properties. For example, if you select storage class `ImportFromFile`, specify a value for the property **HeaderFile**.
5. Save the model.

Override Default Data Interface for Individual Data Elements

1. Click the **Model Data Editor** tab.
2. In the Model Data Editor, with the view set to **Code**, click the tab for the type of data element for which you want to override the default configuration.
3. In the filter text box, enter a string that will help you find the row for that data element.
4. In the **Storage Class** column, select a storage class.
5. In the table or Property Inspector, set values for available properties.
6. Save the model.

Configure Entry-Point Function Interfaces

Define Function Customization Templates

Unless someone has defined function customization templates for a model, the Code Mappings editor presents `Default` as the only template option. To define a template, use the Embedded Coder Dictionary.

1. In the Code Mappings editor, click the Embedded Coder Dictionary button  .
2. In the Embedded Coder Dictionary, click the **Function Customization Templates** tab.
3. Click **Add**.
4. In the new row of the table, name the template.
5. As required by your function interface:

   - In the **Function Name** column, specify a default naming rule for entry-point functions.
   - In the **Memory Section** column, specify the name of an available memory section.

   The preview shows the results of your changes and additions.
6. Close the dictionary.

Configure Default Code Generation for Entry-Point Functions

1. Define a function customization template.
2. In the Code Mappings editor, click the **Function Defaults** tab.
3. In the **Function Defaults** table, select a row for a model function category.
4. In the **Function Customization Template** column, select a customization template. If your model is linked to a Simulink data dictionary that includes a shared coder dictionary for which defaults are set up, you can select `Dictionary Default`. For information on using dictionary defaults, see “Map Categories of Data and Functions to Shared Coder Dictionary Defaults” on page 31-22. If you need to define a new customization template, for more information, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2.

5 Save the model.

Override Default Code Generation for Entry-Point Functions

1 In the Code Mappings editor, click the **Entry-Point Functions** tab.

2 In the **Source** column, select an entry-point function that you want to override the default interface configuration.

3 As required by your function interface:

- Select a function customization template.
- Specify a unique function name.

4 If your entry-point function is an execution function, you can customize the interface arguments. By default, the code generator produces a `void-void` interface (without arguments) and assumes variables are global. To configure the interface to pass arguments, in the **Function Preview** column, click on the prototype hyperlink to open a configuration dialog box.

5 In the configuration dialog box, select **Configure arguments for [function name] function prototype**.

6 Click **Get Default**. A table opens to list the current argument settings.

7 In the table, you can change the type qualifiers, identifier names, and argument order as required by the function interface. Change the order of the arguments by dragging them to locations in the list. As you make changes, use the prototype preview near the top of the dialog box to verify the results.

8 Validate your changes and save the model.

Configure Internal Data

Configure Default Representation of Internal Data

1. In the Code Mapping Editor, click the **Data Defaults** tab.
2. Select the row representing the category of internal data that you want to configure.
3. In the **Storage Class** column, select a storage class. If your model is linked to a Simulink data dictionary that includes a shared coder dictionary for which defaults are set up, you can select `Dictionary Default`. For help on choosing a storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69. For information on using dictionary defaults, see “Map Categories of Data and Functions to Shared Coder Dictionary Defaults” on page 31-22. If you need to define a new storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2.
4. In the Property Inspector, add values for unspecified properties. For example, if you select storage class `Const`, specify values for properties **HeaderFile** and **DefinitionFile**.
5. Save the model.

Make Parameters Tunable

1. Click the **Model Data Editor** tab.
2. In the Model Data Editor, with the view set to **Code**, click the **Parameters** tab.
3. Update the model to include the latest model data by clicking the update model data  button.
4. In the filter text box, enter a string that will help you find the row for the parameter that you want to configure for tunability.
5. In the **Storage Class** column, select a storage class. For example, you might want to change the storage class setting for Model Workspace parameters to `Model default`.
6. In the table or Property Inspector, set values for available properties.
7. Save the model.

Configure Subsystem Function Interface

1. In the Simulink Editor, select the subsystem that you want to configure.
2. In the Property Inspector, expand **Code Generation**.
3. Set **Function packaging** to `Nonresuable function`, or `Reusable function`.
4. Configure the function name. Set **Function name options** to `Use subsystem name` or `User specified`. If you select `User specified`, specify a value for the **Function name** property.
5. If you set **Function packaging** to `Nonresuable function`, configure the function interface. Set **Function interface** to `void-void` or `Allow arguments`.
6. Save the model.

For more information, see “Control Generation of Functions for Subsystems” on page 3-2.

Data Representation in Simulink Coder

Configure Data Accessibility for Rapid Prototyping

As you iteratively develop a model, you capture the values of signals and states that model execution generates. You also tune parameter values during execution to observe results on the signals and states. You can then base your design decisions upon analysis of these outputs. To access signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

Depending on the system target file that you use (such as `grt.tlc`), by default, optimization settings can make the generated code more efficient by:

- Eliminating unnecessary global and local storage for signals and some states.

  However, the optimizations do not eliminate storage for root-level Inport and Outport blocks, which represent the primary inputs and outputs of a system. To access this data, you do not need to take optimizations into consideration.
- Inlining the numeric values of block parameters. The code does not store the parameters in memory, so you cannot interact with the parameters during code execution.

To generate code that instead allocates addressable memory for this data, you can disable the optimizations, or override the optimizations by specifying code generation settings for individual data items.

Access Signal, State, and Parameter Data During Execution

For an example that shows how to configure data accessibility for rapid prototyping, see “Access Signal, State, and Parameter Data During Execution” on page 32-7.

Configure Data Accessibility

Goal	Considerations and More Information
Configure signals as accessible and parameters as tunable by default	Clear the model configuration parameter **Signal storage reuse** and set the configuration parameter **Default parameter behavior** to `Tunable`. These settings prevent the elimination of storage for signals and prevent parameter inlining. Each block parameter and signal line appears in the generated code as a field of a structure. For more information about these data structures, see “How Generated Code Exchanges Data with an Environment” on page 32-33 and “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50. For more information about **Default parameter behavior**, see “Default parameter behavior” (Simulink Coder). For more information about optimizations that eliminate storage for signals, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50 and “Minimize Computations and Storage for Intermediate Results at Block Outputs” (Simulink Coder).
Preserve accessibility and tunability of a data item after you select optimizations	You can generate more efficient code by selecting optimizations such as **Signal storage reuse**, but the code generator eliminates storage for as many data items as possible. To exclude individual data items from the optimizations: • Configure a signal as a test point (see “Configure Signals as Test Points” (Simulink)) or apply a storage class such as `ExportedGlobal` to the signal (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81). If you use test points, when you later configure the model for efficient production code, you can subject the test-point signals to optimizations by selecting the model configuration parameter **Ignore test point signals**. Apply a storage class only when you need to control the representation of the signal in the code. • Apply a storage class, such as `ExportedGlobal`, to states and parameters. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.

Goal	Considerations and More Information
Represent a data item as a separate global variable in the generated code	When you disable optimizations, signal lines, block states, and parameters appear in the generated code as fields of structures. You cannot control the names of the structures without Embedded Coder. To instead store a data item in a separate global variable whose name, file placement, and other characteristics you can control, apply a storage class to a signal, state, or `Simulink.Parameter` object. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.
Generate a standardized C-code interface for accessing data	You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For more information, see “Exchange Data Between Generated and External Code Using C API” on page 57-2.
Tune parameters and monitor signals during external mode simulation	When you generate code and an external executable from a model, you can simulate the model in external mode to communicate with the running executable. You can tune parameters and monitor signals during the simulation. However, in this simulation mode, parameter tunability limitations that apply to code generation also apply to the simulation. For information about the code generation limitations, see “Limitations for Block Parameter Tunability in Generated Code” on page 32-135. For information about external mode, see “Host-Target Communication with External Mode Simulation” on page 55-2.
Tune parameters and monitor signals with Simulink Real-Time	If you have Simulink Real-Time, you can tune parameters and monitor signals during execution of your real-time application. Make signals accessible and parameters tunable by clearing optimizations and applying test points and storage classes. See “Parameter Tuning with Simulink Real-Time Explorer” (Simulink Real-Time).

Limitations

For information about limitations that apply to the tunability of parameters in the generated code, see “Limitations for Block Parameter Tunability in Generated Code” on page 32-135.

Access Signal, State, and Parameter Data During Execution

As you iteratively develop a model, you capture output signal and state data that model execution generates. You also tune parameter values during execution to observe results on the outputs. You can then base your design decisions upon analysis of these outputs. To access this signal, state, and parameter data in a rapid prototyping environment, you can configure the generated code to store the data in addressable memory.

By default, optimization settings make the generated code more efficient by eliminating unnecessary signal storage and inlining the numeric values of block parameters. To generate code that instead allocates addressable memory for this data, you can disable the optimizations or specify code generation settings for individual data items.

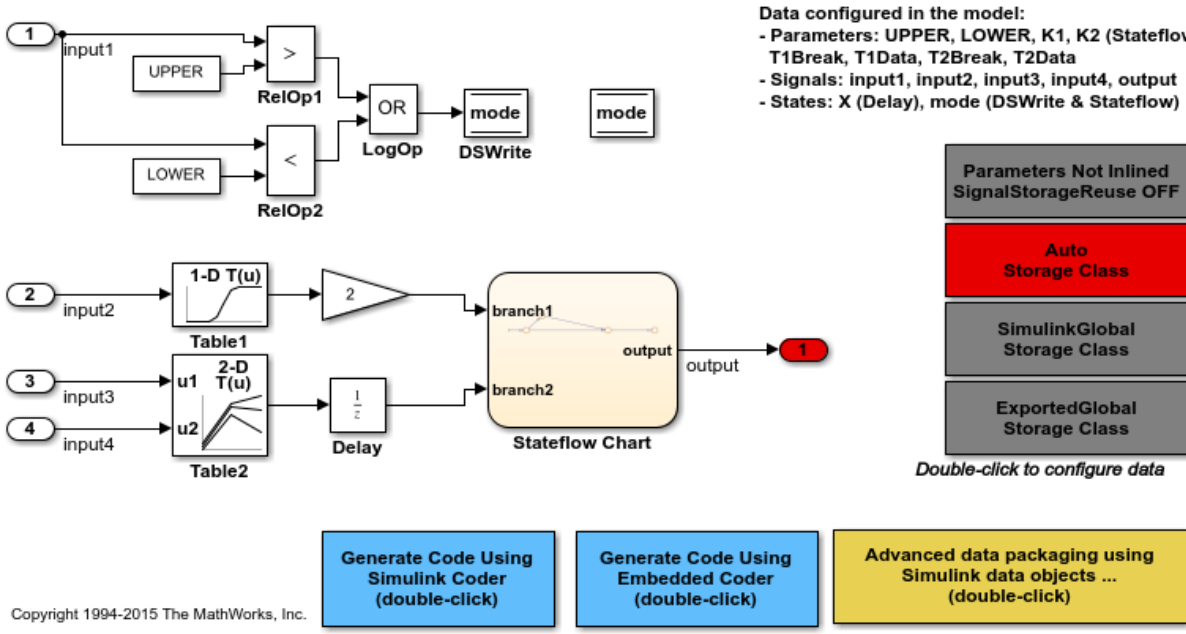
Explore Example Model

Run a script that prepares the model `rtwdemo_basicsc` for this example.

```
run(fullfile(matlabroot,'examples','simulinkcoder','main','prepare_rtwdemo_basicsc'));
```

Open the example model, `rtwdemo_basicsc`.

```
rtwdemo_basicsc
```



The model loads numeric MATLAB variables into the base workspace. The workspace variables set some block parameters in the model. However, The Gain block in the model uses the literal value 2.

Disable Optimizations

In the model, clear the model configuration parameter **Signal storage reuse**. When you clear this optimization and other optimizations such as **Eliminate superfluous local variables (expression folding)**, the generated code allocates memory for signal lines. Clearing **Signal storage reuse** disables most of the other optimizations.

```
set_param('rtwdemo_basicsc','OptimizeBlockIOStorage','off')
```

Set the optimization **Configuration Parameters > Optimization > Default parameter behavior** to `Tunable`. When set to `Tunable`, this configuration parameter causes the generated code to allocate memory for block parameters and workspace variables.

```
set_param('rtwdemo_basicsc','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')

### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc.h`. This header file defines a structure type that contains signal data. The structure contains fields that each represent a signal line in the model. For example, the output signal of the Gain block, whose name is `Gain`, appears as the field `Gain`.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* Block signals (default storage) */',...
    'B_rtwdemo_basicsc_T;',1,1)

/* Block signals (default storage) */
typedef struct {
  real32_T Table1;                     /* '<Root>/Table1' */
  real32_T Gain;                       /* '<Root>/Gain' */
  real32_T Delay;                      /* '<Root>/Delay' */
  real32_T Table2;                     /* '<Root>/Table2' */
  boolean_T RelOp1;                    /* '<Root>/RelOp1' */
  boolean_T RelOp2;                    /* '<Root>/RelOp2' */
  boolean_T LogOp;                     /* '<Root>/LogOp' */
} B_rtwdemo_basicsc_T;
```

The file defines a structure type that contains block parameter data. For example, the **Gain** parameter of the Gain block appears as the field `Gain_Gain`. The other fields of the structure represent other block parameters and workspace variables from the model, including initial conditions for signals and states.

```
rtwdemodbtype(file,'/* Parameters (default storage) */',...
    '/* Real-time Model Data Structure */',1,0)

/* Parameters (default storage) */
struct P_rtwdemo_basicsc_T_ {
  real_T K2;                           /* Variable: K2
                                        * Referenced by: '<Root>/Stateflow Chart'
                                        */
  real32_T LOWER;                      /* Variable: LOWER
                                        * Referenced by: '<Root>/Constant2'
                                        */
  real32_T T1Break[11];                /* Variable: T1Break
                                        * Referenced by: '<Root>/Table1'
```

```
                                       */
  real32_T T1Data[11];                /* Variable: T1Data
                                       * Referenced by: '<Root>/Table1'
                                       */
  real32_T T2Break[3];                /* Variable: T2Break
                                       * Referenced by: '<Root>/Table2'
                                       */
  real32_T T2Data[9];                 /* Variable: T2Data
                                       * Referenced by: '<Root>/Table2'
                                       */
  real32_T UPPER;                     /* Variable: UPPER
                                       * Referenced by: '<Root>/Constant1'
                                       */
  real32_T Gain_Gain;                 /* Computed Parameter: Gain_Gain
                                       * Referenced by: '<Root>/Gain'
                                       */
  real32_T Delay_InitialCondition; /* Computed Parameter: Delay_InitialCondition
                                    * Referenced by: '<Root>/Delay'
                                    */
  uint32_T Table2_maxIndex[2];        /* Computed Parameter: Table2_maxIndex
                                       * Referenced by: '<Root>/Table2'
                                       */
  boolean_T DataStoreMemory_InitialValue;
                              /* Computed Parameter: DataStoreMemory_InitialValue
                               * Referenced by: '<Root>/Data Store Memory'
                               */
};
```

View the file `rtwdemo_basicsc_data.c`. This source file allocates global memory for a parameter structure and initializes the field values based on the parameter values in the model.

View the source file `rtwdemo_basicsc.c`. The code allocates global memory for a structure variable that contains signal data.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Block signals (default storage) */',...
    'B_rtwdemo_basicsc_T rtwdemo_basicsc_B;',1,1)
```

```
/* Block signals (default storage) */
B_rtwdemo_basicsc_T rtwdemo_basicsc_B;
```

The code algorithm in the model `step` function calculates the signal values. It then assigns these values to the fields of the signal structure. To perform the calculations, the algorithm uses the parameter values from the fields of the parameter structure.

Exclude Data Items from Optimizations

When you want to select code generation optimizations such as **Signal storage reuse**, you can preserve individual data items from the optimizations. The generated code then allocates addressable memory for the items.

Select the optimizations that you previously cleared.

```
set_param('rtwdemo_basicsc','OptimizeBlockIOStorage','on')
set_param('rtwdemo_basicsc','LocalBlockOutputs','on')
set_param('rtwdemo_basicsc','DefaultParameterBehavior','Inlined')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Signals** tab.

Set the **Change view** drop-down list to `Instrumentation`.

In the model, select the output signal of the Gain block.

In the Model Data Editor, select the check box in the **Test Point** column.

```
portHandle = get_param('rtwdemo_basicsc/Gain','PortHandles');
portHandle = portHandle.Outport;
set_param(portHandle,'TestPoint','on')
```

Inspect the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the gain value to `K1`.

Next to `K1`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(2)` and click **Create**. A `Simulink.Parameter` object named `K1`, with value `2`, appears in the base workspace.

In the property dialog box for `K1`, apply a storage class other than `Auto` by using **Storage class**. For example, use the storage class `Model default` to represent the parameter object as a field of the global parameters structure.

```
set_param('rtwdemo_basicsc/Gain','Gain','K1');
K1 = Simulink.Parameter(2);
K1.StorageClass = 'Model default';
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the file `rtwdemo_basicsc.h`. The structure that contains signal data now defines only one field, `Gain`, which represents the test-pointed output of the Gain block.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.h');
rtwdemodbtype(file,'/* Block signals (default storage) */',...
    'B_rtwdemo_basicsc_T;',1,1)
```

```
/* Block signals (default storage) */
typedef struct {
  real32_T Gain;                       /* '<Root>/Gain' */
} B_rtwdemo_basicsc_T;
```

The structure that contains block parameter data defines one field, `K1`, which represents the parameter object `K1`.

```
rtwdemodbtype(file,'/* Parameters (default storage) */',...
    '/* Real-time Model Data Structure */',1,0)
```

```
/* Parameters (default storage) */
struct P_rtwdemo_basicsc_T_ {
  real32_T K1;                         /* Variable: K1
                                        * Referenced by: '<Root>/Gain'
                                        */
};
```

Access Data Through Generated Interfaces

You can configure the generated code to contain extra code and files so that you can access model data through standardized interfaces. For example, use the C API to log signal data and tune parameters during execution.

Copy this custom source code into a file named `ex_myHandCode.c` in your current folder.

```
#include "ex_myHandHdr.h"

#define paramIdx 0 /* Index of the target parameter,
determined by inspecting the array of structures generated by the C API. */
#define sigIdx 0 /* Index of the target signal,
determined by inspecting the array of structures generated by the C API. */

void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
    /* Take action with the parameter value only at
       the beginning of simulation and at the 5-second mark. */
    if (*tPtr == 0 || *tPtr == 5) {

        /* Local variables to store information extracted from
           the model mapping information (mmi). */
        void** dataAddrMap;
        const rtwCAPI_DataTypeMap *dataTypeMap;
        const rtwCAPI_ModelParameters *params;
        int_T addrIdx;
        uint16_T dTypeIdx;
        uint8_T slDataType;

        /* Use built-in C API macros to extract information. */
        dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
        dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
        params = rtwCAPI_GetModelParameters(mmi);
        addrIdx = rtwCAPI_GetModelParameterAddrIdx(params,paramIdx);
        dTypeIdx =  rtwCAPI_GetModelParameterDataTypeIdx(params,paramIdx);
        slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);

        /* Handle data types 'double' and 'int8'. */
        switch (slDataType) {

            case SS_DOUBLE: {
                real_T* dataAddress;
```

```
                dataAddress = dataAddrMap[addrIdx];
                /* At the 5-second mark, increment the parameter value by 1. */
                if (*tPtr == 5) {
                    (*dataAddress)++;
                }
                printf("Parameter value is %f\n", *dataAddress);
                break;
            }

            case SS_INT8: {
                int8_T* dataAddress;
                dataAddress = dataAddrMap[addrIdx];
                if (*tPtr == 5) {
                    (*dataAddress)++;
                }
                printf("Parameter value is %i\n", *dataAddress);
                break;
            }
        }
    }
}

void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr)
{
    /* Take action with the signal value only when
       the simulation time is an integer value. */
    if (*tPtr-(int_T)*tPtr == 0) {

        /* Local variables to store information extracted from
           the model mapping information (mmi). */
        void** dataAddrMap;
        const rtwCAPI_DataTypeMap *dataTypeMap;
        const rtwCAPI_Signals *sigs;
        int_T addrIdx;
        uint16_T dTypeIdx;
        uint8_T slDataType;

        /* Use built-in C API macros to extract information. */
        dataAddrMap = rtwCAPI_GetDataAddressMap(mmi);
        dataTypeMap = rtwCAPI_GetDataTypeMap(mmi);
        sigs = rtwCAPI_GetSignals(mmi);
        addrIdx = rtwCAPI_GetSignalAddrIdx(sigs,sigIdx);
        dTypeIdx =  rtwCAPI_GetSignalDataTypeIdx(sigs,sigIdx);
        slDataType = rtwCAPI_GetDataTypeSLId(dataTypeMap, dTypeIdx);
```

```
        /* Handle data types 'double' and 'single'. */
        switch (slDataType) {

            case SS_DOUBLE: {
                real_T* dataAddress;
                dataAddress = dataAddrMap[addrIdx];
                printf("Signal value is %f\n", *dataAddress);
                break;
            }

            case SS_SINGLE: {
                real32_T* dataAddress;
                dataAddress = dataAddrMap[addrIdx];
                printf("Signal value is %f\n", *dataAddress);
                break;
            }
        }
    }
}
```

Copy this custom header code into a file named `ex_myHandHdr.h` in your current folder.

```
#include <stdio.h>
#include <string.h>
#include <math.h>
/* Include rtw_modelmap.h for definitions of C API macros. */
#include "rtw_modelmap.h"
#include "builtin_typeid_types.h"
#include "rtwtypes.h"
void tuneFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
void logFcn(rtwCAPI_ModelMappingInfo *mmi, time_T *tPtr);
```

These files use the C API to access signal and parameter data in the code that you generate from the example model.

In the model, set **Configuration Parameters > Code Generation > Custom Code > Insert custom C code in generated > Header file** to `#include "ex_myHandHdr.h"`. In the same pane in the Configuration Parameters dialog box, set **Additional Build Information > Source files** to `ex_myHandCode.c`.

```
set_param('rtwdemo_basicsc','CustomHeaderCode','#include "ex_myHandHdr.h"')
set_param('rtwdemo_basicsc','CustomSource','ex_myHandCode.c')
```

Select **Configuration Parameters > MAT-file Logging**. The generated executable runs only until the simulation stop time (which you set in the model configuration parameters).

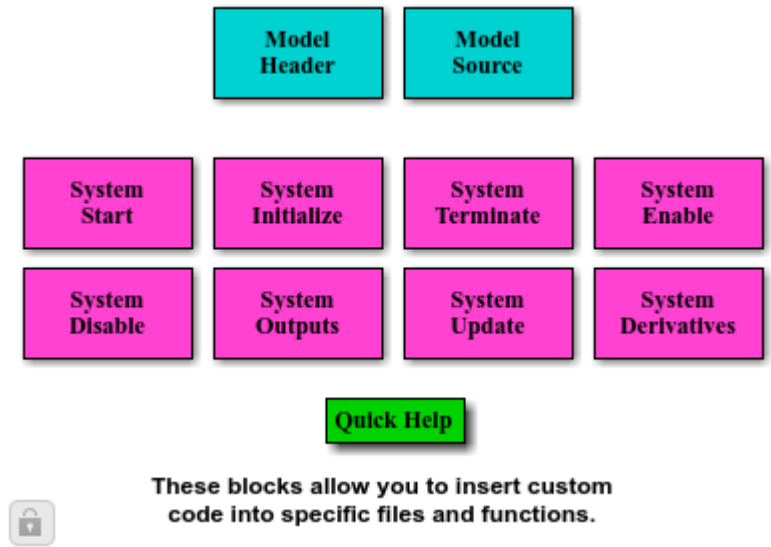
```
set_param('rtwdemo_basicsc','MatFileLogging','on')
```

Select the options under **Configuration Parameters > Code Generation > Interface > Generate C API for**.

```
set_param('rtwdemo_basicsc','RTWCAPIParams','on')
set_param('rtwdemo_basicsc','RTWCAPISignals','on')
set_param('rtwdemo_basicsc','RTWCAPIStates','on')
set_param('rtwdemo_basicsc','RTWCAPIRootIO','on')
```

Load the Custom Code block library.

```
custcode
```



Add a System Outputs block to the model.

```
add_block('custcode/System Outputs','rtwdemo_basicsc/System Outputs')
```

In the System Outputs block dialog box, set **System Outputs Function Execution Code** to this code:

```
{
rtwdemo_basicsc_U.input2++;
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

In the block dialog box, set **System Outputs Function Exit Code** to this code:

```
{
rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
logFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

Alternatively, to configure the System Outputs block, at the command prompt, use these commands:

```
temp.TLCFile = 'custcode';
temp.Location = 'System Outputs Function';
temp.Middle = sprintf(['{\nrtwdemo_basicsc_U.input2++;'...
    '\nrtwCAPI_ModelMappingInfo *MMI = '...
    '&(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);'...
    '\ntuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));\n}']);
temp.Bottom = sprintf(['{\nrtwCAPI_ModelMappingInfo *MMI = '...
    '&(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);'...
    '\nlogFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));\n}']);
set_param('rtwdemo_basicsc/System Outputs','RTWdata',temp)
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

In the code generation report, view the interface file `rtwdemo_basicsc_capi.c`. This file initializes the arrays of structures that you can use to interact with data items through the C API. For example, in the array of structures `rtBlockSignals`, the first structure (index 0) describes the test-pointed output signal of the Gain block in the model.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc_capi.c');
rtwdemodbtype(file,'/* Block output signal information */',...
    '/* Individual block tuning',1,0)
```

```
/* Block output signal information */
```

```
static const rtwCAPI_Signals rtBlockSignals[] = {
  /* addrMapIndex, sysNum, blockPath,
   * signalName, portNumber, dataTypeIndex, dimIndex, fxpIndex, sTimeIndex
   */
  { 0, 0, TARGET_STRING("rtwdemo_basicsc/Gain"),
    TARGET_STRING(""), 0, 0, 0, 0, 0 },

  {
    0, 0, (NULL), (NULL), 0, 0, 0, 0, 0
  }
};
```

The fields of the structure, such as `addrMapIndex`, indicate indices into other arrays of structures, such as `rtDataAddrMap`, that describe the characteristics of the signal. These characteristics include the address of the signal data (a pointer to the data), the numeric data type, and the dimensions of the signal.

In the file `rtwdemo_basicsc.c`, view the code algorithm in the model `step` function. The algorithm first executes the code that you specified in the System Outputs block.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* user code (Output function Body) */',...
    '/* Logic: ''<Root>/LogOp'' incorporates:',1,0)
```

```
  /* user code (Output function Body) */

  /* System '<Root>' */
  {
    rtwdemo_basicsc_U.input2++;
    rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
    tuneFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
  }

  /* DataStoreWrite: '<Root>/DSWrite' incorporates:
   *  Constant: '<Root>/Constant1'
   *  Constant: '<Root>/Constant2'
   *  Inport: '<Root>/In1'
   *  Logic: '<Root>/LogOp'
   *  RelationalOperator: '<Root>/RelOp1'
   *  RelationalOperator: '<Root>/RelOp2'
   */
  rtwdemo_basicsc_DW.mode = ((rtwdemo_basicsc_U.input1 > 10.0F) ||
    (rtwdemo_basicsc_U.input1 < -10.0F));
```

```
/* Gain: '<Root>/Gain' incorporates:
 *  Inport: '<Root>/In2'
 *  Lookup_n-D: '<Root>/Table1'
 */
rtwdemo_basicsc_B.Gain = rtwdemo_basicsc_P.K1 * look1_iflf_binlx
  (rtwdemo_basicsc_U.input2, rtCP_Table1_bp01Data, rtCP_Table1_tableData, 10U);

/* Chart: '<Root>/Stateflow Chart' */

    (&rtmGetErrorStatus(rtwdemo_basicsc_M)));

  /* Start for DataStoreMemory: '<Root>/Data Store Memory' */
  rtwdemo_basicsc_DW.mode = false;

  /* InitializeConditions for UnitDelay: '<Root>/Delay' */
  rtwdemo_basicsc_DW.X = 0.0F;
}

/* Model terminate function */
void rtwdemo_basicsc_terminate(void)
{
  /* (no terminate code required) */
}
```

This code first perturbs the input signal `input2` by incrementing the value of the signal each time the `step` function executes. The code then uses the built-in macro `rtmGetDataMapInfo` to extract model mapping information from the model data structure `rtwdemo_basicsc_M`. The pointer `MMI` points to the extracted mapping information, which allows the functions `tuneFcn` and `logFcn` to access the information contained in the arrays of structures that the C API file `rtwdemo_basicsc_capi.c` defines.

View the function `tuneFcn` in the file `ex_myHandCode.c`. This function uses the C API (through the model mapping information `mmi`) and a pointer to the simulation time to print the value of the parameter `K1` at specific times during code execution. When the simulation time reaches 5 seconds, the function changes the parameter value in memory. By using a `switch case` block, the function can access the parameter data whether the data type is `int8` or `double`.

View the code algorithm in the model `step` function again. Near the end of the function, the algorithm executes the code that you specified in the System Outputs block. This code calls the function `logFcn`.

```
rtwdemodbtype(file,'/* user code (Output function Trailer) */',...
    '/* Matfile logging */',1,0)
```

```
  /* user code (Output function Trailer) */
```

```
/* System '<Root>' */
{
  rtwCAPI_ModelMappingInfo *MMI = &(rtmGetDataMapInfo(rtwdemo_basicsc_M).mmi);
  logFcn(MMI, rtmGetTPtr(rtwdemo_basicsc_M));
}
```

View the function `logFcn` in the file `ex_myHandCode.c`. The function uses the C API to print the value of the test-pointed signal. The function can access the signal data whether the data type is `single` or `double`.

At the command prompt, run the generated executable `rtwdemo_bascisc.exe`.

```
system('rtwdemo_basicsc')
```

The parameter and signal values appear in the Command Window output.

For more information about data interfaces, including the C API, see “Data Exchange Interfaces” (Simulink Coder).

Standard Data Structures in the Generated Code

By default, signal lines, block parameters, states, and other model data appear in the generated code as fields of standard structures. For general information, see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder).

The table shows some common data structures in the generated code. The name of the structure type and, if applicable, structure variable in the code that you generate from a model depends on the model settings. Regardless of the settings, the name of the structure type in the code contains the short name from the **Short Name of Structure Type** column in the table.

Data Structures Generated for a Model

Short Name of Structure Type	Data Represented in the Structure
`ExtU`	Data from root Inport blocks
`ExtY`	Data from root Outport blocks
`B`	Block output signals
`ConstB`	Block outputs that have constant values
`P`	Block parameters
`ConstP`	Constant parameters
`DW`	Discrete block states
`XDis`	Status of enabled subsystems

For additional structures, see “System-generated identifiers” (Simulink Coder).

You can exclude data from appearing in these structures by using:

- Direct application of storage classes. For example, you can use storage classes to represent signals, tunable parameters, and states as individual global variables. For more information, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.
- Configuration parameters, such as those on the **Optimization** pane in the Configuration Parameters dialog box. You can adjust these configuration parameters to control the default representation of data. For more information, see “Model Configuration Parameters: Code Generation Optimization” (Simulink Coder).

Control Characteristics of Data Structures (Embedded Coder)

To control the characteristics of the standard data structures, use the information in the table.

Name	How to Change Name
Structure types	Specify a naming rule to use for the types. Set a value for **Configuration Parameters > Global types**.
Global structure variables	Specify a naming rule with **Configuration Parameters > Global variables**.
Names of structure fields	By default, the name of each structure field derives from the name of the data item in the model (for example, the name of a block state, which you specify by using the **State name** block parameter). Specify a naming rule with **Configuration Parameters > Field name of global types**.
Data types of structure fields	Use `Simulink.AliasType` objects and data type replacement to rename primitive types for the corresponding data items in the model. See “Control Data Type Names in Generated Code” on page 34-2.

For more information about configuration parameters that control names and other identifiers in the generated code, see “Customize Generated Identifiers” on page 88-21.

Use the Real-Time Model Data Structure

The code generator uses the real-time model (RT_MODEL) data structure. This structure is also referred to as the `rtModel` data structure. You can access `rtModel` data by using a set of macros analogous to the `ssSetxxx` and `ssGetxxx` macros that S-functions use to access `SimStruct` data, including noninlined S-functions compiled by the code generator.

You need to use the set of macros `rtmGetxxx` and `rtmSetxxx` to access the real-time model data structure. The `rtModel` is an optimized data structure that replaces `SimStruct` as the top level data structure for a model. The `rtmGetxxx` and `rtmSetxxx` macros are used in the generated code as well as from the `main.c` or `main.cpp` module. If you are customizing `main.c` or `main.cpp` (either a static file or a generated file), you need to use `rtmGetxxx` and `rtmSetxxx` instead of the `ssSetxxx` and `ssGetxxx` macros.

Usage of `rtmGetxxx` and `rtmSetxxx` macros is the same as for the `ssSetxxx` and `ssGetxxx` versions, except that you replace `SimStruct S` by real-time model data structure `rtM`. The following table lists `rtmGetxxx` and `rtmSetxxx` macros that are used in `grt_main.c` and `grt_main.cpp`.

Macros for Accessing the Real-Time Model Data Structure

rtm Macro Syntax	Description
`rtmGetdX(rtm)`	Get the derivatives of block continuous states
`rtmGetOffsetTimePtr(RT_MDL rtM)`	Return the pointer to vector that stores sample time offsets of the model associated with rtM
`rtmGetNumSampleTimes(RT_MDL rtM)`	Get the number of sample times that a block has
`rtmGetPerTaskSampleHitsPtr(RT_MDL)`	Return a pointer to `NumSampleTime` × `NumSampleTime` matrix
`rtmGetRTWExtModeInfo(RT_MDL rtM)`	Return an external mode information data structure of the model (used internally for external mode)
`rtmGetRTWLogInfo(RT_MDL)`	Return a data structure used by code generator logging (internal use only)
`rtmGetRTWRTModelMethodsInfo(RT_MDL)`	Return a data structure of real-time model methods information (internal use only)
`rtmGetRTWSolverInfo(RT_MDL)`	Return data structure containing solver information of the model (internal use only)
`rtmGetSampleHitPtr(RT_MDL)`	Return a pointer to Sample Hit flag vector
`rtmGetSampleTime(RT_MDL rtM, int TID)`	Get task sample time
`rtmGetSampleTimePtr(RT_MDL rtM)`	Get pointer to a task sample time
`rtmGetSampleTimeTaskIDPtr(RT_MDL rtM)`	Get pointer to a task ID
`rtmGetSimTimeStep(RT_MDL)`	Return simulation step type ID (`MINOR_TIME_STEP`, `MAJOR_TIME_STEP`)
`rtmGetStepSize(RT_MDL)`	Return the fundamental step size of the model
`rtmGetT(RT_MDL,t)`	Get the current simulation time
`rtmSetT(RT_MDL,t)`	Set the time of the next sample hit
`rtmGetTaskTime(RT_MDL,tid)`	Get the current time for the current task
`rtmGetTFinal(RT_MDL)`	Get the simulation stop time
`rtmSetTFinal(RT_MDL,finalT)`	Set the simulation stop time
`rtmGetTimingData(RT_MDL)`	Return a data structure used by timing engine of the model (internal use only)

rtm Macro Syntax	Description
`rtmGetTPtr(RT_MDL)`	Return a pointer to the current time
`rtmGetTStart(RT_MDL)`	Get the simulation start time
`rtmIsContinuousTask(rtm)`	Determine whether a task is continuous
`rtmIsMajorTimeStep(rtm)`	Determine whether the simulation is in a major step
`rtmIsSampleHit(RT_MDL,tid)`	Determine whether the sample time is hit
`rtmGetErrorStatus(rtm)`	Get the current error status
`rtmSetErrorStatus(rtm,val)`	Set the current error status
`rtmGetErrorStatusPointer(rtm)`	Return a pointer to the current error status
`rtmGetStopRequested(rtm)`	Return whether a stop is requested
`rtmGetBlockIO(rtm)`	Get the block I/O data structure
`rtmSetBlockIO(rtm,val)`	Set the block I/O data structure
`rtmGetContStates(rtm)`	Get the continuous states data structure
`rtmSetContStates(rtm,val)`	Set the continuous states data structure
`rtmGetDefaultParam(rtm)`	Get the default parameters data structure
`rtmSetDefaultParam(rtm,val)`	Set the default parameters data structure
`rtmGetPrevZCSigState(rtm)`	Get the previous zero-crossing signal state data structure
`rtmSetPrevZCSigState(rtm,val)`	Set the previous zero-crossing signal state data structure
`rtmGetRootDWork(rtm)`	Get the DWork data structure
`rtmSetRootDWork(rtm,val)`	Set the DWork data structure
`rtmGetU(rtm)`	Get the root inputs data structure (when root inputs are passed as part of the model data structure)
`rtmSetU(rtm,val)`	Set the root inputs data structure (when root inputs are passed as part of the model data structure)

rtm Macro Syntax	Description
`rtmGetY(rtm)`	Get the root outputs data structure (when root outputs are passed as part of the model data structure)
`rtmSetY(rtm,val)`	Set the root outputs data structure (when root outputs are passed as part of the model data structure)

For additional details on usage, see “SimStruct Macros and Functions Listed by Usage” (Simulink).

How Generated Code Exchanges Data with an Environment

To use the code that you generate from a model, you call the generated entry-point functions such as `step` and `initialize`. The environment in which you call these functions must provide input signal data and, depending on your application, scheduling information. The generated algorithm then calculates output data that the calling environment can use. The environment and the algorithm can exchange this data through global variables or through formal parameters (arguments).

The set of input and output data and the exchange mechanisms constitute the interfaces of the entry-point functions. When you understand the default interfaces and how to control them, you can:

- Write code that calls the generated code.
- Generate reusable (reentrant) code that you can call multiple times in a single application.
- Integrate the generated code with other, external code in your application.

In a model, root-level Inport and Outport blocks represent the primary inputs and outputs of the block algorithm. By default, the code generator aggregates these blocks into standard structures that store input and output data.

For information about how the generated code stores internal data, which does not participate in the model interface, see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50.

Data Interfaces in the Generated Code

This example shows how the generated code exchanges data with an environment.

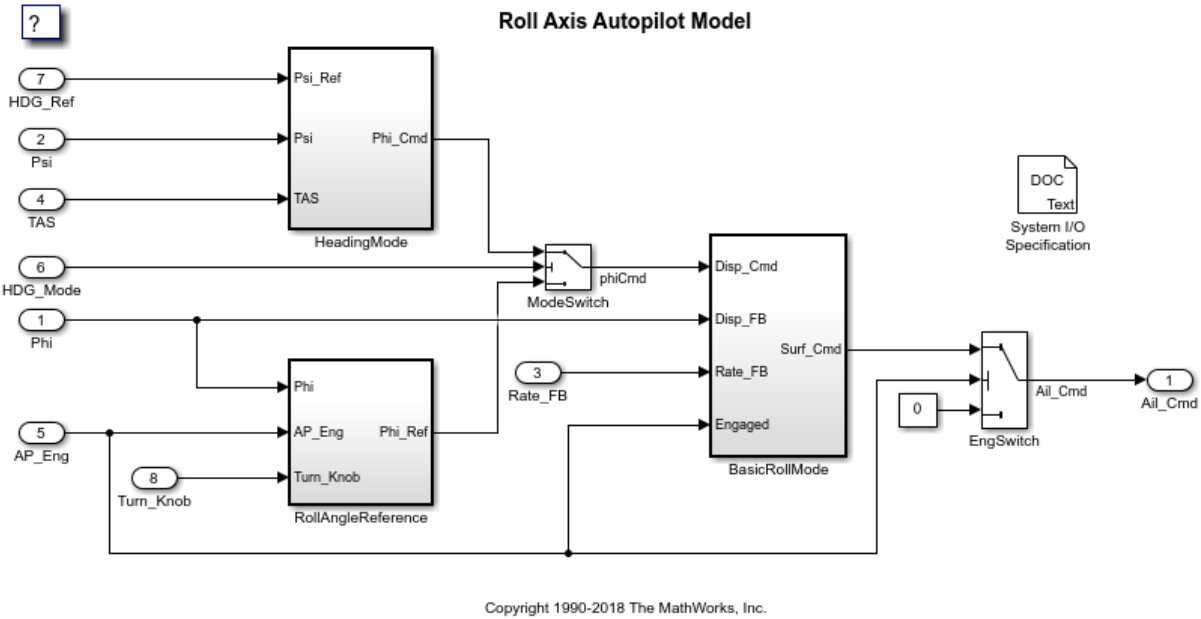
Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```



At the root level, the model has a number of Inport blocks and one Outport block.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```
set_param('rtwdemo_roll','SystemTargetFile','grt.tlc')
```

Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting `Nonreusable function` means that the generated code is not reusable (not reentrant).

