# **MPC** Designer

Design and simulate model predictive controllers

## **Description**

The **MPC Designer** app lets you design and simulate model predictive controllers in MATLAB® and Simulink®.

Using this app, you can:

- Interactively design model predictive controllers and validate their performance using simulation scenarios
- Obtain linear plant models by linearizing Simulink models (requires Simulink Control Design™)
- Review controller designs for potential run-time stability or numerical issues
- Compare response plots for multiple model predictive controllers
- Generate Simulink models with an MPC controller and plant model
- Generate MATLAB scripts to automate MPC controller design and simulation tasks

### Limitations

The following advanced MPC features are not available in the MPC Designer app:

- Explicit MPC design
- · Adaptive MPC design
- Nonlinear MPC design
- Mixed input/output constraints (setconstraint)
- Terminal weight specification (setterminal)
- Custom state estimation (setEstimator)
- Sensitivity analysis (sensitivity)
- · Alternative cost functions with off-diagonal weights
- Specification of initial plant and controller states for simulation

- Specification of nominal state values using mpcObj.Model.Nominal.X and mpcObj.Model.Nominal.DX
- Updating weights, constraints, MV targets, and external MV online during simulations

If your application requires any of these features, design and simulate your controller at the command line. You can also run simulations in Simulink when using these features.

When using **MPC Designer** in MATLAB Online<sup>™</sup>, the following features are not available:

- Designing controllers in Simulink
- Generating Simulink models for your controller and plant

# Open the MPC Designer App

- MATLAB Toolstrip: On the Apps tab, under Control System Design and Analysis, click the app icon.
- MATLAB command prompt: Enter mpcDesigner.
- Simulink model editor: In the MPC Controller Block Parameters dialog box, click **Design**.

# **Examples**

- "Design Controller Using MPC Designer"
- "Design MPC Controller in Simulink"
- "Compare Multiple Controller Responses Using MPC Designer"
- "Generate MATLAB Code from MPC Designer"
- "Generate Simulink Model from MPC Designer"

### **Programmatic Use**

mpcDesigner opens the MPC Designer app. You can then import a plant or controller to start the design process, or open a saved design session.

mpcDesigner(plant) opens the app and creates a default MPC controller using plant as the internal prediction model. Specify plant as an ss, tf, or zpk LTI model.

If plant is a stable, continuous-time LTI system, **MPC Designer** sets the controller sample time to  $0.1 T_r$ , where  $T_r$  is the average rise time of the plant. If plant is an unstable, continuous-time system, **MPC Designer** sets the controller sample time to 1.

By default, plant input and output signals are treated as manipulated variables and measured outputs respectively. To specify a different input/output channel configuration, use setmpcsignals before opening MPC Designer.

You can also specify plant as a linear System Identification Toolbox™ model, such as an idss or idtf system. The app converts the identified model to a state-space system, discarding any noise channels. To convert noise channels to unmeasured disturbances, convert the identified model to a state-space model using the 'augmented' option. For more information on identifying plant models, see "Identify Plant from Data".

mpcDesigner(MPCobj) opens the app and imports the model predictive controller MPCobj from the MATLAB workspace. To create an MPC controller, use mpc.

mpcDesigner(MPCobjs) opens the app and imports multiple MPC controllers specified
in the cell array MPCobjs. All of the controllers in MPCobjs must have the same input/
output channel configuration.

mpcDesigner(MPCobjs,names) additionally specifies controller names when opening the app with multiple MPC controllers. Specify names as a cell array of character vectors or string array with the same length as MPCobjs. Specify a unique name for each controller.

mpcDesigner(sessionFile) opens the app and loads a previously saved session.
Specify sessionFile as one of the following:

- The name of a session data file in the current working directory or on the MATLAB path, specified as a character vector or string. To save session data to disk, in the
  - MPC Designer app, on the MPC Designer tab, click Save Session. The saved session data includes all plants, controllers, and scenarios in the Data Browser, the current MPC structure, and the current plot configuration.
- A previously loaded SessionData object in the MATLAB workspace. To load a SessionData object from a session data file, at the command line, enter:

load sessionFile

# **Functions — Alphabetical List**

### cloffset

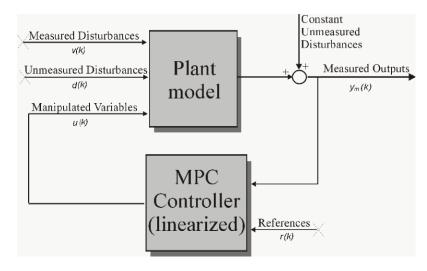

Compute MPC closed-loop DC gain from output disturbances to measured outputs assuming constraints are inactive at steady state

## **Syntax**

DCgain = cloffset(MPCobj)

# **Description**

The cloff function computes the DC gain from output disturbances to measured outputs, assuming constraints are not active, based on the feedback connection between Model.Plant and the linearized MPC controller, as depicted below.

### **Computing the Effect of Output Disturbances**

By superposition of effects, the gain is computed by zeroing references, measured disturbances, and unmeasured input disturbances.

DCgain = cloffset(MPCobj) returns an  $n_{ym}$ -by- $n_{ym}$  DC gain matrix DCgain, where  $n_{ym}$  is the number of measured plant outputs. MPCobj is the MPC object specifying the controller for which the closed-loop gain is calculated. DCgain(i,j) represents the gain from an additive (constant) disturbance on output j to measured output i. If row i contains all zeros, there will be no steady-state offset on output i.

"Compute Steady-State Gain"

**Introduced before R2006a** 

### compare

Compare two MPC objects

## **Syntax**

yesno = compare(MPC1,MPC2)

# **Description**

The compare function compares the contents of two MPC objects MPC1, MPC2. If the design specifications (models, weights, horizons, etc.) are identical, then yesno is equal to 1.

**Note** compare may return yesno = 1 even if the two objects are not identical. For instance, MPC1 may have been initialized while MPC2 may have not, so that they may have different sizes in memory. In any case, if yesno = 1, the behavior of the two controllers will be identical.

Introduced before R2006a

### convertToMPC

Convert nlmpc object into one or more mpc objects

In practice, when producing comparable performance, linear MPC is preferred over nonlinear MPC due to its higher computational efficiency. Using the <code>convertToMPC</code> function, you can convert a nonlinear MPC controller into one or more linear MPC controllers at specific operating points. You can then implement gain-scheduled or adaptive MPC using the linear controllers and compare their performance to the benchmark nonlinear MPC controller. For an example, see "Nonlinear and Gain-Scheduled MPC Control of an Ethylene Oxidation Plant".

To use convertToMPC, your nonlinear controller must not have custom cost or constraint functions, since these custom functions are not supported for linear MPC controllers.

# **Syntax**

```
mpcobj = convertToMPC(nlmpcobj,states,inputs)
mpcobj = convertToMPC(nlmpcobj,states,inputs,MOIndex)
mpcobj = convertToMPC(nlmpcobj,states,inputs,MOIndex,parameters)
```

# **Description**

mpcobj = convertToMPC(nlmpcobj, states, inputs) converts the nonlinear MPC controller object nlmpcobj into one or more linear MPC controller objects at the nominal conditions specified in states and inputs. The number of linear MPC controllers, N, is equal to the number of rows in states and inputs.

mpcobj = convertToMPC(nlmpcobj, states, inputs, MOIndex) specifies the
indices of the measured outputs. Use this syntax when your controller has unmeasured
output signals.

mpcobj = convertToMPC(nlmpcobj, states, inputs, MOIndex, parameters)
specifies the values of prediction model parameters for each nominal condition. Use this
syntax when your controller prediction model has optional parameters.

# **Examples**

#### Create Linear MPC Controllers from Nonlinear MPC Controller

Create a nonlinear MPC controller with four states, one output variable, one manipulated variable, and one measured disturbance.

```
nlobj = nlmpc(4,1,'MV',1,'MD',2);
Specify the controller sample time and horizons.
nlobi.PredictionHorizon = 10:
nlobj.ControlHorizon = 3:
Specify the state function of the prediction model.
nlobj.Model.StateFcn = 'oxidationStateFcn';
Specify the prediction model output function and the output variable scale factor.
nlobj.Model.OutputFcn = @(x,u) x(3);
nlobj.OutputVariables.ScaleFactor = 0.03;
Specify the manipulated variable constraints and scale factor.
nlobj.ManipulatedVariables.Min = 0.0704;
nlobi.ManipulatedVariables.Max = 0.7042:
nlobj.ManipulatedVariables.ScaleFactor = 0.6;
Specify the measured disturbance scale factor.
nlobj.MeasuredDisturbances.ScaleFactor = 0.5;
Compute the state and input operating conditions for three linear MPC controllers using
the fsolve function.
options = optimoptions('fsolve', 'Display', 'none');
uLow = [0.38 \ 0.5];
xLow = fsolve(@(x) oxidationStateFcn(x,uLow),[1 0.3 0.03 1],options);
uMedium = [0.24 \ 0.5];
xMedium = fsolve(@(x) oxidationStateFcn(x,uMedium),[1 0.3 0.03 1],options);
```

```
uHigh = [0.15 \ 0.5];
xHigh = fsolve(@(x) oxidationStateFcn(x,uHigh),[1 0.3 0.03 1],options);
Create linear MPC controllers for each of these nominal conditions.
mpcobjLow = convertToMPC(nlobj,xLow,uLow);
mpcobjMedium = convertToMPC(nlobj,xMedium,uMedium);
mpcobjHigh = convertToMPC(nlobj,xHigh,uHigh);
You can also create multiple controllers using arrays of nominal conditions. The number
of rows in the arrays specifies the number controllers to create. The linear controllers are
returned as cell array of mpc objects.
u = [uLow; uMedium; uHigh];
x = [xLow; xMedium; xHigh];
mpcobjs = convertToMPC(nlobj,x,u);
View the properties of the mpcobjLow controller.
mpcobjLow
MPC object (created on 02-Mar-2019 12:36:35):
Sampling time: 1 (seconds)

         Measurement noise model: default (unity gain after scaling)
```

### **Input Arguments**

#### nlmpcobj - Nonlinear MPC controller

nlmpc object

Nonlinear MPC controller, specified as an nlmpc object.

**Note** Your nlmpc controller object must not have custom cost or constraint functions.

#### states — Nominal state values

array

Nominal state values, specified as an N-by- $N_x$  array, where  $N_x$  is equal to nlmpcobj.Dimensions.NumberOfStates. Each row of States specifies a nominal set of states to be used in conversion.

The number of rows in states and inputs must match.

#### inputs — Nominal input values

array

Nominal input values, specified as an N-by- $N_u$  array, where  $N_u$  is equal to nlmpcobj.Dimensions.NumberOfInputs. Each row of Inputs specifies a nominal set of inputs to be used in conversion.

The number of rows in states and inputs must match.

#### M0Index — Measured output indices

[] (default) | vector

Measured output indices, specified as a vector of length  $N_y$ , where  $N_y$  is the number of outputs. If MOIndex is [], every output is measured. Otherwise, any outputs not listed in MOIndex are unmeasured.

convertToMPC uses MOIndex to configure the default state estimators in mpcobj.

#### parameters — Prediction model parameter values

{} (default) | cell array

Prediction model parameter values, specified as an N-by- $N_p$  cell array, where  $N_p$  is equal to nlmpcobj. Model. NumberOfParameters. Each row of parameters specifies the model parameter values for a given nominal condition. In each row, the order of the parameters must match the order specified in the model functions. Each parameter must be a numeric parameter with the correct dimensions; that is, the dimensions expected by the prediction model functions.

For each nominal condition, these parameters are passed to the state function (nlmpcobj.Model.StateFcn) and output function (nlmpcobj.Model.OutputFcn) of the nonlinear MPC controller.

The number of rows in parameters must match the number of rows in states and inputs.

If your controller prediction model has optional parameters, you must specify parameters.

### **Output Arguments**

### mpcobj — Linear MPC controllers

mpc object | cell array of mpc objects

Linear MPC controllers created for each nominal condition, returned as one of the following:

- Single mpc object when N = 1.
- Cell array of mpc objects of length N when N > 1. Each object corresponds to one nominal condition.

convertToMPC copies the following controller properties from nlmpcobj to the
controllers in mpcobj:

- Sample time
- · Prediction and control horizons
- Tuning weights
- Bounds on output variables, manipulated variables, and manipulated variable rates
- Scale factors, names, and units for variables and disturbances

#### If nlmpcobj:

- Has unmeasured disturbance channels, then the controllers in mpcobj have unity gains for their input and output disturbance models.
- Does not have unmeasured disturbance channels, then the controllers in mpcobj have default output disturbance models.

Any state bounds in nlmpcobj are dropped during conversion.

"Nonlinear MPC"

"Nonlinear and Gain-Scheduled MPC Control of an Ethylene Oxidation Plant"

#### Introduced in R2018b

### createParameterBus

Create Simulink bus object and configure Bus Creator block for passing model parameters to Nonlinear MPC Controller block

## **Syntax**

createParameterBus(nlmpcobj,nlmpcblk,busName,parameters)

## **Description**

createParameterBus(nlmpcobj,nlmpcblk,busName,parameters) creates a Simulink.Bus object, busName, in the MATLAB workspace for passing model parameters to a Nonlinear MPC Controller block, nlmpcblk. createParameterBus requires you to connect a Bus Creator block to the Nonlinear MPC Controller block in advance so that it can configure the Bus Creator block to use the bus object.

## **Examples**

#### Create Parameter Bus for Nonlinear MPC Controller Block

Create a nonlinear MPC controller with four states, two outputs, and one input.

```
nlobj = nlmpc(4,2,1);
```

In standard cost function, zero weights are applied by default to one or more OVs became

Specify the sample time and horizons of the controller.

```
Ts = 0.1;
nlobj.Ts = Ts;
nlobj.PredictionHorizon = 10;
nlobj.ControlHorizon = 5;
```

Specify the state function for the controller, which is in the file pendulumDT0.m. This discrete-time model integrates the continuous-time model defined in pendulumCT0.m using a multistep forward Euler method.

```
nlobj.Model.StateFcn = "pendulumDTO";
nlobj.Model.IsContinuousTime = false;
```

The prediction model uses an optional parameter, Ts, to represent the sample time. Specify the number of parameters.

```
nlobj.Model.NumberOfParameters = 1;
```

Specify the output function of the model, passing the sample-time parameter as an input argument.

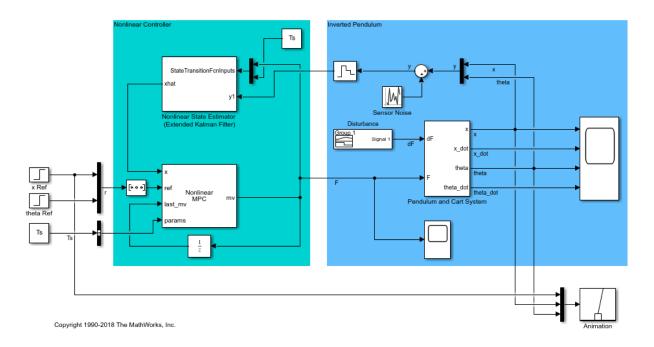

```
nlobj.Model.OutputFcn = @(x,u,Ts)[x(1); x(3)];
```

Define standard constraints for the controller.

```
nlobj.Weights.OutputVariables = [3 3];
nlobj.Weights.ManipulatedVariablesRate = 0.1;
nlobj.OV(1).Min = -10;
nlobj.OV(1).Max = 10;
nlobj.MV.Min = -100;
nlobj.MV.Max = 100;
```

Open Simulink model.

```
mdl = 'mpc_pendcartNMPC';
open_system(mdl)
```

In this model, the Nonlinear MPC Controller block is configured to use the controller nlobj.

To use the optional parameter in the prediction model, the model has a Simulink Bus block connected to the params input port of the Nonlinear MPC Controller block. To configure this bus block to use the Ts parameter, create a Bus object in the MATLAB® workspace, and configure the Bus Creator block to use this object. Name the Bus object 'myBusObject'.

```
createParameterBus(nlobj,[mdl '/Nonlinear MPC Controller'],'myBusObject',{Ts});
bdclose(mdl)
```

A Simulink Bus object "myBusObject" created in the MATLAB Workspace, and Bus Creator b

# **Input Arguments**

nlmpcobj — Nonlinear MPC controller
nlmpc object

Nonlinear MPC controller, specified as an nlmpc object.

#### nlmpcblk — Block path of Nonlinear MPC Controller block

string | string | character vector

Block path of Nonlinear MPC Controller block, specified as a string or character vector.

#### busName — Name of Simulink bus object

string | string | character vector

Name of Simulink bus object to be created in the MATLAB workspace and set in the Bus Creator block, specified as a string or character vector.

The corresponding Bus Creator block must already be connected to the params input port of the Nonlinear MPC Controller block specified by nlmpcblk. Also, the Bus Creator block must have the correct number of input ports, and these ports must already be properly connected.

# parameters — Nominal prediction model parameter values cell array

Nominal prediction model parameter values, specified as a cell array of length  $N_p$ , where  $N_p$  is equal to nlmpcobj.Model.NumberOfParameters. The order of the parameters must match the order specified in the model functions, and each parameter must be a numeric parameter with the correct dimensions.

### **Topics**

"Specify Prediction Model for Nonlinear MPC"

#### Introduced in R2018b

### d2d

Change MPC controller sample

## **Syntax**

MPCobj = d2d(MPCobj,Ts)

# **Description**

The d2d function changes the sample time of the MPC controller MPCobj to Ts. All models are sampled or resampled as soon as the QP matrices must be computed, for example when sim or mpcmove are called.

### **See Also**

mpc | set

Introduced before R2006a

# generateExplicitMPC

Convert implicit MPC controller to explicit MPC controller

Given a traditional Model Predictive Controller design in the implicit form, convert it to the explicit form for real-time applications requiring fast sample time.

## **Syntax**

```
EMPCobj = generateExplicitMPC(MPCobj, range)
EMPCobj = generateExplicitMPC(MPCobj, range, opt)
```

# **Description**

EMPCobj = generateExplicitMPC(MPCobj, range) converts a traditional (implicit) MPC controller to the equivalent explicit MPC controller, using the specified parameter bounds. This calculation usually requires significant computational effort because a multiparametric quadratic programming problem is solved during the conversion.

EMPCobj = generateExplicitMPC(MPCobj, range, opt) converts the MPC controller using additional optimization options.

## **Examples**

#### **Generate Explicit MPC Controller**

Generate an explicit MPC controller based upon a traditional MPC controller for a double-integrator plant.

Define the double-integrator plant.

```
plant = tf(1,[1 \ 0 \ 0]);
```

Create a traditional (implicit) MPC controller for this plant, with sample time 0.1, a prediction horizon of 10, and a control horizon of 3.

```
Ts = 0.1;
p = 10;
m = 3:
MPCobj = mpc(plant,Ts,p,m);
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defail
-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
To generate an explicit MPC controller, you must specify the ranges of parameters such
as state values and manipulated variables. To do so, generate a range structure. Then,
modify values within the structure to the desired parameter ranges.
range = generateExplicitRange(MPCobj);
-->Converting the "Model.Plant" property of "mpc" object to state-space.
--->Converting model to discrete time.
   Assuming no disturbance added to measured output channel #1.
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ear
range.State.Min(:) = [-10;-10];
range.State.Max(:) = [10;10];
range.Reference.Min = -2;
range.Reference.Max = 2;
range.ManipulatedVariable.Min = -1.1;
range.ManipulatedVariable.Max = 1.1;
Use the more robust reduction method for the computation. Use
generateExplicitOptions to create a default options set, and then modify the
polyreduction option.
opt = generateExplicitOptions(MPCobj);
opt.polyreduction = 1;
Generate the explicit MPC controller.
EMPCobj = generateExplicitMPC(MPCobj,range,opt)
Explicit MPC Controller
Controller sample time: 0.1 (seconds)
Polyhedral regions:
                            1
Number of parameters:
                            4
Is solution simplified:
                            No
```

```
State Estimation: Default Kalman gain

Type 'EMPCobj.MPC' for the original implicit MPC design.

Type 'EMPCobj.Range' for the valid range of parameters.

Type 'EMPCobj.OptimizationOptions' for the options used in multi-parametric QP computation of the options and gain in each solution.
```

### **Input Arguments**

#### **MPCobj** — **Traditional MPC controller**

MPC controller object

Traditional MPC controller, specified as an MPC controller object. Use the mpc command to create a traditional MPC controller.

#### range — Parameter bounds

structure

Parameter bounds, specified as a structure that you create with the <code>generateExplicitRange</code> command. This structure specifies the bounds on the parameters upon which the explicit MPC control law depends, such as state values, measured disturbances, and manipulated variables. See <code>generateExplicitRange</code> for detailed descriptions of these parameters.

#### opt — optimization options

structure

Optimization options for the conversion computation, specified as a structure that you create with the mpcExplicitOptions command. See generateExplicitOptions for detailed descriptions of these options.

# **Output Arguments**

### EMPCobj — Explicit MPC controller

explicit MPC controller object

Explicit MPC controller that is equivalent to the input traditional controller, returned as an explicit MPC controller object. The properties of the explicit MPC controller object are summarized in the following table.

Property	Description
MPC	Traditional (implicit) controller object used to generate the explicit MPC controller. You create this MPC controller using is the mpc command. It is the first argument to generateExplicitMPC when you create the explicit MPC controller. See "MPC Controller Object" on page 4-2 or type mpcprops for details regarding the properties of the MPC controller.
Range	1-D structure containing the parameter bounds used to generate the explicit MPC controller. These determine the resulting controller's valid operating range. This property is automatically populated by the range input argument to generateExplicitMPC when you create the explicit MPC controller. See generateExplicitRange for details about this structure.
OptimizationOptions	1-D structure containing user-modifiable options used to generate the explicit MPC controller. This property is automatically populated by the opt argument to generateExplicitMPC when you create the explicit MPC controller. See generateExplicitOptions for details about this structure.
PiecewiseAffineSolution	$n_r$ -dimensional structure, where $n_r$ is the number of piecewise affine (PWA) regions required to represent the control law. The $i$ th element contains the details needed to compute the optimal manipulated variables when the solution lies within the $i$ th region. See "Implementation".

Property	Description
IsSimplified	Logical switch indicating whether the explicit control law has been modified using the simplify command such that the explicit control law approximates the base (implicit) MPC controller. If the control law has not been modified, the explicit controller should reproduce the base controller's behavior exactly, provided both operate within the bounds described by the Range property.

# **Tips**

- Using Explicit MPC, you will most likely achieve best performance in small control problems, which involve small numbers of plant inputs/outputs/states as well as the number of constraints.
- Test the implicit controller thoroughly before attempting a conversion. This helps to
  determine the range of controller states and other parameters needed to generate the
  explicit controller.
- Simulate the explicit controller's performance using the sim or mpcmoveExplicit commands, or the Explicit MPC Controller block in Simulink.
- generateExplicitMPC displays progress messages in the command window. Use mpcverbosity to turn off the display.

# generateExplicitOptions

Optimization options for explicit MPC generation

# **Syntax**

```
opt = generateExplicitOptions(MPCobj)
```

# **Description**

opt = generateExplicitOptions(MPCobj) creates a set of options to use when converting a traditional MPC controller, MPCobj, to explicit form using generateExplicitMPC. The options set is returned with all options set to default values. Use dot notation to modify the options.

# **Examples**

### **Generate Explicit MPC Controller**

Generate an explicit MPC controller based upon a traditional MPC controller for a double-integrator plant.

Define the double-integrator plant.

```
plant = tf(1,[1 \ 0 \ 0]);
```

Create a traditional (implicit) MPC controller for this plant, with sample time 0.1, a prediction horizon of 10, and a control horizon of 3.

```
Ts = 0.1;
p = 10;
m = 3;
MPCobj = mpc(plant,Ts,p,m);
```

```

# **Input Arguments**

#### MPCobj — Traditional MPC controller

MPC controller object

Traditional MPC controller, specified as an MPC controller object. Use the mpc command to create a traditional MPC controller.

## **Output Arguments**

#### opt — Options for generating explicit MPC controller

structure

Options for generating explicit MPC controller, returned as a structure. When you create the structure, all the options are set to default values. Use dot notation to modify any options you want to change. The fields and their default values are as follows.

#### zerotol — Zero-detection tolerance

1e-8 (default) | positive scalar value

Zero-detection tolerance used by the NNLS solver, specified as a positive scalar value.

#### removetol — Redundant-inequality-constraint detection tolerance

1e-4 (default) | positive scalar value

Redundant-inequality-constraint detection tolerance, specified as a positive scalar value.

### flattol — Flat region detection tolerance

1e-5 (default) | positive scalar value

Flat region detection tolerance, specified as a positive scalar value.

#### normalization — Constraint normalization tolerance

0.01 (default) | positive scalar value

Constraint normalization tolerance, specified as a positive scalar value.

#### maxiterNNLS — Maximum number of NNLS solver iterations

500 (default) | positive integer

Maximum number of NNLS solver iterations, specified as a positive integer.

### maxiterQP — Maximum number of QP solver iterations

200 (default) | positive integer

Maximum number of QP solver iterations, specified as a positive integer.

#### maxiterBS — Maximum number of bisection method iterations

100 (default) | positive integer

Maximum number of bisection method iterations used to detect region flatness, specified as a positive integer.

### polyreduction — Method for removing redundant inequalities

2 (default) | 1

Method used to remove redundant inequalities, specified as either 1 (robust) or 2 (fast).

# generateExplicitRange

Bounds on explicit MPC control law parameters

## **Syntax**

```
Range = generateExplicitRange(MPCobj)
```

## **Description**

Range = generateExplicitRange(MPCobj) creates a structure of parameter bounds based upon a traditional (implicit) MPC controller object. The range structure is intended for use as an input argument to generateExplicitMPC. Usually, the initial range values returned by generateExplicitRange are not suitable for generating an explicit MPC controller. Therefore, use dot notation to set the values of the range structure before calling generateExplicitMPC.

## **Examples**

### **Generate Explicit MPC Controller**

Generate an explicit MPC controller based upon a traditional MPC controller for a double-integrator plant.

Define the double-integrator plant.

```
plant = tf(1,[1 \ 0 \ 0]);
```

Create a traditional (implicit) MPC controller for this plant, with sample time 0.1, a prediction horizon of 10, and a control horizon of 3.

```
Ts = 0.1;
p = 10;
m = 3;
MPCobj = mpc(plant,Ts,p,m);
```

```

## **Input Arguments**

#### MPCobj — Traditional MPC controller

MPC controller object

Traditional MPC controller, specified as an MPC controller object. Use the mpc command to create a traditional MPC controller.

## **Output Arguments**

#### Range — Parameter bounds

structure

Parameter bounds for generating an explicit MPC controller from MPCobj, returned as a structure.

Initially, each parameter's minimum and maximum bounds are identical. All such parameters are considered fixed. When you generate an explicit controller, any fixed parameters must be constant when the controller operates. This is unlikely to happen in general. Thus, you must specify valid bounds for all parameters. Use dot notation to set the values of the range structure as appropriate for your system.

The fields of the range structure are as follows.

#### State — Bounds on controller state values

structure

Bounds on controller state values, specified as a structure containing fields Min and Max. Each of Min and Max is a vector of length  $n_x$ , where  $n_x$  is the number of controller states. Range.State.Min and Range.State.Max contain the minimum and maximum values, respectively, of all controller states. For example, suppose you are designing a two-state controller. You have determined that the range of the first controller state is [-1000,1000], and that of the second controller state is [0,2\*pi]. Set these bounds as follows:

```
Range.State.Min(:) = [-1000,0];
Range.State.Max(:) = [1000,2*pi];
```

MPC controller states include states from plant model, disturbance model, and noise model, in that order. Setting the range of a state variable is sometimes difficult when a state does not correspond to a physical parameter. In that case, multiple runs of open-loop plant simulation with typical reference and disturbance signals are recommended in order to collect data that reflect the ranges of states.

### Reference — Bounds on controller reference signal values

structure

Bounds on controller reference signal values, specified as a structure containing fields Min and Max. Each of Min and Max is a vector of length  $n_y$ , where  $n_y$  is the number of plant outputs. Range.Reference.Min and Range.Reference.Max contain the minimum and maximum values, respectively, of all reference signal values. For example, suppose you are designing a controller for a two-output plant. You have determined that the range of the first plant output is [-1000, 1000], and that of the second plant output is [0, 2\*pi]. Set these bounds as follows:

```
Range.Reference.Min(:) = [-1000,0];
Range.Reference.Max(:) = [1000,2*pi];
```

Usually you know the practical range of the reference signals being used at the nominal operating point in the plant. The ranges used to generate the explicit MPC controller must be at least as large as the practical range.

# **MeasuredDisturbance** — **Bounds on measured disturbance values** structure

Bounds on measured disturbance values, specified as a structure containing fields Min and Max. Each of Min and Max is a vector of length  $n_{md}$ , where  $n_{md}$  is the number of measured disturbances. If your system has no measured disturbances, leave the generated values of this field unchanged.

Range.MeasuredDisturbance.Min and Range.MeasuredDisturbance.Max contain the minimum and maximum values, respectively, of all measured disturbance signals. For example, suppose you are designing a controller for a system with two measured disturbances. You have determined that the range of the first disturbance is [-1,1], and that of the second disturbance is [0,0.1]. Set these bounds as follows:

```
Range.Reference.Min(:) = [-1,0];
Range.Reference.Max(:) = [1,0.1];
```

Usually you know the practical range of the measured disturbance signals being used at the nominal operating point in the plant. The ranges used to generate the explicit MPC controller must be at least as large as the practical range.

### ManipulatedVariable — Bounds on manipulated variable values

structure

Bounds on manipulated variable values, specified as a structure containing fields Min and Max. Each of Min and Max is a vector of length  $n_u$ , where  $n_u$  is the number of manipulated variables. Range.ManipulatedVariable.Min and

Range.ManipulatedVariable.Max contain the minimum and maximum values, respectively, of all manipulated variables. For example, suppose your system has two manipulated variables. The range of the first manipulated variable is [-1,1], and that of the second variable is [0,0.1]. Set these bounds as follows:

```
Range.ManipulatedVariable.Min(:) = [-1,0];
Range.ManipulatedVariable.Max(:) = [1,0.1];
```

If manipulated variables are constrained, the ranges used to generate the explicit MPC controller must be at least as large as these limits.

# generatePlotParameters

Parameters for plotSection

## **Syntax**

```
plotParams = generatePlotParameters(EMPCobj)
```

# **Description**

plotParams = generatePlotParameters (EMPCobj) creates a structure of parameters for a 2-D sectional plot of the explicit MPC control law of the explicit MPC controller, EMPCobj. You set the fields of this structure and use it to generate the plot using the plotSection command.

## **Examples**

### Specify Fixed Parameters for 2-D Plot of Explicit Control Law

Define a double integrator plant model and create a traditional implicit MPC controller for this plant. Constrain the manipulated variable to have an absolute value less than 1.

```
plant = tf(1,[1 0 0]);
MPCobj = mpc(plant,0.1,10,3);

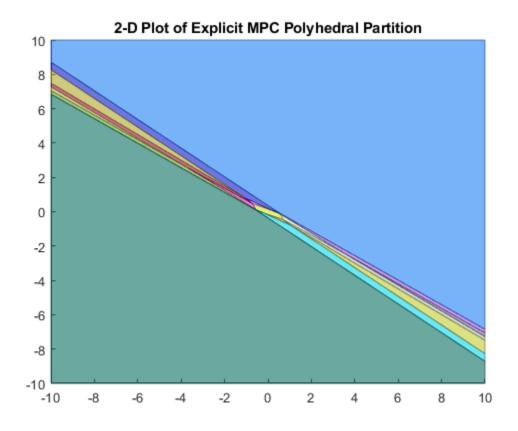

-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defar->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming of -->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
MPCobj.MV = struct('Min',-1,'Max',1);

Define the parameter bounds for generating an explicit MPC controller.

range = generateExplicitRange(MPCobj);
```

```
-->Converting the "Model.Plant" property of "mpc" object to state-space.
-->Converting model to discrete time.
```

```
Assuming no disturbance added to measured output channel #1.
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ear
range.State.Min(:) = [-10; -10];
range.State.Max(:) = [10;10];
range.Reference.Min(:) = -2;
range.Reference.Max(:) = 2;
range.ManipulatedVariable.Min(:) = -1.1;
range.ManipulatedVariable.Max(:) = 1.1;
Create an explicit MPC controller.
EMPCobj = generateExplicitMPC(MPCobj,range);
Regions found / unexplored:
                                               (-)
                                    19/
Create a default plot parameter structure, which specifies that all of the controller
parameters are fixed at their nominal values for plotting.
plotParams = generatePlotParameters(EMPCobj);
Allow the controller states to vary when creating a plot.
plotParams.State.Index = [];
plotParams.State.Value = [];
Fix the manipulated variable and reference signal to 0 for plotting.
plotParams.ManipulatedVariable.Index(1) = 1;
plotParams.ManipulatedVariable.Value(1) = 0;
plotParams.Reference.Index(1) = 1;
plotParams.Reference.Value(1) = 0;
Generate the 2-D section plot for the explicit MPC controller.
plotSection(EMPCobj,plotParams)
```

## **Input Arguments**

#### **EMPCobj** — **Explicit MPC** controller

explicit MPC controller object

Explicit MPC controller for which you want to create a 2-D sectional plot, specified as an Explicit MPC controller object. Use generateExplicitMPC to create an explicit MPC controller.

## **Output Arguments**

#### plotParams — Parameters for sectional plot

structure

Parameters for sectional plot of explicit MPC control law, returned as a structure.

As returned by generatePlotParameters, the plotParams structure command fixes all the control law's parameters at their nominal values. To obtain the desired plot, eliminate the Index and Value entries of the two parameters forming the plot axes, and modify fixed values as necessary. Then, use the plotSection command to display the 2-D sectional plot of the explicit control law's PWA regions with the remaining free parameters as the x and y axes.

The fields of the plot-parameters structure are as follows.

#### State — Fixed controller states

structure

Fixed controller states, specified as a structure having an Index field and a Value field. The field plotParams.State.Index is a vector that contains the indices of the controller states to fix for the plot, and plotParams.State.Value contains the corresponding constant state values.

Modify the default value of plotParams. State to generate the desired plot. See "Specify Fixed Parameters for 2-D Plot of Explicit Control Law" on page 2-31.

### Reference — Fixed reference signal values

structure

Fixed reference signal values, specified as a structure having an Index field and a Value field. The field plotParams.Reference.Index is a vector that contains the indices of

the reference signals to fix for the plot, and plotParams.Reference.Value contains the corresponding constant reference signal values.

Modify the default value of plotParams.Reference to generate the desired plot. See "Specify Fixed Parameters for 2-D Plot of Explicit Control Law" on page 2-31.

#### MeasuredDisturbance — Fixed measured disturbance values

structure

Fixed measured disturbance values, specified as a structure having an Index field and a Value field. The field plotParams.MeasuredDisturbance.Index is a vector that contains the indices of the measured disturbances to fix for the plot, and plotParams.MeasuredDisturbance.Value contains the corresponding constant measured disturbance values.

Modify the default value of plotParams.MeasuredDisturbance to generate the desired plot. See "Specify Fixed Parameters for 2-D Plot of Explicit Control Law" on page 2-31.

### ManipulatedVariable — Fixed manipulated variable values

structure

Fixed manipulated variable values, specified as a structure having an Index field and a Value field. The field plotParams.ManipulatedVariable.Index is a vector that contains the indices of the manipulated variables to fix for the plot, and plotParams.ManipulatedVariable.Value contains the corresponding constant manipulated variable values.

Modify the default value of plotParams.ManipulatedVariable to generate the desired plot. See "Specify Fixed Parameters for 2-D Plot of Explicit Control Law" on page 2-31.

# get

MPC property values

## **Syntax**

```
Value = get(MPCobj,PropertyName)
Struct = get(MPCobj)
get(MPCobj)
```

## **Description**

Value = get(MPCobj, PropertyName) returns the current value of the property PropertyName of the MPC controller MPCobj. Specify PropertyName as a character vector or string that contains the full property name (for example, 'UserData') or any unambiguous case-insensitive abbreviation (for example, 'user'). You can specify any generic MPC property.

Struct = get(MPCobj) converts the MPC controller MPCobj into a standard MATLAB structure with the property names as field names and the property values as field values.

get(MPCobj) without a left-side argument displays all properties of MPCobj and their values.

## **Tips**

```
An alternative to the syntax

Value = get(MPCobj,'PropertyName')

is the structure-like referencing

Value = MPCobj.PropertyName

For example,
```

MPCobj.Ts MPCobj.p

return the values of the sampling time and prediction horizon of the MPC controller  $\ensuremath{\mathsf{MPCobj}}$  .

# getCodeGenerationData

Create data structures for mpcmoveCodeGeneration

## **Syntax**

```
[configData,stateData,onlineData] = getCodeGenerationData(MPCobj)
[____] = getCodeGenerationData(____,Name,Value)
```

# **Description**

```
[configData,stateData,onlineData] = getCodeGenerationData(MPCobj)
creates data structures for use with mpcmoveCodeGeneration.

[____] = getCodeGenerationData(____,Name,Value) specifies additional options
using one or more Name,Value pair arguments.
```

## **Examples**

#### **Create MPC Code Generation Data Structures**

Create a plant model, and define the MPC signal types.

```
plant = rss(3,2,2);
plant.D = 0;
plant = setmpcsignals(plant, 'mv',1, 'ud',2, 'mo',1, 'uo',2);

Create an MPC controller.

mpcObj = mpc(plant,0.1);

-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defau
```

-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming

```
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
   for output(s) y1 and zero weight for output(s) y2
Configure your controller parameters. For example, define bounds for the manipulated
variable.
mpcObj.ManipulatedVariables.Min = -1;
mpcObj.ManipulatedVariables.Max = 1;
Create code generation data structures.
[configData,stateData,onlineData] = getCodeGenerationData(mpcObj);
--->Converting model to discrete time.
-->The "Model.Disturbance" property of "mpc" object is empty:

-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Create code generation data structures. Configure options to:

- · Use single-precision floating-point values in the generated code
- Improve computational efficiency by not computing optimal sequence data.
- Use run your MPC controller in adaptive mode.

## **Input Arguments**

### MPCobj — Model predictive controller

implicit MPC controller object | explicit MPC controller object

Model predictive controller, specified as one of the following:

- ullet Implicit MPC controller object To create an implicit MPC controller, use mpc.
- Explicit MPC controller object To create an explicit MPC controller, design an implicit controller and then use generateExplicitMPC.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'DataType', 'single' specifies that the generated code uses single-precision floating point values.

#### InitialState — Initial controller state

mpcstate object

Initial controller state, specified as the comma-separated pair consisting of 'InitialState' and an mpcstate object. This state is used in place of the default state information from MPCobj.

#### DataType — Data type used in generated code

'double' (default) | 'single'

Data type used in generated code, specified as specified as the comma-separated pair consisting of 'DataType' and one of the following:

- 'double' Use double-precision floating point values.
- 'single' Use single-precision floating point values.

#### OnlyComputeCost — Toggle for computing only optimal cost

false (default) | true

Toggle for computing only optimal cost during simulation, specified as specified as the comma-separated pair consisting of 'OnlyComputeCost' and either true or false. To reduce computational load by not calculating optimal sequence data, set OnlyComputeCost to true.

### IsAdaptive — Adaptive MPC indicator

false (default) | true

Adaptive MPC indicator, specified as specified as the comma-separated pair consisting of 'IsAdaptive' and either true or false. Set IsAdaptive to true if your controller is running in adaptive mode.

For more information on adaptive MPC, see "Adaptive MPC".

**Note** IsAdaptive and IsLTV cannot be true at the same time.

### IsLTV — Time-varying MPC indicator

false (default) | true

Time-varying MPC indicator, specified as the comma-separated pair consisting of 'IsLTV' and either true or false. Set IsLTV to true if your controller is running in time-varying mode.

For more information on time-varying MPC, see "Time-Varying MPC".

**Note** IsAdaptive and IsLTV cannot be true at the same time.

#### UseVariableHorizon — Variable horizon indicator

false (default) | true

Variable horizon indicator, specified as the comma-separated pair consisting of 'UseVariableHorizon' and either true or false. To vary your prediction and control horizons at run time, set UseVariableHorizons to true.

When you use variable horizons, mpcmoveCodeGeneration ignores the horizons specified in configData and instead uses the prediction and control horizon specified in onlineData.horizons.

For more information, see "Adjust Horizons at Run Time".

## **Output Arguments**

### configData — MPC configuration parameters

structure

MPC configuration parameters that are constant at run time, returned as a structure. These parameters are derived from the controller settings in MPCobj. When simulating your controller, pass configData to mpcmoveCodeGeneration without changing any parameters.

For more information on how generated MPC code uses constant matrices in configData to solve the QP problem, see "QP Problem Construction for Generated C Code".

#### stateData — Initial controller states

structure

Initial controller states, returned as a structure. To initialize your simulation with the initial states defined in MPCobj, pass stateData to mpcmoveCodeGeneration. To use different initial conditions, modify stateData. You can specify nondefault controller states using InitialState.

For more information on the stateData fields, see mpcmoveCodeGeneration.

stateData has the following fields.

Field	Description
Plant	Plant model state estimates
Disturbance	Unmeasured disturbance model state estimates
Noise	Output measurement noise model state estimates
LastMove	Manipulated variable control moves from previous control interval
Covariance	Covariance matrix for controller state estimates
iA	Active inequality constraints

### onlineData — Online controller data

structure

Online controller data that you must update at each control interval, returned as a structure with the following fields.

Field	Description		
signals	Input and output signals, returned as a structure with the following fields.		
	Field	Description	
	ym	Measured outputs	
	ref	Output references	
	md	Measured disturbances	
	mvTarget	Targets for manipulated variables	
	externalMV	Manipulated variables externally applied to the plant	

Field	Description	Description		
limits		Input and output constraints, returned as a structure with the following fields:		
	Field	Description		
	ymin	Lower bounds on output signals		
	ymax	Upper bounds on output signals		
	umin	Lower bounds on input signals		
	umax	Upper bounds on input signals		
weights	mpcmoveCode Updated QP o	When MPCobj is an explicit MPC controller, mpcmoveCodeGeneration ignores the limits field.  Updated QP optimization weights, returned as a structure with the following fields:		
	Field	Description		
	ywt	Output weights		
	uwt	Manipulated variable weights		
	duwt	Manipulated variable rate weights		
	ecr	Weight on slack variable used for constraint softening		
		is an explicit MPC controller, Generation ignores the weights field.		

Field	Description		
customconstraint s	Updated custom mixed input/output constraints, returned as a structure with the following fields:		
	Field	Description	
	E	Manipulated variable constraint constant	
	F	Controlled output constraint constant	
	G	Mixed input/output constraint constant	
	S	Measured disturbance constraint constant	
horizons	When MPCobj is an explicit MPC controller, mpcmoveCodeGeneration ignores the customconstraints field.  Updated controller horizon values, returned as a structure with the following fields:		
	Field	Description	
	p	Prediction horizon	
	m	Control horizon	
	The horizons field is returned only when the UseVariableHorizon name-value pair is true.  When MPCobj is an explicit MPC controller, mpcmoveCodeGeneration ignores the horizons field.		

Field	Description		
model	Updated plant and nominal values for adaptive MPC and time- varying MPC, returned as a structure with the following fields:		
	Field	Description	
	A, B, C, D	State-space matrices of discrete-time state-space model.	
	X	Nominal plant states	
	U	Nominal plant inputs	
	Υ	Nominal plant outputs	
	DX	Nominal plant state derivatives	
	The model field is re	turned only when either the IsAdaptive or air is true.	

getCodeGenerationData returns onlineData with empty matrices for all structure fields, except signals.ref, signals.ym, and signals.md. These fields contain the corresponding nominal signal values from MPCobj. If your controller does not have measured disturbances, signals.md is returned as an empty matrix.

For more information on configuring onlineData fields, see mpcmoveCodeGeneration.

# getconstraint

Obtain mixed input/output constraints from model predictive controller

## **Syntax**

[E,F,G,V,S] = getconstraint(MPCobj)

## **Description**

[E,F,G,V,S] = getconstraint(MPCobj) returns the mixed-input/output constraints previously defined for the MPC controller, MPCobj. The constraints are in the general form:

$$Eu(k + j|k) + Fy(k + j|k) + Sv(k + j|k) \le G + \varepsilon V$$

where j = 0,...,p, and:

- *p* is the prediction horizon.
- *k* is the current time index.
- u is a column vector manipulated variables.
- ullet y is a column vector of all plant output variables.
- *v* is a column vector of measured disturbance variables.
- $\varepsilon$  is a scalar slack variable used for constraint softening (as in "Standard Cost Function").
- E, F, G, V, and S are constant matrices.

Since the MPC controller does not optimize u(k+p|k), getconstraint calculates the last constraint at time k+p assuming that u(k+p|k) = u(k+p-1|k).

# **Examples**

#### **Retrieve Custom Constraints from MPC Controller**

Create a third-order plant model with two manipulated variables, one measured disturbance, and two measured outputs.

```
plant = rss(3,2,3);
plant.D = 0;
plant = setmpcsignals(plant,'mv',[1 2],'md',3);
```

Create an MPC controller for this plant.

```
MPCobj = mpc(plant,0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defactions of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming default 1
```

Assume that you have two soft constraints.

```
u_1 + u_2 \le 5<br/>y_2 + v \le 10
```

Set the constraints for the MPC controller.

```
E = [1 1; 0 0];
F = [0 0; 0 1];
G = [5;10];
V = [1;1];
S = [0;1];
setconstraint(MPCobj,E,F,G,V,S)
```

Retrieve the constraints from the controller.

```
[E,F,G,V,S] = getconstraint(MPCobj)
E = 2 \times 2
\begin{array}{ccc} 1 & 1 \\ 0 & 0 \end{array}
F = 2 \times 2
```

0 0 0

 $G = 2 \times 1$ 

5 10

 $V = 2 \times 1$ 

1

 $S = 2 \times 1$ 

0

## **Input Arguments**

### MPCobj — Model predictive controller

MPC controller object

Model predictive controller, specified as an MPC controller object. To create an MPC controller, use mpc.

## **Output Arguments**

### **E** — Manipulated variable constraint constant

 $N_c$ -by- $N_{mv}$  array | []

Manipulated variable constraint constant, returned as an  $N_c$ -by- $N_{mv}$  array, where  $N_c$  is the number of constraints, and  $N_{mv}$  is the number of manipulated variables.

If MPCobj has no mixed input/output constraints, then E is [].

#### F — Controlled output constraint constant

```
N_c-by-N_v array | []
```

Controlled output constraint constant, returned as an  $N_c$ -by- $N_y$  array, where  $N_y$  is the number of controlled outputs (measured and unmeasured).

If MPCobj has no mixed input/output constraints, then F is [].

### **G** — Mixed input/output constraint constant

```
column vector of length N_c | []
```

Mixed input/output constraint constant, returned as a column vector of length  $N_c$ , where  $N_c$  is the number of constraints.

If MPCobj has no mixed input/output constraints, then G is [].

#### V — Constraint softening constant

```
column vector of length N_c \mid []
```

Constraint softening constant representing the equal concern for the relaxation (ECR), returned as a column vector of length  $N_c$ , where  $N_c$  is the number of constraints. If MPCobj has no mixed input/output constraints, then V is [].

If V is not specified, a default value of 1 is applied to all constraint inequalities and all constraints are soft. This behavior is the same as the default behavior for output bounds, as described in "Standard Cost Function".

To make the  $i^{th}$  constraint hard, specify V(i) = 0.

To make the  $i^{\rm th}$  constraint soft, specify V(i) > 0 in keeping with the constraint violation magnitude you can tolerate. The magnitude violation depends on the numerical scale of the variables involved in the constraint.

In general, as V(i) decreases, the controller hardens the constraints by decreasing the constraint violation that is allowed.

#### S — Measured disturbance constraint constant

```
N_c-by-N_v array | []
```

Measured disturbance constraint constant, returned as an  $N_c$ -by- $N_{\nu}$  array, where  $N_{\nu}$  is the number of measured disturbances.

If there are no measured disturbances in the mixed input/output constraints, or MPCobj has no mixed input/output constraints, then S is [].

# getEstimator

Obtain Kalman gains and model for estimator design

## **Syntax**

```
[L,M] = getEstimator(MPCobj)
[L,M,A,Cm,Bu,Bv,Dvm] = getEstimator(MPCobj)
[L,M,model,index] = getEstimator(MPCobj,'sys')
```

## **Description**

[L,M] = getEstimator(MPCobj) extracts the Kalman gains used by the state estimator in a model predictive controller. The estimator updates the states of internal plant, disturbance, and noise models at the beginning of each controller interval.

[L,M,A,Cm,Bu,Bv,Dvm] = getEstimator(MPCobj) also returns the system matrices used to calculate the estimator gains.

[L,M,model,index] = getEstimator(MPCobj,'sys') returns an LTI state-space representation of the system used for state-estimator design and a structure summarizing the I/O signal types of the system.

## **Examples**

#### **Extract Parameters for State Estimation**

The plant is a stable, discrete LTI state-space model with four states, three inputs, and three outputs. The manipulated variables are inputs 1 and 2. Input 3 is an unmeasured disturbance. Outputs 1 and 3 are measured. Output 2 is unmeasured.

Create a model of the plant and specify the signals for MPC.

```
rng(1253) % For repeatable results
Plant = drss(4,3,3);
```

```
Plant.Ts = 0.25;
Plant = setmpcsignals(Plant, 'MV', [1,2], 'UD', 3, 'MO', [1 3], 'UO', 2);
Plant.d(:,[1,2]) = 0;
```

The last command forces the plant to satisfy the assumption of no direct feedthrough.

Calculate the default model predictive controller for this plant.

```
MPCobj = mpc(Plant);
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defactions of "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming default 1 for output(s) y1 y3 and zero weight for output(s) y2
```

Obtain the parameters to be used in state estimation.

[L,M,A,Cm,Bu,Bv,Dvm] = getEstimator(MPCobj);

```
-->The "Model.Disturbance" property of "mpc" object is empty:
    Assuming unmeasured input disturbance #3 is integrated white noise.
-->Assuming output disturbance added to measured output channel #1 is integrated white Assuming no disturbance added to measured output channel #3.
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each
```

Based on the estimator state equation, the estimator poles are given by the eigenvalues of A - L\*Cm. Calculate and display the poles.

```
Poles = eig(A - L*Cm)

Poles = 6×1

-0.7467
-0.5019
0.0769
0.4850
0.8825
0.8291
```

Confirm that the default estimator is asymptotically stable.

```
max(abs(Poles))
```

```
ans = 0.8825
```

This value is less than 1, so the estimator is asymptotically stable.

Verify that in this case, L = A\*M.

```
L - A*M

ans = 6\times2

10^{-15} ×

0.1665 0.1527

0.0278 0.1110

-0.1110 -0.1388

0.0139 0

-0.0763 -0.0278

0.0139 -0.1110
```

## **Input Arguments**

### MPCobj — MPC controller

MPC controller object

MPC controller, specified as an MPC controller object. Use the mpc command to create the MPC controller.

## **Output Arguments**

### L — Kalman gain matrix for time update

matrix

Kalman gain matrix for the time update, returned as a matrix. The dimensions of L are  $n_x$ -by- $n_{ym}$ , where  $n_x$  is the total number of controller states, and  $n_{ym}$  is the number of measured outputs. See "State Estimator Equations" on page 2-56.

### M — Kalman gain matrix for measurement update

matrix

Kalman gain matrix for the measurement update, returned as a matrix. The dimensions of L are  $n_x$ -by- $n_{ym}$ , where  $n_x$  is the total number of controller states, and  $n_{ym}$  is the number of measured outputs. See "State Estimator Equations" on page 2-56.

#### A, Cm, Bu, Bv, Dvm — System matrices

matrices

System matrices used to calculate the estimator gains, returned as matrices of various dimensions. For definitions of these system matrices, see "State Estimator Equations" on page 2-56.

### model — System used for state-estimator design

state-space model

System used for state-estimator design, returned as a state-space (ss) model. The input to model is a vector signal comprising the following components, concatenated in the following order:

- Manipulated variables
- Measured disturbance variables
- 1
- Noise inputs to disturbance models
- Noise inputs to measurement noise model

The number of noise inputs depends on the disturbance and measurement noise models within MPCobj. For the category noise inputs to disturbance models, inputs to the input disturbance model (if any) precede those entering the output disturbance model (if any). The constant input, 1, accounts for nonequilibrium nominal values (see "MPC Modeling").

To make the calculation of gains L and M more robust, additive white noise inputs are assumed to affect the manipulated variables and measured disturbances (see "Controller State Estimation"). These white noise inputs are not included in model.

#### index — Locations of variables within model

structure

Locations of variables within the inputs and outputs of model. The structure summarizes these locations with the following fields and values.

Field Name	Value
ManipulatedVariables	Indices of manipulated variables within the input vector of model.
MeasuredDisturbances	Indices of measured input disturbances within the input vector of model.
Offset	Index of the constant input 1 within the input vector of model.
WhiteNoise	Indices of unmeasured disturbance inputs within the input vector of model.
MeasuredOutputs	Indices of measured outputs within the output vector of model.
UmeasuredOutputs	Indices of unmeasured outputs within the output vector of model.

### **Definitions**

### **State Estimator Equations**

The following equations describe the state estimation. For more details, see "Controller State Estimation".

Output estimate:  $y_m[n|n-1] = C_m x[n|n-1] + D_{vm} v[n]$ .

Measurement update:  $x[n|n] = x[n|n-1] + M (y_m[n] - y_m[n|n-1]).$ 

Time update:  $x[n+1|n] = A x[n|n-1] + B_u u[n] + B_v v[n] + L (y_m[n] - y_m[n|n-1]).$ 

Estimator state:  $x[n+1|n] = (A - L C_m) x[n|n-1] + B_u u[n] + (B_v-L D_{vm}) v[n] + L y_m[v]$ . The estimator state is based on the current measurement of  $y_m[n]$  and v[n] as well as the optimal control action u[n] computed at the current control interval.

The variables in these equations are summarized in the following table.

Symbol	Description	
Х	Controller state vector, length $n_x$ . It includes (in this sequence):	
	<ul> <li>Plant model state estimates. Dimension obtained by conversion of MPCobj.Model.Plant to discrete LTI state- space form (if necessary), followed by use of absorbDelay to convert any delays to additional states.</li> </ul>	
	• Input disturbance model state estimates (if any). Use the getindist command to review the input disturbance model structure.	
	<ul> <li>Output disturbance model state estimates (if any). Use the getoutdist command to review the output disturbance model structure.</li> </ul>	
	Output measurement noise states (if any) as specified by MPCobj.Model.Noise.	
	The length $n_x$ is the sum of the number of states in the above four categories.	
$\mathcal{Y}_m$	Vector of measured outputs or an estimate of their true values, length $n_{ym}$ .	
u	Vector of manipulated variables, length $n_u$ .	
ν	Vector of measured input disturbances, length $n_{\nu}$ .	
[j k]	Denotes an estimate of a state or output at time $t_j$ based on data available at time $t_k$ .	
[k]	Denotes a quantity known at time $t_k$ , i.e., not an estimate.	
A	$n_x$ -by- $n_x$ state transition matrix.	
$B_u$	$n_x$ -by- $n_u$ matrix mapping $u$ to $x$ .	
$B_{\nu}$	$n_x$ -by- $n_x$ matrix mapping $\nu$ to $x$ .	
$C_m$	$n_{ym}$ -by- $n_x$ matrix mapping $x$ to $y_m$ .	
$D_{vm}$	$n_{ym}$ -by- $n_v$ matrix mapping $v$ to $y_m$ . Note that $D_{um}=0$ because there can be no direct feedthrough between any manipulated variable and any measured output.	

Symbol	Description
L	$n_x$ -by- $n_{ym}$ Kalman gain matrix for the time update. (See kalmd in the Control System Toolbox <sup>TM</sup> documentation.) Note that $L = A*M$ minimizes the expected state estimation error for most combinations of plant and disturbance models used in MPC, but this is not true in general.
M	$n_x$ -by- $n_{ym}$ Kalman gain matrix for the measurement update. (See kalmd in the Control System Toolbox documentation.)

Introduced in R2014b

# getindist

Retrieve unmeasured input disturbance model

## **Syntax**

```
indist = getindist(MPCobj)
[indist,channels] = getindist(MPCobj)
```

## **Description**

indist = getindist(MPCobj) returns the input disturbance model, indist, used by the model predictive controller, MPCobj.

[indist,channels] = getindist(MPCobj) also returns the input channels to which integrated white noise has been added by default. For more information on the default model, see "MPC Modeling".

# **Examples**

### **Retrieve Input Disturbance Model**

Define a plant model with no direct feedthrough.

```
plant = rss(3,1,2);
plant.D = 0;
```

Set the first input signal as a manipulated variable and the second input as an unmeasured disturbance.

```
plant = setmpcsignals(plant, 'MV',[1], 'UD',[2]);
```

Create an MPC controller for the defined plant.

```
MPCobj = mpc(plant,0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defaction of "weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming defaction of "weights.OutputVariables" property of "mpc" object is empty. Assuming default 1

Extract the input disturbance model.

indist = getindist(MPCobj);

-->Converting model to discrete time.
-->The "Model.Disturbance" property of "mpc" object is empty:
    Assuming unmeasured input disturbance #2 is integrated white noise.
    Assuming no disturbance added to measured output channel #1.
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each
```

#### Retrieve Input Disturbance Model Channels with Default Integrated White Noise

Define a plant model with no direct feedthrough.

```
plant = rss(3,1,3);
plant.D = 0;
```

Set the first input signal as a manipulated variable and the other two inputs as unmeasured disturbances.

```
plant = setmpcsignals(plant, 'MV',[1], 'UD',[2 3]);
```

Create an MPC controller for the defined plant.

```
MPCobj = mpc(plant,0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default
```

-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming default 1

Extract the default output disturbance model.

```
[indist,channels] = getindist(MPCobj);
-->Converting model to discrete time.
-->The "Model.Disturbance" property of "mpc" object is empty:
```

```
Assuming unmeasured input disturbance #2 is integrated white noise.

Assuming unmeasured input disturbance #3 is white noise.

Assuming no disturbance added to measured output channel #1.