For this example, to generate simpler code, clear the **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```
set_param('rtwdemo_roll','MatFileLogging','off')
```

Generate Nonreusable Code

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Inspect the file `rtwdemo_roll.h`. The file defines a structure type that represents input data and a type that represents output data.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
    '/* External inputs (root inport signals with default storage) */',...
    '} ExtY_rtwdemo_roll_T;',1,1)
```

```
/* External inputs (root inport signals with default storage) */
typedef struct {
  real32_T Phi;                        /* '<Root>/Phi' */
  real32_T Psi;                        /* '<Root>/Psi' */
  real32_T Rate_FB;                    /* '<Root>/Rate_FB' */
  real32_T TAS;                        /* '<Root>/TAS' */
  boolean_T AP_Eng;                    /* '<Root>/AP_Eng' */
  boolean_T HDG_Mode;                  /* '<Root>/HDG_Mode' */
  real32_T HDG_Ref;                    /* '<Root>/HDG_Ref' */
  real32_T Turn_Knob;                  /* '<Root>/Turn_Knob' */
} ExtU_rtwdemo_roll_T;

/* External outputs (root outports fed by signals with default storage) */
typedef struct {
  real32_T Ail_Cmd;                    /* '<Root>/Ail_Cmd' */
} ExtY_rtwdemo_roll_T;
```

Each field corresponds to an Inport or Outport block at the root level of the model. The name of each field derives from the name of the block.

The file also defines a structure type, the *real-time model data structure*, whose single field stores a run-time indication of whether the generated code has encountered an error during execution.

```
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
    '/* Block states (default storage) */',1,0)
```

```
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
  const char_T *errorStatus;
};
```

When you modify model configuration parameters to suit your application, this structure can also contain other data that pertain to the entire model, such as scheduling information.

For the structure type that represents the real-time model data structure, the file `rtwdemo_roll_types.h` creates an alias (`typedef`) that the generated code later uses to allocate memory for the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll_types.h');
rtwdemodbtype(file,'/* Forward declaration for rtModel */',...
    'RT_MODEL_rtwdemo_roll_T;',1,1)
```

```
/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;
```

Using these structure types, the file `rtwdemo_roll.c` defines (allocates memory for) global structure variables that store input and output data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,...
    '/* External inputs (root inport signals with default storage) */',...
    '= &rtwdemo_roll_M_;',1,1)
```

```
/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;

/* External outputs (root outports fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;

/* Real-time model */
RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M_;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M_;
```

The file `rtwdemo_roll.h` declares these structure variables. Your external code can include (`#include`) this file, whose general name is *`model`*`.h` where *`model`* is the name of the model, to access data that participate in the model interface.

In `rtwdemo_roll.c`, the model `step` function, which represents the primary model algorithm, uses a `void` `void` interface (without arguments).

```
rtwdemodbtype(file,...
    '/* Model step function */','void rtwdemo_roll_step(void)',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(void)
```

In the function definition, the algorithm reads input data and writes output data by directly accessing the global structure variables. For example, near the end of the algorithm, the code for the `EngSwitch` block reads the value of the `AP_Eng` field (which represents an input) and, based on that value, conditionally writes a constant value to the `Ail_Cmd` field (which represents an output).

```
rtwdemodbtype(file,'if (rtwdemo_roll_U.AP_Eng) {','      }',1,1)
```

```
  if (rtwdemo_roll_U.AP_Eng) {
    /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
    /* Saturate: '<S1>/CmdLimit' */
    if (rtwdemo_roll_Y.Ail_Cmd > 15.0F) {
      /* Sum: '<S1>/Sum2' incorporates:
       *  Outport: '<Root>/Ail_Cmd'
       */
      rtwdemo_roll_Y.Ail_Cmd = 15.0F;
    } else {
      if (rtwdemo_roll_Y.Ail_Cmd < -15.0F) {
        /* Sum: '<S1>/Sum2' incorporates:
         *  Outport: '<Root>/Ail_Cmd'
         */
        rtwdemo_roll_Y.Ail_Cmd = -15.0F;
      }
```

Due to the `void void` interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call reads and writes input and output data to the same global structure variables, resulting in data corruption and unintentional interaction between the calls.

The model initialization function, `rtwdemo_roll_initialize`, initializes input and output data to zero. The function also initializes the error status. The function directly accesses the global variables, which means the function is not reentrant.

```
rtwdemodbtype(file,'/* Model initialize function */',...
    'rtmSetErrorStatus(rtwdemo_roll_M, (NULL));',1,1)
```

```
/* Model initialize function */
void rtwdemo_roll_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

rtwdemodbtype(file,'  /* external inputs */',...
    '/* SystemInitialize for Atomic SubSystem:',1,0)

  /* external inputs */
  (void)memset(&rtwdemo_roll_U, 0, sizeof(ExtU_rtwdemo_roll_T));

  /* external outputs */
  rtwdemo_roll_Y.Ail_Cmd = 0.0F;
```

Generate Reusable Code

You can configure the generated code as reentrant, which means that you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions exchange input, output, and other model data through formal parameters (pointer arguments). With these pointer arguments, each call can read inputs and write outputs to a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to `Reusable function`.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Reusable function')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')

### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the input data, the output data, and additional data in the form of a `DWork` substructure (which stores, for example, block states such as the state of a Discrete-Time Integrator block).

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
    '/* External data declarations for dependent source files */',1,0)
```

```
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
  const char_T *errorStatus;
  ExtU_rtwdemo_roll_T *inputs;
  ExtY_rtwdemo_roll_T *outputs;
  DW_rtwdemo_roll_T *dwork;
};
```

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the input and output structures.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Model data allocation function */',...
    'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)
```

```
/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)
```

In `rtwdemo_roll.c`, the model `step` function accepts an argument that represents the real-time model data structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,...
    '/* Model step function */','void rtwdemo_roll_step',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```
rtwdemodbtype(file,...
    '*rtwdemo_roll_DW =','rtwdemo_roll_M->outputs;',1,1)
```

```
  DW_rtwdemo_roll_T *rtwdemo_roll_DW = ((DW_rtwdemo_roll_T *)
    rtwdemo_roll_M->dwork);
  ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
    rtwdemo_roll_M->inputs;
  ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
    rtwdemo_roll_M->outputs;
```

Then, to access the input and output data stored in global memory, the algorithm interacts with these local variables.

```
rtwdemodbtype(file,'  if (rtwdemo_roll_U->AP_Eng) {',...
    '  /* End of Switch: ''<Root>/EngSwitch'' */',1,1)
```

```
  if (rtwdemo_roll_U->AP_Eng) {
    /* Outputs for Atomic SubSystem: '<Root>/BasicRollMode' */
    /* Saturate: '<S1>/CmdLimit' */
    if (rtwdemo_roll_Y->Ail_Cmd > 15.0F) {
      /* Sum: '<S1>/Sum2' incorporates:
       *  Outport: '<Root>/Ail_Cmd'
       */
      rtwdemo_roll_Y->Ail_Cmd = 15.0F;
    } else {
      if (rtwdemo_roll_Y->Ail_Cmd < -15.0F) {
        /* Sum: '<S1>/Sum2' incorporates:
         *  Outport: '<Root>/Ail_Cmd'
         */
        rtwdemo_roll_Y->Ail_Cmd = -15.0F;
      }
    }

    /* End of Saturate: '<S1>/CmdLimit' */
    /* End of Outputs for SubSystem: '<Root>/BasicRollMode' */
  } else {
    /* Sum: '<S1>/Sum2' incorporates:
     *  Constant: '<Root>/Zero'
     *  Outport: '<Root>/Ail_Cmd'
     */
    rtwdemo_roll_Y->Ail_Cmd = 0.0F;
  }
```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```
rtwdemodbtype(file,...
    '/* Model initialize function */','void rtwdemo_roll_initialize',1,1)

/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

Configure Data Interface

To control the characteristics of the data interface in the generated code, see “Control Data and Function Interface in Generated Code” on page 32-42.

Control Data and Function Interface in Generated Code

To use the code that you generate from a model, you call generated entry-point functions such as `step` and `initialize`. The calling environment and the generated functions exchange input and output data through global variables or through formal parameters (arguments). This data and the exchange mechanisms constitute the interfaces of the entry-point functions. For information about the default interfaces for reentrant and nonreentrant models in the generated code, see “How Generated Code Exchanges Data with an Environment” on page 32-33.

By controlling the interfaces that appear in the generated code, you can:

- Minimize the modifications that you must make to existing code.
- Generate stable interfaces that do not change or minimally change when you make changes to the model.
- Generate code that exchanges data more efficiently (for example, by using pointers and pass-by-reference arguments for nonscalar data).

Control Type Names, Field Names, and Variable Names of Standard I/O Structures (Embedded Coder)

By default, for nonreentrant code, Inport blocks at the root level of the model appear in the generated code as fields of a global structure variable. Similarly, Outport blocks appear in a different structure. For reentrant code, depending on your setting for model configuration parameter **Pass root-level I/O**, the code generator can also package input and output data into standard structures.

With Embedded Coder, you can control these names. See “Control Characteristics of Data Structures (Embedded Coder)” (Simulink Coder).

Control Names of Generated Entry-Point Functions (Embedded Coder)

To use the generated code, you write code that calls generated entry-point functions. For example, entry-point functions include *`model`*`_step`, *`model`*`_initialize`, and top-level functions generated from an export-function model. To control the names of the model entry-point functions, use the Code Mappings editor (requires Embedded Coder) to apply a combination of these techniques:

- On the **Function Defaults** tab, specify default naming rules for categories of entry-point functions by applying function customization templates in the Code Mappings editor. With this technique, a naming rule applies to functions in a category. For more information, see “Configure Default Code Generation for Functions” on page 31-16.
- On the **Entry-Point Functions** tab, specify names for individual entry-point functions by either directly editing the **Function Name** column or through a configuration dialog box opened from the **Function Preview** column. Names that you specify override default naming rules specified by function customization templates. For more information, see “Customize Generated C Function Interfaces” on page 39-2

Control Data Interface for Nonreentrant Code

When you set the model configuration parameter **Code interface packaging** to `Nonreusable function` (the default), generated entry-point functions are not reentrant. Typically, the functions exchange data with the calling environment through direct access to global variables.

Configure Inport or Outport Block as Separate Global Variable

To remove the block from the standard I/O structures by creating a separate global variable, apply a storage class, such as `ExportedGlobal` or `ExportToFile`, to the signal that the block represents.

- To specify a default storage class for Inport blocks and a different default for Outport blocks, use the Code Mappings editor. As you add such blocks to the model, they acquire the storage class that you specify. You do not need to configure each individual block.

  For this technique, you must have Embedded Coder.
- To override the default for an individual block, apply a different storage class by using other tools such as the Model Data Editor or the Property Inspector. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder).

For an example, see “Design Data Interface by Configuring Inport and Outport Blocks” (Simulink Coder). For general information about storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).

Configure Generated Code to Read or Write to Global Variables Defined by External Code

If your calling code already defines a global variable that you want the generated code to use as input data or use to store output data, you can reuse the variable by preventing the code generator from duplicating the definition. Apply a storage class to the corresponding Inport or Outport block in the model. Choose a storage class that specifies an imported data scope, such as `ImportedExtern` or `ImportFromFile`. For information about applying storage classes, see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder) and "Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements" on page 36-28.

Package Multiple Inputs or Outputs into Custom Structure

You can configure a single Inport or Outport block to appear in the generated code as a custom structure that contains multiple input or output signals. You can also configure the block to appear as a substructure of the default I/O structures or as a separate structure variable.

Configure the block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object.

- To generate the bus signal as a substructure in the standard I/O structures, leave the block storage class at the default setting, `Auto`. If you have Embedded Coder, in the Code Mappings editor, on the **Data Defaults** tab, set the storage class for categories **Inports** and **Outports** to `Default`.
- To generate the bus signal as a separate global structure variable, apply a storage class such as `ExportedGlobal` or `ExportToFile`.

For more information about grouping signals into custom structures in the generated code, see "Organize Data into Structures in Generated Code" on page 32-181.

Configure Inport or Outport Block as Function Call (Embedded Coder)

If your external code defines a function that returns input data for the generated code or accepts output data that the generated code produces, you can configure an Inport or Outport block so that the generated code calls the function instead of accessing a global variable. Apply the Embedded Coder storage class `GetSet`. For more information, see "Access Data Through Functions with Custom Storage Class GetSet" on page 36-51.

Pass Inputs and Outputs Through Function Arguments (Embedded Coder)

With Embedded Coder, you can optionally configure the model step (execution) function to access root-level input and output through arguments instead of directly reading and writing to global variables. Completely control the argument characteristics such as name, order, and passing mechanism (by reference or by value). This level of configuration can help to integrate generated code with your external code.

To pass inputs and outputs through arguments, in the Configure C Step Function interface dialog box, select **Configure arguments for Step function prototype**. Each Inport and Outport block at the root level of the model appears in the code as an argument of the execution function. For more information, see “Customize Generated C Function Interfaces” on page 39-2.

Configure Referenced Model Inputs and Outputs as Global Variables (void-void)

By default, for a nonreentrant referenced model, the generated code passes root-level input and output through function arguments. A nonreentrant referenced model is one in which you set model configuration parameter **Total number of instances allowed per top model** to `One`.

To pass this data through global variables instead (for a `void-void` interface), in the referenced model, apply storage classes such as `ExportedGlobal` and `ExportToFile` to root-level Inport and Outport blocks.

- To apply a default storage class to such blocks, use the Code Mapping Editor, which requires Embedded Coder. With this technique, as you add such blocks to the model, the blocks acquire the default storage class, preserving the `void-void` interface. For more information, see “Configure Default Code Generation for Data” on page 31-8.
- To override the default storage class, apply storage classes directly to individual blocks by using the Model Data Editor. See “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.
- For an example that requires Embedded Coder, see “Establish Data Ownership in a System of Components” on page 33-15.

Control Data Interface for Reentrant Code

When you set **Code interface packaging** to `Reusable function`, generated entry-point functions are reentrant. The functions exchange data with the calling environment through formal parameters (arguments). By default, each root-level Inport and Outport

block appears in the generated code as a separate argument instead of a field of the standard I/O structures.

- To reduce the number of arguments, see “Reduce Number of Arguments by Using Structures” (Simulink Coder).
- To control the data types of the arguments, see “Control Data Types of Arguments” (Simulink Coder).

Prevent Unintended Changes to the Interface

Some changes that you make to a model change the entry-point function interfaces in the generated code. For example, if you change the name of the model, the names of the functions can change. If you configure the model code to exchange data through arguments, when you add or remove Inport or Outport blocks or change the names of the blocks, the corresponding arguments can change.

For easier maintenance of your calling code, prevent changes to the interfaces of the entry-point functions.

- If you exchange input and output data through arguments, configure the generated code to package Inport and Outport blocks into structures instead of allowing each block to appear as a separate argument (the default). Then, when you add or remove Inport or Outport blocks, or change their properties such as name and data type, the fields of the structures change, but the function interfaces do not change. See “Reduce Number of Arguments by Using Structures” on page 32-47.
- Set the data types of Inport and Outport blocks explicitly instead of using an inherited data type setting (which these blocks use by default). Inherited data type settings can cause the blocks to use different data types depending on the data types of upstream and downstream signals. For more information about configuring data types, see “Control Signal Data Types” (Simulink).
- With Embedded Coder, specify function names that do not depend on the model name. If you specify a naming rule with a function customization template, do not use the token $R in the rule. See “Control Names of Generated Entry-Point Functions (Embedded Coder)” (Simulink Coder).

Reduce Number of Arguments by Using Structures

Reducing the number of arguments of a function can improve the readability of the code and reduce consumption of stack memory. To create a structure argument that can pass multiple pieces of data at one time, use these techniques:

- Manually combine multiple Inport or Outport blocks so that they appear in the generated code as fields of a structure or substructure of a standard data structure. The generated entry-point function or functions accept the address of the structure as a separate argument or as a substructure (field) of the standard I/O structures.

  Replace the Inport or Outport blocks with a single block, and configure the new block as a nonvirtual bus by using a `Simulink.Bus` object as the data type of the block. If your external code defines the structure type, consider using the `Simulink.importExternalCTypes` function to generate the bus object. See “Organize Data into Structures in Generated Code” on page 32-181 and `Simulink.importExternalCTypes`.
- When you generate reentrant code with Embedded Coder, configure Inport and Outport blocks to appear in aggregated structures by default. Set model configuration parameter **Pass root-level I/O as** to a setting other than `Individual arguments`.

  - To package Inport and Outport blocks into the real-time model data structure, select `Part of model data structure`. The code generator aggregates the blocks into the default I/O structures to which the real-time model data structure points. The generated entry-point function or functions accept the real-time model data structure as a single argument. If you choose this setting, the function has the smallest number of arguments.
  - To aggregate Inport blocks into a structure and Outport blocks into a different structure, select `Structure reference`. The generated entry-point function or functions accept the address of each structure as an argument. Another argument accepts the real-time model data structure. If you choose this setting, the inputs and outputs are more identifiable in the function interfaces.

    With this setting, if you remove the root-level Inport blocks or the root-level Outport blocks, the function signature can change. Similarly, the signature can change if you add a root-level Inport or Outport block to a model that does not include such blocks.
  - For more control over the characteristics of the structures, set **Pass root-level I/O as** to `Part of model data structure`. Then, set the default storage class for

Inport and Outport blocks to a structured storage class that you create. With this technique:

- You can create a single structure for the blocks or create two separate structures.
- You can control the names of the structure types.
- The structures appear as substructures of the real-time model data structure. You must set **Pass root-level I/O as** to `Part of model data structure`.

Create the storage class by using the Embedded Coder Dictionary (see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2). Apply the storage class by using the Code Mappings editor (see “Configure Default Code Generation for Data” on page 31-8).

For more information, see “Pass root-level I/O as” (Simulink Coder).

Control Data Types of Arguments

You can configure the generated entry-point functions to exchange data through arguments. For a scalar or array argument, to control the name of the primitive data type, use a `Simulink.AliasType` object to either set the data type of the corresponding block or to configure data type replacements for the entire model. These techniques require Embedded Coder. For more information, see “Control Data Type Names in Generated Code” on page 34-2.

Promote Data Item to the Interface

By default, the code generator assumes that Inport and Outport blocks at the root level of the model constitute the data interface of the model. You can promote an arbitrary signal, block parameter, or block state to the interface so that other systems and components can access it. See “Promote Internal Data to the Interface” on page 32-63.

How Generated Code Stores Internal Signal, State, and Parameter Data

To calculate outputs from inputs, the generated code stores some internal data in global memory. A signal that does not connect to a root-level input or output (Inport or Outport block) is internal data.

Internal data can also include:

- A block state such as the state of a Unit Delay block. The algorithm must retain the state value between execution cycles, so the generated code typically stores states in global memory (for example, as a global variable or a field of a global structure variable).
- A block parameter, such as the **Gain** parameter of a Gain block, whose value the code generator cannot inline in the code. For example, the code generator cannot inline the value of a nonscalar parameter.
- The status indicator of a conditionally executed subsystem such as an enabled subsystem.

For more efficient code, you can configure optimizations such as **Configuration Parameters > Default parameter behavior** and **Configuration Parameters > Signal storage reuse** that attempt to eliminate storage for internal data. However, the optimizations cannot eliminate storage for some data, which consume memory in the generated code.

When you understand the default format in which the generated code stores internal data, you can:

- Make signals accessible and parameters tunable by default. You can then interact with and monitor the code during execution.
- Generate efficient production code by eliminating storage for internal data and, depending on your hardware and build toolchain, controlling the placement in memory of data that the optimizations cannot eliminate.
- Promote pieces of internal data to the model interface so that other components and systems can access that data.

For information about how the generated code exchanges data with a calling environment through interfaces, see “How Generated Code Exchanges Data with an Environment” on page 32-33.

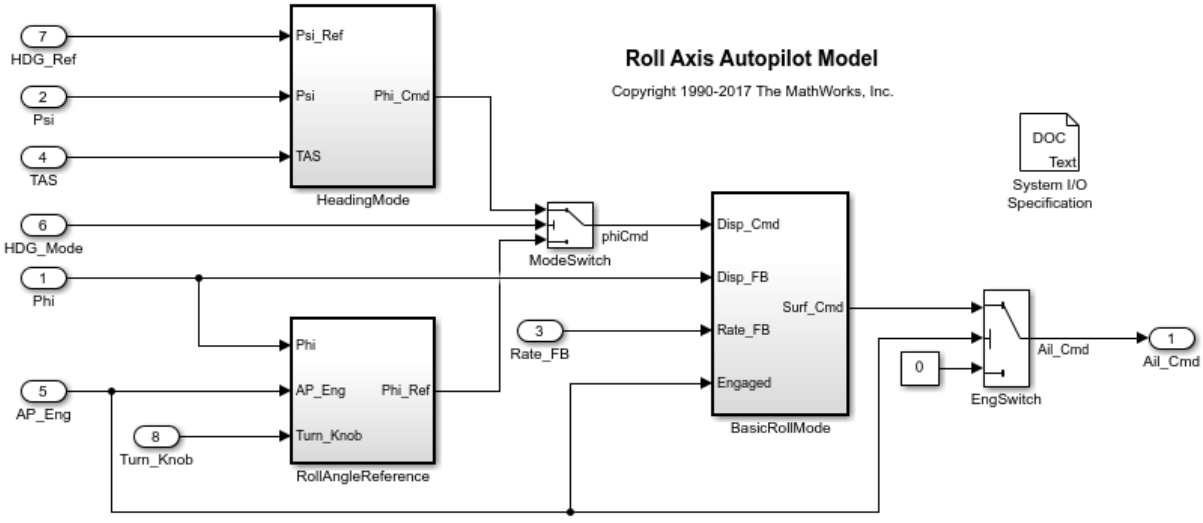
Internal Data in the Generated Code

This example shows how the generated code stores internal data such as block states.

Explore Example Model

Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```



The model contains internal signals that do not connect to root-level Inport or Outport blocks. Some of the signals have a name, such as the `phiCmd` signal.

The model also contains some blocks that maintain state data. For example, in the `BasicRollMode` subsystem, a Discrete-Time Integrator block labeled `Integrator` maintains a state.

In the model, set **Configuration Parameters > Code Generation > System target file** to `grt.tlc`.

```
set_param('rtwdemo_roll','SystemTargetFile','grt.tlc')
```

Inspect the setting for **Configuration Parameters > Code Generation > Interface > Code interface packaging**. The setting `Nonreusable function` means that the generated code is not reusable (reentrant).

For this example, generate simpler code by clearing **Configuration Parameters > Code Generation > Interface > Advanced parameters > Mat-file logging**.

```
set_param('rtwdemo_roll','MatFileLogging','off')
```

Generate Nonreusable Code

Set these configuration parameters:

- Set **Default parameter behavior** to `Tunable`.
- Clear **Signal storage reuse**.

```
set_param('rtwdemo_roll','DefaultParameterBehavior','Tunable',...
    'OptimizeBlockIOStorage','off')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

The file `rtwdemo_roll.h` defines several structure types that represent internal data. For example, the block input and output structure defines one field for each internal signal in the model. Each field name derives from the name of the block that generates the signal or, if you specify a name for the signal, from the name of the signal.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
    '/* Block signals (default storage) */','} B_rtwdemo_roll_T;',1,1)
```

```
/* Block signals (default storage) */
typedef struct {
  real32_T phiCmd;                     /* '<Root>/ModeSwitch' */
  real32_T Abs;                        /* '<S3>/Abs' */
  real32_T FixPtUnitDelay1;            /* '<S7>/FixPt Unit Delay1' */
  real32_T Xnew;                       /* '<S7>/Enable' */
  real32_T TKSwitch;                   /* '<S3>/TKSwitch' */
  real32_T RefSwitch;                  /* '<S3>/RefSwitch' */
```

```
  real32_T Integrator;                 /* '<S1>/Integrator' */
  real32_T DispLimit;                  /* '<S1>/DispLimit' */
  real32_T Sum;                        /* '<S1>/Sum' */
  real32_T DispGain;                   /* '<S1>/DispGain' */
  real32_T RateLimit;                  /* '<S1>/RateLimit' */
  real32_T Sum1;                       /* '<S1>/Sum1' */
  real32_T RateGain;                   /* '<S1>/RateGain' */
  real32_T Sum2;                       /* '<S1>/Sum2' */
  real32_T CmdLimit;                   /* '<S1>/CmdLimit' */
  real32_T IntGain;                    /* '<S1>/IntGain' */
  real32_T hdgError;                   /* '<S2>/Sum' */
  real32_T DispGain_a;                 /* '<S2>/DispGain' */
  real32_T Product;                    /* '<S2>/Product' */
  boolean_T NotEngaged;                /* '<S3>/NotEngaged' */
  boolean_T TKThreshold;               /* '<S3>/TKThreshold' */
  boolean_T RefThreshold2;             /* '<S3>/RefThreshold2' */
  boolean_T RefThreshold1;             /* '<S3>/RefThreshold1' */
  boolean_T Or;                        /* '<S3>/Or' */
  boolean_T NotEngaged_e;              /* '<S1>/NotEngaged' */
} B_rtwdemo_roll_T;
```

The file defines a structure type, the DWork structure, to represent block states such as the state of the Discrete-Time Integrator block.

```
rtwdemodbtype(file,...
    '/* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)
```

```
/* Block states (default storage) for system '<Root>' */
typedef struct {
  real32_T FixPtUnitDelay1_DSTATE;     /* '<S7>/FixPt Unit Delay1' */
  real32_T Integrator_DSTATE;          /* '<S1>/Integrator' */
  int8_T Integrator_PrevResetState;    /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;
```

The file defines a structure type to represent parameter data. Each tunable block parameter in the model, such as the **Gain** parameter of a Gain block, appears as a field of this structure. If a block parameter acquires its value from a MATLAB variable or a `Simulink.Parameter` object, the variable or object appears as a field, not the block parameter.

The file also defines a structure type, the *real-time model data structure*, whose single field represents a run-time indication of whether the generated code has encountered an error during execution.

```
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
    '/* Block parameters (default storage) */',1,0)
```

```
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
  const char_T *errorStatus;
};
```

For the structure type that represents the real-time model data structure, the file `rtwdemo_roll_types.h` creates an alias that the generated code later uses to allocate memory for the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll_types.h');
rtwdemodbtype(file,'/* Forward declaration for rtModel */',...
    'RT_MODEL_rtwdemo_roll_T;',1,1)
```

```
/* Forward declaration for rtModel */
typedef struct tag_RTM_rtwdemo_roll_T RT_MODEL_rtwdemo_roll_T;
```

Using these structure types, the file `rtwdemo_roll.c` defines (allocates memory for) global structure variables that store internal data for the generated algorithm. The file also defines variables that represent the real-time model data structure and a pointer to the structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Block signals (default storage) */',...
    '= &rtwdemo_roll_M_;',1,1)
```

```
/* Block signals (default storage) */
B_rtwdemo_roll_T rtwdemo_roll_B;

/* Block states (default storage) */
DW_rtwdemo_roll_T rtwdemo_roll_DW;

/* External inputs (root inport signals with default storage) */
ExtU_rtwdemo_roll_T rtwdemo_roll_U;

/* External outputs (root outports fed by signals with default storage) */
ExtY_rtwdemo_roll_T rtwdemo_roll_Y;

/* Real-time model */
```

```
RT_MODEL_rtwdemo_roll_T rtwdemo_roll_M_;
RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M = &rtwdemo_roll_M_;
```

The model `step` function, which represents the primary model algorithm, uses a `void void` interface (with no arguments).

```
rtwdemodbtype(file,...
    '/* Model step function */','void rtwdemo_roll_step(void)',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(void)
```

In the function definition, the algorithm performs calculations and stores intermediate results in the signal and state structures by directly accessing the global variables. The algorithm also reads parameter data from the corresponding global variable. For example, in the `BasicRollMode` subsystem, the code generated for the `Integrator` block reads and writes signal, state, and parameter data from the structures.

```
rtwdemodbtype(file,'/* DiscreteIntegrator: ''<S1>/Integrator'' *',...
    '/* End of DiscreteIntegrator: ''<S1>/Integrator'' */',1,1)
```

```
  /* DiscreteIntegrator: '<S1>/Integrator' */
  if (rtwdemo_roll_B.NotEngaged_e || (rtwdemo_roll_DW.Integrator_PrevResetState
       != 0)) {
    rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
  }

  if (rtwdemo_roll_DW.Integrator_DSTATE >= rtwdemo_roll_P.intLim) {
    rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.intLim;
  } else {
    if (rtwdemo_roll_DW.Integrator_DSTATE <= rtwdemo_roll_P.Integrator_LowerSat)
    {
      rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_LowerSat;
    }
  }

  rtwdemo_roll_B.Integrator = rtwdemo_roll_DW.Integrator_DSTATE;
```

Due to the `void void` interface and the direct data access, the function is not reentrant. If you call the function multiple times in an application, each call writes data to the global structure variables and the subsequent call can read that data, resulting in unintentional interference between the calls.

The model initialization function `rtwdemo_roll_initialize` initializes all of the internal data to zero. The function also initializes the error status by calling a specialized macro function. The initialization function directly accesses the global variables, which means that the function is not reentrant.

```
rtwdemodbtype(file,'/* Model initialize function */',...
    'sizeof(DW_rtwdemo_roll_T));',1,1)
```

```
/* Model initialize function */
void rtwdemo_roll_initialize(void)
{
  /* Registration code */

  /* initialize error status */
  rtmSetErrorStatus(rtwdemo_roll_M, (NULL));

  /* block I/O */
  (void) memset(((void *) &rtwdemo_roll_B), 0,
                sizeof(B_rtwdemo_roll_T));

  /* states (dwork) */
  (void) memset((void *)&rtwdemo_roll_DW, 0,
                sizeof(DW_rtwdemo_roll_T));
```

The function then initializes the block states in the DWork structure to the initial values that the block parameters in the model specify. Two of the three states in the model have tunable initial values, so the code initializes them by reading data from the parameters structure.

```
rtwdemodbtype(file,...
    '/* SystemInitialize for Atomic SubSystem: ''<Root>/RollAngleReference'' */',...
    '/* Model terminate function */',1,0)
```

```
  /* SystemInitialize for Atomic SubSystem: '<Root>/RollAngleReference' */
  /* InitializeConditions for UnitDelay: '<S7>/FixPt Unit Delay1' */
  rtwdemo_roll_DW.FixPtUnitDelay1_DSTATE = rtwdemo_roll_P.LatchPhi_vinit;

  /* End of SystemInitialize for SubSystem: '<Root>/RollAngleReference' */

  /* SystemInitialize for Atomic SubSystem: '<Root>/BasicRollMode' */
  /* InitializeConditions for DiscreteIntegrator: '<S1>/Integrator' */
  rtwdemo_roll_DW.Integrator_DSTATE = rtwdemo_roll_P.Integrator_IC;
  rtwdemo_roll_DW.Integrator_PrevResetState = 0;
```

```
  /* End of SystemInitialize for SubSystem: '<Root>/BasicRollMode' */
}
```

Generate Reusable Code

You can configure the generated code as reentrant, which means you can call the entry-point functions multiple times in an application. With this configuration, instead of directly accessing global variables, the entry-point functions accept internal data through formal parameters (pointer arguments). With these pointer arguments, each call can maintain internal data in a set of separate global variables, preventing unintentional interaction between the calls.

In the model, set **Configuration Parameters > Code Generation > Interface > Code interface packaging** to `Reusable function`.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Reusable function')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Now, in `rtwdemo_roll.h`, the real-time model data structure contains pointers to the error indication, the internal data, and primary input and output data in the form of `ExtU` and `ExtY` substructures (the fields of which represent Inport and Outport blocks at the root level of the model).

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,'/* Real-time Model Data Structure */',...
    '/* External data declarations for dependent source files */',1,0)
```

```
/* Real-time Model Data Structure */
struct tag_RTM_rtwdemo_roll_T {
  const char_T *errorStatus;
  B_rtwdemo_roll_T *blockIO;
  P_rtwdemo_roll_T *defaultParam;
  ExtU_rtwdemo_roll_T *inputs;
  ExtY_rtwdemo_roll_T *outputs;
  boolean_T paramIsMalloced;
  DW_rtwdemo_roll_T *dwork;
};
```

To call the generated code multiple times in an application, your code must allocate memory for a real-time model data structure per call. The file `rtwdemo_roll.c` defines a specialized function that allocates memory for a new real-time model data structure and returns a pointer to the structure. The function also allocates memory for the substructures that the fields in the model data structure point to, such as the DWork structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Model data allocation function */',...
    'RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)',1,1)
```

```
/* Model data allocation function */
RT_MODEL_rtwdemo_roll_T *rtwdemo_roll(void)
```

The model `step` function accepts an argument that represents the real-time model data structure.

```
rtwdemodbtype(file,'/* Model step function */','void rtwdemo_roll_step',1,1)
```

```
/* Model step function */
void rtwdemo_roll_step(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

In the function definition, the algorithm first extracts each pointer from the real-time model data structure into a local variable.

```
rtwdemodbtype(file,'*rtwdemo_roll_P_e =','rtwdemo_roll_M->outputs;',1,1)
```

```
  P_rtwdemo_roll_T *rtwdemo_roll_P_e = ((P_rtwdemo_roll_T *)
    rtwdemo_roll_M->defaultParam);
  B_rtwdemo_roll_T *rtwdemo_roll_B = ((B_rtwdemo_roll_T *)
    rtwdemo_roll_M->blockIO);
  DW_rtwdemo_roll_T *rtwdemo_roll_DW = ((DW_rtwdemo_roll_T *)
    rtwdemo_roll_M->dwork);
  ExtU_rtwdemo_roll_T *rtwdemo_roll_U = (ExtU_rtwdemo_roll_T *)
    rtwdemo_roll_M->inputs;
  ExtY_rtwdemo_roll_T *rtwdemo_roll_Y = (ExtY_rtwdemo_roll_T *)
    rtwdemo_roll_M->outputs;
```

Then, to access the internal data stored in global memory, the algorithm interacts with these local variables.

```
rtwdemodbtype(file,'/* DiscreteIntegrator: ''<S1>/Integrator'' */',...
    '/* End of DiscreteIntegrator: ''<S1>/Integrator'' */',1,1)
```

```
  /* DiscreteIntegrator: '<S1>/Integrator' */
  if (rtwdemo_roll_B->NotEngaged_e ||
      (rtwdemo_roll_DW->Integrator_PrevResetState != 0)) {
    rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->Integrator_IC;
  }

  if (rtwdemo_roll_DW->Integrator_DSTATE >= rtwdemo_roll_P_e->intLim) {
    rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->intLim;
  } else {
    if (rtwdemo_roll_DW->Integrator_DSTATE <=
        rtwdemo_roll_P_e->Integrator_LowerSat) {
      rtwdemo_roll_DW->Integrator_DSTATE = rtwdemo_roll_P_e->Integrator_LowerSat;
    }
  }

  rtwdemo_roll_B->Integrator = rtwdemo_roll_DW->Integrator_DSTATE;
```

Similarly, the model initialization function accepts the real-time model data structure as an argument.

```
rtwdemodbtype(file,...
    '/* Model initialize function */','void rtwdemo_roll_initialize',1,1)
```

```
/* Model initialize function */
void rtwdemo_roll_initialize(RT_MODEL_rtwdemo_roll_T *const rtwdemo_roll_M)
```

Because each call that you make to an entry-point function interacts with a separate real-time model data structure, you avoid unintentional interaction between the calls.

Eliminate Internal Data with Code Generation Optimizations

For more efficient code that consumes less memory, select the optimizations, such as **Default parameter behavior**, that you cleared earlier.

```
set_param('rtwdemo_roll','DefaultParameterBehavior','Inlined',...
    'OptimizeBlockIOStorage','on',...
    'LocalBlockOutputs','on')
```

In this example, for simpler code, set **Code interface packaging** to `Nonreusable function`.

```
set_param('rtwdemo_roll','CodeInterfacePackaging','Nonreusable function')
```

Generate code from the model.

```
rtwbuild('rtwdemo_roll')
```

```
### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Now, `rtwdemo_roll.h` does not define a structure for block inputs and outputs. For all of the internal signals in the model, the optimizations either eliminated storage or created local function variables instead of global structure fields.

The optimizations were not able to eliminate storage for the three block states, so the file continues to define the DWork structure type.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.h');
rtwdemodbtype(file,...
    '/* Block states (default storage) for system','} DW_rtwdemo_roll_T;',1,1)
```

```
/* Block states (default storage) for system '<Root>' */
typedef struct {
  real32_T FixPtUnitDelay1_DSTATE;     /* '<S7>/FixPt Unit Delay1' */
  real32_T Integrator_DSTATE;          /* '<S1>/Integrator' */
  int8_T Integrator_PrevResetState;    /* '<S1>/Integrator' */
} DW_rtwdemo_roll_T;
```

The code generated for the Discrete-Time Integrator block now stores state and output data only in the DWork structure.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Update for DiscreteIntegrator: ''<S1>/Integrator''',...
    '/* End of Update for DiscreteIntegrator: ''<S1>/Integrator'' */',1,1)
```

```
  /* Update for DiscreteIntegrator: '<S1>/Integrator' incorporates:
   *  Gain: '<S1>/IntGain'
   */
  rtwdemo_roll_DW.Integrator_DSTATE += 0.5F * rtb_TKSwitch * 0.025F;
  if (rtwdemo_roll_DW.Integrator_DSTATE >= 5.0F) {
    rtwdemo_roll_DW.Integrator_DSTATE = 5.0F;
```

```
} else {
  if (rtwdemo_roll_DW.Integrator_DSTATE <= -5.0F) {
    rtwdemo_roll_DW.Integrator_DSTATE = -5.0F;
  }
}

rtwdemo_roll_DW.Integrator_PrevResetState = (int8_T)rtb_NotEngaged_f;
```

The optimizations also eliminated storage for the block parameters in the model. For example, in the Discrete-Time Integrator block, the **Upper saturation limit** and **Lower saturation limit** parameters are set to `intLim` and `-intLim`. `intLim` is a `Simulink.Parameter` object that stores the value `5`. In the code generated for the Discrete-Time Integrator, these block parameters and `intLim` appear as inlined literal numbers `5.0F` and `-5.0F`.

If a model contains a parameter that the code generator cannot inline directly (for example, an array parameter), the code defines a structure type that represents the data. This *constant parameters* structure uses the `const` storage type qualifier, so some build toolchains can optimize the assembly code further.

Local Variables in the Generated Code

When you select the optimization **Configuration Parameters > Enable local block outputs**, the code generator attempts to yield more efficient code by representing internal signals as local variables instead of fields of a global structure. If the memory consumed by local variables risks exceeding the stack space available on your target hardware, consider indicating the maximum stack size by setting **Configuration Parameters > Maximum stack size (bytes)**. For more information, see “Maximum stack size (bytes)” (Simulink Coder).

Appearance of Test Points in the Generated Code

A *test point* is a signal that is stored in a unique memory location. For information about including test points in your model, see “Test Points” (Simulink).

When you generate code for models that include test points, the build process allocates a separate memory buffer for each test point. By default, test points are stored as members of a standard data structure such as *`model`*`_B`.

If you have Embedded Coder:

- You can control the default representation of test points by specifying code generation settings for the **Internal data** category of data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 31-8).
- You can specify that the build process ignore test points in the model, allowing optimal buffer allocation, by using the “Ignore test point signals” (Simulink Coder) parameter. Ignoring test points facilitates transitioning from prototyping to deployment and avoids accidental degradation of generated code due to workflow artifacts. See “Ignore test point signals” (Simulink Coder).

Virtual buses do not appear in generated code, even when associated with a test point. To display a bus in generated code, use a nonvirtual bus or a virtual bus converted to a nonvirtual bus by a Signal Conversion block.

Appearance of Workspace Variables in the Generated Code

Workspace variables are variables that you use to specify block parameter values in a model. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary.

When you set **Default parameter behavior** to `Tunable`, by default, workspace variables appear in the generated code as tunable fields of the global parameters structure. If you use such a variable to specify multiple block parameter values, the variable appears as a single field of the global parameters structure. The code does not create multiple fields to represent the block parameters. Therefore, tuning the field value during code execution changes the mathematical behavior of the model in the same way as tuning the value of the MATLAB variable or parameter object during simulation.

If you have Embedded Coder, you can control the default representation of workspace variables by specifying code generation settings for categories of parameter data in the Code Mapping Editor (see “Configure Default Code Generation for Data” on page 31-8).

- The **Local parameters** category applies to variables that you store in a model workspace.
- The **Global parameters** category applies to variables that you store in the base workspace or a data dictionary.

Promote Internal Data to the Interface

By default, the code generator assumes that other systems and components in your application do not need to access internal data. For example, internal data are subject to optimizations that can eliminate them from the generated code. For prototyping and testing purposes, you can access internal data by clearing the optimizations or by configuring test points and applying storage classes (see “Configure Data Accessibility for Rapid Prototyping” on page 32-3). For optimized production code, configure individual data items to appear in the generated code as part of the model interface.

Data That You Can Promote

Depending on the reentrancy of the generated code, that is, the setting that you choose for **Code interface packaging**, you can configure each data item in a model to participate in the interface by appearing in the code as one of these entities:

- A global symbol, such as a global variable or a call to a specialized function
- A formal parameter (argument) of the generated entry-point functions

The table shows the mechanisms that each category of data can use to participate in the interface.

Category of Data	Appear as Global Symbol	Appear as Argument of Entry-Point Function
Root-level Inport or Outport block	Only for a nonreentrant model.	Yes.
Signal connecting two blocks	Only for a nonreentrant model.	Only for a reentrant model and only as a field of a structure. Alternatively, connect the signal to a root-level Outport block.
Block state	Only for a nonreentrant model.	Only for a reentrant model and only as a field of a structure.

Category of Data	Appear as Global Symbol	Appear as Argument of Entry-Point Function
Data store such as a Data Store Memory block	Yes.	Only for a reentrant model and only as a field of a structure.
Block parameter or parameter object such as `Simulink.Parameter`	Yes.	Only as a field of a structure.

Single-Instance Algorithm

For a single-instance algorithm (you set **Code interface packaging** to `Nonreusable function`), apply storage classes directly to individual data items by using the Model Data Editor or the Property Inspector. With a directly applied storage class, a data item appears in the code as a global symbol such as a global variable. The storage class also prevents optimizations from eliminating storage for the data item.

You can apply storage classes to signals, block states, and block parameters. (For block parameters, you apply storage classes indirectly through parameter objects such as `Simulink.Parameter`). However, for a signal, consider connecting the signal to an Outport block at the root level of the model. Then, optionally, you can apply a storage class to the block. In the block diagram, the Outport block shows that the signal represents a system output.

For more information about storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.

Reentrant Algorithm

For a reentrant algorithm (you set **Code interface packaging** to `Reusable function`), use different techniques to configure data items to appear in the code as formal parameters (arguments) of the generated entry-point functions.

- For an internal signal, directly apply the storage class `Model default` (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81). If you have Embedded Coder, in the Code Mapping Editor, for the **Internal data** category, set the default storage class to `Default` or to a structured storage class that you define in an Embedded Coder Dictionary (see “Create Code Definitions for Use as Default Code Generation Settings” on page 30-2). Alternatively, configure the signal as a test point (see “Appearance of Test Points in the Generated Code” on

page 32-61). By default, the signal appears as a field of one of the standard data structures (see "How Generated Code Stores Internal Signal, State, and Parameter Data" on page 32-50). If you do not want the signal to appear in production code, use a test point so that you can later select the model configuration parameter **Ignore test point signals**.

Alternatively, connect the signal to an Outport block at the root level of the model. Connecting the signal to a root-level Outport block prevents optimizations from eliminating the signal from the code. To help with signal routing in a large model, use Goto and From blocks.

- For a block parameter, create a parameter object such as `Simulink.Parameter` and directly apply a storage class other than `Auto` to the object. The storage class prevents optimizations from inlining the parameter value in the code.

  With the storage class, the parameter is shared between instances of the model, which are calls to the entry-point functions. The functions access the parameter data directly, as a global symbol, not an argument. You cannot configure a parameter to appear in the code as an argument, so you cannot enable each instance of the model to use a different value for the parameter.

  For information about applying storage classes, see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder).

Control Default Representation of Internal Data (Embedded Coder)

By default, the code generator aggregates internal data that optimizations cannot eliminate, such as most state data, into standard structures such as the DWork structure. With Embedded Coder, you can control how the generated code stores this data.

Control Placement of Data in Memory by Inserting Pragmas

Use the Code Mapping Editor to specify a default memory section for each category of data such as states and signals (**Internal data**). In the generated code, your custom pragmas or other decorations surround the data definitions and declarations.

You can also partition the structures according to atomic subsystems in your model so that you can specify different default memory sections for the data of subroutines and other algorithmic subcomponents.

For more information, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2.

Control Names of Types, Fields, and Global Variables for Standard Data Structures

You can control some characteristics of the standard data structures. For more information, see “Control Characteristics of Data Structures (Embedded Coder)” (Simulink Coder).

For additional control over structure characteristics, such as placement in generated code files, create your own structured storage class by using the Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. The storage class removes the data from the standard structures, creating other structures that you can more finely control. For more information about applying default storage classes to categories of data, see “Configure Default Code Generation for Data” on page 31-8. For more information about creating a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2.

Organize Data into Structures According to Subcomponents

- In the standard data structures, to create substructures that contain the data for a single-instance (nonreentrant) subroutine or subcomponent, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set **Function packaging** to `Reusable function`. For more information, see “Generate Modular Function Code for Nonvirtual Subsystems” on page 39-64.

  Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `Multiple`. For more information, see “Code Generation of Referenced Models” on page 4-2.
- To create separate, standalone structures that contain the data for a multi-instance (reentrant) subroutine or subcomponent, in the model, use an atomic subsystem to encapsulate the corresponding blocks. In the subsystem parameters, set **Function packaging** to `Nonreusable function` and select **Function with separate data**. For more information, see “Generate Modular Function Code for Nonvirtual Subsystems” on page 39-64.

  Alternatively, encapsulate the blocks in a model and use a Model block. In the referenced model, choose one of these techniques:

- Set **Configuration Parameters > Model Referencing > Total number of instances allowed per top model** to `One`. For more information, see “Code Generation of Referenced Models” on page 4-2.
- Set **Total number of instances allowed per top model** to `Multiple` and create a structured storage class by using an Embedded Coder Dictionary. Then, apply the storage class to categories of data by using the Code Mapping Editor. To create a storage class, see “Define Storage Classes, Memory Sections, and Function Templates for Software Architecture” on page 30-2. To apply the storage class to categories of data, see “Configure Default Code Generation for Data” on page 31-8.

Organize Signal and Parameter Data into Meaningful, Custom Structures and Substructures

To organize arbitrary signals and parameters into custom structures and substructures, create nonvirtual bus signals and parameter structures. Optionally, to prevent optimizations from eliminating the data from the code, set the storage class of a bus signal or parameter structure to a value other than `Auto` (the default setting).

As you add blocks to the model, you must explicitly place each new signal and parameter into a bus or a structure.

For more information, see “Organize Data into Structures in Generated Code” on page 32-181.

Create Separate Global Variables Instead of Structure Fields

To make a category of internal data appear in the generated code as separate, unstructured global variables instead of fields of a standard data structure, apply an unstructured storage class to the data category by using the Code Mapping Editor. For example, apply the storage class `ExportedGlobal`. However, if you generate multi-instance, reentrant code by setting the configuration parameter **Code interface packaging** to a value other than `Nonreusable function`, you cannot use this technique for some categories of data (see “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder)).

To apply default storage classes to categories of data by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 31-8. To choose a storage class, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).

Choose Storage Class for Controlling Data Representation in Generated Code

A storage class is a code generation setting that you apply to model data, such as signals, block parameters, and states. Use storage classes to control the appearance of data elements in the generated code.

The table shows built-in storage classes that you can choose. These storage classes come with Simulink Coder.

Storage Class Name	Description
`Auto`	`Auto` is the default storage class setting for each data element in a model. The data element is subject to code generation optimizations, which can eliminate the element from the code or change the representation of the element. For information about these optimizations, such as those on the **Configuration Parameters > Code Generation > Optimization** pane, see "How Generated Code Stores Internal Signal, State, and Parameter Data" (Simulink Coder). Optimizations cannot eliminate some data, such as most block states, from the code. This remaining data acquire a default storage class that you specify with the Code Mapping Editor (see "Configure Default Code Generation for Data" on page 31-8—requires Embedded Coder). If you leave the storage class setting in the Code Mapping Editor at the default value, `Default`, the data element appears as a field of a standard data structure (see "How Generated Code Stores Internal Signal, State, and Parameter Data" on page 32-50). If optimizations cannot eliminate the data element, the name of the element in the code is based on naming rules that you specify with model configuration parameters (see "Identifier Format Control" on page 50-24—requires Embedded Coder). Use this storage class to enable optimizations to operate on the data

Storage Class Name	Description
	element, potentially generating more efficient code.
`Model default`	The data element acquires the corresponding default storage class that you specify with the Code Mapping Editor. The name of the data element in the code is the same as the name in the model. Use this storage class to prevent optimizations from eliminating storage for a data element (see “How Generated Code Stores Internal Signal, State, and Parameter Data” (Simulink Coder)).
`ExportedGlobal`	Generate a global variable definition and declaration. The name of the variable is the name of the data element. The code declares the variable in the generated file *`model`*`.h`, which you can include (`#include`) in your external code.
`ImportedExtern`	Generate code that reads from and writes to a global variable defined by your external code. The generated code declares the variable in the generated file *`model`*`_private.h` so that the model entry-point functions can read and write to the variable. Use this storage class to make a data element in a model represent a global variable that your external code defines. The generated algorithmic code uses the variable without defining it.

Storage Class Name	Description
`ImportedExternPointer`	Generate code that reads from and writes to a global pointer variable defined by your external code. The generated code declares the variable in the generated file *`model`*`_private.h` and reads and writes to the data by dereferencing the pointer. Use this storage class when your external code defines a data element and provides a pointer for accessing that data.

If you have Embedded Coder, you can choose additional built-in storage classes, shown in the next table.

Storage Class Name	Description	Use for Signal or State Data	Use for Parameter Data
`BitField`	Generate a structure that stores Boolean data in named bit fields. For an example, see “Bitfields” on page 24-87. You cannot use this storage class in the Code Mapping Editor.	Yes	Yes

Storage Class Name	Description	Use for Signal or State Data	Use for Parameter Data
`CompilerFlag`	Supports preprocessor conditionals defined via compiler flag or option. See "Generate Preprocessor Conditionals for Variant Systems" on page 25-35. If you build the generated code by using Embedded Coder (you clear **Configuration Parameters > Generate code only**), to specify the compiler option, you can use the model configuration parameter **Configuration Parameters > Code Generation > Custom Code > Additional build information > Defines**. See Code Generation Pane: Custom Code: Additional Build Information: Defines (Simulink Coder).	No	Yes
`Const`	Generate a global variable definition and declaration with the `const` type qualifier.	No	Yes
`ConstVolatile`	Generate a global variable definition and declaration with the `const` and `volatile` type qualifiers. For an example, see "Type Qualifiers" on page 24-15.	No	Yes
`Define`	Generate a macro (`#define` directive) such as `#define myParam 5`. For an example, see "Macro Definitions (#define)" on page 24-69.	No	Yes
`ExportToFile`	Generate a global variable definition and declaration. You can specify the names of the files that define and declare the variable.	Yes	Yes

Storage Class Name	Description	Use for Signal or State Data	Use for Parameter Data
`FileScope`	Generate a global variable definition and declaration with the `static` type qualifier. In the generated code, the scope of the variable is limited to the current file, which is typically *`model`*`.c`. In a model reference hierarchy, if a referenced model uses a parameter object (such as `Simulink.Parameter`) that you create in the base workspace or a data dictionary, you cannot apply `FileScope` to the object. As a workaround, move the parameter object into the model workspace of the referenced model. Then, you can use `FileScope`.	Yes	Yes
`GetSet`	Generate code that interacts with data by calling your custom accessor functions. Your external code defines the data and provides the function definitions. For examples, see “Access Data Through Functions with Custom Storage Class GetSet” on page 36-51.	Yes	Yes
`ImportedDefine`	Generate code that uses a macro (`#define` directive) defined in a header file in your external code. For an example, see “Macro Definitions (#define)” on page 24-69.	No	Yes
`ImportFromFile`	Generate code that reads from and writes to a global variable defined by your external code. Similar to `ExportToFile`, but the generated code does not define the variable.	Yes	Yes

Storage Class Name	Description	Use for Signal or State Data	Use for Parameter Data
`Reusable`	Generate more efficient code that stores intermediate calculations of a data path (a series of connected blocks) in a single, reused global variable. For an example, see "Specify Buffer Reuse by Using Simulink.Signal Objects" on page 69-19. You can apply this storage class only to a `Simulink.Signal` object that represents multiple signal lines in a model.	Yes	No
`Struct`	Generate a global structure whose name you can specify. For examples, see "Organize Parameter Data into a Structure by Using the Struct Custom Storage Class" on page 36-32 and "Structures of Signals" on page 24-79. You cannot use this storage class in the Code Mapping Editor.	Yes	Yes
`Volatile`	Generate a global variable definition and declaration with the `volatile` type qualifier.	Yes	Yes
`Localizable`	For signals, if possible, generate variables that are local to functions rather than in global storage. Generating local variables prevents the code generator from implementing optimizations that remove the variables from the generated code. For an example, see "Generate Local Variables with Localizable Custom Storage Class" on page 36-109.	Yes (signals not states)	No

These storage classes are examples of storage classes that you can add to an Embedded Coder Dictionary. These examples are defined and made available when you prepare a model for code generation with the Quick Start tool.

Storage Class Name	Description	Use for Signal or State Data	Use for Parameter Data
`ParamStruct`	Generate global structures that contain parameter data. In a hierarchy of components (referenced models or atomic subsystems), you can use this example storage class to create a corresponding hierarchy of parameter structures. This storage class appears only in the Code Mapping Editor for data category **Local parameters** after preparing a model for code generation with the Quick Start tool.	No	Yes
`SignalStruct`	Generate global structures that contain signal or state data. In a hierarchy of components (referenced models or atomic subsystems), you can use this example storage class to create a corresponding hierarchy of signal and state structures. This storage class appears only in the Code Mapping Editor after preparing a model for code generation with the Quick Start tool.	Yes	No

When you generate reentrant, multi-instance code, limitations and restrictions apply if you want to use storage classes. See “Use Storage Classes in Reentrant, Multi-Instance Models and Components” (Simulink Coder).

Specify File Names and Other Data Attributes With Storage Class (Embedded Coder)

After you apply some storage classes, such as `ExportToFile`, you can specify additional settings such as declaration (header) and definition file names. In the Code Mapping Editor, to access these additional settings, you use the Property Inspector.

With other storage classes, you cannot specify additional settings.

- These built-in Simulink Coder storage classes do not allow you to specify additional settings:
  - `ExportedGlobal`
  - `ImportedExtern`
  - `ImportedExternPointer`
- The built-in Embedded Coder storage classes typically allow you to specify declaration and definition file names.
- For the `ExportToFile` storage class, the definition file setting is honored only for single-instance models. The setting is ignored for reusable multi-instance models because the data definition is handled at the parent level.
- When you create a storage class with the Custom Storage Class Designer, you can choose whether the user of the storage class can specify additional settings. See “Allow Users of Custom Storage Class to Specify Property Value” on page 36-41.

Specify Default #include Syntax for Header Files That Declare Data (Embedded Coder)

To control the file placement of a data item, such as a signal line or block state, in the generated code, you can apply a storage class to the data item (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28). You then use the **Header file** custom attribute to specify the generated or external header file that contains the declaration of the data.

To reduce maintenance effort and data entry, when you specify **Header file**, you can omit delimiters (" or <>) and use only the file name. You can then control the default delimiters that the generated code uses for the corresponding `#include` directives. To use angle brackets by default, set **Configuration Parameters** > **Code Generation** > **Code Placement** > **#include file delimiters** to `#include <header.h>`.

Storage Class Limitations

- When you use storage classes in the Code Mapping Editor (Embedded Coder), some limitations apply. See “Limitations” on page 31-33.
- Data objects cannot use an Embedded Coder storage class and a multiword data type.

- The Fcn block does not support parameters with an Embedded Coder storage class in code generation.
- For Embedded Coder storage classes in models that use referenced models:
  - If you apply a grouped storage class to multiple data items, the storage class **Data scope** property must be set to `Imported` and you must provide the data declaration in an external header file. Grouped storage classes use a single variable in the generated code to represent multiple data objects. For example, the storage classes `BitField` and `Struct` are grouped storage classes.
  - If a parameter object exists in the base workspace or a data dictionary, and a referenced model uses the object, you cannot apply the storage class `FileScope`. As a workaround, move the object into the model workspace of the referenced model. Then, you can use `FileScope`.
- You cannot apply the storage class `FileScope` to data items used by a data exchange interface (C API, external mode, or ASAP2) or MAT-file logging. File-scoped data is not externally accessible.

Use Storage Classes in Reentrant, Multi-Instance Models and Components

The code that you generate from a model or component (referenced model or subsystem) is multi-instance code if it allows your application to maintain multiple independent instances of the component during execution. For example, you can generate reentrant, multi-instance code from an entire model by setting the model configuration parameter **Code interface packaging** to `Reusable function`. For general information about multi-instance models and components, see "Code Reuse" (Simulink Coder).

Under some circumstances, applying storage classes can:

- Prevent you from generating multi-instance code.
- Cause some data elements to appear in the generated code as singletons, which means that each instance of the model or component directly accesses the same shared, global data, creating dependencies between the instances.

To avoid errors and unexpected generation of single-instance code and singleton data, observe the guidelines and limitations below.

Directly Applied Storage Classes

When you apply a storage class directly to a data element (see "Apply Storage Classes to Individual Signal, State, and Parameter Data Elements" (Simulink Coder)):

- To generate multi-instance code, you must apply the storage class only to parameter objects, global data stores, shared local data stores, and root-level I/O.
- The storage class yields only singleton data.

Storage Classes Applied by Default

When you apply a default storage class by using the Code Mapping Editor (see "Configure Default Code Generation for Data" on page 31-8—requires Embedded Coder):

- For these data categories, you can generate only singleton data:
  - **Local parameters**
  - **Global parameters**

  - **Global data stores**
  - **Shared local data stores**
- For **Internal data**, you can generate only instance-specific data, which means each instance of the model or component operates on a separate copy of the data. For this category, you must use the example storage class `SignalStruct`, which appears after preparing a model for code generation with the Quick Start tool. Alternatively, you can create and use your own structured storage class by using an Embedded Coder Dictionary.

Apply Storage Classes to Individual Signal, State, and Parameter Data Elements

A storage class is a code generation setting that you apply to a data item (signal, block parameter, or state) in a model. When you directly apply it to a data item, a storage class:

- Causes the data item to appear in the generated code as a global symbol, typically a global variable.
- Prevents optimizations such as **Default parameter behavior** and **Signal storage reuse** from eliminating the data item from the generated code.
- With Embedded Coder, you can configure the format in which the generated code stores or otherwise defines the data item. For example, you can apply the storage type qualifiers `const` or `volatile` or configure a parameter data item to appear as a macro (`#define`).

Directly apply storage classes to individual data items to:

- Tune parameters and monitor signals and states during execution.
- Configure data placement in memory through memory sections.
- Generate code that exchanges data (for example, global variables) with your external code.

For information about applying storage classes to categories of data by default, by using the Code Mapping Editor, see “Configure Default Code Generation for Data” on page 31-8.

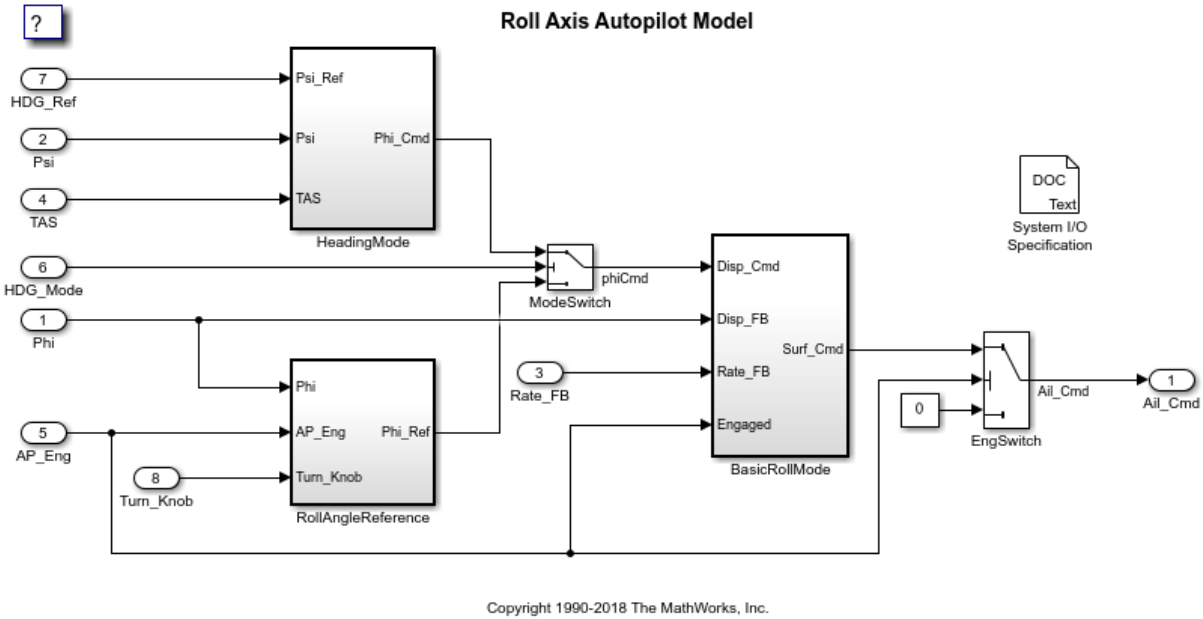
Apply Storage Classes to Data Items

This example shows how to apply storage classes to a signal, a block state, and a block parameter in a model.

Explore Example Model

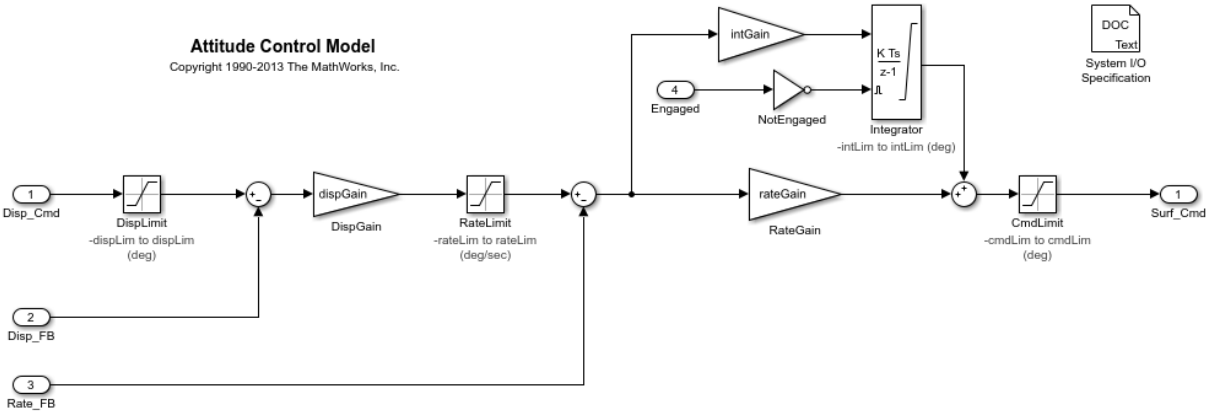
Open the example model `rtwdemo_roll`.

```
open_system('rtwdemo_roll')
```



Navigate into the `BasicRollMode` subsystem.

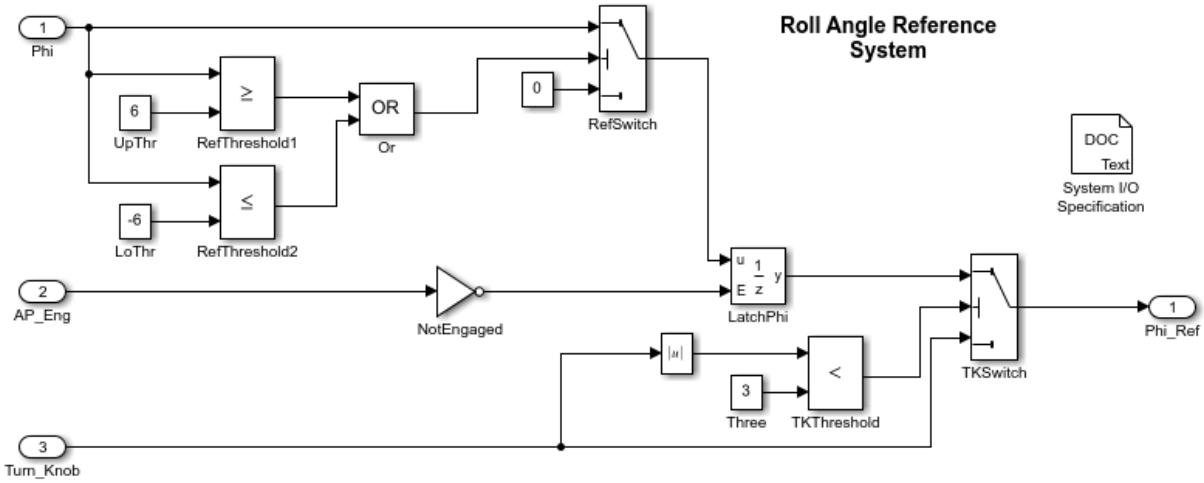
```
open_system('rtwdemo_roll/BasicRollMode')
```



The subsystem contains an Integrator block, which maintains a piece of state data.

From the root level of the model, navigate into the `RollAngleReference` subsystem.

```
open_system('rtwdemo_roll/RollAngleReference')
```



The subsystem contains a Constant block labeled UpThr.

In this example, you configure the state and output signal of the Integrator block and the **Constant value** parameter of the Constant block to appear in the generated code as separate global variables.

Apply Storage Classes

1. Navigate to the root level of the model.
2. Select **View > Model Data Editor**.
3. To see the data items in the subsystems, activate the **Change scope** button.
4. Select the **Signals** tab.
5. Set the **Change view** drop-down list to `Code`.
6. In the **Filter contents** box, enter `integrator`.
7. Optionally, use the **Name** column to specify a name for the output signal of the Integrator block, such as `mySignal`.
8. Use the **Storage Class** column to apply the storage class `ExportedGlobal`.

9. Select the **States** tab.
10. Optionally, use the **Name** column to specify a name for the state, such as `myState`.
11. Use the **Storage Class** column to apply the storage class `ExportedGlobal`.
12. Select the **Parameters** tab. You cannot apply a storage class directly to a block parameter. Instead, you must create a parameter object, such as `Simulink.Parameter`, use the object to set the value of the block parameter, and apply the storage class to the object.
13. Set the **Change view** drop-down list to `Design`.
14. In the **Filter contents** box, enter `UpThr`.
15. Use the **Value** column to change the parameter value from `6` to `UpThr`.
16. While editing the parameter value, next to `UpThr`, click the action button (with three vertical dots) and select **Create**.
17. In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter` and click **OK**. A `Simulink.Parameter` object named `UpThr` appears in the base workspace.
18. In the `UpThr` property dialog box, set **Value** to `6` and **Storage class** to `ExportedGlobal`. Click **OK**.

Alternatively, you can use these commands at the command prompt to configure the signal, state, and parameter data.

```
% Configure signal
portHandles = get_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'PortHandles');
outportHandle = portHandles.Outport;
set_param(outportHandle,'Name','mySignal')
set_param(outportHandle,'StorageClass','ExportedGlobal')

% Configure state
set_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'StateName','myState')
set_param('rtwdemo_roll/BasicRollMode/Integrator',...
    'StateStorageClass','ExportedGlobal')

% Configure parameter
set_param('rtwdemo_roll/RollAngleReference/UpThr','Value','UpThr')
UpThr = Simulink.Parameter(6);
UpThr.StorageClass = 'ExportedGlobal';
```

Generate and Inspect Code

Generate code from the model.

```
set_param('rtwdemo_roll','SystemTargetFile','grt.tlc')
rtwbuild('rtwdemo_roll')
```

```
### Starting build procedure for model: rtwdemo_roll
### Successful completion of build procedure for model: rtwdemo_roll
```

Inspect the file `rtwdemo_roll.c`. The file defines the global variables.

```
file = fullfile('rtwdemo_roll_grt_rtw','rtwdemo_roll.c');
rtwdemodbtype(file,'/* Exported block signals */','real32_T myState;',1,1)
```

```
/* Exported block signals */
real32_T mySignal;                     /* '<S1>/Integrator' */

/* Exported block parameters */
real32_T UpThr = 6.0F;                 /* Variable: UpThr
                                        * Referenced by: '<S3>/UpThr'
                                        */

/* Exported block states */
real32_T myState;                      /* '<S1>/Integrator' */
```

The file `rtwdemo_roll.h` declares the variables. To access these variables, your external code can include (`#include`) this header file.

In `rtwdemo_roll.c`, search the file for the names of the variables, such as `UpThr`. The model algorithm in the `rtwdemo_roll_step` function reads and writes to the variables.

Built-In Storage Classes You Can Choose

The default storage class setting for a data item is `Auto`, which means the code generator determines how the item appears in the code. For a list of built-in storage classes that you can choose, see “Choose Storage Class for Controlling Data Representation in Generated Code” (Simulink Coder).

Decide Where to Store Storage Class Specification

For each individual signal or state data item (including Data Store Memory blocks) to which you directly apply a storage class, Simulinkstores your storage class specification

either in the model file or in the properties of a signal data object (`Simulink.Signal`), which you create in the base workspace, a model workspace, or a data dictionary. To apply a storage class to a block parameter, you must create a parameter data object (such as `Simulink.Parameter`) and specify the storage class in the object.

- When you apply a storage class to a signal or state in a model, for example, by using the Model Data Editor or the Property Inspector, you store the storage class specification in the model file.

  If you use this technique, you cannot control other characteristics of the data item, such as data type, by using an external signal data object.

- When you create a signal or parameter data object, you apply the storage class by using the `CoderInfo` property of the object. The value of the property is a `Simulink.CoderInfo` object, whose `StorageClass` property you use to specify the storage class. After you associate the data item in the model with the object, the data item acquires the storage class from the object.

For signals, states, and Data Store Memory blocks, to decide whether to store the storage class specification in the model or in a data object, see "Store Design Attributes of Signals and States" (Simulink).

Apply Storage Classes to Outport Blocks by Using the Model Data Editor

You can use the Model Data Editor to apply a storage class directly to a root-level Outport block or to the input signal that drives the block.

- To store the storage class specification in the Outport block, use the **Inports/Outports** tab in the Model Data Editor. When you use this technique, the specification remains after you delete the input signal that drives the block. Use this technique to configure the model interface before you develop the internal algorithm.
- To store the specification in the input signal that drives the block, use the **Signals** tab in the Model Data Editor.

Techniques to Apply Storage Classes Interactively

To apply storage classes to multiple data items in a list that you can search, sort, and filter, use the Model Data Editor (**View > Model Data Editor**) as shown in "Apply Storage Classes to Data Items" on page 32-81.

To apply a storage class while focusing on a single signal, block state, or parameter, use the Property Inspector (**View > Property Inspector**), the Signal Properties dialog box

(for a signal), or the block dialog box (for a state or parameter). Under **Code Generation**, apply the storage class.

- For a parameter, first set the value of the parameter to the name that you want to use for the required parameter object. Then, create and configure the parameter object as shown in “Create Tunable Calibration Parameter in the Generated Code” on page 32-121.
- For a signal, state, or Data Store Memory block, first give the signal or state a name, which the code generator uses as the name of the corresponding global symbol. Then, either specify a storage class using **Storage class** (in which case the model file stores the specification) or create a signal data object as shown in “Use Data Objects in Simulink Models” (Simulink) and apply a storage class to the object.

Techniques to Apply Storage Classes Programmatically

- For a block parameter, use `set_param` to set the value of the parameter. Use other commands to create and configure the properties of the required parameter object. For an example, see “Create Tunable Calibration Parameter in the Generated Code” on page 32-121.
- For a signal, use `get_param` or `find_system` to return a handle to the block port that generates the signal. Use the parameters of the handle to name the signal, then apply the storage class directly (see “Apply Storage Class Directly to Signal Line” (Simulink Coder)) or configure the signal to acquire settings, including the storage class, from a signal object (see “Use Data Objects in Simulink Models” (Simulink)).
- For an Inport block, configure the signal line that exits the block. For an Outport block, configure the block or the signal line that enters the block. For an example, see “Design Data Interface by Configuring Inport and Outport Blocks” on page 32-210.
- For a block state, use `set_param` to interact with the block. Name the state, then apply the storage class directly (see “Apply Storage Class Directly to Block State” (Simulink Coder)) or configure the state to acquire the storage class from a signal object (see “Use Data Objects in Simulink Models” (Simulink)).
- For a Data Store Memory block, use `set_param` to interact with the block. Because the data store already has a name, you do not need to specify a name. Apply the storage class directly by using the `StateStorageClass` parameter or configure the data store to acquire the storage class from a signal object.

To interact with a signal or parameter data object that you store in a model workspace or data dictionary, use the programmatic interface of the workspace or dictionary. See “Interact With Variables Programmatically” (Simulink).

Apply Storage Class Directly to Signal Line

This example shows how to programmatically apply a storage class directly to a signal line.

1. Open the example model `rtwdemo_secondOrderSystem`.

   ```
   rtwdemo_secondOrderSystem
   ```

2. Get a handle to the output of the block named Force: f(t).

   ```
   portHandles = ...
        get_param('rtwdemo_secondOrderSystem/Force: f(t)','PortHandles');
   outportHandle = portHandles.Outport;
   ```

3. Set the name of the corresponding signal to `ForceSignal`.

   ```
   set_param(outportHandle,'Name','ForceSignal')
   ```

4. Set the storage class of the signal to `ExportedGlobal`.

   ```
   set_param(outportHandle,'StorageClass','ExportedGlobal')
   ```

5. Generate code from the model. The code declares and defines a global variable `ForceSignal` to represent the signal.

Apply Storage Class Directly to Block State

This example shows how to programmatically apply a storage class to a block state.

1. Open the example model `rtwdemo_basicsc`.

   ```
   rtwdemo_basicsc
   ```

2. Name the state of the Delay block as `myState`.

   ```
   set_param('rtwdemo_basicsc/Delay','StateName','myState')
   ```

3. Set the storage class of the state to `ExportedGlobal`.

   ```
   set_param('rtwdemo_basicsc/Delay',...
       'StateStorageClass','ExportedGlobal')
   ```

4. Generate code from the model. The code declares and defines a global variable `myState` to represent the state.

Parameter Object Configuration Quick Reference Diagram

This diagram shows the code generation and storage class options that control the representation of parameter objects in the generated code.

Use Enumerated Data in Generated Code

In this section...

Enumerated Data Types

Enumerated data is data that is restricted to a finite set of values. An *enumerated data type* is a MATLAB class that defines a set of *enumerated values*. Each enumerated value consists of an *enumerated name* and an *underlying integer* which the software uses internally and in generated code. The following is a MATLAB class definition for an enumerated data type named `BasicColors`, which is used in the examples in this section.

```
classdef BasicColors < Simulink.IntEnumType
  enumeration
    Red(0)
    Yellow(1)
    Blue(2)
  end
end
```

For basic information about enumerated data types and their use in Simulink models, see “Use Enumerated Data in Simulink Models” (Simulink). For information about enumerated data types in Stateflow charts, see “Define Enumerated Data Types” (Stateflow).

Specify Integer Data Type for Enumeration

When you specify a data type for your enumeration, you can:

- Control the size of enumerated data types in the generated code by specifying a superclass.

- Reduce RAM/ROM usage.
- Improve code portability.
- Improve integration with legacy code.

You can specify these integer data types:

- `int8`
- `uint8`
- `int16`
- `uint16`
- `int32`
- `Simulink.IntEnumType`. Specify values in the range of the signed integer for your hardware platform.

Use a Class Definition in a MATLAB File

To specify an integer data type size, derive your enumeration class from the integer data type.