-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each
```

Check which input disturbance channels have integrated white noise added by default.

#### channels

```
channels = 1
```

An integrator has been added only to the first unmeasured input disturbance. The other input disturbance uses a static unity gain to preserve state observability.

# **Input Arguments**

#### MPCobj — Model predictive controller

MPC controller object

Model predictive controller, specified as an MPC controller object. To create an MPC controller, use mpc.

# **Output Arguments**

### indist — Input disturbance model

discrete-time, delay-free, state-space model

Input disturbance model used by the model predictive controller, MPCobj, returned as a discrete-time, delay-free, state-space model.

The input disturbance model has:

- Unit-variance white noise input signals. By default, the number of inputs depends
  upon the number of unmeasured input disturbances and the need to maintain
  controller state observability. For custom input disturbance models, the number of
  inputs is your choice.
- $n_d$  outputs, where  $n_d$  is the number of unmeasured disturbance inputs defined in MPCobj.Model.Plant. Each disturbance model output is sent to the corresponding plant unmeasured disturbance input.

If MPCobj does not have any unmeasured disturbance, indist is returned as an empty state-space model.

This model, in combination with the output disturbance model (if any), governs how well the controller compensates for unmeasured disturbances and modeling errors. For more information on the disturbance modeling in MPC and about the model used during state estimation, see "MPC Modeling" and "Controller State Estimation".

#### channels — Input channels with integrated white noise

vector of input indices

Input channels with integrated white noise added by default, returned as a vector of input indices. If you set indist to a custom input disturbance model using setindist, channels is empty.

# **Tips**

To specify a custom input disturbance model, use the setindist command.

#### Introduced in R2006a

# getname

Retrieve I/O signal names in MPC prediction model

# **Syntax**

```
name = getname(MPCobj,'input',I)
name = getname(MPCobj,'output',I)
```

# **Description**

name = getname(MPCobj,'input',I) returns the name of the Ith input signal in variable name. This is equivalent to name = MPCobj.Model.Plant.InputName{I}. The name property is equal to the contents of the corresponding Name field of MPCobj.DisturbanceVariables or MPCobj.ManipulatedVariables.

name = getname(MPCobj,'output',I) returns the name of the Ith output signal in variable name. This is equivalent to name=MPCobj.Model.Plant.OutputName{I}. The name property is equal to the contents of the corresponding Name field of MPCobj.OutputVariables.

-->Assuming output disturbance added to measured output channel #1 is integrated white
-->Assuming output disturbance added to measured output channel #2 is integrated white
-->Assuming output disturbance added to measured output channel #3 is integrated white
```

-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each

Check which channels have default integrated white noise disturbances.

#### channels

```
channels = 1 \times 3

1 2 3
```

Integrators have been added to all three output channels.

# **Input Arguments**

#### MPCobj — Model predictive controller

MPC controller object

Model predictive controller, specified as an MPC controller object. To create an MPC controller, use mpc.

# **Output Arguments**

#### outdist — Output disturbance model

discrete-time, delay-free, state-space model

Output disturbance model used by the model predictive controller, MPCobj, returned as a discrete-time, delay-free, state-space model.

The output disturbance model has:

- $n_y$  outputs, where  $n_y$  is the number of plant outputs defined in MPCobj.Model.Plant. Each disturbance model output is added to the corresponding plant output. By default, disturbance models corresponding to unmeasured output channels are zero.
- Unit-variance white noise input signals. By default, the number of inputs is equal to the number of default integrators added.

This model, in combination with the input disturbance model (if any), governs how well the controller compensates for unmeasured disturbances and modeling errors. For more information on the disturbance modeling in MPC and about the model used during state estimation, see "MPC Modeling" and "Controller State Estimation".

### channels — Output channels with integrated white noise

vector of output indices

Output channels with integrated white noise added by default, returned as a vector of output indices. If you set outdist to a custom output disturbance model using setoutdist, channels is empty.

# **Tips**

• To specify a custom output disturbance model, use the setoutdist command.

"MPC Modeling"

"Controller State Estimation"

#### **Introduced before R2006a**

# gpc2mpc

Generate MPC controller using generalized predictive controller (GPC) settings

# **Syntax**

```
mpcObj = gpc2mpc(plant)
gpcOptions = gpc2mpc
mpcObj = gpc2mpc(plant,gpcOptions)
```

# **Description**

mpcObj = gpc2mpc(plant) generates a single-input single-output MPC controller with
default GPC settings and sample time of the specified plant, plant. The GPC is a
nonminimal state-space representation described in [1]. plant is a discrete-time LTI
model with sample time greater than 0.

gpcOptions = gpc2mpc creates a structure gpcOptions containing default values of GPC settings.

mpcObj = gpc2mpc(plant,gpcOptions) generates an MPC controller using the GPC
settings in gpcOptions.

# **Input Arguments**

### plant

Discrete-time LTI model with sampling time greater than 0.

### gpcOptions

GPC settings, specified as a structure with the following fields.

N1 Starting interval in prediction horizon, specified as a

positive integer.

**Default:** 1

N2 Last interval in prediction horizon, specified as a positive

integer greater than N1. Default: 10

NU Control horizon, specified as a positive integer less than

the prediction horizon.

**Default:** 1

Lam Penalty weight on changes in manipulated variable,

specified as a positive integer greater than or equal to 0.

Default: 0

T Numerator of the GPC disturbance model, specified as a

row vector of polynomial coefficients whose roots lie

within the unit circle.

Default: [1].

MVindex Index of the manipulated variable for multi-input plants,

specified as a positive integer.

Default: 1

Default:

# **Examples**

Design an MPC controller using GPC settings:

```
% Specify the plant described in Example 1.8 of
% [1].
G = tf(9.8*[1 -0.5 6.3],conv([1 0.6565],[1 -0.2366 0.1493]));
% Discretize the plant with sample time of 0.6 seconds.
Ts = 0.6;
Gd = c2d(G, Ts);
% Create a GPC settings structure.
```

```
GPCoptions = qpc2mpc;
% Specify the GPC settings described in example 4.11 of
% [1].
% Hu
GPCoptions.NU = 2;
% Hp
GPCoptions.N2 = 5;
% R
GPCoptions.Lam = 0;
GPCoptions.T = [1 - 0.8];
% Convert GPC to an MPC controller.
mpc = gpc2mpc(Gd, GPCoptions);
% Simulate for 50 steps with unmeasured disturbance between
% steps 26 and 28, and reference signal of 0.
SimOptions = mpcsimopt(mpc);
SimOptions.UnmeasuredDisturbance = [zeros(25,1); ...
-0.1*ones(3,1); 0];
sim(mpc, 50, 0, SimOptions);
```

# **Tips**

- For plants with multiple inputs, only one input is the manipulated variable, and the remaining inputs are measured disturbances in feedforward compensation. The plant output is the measured output of the MPC controller.
- Use the MPC controller with Model Predictive Control Toolbox software for simulation and analysis of the closed-loop performance.

## mpc

Create MPC controller

# **Syntax**

```
MPCobj = mpc(Plant)
MPCobj = mpc(Plant,Ts)
MPCobj = mpc(Plant,Ts,p,m,W,MV,OV,DV)
MPCobj = mpc(Models,Ts,p,m,W,MV,OV,DV)
```

# **Description**

MPCobj = mpc(Plant) creates a model predictive controller object based on a discrete-time prediction model. The prediction model Plant can be either an LTI model with a specified sample time or a linear System Identification Toolbox model. The controller, MPCobj, inherits its control interval from Plant.Ts, and its time unit from Plant.TimeUnit. All other controller properties are default values. After you create the MPC controller, you can set its properties using MPCobj.PropertyName = PropertyValue.

MPCobj = mpc(Plant, Ts) specifies a control interval of Ts. If Plant is a discrete-time LTI model with an unspecified sample time (Plant.Ts = -1), it inherits sample time Ts when used for predictions.

MPCobj = mpc(Plant,Ts,p,m,W,MV,OV,DV) specifies additional controller properties such as the prediction horizon (p), control horizon (m), and input, input increment, and output weights (W). You can also set the properties of manipulated variables (MV), output variables (OV), and input disturbance variables (DV). If any of these values are omitted or empty, the default values apply.

MPCobj = mpc(Models,Ts,p,m,W,MV,OV,DV) creates a model predictive controller object based on a prediction model set, Models. This set includes plant, input disturbance, and measurement noise models along with the nominal conditions at which the models were obtained.

# **Input Arguments**

#### **Plant**

Plant model to be used in predictions, specified as an LTI model (tf, ss, or zpk) or a linear System Identification Toolbox model. If the Ts input argument is unspecified, Plant must be either a discrete-time LTI object with a specified sample time or a System Identification Toolbox model.

Unless you specify otherwise, controller design assumes that all plant inputs are manipulated variables and all plant outputs are measured. Use the setmpcsignals command or the LTI InputGroup and OutputGroup properties to designate other signal types.

If you specify Plant as a linear System Identification Toolbox model, any noise channels are discarded by default. To convert noise channels to unmeasured disturbances, first convert the identified model to a state-space model using the 'augmented' option. For more information on identifying plant models, see "Identify Plant from Data".

#### Ts

Controller sample time (control interval), specified as a positive scalar value.

#### р

Prediction horizon, specified as a positive integer. The control interval, Ts, determines the duration of each step. The default value is 10 + maximum intervals of delay (if any).

#### m

Control horizon, Specified as one of the following:

- Positive integer signal less than or equal to the prediction horizon.
- Vector signal of positive integers specifying blocking interval lengths. For more information, see "Manipulated Variable Blocking".

The default value is 2.

#### W

Controller tuning weights, specified as a structure. For details about how to specify this structure, see "Weights" on page 2-78.

#### MV

Bounds and other properties of manipulated variables, specified as a 1-by-nu structure array, where nu is the number of manipulated variables defined in the plant model. For details about how to specify this structure, see "ManipulatedVariables" on page 2-75.

#### **0V**

Bounds and other properties of the output variables, specified as a 1-by-ny structure array, where ny is the number of output variables defined in the plant model. For details about how to specify this structure, see "OutputVariables" on page 2-77.

#### DV

Scale factors and other properties of the disturbance inputs, specified as a 1-by-nd structure array, where nd is the number of disturbance inputs (measured + unmeasured) defined in the plant model. For details about how to specify this structure, see "DisturbanceVariables" on page 2-77.

#### Models

Plant, input disturbance, and measurement noise models, along with the nominal conditions at which these models were obtained, specified as a structure. For details about how to specify this structure, see "Model" on page 2-80.

### **Construction and Initialization**

To minimize computational overhead, Model Predictive Controller creation occurs in two phases. The first happens at construction when you invoke the mpc command, or when you change a controller property. Construction involves simple validity and consistency checks, such as signal dimensions and non-negativity of weights.

The second phase is initialization, which occurs when you use the object for the first time in a simulation or analytical procedure. Initialization computes all constant properties required for efficient numerical performance, such as matrices defining the optimal control problem and state estimator gains. Additional, diagnostic checks occur during initialization, such as verification that the controller states are observable.

By default, both phases display informative messages in the command window. You can turn these messages on or off using the mpcverbosity command.

# **Properties**

All of the parameters defining the traditional (implicit) MPC control law are stored in an MPC object, whose properties are listed in the following table.

### **MPC Controller Object**

Property	Description
ManipulatedVariables (or MV or Manipulated or Input)	Scale factors, input bounds, input-rate bounds, corresponding ECR values, target values, signal names, and units.
OutputVariables (or OV or Controlled or Output)	Scale factors, input bounds, input-rate bounds, corresponding ECR values, target values, signal names, and units.
DisturbanceVariables (or DV or Disturbance)	Disturbance scale factors, names, and units
Weights	Weights used in computing the performance (cost) function
Model	Plant, input disturbance, and output noise models, and nominal conditions.
Ts	Controller sample time
Optimizer	Parameters controlling the QP solver
PredictionHorizon	Prediction horizon
ControlHorizon	Number of free control moves or vector of blocking moves
History	Creation time
Notes	Text or comments about the MPC controller object
UserData	Any additional data

### **ManipulatedVariables**

Manipulated Variables (or MV or Manipulated or Input) is an  $n_u$ -dimensional array of structures ( $n_u$  = number of manipulated variables), one per manipulated variable. Each structure has the fields described in the following table, where p denotes the prediction horizon. Unless indicated otherwise, numerical values are in engineering units.

### **Manipulated Variable Structure**

Field Name	Content	Default
ScaleFactor	Nonnegative scale factor for this MV	1
Min	1 to <i>p</i> length vector of lower bounds on this MV	-Inf
Max	$\begin{bmatrix} 1 \text{ to } p \text{ length vector of upper bounds on this} \\ MV \end{bmatrix}$	Inf
MinECR	1 to $p$ length vector of nonnegative parameters specifying the Min bound softness (0 = hard).	0 (dimensionless)
MaxECR	1 to $p$ length vector of nonnegative parameters specifying the Max bound softness (0 = hard).	0 (dimensionless)
Target	1 to $p$ length vector of target values for this MV	'nominal'
RateMin	1 to <i>p</i> length vector of lower bounds on the interval-to-interval change for this MV	-Inf
RateMax	1 to <i>p</i> length vector of upper bounds on the interval-to-interval change for this MV	Inf
RateMinECR	1 to $p$ length vector of nonnegative parameters specifying the RateMin bound softness (0 = hard).	0 (dimensionless)
RateMaxECR	1 to $p$ length vector of nonnegative parameters specifying the RateMax bound softness (0 = hard).	0 (dimensionless)
Name	Read-only MV signal name (character vector)	InputName of LTI plant model
Units	Read-only MV signal units (character vector)	InputUnit of LTI plant model

**Note** Rates refer to the difference  $\Delta u(k) = u(k) - u(k-1)$ . Constraints and weights based on derivatives du/dt of continuous-time input signals must be properly reformulated for the discrete-time difference  $\Delta u(k)$ , using the approximation  $du/dt \cong \Delta u(k)/T_s$ .

### **OutputVariables**

OutputVariables (or OV or Controlled or Output) is an  $n_y$ -dimensional array of structures ( $n_y$  = number of outputs), one per output signal. Each structure has the fields described in the following table. p denotes the prediction horizon. Unless specified otherwise, values are in engineering units.

#### **Output Variable Structure**

Field Name	Content	Default
ScaleFactor	Nonnegative scale factor for this OV	1
Min	1 to $p$ length vector of lower bounds on this OV	-Inf
Max	1 to $p$ length vector of upper bounds on this OV	Inf
MinECR	1 to $p$ length vector of nonnegative parameters specifying the Min bound softness (0 = hard).	1 (dimensionless)
MaxECR	1 to $p$ length vector of nonnegative parameters specifying the Max bound softness (0 = hard).	1 (dimensionless)
Name	Read-only OV signal name (character vector)	OutputName of LTI plant model
Units	Read-only OV signal units (character vector)	OutputUnit of LTI plant model

In order to reject constant disturbances due, for instance, to gain nonlinearities, the default measured output disturbance model used in Model Predictive Control Toolbox software is integrated white noise (see "Output Disturbance Model").

### **DisturbanceVariables**

DisturbanceVariables (or DV or Disturbance) is an  $(n_v+n_d)$ -dimensional array of structures ( $n_v$  = number of measured input disturbances,  $n_d$  = number of unmeasured input disturbances). Each structure has the fields described in the following table.

#### **Disturbance Variable Structure**

Field Name	Content	Default
ScaleFactor	Nonnegative scale factor for this DV	1
Name	Read-only DV signal name (character vector)	InputName of LTI plant model
Units	Read-only DV signal units (character vector)	InputUnit of LTI plant model

The order of the disturbance signals within the array DV is the following: the first  $n_{\rm v}$  entries relate to measured input disturbances, the last  $n_{\rm d}$  entries relate to unmeasured input disturbances.

### Weights

Weights is the structure defining the QP weighting matrices. It contains four fields. The values of these fields depend on whether you are using the standard quadratic cost function (see "Standard Cost Function") or the alternative cost function (see "Alternative Cost Function").

#### **Standard Cost Function**

The following table lists the content of the four structure fields. In the table, p denotes the prediction horizon,  $n_{\rm u}$  the number of manipulated variables, and  $n_{\rm y}$  the number of output variables.

For the MV, MVRate and OV weights, if you specify fewer than p rows, the last row repeats automatically to form a matrix containing p rows.

#### **Weights for the Standard Cost Function**

Field Name (Abbreviations)	Content	Default (dimensionless)
ManipulatedVariables (or MV or Manipulated or Input)	(1 to $p$ )-by- $n_u$ dimensional array of nonnegative MV weights	zeros(1,nu)
ManipulatedVariablesRate (or MVRate or ManipulatedRate or InputRate)	(1 to $p$ )-by- $n_u$ dimensional array of MV-increment weights	0.1*ones(1,nu)
OutputVariables (or OV or Controlled or Output)	OV weights	1 (The default for output weights is the following: if $n_u \ge n_y$ , all outputs are weighted with unit weight; if $n_u < n_y$ , $n_u$ outputs default to 1, with preference given to measured outputs, and the rest default to 0.)
ECR	Scalar weight on the slack variable $\varepsilon$ used for constraint softening	1e5*(max weight)

**Note** If all MVRate weights are strictly positive, the resulting QP problem is strictly convex. If some MVRate weights are zero, the QP Hessian could be positive semidefinite. To keep the QP problem strictly convex, when the condition number of the Hessian matrix  $K_{\Delta U}$  is larger than  $10^{12}$ , the quantity 10\*sqrt(eps) is added to each diagonal term. See "Cost Function".

#### **Alternative Cost Function**

You can specify off-diagonal Q and R weight matrices in the cost function. To do so, define the fields ManipulatedVariables, ManipulatedVariablesRate, and OutputVariables as cell arrays, each containing a single positive-semi-definite matrix of the appropriate size. Specifically, OutputVariables must be a cell array containing the  $n_y$ -by- $n_y$  Q matrix, ManipulatedVariables must be a cell array containing the  $n_u$ -by- $n_u$   $R_{\Delta u}$  matrix, and ManipulatedVariablesRate must be a cell array containing the  $n_u$ -by- $n_u$   $R_{\Delta u}$  matrix (see "Alternative Cost Function" and the mpcweightsdemo example). You can use diagonal weight matrices for one or more of these fields. If you omit a field, the MPC controller uses the defaults shown in the table above.

For example, you can specify off-diagonal weights, as follows

```
MPCobj.Weights.OutputVariables = {Q}; MPCobj.Weights.ManipulatedVariables = {Ru}; MPCobj.Weights.ManipulatedVariablesRate = {Rdu}; where Q = Q. Ru = R_{\rm u}, and Rdu = R_{\rm Au} are positive semidefinite matrices.
```

**Note** You cannot specify nondiagonal weights that vary at each prediction horizon step. The same Q, Ru, and Rdu weights apply at each step.

#### Model

The property Model specifies plant, input disturbance, and output noise models, and nominal conditions, according to the model setup described in "Controller State Estimation". It is a 1-D structure containing the following fields.

### **Models Used by MPC**

Field Name	Content	Default
Plant	LTI model or identified linear model of the plant	No default
Disturbance	LTI model describing expected unmeasured input disturbances	[ ] (By default, input disturbances are expected to be integrated white noise. To model the signal, an integrator with dimensionless unity gain is added for each unmeasured input disturbance, unless the addition causes the controller to lose state observability. In that case, the disturbance is expected to be white noise, and so, a dimensionless unity gain is added to that channel instead.)
Noise	LTI model describing expected noise for output measurements	[ ] (By default, measurement noise is expected to be white noise with unit variance. To model the signal, a dimensionless unity gain is added for each measured channel.)

Field Name	Content	Defa	Default		
state, in	Structure containing the state, input, and output values where Model.Plant	show	The default values of the fields are shown in the following table:		
	is linearized	Fiel d	Description	Defa ult	
		Х	Plant state at operating point	[]	
		U	Plant input at operating point, including manipulated variables and measured and unmeasured disturbances	[]	
		Υ	Plant output at operating point	[]	
		DX	For continuous-time models, DX is the state derivative at operating point: $DX=f(X,U)$ . For discrete-time models, $DX=x(k+1)-x(k)=f(X,U)-X$ .	[]	

**Note** Direct feedthrough from manipulated variables to any output in Model.Plant is not allowed. See "MPC Modeling".

Specify input and output signal types via the InputGroup and OutputGroup properties of Model.Plant, or, more conveniently, use the setmpcsignals command. Valid signal types are listed in the following tables.

### **Input Groups in Plant Model**

Name (Abbreviations)	Value
	Indices of manipulated variables in Model.Plant
MeasuredDisturbances (or MD or Measured)	Indices of measured disturbances in Model.Plant
UnmeasuredDisturbances (or UD or Unmeasured)	Indices of unmeasured disturbances in Model.Plant

### **Output Groups in Plant Model**

Name (Abbreviations)	Value
	Indices of measured outputs in Model.Plant
· `	Indices of unmeasured outputs in Model.Plant

By default, all  ${\tt Model.Plant}$  inputs are manipulated variables, and all outputs are measured.

The structure Nominal contains the values (in engineering units) for states, inputs, outputs, and state derivatives/differences at the operating point where Model.Plant applies. This point is typically a linearization point. The fields are reported in the following table (see also "MPC Modeling").

### **Nominal Values at Operating Point**

Field	Description	Default
Х	Plant state at operating point	[]
U	Plant input at operating point, including manipulated variables and measured and unmeasured disturbances	[]
Υ	Plant output at operating point	[]
DX	For continuous-time models, DX is the state derivative at operating point: $DX=f(X,U)$ . For discrete-time models, $DX=x(k+1)-x(k)=f(X,U)-X$ .	[]

#### Ts

Sample time of the MPC controller. By default, if Model.Plant is a discrete-time model, Ts = Model.Plant.ts. For continuous-time plant models, specify a controller Ts. The Ts measurement unit is inherited from Model.Plant.TimeUnit.

### **Optimizer**

Optimizer is a structure with fields that contain parameters for the QP optimization.

### **Optimizer Properties**

Field	Description	Default
MaxIter	Maximum number of iterations allowed in the QP solver, specified as one of the following:	'Default'
	'Default' — The MPC controller automatically computes the maximum number of QP solver iterations as:	
	$MaxIter = 4(n_C + n_V)$	
	where	
	• $n_{cy}$ is the total number of constraints across the prediction horizon.	
	• $n_{v}$ is the total number of optimization variables across the control horizon.	
	The default MaxIter value has a lower bound of 120.	
	Positive integer — The QP solver stops after MaxIter iterations. If the solver fails to converge in the final iteration, the controller:	
	<ul> <li>Freezes the controller movement if UseSuboptimalSolution is false.</li> </ul>	
	Applies the suboptimal solution reached after the final iteration if UseSuboptimalSolution is true.	
	If CustomSolver or CustomSolverCodeGen is true, the controller does not require the custom solver to honor MaxIter.	

Field	Description	Default
MinOutputECR	Minimum value allowed for OutputMinECR and OutputMaxECR, specified as a nonnegative scalar. A value of 0 indicates that hard output constraints are allowed. If either of the OutputVariables.MinECR or OutputVariables.MaxECR properties of an MPC controller are less than MinOutputECR, a warning is displayed and the value is raised to MinOutputECR during computation.	0
UseSuboptimalSol ution	Flag indicating whether to apply a suboptimal solution after the number of optimization iterations exceeds MaxIter, specified as a logical value.	false
UseWarmStart	Flag indicating whether to warm start each QP solver iteration by passing in a list of active inequalities from the previous iteration, specified as a logical value. Inequalities are active when their equal portion is true.  If CustomSolver or CustomSolverCodeGen is true, the controller does not require the custom solver to honor UseWarmStart.	true

Field	Description	Default
CustomSolver	Flag indicating whether to use a custom QP solver for simulation, specified as a logical value. If CustomSolver is true, the user must provide an mpcCustomSolver function on the MATLAB path.	false
	This custom solver is not used for code generation. To generate code for a controller with a custom solver, use CustomSolverCodeGen.	
	If CustomSolver is true, the controller does not require the custom solver to honor MaxIter and UseWarmStart.	
	For more information on specifying custom solvers, see "Custom QP Solver".	
CustomSolverCode Gen	Flag indicating whether to use a custom QP solver for code generation, specified as a logical value. If CustomSolverCodeGen is true, the user must provide an mpcCustomSolverCodeGen function on the MATLAB path.	false
	This custom solver is not used for simulation. To simulate a controller with a custom solver, use CustomSolver.	
	If CustomSolverCodeGen is true, the controller does not require the custom solver to honor MaxIter and UseWarmStart.	
	For more information on specifying custom solvers, see "Custom QP Solver".	

**Note** The default MaxIter value can be very large for some controller configurations, such as those with large prediction and control horizons. When simulating such

controllers, if the QP solver cannot find a feasible solution, the simulation can appear to stop responding, since the solver continues searching for MaxIter iterations.

#### **PredictionHorizon**

PredictionHorizon is the integer number of prediction horizon steps. The control interval, Ts, determines the duration of each step. The default value is 10 + maximum intervals of delay (if any).

### **ControlHorizon**

ControlHorizon is either a number of free control moves, or a vector of blocking moves (see "Manipulated Variable Blocking"). The default value is 2.

### **History**

History stores the time the MPC controller was created (read-only).

### **Notes**

Notes stores text or comments as a cell array of character vectors.

### **UserData**

Any additional data stored within the MPC controller object.

# **Examples**

### **Create MPC Controller with Specified Prediction and Control Horizons**

Create a plant model with the transfer function  $(s + 1)/(s^2 + 2s)$ .

```
Plant = tf([1 1],[1 2 0]);
```

The plant is SISO, so its input must be a manipulated variable and its output must be measured. In general, it is good practice to designate all plant signal types using either the setmpcsignals command, or the LTI InputGroup and OutputGroup properties.

Specify a sample time for the controller.

```
Ts = 0.1;
```

Define bounds on the manipulated variable, u, such that  $-1 \le u \le 1$ .

```
MV = struct('Min', -1, 'Max', 1);
```

MV contains only the upper and lower bounds on the manipulated variable. In general, you can specify additional MV properties. When you do not specify other properties, their default values apply.

Specify a 20-interval prediction horizon and a 3-interval control horizon.

```
p = 20;
m = 3;
```

Create an MPC controller using the specified values. The fifth input argument is empty, so default tuning weights apply.

```
MPCobj = mpc(Plant,Ts,p,m,[],MV);
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default -->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming default 1
```

# **Compatibility Considerations**

# Support for implementing economic MPC using a linear MPC controller has been removed

Errors starting in R2018b

Support for implementing economic MPC using a linear MPC controller has been removed. Implement economic MPC using the new nonlinear MPC controller instead. For more information on nonlinear MPC controllers, see "Nonlinear MPC".

#### **Update Code**

If you previously saved a linear MPC object configured with custom cost or constraint functions, the software generates a warning when the object is loaded and an error if it is simulated. To suppress the error and warning messages and continue using your linear MPC controller, mpcobj, without the custom costs and constraints, set the IsEconomicMPC flag to false.

mpcobj.IsEconomicMPC = false;

To implement your economic MPC controller using a nonlinear MPC object:

- 1 Create an nlmpc object.
- 2 Convert your custom cost function to the format required for nonlinear MPC. For more information on nonlinear MPC cost functions, see "Specify Cost Function for Nonlinear MPC".
- 3 Convert your custom constraint function to the format required for nonlinear MPC. For more information on nonlinear MPC constraints, see "Specify Constraints for Nonlinear MPC".
- 4 Implement your linear prediction model using state and output functions. For more information on nonlinear MPC prediction models, see "Specify Prediction Model for Nonlinear MPC".

### **Topics**

"MPC Modeling"

"Design MPC Controller at the Command Line"

#### Introduced before R2006a

# mpcmove

Compute optimal control action

# **Syntax**

```
mv = mpcmove(MPCobj,x,ym,r,v)
[mv,info] = mpcmove(MPCobj,x,ym,r,v)
[____] = mpcmove(____,options)
```

# **Description**

mv = mpcmove(MPCobj,x,ym,r,v) computes the optimal manipulated variable moves, u(k), at the current time. u(k) is calculated given the current estimated extended state, x(k), the measured plant outputs,  $y_m(k)$ , the output references, r(k), and the measured disturbances, v(k), at the current time k. Call mpcmove repeatedly to simulate closed-loop model predictive control.

[mv,info] = mpcmove(MPCobj,x,ym,r,v) returns additional information regarding the model predictive controller in the second output argument info.

[\_\_\_] = mpcmove(\_\_\_,options) overrides default constraints and weights settings in MPCobj with the values specified by Options, an mpcmoveopt object. Use Options to provide run-time adjustment of constraints and weights during the closed-loop simulation.

# **Input Arguments**

### MPCobj — Model predictive controller

MPC controller object

Model predictive controller, specified as an MPC controller object. To create an MPC controller, use mpc.

#### x — Current controller state

mpcstate object

Current controller state, specified as an mpcstate object.

Before you begin a simulation with mpcmove, initialize the controller state using x = mpcstate(MPCobj). Then, modify the default properties of x as appropriate.

If you are using default state estimation, mpcmove expects x to represent x[n|n-1]. The mpcmove command updates the state values in the previous control interval with that information. Therefore, you should not programmatically update x at all. The default state estimator employs a steady-state Kalman filter.

If you are using custom state estimation, mpcmove expects x to represent x[n|n]. Therefore, prior to each mpcmove command, you must set x.Plant, x.Disturbance, and x.Noise to the best estimates of these states (using the latest measurements) at the current control interval.

#### ym — Current measured output values

column vector of length  $N_{vm}$ 

Current measured output values at time k, specified as a column vector of length  $N_{ym}$ , where  $N_{ym}$  is the number of measured outputs.

If you are using custom state estimation, set ym = [].

### r — Plant output reference values

p-by- $N_y$  array

Plant output reference values, specified as a p-by- $N_y$  array, where p is the prediction horizon of MPCobj and  $N_y$  is the number of outputs. Row r(i,:) defines the reference values at step i of the prediction horizon.

r must contain at least one row. If r contains fewer than p rows, mpcmove duplicates the last row to fill the p-by- $N_y$  array. If you supply exactly one row, therefore, a constant reference applies for the entire prediction horizon.

To implement reference previewing, which can improve tracking when a reference varies in a predictable manner, r must contain the anticipated variations, ideally for p steps.

### v — Current and anticipated measured disturbances

(p+1)-by- $N_{md}$  array

Current and anticipated measured disturbances, specified as a (p+1)-by- $N_{md}$  array, where p is the prediction horizon of MPCobj and  $N_{md}$  is the number of measured disturbances.

The first row of v specifies the current measured disturbance values. Row v(i+1,:) defines the anticipated disturbance values at step i of the prediction horizon.

Modeling of measured disturbances provides feedforward control action. If your plant model does not include measured disturbances, use v = [].

If your model includes measured disturbances, v must contain at least one row. If v contains fewer than p+1 rows, mpcmove duplicates the last row to fill the (p+1)-by- $N_{md}$  array. If you supply exactly one row, a constant measured disturbance applies for the entire prediction horizon.

To implement disturbance previewing, which can improve tracking when a disturbance varies in a predictable manner, v must contain the anticipated variations, ideally for p steps.

#### options — Run-time options

mpcmoveopt object

Run-time options, specified as an mpcmoveopt object. Use options to override selected properties of MPCobj during simulation. These options apply to the current mpcmove time instant only. Using options yields the same result as redefining or modifying MPCobj before each call to mpcmove, but involves considerably less overhead. Using options is equivalent to using an MPC Controller Simulink block in combination with optional input signals that modify controller settings, such as MV and OV constraints.

# **Output Arguments**

### mv — Optimal manipulated variable moves

column vector

Optimal manipulated variable moves, returned as a column vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

If the controller detects an infeasible optimization problem or encounters numerical difficulties in solving an ill-conditioned optimization problem, mv remains at its most recent successful solution, x.LastMove.

Otherwise, if the optimization problem is feasible and the solver reaches the specified maximum number of iterations without finding an optimal solution, mv:

- Remains at its most recent successful solution if the Optimizer.UseSuboptimalSolution property of the controller is false.
- Is the suboptimal solution reached after the final iteration if the Optimizer.UseSuboptimalSolution property of the controller is true. For more information, see "Suboptimal QP Solution".

#### info — Solution details

structure

Solution details, returned as a structure with the following fields.

#### **Uopt** — **Optimal** manipulated variable sequence

(p+1)-by- $N_{mv}$  array

Predicted optimal manipulated variable adjustments (moves), returned as a (p+1)-by- $N_{mv}$  array, where p is the prediction horizon and  $N_{mv}$  is the number of manipulated variables.

Uopt(i,:) contains the calculated optimal values at time k+i-1, for  $i=1,\ldots,p$ , where k is the current time. The first row of Info.Uopt contains the same manipulated variable values as output argument mv. Since the controller does not calculate optimal control moves at time k+p, Uopt(p+1,:) is equal to Uopt(p,:).

### Yopt — Optimal output variable sequence

(p+1)-by- $N_v$  array

Optimal output variable sequence, returned as a (p+1)-by- $N_y$  array, where p is the prediction horizon and  $N_y$  is the number of outputs.

The first row of Info.Yopt contains the calculated outputs at time k based on the estimated states and measured disturbances; it is not the measured output at time k. Yopt(i,:) contains the predicted output values at time k+i-1, for  $i=1,\ldots,p+1$ .

Yopt(i,:) contains the calculated output values at time k+i-1, for  $i=2,\ldots,p+1$ , where k is the current time. Yopt(1,:) is computed based on the estimated states and measured disturbances.

### Xopt — Optimal prediction model state sequence

(p+1)-by- $N_x$  array

Optimal prediction model state sequence, returned as a (p+1)-by- $N_x$  array, where p is the prediction horizon and  $N_x$  is the number of states in the plant and unmeasured disturbance models (states from noise models are not included).

Xopt(i,:) contains the calculated state values at time k+i-1, for  $i=2,\ldots,p+1$ , where k is the current time. Xopt(1,:) is the same as the current states state values.

#### **Topt — Time intervals**

column vector of length p+1

Time intervals, returned as a column vector of length p+1. Topt(1) = 0, representing the current time. Subsequent time steps Topt(i) are given by Ts\*(i-1), where Ts = MPCobj.Ts is the controller sample time.

Use Topt when plotting Uopt, Xopt, or Yopt sequences.

#### Slack — Slack variable

nonnegative scalar

Slack variable,  $\varepsilon$ , used in constraint softening, returned as  $\theta$  or a positive scalar value.

- $\varepsilon = 0$  All constraints were satisfied for the entire prediction horizon.
- $\epsilon > 0$  At least one soft constraint is violated. When more than one constraint is violated,  $\epsilon$  represents the worst-case soft constraint violation (scaled by your ECR values for each constraint).

See "Optimization Problem" for more information.

#### Iterations — Number of solver iterations

positive integer | 0 | -1 | -2

Number of solver iterations, returned as one of the following:

- Positive integer Number of iterations needed to solve the optimization problem that determines the optimal sequences.
- 0 Optimization problem could not be solved in the specified maximum number of iterations.
- -1 Optimization problem was infeasible. An optimization problem is infeasible if no solution can satisfy all the hard constraints.
- -2 Numerical error occurred when solving the optimization problem.

### QPCode — Optimization solution status

```
'feasible' | 'infeasible' | 'unrealiable'
```

Optimization solution status, returned as one of the following:

- 'feasible' Optimal solution was obtained (Iterations > 0)
- 'infeasible' Solver detected a problem with no feasible solution (Iterations = -1) or a numerical error occurred (Iterations = -2)
- 'unreliable' Solver failed to converge (Iterations = 0). In this case, if MPCobj.Optimizer.UseSuboptimalSolution is false, u freezes at the most recent successful solution. Otherwise, it uses the suboptimal solution found during the last solver iteration.

#### **Cost** — Objective function cost

nonnegative scalar

Objective function cost, returned as a nonnegative scalar value. The cost quantifies the degree to which the controller has achieved its objectives. For more information, see "Optimization Problem".

The cost value is only meaningful when QPCode = 'feasible', or when QPCode = 'feasible' and MPCobj.Optimizer.UseSuboptimalSolution is true.

# **Examples**

### **Analyze Closed-Loop Response**

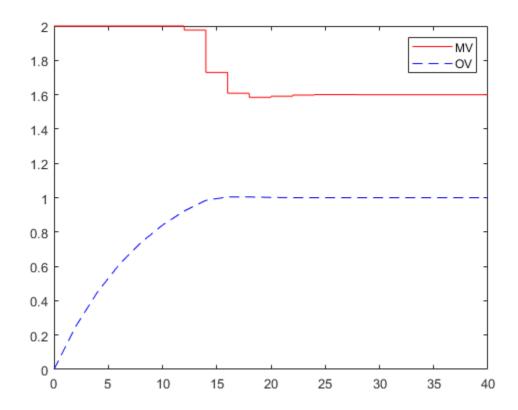

Perform closed-loop simulation of a plant with one MV and one measured OV.

Define a plant model and create a model predictive controller with MV constraints.

```
ts = 2;
Plant = ss(0.8,0.5,0.25,0,ts);
MPCobj = mpc(Plant);
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defail -->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming control -->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
MPCobj.MV(1).Min = -2;
MPCobj.MV(1).Max = 2;
```

Initialize an mpcstate object for simulation. Use the default state properties.

```
x = mpcstate(MPCobj);
-->Assuming output disturbance added to measured output channel #1 is integrated white
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ear
Set the reference signal. There is no measured disturbance.
r = 1;
Simulate the closed-loop response by calling mpcmove iteratively.
t = [0:ts:40];
N = length(t);
y = zeros(N,1);
u = zeros(N,1);
for i = 1:N
    % simulated plant and predictive model are identical
    y(i) = 0.25*x.Plant;
    u(i) = mpcmove(MPCobj,x,y(i),r);
end
y and u store the OV and MV values.
Analyze the result.
[ts,us] = stairs(t,u);
plot(ts,us,'r-',t,y,'b--')
legend('MV','OV')
```

Modify the MV upper bound as the simulation proceeds using an mpcmoveopt object.

```
MPCopt = mpcmoveopt;
MPCopt.MVMin = -2;
MPCopt.MVMax = 2;
```

Simulate the closed-loop response and introduce the real-time upper limit change at eight seconds (the fifth iteration step).

```
x = mpcstate(MPCobj);
y = zeros(N,1);
u = zeros(N,1);
for i = 1:N
% simulated plant and predictive model are identical
```

```
y(i) = 0.25*x.Plant;
       if i == 5
           MPCopt.MVMax = 1;
       end
       u(i) = mpcmove(MPCobj,x,y(i),r,[],MPCopt);
  end
  Analyze the result.
  [ts,us] = stairs(t,u);
  plot(ts,us,'r-',t,y,'b--')
legend('MV','OV')
 2
                                                                    ΜV
1.8
                                                                  - ov

### **Evaluate Scenario at Specific Time Instant**

Define a plant model.

```
ts = 2;
Plant = ss(0.8, 0.5, 0.25, 0, ts);
```

Create a model predictive controller with constraints on both the manipulated variable and the rate of change of the manipulated variable. The prediction horizon is 10 intervals, and the control horizon is blocked.

```
and the control horizon is blocked.

MPCobj = mpc(Plant,ts,10,[2 3 5]);

-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defarables. "The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming default 1.

MPCobj.MV(1).Min = -2;
MPCobj.MV(1).Max = 2;
MPCobj.MV(1).RateMin = -1;
MPCobj.MV(1).RateMax = 1;

Initialize an mpcstate object for simulation from a particular state.

x = mpcstate(MPCobj);

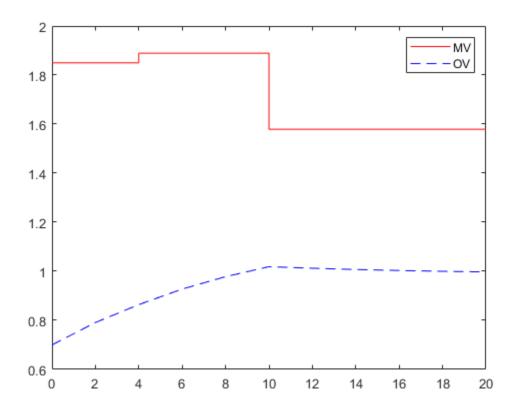

-->Assuming output disturbance added to measured output channel #1 is integrated white -->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on early the compute the optimal control at current time.

Compute the optimal control at current time.
```

```
y = 0.25*x.Plant;
r = 1;
[u,Info] = mpcmove(MPCobj,x,y,r);
```

Analyze the predicted optimal sequences.

```
[ts,us] = stairs(Info.Topt,Info.Uopt);
plot(ts,us,'r-',Info.Topt,Info.Yopt,'b--')
legend('MV','0V')
```

plot ignores Info.Uopt(end) as it is NaN.

Examine the optimal cost.

Info.Cost

ans = 0.0793

# Tips

• mpcmove updates x.

- If ym, r or v is specified as [], mpcmove uses the appropriate MPCobj.Model.Nominal value instead.
- To view the predicted optimal behavior for the entire prediction horizon, plot the appropriate sequences provided in Info.
- To determine the optimization status, check Info.Iterations and Info.QPCode.

# **Alternatives**

- Use sim for plant mismatch and noise simulation when not using run-time constraints or weight changes.
- Use the MPC Designer app to interactively design and simulate model predictive controllers.
- Use the MPC Controller block in Simulink and for code generation.
- Use mpcmoveCodeGeneration for code generation.

#### Introduced before R2006a

# mpcmoveAdaptive

Compute optimal control with prediction model updating

# **Syntax**

```
mv = mpcmoveAdaptive(MPCobj,x,Plant,Nominal,ym,r,v)
[mv,info] = mpcmoveAdaptive(MPCobj,x,Plant,Nominal,ym,r,v)
[___] = mpcmoveAdaptive(___,options)
```

# **Description**

mv = mpcmoveAdaptive(MPCobj,x,Plant,Nominal,ym,r,v) computes the optimal manipulated variable moves at the current time. This result depends on the properties contained in the MPC controller, the controller states, an updated prediction model, and the nominal values. The result also depends on the measured output variables, the output references (setpoints), and the measured disturbance inputs. mpcmoveAdaptive updates the controller state, x, when using default state estimation. Call mpcmoveAdaptive repeatedly to simulate closed-loop model predictive control.

[mv,info] = mpcmoveAdaptive(MPCobj,x,Plant,Nominal,ym,r,v) returns additional details about the solution in a structure. To view the predicted optimal trajectory for the entire prediction horizon, plot the sequences provided in info. To determine whether the optimal control calculation completed normally, check info.Iterations and info.OPCode.

[\_\_\_] = mpcmoveAdaptive(\_\_\_,options) alters selected controller settings using options you specify with mpcmoveopt. These changes apply for the current time instant only, enabling a command-line simulation using mpcmoveAdaptive to mimic the Adaptive MPC Controller block in Simulink in a computationally efficient manner.

# **Input Arguments**

MPCobj — MPC controller MPC controller object

MPC controller, specified as an implicit MPC controller object. To create the MPC controller, use the mpc command.

#### x — Current MPC controller state

mpcstate object

Current MPC controller state, specified as an mpcstate object.

Before you begin a simulation with mpcmoveAdaptive, initialize the controller state using x = mpcstate(MPCobj). Then, modify the default properties of x as appropriate.

If you are using default state estimation, mpcmoveAdaptive expects x to represent x[n] n-1]. The mpcmoveAdaptive command updates the state values in the previous control interval with that information. Therefore, you should not programmatically update x at all. The default state estimator employs a linear time-varying Kalman filter.

If you are using custom state estimation, mpcmoveAdaptive expects x to represent x[n] n]. Therefore, prior to each mpcmoveAdaptive command, you must set x.Plant, x.Disturbance, and x.Noise to the best estimates of these states (using the latest measurements) at the current control interval.

For more information on state estimation for adaptive MPC and time-varying MPC, see "State Estimation".

## Plant — Updated prediction model

discrete-time state-space model | model array

Updated prediction model, specified as one of the following:

- A delay-free, discrete-time state-space (ss) model. This plant is the update to MPCobj.Model.Plant and it must:
  - Have the same sample time as the controller; that is, Plant.Ts must match MPCobj.Ts
  - Have the same input and output signal configurations, such as type, order, and dimensions
  - Define the same states as the controller prediction model, MPCobj.Model.Plant
- An array of up to p+1 delay-free, discrete-time state-space models, where p is the prediction horizon of MPCobj. Use this option to vary the controller prediction model over the prediction horizon.

If Plant contains fewer than p+1 models, the last model repeats for the rest of the prediction horizon.

**Tip** If you use a plant other than a delay-free, discrete-time state-space model to define the prediction model in MPCobj, you can convert it to such a model to determine the prediction model structure.

If the original plant is	Then
Not a state- space model	Convert it to a state-space model using ss.
A continuo us-time model	Convert it to a discrete-time model with the same sample time as the controller, MPCobj.Ts, using c2d with default forward Euler discretization.
A model with delays	Convert the delays to states using absorbDelay.

# Nominal — Updated nominal conditions

structure | structure array | []

Updated nominal conditions, specified as one of the following:

• A structure of with the following fields:

Field	Description	Default
Х	Plant state at operating point	[]
U	Plant input at operating point, including manipulated variables and measured and unmeasured disturbances	[]
Υ	Plant output at operating point	[]

Field	Description	Default
	For continuous-time models, DX is the state derivative at operating point: $DX = f(X,U)$ . For discrete-time models, $DX = x(k+1)-x(k)=f(X,U)-X$ .	[]

 An array of up to p+1 nominal condition structures, where p is the prediction horizon of MPCobj. Use this option to vary controller nominal conditions over the prediction horizon.

If Nominal contains fewer than p+1 structures, the last structure repeats for the rest of the prediction horizon.

If Nominal is empty, [], or if a field is missing or empty, mpcmoveAdaptive uses the corresponding MPCobj.Model.Nominal value.

#### ym — Current measured outputs

row vector of length  $N_{vm}$ 

Current measured outputs, specified as a row vector of length  $N_{ym}$  vector, where  $N_{ym}$  is the number of measured outputs.

If you are using custom state estimation, ym is ignored. If you set ym = [], then mpcmoveAdaptive uses the appropriate nominal value.

# r — Plant output reference values

p-by- $N_v$  array | []

Plant output reference values, specified as a p-by- $N_y$  array, where p is the prediction horizon of MPCobj and  $N_y$  is the number of outputs. Row r(i,:) defines the reference values at step i of the prediction horizon.

r must contain at least one row. If r contains fewer than p rows, mpcmoveAdaptive duplicates the last row to fill the p-by- $N_y$  array. If you supply exactly one row, therefore, a constant reference applies for the entire prediction horizon.

If you set r = [], then mpcmoveAdaptive uses the appropriate nominal value.

To implement reference previewing, which can improve tracking when a reference varies in a predictable manner, r must contain the anticipated variations, ideally for p steps.

## v — Current and anticipated measured disturbances

p-by- $N_{md}$  array | []

Current and anticipated measured disturbances, specified as a p-by- $N_{md}$  array, where p is the prediction horizon of MPCobj and  $N_{md}$  is the number of measured disturbances. Row v(i,:) defines the expected measured disturbance values at step i of the prediction horizon.

Modeling of measured disturbances provides feedforward control action. If your plant model does not include measured disturbances, use v = [].

v must contain at least one row. If v contains fewer than p rows, mpcmoveAdaptive duplicates the last row to fill the p-by- $N_{md}$  array. If you supply exactly one row, therefore, a constant measured disturbance applies for the entire prediction horizon.

If you set v = [], then mpcmoveAdaptive uses the appropriate nominal value.

To implement disturbance previewing, which can improve tracking when a disturbance varies in a predictable manner, v must contain the anticipated variations, ideally for p steps.

# options — Override values for selected controller properties mpcmoveopt object

Override values for selected properties of MPCobj, specified as an options object you create with mpcmoveopt. These options apply to the current mpcmoveAdaptive time instant only. Using options yields the same result as redefining or modifying MPCobj before each call to mpcmoveAdaptive, but involves considerably less overhead. Using options is equivalent to using an Adaptive MPC Controller Simulink block in combination with optional input signals that modify controller settings, such as MV and OV constraints.

# **Output Arguments**

## mv — Optimal manipulated variable moves

column vector

Optimal manipulated variable moves, returned as a column vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables.

If the controller detects an infeasible optimization problem or encounters numerical difficulties in solving an ill-conditioned optimization problem, mv remains at its most recent successful solution, x.LastMove.

Otherwise, if the optimization problem is feasible and the solver reaches the specified maximum number of iterations without finding an optimal solution, mv:

- Remains at its most recent successful solution if the Optimizer.UseSuboptimalSolution property of the controller is false.
- Is the suboptimal solution reached after the final iteration if the Optimizer.UseSuboptimalSolution property of the controller is true. For more information, see "Suboptimal QP Solution".

#### info — Solution details

structure

Solution details, returned as a structure with the following fields.

## **Uopt** — **Optimal manipulated variable sequence**

$$(p+1)$$
-by- $N_{mv}$  array

Predicted optimal manipulated variable adjustments (moves), returned as a (p+1)-by- $N_{mv}$  array, where p is the prediction horizon and  $N_{mv}$  is the number of manipulated variables.

Uopt(i,:) contains the calculated optimal values at time k+i-1, for  $i=1,\ldots,p$ , where k is the current time. The first row of Info.Uopt contains the same manipulated variable values as output argument mv. Since the controller does not calculate optimal control moves at time k+p, Uopt(p+1,:) is equal to Uopt(p,:).

## Yopt — Optimal output variable sequence

$$(p+1)$$
-by- $N_y$  array

Optimal output variable sequence, returned as a (p+1)-by- $N_y$  array, where p is the prediction horizon and  $N_y$  is the number of outputs.

The first row of Info.Yopt contains the calculated outputs at time k based on the estimated states and measured disturbances; it is not the measured output at time k. Yopt(i,:) contains the predicted output values at time k+i-1, for  $i=1,\ldots,p+1$ .

Yopt(i,:) contains the calculated output values at time k+i-1, for  $i=2,\ldots,p+1$ , where k is the current time. Yopt(1,:) is computed based on the estimated states and measured disturbances.

# **Xopt — Optimal prediction model state sequence**

(p+1)-by- $N_x$  array

Optimal prediction model state sequence, returned as a (p+1)-by- $N_x$  array, where p is the prediction horizon and  $N_x$  is the number of states in the plant and unmeasured disturbance models (states from noise models are not included).

Xopt(i,:) contains the calculated state values at time k+i-1, for  $i=2,\ldots,p+1$ , where k is the current time. Xopt(1,:) is the same as the current states state values.

#### **Topt — Time intervals**

column vector of length p+1

Time intervals, returned as a column vector of length p+1. Topt(1) = 0, representing the current time. Subsequent time steps Topt(i) are given by Ts\*(i-1), where Ts = MPCobj.Ts is the controller sample time.

Use Topt when plotting Uopt, Xopt, or Yopt sequences.

#### Slack — Slack variable

nonnegative scalar

Slack variable,  $\varepsilon$ , used in constraint softening, returned as 0 or a positive scalar value.

- $\varepsilon = 0$  All constraints were satisfied for the entire prediction horizon.
- $\epsilon > 0$  At least one soft constraint is violated. When more than one constraint is violated,  $\epsilon$  represents the worst-case soft constraint violation (scaled by your ECR values for each constraint).

See "Optimization Problem" for more information.

#### Iterations — Number of solver iterations

positive integer | 0 | -1 | -2

Number of solver iterations, returned as one of the following:

- Positive integer Number of iterations needed to solve the optimization problem that determines the optimal sequences.
- 0 Optimization problem could not be solved in the specified maximum number of iterations.
- -1 Optimization problem was infeasible. An optimization problem is infeasible if no solution can satisfy all the hard constraints.
- -2 Numerical error occurred when solving the optimization problem.

#### **QPCode** — **Optimization solution status**

'feasible'|'infeasible'|'unrealiable'

Optimization solution status, returned as one of the following:

- 'feasible' Optimal solution was obtained (Iterations > 0)
- 'infeasible' Solver detected a problem with no feasible solution (Iterations = -1) or a numerical error occurred (Iterations = -2)
- 'unreliable' Solver failed to converge (Iterations = 0). In this case, if MPCobj.Optimizer.UseSuboptimalSolution is false, u freezes at the most recent successful solution. Otherwise, it uses the suboptimal solution found during the last solver iteration.

#### **Cost** — Objective function cost

nonnegative scalar

Objective function cost, returned as a nonnegative scalar value. The cost quantifies the degree to which the controller has achieved its objectives. For more information, see "Optimization Problem".

The cost value is only meaningful when QPCode = 'feasible', or when QPCode = 'feasible' and MPCobj.Optimizer.UseSuboptimalSolution is true.

# **Tips**

- If the prediction model is time-invariant, use mpcmove.
- Use the Adaptive MPC Controller Simulink block for simulations and code generation.

# Introduced in R2014b

# mpcmoveCodeGeneration

Compute optimal control moves with code generation support

# **Syntax**

```
[mv,newStateData] = mpcmoveCodeGeneration(configData,stateData,
onlineData)
[____,info] = mpcmoveCodeGeneration(____)
```

# **Description**

[mv,newStateData] = mpcmoveCodeGeneration(configData,stateData, onlineData) computes optimal MPC control moves and supports code generation for deployment to real-time targets. The input data structures, generated using getCodeGenerationData, define the MPC controller to simulate.

mpcmoveCodeGeneration does not check input arguments for correct dimensions and data types.

[\_\_\_\_,info] = mpcmoveCodeGeneration(\_\_\_\_) returns additional information about the optimization result, including the number of iterations and the objective function cost.

# **Examples**

# **Compute Optimal Control Moves Using Code Generation Data Structures**

Create a proper plant model.

```
plant = rss(3,1,1);
plant.D = 0;
```

Specify the controller sample time.

```
Ts = 0.1:
```

#### Create an MPC controller.

```
mpcObj = mpc(plant,Ts);
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defau
-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
Create code generation data structures.
```

```
[configData,stateData,onlineData] = getCodeGenerationData(mpcObj);
```

```
--->Converting model to discrete time.
-->Assuming output disturbance added to measured output channel #1 is integrated white
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ear
--->Converting model to discrete time.
-->Assuming output disturbance added to measured output channel #1 is integrated white
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each
```

Initialize the plant states to zero to match the default states used by the MPC controller.

Run a closed-loop simulation. At each control interval, update the online data structure and call mpcmoveCodeGeneration to compute the optimal control moves.