```
classdef Colors < int8
   enumeration
     Red(0)
     Green(1)
     Blue(2)
   end
end
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red      ((Colors)0)
#define Green ((Colors)1)
#define Blue     ((Colors)2)
```

Use the Function Simulink.defineIntEnumType

To specify an integer data type size, specify the name-value pair `StorageType` as the integer data type.

```
Simulink.defineIntEnumType('Colors',{'Red','Green','Blue'},...
[0;1;2],'StorageType','int8')
```

The code generator generates this code:

```
typedef int8_T Colors;

#define Red      ((Colors)0)
#define Green ((Colors)1)
#define Blue     ((Colors)2)
```

Customize Enumerated Data Type

When you generate code from a model that uses enumerated data, you can implement these static methods to customize the behavior of the type during simulation and in generated code:

- `getDefaultValue` — Specifies the default value of the enumerated data type.
- `getDescription` — Specifies a description of the enumerated data type.
- `getHeaderFile` — Specifies a header file where the type is defined for generated code.
- `getDataScope` — Specifies whether generated code exports or imports the enumerated data type definition to or from a separate header file.
- `addClassNameToEnumNames` — Specifies whether the class name becomes a prefix in generated code.

The first of these methods, `getDefaultValue`, is relevant to both simulation and code generation, and is described in “Specify a Default Enumerated Value” (Simulink). The other methods are relevant only to code generation. To customize the behavior of an enumerated type, include a version of the method in the `methods(Static)` section of the enumeration class definition. If you do not want to customize the type, omit the `methods(Static)` section. The table summarizes the methods and the data to supply for each one.

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value
`getDefaultValue`	Specifies the default enumeration member for the class.	First member specified in the enumeration definition	A character vector containing the name of an enumeration member in the class (see “Instantiate Enumerations” (Simulink)).
`getDescription`	Specifies a description of the enumeration class.	`''`	A character vector containing the description of the type.
`getHeaderFile`	Specifies the name of a header file. The method `getDataScope` determines the significance of the file.	`''`	A character vector containing the name of the header file that defines the enumerated type. By default, the generated `#include` directive uses the preprocessor delimiter `"` instead of `<` and `>`. To generate the directive `#include <myTypes.h>`, specify the custom return value as `'<myTypes.h>'`.

Static Method	Purpose	Default Value Without Implementing Method	Custom Return Value
`getDataScope`	Specifies whether generated code exports or imports the definition of the enumerated data type. Use the method `getHeaderFile` to specify the generated or included header file that defines the type.	`'Auto'`	One of: `'Auto'`, `'Exported'`, or `'Imported'`.
`addClassNameToEnumNames`	Specifies whether to prefix the class name in generated code.	`false`	`true` or `false`.

Specify a Description

To specify a description for an enumerated data type, include this method in the `methods(Static)` section of the enumeration class:

```
function retVal = getDescription()
% GETDESCRIPTION  Optional description of the data type.
  retVal = 'description';
end
```

Substitute a MATLAB character vector for *`description`*. The generated code that defines the enumerated type includes the specified description.

Import Type Definition in Generated Code

To prevent generated code from defining an enumerated data type, which allows you to provide the definition in an external file, include these methods in the `methods(Static)` section of the enumeration class:

```
function retVal = getHeaderFile()
  % GETHEADERFILE Specifies the file that defines this type in generated code.
  % The method getDataScope determines the significance of the specified file.
  retVal = 'imported_enum_type.h';
end
```

```
function retVal = getDataScope()
  % GETDATASCOPE Specifies whether generated code imports or exports this type.
  % Return one of:
  % 'Auto':     define type in model_types.h, or import if header file specified
  % 'Exported': define type in a generated header file
  % 'Imported': import type definition from specified header file
  % If you do not define this method, DataScope is 'Auto' by default.
  retVal = 'Imported';
end
```

Instead of defining the type in *`model`*`_types.h`, which is the default behavior, generated code imports the definition from the specified header file using a `#include` statement like:

```
#include "imported_enum_type.h"
```

Generating code does not create the imported header file. You must provide the header file, using the file name specified by the method `getHeaderFile`, that defines the enumerated data type.

To create a Simulink enumeration that corresponds to your existing C-code enumeration, use the `Simulink.importExternalCTypes` function.

Export Type Definition in Generated Code

To generate a separate header file that defines an enumerated data type, include these methods in the `methods(Static)` section of the enumeration class:

```
function retVal = getDataScope()
  % GETDATASCOPE Specifies whether generated code imports or exports this type.
  % Return one of:
  % 'Auto':     define type in model_types.h, or import if header file specified
  % 'Exported': define type in a generated header file
  % 'Imported': import type definition from specified header file
  % If you do not define this method, DataScope is 'Auto' by default.
  retVal = 'Exported';
end

function retVal = getHeaderFile()
  % GETHEADERFILE Specifies the file that defines this type in generated code.
  % The method getDataScope determines the significance of the specified file.
  retVal = 'exported_enum_type.h';
end
```

Generated code exports the enumerated type definition to the generated header file `exported_enum_type.h`.

Add Prefixes To Class Names

By default, enumerated values in generated code have the same names that they have in the enumeration class definition. Alternatively, your code can prefix every enumerated value in an enumeration class with the name of the class. You can use this technique to prevent identifier conflicts or to improve the readability of the code. To specify class name prefixing, include this method in the `methods(Static)` section of an enumeration class:

```
function retVal = addClassNameToEnumNames()
  % ADDCLASSNAMETOENUMNAMES Specifies whether to add the class name
  % as a prefix to enumeration member names in generated code.
  % Return true or false.
  % If you do not define this method, no prefix is added.
  retVal = true;
end
```

Specify the return value as `true` to enable class name prefixing or as `false` to suppress prefixing. If you specify `true`, each enumerated value in the class appears in generated code as *`EnumTypeName_EnumName`*. For the example enumeration class `BasicColors` in “Enumerated Data Types” on page 32-90, the data type definition in generated code might look like this:

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
  BasicColors_Red = 0,            /* Default value */
  BasicColors_Yellow = 1,
  BasicColors_Blue = 2,
} BasicColors;

#endif
```

The enumeration class name `BasicColors` appears as a prefix for each of the enumerated names.

Control Enumerated Type Implementation in Generated Code

Suppose that you define an enumerated type `BasicColors`. You can specify that the generated code implement the type definition using:

- An `enum` block. The native integer type of your hardware is the underlying integer type for the enumeration members.
- A `typedef` statement and a series of `#define` macros. The `typedef` statement bases the enumerated type name on a specific integer data type, such as `int8`. The macros associate the enumeration members with the underlying integer values.

Implement Enumerated Type Using enum Block

To implement the type definition using an `enum` block:

- In Simulink, define the enumerated type using a `classdef` block in a script file. Derive the enumeration from the type `Simulink.IntEnumType`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Do not specify the property `StorageType`.

When you generate code, the type definition appears in an `enum` block.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef enum {
  Red = 0,            /* Default value */
  Yellow,
  Blue,
} BasicColors;

#endif
```

Implement Enumerated Type Using a Specific Integer Type

To implement the type definition using a `typedef` statement and `#define` macros:

- In Simulink, define the enumerated type using a `classdef` block in a script file. Derive the enumeration from a specific integer type such as `int8`.
- Alternatively, use the function `Simulink.defineIntEnumType`. Specify the property `StorageType` using a specific integer type such as `int8`.

When you generate code, the type definition appears as a `typedef` statement and a series of `#define` macros.

```
#ifndef _DEFINED_TYPEDEF_FOR_BasicColors_
#define _DEFINED_TYPEDEF_FOR_BasicColors_

typedef int8_T BasicColors;

#define Red ((BasicColors)0)            /* Default value */
#define Yellow ((BasicColors)1)
#define Blue ((BasicColors)2)
```

```
#endif
```

By default, the generated file *model*`_types.h` contains enumerated type definitions.

Type Casting for Enumerations

Safe Casting

A Simulink Data Type Conversion block accepts a signal of integer type. The block converts the input to one of the underlying values of an enumerated type.

If the input value does not match an underlying value of an enumerated type value, Simulink inserts a safe cast to replace the input value with the enumerated type default value.

Enable and Disable Safe Casting

You can enable or disable safe casting for enumerations during code generation for a Simulink Data Type Conversion block or a Stateflow block.

To control safe casting, enable or disable the **Saturate on integer overflow** block parameter. The parameter works as follows:

- **Enabled:** Simulink replaces a nonmatching input value with the default value of the enumerated values during simulation. The software generates a safe cast function during code generation.
- **Disabled:** For a nonmatching input value, Simulink generates an error during simulation. The software omits the safe cast function during code generation. In this case, the code is more efficient. However, the code may be more vulnerable to run-time errors.

Safe Cast Function in Generated Code

This example shows how the safe cast function `int32_T ET08_safe_cast_to_BasicColors` for the enumeration `BasicColors` appears in generated code when generated for 32-bit hardware.

```
static int32_T ET08_safe_cast_to_BasicColors(int32_T input)
{
    int32_T output;
    /* Initialize output value to default value for BasicColors (Red) */
```

```
    output = 0;
    if ((input >= 0) && (input <= 2)) {
    /* Set output value to input value if it is a member of BasicColors */
        output = input;
    }
    return output;
}
```

Through this function, the enumerated type's default value is used if the input value does not match one of underlying values of the enumerated type's values.

If the block's **Saturate on integer overflow** parameter is disabled, this function does not appear in generated code.

Enumerated Type Limitations

- Generated code does not support logging enumerated data.

Data Stores in Generated Code

In this section...

About Data Stores

A data store contains data that is accessible in a model hierarchy at or below the level in which the data store is defined. Data stores can allow subsystems and referenced models to share data without having to use I/O ports to pass the data from level to level. See “Data Stores with Data Store Memory Blocks” (Simulink) for information about data stores in Simulink. This section provides additional information about data store code generation.

Generate Code for Data Store Memory Blocks

To control the code generated for a Data Store Memory block, apply a storage class to the data store. You can associate a Data Store Memory block with a signal object that you store in a workspace or data dictionary, and control code generation for the block by applying the storage class to the object:

1. In the model, select **View > Model Data Editor**.
2. In the Model Data Editor, select the **Data Stores** tab.
3. Begin editing the name of the target Data Store Memory block by clicking the corresponding row in the **Name** column.
4. Next to the name, click the button ⋮ and select **Create and Resolve**.
5. In the Create New Data dialog box, set **Value** to `Simulink.Signal`. Optionally, use the **Location** drop-down list to choose a workspace for storing the resulting `Simulink.Signal` object.

6 Click **Create**. The `Simulink.Signal` object, which has the same name as the data store, appears in the target workspace. Simulink selects the block parameter **Data store name must resolve to Simulink signal object**.

   The property dialog box for the object opens.

7 Use the **Storage class** drop-down list to apply the target storage class.

Note When a Data Store Memory block is associated with a signal object, the mapping between the **Data store name** and the signal object name must be one-to-one. If two or more identically named entities map to the same signal object, the name conflict is flagged as an error at code generation time. See “Resolve Conflicts in Configuration of Signal Objects for Code Generation” (Simulink) for more information.

Storage Classes for Data Store Memory Blocks

You can control how Data Store Memory blocks in your model are stored and represented in the generated code by assigning storage classes and type qualifiers. You do this in almost exactly the same way you assign storage classes and type qualifiers for block states.

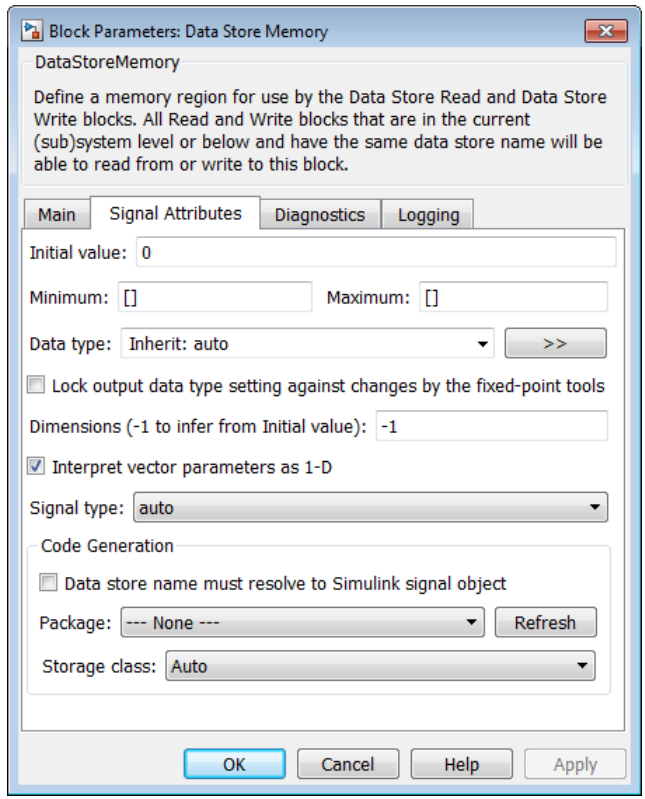
Data Store Memory blocks, like block states, have `Auto` storage class by default, and their memory is stored within the `DWork` vector. The symbolic name of the storage location is based on the data store name.

You can generate code from multiple Data Store Memory blocks that have the same data store name, subject to the following restriction: *at most one* of the identically named blocks can have a storage class other than `Auto`. An error is reported if this condition is not met.

For blocks with `Auto` storage class, the code generator produces a unique symbolic name for each block to avoid name clashes. For Data Store Memory blocks with storage classes other than `Auto`, the generated code uses the data store name as the symbol.

In the following model, a Data Store Write block writes to memory declared by the Data Store Memory block `myData`:

To control the storage declaration for a Data Store Memory block, use the **Code Generation > Signal object class** and **Code Generation > Storage class** drop-down lists of the Data Store Memory block dialog box. Set **Signal object class** to `Simulink.Signal` (the default), and choose a storage class from the **Storage class** drop-down list. The next figure shows the Data Store Memory block dialog box for the preceding model.



To apply storage classes to data stores, you can alternatively use the **Data Stores** tab in the Model Data Editor (in the model, **View > Model Data Editor**).

Data Store Memory blocks are nonvirtual because code is generated for their initialization in `.c` and `.cpp` files and their declarations in header files. The following table shows how the code generated for the Data Store Memory block in the preceding model differs for different storage classes. The table gives the variable declarations and `MdlOutputs` code generated for the `myData` block.

Storage Class	Declaration	Code

`Auto` or `Model default` (when Code Mapping Editor specifies `Default` storage class)	In *`model`*`.h`
	`typedef struct`
	`D_Work_tag`
	`{`
	`  real_T myData;`
	`}`
	`D_Work;`
	In *`model`*`.c` or *`model`*`.cpp`
	`/* Block states (auto storage) */`
	`D_Work` *`model`*`_DWork;`
		`model``_DWork.myData =`
		`  rtb_SineWave;`

`ExportedGlobal`	In *`model`*`.c` or *`model`*`.cpp`
	`/* Exported block states */`
	`real_T myData;`
	In *`model`*`.h`
	`extern real_T myData;`
		`myData = rtb_SineWave;`

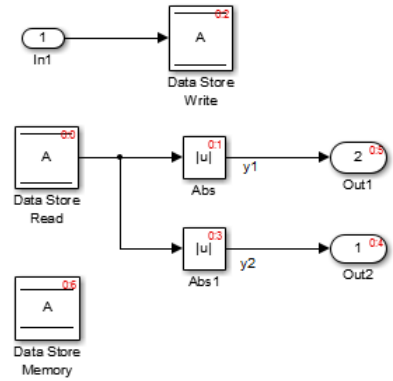
`ImportedExtern`	In *`model`*`_private.h` `extern real_T myData;`	`myData = rtb_SineWave;`
`ImportedExternPointer`	In *`model`*`_private.h` `extern real_T *myData;`	`(*myData) = rtb_SineWave;`

For information about applying storage classes, see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 32-81.

Data Store Buffering in Generated Code

A Data Store Read block is a nonvirtual block that copies the value of the data store to its output buffer when it executes. Since the value is buffered, downstream blocks connected to the output of the data store read utilize the same value, even if a Data Store Write block updates the data store in between execution of two of the downstream blocks.

The next figure shows a model that uses blocks whose priorities have been modified to achieve a particular order of execution:



```
/* local block i/o variables */
real_T rtb_DataStoreRead;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A;
```
Buffer the value of A

```
/* Abs: '<Root>/Abs1' incorporates:
 *  DataStoreRead: '<Root>/Data Store Read'
 */
y1 = fabs(A);
```
Use A (whose value equals the buffered value at this point

```
/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 *  Inport: '<Root>/In1'
 */
A = u1;
```
Update the value of A

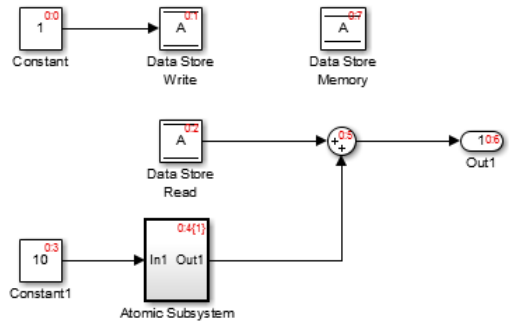
```
/* Abs: '<Root>/Abs' */
y2 = fabs(rtb_DataStoreRead);
```
Consistently use the same buffered value as before the update to A

The following execution order applies:

1. The block Data Store Read buffers the current value of the data store A at its output.
2. The block Abs1 uses the buffered output of Data Store Read.
3. The block Data Store Write updates the data store.
4. The block Abs uses the buffered output of Data Store Read.

Because the output of Data Store Read is a buffer, both Abs and Abs1 use the same value: the value of the data store at the time that Data Store Read executes.

The next figure shows another example:



```
real_T rtb_DataStoreRead;

/* DataStoreWrite: '<Root>/Data Store Write' incorporates:
 *  Constant: '<Root>/Constant'
 */
A = DoBufferDSMRead2_P.Constant_Value;

/* DataStoreRead: '<Root>/Data Store Read' */
rtb_DataStoreRead = A;

/* Outputs for atomic SubSystem: '<Root>/Atomic Subsystem' */
DoBufferDSMRead_AtomicSubsystem();
/* end of Outputs for SubSystem: '<Root>/Atomic Subsystem' */

/* Outport: '<Root>/Out1' incorporates:
 *  Sum: '<Root>/Sum'
 */
DoBufferDSMRead2_Y.Out1 = rtb_DataStoreRead + DoBufferDSMRead2_B.Abs;
```

Buffer the value of A

We don't do a global analysis to detect if this function writes to A

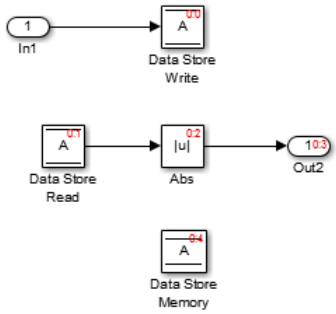
Use the buffered value of A

In this example, the following execution order applies:

1. The block Data Store Read buffers the current value of the data store A at its output.
2. Atomic Subsystem executes.
3. The Sum block adds the output of Atomic Subsystem to the output of Data Store Read.

Simulink assumes that Atomic Subsystem might update the data store, so Simulink buffers the data store. Atomic Subsystem executes after Data Store Read buffers its output, and the buffer provides a way for the Sum block to use the value of the data store as it was when Data Store Read executed.

In some cases, the code generator determines that it can optimize away the output buffer for a Data Store Read block, and the generated code refers to the data store directly, rather than a buffered value of it. The next figure shows an example:



```
/* Model step function */
void DONTbufferDSMRead_step(void)
{
  /* DataStoreWrite: '<Root>/Data Store Write' incorporates:
   *  Inport: '<Root>/In1'
   */
  A = u1;

  /* Abs: '<Root>/Abs' incorporates:
   *  DataStoreRead: '<Root>/Data Store Read'
   */
  y2 = fabs(A);
}
```

In the generated code, the argument of the `fabs()` function is the data store `A` rather than a buffered value.

Data Stores Shared by Instances of a Reusable Model

You can use a data store to share a piece of data between the instances of a reusable referenced model (see “Share Data Among Referenced Model Instances” (Simulink)) or a model that you configure to generate reentrant code (by setting the configuration

parameter **Code interface packaging** to `Reusable function`). If you implement the data store as a Data Store Memory block and select the **Share across model instances** parameter:

- By default, the data store appears in the generated code as a separate global symbol.
- If you have Embedded Coder, to restrict access such that only the code generated from the model can use the data store, configure the data store to appear as `static` by applying the custom storage class `FileScope`. For more information about `FileScope` and other custom storage classes, see “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69.

Structures in Generated Code Using Data Stores

If you use more than one data store to provide global access to multiple signals in generated code, you can combine the signals into a single structure variable by using one data store. This combination of signal data can help you integrate the code generated from a model with other existing code that requires the data in a structure format.

This example shows how to store several model signals in a structure in generated code using a single data store. To store multiple signals in a data store, you configure the data store to accept a composite signal, such as a nonvirtual bus signal or an array of nonvirtual bus signals.

Explore Example Model

1. Open the example model ex_bus_struct_in_code.

   The model contains three subsystems that perform calculations on the inputs from the top level of the model. In each subsystem, a Data Store Memory block stores an intermediate calculated signal.

2. Generate code with the model. In the code generation report, view the file `ex_bus_struct_in_code.c`. The code defines a global variable for each data store.

   ```
   real_T BioBTURate;
   real_T CoalBTURate;
   real_T GasBTURate;
   ```

Suppose that you want to integrate code generated from the example model with other existing code. Suppose also that the existing code requires access to data from the three data stores in a single structure variable. You can use a data store to assemble the target data in a structure in generated code.

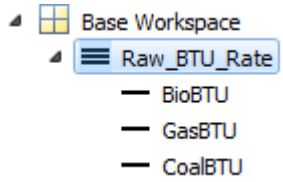
Configure Data Store

Configure a data store to contain multiple signals by creating a bus type to use as the data type of the data store. Define the bus type using the same hierarchy of elements as the structure that you want to appear in generated code.

1. Open the Bus Editor tool.

   ```
   buseditor
   ```

2. Define a new bus type `Raw_BTU_Rate` with one element for each of the three target signals. Name the elements `BioBTU`, `GasBTU`, and `CoalBTU`.



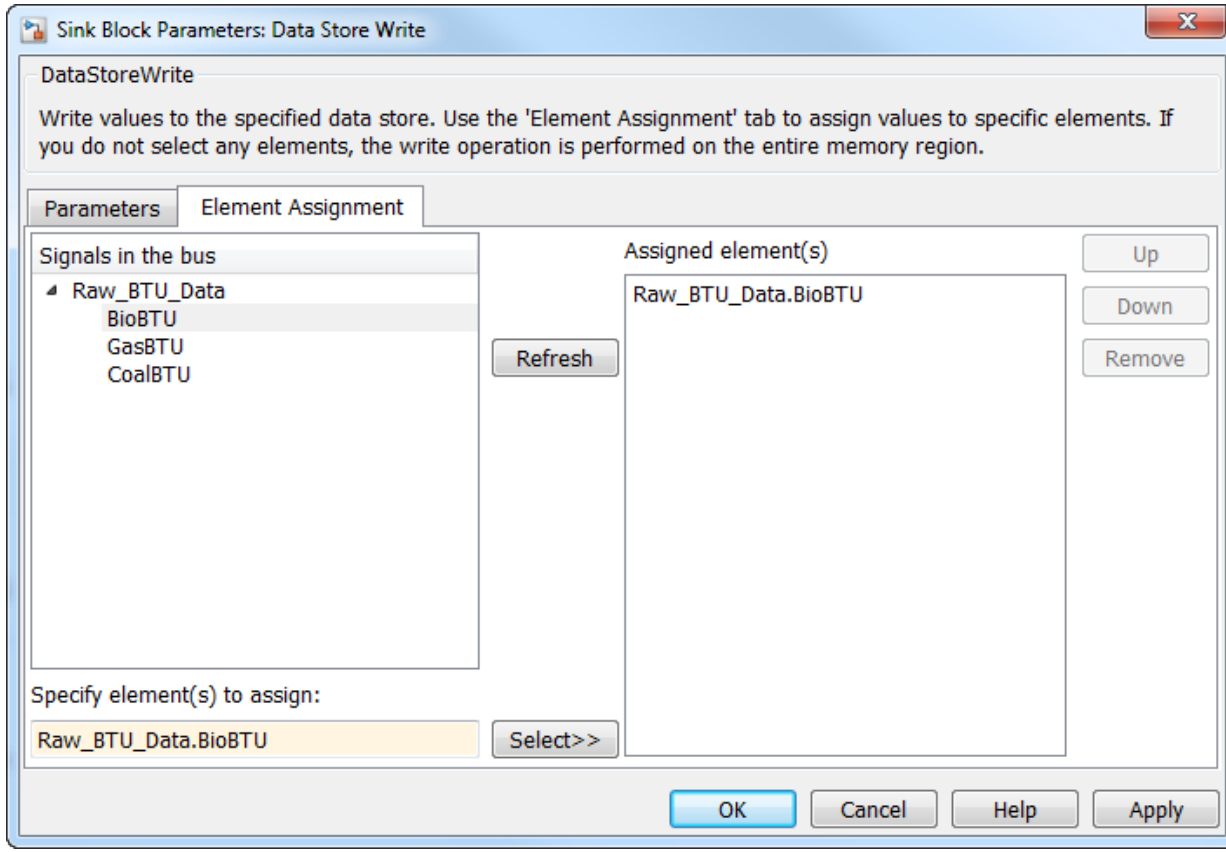
3. At the top level of the example model, add a Data Store Memory block.
4. In the Simulink Editor, select **View** > **Model Data Editor**.
5. In the Model Data Editor, inspect the **Data Stores** tab.
6. For the new Data Store Memory block, use the **Name** column to set the data store name to `Raw_BTU_Data`.
7. Use the **Data Type** column to set the data type of the data store to `Bus: Raw_BTU_Rate`.
8. Set the **Change view** drop-down list to `Code`.
9. Use the **Storage Class** column to apply the storage class `ExportedGlobal`.

Write to Data Store Elements

To write to a specific element of a data store, use a Data Store Write block. On the **Element Assignment** tab in the dialog box, you can specify to write to a single element, a collection of elements, or the entire contents of a data store.

1. Open the **Biomass Calc** subsystem.
2. Delete the Data Store Memory block `BioBTURate`.
3. In the block dialog box for the Data Store Write block, set **Data store name** to `Raw_BTU_Data`.

4 On the **Element Assignment** tab, under **Signals in the bus**, expand the contents of the data store `Raw_BTU_Data`. Click the element `BioBTU`, and then click **Select**. Click **OK**.



5 Modify the **Gas Calc** and **Coal Calc** subsystems similarly.

- Delete the Data Store Memory block in each subsystem.
- In each Data Store Write block dialog box, set **Data store name** to `Raw_BTU_Data`.
- In the **Gas Calc** subsystem, use the Data Store Write block to write to the data store element `GasBTU`. In the **Coal Calc** subsystem, write to the element `CoalBTU`.

Generate Code with Data Store Structure

1. Generate code for the example model.
2. In the code generation report, view the file `ex_bus_struct_in_code_types.h`. The code defines a structure that corresponds to the bus type `Raw_BTU_Rate`.

```
typedef struct {
  real_T BioBTU;
  real_T GasBTU;
  real_T CoalBTU;
} Raw_BTU_Rate;
```

3. View the file `ex_bus_struct_in_code.c`. The code represents the data store with a global variable `Raw_BTU_Data` of the structure type `Raw_BTU_Rate`. In the model step function, the code assigns the data from the calculated signals to the fields of the global variable `Raw_BTU_Data`.

Specify Single-Precision Data Type for Embedded Application

When you want code that uses only single precision, such as when you are targeting a single-precision processor, you can use model configuration parameters and block parameters to prevent the introduction of `double` in the model.

To design and validate a single-precision model, see “Validate a Floating-Point Embedded Model” (Simulink). If you have Fixed-Point Designer, you can use the Single Precision Converter app (see “Single-Precision Design for Simulink” (Fixed-Point Designer)).

Use single Data Type as Default for Underspecified Types

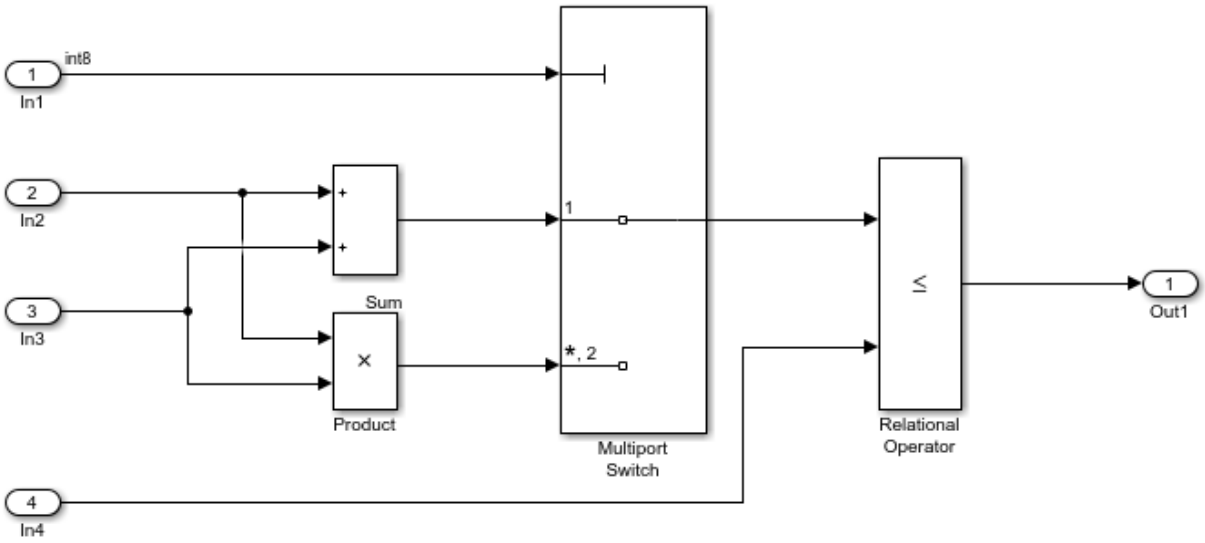
This example shows how to avoid introducing a double-precision data type in code generated for a single-precision hardware target.

If you specify an inherited data type for signals, but data type propagation rules cannot determine data types for the signals, the signal data types default to `double`. You can use a model configuration parameter to specify the default data type as `single`.

Explore Example Model

Open the example model rtwdemo_underspecified_datatype and configure it to show the generated names of blocks.

```
model = 'rtwdemo_underspecified_datatype';
load_system(model)
set_param(model,'HideAutomaticNames','off')
open_system(model);
```



The root inports `In2`, `In3`, and `In4` specify `Inherit: Auto` for the **Data type** block parameter. The downstream blocks also use inherited data types.

Generate Code with `double` as Default Data Type

The model starts with the configuration parameter **System target file** set to `ert.tlc`, which requires Embedded Coder. Set **System target file** to `grt.tlc` instead.

```
set_param(model,'SystemTargetFile','grt.tlc')
```

Generate code from the model.

```
rtwbuild(model)
```

```
### Starting build procedure for model: rtwdemo_underspecified_datatype
### Successful completion of build procedure for model: rtwdemo_underspecified_datatype
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the `double` data type to define the variables `In2`, `In3`, and `In4` because the Inport data types are underspecified in the model.

```
cfile = fullfile('rtwdemo_underspecified_datatype_grt_rtw',...
    'rtwdemo_underspecified_datatype.h');
rtwdemodbtype(cfile,...
    '/* External inputs (root inport signals with default storage) */',...
    '/* External outputs (root outports fed by signals with default storage) */',...
    1, 0);

/* External inputs (root inport signals with default storage) */
typedef struct {
  int8_T In1;                          /* '<Root>/In1' */
  real_T In2;                          /* '<Root>/In2' */
  real_T In3;                          /* '<Root>/In3' */
  real_T In4;                          /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;
```

Generate Code with `single` as Default Data Type

Open the Configuration Parameters dialog box. On the **Math and Data Types** pane, select `single` in the **Default for underspecified data type** drop-down list.

Alternatively, enable the optimization at the command prompt.

```
set_param(model, 'DefaultUnderspecifiedDataType', 'single');
```

Generate code from the model.

```
rtwbuild(model)

### Starting build procedure for model: rtwdemo_underspecified_datatype
### Successful completion of build procedure for model: rtwdemo_underspecified_datatype
```

In the code generation report, view the file `rtwdemo_underspecified_datatype.h`. The code uses the `single` data type to define the variables `In2`, `In3`, and `In4`.

```
rtwdemodbtype(cfile,...
    '/* External inputs (root inport signals with default storage) */',...
    '/* External outputs (root outports fed by signals with default storage) */',...
    1, 0);

/* External inputs (root inport signals with default storage) */
```

```
typedef struct {
  int8_T In1;                          /* '<Root>/In1' */
  real32_T In2;                        /* '<Root>/In2' */
  real32_T In3;                        /* '<Root>/In3' */
  real32_T In4;                        /* '<Root>/In4' */
} ExtU_rtwdemo_underspecified_d_T;
```

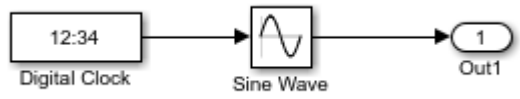
Tune Phase Parameter of Sine Wave Block During Code Execution

Under certain conditions, you cannot configure the **Phase** parameter of a Sine Wave block to appear in the generated code as a tunable global variable (for more information, see the block reference page). This example shows how to generate code so that you can tune the phase during execution.

Create the model `ex_phase_tunable` by using a Digital Clock block.

```
open_system('ex_phase_tunable')
```



Set **Default parameter behavior** to `Tunable` so that the parameters of the Sine Wave block appear in the generated code as tunable fields of the global parameter structure.

```
set_param('ex_phase_tunable','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('ex_phase_tunable')
```

```
### Starting build procedure for model: ex_phase_tunable
### Successful completion of code generation for model: ex_phase_tunable
```

In the code generation report, view the file `ex_phase_tunable.c`. The code algorithm in the model `step` function calculates the Sine Wave block output. The parameters of the block, including **Phase**, appear in the code as tunable structure fields.

```
file = fullfile('ex_phase_tunable_grt_rtw','ex_phase_tunable.c');
rtwdemodbtype(file,'/* Outport: ''<Root>/Out1'' incorporates:',...
    'ex_phase_tunable_P.SineWave_Bias;',1,1)
```

```
  /* Outport: '<Root>/Out1' incorporates:
   *  DigitalClock: '<Root>/Digital Clock'
   *  Sin: '<Root>/Sine Wave'
   */
```

```
ex_phase_tunable_Y.Out1 = sin(ex_phase_tunable_P.SineWave_Freq *
  (((ex_phase_tunable_M->Timing.clockTick1+
     ex_phase_tunable_M->Timing.clockTickH1* 4294967296.0)) * 1.0) +
  ex_phase_tunable_P.SineWave_Phase) * ex_phase_tunable_P.SineWave_Amp +
  ex_phase_tunable_P.SineWave_Bias;
```

During code execution, you can assign new values to the structure field that corresponds to the **Phase** parameter.

Switch Between Output Waveforms During Code Execution for Waveform Generator Block

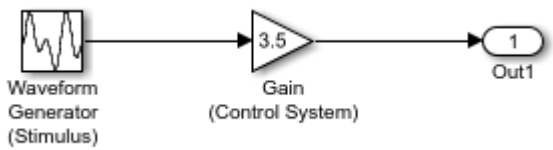
This example shows how to generate code that enables you to switch between stimulus waveforms during code execution.

For a Waveform Generator block, you cannot make the parameters of a waveform, such as amplitude and phase shift, tunable in the generated code. Instead, you can generate code that enables you to choose an active waveform from a set of waveform variants that you specify in the block. During execution of the code, you activate a variant by adjusting the value of a global structure field.

You must set the model configuration parameter **Default parameter behavior** to `Tunable`. Then, by default, block parameters in the model appear tunable in the generated code. These parameters can consume large amounts of memory for a large model.

Create the model `ex_switch_waveform`.

```
open_system('ex_switch_waveform')
```



In the Waveform Generator block, configure this waveform:

```
square(amp,10,0,dutyCycle)
```

In the base workspace, create the variables `amp` and `dutyCycle`.

```
amp = 2.71;
dutyCycle = 50;
```

This waveform represents the baseline stimulus that you want the application to use at the start of execution.

Suppose that, during execution, you want to observe the effects of changing the waveform frequency from 10 to 15 and the phase shift from 0 to 0.5. In the Waveform Generator block, add these waveform variants:

```
square(amp,10,0.5,dutyCycle)
square(amp,15,0,dutyCycle)
square(amp,15,0.5,dutyCycle)
```

Set the model configuration parameter **Default parameter behavior** to `Tunable`.

```
set_param('ex_switch_waveform','DefaultParameterBehavior','Tunable')
```

Generate code from the model.

```
rtwbuild('ex_switch_waveform')
```

```
### Starting build procedure for model: ex_switch_waveform
### Successful completion of code generation for model: ex_switch_waveform
```

The generated file `ex_switch_waveform.h` defines the standard structure type that stores tunable parameter data for the model. The structure contains a field whose value represents the active waveform.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform.h');
rtwdemodbtype(file,'/* Parameters (default storage) */',...
    '/* Real-time Model Data Structure */',1,0)
```

```
/* Parameters (default storage) */
struct P_ex_switch_waveform_T_ {
  real_T WaveformGeneratorStimulus_Selec;
                               /* Mask Parameter: WaveformGeneratorStimulus_Selec
                                * Referenced by: '<S1>/Switch'
                                */
  real_T GainControlSystem_Gain;       /* Expression: 3.5
                                        * Referenced by: '<Root>/Gain (Control System)
                                        */
};
```

The file `ex_switch_waveform_data.c` defines a global structure variable and initializes the field value to `1`. This value represents the baseline waveform.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform_data.c');
rtwdemodbtype(file,'/* Block parameters (default storage) */','};',1,1)
```

```
/* Block parameters (default storage) */
P_ex_switch_waveform_T ex_switch_waveform_P = {
  /* Mask Parameter: WaveformGeneratorStimulus_Selec
   * Referenced by: '<S1>/Switch'
   */
  1.0,

  /* Expression: 3.5
   * Referenced by: '<Root>/Gain (Control System)'
   */
  3.5
};
```

The file `ex_switch_waveform.c` defines the model execution function. The function uses a `switch` statement to determine the value of the active waveform, and then calculates the value of the root-level Outport block, `Out1`.

```
file = fullfile('ex_switch_waveform_grt_rtw','ex_switch_waveform.c');
rtwdemodbtype(file,'switch ((int32_T)',...
    'ex_switch_waveform_Y.Out1 =',1,1)
```

```
  switch ((int32_T)ex_switch_waveform_P.WaveformGeneratorStimulus_Selec) {
   case 1:
    temp = temp - floor(temp) <= 0.5 ? 2.71 : -2.71;
    break;

   case 2:
    temp = (temp - 0.79577471545947676) - floor(temp - 0.79577471545947676) <=
      0.5 ? 2.71 : -2.71;
    break;

   case 3:
    temp = temp_tmp_tmp - floor(temp_tmp_tmp) <= 0.5 ? 2.71 : -2.71;
    break;

   default:
    temp = (temp_tmp_tmp - 1.1936620731892151) - floor(temp_tmp_tmp -
      1.1936620731892151) <= 0.5 ? 2.71 : -2.71;
    break;
  }

  /* End of MultiPortSwitch: '<S1>/MultiportSwitch' */
```

```
/* Outport: '<Root>/Out1' incorporates:
 *  Gain: '<Root>/Gain (Control System)'
 */
ex_switch_waveform_Y.Out1 = ex_switch_waveform_P.GainControlSystem_Gain * temp;
```

During code execution, to change the active waveform, adjust the value of the structure field in the global parameters structure.

Create Tunable Calibration Parameter in the Generated Code

A calibration parameter is a value stored in global memory that an algorithm reads for use in calculations but does not write to. Calibration parameters are tunable because you can change the stored value during algorithm execution. You create calibration parameters so that you can:

- Determine an optimal parameter value by tuning the parameter and monitoring signal values during execution.
- Efficiently adapt an algorithm to different execution conditions by overwriting the parameter value stored in memory. For example, you can use the same control algorithm for multiple vehicles of different masses by storing different parameter values in each vehicle's engine control unit.

In Simulink, create a `Simulink.Parameter` object to represent a calibration parameter. You use the parameter object to set block parameter values, such as the **Gain** parameter of a Gain block. To control the representation of the parameter object in the generated code, you apply a storage class to the object.

To make block parameters accessible in the generated code by default, for example for rapid prototyping, set **Default parameter behavior** (see "Default parameter behavior" (Simulink Coder)) to `Tunable`. For more information, see "Configure Data Accessibility for Rapid Prototyping" on page 32-3.

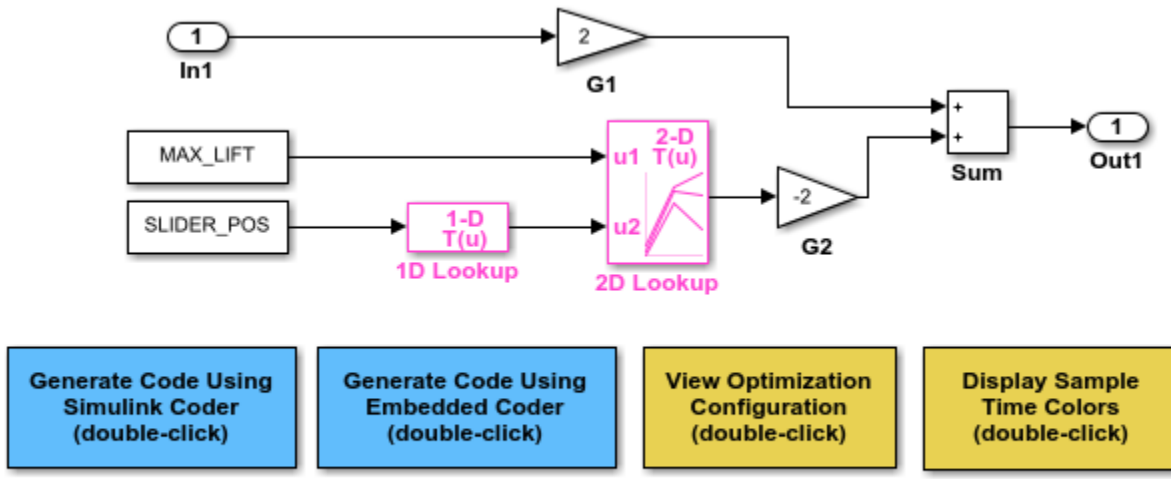
Represent Block Parameter as Tunable Global Variable

This example shows how to create tunable parameter data by representing block parameters as global variables in the generated code.

Configure Block Parameter by Using Parameter Object

Open the example model `rtwdemo_paraminline` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_paraminline')
set_param('rtwdemo_paraminline','HideAutomaticNames','off')
open_system('rtwdemo_paraminline')
```



In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

In the model, click the `G1` Gain block. The Model Data Editor highlights the row that corresponds to the **Gain** parameter of the block.

In the Model Data Editor **Value** column, change the gain value from `2` to `myGainParam`.

Next to `myGainParam`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data block dialog box, set **Value** to `Simulink.Parameter(2)`. Click **Create**. A `Simulink.Parameter` object `myGainParam` stores the parameter value, `2`, in the base workspace.

In the myGainParam dialog box, set **Storage class** to `ExportedGlobal` and click **OK**. This storage class causes the parameter object to appear in the generated code as a tunable global variable.

Alternatively, to create the parameter object and configure the model, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G1','Gain','myGainParam')
myGainParam = Simulink.Parameter(2);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
```

Use the Model Data Editor to create a parameter object, `myOtherGain`, for the `G2` Gain block. Apply the storage class `ExportedGlobal`.

Alternatively, use these commands at the command prompt:

```
set_param('rtwdemo_paraminline/G2','Gain','myOtherGain')
myOtherGain = Simulink.Parameter(-2);
myOtherGain.CoderInfo.StorageClass = 'ExportedGlobal';
```

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('rtwdemo_paraminline')
```

```
### Starting build procedure for model: rtwdemo_paraminline
### Successful completion of build procedure for model: rtwdemo_paraminline
```

The generated file `rtwdemo_paraminline.h` contains `extern` declarations of the global variables `myGainParam` and `myOtherGain`. You can include (`#include`) this header file so that your code can read and write the value of the variable during execution.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.h');
rtwdemodbtype(file,...
    'extern real_T myGainParam;','Referenced by: ''<Root>/G2''',1,1)
```

```
extern real_T myGainParam;             /* Variable: myGainParam
                                        * Referenced by: '<Root>/G1'
                                        */
extern real_T myOtherGain;             /* Variable: myOtherGain
                                        * Referenced by: '<Root>/G2'
```

The file `rtwdemo_paraminline.c` allocates memory for and initializes `myGainParam` and `myOtherGain`.

```
file = fullfile('rtwdemo_paraminline_grt_rtw','rtwdemo_paraminline.c');
rtwdemodbtype(file,...
    '/* Exported block parameters */','Referenced by: ''<Root>/G2''',1,1)
```

```
/* Exported block parameters */
```

```
real_T myGainParam = 2.0;              /* Variable: myGainParam
                                        * Referenced by: '<Root>/G1'
                                        */
real_T myOtherGain = -2.0;             /* Variable: myOtherGain
                                        * Referenced by: '<Root>/G2'
```

The generated code algorithm in the model `step` function uses `myGainParam` and `myOtherGain` for calculations.

```
rtwdemodbtype(file,...
    '/* Model step function */','/* Model initialize function */',1,0)
```

```
/* Model step function */
void rtwdemo_paraminline_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/G1'
   *  Gain: '<Root>/G2'
   *  Inport: '<Root>/In1'
   *  Sum: '<Root>/Sum'
   */
  rtwdemo_paraminline_Y.Out1 = myGainParam * rtwdemo_paraminline_U.In1 +
    myOtherGain * -75.0;
}
```

Apply Storage Class When Block Parameter Refers to Numeric MATLAB Variable

If you use a numeric variable to set the value of a block parameter, you cannot apply a storage class to the variable. As a workaround, you can convert the variable to a parameter object, and then apply a storage class to the object. To convert the variable to a parameter object, choose one of these techniques:

- On the Model Data Editor **Parameters** tab, with **Change view** set to `Code`, find the row that corresponds to the variable. In the **Storage Class** column, from the drop-down list, select `Convert to parameter object`. The Model Data Editor converts the variable to a parameter object. Then, use the **Storage Class** column to apply a storage class to the object.

  You can also use this technique in the Model Explorer.
- Use the Data Object Wizard (see “Create Data Objects for a Model Using Data Object Wizard” (Simulink)). In the Wizard, select the **Parameters** check box. The Wizard

converts variables to objects. Then, apply storage classes to the objects, for example, by using the Model Data Editor or the Model Explorer.

Create Storage Class That Represents Calibration Parameters (Embedded Coder)

This example shows how to create a storage class that yields a calibration parameter in the generated code. The storage class causes each parameter object (`Simulink.Parameter`) to appear as a global variable with special decorations such as keywords and pragmas.

In the generated code, the calibration parameters must appear as global variables defined in a file named `calPrms.c` and declared in `calPrms.h`. The variable definitions must look like these definitions:

```
#pragma SEC(CALPRM)

const volatile float param1 = 3.0F;
const volatile float param2 = 5.0F;
const volatile float param3 = 7.0F;

#pragma SEC()
```

The variables use the keywords `const` and `volatile`. The pragma `#pragma SEC(CALPRM)` controls the placement of the variables in memory. To implement the pragma, variable definitions must appear in a contiguous block of code.

Also, the generated code must include an ASAP2 (`a2l`) description of each parameter.

Create Package for Storing Storage Class and Memory Section Definitions

Now, create a package in your current folder by copying the example package `+SimulinkDemos`. The package stores the definitions of `Parameter` and `Signal` classes that you later use to apply the storage class to data elements in models. Later, the package also stores the definitions of the storage class and an associated memory section.

1. Set your current MATLAB folder to a writable location.
2. Copy the `+SimulinkDemos` package folder into your current folder. Name the copy `+myPackage`.

```
copyfile(fullfile(matlabroot,...
    'toolbox','simulink','simdemos','dataclasses','+SimulinkDemos'),...
    '+myPackage','f')
```

3 Navigate inside the `+myPackage` folder to the file `Signal.m` to edit the definition of the `Signal` class.

4 Uncomment the `methods` section that defines the method `setupCoderInfo`. In the call to the function `useLocalCustomStorageClasses`, replace `'packageName'` with `'myPackage'`. When you finish, the section looks like this:

```
methods
  function setupCoderInfo(h)
    % Use custom storage classes from this package
    useLocalCustomStorageClasses(h, 'myPackage');
  end
end % methods
```

5 Save and close the file.

6 Navigate inside the `+myPackage` folder to the file `Parameter.m` to edit the definition of the `Parameter` class. Uncomment the `methods` section that defines the method `setupCoderInfo` and replace `'packageName'` with `'myPackage'`.

7 Save and close the file.

Create Storage Class and Memory Section

1 Set your current folder to the folder that contains the package folder `+myPackage`.

2 Open the Custom Storage Class Designer.

```
cscdesigner('myPackage')
```

3 In the Custom Storage Class Designer, on the **Memory Sections** tab, click **New**.

4 For the new memory section, set properties according to the table.

Property	Value
Name	`CalMem`
Statements Surround	`Group of variables`
Pre Statement	`#pragma SEC(CALPRM)`
Post Statement	`#pragma SEC()`
Is const	Select
Is volatile	Select

5 Click **Apply**.

6 On the **Custom Storage Class** tab, click **New**.

7 For the new storage class, set properties according to the table.

Property	Value
Name	`CalParam`
For signals	Clear
Data scope	`Exported`
Header File	`calPrms.h`
Definition File	`calPrms.c`
Memory Section	`CalMem`

8 Click **OK**. In response to the message about saving changes, click **Yes**.

Set Default Parameter Object to myPackage.Parameter

To make applying the storage class easier, use the Model Explorer to change the default parameter object from `Simulink.Parameter` to `myPackage.Parameter`.

1 At the command prompt, open the Model Explorer.

```
daexplr
```

2 In the Model Explorer **Model Hierarchy** pane, select **Base Workspace**.
3 In the Model Explorer toolbar, click the arrow next to the **Add Simulink Parameter** button. In the drop-down list, select **Customize class lists**.
4 In the **Customize class lists** dialog box, under **Parameter classes**, select the check box next to **myPackage.Parameter**. Click **OK**.
5 In the Model Explorer toolbar, click the arrow next to the **Add Simulink Parameter** button. In the drop-down list, select **myPackage Parameter**.

   A `myPackage.Parameter` object appears in the base workspace. You can delete this object.

Now, when you use tools such as the Model Data Editor to create parameter objects, Simulink creates `myPackage.Parameter` objects instead of `Simulink.Parameter` objects.

Apply Storage Class

In the example model `rtwdemo_roll`, the `BasicRollMode` subsystem represents a PID controller. Configure the P, I, and D parameters as calibration parameters.

1. Open the model.

   ```
   rtwdemo_roll
   ```
2. In the model, navigate into the `BasicRollMode` subsystem.
3. Select **Code** > **C/C++ Code** > **Configure Model in Code Perspective**.
4. Underneath the block diagram, open the Model Data Editor by selecting the **Model Data Editor** tab.
5. In the Model Data Editor, select the **Parameters** tab and update the block diagram.

   Now, the data table contains rows that correspond to workspace variables used by the Gain blocks (which represent the P, I, and D parameters of the controller).
6. In the Model Data Editor, next to the **Filter contents** box, activate the **Filter using selection** button.
7. In the model, select the three Gain blocks.
8. In the **Filter contents** box, enter `model workspace`.

   The variables that the Gain blocks use are in the model workspace.
9. In the data table, select the three rows and, in the **Storage Class** column for a row, select `Convert to parameter object`.

   The Model Data Editor converts the workspace variables to `myPackage.Parameter` objects. Now, you can apply a storage class to the objects.
10. In the **Storage Class** column for a row, select `CalParam`.

Configure Generation of ASAP2 Interface

Configure the model to generate `a2l` files. Select **Configuration Parameters** > **Code Generation** > **Interface** > **ASAP2 interface**.

Generate and Inspect Code

1. Generate code from the model.
2. In the code generation report, inspect the `calPrms.c` file. The file defines the calibration parameters.

   ```
   /* Exported data definition */
   #pragma SEC(CALPRM)

   /* Definition for custom storage class: CalParam */
   const volatile real32_T dispGain = 0.75F;
   const volatile real32_T intGain = 0.5F;
   const volatile real32_T rateGain = 2.0F;
   ```

```
#pragma SEC()
```

The file `calPrms.h` declares the parameters.

3. Inspect the interface file `rtwdemo_roll.a2l`. The file contains information about each parameter, for example, for `dispGain`.

```
/begin CHARACTERISTIC
  /* Name                    */      dispGain
  /* Long Identifier         */      ""
  /* Type                    */      VALUE
  /* ECU Address             */      0x0000 /* @ECU_Address@dispGain@ */
  /* Record Layout           */      Scalar_FLOAT32_IEEE
  /* Maximum Difference      */      0
  /* Conversion Method       */      rtwdemo_roll_CM_single
  /* Lower Limit             */      -3.4E+38
  /* Upper Limit             */      3.4E+38
/end CHARACTERISTIC
```

Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)

You can generate code that initializes a tunable parameter with a value calculated from some system constants (macros). For example, you can generate this code, which initializes a tunable parameter `totalVol` with a value calculated from macros `numVessels` and `vesInitVol`:

```
#define numVessels 16
#define vesInitVol 18.2

double totalVol = numVessels * vesInitVol;
```

This initialization technique preserves the mathematical relationship between the tunable parameter and the system constants, which can make the generated code more readable and easier to maintain. To generate this code:

1. Create parameter objects that represent the system constants.

```
numVessels = Simulink.Parameter(16);
vesInitVol = Simulink.Parameter(18.2);
```

2. Configure the objects to use the storage class `Define`, which yields a macro in the generated code.

```
numVessels.CoderInfo.StorageClass = 'Custom';
numVessels.CoderInfo.CustomStorageClass = 'Define';

vesInitVol.CoderInfo.StorageClass = 'Custom';
vesInitVol.CoderInfo.CustomStorageClass = 'Define';
```

3. Create another parameter object that represents the tunable parameter. Configure the object to use the storage class `ExportedGlobal`, which yields a global variable in the generated code.

   ```
   totalVol = Simulink.Parameter;
   totalVol.CoderInfo.StorageClass = 'ExportedGlobal';
   ```

4. Set the value of `totalVol` by using the expression `numVessels * vesInitVol`. To specify that the generated code preserve the expression, use the `slexpr` function.

   ```
   totalVol.Value = slexpr('numVessels * vesInitVol');
   ```

5. Use `totalVol` to set block parameter values in your model. The code that you generate from the model initializes the tunable parameter with a value based on the system constants.

For more information and limitations about using an expression to set the value of a `Simulink.Parameter` object, see “Set Variable Value by Using a Mathematical Expression” (Simulink).

Code Generation Impact of Storage Location for Parameter Objects

You can create a parameter object in the base workspace, a model workspace, or a data dictionary. However, when you end your MATLAB session, variables in the base workspace are deleted. To determine where to store parameter objects and other variables that a model uses, see “Determine Where to Store Variables and Objects for Simulink Models” (Simulink).

The location of a parameter object can impact the file placement of the corresponding data definition in the generated code.

- If you place a parameter object in the base workspace or a data dictionary, the code generator assumes that the corresponding parameter data (for example, a global variable) belongs to the system from which you generate code, not to a specific component in the system. For example, if a model in a model reference hierarchy uses a parameter object with a storage class other than `Auto`, the data definition appears in

the code generated for the top model in the hierarchy, not in the code generated for the model that uses the object.

However, if you have Embedded Coder, some custom storage classes enable you to specify the name of the model that owns a piece of data. When you specify an owner model, the code generated for that model defines the data. For more information about data ownership, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 33-2.

- If you place a parameter object in a model workspace, the code generator assumes that the model owns the data. If you generate code from a reference hierarchy that includes the containing model, the data definition appears in the code generated for the containing model.

  For more information about data ownership, see “Control Placement of Global Data Definitions and Declarations in Generated Files” on page 33-2.
- If you apply a storage class other than `Auto` to a parameter object, the object appears in the generated code as a global symbol. Therefore, in a model reference hierarchy, two such objects in different model workspaces or dictionaries cannot have the same name. The name of each object must be unique throughout the model hierarchy.

  However, if you have Embedded Coder, you can use the storage class `FileScope` to prevent name clashes between parameter objects in different model workspaces. See “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28.

If you store an `AUTOSAR.Parameter` object in a model workspace, the code generator ignores the storage class that you specify for the object.

Configure Accessibility of Signal Data

When you tune the value of a parameter during algorithm execution, you monitor or capture output signal values to analyze the results of the tuning. To represent signals in the generated code as accessible data, you can use techniques such as test points and storage classes. See “Configure Data Accessibility for Rapid Prototyping” on page 32-3.

Programmatic Interfaces for Tuning Parameters

You can configure the generated code to include:

- A C application programming interface (API) for tuning parameters independent of external mode. The generated code includes extra code so that you can write your own code to access parameter values. See “Exchange Data Between Generated and External Code Using C API” on page 57-2.
- A Target Language Compiler API for tuning parameters independently of external mode. See “Parameter Functions” (Simulink Coder).

Set Tunable Parameter Minimum and Maximum Values

It is a best practice to specify minimum and maximum values for tunable parameters.

You can specify these minimum and maximum values:

- In the block dialog box that uses the parameter object. Use this technique to store the minimum and maximum information in the model.
- By using the properties of a `Simulink.Parameter` object that you use to set the parameter value. Use this technique to store the minimum and maximum information outside the model.

For more information, see “Specify Minimum and Maximum Values for Block Parameters” (Simulink).

Considerations for Other Modeling Goals

Goal	Considerations and More Information
Apply storage type qualifiers `const` and `volatile`	If you have Embedded Coder, to generate the storage type qualifiers, see “Protect Global Data with const and volatile Type Qualifiers” on page 40-17.
Prevent name clashes between parameters in different components by applying the keyword `static`	If you have Embedded Coder, use the storage class `FileScope` or a similar storage class that you create. See “Choose Storage Class for Controlling Data Representation in Generated Code” on page 32-69.
Generate ASAP2 (`a2l`) description	You can generate an `a2l` file that uses the ASAP2 standard to describe your calibration parameters. For more information, see “Define ASAP2 Information for Parameters and Signals” on page 58-4.

Goal	Considerations and More Information
Generate AUTOSAR XML (`arxml`) description	If you have Embedded Coder, you can generate an `arxml` file that describes calibration parameters used by models that you configure for the AUTOSAR standard. See “Model AUTOSAR Calibration Parameters and Lookup Tables” (AUTOSAR Blockset).
Store lookup table data for calibration	To store lookup table data for calibration according to the ASAP2 or AUTOSAR standards (for example, STD_AXIS, COM_AXIS, or CURVE), you can use `Simulink.LookupTable` and `Simulink.Breakpoint` objects in lookup table blocks. However, some limitations apply. See `Simulink.LookupTable`. To work around the limitations of `Simulink.LookupTable` and `Simulink.Breakpoint` objects, use `Simulink.Parameter` objects instead. For more information, see “Define ASAP2 Information for Parameters and Signals” on page 58-4 and “Configure Lookup Tables for AUTOSAR Measurement and Calibration” (AUTOSAR Blockset).
Use pragmas to store parameter data in specific memory locations	If you have an Embedded Coder license, to generate code that includes custom pragmas, use custom storage classes and memory sections. See “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2.

Limitations for Block Parameter Tunability in Generated Code

A block parameter, MATLAB variable, or `Simulink.Parameter` object is tunable if it appears in the generated code as data stored in memory, such as a global variable. For example, when you apply the storage class `ExportedGlobal` to a parameter object, the parameter object appears tunable in the generated code. When you set **Default parameter behavior** to `Tunable`, MATLAB variables and parameter objects appear tunable in the generated code. By definition, model arguments also appear tunable.

Under certain conditions, the code generator cannot maintain tunability of a parameter, variable, object, or expression. In this case, the code generator inlines the numeric value, preventing you from changing the value during code execution.

To detect these conditions in your model, set the model configuration parameter **Detect loss of tunability** (see "Detect loss of tunability" (Simulink)) to `warning` or `error`.

Tunable Expression Limitations

You can specify block parameter values as expressions that use `Simulink.Parameter` objects or workspace variables. For example, you can use the expression `5 * gainParam`. For general information about using expressions to set block parameter values, see "Use Mathematical Expressions, MATLAB Functions, and Custom Functions" (Simulink). For limitations with respect to expressions that you use to set the values of `Simulink.Parameter` objects, see "Code Generation of Parameter Objects With Expression Values" (Simulink Coder).

A tunable workspace variable is a `Simulink.Parameter` object or workspace variable that appears tunable in the generated code. For example, an object or variable is tunable if you apply a storage class other than `Auto` or if you set **Default parameter behavior** to `Tunable`.

An expression that contains one or more tunable workspace variables, model arguments, or tunable mask parameters is called a tunable expression. The expression is tunable because the code generator attempts to preserve the expression in the code. Because the code generator preserves the expression, you can change the values of the parameter data during code execution.

The code generator reduces certain expressions to an inlined numeric value in the generated code. The inlining renders workspace variables in the expression nontunable. To avoid loss of tunability due to unsupported expressions, observe these guidelines:

- Expressions involving complex (`i`) workspace variables or parameter objects are not supported.
- Certain operators and functions cause the code generator to reduce expressions and remove tunability. To determine whether an operator or function causes loss of tunability, use the information in this table.

Category	Operators or Functions
1	`+ - .* ./ < > <= >= == ~= & |`
2	`* /`
3	`abs`, `acos`, `asin`, `atan`, `atan2`, `boolean`, `ceil`, `cos`, `cosh`, `exp`, `floor`, `log`, `log10`, `sign`, `sin`, `sinh`, `sqrt`, `tan`, `tanh`, `single`, `int8`, `int16`, `int32`, `uint8`, `uint16`, `uint32`
4	`: .^ ^ [] {} . \ .\ ' .' , ;`

  - Use operators from category 1 without loss of tunability.
  - Use operators from category 2 in expressions as long as at least one operand is a scalar. For example, scalar/scalar and scalar/matrix operand combinations are supported, but matrix/matrix combinations are not supported.
  - You can use tunable workspace variables as arguments for the functions in category 3. If you use other functions, the code generator removes the tunability of the arguments.
  - The operators in category 4 are not supported.
- The Fcn and If blocks do not support tunable expressions for code generation or in referenced models.
- You can write mask initialization code that creates and modifies variables. If you use those variables in an expression, the expression is not tunable.
- You can specify a data type for the `Simulink.Parameter` objects or workspace variables that make up expressions. As long as the data type of these variables and objects and the data type of the corresponding block parameters are the same or `double`, the code generator can preserve tunability.

If the code generator preserves tunability of a parameter expression that includes at least one element of an integer type, simulation and execution of generated code can produce

results that are numerically inconsistent. Evaluation of the expression in the generated code results in an overflow while the expression saturates during simulation. For more information, see “Numerical Consistency of Model and Generated Code Simulation Results” (Simulink Coder).

Linear Block Parameter Tunability

These blocks have a `Realization` parameter that affects the tunability of their numeric parameters:

- Transfer Fcn
- State-Space
- Discrete State-Space

To set the `Realization` parameter, you must use the command prompt:

```
set_param(gcb,'Realization','auto')
```

For the `Realization` parameter, you can choose these options:

- `general`: The block's numeric parameters appear tunable in the generated code.
- `sparse`: The generated code represents the block’s parameters as transformed values that increase efficiency. The parameters are not tunable.
- `auto`: The default. If one or more of the block’s parameters are tunable (for example, because you use a tunable parameter object to set a parameter value), then the block uses the `general` realization. Otherwise, the block uses the `sparse` realization.

  To tune the parameter values of one of these blocks during an external mode simulation, the block must use the `general` realization.

Parameter Structures

As described in “Organize Data into Structures in Generated Code” on page 32-181, you can create structures of parameter data in the generated code.

- If a parameter structure is tunable, the numeric fields of the structure are tunable in the generated code. However, if a field contains a nontunable entity, such as a multidimensional array, the structure fields are not tunable.

- You cannot declare individual substructures or fields within a parameter structure as tunable. You cannot use a `Simulink.Parameter` object as the value of a structure field. Instead, you must store the entire structure in the parameter object.

Code Generation of Parameter Objects With Expression Values

As described in “Set Variable Value by Using a Mathematical Expression” (Simulink), you can set the value of a `Simulink.Parameter` object to an expression involving other MATLAB variables or parameter objects. When you generate code from a model that uses such a parameter object, to achieve your goal, use the information in the table.

Goal	Technique and More Information
Generate code without Embedded Coder.	For the parameter object that uses the expression, apply an available storage class (see “Apply Storage Classes to Individual Signal, State, and Parameter Data Elements” (Simulink Coder)). For the parameter objects used in the expression, apply only the storage class `Auto`.
Generate code that defines a global variable and initializes it by using an expression involving system constants and other macros (requires Embedded Coder).	See “Initialize Parameter Value From System Constant or Other Macro (Embedded Coder)” on page 32-129.
Generate code that defines a macro whose value is an expression involving other macros (requires Embedded Coder).	For the parameter object that uses the expression, apply a storage class that yields a macro in the generated code, such as `Define` (see “Macro Definitions (#define)” on page 24-69). For the parameter objects used in the expression, apply storage classes that yield imported macros. For example, use the storage class `ImportedDefine`. Your external code must define these macros.

Considerations and Limitations

- To avoid errors that prevent code generation, if you apply a storage class other than `Auto` to the dependent parameter object (which uses the expression as its value), the

parameter objects used in the expression must use either `Auto` or a storage class that yields a macro in the generated code.

- You cannot set the value of a parameter object that represents a symbolic dimension (see “Implement Dimension Variants for Array Sizes in Generated Code” on page 25-2) to an expression.
- With Embedded Coder, you can generate code that preserves the expression, but only for the purpose of statically initializing the value of a global variable or macro that corresponds to the dependent parameter object. Follow the guidelines in “Expression Preservation” (Simulink Coder).

Expression Preservation

If you want Embedded Coder to preserve expressions in the generated code, adhere to these restrictions and guidelines.

- The dependent parameter object must use a storage class other than `Auto`. For example, to generate a global variable and initialize it by using the expression, use `ExportedGlobal` or `ExportToFile`.
- The parameter objects used in the expression must:
  - Use a storage class that yields a macro in the generated code, such as `Define`.
  - Have scalar, real values if the expression uses operators.
- The expression can use only these operators (in MATLAB syntax):
  - Mathematical: `+`, `-`, `*`
  - Relational: `==`, `~=`, `<`, `>`, `<=`, `>=`
- These data typing guidelines apply:
  - If possible, for a parameter object used in an expression, leave the `DataType` property at the default value, `auto`.

    To use a value other than `auto`, you must set the `DataType` property of the object that uses the expression to the same value. Otherwise, the code generator does not preserve the expression.
  - If you want to use a parameter object in multiple different expressions, and the dependent parameter objects have different data types, leave the `DataType` property of the independent object at the default value, `auto`. In the generated code, the value of the macro is expressed as a floating-point number (with effective

data type `double`), and the code initializes the dependent parameters by typecasting the result of each expression.

Related Examples

- “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder)
- “Share and Reuse Block Parameter Values by Creating Variables” (Simulink)

Specify Instance-Specific Parameter Values for Reusable Referenced Model

When you use model referencing to break a large system into components, each component is a separate model. You can reuse a component by referring to it with multiple Model blocks. Each Model block is an instance of the component. You can then configure a block parameter (such as the **Gain** parameter of a Gain block) to use either the same value or a different value for each instance of the component. To use different values, create and use a model argument to set the value of the block parameter.

When you generate code from a model hierarchy that uses model arguments, the arguments appear in the code as formal parameters of the referenced model entry-point functions, such as the output (`step`) function. The generated code then passes the instance-specific parameter values, which you specify in each Model block, to the corresponding function calls.

Whether you use or do not use model arguments, you can use storage classes to configure block parameters to appear in the generated code as tunable global variables. You can also use storage classes to generate tunable model argument values, which the generated code stores in memory and passes to the function calls. You can then change the values during execution.

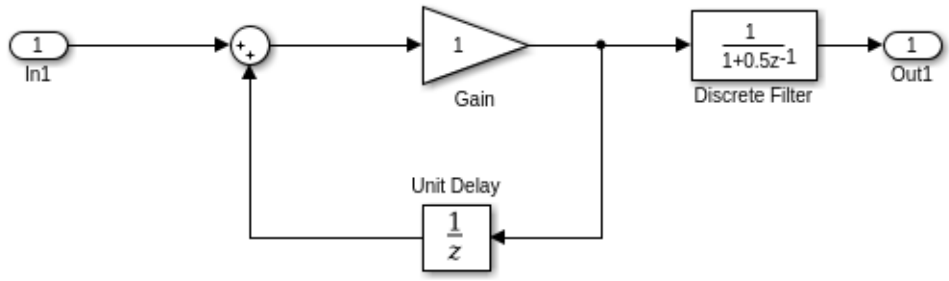
Pass Parameter Data to Referenced Model Entry-Point Functions as Arguments

Configure a referenced model to accept parameter data through formal parameters of the generated model entry-point function. This technique enables you to specify a different parameter value for each instance (Model block) of the referenced model.

Configure Referenced Model to Use Model Arguments

Create the model `ex_arg_code_ref`. This model represents a reusable algorithm.

```
open_system('ex_arg_code_ref')
```



In the model, select **View > Model Data Editor**.

In the Model Data Editor, in the data table, use the **Data Type** column to set the data type of the Inport block to `single`. Due to data type inheritance, the other signals in the model use the same data type.

Select the **Parameters** tab.

In the model, select the Gain block.

In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `gainArg`.

Next to `gainArg`, click the action button ⋮ and select **Create**.

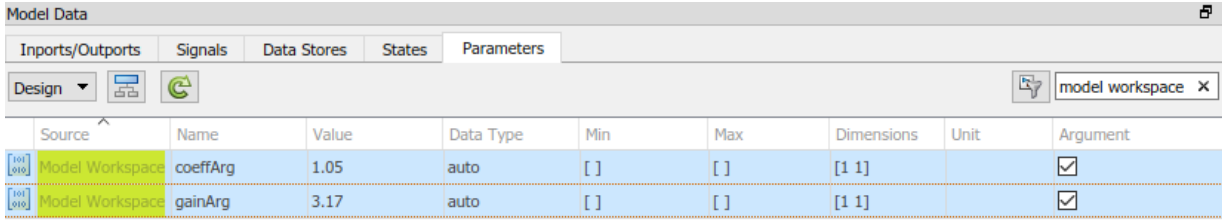
In the Create New Data dialog box, set **Value** to `Simulink.Parameter` and **Location** to `Model Workspace`. Click **Create**.

In the property dialog box, set **Value** to a number, for example, `3.17`. Click **OK**.

Use the Model Data Editor to set the **Numerator** parameter by using a `Simulink.Parameter` object named `coeffArg` whose value is `1.05`. As with `gainArg`, store the parameter object in the model workspace.

In the Model Data Editor, click the **Show/refresh additional information** button.

Use the **Filter contents** box to find each parameter object (`gainArg` and `coeffArg`). For each object, select the check box in the **Argument** column.



Save the `ex_arg_code_ref` model.

Alternatively, at the command prompt, you can use these commands to configure the blocks and the parameter objects:

```
set_param('ex_arg_code_ref/In1','OutDataTypeStr','single')

set_param('ex_arg_code_ref/Gain','Gain','gainArg')
modelWorkspace = get_param('ex_arg_code_ref','ModelWorkspace');
assignin(modelWorkspace,'gainArg',Simulink.Parameter(3.17));

set_param('ex_arg_code_ref/Discrete Filter','Numerator','coeffArg')
assignin(modelWorkspace,'coeffArg',Simulink.Parameter(1.05));

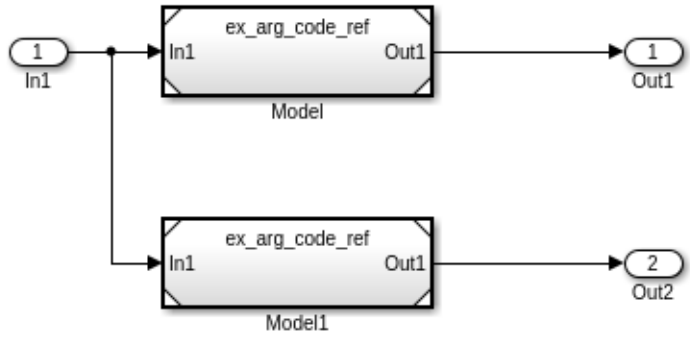
set_param('ex_arg_code_ref','ParameterArgumentNames','coeffArg,gainArg')

save_system('ex_arg_code_ref')
```

Specify Instance-Specific Parameter Values in Model Blocks

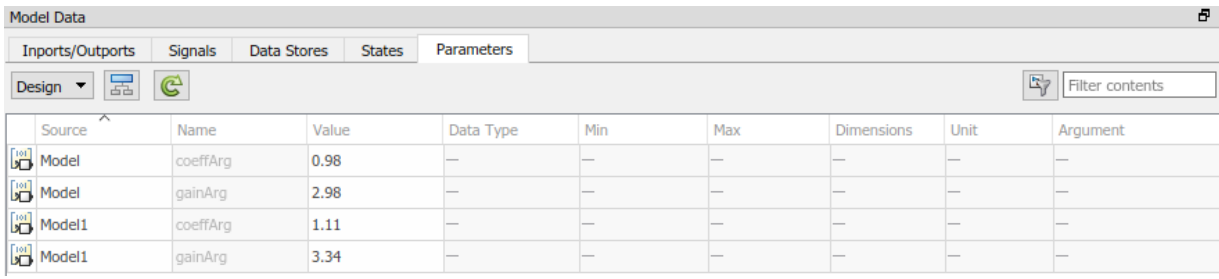
Create the model `ex_arg_code_ref`. This model uses multiple instances (Model blocks) of the reusable algorithm.

```
open_system('ex_arg_code')
```



In the model, open the Model Data Editor **Parameters** tab (**View > Model Data Editor**). The Model Data Editor shows four rows that correspond to the model arguments, `coeffArg` and `gainArg`, that you can specify for the two Model blocks.

Use the Model Data Editor to set values for the model arguments. For example, use the values in the figure.



Alternatively, at the command prompt, you can use these commands to set the values:

```
set_param('ex_arg_code/Model','ParameterArgumentValues',...
    struct('coeffArg','0.98','gainArg','2.98'))

set_param('ex_arg_code/Model1','ParameterArgumentValues',...
    struct('coeffArg','1.11','gainArg','3.34'))
```

Generate code from the top model.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code_ref.c` defines the referenced model entry-point function, `ex_arg_code_ref`. The function has two formal parameters, `rtp_coeffArg` and `rtp_gainArg`, that correspond to the model arguments, `coeffArg` and `gainArg`. The formal parameters use the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
/* Output and update for referenced model:
   'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1,
                     real32_T *rty_Out1,
                     DW_ex_arg_code_ref_f_T *localDW,
                     real32_T rtp_coeffArg,
                     real32_T rtp_gainArg)
```

The file `ex_arg_code.c` contains the definition of the top model entry-point function `ex_arg_code`. This function calls the referenced model entry-point function `ex_arg_code_ref` and uses the model argument values that you specified (such as `1.11` and `3.34`) as the values of `rtp_coeffArg` and `rtp_gainArg`.

```
/* ModelReference: '<Root>/Model' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
                &(ex_arg_code_DW.Model_InstanceData.rtdw), 0.98F, 2.98F);

/* ModelReference: '<Root>/Model1' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
                &(ex_arg_code_DW.Model1_InstanceData.rtdw), 1.11F, 3.34F);
```

The formal parameters use the data type `real32_T` (`single`).

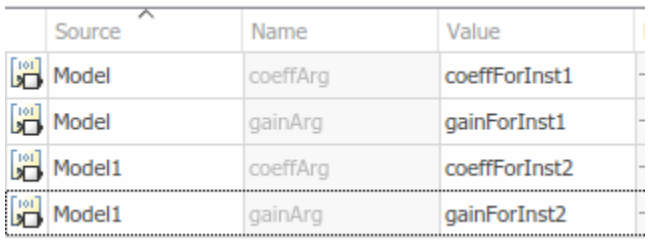
- The block parameters in `ex_arg_code_ref` determine their data types through internal rules. For example, in the Gain block dialog box, on the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default). In this case, the internal rule chooses the same data type as the input and output signals, `single`.
- The model arguments in the model workspace use context-sensitive data typing because the value of the `DataType` property is set to `auto` (the default). With this setting, the model arguments use the same data type as the block parameters, `single`.
- The formal parameters in the generated code use the same data type as the model arguments, `single`.

Generate Tunable Argument Values

You can configure the instance-specific values in the Model blocks to appear in the generated code as tunable global variables. This technique enables you to store the parameter values for each instance in memory and tune the values during code execution.

In the top model `ex_arg_code`, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the values of the model arguments according to this figure.



```
set_param('ex_arg_code/Model','ParameterArgumentValues',...
    struct('coeffArg','coeffForInst1','gainArg','gainForInst1'))
set_param('ex_arg_code/Model1','ParameterArgumentValues',...
    struct('coeffArg','coeffForInst2','gainArg','gainForInst2'))
```

View the contents of the `ex_arg_code_ref` model workspace in Model Explorer by selecting **View** > **Model Explorer** > **Model Explorer**.

Copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace to the base workspace.

Rename `gainArg` as `gainForInst1`. Rename `coeffArg` as `coeffForInst1`.