```
x = zeros(size(plant.B,1),1); % Initialize plant states to zero (|mpcObj| default).
Tsim = 20:
for i = 1:round(Tsim/Ts)+1
    % Update plant output.
    y = plant.C*x;
    % Update measured output in online data.
    onlineData.signals.ym = y;
    % Update reference signal in online data.
    onlineData.signals.ref = 1;
    % Compute control actions.
    [u,statedata] = mpcmoveCodeGeneration(configData,stateData,onlineData);
    % Update plant state.
    x = plant.A*x + plant.B*u;
end
Generate MEX function with MATLAB® Coder™, specifying configData as a constant.
```

```
func = 'mpcmoveCodeGeneration';
funcOutput = 'mpcmoveMEX';
```

```
Cfg = coder.config('mex');
Cfg.DynamicMemoryAllocation = 'off';
codegen('-config',Cfg,func,'-o',funcOutput,'-args',...
{coder.Constant(configData),stateData,onlineData});
```

# **Input Arguments**

### configData — MPC configuration parameters

structure

MPC configuration parameters that are constant at run time, specified as a structure generated using getCodeGenerationData.

**Note** When using codegen, configData must be defined as coder.Constant.

#### stateData — Controller state

structure

Controller state at run time, specified as a structure. Generate the initial state structure using getCodeGenerationData. For subsequent control intervals, use the updated controller state from the previous interval. In general, use the newStateData structure directly.

If custom state estimation is enabled, you must manually update the stateData structure during each control interval. For more information, see "Using Custom State Estimation".

stateData has the following fields:

#### Plant — Plant model state estimates

MPCobj nominal plant states (default) | column vector of length  $n_{xp}$ 

Plant model state estimates, specified as a column vector of length  $n_{xp}$ , where  $n_{xp}$  is the number of plant model states.

**Note** If custom state estimation is enabled, update Plant at each control interval. Otherwise, do not change this field. Instead use the values returned by either getCodeGenerationData or mpcmoveCodeGeneration.

#### Disturbance — Unmeasured disturbance model state estimates

[] (default) | column vector of length  $n_{xd}$ 

Unmeasured disturbance model state estimates, specified as a column vector of length  $n_{xd}$ , where  $n_{xd}$  is the number of unmeasured disturbance model states. Disturbance contains the input disturbance model states followed by the output disturbance model states.

To view the input and output disturbance models, use getindist and getoutdist respectively.

**Note** If custom state estimation is enabled, update Disturbance at each control interval. Otherwise, do not change this field. Instead use the values returned by either getCodeGenerationData or mpcmoveCodeGeneration.

### Noise — Output measurement noise model state estimates

[] (default) | column vector of length  $n_{xn}$ 

Output measurement noise model state estimates, specified as a column vector of length  $n_{xn}$ , where  $n_{xn}$  is the number of noise model states.

**Note** If custom state estimation is enabled, update Noise at each control interval. Otherwise, do not change this field. Instead use the values returned by either getCodeGenerationData or mpcmoveCodeGeneration.

# LastMove — Manipulated variable control moves from previous control interval MPCobj nominal MV values (default) | column vector of length $n_{mv}$

Manipulated variable control moves from previous control interval, specified as a column vector of length  $n_{mv}$ , where  $n_{mv}$  is the number of manipulated variables.

**Note** Do not change the value of LastMove. Always use the values returned by either getCodeGenerationData or mpcmoveCodeGeneration.

# Covariance — Covariance matrix for controller state estimates

symmetrical *n*-by-*n* array

Covariance matrix for controller state estimates, specified as a symmetrical n-by-n array, where n is number of extended controller states; that is, the sum of  $n_{xp}$ ,  $n_{xd}$ , and  $n_{xn}$ .

If the controller uses custom state estimation, Covariance is empty.

**Note** Do not change the value of Covariance. Always use the values returned by either getCodeGenerationData or mpcmoveCodeGeneration.

#### iA — Active inequality constraints

false (default) | logical vector of length m

Active inequality constraints, where the equal portion of the inequality is true, specified as a logical vector of length m. If iA(i) is true, then the ith inequality is active for the latest QP solver solution.

**Note** Do not change the value of iA. Always use the values returned by either getCodeGenerationData or mpcmoveCodeGeneration.

#### onlineData — Online controller data

structure

Online controller data that you must update at run time, specified as a structure with the following fields:

## signals — Updated input and output signals

structure

Updated input and output signals, specified as a structure with the following fields:

## ym — Measured outputs

vector of length  $N_{ym}$ 

Measured outputs, specified as a vector of length  $N_{\it ym}$ , where  $N_{\it ym}$  is the number of measured outputs.

By default, getCodeGenerationData sets ym to the nominal measured output values from the controller.

#### ref — Output references

row vector of length  $N_v \mid p$ -by- $n_v$  array

Output references, specified as one of the following:

- Row vector of length  $N_{\nu}$ , where  $N_{\nu}$  is the number of outputs.
- If you are using reference signal previewing with implicit or adaptive MPC, specify a p-by- $N_{\nu}$  array, where p is the prediction horizon.

By default, getCodeGenerationData sets ref to the nominal output values from the controller.

#### md — Measured disturbances

row vector of length  $N_{md} \mid p$ -by- $N_{md}$  array

Measured disturbances, specified as:

- A row vector of length  $N_{md}$ , where  $N_{md}$  is the number of measured disturbances.
- If you are using signal previewing with implicit or adaptive MPC, specify a p-by- $N_{md}$  array.

By default, if your controller has measured disturbances,getCodeGenerationData sets md to the nominal measured disturbance values from the controller. Otherwise, this field is empty and ignored by mpcmoveCodeGeneration.

# mvTarget — Targets for manipulated variables

[] (default) | vector of length  $N_{mv}$ 

Targets for manipulated variables, which replace the targets defined in configData.uTarget, specified as one of the following:

- Vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables
- [] to use the default targets defined in configData.uTarget

This field is ignored when using an explicit MPC controller.

# externalMV — Manipulated variables externally applied to the plant

[] (default) | vector of length  $N_{mv}$ 

Manipulated variables externally applied to the plant, specified as:

- A vector of length  $N_{mv}$ .
- [] to apply the optimal control moves to the plant.

### weights — Updated QP optimization weights

structure

Updated QP optimization weights, specified as a structure. If you do not expect tuning weights to change at run time, ignore weights. This field is ignored when using an explicit MPC controller.

This structure contains the following fields:

#### y — Output variable tuning weights

```
[] (default) | row vector | array
```

Output variable tuning weights that replace the original controller output weights at run time at run time, specified as a row vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_y$ , where  $N_y$  is the number of output variables.

To vary the tuning weights over the prediction horizon from time k+1 to time k+p, specify an array with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the output variable tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

If y is empty, [], the default weights defined in the original MPC controller are used.

# u — Manipulated variable tuning weights

```
[] (default) | row vector | array
```

Manipulated variable tuning weights that replace the original controller manipulated variable weights at run time, specified as a row vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables.

To vary the tuning weights over the prediction horizon from time k to time k+p-1, specify an array with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the manipulated variable tuning weights for one

prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

If u is empty, [], the default weights defined in the original MPC controller are used.

## du — Manipulated variable rate tuning weights

```
[] (default) | row vector | array
```

Manipulated variable rate tuning weights that replace the original controller manipulated variable rate weights at run time, specified as a row vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables.

To vary the tuning weights over the prediction horizon from time k to time k+p-1, specify an array with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the manipulated variable rate tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

If du is empty, [], the default weights defined in the original MPC controller are used.

## ecr — Weight on slack variable used for constraint softening

[] (default) | nonnegative scalar

Weight on slack variable used for constraint softening, specified as a nonnegative scalar.

If ecr is empty, [], the default weight defined in the original MPC controller are used.

## limits — Updated input and output constraints

structure

Updated input and output constraints, specified as a structure. If you do not expect constraints to change at run time, ignore limits. This field is ignored when using an explicit MPC controller.

This structure contains the following fields:

# ymin — Output variable lower bounds

[] (default) | column vector of length  $N_{v}$ 

Output variable lower bounds, specified as a column vector of length  $N_y$ . ymin(i) replaces the OutputVariables(i). Min constraint from the original controller. If the

OutputVariables(i). Min property of the controller is specified as a vector, ymin(i) replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

If ymin is empty, [], the default bounds defined in the original MPC controller are used.

### ymax — Output variable upper bounds

[] (default) | column vector of length  $N_v$ 

Output variable upper bounds, specified as a column vector of length  $N_y$ . ymax(i) replaces the OutputVariables(i).Max constraint from the original controller. If the OutputVariables(i).Max property of the controller is specified as a vector, ymax(i) replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

If ymax is empty, [], the default bounds defined in the original MPC controller are used.

## umin — Manipulated variable lower bounds

[] (default) | column vector of length  $N_{mv}$ 

Manipulated variable lower bounds, specified as a column vector of length  $N_{m\nu}$ . umin(i) replaces the ManipulatedVariables(i). Min constraint from the original controller. If the ManipulatedVariables(i). Min property of the controller is specified as a vector, umin(i) replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

If umin is empty, [], the default bounds defined in the original MPC controller are used.

# umax — Manipulated variable upper bounds

[] (default) | column vector of length  $N_{mv}$ 

Manipulated variable upper bounds, specified as a column vector of length  $N_{mv}$ . umax(i) replaces the ManipulatedVariables(i). Max constraint from the original controller. If the ManipulatedVariables(i). Max property of the controller is specified as a vector, umax(i) replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

If umax is empty, [], the default bounds defined in the original MPC controller are used.

customconstraints — Updated custom mixed input/output constraints
structure

Updated custom mixed input/output constraints, specified as a structure. This field is ignored when using an explicit MPC controller.

This structure has the following fields:

### **E** — Manipulated variable constraint constant

```
[] (default) | N_c-by-N_{mv} array
```

Manipulated variable constraint constant, specified as an  $N_c$ -by- $N_{mv}$  array, where  $N_c$  is the number of constraints, and  $N_{mv}$  is the number of manipulated variables.

If E is empty, [], the corresponding constraint defined in the original MPC controller are used.

### F — Controlled output constraint constant

```
[] (default) | N_c-by-N_v array
```

Controlled output constraint constant, specified as an  $N_c$ -by- $N_y$  array, where  $N_y$  is the number of controlled outputs (measured and unmeasured).

### G — Mixed input/output constraint constant

[] (default) | column vector of length  $N_c$ 

Mixed input/output constraint constant, specified as a column vector of length  $N_c$ .

#### S — Measured disturbance constraint constant

```
[] (default) | N_c-by-N_{\nu} array
```

Measured disturbance constraint constant, specified as an  $N_c$ -by- $N_{md}$  array, where  $N_{md}$  is the number of measured disturbances.

# horizons — Updated controller horizons

structure

Updated controller horizons, specified as a structure. To vary horizons at run time, first create your data structures using getCodeGenerationData setting the UseVariableHorizon name-value pair to true. When you vary the horizons, you must specify both the prediction horizon and the control horizon. For more information, see "Adjust Horizons at Run Time".

This field is ignored when using an explicit MPC controller.

This structure has the following fields:

#### p — Prediction horizon

[] (default) | positive integer

Prediction horizon, which replaces the value of configData.p at run time, specified as a positive integer.

Specifying p changes the:

- Number of rows in the optimal sequences returned in info
- The maximum dimensions of the fields in model when configData.IsLTV is true

#### m — Control horizon

[] (default) | positive integer | vector of positive integers

Control horizon, which replaces the value of configData.m at run time, specified as one of the following:

- Positive integer, m, between 1 and p, inclusive, where p is the prediction horizon (horizons.p). In this case, the controller computes m free control moves occurring at times k through k+m-1, and holds the controller output constant for the remaining prediction horizon steps from k+m through k+p-1. Here, k is the current control interval. For optimal trajectory planning set m equal to p.
- Vector of positive integers,  $[m_1, m_2, ...]$ , where the sum of the integers equals the prediction horizon, p. In this case, the controller computes M blocks of free moves, where M is the length of the control horizon vector. The first free move applies to times k through  $k+m_1-1$ , the second free move applies from time  $k+m_1$  through  $k+m_1+m_2-1$ , and so on. Using block moves can improve the robustness of your controller compared to the default case.

# model — Updated plant and nominal values

structure

Updated plant and nominal values for adaptive MPC and time-varying MPC, specified as a structure. model is only available if you specify isAdaptive or isLTV as true when creating code generation data structures.

This structure contains the following fields:

# A — State matrix of discrete-time state-space plant model

 $N_x$ -by- $N_x$  array |  $N_x$ -by- $N_x$ -by-(p+1) array

State matrix of discrete-time state-space plant model, specified as an:

- $N_x$ -by- $N_x$  array when using adaptive MPC,
- $N_x$ -by- $N_x$ -by-(p+1) array when using time-varying MPC,

where  $N_x$  is the number of plant states.

# **B** — Input-to-state matrix of discrete-time state-space plant model $N_x$ -by- $N_u$ array | $N_x$ -by- $N_u$ -by-(p+1) array

Input-to-state matrix of discrete-time state-space plant model, specified as an:

- $N_x$ -by- $N_u$  array when using adaptive MPC,
- $N_x$ -by- $N_u$ -by-(p+1) array when using time-varying MPC,

where  $N_{\nu}$  is the number of plant inputs.

# C — State-to-output matrix of discrete-time state-space plant model $N_v$ -by- $N_x$ array | $N_v$ -by- $N_x$ -by-(p+1) array

State-to-output matrix of discrete-time state-space plant model, specified as an:

- $N_{v}$ -by- $N_{x}$  array when using adaptive MPC.
- $N_v$ -by- $N_x$ -by-(p+1) array when using time-varying MPC.

# **D** — Feedthrough matrix of discrete-time state-space plant model $N_v$ -by- $N_u$ array | $N_v$ -by- $N_u$ -by-(p+1) array

Feedthrough matrix of discrete-time state-space plant model, specified as an:

- $N_v$ -by- $N_u$  array when using adaptive MPC.
- $N_v$ -by- $N_u$ -by-(p+1) array when using time-varying MPC.

Since MPC controllers do not support plants with direct feedthrough, specify  $\boldsymbol{D}$  as an array of zeros.

# X — Nominal plant states

column vector of length  $N_x \mid N_x$ -by-1-by-(p+1) array

Nominal plant states, specified as:

- A column vector of length  $N_x$  when using adaptive MPC.
- An  $N_x$ -by-1-by-(p+1) array when using time-varying MPC.

#### **U** — Nominal plant inputs

column vector of length  $N_u \mid N_u$ -by-1-by-(p+1) array

Nominal plant inputs, specified as:

- A column vector of length  $N_u$  when using adaptive MPC.
- An  $N_u$ -by-1-by-(p+1) array when using time-varying MPC.

### Y — Nominal plant outputs

column vector of length  $N_v \mid N_v$ -by-1-by-(p+1) array

Nominal plant outputs, specified as:

- A column vector of length  $N_{\nu}$  when using adaptive MPC.
- An  $N_v$ -by-1-by-(p+1) array when using time-varying MPC.

### DX — Nominal plant state derivatives

column vector of length  $N_x \mid N_x$ -by-1-by-(p+1) array

Nominal plant state derivatives, specified as:

- A column vector of length  $N_x$  when using adaptive MPC.
- An  $N_x$ -by-1-by-(p+1) array when using time-varying MPC.

# **Output Arguments**

# mv — Optimal manipulated variable moves

column vector

Optimal manipulated variable moves, returned as a column vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

If the controller detects an infeasible optimization problem or encounters numerical difficulties in solving an ill-conditioned optimization problem, mv remains at its most recent successful solution, x.LastMove.

Otherwise, if the optimization problem is feasible and the solver reaches the specified maximum number of iterations without finding an optimal solution, mv:

 Remains at its most recent successful solution if the Optimizer.UseSuboptimalSolution property of the controller is false. • Is the suboptimal solution reached after the final iteration if the Optimizer.UseSuboptimalSolution property of the controller is true. For more information, see "Suboptimal QP Solution".

#### newStateData — Updated controller state

structure

Updated controller state, returned as a structure. For subsequent control intervals, pass newStateData to mpcmoveCodeGeneration as stateData.

If custom state estimation is enabled, use newStateData to manually update the state structure before the next control interval. For more information, see "Using Custom State Estimation".

## info — Controller optimization information

structure

Controller optimization information, returned as a structure.

If you are using implicit or adaptive MPC, info contains the following fields:

Field	Description
Iterat ions	Number of QP solver iterations
QPCode	QP solver status code
Cost	Objective function cost
Uopt	Optimal manipulated variable adjustments
Yopt	Optimal predicted output variable sequence
Xopt	Optimal predicted state variable sequence
Topt	Time horizon intervals
Slack	Slack variable used in constraint softening

If configData.OnlyComputeCost is true, the optimal sequence information, Uopt, Yopt, Xopt, Topt, and Slack, is not available:

For more information, see mpcmove and mpcmoveAdaptive.

If you are using explicit MPC, info contains the following fields:

Field	Description
Region	Region in which the optimal solution was found
ExitCo de	Solution status code

For more information, see mpcmoveExplicit.

# See Also

mpcmoveExplicit

# **Topics**

"Generate Code To Compute Optimal MPC Moves in MATLAB"

#### Introduced in R2016a

<sup>&</sup>quot;Generate Code and Deploy Controller to Real-Time Targets"

# mpcmoveExplicit

Compute optimal control using explicit MPC

# **Syntax**

```
mv = mpcmoveExplicit(EMPCobj,x,ym,r,v)
[mv,info] = mpcmoveExplicit(EMPCobj,x,ym,r,v)
[mv,info] = mpcmoveExplicit(EMPCobj,x,ym,r,v,MVused)
```

# **Description**

mv = mpcmoveExplicit(EMPCobj,x,ym,r,v) computes the optimal manipulated variable moves at the current time using an explicit model predictive control law. This result depends on the properties contained in the explicit MPC controller and the controller states. The result also depends on the measured output variables, the output references (setpoints), and the measured disturbance inputs. mpcmoveExplicit updates the controller state, x, when using default state estimation. Call mpcmoveExplicit repeatedly to simulate closed-loop model predictive control.

[mv,info] = mpcmoveExplicit(EMPCobj,x,ym,r,v) returns additional details about the computation in a structure. To determine whether the optimal control calculation completed normally, check the data in info.

[mv,info] = mpcmoveExplicit(EMPCobj,x,ym,r,v,MVused) specifies the manipulated variable values used in the previous mpcmoveExplicit command, allowing a command-line simulation to mimic the Explicit MPC Controller Simulink block with the optional external MV input signal.

# **Input Arguments**

# **EMPCobj** — **Explicit MPC controller**

explicit MPC controller object

Explicit MPC controller to simulate, specified as an Explicit MPC controller object. Use generateExplicitMPC to create an explicit MPC controller.

#### x — Current MPC controller state

mpcstate object

Current MPC controller state, specified as an mpcstate object.

Before you begin a simulation with mpcmoveExplicit, initialize the controller state using x = mpcstate(EMPCobj). Then, modify the default properties of x as appropriate.

If you are using default state estimation, mpcmoveExplicit expects x to represent x[n] n-1]. The mpcmoveExplicit command updates the state values in the previous control interval with that information. Therefore, you should not programmatically update x at all. The default state estimator employs a linear time-varying Kalman filter.

If you are using custom state estimation, mpcmoveExplicit expects x to represent x[n|n]. Therefore, prior to each mpcmoveExplicit command, you must set x.Plant, x.Disturbance, and x.Noise to the best estimates of these states (using the latest measurements) at the current control interval.

#### ym — Current measured outputs

vector

Current measured outputs, specified as a row vector of length  $N_{ym}$ , where  $N_{ym}$  is the number of measured outputs. If you are using custom state estimation, ym is ignored. If you set ym = [], then mpcmoveExplicit uses the appropriate nominal value.

#### r — Plant output reference values

vector

Plant output reference values, specified as a vector of length  $N_y$ . mpcmoveExplicit uses a constant reference for the entire prediction horizon. In contrast to mpcmove and mpcmoveAdaptive, mpcmoveExplicit does not support reference previewing.

If you set r = [], then mpcmoveExplicit uses the appropriate nominal value.

## v — Current and anticipated measured disturbances

vector

Current and anticipated measured disturbances, specified as a vector of length  $N_{md}$ , where  $N_{md}$  is the number of measured disturbances. In contrast to mpcmove and mpcmoveAdaptive, mpcmoveExplicit does not support disturbance previewing. If your plant model does not include measured disturbances, use v = [].

## MVused — Manipulated variable values from previous interval

vector

Manipulated variable values applied to the plant during the previous control interval, specified as a vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables. If this is the first mpcmoveExplicit command in a simulation sequence, omit this argument. Otherwise, if the MVs calculated by mpcmoveExplicit in the previous interval were overridden, set MVused to the correct values in order to improve the controller state estimation accuracy. If you omit MVused, mpcmoveExplicit assumes MVused = x.LastMove.

# **Output Arguments**

#### mv — Optimal manipulated variable moves

column vector

Optimal manipulated variable moves, returned as a column vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

If the controller detects an infeasible optimization problem or encounters numerical difficulties in solving an ill-conditioned optimization problem, mv remains at its most recent successful solution, x.LastMove.

Otherwise, if the optimization problem is feasible and the solver reaches the specified maximum number of iterations without finding an optimal solution, mv:

- Remains at its most recent successful solution if the Optimizer.UseSuboptimalSolution property of the controller is false.
- Is the suboptimal solution reached after the final iteration if the Optimizer.UseSuboptimalSolution property of the controller is true. For more information, see "Suboptimal QP Solution".

## info — Explicit MPC solution status

structure

Explicit MPC solution status, returned as a structure having the following fields.

### ExitCode — Solution status code

1 | 0 | -1

Solution status code, returned as one of the following values:

- 1 Successful solution.
- 0 Failure. One or more controller input parameters is out of range.
- -1 Undefined. Parameters are in range but an extrapolation must be used.

# **Region — Region to which current controller input parameters belong** positive integer $\mid 0$

Region to which current controller input parameters belong, returned as either a positive integer or 0. The integer value is the index of the polyhedron (region) to which the current controller input parameters belong. If the solution failed, Region = 0.

# **Tips**

• Use the Explicit MPC Controller Simulink block for simulation and code generation.

"Explicit MPC"

#### Introduced in R2014b

<sup>&</sup>quot;Design Workflow for Explicit MPC"

# mpcmoveMultiple

Compute gain-scheduling MPC control action at a single time instant

# **Syntax**

```
mv = mpcmoveMultiple(MPCArray, states, index, ym, r, v)
[mv, info] = mpcmoveMultiple(MPCArray, states, index, ym, r, v)
[___] = mpcmoveMultiple(____, options)
```

# **Description**

mv = mpcmoveMultiple(MPCArray, states, index, ym, r, v) computes the optimal manipulated variable moves at the current time using a model predictive controller selected by index from an array of MPC controllers. This results depends upon the properties contained in the MPC controller and the controller states. The result also depends on the measured plant outputs, the output references (setpoints), and the measured disturbance inputs. mpcmoveMultiple updates the controller state when default state estimation is used. Call mpcmoveMultiple repeatedly to simulate closed-loop model predictive control.

[mv,info] = mpcmoveMultiple(MPCArray, states, index, ym, r, v) returns additional details about the computation in a structure. To determine whether the optimal control calculation completed normally, check the data in info.

[\_\_\_\_] = mpcmoveMultiple(\_\_\_\_, options) alters selected controller settings using options you specify with mpcmoveopt. These changes apply for the current time instant only, allowing a command-line simulation using mpcmoveMultiple to mimic the Multiple MPC Controllers block in Simulink in a computationally efficient manner.

# **Input Arguments**

MPCArray — MPC controllers cell array of MPC controller objects

MPC controllers to simulate, specified as a cell array of traditional (implicit) MPC controller objects. Use the mpc command to create the MPC controllers.

All the controllers in MPCArray must use either default state estimation or custom state estimation. Mismatch is not permitted.

#### states — Current MPC controller states

cell array of mpcstate objects

Current controller states for each MPC controller in MPCArray, specified as a cell array of mpcstate objects.

Before you begin a simulation with mpcmoveMultiple, initialize each controller state using x = mpcstate(MPCobj). Then, modify the default properties of each state as appropriate.

If you are using default state estimation, mpcmoveMultiple expects x to represent x[n] n-1] (where x is one entry in states, the current state of one MPC controller in MPCArray). The mpcmoveMultiple command updates the state values in the previous control interval with that information. Therefore, you should not programmatically update x at all. The default state estimator employs a steady-state Kalman filter.

If you are using custom state estimation, mpcmoveMultiple expects x to represent x[n] n]. Therefore, prior to each mpcmoveMultiple command, you must set x.Plant, x.Disturbance, and x.Noise to the best estimates of these states (using the latest measurements) at the current control interval.

#### index — Index of selected controller

positive integer

Index of selected controller in the cell array MPCArray, specified as a positive integer.

### ym — Current measured outputs

row vector

Current measured outputs, specified as a row vector of length  $N_{ym}$ , where  $N_{ym}$  is the number of measured outputs. If you are using custom state estimation, ym is ignored. If you set ym = [], then mpcmoveMultiple uses the appropriate nominal value.

## r — Plant output reference values

array

Plant output reference values, specified as a p-by- $N_y$  array, where p is the prediction horizon of the selected controller and  $N_y$  is the number of outputs. Row r(i,:) defines the reference values at step i of the prediction horizon.

r must contain at least one row. If r contains fewer than p rows, mpcmoveMultiple duplicates the last row to fill the p-by- $N_y$  array. If you supply exactly one row, therefore, a constant reference applies for the entire prediction horizon.

If you set r = [], then mpcmoveMultiple uses the appropriate nominal value.

To implement reference previewing, which can improve tracking when a reference varies in a predictable manner, r must contain the anticipated variations, ideally for *p* steps.

# v — Current and anticipated measured disturbances array

Current and anticipated measured disturbances, specified as a p-by- $N_{md}$  array, where p is the prediction horizon of the selected controller and  $N_{md}$  is the number of measured disturbances. Row v(i,:) defines the expected measured disturbance values at step i of the prediction horizon.

Modeling of measured disturbances provides feedforward control action. If your plant model does not include measured disturbances, use v = [].

v must contain at least one row. If v contains fewer than p rows, mpcmoveMultiple duplicates the last row to fill the p-by- $N_{md}$  array. If you supply exactly one row, therefore, a constant measured disturbance applies for the entire prediction horizon.

If you set v = [], then mpcmoveMultiple uses the appropriate nominal value.

To implement disturbance previewing, which can improve tracking when a disturbance varies in a predictable manner, v must contain the anticipated variations, ideally for p steps.

# options — Override values for selected controller properties mpcmoveopt object

Override values for selected properties of the selected MPC controller, specified as an options object you create with mpcmoveopt. These options apply to the current mpcmoveMultiple time instant only. Using options yields the same result as redefining or modifying the selected controller before each call to mpcmoveMultiple, but involves considerably less overhead. Using options is equivalent to using a Multiple MPC

Controllers Simulink block in combination with optional input signals that modify controller settings, such as MV and OV constraints.

### **Output Arguments**

#### mv — Optimal manipulated variable moves

column vector

Optimal manipulated variable moves, returned as a column vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

If the controller detects an infeasible optimization problem or encounters numerical difficulties in solving an ill-conditioned optimization problem, mv remains at its most recent successful solution, x.LastMove.

Otherwise, if the optimization problem is feasible and the solver reaches the specified maximum number of iterations without finding an optimal solution, mv:

- Remains at its most recent successful solution if the Optimizer.UseSuboptimalSolution property of the controller is false.
- Is the suboptimal solution reached after the final iteration if the Optimizer.UseSuboptimalSolution property of the controller is true. For more information, see "Suboptimal QP Solution".

#### info — Solution details

structure

Solution details, returned as a structure with the following fields.

#### **Uopt** — **Optimal manipulated variable sequence**

(p+1)-by- $N_{mv}$  array

Predicted optimal manipulated variable adjustments (moves), returned as a (p+1)-by- $N_{mv}$  array, where p is the prediction horizon and  $N_{mv}$  is the number of manipulated variables.

Uopt(i,:) contains the calculated optimal values at time k+i-1, for  $i=1,\ldots,p$ , where k is the current time. The first row of Info.Uopt contains the same manipulated variable values as output argument mv. Since the controller does not calculate optimal control moves at time k+p, Uopt(p+1,:) is equal to Uopt(p,:).

#### Yopt — Optimal output variable sequence

(p+1)-by- $N_v$  array

Optimal output variable sequence, returned as a (p+1)-by- $N_y$  array, where p is the prediction horizon and  $N_y$  is the number of outputs.

The first row of Info.Yopt contains the calculated outputs at time k based on the estimated states and measured disturbances; it is not the measured output at time k. Yopt(i,:) contains the predicted output values at time k+i-1, for  $i=1,\ldots,p+1$ .

Yopt(i,:) contains the calculated output values at time k+i-1, for  $i=2,\ldots,p+1$ , where k is the current time. Yopt(1,:) is computed based on the estimated states and measured disturbances.

#### Xopt — Optimal prediction model state sequence

(p+1)-by- $N_x$  array

Optimal prediction model state sequence, returned as a (p+1)-by- $N_x$  array, where p is the prediction horizon and  $N_x$  is the number of states in the plant and unmeasured disturbance models (states from noise models are not included).

Xopt(i,:) contains the calculated state values at time k+i-1, for  $i=2,\ldots,p+1$ , where k is the current time. Xopt(1,:) is the same as the current states state values.

#### **Topt — Time intervals**

column vector of length p+1

Time intervals, returned as a column vector of length p+1. Topt(1) = 0, representing the current time. Subsequent time steps Topt(i) are given by Ts\*(i-1), where Ts = MPCobj.Ts is the controller sample time.

Use Topt when plotting Uopt, Xopt, or Yopt sequences.

#### Slack — Slack variable

nonnegative scalar

Slack variable,  $\epsilon$ , used in constraint softening, returned as  $\theta$  or a positive scalar value.

- $\epsilon = 0$  All constraints were satisfied for the entire prediction horizon.
- $\epsilon > 0$  At least one soft constraint is violated. When more than one constraint is violated,  $\epsilon$  represents the worst-case soft constraint violation (scaled by your ECR values for each constraint).

See "Optimization Problem" for more information.

#### Iterations — Number of solver iterations

positive integer | 0 | -1 | -2

Number of solver iterations, returned as one of the following:

- Positive integer Number of iterations needed to solve the optimization problem that determines the optimal sequences.
- 0 Optimization problem could not be solved in the specified maximum number of iterations.
- -1 Optimization problem was infeasible. An optimization problem is infeasible if no solution can satisfy all the hard constraints.
- -2 Numerical error occurred when solving the optimization problem.

#### QPCode — Optimization solution status

```
'feasible'|'infeasible'|'unrealiable'
```

Optimization solution status, returned as one of the following:

- 'feasible' Optimal solution was obtained (Iterations > 0)
- 'infeasible' Solver detected a problem with no feasible solution (Iterations = -1) or a numerical error occurred (Iterations = -2)
- 'unreliable' Solver failed to converge (Iterations = 0). In this case, if MPCobj.Optimizer.UseSuboptimalSolution is false, u freezes at the most recent successful solution. Otherwise, it uses the suboptimal solution found during the last solver iteration.

#### **Cost** — **Objective function cost**

nonnegative scalar

Objective function cost, returned as a nonnegative scalar value. The cost quantifies the degree to which the controller has achieved its objectives. For more information, see "Optimization Problem".

The cost value is only meaningful when QPCode = 'feasible', or when QPCode = 'feasible' and MPCobj.Optimizer.UseSuboptimalSolution is true.

# **Tips**

• Use the Multiple MPC Controllers Simulink block for simulations and code generation.

setEstimator | sim

Introduced in R2014b

# mpcmoveopt

Option set for mpcmove function

# **Description**

To specify options for the mpcmove, mpcmoveAdaptive, and mpcmoveMultiple functions, use an mpcmoveopt object.

Using this object, you can specify run-time values for a subset of controller properties, such as tuning weights and constraints. If you do not specify a value for one of the mpcmoveopt properties, the value of the corresponding controller option is used instead.

#### Creation

### **Syntax**

options = mpcmoveopt

### **Description**

options = mpcmoveopt creates a default set of options for the mpcmove function. To
modify the property values, use dot notation.

## **Properties**

#### OutputWeights — Output variable tuning weights

[] (default) | vector | array

Output variable tuning weights that replace the Weights.OutputVariables property of the controller at run time, specified as a vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_y$ , where  $N_y$  is the number of output variables.

To vary the tuning weights over the prediction horizon from time k+1 to time k+p, specify an array with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the output variable tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

#### MVWeights — Manipulated variable tuning weights

[] (default) | vector | array

Manipulated variable tuning weights that replace the Weights.ManipulatedVariables property of the controller at run time, specified as a vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables.

To vary the tuning weights over the prediction horizon from time k to time k+p-1, specify an array with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the manipulated variable tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

#### MVRateWeights — Manipulated variable rate tuning weights

[] (default) | vector | array

Manipulated variable rate tuning weights that replace the Weights.ManipulatedVariablesRate property of the controller at run time, specified as a vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables.

To vary the tuning weights over the prediction horizon from time k to time k+p-1, specify an array with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the manipulated variable rate tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

#### ECRWeight — Slack variable tuning weight

[] (default) | positive scalar

Slack variable tuning weight that replaces the Weights. ECR property of the controller at run time, specified as a positive scalar.

#### **OutputMin** — **Output variable lower bounds**

[] (default) | row vector

Output variable lower bounds, specified as a row vector of length  $N_y$ , where  $N_y$  is the number of output variables. OutputMin(i) replaces the OutputVariables(i). Min property of the controller at run time.

If the OutputVariables(i). Min property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), OutputMin(i) replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

#### **OutputMax** — **Output variable upper bounds**

[] (default) | row vector

Output variable upper bounds, specified as a row vector of length  $N_y$ , where  $N_y$  is the number of output variables. OutputMax(i) replaces the OutputVariables(i).Max property of the controller at run time.

If the OutputVariables(i). Max property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), OutputMax(i) replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

#### MVMin — Manipulated variable lower bounds

[] (default) | row vector

Manipulated variable lower bounds, specified as a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables. MVMin(i) replaces the ManipulatedVariables(i).Min property of the controller at run time.

If the ManipulatedVariables(i). Min property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), MVMin(i) replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

#### MVMax — Manipulated variable upper bounds

[] (default) | row vector

Manipulated variable upper bounds, specified as a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables. MVMax(i) replaces the ManipulatedVariables(i).Max property of the controller at run time.

If the ManipulatedVariables(i). Max property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), MVMax(i) replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

#### CustomConstraint — Custom mixed input/output constraints

[] (default) | structure

Custom mixed input/output constraints, specified as a structure with the following fields. These constraints replace the mixed input/output constraints previously set using set constraint.

#### **E** — Manipulated variable constraint constant

array of zeros (default) |  $N_c$ -by- $N_{mv}$  array

Manipulated variable constraint constant, specified as an  $N_c$ -by- $N_{mv}$  array, where  $N_c$  is the number of constraints, and  $N_{mv}$  is the number of manipulated variables.

#### F — Controlled output constraint constant

array of zeros (default) |  $N_c$ -by- $N_y$  array

Controlled output constraint constant, specified as an  $N_c$ -by- $N_y$  array, where  $N_y$  is the number of controlled outputs (measured and unmeasured).

#### **G** — Mixed input/output constraint constant

column vector of zeros (default) | column vector of length  $N_c$ 

Mixed input/output constraint constant, specified as a column vector of length  $N_c$ .

#### S — Measured disturbance constraint constant

array of zeros (default) |  $N_c$ -by- $N_{md}$  array

Measured disturbance constraint constant, specified as an  $N_c$ -by- $N_{md}$  array, where  $N_{md}$  is the number of measured disturbances.

# OnlyComputeCost — Flag indicating whether to calculate the optimal control sequence

0 (default) | 1

Flag indicating whether to calculate the optimal control sequence, specified as one of the following:

- 0 Controller returns the predicted optimal control moves in addition to the objective function cost value.
- 1 Controller returns the objective function cost only, which saves computational
  effort.

# MVused — Manipulated variable values used in the plant during the previous control interval

```
[] (default) | row vector
```

Manipulated variable values used in the plant during the previous control interval, specified as a row vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables. If you do not specify MVused, the mpvmove uses the LastMove property of its current controller state input argument, x.

#### **MVTarget** — **Manipulated variable targets**

```
[] (default) | row vector
```

Manipulated variable targets, specified as a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables. MVTarget(i) replaces the ManipulatedVariables(i). Target property of the controller at run time.

#### PredictionHorizon — Prediction horizon

```
[] (default) | positive integer
```

Prediction horizon, which replaces the PredictionHorizon property of the controller at run time, specified as a positive integer. If you specify PredictionHorizon, you must also specify ControlHorizon.

Specifying PredictionHorizon changes the:

- Number of rows in the optimal sequences returned by the mpcmove and mpcmoveAdaptive functions
- Maximum dimensions of the Plant and Nominal input arguments of mpcmoveAdaptive

This parameter is ignored by the mpcmoveMultiple function.

#### ControlHorizon — Control horizon

[] (default) | positive integer | vector of positive integers

Control horizon, which replaces the ControlHorizon property of the controller at run time, specified as one of the following:

- Positive integer, m, between 1 and p, inclusive, where p is equal to PredictionHorizon. In this case, the controller computes m free control moves occurring at times k through k+m-1, and holds the controller output constant for the remaining prediction horizon steps from k+m through k+p-1. Here, k is the current control interval. For optimal trajectory planning set m equal to p.
- Vector of positive integers,  $[m_1, m_2, ...]$ , where the sum of the integers equals the prediction horizon, p. In this case, the controller computes M blocks of free moves, where M is the length of the ControlHorizon vector. The first free move applies to times k through  $k+m_1-1$ , the second free move applies from time  $k+m_1$  through  $k+m_1+m_2-1$ , and so on. Using block moves can improve the robustness of your controller compared to the default case.

If you specify ControlHorizon, you must also specify PredictionHorizon.

This parameter is ignored by the mpcmoveMultiple function.

### **Object Functions**

mpcmove Compute optimal control action

mpcmoveAdaptive Compute optimal control with prediction model updating

mpcmoveMultiple Compute gain-scheduling MPC control action at a single time instant

## **Examples**

#### **Simulation with Varying Controller Property**

Vary a manipulated variable upper bound during a simulation.

Define the plant, which includes a 4-second input delay. Convert to a delay-free, discrete, state-space model using a 2-second control interval. Create the corresponding default controller, and specify MV bounds at +/-2.

```
Ts = 2;
Plant = absorbDelay(c2d(ss(tf(0.8,[5 1],'InputDelay',4)),Ts));
MPCobj = mpc(Plant,Ts);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defaction of "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming of the "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1

MPCobj.MV(1).Min = -2;
MPCobj.MV(1).Max = 2;
```

Create an empty mpcmoveopt object. During simulation, you can set properties of the object to specify controller parameters.

```
options = mpcmoveopt;
```

Pre-allocate storage and initialize the controller state.

```
v = [];
t = [0:Ts:20];
N = length(t);
y = zeros(N,1);
u = zeros(N,1);
x = mpcstate(MPCobj);
```

-->Assuming output disturbance added to measured output channel #1 is integrated white -->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each

Use mpcmove to simulate the following:

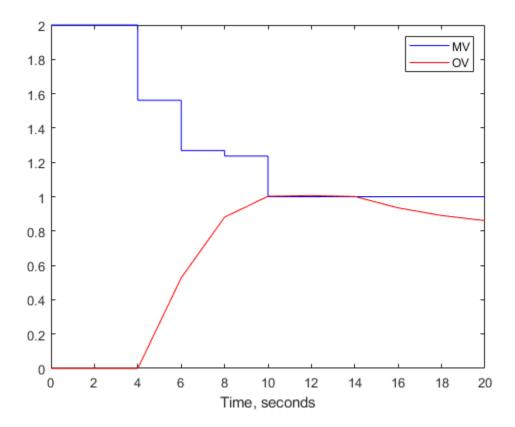

- Reference (setpoint) step change from initial condition r = 0 to r = 1 (servo response)
- MV upper bound step decrease from 2 to 1, occurring at t = 10

```
r = 1;
for i = 1:N
    y(i) = Plant.C*x.Plant;
    if t(i) >= 10
        options.MVMax = 1;
    end
    [u(i),Info] = mpcmove(MPCobj,x,y(i),r,v,options);
end
```

As the loop executes, the value of options.MVMax is reset to 1 for all iterations that occur after t=10. Prior to that iteration, options.MVMax is empty. Therefore, the controller's value for MVMax is used, MPCobj.MV(1).Max = 2.

Plot the results of the simulation.

```
[Ts,us] = stairs(t,u);
plot(Ts,us,'b-',t,y,'r-')
legend('MV','0V')
xlabel(sprintf('Time, %s',Plant.TimeUnit))
```

From the plot, you can observe that the original MV upper bound is active until t=4. After the input delay of 4 seconds, the output variable (OV) moves smoothly to its new target of r=1. reaching the target at t=10. The new MV bound imposed at t=10 becomes active immediately. This forces the OV below its target, after the input delay elapses.

Now assume that you want to impose an OV upper bound at a specified location relative to the OV target. Consider the following constraint design command:

```
MPCobj.OV(1).Max = [Inf,Inf,0.4,0.3,0.2];
```

This is a horizon-varying constraint. The known input delay makes it impossible for the controller to satisfy an OV constraint prior to the third prediction-horizon step. Therefore, a finite constraint during the first two steps would be poor practice. For illustrative purposes, the previous constraint also decreases from 0.4 at step 3 to 0.2 at step 5 and thereafter.

The following commands produce the same results shown in the previous plot. The OV constraint is never active because it is being varied in concert with the setpoint, r.

```
x = mpcstate(MPCobj);
-->Assuming output disturbance added to measured output channel #1 is integrated white
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ear

OPTobj = mpcmoveopt;
for i = 1:N
    y(i) = Plant.C*x.Plant;
    if t(i) >= 10
        OPTobj.MVMax = 1;
    end
    OPTobj.OutputMax = r + 0.4;
    [u(i),Info] = mpcmove(MPCobj,x,y(i),r,v,OPTobj);
end
```

The scalar value r+0.4 replaces the first finite value in the MPCobj.OV(1).Max vector, and the remaining finite values adjust to maintain the original profile, that is, the numerical difference between these values is unchanged. r=1 for the simulation, so the previous use of the mpcmoveopt object is equivalent to the command

```
MPCobj.OV(1).Max = [Inf, Inf, 1.4, 1.3, 1.2];
```

However, using the mpcmoveopt object involves much less computational overhead.

### **Tips**

• If a variable is unconstrained in the initial controller design, you cannot constrain it using mpcmoveopt. The controller ignores any such specifications.

• You cannot remove a constraint from a variable that is constrained in the initial controller design. However, you can change it to a large (or small) value such that it is unlikely to become active.

# mpcqpsolver

Solve a quadratic programming problem using the KWIK algorithm

## **Syntax**

```
[x,status] = mpcqpsolver(Linv,f,A,b,Aeq,beq,iA0,options)
[x,status,iA,lambda] = mpcqpsolver(Linv,f,A,b,Aeq,beq,iA0,options)
```

# **Description**

[x,status] = mpcqpsolver(Linv,f,A,b,Aeq,beq,iA0,options) finds an optimal solution, x, to a quadratic programming problem by minimizing the objective function:

$$J = \frac{1}{2} X^{\mathsf{T}} H X + f^{\mathsf{T}} X$$

subject to inequality constraints  $Ax \ge b$ , and equality constraints  $A_{eq}x = b_{eq}$ . status indicates the validity of x.

[x,status,iA,lambda] = mpcqpsolver(Linv,f,A,b,Aeq,beq,iA0,options) also returns the active inequalities, iA, at the solution, and the Lagrange multipliers, lambda, for the solution.

### **Examples**

#### **Solve Quadratic Programming Problem**

Find the values of x that minimize

$$f(x) = 0.5x_1^2 + x_2^2 - x_1x_2 - 2x_1 - 6x_2$$

subject to the constraints

```
x_1 \ge 0

x_2 \ge 0

x_1 + x_2 \le 2

-x_1 + 2x_2 \le 2

2x_1 + x_2 \le 3.
```

Specify the Hessian and linear multiplier vector for the objective function.

```
H = [1 -1; -1 2];

f = [-2; -6];
```

Specify the inequality constraint parameters.

```
A = [1 \ 0; \ 0 \ 1; \ -1 \ -1; \ 1 \ -2; \ -2 \ -1];

b = [0; \ 0; \ -2; \ -2; \ -3];
```

Define Aeq and beq to indicate that there are no equality constraints.

```
Aeq = [];
beq = zeros(0,1);
```

Find the lower-triangular Cholesky decomposition of H.

```
[L,p] = chol(H,'lower');
Linv = inv(L);
```

It is good practice to verify that H is positive definite by checking if p = 0.

p p = 0

Create a default option set for mpcqpsolver.

```
opt = mpcqpsolver0ptions;
```

To cold start the solver, define all inequality constraints as inactive.

```
iA0 = false(size(b));
```

Solve the QP problem.

```
[x,status] = mpcqpsolver(Linv,f,A,b,Aeq,beq,iA0,opt);
```

Examine the solution, x.

```
x
x = 2×1
0.6667
1.3333
```

#### **Check Active Inequality Constraints for QP Solution**

Find the values of *x* that minimize

$$f(x) = 3x_1^2 + 0.5x_2^2 - 2x_1x_2 - 3x_1 + 4x_2$$

subject to the constraints

$$x_1 \ge 0$$
  
 $x_1 + x_2 \le 5$   
 $x_1 + 2x_2 \le 7$ .

Specify the Hessian and linear multiplier vector for the objective function.

```
H = [6 -2; -2 1];

f = [-3; 4];
```

Specify the inequality constraint parameters.

```
A = [1 \ 0; -1 \ -1; -1 \ -2];

b = [0; -5; -7];
```

Define Aeq and beq to indicate that there are no equality constraints.

```
Aeq = [];
beq = zeros(0,1);
```

Find the lower-triangular Cholesky decomposition of H.

```
[L,p] = chol(H,'lower');
Linv = inv(L);
```

Verify that H is positive definite by checking if p = 0.

```
p
p = 0
Create a default option set for mpcqpsolver.
opt = mpcqpsolverOptions;
To cold start the solver, define all inequality constraints as inactive.
iA0 = false(size(b));
```

[x,status,iA,lambda] = mpcqpsolver(Linv,f,A,b,Aeq,beq,iA0,opt);

Check the active inequality constraints. An active inequality constraint is at equality for the optimal solution.

#### iΑ

```
iA = 3x1 logical array

1
0
0
```

Solve the QP problem.

There is a single active inequality constraint.

View the Lagrange multiplier for this constraint.

```
lambda.ineqlin(1)
ans = 5.0000
```

## **Input Arguments**

**Linv** — Inverse of lower-triangular Cholesky decomposition of Hessian matrix n-by-n matrix

Inverse of lower-triangular Cholesky decomposition of Hessian matrix, specified as an n-by-n matrix, where n > 0 is the number of optimization variables. For a given Hessian matrix, H, Linv can be computed as follows:

```
[L,p] = chol(H,'lower');
Linv = inv(L);
```

H is an n-by-n matrix, which must be symmetric and positive definite. If p = 0, then H is positive definite.

**Note** The KWIK algorithm requires the computation of Linv instead of using H directly, as in the quadprog command.

#### f — Multiplier of objective function linear term

column vector

Multiplier of objective function linear term, specified as a column vector of length n.

#### A — Linear inequality constraint coefficients

```
m-by-n matrix | []
```

Linear inequality constraint coefficients, specified as an m-by-n matrix, where m is the number of inequality constraints.

If your problem has no inequality constraints, use [].

#### **b** — Right-hand side of inequality constraints

column vector of length *m* 

Right-hand side of inequality constraints, specified as a column vector of length m.

If your problem has no inequality constraints, use zeros(0,1).

#### Aeq — Linear equality constraint coefficients

```
q-by-n matrix | []
```

Linear equality constraint coefficients, specified as a q-by-n matrix, where q is the number of equality constraints, and  $q \le n$ . Equality constraints must be linearly independent with rank(Aeq) = q.

If your problem has no equality constraints, use [].

#### beq — Right-hand side of equality constraints

column vector of length q

Right-hand side of equality constraints, specified as a column vector of length q.

If your problem has no equality constraints, use zeros(0,1).

#### iA0 — Initial active inequalities

logical vector of length *m* 

Initial active inequalities, where the equal portion of the inequality is true, specified as a logical vector of length *m* according to the following:

- If your problem has no inequality constraints, use false(0,1).
- For a cold start, false(m,1).
- For a warm start, set iAO(i) == true to start the algorithm with the ith inequality constraint active. Use the optional output argument iA from a previous solution to specify iAO in this way. If both iAO(i) and iAO(j) are true, then rows i and j of A should be linearly independent. Otherwise, the solution can fail with status = -2.

#### options — Option set for mpcqpsolver

structure

Option set for mpcqpsolver, specified as a structure created using mpcqpsolverOptions.

# **Output Arguments**

#### x — Optimal solution to the QP problem

column vector

Optimal solution to the QP problem, returned as a column vector of length n. mpcqpsolver always returns a value for x. To determine whether the solution is optimal or feasible, check the solution status.

#### status — Solution validity indicator

positive integer | 0 | -1 | -2

Solution validity indicator, returned as an integer according to the following:

Value	Description
> 0	x is optimal. status represents the number of iterations performed during optimization.
Θ	The maximum number of iterations was reached. The solution, x, may be suboptimal or infeasible.
- 1	The problem appears to be infeasible, that is, the constraint $Ax \ge b$ cannot be satisfied.
-2	An unrecoverable numerical error occurred.

#### iA — Active inequalities

logical vector of length *m* 

Active inequalities, where the equal portion of the inequality is true, returned as a logical vector of length m. If iA(i) = true, then the ith inequality is active for the solution x.

Use iA to warm start a subsequent mpcqpsolver solution.

#### lambda — Lagrange multipliers

structure

Lagrange multipliers, returned as a structure with the following fields:

Field	Description
ineqli n	Multipliers of the inequality constraints, returned as a vector of length $n$ . When the solution is optimal, the elements of ineqlin are nonnegative.
	Multipliers of the equality constraints, returned as a vector of length $q$ . There are no sign restrictions in the optimal solution.

### **Tips**

 The KWIK algorithm requires that the Hessian matrix, H, be positive definite. When calculating Linv, use:

```
[L, p] = chol(H, 'lower');
```

If p = 0, then H is positive definite. Otherwise, p is a positive integer.

• mpcqpsolver provides access to the QP solver used by Model Predictive Control Toolbox software. Use this command to solve QP problems in your own custom MPC

applications. For an example of a custom MPC application using mpcqpsolver, see "Solve Custom MPC Quadratic Programming Problem and Generate Code".

# **Algorithms**

mpcqpsolver solves the QP problem using an active-set method, the KWIK algorithm, based on [1]. For more information, see "QP Solver".

The KWIK algorithm defines inequality constraints as  $Ax \ge b$  rather than  $Ax \le b$ , as in the quadprog command.

# **Extended Capabilities**

### **C/C++ Code Generation**

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

• You can use mpcqpsolver as a general-purpose QP solver that supports code generation. Create the function myCode that uses mpcqpsolver.

```
function [out1,out2] = myCode(in1,in2)
%#codegen
...
[x,status] = mpcqpsolver(Linv,f,A,b,Aeq,Beq,iA0,options);
...

Generate C code with MATLAB Coder™.

func = 'myCode';
cfg = coder.config('mex'); % or 'lib', 'dll'
codegen('-config',cfg,func,'-o',func);
```

• For code generation, use the same precision for all real inputs, including options. Configure the precision as 'double' or 'single' using mpcqpsolverOptions.

"QP Solver"

"Solve Custom MPC Quadratic Programming Problem and Generate Code"

#### Introduced in R2015b

# mpcqpsolverOptions

Create default option set for mpcqpsolver

### **Syntax**

```
options = mpcqpsolverOptions
options = mpcqpsolverOptions(type)
```

# **Description**

options = mpcqpsolverOptions creates a structure of default options for mpcqpsolver, which solves a quadratic programming (QP) problem using the KWIK algorithm.

options = mpcqpsolverOptions(type) creates a default option set using the specified input data type. All real options are specified using this data type.

# **Examples**

#### Create Default Option Set for MPC QP Solver

```
opt = mpcqpsolverOptions;
```

#### Create and Modify Default MPC QP Solver Option Set

```
Create default option set.
opt = mpcqpsolverOptions;
Specify the maximum number of iterations allowed during computation.
opt.MaxIter = 100;
```

Specify a feasibility tolerance for verifying that the optimal solution satisfies the inequality constraints.

```
opt.FeasibilityTol = 1.0e-3;
```

#### **Create Option Set Specifying Input Argument Type**

```
opt = mpcqpsolverOptions('single');
```

# **Input Arguments**

#### type — MPC QP solver input argument data type

'double' (default) | 'single'

MPC QP solver input argument data type, specified as either 'double' or 'single'. This data type is used for both simulation and code generation. All real options in the option set are specified using this data type, and all real input arguments to mpcqpsolver must match this type.

# **Output Arguments**

#### options — Option set for mpcqpsolver

structure

Option set for mpcqpsolver, returned as a structure with the following fields:

Field	Description	Default
DataTyp e	Input argument data type, specified as either 'double' or 'single'. This data type is used for both simulation and code generation, and all real input arguments to mpcqpsolver must match this type.	'double
MaxIter	Maximum number of iterations allowed when computing the QP solution, specified as a positive integer.	200

Field	Description	Default
	Tolerance used to verify that inequality constraints are satisfied by the optimal solution, specified as a positive scalar. A larger FeasibilityTol value allows for larger constraint violations.	1.0e-6
	Indicator of whether integrity checks are performed on the mpcqpsolver input data, specified as a logical value. If IntegrityChecks is true, then integrity checks are performed and diagnostic messages are displayed. Use false for code generation only.

# mpcsimopt

MPC simulation options

### **Syntax**

options = mpcsimopt(MPCobj)

# **Description**

options = mpcsimopt(MPCobj) creates an set of options for specifying additional parameters for simulating an mpc controller, MPCobj, with sim. Initially, options is empty. Use dot notation to change the options as needed for the simulation.

# **Output Arguments**

#### options

Options for simulating an mpc controller using sim. options has the following properties.

### **MPC Simulation Options Properties**

Property	Description
PlantInitialState	Initial state vector of the plant model generating the data.
ControllerInitialState	Initial condition of the MPC controller. This must be a valid mpcstate object.
	Note Nonzero values of ControllerInitialState.LastMove are only meaningful if there are constraints on the increments of the manipulated variables.
UnmeasuredDisturbance	Unmeasured disturbance signal entering the plant.
	An array with as many rows as simulation steps, and as many columns as unmeasured disturbances.  Default: 0
InputNoise	Noise on manipulated variables.
	An array with as many rows as simulation steps, and as many columns as manipulated variables. The last sample of the array is extended constantly over the horizon to obtain the correct size. Default: 0
OutputNoise	Noise on measured outputs.
	An array with as many rows as simulation steps, and as many columns as measured outputs. The last sample of the array is extended constantly over the horizon to obtain the correct size. Default: 0
RefLookAhead	Preview on reference signal ('on' or 'off'). Default: 'off'
MDLookAhead	Preview on measured disturbance signal ('on' or 'off').
Constraints	Use MPC constraints ('on' or 'off'). Default: 'on'

Property	Description
Model	Model used in simulation for generating the data.
	This property is useful for simulating the MPC controller under model mismatch. The LTI object specified in Model can be either a replacement for Model.Plant, or a structure with fields Plant and Nominal. By default, Model is equal to MPCobj.Model (no model mismatch). If Model is specified, then PlantInitialState refers to the initial state of Model.Plant and is defaulted to Model.Nominal.x.  If Model.Nominal is empty, Model.Nominal.U and Model.Nominal.Y are inherited from
	MPCobj.Model.Nominal.Model.Nominal.X/DX is only inherited if both plants are state-space objects with the same state dimension.
StatusBar	Display the wait bar ('on' or 'off'). Default: 'off'
MVSignal	Sequence of manipulated variables (with offsets) for open-loop simulation (no MPC action).
	An array with as many rows as simulation steps, and as many columns as manipulated variables. Default: 0
OpenLoop	Perform open-loop simulation ('on' or 'off'). Default: 'off'

# **Examples**

#### **Simulate MPC Control with Plant Model Mismatch**

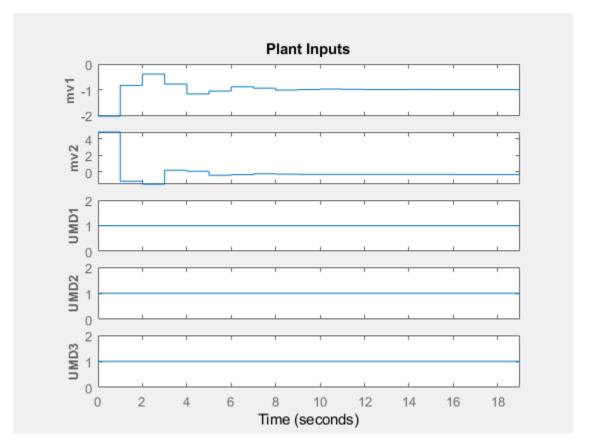

Simulate the MPC control of a multi-input, multi-output (MIMO) system with a mismatch between the predicted and actual plant models. The system has two manipulated variables, two unmeasured disturbances, and two measured outputs.

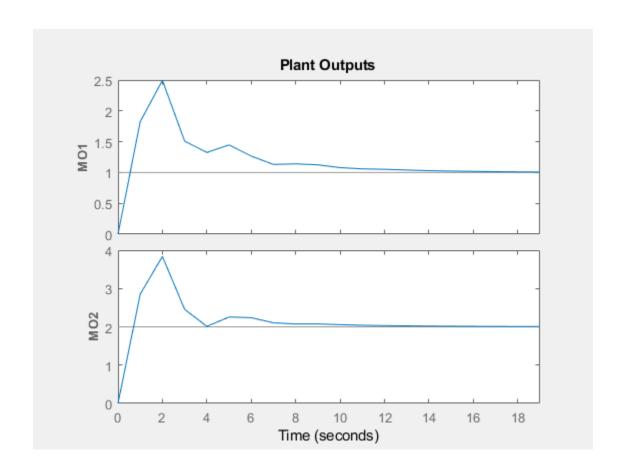

Define the predicted plant model. p1 = tf(1,[1 2 1])\*[1 1;0 1];

```
plantPredict = ss([p1 p1]);
plantPredict.InputName = {'mv1','mv2','umd3','umd4'};
Specify the MPC signal types.
plantPredict = setmpcsignals(plantPredict, 'MV', [1 2], 'UD', [3 4]);
Create the MPC controller.
mpcobj = mpc(plantPredict,1,40,2);
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defail
-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
Define the unmeasured input disturbance model used by the controller.
distModel = eye(2,2)*ss(-0.5,1,1,0);
mpcobi.Model.Disturbance = distModel:
Define an actual plant model which differs from the predicted model and has unforeseen
unmeasured disturbance inputs.
p2 = tf(1.5, [0.1 1 2 1])*[1 1;0 1];
plantActual = ss([p2 p2 tf(1,[1 1])*[0;1]]);
plantActual = setmpcsignals(plantActual, 'MV',[1 2], 'UD',[3 4 5]);
Configure the unmeasured disturbance and output reference trajectories.
dist = ones(1,3);
refs = [1 \ 2]:
Create and configure a simulation option set.
options = mpcsimopt(mpcobj);
options.UnmeasuredDisturbance = dist;
options.Model = plantActual;
Simulate the system.
sim(mpcobj,20,refs,options)
-->Converting model to discrete time.
-->Assuming output disturbance added to measured output channel #1 is integrated white
```

- -->Assuming output disturbance added to measured output channel #2 is integrated white -->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each
- --->Converting model to discrete time.

- -->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon -->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
  -->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defau
- -->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming default 1

### **Topics**

"Simulate Controller with Nonlinear Plant"

#### **Introduced before R2006a**

# mpcstate

Define MPC controller state

### **Syntax**

```
xmpc = mpcstate(MPCobj)
xmpc = mpcstate(MPCobj,xp,xd,xn,u,p)
xmpc = mpcstate
```

# **Description**

xmpc = mpcstate(MPCobj) creates a controller state object compatible with the
controller object, MPCobj, in which all fields are set to their default values that are
associated with the controller's nominal operating point.

xmpc = mpcstate(MPCobj,xp,xd,xn,u,p) sets the state fields of the controller state
object to specified values. The controller may be an implicit or explicit controller object.
Use this controller state object to initialize an MPC controller at a specific state other
than the default state.

xmpc = mpcstate returns an mpcstate object in which all fields are empty.

mpcstate objects are updated by mpcmove through the internal state observer based on the extended prediction model. The overall state is updated from the measured output  $y_m(k)$  by a linear state observer (see "State Observer").

# **Input Arguments**

#### MPCobj

MPC controller, specified as either a traditional MPC controller (mpc) or explicit MPC controller (generateExplicitMPC).

#### хp

Plant model state estimates, specified as a vector with  $N_{xp}$  elements, where  $N_{xp}$  is the number of states in the plant model.

#### xd

Disturbance model state estimates, specified as a vector with  $N_{xd}$  elements, where  $N_{xd}$  is the total number of states in the input and output disturbance models. The disturbance model states are ordered such that input disturbance model states are followed by output disturbance model state estimates.

#### xn

Measurement noise model state estimates, specified as a vector with  $N_{xn}$  elements, where  $N_{xn}$  is the number of states in the measurement noise model.

#### u

Values of the manipulated variables during the previous control interval, specified as a vector with  $N_u$  elements, where  $N_u$  is the number of manipulated variables.

#### p

Covariance matrix for the state estimates, specified as an *N*-by-*N* matrix, where *N* is the sum of  $N_{xp}$ ,  $N_{xd}$  and  $N_{xn}$ ).

### **Output Arguments**

#### **xmpc**

MPC state object, containing the following properties.

Property	Description
Plant	Vector of state estimates for the controller's plant model. Values are in engineering units and are absolute, i.e., they include state offsets.
	If the controller's plant model includes delays, the Plant field of the MPC state object includes states that model the delays.  Therefore length(Plant) > order of undelayed controller plant model.
	Default: controller's Model.Nominal.X property.
Disturbance	Vector of unmeasured disturbance model state estimates. This comprises the states of the input disturbance model followed by the states of the output disturbances model.
	Disturbance models may be created by default. Use the getindistand getoutdistcommands to view the two disturbance model structures.
	Default: zero, or empty if there are no disturbance model states.
Noise	Vector of output measurement noise model state estimates.
	Default: zero, or empty if there are no noise model states.
LastMove	Vector of manipulated variables used in the previous control interval, $u(k-1)$ . Values are absolute, i.e., they include manipulated variable offsets.
	Default: nominal values of the manipulated variables.
Covariance	n-by- $n$ symmetrical covariance matrix for the controller state estimates, where $n$ is the dimension of the extended controller state, i.e., the sum of the number states contained in the Plant, Disturbance, and Noise fields.
	Default: If the controller is employing default state estimation the default is the steady-state covariance computed according to the assumptions in "Controller State Estimation". See also the description of the P matrix in the Control System Toolbox kalmd command. If the controller is employing custom state estimation, this field is empty (not used).

## **Examples**

### **Get Controller State Object**

Create a Model Predictive Controller for a single-input-single-output (SISO) plant. For this example, the plant includes an input delay of 0.4 time units, and the control interval to 0.2 time units.

```
H = tf(1,[10 1],'InputDelay',0.4);
MPCobj = mpc(H,0.2);
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1.
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1.
```

Create the corresponding controller state object in which all states are at their default values.

The plant model, H, is a first-order, continuous-time transfer function. The Plant property of the mpcstate object contains two additional states to model the two intervals of delay. Also, by default the controller contains a first-order output disturbance model (an integrator) and an empty measured output noise model.

View the default covariance matrix.

Covariance: [4x4 double]

```
xMPC.Covariance
```

#### Introduced before R2006a

# mpcverbosity

Change toolbox verbosity level

## **Syntax**

```
mpcverbosity on
mpcverbosity off
old_status = mpcverbosity(new_status)
mpcverbosity
```

# **Description**

mpcverbosity on enables messages displaying default operations taken by Model Predictive Control Toolbox software during the creation and manipulation of model predictive control objects.

mpcverbosity off turns messages off.

old\_status = mpcverbosity(new\_status) sets the verbosity level to the specified
value, new\_status. The function returns the original value of the verbosity level as
old\_status. Specify new\_status as either 'on' or 'off'.

mpcverbosity just shows the verbosity status.

By default, messages are turned on.

See also "Construction and Initialization" on page  $4\mbox{-}15$  .

# nlmpc

Nonlinear model predictive controller

# **Description**

A nonlinear model predictive controller computes optimal control moves across the prediction horizon using a nonlinear prediction model, a nonlinear cost function, and nonlinear constraints. For more information on nonlinear MPC, see "Nonlinear MPC".

## Creation

## **Syntax**

```
nlobj = nlmpc(nx,ny,nu)
nlobj = nlmpc(nx,ny,'MV',mvIndex,'MD',mdIndex)
nlobj = nlmpc(nx,ny,'MV',mvIndex,'UD',udIndex)
nlobj = nlmpc(nx,ny,'MV',mvIndex,'MD',mdIndex,'UD',udIndex)
```

## **Description**

nlobj = nlmpc(nx,ny,nu) creates an nlmpc object whose prediction model has nx states, ny outputs, and nu inputs, where all inputs are manipulated variables. Use this syntax if your model has no measured or unmeasured disturbance inputs.

nlobj = nlmpc(nx,ny,'MV',mvIndex,'MD',mdIndex) creates an nlmpc object
whose prediction model has measured disturbance inputs. Specify the input indices for
the manipulated variables, mvIndex, and measured disturbances, mdIndex.

nlobj = nlmpc(nx,ny,'MV',mvIndex,'UD',udIndex) creates an nlmpc object whose prediction model has unmeasured disturbance inputs. Specify the input indices for the manipulated variables and unmeasured disturbances, udIndex.

nlobj = nlmpc(nx,ny,'MV',mvIndex,'MD',mdIndex,'UD',udIndex) creates an
nlmpc object whose prediction model has both measured and unmeasured disturbance

inputs. Specify the input indices for the manipulated variables, measured disturbances, and unmeasured disturbances.

## **Input Arguments**

#### nx — Number of prediction model states

positive integer

Number of prediction model states, specified as a positive integer. You cannot change the number of states after creating the controller object.

#### ny — Number of prediction model outputs

positive integer

Number of prediction model outputs, specified as a positive integer. You cannot change the number of outputs after creating the controller object.

#### nu — Number of prediction model inputs

positive integer

Number of prediction model inputs, which are all manipulated variables, specified as a positive integer. You cannot change the number of manipulated variables after creating the controller object.

### mvIndex — Manipulated variable indices

vector of positive integers

Manipulated variable indices, specified as a vector of positive integers. You cannot change these indices after creating the controller object. This value is stored in the Dimensions.MVIndex controller property.

The combined set of indices from mvIndex, mdIndex, and udIndex must contain all integers from 1 through  $N_{u}$ , where  $N_{u}$  is the number of prediction model inputs.

#### mdIndex — Measured disturbance indices

vector of positive integers

Measured disturbance indices, specified as a vector of positive integers. You cannot change these indices after creating the controller object. This value is stored in the Dimensions.MDIndex controller property.

The combined set of indices from mvIndex, mdIndex, and udIndex must contain all integers from 1 through  $N_{\nu}$ , where  $N_{\nu}$  is the number of prediction model inputs.

#### udIndex — Unmeasured disturbance indices

vector of positive integers

Unmeasured disturbance indices, specified as a vector of positive integers. You cannot change these indices after creating the controller object. This value is stored in the <code>Dimensions.UDIndex</code> controller property.

The combined set of indices from mvIndex, mdIndex, and udIndex must contain all integers from 1 through  $N_u$ , where  $N_u$  is the number of prediction model inputs.

## **Properties**

#### Ts — Prediction model sample time

1 (default) | positive finite scalar

Prediction model sample time, specified as a positive finite scalar. The controller uses a discrete-time model with sample time Ts for prediction. If you specify a continuous-time prediction model (Model.IsContinuousTime is true), then the controller discretizes the model using the built-in implicit trapezoidal rule with a sample time of Ts.

#### PredictionHorizon — Prediction horizon

10 (default) | positive integer

Prediction horizon steps, specified as a positive integer. The product of PredictionHorizon and Ts is the prediction time; that is, how far the controller looks into the future.

#### ControlHorizon — Control horizon

2 (default) | positive integer | vector of positive integers

Control horizon, specified as one of the following:

 Positive integer, m, between 1 and p, inclusive, where p is equal to PredictionHorizon. In this case, the controller computes m free control moves occurring at times k through k+m-1, and holds the controller output constant for the remaining prediction horizon steps from k+m through k+p-1. Here, k is the current control interval.

- Vector of positive integers  $[m_1, m_2, ...]$ , specifying the lengths of blocking intervals. By default the controller computes M blocks of free moves, where M is the number of blocking intervals. The first free move applies to times k through  $k+m_1-1$ , the second free move applies from time  $k+m_1$  through  $k+m_1+m_2-1$ , and so on. Using block moves can improve the robustness of your controller. The sum of the values in ControlHorizon must match the prediction horizon p. If you specify a vector whose sum is:
  - Less than the prediction horizon, then the controller adds a blocking interval. The length of this interval is such that the sum of the interval lengths is p. For example, if p=10 and you specify a control horizon of ControlHorizon=[1 2 3], then the controller uses four intervals with lengths [1 2 3 4].
  - Greater than the prediction horizon, then the intervals are truncated until the sum
    of the interval lengths is equal to p. For example, if p=10 and you specify a control
    horizon of ControlHorizon= [1 2 3 6 7], then the controller uses four
    intervals with lengths [1 2 3 4].

Piecewise constant blocking moves are often too restrictive for optimal path planning applications. To produce a less-restrictive, better-conditioned nonlinear programming problem, you can specify piecewise linear manipulated variable blocking intervals. To do so, set the <code>Optimization.MVInterpolationOrder</code> property of your <code>nlmpc</code> controller object to 1.

For more information on how manipulated variable blocking works with different interpolation methods, see "Manipulated Variable Blocking".

# ${\bf Dimensions-Prediction\ model\ dimensional\ information}$

structure

This property is read-only.

Prediction model dimensional information, specified when the controller is created and stored as a structure with the following fields.

#### NumberOfStates — Number of states

positive integer

Number of states in the prediction model, specified as a positive integer. This value corresponds to nx.

## Number 0 f 0 utputs — Number of outputs

positive integer

Number of outputs in the prediction model, specified as a positive integer. This value corresponds to ny.

#### NumberOfInputs — Number of states

positive integer

Number of inputs in the prediction model, specified as a positive integer. This value corresponds to either nmv or the sum of the lengths of mvIndex, mdIndex, and udIndex.

#### **MVIndex** — Manipulated variable indices

vector of positive integers

Manipulated variable indices for the prediction model, specified as a vector of positive integers. This value corresponds to mvIndex.

#### MDIndex — Measured disturbance indices

vector of positive integers

Measured disturbance indices for the prediction model, specified as a vector of positive integers. This value corresponds to mdIndex.

#### **UDIndex** — Unmeasured disturbance indices

vector of positive integers

Unmeasured disturbance indices for the prediction model, specified as a vector of positive integers. This value corresponds to udIndex.

#### **Model** — **Prediction model**

structure

Prediction model, specified as a structure with the following fields.

#### StateFcn — State function

string | character vector | function handle

State function, specified as a string, character vector, or function handle. For a continuous-time prediction model, StateFcn is the state derivative function. For a discrete-time prediction model, StateFcn is the state update function.

If your state function is continuous-time, the controller automatically discretizes the model using the implicit trapezoidal rule. This method can handle moderately stiff models, and its prediction accuracy depends on the controller sample time Ts; that is, a large sample time leads to inaccurate prediction.

If the default discretization method does not provide satisfactory prediction for your application, you can specify your own discrete-time prediction model that uses a different method, such as the multistep forward Euler rule.

You can specify your state function in one of the following ways:

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Model.StateFcn = "myStateFunction";
```

Handle to a function in the current working folder or on the MATLAB path

```
Model.StateFcn = @myStateFunction;
```

Anonymous function

```
Model.StateFcn = @(x,u,params) myStateFunction(x,u,params)
```

For more information, see "Specify Prediction Model for Nonlinear MPC".

#### **OutputFcn** — **Output function**

```
[] (default) | string | character vector | function handle
```

Output function, specified as a string, character vector, or function handle. If the number of states and outputs of the prediction model are the same, you can omit OutputFcn, which implies that all states are measurable; that is, each output corresponds to one state.

**Note** You output function cannot have direct feedthrough from any manipulated variable to any output at any time.

You can specify your output function in one of the following ways:

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Model.OutputFcn = "myOutputFunction";
```

Handle to a function in the current working folder or on the MATLAB path

```
Model.OutputFcn = @myOutputFunction;
```

Anonymous function

Model.OutputFcn = @(x,u,params) myOutputFunction(x,u,params)

For more information, see "Specify Prediction Model for Nonlinear MPC".

# IsContinuousTime — Flag indicating prediction model time domain true (default) | false

Flag indicating prediction model time domain, specified as one of the following:

- true Continuous-time prediction model. In this case, the controller automatically discretizes the model during prediction using Ts.
- false Discrete-time prediction model. In this case, Ts is the sample time of the model.

**Note** IsContinuousTime must be consistent with the functions specified in Model.StateFcn and Model.OutputFcn.

## NumberOfParameters — Number of optional model parameters

0 (default) | nonnegative integer

Number of optional model parameters used by the prediction model, custom cost function, and custom constraint functions, specified as a nonnegative integer. The number of parameters includes all the parameters used by these functions. For example, if the state function uses only parameter p1, the constraint functions use only parameter p2, and the cost function uses only parameter p3, then NumberOfParameters is 3.

### States — State information, bounds, and scale factors

structure array

State information, bounds, and scale factors, specified as a structure array with  $N_x$  elements, where  $N_x$  is the number of states. Each structure element has the following fields.

#### Min — State lower bound

-Inf (default) | scalar | vector

State lower bound, specified as a scalar or vector. By default, the lower bound is unconstrained.

To use the same bound across the prediction horizon, specify a scalar value.

To vary the bound over the prediction horizon from time k+1 to time k+p, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final bound is used for the remaining steps of the prediction horizon.

State bounds are always hard constraints.

#### Max — State upper bound

Inf (default) | scalar | vector

State upper bound, specified as a scalar or vector. By default, the upper bound is unconstrained.

To use the same bound across the prediction horizon, specify a scalar value.

To vary the bound over the prediction horizon from time k+1 to time k+p, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final bound is used for the remaining steps of the prediction horizon.

State bounds are always hard constraints.

#### Name — State name

string | character vector

State name, specified as a string or character vector. The default state name is "x#", where # is its state index.

#### Units — State units

"" (default) | string | character vector

State units, specified as a string or character vector.

#### ScaleFactor — State scale factor

1 (default) | positive finite scalar

State scale factor, specified as a positive finite scalar. In general, use the operating range of the state. Specifying the proper scale factor can improve numerical conditioning for optimization.

**OutputVariables** — **Output variable information, bounds, and scale factors** structure array

Output variable (OV) information, bounds, and scale factors, specified as a structure array with  $N_y$  elements, where  $N_y$  is the number of output variables. To access this property, you can use the alias OV instead of OutputVariables.

Each structure element has the following fields.

#### Min — OV lower bound

-Inf (default) | scalar | vector

OV lower bound, specified as a scalar or vector. By default, this lower bound is unconstrained.

To use the same bound across the prediction horizon, specify a scalar value.

To vary the bound over the prediction horizon from time k+1 to time k+p, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final bound is used for the remaining steps of the prediction horizon.

#### Max — OV upper bound

Inf (default) | scalar | vector

OV upper bound, specified as a scalar or vector. By default, this upper bound is unconstrained.

To use the same bound across the prediction horizon, specify a scalar value.

To vary the bound over the prediction horizon from time k+1 to time k+p, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final bound is used for the remaining steps of the prediction horizon.

#### MinECR — OV lower bound softness

1 (default) | nonnegative finite scalar | vector

OV lower bound softness, where a larger ECR value indicates a softer constraint, specified as a nonnegative finite scalar or vector. By default, OV upper bounds are soft constraints.

To use the same ECR value across the prediction horizon, specify a scalar value.

To vary the ECR value over the prediction horizon from time k+1 to time k+p, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you

specify fewer than p values, the final ECR value is used for the remaining steps of the prediction horizon.

#### MaxECR — OV upper bound softness

1 (default) | nonnegative finite scalar | vector

OV upper bound softness, where a larger ECR value indicates a softer constraint, specified as a nonnegative finite scalar or vector. By default, OV lower bounds are soft constraints.

To use the same ECR value across the prediction horizon, specify a scalar value.

To vary the ECR value over the prediction horizon from time k+1 to time k+p, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final ECR value is used for the remaining steps of the prediction horizon.

#### Name — OV name

string | character vector

OV name, specified as a string or character vector. The default OV name is "y#", where # is its output index.

#### Units — OV units

"" (default) | string | character vector

OV units, specified as a string or character vector.

#### ScaleFactor — OV scale factor

1 (default) | positive finite scalar

OV scale factor, specified as a positive finite scalar. In general, use the operating range of the output variable. Specifying the proper scale factor can improve numerical conditioning for optimization.

# ManipulatedVariables — Manipulated variable information, bounds, and scale factors

structure array

Manipulated Variable (MV) information, bounds, and scale factors, specified as a structure array with  $N_{mv}$  elements, where  $N_{mv}$  is the number of manipulated variables. To access this property, you can use the alias MV instead of ManipulatedVariables.

Each structure element has the following fields.

#### Min — MV lower bound

-Inf (default) | scalar | vector

MV lower bound, specified as a scalar or vector. By default, this lower bound is unconstrained.

To use the same bound across the prediction horizon, specify a scalar value.

To vary the bound over the prediction horizon from time k to time k+p-1, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final bound is used for the remaining steps of the prediction horizon.

#### Max — MV upper bound

Inf (default) | scalar | vector

MV upper bound, specified as a scalar or vector. By default, this upper bound is unconstrained.

To use the same bound across the prediction horizon, specify a scalar value.

To vary the bound over the prediction horizon from time k to time k+p-1, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final bound is used for the remaining steps of the prediction horizon

#### MinECR — MV lower bound softness

0 (default) | nonnegative scalar | vector

MV lower bound softness, where a larger ECR value indicates a softer constraint, specified as a nonnegative scalar or vector. By default, MV lower bounds are hard constraints.

To use the same ECR value across the prediction horizon, specify a scalar value.

To vary the ECR value over the prediction horizon from time k to time k+p-1, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final ECR value is used for the remaining steps of the prediction horizon.

#### MaxECR — MV upper bound

0 (default) | nonnegative scalar | vector

MV upper bound softness, where a larger ECR value indicates a softer constraint, specified as a nonnegative scalar or vector. By default, MV upper bounds are hard constraints.

To use the same ECR value across the prediction horizon, specify a scalar value.

To vary the ECR value over the prediction horizon from time k to time k+p-1, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final ECR value is used for the remaining steps of the prediction horizon.

#### RateMin — MV rate of change lower bound

-Inf (default) | nonpositive scalar | vector

MV rate of change lower bound, specified as a nonpositive scalar or vector. The MV rate of change is defined as MV(k) - MV(k-1), where k is the current time. By default, this lower bound is unconstrained.

To use the same bound across the prediction horizon, specify a scalar value.

To vary the bound over the prediction horizon from time k to time k+p-1, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final bound is used for the remaining steps of the prediction horizon.

## RateMax — MV rate of change upper bound

Inf (default) | nonnegative scalar | vector

MV rate of change upper bound, specified as a nonnegative scalar or vector. The MV rate of change is defined as MV(k) - MV(k-1), where k is the current time. By default, this lower bound is unconstrained.

To use the same bound across the prediction horizon, specify a scalar value.

To vary the bound over the prediction horizon from time k to time k+p-1, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final bound is used for the remaining steps of the prediction horizon.

#### RateMinECR — MV rate of change lower bound softness

0 (default) | nonnegative finite scalar | vector

MV rate of change lower bound softness, where a larger ECR value indicates a softer constraint, specified as a nonnegative finite scalar or vector. By default, MV rate of change lower bounds are hard constraints.

To use the same ECR value across the prediction horizon, specify a scalar value.

To vary the ECR values over the prediction horizon from time k to time k+p-1, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final ECR values are used for the remaining steps of the prediction horizon.

#### RateMaxECR — MV rate of change upper bound softness

0 (default) | nonnegative finite scalar | vector

MV rate of change upper bound softness, where a larger ECR value indicates a softer constraint, specified as a nonnegative finite scalar or vector. By default, MV rate of change upper bounds are hard constraints.

To use the same ECR value across the prediction horizon, specify a scalar value.

To vary the ECR values over the prediction horizon from time k to time k+p-1, specify a vector of up to p values. Here, k is the current time and p is the prediction horizon. If you specify fewer than p values, the final ECR values are used for the remaining steps of the prediction horizon.

#### Name — MV name

string | character vector

MV name, specified as a string or character vector. The default MV name is "u#", where # is its input index.

#### Units — MV units

"" (default) | string | character vector

MV units, specified as a string or character vector.

#### ScaleFactor — MV scale factor

1 (default) | positive finite scalar

MV scale factor, specified as a positive finite scalar. In general, use the operating range of the manipulated variable. Specifying the proper scale factor can improve numerical conditioning for optimization.

# MeasuredDisturbances — Measured disturbance information and scale factors structure array

Measured disturbance (MD) information and scale factors, specified as a structure array with  $N_{md}$  elements, where  $N_{md}$  is the number of measured disturbances. If your model does not have measured disturbances, then MeasuredDisturbances is []. To access this property, you can use the alias MD instead of MeasuredDisturbances.

Each structure element has the following fields.

#### Name — MD name

string | character vector

MD name, specified as a string or character vector. The default MD name is "u#", where # is its input index.

#### Units — MD units

"" (default) | string | character vector

MD units, specified as a string or character vector.

#### ScaleFactor — MD scale factor

1 (default) | positive finite scalar

MD scale factor, specified as a positive finite scalar. In general, use the operating range of the disturbance. Specifying the proper scale factor can improve numerical conditioning for optimization.

### Weights — Standard cost function tuning weights

structure

Standard cost function tuning weights, specified as a structure. The controller applies these weights to the scaled variables. Therefore, the tuning weights are dimensionless values.

**Note** If you define a custom cost function using Optimization.CustomCostFcn and set Optimization.ReplaceStandardCost to true, then the controller ignores the standard cost function tuning weights in Weights.

Weights has the following fields.

## ManipulatedVariables — Manipulated variable tuning weights

row vector | array

Manipulated variable tuning weights, which penalize deviations from MV targets, specified as a row vector or array of nonnegative values. The default weight for all manipulated variables is  $\theta$ .

To use the same weights across the prediction horizon, specify a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables.

To vary the tuning weights over the prediction horizon from time k to time k+p-1, specify an array with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the manipulated variable tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

To specify MV targets at run time, create an nlmpcmoveopt object, and set its MVTarget property.

# ManipulatedVariablesRate — Manipulated variable rate tuning weights row vector | array

Manipulated variable rate tuning weights, which penalize large changes in control moves, specified as a row vector or array of nonnegative values. The default weight for all manipulated variable rates is 0.1.

To use the same weights across the prediction horizon, specify a row vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

To vary the tuning weights over the prediction horizon from time k to time k+p-1, specify an array with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the manipulated variable rate tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

## OutputVariables — Output variable tuning weights

vector | array

Output variable tuning weights, which penalize deviation from output references, specified as a row vector or array of nonnegative values. The default weight for all output variables is 1.

To use the same weights across the prediction horizon, specify a row vector of length  $N_y$ , where  $N_y$  is the number of output variables.

To vary the tuning weights over the prediction horizon from time k+1 to time k+p, specify an array with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the output variable tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

#### **ECR** — Slack variable tuning weight

1e5 (default) | positive scalar

Slack variable tuning weight, specified as a positive scalar.

## ${\tt Optimization-Custom\ optimization\ functions\ and\ solver}$

structure

Custom optimization functions and solver, specified as a structure with the following fields.

#### CustomCostFcn — Custom cost function

```
[] | string | character vector | function handle
```

Custom cost function, specified as one of the following:

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Optimization.CustomCostFcn = "myCostFunction";
```

Handle to a function in the current working folder or on the MATLAB path

```
Optimization.CustomCostFcn = @myCostFunction;
```

Anonymous function

```
Optimization.CustomCostFcn = @(X,U,e,data,params) myCostFunction(X,U,e,data,params);
```

Your cost function must have the signature:

```
function J = myCostFunction(X,U,e,data,params)
```

For more information, see "Specify Cost Function for Nonlinear MPC".

# ReplaceStandardCost — Flag indicating whether to replace the standard cost function

```
true (default) | false
```

Flag indicating whether to replace the standard cost function with the custom cost function, specified as one of the following:

- true The controller uses the custom cost alone as the objective function during optimization. In this case, the Weights property of the controller is ignored.
- false The controller uses the sum of the standard cost and custom cost as the objective function during optimization.

If you do not specify a custom cost function using CustomCostFcn, then the controller ignores RepalceStandardCost.

For more information, see "Specify Cost Function for Nonlinear MPC".

#### **CustomEqConFcn** — **Custom equality constraint function**

```
[] (default) | string | character vector | function handle
```

Custom equality constraint function, specified as one of the following:

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Optimization.CustomEqConFcn = "myEqConFunction";
```

• Handle to a function in the current working folder or on the MATLAB path

```
Optimization.CustomEqConFcn = @myEqConFunction;
```

Anonymous function

```
Optimization.CustomEqConFcn = @(X,U,data,params) myEqConFunction(X,U,data,params);
```

Your equality constraint function must have the signature:

```
function ceg = myEqConFunction(X,U,data,p1,p2,...)
```

For more information, see "Specify Constraints for Nonlinear MPC".

## **CustomIneqConFcn** — **Custom inequality constraint function**

```
[] (default) | string | character vector | function handle
```

Custom inequality constraint function, specified as one of the following:

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Optimization.CustomIneqConFcn = "myIneqConFunction";
```

• Handle to a function in the current working folder or on the MATLAB path

```
Optimization.CustomIneqConFcn = @myIneqConFunction;
```

Anonymous function

```
Optimization.CustomIneqConFcn = @(X,U,data,params) myIneqConFunction(X,U,data,params);
```

Your equality constraint function must have the signature:

```
function cineq = myIneqConFunction(X,U,data,params)
```

For more information, see "Specify Constraints for Nonlinear MPC".

#### CustomSolverFcn — Custom nonlinear programming solver

```
[] (default) | string | character vector | function handle
```

Custom nonlinear programming solver function, specified as a string, character vector, or function handle. If you do not have Optimization Toolbox $^{\text{\tiny MM}}$  software, you must specify your own custom nonlinear programming solver. You can specify your custom solver function in one of the following ways:

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Optimization.CustomSolverFcn = "myNLPSolver";
```

Handle to a function in the current working folder or on the MATLAB path

```
Optimization.CustomSolverFcn = @myNLPSolver;
```

For more information, see "Configure Optimization Solver for Nonlinear MPC".

## **SolverOptions** — **Solver options**

```
options object for fmincon | []
```

Solver options, specified as an options object for fmincon or [].

If you have Optimization Toolbox software, SolverOptions contains an options object for the fmincon solver.

If you do not have Optimization Toolbox, SolverOptions is [].

For more information, see "Configure Optimization Solver for Nonlinear MPC".

# RunAsLinearMPC — Flag indicating whether to simulate as a linear controller "off" (default) | "Adaptive" | "TimeVarying"

Flag indicating whether to simulate as a linear controller, specified as one of the following:

- "off" Simulate the controller as a nonlinear controller with a nonlinear prediction model.
- "Adaptive" For each control interval, a linear model is obtained from the specified
  nonlinear state and output functions at the current operating point and used across
  the prediction horizon. To determine if an adaptive MPC controller provides
  comparable performance to the nonlinear controller, use this option. For more
  information on adaptive MPC, see "Adaptive MPC".
- "TimeVarying" For each control interval, p linear models are obtained from the
  specified nonlinear state and output functions at the p operating points predicted from
  the previous interval, one for each prediction horizon step. To determine if a linear
  time-varying MPC controller provides comparable performance to the nonlinear
  controller, use this option. For more information on time-varying MPC, see "TimeVarying MPC".

To use the either the "Adaptive" or "TimeVarying" option, your controller must have no custom constraints and no custom cost function.

For an example that simulates a nonlinear MPC controller as a linear controller, see "Optimization and Control of a Fed-Batch Reactor Using Nonlinear MPC".

# UseSuboptimalSolution — Flag indicating whether a suboptimal solution is acceptable

false (default) | true

Flag indicating whether a suboptimal solution is acceptable, specified as a logical value. When the nonlinear programming solver reaches the maximum number of iterations without finding a solution (the exit flag is  $\theta$ ), the controller:

- Freezes the MV values if UseSuboptimalSolution is false
- Applies the suboptimal solution found by the solver after the final iteration if UseSuboptimalSolution is true

To specify the maximum number of iterations, use Optimization.SolverOptions.MaxIter.

# MVInterpolationOrder — Linear interpolation order used for block moves 0 (default) | 1

Linear interpolation order used by block moves, specified as one of the following:

- 0 Use piecewise constant manipulated variable intervals.
- 1 Use piecewise linear manipulated variable intervals.

If the control horizon is a scalar, then the controller ignores MVInterpolationOrder.

For more information on manipulated variable blocking, see "Manipulated Variable Blocking".

# Jacobian — Jacobians of model functions, and custom cost and constraint functions

structure

Jacobians of model functions, and custom cost and constraint functions, specified as a structure. It is best practice to use Jacobians whenever they are available, since they improve optimization efficiency. If you do not specify a Jacobian for a given function, the nonlinear programming solver must numerically compute the Jacobian.

The Jacobian structure contains the following fields.

### StateFcn — Jacobian of state function

[] (default) | string | character vector | function handle

Jacobian of state function z from Model.StateFcn, specified as one of the following

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Model.StateFcn = "myStateJacobian";
```

Handle to a function in the current working folder or on the MATLAB path

```
Model.StateFcn = @myStateJacobian;
```

Anonymous function

```
Model.StateFcn = @(x,u,params) myStateJacobian(x,u,params)
```

For more information, see "Specify Prediction Model for Nonlinear MPC".

#### **OutputFcn** — Jacobian of output function

[] (default) | string | character vector | function handle

Jacobian of output function y from Model.OutputFcn, specified as one of the following:

• Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Model.StateFcn = "myOutputJacobian";
```

• Handle to a function in the current working folder or on the MATLAB path

```
Model.StateFcn = @myOutputJacobian;
```

• Anonymous function

```
Model.StateFcn = @(x,u,params) myOutputJacobian(x,u,params)
```

For more information, see "Specify Prediction Model for Nonlinear MPC".

### CustomCostFcn — Jacobian of custom cost function

[] | string | character vector | function handle

Jacobian of custom cost function J from Optimization. CustomCostFcn, specified as one of the following:

• Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Jacobian.CustomCostFcn = "myCostJacobian";
```

• Handle to a function in the current working folder or on the MATLAB path

```
Jacobian.CustomCostFcn = @myCostJacobian;
```

Anonymous function

```
Jacobian.CustomCostFcn = @(X,U,e,data,params) myCostJacobian(X,U,e,data,params)
```

Your cost Jacobian function must have the signature:

```
function [G,Gmv,Ge] = myCostJacobian(X,U,e,data,params)
```

For more information, see "Specify Cost Function for Nonlinear MPC".

#### CustomEqConFcn — Jacobian of custom equality constraints

[] (default) | string | character vector | function handle

Jacobian of custom equality constraints ceq from Optimization.CustomEqConFcn, specified as one of the following:

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Jacobian.CustomEqConFcn = "myEqConJacobian";
```

Handle to a function in the current working folder or on the MATLAB path

```
Jacobian.CustomEqConFcn = @myEqConJacobian;
```

Anonymous function

```
Jacobian.CustomEqConFcn = @(X,U,data,params) myEqConJacobian(X,U,data,params);
```

Your equality constraint Jacobian function must have the signature:

```
function [G,Gmv] = myEqConJacobian(X,U,data,params)
```

For more information, see "Specify Constraints for Nonlinear MPC".

## CustomIneqConFcn — Jacobian of custom inequality constraints

```
[] (default) | string | character vector | function handle
```

Jacobian of custom inequality constraints c from Optimization.CustomIneqConFcn, specified as one of the following:

 Name of a function in the current working folder or on the MATLAB path, specified as a string or character vector

```
Jacobian.CustomEqConFcn = "myIneqConJacobian";
```

Handle to a function in the current working folder or on the MATLAB path

```
Jacobian.CustomEqConFcn = @myIneqConJacobian;
```

Anonymous function

```
Jacobian.CustomEqConFcn = @(X,U,data,params) myIneqConJacobian(X,U,data,params);
```

Your inequality constraint Jacobian function must have the signature:

```
function [G,Gmv,Ge] = myIneqConJacobian(X,U,data,params)
```

For more information, see "Specify Constraints for Nonlinear MPC".

## **Object Functions**

nlmpcmove Compute optimal control action for nonlinear MPC controller validateFcns Examine prediction model and custom functions of nlmpc object

for potential problems

convertToMPC Convert nlmpc object into one or more mpc objects

createParameterBus Create Simulink bus object and configure Bus Creator block for

passing model parameters to Nonlinear MPC Controller block

## **Examples**

#### Create Nonlinear MPC Controller with Discrete-Time Prediction Model

Create a nonlinear MPC controller with four states, two outputs, and one input.

```
nx = 4;
ny = 2;
nu = 1;
nlobj = nlmpc(nx,ny,nu);
```

In standard cost function, zero weights are applied by default to one or more OVs became

Specify the sample time and horizons of the controller.

```
Ts = 0.1;
nlobj.Ts = Ts;
nlobj.PredictionHorizon = 10;
nlobj.ControlHorizon = 5;
```

Specify the state function for the controller, which is in the file pendulumDT0.m. This discrete-time model integrates the continuous time model defined in pendulumCT0.m using a multistep forward Euler method.

```
nlobj.Model.StateFcn = "pendulumDTO";
nlobj.Model.IsContinuousTime = false;
```

The discrete-time state function uses an optional parameter, the sample time Ts, to integrate the continuous-time model. Therefore, you must specify the number of optional parameters as 1.

```
nlobj.Model.NumberOfParameters = 1;
```

Specify the output function for the controller. In this case, define the first and third states as outputs. Even though this output function does not use the optional sample time parameter, you must specify the parameter as an input argument (Ts).

```
nlobj.Model.OutputFcn = @(x,u,Ts) [x(1); x(3)];
```

Validate the prediction model functions for nominal states x0 and nominal inputs u0. Since the prediction model uses a custom parameter, you must pass this parameter to validateFcns.

```
x0 = [0.1;0.2;-pi/2;0.3];
u0 = 0.4;
validateFcns(nlobj, x0, u0, [], {Ts});

Model.StateFcn is OK.
Model.OutputFcn is OK.
Analysis of user-provided model, cost, and constraint functions complete.
```

#### Create Nonlinear MPC Controller with Measured and Unmeasured Disturbances

Create a nonlinear MPC controller with three states, one output, and four inputs. The first two inputs are measured disturbances, the third input is the manipulated variable, and the fourth input is an unmeasured disturbance.

```
nlobj = nlmpc(3,1,'MV',3,'MD',[1 2],'UD',4);
```

To view the controller state, output, and input dimensions and indices, use the Dimensions property of the controller.

#### nlobj.Dimensions

Specify the controller sample time and horizons.

```
nlobj.Ts = 0.5;
nlobj.PredictionHorizon = 6;
nlobj.ControlHorizon = 3;
```

Specify the prediction model state function, which is in the file exocstrStateFcnCT.m.

```
nlobj.Model.StateFcn = 'exocstrStateFcnCT';
```

Specify the prediction model output function, which is in the file exocstrOutputFcn.m.

```
nlobj.Model.OutputFcn = 'exocstrOutputFcn';
```

Validate the prediction model functions using the initial operating point as the nominal condition for testing and setting the unmeasured disturbance state, x0(3), to 0. Since the model has measured disturbances, you must pass them to validateFcns.

```
x0 = [311.2639; 8.5698; 0];
u0 = [10; 298.15; 298.15];
validateFcns(nlobj,x0,u0(3),u0(1:2)');

Model.StateFcn is OK.
Model.OutputFcn is OK.
Analysis of user-provided model, cost, and constraint functions complete.
```

#### Validate Nonlinear MPC Prediction Model and Custom Functions

Create nonlinear MPC controller with six states, six outputs, and four inputs.

```
nx = 6;
ny = 6;
nu = 4;
nlobj = nlmpc(nx,ny,nu);
```

In standard cost function, zero weights are applied by default to one or more OVs became

Specify the controller sample time and horizons.

```
Ts = 0.4;
p = 30;
c = 4;
nlobj.Ts = Ts;
```

```
nlobj.PredictionHorizon = p;
nlobj.ControlHorizon = c;
```

Specify the prediction model state function and the Jacobian of the state function. For this example, use a model of a flying robot.

```
nlobj.Model.StateFcn = "FlyingRobotStateFcn";
nlobj.Jacobian.StateFcn = "FlyingRobotStateJacobianFcn";
```

Specify a custom cost function for the controller that replaces the standard cost function.

```
nlobj.Optimization.CustomCostFcn = @(X,U,e,data) Ts*sum(sum(U(1:p,:))); nlobj.Optimization.ReplaceStandardCost = true;
```

Specify a custom constraint function for the controller.

```
nlobj.Optimization.CustomEqConFcn = @(X,U,data) X(end,:)';
```

Validate the prediction model and custom functions at the initial states (x0) and initial inputs (u0) of the robot.

```
x0 = [-10;-10;pi/2;0;0;0];
u0 = zeros(nu,1);
validateFcns(nlobj,x0,u0);

Model.StateFcn is OK.
Jacobian.StateFcn is OK.
No output function specified. Assuming "y = x" in the prediction model.
Optimization.CustomCostFcn is OK.
Optimization.CustomEqConFcn is OK.
Analysis of user-provided model, cost, and constraint functions complete.
```

#### Create Linear MPC Controllers from Nonlinear MPC Controller

Create a nonlinear MPC controller with four states, one output variable, one manipulated variable, and one measured disturbance.

```
nlobj = nlmpc(4,1,'MV',1,'MD',2);
```

Specify the controller sample time and horizons.

```
nlobj.PredictionHorizon = 10;
nlobj.ControlHorizon = 3;
```

Specify the state function of the prediction model.

```
nlobj.Model.StateFcn = 'oxidationStateFcn';
```

Specify the prediction model output function and the output variable scale factor.

```
nlobj.Model.OutputFcn = @(x,u) x(3);
nlobj.OutputVariables.ScaleFactor = 0.03;
```

Specify the manipulated variable constraints and scale factor.

```
nlobj.ManipulatedVariables.Min = 0.0704;
nlobj.ManipulatedVariables.Max = 0.7042;
nlobj.ManipulatedVariables.ScaleFactor = 0.6;
```

Specify the measured disturbance scale factor.

```
nlobj.MeasuredDisturbances.ScaleFactor = 0.5;
```

Compute the state and input operating conditions for three linear MPC controllers using the fsolve function.

```
options = optimoptions('fsolve','Display','none');
uLow = [0.38 0.5];
xLow = fsolve(@(x) oxidationStateFcn(x,uLow),[1 0.3 0.03 1],options);
uMedium = [0.24 0.5];
xMedium = fsolve(@(x) oxidationStateFcn(x,uMedium),[1 0.3 0.03 1],options);
uHigh = [0.15 0.5];
xHigh = fsolve(@(x) oxidationStateFcn(x,uHigh),[1 0.3 0.03 1],options);
```

Create linear MPC controllers for each of these nominal conditions.

```
mpcobjLow = convertToMPC(nlobj,xLow,uLow);
mpcobjMedium = convertToMPC(nlobj,xMedium,uMedium);
mpcobjHigh = convertToMPC(nlobj,xHigh,uHigh);
```

You can also create multiple controllers using arrays of nominal conditions. The number of rows in the arrays specifies the number controllers to create. The linear controllers are returned as cell array of mpc objects.

```
u = [uLow; uMedium; uHigh];
x = [xLow; xMedium; xHigh];
mpcobjs = convertToMPC(nlobj,x,u);
```

View the properties of the mpcobjLow controller.

#### mpcobjLow

## Plan Optimal Trajectory Using Nonlinear MPC

Create nonlinear MPC controller with six states, six outputs, and four inputs.

```
nx = 6;
ny = 6;
nu = 4:
nlobj = nlmpc(nx,ny,nu);
In standard cost function, zero weights are applied by default to one or more OVs becau
Specify the controller sample time and horizons.
Ts = 0.4;
p = 30;
c = 4;
nlobi.Ts = Ts;
nlobj.PredictionHorizon = p;
nlobj.ControlHorizon = c;
Specify the prediction model state function and the Jacobian of the state function. For this
example, use a model of a flying robot.
nlobj.Model.StateFcn = "FlyingRobotStateFcn";
nlobj.Jacobian.StateFcn = "FlyingRobotStateJacobianFcn";
Specify a custom cost function for the controller that replaces the standard cost function.
nlobj.Optimization.CustomCostFcn = @(X,U,e,data) Ts*sum(sum(U(1:p,:)));
nlobj.Optimization.ReplaceStandardCost = true;
Specify a custom constraint function for the controller.
nlobj.Optimization.CustomEqConFcn = @(X,U,data) X(end,:)';
Specify linear constraints on the manipulated variables.
for ct = 1:nu
    nlobj.MV(ct).Min = 0;
    nlobj.MV(ct).Max = 1;
end
Validate the prediction model and custom functions at the initial states (x0) and initial
inputs (u0) of the robot.
x0 = [-10; -10; pi/2; 0; 0; 0];
u0 = zeros(nu,1);
validateFcns(nlobj,x0,u0);
Model.StateFcn is OK.
Jacobian.StateFcn is OK.
```

```
No output function specified. Assuming "y = x" in the prediction model. Optimization.CustomCostFcn is OK. Optimization.CustomEqConFcn is OK. Analysis of user-provided model, cost, and constraint functions complete.
```

Compute the optimal state and manipulated variable trajectories, which are returned in the info.

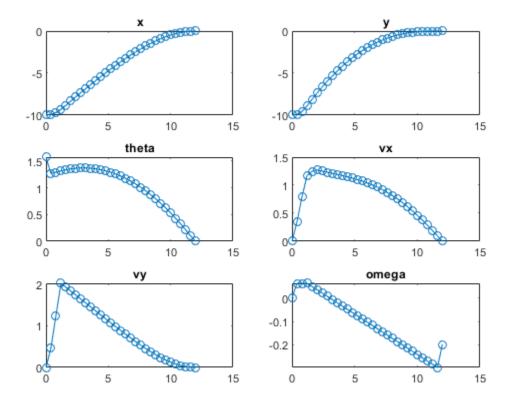

```
[\sim, \sim, info] = nlmpcmove(nlobj, x0, u0);
```

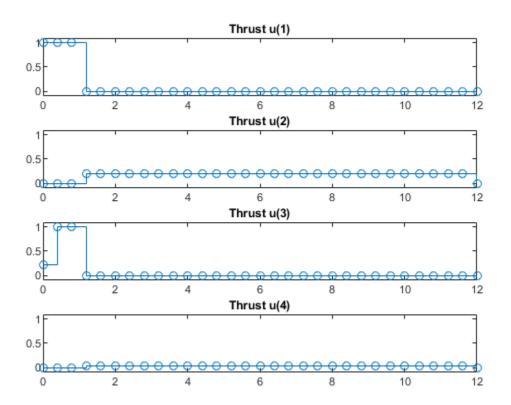

Slack variable unused or zero-weighted in your custom cost function. All constraints was

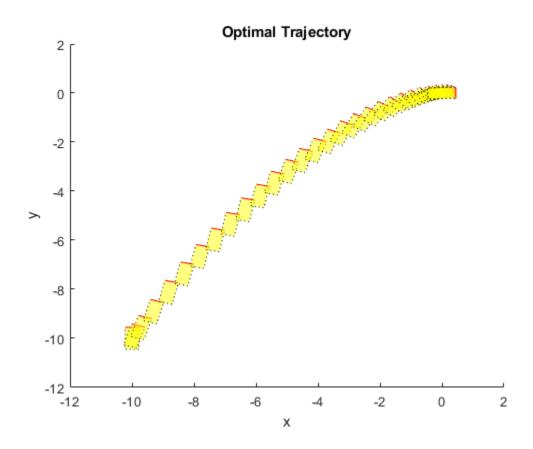

Plot the optimal trajectories.

#### FlyingRobotPlotPlanning(info)

Optimal fuel consumption = 4.712383

#### Simulate Closed-Loop Control using Nonlinear MPC Controller

Create a nonlinear MPC controller with four states, two outputs, and one input.

$$nlobj = nlmpc(4,2,1);$$

In standard cost function, zero weights are applied by default to one or more OVs became

Specify the sample time and horizons of the controller.

```
nlobj.PredictionHorizon = 10;
nlobj.ControlHorizon = 5;
```

Specify the state function for the controller, which is in the file pendulumDT0.m. This discrete-time model integrates the continuous time model defined in pendulumCT0.m using a multistep forward Euler method.

```
nlobj.Model.StateFcn = "pendulumDTO";
nlobj.Model.IsContinuousTime = false;
```

The prediction model uses an optional parameter, Ts, to represent the sample time. Specify the number of parameters.

```
nlobj.Model.NumberOfParameters = 1;
```

Specify the output function of the model, passing the sample time parameter as an input argument.

```
nlobj.Model.OutputFcn = @(x,u,Ts) [x(1); x(3)];
```

Define standard constraints for the controller.

```
nlobj.Weights.OutputVariables = [3 3];
nlobj.Weights.ManipulatedVariablesRate = 0.1;
nlobj.OV(1).Min = -10;
nlobj.OV(1).Max = 10;
nlobj.MV.Min = -100;
nlobj.MV.Max = 100;
```

Validate the prediction model functions.

```
x0 = [0.1;0.2;-pi/2;0.3];
u0 = 0.4;
validateFcns(nlobj, x0, u0, [], {Ts});
Model.StateFcn is OK.
Model.OutputFcn is OK.
Analysis of user-provided model, cost, and constraint functions complete.
```

Only two of the plant states are measurable. Therefore, create an extended Kalman filter for estimating the four plant states. Its state transition function is defined in pendulumStateFcn.m and its measurement function is defined in pendulumMeasurementFcn.m.

```
EKF = extendedKalmanFilter(@pendulumStateFcn,@pendulumMeasurementFcn);
```

Define initial conditions for the simulation, initialize the extended Kalman filter state, and specify a zero initial manipulated variable value.

```
x = [0;0;-pi;0];
y = [x(1);x(3)];
EKF.State = x;
mv = 0;
```

Specify the output reference value.

```
yref = [0 \ 0];
```

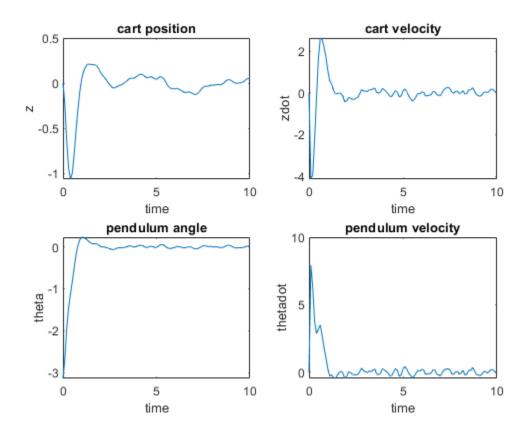

Create an nlmpcmoveopt object, and specify the sample time parameter.

```
nloptions = nlmpcmoveopt;
nloptions.Parameters = {Ts};
```

Run the simulation for 10 seconds. During each control interval:

- **1** Correct the previous prediction using the current measurement.
- 2 Compute optimal control moves using nlmpcmoveopt. This function returns the computed optimal sequences in nloptions. Passing the updated options object to nlmpcmoveopt in the next control interval provides initial guesses for the optimal sequences.
- **3** Predict the model states.
- **4** Apply the first computed optimal control move to the plant, updating the plant states.
- **5** Generate sensor data with white noise.
- **6** Save the plant states.

```
% Save plant states
    xHistory = [xHistory x];
end
Plot the resulting state trajectories.

#### Introduced in R2018b

# nImpcmove

Compute optimal control action for nonlinear MPC controller

# **Syntax**

```
mv = nlmpcmove(nlmpcobj,x,lastmv)
mv = nlmpcmove(nlmpcobj,x,lastmv,ref)
mv = nlmpcmove(nlmpcobj,x,lastmv,ref,md)
mv = nlmpcmove(nlmpcobj,x,lastmv,ref,md,options)
[mv,opt] = nlmpcmove(____)
[mv,opt,info] = nlmpcmove(____)
```

# **Description**

mv = nlmpcmove(nlmpcobj,x,lastmv) computes the optimal manipulated variable control action for the current time. To simulate closed-loop nonlinear MPC control, call nlmpcmove repeatedly.

mv = nlmpcmove(nlmpcobj,x,lastmv,ref) specifies reference values for the plant outputs. If you do not specify reference values, nlmpcmove uses zeros by default.

mv = nlmpcmove(nlmpcobj,x,lastmv,ref,md) specifies run-time measured disturbance values. If your controller has measured disturbances, you must specify md.

mv = nlmpcmove(nlmpcobj,x,lastmv,ref,md,options) specifies additional runtime options for computing optimal control moves. Using options, you can specify initial guesses for state and manipulated variable trajectories, update tuning weights at constraints, or modify prediction model parameters.

[mv,opt] = nlmpcmove(\_\_\_\_) returns an nlmpcmoveopt object that contains initial guesses for the state and manipulated trajectories to be used in the next control interval.

[mv,opt,info] = nlmpcmove(\_\_\_\_) returns additional solution details, including the final optimization cost function value and the optimal manipulated variable, state, and output trajectories.

# **Examples**

#### Plan Optimal Trajectory Using Nonlinear MPC

nlobj.MV(ct).Max = 1;

Create nonlinear MPC controller with six states, six outputs, and four inputs.

```
nx = 6:
ny = 6;
nu = 4;
nlobj = nlmpc(nx,ny,nu);
In standard cost function, zero weights are applied by default to one or more OVs becau
Specify the controller sample time and horizons.
Ts = 0.4;
p = 30;
c = 4;
nlobj.Ts = Ts;
nlobj.PredictionHorizon = p;
nlobj.ControlHorizon = c;
Specify the prediction model state function and the Jacobian of the state function. For this
example, use a model of a flying robot.
nlobj.Model.StateFcn = "FlyingRobotStateFcn";
nlobj.Jacobian.StateFcn = "FlyingRobotStateJacobianFcn";
Specify a custom cost function for the controller that replaces the standard cost function.
nlobj.Optimization.CustomCostFcn = @(X,U,e,data) Ts*sum(sum(U(1:p,:)));
nlobj.Optimization.ReplaceStandardCost = true;
Specify a custom constraint function for the controller.
nlobj.Optimization.CustomEqConFcn = @(X,U,data) X(end,:)';
Specify linear constraints on the manipulated variables.
for ct = 1:nu
    nlobj.MV(ct).Min = 0;
```

end

Validate the prediction model and custom functions at the initial states (x0) and initial inputs (u0) of the robot.

```
x0 = [-10;-10;pi/2;0;0;0];
u0 = zeros(nu,1);
validateFcns(nlobj,x0,u0);

Model.StateFcn is OK.
Jacobian.StateFcn is OK.
No output function specified. Assuming "y = x" in the prediction model.
Optimization.CustomCostFcn is OK.
Optimization.CustomEqConFcn is OK.
Analysis of user-provided model, cost, and constraint functions complete.
```

Compute the optimal state and manipulated variable trajectories, which are returned in the info.

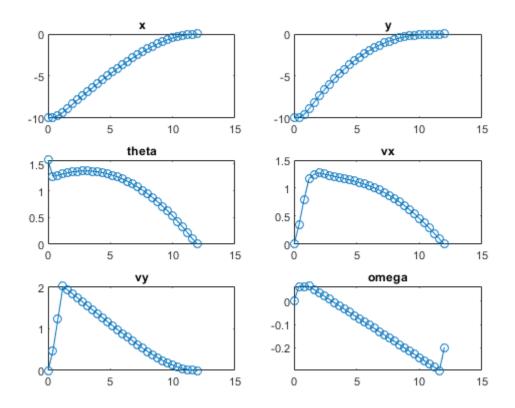

```
[\sim, \sim, info] = nlmpcmove(nlobj, x0, u0);
```

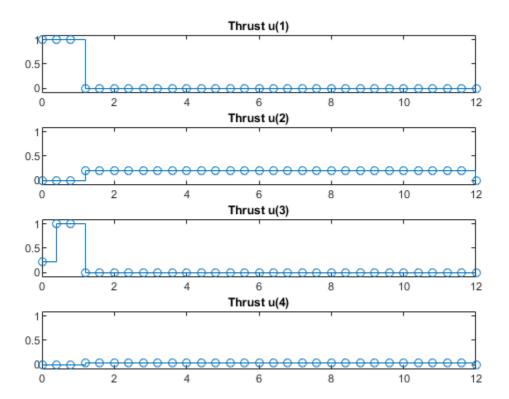

Slack variable unused or zero-weighted in your custom cost function. All constraints w

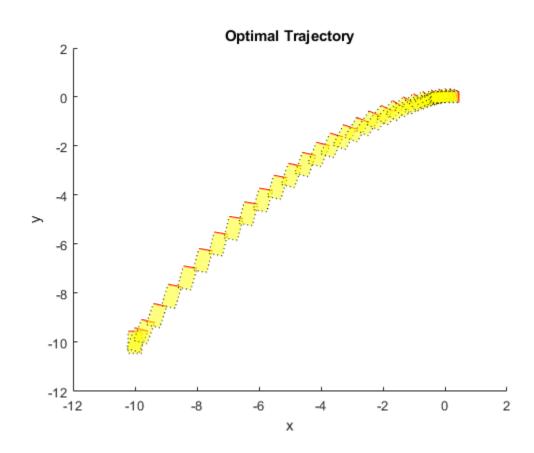

Plot the optimal trajectories.

#### FlyingRobotPlotPlanning(info)

```
Optimal fuel consumption = 4.712383
```

#### Simulate Closed-Loop Control using Nonlinear MPC Controller

Create a nonlinear MPC controller with four states, two outputs, and one input.

$$nlobj = nlmpc(4,2,1);$$

In standard cost function, zero weights are applied by default to one or more OVs became

Specify the sample time and horizons of the controller.

```
nlobj.PredictionHorizon = 10;
nlobj.ControlHorizon = 5;
```

Specify the state function for the controller, which is in the file pendulumDT0.m. This discrete-time model integrates the continuous time model defined in pendulumCT0.m using a multistep forward Euler method.

```
nlobj.Model.StateFcn = "pendulumDTO";
nlobj.Model.IsContinuousTime = false;
```

The prediction model uses an optional parameter, Ts, to represent the sample time. Specify the number of parameters.

```
nlobj.Model.NumberOfParameters = 1;
```

Specify the output function of the model, passing the sample time parameter as an input argument.

```
nlobj.Model.OutputFcn = @(x,u,Ts) [x(1); x(3)];
```

Define standard constraints for the controller.

```
nlobj.Weights.OutputVariables = [3 3];
nlobj.Weights.ManipulatedVariablesRate = 0.1;
nlobj.OV(1).Min = -10;
nlobj.OV(1).Max = 10;
nlobj.MV.Min = -100;
nlobj.MV.Max = 100;
```

Validate the prediction model functions.

```
x0 = [0.1;0.2;-pi/2;0.3];
u0 = 0.4;
validateFcns(nlobj, x0, u0, [], {Ts});
Model.StateFcn is OK.
Model.OutputFcn is OK.
Analysis of user-provided model, cost, and constraint functions complete.
```

Only two of the plant states are measurable. Therefore, create an extended Kalman filter for estimating the four plant states. Its state transition function is defined in pendulumStateFcn.m and its measurement function is defined in pendulumMeasurementFcn.m.

```
EKF = extendedKalmanFilter(@pendulumStateFcn,@pendulumMeasurementFcn);
```

Define initial conditions for the simulation, initialize the extended Kalman filter state, and specify a zero initial manipulated variable value.

```
x = [0;0;-pi;0];
y = [x(1);x(3)];
EKF.State = x;
mv = 0;
```

Specify the output reference value.

```
yref = [0 \ 0];
```

Create an nlmpcmoveopt object, and specify the sample time parameter.