```
gainForInst1 = getVariable(modelWorkspace,'gainArg');
gainForInst1 = copy(gainForInst1);
coeffForInst1 = getVariable(modelWorkspace,'coeffArg');
coeffForInst1 = copy(coeffForInst1);
```

Copy `gainForInst1` and `coeffForInst1` as `gainForInst2` and `coeffForInst2`.

```
gainForInst2 = copy(gainForInst1);
coeffForInst2 = copy(coeffForInst1);
```

Set the instance-specific parameter values by using the `Value` property of the parameter objects in the base workspace.

```
gainForInst1.Value = 2.98;
coeffForInst1.Value = 0.98;

gainForInst2.Value = 3.34;
coeffForInst2.Value = 1.11;
```

In the Model Data Editor for the top model `ex_arg_code`, click the **Show/refresh additional information** button.

Set the **Change view** drop-down list to `Code`.

For the new parameter objects, set the value in the **Storage Class** column to `ExportedGlobal`. This setting causes the parameter objects to appear in the generated code as tunable global variables.

```
gainForInst1.StorageClass = 'ExportedGlobal';
coeffForInst1.StorageClass = 'ExportedGlobal';
gainForInst2.StorageClass = 'ExportedGlobal';
coeffForInst2.StorageClass = 'ExportedGlobal';
```

Generate code from the top model.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code.c` defines the global variables that correspond to the parameter objects in the base workspace.

```
/* Exported block parameters */
real32_T coeffForInst1 = 0.98F;        /* Variable: coeffForInst1
                                        * Referenced by: '<Root>/Model'
                                        */
real32_T coeffForInst2 = 1.11F;        /* Variable: coeffForInst2
                                        * Referenced by: '<Root>/Model1'
                                        */
real32_T gainForInst1 = 2.98F;         /* Variable: gainForInst1
                                        * Referenced by: '<Root>/Model'
                                        */
real32_T gainForInst2 = 3.34F;         /* Variable: gainForInst2
                                        * Referenced by: '<Root>/Model1'
                                        */
```

In each call to `ex_arg_code_ref`, the top model algorithm uses the global variables to set the values of the formal parameters.

```
/* ModelReference: '<Root>/Model' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
                &(ex_arg_code_DW.Model_InstanceData.rtdw), coeffForInst1,
                gainForInst1);

/* ModelReference: '<Root>/Model1' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
                &(ex_arg_code_DW.Model1_InstanceData.rtdw), coeffForInst2,
                gainForInst2);
```

The global variables in the generated code use the data type `real32_T` (`single`).

- The parameter objects in the base workspace use context-sensitive data typing because the `DataType` property is set to `auto` (the default). With this setting, the parameter objects in the base workspace use the same data type as the model arguments, `single`.
- The global variables in the generated code use the same data type as the parameter objects in the base workspace.

Group Multiple Model Arguments into Single Structure

Use the Model Explorer to copy `gainArg` and `coeffArg` from the `ex_arg_code_ref` model workspace into the base workspace.

```
temp = getVariable(modelWorkspace,'gainArg');
gainArg = copy(temp);
temp = getVariable(modelWorkspace,'coeffArg');
coeffArg = copy(temp);
```

At the command prompt, combine these two parameter objects into a structure, `structArg`.

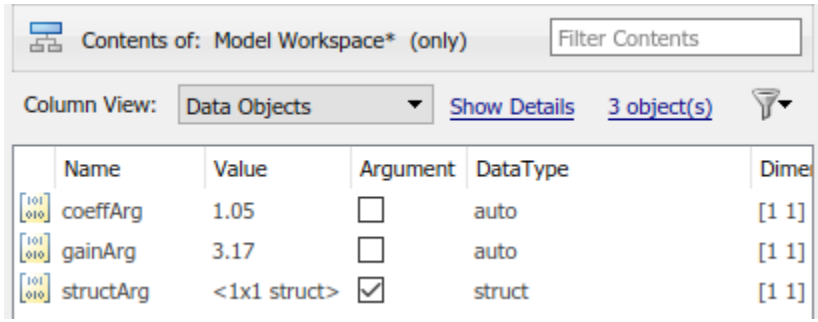
```
structArg = Simulink.Parameter(struct('gain',gainArg.Value,...
    'coeff',coeffArg.Value));
```

Use the Model Explorer to move `structArg` into the model workspace.

```
assignin(modelWorkspace,'structArg',copy(structArg));
clear structArg gainArg coeffArg
```

In the **Contents** pane, configure `structArg` as the only model argument.

```
set_param('ex_arg_code_ref','ParameterArgumentNames','structArg')
```



In the `ex_arg_code_ref` model, select the Model Data Editor **Parameters** tab.

Use the Model Data Editor to set the value of the **Gain** parameter to `structArg.gain` and the value of the **Numerator** parameter to `structArg.coeff`. Save the model.

```
set_param('ex_arg_code_ref/Gain','Gain','structArg.gain')
set_param('ex_arg_code_ref/Discrete Filter',...
    'Numerator','structArg.coeff')

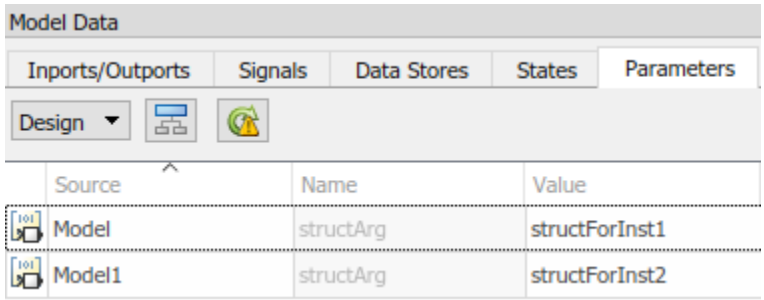
save_system('ex_arg_code_ref')
```

At the command prompt, combine the four parameter objects in the base workspace into two structures. Each structure stores the parameter values for one instance of `ex_arg_code_ref`.

```
structForInst1 = Simulink.Parameter(struct('gain',gainForInst1.Value,...
    'coeff',coeffForInst1.Value));

structForInst2 = Simulink.Parameter(struct('gain',gainForInst2.Value,...
    'coeff',coeffForInst2.Value));
```

In the top model `ex_arg_code`, set the **Change view** drop-down list to `Design`. Use the Model Data Editor to set the argument values according to this figure.



```
set_param('ex_arg_code/Model','ParameterArgumentValues',...
    struct('structArg','structForInst1'))
set_param('ex_arg_code/Model1','ParameterArgumentValues',...
    struct('structArg','structForInst2'))
```

Click the **Show/refresh additional information** button.

For the new parameter objects `structForInst1` and `structForInst2`, use the Model Data Editor to apply the storage class `ExportedGlobal`.

```
structForInst1.StorageClass = 'ExportedGlobal';
structForInst2.StorageClass = 'ExportedGlobal';
```

At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1.Value);
```

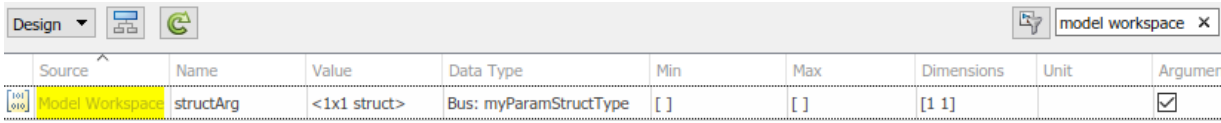
Rename the bus object as `myParamStructType` by copying it.

```
myParamStructType = copy(slBus1);
```

In the Model Data Editor for `ex_arg_code`, set **Change view** to `Design`. Use the **Data Type** column to set the data type of `structForInst1` and `structForInst2` to `Bus: myParamStructType`.

```
structForInst1.DataType = 'Bus: myParamStructType';
structForInst2.DataType = 'Bus: myParamStructType';
```

In the Model Data Editor for `ex_arg_code_ref`, use the Model Data Editor to set the data type of `structArg` to `Bus: myParamStructType`.



```
temp = getVariable(modelWorkspace,'structArg');
temp = copy(temp);
temp.DataType = 'Bus: myParamStructType';
assignin(modelWorkspace,'structArg',copy(temp));
```

Save the `ex_arg_code_ref` model.

```
save_system('ex_arg_code_ref')
```

When you use structures to group parameter values, you cannot take advantage of context-sensitive data typing to control the data types of the fields of the structures (for example, the fields of `structForInst1`). However, you can use the properties of the bus object to control the field data types.

At the command prompt, set the data type of the elements in the bus object to `single`. The corresponding fields in the structures (such as `structForInst1` and `structArg`) use the same data type.

```
myParamStructType.Elements(1).DataType = 'single';
myParamStructType.Elements(2).DataType = 'single';
```

Generate code from the top model `ex_arg_code`.

```
rtwbuild('ex_arg_code')
```

The file `ex_arg_code_types.h` defines the structure type `myParamStructType`, which corresponds to the `Simulink.Bus` object.

```
typedef struct {
  real32_T gain;
  real32_T coeff;
} myParamStructType;
```

In the file `ex_arg_code_ref.c`, the referenced model entry-point function has a formal parameter, `rtp_structArg`, that corresponds to the model argument `structArg`.

```
/* Output and update for referenced model:
   'ex_arg_code_ref' */
void ex_arg_code_ref(const real32_T *rtu_In1,
```

```
                    real32_T *rty_Out1,
                    DW_ex_arg_code_ref_f_T *localDW,
                    const myParamStructType *rtp_structArg)
```

The file `ex_arg_code.c` defines the global structure variables that correspond to the parameter objects in the base workspace.

```
/* Exported block parameters */
myParamStructType structForInst1 = {
  2.98F,
  0.98F
} ;                                    /* Variable: structForInst1
                                        * Referenced by: '<Root>/Model'
                                        */

myParamStructType structForInst2 = {
  3.34F,
  1.11F
} ;                                    /* Variable: structForInst2
                                        * Referenced by: '<Root>/Model1'
                                        */
```

The top model algorithm in the file `ex_arg_code.c` passes the addresses of the structure variables to the referenced model entry-point function.

```
/* ModelReference: '<Root>/Model' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out1'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out1,
                &(ex_arg_code_DW.Model_InstanceData.rtdw), &structForInst1);

/* ModelReference: '<Root>/Model1' incorporates:
 *  Inport: '<Root>/In1'
 *  Outport: '<Root>/Out2'
 */
ex_arg_code_ref(&ex_arg_code_U.In1, &ex_arg_code_Y.Out2,
                &(ex_arg_code_DW.Model1_InstanceData.rtdw), &structForInst2);
```

Control Data Types of Model Arguments and Argument Values

When you use model arguments, you can apply a data type to:

- The block parameters that use the arguments (for certain blocks, such as those in the Discrete library).
- The arguments in the referenced model workspace.

- The argument values that you specify in Model blocks.

To generate efficient code by eliminating unnecessary typecasts and C shifts, consider using inherited and context-sensitive data typing to match the data types.

- In the model workspace, use a MATLAB variable whose data type is `double` or a parameter object whose `DataType` property is set to `auto`. In this case, the variable or object uses the same data type as the block parameter.
- When you set the argument values in Model blocks, take advantage of context-sensitive data typing. To set an argument value, use an untyped value.

  - A literal number such as `15.23`. Do not use a typed expression such as `single(15.23)`.
  - A MATLAB variable whose data type is `double`.
  - A `Simulink.Parameter` object whose `DataType` property is set to `auto`.

  In these cases, the number, variable, or object uses the same data type as the model argument in the referenced model workspace. If you also configure the model argument to use context-sensitive data typing, you can control the data types of the block parameter, the argument, and the argument value by specifying the type only for the block parameter.

For basic information about controlling parameter data types, see “Parameter Data Types in the Generated Code” on page 32-161.

Use Model Argument in Different Data Type Contexts

If you use a model argument to set multiple block parameter values, and the data types of the block parameters differ, you cannot use context-sensitive data typing (`double` or `auto`) for the argument in the model workspace. You must explicitly specify a data type for the argument. For example, if the argument in the model workspace is a parameter object (such as `Simulink.Parameter`), set the `DataType` property to a value other than `auto`. For more information about this situation, see “Reuse Parameter Data in Different Data Type Contexts” on page 32-177.

In this case, you can continue to take advantage of context-sensitive data typing to control the data type of the argument values that you specify in Model blocks. Each argument value uses the data type that you specify for the corresponding argument in the model workspace.

Configure Packaging of Parameter Arguments in Generated Code

To customize the implementation of instance-specific parameters in the generated code, you can configure the packaging of these parameters in the model where they are defined. Configure the default mapping and individual mapping for instance-specific parameters by using one of these storage classes:

- `Auto` — The parameter appears as an individual model function argument in the generated code. If a block in the model does not reference the parameter, it can be optimized away by the code generator.
- `Model default` — Each instance of the parameter is allocated a piece of memory in a structure as defined by the code definition of the default storage class. Specify this default storage class through the model default mapping.
- A structured storage class — Each instance of the parameter is allocated a piece of memory in a structure as defined by the coder definition of that storage class.

If you use edit-time checking for code generation, you get an error for an invalid storage class.

For an instance-specific parameter with a non-`Auto` storage class:

- On the Model block, you can specify the per-instance value as either a literal, a numeric MATLAB variable, or a `Simulink.Parameter` object.
- If the per-instance value is a `Simulink.Parameter` object, the object must have storage class `Auto`.
- If the per-instance value is a value expression, the evaluated value of the expression is used to statically initialize the parameter.

If you do not specify a default or individual storage class for an instance-specific parameter, the code generator applies an internal storage class, `InstP`, to the parameter. The `Instp` storage class has these properties:

- Exported scope
- Type naming rule is `$R_InstP$M`
- Instance name is `InstP$R$M`

Code Generation Behavior

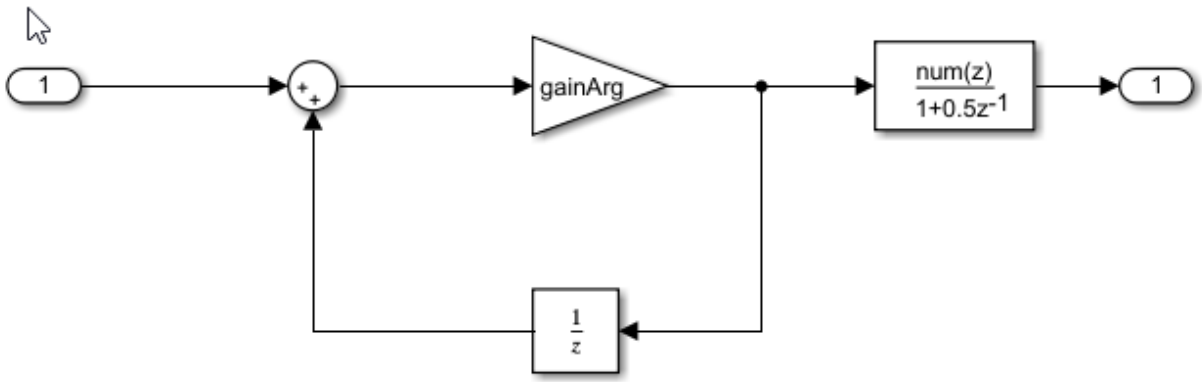
For single-instance referenced models, the instance-specific parameters reside in a standalone global structure. The top model defines the structure. The referenced model declares and uses the structure.

For multi-instance referenced models, the instance-specific parameters are part of a hierarchically nested structure that the top model declares and defines. The referenced model has access to its parameter values through a pointer in its self structure. The self structure points to a substructure of the structure that the top model defines.

For parameter arguments defined in the top model, if the argument does not have a storage class, it is inlined. If it has a storage class, the resulting code depends on the value of the Code interface packaging parameter:

- `Nonreusable function` — The parameter is generated in a structure defined in the top model.
- `Reusable function` — The parameter is generated in a structure passed as part of the first argument of the function.

To understand the behavior of instant-specific parameters in the generated code for referenced models, open model `ex_arg_code_ref`.



First consider a referenced model configured to support only a single instance, with model argument `gainArg` defined for the Gain block and model argument `coeffArg` defined for the Discrete Filter block. The default mapping for model arguments does not

have a storage class. In the `ex_arg_code_ref.h` file, there is a type definition and a declaration for the instance-specific parameters.

```
/* instance parameters */
extern ex_arg_code_ref_InstP ex_arg_code_refrtInstP;
```

```
/* instance parameters, for model 'ex_arg_code_ref' */
typedef struct {
  real32_T coeffArg;                   /* Variable: coeffArg
                                        * Referenced by: synthesized block
                                        */
  real32_T gainArg;                    /* Variable: gainArg
                                        * Referenced by: synthesized block
                                        */
} ex_arg_code_ref_InstP;
```

When the top model references this model and supplies values for the instance-specific parameters, the code for the top model defines the instance-specific parameters by using the values provided by the top model.

```
/* Define buffer for instance parameters, Block: '<Root>/Model' */
ex_arg_code_ref_InstP ex_arg_code_refrtInstP = {
  1.98F,
  3.98F
};
```

Now consider if the referenced model is configured to support multiple instances. `ex_arg_code_ref.h` contains the same type definition as the single-instance, but the self for the model also contains a pointer to an instance of that data structure. There is no pointer declaration to a standalone global variable of that structure.

```
/* instance parameters, for model 'ex_arg_code_ref' */
typedef struct {
  real32_T coeffArg;                   /* Variable: coeffArg
                                        * Referenced by: synthesized block
                                        */
  real32_T gainArg;                    /* Variable: gainArg
                                        * Referenced by: synthesized block
                                        */
} ex_arg_code_ref_InstP;

/* Real-time Model Data Structure */
struct ex_arg_code_ref_tag_RTM {
  ex_arg_code_ref_InstP *ex_arg_code_ref_InstP_ref;
};
```

The top model declares a parent structure, including an instance of this substructure, and initializes the pointer in the self structure for the referenced model.

```
  /* Assign pointer for instance parameters, Block: '<Root>/Model' */
  ex_arg_code_DW->Model_InstanceData.rtm.ex_arg_code_ref_InstP_ref =
    &ex_arg_code_M->ex_arg_code_InstP_ref->InstP_Model;

  /* Assign pointer for instance parameters, Block: '<Root>/Model1' */
  ex_arg_code_DW->Model1_InstanceData.rtm.ex_arg_code_ref_InstP_ref =
    &ex_arg_code_M->ex_arg_code_InstP_ref->InstP_Model1;
}
```

Limitations

When you configure an instance-specific parameter for code generation, these limitations apply:

- The default mapping for parameter arguments cannot be reused for local parameters or global parameters.

- At the time of code generation, you must provide a value for each instance of the parameter within the model reference hierarchy. Failure to supply a value results in a code generation error.
- Instance-specific parameter values must be finite.
- Parameter arguments with a non-`Auto` storage class are not supported for C++ code generation with a C++ class code interface.

Parameter Data Types in the Generated Code

The data type of a block parameter (such as the **Gain** parameter of a Gain block), numeric MATLAB variable, or `Simulink.Parameter` object determines the data type that the corresponding entity in the generated code uses (for example, a global variable or an argument of a function). To generate more efficient code, you can match parameter data types with signal data types or store parameters in smaller data types.

For basic information about setting block parameter data types in a model, see “Control Block Parameter Data Types” (Simulink).

Significance of Parameter Data Types

The data type that a block parameter, MATLAB variable, or parameter object uses determines the data type that the generated code uses to store the parameter value in memory. For example:

- If you set the model configuration parameter **Default parameter behavior** (see “Default parameter behavior” (Simulink Coder)) to `Tunable`, the **Gain** parameter of a Gain block appears in the generated code as a field of a global structure that stores parameter data. If you apply the data type `single` to the block parameter in the model, the structure field in the code uses the corresponding data type, `real32_T`.
- If you apply the storage class `ExportedGlobal` to a `Simulink.Parameter` object, the object appears in the generated code as a separate global variable. If you set the `DataType` property of the object to `int8`, the global variable in the code uses the corresponding data type, `int8_T`.
- If you configure a `Simulink.Parameter` object in a model workspace as a model argument, the object appears in the generated code as a formal parameter (argument) of a model entry-point function, such as the `step` function. The `DataType` property of the object determines the data type of the formal parameter.

Other than determining the data type that the generated code uses to store parameter values in memory, the data type of a parameter, variable, or object can also:

- Cause the block to cast the value of the parameter prior to code generation. The cast can result in overflow, underflow, or quantization.
- Cause the generated code to include extra code, for example saturation code.

Typecasts Due to Parameter Data Type Mismatches

When the data types of block parameters, workspace variables, and signals differ, blocks can use typecasts to reconcile the data type mismatches. These typecasts can cause the generated code algorithm, including the model `step` function, to include explicit casts to reconcile mismatches in storage data type and C bit shifts to reconcile mismatches in fixed-point scaling.

Parameter data type mismatches can occur when:

- The data type that you specify for a MATLAB variable or parameter object (`Simulink.Parameter`) differs from the data type of a block parameter. The block parameter typecasts the value of the variable or object.
- The data type that you specify for an initial value differs from the data type of the initialized signal or state.
- The data type that you specify for a block parameter differs from the data type of the signal or signals that the parameter operates on. Some blocks typecast the parameter to perform the operation. For example, the Gain block performs this typecast.

If you configure a variable or object to use bias or fractional fixed-point slope, the block parameter cannot perform the typecast. In this case, you must match the data type of the variable or parameter object with the data type of the block parameter. Use one of these techniques:

- Use context-sensitive data typing for the variable or parameter object. For a MATLAB variable, use a `double` number to set the value of the variable. For a parameter object, set the `DataType` property to `auto`.
- Use a `Simulink.AliasType` or `Simulink.NumericType` object to set the data type of the block parameter and the data type of a parameter object.

  Use this technique when you cannot rely on context-sensitive data typing, for example, when you use the field of a structure to set the value of the block parameter.
- Manually specify the same data type for the block parameter and the variable or parameter object.

  Use this technique to reduce the dependence of the model on inherited and context-sensitive data types and on external variables and objects.

For blocks that access parameter data through pointer or reference in the generated code, if you specify different data types for the workspace variable and the block

parameter, the generated code implicitly casts the data type of the variable to the data type of the block parameter. Note, that an implicit cast requires a data copy which could significantly increase RAM consumption and slow down code execution speed for large data sets. For example, Lookup Table blocks often access large vectors or matrices through pointer or reference in the generated code.

For information about matching parameter data types when you use model arguments, see “Control Data Types of Model Arguments and Argument Values” on page 32-153.

Detect Downcast and Loss of Precision due to Data Type Mismatches

You can configure diagnostic configuration parameters to detect unintentional data type mismatches that result in quantization and loss of parameter precision. See “Model Configuration Parameters: Data Validity Diagnostics” (Simulink).

Considerations for Other Modeling Patterns

When you use specific modeling patterns and constructs such as fixed-point data types, parameter structures, and lookup table objects, use different techniques to control parameter data types.

Tunable Parameters and Best-Precision Fixed-Point Scaling

To apply best-precision fixed-point scaling to a tunable block parameter or parameter object, you can use the Fixed-Point Tool to autoscale an entire system or use the Data Type Assistant to configure individual parameters or objects. See “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” (Simulink).

If a tunable parameter uses best-precision fixed-point scaling, Simulink chooses a data type based on the minimum and maximum values that you specify for the parameter (see “Specify Minimum and Maximum Values for Block Parameters” (Simulink)). You can specify these values in the block dialog box that uses the parameter or in the properties of a `Simulink.Parameter` object.

If you do not specify a minimum or maximum, Simulink chooses a data type based on the value of the parameter. The chosen scaling might restrict the range of possible tuning

values. Therefore, it is a best practice to specify minimum and maximum values for each tunable parameter.

A tunable parameter can use best-precision scaling even if you do not specify it in the parameter data type. For example, the Gain block can choose a best-precision scaling if the **Parameter data type** in the block dialog box is set to `Inherit: Inherit via internal rule`. This setting is the default for the block.

Control Data Types of Structure Fields

When you use a structure as the value of a block parameter (for example to initialize a bus signal), or when you organize multiple block parameter values into a single structure, you can create a `Simulink.Bus` object to use as the data type of a `Simulink.Parameter` object. You can then control the data types of individual fields in the structure. See "Control Field Data Types and Characteristics by Creating Parameter Object" (Simulink) and "Control Data Types of Initial Condition Structure Fields" (Simulink).

Control Data Types of Lookup Table Objects

When you use `Simulink.LookupTable` and `Simulink.Breakpoint` objects to store table and breakpoint data for a lookup table block, to control the data types of the table and breakpoint data, use one of these techniques:

- Set the `Value` property of the embedded `Simulink.lookuptable.Table` and `Simulink.lookuptable.Breakpoint` objects by using untyped expressions such as `[1 2 3]`, which returns a `double` vector. To control the data type, set the `DataType` property to a value other than `auto`.

  Use this technique to separate the value of the table or breakpoint data from the data type, which can improve readability and understanding of your design. You can then use a `Simulink.NumericType` or `Simulink.AliasType` object to:

  - Customize the name of the data type in the generated code.
  - Match the data type of the table or breakpoint data with the data type of a signal in the model.
- Set the `Value` property of the embedded objects by using typed expressions such as `single([1 2 3])`. To use a fixed-point data type, set the `Value` property with an `fi` object.

Set the `DataType` property of the embedded objects to the default value, `auto`. The table and breakpoint data then acquire the data type that you use to set the `Value` property.

Use this technique to store the data type information in the `Value` property, which can simplify the way you interact with the `Simulink.LookupTable` and `Simulink.Breakpoint` objects. You can leave the `DataType` property at the default value.

When you later change the breakpoint or table data in the `Value` property, preserve the data type information by using a typed expression. Alternatively, if you use a command at the command prompt or a script to change the data, to avoid using a typed expression, use subscripted assignment, `(:)`.

```
myLUTObject.Table.Value(:) = [4 5 6];
```

When you change the data stored in the `Value` property, if you do not use a typed expression or subscripted assignment, you lose the data type information.

When blocks in a subsystem use `Simulink.LookupTable` or `Simulink.Breakpoint` objects, you cannot set data type override (see “Control Fixed-Point Instrumentation and Data Type Override” (Simulink)) only on the subsystem. Instead, set data type override on the entire model.

Data Typing for Expressions in Parameter Objects

You can use an expression to set the value of a parameter object (such as `Simulink.Parameter`). The expression encodes mathematical relationships between different objects. When you use this technique, different data typing rules apply. See “Set Variable Value by Using a Mathematical Expression” (Simulink).

Generate Efficient Code by Specifying Data Types for Block Parameters

To generate more efficient code, match the data types of block parameters (such as the **Gain** parameter of a Gain block) with signal data types. Alternatively, you can store parameters in smaller data types.

Eliminate Unnecessary Typecasts and Shifts by Matching Data Types

These examples show how to generate efficient code by configuring a block parameter to use the same data type as a signal that the block operates on.

Store Data Type Information in Model

Open the example model `rtwdemo_basicsc` and configure it to show the generated names of blocks.

```
load_system('rtwdemo_basicsc')
set_param('rtwdemo_basicsc','HideAutomaticNames','off')
open_system('rtwdemo_basicsc')
```

Identify the Gain block in the model, which uses the base workspace variable `K1` to set the value of the **Gain** parameter. The input signal of this block uses the data type `single`.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Parameters** tab.

In the model, select the Gain block. In the Model Data Editor, the **Data Type** column shows that the data type of the **Gain** parameter of the block is set to `Inherit: Same as input`. With this setting, the **Gain** parameter of this block uses the same data type as the input signal.

In the Model Data Editor, set the **Change view** drop-down list to `Code`.

Update the block diagram. Now, in the Model Data Editor, the data table shows rows that correspond to workspace variables that the model uses, including `K1`.

In the Model Data Editor, find the row that corresponds to `K1`. For that row, in the **Storage Class** column, select `Convert to parameter object`. Simulink converts `K1` to a `Simulink.Parameter` object.

Use the **Storage Class** column to apply the storage class `ExportedGlobal`. With this setting, the object appears in the generated code as a global variable.

In the Model Data Editor, set **Change view** to `Design`.

In the data table, for the row that represents `K1`, in the **Data Type** column, select `auto`. With this setting, the parameter object acquires its data type from the block parameters that use the object (in this case, the **Gain** block parameter).

Alternatively, to create and configure the object, use these commands at the command prompt:

```
K1 = Simulink.Parameter(2);
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated file `rtwdemo_basicsc.c` defines the global variable `K1` by using the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)
```

```
/* Exported block parameters */
real32_T K1 = 2.0F;                    /* Variable: K1
```

The generated code algorithm in the model `step` function uses `K1` directly without typecasting.

```
rtwdemodbtype(file,' rtwdemo_basicsc_DW.X = K1',...
    ' rtCP_Table1_bp01Data, rtCP_Table1_tableData,',1,1)
```

```
    rtwdemo_basicsc_DW.X = K1 * look1_iflf_binlx(rtwdemo_basicsc_U.input2,
      rtCP_Table1_bp01Data, rtCP_Table1_tableData, 10U);
```

On the Model Data Editor **Parameters** tab, you can optionally set the data type of the **Gain** block parameter to `Inherit: Inherit via internal rule` (the default). In

this case, the block parameter chooses the same data type as the input signal, `single`. However, when you use `Inherit: Inherit via internal rule`, under other circumstances (for example, when you use fixed-point data types), the block parameter might choose a different data type.

Store Data Type Information in Parameter Object

When you use a `Simulink.Parameter` object to export or import parameter data from the generated code to your external code, for example by applying the storage class `ImportedExtern`, you can specify data type information in the parameter object. To match the data type of the parameter object with a signal data type, create a `Simulink.NumericType` or `Simulink.AliasType` object. You can strictly control the data type that the parameter object uses in the generated code, eliminating the risk that Simulink chooses a different data type when you make changes to the model.

At the command prompt, create a `Simulink.NumericType` object that represents the data type `single`.

```
myType = Simulink.NumericType;
myType.DataTypeMode = 'Single';
```

Use the Model Data Editor **Data Type** column to set these data types to `myType`:

- The parameter object. Use the **Parameters** tab.
- The Inport block named `In2`. Use the **Inports/Outports** tab. Due to data type propagation, the input signal of the Gain block also uses `myType`.

Use the Model Data Editor **Parameters** tab to set the data type of the **Gain** block parameter to `Inherit: Inherit from 'Gain'`. Use this data type object as the data type of the parameter object.

Alternatively, to configure the object and the blocks, use these commands at the command prompt:

```
K1.DataType = 'myType';
set_param('rtwdemo_basicsc/In2','OutDataTypeStr','myType')
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr','Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The global variable K1 continues to use the data type `real32_T`.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','real32_T K1 = 2.0F;',1,1)
```

```
/* Exported block parameters */
real32_T K1 = 2.0F;                    /* Variable: K1
```

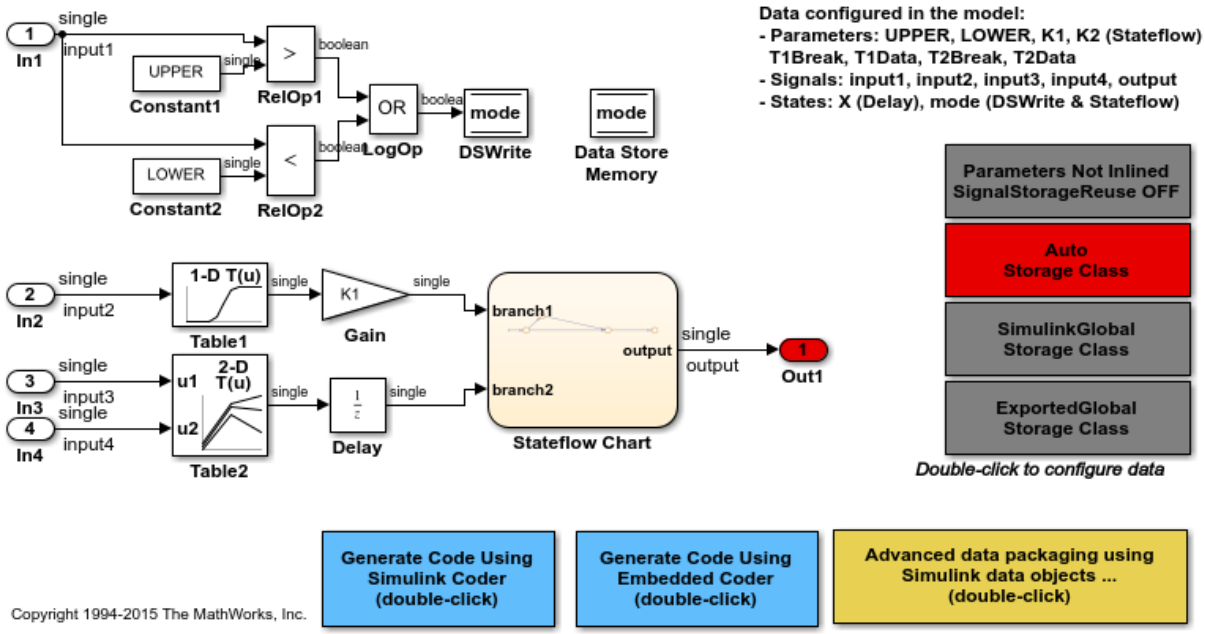
Reduce Memory Consumption by Storing Parameter Value in Small Data Type

When you use a parameter object (for example, `Simulink.Parameter`) to set block parameter values, you can configure the object to appear in the generated code as a tunable global variable. By default, the parameter object and the corresponding global variable typically uses the same data type as the signal or signals on which the block operates. For example, if the input signal of a Gain block uses the data type `int16`, the parameter object typically use the same data type. To reduce the amount of memory that this variable consumes, specify that the variable use a smaller integer data type such as `int8`.

Store Parameter Value in Integer Data Type

Run the script `prepare_rtwdemo_basicsc_2`, which prepares the model `rtwdemo_basicsc` for this example.

```
run(fullfile(matlabroot,'examples','simulinkcoder',...
    'main','prepare_rtwdemo_basicsc_2'))
```



Many of the signals in the model use the data type `single`.

In the model, select **View > Model Data Editor**.

In the Model Data Editor, inspect the **Parameters** tab.

Click the **Show/refresh additional information** button.

Next to the **Filter contents** box, activate the **Filter using selection** button.

In the model, click the Gain block. The Model Data Editor shows one row that corresponds to the **Gain** parameter of the block and one row that corresponds to the MATLAB variable `K1`, which sets the parameter value to `2`. `K1` resides in the base workspace.

In the Model Data Editor, set the **Change view** drop-down list to `Code`.

In the data table, for the row that corresponds to `K1`, in the **Storage Class** column, from the drop-down list, select `Convert to parameter object`. Simulink converts `K1` to a `Simulink.Parameter` object.

```
K1 = Simulink.Parameter(K1);
```

Use the **Storage Class** column to apply the storage class `ExportedGlobal` to `K1`. With this setting, `K1` appears in the generated code as a global variable.

```
K1.CoderInfo.StorageClass = 'ExportedGlobal';
```

In the Model Data Editor, set **Change view** to `Design` and use the **Data Type** column to apply the data type `int8` to `K1`.

```
K1.DataType = 'int8';
```

For the row that represents the **Gain** block parameter, in the **Data Type** column, set the drop-down list to `Inherit: Inherit from 'Gain'`. With this setting, the **Gain** parameter of the block inherits the `int8` data type from the parameter object.

```
set_param('rtwdemo_basicsc/Gain','ParamDataTypeStr',...
    'Inherit: Inherit from ''Gain''')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc')
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

The generated file `rtwdemo_basicsc.c` defines the global variable `K1` by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block parameters */','int8_T K1 = 2;',1,1)
```

```
/* Exported block parameters */
int8_T K1 = 2;                         /* Variable: K1
```

The code algorithm in the model `step` function uses `K1` to calculate the output of the Gain block. The algorithm casts `K1` to the data type `real32_T` (`single`) because the signals involved in the calculation use the data type `real32_T`.

```
rtwdemodbtype(file,' rtwdemo_basicsc_DW.X =','10U);',1,1)
```

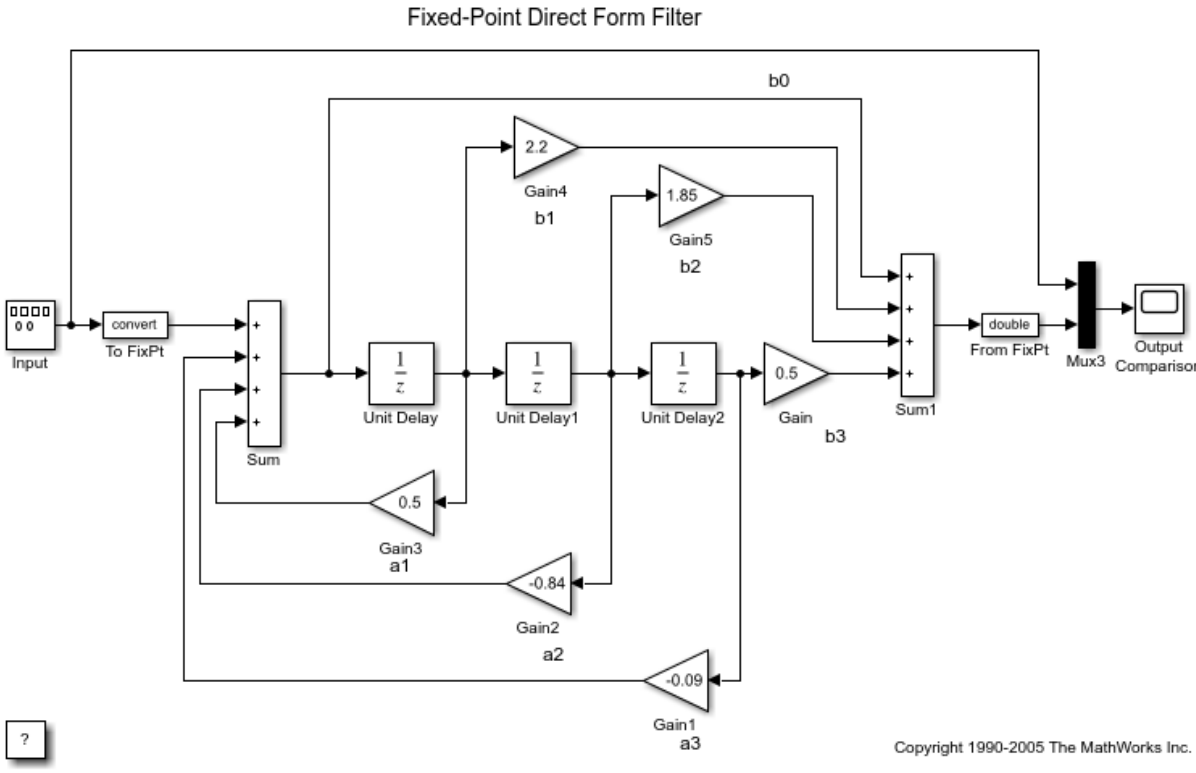
```
    rtwdemo_basicsc_DW.X = (real32_T)K1 * look1_iflf_binlx
      (rtwdemo_basicsc_U.input2, rtCP_Table1_bp01Data, rtCP_Table1_tableData,
       10U);
```

Store Fixed-Point Parameter Value in Smaller Integer Data Type

Suppose you configure the signals in your model to use fixed-point data types. You want a gain parameter to appear in the generated code as a tunable global variable. You know the range of real-world values that you expect the parameter to assume (for example, between 0 and 4). If you can meet your application requirements despite reduced precision, you can reduce memory consumption by configuring the parameter to use a different data type than the input and output signals of the block.