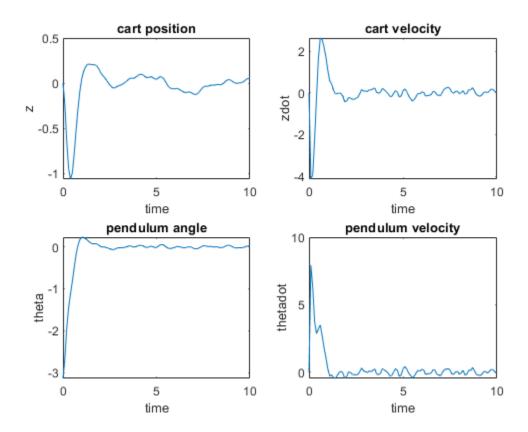

```
nloptions = nlmpcmoveopt;
nloptions.Parameters = {Ts};
```

Run the simulation for 10 seconds. During each control interval:

- **1** Correct the previous prediction using the current measurement.
- 2 Compute optimal control moves using nlmpcmoveopt. This function returns the computed optimal sequences in nloptions. Passing the updated options object to nlmpcmoveopt in the next control interval provides initial guesses for the optimal sequences.
- **3** Predict the model states.
- 4 Apply the first computed optimal control move to the plant, updating the plant states.
- **5** Generate sensor data with white noise.
- **6** Save the plant states.

```
Duration = 10;
xHistory = x;
for ct = 1:(Duration/Ts)
    % Correct previous prediction
    xk = correct(EKF,y);
    % Compute optimal control moves
    [mv,nloptions] = nlmpcmove(nlobj,xk,mv,yref,[],nloptions);
    % Predict prediction model states for the next iteration
    predict(EKF,[mv; Ts]);
    % Implement first optimal control move
    x = pendulumDTO(x,mv,Ts);
    % Generate sensor data
    y = x([1 3]) + randn(2,1)*0.01;
```

```
% Save plant states
    xHistory = [xHistory x];
end
Plot the resulting state trajectories.

# **Input Arguments**

#### nlmpcobj — Nonlinear MPC controller

nlmpc object

Nonlinear MPC controller, specified as an  ${\tt nlmpc}$  object.

#### x — Current prediction model states

vector

Current prediction model states, specified as a vector of length  $N_x$ , where  $N_x$  is the number of prediction model states. Since the nonlinear MPC controller does not perform

state estimation, you must either measure or estimate the current prediction model states at each control interval.

# lastmv — Control signals used in plant at previous control interval vector

Control signals used in plant at previous control interval, specified as a vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

**Note** Specify last\_mv as the MV signals applied to the plant in the previous control interval. Typically, these MV signals are the values generated by the controller, though this is not always the case. For example, if your controller is offline and running in tracking mode; that is, the controller output is not driving the plant, then feeding the actual control signal to last\_mv can help achieve bumpless transfer when the controller is switched back online.

#### ref - Plant output reference values

[] (default) | row vector | array

Plant output reference values, specified as a row vector of length  $N_y$  or an array with  $N_y$  columns, where  $N_y$  is the number of output variables. If you do not specify ref, the default reference values are zero.

To use the same reference values across the prediction horizon, specify a row vector.

To vary the reference values over the prediction horizon from time k+1 to time k+p, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the reference values for one prediction horizon step. If you specify fewer than p rows, the values in the final row are used for the remaining steps of the prediction horizon.

#### md — Measured disturbance values

[] (default) | row vector | array

Measured disturbance values, specified as a row vector of length  $N_{md}$  or an array with  $N_{md}$  columns, where  $N_{md}$  is the number of measured disturbances. If your controller has measured disturbances, you must specify md. If your controller has no measured disturbances, specify md as [].

To use the same disturbance values across the prediction horizon, specify a row vector.

To vary the disturbance values over the prediction horizon from time k to time k+p, specify an array with up to p+1 rows. Here, k is the current time and p is the prediction horizon. Each row contains the disturbance values for one prediction horizon step. If you specify fewer than p rows, the values in the final row are used for the remaining steps of the prediction horizon.

#### options — Run-time options

nlmpcmoveopt object

Run-time options, specified as an nlmpcmoveopt object. Using these options, you can:

- · Tune controller weights
- · Update linear constraints
- Set manipulated variable targets
- Specify prediction model parameters
- Provide initial guesses for state and manipulated variable trajectories

These options apply to only the current nlmpcmove time instant.

To improve solver efficiency, it is best practice to specify initial guesses for the state and manipulated variable trajectories.

# **Output Arguments**

#### mv — Optimal manipulated variable control action

column vector

Optimal manipulated variable control action, returned as a column vector of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

If the solver converges to a local optimum solution (info.ExitFlag is positive), then mv contains the optimal solution.

If the solver reaches the maximum number of iterations without finding an optimal solution (info.ExitFlag = 0) and:

• nlmpcobj.Optimization.UseSuboptimalSolution is true, then mv contains the suboptimal solution

 nlmpcobj.Optimization.UseSuboptimalSolution is false, then mv contains lastmv

If the solver fails (info.ExitFlag is negative), then mv contains lastmv.

#### opt — Run-time options with initial guesses

nlmpcmoveopt object

Run-time options with initial guesses for the state and manipulated variable trajectories to be used in the next control interval, returned as an nlmpcmoveopt object. Any run-time options that you specified using options, such as weights, constraints, or parameters, are copied to opt.

The initial guesses for the states (opt.X0) and manipulated variables (opt.MV0) are the optimal trajectories computed by nlmpcmove and correspond to the last p-1 rows of info.Xopt and info.MVopt, respectively.

To use these initial guesses in the next control interval, specify opt as the options input argument to nlmpcmove.

#### info — Solution details

structure

Solution details, returned as a structure with the following fields.

# MVopt — Optimal manipulated variable sequence

array

Optimal manipulated variable sequence, returned as a (p+1)-by- $N_{mv}$  array, where p is the prediction horizon and  $N_{mv}$  is the number of manipulated variables.

MVopt(i,:) contains the calculated optimal manipulated variable values at time k+i-1, for i = 1, ..., p, where k is the current time. MVopt(1,:) contains the same manipulated variable values as output argument mv. Since the controller does not calculate optimal control moves at time k+p, MVopt(p+1,:) is equal to MVopt(p,:).

# **Xopt — Optimal prediction model state sequence** array

Optimal prediction model state sequence, returned as a (p+1)-by- $N_x$  array, where p is the prediction horizon and  $N_x$  is the number of states in the prediction model.

Xopt(i,:) contains the calculated state values at time k+i-1, for  $i=2,\ldots,p+1$ , where k is the current time. Xopt(1,:) is the same as the current states in x.

#### Yopt — Optimal output variable sequence

array

Optimal output variable sequence, returned as a (p+1)-by- $N_y$  array, where p is the prediction horizon and  $N_y$  is the number of outputs.

Yopt(i,:) contains the calculated output values at time k+i-1, for  $i=2,\ldots,p+1$ , where k is the current time. Yopt(1,:) is computed based on the current states in x and the current measured disturbances in md, if any.

#### Topt — Prediction horizon time sequence

column vector

Prediction horizon time sequence, returned as a column vector of length p+1, p is the prediction horizon. Topt contains the time sequence from time k to time k+p, where k is the current time.

Topt(1) = 0 represents the current time. Subsequent time steps Topt(i) are Ts\*(i-1), where Ts = nlmpcobj.Ts is the controller sample time.

Use Topt when plotting Uopt, Xopt, or Yopt sequences.

#### Slack — Slack variable

nonnegative scalar

Slack variable,  $\varepsilon$ , used in constraint softening, returned as a nonnegative scalar value.

- $\varepsilon = 0$  All soft constraints are satisfied over the entire prediction horizon.
- $\epsilon > 0$  At least one soft constraint is violated. When more than one constraint is violated,  $\epsilon$  represents the worst-case soft constraint violation (scaled by your ECR values for each constraint).

#### ExitFlag — Optimization exit code

integer

Optimization exit code, returned as one of the following:

• Positive Integer — Solver converged to an optimal solution

- 0 Maximum number of iterations reached without converging to an optimal solution
- Negative integer Solver failed

#### **Cost** — **Objective function cost**

nonnegative scalar

Objective function cost, returned as a nonnegative scalar value. The cost quantifies the degree to which the controller has achieved its objectives.

The cost value is only meaningful when ExitFlag is nonnegative.

# **Tips**

During closed-loop simulations, it is best practice to *warm start* the nonlinear solver by using the predicted state and manipulated variable trajectories from the previous control interval as the initial guesses for the current control interval. To use these trajectories as initial guesses:

- 1 Return the opt output argument when calling nlmpcmove. This nlmpcmoveopt object contains any run-time options you specified in the previous call to nlmpcmove, along with the initial guesses for the state (opt.X0) and manipulated variable (opt.MV0) trajectories.
- Pass this object in as the options input argument to nlmpcmove for the next control interval.

These steps are a best practice, even if you do not specify any other run-time options.

#### Introduced in R2018b

# nImpcmoveopt

Option set for nlmpcmove function

# **Description**

To specify options for the nlmpcmove function, use an nlmpcmoveopt option set.

Using this option set, you can specify run-time values for a subset of controller properties, such as tuning weights and constraints. If you do not specify a value for one of the nlmpcmoveopt properties, the corresponding value defined in the nlmpc controller object is used instead.

#### Creation

# **Syntax**

options = nlmpcmoveopt

#### **Description**

options = nlmpcmoveopt creates a default set of options for the nlmpcmove function.
To modify the property values, use dot notation.

# **Properties**

#### OutputWeights — Output variable tuning weights

[] (default) | row vector | array

Output variable tuning weights that replace the Weights.OutputVariables property of the controller at run time, specified as a row vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_y$ , where  $N_y$  is the number of output variables.

To vary the tuning weights over the prediction horizon from time k+1 to time k+p, specify an array with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the output variable tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

#### MVWeights — Manipulated variable tuning weights

[] (default) | row vector | array

Manipulated variable tuning weights that replace the Weights.ManipulatedVariables property of the controller at run time, specified as a row vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables.

To vary the tuning weights over the prediction horizon from time k to time k+p-1, specify an array with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the manipulated variable tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

#### MVRateWeights — Manipulated variable rate tuning weights

[] (default) | row vector | array

Manipulated variable rate tuning weights that replace the Weights.ManipulatedVariablesRate property of the controller at run time, specified as a row vector or array of nonnegative values.

To use the same weights across the prediction horizon, specify a row vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is the number of manipulated variables.

To vary the tuning weights over the prediction horizon from time k to time k+p-1, specify an array with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the manipulated variable rate tuning weights for one prediction horizon step. If you specify fewer than p rows, the weights in the final row are used for the remaining steps of the prediction horizon.

#### ECR Weight — Slack variable tuning weight

[] (default) | positive scalar

Slack variable tuning weight that replaces the Weights. ECR property of the controller at run time, specified as a positive scalar.

#### OutputMin — Output variable lower bounds

```
[] (default) | row vector | array
```

Output variable lower bounds, specified as a row vector of length  $N_y$  or an array with  $N_y$  columns, where  $N_y$  is the number of output variables. OutputMin(:,i) replaces the OutputVariables(i).Min property of the controller at run time.

To use the same bounds across the prediction horizon, specify a row vector.

To vary the bounds over the prediction horizon from time k+1 to time k+p, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the final bounds are used for the remaining steps of the prediction horizon.

#### **OutputMax** — **Output variable upper bounds**

```
[] (default) | row vector | array
```

Output variable upper bounds, specified as a row vector of length  $N_y$  or an array with  $N_y$  columns, where  $N_y$  is the number of output variables. OutputMax(:,i) replaces the OutputVariables(i).Max property of the controller at run time.

To use the same bounds across the prediction horizon, specify a row vector.

To vary the bounds over the prediction horizon from time k+1 to time k+p, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the final bounds are used for the remaining steps of the prediction horizon.

#### MVMin — Manipulated variable lower bounds

```
[] (default) | row vector | array
```

Manipulated variable lower bounds, specified as a row vector of length  $N_{m\nu}$  or an array with  $N_{m\nu}$  columns, where  $N_{m\nu}$  is the number of manipulated variables. MVMin(:,i) replaces the ManipulatedVariables(i). Min property of the controller at run time.

To use the same bounds across the prediction horizon, specify a row vector.

To vary the bounds over the prediction horizon from time k to time k+p-1, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each

row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the final bounds are used for the remaining steps of the prediction horizon.

#### MVMax — Manipulated variable upper bounds

[] (default) | row vector | array

Manipulated variable upper bounds, specified as a row vector of length  $N_{m\nu}$  or an array with  $N_{m\nu}$  columns, where  $N_{m\nu}$  is the number of manipulated variables. MVMax(:,i) replaces the ManipulatedVariables(i).Max property of the controller at run time.

To use the same bounds across the prediction horizon, specify a row vector.

To vary the bounds over the prediction horizon from time k to time k+p-1, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the final bounds are used for the remaining steps of the prediction horizon.

#### MVRateMin — Manipulated variable rate lower bounds

[] (default) | row vector | array

Manipulated variable rate lower bounds, specified as a row vector of length  $N_{mv}$  or an array with  $N_{mv}$  columns, where  $N_{mv}$  is the number of manipulated variables. MVRateMin(:,i) replaces the ManipulatedVariables(i).RateMin property of the controller at run time. MVRateMin bounds must be nonpositive.

To use the same bounds across the prediction horizon, specify a row vector.

To vary the bounds over the prediction horizon from time k to time k+p-1, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the final bounds are used for the remaining steps of the prediction horizon.

#### MVRateMax — Manipulated variable rate upper bounds

[] (default) | row vector | array

Manipulated variable rate upper bounds, specified as a row vector of length  $N_{mv}$  or an array with  $N_{mv}$  columns, where  $N_{mv}$  is the number of manipulated variables. MVRateMax(:,i) replaces the ManipulatedVariables(i).RateMax property of the controller at run time. MVRateMax bounds must be nonnegative.

To use the same bounds across the prediction horizon, specify a row vector.

To vary the bounds over the prediction horizon from time k to time k+p-1, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the final bounds are used for the remaining steps of the prediction horizon.

#### StateMin — State lower bounds

```
[] (default) | row vector | array
```

State lower bounds, specified as a row vector of length  $N_x$  or an array with  $N_x$  columns, where  $N_x$  is the number of states. StateMin(:,i) replaces the States(i).Min property of the controller at run time.

To use the same bounds across the prediction horizon, specify a row vector.

To vary the bounds over the prediction horizon from time k+1 to time k+p, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the final bounds are used for the remaining steps of the prediction horizon.

#### StateMax — State upper bounds

```
[] (default) | row vector | array
```

State upper bounds, specified as a row vector of length  $N_x$  or an array with  $N_x$  columns, where  $N_x$  is the number of states. StateMax(:,i) replaces the States(i).Max property of the controller at run time.

To use the same bounds across the prediction horizon, specify a row vector.

To vary the bounds over the prediction horizon from time k+1 to time k+p, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the final bounds are used for the remaining steps of the prediction horizon.

#### MVTarget — Manipulated variable targets

```
[] (default) | row vector | array
```

Manipulated variable targets, specified as a row vector of length  $N_{mv}$  or an array with  $N_{mv}$  columns, where  $N_{mv}$  is the number of manipulated variables.

To use the same manipulated variable targets across the prediction horizon, specify a row vector.

To vary the targets over the prediction horizon (previewing) from time k to time k+p-1, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the targets for one prediction horizon step. If you specify fewer than p rows, the final targets are used for the remaining steps of the prediction horizon.

#### Parameters — Parameter values

{} (default) | cell vector

Parameter values used by the prediction model, custom cost function, and custom constraints, specified as a cell vector with length equal to the Model.NumberOfParameters property of the controller. If the controller has no parameters, then Parameters must be {}.

The controller, nlmpcobj, passes these parameters to the:

- Model functions in nlmpcobj.Model (StateFcn and OutputFcn)
- Cost function nlmpcobj.Optimization.CustomCostFcn
- Constraint functions in nlmpcobj.Optimization (CustomEqConFcn and CustomIneqConFcn)
- Jacobian functions in nlmpcobj.Jacobian

The order of the parameters must match the order defined for these functions.

#### X0 — Initial guesses for the optimal state solutions

[] (default) | vector | array

Initial guesses for the optimal state solutions, specified as a row vector of length  $N_x$  or an array with  $N_x$  columns, where  $N_x$  is the number of states.

To use the same initial guesses across the prediction horizon, specify a row vector.

To vary the initial guesses over the prediction horizon from time k+1 to time k+p, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the initial guesses for one prediction horizon step. If you specify fewer than p rows, the final guesses are used for the remaining steps of the prediction horizon.

If X0 is [], the default initial guesses are the current states of the prediction model (x input argument to nlmpcmove).

In general, during closed-loop simulation, you do not specify X0 yourself. Instead, when calling nlmpcmove, return the opt output argument, which is an nlmpcmoveopt object.

opt.X0 contains the calculated optimal state trajectories as initial guesses. You can then pass opt in as the options input argument to nlmpcmove for the next control interval. These steps are a best practice, even if you do not specify any other run-time options.

#### MV0 — Initial guesses for the optimal manipulated variable solutions

[] (default) | vector | array

Initial guesses for the optimal manipulated variable solutions, specified as a row vector of length  $N_{m\nu}$  or an array with  $N_{m\nu}$  columns, where  $N_{m\nu}$  is the number of manipulated variables.

To use the same initial guesses across the prediction horizon, specify a row vector.

To vary the initial guesses over the prediction horizon from time k to time k+p-1, specify an array with up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the initial guesses for one prediction horizon step. If you specify fewer than p rows, the final guesses are used for the remaining steps of the prediction horizon.

If MVO is [], the default initial guesses are the control signals used in the plant at the previous control interval (lastmv input argument to nlmpcmove).

In general, during closed-loop simulation, you do not specify MVO yourself. Instead, when calling nlmpcmove, return the opt output argument, which is an nlmpcmoveopt object. opt.MVO contains the calculated optimal manipulated variable trajectories as initial guesses. You can then pass opt in as the options input argument to nlmpcmove for the next control interval. These steps are a best practice, even if you do not specify any other run-time options.

#### Slack0 — Initial guess for the slack variable at the solution

[] (default) | nonnegative scalar

Initial guess for the slack variable at the solution, specified as a nonnegative scalar. If Slack0 is [], the default initial guess is 0.

In general, during closed-loop simulation, you do not specify Slack0 yourself. Instead, when calling nlmpcmove, return the opt output argument, which is an nlmpcmoveopt object. opt.Slack contains the calculated slack variable as an initial guess. You can then pass opt in as the options input argument to nlmpcmove for the next control interval. These steps are a best practice, even if you do not specify any other run-time options.

# **Object Functions**

nlmpcmove Compute optimal control action for nonlinear MPC controller

# **Examples**

#### Specify Run-Time Parameters for Nonlinear MPC

Create a default nlmpcmoveopt option set.

```
options = nlmpcmoveopt;
```

Specify the run-time values for the controller prediction model parameters. For this example, assume that the controller has the following optional parameters, which are input arguments to all the prediction model functions and custom functions of the controller.

- Sample time of the model, specified as a single numeric value. Specify a value of 0.25.
- Gain factors, specified as a two-element row vector. Specify a value of [0.7 0.35].

The order in which you specify the parameters must match the order specified in the custom function argument lists. Also, the dimensions of the parameters must match the dimensions expected by the custom functions.

```
options.Parameters = \{0.25, [0.7 \ 0.35]\};
```

To use these parameters when computing optional control actions for a nonlinear MPC controller, pass options to the nlmpcmove function.

# plot

Plot responses generated by MPC simulations

# **Syntax**

plot(MPCobj,t,y,r,u,v,d)

# **Description**

plot(MPCobj,t,y,r,u,v,d) plots the results of a simulation based on the MPC object MPCobj.t is a vector of length Nt of time values, y is a matrix of output responses of size [Nt,Ny] where Ny is the number of outputs, r is a matrix of setpoints and has the same size as y, u is a matrix of manipulated variable inputs of size [Nt,Nu] where Nu is the number of manipulated variables, v is a matrix of measured disturbance inputs of size [Nt,Nv] where Nv is the number of measured disturbance inputs, and d is a matrix of unmeasured disturbance inputs of size [Nt,Nd] where Nd is the number of unmeasured disturbances input.

mpc|sim

Introduced before R2006a

# plotSection

Visualize explicit MPC control law as 2-D sectional plot

# **Syntax**

```
plotsection(EMPCobj,plotParams)
```

# **Description**

plotsection(EMPCobj, plotParams) displays a 2-D sectional plot of the piecewise affine regions used by an explicit MPC controller. All but two of the control law's free parameters are fixed, as specified by plotParams. The two remaining variables form the plot axes. By default, the EMPCobj. Range property sets the bounds for these axes.

# **Examples**

#### Specify Fixed Parameters for 2-D Plot of Explicit Control Law

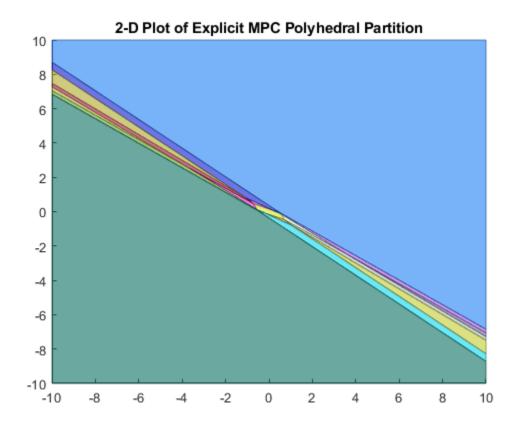

Define a double integrator plant model and create a traditional implicit MPC controller for this plant. Constrain the manipulated variable to have an absolute value less than 1.

```
plant = tf(1,[1 \ 0 \ 0]);
MPCobj = mpc(plant, 0.1, 10, 3);
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defail
-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
MPCobj.MV = struct('Min', -1, 'Max', 1);
```

Define the parameter bounds for generating an explicit MPC controller.

```
range = generateExplicitRange(MPCobj);
-->Converting the "Model.Plant" property of "mpc" object to state-space.
-->Converting model to discrete time.
```

```
Assuming no disturbance added to measured output channel #1.
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ear
range.State.Min(:) = [-10; -10];
range.State.Max(:) = [10;10];
range.Reference.Min(:) = -2;
range.Reference.Max(:) = 2;
range.ManipulatedVariable.Min(:) = -1.1;
range.ManipulatedVariable.Max(:) = 1.1;
Create an explicit MPC controller.
EMPCobj = generateExplicitMPC(MPCobj,range);
Regions found / unexplored:
                                               (-)
                                    19/
Create a default plot parameter structure, which specifies that all of the controller
parameters are fixed at their nominal values for plotting.
plotParams = generatePlotParameters(EMPCobj);
Allow the controller states to vary when creating a plot.
plotParams.State.Index = [];
plotParams.State.Value = [];
Fix the manipulated variable and reference signal to 0 for plotting.
plotParams.ManipulatedVariable.Index(1) = 1;
plotParams.ManipulatedVariable.Value(1) = 0;
plotParams.Reference.Index(1) = 1;
plotParams.Reference.Value(1) = 0;
Generate the 2-D section plot for the explicit MPC controller.
plotSection(EMPCobj,plotParams)
```

# **Input Arguments**

#### **EMPCobj** — **Explicit MPC** controller

explicit MPC controller object

Explicit MPC controller for which you want to create a 2-D sectional plot, specified as an Explicit MPC controller object. Use generateExplicitMPC to create an explicit MPC controller.

#### plotParams — Parameters for sectional plot

structure

Parameters for sectional plot of explicit MPC control law, specified as a structure. Use generatePlotParameters to create an initial structure in which all the parameters of the controller are fixed at their nominal values. Then, modify this structure as necessary before invoking plotSection. See generatePlotParameters for more information.

#### See Also

generateExplicitMPC|generatePlotParameters

Introduced in R2014b

#### review

Examine MPC controller for design errors and stability problems at run time

# **Syntax**

```
review(mpcobj)
results = review(mpcobj)
```

# **Description**

review(mpcobj) checks for potential design issues in the model predictive controller, mpcobj, and generates a testing report. The testing report provides information about each test, highlights test warnings and failures, and suggests possible solutions. For more information on the tests performed by the review function, see "Algorithms" on page 2-245.

results = review(mpcobj) returns the test results and suppresses the testing report.

# **Examples**

#### **Examine MPC Controller for Design Errors or Stability Problems**

Define a plant model, and create an MPC controller.

```
plant = tf(1, [10 1]);
Ts = 2;
MPCobj = mpc(plant,Ts);

-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Set hard upper and lower bounds on the manipulated variable and its rate of change.

```
MV = MPCobj.MV;

MV.Min = -2;

MV.Max = 2;

MV.RateMin = -4;

MV.RateMax = 4;

MPCobj.MV = MV;
```

Review the controller design. The review function generates and opens a report in the Web Browser window.

#### review(MPCobj)

```
-->Converting the "Model.Plant" property of "mpc" object to state-space.
-->Converting model to discrete time.
-->Assuming output disturbance added to measured output channel #1 is integrated white
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each
```

# Design Review for Model Predictive Controller "MPCobj"

#### Summary of Performed Tests

Test	Status
MPC Object Creation	Pass
<b>QP</b> Hessian Matrix Validity	Pass
Closed-Loop Internal Stability	Pass
Closed-Loop Nominal Stability	Pass
Closed-Loop Steady-State Gains	Pass
Hard MV Constraints	Warning
Other Hard Constraints	Pass
Soft Constraints	Pass
Memory Size for MPC Data	Pass

review flags a potential constraint conflict that could result if this controller was used to control a real process. To view details about the warning, click **Hard MV Constraints**.

#### Hard MV Constraints

The controller should always satisfy hard bounds on a manipulated variable OR its rate-of-change. If you specify both constraint types simultaneously, however, they might conflict during real-time use.

For example, if an event pushes an MV outside a specified hard bound and the hard MV rate bounds are too small, the resulting QP will be *infeasible*.

Avoid such conflicts by specifying hard MV bounds *OR* hard MV rate bounds, but not both. Or if you want to specify both, soften the lower-priority constraint by setting its ECR to a value greater than zero.

Warning: your constraint definitions may conflict. The following table lists potential conflicts for each MV. The tabular entries show the location of each conflict in the prediction horizon and the type of conflict.

MV name	Horizon k	Conflict Type
MV1	1	Min & RateMax
MV1	1	Max & RateMin

plant = rss(3,1,1);

### **Obtain Test Results and Suppress Testing Report**

Define a plant model, and create an MPC controller.

```
plant.D = 0;
Ts = 0.1;
MPCobj = mpc(plant,Ts);

-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defails to the "Weights.ManipulatedVariables of "mpc" object is empty. Assuming defails to the "Weights.ManipulatedVariables of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming of "mpc" object is empty.
```

-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1

Specify constraints for the controller.

```
MV = MPCobj.MV;

MV.Min = -2;

MV.Max = 2;

MV.RateMin = -4;

MV.RateMax = 4;

MPCobj.MV = MV;
```

Review the controller design, and suppress the testing report.

results = review(MPCobj)

All of the tests passed, except for the the hard MV constraints test, which generated a warning.

### **Obtain Test Results for Multiple Controllers**

Create and review designs for gain-scheduled model predictive controllers for two plant operating conditions.

Define the model parameters.

```
M1 = 1;

M2 = 5;

k1 = 1;

k2 = 0.1;

b1 = 0.3;

b2 = 0.8;
```

```
yeq1 = 10;
yeq2 = -10;
Create plant models for each of the two operating conditions.
A1 = [0 1; -k1/M1 -b1/M1];
B1 = [0 \ 0; -1/M1 \ k1*yeq1/M1];
C1 = [1 \ 0];
D1 = [0 \ 0];
sys1 = ss(A1,B1,C1,D1);
sys1 = setmpcsignals(sys1, 'MV',1, 'MD',2);
A2 = [0 1; -(k1+k2)/(M1+M2) -(b1+b2)/(M1+M2)];
B2 = [0 \ 0; -1/(M1+M2) \ (k1*veq1+k2*veq2)/(M1+M2)];
C2 = [1 \ 0]:
D2 = [0 \ 0];
sys2 = ss(A2,B2,C2,D2);
sys2 = setmpcsignals(sys2,'MV',1,'MD',2);
Design an MPC controller for each operating condition.
Ts = 0.2;
p = 6;
m = 2;
MPC1 = mpc(sys1, Ts, p, m);
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defail
-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
MPC2 = mpc(sys2, Ts, p, m);
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defail
-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
controllers = {MPC1,MPC2};
Review the controller designs, and store the test result structures.
for i = 1:2
    results(i) = review(controllers{i});
end
-->Converting model to discrete time.
-->Assuming output disturbance added to measured output channel #1 is integrated white
```

- -->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ear-->Converting model to discrete time.
- -->Assuming output disturbance added to measured output channel #1 is integrated white -->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each

## **Input Arguments**

#### mpcobj — MPC controller

mpc object

MPC controller object, specified as an mpc object.

# **Output Arguments**

#### results — Test results

structure

Test results, returned as a structure with the following fields:

- ObjectCreation MPC object creation test
- HessianMatrix QP Hessian matrix validity test
- InternalStability Internal stability test
- $\bullet \quad {\tt NominalStability} {\tt Nominal} \ {\tt stability} \ {\tt test}$
- SteadyState Closed-loop steady-state gains test
- HardMVConstraints Hard MV constraints test
- HardOtherConstraints Other hard constraints test
- SoftConstraints Soft constraints test

For more information on the tests performed by the review function, see "Algorithms" on page 2-245.

The results structure does not contain a field for the **Memory Size for MPC Data** test.

For each test, the result is returned as one of the following:

• 1 — Pass

- 0 Warning
- -1 Fail

If a given test generates a warning or fails, generate a testing report by calling review without an output argument. The testing report provides details about the warnings and failures, and suggests possible solutions.

# **Tips**

- You can also review your controller design in the MPC Designer app. On the Tuning tab, in the Analysis section, click Review Design.
- Test your controller design using techniques such as simulations, since review cannot detect all possible performance factors.

# **Algorithms**

The review command performs the following tests.

Test	Description
MPC Object Creation	Test whether the controller specifications generate a valid MPC controller. If the controller is invalid, additional tests are not performed.
QP Hessian Matrix Validity	Test whether the MPC quadratic programming (QP) problem for the controller has a unique solution. You must choose cost function parameters (penalty weights) and horizons such that the QP Hessian matrix is positive-definite.
Closed-Loop Internal Stability	Extract the A matrix from the state-space realization of the unconstrained controller, and then calculate its eigenvalues. If the absolute value of each eigenvalue is less than or equal to 1 and the plant is stable, then your feedback system is internally stable.

Test	Description
Closed-Loop Nominal Stability	Extract the A matrix from the discrete-time state-space realization of the closed-loop system; that is, the plant and controller connected in a feedback configuration. Then calculate the eigenvalues of A. If the absolute value of each eigenvalue is less than or equal to 1, then the nominal (unconstrained) system is stable.
Closed-Loop Steady-State Gains	Test whether the controller forces all controlled output variables to their targets at steady state in the absence of constraints.
Hard MV Constraints	Test whether the controller has hard constraints on both a manipulated variable and its rate of change, and if so, whether these constraints may conflict at run time.
Other Hard Constraints	Test whether the controller has hard output constraints or hard mixed input/output constraints, and if so, whether these constraints may become impossible to satisfy at run time.
Soft Constraints	Test whether the controller has the proper balance of hard and soft constraints by evaluating the constraint ECR parameters.
<b>Memory Size for MPC Data</b>	Estimate the memory size required by the controller at run time.

### **Alternatives**

review automates certain tests that you can perform at the command line.

- To test for steady-state tracking errors, use cloffset.
- To test the internal stability of a controller, check the eigenvalues of the mpc object. Convert the mpc object to a state-space model using ss, and call isstable.

"Simulation and Code Generation Using Simulink Coder"
"Review Model Predictive Controller for Stability and Robustness Issues"

### **Introduced in R2011b**

# sensitivity

Compute effect of controller tuning weights on performance

# **Syntax**

```
[J,sens] =
sensitivity(MPCobj,PerfFunc,PerfWeights,Tstop,r,v,simopt,utarget)
[J,sens] = sensitivity(MPCobj,'perf fun',param1,param2,...)
```

# **Description**

The sensitivity function is a controller tuning aid. J specifies a scalar performance metric. sensitivity computes J and its partial derivatives with respect to the controller tuning weights. These *sensitivities* suggest tuning weight adjustments that should improve performance; that is, reduce J.

```
[J,sens] = sensitivity(MPCobj,PerfFunc,PerfWeights,Tstop,r,v,simopt,utarget) calculates the scalar performance metric, J, and sensitivities, sens, for the controller defined by the MPC controller object MPCobj.
```

PerfFunc must be one of the following:

'ISE' (integral squared error) for which the performance metric is

$$J = \sum_{i=1}^{Tstop} \left( \sum_{j=1}^{n_y} (w_j^y e_{yij})^2 + \sum_{j=1}^{n_u} [(w_j^u e_{uij})^2 + (w_j^{\Delta u} \Delta u_{ij})^2] \right)$$

'IAE' (integral absolute error) for which the performance metric is

$$J = \sum_{i=1}^{Tstop} \left( \sum_{j=1}^{n_y} \left| w_j^y e_{yij} \right| + \sum_{j=1}^{n_u} (\left| w_j^u e_{uij} \right| + \left| w_j^{\Delta u} \Delta u_{ij} \right|) \right)$$

'ITSE' (integral of time-weighted squared error) for which the performance metric is

$$J = \sum_{i=1}^{Tstop} i\Delta t \left( \sum_{j=1}^{n_y} (w_j^y e_{yij})^2 + \sum_{j=1}^{n_u} [(w_j^u e_{uij})^2 + (w_j^{\Delta u} \Delta u_{ij})^2] \right)$$

'ITAE' (integral of time-weighted absolute error) for which the performance metric is

$$J = \sum_{i=1}^{Tstop} i\Delta t \left( \sum_{j=1}^{n_y} \left| w_j^y e_{yij} \right| + \sum_{j=1}^{n_u} (\left| w_j^u e_{uij} \right| + \left| w_j^{\Delta u} \Delta u_{ij} \right|) \right)$$

In the above expressions  $n_y$  is the number of controlled outputs and  $n_u$  is the number of manipulated variables.  $e_{yij}$  is the difference between output j and its setpoint (or reference) value at time interval i.  $e_{uij}$  is the difference between manipulated variable j and its target at time interval i.

The w parameters are nonnegative performance weights defined by the structure PerfWeights, which contains the following fields:

- ullet OutputVariables  $-n_y$  element row vector that contains the  $w_j^y$  values
- ManipulatedVariables  $n_u$  element row vector that contains the  $w_j^u$  values
- ManipulatedVariablesRate  $n_u$  element row vector that contains the  $w_i^{\Delta u}$  values

If PerfWeights is unspecified, it defaults to the corresponding weights in MPCobj. In general, however, the performance weights and those used in the controller have different purposes and should be defined accordingly.

Inputs Tstop, r, v, and simopt define the simulation scenario used to evaluate performance. See sim for details.

Tstop is the integer number of controller sampling intervals to be simulated. The final time for the simulations will be  $Tstop \times \Delta t$ , where  $\Delta t$  is the controller sampling interval specified in MPCobj.

The optional input utarget is a vector of  $n_u$  manipulated variable targets. Their defaults are the nominal values of the manipulated variables.  $\Delta u_{ij}$  is the change in manipulated variable j and its target at time interval i.

The structure variable sens contains the computed sensitivities (partial derivatives of J with respect to the MPCobj tuning weights.) Its fields are:

- OutputVariables  $n_y$  element row vector of sensitivities with respect to MPCobj.Weights.OutputVariables
- ManipulatedVariables  $n_u$  element row vector of sensitivities with respect to MPCobj. Weights. ManipulatedVariables
- ManipulatedVariablesRate  $n_u$  element row vector of sensitivities with respect to MPCobj.Weights.ManipulatedVariablesRate

See "Weights" on page 2-78 for details on the tuning weights contained in MPCobj.

[J,sens] = sensitivity(MPCobj,'perf\_fun',param1,param2,...) employs a performance function 'perf\_fun' to define J. Its function definition must be in the form

```
function J = perf fun(MPCobj, param1, param2, ...)
```

That is, it must compute J for the given controller and optional parameters param1, param2, ... and it must be on the MATLAB path.

**Note** While performing the sensitivity analysis, the software ignores time-varying, nondiagonal, and ECR slack variable weights.

# **Examples**

### **Compute Controller Performance and Sensitivity**

Define a third-order plant model with three manipulated variables and two controlled outputs.

```
plant = rss(3,2,3);
plant.D = 0;
```

Create an MPC controller for the plant.

```
MPCobj = mpc(plant,1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Specify an integral absolute error performance function and set the performance weights.

```
PerfFunc = 'IAE';
PerfWts.OutputVariables = [1 0.5];
PerfWts.ManipulatedVariables = zeros(1,3);
PerfWts.ManipulatedVariablesRate = zeros(1,3);
```

Define a 20 second simulation scenario with a unit step in the output 1 setpoint and a setpoint of zero for output 2.

```
Tstop = 20; r = [1 0];
```

Define the nominal values of the manipulated variables to be zeros.

```
utarget = zeros(1,3);
```

Calculate the performance metric, J, and sensitivities, sens, for the specified controller and simulation scenario.

```
[J,sens] = sensitivity(MPCobj,PerfFunc,PerfWts,Tstop,r,[],[],utarget);
```

```
--->Converting model to discrete time.
```

- -->Assuming output disturbance added to measured output channel #1 is integrated white -->Assuming output disturbance added to measured output channel #2 is integrated white
- -->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ea

Introduced in R2009a

### set

Set or modify MPC object properties

# **Syntax**

```
set(MPCobj,Property,Value)
set(MPCobj,Property1,Value1,Property2,Value2,...)
set(MPCobj,Property)
set(sys)
```

# **Description**

The set function is used to set or modify the properties of an MPC controller (see "MPC Controller Object" on page 4-2 for background on MPC properties). set uses property Name, Value pairs to update property values.

set(MPCobj, Property, Value) assigns the value Value to the property of the MPC
controller MPCobj specified by the character vector or string Property. Property can
be the full property name (for example, 'UserData') or any unambiguous caseinsensitive abbreviation (for example, 'user').

set (MPCobj, Property1, Value1, Property2, Value2,...) sets multiple property values with a single statement. Each property Name, Value pair updates one particular property.

set(MPCobj, Property) displays admissible values for the property specified by the character vector Property. See "MPC Controller Object" on page 4-2 for an overview of legitimate MPC property values.

set(sys) displays all assignable properties of sys and their admissible values.

#### **Introduced before R2006a**

## setconstraint

Set mixed input/output constraints for model predictive controller

# **Syntax**

```
setconstraint(MPCobj,E,F,G)
setconstraint(MPCobj,E,F,G,V)
setconstraint(MPCobj,E,F,G,V,S)
setconstraint(MPCobj)
```

# **Description**

setconstraint(MPCobj,E,F,G) specifies mixed input/output constraints of the
following form for the MPC controller, MPCobj:

```
Eu(k+j|k)+Fy(k+j|k) \le G+\varepsilon
where j=0,\ldots,p, and:
```

- *p* is the prediction horizon.
- *k* is the current time index.
- *E*, *F*, and *G* are constant matrices. Each row of *E*, *F*, and *G* represents a linear constraint to be imposed at each prediction horizon step.
- *u* is a column vector of manipulated variables.
- y is a column vector of all plant output variables.
- $\epsilon$  is a slack variable used for constraint softening (as in "Standard Cost Function").

setconstraint(MPCobj,E,F,G,V) adds constraints of the following form:

$$Eu(k + j|k) + Fy(k + j|k) \le G + \varepsilon V$$

where V is a constant vector representing the equal concern for the relaxation (ECR).

setconstraint(MPCobj,E,F,G,V,S) adds constraints of the following form:

$$Eu(k + j|k) + Fy(k + j|k) + Sv(k + j|k) \le G + \varepsilon V$$

where:

- *v* is a column vector of measured disturbance variables.
- *S* is a constant matrix.

setconstraint(MPCobj) removes all mixed input/output constraints from the MPC
controller, MPCobj.

# **Examples**

#### Specify Custom Constraints on Linear Combination of Inputs and Outputs

Specify a constraint of the form  $0 \le u_2 - 2u_3 + y_2 \le 15$  on an MPC controller.

Create a third-order plant model with three manipulated variables and two measured outputs.

```
plant = rss(3,2,3);
plant.D = 0;
```

Create an MPC controller for this plant.

```
MPCobj = mpc(plant,0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Formulate the constraint in the required form:

$$\begin{bmatrix} 0 & -1 & 2 \\ 0 & 1 & -2 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \\ u_3 \end{bmatrix} + \begin{bmatrix} 0 & -1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} \le \begin{bmatrix} 0 \\ 15 \end{bmatrix} + \varepsilon \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Specify the constraint matrices.

```
E = [0 -1 2; 0 1 -2];

F = [0 -1; 0 1];

G = [0; 15];
```

Set the constraints in the MPC controller.

```
setconstraint(MPCobj,E,F,G)
```

#### **Specify Custom Hard Constraints for MPC Controller**

Create a third-order plant model with two manipulated variables and two measured outputs.

```
plant = rss(3,2,2);
plant.D = 0;
```

Create an MPC controller for this plant.

```
MPCobj = mpc(plant,0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Assume that you have two hard constraints.

```
u_1 + u_2 \le 5
v_1 + v_2 \le 10
```

Specify the constraint matrices.

```
E = [1 1; 0 0];

F = [0 0; 1 1];

G = [5;10];
```

Specify the constraints as hard by setting  $\boldsymbol{V}$  to zero for both constraints.

```
V = [0;0];
```

Set the constraints in the MPC controller.

```
setconstraint(MPCobj,E,F,G,V)
```

#### Specify Custom Constraints for MPC Controller with Measured Disturbances

Create a third-order plant model with two manipulated variables, two measured disturbances, and two measured outputs.

```
plant = rss(3,2,4);
plant.D = 0;
plant = setmpcsignals(plant, 'mv',[1 2], 'md',[3 4]);
```

Create an MPC controller for this plant.

```
MPCobj = mpc(plant, 0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon -->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1.
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1.
```

Assume that you have three soft constraints.

```
u_1 + u_2 \le 5

y_1 + v_1 \le 10

y_2 + v_2 \le 12
```

Specify the constraint matrices.

```
E = [1 1; 0 0; 0 0];
F = [0 0; 1 0; 0 1];
G = [5;10;12];
S = [0 0; 1 0; 0 1];
```

Set the constraints in the MPC controller using the default value for  ${\sf V}.$ 

```
setconstraint(MPCobj,E,F,G,[],S)
```

#### Remove All Custom Constraints from MPC Controller

Define a plant model and create an MPC controller.

```
plant = rss(3,2,2);
plant.D = 0;
MPCobj = mpc(plant,0.1);

-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1.
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1.
```

Define controller custom constraints.

```
E = [-1 2; 1 -2];
F = [0 1; 0 -1];
G = [0; 10];
setconstraint(MPCobj,E,F,G)
```

Remove the custom constraints.

```
setconstraint(MPCobj)
```

-->Removing mixed input/output constraints.

# **Input Arguments**

### MPCobj — Model predictive controller

MPC controller object

Model predictive controller, specified as an MPC controller object. To create an MPC controller, use mpc.

### **E** — Manipulated variable constraint constant

```
array of zeros (default) | N_c-by-N_{mv} array
```

Manipulated variable constraint constant, specified as an  $N_c$ -by- $N_{mv}$  array, where  $N_c$  is the number of constraints, and  $N_{mv}$  is the number of manipulated variables.

#### F — Controlled output constraint constant

array of zeros (default) |  $N_c$ -by- $N_v$  array

Controlled output constraint constant, specified as an  $N_c$ -by- $N_y$  array, where  $N_y$  is the number of controlled outputs (measured and unmeasured).

#### G — Mixed input/output constraint constant

column vector of zeros (default) | column vector of length  $N_c$ 

Mixed input/output constraint constant, specified as a column vector of length  $N_c$ .

#### V — Constraint softening constant

column vector of ones (default) | specified as a column vector of length  $N_c$ 

Constraint softening constant representing the equal concern for the relaxation (ECR), specified as a column vector of length  $N_c$ .

If V is not specified, a default value of 1 is applied to all constraint inequalities and all constraints are soft. This behavior is the same as the default behavior for output bounds, as described in "Standard Cost Function".

To make the  $i^{th}$  constraint hard, specify V(i) = 0.

To make the  $i^{\rm th}$  constraint soft, specify V(i) > 0 in keeping with the constraint violation magnitude you can tolerate. The magnitude violation depends on the numerical scale of the variables involved in the constraint.

In general, as V(i) decreases, the controller hardens the constraints by decreasing the constraint violation that is allowed.

**Note** If a constraint is difficult to satisfy, reducing its V(i) value to make it harder can be counterproductive. Doing so can lead to erratic control actions, instability, or failure of the QP solver that determines the control action.

#### S — Measured disturbance constraint constant

array of zeros (default) |  $N_c$ -by- $N_{md}$  array

Measured disturbance constraint constant, specified as an  $N_c$ -by- $N_{md}$  array, where  $N_{md}$  is the number of measured disturbances.

# **Tips**

- The outputs, *y*, are being predicted using a model. If the model is imperfect, there is no quarantee that a constraint can be satisfied.
- Since the MPC controller does not optimize u(k + p|k), the last constraint at time k + p assumes that u(k+p|k) = u(k+p-1|k).
- When simulating an MPC controller, you can update the E, F, G, and S constraint arrays at run time. For more information, see "Update Constraints at Run Time".

### setEstimator

Modify a model predictive controller's state estimator

# **Syntax**

```
setEstimator(MPCobj,L,M)
setEstimator(MPCobj,'default')
setEstimator(MPCobj,'custom')
```

# **Description**

<code>setEstimator(MPCobj,L,M)</code> sets the gain matrices used for estimation of the states of an MPC controller. See "State Estimator Equations" on page 2-264. If L is empty, it defaults to L = A\*M, where A is the state transition matrix defined in "State Estimator Equations" on page 2-264. If M is omitted or empty, it defaults to a zero matrix, and the state estimator becomes a Luenberger observer.

setEstimator(MPCobj, 'default') restores the gain matrices L and M to their default
values. The default values are the optimal static gains calculated by the Control System
Toolbox function kalmd for the plant, disturbance, and measurement noise models
specified in MPCobj.

<code>setEstimator(MPCobj, 'custom')</code> specifies that controller state estimation will be performed by a user-supplied procedure rather than the equations described in "State Estimator Equations" on page 2-264. This option suppresses calculation of L and M. When the controller is operating in this way, the procedure must supply the state estimate x[n|n] to the controller at the beginning of each control interval.

# **Examples**

### **Design State Estimator by Pole Placement**

Design an estimator using pole placement, assuming the linear system AM = L is solvable.

Create a plant model.

```
G = tf({1,1,1},{[1 .5 1],[1 1],[.7 .5 1]});
```

To improve the clarity of this example, call mpcverbosity to suppress messages related to working with an MPC controller.

```
old status = mpcverbosity('off');
```

Create a model predictive controller for the plant. Specify the controller sample time as 0.2 seconds.

```
MPCobj = mpc(G, 0.2);
```

Obtain the default state estimator gain.

```
[~,M,A1,Cm1] = getEstimator(MPCobj);
```

Calculate the default observer poles.

```
e = eig(A1-A1*M*Cm1);
abs(e)
ans = 6 \times 1
0.9402
```

0.9402 0.8816

0.8816

0.7430

0.9020

Specify faster observer poles.

```
new_poles = [.8 .75 .7 .85 .6 .81];
```

Compute a state-gain matrix that places the observer poles at new\_poles.

```
L = place(A1',Cm1',new_poles)';
```

place returns the controller-gain matrix, whereas you want to compute the observer-gain matrix. Using the principle of duality, which relates controllability to observability, you specify the transpose of A1 and Cm1 as the inputs to place. This function call yields the observer gain transpose.

Obtain the estimator gain from the state-gain matrix.

```
M = A1\L;
```

Specify M as the estimator for MPCobj.

```
setEstimator(MPCobj,L,M)
```

The pair,  $(A_1, C_{m1})$ , describing the overall state-space realization of the combination of plant and disturbance models must be observable for the state estimation design to succeed. Observability is checked in Model Predictive Control Toolbox software at two levels: (1) observability of the plant model is checked *at construction* of the MPC object, provided that the model of the plant is given in state-space form; (2) observability of the overall extended model is checked *at initialization* of the MPC object, after all models have been converted to discrete-time, delay-free, state-space form and combined together.

```
Restore mpcverbosity.
mpcverbosity(old_status);
```

# **Input Arguments**

### MPCobj — MPC controller

MPC controller object

MPC controller, specified as an MPC controller object. Use the mpc command to create the MPC controller.

### L — Kalman gain matrix for time update

A\*M (default) | matrix

Kalman gain matrix for the time update, specified as a matrix. The dimensions of L are  $n_x$ -by- $n_{ym}$ , where  $n_x$  is the total number of controller states, and  $n_{ym}$  is the number of measured outputs. See "State Estimator Equations" on page 2-264.

If L is empty, it defaults to L = A\*M, where A is the state transition matrix defined in "State Estimator Equations" on page 2-264.

### M — Kalman gain matrix for measurement update

0 (default) | matrix

Kalman gain matrix for the measurement update, specified as a matrix. The dimensions of L are  $n_x$ -by- $n_{ym}$ , where  $n_x$  is the total number of controller states, and  $n_{ym}$  is the number of measured outputs. See "State Estimator Equations" on page 2-264.

If M is omitted or empty, it defaults to a zero matrix, and the state estimator becomes a Luenberger observer.

### **Definitions**

### **State Estimator Equations**

The following equations describe the state estimation. For more details, see "Controller State Estimation".

Output estimate:  $y_m[n|n-1] = C_m x[n|n-1] + D_{vm} v[n]$ .

Measurement update:  $x[n|n] = x[n|n-1] + M(y_m[n] - y_m[n|n-1])$ .

Time update:  $x[n+1|n] = A x[n|n-1] + B_u u[n] + B_v v[n] + L (y_m[n] - y_m[n|n-1]).$ 

Estimator state:  $x[n+1|n] = (A - L C_m) x[n|n-1] + B_u u[n] + (B_v-L D_{vm}) v[n] + L y_m[v]$ . The estimator state is based on the current measurement of  $y_m[n]$  and v[n] as well as the optimal control action u[n] computed at the current control interval.

The variables in these equations are summarized in the following table.

Symbol	Description	
Х	Controller state vector, length $n_x$ . It includes (in this sequence):	
	<ul> <li>Plant model state estimates. Dimension obtained by conversion of MPCobj.Model.Plant to discrete LTI state-space form (if necessary), followed by use of absorbDelay to convert any delays to additional states.</li> <li>Input disturbance model state estimates (if any). Use the getindist command to review the input disturbance model structure.</li> </ul>	
	<ul> <li>Output disturbance model state estimates (if any). Use the getoutdist command to review the output disturbance model structure.</li> </ul>	
	Output measurement noise states (if any) as specified by MPCobj.Model.Noise.	
	The length $n_x$ is the sum of the number of states in the above four categories.	
$\mathcal{Y}_m$	Vector of measured outputs or an estimate of their true values, length $n_{vm}$ .	
u	Vector of manipulated variables, length $n_u$ .	
ν	Vector of measured input disturbances, length $n_{\nu}$ .	
[j k]	Denotes an estimate of a state or output at time $t_j$ based on data available at time $t_k$ .	
[k]	Denotes a quantity known at time $t_k$ , i.e., not an estimate.	
A	$n_x$ -by- $n_x$ state transition matrix.	
$B_u$	$n_x$ -by- $n_u$ matrix mapping $u$ to $x$ .	
$B_{\nu}$	$n_x$ -by- $n_x$ matrix mapping $\nu$ to $x$ .	
$C_m$	$n_{ym}$ -by- $n_x$ matrix mapping x to $y_m$ .	
$D_{vm}$	$n_{ym}$ -by- $n_{v}$ matrix mapping $v$ to $y_{m}$ . Note that $D_{um}=0$ because there can be no direct feedthrough between any manipulated variable and any measured output.	

Symbol	Description
L	$n_x$ -by- $n_{ym}$ Kalman gain matrix for the time update. (See kalmd in the Control System Toolbox documentation.) Note that $L = A*M$ minimizes the expected state estimation error for most combinations of plant and disturbance models used in MPC, but this is not true in general.
M	$n_x$ -by- $n_{ym}$ Kalman gain matrix for the measurement update. (See kalmd in the Control System Toolbox documentation.)

### Introduced in R2014b

## setindist

Modify unmeasured input disturbance model

# **Syntax**

```
setindist(MPCobj,'model',model)
setindist(MPCobj,'integrators')
```

# **Description**

setindist(MPCobj, 'model', model) sets the input disturbance model used by the model predictive controller, MPCobj, to a custom model.

setindist(MPCobj, 'integrators') sets the input disturbance model to its default value. Use this syntax if you previously set a custom input disturbance model and you want to change back to the default model. For more information on the default input disturbance model, see "MPC Modeling".

# **Examples**

### **Specify Input Disturbance Model Using Transfer Functions**

Define a plant model with no direct feedthrough.

```
plant = rss(3,4,4);
plant.D = 0;
```

Set the first input signal as a manipulated variable and the remaining inputs as input disturbances.

```
plant = setmpcsignals(plant, 'MV', 1, 'UD', [2 3 4]);
```

Create an MPC controller for the defined plant.

```
MPCobj = mpc(plant,0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defactions of "weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming control to the "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1 for output(s) y1 and zero weight for output(s) y2 y3 y4
```

#### Define disturbance models such that:

- Input disturbance 1 is random white noise with a magnitude of 2.
- Input disturbance 2 is random step-like noise with a magnitude of 0.5.
- Input disturbance 3 is random ramp-like noise with a magnitude of 1.

```
mod1 = tf(2,1);

mod2 = tf(0.5,[1 0]);

mod3 = tf(1,[1 0 0]);
```

Construct the input disturbance model using the above transfer functions. Use a separate noise input for each input disturbance.

```
indist = [mod1 \ 0 \ 0; \ 0 \ mod2 \ 0; \ 0 \ 0 \ mod3];
```

Set the input disturbance model in the MPC controller.

```
setindist(MPCobj,'model',indist)
```

View the controller input disturbance model.

#### getindist(MPCobj)

```
ans =
  A =
            x2
       x1
                 х3
       1 0
                  0
  x1
            1
                  (-)
  x2
        0
  х3
        0 0.1
                  1
  B =
      Noise#1 Noise#2
                       Noise#3
                  0.05
  x1
           0
                              0
            0
                            0.1
  x2
                    0
  х3
            0
                     0
                          0.005
```

```
C =
     x1 x2 x3
UD1
     0 0 0
UD2
     1 0 0
     0 0 1
UD3
D =
     Noise#1 Noise#2 Noise#3
UD1
           2
                    0
                            (-)
UD2
           (-)
                    (-)
                            (-)
UD3
           (-)
                    (-)
                            0
```

Sample time: 0.1 seconds Discrete-time state-space model.

The controller converts the continuous-time transfer function model, indist, into a discrete-time state-space model.

#### **Remove Input Disturbance for Particular Channel**

Define a plant model with no direct feedthrough.

```
plant = rss(3,4,4);
plant.D = 0;
```

Set the first input signal as a manipulated variable and the remaining inputs as input disturbances.

```
plant = setmpcsignals(plant, 'MV', 1, 'UD', [2 3 4]);
```

Create an MPC controller for the defined plant.

```
MPCobj = mpc(plant,0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defact
-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming default 1 for output(s) y1 and zero weight for output(s) y2 y3 y4
```

Retrieve the default input disturbance model from the controller.

```
distMod = getindist(MPCobj);
```

```
-->Converting model to discrete time.
-->The "Model.Disturbance" property of "mpc" object is empty:
    Assuming unmeasured input disturbance #2 is integrated white noise.
    Assuming unmeasured input disturbance #3 is integrated white noise.
    Assuming unmeasured input disturbance #4 is integrated white noise.
-->Assuming output disturbance added to measured output channel #1 is integrated white Assuming no disturbance added to measured output channel #2.
    Assuming no disturbance added to measured output channel #3.
    Assuming no disturbance added to measured output channel #4.
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each
```

Remove the integrator from the second input disturbance. Construct the new input disturbance model by removing the second input channel and setting the effect on the second output by the other two inputs to zero.

When removing an integrator from the input disturbance model in this way, use sminreal to make the custom model structurally minimal.

View the input disturbance model.

```
tf(getindist(MPCobj))
```

```
z - 1
Sample time: 0.1 seconds
Discrete-time transfer function.
```

The integrator has been removed from the second channel. The first and third channels of the input disturbance model remain at their default values as discrete-time integrators.

#### **Set Input Disturbance Model to Default Value**

Define a plant model with no direct feedthrough.

```
plant = rss(2,2,3);
plant.D = 0;
```

Set the second and third input signals as input disturbances.

```
plant = setmpcsignals(plant, 'MV', 1, 'UD', [2 3]);
```

Create an MPC controller for the defined plant.

```
MPCobj = mpc(plant,0.1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defactions—->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Set the input disturbance model to unity gain for both channels.

for output(s) y1 and zero weight for output(s) y2

```
setindist(MPCobj,'model',tf(eye(2)))
```

Restore the default input disturbance model.

```
setindist(MPCobj,'integrators')
```

# **Input Arguments**

#### MPCobj — Model predictive controller

MPC controller object

Model predictive controller, specified as an MPC controller object. To create an MPC controller, use mpc.

#### model — Custom input disturbance model

[] (default) | ss object | tf object | zpk object

Custom input disturbance model, specified as a state-space (ss), transfer function (tf), or zero-pole-gain (zpk) model. The MPC controller converts the model to a discrete-time, delay-free, state-space model. Omitting model or specifying model as [] is equivalent to using setindist(MPCobj, 'integrators').

The input disturbance model has:

- Unit-variance white noise input signals. For custom input disturbance models, the number of inputs is your choice.
- $n_d$  outputs, where  $n_d$  is the number of unmeasured disturbance inputs defined in MPCobj.Model.Plant. Each disturbance model output is sent to the corresponding plant unmeasured disturbance input.

This model, in combination with the output disturbance model (if any), governs how well the controller compensates for unmeasured disturbances and prediction errors. For more information on the disturbance modeling in MPC and about the model used during state estimation, see "MPC Modeling" and "Controller State Estimation".

setindist does not check custom input disturbance models for violations of state observability. This check is performed later in the MPC design process when the internal state estimator is constructed using commands such as sim or mpcmove. If the controller states are not fully observable, these commands generate an error.

This syntax is equivalent to MPCobj.Model.Disturbance = model.

# **Tips**

• To view the current input disturbance model, use the getindist command.

### **Introduced before R2006a**

# setmpcsignals

Set signal types in MPC plant model

# **Syntax**

P = setmpcsignals(P,SignalType1,Channels1,SignalType2,Channels2,...)

# **Description**

The purpose of setmpcsignals is to configure the input/output channels of the MPC plant model P. P must be an LTI object. Valid signal types, their abbreviations, and the channel type they refer to are listed below.

Signal Type	Abbreviation	Channel
'Manipulated'	'MV'	Input
'MeasuredDisturbances'	'MD'	Input
'UnmeasuredDisturbances'	'UD'	Input
'MeasuredOutputs'	' MO '	Output
'UnmeasuredOutputs'	'U0'	Output

Unambiguous abbreviations of signal types are also accepted.

**Note** When using setmpcsignals to modify an existing MPC object, be sure that the fields Weights, MV, OV, DV, Model.Noise, and Model.Disturbance are consistent with the new I/O signal types.

P = setmpcsignals(P) sets channel assignments to default, namely all inputs are manipulated variables (MVs), all outputs are measured outputs (MOs). More generally, input signals that are not explicitly assigned are assumed to be MVs, while unassigned output signals are considered as MOs.

# **Examples**

#### **Set MPC Signal Types and Create MPC Controller**

Create a four-input, two output state-space plant model. By default all input signals are manipulated variables and all outputs are measured outputs.

```
plant = rss(3,2,4);
plant.D = 0;
```

Configure the plant input/output channels such that:

- The second and third inputs are measured disturbances.
- The fourth input is an unmeasured disturbance.
- The second output is unmeasured.

```
plant = setmpcsignals(plant, 'MD', [2 3], 'UD', 4, 'U0', 2);
-->Assuming unspecified input signals are manipulated variables.
-->Assuming unspecified output signals are measured outputs.
```

for output(s) y1 and zero weight for output(s) y2

#### Create an MPC controller.

```
MPCobj = mpc(plant,1);
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defail the "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming of "mpc" object is empty.
```

-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1

## **See Also**

```
mpc | set
```

### **Topics**

"MPC Modeling"

### **Introduced before R2006a**

### setname

Set I/O signal names in MPC prediction model

# **Syntax**

```
setname(MPCobj,'input',I,name)
setname(MPCobj,'output',I,name)
```

# **Description**

setname(MPCobj, 'input', I, name) changes the name of the Ith input signal to name. This is equivalent to MPCobj.Model.Plant.InputName{I}=name. Specify name as a character vector or string. Note that setname also updates the read-only Name fields of MPCobj.DisturbanceVariables and MPCobj.ManipulatedVariables.

setname(MPCobj,'output',I,name) changes the name of the Ith output signal to
name. This is equivalent to MPCobj.Model.Plant.OutputName{I} = name. Specify
name as a character vector or string. Note that setname also updates the read-only Name
field of MPCobj.OutputVariables.

**Note** The Name properties of ManipulatedVariables, OutputVariables, and DisturbanceVariables are read-only. You must use setname to assign signal names, or equivalently modify the Model.Plant.InputName and Model.Plant.OutputName properties of the MPC object.

getname | mpc | set

## setoutdist

Modify unmeasured output disturbance model

# **Syntax**

```
setoutdist(MPCobj,'model',model)
setoutdist(MPCobj,'integrators')
```

# **Description**

setoutdist(MPCobj, 'model', model) sets the output disturbance model used by the model predictive controller, MPCobj, to a custom model.

setoutdist(MPCobj, 'integrators') sets the output disturbance model to its default value. Use this syntax if you previously set a custom output disturbance model and you want to change back to the default model. For more information on the default output disturbance model, see "MPC Modeling".

# **Examples**

### **Specify Output Disturbance Model Using Transfer Functions**

Define a plant model with no direct feedthrough, and create an MPC controller for that plant.

```
plant = rss(3,3,3,3);
plant.D = 0;
MPCobj = mpc(plant,0.1);

-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Define disturbance models for each output such that the output disturbance for:

- Channel 1 is random white noise with a magnitude of 2.
- Channel 2 is random step-like noise with a magnitude of 0.5.
- Channel 3 is random ramp-like noise with a magnitude of 1.