Open the example model `fxpdemo_direct_form2` and configure it to show the generated names of blocks.

```
load_system('fxpdemo_direct_form2')
set_param('fxpdemo_direct_form2','HideAutomaticNames','off')
open_system('fxpdemo_direct_form2')
```



Update the block diagram. Signals in this model use signed fixed-point data types with a word length of 16 and binary-point-only scaling.

Open the Gain5 block dialog box. The **Gain** parameter is set to `1.85`. Suppose you want to configure this parameter.

Set **Gain** to `myGainParam` and click **Apply**.

Click the action button (with three vertical dots) next to the parameter value. Select **Create**.

In the Create New Data dialog box, set **Value** to `Simulink.Parameter(1.85)` and click **Create**. The `Simulink.Parameter` object `myGainParam` appears in the base workspace.

In the `myGainParam` property dialog box, set **Storage class** to `ExportedGlobal` and click **OK**. With this setting, `myGainParam` appears in the generated code as a global variable.

In the block dialog box, on the **Parameter Attributes** tab, set **Parameter minimum** to `0` and **Parameter maximum** to 4.

Set **Parameter data type** to `fixdt(0,8)` and click **Apply**.

Click the **Show Data Type Assistant** button. The Data Type Assistant shows that the expression `fixdt(0,8)` specifies an unsigned fixed-point data type with a word length of 8 and best-precision scaling. When you simulate or generate code, the block parameter chooses a fraction length (scaling) that enables the data type to represent values between the parameter minimum and maximum (0 and 4) with the best possible precision.

In the Data Type Assistant, set **Scaling** to `Binary point`. Click **Calculate Best-Precision Scaling**, **Fixed-point details**, and **Refresh Details**. The information under **Fixed-point details** shows that a fraction length of 5 can represent the parameter values with a precision of 0.03125.

Set **Scaling** back to `Best precision` and click **OK**. In this example, when you simulate or generate code, the block parameter chooses a fraction length of 5.

Alternatively, you can use these commands at the command prompt to create the object and configure the block:

```
myGainParam = Simulink.Parameter(1.85);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
```

```
set_param('fxpdemo_direct_form2/Gain5','Gain','myGainParam')
set_param('fxpdemo_direct_form2/Gain5','ParamMin','0','ParamMax','4')
set_param('fxpdemo_direct_form2/Gain5','ParamDataTypeStr','fixdt(0,8)')
```

Configure the model to produce a code generation report. To reduce clutter in the Command Window, clear the configuration parameter **Verbose build**.

```
set_param('fxpdemo_direct_form2','GenerateReport','on',...
    'LaunchReport','on','RTWVerbose','off')
```

Generate code from the model.

```
evalc('rtwbuild(''fxpdemo_direct_form2'')');
```

The generated file `fxpdemo_direct_form2.c` defines the global variable `myGainParam` by using the data type `uint8_T`, which corresponds to the specified word length, 8. The code initializes the variable by using an integer value that, given the fraction length of 5, represents the real-world parameter value 1.85.

```
file = fullfile('fxpdemo_direct_form2_grt_rtw','fxpdemo_direct_form2.c');
rtwdemodbtype(file,'/* Exported block parameters */','uint8_T myGainParam = 59U;',1,1)
```

```
/* Exported block parameters */
uint8_T myGainParam = 59U;             /* Variable: myGainParam
```

The code algorithm uses `myGainParam` to calculate the output of the Gain5 block. The algorithm uses a C shift to scale the result of the calculation.

```
rtwdemodbtype(file,'/* Gain: ''<Root>/Gain5'' */',...
'/* Gain: ''<Root>/Gain'' incorporates:',1,0)
```

```
  /* Gain: '<Root>/Gain5' */
  fxpdemo_direct_form2_B.Gain5 = (int16_T)((myGainParam *
    fxpdemo_direct_form2_B.UnitDelay1) >> 5);
```

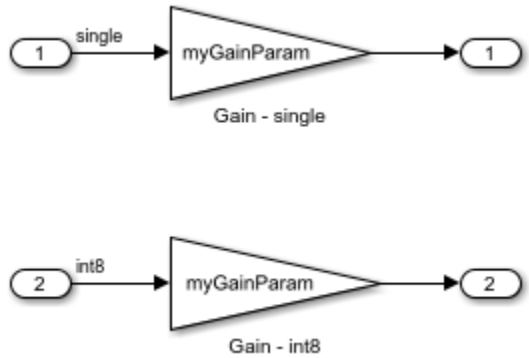
Reuse Parameter Data in Different Data Type Contexts

When you use a `Simulink.Parameter` object or a numeric MATLAB variable to set two or more block parameter values, if the block parameters have different data types, you must explicitly specify the data type of the object or variable. For example, you cannot leave the data type of the parameter object at the default value, `auto`.

Create and Configure Example Model

Create the model `ex_paramdt_contexts`.

```
ex_paramdt_contexts
```



In the model, select **View > Model Data Editor**.

In the Model Data Editor, on the **Inports/Outports** tab, use the **Data Type** column to set the data type of the `In1` Inport block to `single` and the data type of the `In2` block to `int8`.

On the **Signals** tab, set the data types of the Gain block outputs to `Inherit: Same as input`.

On the **Parameters** tab, for the **Gain** parameters of the Gain blocks, set **Data Type** to `Inherit: Same as input`.

For the **Gain** parameters, set **Value** to `myGainParam`.

Alternatively, to configure the blocks, use these commands at the command prompt:

```
set_param('ex_paramdt_contexts/In1','OutDataTypeStr','single')
set_param('ex_paramdt_contexts/In2','OutDataTypeStr','int8')
set_param('ex_paramdt_contexts/Gain - single','Gain','myGainParam',...
    'OutDataTypeStr','Inherit: Same as input',...
    'ParamDataTypeStr','Inherit: Same as input')
set_param('ex_paramdt_contexts/Gain - int8','Gain','myGainParam',...
    'OutDataTypeStr','Inherit: Same as input',...
    'ParamDataTypeStr','Inherit: Same as input')
```

In the Model Data Editor, for either **Gain** block parameter, click the cell in the **Value** column. Next to `myGainParam`, click the action button (with three vertical dots) and select **Create**.

In the **Create New Data** dialog box, set **Value** to `Simulink.Parameter(3)` and click **Create**. A `Simulink.Parameter` object with value `3` appears in the base workspace.

In the **myGainParam** property dialog box, set **Data type** to `int8` and **Storage class** to `ExportedGlobal`. With the storage class `ExportedGlobal`, the object appears in the generated code as a global variable.

Alternatively, to create and configure the parameter object, use these commands at the command prompt:

```
myGainParam = Simulink.Parameter(3);
myGainParam.CoderInfo.StorageClass = 'ExportedGlobal';
myGainParam.DataType = 'int8';
```

In this model, you use the parameter object `myGainParam` to set two block parameter values. The block parameters inherit different data types from the block input signals (`single` or `int8`). To use `myGainParam` in these different data type contexts, you explicitly specify the data type of the parameter object by setting the `DataType` property to `int8`.

Match Parameter Object Data Type with Signal Data Type

Optionally, use a `Simulink.NumericType` or `Simulink.AliasType` object to set the parameter object data type and one of the signal data types. This technique eliminates unnecessary typecasts and shifts in the generated code due to a mismatch between the parameter object data type and the signal data type.

At the command prompt, create a `Simulink.NumericType` object to represent the data type `int8`.

```
sharedType_int8 = fixdt('int8');
```

In the Model Data Editor, on the **Inports/Outports** tab, set the data type of the `In2` Inport block to `sharedType_int8`.

On the **Parameters** tab, update the block diagram. The data table now contains a row that represents the parameter object, `myGainParam`.

Use the **Data Type** column to set the data type of the parameter object to `sharedType_int8`.

Alternatively, to configure the block and the object, use these commands at the command prompt:

```
myGainParam.DataType = 'sharedType_int8';
set_param('ex_paramdt_contexts/In2','OutDataTypeStr','sharedType_int8')
```

The parameter object and the signal use the data type `int8`. To change this data type, adjust the properties of the data type object `sharedType_int8`.

Generate and Inspect Code

Generate code from the model.

```
rtwbuild('ex_paramdt_contexts')
```

```
### Starting build procedure for model: ex_paramdt_contexts
### Successful completion of build procedure for model: ex_paramdt_contexts
```

The generated file `ex_paramdt_contexts.c` defines the global variable `myGainParam` by using the data type `int8_T`, which corresponds to the data type `int8` in Simulink.

```
file = fullfile('ex_paramdt_contexts_grt_rtw','ex_paramdt_contexts.c');
rtwdemodbtype(file,'/* Exported block parameters */','int8_T myGainParam = 3;',1,1)
```

```
/* Exported block parameters */
int8_T myGainParam = 3;                /* Variable: myGainParam
```

The generated code algorithm in the model `step` function uses `myGainParam` to calculate the outputs of the two Gain blocks. In the case of the Gain block whose input signal uses the data type `single`, the code algorithm casts `myGainParam` to the data type `real32_T`, which corresponds to the data type `single` in Simulink.

```
rtwdemodbtype(file,'/* Model step function */',...
    '/* Model initialize function */',1,0)
```

```
/* Model step function */
void ex_paramdt_contexts_step(void)
{
  /* Outport: '<Root>/Out1' incorporates:
   *  Gain: '<Root>/Gain - single'
   *  Inport: '<Root>/In1'
   */
  ex_paramdt_contexts_Y.Out1 = (real32_T)myGainParam * ex_paramdt_contexts_U.In1;

  /* Outport: '<Root>/Out2' incorporates:
   *  Gain: '<Root>/Gain - int8'
   *  Inport: '<Root>/In2'
   */
  ex_paramdt_contexts_Y.Out2 = (int8_T)(myGainParam * ex_paramdt_contexts_U.In2);
}
```

Organize Data into Structures in Generated Code

In C code, you use structures (`struct`) to store data in contiguous locations in memory. You can organize data, such as signals and states, by using meaningful names. Each structure acts as a namespace, so you can reuse a name to designate multiple data items. Like arrays, with structures, you can write code that efficiently transfers and operates on large amounts of data by using pointers.

By default, the code generator aggregates data into standard structures (see “How Generated Code Stores Internal Signal, State, and Parameter Data” on page 32-50). To control the characteristics of these structures or to override this default behavior by creating different structures, use the information in the table.

Goal	Technique
Control the characteristics of the standard data structures. For example, specify the names of the structure types, structure variables, and field names.	With Embedded Coder, see “Control Characteristics of Data Structures (Embedded Coder)” on page 32-27.
Control the placement of the structures in memory, for example, by inserting pragmas or other code decorations.	With Embedded Coder, see “Control Data and Function Placement in Memory by Inserting Pragmas” on page 40-2.

Goal	Technique
Aggregate data into structures whose names and other basic characteristics you can control. As you add blocks and signals to the model, the resulting new data appears in these structures by default.	With Embedded Coder, apply a structured custom storage class to a category of data by using the Code Mapping Editor. • When you generate nonreetrant, single-instance code by setting the model configuration parameter **Code interface packaging** to `Nonreusable function`, create flat, global structure variables by applying the built-in storage class `Struct`. Alternatively, use example storage classes created by Quick Start tool, `ParamStruct` and `SignalStruct`, or create and apply your own structured custom storage class. • When you generate multi-instance (reentrant) code from a model or a component, for example by setting **Code interface packaging** to a value other than `Nonreusable function`, in the Code Mappings editor, you cannot use the built-in storage class `Struct` or a structured storage class that you create in a package. Instead, create your own structured custom storage class by using an Embedded Coder Dictionary. If you use the Embedded Coder Quick Start tool to prepare the model for code generation (see “Generate Code by Using the Quick Start Tool” on page 48-10), you can use example storage classes `ParamStruct` and `SignalStruct`. • You cannot use this technique to aggregate global data stores or global parameters (which include parameter objects that you store in the base

Goal	Technique
	workspace or a data dictionary). For these kinds of data, use other techniques to create structures. For more information about the Code Mapping Editor, see "Configure Default C Code Generation for Categories of Model Data and Functions" on page 31-7. To create your own storage class, see "Define Storage Classes, Memory Sections, and Function Templates for Software Architecture" on page 30-2.
Improve readability of the generated code by organizing individual data items into a custom structure whose characteristics you can finely control.	Create a `Simulink.Bus` object that represents the structure type that you want. Use the bus object to set the data types of nonvirtual bus signals and parameter structures in your model. • For an example that shows how to organize parameter data, see "Structures of Parameters" on page 32-189. • For an example that shows how to organize signal data, see "Structures of Signals" on page 32-191. To create an array of structures, see "Arrays of Structures" on page 32-198.

Goal	Technique
Exchange structured data between generated code and your external code, for example, when the external code already defines a custom structure type and a corresponding global variable.	Create a `Simulink.Bus` object that represents the structure type that you want. If your external code already defines the type, use the `Simulink.importExternalCTypes` function to generate the bus object. Use the bus object to set the data types of nonvirtual bus signals and parameter structures in your model. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” on page 34-34.

Goal	Technique

Reduce the number of arguments (formal parameters) for generated functions.	• To reduce the number of arguments for the entry-point functions of the model from which you generate code, such as *`model`*`_step`, see “Reduce Number of Arguments by Using Structures” on page 32-47.
	• To reduce the number of arguments for the entry-point functions of a referenced model, in the referenced model:
	  • Configure root-level Inport and Outport blocks to appear in the code as structure fields. Replace multiple such blocks with a single block that you configure as a nonvirtual bus signal. With this technique, you have the greatest control over the structure characteristics. As you add blocks to the model, you must manually modify the bus definitions. See “Nonvirtual Buses and Parameter Structures” on page 32-188.
	  • Organize model arguments into a custom structure (see “Specify Instance-Specific Parameter Values for Reusable Referenced Model” on page 32-142).
	• To reduce the number of arguments for the entry-point functions of a masked, reentrant subsystem, aggregate mask parameters into a custom structure.

Organize lookup table data into a structure.	Use `Simulink.LookupTable` and `Simulink.Breakpoint` objects. See `Simulink.LookupTable`.

Goal	Technique
Generate bit fields.	See “Bitfields” on page 24-87 and “Optimize Generated Code By Packing Boolean Data Into Bitfields” on page 71-12.

Techniques to Create Structures

To create structures in the generated code, you can use these techniques:

- Apply a structured storage class to categories of data by using the Code Mapping Editor. As you add blocks and signals to a model, new data elements acquire this storage class by default.
- Apply a structured storage class, such as the built-in custom storage class `Struct`, directly to individual data items by using the Model Data Editor.
- Create custom nonvirtual buses and parameter structures.

To decide which techniques to use, use the information in the table.

Capability	Default Application of Structured Storage Class	Direct Application of Structured Storage Class	Nonvirtual Buses and Parameter Structures
Aggregate new data items into a structure by default	Yes	No	No
Prevent elimination of the target data by optimizations (specify that the data appear in the generated code)	No	Yes	Only if you directly apply a storage class such as `ExportedGlobal` to the bus or structure
Aggregate data into a structure without changing the appearance of the block diagram	Yes	Yes	No

Capability	Default Application of Structured Storage Class	Direct Application of Structured Storage Class	Nonvirtual Buses and Parameter Structures
Place signal, state, and parameter data in the same structure	No	Yes	No
Include state data in a structure	Yes	Yes	No
Organize structures into nested structures	No	No	Yes
Organize structures into an array of structures	No	No	Yes
Control name of structure type	Yes	Yes, but the type name derives from the variable name, which you specify	Yes
Create a structure to reduce the number of arguments in a generated function	Yes, but you must create your own storage class by using an Embedded Coder Dictionary	No	Yes
Requires Embedded Coder	Yes	Yes	No

Default Application of Structured Storage Class

You can apply a default storage class to a category of model data. As you add blocks and signals to the model, the associated data acquire the default storage class that you specify. To aggregate new data into structures by default, you can apply structured storage classes. You must use example storage classes `ParamStruct` and `SignalStruct` created by the Quick Start tool or create your own storage class by using an Embedded Coder Dictionary.

You cannot use default application to aggregate global data stores or global parameters (parameter objects that you store in the base workspace or a data dictionary).

To apply default storage classes, use the Code Mapping Editor. In a model window, select **Code > C/C++ Code > Configure Model in Code Perspective**. Then, under **Code Mappings > Data Defaults**, apply storage classes by using the **Storage Class** column.

For more information about the Code Mapping Editor, see “Configure Default C Code Generation for Categories of Model Data and Functions” on page 31-7. To create your own storage class by using an Embedded Coder Dictionary, see “Create Code Definitions for Use as Default Code Generation Settings” on page 30-2.

Direct Application of Structured Storage Class

You can apply a structured storage class to individual data items. The direct application prevents code generation optimizations, such as **Default parameter behavior** and **Signal storage reuse**, from eliminating each data item from the generated code. The direct application also overrides the default storage classes that you specify with **Code Mappings > Data Defaults**.

To directly apply a storage class, use the Model Data Editor (**View > Model Data Editor**). Set **Change view** to `Code` and apply the storage class by using the **Storage Class** column.

For an example that shows how to use `Struct`, see “Organize Parameter Data into a Structure by Using the Struct Custom Storage Class” on page 36-32. For more information about applying storage classes, see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” on page 36-28.

Nonvirtual Buses and Parameter Structures

- To create a nonvirtual bus signal, use a Bus Creator block to organize multiple signal lines into a single bus, or configure an Inport block or Outport block as a nonvirtual bus. You must create a `Simulink.Bus` object that represents the structure type. For an example, see “Structures of Signals” on page 32-191. For general information about nonvirtual buses, see “Getting Started with Buses” (Simulink).
- To create a parameter structure, use MATLAB commands or the Variable Editor to organize the values of multiple block parameters into a MATLAB structure. Optionally, create a `Simulink.Bus` object so that you can control the name of the structure type and other characteristics such as the data type and dimensions of each field. For an example, see “Structures of Parameters” on page 32-189. For general information about parameter structures, see “Organize Related Block Parameter Definitions in Structures” (Simulink).

Structures of Parameters

Create a structure in the generated code. The structure stores parameter data.

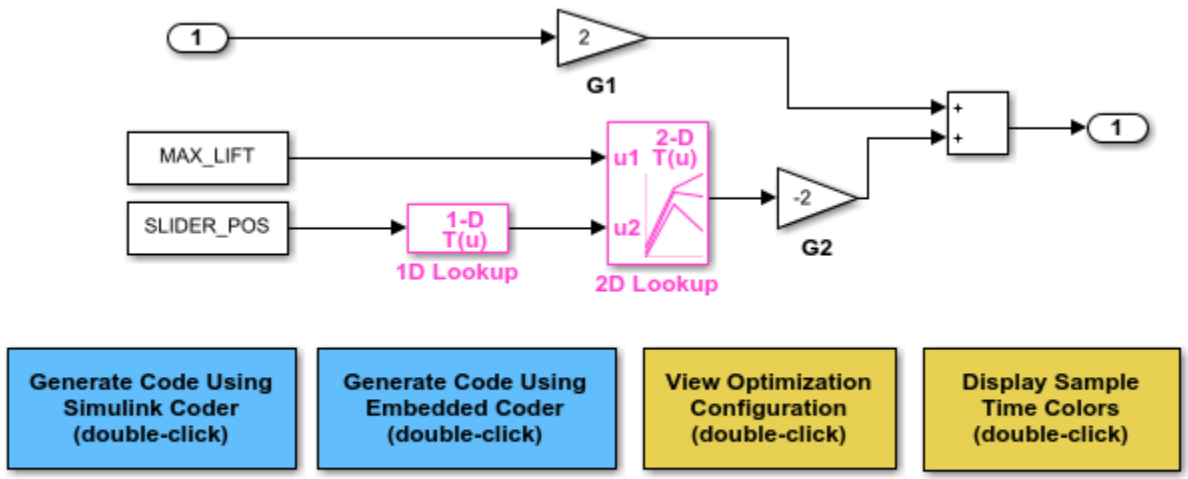
C Construct

```
typedef struct {
  double G1;
  double G2;
} myStructType;

myStructType myStruct = {
  2.0,
  -2.0
} ;
```

Procedure

1. Open the example model `rtwdemo_paraminline`.



2. Select **View > Model Data Editor**. In the Model Data Editor, select the **Parameters** tab.

3. In the model, click the Gain block labeled `G1`. In the Model Data Editor, use the **Value** column to set the value of the **Gain** parameter to `myStruct.G1`.

4. Set the value of the **Gain** parameter in the `G2` block to `myStruct.G2`.

5. Next to `myStruct.G2`, click the action button (with three vertical dots) and select **Create**.

6. In the Create New Data dialog box, set **Value** to `Simulink.Parameter(struct)` and click **Create**. A `Simulink.Parameter` object named `myStruct` appears in the base workspace.

7. In the Simulink.Parameter property dialog box, next to the **Value** property, click the action button and select **Open Variable Editor**.

8. Right-click the white space under the **Field** column and select **New**. Name the new structure field `G1`. Use the **Value** column to set the value of the field to `2`.

9. Add a field `G2` whose value is `-2`, and then close the Variable Editor.

10. In the Simulink.Parameter property dialog box, set **Storage class** to `ExportedGlobal`. The structure `myStruct` appears in the generated code as a global variable.

11. Generate code from the model.

Results

The generated header file `rtwdemo_paraminline_types.h` defines a structure type that has a random name a random name.

```
typedef struct {
  real_T G1;
  real_T G2;
} struct_6h72eH5WFuEIyQr5YrdGuB;
```

The source file `rtwdemo_paraminline.c` defines and initializes the structure variable `myStruct`.

```
/* Exported block parameters */
struct_6h72eH5WFuEIyQr5YrdGuB myStruct = {
```

```
  2.0,
  -2.0
} ;                                     /* Variable: myStruct
                                         * Referenced by:
                                         *   '<Root>/G1'
                                         *   '<Root>/G2'
                                         */
```

Specify Name of Structure Type

1. Optionally, specify a name to use for the structure type definition (`struct`). At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object that represents the structure type.

2. The default name of the object is `slBus1`. Change the name by copying the object into a new MATLAB variable.

3. In the Model Data Editor, click the **Show/refresh additional information** button.

4. In the data table, find the row that corresponds to `myStruct`. Use the **Data Type** column to set the data type of `myStruct` to `Bus: myStructType`.

5. Generate code from the model.

The code generates the definition of the structure type `myStructType` and uses this type to define the global variable `myStruct`.

```
myStructType myStruct = {
  2.0,
  -2.0
} ;                                     /* Variable: myStruct
```

Structures of Signals

This example shows how to create a structure of signal data in the generated code.

C Construct

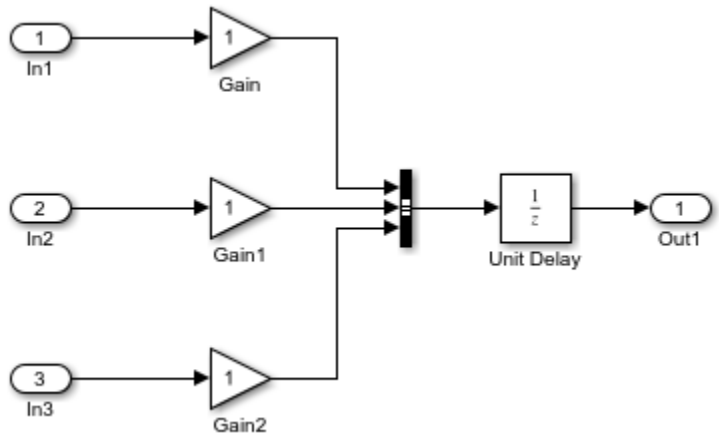
```
typedef struct {
   double signal1;
   double signal2;
```

```
   double signal3;
} my_signals_type;
```

Procedure

1. To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

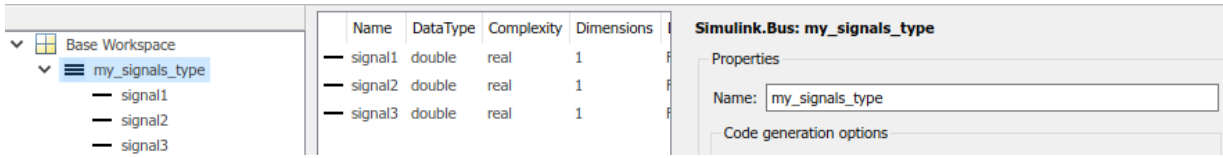
2. Create the `ex_signal_struct` model by using Gain blocks, a Bus Creator block, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.



3. To configure the Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to 3.

4. In the model, select **Edit > Bus Editor**.

5. Use the Bus Editor to create a `Simulink.Bus` object named `my_signals_type` that contains three signal elements: `signal1`, `signal2`, and `signal3`. See “Create Bus Objects with the Bus Editor” (Simulink).



This bus object represents the structure type that you want the generated code to use.

6. In the Bus Creator block dialog box, set **Output data type** to `Bus: my_signals_type`.

7. Select **Output as nonvirtual bus**. Click **OK**. A nonvirtual bus appears in the generated code as a structure.

8. In the model, select **View > Model Data Editor**. In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select `Code`.

9. In the model, click the output signal of the Bus Creator block.

10. In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

11. Set **Storage Class** to `ExportedGlobal`. The output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

12. Generate code from the model.

Results

The generated header file `ex_signal_struct_types.h` defines the structure type `my_signals_type`.

```
typedef struct {
  real_T signal1;
  real_T signal2;
  real_T signal3;
} my_signals_type;
```

The source file `ex_signal_struct.c` allocates memory for the global variable `sig_struct_var`, which represents the output of the Bus Creator block.

```
/* Exported block signals */
my_signals_type sig_struct_var;        /* '<Root>/Bus Creator' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

Nested Structures of Signals

You can create nested structures of signal data in the generated code.

C Construct

```
typedef struct {
  double signal1;
  double signal2;
  double signal3;
} B_struct_type;

typedef struct {
  double signal1;
  double signal2;
} C_struct_type;

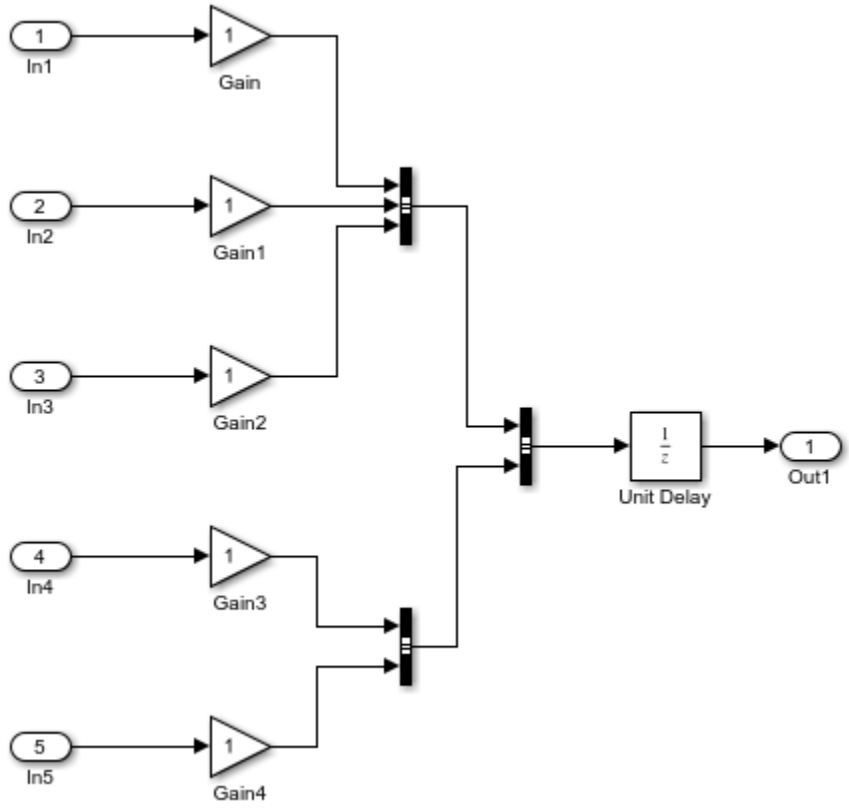
typedef struct {
  B_struct_type subStruct_B;
  C_struct_type subStruct_C;
} A_struct_type;
```

Procedure

To represent a structure type in a model, create a `Simulink.Bus` object. Use the object as the data type of bus signals in your model.

To nest a structure inside another structure, use a bus object as the data type of a signal element in another bus object.

1. Create the `ex_signal_nested_struct` model with Gain blocks, Bus Creator blocks, and a Unit Delay block. The Gain and Unit Delay blocks make the structure more identifiable in the generated code.

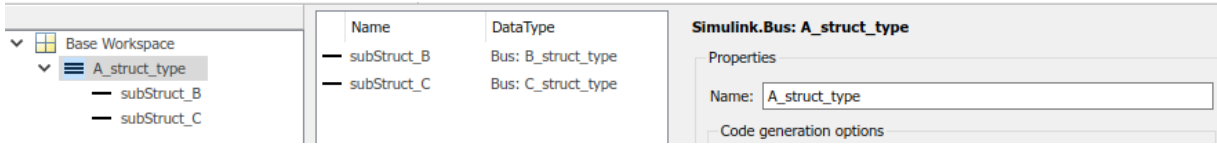


2. To configure a Bus Creator block to accept three inputs, in the block dialog box, set **Number of inputs** to `3`.

3. In the model, select **Edit > Bus Editor**.

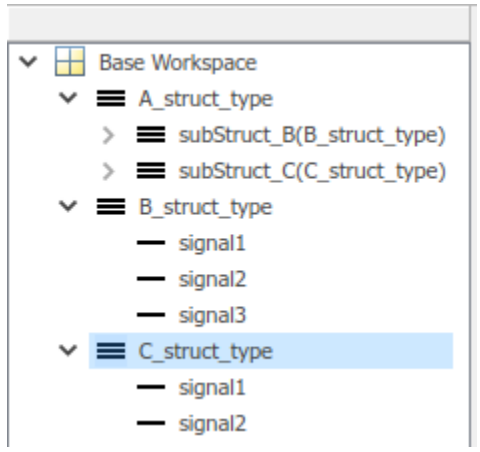
Use the Bus Editor to create a `Simulink.Bus` object named `A_struct_type` that contains two signal elements: `subStruct_B` and `subStruct_C`. To create bus objects with the Bus Editor, see “Create Bus Objects with the Bus Editor” (Simulink). This bus object represents the top-level structure type that you want the generated code to use.

4. For the `subStruct_B` element, set **DataType** to `Bus: B_struct_type`. Use a similar type name for `subStruct_C`.



Each signal element in `A_struct_type` uses another bus object as a data type. Now, these elements represent substructures.

5. Use the Bus Editor to create the `Simulink.Bus` objects `B_struct_type` (with three signal elements) and `C_struct_type` (with two signal elements).



6. In the dialog box of the Bus Creator block that collects the three Gain signals, set **Output data type** to `Bus: B_struct_type`. Click **Apply**.

7. Select **Output as nonvirtual bus** and click **OK**.

8. In the dialog box of the other subordinate Bus Creator block, set **Output data type** to `Bus: C_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

9. In the last Bus Creator block dialog box, set **Output data type** to `Bus: A_struct_type` and select **Output as nonvirtual bus**. Click **OK**.

10. In the model, select **View > Model Data Editor**.

11. In the Model Data Editor, on the **Signals** tab, from the **Change view** drop-down list, select `Code`.

12. In the model, click the output signal of the `A_struct_type` Bus Creator block, which feeds the Unit Delay block.

13. In the Model Data Editor, for the output of the Bus Creator block, set **Name** to `sig_struct_var`.

14. Set **Storage Class** to `ExportedGlobal`. With this setting, the output of the Bus Creator block appears in the generated code as a separate global structure variable named `sig_struct_var`.

15. Generate code from the model.

Results

The generated header file `ex_signal_nested_struct_types.h` defines the structure types. Each structure type corresponds to a `Simulink.Bus` object.

```
typedef struct {
  real_T signal1;
  real_T signal2;
  real_T signal3;
} B_struct_type;

typedef struct {
  real_T signal1;
  real_T signal2;
} C_struct_type;

typedef struct {
  B_struct_type subStruct_B;
  C_struct_type subStruct_C;
} A_struct_type;
```

The generated source file `ex_signal_nested_struct.c` allocates memory for the global structure variable `sig_struct_var`. By default, the name of the `A_struct_type` Bus Creator block is `Bus Creator2`.

```
/* Exported block signals */
A_struct_type sig_struct_var;          /* '<Root>/Bus Creator2' */
```

In the same file, in the model `step` function, the algorithm accesses `sig_struct_var` and the fields of `sig_struct_var`.

Combine Techniques to Work Around Limitations

To work around some of the limitations of each technique, you can combine structured custom storage classes with nonvirtual buses and parameter structures. For example, you can:

- Include a structure of signal data and a structure of parameter data in the same parent structure.
- Nest structures while aggregating new data by default.

In the generated code, a flat parent structure, which corresponds to the structured custom storage class, contains substructures, which correspond to each bus and parameter structure. Choose one of these combined techniques:

- Apply the structured custom storage class directly to each bus and parameter structure. For example, set the storage class of two nonvirtual bus signals to `Struct`. Each bus appears in the generated code as a field (substructure) of a single structure.
- Leave the storage class of each bus and parameter structure at the default setting, `Auto`, or at `Model default`, which prevents code generation optimizations from eliminating the bus or parameter structure. Then, configure default storage classes such that signal data and parameter data use the structured custom storage class by default.

Arrays of Structures

You can further package multiple consistent bus signals or parameter structures into an array. The array of buses or parameter structures appears in the generated code as an array of structures. To create arrays of buses, see “Combine Buses into an Array of Buses” (Simulink). To create arrays of parameter structures, see “Group Multiple Parameter Structures into an Array” (Simulink).

Structure Padding

By default, the code generator does not explicitly add padding fields to structure types. Structure types can appear in the generated code through, for example, the standard data

structures (see “Standard Data Structures in the Generated Code” (Simulink Coder)), `Simulink.Bus` objects, and parameter structures that you use in a model.

However, when you use a code replacement library with Embedded Coder, you can specify data alignment (including structure padding) as part of the replacement library. For more information, see “Provide Data Alignment Specifications for Compilers” on page 65-139.

Limitations

- With built-in Simulink Coder and Embedded Coder features, you cannot generate or use a custom structure that contains a field whose value is a pointer. You can do so manually by creating an advanced custom storage class and writing accompanying TLC code (see “Finely Control Data Representation by Writing TLC Code for a Custom Storage Class” on page 36-48).
- You cannot use the built-in storage class `Struct`, or a structured storage class that you create with the Custom Storage Class Designer (you set the storage class property **Type** to `FlatStructure`), to set data defaults in the Code Mapping Editor.

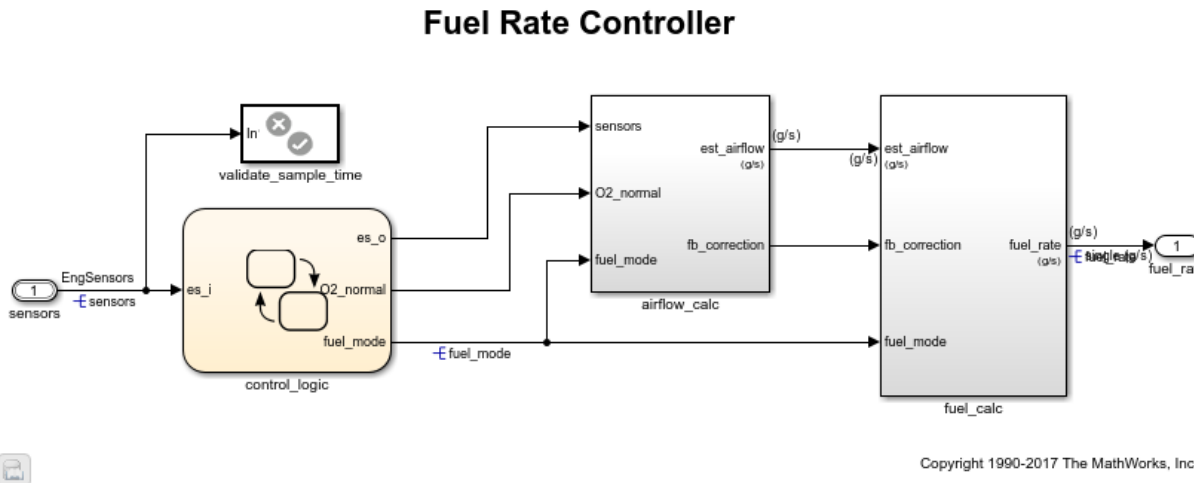
Switch Between Sets of Parameter Values During Simulation and Code Execution

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

Explore Example Model

Open the example model.

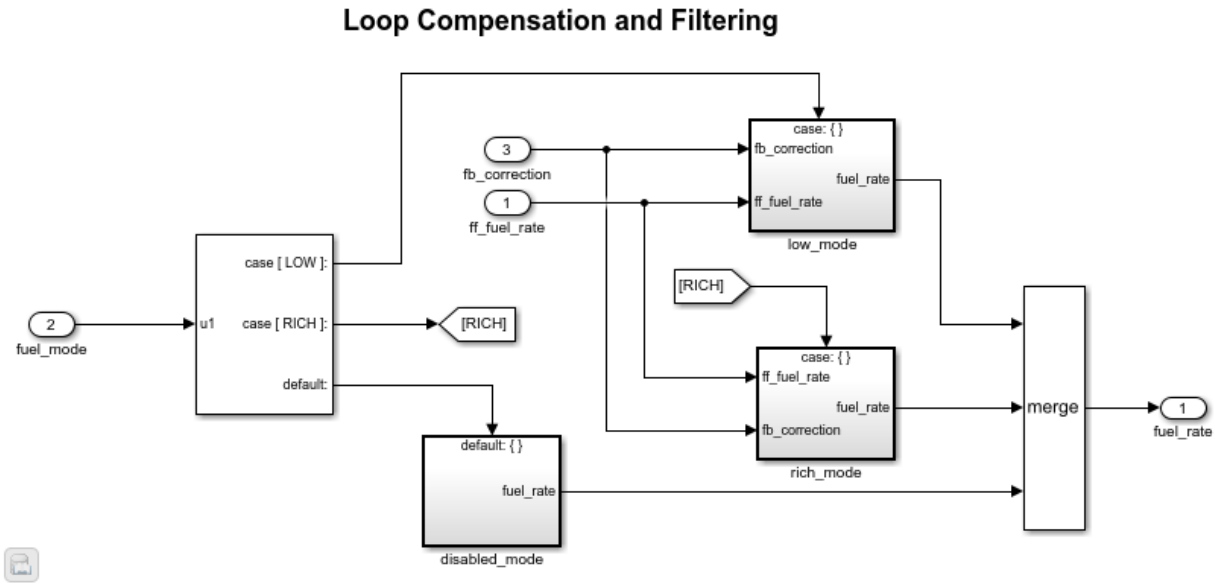
```
open_system('sldemo_fuelsys_dd_controller')
```



This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

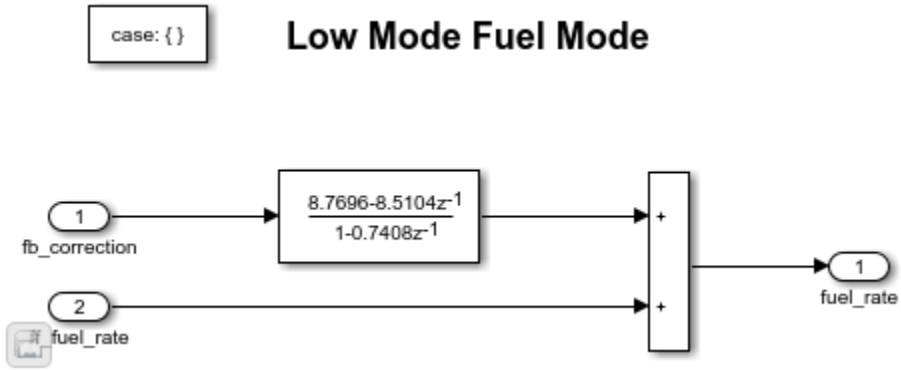
```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
     'switchable_compensation'])
```



This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
     'switchable_compensation/low_mode'])
```



The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the data dictionary badge. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane, view the properties of the `Simulink.NumericType` objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a `Simulink.Parameter` object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```
lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
    'switchable_compensation/low_mode/Discrete Filter'];
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
    'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock,'Numerator'));
params.richNumerator = eval(get_param(richBlock,'Numerator'));
params = Simulink.Parameter(params);
```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```
temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp
```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

Create Variable to Switch Between Parameter Sets

Create a `Simulink.Parameter` object named `Ctrl`.

```
Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';
```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```
set_param(lowBlock,'Numerator','params(Ctrl).lowNumerator');
```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```
set_param(richBlock,'Numerator','params(Ctrl).richNumerator');
```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs',{'Weak','Aggressive'},[1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index `2`.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary `sldemo_fuelsys_dd_controller.sldd`.

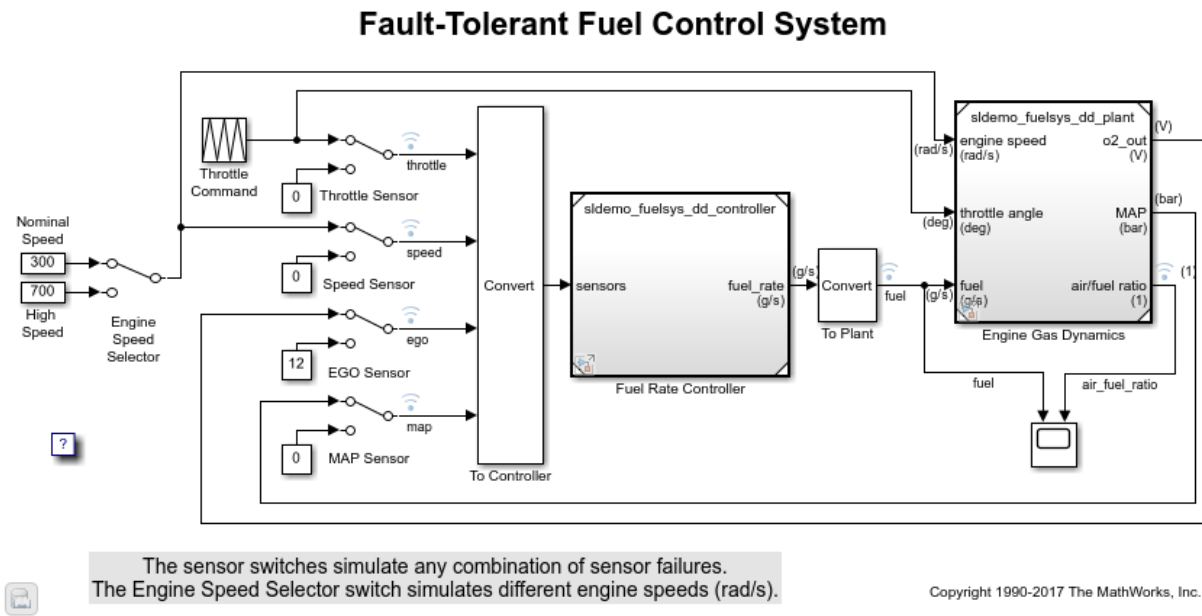
```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.sldd');
sectObj = getSection(dictObj,'Design Data');
addEntry(sectObj,'Ctrl',Ctrl)
addEntry(sectObj,'params',params)
addEntry(sectObj,'paramsType',paramsType)
```

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.sldd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary” (Simulink).

Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```



Set the simulation stop time to `Inf` so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the `fuel` signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to `Storage Class`.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj,'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,params);

tempEntryObj = getEntry(sectObj,'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj,Ctrl);
```

Generate code from the controller model.

```
rtwbuild('sldemo_fuelsys_dd_controller')

### Starting build procedure for model: sldemo_fuelsys_dd_controller
### Successful completion of code generation for model: sldemo_fuelsys_dd_controller
```

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',...
    '/* Forward declaration for rtModel */',1,0)

#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
  Weak = 1,                            /* Default value */
  Aggressive
} FilterCoeffs;

#endif
```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```
rtwdemodbtype(file,'#ifndef DEFINED_TYPEDEF_FOR_paramsType_',...
    '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',1,0)

#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_

typedef struct {
  real32_T lowNumerator[2];
  real32_T richNumerator[2];
} paramsType;

#endif
```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
    'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file,'FilterCoeffs Ctrl = Aggressive;',...
    '/* Block signals (default storage) */',1,0)
```

```
FilterCoeffs Ctrl = Aggressive;        /* Variable: Ctrl
                                        * Referenced by:
                                        *   '<S12>/Discrete Filter'
                                        *   '<S13>/Discrete Filter'
                                        */
```

The code also defines the array of structures `params`.

```
rtwdemodbtype(file,'/* Exported block parameters */',...
    '/* Variable: params',1,1)
```

```
/* Exported block parameters */
paramsType params[2] = { {
    { 8.7696F, -8.5104F },

    { 0.0F, 0.2592F }
  }, { { 17.5392F, -17.0208F },

    { 0.0F, 0.5184F }
  } } ;                                /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

Close the connections to the data dictionary. This example discards unsaved changes. To save the changes, use the `'-save'` option.

```
Simulink.data.dictionary.closeAll('sldemo_fuelsys_dd_controller.sldd','-discard')
```

Design Data Interface by Configuring Inport and Outport Blocks

The data interface of a model is the means by which the model exchanges data (for example, signal values) with other, external models or systems. Customize the data interface of a model to:

- Enable integration of the generated code with your own code.
- Improve traceability and readability of the code.

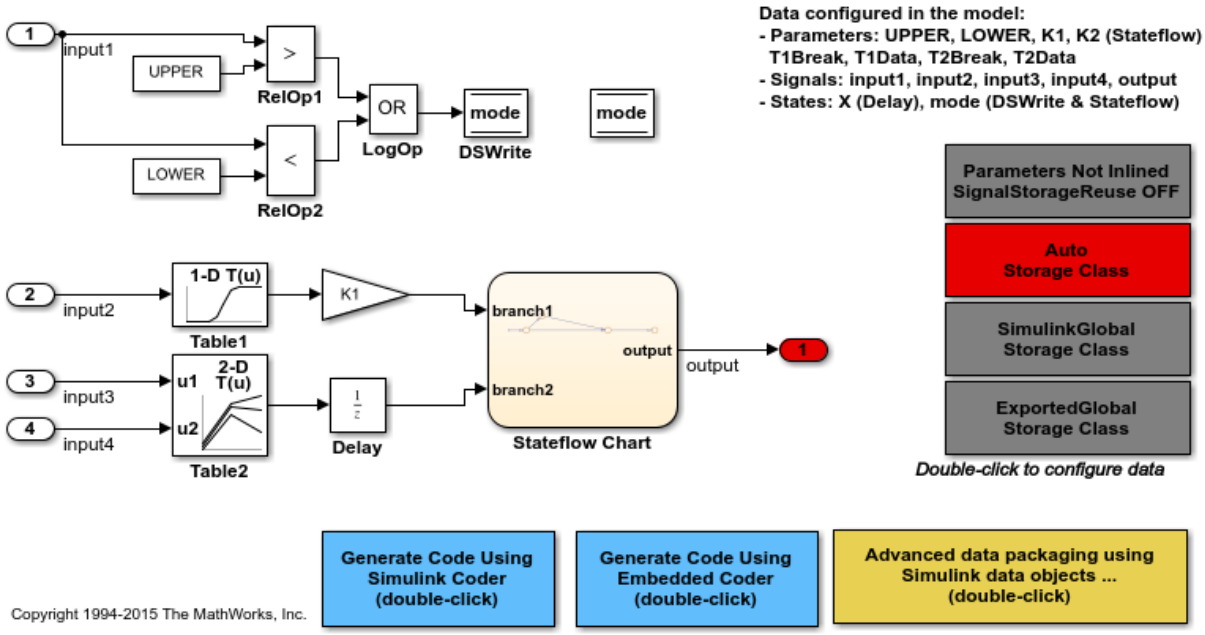
At the top level of a model, Inport and Outport blocks represent the input and output signals of the model. To customize the data interface in the generated code, configure these blocks. Early in the design process, when a model can contain unconnected Inport and Outport blocks, use this technique to specify the interface before developing the internal algorithm.

When you apply storage classes to Inport and Outport blocks, each block appears in the generated code as a field of a global structure or as a separate global variable that the generated algorithm references directly. If you have Embedded Coder, you can use function prototype control instead of storage classes to pass data into and out of the model `step` function as formal parameters. See “Customize Generated C Function Interfaces” on page 39-2.

Design Data Interface

Open the example model `rtwdemo_basicsc`.

```
open_system('rtwdemo_basicsc')
```



Configure the model to show the generated names of blocks.

```
set_param('rtwdemo_basicsc','HideAutomaticNames','off')
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Inports/Outports** tab. Each row in the table represents an Outport block or a signal that exits an Inport block.

Name the signal data that the Outport block `Out1` represents. Set **Signal Name** to `output_sig`.

For each of the signals that exit the Inport blocks, set **Data Type** to `single` or to a different data type. Due to the data type inheritance settings that the other blocks in the model use by default, downstream signals in the rest of the model use the same or a similar data type.

Optionally, configure other design attributes such as **Min** and **Max** (minimum and maximum values).

Set the **Change View** drop-down list to `Code`.

For the Outport block and Inport blocks, set **Storage Class** to `ExportedGlobal`. To configure the blocks in one step, select the rows in the table.

To configure the blocks and signals, you can use these commands at the command prompt.

```
portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','ExportedGlobal');

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',...
    'StorageClass','ExportedGlobal')
```

Generate code from the model.

```
rtwbuild('rtwdemo_basicsc');
```

```
### Starting build procedure for model: rtwdemo_basicsc
### Successful completion of build procedure for model: rtwdemo_basicsc
```

View the generated file `rtwdemo_basicsc.c`. Because you applied the storage class `ExportedGlobal` to the Inport and Outport blocks, the code creates separate global variables that represent the inputs and the output.

```
file = fullfile('rtwdemo_basicsc_grt_rtw','rtwdemo_basicsc.c');
rtwdemodbtype(file,'/* Exported block signals */','real32_T output_sig;',1,1)
```

```
/* Exported block signals */
real32_T input1;                       /* '<Root>/In1' */
real32_T input2;                       /* '<Root>/In2' */
```

```
real32_T input3;                       /* '<Root>/In3' */
real32_T input4;                       /* '<Root>/In4' */
real32_T output_sig;                   /* '<Root>/Out1' */
```

The generated algorithm in the model `step` function directly references these global variables to calculate and store the output signal value, `output_sig`.

While you use the Model Data Editor to configure the interface of a system, consider using the interface display to view the system inputs and outputs (Inport and Outport blocks) at a high level. See “Configure Data Interface for Component” (Simulink).

Reduce Manual Data Entry by Configuring Default Storage Class (Embedded Coder)

If you have Embedded Coder, you can configure a default storage class for Inport blocks and Outport blocks. As you add such blocks to the model, they acquire the storage class that you specify.

In the model, set **Configuration Parameters > Code Generation > System target file** to `ert.tlc`.

In the model, select **Code > C/C++ Code > Configure Model in Code Perspective**.

Underneath the block diagram, under **Code Mappings > Data Defaults**, for the **Inports** and **Outports** rows, set **Storage Class** to `ExportedGlobal`.

Underneath the block diagram, open the Model Data Editor by clicking the **Model Data Editor** tab.

Use the Model Data Editor to set the storage class of the Inport and Outport blocks to `Auto`. With this setting, the blocks acquire the default storage classes that you specified in **Code Mappings > Data Defaults**.

With `Auto`, the global variables that correspond to the Inport and Outport blocks are subject to a naming rule that you specify in the model configuration parameters. By default, the naming rule adds the name of the model to the name of each variable. To remove the model name, change the value of **Configuration Parameters > Code Generation > Symbols > Global variables** from `$R$N$M` to `$N$M`. The token `$R` represents the model name.

Alternatively, to configure the data defaults and the configuration parameter, at the command prompt, use these commands:

```
set_param('rtwdemo_basicsc','SystemTargetFile','ert.tlc')

coder.mapping.create('rtwdemo_basicsc')
coder.mapping.defaults.set('rtwdemo_basicsc','Inports',...
    'StorageClass','ExportedGlobal')
coder.mapping.defaults.set('rtwdemo_basicsc','Outports',...
    'StorageClass','ExportedGlobal')

portHandles = get_param('rtwdemo_basicsc/In1','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In2','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In3','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

portHandles = get_param('rtwdemo_basicsc/In4','portHandles');
outPortHandle = portHandles.Outport;
set_param(outPortHandle,'StorageClass','Auto');

set_param('rtwdemo_basicsc/Out1','SignalName','output_sig',...
    'StorageClass','Auto')

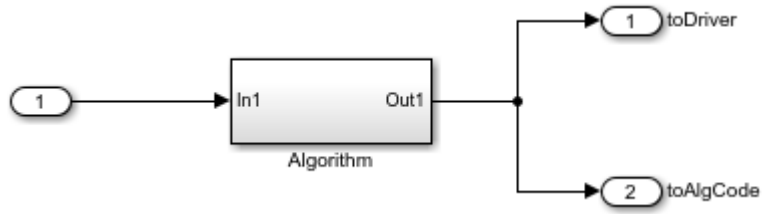
set_param('rtwdemo_basicsc','CustomSymbolStrGlobalVar','$N$M')
```

Route Signal Data to Multiple Outputs

You can route a single signal to multiple Outport blocks and apply a different storage class to each Outport. For example, use this technique to send signal data to a custom function (such as a device driver) and to a global variable that your custom algorithmic code can use:

1. Branch the target signal line to each Outport block.
2. For more efficient code, set the storage class of the target signal line to `Auto` (the default). Optimizations can then eliminate the signal line from the generated code.
3. Use the Model Data Editor to apply the custom storage class `GetSet` to one Outport block and `ExportToFile` to the other Outport block. Apply a signal name to each block.

```
open_system('ex_route_sig')
```



Limitations

You cannot apply a storage class to an Outport block if the input to the block has a variable size. Instead, apply the storage class to the signal line.

Generate Efficient Code for Bus Signals

In this section...

In a model, you use bus signals to package multiple signals together into a single signal line. You can create virtual or nonvirtual bus signals. The representation in the generated code depends on:

- For a virtual bus, the generated code appears as if the bus did not exist.
- Generated code for a nonvirtual bus represents the bus data with a structure. When you want to trace the correspondence between the model and the code, the use of a structure in the generated code can be helpful. To generate structures using nonvirtual bus signals, see “Organize Data into Structures in Generated Code” on page 32-181.

For general information about buses, see and “Virtual and Nonvirtual Buses” (Simulink).

To generate efficient code from models that contain bus signals, eliminate unnecessary data copies by following best practices as you construct the model.

Code Efficiency for Bus Signals

When you use buses in a model for which you intend to generate code:

- Setting bus diagnostic configuration parameters can make model development easier.
- The bus implementation techniques, and the choice of a nonvirtual or virtual bus, can influence the speed, size, and clarity of the generated code.
- Some useful bus implementation techniques are not immediately obvious.

When you work with buses, these guidelines help you to improve the results. The guidelines describe techniques to:

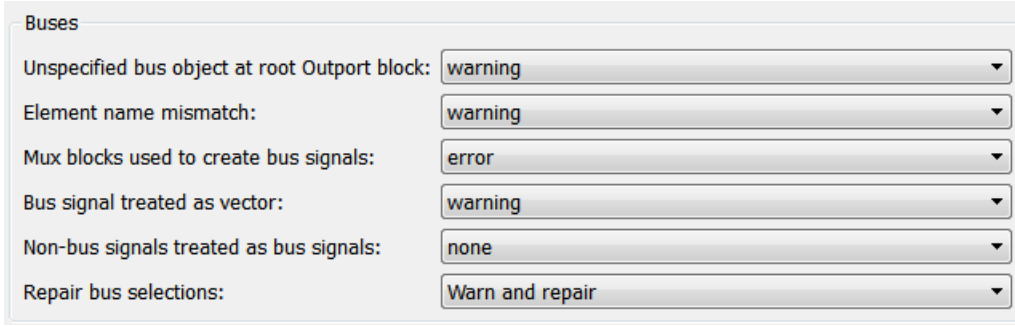
- Simplify the layout of the model.
- Increase the efficiency of generated code.

- Define data structures for function (subsystem) interfaces.
- Define data structures that match existing data structures in external C code.

There are some trade-offs among speed, size, and clarity. For example, the code for nonvirtual buses is easier to read because the buses appear in the code as structures, but the code for virtual buses is faster because virtual buses do not require copying signal data. Apply some of the guidelines based on where you are in the application development process.

Set Bus Diagnostics

Simulink provides diagnostics that you can use to optimize bus usage. Set the following values on the **Configuration Parameters > Diagnostics > Connectivity** pane.



Optimize Virtual and Nonvirtual Buses

Virtual buses are graphical conveniences that do not affect generated code. As a result, the code generation engine is able to fully optimize the signals in the bus. Use virtual buses rather than nonvirtual buses wherever possible. You can convert between virtual and nonvirtual buses by using Signal Conversion blocks. In some cases, Simulink automatically converts a virtual bus to a nonvirtual bus when required. For example, a Stateflow chart converts an input virtual bus to a nonvirtual bus.

To bundle function-call signals, you must use a virtual bus.

You must use nonvirtual buses for:

- Nonauto storage classes

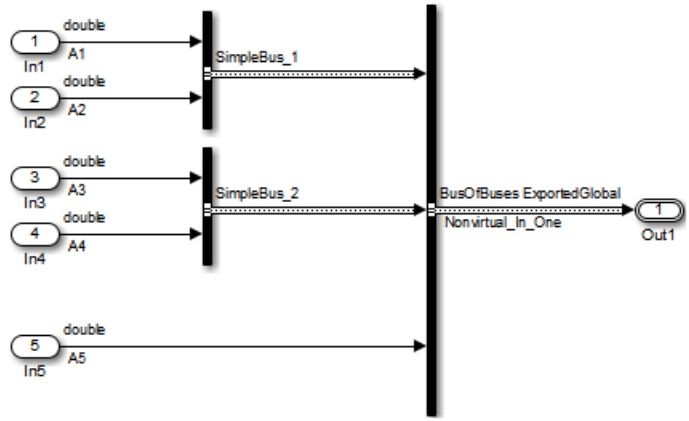
- Generating a specific structure from the bus
- Root-level Inport or Outport blocks when the bus has mixed data types

Avoid Nonlocal Nested Buses in Nonvirtual Buses

Buses can contain subordinate buses. To generate efficient code, set the storage classes of subordinate buses to `Auto`. Setting the storage class to `Auto` eliminates:

- Allocation of redundant memory for the subordinate bus signal and for the parent bus signal
- Additional copy operations (copying data to the subordinate bus, and then copying from the subordinate bus to the final bus)

This model contains nonvirtual bus signals. The subordinate bus signals `Sub_Bus_1` and `Sub_Bus_2` use the storage class `Auto`.



The generated code algorithm efficiently assigns the input signal data to the bus signals.

```
void ex_nonvirtual_buses_step(void)
{
  Nonvirtual_In_One.SimpleBus_1.A1 = A1;
  Nonvirtual_In_One.SimpleBus_1.A2 = A2;
  Nonvirtual_In_One.SimpleBus_2.A3 = A3;
  Nonvirtual_In_One.SimpleBus_2.A4 = A4;
  Nonvirtual_In_One.A5 = A5;
}
```

Control Signal and State Initialization in the Generated Code

To initialize signals and discrete states with custom values for simulation and code generation, you can use signal objects and block parameters. Data initialization increases application reliability and is a requirement of safety critical applications. Initializing signals for both simulation and code generation can expedite transitions between phases of Model-Based Design.

For basic information about specifying initial values for signals and discrete states in a model, see “Initialize Signals and Discrete States” (Simulink).

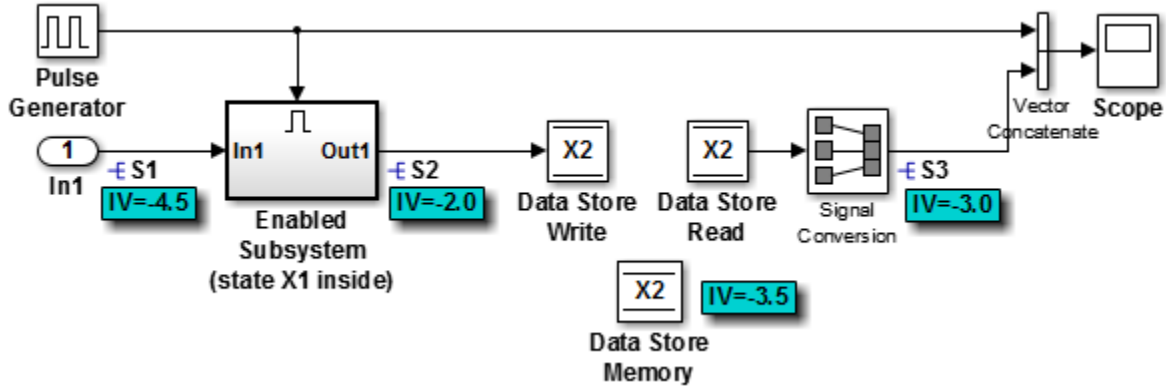
Signal and State Initialization in the Generated Code

The initialization behavior for code generation is the same as that for model simulation with the following exceptions:

- RSim executables can use the **Data Import/Export** pane of the Configuration Parameters dialog box to load input values from MAT-files. GRT and ERT executables cannot load input values from MAT-files.
- The initial value for a block output signal or root level input or output signal can be overwritten by an external (calling) program.
- Setting the initial value for persistent signals is relevant if the value is used or viewed by an external application.

When you generate code, initialization statements are placed in *`model`*`.c` or *`model`*`.cpp` in the model's initialize code.

For example, consider the model `rtwdemo_sigobj_iv`.



If you create and initialize signal objects in the base workspace, the code generator places initialization code for the signals in the file `rtwdemo_sigobj_iv.c` under the `rtwdemo_sigobj_iv_initialize` function, as shown below.

```
 /* Model initialize function */

      void rtwdemo_sigobj_iv_initialize(void)

      {
          .
          .
          .
 /* exported global signals */
 S3 = -3.0;

 S2 = -2.0;
          .
          .
          .
/* exported global states */
X1 = 0.0;
X2 = 0.0;

/* external inputs */
S1 = -4.5;
          .
          .
          .
```

The following code shows the initialization code for the enabled subsystem's Unit Delay block state `X1` and output signal `S2`.

```
void MdlStart(void) {
           .
           .
           .
 /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
  X1 = aa1;
```

```
 /* Start for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */

  /* virtual outports code */

  /* (Virtual) Outport Block: '<S2>/Out1' */

  S2 = aa2;

}
```

For an enabled subsystem, the initial value is also used as a reset value if the subsystem's Outport block parameter **Output when disabled** is set to `reset`. The following code from `rtwdemo_sigobj_iv.c` shows the assignment statement for `S3` as it appears in the model output function `rtwdemo_sigobj_iv_output`.

```
/* Model output function */

static void rtwdemo_sigobj_iv_output(void)
{
         .
         .
         .
 /* Disable for enable system: '<Root>/Enabled Subsystem (state X1 inside)' */

    /* (Virtual) Outport Block: '<S2>/Out1' */

    S2 = aa2;
```

Generate Tunable Initial Conditions

You can represent initial conditions for signals and states by creating tunable global variables in the generated code. These variables allow you to restart an application by using initial conditions that are stored in memory.

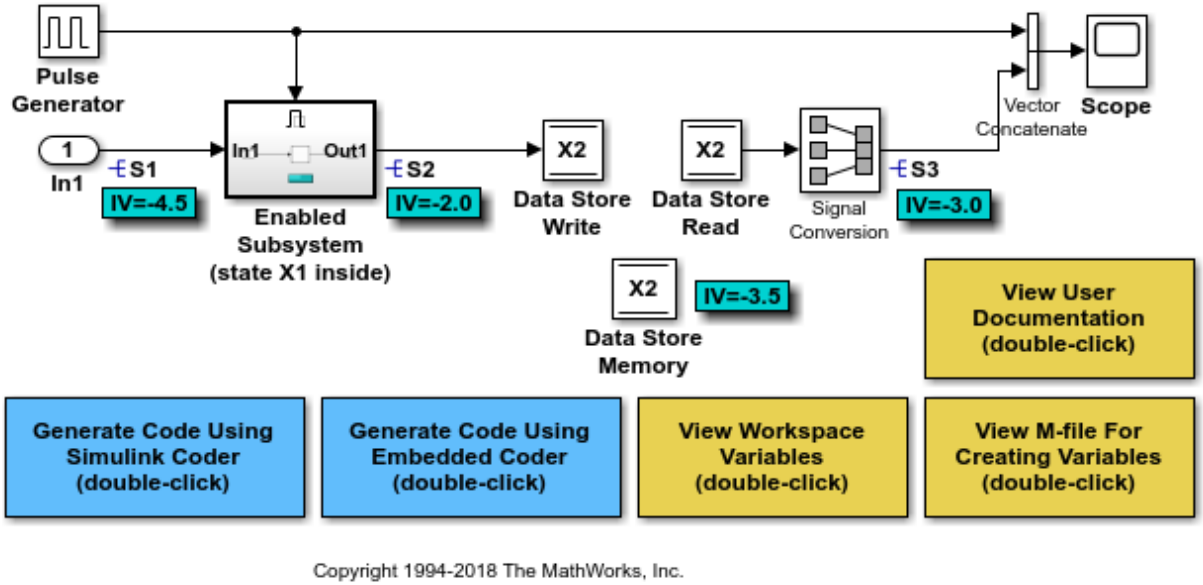
If you set **Configuration Parameters > Optimization > Default parameter behavior** to `Tunable`, initial conditions appear as tunable fields of the global parameters structure.

Whether you set **Default parameter behavior** to `Tunable` or `Inlined`, you can use a tunable parameter to specify the `InitialValue` property of a signal object or the **Initial condition** parameter of a block. For basic information about tunable parameters, see “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

This example shows how to use tunable parameters to specify initial conditions for signals and states.

Explore Example Model

Open the example model `rtwdemo_sigobj_iv` and configure it to show the generated names of blocks. The signal `S2` uses a `Simulink.Signal` object in the base workspace.



Double-click the `Simulink.Signal` object `S2` to view its properties. The **Initial value** property is set to `aa2`. The object uses the variable `aa2` to specify an initial condition for the signal `S2`. The **Storage class** property is set to `ExportedGlobal`. To use a `Simulink.Signal` object to initialize a signal, the signal object must use a storage class other than `Auto` or, if the corresponding data category in the Code Mapping Editor uses a storage class setting other than `Default`, `Model default`.

On the **Optimization** pane, in the Configuration Parameters dialog box, click **Configure**. The variable `aa2` is a tunable parameter that uses the storage class `ExportedGlobal`.

In the model, open the Enabled Subsystem. In the Outport block dialog box, the parameter **Output when disabled** is set to `reset`. When the subsystem becomes disabled, the output signal `S2` resets to the initial value `aa2`.

Open the Unit Delay block dialog box. On the **State Attributes** tab, the **State name** box is set to `X1`.

Open the Enable block dialog box. The parameter **States when enabling** is set to `reset`. When the subsystem transitions from a disabled state to an enabled state, it resets internal block states, such as `X1`, to their initial values.

In the base workspace, double-click the `Simulink.Signal` object `X1` to view its properties. The **Initial value** property is set to `aa1`.

Double-click the `Simulink.Parameter` object `aa1` to view its properties. The **Storage class** property is set to `ExportedGlobal`. You can generate tunable initial conditions for block states by using tunable parameters such as `aa1` and `Simulink.Signal` objects such as `X1`.

Generate and Inspect Code

Generate code with the example model.

```
### Starting build procedure for model: rtwdemo_sigobj_iv
### Successful completion of build procedure for model: rtwdemo_sigobj_iv
```

In the code generation report, view the file `rtwdemo_sigobj_iv.c`. The code uses global variables to represent the block state `X1` and the signal `S2`.

```
/* Exported block states */
real_T X1;                             /* '<S2>/Unit Delay' */

/* Exported block signals */
real_T S1;                             /* '<Root>/In1' */
real_T S3;                             /* '<Root>/Signal Conversion' */
real_T S2;                             /* '<S2>/Unit Delay' */
```

The code uses global variable to represent the tunable parameter `aa1`.

```
/* Exported block parameters */
real_T aa1 = -2.5;                     /* Variable: aa1
```

The model initialization function uses the tunable parameter `aa1` to initialize the state `X1`. The function also uses the tunable parameter `aa2` to initialize the signal `S2`.

```
  /* SystemInitialize for Enabled SubSystem: '<Root>/Enabled Subsystem (state X1 inside
  /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
  X1 = aa1;

  /* SystemInitialize for Outport: '<S2>/Out1' */
  S2 = 0.0;
```

In the model step function, when the Enabled Subsystem transitions from a disabled state to an enabled state, the Unit Delay block state `X1` resets to its initial value.

```
if (rtb_PulseGenerator > 0) {
  if (!rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
    /* InitializeConditions for UnitDelay: '<S2>/Unit Delay' */
    X1 = aa1;
    rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = true;
  }
```

If the Enabled Subsystem becomes disabled during code execution, the algorithm uses the tunable initial condition `aa2` to set the value of the signal `S2`.

```
} else {

  if (rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M) {
    /* Disable for Outport: '<S2>/Out1' */
    S2 = 0.0;
    rtwdemo_sigobj_iv_DW.EnabledSubsystemstateX1inside_M = false;
  }
}
```

Generate Tunable Initial Condition Structure for Bus Signal

When you use a MATLAB® structure to specify initialization values for the signal elements in a bus, you can create a tunable global structure in the generated code.

If you set **Configuration Parameters > Optimization > Default parameter behavior** to `Tunable`, the initial condition appears as a tunable substructure of the global parameters structure.

Whether you set **Default parameter behavior** to `Tunable` or `Inlined`, you can specify the initial condition by using a tunable `Simulink.Parameter` object whose value is a structure. If you apply a storage class other than `Auto` to the parameter object, the structure is tunable in the generated code.

To generate efficient code by avoiding data type mismatches between the structure and the bus signal, use either:

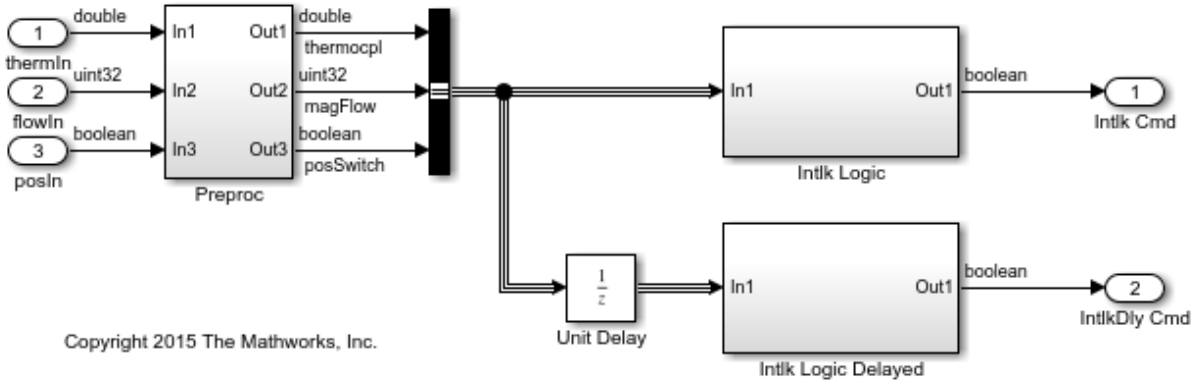
- Typed expressions to specify the values of the structure fields. Match the data type of each field with the data type of the corresponding signal element.
- A `Simulink.Bus` object to control the data types of the structure fields and the signal elements.

For basic information about using structures to initialize bus signals, and to decide how to control field data types, see “Specify Initial Conditions for Bus Signals” (Simulink).

Generate Tunable Initial Condition Structure

This example shows how to use a tunable structure parameter to initialize a virtual bus signal.

Open the example model `rtwdemo_tunable_init_struct` and configure it to show the generated names of blocks.



In the model, select **View > Model Data Editor**.

On the **Inports/Outports** tab, the **Data Types** column shows that each Inport block in the model uses a different output data type.

Open the Bus Creator block dialog box. The block output is a virtual bus.

In the Configuration Parameters dialog box, open the **Optimization** pane. The configuration parameter **Default parameter behavior** is set to `Tunable`. By default, block parameters, including initial conditions, appear in the generated code as tunable fields of the global parameters structure.

In the Model Data Editor, inspect the **States** tab.

For the Unit Delay block, set **Initial Value** to a structure that specifies an initial condition for each of the three signal elements. To generate efficient code, match the data types of the structure fields with the data types of the corresponding signal elements. For example, set **Initial Value** to the expression `struct('thermocpl',15.23,'magFlow',uint32(79),'posSwitch',false)`.

```
set_param('rtwdemo_tunable_init_struct/Unit Delay','InitialCondition',...
'struct(''thermocpl'',15.23,''magFlow'',uint32(79),''posSwitch'',false)')
```

Generate code from the example model.

```
### Starting build procedure for model: rtwdemo_tunable_init_struct
### Successful completion of build procedure for model: rtwdemo_tunable_init_struct
```

In the code generation report, view the file `rtwdemo_tunable_init_struct_types.h`. The code defines a structure type whose fields use the data types that you specified in the `struct` expression.

```
#ifndef DEFINED_TYPEDEF_FOR_struct_mqGi1jsItE0G7cf1bNqMu_
#define DEFINED_TYPEDEF_FOR_struct_mqGi1jsItE0G7cf1bNqMu_

typedef struct {
  real_T thermocpl;
  uint32_T magFlow;
  boolean_T posSwitch;
} struct_mqGi1jsItE0G7cf1bNqMu;
```

View the file `rtwdemo_tunable_init_struct.h`. The `struct` type definition of the global parameters structure contains a substructure, `UnitDelay_InitialCondition`, which represents the **Initial condition** parameter of the Unit Delay block.

```
struct P_rtwdemo_tunable_init_struct_T_ {
  struct_mqGi1jsItE0G7cf1bNqMu UnitDelay_InitialCondition;
```

View the file `rtwdemo_tunable_init_struct_data.c`. This source file allocates memory for the global parameters structure. The substructure `UnitDelay_InitialCondition` appears.

```
/* Block parameters (default storage) */
```

```
P_rtwdemo_tunable_init_struct_T rtwdemo_tunable_init_struct_P = {
  /* Mask Parameter: UnitDelay_InitialCondition
   * Referenced by:
   *   '<Root>/Unit Delay'
   *   '<Root>/Unit Delay'
   *   '<Root>/Unit Delay'
   */
  {
    15.23,
    79U,
    0
  },
```

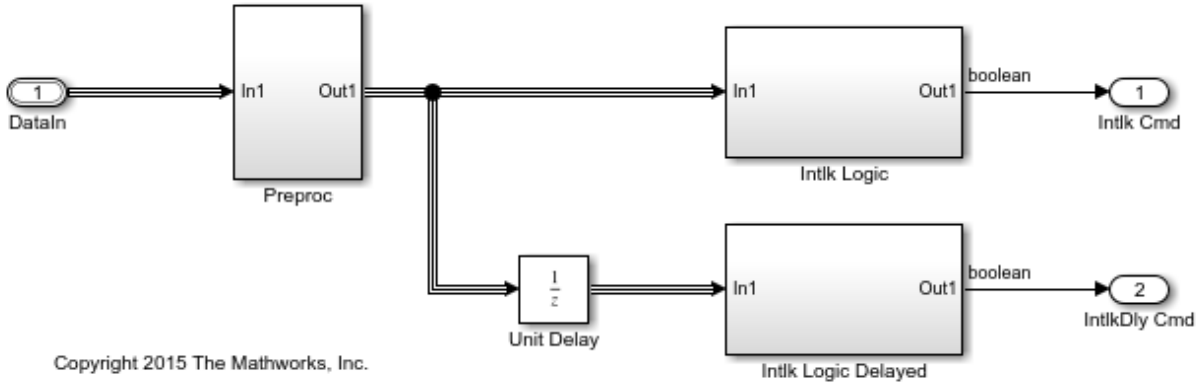
View the file `rtwdemo_tunable_init_struct.c`. The model initialization function uses the fields of the substructure to initialize the block states.

```
  /* InitializeConditions for UnitDelay: '<Root>/Unit Delay' */
  rtwdemo_tunable_init_struct_DW.UnitDelay_1_DSTATE =
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.thermocpl;
  rtwdemo_tunable_init_struct_DW.UnitDelay_2_DSTATE =
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.magFlow;
  rtwdemo_tunable_init_struct_DW.UnitDelay_3_DSTATE =
    rtwdemo_tunable_init_struct_P.UnitDelay_InitialCondition.posSwitch;
```

Use Bus Object to Specify Data Types

If you create a bus object, you can use it to specify the data type of the bus signal and the tunable initial condition structure. Before code generation, the `Simulink.Parameter` object casts the values of the structure fields to the data types of the signal elements. For basic information about creating bus objects and using them in models, see “When to Use Bus Objects” (Simulink).

Open the example model `rtwdemo_init_struct_busobj` and configure it to show the generated names of blocks.



In the base workspace, double-click the `Simulink.Bus` object `ComponentData`. The object defines three signal elements: `thermocpl`, `magFlow`, and `posSwitch`. The elements each use a different data type.

In the model, open the Model Data Editor (**View > Model Data Editor**). The **Inports/Outports** tab shows that for the Inport block `DataIn`, the output data type (**Data Type** column) is set to `Bus: ComponentData`.

At the command prompt, create the structure parameter `initStruct`. You can specify the field values by using untyped expressions. To improve readability, specify the field `posSwitch` with a Boolean value.