```
mod1 = tf(2,1);

mod2 = tf(0.5,[1 0]);

mod3 = tf(1,[1 0 0]);
```

Construct the output disturbance model using these transfer functions. Use a separate noise input for each output disturbance.

```
outdist = [mod1 0 0; 0 mod2 0; 0 0 mod3];
```

Set the output disturbance model in the MPC controller.

```
setoutdist(MPCobj, 'model', outdist)
```

View the controller output disturbance model.

```
getoutdist(MPCobj)
```

```
ans =

              0
                        0
                              0.005
  C =
        x1 x2
                 х3
         0
             0
                   0
   M01
   M<sub>0</sub>2
         1
              0
                   0
   M03
          0
            0
                   1
  D =
```

	Noise#1	Noise#2	Noise#3
M01	2	0	0
M02	0	0	0
M03	0	0	0

```
Sample time: 0.1 seconds Discrete-time state-space model.
```

The controller converts the continuous-time transfer function model, outdist, into a discrete-time state-space model.

#### **Remove Output Disturbance from Particular Output Channel**

Define a plant model with no direct feedthrough, and create an MPC controller for that plant.

```
plant = rss(3,3,3);
plant.D = 0;
MPCobj = mpc(plant,0.1);

-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Retrieve the default output disturbance model from the controller.

```
distMod = getoutdist(MPCobj);
```

```
-->Converting model to discrete time.
-->Assuming output disturbance added to measured output channel #1 is integrated white
-->Assuming output disturbance added to measured output channel #2 is integrated white
-->Assuming output disturbance added to measured output channel #3 is integrated white
-->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on each
```

Remove the integrator from the second output channel. Construct the new output disturbance model by removing the second input channel and setting the effect on the second output by the other two inputs to zero.

```
distMod = sminreal([distMod(1,1) distMod(1,3); 0 0; distMod(3,1) distMod(3,3)]);
setoutdist(MPCobj, 'model', distMod)
```

When removing an integrator from the output disturbance model in this way, use sminreal to make the custom model structurally minimal.

View the output disturbance model.

```
tf(getoutdist(MPCobj))
ans =
  From input "Noise#1" to output...
         0.1
   M01: ----
        z - 1
  M02: 0
  M03: 0
  From input "Noise#2" to output...
  M01: 0
  M02: 0
         0.1
   M03: ----
        z - 1
Sample time: 0.1 seconds
Discrete-time transfer function.
```

The integrator has been removed from the second channel. The disturbance models for channels 1 and 3 remain at their default values as discrete-time integrators.

### **Remove Output Disturbances from All Output Channels**

Define a plant model with no direct feedthrough and create an MPC controller for that plant.

```
plant = rss(3,3,3);
plant.D = 0;
MPCobj = mpc(plant,1);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defactions of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming of "mpc" object is empty. Assuming default 1
```

Set the output disturbance model to zero for all three output channels.

```
setoutdist(MPCobj,'model',tf(zeros(3,1)))
```

View the output disturbance model.

```
getoutdist(MPCobj)
```

Static gain.

A static gain of  $\theta$  for all output channels indicates that the output disturbances were removed.

### **Set Output Disturbance Model to Default Value**

Define a plant model with no direct feedthrough and create an MPC controller for that plant.

```
plant = rss(2,2,2);
plant.D = 0;
MPCobj = mpc(plant,0.1);
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Remove the output disturbances for all channels.

```
setoutdist(MPCobj, 'model', tf(zeros(2,1)))
Restore the default output disturbance model.
setoutdist(MPCobj, 'integrators')
```

## **Input Arguments**

#### MPCobj — Model predictive controller

MPC controller object

Model predictive controller, specified as an MPC controller object. To create an MPC controller, use mpc.

### model — Custom output disturbance model

```
[] (default) | ss object | tf object | zpk object
```

Custom output disturbance model, specified as a state-space (ss), transfer function (tf), or zero-pole-gain (zpk) model. The MPC controller converts the model to a discrete-time, delay-free, state-space model. Omitting model or specifying model as [] is equivalent to using setoutdist(MPCobj, 'integrators').

The output disturbance model has:

- Unit-variance white noise input signals. For custom output disturbance models, the number of inputs is your choice.
- $n_y$  outputs, where  $n_y$  is the number of plant outputs defined in MPCobj.Model.Plant. Each disturbance model output is added to the corresponding plant output.

This model, along with the input disturbance model (if any), governs how well the controller compensates for unmeasured disturbances and modeling errors. For more information on the disturbance modeling in MPC and about the model used during state estimation, see "MPC Modeling" and "Controller State Estimation".

setoutdist does not check custom output disturbance models for violations of state observability. This check is performed later in the MPC design process when the internal state estimator is constructed using commands such as sim or mpcmove. If the controller states are not fully observable, these commands will generate an error.

# **Tips**

• To view the current output disturbance model, use the getoutdist command.

## setterminal

Terminal weights and constraints

# **Syntax**

```
setterminal(MPCobj,Y,U)
setterminal(MPCobj,Y,U,Pt)
```

# **Description**

setterminal (MPCobj, Y, U) specifies diagonal quadratic penalty weights and constraints at the last step in the prediction horizon. The weights and constraints are on the terminal output y(t+p) and terminal input u(t+p-1), where p is the prediction horizon of the MPC controller MPCobj.

setterminal (MPCobj, Y, U, Pt) specifies diagonal quadratic penalty weights and constraints from step Pt to the horizon end. By default, Pt is the last step in the horizon.

# **Input Arguments**

### **MPCobj**

MPC controller, specified as an MPC controller object on page 2-72

#### **Default:**

Υ

Terminal weights and constraints for the output variables, specified as a structure with the following fields:

Weight

1-by- $n_y$  vector of nonnegative weights

Min

1-by- $n_{v}$  vector of lower bounds

Max  $1-by-n_v$  vector of upper bounds

MinECR 1-by- $n_{\nu}$  vector of constraint-softening Equal Concern for the

Relaxation (ECR) values for the lower bounds

MaxECR 1-by- $n_{\nu}$  vector of constraint-softening ECR values for the upper

bounds

 $n_{\nu}$  is the number of controlled outputs of the MPC controller.

If the Weight, Min or Max field is empty, the values in MPCobj are used at all prediction horizon steps including the last. For the standard bounds, if any element of the Min or Max field is infinite, the corresponding variable is unconstrained at the terminal step.

Off-diagonal weights are zero (as described in "Standard Cost Function"). To apply nonzero off-diagonal terminal weights, you must augment the plant model. See "Designing Model Predictive Controller Equivalent to Infinite-Horizon LQR".

By default, Y.MinECR = Y.MaxECR = 1 (soft output constraints).

Choose the ECR magnitudes carefully, accounting for the importance of each constraint and the numerical magnitude of a typical violation.

#### **Default:**

#### U

Terminal weights and constraints for the manipulated variables, specified as a structure with the following fields:

Weight 1-by- $n_u$  vector of nonnegative weights

Min 1-by- $n_u$  vector of lower bounds Max 1-by- $n_u$  vector of upper bounds

MinECR 1-by- $n_{\mu}$  vector of constraint-softening Equal Concern for the

Relaxation (ECR) values for the lower bounds

MaxECR 1-by- $n_{\nu}$  vector of constraint-softening ECR values for the

upper bounds

 $n_u$  is the number of manipulated variables of the MPC controller.

If the Weight, Min or Max field is empty, the values in MPCobj are used at all prediction horizon steps including the last. For the standard bounds, if individual elements of the

 $\mbox{Min}$  or  $\mbox{Max}$  fields are infinite, the corresponding variable is unconstrained at the terminal step.

Off-diagonal weights are zero (as described in "Standard Cost Function"). To apply nonzero off-diagonal terminal weights, you must augment the plant model. See "Designing Model Predictive Controller Equivalent to Infinite-Horizon LQR".

By default, U.MinECR = U.MaxECR = 0 (hard manipulated variable constraints)

Choose the ECR magnitudes carefully, accounting for the importance of each constraint and the numerical magnitude of a typical violation.

#### **Default:**

#### Pt

Step in the prediction horizon, specified as an integer between 1 and p, where p is the prediction horizon. The terminal values are applied to Y and U from prediction step Pt to the end.

**Default:** Prediction horizon p

# **Examples**

### Specify Constraints and Penalty Weights at Last Prediction Horizon Step

for output(s) y1 y2 and zero weight for output(s) y3

Create an MPC controller for a plant with three output variables and two manipulated variables.

```
plant = rss(3,3,2);
plant.D = 0;
MPCobj = mpc(plant,0.1);
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming default 1
-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1
```

Specify a prediction horizon of 8.

```
MPCobj.PredictionHorizon = 8;
```

Define the following penalty weights and constraints:

- Diagonal penalty weights of 1 and 10 on the first two output variables
- Lower bounds of 0 and -1 on the first and third outputs respectively
- Upper bound of 2 on the second output
- Lower bound of 1 on the first manipulated variable

```
Y = struct('Weight',[1,10,0],'Min',[0,-Inf,-1],'Max',[Inf,2,Inf]);
U = struct('Min',[1,-Inf]);
```

Specify the constraints and penalty weights at the last step of the prediction horizon.

```
setterminal(MPCobj,Y,U)
```

#### Specify Terminal Constraints For Final Prediction Horizon Range

Create an MPC controller for a plant with three output variables and two manipulated variables.

```
plant = rss(3,3,2);
plant.D = 0;
MPCobj = mpc(plant,0.1);

-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon
-->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defailed-->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming default 1
for output(s) y1 y2 and zero weight for output(s) y3
```

Specify a prediction horizon of 10.

```
MPCobj.PredictionHorizon = 10;
```

Define the following terminal constraints:

- Lower bounds of 0 and -1 on the first and third outputs respectively
- Upper bound of 2 on the second output

• Lower bound of 1 on the first manipulated variable

```
Y = struct('Min',[0,-Inf,-1],'Max',[Inf,2,Inf]);
U = struct('Min',[1,-Inf]);
```

Specify the constraints beginning at step 5 and ending at the last step of the prediction horizon.

```
setterminal(MPCobj,Y,U,5)
```

## **Tips**

• Advanced users can impose terminal polyhedral state constraints:

$$K_1 \le Hx \le K_2$$
.

First, augment the plant model with additional artificial (unmeasured) outputs, y = Hx. Then specify bounds  $K_1$  and  $K_2$  on these y outputs.

## sim

Simulate closed-loop/open-loop response to arbitrary reference and disturbance signals for implicit or explicit MPC

# **Syntax**

```
sim(MPCobj,T,r)
sim(MPCobj,T,r,v)
sim(____,SimOptions)
[y,t,u,xp,xmpc,SimOptions] = sim(____)
```

# **Description**

Use sim to simulate the implicit (traditional) or explicit MPC controller in closed loop with a linear time-invariant model, which, by default, is the plant model contained in MPCobj.Model.Plant. As an alternative, sim can simulate the open-loop behavior of the model of the plant, or the closed-loop behavior in the presence of a model mismatch, when the controller's prediction model differs from the actual plant model.

sim(MPCobj,T,r) simulates the closed-loop system formed by the plant model specified
in MPCobj.Model.Plant and by the MPC controller specified by the MPC controller
MPCobj, in response to the specified reference signal, r. The MPC controller can be
either a traditional MPC controller (mpc) or explicit MPC controller (explicitMPC). The
simulation runs for the specified number of simulation steps, T. sim plots the simulation
results.

sim(MPCobj,T,r,v) also specifies the measured disturbance signal v.

sim( \_\_\_\_, SimOptions) specifies additional simulation options, which you create with mpcsimopt. This syntax allows you to alter the default simulation options, such as initial states, input/output noise and unmeasured disturbances, plant mismatch, etc. You can use SimOptions with any of the previous input combinations.

 $[y,t,u,xp,xmpc,SimOptions] = sim(\___)$  suppresses plotting and instead returns the sequence of plant outputs y, the time sequence t (equally spaced by MPCobj.Ts), the manipulated variables u generated by the MPC controller, the sequence xp of states of

the model of the plant used for simulation, the sequence xmpc of states of the MPC controller (provided by the state observer), and the simulation options, SimOptions. You can use this syntax with any of the allowed input argument combinations.

## **Input Arguments**

### **MPCobj**

MPC controller containing the parameters of the Model Predictive Control law to simulate, specified as either an implicit MPC controller (mpc) or an explicit MPC controller (generateExplicitMPC).

#### Т

Number of simulation steps, specified as a positive integer.

If you omit T, the default value is the row size of whichever of the following arrays has the largest row size:

- The input argument r
- The input argument v
- The UnmeasuredDisturbance property of SimOptions, if specified
- The OutputNoise property of SimOptions, if specified

Default: The largest row size of r, v, UnmeasuredDisturbance, and OutputNoise

#### r

Reference signal, specified as an array. This array has ny columns, where ny is the number of plant outputs. r can have anywhere from 1 to T rows. If the number of rows is less than T, the missing rows are set equal to the last row.

**Default:** MPCobj.Model.Nominal.Y

#### ٧

Measured disturbance signal, specified as an array. This array has nv columns, where nv is the number of measured input disturbances. v can have anywhere from 1 to T rows. If the number of rows is less than T, the missing rows are set equal to the last row.

**Default:** Corresponding entries from MPCobj.Model.Nominal.U

### SimOptions

Simulation options, specified as an options object you create using mpcsimopt.

Default: []

# **Output Arguments**

#### у

Sequence of controlled plant outputs, returned as a T-by-Ny array, where T is the number of simulation steps and Ny is the number of plant outputs. The values in y do not include additive measurement noise, if any).

#### t

Time sequence, returned as a T-by-1 array, where T is the number of simulation steps. The values in t are equally spaced by MPCobj.Ts.

#### u

Sequence of manipulated variables generated by the MPC controller, returned as a T-by-Nu array, where T is the number of simulation steps and Nu is the number of manipulated variables.

#### хp

Sequence of plant model states, T-by-Nxp array, where T is the number of simulation steps and Nxp is the number of states in the plant model. The plant model is either MPCobj.Model or SimOptions.Model, if the latter is specified.

#### xmpc

Sequence of MPC controller state estimates, returned as a T-by-1 structure array. Each entry in the structure array has the same fields as an mpcstate object. The state estimates include plant, disturbance, and noise model states at each time step.

### SimOptions

Simulation options used, returned as a mpcsimopt object.

## **Examples**

#### Simulate MPC Control of MISO Plant

Simulate the MPC control of a MISO system. The system has one manipulated variable, one measured disturbance, one unmeasured disturbance, and one output.

Create the continuous-time plant model. This plant will be used as the prediction model for the MPC controller.

```
sys = ss(tf({1,1,1},{[1 .5 1],[1 1],[.7 .5 1]}));
```

Discretize the plant model using a sampling time of 0.2 units.

```
Ts = 0.2;

sysd = c2d(sys,Ts);
```

Specify the MPC signal type for the plant input signals.

```
sysd = setmpcsignals(sysd,'MV',1,'MD',2,'UD',3);
```

Create an MPC controller for the sysd plant model. Use default values for the weights and horizons.

```
MPCobj = mpc(sysd);
```

```
-->The "PredictionHorizon" property of "mpc" object is empty. Trying PredictionHorizon -->The "ControlHorizon" property of the "mpc" object is empty. Assuming 2.
-->The "Weights.ManipulatedVariables" property of "mpc" object is empty. Assuming defails -->The "Weights.ManipulatedVariablesRate" property of "mpc" object is empty. Assuming of the "mpc" object is empty. Assuming of the "mpc" object is empty. Assuming of the "mpc" object is empty.
```

-->The "Weights.OutputVariables" property of "mpc" object is empty. Assuming default 1

Constrain the manipulated variable to the [0 1] range.

```
MPCobj.MV = struct('Min',0,'Max',1);
```

Specify the simulation stop time.

```
Tstop = 30;
```

Define the reference signal and the measured disturbance signal.

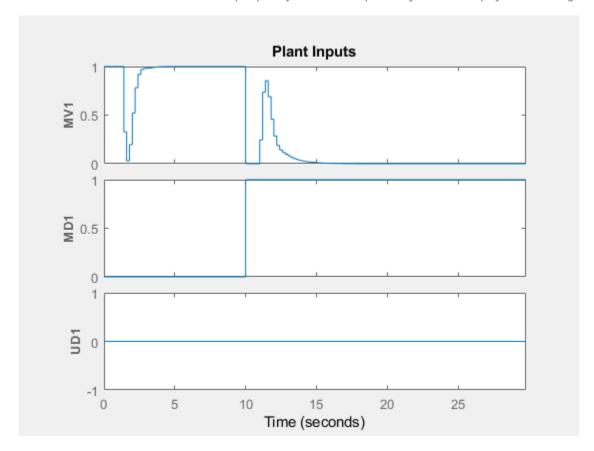

```
num_sim_steps = round(Tstop/Ts);
r = ones(num_sim_steps,1);
v = [zeros(num_sim_steps/3,1); ones(2*num_sim_steps/3,1)];
```

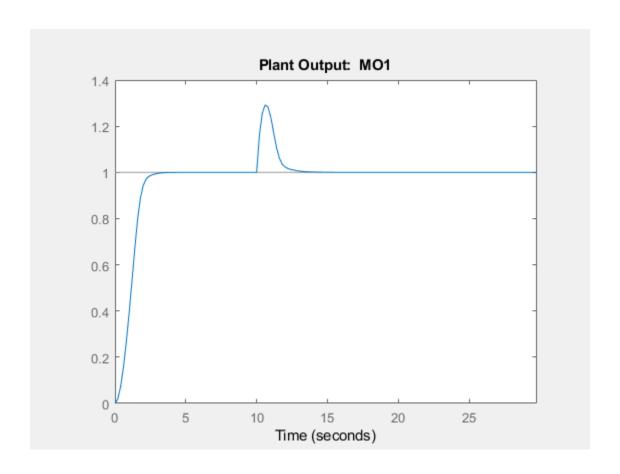

The reference signal, r, is a unit step. The measured disturbance signal, v, is a unit step, with a 10 unit delay.

Simulate the controller.

```
sim(MPCobj,num_sim_steps,r,v)
```

- -->The "Model.Disturbance" property of "mpc" object is empty:
   Assuming unmeasured input disturbance #3 is integrated white noise.
   Assuming no disturbance added to measured output channel #1.
- -->The "Model.Noise" property of the "mpc" object is empty. Assuming white noise on ear

# See Also

mpc | mpcmove | mpcsimopt

# simplify

Reduce explicit MPC controller complexity and memory requirements

# **Syntax**

```
EMPCreduced = simplify(EMPCobj,'exact')
EMPCreduced = simplify(EMPCobj,'exact',uniteeps)
EMPCreduced = simplify(EMPCobj,'radius',r)
EMPCreduced = simplify(EMPCobj,'sequence',index)
simplify(EMPCobj, )
```

# **Description**

EMPCreduced = simplify(EMPCobj,'exact') attempts to reduce the number of piecewise affine (PWA) regions in an explicit MPC controller by merging regions that have identical controller gains and whose union is a convex set. Reducing the number of PWA regions reduces memory requirements of the controller. This command returns a reduced controller, EMPCreduced.

EMPCreduced = simplify(EMPCobj,'exact',uniteeps) specifies the tolerance for identifying regions that can be merged.

EMPCreduced = simplify(EMPCobj, 'radius', r) retains only regions whose Chebyshev radius (the radius of the largest ball contained in the region) is larger than r.

EMPCreduced = simplify(EMPCobj,'sequence',index) eliminates all regions except those specified in an index vector.

simplify(EMPCobj, \_\_\_\_) applies the reduction to the explicit MPC controller EMPCobj, rather than returning a new controller object. You can use this syntax with any of the previous reduction options.

# **Input Arguments**

#### **EMPCobj** — **Explicit MPC controller**

explicit MPC controller object

Explicit MPC controller to reduce, specified as an Explicit MPC controller object. Use generateExplicitMPC to create an explicit MPC controller.

### uniteeps — Tolerance for joining regions

0.001 (default) | positive scalar

Tolerance for joining PWA regions, specified as a positive scalar.

#### r — Minimum Chebyshev radius

0 (default) | nonnegative scalar

Minimum Chebyshev radius for retaining PWA regions, specified as a nonnegative scalar. When you use the 'radius' option, simplify keeps only the regions whose Chebyshev radius is larger than r. The default value is 0, which causes all regions to be retained.

### index — Indices of PWA regions to retain

1:nr (default) | vector

Indices of PWA regions to retain, specified as a vector. The default value is [1:nr], where nr is the number of PWA regions in EMPCobj. Thus, by default, all regions are retained. You can obtain a sequence of regions to retain by performing simulations using EMPCobj and recording the indices of regions actually encountered.

# **Output Arguments**

#### **EMPCreduced** — Reduced MPC controller

explicit MPC controller object

Reduced MPC controller, returned as an Explicit MPC controller object.

### See Also

generateExplicitMPC

### Introduced in R2014b

## size

Size and order of MPC Controller

# **Syntax**

```
mpc_obj_size = size(MPCobj)
mpc_obj_size = size(MPCobj, signal_type)
size(MPCobj)
```

# **Description**

mpc\_obj\_size = size(MPCobj) returns a row vector specifying the number of manipulated inputs and measured controlled outputs of an MPC controller. This row vector contains the elements [ $n_u n_{ym}$ ], where  $n_u$  is the number of manipulated inputs and  $n_{vm}$  is the number of measured controlled outputs.

mpc\_obj\_size = size(MPCobj,signal\_type) returns the number of signals of the
specified type that are associated with the MPC controller.

You can specify signal\_type as one of the following:

- 'uo' Unmeasured controlled outputs
- 'md' Measured disturbances
- 'ud' Unmeasured disturbances
- 'mv' Manipulated variables
- 'mo' Measured controlled outputs

size(MPCobj) displays the size information for all the signal types of the MPC controller.

### See Also

mpc|set

### SS

Convert unconstrained MPC controller to state-space linear system

# **Syntax**

```
sys = ss(MPCobj)
sys = ss(MPCobj,signals)
sys = ss(MPCobj,signals,ref_preview,md_preview)
[sys,ut] = ss(MPCobj)
```

# **Description**

The ss command returns a linear controller in the state-space form. The controller is equivalent to the traditional (implicit) MPC controller MPCobj when no constraints are active. You can then use Control System Toolbox software for sensitivity analysis and other diagnostic calculations.

sys = ss(MPCobj) returns the linear discrete-time dynamic controller sys.

$$x(k + 1) = Ax(k) + By_m(k)$$
  
$$u(k) = Cx(k) + Dy_m(k)$$

where  $y_m$  is the vector of measured outputs of the plant, and u is the vector of manipulated variables. The sampling time of controller sys is MPCobj.Ts.

**Note** Vector x includes the states of the observer (plant + disturbance + noise model states) and the previous manipulated variable u(k-1).

sys = ss(MPCobj, signals) returns the linearized MPC controller in its full form and allows you to specify the signals that you want to include as inputs for sys.

The full form of the MPC controller has the following structure:

$$x(k+1) = Ax(k) + By_m(k) + B_r r(k) + B_v v(k) + B_{ut} u_{target}(k) + B_{off}$$

$$u(k) = Cx(k) + Dy_m(k) + D_r r(k) + D_v v(k) + D_{ut} u_{target}(k) + D_{off}$$

#### Here:

- r is the vector of setpoints for both measured and unmeasured plant outputs
- *v* is the vector of measured disturbances.
- $u_{target}$  is the vector of preferred values for manipulated variables.

Specify signals as a character vector or string with any combination that contains one or more of the following characters:

- 'r' Output references
- 'v' Measured disturbances
- 'o' Offset terms
- 't' Input targets

For example, to obtain a controller that maps  $[y_m; r; v]$  to u, use:

In the general case of nonzero offsets,  $y_{\rm m}$ , r, v, and  $u_{\rm target}$  must be interpreted as the difference between the vector and the corresponding offset. Offsets can be nonzero is MPCobj.Model.Nominal.Y or MPCobj.Model.Nominal.U are nonzero.

Vectors  $B_{off}$  and  $D_{off}$  are constant terms. They are nonzero if and only if MPCobj.Model.Nominal.DX is nonzero (continuous-time prediction models), or MPCobj.Model.Nominal.Dx-MPCobj.Model.Nominal.X is nonzero (discrete-time prediction models). In other words, when Nominal.X represents an equilibrium state,  $B_{off}$ ,  $D_{off}$  are zero.

Only the following fields of MPCobj are used when computing the state-space model: Model, PredictionHorizon, ControlHorizon, Ts, Weights.

sys = ss(MPCobj, signals, ref\_preview, md\_preview) specifies if the MPC controller has preview actions on the reference and measured disturbance signals. If the flag ref\_preview = 'on', then matrices  $B_r$  and  $D_r$  multiply the whole reference sequence:

$$x(k+1) = Ax(k) + By_m(k) + B_r[r(k); r(k+1); ...; r(k+p-1)] + ...$$

```
u(k) = Cx(k) + Dy_m(k) + D_r[r(k);r(k+1);...;r(k+p-1)] +...
```

Similarly if the flag  $md_preview='on'$ , then matrices  $B_{\nu}$  and  $D_{\nu}$  multiply the whole measured disturbance sequence:

```
x(k+1) = Ax(k) + ... + B_{\nu}[\nu(k);\nu(k+1);...;\nu(k+p)] + ...
u(k) = Cx(k) + ... + D_{\nu}[\nu(k);\nu(k+1);...;\nu(k+p)] + ...
```

[sys,ut] = ss(MPCobj) also returns the input target values for the full form of the controller.

ut is returned as a vector of doubles, [utarget(k); utarget(k+1); ...
utarget(k+h)].

#### Here:

- h Maximum length of previewed inputs; that is, h = max(length(MPCobj.ManipulatedVariables(:).Target))
- utarget Difference between the input target and corresponding input offsets; that is, MPCobj.ManipulatedVariables(:).Targets MPCobj.Model.Nominal.U

# **Examples**

### **Convert Unconstrained MPC Controller to State-Space Model**

To improve the clarity of the example, suppress messages about working with an MPC controller.

```
old_status = mpcverbosity('off');
```

Create the plant model.

```
G = rss(5,2,3);
G.D = 0;
G = setmpcsignals(G,'mv',1,'md',2,'ud',3,'mo',1,'uo',2);
```

Configure the MPC controller with nonzero nominal values, weights, and input targets.

```
C = mpc(G, 0.1);

C.Model.Nominal.U = [0.7 0.8 0];
```

```
C.Model.Nominal.Y = [0.5 0.6];
C.Model.Nominal.DX = rand(5,1);
C.Weights.MV = 2;
C.Weights.OV = [3 4];
C.MV.Target = [0.1 0.2 0.3];
```

C is an unconstrained MPC controller. Specifying C.Model.Nominal.DX as nonzero means that the nominal values are not at steady state. C.MV.Target specifies three preview steps.

Convert C to a state-space model.

```
sys = ss(C);
```

The output, sys, is a seventh-order SISO state-space model. The seven states include the five plant model states, one state from the default input disturbance model, and one state from the previous move, u(k-1).

Restore mpcverbosity.

```
mpcverbosity(old_status);
```

mpc|set|tf|zpk

## tf

Convert unconstrained MPC controller to linear transfer function

## **Syntax**

sys=tf(MPCobj)

# **Description**

The tf function computes the transfer function of the linear controller ss(MPCobj) as an LTI system in tf form corresponding to the MPC controller when the constraints are not active. The purpose is to use the linear equivalent control in Control System Toolbox software for sensitivity and other linear analysis.

### See Also

ss | zpk

## trim

Compute steady-state value of MPC controller state for given inputs and outputs

# **Syntax**

```
x = trim(MPCobj, y, u)
```

# **Description**

The trim function finds a steady-state value for the plant state or the best approximation in a least squares sense such that:

$$x - x_{off} = A(x - x_{off}) + B(u - u_{off})$$
  
$$y - y_{off} = C(x - x_{off}) + D(u - u_{off})$$

Here,  $x_{off}$ ,  $u_{off}$ , and  $y_{off}$  are the nominal values of the extended state x, input u, and output y respectively.

x is returned as an mpcstate object. Specify y and u as doubles. y specifies the measured and unmeasured output values. u specifies the manipulated variable, measured disturbance, and unmeasured disturbance values. The values for unmeasured disturbances must be  $\theta$ .

trim assumes the disturbance model and measurement noise model to be zero when computing the steady-state value. The software uses the extended state vector to perform the calculation.

mpc | mpcstate

## validateFcns

Examine prediction model and custom functions of nlmpc object for potential problems

validateFunctions tests the prediction model, custom cost, custom constraint, and Jacobian functions of a nonlinear MPC controller for potential problems. When you first design your nonlinear MPC controller, or when you make significant changes to an existing controller, it is best practice to validate your controller functions.

# **Syntax**

```
validateFcns(nlmpcobj,x,mv)
validateFcns(nlmpcobj,x,mv,md)
validateFcns(nlmpcobj,x,mv,md,parameters)
validateFcns(nlmpcobj,x,mv,md,parameters,ref)
validateFcns(nlmpcobj,x,mv,md,parameters,ref,mvtarget)
```

# **Description**

validateFcns(nlmpcobj,x,mv) tests the functions of nonlinear MPC controller nlmpcobj for potential problems. The functions are tested using specified nominal state values, x, and manipulated variable values, mv. Use this syntax if your controller has no measured disturbances and no parameters.

validateFcns(nlmpcobj,x,mv,md) specifies nominal measured disturbance values. If your controller has measured disturbance channels, you must specify md.

validateFcns(nlmpcobj,x,mv,md,parameters) specifies nominal parameter values. If your controller has parameters, you must specify parameters.

validateFcns(nlmpcobj,x,mv,md,parameters,ref) specifies nominal output
references.

validateFcns(nlmpcobj,x,mv,md,parameters,ref,mvtarget) specifies nominal manipulated variable targets.

# **Examples**

#### Validate Nonlinear MPC Prediction Model and Custom Functions

Create nonlinear MPC controller with six states, six outputs, and four inputs.

```
nx = 6;
ny = 6;
nu = 4;
nlobj = nlmpc(nx,ny,nu);
In standard cost function, zero weights are applied by default to one or more OVs because Specify the controller sample time and horizons.
```

```
Ts = 0.4;
p = 30;
c = 4;
nlobj.Ts = Ts;
nlobj.PredictionHorizon = p;
nlobj.ControlHorizon = c;
```

Specify the prediction model state function and the Jacobian of the state function. For this example, use a model of a flying robot.

```
nlobj.Model.StateFcn = "FlyingRobotStateFcn";
nlobj.Jacobian.StateFcn = "FlyingRobotStateJacobianFcn";
```

Specify a custom cost function for the controller that replaces the standard cost function.

```
nlobj.Optimization.CustomCostFcn = @(X,U,e,data) Ts*sum(sum(U(1:p,:)));
nlobj.Optimization.ReplaceStandardCost = true;
```

Specify a custom constraint function for the controller.

```
nlobj.Optimization.CustomEqConFcn = @(X,U,data) X(end,:)';
```

Validate the prediction model and custom functions at the initial states (x0) and initial inputs (u0) of the robot.

```
x0 = [-10;-10;pi/2;0;0;0];
u0 = zeros(nu,1);
validateFcns(nlobj,x0,u0);
```

```
Model.StateFcn is OK.

Jacobian.StateFcn is OK.

No output function specified. Assuming "y = x" in the prediction model.

Optimization.CustomCostFcn is OK.

Optimization.CustomEqConFcn is OK.

Analysis of user-provided model, cost, and constraint functions complete.
```

#### Create Nonlinear MPC Controller with Discrete-Time Prediction Model

Create a nonlinear MPC controller with four states, two outputs, and one input.

```
nx = 4;
ny = 2;
nu = 1;
nlobj = nlmpc(nx,ny,nu);
```

In standard cost function, zero weights are applied by default to one or more OVs became

Specify the sample time and horizons of the controller.

```
Ts = 0.1;
nlobj.Ts = Ts;
nlobj.PredictionHorizon = 10;
nlobj.ControlHorizon = 5;
```

Specify the state function for the controller, which is in the file pendulumDTO.m. This discrete-time model integrates the continuous time model defined in pendulumCTO.m using a multistep forward Euler method.

```
nlobj.Model.StateFcn = "pendulumDTO";
nlobj.Model.IsContinuousTime = false;
```

The discrete-time state function uses an optional parameter, the sample time Ts, to integrate the continuous-time model. Therefore, you must specify the number of optional parameters as 1.

```
nlobj.Model.NumberOfParameters = 1;
```

Specify the output function for the controller. In this case, define the first and third states as outputs. Even though this output function does not use the optional sample time parameter, you must specify the parameter as an input argument (Ts).

```
nlobj.Model.OutputFcn = @(x,u,Ts)[x(1); x(3)];
```

Validate the prediction model functions for nominal states x0 and nominal inputs u0. Since the prediction model uses a custom parameter, you must pass this parameter to validateFcns.

```
x0 = [0.1;0.2;-pi/2;0.3];
u0 = 0.4;
validateFcns(nlobj, x0, u0, [], {Ts});

Model.StateFcn is OK.
Model.OutputFcn is OK.
Analysis of user-provided model, cost, and constraint functions complete.
```

#### Create Nonlinear MPC Controller with Measured and Unmeasured Disturbances

Create a nonlinear MPC controller with three states, one output, and four inputs. The first two inputs are measured disturbances, the third input is the manipulated variable, and the fourth input is an unmeasured disturbance.

```
nlobj = nlmpc(3,1,'MV',3,'MD',[1 2],'UD',4);
```

To view the controller state, output, and input dimensions and indices, use the Dimensions property of the controller.

#### nlobj.Dimensions

Specify the controller sample time and horizons.

```
nlobj.Ts = 0.5;
nlobj.PredictionHorizon = 6;
nlobj.ControlHorizon = 3;
```

Specify the prediction model state function, which is in the file  ${\tt exocstrStateFcnCT.m.}$ 

```
nlobj.Model.StateFcn = 'exocstrStateFcnCT';
```

Specify the prediction model output function, which is in the file exocstrOutputFcn.m.

```
nlobj.Model.OutputFcn = 'exocstrOutputFcn';
```

Validate the prediction model functions using the initial operating point as the nominal condition for testing and setting the unmeasured disturbance state, x0(3), to 0. Since the model has measured disturbances, you must pass them to validateFcns.

```
x0 = [311.2639; 8.5698; 0];
u0 = [10; 298.15; 298.15];
validateFcns(nlobj,x0,u0(3),u0(1:2)');

Model.StateFcn is OK.
Model.OutputFcn is OK.
Analysis of user-provided model, cost, and constraint functions complete.
```

# **Input Arguments**

### nlmpcobj — Nonlinear MPC controller

nlmpc object

Nonlinear MPC controller, specified as an nlmpc object.

#### x — Nominal state values

vector

Nominal state values, specified as a vector of length  $N_x$ ,  $N_x$  is equal to nlmpcobj.Dimensions.NumberOfStates

### mv — Nominal manipulated variable values

vector

Nominal manipulated variable values, specified as a vector of length  $N_{m\nu}$ , where  $N_{m\nu}$  is equal to the length of nlmpcobj.Dimensions.MVIndex.

#### md — Nominal measured disturbance values

```
[] (default) | vector
```

Nominal measured disturbance values, specified as a vector of length  $N_{md}$ , where  $N_{md}$  is equal to the length of nlmpcobj. Dimensions .MDIndex. If your controller has measured

disturbance channels, you must specify md. If your controller does not have measured disturbance channels, specify md as [].

#### parameters — Nominal parameter values

[] (default) | cell array

Nominal parameter values used by the prediction model, custom cost function, and custom constraints, specified as a cell array of length  $N_p$ , where  $N_p$  is equal to nlmpcobj.Model.NumberOfParameters. The order of the parameters must match the order specified in the model functions, and each parameter must be a numeric parameter with the correct dimensions.

If your controller has parameters, you must specify parameters. If your controller does not have parameters, specify parameters as [].

#### ref — Nominal output reference values

[] (default) | vector

Nominal output reference values, specified as a vector of length  $N_y$ , where Ny is equal to nlmpcobj.Dimensions.NumberOfOutputs. ref is passed to the custom cost and constraint function. If you do not specify ref, the controller passes a vector of zeros to the custom functions.

### mvtarget — Nominal manipulated variable targets

[] (default) | vector

Nominal manipulated variable targets, specified as a vector of length  $N_{mv}$ , where  $N_{mv}$  is equal to the length of nlmpcobj.Dimensions.MVIndex.mvtarget is passed to the custom cost and constraint function. If you do not specify mvtarget, the controller passes a vector of zeros to the custom functions.

# **Tips**

When you provide your own analytical Jacobian functions, it is especially important
that these functions return valid Jacobian values. If validateFunctions detects
large differences between the values returned by your user-defined Jacobian functions
and the finite-difference approximation, verify the code in your Jacobian
implementations.

# **Algorithms**

For each controller function, validateFunctions checks whether the function:

- Exists on the MATLAB path
- Has the required number of input arguments
- Can be executed successfully without errors
- Returns the output arguments with the correct size and dimensions
- Returns valid numerical data; that is, it does not return Inf or NaN values

For Jacobian functions, validateFunctions checks whether the returned values are comparable to a finite-difference approximation of the Jacobian values. These finite-difference values are computed using numerical perturbation.

"Specify Prediction Model for Nonlinear MPC"

### Introduced in R2018b

<sup>&</sup>quot;Specify Cost Function for Nonlinear MPC"

<sup>&</sup>quot;Specify Constraints for Nonlinear MPC"

# zpk

Convert unconstrained MPC controller to zero/pole/gain form

# **Syntax**

sys=zpk(MPCobj)

# **Description**

The zpk function computes the zero-pole-gain form of the linear controller ss(MPCobj) as an LTI system in zpk form corresponding to the MPC controller when the constraints are not active. The purpose is to use the linear equivalent control in Control System Toolbox software for sensitivity and other linear analysis.

# **Block Reference**

# **MPC Controller**

Compute MPC control law

# Library

MPC Simulink Library

# **Description**

The MPC Controller block receives the current measured output signal (mo), reference signal (ref), and optional measured disturbance signal (md). The block computes the optimal manipulated variables (mv) by solving a quadratic programming problem using either the default KWIK solver or a custom QP solver. For more information, see "QP Solver".

To use the block in simulation and code generation, you must specify an mpc object, which defines a model predictive controller. This controller must have already been designed for the plant that it controls.

Because the MPC Controller block uses MATLAB Function blocks, it requires compilation each time you change the MPC object and block. Also, because MATLAB does not allow compiled code to reside in any MATLAB product folder, you must use a non-MATLAB folder to work on your Simulink model when you use MPC blocks.

# **Dialog Box**

The MPC Controller block has the following parameter groupings:

- "Parameters" on page 3-3
- "Required Inports" on page 3-4
- "Required Outports" on page 3-5
- "Additional Inports (General Section)" on page 3-6
- "Additional Outports (General Section)" on page 3-9
- "State Estimation (General Section)" on page 3-11
- "Constraints (Online Features Section)" on page 3-11
- "Weights (Online Features Section)" on page 3-14
- "Prediction and Control Horizons (Online Features Section)" on page 3-17
- "Default Conditions Section" on page 3-18
- "Others Section" on page 3-18

# **Parameters**

### **MPC Controller**

You must provide an mpc object that defines an implicit MPC controller. To do so:

• Enter the name of an mpc object in the MPC Controller edit box. This object must be present in the MATLAB workspace.

If you want to modify the controller settings in a graphical environment, open the **MPC Designer** app by clicking **Design**. For example, you can:

- · Import a new prediction model.
- Change horizons, constraints, and weights.
- Evaluate MPC performance with a linear plant.
- Export the updated controller to the MATLAB workspace.

To see how well the controller works for the nonlinear plant, run a closed-loop Simulink simulation.

If you do not have an existing mpc object in the MATLAB workspace, leave the MPC controller field empty. With the MPC Controller block connected to the plant, click Design to open MPC Designer. Using the app, linearize the Simulink model at a specified operating point, and design your controller. For more information, see "Design MPC Controller in Simulink" and "Linearize Simulink Models Using MPC Designer".

To use this design approach, you must have Simulink Control Design software.

Once you specify a controller in the **MPC Controller** field, you can review your design for run-time stability and robustness issues by clicking **Review**. For more information, see "Review Model Predictive Controller for Stability and Robustness Issues".

### Initial controller state

Specifies the initial controller state. If this parameter is left blank, the block uses the nominal values that are defined in the Model.Nominal property of the mpc object. To override the default, create an mpcstate object in your workspace, and enter its name in the field.

# **Required Inports**

# Measured output or State estimate

If your controller uses default state estimation, this inport is labeled mo. Connect this inport to the measured plant output signals. The MPC controller uses measured plant outputs to improve its state estimates.

To enable custom state estimation, in the **General** section, check **Use custom estimated states instead of measured outputs**. Checking this option changes the label on this inport to x[k|k]. Connect a signal that provides estimates of the controller state (plant, disturbance, and noise model states). Use custom state estimates when an alternative estimation technique is considered superior to the built-in estimator or when the states are fully measurable.

### Reference

The ref dimension must not change from one control instant to the next. Each element must be a real number.

When ref is a 1-by- $n_y$  signal, where  $n_y$  is the number of outputs, there is no reference signal previewing. The controller applies the current reference values across the prediction horizon.

To use signal previewing, specify ref as an N-by- $n_y$  signal, where N is the number of time steps for which you are specifying reference values. Here,  $1 < N \le p$ , and p is the prediction horizon. Previewing usually improves performance, since the controller can anticipate future reference signal changes. The first row of ref specifies the  $n_y$  references for the first step in the prediction horizon (at the next control interval k = 1), and so on for N steps. If N < p, the last row designates constant reference values for the remaining  $p \cdot N$  steps.

For example, suppose  $n_y = 2$  and p = 6. At a given control instant, the signal connected to the ref inport is:

```
 \begin{bmatrix} 2 & 5 & \leftarrow & k=1 \\ 2 & 6 & \leftarrow & k=2 \\ 2 & 7 & \leftarrow & k=3 \\ 2 & 8 \end{bmatrix} \leftarrow k=4
```

The signal informs the controller that:

- Reference values for the first prediction horizon step k = 1 are 2 and 5.
- The first reference value remains at 2, but the second increases gradually.
- The second reference value becomes 8 at the beginning of the fourth step k = 4 in the prediction horizon.
- Both values remain constant at 2 and 8 respectively for steps 5-6 of the prediction horizon.

mpcpreview shows how to use reference previewing in a specific case. For calculation details on the use of the reference signal, see "Optimization Problem".

# **Required Outports**

# **Manipulated Variables**

The mv outport provides a signal defining the  $n_u \ge 1$  manipulated variables for controlling the plant. At each control instant, the controller updates its mv outport by solving a quadratic programming problem using either the default KWIK solver or a custom QP solver. For more information, see "QP Solver".

If the controller detects an infeasible optimization problem or encounters numerical difficulties in solving an ill-conditioned optimization problem, mv remains at its most recent successful solution; that is, the controller output freezes.

Otherwise, if the optimization problem is feasible and the solver reaches the specified maximum number of iterations without finding an optimal solution, mv:

- Remains at its most recent successful solution if the Optimizer.UseSuboptimalSolution property of the controller is false.
- Is the suboptimal solution reached after the final iteration if the Optimizer.UseSuboptimalSolution property of the controller is true. For more information, see "Suboptimal QP Solution".

# **Additional Inports (General Section)**

### Measured disturbance

Add an inport (md) to which you connect a measured disturbance signal. The number of measured disturbances defined for your controller,  $n_{md} \ge 1$ , must match the dimensions of the connected disturbance signal.

The number of measured disturbances must not change from one control instant to the next, and each disturbance value must be a real number.

When md is a 1-by- $n_{md}$  signal, there is no measured disturbance previewing. The controller applies the current disturbance values across the prediction horizon.

To use disturbance previewing, specify md as an N-by- $n_{md}$  signal, where N is the number of time steps for which the measured disturbances are known. Here,  $1 < N \le p+1$ , and p is the prediction horizon. Previewing usually improves performance, since the controller can anticipate future disturbances. The first row of md specifies the  $n_{md}$  current disturbance values (k=1), with other rows specifying disturbances for subsequent control intervals. If N < p+1, the controller applies the last row for the remaining  $p \cdot N+1$  steps.

For example, suppose  $n_{md} = 2$  and p = 6. At a given control instant, the signal connected to the md inport is:

```
 \begin{bmatrix} 2 & 5 & \leftarrow & k=0 \\ 2 & 6 & \leftarrow & k=1 \\ 2 & 7 & \leftarrow & k=2 \\ 2 & 8 \end{bmatrix} \leftarrow k=3
```

This signal informs the controller that:

- The current MD values are 2 and 5 at k = 0.
- The first MD remains at 2, but the second increases gradually.
- The second MD becomes 8 at the beginning of the third step k=3 in the prediction horizon.
- Both values remain constant at 2 and 8 respectively for steps 4-6 of the prediction horizon.

mpcpreview shows how to use MD previewing in a specific case.

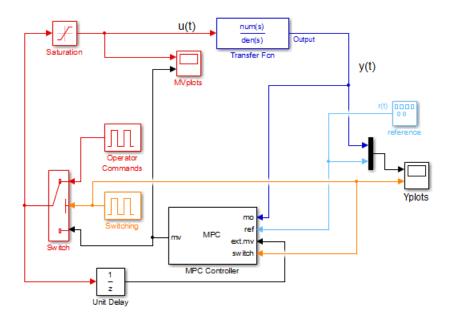

For calculation details, see "MPC Modeling" and "QP Matrices".

### **External manipulated variable**

Add an inport (ext.mv) to which you connect a vector signal that contains the actual  $n_u$  manipulated variables (MV) used in the plant. Use this option when the MV applied to the plant between time  $t_{k-1}$  and  $t_k$  is different than the optimal MV computed at the last control interval, for example due to signal saturation or an override condition. When enabled, the block uses this signal to correct controller state estimates at  $t_k$ .

Controller state estimation assumes that the MV is piecewise constant. At time  $t_k$ , the ext.mv value must be the effective MV between times  $t_{k-1}$  and  $t_k$ . For example, if the MV is actually varying over this interval, you might supply the time-averaged value evaluated at time  $t_k$ .

The following example, from the model  $mpc\_bumpless$ , includes a switch that can override the controller output with a signal supplied by the operator. Also, the controller output may saturate. Feeding back the actual MV used in the plant (labeled u(t) in the example) improves the accuracy of controller state estimates.

If the external MV option is inactive or the ext.mv inport in unconnected, the controller assumes that its MV output is used in the plant without modification.

**Note** Using this option can cause an algebraic loop in the Simulink model, since there is direct feedthrough from the ext.mv inport to the mv outport. To prevent such algebraic loops, insert a Memory block or Unit Delay block.

# Targets for manipulated variables

If you want one or more manipulated variables (MV) to track target values that change with time, use this option to add an mv.target inport. Connect this port to a target signal with dimension  $n_u$ , where  $n_u$  is the number of MVs.

For this to be effective, the corresponding MV(s) must have nonzero penalty weights (these weights are zero by default).

# **Additional Outports (General Section)**

### **Optimal cost**

Add an outport (cost) that provides the optimal quadratic programming objective function value at the current time (a nonnegative scalar). If the controller is performing well and no constraints have been violated, the value should be small. If the optimization problem is infeasible, however, the value is meaningless. (See qp.status.)

### **Optimization status**

Add an outport (qp.status) that allows you to monitor the status of the QP solver.

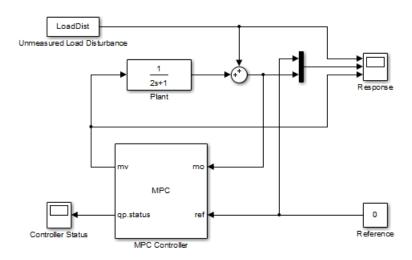

If a QP problem is solved successfully at a given control interval, the qp.status output returns the number of QP solver iterations used in computation. This value is a finite, positive integer and is proportional to the time required for the calculations. Thus, a large value means a relatively slow block execution for this time interval.

The QP solver can fail to find an optimal solution for the following reasons:

- qp.status = 0 The QP solver cannot find a solution within the maximum number of iterations specified in the mpc object. In this case, if the Optimizer.UseSuboptimalSolution property of the MPC controller is false, the block holds its mv output at the most recent successful solution. Otherwise, it uses the suboptimal solution found during the last solver iteration.
- qp.status = -1 The QP solver detects an infeasible QP problem. See "Monitoring Optimization Status to Detect Controller Failures" for an example where a large, sustained disturbance drives the OV outside its specified bounds. In this case, the block holds its mv output at the most recent successful solution.
- qp.status = -2 The QP solver has encountered numerical difficulties in solving a severely ill-conditioned QP problem. In this case, the block holds its mv output at the most recent successful solution.

In a real-time application, you can use qp.status to set an alarm or take other special action.

The following diagram shows how to use the status indicator to monitor the MPC Controller block in real time. For more information, see "Monitoring Optimization Status to Detect Controller Failures".

### **Estimated controller states**

Add an outport (est.state) to receive the controller state estimates, x[k|k], at each control instant. These include the plant, disturbance, and noise model states.

## **Optimal control sequence**

Add an outport (mv.seq) that provides the predicted optimal MV adjustments (moves) over the entire prediction horizon from k to k+p, where k is the current time and p is the prediction horizon. This signal is a (p+1)-by- $n_u$  matrix, where and  $n_u$  is the number of manipulated variables.

mv.seq contains the calculated optimal MV moves at time k+i-1, for  $i=1,\ldots,p$ . The first row of mv.seq is identical to the mv outport signal, which is the current MV adjustment applied at time k. Since the controller does not calculate optimal control moves at time k+p, the last row of mv.seq duplicates the previous row.

# **Optimal state sequence**

Add an outport (x.seq) that provides the predicted optimal state variable sequence over the entire prediction horizon from k to k+p, where k is the current time and p is the prediction horizon. This signal is a (p+1)-by- $n_x$  matrix, where  $n_x$  is the number of states in the plant and unmeasured disturbance models (states from noise models are not included).

x.seq contains the calculated optimal state values at time k+i, for i=1,...,p. The first row of x.seq contains the current states at time k as determined by state estimation.

### **Optimal output sequence**

Add an outport (y.seq) that provides the predicted optimal output variable sequence over the entire prediction horizon from k to k+p, where k is the current time and p is the prediction horizon. This signal is a (p+1)-by- $n_y$  matrix, where and  $n_y$  is the number of outputs.

y.seq contains the calculated optimal output values at time k+i-1, for  $i=1,\ldots,p+1$ . The first row of y.seq contains the current outputs at time k based on the estimated states and measured disturbances; it is not the measured output at time k.

# **State Estimation (General Section)**

### Use custom estimated states instead of using the built-in Kalman filter

Replace mo with the x[k|k] inport for custom state estimation as described in "Required Inports" on page 3-4.

# **Constraints (Online Features Section)**

### **Lower MV limits**

Add inport umin that you can connect to a run-time constraint signal for manipulated variable lower bounds. This signal is a vector with  $n_u$  finite values. The ith element of umin replaces the ManipulatedVariables (i). Min property of the controller at run time.

If a manipulated variable does not have a lower bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

If the ManipulatedVariables(i). Min property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), the ith element of umin

replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

### **Upper MV limits**

Add inport umax that you can connect to a run-time constraint signal for manipulated variable upper bounds. This signal is a vector with  $n_u$  finite values. The ith element of umax replaces the ManipulatedVariables (i). Max property of the controller at run time.

If a manipulated variable does not have an upper bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

If the ManipulatedVariables (i). Max property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), the ith element of umax replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

### **Lower OV limits**

Add inport ymin that you can connect to a run-time constraint signal for output variable lower bounds. This signal is a vector with  $n_y$  finite values. The ith element of ymin replaces the OutputVariables (i). Min property of the controller at run time.

If an output variable does not have a lower bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

If the OutputVariables (i). Min property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), the ith element of ymin replaces

the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

### **Upper OV limits**

Add inport ymax that you can connect to a run-time constraint signal for output variable upper bounds. This signal is a vector with  $n_y$  finite values. The ith element of ymax replaces the OutputVariables(i). Max property of the controller at run time.

If an output variable does not have an upper bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

If the OutputVariables(i). Max property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), the ith element of ymax replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

### **Custom constraints**

Add inports E, F, G, and S to the block that you can connect to the following run-time custom constraint matrix signals:

- E Manipulated variable constraint matrix with size  $n_c$ -by- $n_u$ , where  $n_c$  is the number of custom constraints
- F Controlled output constraint matrix with size  $n_c$ -by- $n_y$
- G Custom constraint matrix with size 1-by- $n_c$
- S Measured disturbance constraint matrix, with size  $n_c$ -by- $n_v$ , where  $n_v$  is the number of measured disturbances. S is added only if the mpc object has measured disturbances.

These constraints replace the custom constraints previously set using setconstraint.

If you define E, F, G, or S in the mpc object, you must connect a signal to the corresponding inport, and that signal must have the same dimensions as the array

specified in the controller. If an array is not defined in the controller object, use a zero matrix with the correct size.

The custom constraints are of the form  $Eu + Fy + Sv \le G$ , where:

- *u* is a vector of manipulated variable values.
- y is a vector of predicted plant output values.
- v is a vector of measured plant disturbance input values.

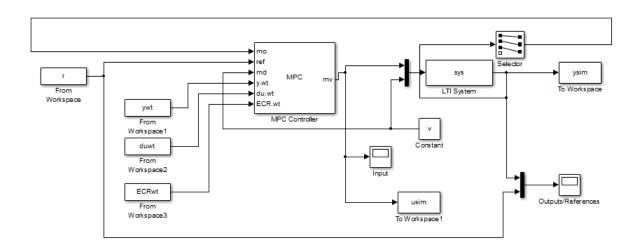

For more information, see "Constraints on Linear Combinations of Inputs and Outputs".

# **Weights (Online Features Section)**

A controller intended for real-time applications should have "knobs" you can use to tune its performance when it operates with the real plant. This group of optional inports serves that purpose.

The diagram shown below shows three of the MPC Controller tuning inports. In this simulation context, the inports are tuned using pre-stored signals (the ywt, duwt, and ECRwt variables in the From Workspace blocks). In practice, you would connect a knob or similar manual adjustment.

**Note** You cannot specify time-varying weights at run time using a matrix signal.

### **OV** weights

Add an inport (y.wt) that you can connect to a run-time output variable (OV) weight signal. This signal overrides the Weights.OV property of the mpc object, which establishes the relative importance of OV reference tracking.

To use the same tuning weights over the prediction horizon, connect y.wt to a vector signal with  $n_y$  elements, where  $n_y$  is the number of controlled outputs. Each element specifies a nonnegative tuning weight for each controlled output variable. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect y.wt to a matrix signal with  $n_y$  columns and up to p rows, where p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

If you do not connect a signal to the y.wt inport, the block uses the OV weights specified in your mpc object.

# **MV** weights

Add an inport (u.wt) that you can connect to a run-time manipulated variable (MV) weight signal. This signal overrides the Weights.MV property of the mpc object, which establishes the relative importance of MV target tracking.

To use the same tuning weights over the prediction horizon, connect u.wt to a vector signal with  $n_u$  elements, where  $n_u$  is the number of manipulated variables. Each element specifies a nonnegative tuning weight for each manipulated variable. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect  ${\tt u.wt}$  to a matrix signal with  $n_u$  columns and up to p rows, where p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

If you do not connect a signal to the u.wt inport, the block uses the MV weights specified in your mpc object.

### **MVRate weights**

Add an inport (du.wt) that you can connect to a run-time manipulated variable (MV) rate weight signal. This signal overrides the Weights.MVrate property of the mpc object, which establishes the relative importance of MV changes.

To use the same tuning weights over the prediction horizon, connect  $\mathtt{du.wt}$  to a vector signal with  $n_u$  elements, where  $n_u$  is the number of manipulated variables. Each element specifies a nonnegative tuning weight for each manipulated variable rate. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect  $\mathtt{du.wt}$  to a matrix signal with  $n_u$  columns and up to p rows, where p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

If you do not connect a signal to the du.wt inport, the block uses the MV rate weights specified in your mpc object.

# Slack variable weight

Add an inport (ecr.wt), for a scalar nonnegative signal that overrides the MPCobj.Weights.ECR property of the mpc controller. This inport has no effect unless your controller object defines soft constraints whose associated ECR values are nonzero.

If there are soft constraints, increasing the ecr.wt value makes these constraints relatively harder. The controller then places a higher priority on minimizing the magnitude of the predicted worst-case constraint violation.

You may not be able to avoid violations of an output variable constraint. Thus, increasing the ecr.wt value is often counterproductive. Such an increase causes the controller to pay less attention to its other objectives and does not help reduce constraint violations. You usually need to tune ecr.wt to achieve the proper balance in relation to the other control objectives.

# **Prediction and Control Horizons (Online Features Section)**

### Adjust prediction horizon and control horizon at run time

If you want to vary your prediction and control horizons at run time, select this parameter. Doing so adds the following input ports to the block:

- p Prediction horizon, specified as positive integer signal. The prediction horizon signal value must be less than or equal to the **Maximum prediction horizon** parameter.
- m Control horizon, specified as one of the following:
  - Positive integer signal less than or equal to the prediction horizon.
  - Vector signal of positive integers specifying blocking interval lengths. For more information, see "Manipulated Variable Blocking".

At run time, the values of the p and m signals override the default horizons specified in the controller object.

For more information, see "Adjust Horizons at Run Time".

# **Maximum prediction horizon**

Specify the maximum prediction horizon value when varying the prediction horizon at run time. This value,  $P_{max}$ , is used to define:

- The number of rows in the optimal sequence output signals mv.seq, x.seq, and y.seq. When varying your prediction horizon at run time, these signals have  $P_{max}+1$  rows.
- The maximum number of rows for the time-varying weights input signals y.wt, u.wt, and du.wt. When varying your prediction horizon at run time, these signals can have at most  $P_{max}$  rows.

To enable this parameter, select the **Adjust prediction horizon and control horizon at run time** parameter.

For more information, see "Adjust Horizons at Run Time".

### **Default Conditions Section**

Specify the default block sample time and signal dimensions for performing simulation, trimming, or linearization. In these cases, the mv output signal remains at zero. You must specify default condition values that are compatible with your Simulink model design.

**Note** These default conditions apply only if the **MPC Controller** field is empty. If you specify a controller from the MATLAB workspace, the sample time and signal sizes from the specified controller are used.

### **Sample Time**

Specify the default controller sample time.

## **Plant Input Signal Sizes**

Specify the default signal dimensions for the following input signal types:

- · Manipulated variables
- Unmeasured disturbances
- Measured disturbances

**Note** You can specify the measured disturbances signal dimension only if, on the **General** section, in the **Additional Inports** section, the **Measured disturbance** option is selected.

# **Plant Output Signal Sizes**

Specify the default signal dimensions for the following output signal types:

- Measured outputs
- Unmeasured outputs

# **Others Section**

# Block data type

Specify the block data type of the manipulated variables as one of the following:

- double Double-precision floating point (default)
- single Single-precision floating point

If you are implementing the block on a single-precision target, specify the output data type as single.

For an example of double-precision and single-precision simulation and code generation for an MPC controller, see "Simulation and Code Generation Using Simulink Coder".

To view the port data types in a model, in the Simulink Editor, select **Display > Signals & PortsPort Data Types**.

### Inherit sample time

Use the sample time of the parent subsystem as the block sample time. Doing so allows you to conditionally execute this block inside Function-Call Subsystem or Triggered Subsystem blocks. For an example, see "Using MPC Controller Block Inside Function-Call and Triggered Subsystems".

**Note** You must execute Function-Call Subsystem or Triggered Subsystem blocks at the sample rate of the controller. Otherwise, you can see unexpected results.

To view the sample time of a block, in the Simulink Editor, select **Display > Sample Time**. Select **Colors**, **Annotations**, or **All**. For more information, see "View Sample Time Information" (Simulink).

# Use external signal to enable or disable optimization

Add an inport (switch) whose input specifies whether the controller performs optimization calculations. If the input signal is zero, the controller behaves normally. If the input signal is nonzero, the MPC Controller block turns off the controller optimization calculations. This action reduces computational effort when the controller output is not needed, such as when the system is operating manually or another controller has taken over. However, the controller continues to update its internal state estimates in the usual way. Thus, it is ready to resume optimization calculations whenever the switch signal returns to zero. While controller optimization is off, the MPC Controller block passes the current ext.mv signal to the controller output. If the ext.mv inport is not enabled, the controller output is held at the value it had when optimization was disabled.

# **Compatibility Considerations**

# MPC Simulink block mv. seq output port signal dimensions have changed

Behavior changed in R2018b

The signal dimensions of the mv.seq output port of the MPC Controller block have changed. Previously, this signal was a p-by- $N_{mv}$  matrix, where p is the prediction horizon and  $N_{mv}$  is the number of manipulated variables. Now, mv.seq is a (p+1)-by- $N_{mv}$  matrix, where row p+1 duplicates row p.

# **Multiple MPC Controllers**

Simulate switching between multiple implicit MPC controllers

# Library

MPC Simulink Library

# **Description**

At each control instant the Multiple MPC Controllers block receives the current measured plant output, reference, and measured plant disturbance (if any). In addition, it receives a switching signal that selects the *active controller* from a list of candidate MPC controllers designed at different operating points within the operating range. The active controller then solves a quadratic program to determine the optimal plant manipulated variables for the current input signals.

The Multiple MPC Controllers block enables you to achieve better control when operating conditions change. Using available measurements, you can detect the current operating region at run time and choose the appropriate active controller via the switch inport. Switching controllers for different operating regions is a common approach to solving nonlinear control problems using linear control techniques.

To improve efficiency, inactive controllers do not compute optimal control moves. However, to provide bumpless transfer between controllers, the inactive controllers continue to perform state estimation.

The Multiple MPC Controllers block lacks several optional features found in the MPC Controller block, as follows:

- You cannot disable optimization. One controller must always be active.
- You cannot initiate a controller design from within the block dialog box; that is, there
  is no **Design** button. Design all candidate controllers before configuring the Multiple
  MPC Controllers block.
- Similarly, there is no Review button. Instead, use the review command or the MPC Designer app.
- You cannot update custom constraints on linear combinations of inputs and outputs at run time.

The Adaptive MPC Controller block compensates for operating point variations by modifying its prediction model. The advantages of the Multiple MPC Controllers block over Adaptive MPC Controller block are as follows:

- Simpler configuration There is no need to identify prediction model parameters using online data.
- Its candidate controllers form a limited set that you can test thoroughly.

Both the Multiple MPC Controllers block and the Adaptive MPC Controller block enable your control system to adapt to changing operating conditions at run time. The following table lists the advantages of using each block.

Block	Adaptive MPC Controller	Multiple MPC Controllers
	1 + +	Switch between multiple controllers designed for different operating regions

Block	Adaptive MPC Controller	Multiple MPC Controllers
Advantages	Only need to design a single controller offline	No need for online estimation of plant model
	Less run-time computational effort and smaller memory footprint	Controllers can have different sample time, horizons, and weights
	More robust to real-life changes in plant conditions	Prediction models can have different orders or time domains
		Finite set of candidate controllers can be tested thoroughly

# **Dialog Box**

The Multiple MPC Controller block has the following parameter groupings:

- "Parameters" on page 3-24
- "Required Inports" on page 3-25
- "Required Outports" on page 3-27
- "Additional Inports (General Section)" on page 3-27
- "Additional Outports (General Section)" on page 3-29
- "State Estimation (General Section)" on page 3-31
- "Constraints (Online Features Section)" on page 3-31
- "Weights (Online Features Section)" on page 3-33
- "Others Section" on page 3-34

# **Parameters**

# **Cell Array of MPC Controllers**

Candidate controllers, specified as:

• A cell array of mpc objects.

 A cell array of character vectors, where each element is the name of an mpc object in the MATLAB workspace.

The specified array must contain at least two candidate controllers. The first entry in the cell array is the controller that corresponds to a switch input value of 1, the second corresponds to a switch input value of 2, and so on.

### **Cell Array of Initial Controller States**

Optional initial states for each candidate controller, specified as:

- A cell array of mpcstate objects.
- A cell array of character vectors, where each element is the name of an mpcstate object in the MATLAB workspace.
- {[],[],...} or {'[]','[]',...} Use the nominal condition defined in Model.Nominal as the initial state for each controller.

# **Required Inports**

### **Controller Selection**

The switch input signal must be a scalar integer between 1 and  $n_{\rm c}$ , where  $n_{\rm c}$  is the number of specified candidate controllers. At each control instant, this signal designates the active controller. A switch value of 1 corresponds to the first entry in the cell array of candidate controllers, a value of 2 corresponds to the second controller, and so on.

If the switch signal is outside of the range 1 and  $n_c$ , the previous controller output is retained.

# Measured output or State estimate

If candidate controllers use default state estimation, this inport is labeled mo. Connect this inport to the measured plant output signals.

If your candidate controllers use custom state estimation, check **Use custom estimated states instead of measured outputs** in the **General** section. Checking this option changes the label on this inport to x[k|k]. Connect a signal providing the controller state estimates. (The controller state includes the plant, disturbance, and noise model states.) The estimates supplied at time  $t_k$  must be based on the measurements and other data available at time  $t_k$ .

All candidate controllers must use the same state estimation option, either default or custom. When you use custom state estimation, all candidate controllers must have the same dimension.

### Reference

The ref dimension must not change from one control instant to the next. Each element must be a real number.

When ref is a 1-by- $n_y$  signal, where  $n_y$  is the number of outputs, there is no reference signal previewing. The controller applies the current reference values across the prediction horizon.

To use signal previewing, specify ref as an N-by- $n_y$  signal, where N is the number of time steps for which you are specifying reference values. Here,  $1 < N \le p$ , and p is the prediction horizon. Previewing usually improves performance, since the controller can anticipate future reference signal changes. The first row of ref specifies the  $n_y$  references for the first step in the prediction horizon (at the next control interval k=1), and so on for N steps. If N < p, the last row designates constant reference values for the remaining  $p \cdot N$  steps.

For example, suppose  $n_y = 2$  and p = 6. At a given control instant, the signal connected to the ref inport is:

The signal informs the controller that:

- Reference values for the first prediction horizon step k = 1 are 2 and 5.
- The first reference value remains at 2, but the second increases gradually.
- The second reference value becomes 8 at the beginning of the fourth step k = 4 in the prediction horizon.
- Both values remain constant at 2 and 8 respectively for steps 5-6 of the prediction horizon.

mpcpreview shows how to use reference previewing in a specific case. For calculation details on the use of the reference signal, see "Optimization Problem".

# **Required Outports**

### **Manipulated Variables**

The mv outport provides a signal defining the  $n_u \ge 1$  manipulated variables for controlling the plant. The active controller updates its manipulated variable output by solving a quadratic programming problem using either the default KWIK solver or a custom QP solver. For more information, see "QP Solver".

The Multiple MPC Controller block passes the output of the active controller to the mv outport.

If the active controller detects an infeasible QP problem or encounters numerical difficulties in solving an ill-conditioned QP problem, mv remains at its most recent successful solution, x.LastMove.

Otherwise, if the QP problem is feasible and the solver reaches the specified maximum number of iterations without finding a solution, mv:

- Remains at its most recent successful solution if the Optimizer.UseSuboptimalSolution property of the active controller is false.
- Is the suboptimal solution reached after the final iteration if the Optimizer.UseSuboptimalSolution property of the active controller is true. For more information, see "Suboptimal QP Solution".

# **Additional Inports (General Section)**

### Measured disturbance

Add an inport (md) to which you connect a measured disturbance signal. The number of measured disturbances defined for your controller,  $n_{md} \ge 1$ , must match the dimensions of the connected disturbance signal.

The number of measured disturbances must not change from one control instant to the next, and each disturbance value must be a real number.

When md is a 1-by- $n_{md}$  signal, there is no measured disturbance previewing. The controller applies the current disturbance values across the prediction horizon.

To use disturbance previewing, specify md as an N-by- $n_{md}$  signal, where N is the number of time steps for which the measured disturbances are known. Here,  $1 < N \le p+1$ , and p

is the prediction horizon. Previewing usually improves performance, since the controller can anticipate future disturbances. The first row of md specifies the  $n_{md}$  current disturbance values (k=1), with other rows specifying disturbances for subsequent control intervals. If N < p+1, the controller applies the last row for the remaining p - N + 1 steps.

For example, suppose  $n_{md} = 2$  and p = 6. At a given control instant, the signal connected to the md inport is:

This signal informs the controller that:

- The current MD values are 2 and 5 at k = 0.
- The first MD remains at 2, but the second increases gradually.
- The second MD becomes 8 at the beginning of the third step k=3 in the prediction horizon.
- Both values remain constant at 2 and 8 respectively for steps 4–6 of the prediction horizon.

mpcpreview shows how to use MD previewing in a specific case.

For calculation details, see "MPC Modeling" and "QP Matrices".

# **External manipulated variable**

Add an inport (ext.mv) to which you connect a vector signal that contains the actual manipulated variables (MV) used in the plant. All candidate controllers use this signal to update their controller state estimates at each control interval. Using this inport improves state estimation accuracy when the MVs used in the plant differ from the MVs calculated by the block, for example due to signal saturation or an override condition.

For additional information, see the corresponding section of the MPC Controller block reference page.

### Targets for manipulated variables

If you want one or more manipulated variables (MV) to track target values that change with time, use this option to add an mv.target inport. Connect this port to a target signal with dimension  $n_u$ , where  $n_u$  is the number of MVs.

For this to be effective, the corresponding MV(s) must have nonzero penalty weights (these weights are zero by default).

# **Additional Outports (General Section)**

You can configure several optional output signals. At each sampling instant, the active controller determines their values. The following describes each briefly. For more details, see the MPC Controller block documentation.

### **Optimal cost**

Add an outport (cost) that provides the optimal quadratic programming objective function value at the current time (a nonnegative scalar). If the controller is performing well and no constraints have been violated, the value should be small. If the optimization problem is infeasible, however, the value is meaningless. (See qp.status.)

### **Optimization status**

Add an outport (qp.status) that allows you to monitor the status of QP solver for the active controller.

If a QP problem is solved successfully at a given control interval, the qp.status output returns the number of QP solver iterations used in computation. This value is a finite, positive integer and is proportional to the time required for the calculations. Thus, a large value means a relatively slow block execution for this time interval.

The QP solver can fail to find an optimal solution for the following reasons:

- qp.status = 0 The QP solver cannot find a solution within the maximum number
  of iterations specified in the mpc object. In this case, if the
  Optimizer.UseSuboptimalSolution property of the MPC controller is false, the
  block holds its mv output at the most recent successful solution. Otherwise, it uses the
  suboptimal solution found during the last solver iteration.
- qp.status = -1 The QP solver detects an infeasible QP problem. See "Monitoring Optimization Status to Detect Controller Failures" for an example where a large,

sustained disturbance drives the OV outside its specified bounds. In this case, the block holds its mv output at the most recent successful solution.

 qp.status = -2 — The QP solver has encountered numerical difficulties in solving a severely ill-conditioned QP problem. In this case, the block holds its mv output at the most recent successful solution.

In a real-time application, you can use <code>qp.status</code> to set an alarm or take other special action.

### **Estimated controller states**

Add an outport (est.state) for the active controller state estimates, x[k|k], at each control instant. These estimates include the plant, disturbance, and noise model states.

### **Optimal control sequence**

Add an outport (mv.seq) that provides the predicted optimal MV adjustments (moves) over the entire prediction horizon from k to k+p, where k is the current time and p is the prediction horizon. This signal is a (p+1)-by- $n_u$  matrix, where and  $n_u$  is the number of manipulated variables.

mv.seq contains the calculated optimal MV moves at time k+i-1, for  $i=1,\ldots,p$ . The first row of mv.seq is identical to the mv outport signal, which is the current MV adjustment applied at time k. Since the controller does not calculate optimal control moves at time k+p, the last row of mv.seq duplicates the previous row.

## Optimal state sequence

Add an outport (x.seq) that provides the predicted optimal state variable sequence over the entire prediction horizon from k to k+p, where k is the current time and p is the prediction horizon. This signal is a (p+1)-by- $n_x$  matrix, where  $n_x$  is the number of states in the plant and unmeasured disturbance models (states from noise models are not included).

x.seq contains the calculated optimal state values at time k+i, for i=1,...,p. The first row of x.seq contains the current states at time k as determined by state estimation.

# **Optimal output sequence**

Add an outport (y.seq) that provides the predicted optimal output variable sequence over the entire prediction horizon from k to k+p, where k is the current time and p is the

prediction horizon. This signal is a (p+1)-by- $n_y$  matrix, where and  $n_y$  is the number of outputs.

y.seq contains the calculated optimal output values at time k+i-1, for  $i=1,\ldots,p+1$ . The first row of y.seq contains the current outputs at time k based on the estimated states and measured disturbances; it is not the measured output at time k.

# **State Estimation (General Section)**

### Use custom estimated states instead of using the built-in Kalman filter

Replace mo with the x[k|k] inport for custom state estimation as described in "Required Inports" on page 3-25. All candidate controllers must use the same state estimation option, either default or custom. When you use custom state estimation, all candidate controllers must have the same dimension.

# **Constraints (Online Features Section)**

At each control instant, the optional features described below apply to the active controller.

### **Lower MV limits**

Add inport umin that you can connect to a run-time constraint signal for manipulated variable lower bounds. This signal is a vector with  $n_u$  finite values.

If a manipulated variable does not have a lower bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within the active controller.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

# **Upper MV limits**

Add inport umax that you can connect to a run-time constraint signal for manipulated variable upper bounds. This signal is a vector with  $n_u$  finite values.

If a manipulated variable does not have an upper bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within the active controller.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

### **Lower OV limits**

Add inport ymin that you can connect to a run-time constraint signal for output variable lower bounds. This signal is a vector with  $n_v$  finite values.

If an output variable does not have a lower bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within the active controller.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

## **Upper OV limits**

Add inport ymax that you can connect to a run-time constraint signal for output variable upper bounds. This signal is a vector with  $n_{\nu}$  finite values.

If this parameter is not selected, the block uses the constant constraint values stored within the active controller.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

# **Weights (Online Features Section)**

The optional inputs described below function as controller "tuning knobs." By default (or when a signal is unconnected), the stored tuning weights of the active controller apply.

When using these online tuning features, care must be taken to prevent an unexpected change in the active controller. Otherwise, settings intended for a particular candidate controller can instead retune another.

### **OV** weights

Add an inport (y.wt) that you can connect to a run-time output variable (OV) weight signal. This signal overrides the Weights.OV property of the mpc object, which establishes the relative importance of OV reference tracking.

To use the same tuning weights over the prediction horizon, connect y.wt to a vector signal with  $n_y$  elements, where  $n_y$  is the number of controlled outputs. Each element specifies a nonnegative tuning weight for each controlled output variable. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect y. wt to a matrix signal with  $n_y$  columns and up to p rows, where p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

If you do not connect a signal to the y.wt inport, the block uses the OV weights specified in the active controller, and these values remain constant.

# **MV** weights

Add an inport (u.wt) that you can connect to a run-time manipulated variable (MV) weight signal. This signal overrides the Weights.MV property of the mpc object, which establishes the relative importance of MV target tracking.

To use the same tuning weights over the prediction horizon, connect u.wt to a vector signal with  $n_u$  elements, where  $n_u$  is the number of manipulated variables. Each element specifies a nonnegative tuning weight for each manipulated variable. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect u.wt to a matrix signal with  $n_u$  columns and up to p rows, where p is the prediction horizon. Each row contains

the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

### **MVRate weights**

Add an inport (du.wt) that you can connect to a run-time manipulated variable (MV) rate weight signal. This signal overrides the Weights.MVrate property of the mpc object, which establishes the relative importance of MV changes.

To use the same tuning weights over the prediction horizon, connect  $\mathtt{du.wt}$  to a vector signal with  $n_u$  elements, where  $n_u$  is the number of manipulated variables. Each element specifies a nonnegative tuning weight for each manipulated variable rate. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect  $\mathtt{du.wt}$  to a matrix signal with  $n_u$  columns and up to p rows, where p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

If you do not connect a signal to the du.wt inport, the block uses the Weights.MVrate property specified in the active controller, and these values remain constant.

# Slack variable weight

Add an inport (ecr.wt), for a scalar nonnegative signal that overrides the active controller's MPCobj.Weights.ECR property. This inport has no effect unless the active controller defines soft constraints whose associated ECR values are nonzero.

# **Others Section**

# Block data type

Specify the block data type of the manipulated variables as one of the following:

- double Double-precision floating point (default)
- single Single-precision floating point

If you are implementing the block on a single-precision target, specify the output data type as single.

For an example of double-precision and single-precision simulation and code generation for an MPC controller, see "Simulation and Code Generation Using Simulink Coder".

To view the port data types in a model, in the Simulink Editor, select **Display > Signals & PortsPort Data Types**.

### Inherit sample time

Use the sample time of the parent subsystem as the block sample time. Doing so allows you to conditionally execute this block inside Function-Call Subsystem or Triggered Subsystem blocks. For an example, see "Using MPC Controller Block Inside Function-Call and Triggered Subsystems".

**Note** You must execute Function-Call Subsystem or Triggered Subsystem blocks at the sample rate of the controller. Otherwise, you can see unexpected results.

To view the sample time of a block, in the Simulink Editor, select **Display > Sample Time**. Select **Colors**, **Annotations**, or **All**. For more information, see "View Sample Time Information" (Simulink).

# **Compatibility Considerations**

# MPC Simulink block mv. seq output port signal dimensions have changed

Behavior changed in R2018b

The signal dimensions of the mv.seq output port of the Multiple MPC Controllers block have changed. Previously, this signal was a p-by- $N_{mv}$  matrix, where p is the prediction horizon and  $N_{mv}$  is the number of manipulated variables. Now, mv.seq is a (p+1)-by- $N_{mv}$  matrix, where row p+1 duplicates row p.

# **Explicit MPC Controller**

Design and simulate explicit model predictive controller

# Library

MPC Simulink Library

# **Description**

The Explicit MPC Controller block uses the following input signals:

- Measured plant outputs (mo)
- Reference or setpoint (ref)
- Measured plant disturbance (md), if any

The key difference is that the Explicit MPC Controller block uses a table-lookup control law during each control interval rather than solving a quadratic program. The reduced online computational effort is advantageous in applications requiring a short control interval. The primary trade-off is a heavier offline computational effort to determine the control law and a larger memory footprint to store it. The combinatorial character of this computation restricts its use to applications with relatively few input, output, and state variables, a short prediction horizon, and few output constraints.

The Explicit MPC Controller supports only a subset of optional MPC features, as outlined in the following table.

Supported Features	Unsupported Features	
Custom state estimation (default state estimation uses a static Kalman filter)	Online tuning (penalty weight adjustments)	
• Outport for state estimation results	Online constraint adjustments	
External manipulated variable feedback signal inport	Online manipulated variable target adjustments	
• Single-precision block data (default is double precision)	Reference and/or measured disturbance previewing	
Inherited sample time		

# **Dialog Box**

The Explicit MPC Controller block has the following parameter groupings:

- "Parameters" on page 3-38
- "Required Inports" on page 3-39
- "Required Outports" on page 3-39
- "Additional Inports (General Section)" on page 3-39
- "Additional Outports (General Section)" on page 3-40
- "State Estimation (General Section)" on page 3-41
- "Others Section" on page 3-41

## **Parameters**

### **Explicit MPC Controller**

An Explicit MPC controller on page 4-23 object containing the control law to be used. It must exist in the workspace. Use the <code>generateExplicitMPC</code> command to create this object.

#### **Initial Controller State**

An optional mpcstate object specifying the initial controller state. By default the block uses the Model.Nominal property of the controller object.

# **Required Inports**

### Measured output or State estimate

If your controller uses default state estimation, this inport is labeled mo. Connect this inport to the measured plant output signals. The MPC controller uses measured plant outputs to improve its state estimates.

To enable custom state estimation, in the **General** section, check **Use custom estimated states instead of measured outputs**. Checking this option changes the label on this inport to x[k|k]. Connect a signal that provides estimates of the controller state (plant, disturbance, and noise model states). Use custom state estimates when an alternative estimation technique is considered superior to the built-in estimator or when the states are fully measurable.

#### Reference

At each control instant, the ref signal must contain the current reference values (targets or setpoints) for the  $n_y$  output variables, where  $n_y$  is the total number of outputs, including measured and unmeasured outputs. Since this block does not support reference previewing, ref cannot be defined as a matrix.

# **Required Outports**

### **Manipulated Variables**

The mv outport provides a signal defining the  $n_u \ge 1$  manipulated variables for controlling the plant. The controller updates its mv outport at each control instant using the control law contained in the explicit MPC controller object. If the control law evaluation fails, this signal is unchanged; that is, it is held at the previous successful result.

# **Additional Inports (General Section)**

#### Measured disturbance

Add an inport (md) to which you can connect a vector signal containing  $n_{md}$  elements, where  $n_{md}$  is the number of measured disturbances.

Since this block does not support measured disturbance previewing, md cannot be defined as a matrix.

### **External manipulated variable**

Add an inport (ext.mv) to which you connect a vector signal that contains the actual manipulated variables (MV) used in the plant. The controller uses this signal to update their controller state estimates at each control interval. Using this inport improves state estimation accuracy when the MVs used in the plant differ from the MVs calculated by the block, for example due to signal saturation or an override condition.

**Note** Using this option can cause an algebraic loop in the Simulink model, since there is direct feedthrough from the ext.mv inport to the mv outport. To prevent such algebraic loops, insert a Memory block or Unit Delay block.

For additional information, see the corresponding section of the MPC Controller block reference page.

## **Additional Outports (General Section)**

#### Status of piecewise affine function evaluation

Add an outport (status) that indicates whether the latest explicit MPC control-law evaluation succeeded. The outport provides a scalar signal that has one of the following values:

- 1 Successful explicit control law evaluation
- 0 Failure: One or more control law parameters out of range.
- -1 Undefined: Control law parameters were within the valid range but an extrapolation was necessary.

If status is either 0 or -1, the mv outport remains at the last known good value.

## Region number of evaluated piecewise affine function

Add an outport (region) providing the index of the polyhedral region used in the latest explicit control law evaluation (a scalar). If the control law evaluation fails, the signal at this outport equals zero.

## Estimated plant, disturbance, and noise model states

Add an outport (est.state) for the controller state estimates, x[k|k], at each control instant. These estimates include the plant, disturbance, and noise model states.

## **State Estimation (General Section)**

#### Use custom estimated states instead of measured outputs

Replace mo with the x[k|k] inport for custom state estimation as described in "Required Inports" on page 3-39.

#### Others Section

### Block data type

Specify the block data type of the manipulated variables as one of the following:

- double Double-precision floating point (default)
- single Single-precision floating point

If you are implementing the block on a single-precision target, specify the output data type as single.

For an example of double-precision and single-precision simulation and code generation for an MPC controller, see "Simulation and Code Generation Using Simulink Coder".

To view the port data types in a model, in the Simulink Editor, select **Display > Signals & PortsPort Data Types**.

## Inherit sample time

Use the sample time of the parent subsystem as the block sample time. Doing so allows you to conditionally execute this block inside Function-Call Subsystem or Triggered Subsystem blocks. For an example, see "Using MPC Controller Block Inside Function-Call and Triggered Subsystems".

**Note** You must execute Function-Call Subsystem or Triggered Subsystem blocks at the sample rate of the controller. Otherwise, you can see unexpected results.

To view the sample time of a block, in the Simulink Editor, select **Display > Sample Time**. Select **Colors**, **Annotations**, or **All**. For more information, see "View Sample Time Information" (Simulink).

#### Use external signal to enable controller evaluation

Add an inport (switch) whose input specifies whether the controller evaluates its control law. If the input signal is zero, the controller behaves normally. If the input signal is nonzero, the Explicit MPC Controller block turns off controller evaluation. This action reduces computational effort when the controller output is not needed, such as when the system is operating manually or another controller has taken over. However, the controller continues to update its internal state estimates in the usual way. Thus, it is ready to resume optimization calculations whenever the switch signal returns to zero. While controller evaluation is off, the MPC Controller block passes the current ext.mv signal to the controller output. If the ext.mv inport is not enabled, the controller output is held at the value it had when evaluation was disabled.

# Introduced in R2014b

# **Adaptive MPC Controller**

Design and simulate adaptive and time-varying model predictive controllers

# Library

MPC Simulink Library

# **Description**

The Adaptive MPC Controller block uses the following input signals:

- Measured plant outputs (mo)
- Reference or setpoint (ref)
- Measured plant disturbance (md), if any

In addition, the required model input signal specifies the prediction model to use when computing the optimal plant manipulated variables mv. The linear prediction model can change at each control interval in response to changes in the real plant at run time. The prediction model can represent a single LTI plant used for all prediction steps (adaptive MPC mode) or an array of LTI plants for different prediction steps (time-varying MPC mode). Two common ways to modify this model are as follows:

- Given a nonlinear plant model, linearize it at the current operating point.
- Use plant data to estimate parameters in an empirical linear-time-varying (LTV) model.

By default, the block estimates its prediction model states. Since the prediction model parameters change at run time, the static Kalman filter used in the MPC Controller block

is inappropriate. Instead, the Adaptive MPC Controller block uses a linear-time-varying Kalman filter (LTVKF). For more information, see "Adaptive MPC".

In all other ways, the Adaptive MPC Controller block mimics the MPC Controller block. Since the adaptive version involves additional overhead, use the MPC Controller block unless you need to control a nonlinear plant across a wide range of operating conditions where plant dynamics vary significantly.

Both the Adaptive MPC Controller block and the Multiple MPC Controllers block enable your control system to adapt to changing operating conditions at run time. The following table lists the advantages of using each block.

Block	Adaptive MPC Controller	Multiple MPC Controllers	
Adaptation approach	Update prediction model for a single controller as operating conditions change	Switch between multiple controllers designed for different operating regions	
Advantages	Only need to design a single controller offline	No need for online estimation of plant model	
	Less run-time computational effort and smaller memory footprint	Controllers can have different sample time, horizons, and weights	
	More robust to real-life changes in plant conditions	Prediction models can have different orders or time domains	
		Finite set of candidate controllers can be tested thoroughly	

# **Dialog Box**

The Adaptive MPC Controller block has the following parameter groupings:

- "Parameters" on page 3-46
- "Required Inports" on page 3-47
- "Required Outports" on page 3-49
- "Additional Inports (General Section)" on page 3-50

- "Additional Outports (General Section)" on page 3-51
- "State Estimation (General Section)" on page 3-53
- "Prediction Model (Online Features Section)" on page 3-54
- "Constraints (Online Features Section)" on page 3-54
- "Weights (Online Features Section)" on page 3-57
- "Prediction and Control Horizons (Online Features Section)" on page 3-59
- "Others Section" on page 3-60

#### **Parameters**

#### **Adaptive MPC Controller**

An mpc controller object designed at the nominal operating point. At run time, the controller replaces the original prediction model (A, B, C, D) and nominal values (U, Y, X, DX) with the data specified in the model inport at each control instant.

By default, the block assumes all other controller object properties (for example tuning weights, constraints) are constant. You can override this assumption using the options in the **Online Features** section.

The following restrictions apply to the mpc controller object:

- It must exist in the MATLAB workspace.
- Its prediction model must be an LTI discrete-time, state-space object with no delays. Use the absorbDelay command to convert delays to discrete states. The dimensions of the A, B, C, and D matrices in the prediction determine the dimensions required by the model inport signal.

#### Initial controller state

Specifies the initial controller state. If this parameter is left blank, the block uses the nominal values that are defined in the Model.Nominal property of the mpc object. To override the default, create an mpcstate object in your workspace, and enter its name in the field.

# **Required Inports**

#### Model

Connect a bus signal to the model inport. This signal modifies the controller object Model.Plant and Model.Nominal properties at the beginning of each control interval.

The Adaptive MPC Controller requires Model.Plant to be an LTI discrete-time state-space object with no delays. The following command extracts the state-space matrices comprising such a model:

```
[A,B,C,D] = ssdata(MPCobj.Model.Plant)
```

The purpose of the model inport is to replace these matrices with new ones having the same dimensions, and representing the same control interval. You must also retain the sequence in which the input, output, and state variables appear in Model.Plant.

### When operating in:

- Adaptive MPC mode, the bus you connect to the model inport must contain the following signals, each identified by the specified name:
  - A  $-n_x$ -by- $n_x$  matrix signal, where  $n_x$  is the number of plant model states.
  - B  $n_x$ -by- $n_u$  matrix signal, where  $n_u$  is the total number of plant model inputs (i.e., manipulated variables, measured disturbances, and unmeasured disturbances).
  - $C n_y$ -by- $n_x$  matrix signal, where  $n_y$  is the number of plant model outputs.
  - D  $n_v$ -by- $n_u$  matrix signal.
  - X Vector signal of length  $n_x$ , replacing the controller Model.Nominal.X property.
  - Y Vector signal of length n<sub>y</sub>, replacing the controller Model.Nominal.Y property.
  - U Vector signal of length n<sub>u</sub>, replacing the controller Model.Nominal.U property.
  - DX Vector signal of length  $n_x$ , replacing the controller Model.Nominal.DX property. It must be appropriate for use with a discrete-time model of the assumed control interval. For more information, see "Adaptive MPC".

- Time-varying MPC mode, the bus you connect to the model inport must contain the following 3-dimensional bus signals:
  - A  $n_x$ -by- $n_x$ -by-(p+1) matrix signal
  - B  $n_x$ -by- $n_y$ -by-(p+1) matrix signal
  - $C n_y$ -by- $n_x$ -by-(p+1)
  - D  $n_v$ -by- $n_u$ -by-(p+1) matrix signal
  - $X n_x$ -by-(p+1) matrix signal
  - Y  $n_v$ -by-(p+1) matrix signal
  - $U n_u$ -by-(p+1) matrix signal
  - DX  $n_x$ -by-(p+1) matrix signal

Here, p is the controller prediction horizon. For each signal, specify p+1 values representing the model and nominal conditions at each step of the prediction horizon. For more information, see "Time-Varying MPC".

One way to form the bus is to use a Bus Creator block.

### Measured output or State estimate

If your controller uses default state estimation, this inport is labeled mo. Connect this inport to the measured plant output signals. The MPC controller uses measured plant outputs to improve its state estimates.

To enable custom state estimation, in the **General** section, check **Use custom estimated states instead of measured outputs**. Checking this option changes the label on this inport to x[k|k]. Connect a signal that provides estimates of the controller state (plant, disturbance, and noise model states). Use custom state estimates when an alternative estimation technique is considered superior to the built-in estimator or when the states are fully measurable.

#### Reference

The ref dimension must not change from one control instant to the next. Each element must be a real number.

When ref is a 1-by- $n_y$  signal, where  $n_y$  is the number of outputs, there is no reference signal previewing. The controller applies the current reference values across the prediction horizon.

To use signal previewing, specify ref as an N-by- $n_y$  signal, where N is the number of time steps for which you are specifying reference values. Here,  $1 < N \le p$ , and p is

the prediction horizon. Previewing usually improves performance, since the controller can anticipate future reference signal changes. The first row of ref specifies the  $n_y$  references for the first step in the prediction horizon (at the next control interval k=1), and so on for N steps. If N < p, the last row designates constant reference values for the remaining p - N steps.

For example, suppose  $n_y = 2$  and p = 6. At a given control instant, the signal connected to the ref inport is:

```
[2 5 \leftarrow k=1
2 6 \leftarrow k=2
2 7 \leftarrow k=3
2 8] \leftarrow k=4
```

The signal informs the controller that:

- Reference values for the first prediction horizon step k = 1 are 2 and 5.
- The first reference value remains at 2, but the second increases gradually.
- The second reference value becomes 8 at the beginning of the fourth step k = 4 in the prediction horizon.
- Both values remain constant at 2 and 8 respectively for steps 5-6 of the prediction horizon.

mpcpreview shows how to use reference previewing in a specific case. For calculation details on the use of the reference signal, see "Optimization Problem".

## **Required Outports**

### **Manipulated Variables**

The mv outport provides a signal defining the  $n_u \ge 1$  manipulated variables for controlling the plant. At each control instant, the controller updates its mv outport by solving a quadratic programming problem using either the default KWIK solver or a custom QP solver. For more information, see "QP Solver".

If the controller detects an infeasible optimization problem or encounters numerical difficulties in solving an ill-conditioned optimization problem, mv remains at its most recent successful solution; that is, the controller output freezes.

Otherwise, if the optimization problem is feasible and the solver reaches the specified maximum number of iterations without finding an optimal solution, mv:

- Remains at its most recent successful solution if the Optimizer.UseSuboptimalSolution property of the controller is false.
- Is the suboptimal solution reached after the final iteration if the Optimizer.UseSuboptimalSolution property of the controller is true. For more information, see "Suboptimal QP Solution".

# **Additional Inports (General Section)**

#### Measured disturbance

Add an inport (md) to which you connect a measured disturbance signal. The number of measured disturbances defined for your controller,  $n_{md} \ge 1$ , must match the dimensions of the connected disturbance signal.

The number of measured disturbances must not change from one control instant to the next, and each disturbance value must be a real number.

When md is a 1-by- $n_{md}$  signal, there is no measured disturbance previewing. The controller applies the current disturbance values across the prediction horizon.

To use disturbance previewing, specify md as an N-by- $n_{md}$  signal, where N is the number of time steps for which the measured disturbances are known. Here,  $1 < N \le p+1$ , and p is the prediction horizon. Previewing usually improves performance, since the controller can anticipate future disturbances. The first row of md specifies the  $n_{md}$  current disturbance values (k=1), with other rows specifying disturbances for subsequent control intervals. If N < p+1, the controller applies the last row for the remaining p-N+1 steps.

For example, suppose  $n_{md} = 2$  and p = 6. At a given control instant, the signal connected to the md inport is:

This signal informs the controller that:

- The current MD values are 2 and 5 at k = 0.
- The first MD remains at 2, but the second increases gradually.

- The second MD becomes 8 at the beginning of the third step k=3 in the prediction horizon.
- Both values remain constant at 2 and 8 respectively for steps 4-6 of the prediction horizon.

mpcpreview shows how to use MD previewing in a specific case.

For calculation details, see "MPC Modeling" and "QP Matrices".

### **External manipulated variable**

Add an inport (ext.mv) to which you connect a vector signal that contains the actual manipulated variables (MV) used in the plant. The controller uses this signal to update their controller state estimates at each control interval. Using this inport improves state estimation accuracy when the MVs used in the plant differ from the MVs calculated by the block, for example due to signal saturation or an override condition.

**Note** Using this option can cause an algebraic loop in the Simulink model, since there is direct feedthrough from the ext.mv inport to the mv outport. To prevent such algebraic loops, insert a Memory block or Unit Delay block.

For additional information, see the corresponding section of the MPC Controller block reference page.

### Targets for manipulated variables

If you want one or more manipulated variables (MV) to track target values that change with time, use this option to add an mv.target inport. Connect this port to a target signal with dimension  $n_u$ , where  $n_u$  is the number of MVs.

For this to be effective, the corresponding MV(s) must have nonzero penalty weights (these weights are zero by default).

# **Additional Outports (General Section)**

### **Optimal cost**

Add an outport (cost) that provides the optimal quadratic programming objective function value at the current time (a nonnegative scalar). If the controller is performing

well and no constraints have been violated, the value should be small. If the optimization problem is infeasible, however, the value is meaningless. (See qp.status.)

### **Optimization status**

Add an outport (qp.status) that allows you to monitor the status of the QP solver.

If a QP problem is solved successfully at a given control interval, the qp.status output returns the number of QP solver iterations used in computation. This value is a finite, positive integer and is proportional to the time required for the calculations. Thus, a large value means a relatively slow block execution for this time interval.

The QP solver can fail to find an optimal solution for the following reasons:

- qp.status = 0 The QP solver cannot find a solution within the maximum number
  of iterations specified in the mpc object. In this case, if the
  Optimizer.UseSuboptimalSolution property of the MPC controller is false, the
  block holds its mv output at the most recent successful solution. Otherwise, it uses the
  suboptimal solution found during the last solver iteration.
- qp.status = -1 The QP solver detects an infeasible QP problem. See "Monitoring Optimization Status to Detect Controller Failures" for an example where a large, sustained disturbance drives the OV outside its specified bounds. In this case, the block holds its mv output at the most recent successful solution.
- qp.status = -2 The QP solver has encountered numerical difficulties in solving a severely ill-conditioned QP problem. In this case, the block holds its mv output at the most recent successful solution.

In a real-time application, you can use qp.status to set an alarm or take other special action.

#### **Estimated controller states**

Add an outport (est.state) to receive the controller state estimates, x[k|k], at each control instant. These include the plant, disturbance, and noise model states.

### **Optimal control sequence**

Add an outport (mv.seq) that provides the predicted optimal MV adjustments (moves) over the entire prediction horizon from k to k+p, where k is the current time and p is the prediction horizon. This signal is a (p+1)-by- $n_u$  matrix, where and  $n_u$  is the number of manipulated variables.

mv.seq contains the calculated optimal MV moves at time k+i-1, for  $i=1,\ldots,p$ . The first row of mv.seq is identical to the mv outport signal, which is the current MV adjustment applied at time k. Since the controller does not calculate optimal control moves at time k+p, the last row of mv.seq duplicates the previous row.

#### **Optimal state sequence**

Add an outport (x.seq) that provides the predicted optimal state variable sequence over the entire prediction horizon from k to k+p, where k is the current time and p is the prediction horizon. This signal is a (p+1)-by- $n_x$  matrix, where  $n_x$  is the number of states in the plant and unmeasured disturbance models (states from noise models are not included).

x.seq contains the calculated optimal state values at time k+i, for  $i=1,\ldots,p$ . The first row of x.seq contains the current states at time k as determined by state estimation.

### **Optimal output sequence**

Add an outport (y.seq) that provides the predicted optimal output variable sequence over the entire prediction horizon from k to k+p, where k is the current time and p is the prediction horizon. This signal is a (p+1)-by- $n_y$  matrix, where and  $n_y$  is the number of outputs.

y.seq contains the calculated optimal output values at time k+i-1, for  $i=1,\ldots,p+1$ . The first row of y.seq contains the current outputs at time k based on the estimated states and measured disturbances; it is not the measured output at time k.

### **State Estimation (General Section)**

### Use custom estimated states instead of using the built-in Kalman filter

Replace mo with the x[k|k] inport for custom state estimation as described in "Required Inports" on page 3-47.

### **Prediction Model (Online Features Section)**

#### **Linear Time-Varying (LTV) plants**

To operate your controller in time-varying MPC mode, select this option. When operating in this mode, connect a 3-dimensional bus signal to the model inport as described in "Required Inports" on page 3-47.

For an example, see "Time-Varying MPC Control of a Time-Varying Plant".

## **Constraints (Online Features Section)**

#### **Lower MV limits**

Add inport umin that you can connect to a run-time constraint signal for manipulated variable lower bounds. This signal is a vector with  $n_u$  finite values. The ith element of umin replaces the ManipulatedVariables (i). Min property of the controller at run time.

If a manipulated variable does not have a lower bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

If the ManipulatedVariables (i). Min property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), the ith element of umin replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

### **Upper MV limits**

Add inport umax that you can connect to a run-time constraint signal for manipulated variable upper bounds. This signal is a vector with  $n_u$  finite values. The ith element of umax replaces the ManipulatedVariables(i). Max property of the controller at run time.

If a manipulated variable does not have an upper bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

If the ManipulatedVariables (i). Max property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), the ith element of umax replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

#### **Lower OV limits**

Add inport ymin that you can connect to a run-time constraint signal for output variable lower bounds. This signal is a vector with  $n_y$  finite values. The ith element of ymin replaces the OutputVariables(i). Min property of the controller at run time.

If an output variable does not have a lower bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

If the OutputVariables(i). Min property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), the ith element of ymin replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

### **Upper OV limits**

Add inport ymax that you can connect to a run-time constraint signal for output variable upper bounds. This signal is a vector with  $n_y$  finite values. The ith element of ymax replaces the OutputVariables(i). Max property of the controller at run time.

If an output variable does not have an upper bound specified in the controller object, then the corresponding connected signal value is ignored.

If this parameter is not selected, the block uses the constant constraint values stored within its mpc object.

**Note** You cannot specify time-varying constraints at run time using a matrix signal.

If the <code>OutputVariables(i)</code> . Max property of the controller is specified as a vector (that is, the constraint varies over the prediction horizon), the <code>ith</code> element of <code>ymax</code> replaces the first finite entry in this vector, and the remaining values shift to retain the same constraint profile.

#### **Custom constraints**

Add inports E, F, G, and S to the block that you can connect to the following run-time custom constraint matrix signals:

- E Manipulated variable constraint matrix with size  $n_c$ -by- $n_u$ , where  $n_c$  is the number of custom constraints
- F Controlled output constraint matrix with size  $n_c$ -by- $n_v$
- G Custom constraint matrix with size 1-by-n<sub>c</sub>
- S Measured disturbance constraint matrix, with size  $n_c$ -by- $n_v$ , where  $n_v$  is the number of measured disturbances. S is added only if the mpc object has measured disturbances.

These constraints replace the custom constraints previously set using setconstraint.

If you define E, F, G, or S in the mpc object, you must connect a signal to the corresponding inport, and that signal must have the same dimensions as the array specified in the controller. If an array is not defined in the controller object, use a zero matrix with the correct size.

The custom constraints are of the form  $Eu + Fy + Sv \le G$ , where:

- u is a vector of manipulated variable values.
- y is a vector of predicted plant output values.
- *v* is a vector of measured plant disturbance input values.

For more information, see "Constraints on Linear Combinations of Inputs and Outputs".

# **Weights (Online Features Section)**

A controller intended for real-time applications should have "knobs" you can use to tune its performance when it operates with the real plant. This group of optional inports serves that purpose.

### **OV** weights

Add an inport (y.wt) that you can connect to a run-time output variable (OV) weight signal. This signal overrides the Weights.OV property of the mpc object, which establishes the relative importance of OV reference tracking.

To use the same tuning weights over the prediction horizon, connect y.wt to a vector signal with  $n_y$  elements, where  $n_y$  is the number of controlled outputs. Each element specifies a nonnegative tuning weight for each controlled output variable. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect y. wt to a matrix signal with  $n_y$  columns and up to p rows, where p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

If you do not connect a signal to the y.wt inport, the block uses the OV weights specified in your mpc object.

### **MV** weights

Add an inport (u.wt) that you can connect to a run-time manipulated variable (MV) weight signal. This signal overrides the Weights.MV property of the mpc object, which establishes the relative importance of MV target tracking.

To use the same tuning weights over the prediction horizon, connect u.wt to a vector signal with  $n_u$  elements, where  $n_u$  is the number of manipulated variables. Each element specifies a nonnegative tuning weight for each manipulated variable. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect u.wt to a matrix signal with  $n_u$  columns and up to p rows, where p is the prediction horizon. Each row contains

the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

If you do not connect a signal to the u.wt inport, the block uses the MV weights specified in your mpc object.

### **MVRate weights**

Add an inport (du.wt) that you can connect to a run-time manipulated variable (MV) rate weight signal. This signal overrides the Weights.MVrate property of the mpc object, which establishes the relative importance of MV changes.

To use the same tuning weights over the prediction horizon, connect  $\mathtt{du.wt}$  to a vector signal with  $n_u$  elements, where  $n_u$  is the number of manipulated variables. Each element specifies a nonnegative tuning weight for each manipulated variable rate. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon, connect  $\mathtt{du.wt}$  to a matrix signal with  $n_u$  columns and up to p rows, where p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

If you do not connect a signal to the du.wt inport, the block uses the MV rate weights specified in your mpc object.

### Slack variable weight

Add an inport (ecr.wt), for a scalar nonnegative signal that overrides the MPCobj.Weights.ECR property of the mpc controller. This inport has no effect unless your controller object defines soft constraints whose associated ECR values are nonzero.

If there are soft constraints, increasing the ecr.wt value makes these constraints relatively harder. The controller then places a higher priority on minimizing the magnitude of the predicted worst-case constraint violation.

You may not be able to avoid violations of an output variable constraint. Thus, increasing the ecr.wt value is often counterproductive. Such an increase causes the controller to pay less attention to its other objectives and does not help reduce constraint violations.

You usually need to tune ecr.wt to achieve the proper balance in relation to the other control objectives.

# **Prediction and Control Horizons (Online Features Section)**

### Adjust prediction horizon and control horizon at run time

If you want to vary your prediction and control horizons at run time, select this parameter. Doing so adds the following input ports to the block:

- p Prediction horizon, specified as positive integer signal. The prediction horizon signal value must be less than or equal to the **Maximum prediction horizon** parameter.
- m Control horizon, specified as one of the following:
  - Positive integer signal less than or equal to the prediction horizon.
  - Vector signal of positive integers specifying blocking interval lengths. For more information, see "Manipulated Variable Blocking".

At run time, the values of the p and m signals override the default horizons specified in the controller object.

For more information, see "Adjust Horizons at Run Time".

## Maximum prediction horizon

Specify the maximum prediction horizon value when varying the prediction horizon at run time. This value,  $P_{max}$ , is used to define:

- The number of rows in the optimal sequence output signals mv.seq, x.seq, and y.seq. When varying your prediction horizon at run time, these signals have  $P_{max}+1$  rows.
- The maximum number of rows for the time-varying weights input signals y.wt, u.wt, and du.wt. When varying your prediction horizon at run time, these signals can have at most  $P_{max}$  rows.
- The maximum dimensions of the plant and nominal condition matrices specified in the model input signal (when the **Linear Time-Varying (LTV) plants** parameter is selected). When varying your prediction horizon at run time, the third dimension of these matrices can be at most  $P_{max}+1$ .

To enable this parameter, select the **Adjust prediction horizon and control horizon at run time** parameter.

For more information, see "Adjust Horizons at Run Time".

#### Others Section

### Block data type

Specify the block data type of the manipulated variables as one of the following:

- double Double-precision floating point (default)
- single Single-precision floating point

If you are implementing the block on a single-precision target, specify the output data type as single.

For an example of double-precision and single-precision simulation and code generation for an MPC controller, see "Simulation and Code Generation Using Simulink Coder".

To view the port data types in a model, in the Simulink Editor, select **Display > Signals & PortsPort Data Types**.

### Inherit sample time

Use the sample time of the parent subsystem as the block sample time. Doing so allows you to conditionally execute this block inside Function-Call Subsystem or Triggered Subsystem blocks. For an example, see "Using MPC Controller Block Inside Function-Call and Triggered Subsystems".

**Note** You must execute Function-Call Subsystem or Triggered Subsystem blocks at the sample rate of the controller. Otherwise, you can see unexpected results.

To view the sample time of a block, in the Simulink Editor, select **Display > Sample Time**. Select **Colors**, **Annotations**, or **All**. For more information, see "View Sample Time Information" (Simulink).

### Use external signal to enable or disable optimization

Add an inport (switch) whose input specifies whether the controller performs optimization calculations. If the input signal is zero, the controller behaves normally. If

the input signal is nonzero, the MPC Controller block turns off the controller optimization calculations. This action reduces computational effort when the controller output is not needed, such as when the system is operating manually or another controller has taken over. However, the controller continues to update its internal state estimates in the usual way. Thus, it is ready to resume optimization calculations whenever the switch signal returns to zero. While controller optimization is off, the MPC Controller block passes the current ext.mv signal to the controller output. If the ext.mv inport is not enabled, the controller output is held at the value it had when optimization was disabled.

# **Compatibility Considerations**

# MPC Simulink block mv. seq output port signal dimensions have changed

Behavior changed in R2018b

The signal dimensions of the mv.seq output port of the Adaptive MPC Controller block have changed. Previously, this signal was a p-by- $N_{mv}$  matrix, where p is the prediction horizon and  $N_{mv}$  is the number of manipulated variables. Now, mv.seq is a (p+1)-by- $N_{mv}$  matrix, where row p+1 duplicates row p.

# **Multiple Explicit MPC Controllers**

Simulate switching between multiple explicit MPC controllers

# Library

MPC Simulink Library

# **Description**

The Multiple Explicit MPC Controllers block uses the following input signals:

- Measured plant outputs (mo)
- Reference or setpoint (ref)
- Measured plant disturbance (md), if any
- Switching signal (switch)

The switching signal selects the *active controller* from among a list of two or more candidate controllers. However, for the Multiple Explicit MPC Controllers block, the candidates are explicit MPC controllers. These controllers reduce online computational effort by using a table-lookup control law during each control interval rather than solving a quadratic program. For more information, see Explicit MPC Controller.

The Multiple Explicit MPC Controllers block enables you to transition between multiple explicit MPC controllers in real time based on the current operating conditions. Typically, you design each controller for a particular region of the operating space. Using available

measurements, you detect the current operating region and select the appropriate active controller via the switch inport.

To improve efficiency, inactive controllers do not evaluate their control law. However, to provide bumpless transfer between controllers, the inactive controllers continue to perform state estimation.

Like for the Multiple MPC Controllers block, you cannot disable evaluation for the Multiple Explicit MPC Controllers. One controller must always be active.

Like the Explicit MPC Controller block, the Multiple Explicit MPC Controllers supports only a subset of optional MPC features, as outlined in the following table.

Supported Features		Unsupported Features	
•	Custom state estimation (default state estimation uses a static Kalman filter)	•	Online tuning (penalty weight adjustments)
•	Outport for state estimation results	•	Online constraint adjustments
•	External manipulated variable feedback signal inport	•	Online manipulated variable target adjustments
•	Single-precision block data (default is double precision)	•	Reference and/or measured disturbance previewing
•	Inherited sample time		

# **Dialog Box**

The Multiple Explicit MPC Controller block has the following parameter groupings:

- "Parameters" on page 3-65
- "Required Inports" on page 3-65
- "Required Outports" on page 3-66
- "Additional Inports (General Section)" on page 3-66
- "Additional Outports (General Section)" on page 3-67
- "State Estimation (General Section)" on page 3-67
- "Others Section" on page 3-68

### **Parameters**

### **Cell Array of Explicit MPC Controllers**

Candidate controllers, specified as:

- A cell array of Explicit MPC controller on page 4-23 objects. Use the generateExplicitMPC command to create these objects.
- A cell array of character vectors, where each element is the name of an explicit MPC controller object in the MATLAB workspace.

The specified array must contain at least two candidate controllers. The first entry in the cell array is the controller that corresponds to a switch input value of 1, the second corresponds to a switch input value of 2, and so on.

### **Cell Array of Initial Controller States**

Optional initial states for each candidate controller, specified as:

- A cell array of mpcstate objects.
- A cell array of character vectors, where each element is the name of an mpcstate object in the MATLAB workspace.
- {[],[],...} or {'[]','[]',...} Use the nominal condition defined in Model.Nominal as the initial state for each controller.

# **Required Inports**

#### **Controller Selection**

The switch input signal must be a scalar integer between 1 and  $n_{\rm c}$ , where  $n_{\rm c}$  is the number of specified candidate controllers. At each control instant, this signal designates the active controller. A switch value of 1 corresponds to the first entry in the cell array of candidate controllers, a value of 2 corresponds to the second controller, and so on.

If the switch signal is outside of the range 1 and  $n_c$ , the previous controller output is retained.

### Measured output or State estimate

If candidate controllers use default state estimation, this inport is labeled mo. Connect this inport to the measured plant output signals.

If your candidate controllers use custom state estimation, check **Use custom estimated states instead of measured outputs** in the **General** section. Checking

this option changes the label on this inport to x[k|k]. Connect a signal providing the controller state estimates. (The controller state includes the plant, disturbance, and noise model states.) The estimates supplied at time  $t_k$  must be based on the measurements and other data available at time  $t_k$ .

All candidate controllers must use the same state estimation option, either default or custom. When you use custom state estimation, all candidate controllers must have the same dimension.

#### Reference

At each control instant, the ref signal must contain the current reference values (targets or setpoints) for the  $n_y$  output variables, where  $n_y$  is the total number of outputs, including measured and unmeasured outputs. Since this block does not support reference previewing, ref cannot be defined as a matrix.

## **Required Outports**

### **Manipulated Variables**

The mv outport provides a signal defining the  $n_u \ge 1$  manipulated variables for controlling the plant. The active controller updates its manipulated variable output at each control instant using the control law contained in its explicit MPC controller object. If the control law evaluation fails, this signal is unchanged; that is, it is held at the previous successful result. The Multiple Explicit MPC Controller block passes the output of the active controller to the mv outport.

# Additional Inports (General Section)

#### Measured disturbance

Add an inport (md) to which you can connect a vector signal containing  $n_{md}$  elements, where  $n_{md}$  is the number of measured disturbances.

Since this block does not support measured disturbance previewing, md cannot be defined as a matrix.

### **External manipulated variable**

Add an inport (ext.mv) to which you connect a vector signal that contains the actual manipulated variables (MV) used in the plant. All candidate controllers use this signal to update their controller state estimates at each control interval. Using this inport improves

state estimation accuracy when the MVs used in the plant differ from the MVs calculated by the block, for example due to signal saturation or an override condition.

For additional information, see the corresponding section of the MPC Controller block reference page.

# **Additional Outports (General Section)**

### Status of piecewise affine function evaluation

Add an outport (status) that indicates whether the latest explicit MPC control-law evaluation succeeded. The outport provides a scalar signal that has one of the following values:

- 1 Successful explicit control law evaluation
- 0 Failure: One or more control law parameters out of range.
- -1 Undefined: Control law parameters were within the valid range but an extrapolation was necessary.

If status is either 0 or -1, the mv outport remains at the last known good value.

## Region number of evaluated piecewise affine function

Add an outport (region) providing the index of the polyhedral region used in the latest explicit control law evaluation (a scalar). If the control law evaluation fails, the signal at this outport equals zero.

## Estimated plant, disturbance, and noise model states

Add an outport (est.state) for the controller state estimates, x[k|k], at each control instant. These estimates include the plant, disturbance, and noise model states.

## **State Estimation (General Section)**

### Use custom estimated states instead of measured outputs

Replace mo with the x[k|k] inport for custom state estimation as described in "Required Inports" on page 3-65. All candidate controllers must use the same state estimation option, either default or custom. When you use custom state estimation, all candidate controllers must have the same dimension.

### Others Section

### Block data type

Specify the block data type of the manipulated variables as one of the following:

- double Double-precision floating point (default)
- single Single-precision floating point

If you are implementing the block on a single-precision target, specify the output data type as single.

For an example of double-precision and single-precision simulation and code generation for an MPC controller, see "Simulation and Code Generation Using Simulink Coder".

To view the port data types in a model, in the Simulink Editor, select **Display > Signals & PortsPort Data Types**.

#### Inherit sample time

Use the sample time of the parent subsystem as the block sample time. Doing so allows you to conditionally execute this block inside Function-Call Subsystem or Triggered Subsystem blocks. For an example, see "Using MPC Controller Block Inside Function-Call and Triggered Subsystems".

**Note** You must execute Function-Call Subsystem or Triggered Subsystem blocks at the sample rate of the controller. Otherwise, you can see unexpected results.

To view the sample time of a block, in the Simulink Editor, select **Display > Sample Time**. Select **Colors**, **Annotations**, or **All**. For more information, see "View Sample Time Information" (Simulink).

### Introduced in R2016b

# **Nonlinear MPC Controller**

Simulate nonlinear model predictive controllers **Library:** Model Predictive Control Toolbox

# **Description**

The Nonlinear MPC Controller block simulates a nonlinear model predictive controller. At each control interval, the block computes optimal control moves by solving a nonlinear programming problem. For more information on nonlinear MPC, see "Nonlinear MPC".

To use this block, you must first create an nlmpc object in the MATLAB workspace.

# Limitations

None of the Nonlinear MPC Controller block parameters are tunable.

# **Ports**

## Input

**Required Inputs** 

## x — input

vector

Current prediction model states, specified as a vector signal of length  $N_x$ , where  $N_x$  is the number of prediction model states. Since the nonlinear MPC controller does not perform

state estimation, you must either measure or estimate the current prediction model states at each control interval.

## ref — Model output reference values

row vector | matrix

Plant output reference values, specified as a row vector signal or matrix signal.

To use the same reference values across the prediction horizon, connect **ref** to a row vector signal with  $N_Y$  elements, where  $N_y$  is the number of output variables. Each element specifies the reference for an output variable.

To vary the references over the prediction horizon (previewing) from time k to time k+p-1, connect **ref** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the references for one prediction horizon step. If you specify fewer than p rows, the final references are used for the remaining steps of the prediction horizon.

## last\_mv — Control signals used in plant at previous control interval vector

Control signals used in plant at previous control interval, specified as a vector signal of length $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

**Note** Connect **last\_mv** to the MV signals actually applied to the plant in the previous control interval. Typically, these MV signals are the values generated by the controller, though this is not always the case. For example, if your controller is offline and running in tracking mode; that is, the controller output is not driving the plant, then feeding the actual control signal to **last\_mv** can help achieve bumpless transfer when the controller is switched back online.

#### **Additional Inputs**

#### md — input

row vector | matrix

If your controller model has measured disturbances, enable this input port, and connect a row vector or matrix signal. If your controller has measured disturbances, you must enable this port.

To use the same measured disturbance values across the prediction horizon, connect  $\mathbf{md}$  to a row vector signal with  $N_{md}$  elements, where  $N_{md}$  is the number of manipulated variables. Each element specifies the value for a measured disturbance.

To vary the disturbances over the prediction horizon (previewing) from time k to time k+p-1, connect  $\mathbf{md}$  to a matrix signal with  $N_{md}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the disturbances for one prediction horizon step. If you specify fewer than p rows, the final disturbances are used for the remaining steps of the prediction horizon.

## params — Optional parameters

bus

If your controller uses optional parameters in its prediction model, custom cost function, or custom constraint functions, enable this input port, and connect a parameter bus signal with  $N_p$  elements, where  $N_p$  is the number of parameters. For more information on creating a parameter bus signal, see createParameterBus. The controller, passes these parameters to its model functions, cost function, constraint functions, and Jacobian functions.

If your controller does not use optional parameters, you must disable **params**.

## **Dependencies**

To enable this port, select the **Model parameters** parameter.

## mv.target — Manipulated variable targets

row vector | array

To specify manipulated variable targets, enable this input port, and connect a row vector or matrix signal.

To use the same manipulated variable targets across the prediction horizon, connect **mv.target** to a row vector signal with  $N_{mv}$  elements, where  $N_{mv}$  is the number of manipulated variables. Each element specifies the target for a manipulated variable.

To vary the targets over the prediction horizon (previewing) from time k to time k+p-1, connect **mv.target** to a matrix signal with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the targets for one prediction horizon step. If you specify fewer than p rows, the final targets are used for the remaining steps of the prediction horizon.

To enable this port, select the **Targets for manipulated variables** parameter.

#### **Online Constraints**

## y.min — Minimum output variable constraints

row vector | matrix

To specify run-time minimum output variable constraints, enable this input port. If this port is disabled, the block uses the lower bounds specified in the OutputVariables.Min property of its controller object.

To use the same bounds over the prediction horizon, connect **y.min** to a row vector signal with  $N_y$  elements, where  $N_y$  is the number of outputs. Each element specifies the lower bound for an output variable.

To vary the bounds over the prediction horizon from time k to time k+p-1, connect **y.min** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the bounds in the final row apply for the remainder of the prediction horizon.

#### **Dependencies**

To enable this port, select the **Lower OV limits** parameter.

## y.max — Maximum output variable constraints

row vector | matrix

To specify run-time maximum output variable constraints, enable this input port. If this port is disabled, the block uses the upper bounds specified in the OutputVariables.Min property of its controller object.

To use the same bounds over the prediction horizon, connect **y.max** to a row vector signal with  $N_y$  elements, where  $N_y$  is the number of outputs. Each element specifies the upper bound for an output variable.

To vary the bounds over the prediction horizon from time k to time k+p-1, connect **y.max** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the bounds in the final row apply for the remainder of the prediction horizon.

To enable this port, select the **Upper OV limits** parameter.

## mv.min — Minimum manipulated variable constraints

row vector | matrix

To specify run-time minimum manipulated variable constraints, enable this input port. If this port is disabled, the block uses the lower bounds specified in the ManipulatedVariables.Min property of its controller object.

To use the same bounds over the prediction horizon, connect **mv.min** to a row vector signal with  $N_{mv}$  elements, where  $N_{mv}$  is the number of outputs. Each element specifies the lower bound for a manipulated variable.

To vary the bounds over the prediction horizon from time k to time k+p-1, connect **mv.min** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the bounds in the final row apply for the remainder of the prediction horizon.

### **Dependencies**

To enable this port, select the **Lower MV limits** parameter.

### mv.max — Maximum manipulated variable constraints

row vector | matrix

To specify run-time maximum manipulated variable constraints, enable this input port. If this port is disabled, the block uses the upper bounds specified in the ManipulatedVariables.Min property of its controller object.

To use the same bounds over the prediction horizon, connect **mv.max** to a row vector signal with  $N_{mv}$  elements, where  $N_{mv}$  is the number of outputs. Each element specifies the upper bound for a manipulated variable.

To vary the bounds over the prediction horizon from time k to time k+p-1, connect **mv.max** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the bounds in the final row apply for the remainder of the prediction horizon.

To enable this port, select the **Upper MV limits** parameter.

## dmv.min — Minimum manipulated variable rate constraints

row vector | matrix

To specify run-time minimum manipulated variable rate constraints, enable this input port. If this port is disabled, the block uses the lower bounds specified in the ManipulatedVariable.RateMin property of its controller object. **dmv.min** bounds must be nonpositive.

To use the same bounds over the prediction horizon, connect **dmv.min** to a row vector signal with  $N_{mv}$  elements, where  $N_{mv}$  is the number of outputs. Each element specifies the lower bound for a manipulated variable rate of change.

To vary the bounds over the prediction horizon from time k to time k+p-1, connect **dmv.min** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the bounds in the final row apply for the remainder of the prediction horizon.

#### **Dependencies**

To enable this port, select the **Lower MVRate limits** parameter.

#### dmv.max — Maximum manipulated variable rate constraints

row vector | matrix

To specify run-time maximum manipulated variable rate constraints, enable this input port. If this port is disabled, the block uses the upper bounds specified in the ManipulatedVariables.RateMax property of its controller object. dmv.max bounds must be nonnegative.

To use the same bounds over the prediction horizon, connect **dmv.max** to a row vector signal with  $N_{mv}$  elements, where  $N_{mv}$  is the number of outputs. Each element specifies the upper bound for a manipulated variable rate of change.

To vary the bounds over the prediction horizon from time k to time k+p-1, connect **dmv.max** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the bounds in the final row apply for the remainder of the prediction horizon.

To enable this port, select the **Upper MVRate limits** parameter.

#### x.min — Minimum state constraints

row vector | matrix

To specify run-time minimum state constraints, enable this input port. If this port is disabled, the block uses the lower bounds specified in the States.Min property of its controller object.

To use the same bounds over the prediction horizon, connect **x.min** to a row vector signal with  $N_x$  elements, where  $N_x$  is the number of outputs. Each element specifies the lower bound for a state.

To vary the bounds over the prediction horizon from time k to time k+p-1, connect **x.min** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the bounds in the final row apply for the remainder of the prediction horizon.

### **Dependencies**

To enable this port, select the **Lower state limits** parameter.

#### x.max — Maximum state constraints

row vector | matrix

To specify run-time maximum state constraints, enable this input port. If this port is disabled, the block uses the upper bounds specified in the States. Max property of its controller object.

To use the same bounds over the prediction horizon, connect **x.max** to a row vector signal with  $N_x$  elements, where  $N_x$  is the number of outputs. Each element specifies the upper bound for a state.

To vary the bounds over the prediction horizon from time k to time k+p-1, connect **x.max** to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the bounds for one prediction horizon step. If you specify fewer than p rows, the bounds in the final row apply for the remainder of the prediction horizon.

To enable this port, select the **Upper state limits** parameter.

#### **Online Tuning Weights**

## y.wt — Output variable tuning weights

row vector | matrix

To specify run-time output variable tuning weights, enable this input port. If this port is disabled, the block uses the tuning weights specified in the Weights.OutputVariables property of its controller object. These tuning weights penalize deviations from output references.

To use the same tuning weights over the prediction horizon, connect  $\mathbf{y.wt}$  to a row vector signal with  $N_y$  elements, where  $N_y$  is the number of outputs. Each element specifies a nonnegative tuning weight for an output variable. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon from time k+1 to time k+p, connect  $\mathbf{y.wt}$  to a matrix signal with  $N_y$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

#### **Dependencies**

To enable this port, select the **OV weights** parameter.

## mv.wt — Manipulated variable tuning weights

row vector | matrix

To specify run-time manipulated variable tuning weights, enable this input port. If this port is disabled, the block uses the tuning weights specified in the Weights.ManipulatedVariables property of its controller object. These tuning weights penalize deviations from MV targets.

To use the same tuning weights over the prediction horizon, connect  $\mathbf{mv.wt}$  to a row vector signal with  $N_{mv}$  elements, where  $N_{mv}$  is the number of manipulated variables. Each element specifies a nonnegative tuning weight for a manipulated variable. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon from time k to time k+p-1, connect **mv.wt** to a matrix signal with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

#### **Dependencies**

To enable this port, select the **MV weights** parameter.

## dmv.wt — Manipulated variable rate tuning weights

row vector | matrix

To specify run-time manipulated variable rate tuning weights, enable this input port. If this port is disabled, the block uses the tuning weights specified in the Weights.ManipulatedVariablesRate property of its controller object. These tuning weights penalize large changes in control moves.

To use the same tuning weights over the prediction horizon, connect **dmv.wt** to a row vector signal with  $N_{mv}$  elements, where  $N_{mv}$  is the number of manipulated variables. Each element specifies a nonnegative tuning weight for a manipulated variable rate. For more information on specifying tuning weights, see "Tune Weights".

To vary the tuning weights over the prediction horizon from time k to time k+p-1, connect **dmv.wt** to a matrix signal with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the tuning weights for one prediction horizon step. If you specify fewer than p rows, the tuning weights in the final row apply for the remainder of the prediction horizon. For more information on varying weights over the prediction horizon, see "Time-Varying Weights and Constraints".

#### **Dependencies**

To enable this port, select the **MVRate weights** parameter.

## ecr.wt — Slack variable tuning weight

scalar

To specify a run-time slack variable tuning weight, enable this input port and connect a scalar signal. If this port is disabled, the block uses the tuning weight specified in the Weights.ECR property of its controller object.

The slack variable tuning weight has no effect unless your controller object defines soft constraints whose associated ECR values are nonzero. If there are soft constraints.

increasing the **ecr.wt** value makes these constraints relatively harder. The controller then places a higher priority on minimizing the magnitude of the predicted worst-case constraint violation.

### **Dependencies**

To enable this port, select the **ECR weight** parameter.

#### **Initial Guesses**

## mv.init — Initial guesses for the optimal manipulated variable solutions vector | matrix

To specify initial guesses for the optimal manipulated variable solutions, enable this input port. If this port is disabled, the block uses the optimal control sequences calculated in the previous control interval as initial guesses.

To use the same initial guesses over the prediction horizon, connect **mv.init** to a vector signal with  $N_{mv}$  elements, where  $N_{mv}$  is the number of manipulated variables. Each element specifies the initial guess for a manipulated variable.

To vary the initial guesses over the prediction horizon from time k to time k+p-1, connect **mv.init** to a matrix signal with  $N_{mv}$  columns and up to p rows. Here, k is the current time and p is the prediction horizon. Each row contains the initial guesses for one prediction horizon step. If you specify fewer than p rows, the guesses in the final row apply for the remainder of the prediction horizon.

### **Dependencies**

To enable this port, select the **Initial guess** parameter.

## x.init — Initial guesses for the optimal state variable solutions vector | matrix

To specify initial guesses for the optimal state solutions, enable this input port. If this port is disabled, the block uses the optimal state sequences calculated in the previous control interval as intiial guesses.

To use the same initial guesses over the prediction horizon, connect **x.init** to a vector signal with  $N_x$  elements, where  $N_x$  is the number of states. Each element specifies the initial guess for a state.

To vary the initial guesses over the prediction horizon from time k to time k+p-1, connect **x.init** to a matrix signal with  $N_x$  columns and up to p rows. Here, k is the current time and

p is the prediction horizon. Each row contains the initial guesses for one prediction horizon step. If you specify fewer than p rows, the guesses in the final row apply for the remainder of the prediction horizon.

## **Dependencies**

To enable this port, select the **Initial guess** parameter.

## e.init — Initial guess for the slack variable at the solution

nonnegative scalar

To specify an initial guess for the slack variable at the solution, enable this input port and connect a nonnegative scalar signal. If this port is disabled, the block uses an initial guess of  $\theta$ .

#### **Dependencies**

To enable this port, select the **Initial guess** parameter.

## **Output**

#### **Required Output**

## mv — Optimal manipulated variable control action

column vector

Optimal manipulated variable control action, output as a column vector signal of length  $N_{mv}$ , where  $N_{mv}$  is the number of manipulated variables.

If the solver converges to a local optimum solution (**nlp.status** is positive), then **mv** contains the optimal solution.

If the solver reaches the maximum number of iterations without finding an optimal solution (**nlp.status** is zero) and the Optimization.UseSuboptimalSolution property of the controller is:

- true, then **mv** contains the suboptimal solution
- false, then mv is the same as last\_mv

If the solver fails (**nlp.status** is negative), then **mv** is the same as **last\_mv**.

### **Additional Outputs**

## cost — Objective function cost

nonnegative scalar

Objective function cost, output as a nonnegative scalar signal. The cost quantifies the degree to which the controller has achieved its objectives.

The cost value is only meaningful when the **nlp.status** output is nonnegative.

#### **Dependencies**

To enable this port, select the **Optimal cost** parameter.

#### slack - Slack variable

0 | nonnegative scalar

Slack variable,  $\varepsilon$ , used in constraint softening, output as 0 or a positive scalar value.

- $\varepsilon = 0$  All soft constraints are satisfied over the entire prediction horizon.
- $\epsilon > 0$  At least one soft constraint is violated. When more than one constraint is violated,  $\epsilon$  represents the worst-case soft constraint violation (scaled by the ECR values for each constraint).

### **Dependencies**

To enable this port, select the **Slack variable** parameter.

## nlp.status — Optimization status

scalar

Optimization status, output as one of the following:

- $\bullet \quad \hbox{Positive Integer} \hbox{Solver converged to an optimal solution}$
- $\bullet$  0 Maximum number of iterations reached without converging to an optimal solution
- Negative integer Solver failed

## **Dependencies**

To enable this port, select the **Optimization status** parameter.

#### **Optimal Sequences**

## mv.seq — Optimal manipulated variable sequence matrix

Optimal manipulated variable sequence, returned as a matrix signal with p+1 rows and  $N_{mv}$  columns, where p is the prediction horizon and  $N_{mv}$  is the number of manipulated variables.

The *i*th row of **mv.seq** contains the calculated optimal manipulated variable values at time k+i-1, for i=1,...,p+1, where k is the current time. The first row of **mv.seq** contains the current manipulated variables values (output **mv**). Since the controller does not calculate optimal control moves at time k+p, the final two rows of **mv.seq** are identical.

#### **Dependencies**

To enable this port, select the **Optimal control sequence** parameter.

## x.seq — Optimal prediction model state sequence matrix

Optimal prediction model state sequence, returned as a matrix signal with p+1 rows and  $N_x$  columns, where p is the prediction horizon and  $N_x$  is the number of states.

The *i*th row of **x.seq** contains the calculated state values at time k+i-1, for i=1,...,p+1, where k is the current time. The first row of **x.seq** contains the current state values (output **x**).

#### **Dependencies**

To enable this port, select the **Optimal state sequence** parameter.

## y.seq — Optimal output variable sequence matrix

Optimal output variable sequence, returned as a matrix signal with p+1 rows and  $N_y$  columns, where p is the prediction horizon and  $N_y$  is the number of output variables.

The *i*th row of **y.sseq** contains the calculated state values at time k+i-1, for i=1, ..., p+1, where k is the current time. The first row of **y.seq** is computed based on the current states (output **x**) and the current measured disturbances (first row of input **md**).

To enable this port, select the **Optimal output sequence** parameter.

## **Parameters**

#### Nonlinear MPC Controller — Parameter

nlmpc object name

You must provide an nlmpc object that defines a nonlinear MPC controller. To do so, enter the name of an nlmpc object in the MATLAB workspace.

## **Programmatic Use**

Block Parameter: nlmpcobj

Type: character vector

Values: name of nlmpc object

Default: ''

## Use prediction model sample time — Parameter

on (default) | off

Select this parameter to run the controller using the same sample time as its prediction model. To use a different controller sample time, clear this parameter, and specify the sample time using the **Make block run at a different sample time** parameter.

#### **Programmatic Use**

**Block Parameter:** UseObjectTs

Type: character vector Values: 'on', 'off'

Default: 'on'

## Make block run at a different sample time — Controller sample time

positive finite scalar

Specify this parameter to run the controller using a different sample time from its prediction model.

### **Dependencies**

To enable this parameter, clear the **Use prediction model sample time** parameter.

## **Programmatic Use**

**Block Parameter:** TsControl

**Type:** character vector **Values:** positive finite scalar

Default: ''

## **General Tab**

## Measured disturbances — Add measured disturbance input port

off (default) | on

If your controller has measured disturbances, you must select this parameter to add the **md** output port to the block.

#### **Programmatic Use**

Block Parameter: md enabled

Type: character vector Values: 'off', 'on' Default: 'off'

# Targets for manipulated variables — Add manipulated variable target input port

off (default) | on

Select this parameter to add the **mv.target** input port to the block.

#### **Programmatic Use**

Block Parameter: mvtarget enabled

Type: character vector Values: 'off', 'on' Default: 'off'

## Model parameters — Add model parameters input port

off (default) | on

If your controller uses optional parameters, you must select this parameter to add the **params** output port to the block.

For more information on creating a parameter bus signal, see createParameterBus.

#### **Programmatic Use**

Block Parameter: param enabled

Type: character vector Values: 'off', 'on' Default: 'off'

## Optimal cost — Odd optimal cost output port

off (default) | on

Select this parameter to add the **cost** output port to the block.

#### **Programmatic Use**

Block Parameter: cost enabled

Type: character vector Values: 'off', 'on' Default: 'off'

## Optimal control sequence — Add optimal control sequence output port

off (default) | on

Select this parameter to add the **mv.seq** output port to the block.

## **Programmatic Use**

Block Parameter: mvseq enabled

Type: character vector Values: 'off', 'on' Default: 'off'

## Optimal state sequence — Add optimal state sequence output port

off (default) | on

Select this parameter to add the x.seq output port to the block.

#### **Programmatic Use**

Block Parameter: stateseq\_enabled

Type: character vector Values: 'off', 'on' Default: 'off'

## Optimal output sequence — Add optimal output sequence output port

off (default) | on

Select this parameter to add the y.seq output port to the block.

#### **Programmatic Use**

**Block Parameter:** ovseq\_enabled

Type: character vector Values: 'off', 'on' Default: 'off'

## Slack variable — Add slack variable output port

off (default) | on

Select this parameter to add the **slack** output port to the block.

### **Programmatic Use**

**Block Parameter:** slack\_enabled

Type: character vector Values: 'off', 'on' Default: 'off'

## Optimization status — Add optimization status output port

off (default) | on

Select this parameter to add the **nlp.status** output port to the block.

#### **Programmatic Use**

**Block Parameter:** status\_enabled

Type: character vector Values: 'off', 'on' Default: 'off'

## **Online Features Tab**

## Lower OV limits — Add minimum OV constraint input port

off (default) | on

Select this parameter to add the **ov.min** input port to the block.

#### **Programmatic Use**

Block Parameter: ov\_min Type: character vector Values: 'off', 'on' Default: 'off'

## Upper OV limits — Add maximum OV constraint input port

off (default) | on

Select this parameter to add the **ov.max** input port to the block.

### **Programmatic Use**

Block Parameter: ov\_max Type: character vector Values: 'off', 'on' Default: 'off'

## Lower MV limits — Add minimum MV constraint input port

off (default) | on

Select this parameter to add the **mv.min** input port to the block.

#### **Programmatic Use**

Block Parameter: mv\_min Type: character vector Values: 'off', 'on' Default: 'off'

## Upper MV limits — Add maximum MV constraint input port

off (default) | on

Select this parameter to add the **mv.max** input port to the block.

#### **Programmatic Use**

Block Parameter: mv\_max Type: character vector Values: 'off', 'on' Default: 'off'

## Lower MVRate limits — Add minimum MV rate constraint input port

off (default) | on

Select this parameter to add the **dmv.min** input port to the block.

## **Programmatic Use**

Block Parameter: mvrate\_min

Type: character vector Values: 'off', 'on' Default: 'off'

## Upper MVRate limits — Add maximum MV rate constraint input port

off (default) | on

Select this parameter to add the **dmv.max** input port to the block.

### **Programmatic Use**

**Block Parameter:** mvrate\_max

Type: character vector Values: 'off', 'on' Default: 'off'

## Lower state limits — Add minimum state constraint input port

off (default) | on

Select this parameter to add the **x.min** input port to the block.

#### **Programmatic Use**

**Block Parameter:** state\_min

Type: character vector Values: 'off', 'on' Default: 'off'

## Upper state limits — Add maximum state constraint input port

off (default) | on

Select this parameter to add the **x.max** input port to the block.

### **Programmatic Use**

Block Parameter: state max

Type: character vector Values: 'off', 'on' Default: 'off'

## **OV** weights — Add **OV** tuning weights input port

off (default) | on

Select this parameter to add the **y.wt** input port to the block.

#### **Programmatic Use**

Block Parameter: ov weight

Type: character vector Values: 'off', 'on' Default: 'off'

## MV weights — Add MV tuning weights input port

off (default) | on

Select this parameter to add the **mv.wt** input port to the block.

#### **Programmatic Use**

Block Parameter: mv weight

Type: character vector Values: 'off', 'on' Default: 'off'

## MVRate weights — Add MV rate tuning weights input port

off (default) | on

Select this parameter to add the **dmv.wt** input port to the block.

#### **Programmatic Use**

Block Parameter: mvrate weight

Type: character vector Values: 'off', 'on' Default: 'off'

## ECR weight — Add ECR tuning weight input port

off (default) | on

Select this parameter to add the **ecr.wt** input port to the block.

### **Programmatic Use**

Block Parameter: ecr\_weight

Type: character vector Values: 'off', 'on' Default: 'off'

## Initial guess — Add initial guess input ports

off (default) | on

Select this parameter to add the **mv.init**, **x.init**, and **e.init** input ports to the block.

**Note** By default, the Nonlinar MPC Controller block uses the calculated optimal manipulated variable and state trajectories from one control interval as the initial guesses for the next control interval.

Enable the initial guess ports only if it is necessary for your application.

**Programmatic Use** 

Block Parameter: nlp\_initialize

Type: character vector Values: 'off', 'on' Default: 'off'

## **Topics**

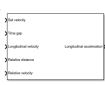

"Nonlinear MPC"

Introduced in R2018b

## **Adaptive Cruise Control System**

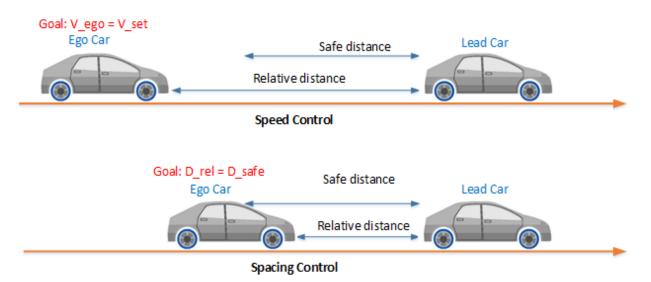

Simulate adaptive cruise control using model predictive controller

Library: Model Predictive Control Toolbox / Automated Driving

## **Description**

The Adaptive Cruise Control System block simulates an adaptive cruise control (ACC) system that tracks a set velocity and maintains a safe distance from a lead vehicle by adjusting the longitudinal acceleration of an ego vehicle. The block computes optimal control actions while satisfying safe distance, velocity, and acceleration constraints using model predictive control (MPC).

To customize your controller, for example to use advanced MPC features or modify controller initial conditions, click **Create ACC subsystem**.

## **Ports**

## Input

## Set velocity - Ego vehicle velocity setpoint

nonnegative scalar

Ego vehicle velocity setpoint in m/s. When there is no lead vehicle, the controller tracks this velocity.

## Time gap — Safe time gap

nonnegative scalar

Safe time gap in seconds between the lead vehicle and the ego vehicle. This time gap is used to calculate the minimum safe following distance constraint. For more information, see "Safe Following Distance" on page 3-97.

## Longitudinal velocity — Ego vehicle velocity

nonnegative scalar

Ego vehicle velocity in m/s.

# Relative distance — Distance between lead vehicle and ego vehicle positive scalar

Distance in meters between lead vehicle and ego vehicle. To calculate this signal, subtract the ego vehicle position from the lead vehicle position.

# **Relative velocity — Velocity difference between lead vehicle and ego vehicle** scalar

Velocity difference in meters per second between lead vehicle and ego vehicle. To calculate this signal, subtract the ego vehicle velocity from the lead vehicle velocity.

# Minimum longitudinal acceleration — Minimum ego vehicle acceleration negative scalar

Minimum ego vehicle longitudinal acceleration constraint in  $m/s^2$ . Use this input port when the minimum acceleration varies at run time.

#### **Dependencies**

To enable this port, select **Use external source** for the **Minimum longitudinal acceleration** parameter.

**Maximum longitudinal acceleration — Maximum ego vehicle acceleration** positive scalar

Maximum ego vehicle longitudinal acceleration constraint in m/s<sup>2</sup>. Use this input port when the maximum acceleration varies at run time.

## **Dependencies**

To enable this port, select **Use external source** for the **Maximum longitudinal acceleration** parameter.

# **Enable optimization — Controller optimization enable signal** scalar

Controller optimization enable signal. When this signal is:

- Nonzero, the controller performs optimization calculations and generates a Longitudinal acceleration control signal.
- Zero, the controller does not perform optimization calculations. In this case, the
   Longitudinal acceleration output signal remains at the value it had when the
   optimization was disabled. The controller continues to update its internal state
   estimates.

#### **Dependencies**

To enable this port, select the **Use external signal to enable or disable optimization** parameter.

## **External control signal — Longitudinal acceleration applied to ego vehicle** scalar

Actual longitudinal acceleration in  $m/s^2$  applied to the ego vehicle. The controller uses this signal to estimate the ego vehicle model states. Use this input port when the control signal applied to the ego vehicle does not match the optimal control signal computed by the model predictive controller. This mismatch can occur when, for example:

- The Adaptive Cruise Control System is not the active controller. Maintaining an accurate state estimate when the controller is not active prevents bumps in the control signal when the controller becomes active.
- The acceleration actuator fails and does not provide the correct control signal to the ego vehicle.

To enable this port, select the **Use external control signal for bumpless transfer between ACC and other controllers** parameter.

## **Output**

## **Longitudinal acceleration — Acceleration control signal** scalar

Acceleration control signal in m/s<sup>2</sup> generated by the controller.

## **Parameters**

## **Parameters Tab**

## **Ego Vehicle Model**

# Linear model from longitudinal acceleration to longitudinal velocity — Ego vehicle model

tf(1,[0.5,1,0]) (default) | LTI model | linear System Identification Toolbox model

The linear model from the ego vehicle longitudinal acceleration to its longitudinal velocity, specified as an LTI model or a linear System Identification Toolbox model. The controller creates its internal predictive model by augmenting the ego vehicle dynamic model.

# Initial condition for longitudinal velocity — Initial velocity of the ego vehicle model

20 (default) | nonnegative scalar

Initial velocity in m/s of the ego vehicle model, which can differ from the actual ego vehicle initial velocity.

This value is used to configure the initial conditions of the model predictive controller. For more information, see "Initial Conditions" on page 3-98.

## Default spacing — Minimum spacing to lead vehicle

10 (default) | nonnegative scalar

Minimum spacing in meters between the lead vehicle and the ego vehicle. This value corresponds to the target relative distance between the ego and lead vehicles when the ego vehicle velocity is zero.

This value is used to calculate the:

- Minimum safe following distance. For more information, see "Safe Following Distance" on page 3-97.
- Controller initial conditions. For more information, see "Initial Conditions" on page 3-98.

## Maximum velocity — Maximum longitudinal velocity

50 (default) | positive scalar

Maximum ego vehicle longitudinal velocity in m/s.

## **Adaptive Cruise Controller Constraints**

# Minimum longitudinal acceleration — Minimum ego vehicle acceleration -3 (default) | negative scalar

Minimum ego vehicle longitudinal acceleration constraint in m/s<sup>2</sup>.

If the minimum acceleration varies over time, add the **Minimum longitudinal** acceleration input port to the block by selecting **Use external source**.

# Maximum longitudinal acceleration — Maximum ego vehicle acceleration 2 (default) | nonnegative scalar

Maximum ego vehicle longitudinal acceleration constraint in m/s<sup>2</sup>.

If the maximum acceleration varies over time, add the **Maximum longitudinal** acceleration input port to the block by selecting **Use external source**.

### Model Predictive Controller Settings

## Sample time — Controller sample time

0.1 (default) | positive scalar

Controller sample time in seconds.

## Prediction horizon — Controller prediction horizon

10 (default) | positive integer

Controller prediction horizon steps. The controller prediction time is the product of the sample time and the prediction horizon.

## Controller behavior — Closed-loop controller performance

0.5 (default) | scalar between 0 and 1

Closed-loop controller performance. The default parameter value provides a balanced controller design. Specifying a:

- Smaller value produces a more robust controller with smoother control actions.
- Larger value produces a more aggressive controller with a faster response time.

When you modify this parameter, the change is applied to the controller immediately.

## **Block Tab**

# Use suboptimal solution — Apply suboptimal solution after specified number of iterations

off (default) | on

Configure the controller to apply a suboptimal solution after a specified maximum number of iterations, which guarantees the worst-case execution time for your controller.

For more information, see "Suboptimal QP Solution".

## **Dependencies**

After selecting this parameter, specify the **Maximum iteration number** parameter.

## Maximum iteration number — Maximum optimization iterations

10 (default) | positive integer

Maximum number of controller optimization iterations.

To enable this parameter, select the **Use suboptimal solution** parameter.

Use external signal to enable or disable optimization — Add port for enabling optimization

off (default) | on

To add the **Enable optimization** input port to the block, select this parameter.

Use external signal for bumpless transfer between ACC and other controllers — Add external control signal input port off (default) | on

Select this parameter to add the **External control signal** input port to the block.

## Create ACC subsystem — Create custom controller button

Generate a custom ACC subsystem, which you can modify for your application. The configuration data for the custom controller is exported to the MATLAB workspace as a structure.

You can modify the custom controller subsystem to:

- Modify default MPC settings or use advanced MPC features.
- Modify the default controller initial conditions.
- Use different application settings, such as a custom safe following distance definition.

## **Algorithms**

## **Safe Following Distance**

By default, the model predictive controller computes the safe following distance constraint; that is, the minimum relative distance between the lead and ego vehicle, as:

$$D_R = D_S + G_T * V_E$$

Here:

- $D_S$  is the **Default spacing** parameter.
- $G_T$  is the **Time gap** input signal.
- $V_E$  is the **Longitudinal velocity** input signal.

To define a different safe following distance constraint, create a custom cruise control system by, on the **Block** tab, clicking **Create ACC subsystem**.

## **Initial Conditions**

By default, the model predictive controller assumes the following initial conditions:

- Longitudinal velocity of both the ego vehicle and the lead vehicle equal the Initial condition for longitudinal velocity parameter value.
- Ego vehicle longitudinal acceleration is zero.
- Relative distance between the lead vehicle and ego vehicle is:

$$D_R = D_S + G_T * V_E$$

#### Here:

- $D_S$  is the **Default spacing** parameter.
- $G_T$  is the time gap and is assumed to be 1.4.
- $V_E$  is the **Initial longitudinal velocity** parameter.

If the initial conditions in your model do not match these conditions, the **Longitudinal acceleration** output can exhibit an initial bump at the start of the simulation.

To modify the controller initial conditions to match your simulation, create a custom cruise control system by, on the **Block** tab, clicking **Create ACC subsystem**.

## **Extended Capabilities**

MPC Controller

Introduced in R2018a

## **Lane Keeping Assist System**

Simulate lane-keeping assistance using adaptive model predictive controller **Library:** Model Predictive Control Toolbox / Automated Driving

Curvature

Longitudinal velocity

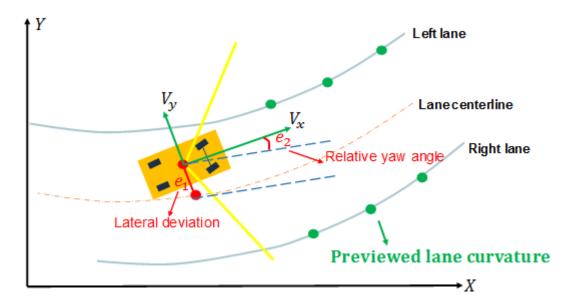

Steering angle

Lateral deviation

Relative yew angle

## **Description**

The Lane Keeping Assist System block simulates a lane keeping assist (LKA) system that keeps an ego vehicle traveling along the center of a straight or curved road by adjusting the front steering angle. The controller reduces the lateral deviation and relative yaw angle of the ego vehicle with respect to the lane centerline. The block computes optimal control actions while satisfying steering angle constraints using adaptive model predictive control (MPC).

To customize your controller, for example to use advanced MPC features or modify controller initial conditions, click **Create LKA subsystem**.

## **Ports**

## Input

### Curvature — Road curvature

scalar

Road curvature, specified as 1/R, where R is the radius of the curve in meters.

The road curvature is:

- Positive when the road curves toward the positive Y axis of the global coordinate system.
- Negative when the road curves toward the negative Y axis of the global coordinate system.
- Zero for a straight road.

The controller models the road curvature as a measured disturbance with previewing. You can specify the curvature as a:

- Scalar signal Specify the curvature for the current control interval. The controller uses this curvature value across the prediction horizon.
- Vector signal with length less than or equal to the **Prediction Horizon** Specify the current and predicted curvature values across the prediction horizon. If the length of the vector is less than the prediction horizon, then the controller uses the final curvature value in the vector for the remainder of the prediction horizon.

## Longitudinal velocity — Ego vehicle velocity

nonnegative scalar

Ego vehicle velocity in m/s.

## Lateral deviation — Ego vehicle lateral deviation

scalar

Ego vehicle lateral deviation in meters from the centerline of the lane.

## Relative yaw angle — Angle from lane centerline

scalar

Ego vehicle longitudinal axis angle in radians from the centerline of the lane.

## Minimum steering angle — Minimum front steering angle

scalar

Minimum front steering angle constraint in radians. Use this input port when the minimum steering angle varies at run time.

## **Dependencies**

To enable this port, select **Use external source** for the **Minimum steering angle** parameter.

## Maximum steering angle — Maximum front steering angle scalar

Maximum front steering angle constraint in radians. Use this input port when the maximum steering angle varies at run time.

To enable this port, select **Use external source** for the **Maximum steering angle** parameter.

## **Enable optimization — Controller optimization enable signal** scalar

Controller optimization enable signal. When this signal is:

- Nonzero, the controller performs optimization calculations and generates a Steering angle control signal.
- Zero, the controller does not perform optimization calculations. In this case, the **Steering angle** output signal remains at the value it had when the optimization was disabled. The controller continues to update its internal state estimates.

## **Dependencies**

To enable this port, select the **Use external signal to enable or disable optimization** parameter.

# External control signal — Steering angle applied to ego vehicle scalar

Actual steering angle in radians applied to the ego vehicle. The controller uses this signal to estimate the ego vehicle model states. Use this input port when the control signal applied to the ego vehicle does not match the optimal control signal computed by the model predictive controller. This mismatch can occur when, for example:

- The Lane Keeping Assist System is not the active controller. Maintaining an accurate state estimate when the controller is not active prevents bumps in the control signal when the controller becomes active.
- The steering actuator fails and does not provide the correct control signal to the ego vehicle.

#### **Dependencies**

To enable this port, select the **Use external control signal for bumpless transfer between PFC and other controllers** parameter.

Vehicle dynamics matrix A — State matrix of ego vehicle predictive model square matrix

State matrix of ego vehicle predictive model. The number of rows in the state matrix corresponds to the number of states in the predictive model. This matrix must be square.

The ego vehicle predictive model defined by **Vehicle dynamics matrix A**, **Vehicle dynamics matrix B**, and **Vehicle dynamics matrix C** must be minimal.

#### **Dependencies**

To enable this port, select the **Use vehicle model** parameter.

## Vehicle dynamics matrix B — Input-to-state matrix of ego vehicle predictive model

column vector

Input-to-state matrix of ego vehicle predictive model. The number of rows in this signal must match the number of rows in **Vehicle dynamics matrix A**.

The ego vehicle predictive model defined by **Vehicle dynamics matrix A**, **Vehicle dynamics matrix B**, and **Vehicle dynamics matrix C** must be minimal.

## **Dependencies**

To enable this port, select the Use vehicle model parameter.

# Vehicle dynamics matrix C — State-to-output matrix of ego vehicle predictive model

matrix with two rows

State-to-output matrix of ego vehicle predictive model. The number of columns in this signal must match the number of rows in **Vehicle dynamics matrix A**.

The ego vehicle predictive model defined by **Vehicle dynamics matrix A**, **Vehicle dynamics matrix B**, and **Vehicle dynamics matrix C** must be minimal.

### **Dependencies**

To enable this port, select the **Use vehicle model** parameter.

## **Output**

## Steering angle — Front steering angle control signal

scalar

Front steering angle control signal in radians generated by the controller. The front steering angle is the angle of the front tires from the longitudinal axis of the vehicle. The steering angle is positive towards the positive lateral axis of the ego vehicle.

## **Parameters**

## **Parameters Tab**

### **Ego Vehicle**

Use vehicle parameters — Define ego vehicle model using vehicle properties on  $(default) \mid off$ 

Select this parameter to define the ego vehicle model used by the MPC controller by specifying properties of the ego vehicle. The ego vehicle model is the linear model from the front steering angle to the lateral velocity and yaw angle rate. For more information, see "Ego Vehicle Predictive Model" on page 3-111.

To define the vehicle model, specify the following block parameters:

- Total mass
- Yaw moment of inertia
- Longitudinal distance from center of gravity to front tires
- Longitudinal distance from center of gravity to rear tires
- · Cornering stiffness of front tires
- Cornering stiffness of rear tires

For more information on the ego vehicle model, see "Ego Vehicle Predictive Model" on page 3-111.

Selecting this parameter clears the Use vehicle model parameter.

# Use vehicle model — Define ego vehicle model using state-space matrices off $(default) \mid on$

Select this parameter to define the state-space matrices of the ego vehicle model used by the MPC controller. This model is the linear model from the front steering angle in radians to the lateral velocity in meters per second and yaw angle rate in radians per second. For more information on the ego vehicle model, see "Ego Vehicle Predictive Model" on page 3-111.

To define the initial internal model, specify the A, B, and C state-space matrices. The internal model must be a minimal realization with no direct feedthrough, and the dimensions of A, B, and C must be consistent.

Typically, the ego vehicle steering model is velocity-dependent, and therefore, it varies over time. To update the internal model at run time, use the **Vehicle dynamics A**, **Vehicle dynamics B**, and **Vehicle dynamics C** input ports.

Selecting this parameter clears the **Use vehicle parameters** parameter.

## Total mass — Ego vehicle mass

1575 (default) | positive scalar

Ego vehicle mass in kg.

## **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

Yaw moment of inertia — Moment of inertia about the ego vehicle vertical axis 2875 (default) | positive scalar

Moment of inertia about the ego vehicle vertical axis in  $mNs^2$ .

### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

# Longitudinal distance from center of gravity to front tires — Distance from the ego vehicle center of mass to its front tires

1.2 (default) | positive scalar

Distance from the ego vehicle center of mass to its front tires in meters, measured along the longitudinal axis of the vehicle.

## **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

## Longitudinal distance from center of gravity to rear tires — Distance from the ego vehicle center of mass to its rear tires

1.6 (default) | positive scalar

Distance from the ego vehicle center of mass to its rear tires in meters, measured along the longitudinal axis of the vehicle.

#### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

### Cornering stiffness of front tires — Front tire stiffness

19000 (default) | positive scalar

Front tire stiffness in N/rad, defined as the relationship between the side force on the front tires and the angle of the tires to the longitudinal axis of the vehicle.

### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

### Cornering stiffness of rear tires — Reartire stiffness

33000 (default) | positive scalar

Rear tire stiffness in N/rad, defined as the relationship between the side force on the rear tires and the angle of the tires to the longitudinal axis of the vehicle.

#### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

### A — Initial state matrix of ego vehicle predictive model

square matrix

Initial state matrix of ego vehicle predictive model. The number of rows in the state matrix corresponds to the number of states in the predictive model. This matrix must be square.

The initial ego vehicle predictive model defined by  ${\bf A}$ ,  ${\bf B}$ , and  ${\bf C}$  must be minimal.

Typically, the ego vehicle model varies over time. To update the state matrix at run time, use the **Vehicle dynamics A** input port.

#### **Dependencies**

To enable this parameter, select the **Use vehicle model** parameter.

## **B** — Initial input-to-state matrix of ego vehicle predictive model column vector

Initial input-to-state matrix of ego vehicle predictive model. The number of rows in this parameter must match the number of rows in **A**.

The initial ego vehicle predictive model defined by **A**, **B**, and **C** must be minimal.

Typically, the ego vehicle model varies over time. To update the input-to-state matrix at run time, use the **Vehicle dynamics B** input port.

#### **Dependencies**

To enable this parameter, select the **Use vehicle model** parameter.

## C — Initial state-to-output matrix of ego vehicle predictive model matrix with two rows

Initial state-to-output matrix of ego vehicle predictive model. The number of columns in this parameter must match the number of rows in  $\bf A$ .

The initial ego vehicle predictive model defined by **A**, **B**, and **C** must be minimal.

Typically, the ego vehicle model varies over time. To update the state-to-output matrix at run time, use the **Vehicle dynamics C** input port.

### **Dependencies**

To enable this parameter, select the **Use vehicle model** parameter.

## Initial longitudinal velocity — Initial velocity of the ego vehicle 15 (default) | positive scalar

Initial velocity of the ego vehicle model when the lane-keeping assist is enabled in m/s. This velocity can differ from the actual ego vehicle initial velocity.

## Transport lag between model inputs and outputs — Total transport lag in ego vehicle model

0 (default) | nonnegative scalar

Total transport lag,  $\tau$ , in the ego vehicle model in seconds. This lag includes actuator, sensor, and communication lags. For each input-output channel, the transport lag is approximated by:

$$\frac{1}{\tau s + 1}$$

#### **Lane Keeping Controller Constraints**

### Minimum steering angle — Minimum front steering angle

-0.26 (default) | scalar between -pi/2 and pi/2

Minimum front steering angle constraint in radians.

If the minimum steering angle varies over time, add the **Minimum steering angle** input port to the block by selecting **Use external source**.

#### **Dependencies**

This parameter must be less than the **Maximum steering angle** parameter.

### Maximum steering angle — Maximum front steering angle

0.26 (default) | scalar between -pi/2 and pi/2

Maximum front steering angle constraint in radians.

If the maximum steering angle varies over time, add the **Maximum steering angle** input port to the block by selecting **Use external source**.

### **Dependencies**

This parameter must be greater than the **Minimum steering angle** parameter.

#### **Model Predictive Controller Settings**

### Sample time — Controller sample time

0.1 (default) | positive scalar

Controller sample time in seconds.

### Prediction horizon — Controller prediction horizon

10 (default) | positive integer

Controller prediction horizon steps. The controller prediction time is the product of the sample time and the prediction horizon.

### Controller behavior — Closed-loop controller performance

0.5 (default) | scalar between 0 and 1

Closed-loop controller performance. The default parameter value provides a balanced controller design. Specifying a:

- Smaller value produces a more robust controller with smoother control actions.
- Larger value produces a more aggressive controller with a faster response time.

When you modify this parameter, the change is applied to the controller immediately.

#### **Block Tab**

## Use suboptimal solution — Apply suboptimal solution after specified number of iterations

off (default) | on

Configure the controller to apply a suboptimal solution after a specified maximum number of iterations, which guarantees the worst-case execution time for your controller.

For more information, see "Suboptimal QP Solution".

### **Dependencies**

After selecting this parameter, specify the **Maximum iteration number** parameter.

## Maximum iteration number — Maximum optimization iterations

10 (default) | positive integer

Maximum number of controller optimization iterations.

### **Dependencies**

To enable this parameter, select the **Use suboptimal solution** parameter.

## Use external signal to enable or disable optimization — Add port for enabling optimization

off (default) | on

To add the **Enable optimization** input port to the block, select this parameter.

Use external signal for bumpless transfer between LKA and other controllers — Add external control signal input port off (default) | on

To add the **External control signal** input port to the block, select this parameter.

## **Create LKA subsystem — Create custom controller** button

Generate a custom LKA subsystem, which you can modify for your application. The controller configuration data for the custom controller is exported to the MATLAB workspace as a structure.

You can modify the custom controller subsystem to:

- Modify default MPC settings or use advanced MPC features.
- Modify the default controller initial conditions.

## **Algorithms**

### **Ego Vehicle Predictive Model**

The default ego vehicle predictive model is the following state-space model:

$$A = \begin{bmatrix} -2(C_F + C_R)/m/V_X & -V_X - 2(C_F L_F - C_R L_R)/m/V_X \\ -2(C_F L_F - C_R L_R)/I_Z/V_X & -2(C_F L_F^2 + C_R L_R^2)/I_Z/V_X \end{bmatrix}$$

$$B = 2C_F \begin{bmatrix} 1/m \\ L_F/I_Z \end{bmatrix}$$

$$C = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$D = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Here:

- $V_X$  is the longitudinal velocity of the car. At the start of the simulation, this velocity is equal to the **Initial condition for longitudinal velocity** parameter. At run time, this velocity is equal to the **Longitudinal velocity** input signal.
- *m* is the **Total mass** parameter.
- $I_Z$  is the **Yaw moment of inertia** parameter.
- L<sub>F</sub> is the Longitudinal distance from center of gravity to front tires parameter.
- $L_R$  is the **Longitudinal distance from center of gravity to rear tires** parameter.
- $C_F$  is the **Cornering stiffness of front tires** parameter.
- $C_R$  is the **Cornering stiffness of rear tires** parameter.

The input to this model is the steering angle in radians, and the outputs are the lateral velocity in meters per second and yaw angle rate in radians per second.

To define a different ego vehicle predictive model, select the **Use vehicle model** parameter, and specify the initial state-space model. Then, specify the run-time values of the state-space matrices using the **Vehicle dynamics A**, **Vehicle dynamics B**, and **Vehicle dynamics C** input signals.

The controller creates its internal predictive model by augmenting the ego vehicle dynamic model. The augmented model includes the road curvature as a measured disturbance input signal.

### **Initial Conditions**

By default, the model predictive controller assumes the following initial conditions for the ego vehicle:

- Longitudinal velocity is equal to the **Initial longitudinal velocity** parameter.
- Lateral velocity is zero.
- Steering angle is zero.
- Yaw angle rate is zero.

If the initial conditions in your model do not match these conditions, the **Steering angle** output can exhibit an initial bump at the start of the simulation.

To modify the controller initial conditions to match your simulation, create a custom lane-keeping control system by, on the **Block** tab, clicking **Create LKA subsystem**.

## **Description**

The Path Following Control System block simulates a path-following control (PFC) system that keeps an ego vehicle traveling along the center of a straight or curved road while tracking a set velocity and maintaining a safe distance from a lead vehicle. To do so, the controller adjusts both the longitudinal acceleration and front steering angle of the ego vehicle. The block computes optimal control actions while satisfying safe distance, velocity, acceleration, and steering angle constraints using adaptive model predictive control (MPC).

This block combines the capabilities of the Lane Keeping Assist System and Adaptive Cruise Control System blocks into a single controller.

To customize your controller, for example to use advanced MPC features or modify controller initial conditions, click **Create PFC subsystem**.

### **Ports**

### Input

### Set velocity — Ego vehicle velocity setpoint

nonnegative scalar

Ego vehicle velocity setpoint in m/s. When there is no lead vehicle, the controller tracks this velocity.

### Time gap — Safe time gap

nonnegative scalar

Safe time gap in seconds between the lead vehicle and the ego vehicle. This time gap is used to calculate the minimum safe following distance constraint. For more information, see "Safe Following Distance" on page 3-131.

## **Relative distance — Distance between lead vehicle and ego vehicle** positive scalar

Distance in meters between lead vehicle and ego vehicle. To calculate this signal, subtract the ego vehicle position from the lead vehicle position.

## **Relative velocity — Velocity difference between lead vehicle and ego vehicle** scalar

Velocity difference in meters per second between lead vehicle and ego vehicle. To calculate this signal, subtract the ego vehicle velocity from the lead vehicle velocity.

### Longitudinal velocity — Ego vehicle velocity

nonnegative scalar

Ego vehicle velocity in m/s.

#### Curvature — Road curvature

scalar

Road curvature, specified as 1/R, where R is the radius of the curve in meters.

The road curvature is:

- Positive when the road curves toward the positive Y axis of the global coordinate system.
- Negative when the road curves toward the negative Y axis of the global coordinate system.
- · Zero for a straight road.

The controller models the road curvature as a measured disturbance with previewing. You can specify the curvature as a:

- Scalar signal Specify the curvature for the current control interval. The controller uses this curvature value across the prediction horizon.
- Vector signal with length less than or equal to the **Prediction Horizon** Specify the current and predicted curvature values across the prediction horizon. If the length of the vector is less than the prediction horizon, then the controller uses the final curvature value in the vector for the remainder of the prediction horizon.

### Lateral deviation — Ego vehicle lateral deviation

scalar

Ego vehicle lateral deviation in meters from the centerline of the lane.

## **Relative yaw angle — Angle from lane centerline** scalar

Ego vehicle longitudinal axis angle in radians from the centerline of the lane.

## Minimum longitudinal acceleration — Minimum ego vehicle acceleration scalar

Minimum ego vehicle longitudinal acceleration constraint in m/s<sup>2</sup>. Use this input port when the minimum acceleration varies at run time.

#### **Dependencies**

To enable this port, select **Use external source** for the **Minimum longitudinal acceleration** parameter.

## **Maximum longitudinal acceleration — Maximum ego vehicle acceleration** scalar

Maximum ego vehicle longitudinal acceleration constraint in m/s<sup>2</sup>. Use this input port when the maximum acceleration varies at run time.

#### **Dependencies**

To enable this port, select **Use external source** for the **Maximum longitudinal acceleration** parameter.

## Minimum steering angle — Minimum front steering angle scalar

Minimum front steering angle constraint in radians. Use this input port when the minimum steering angle varies at run time.

#### **Dependencies**

To enable this port, select **Use external source** for the **Minimum steering angle** parameter.

## **Maximum steering angle — Maximum front steering angle** scalar

Maximum front steering angle constraint in radians. Use this input port when the maximum steering angle varies at run time.

#### **Dependencies**

To enable this port, select **Use external source** for the **Maximum steering angle** parameter.

## **Enable optimization — Controller optimization enable signal** scalar

Controller optimization enable signal. When this signal is:

- Nonzero, the controller performs optimization calculations and generates the Longitudinal acceleration and Steering angle control signals.
- Zero, the controller does not perform optimization calculations. In this case, the
   Longitudinal acceleration and Steering angle output signals remain at the values
   they had when the optimization was disabled. The controller continues to update its
   internal state estimates

#### **Dependencies**

To enable this port, select the **Use external signal to enable or disable optimization** parameter.

## **External control signal — Control signals applied to ego vehicle** vector of length two

Actual control signals applied to the ego vehicle. The first element of this signal is the longitudinal acceleration in  $m/s^2$ , and the second element is the steering angle in radians. The controller uses these signals to estimate the ego vehicle model states. Use this input port when the control signals applied to the ego vehicle do not match the optimal control signals computed by the model predictive controller. This mismatch can occur when, for example:

- The Path Following Control System is not the active controller. Maintaining an accurate state estimate when the controller is not active prevents bumps in the control signals when the controller becomes active.
- The steering or acceleration actuator fails and does not provide the correct control signal to the ego vehicle.

#### **Dependencies**

To enable this port, select the **Use external control signal for bumpless transfer between PFC and other controllers** parameter.

Vehicle dynamics matrix A — State matrix of ego vehicle predictive model square matrix

State matrix of ego vehicle predictive model. The number of rows in the state matrix corresponds to the number of states in the predictive model. This matrix must be square.

The ego vehicle predictive model defined by **Vehicle dynamics matrix A**, **Vehicle dynamics matrix B**, and **Vehicle dynamics matrix C** must be minimal.

#### **Dependencies**

To enable this port, select the **Use vehicle model** parameter.

## Vehicle dynamics matrix B — Input-to-state matrix of ego vehicle predictive model

matrix with two columns

Input-to-state matrix of ego vehicle predictive model. The number of rows in this signal must match the number of rows in **Vehicle dynamics matrix A**.

The ego vehicle predictive model defined by **Vehicle dynamics matrix A**, **Vehicle dynamics matrix B**, and **Vehicle dynamics matrix C** must be minimal.

#### **Dependencies**

To enable this port, select the **Use vehicle model** parameter.

## Vehicle dynamics matrix C — State-to-output matrix of ego vehicle predictive model

matrix with three rows

State-to-output matrix of ego vehicle predictive model. The number of columns in this signal must match the number of rows in **Vehicle dynamics matrix A**.

The ego vehicle predictive model defined by **Vehicle dynamics matrix A**, **Vehicle dynamics matrix B**, and **Vehicle dynamics matrix C** must be minimal.

### **Dependencies**

To enable this port, select the **Use vehicle model** parameter.

### **Output**

## **Longitudinal acceleration — Acceleration control signal** scalar

Acceleration control signal in m/s<sup>2</sup> generated by the controller.

## **Steering angle — Front steering angle control signal** scalar

Front steering angle control signal in radians generated by the controller. The front steering angle is the angle of the front tires from the longitudinal axis of the vehicle. The steering angle is positive towards the positive lateral axis of the ego vehicle.

### **Parameters**

### **Parameters Tab**

### **Ego Vehicle**

## Use vehicle parameters — Define ego vehicle model using vehicle properties on $(default) \mid off$

Select this parameter to define the ego vehicle model used by the MPC controller by specifying properties of the ego vehicle. The ego vehicle model is the linear model from the longitudinal acceleration and front steering angle to the longitudinal velocity, lateral velocity, and yaw angle rate.

To define the vehicle model, specify the following block parameters:

- Total mass
- Yaw moment of inertia
- Longitudinal distance from center of gravity to front tires
- Longitudinal distance from center of gravity to rear tires

- Cornering stiffness of front tires
- Cornering stiffness of rear tires
- · Longitudinal acceleration tracking time constant

For more information on the ego vehicle model, see "Ego Vehicle Predictive Model" on page 3-129

Selecting this parameter clears the **Use vehicle model** parameter.

## Use vehicle model — Define ego vehicle model using state-space matrices off (default) $\mid$ on

Select this parameter to define the state-space matrices of the ego vehicle model used by the MPC controller. The ego vehicle model is the linear model from the longitudinal acceleration and front steering angle to the longitudinal velocity, lateral velocity, and yaw angle rate.

To define the initial internal model, specify the A, B, and C state-space matrices. The internal model must be a minimal realization with no direct feedthrough, and the dimensions of A, B, and C must be consistent.

Typically, the ego vehicle model is velocity-dependent, and therefore, it varies over time. To update the internal model at run time, use the **Vehicle dynamics A**, **Vehicle dynamics B**, and **Vehicle dynamics C** input ports.

For more information on the ego vehicle model, see "Ego Vehicle Predictive Model" on page 3-129

Selecting this parameter clears the **Use vehicle parameters** parameter.

### Total mass — Ego vehicle mass

1575 (default) | positive scalar

Ego vehicle mass in kg.

### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

Yaw moment of inertia — Moment of inertia about the ego vehicle vertical axis 2875 (default) | positive scalar

Moment of inertia about the ego vehicle vertical axis in  $mNs^2$ .

#### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

### Longitudinal distance from center of gravity to front tires — Distance from the ego vehicle center of mass to its front tires

1.2 (default) | positive scalar

Distance from the ego vehicle center of mass to its front tires in meters, measured along the longitudinal axis of the vehicle.

#### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

### Longitudinal distance from center of gravity to rear tires — Distance from the ego vehicle center of mass to its rear tires

1.6 (default) | positive scalar

Distance from the ego vehicle center of mass to its rear tires in meters, measured along the longitudinal axis of the vehicle.

#### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

## Cornering stiffness of front tires — Front tire stiffness

19000 (default) | positive scalar

Front tire stiffness in N/rad, defined as the relationship between the side force on the front tires and the angle of the tires to the longitudinal axis of the vehicle.

### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

### Cornering stiffness of rear tires — Rear tire stiffness

33000 (default) | positive scalar

Rear tire stiffness in N/rad, defined as the relationship between the side force on the rear tires and the angle of the tires to the longitudinal axis of the vehicle.

### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

## Longitudinal acceleration tracking time constant — Time constant for acceleration tracking

0.5 (default) | positive scalar

Time constant for tracking longitudinal acceleration, specified in seconds.

#### **Dependencies**

To enable this parameter, select the **Use vehicle parameters** parameter.

### A — Initial state matrix of ego vehicle predictive model

square matrix

Initial state matrix of ego vehicle predictive model. The number of rows in the state matrix corresponds to the number of states in the predictive model. This matrix must be square.

The initial eqo vehicle predictive model defined by A, B, and C must be minimal.

Typically, the ego vehicle model varies over time. To update the state matrix at run time, use the **Vehicle dynamics A** input port.

#### **Dependencies**

To enable this parameter, select the **Use vehicle model** parameter.

### B — Initial input-to-state matrix of ego vehicle predictive model

matrix with two columns

Initial input-to-state matrix of ego vehicle predictive model. The number of rows in this parameter must match the number of rows in  $\bf A$ .

The initial ego vehicle predictive model defined by A, B, and C must be minimal.

Typically, the ego vehicle model varies over time. To update the input-to-state matrix at run time, use the  $Vehicle\ dynamics\ B$  input port.

### **Dependencies**

To enable this parameter, select the **Use vehicle model** parameter.

### C — Initial state-to-output matrix of ego vehicle predictive model

matrix with three rows

Initial state-to-output matrix of ego vehicle predictive model. The number of columns in this parameter must match the number of rows in  $\bf A$ .

The initial ego vehicle predictive model defined by A, B, and C must be minimal.

Typically, the ego vehicle model varies over time. To update the state-to-output matrix at run time, use the **Vehicle dynamics C** input port.

#### **Dependencies**

To enable this parameter, select the **Use vehicle model** parameter.

## Initial longitudinal velocity — Initial velocity of the ego vehicle model 15 (default) | nonnegative scalar

Initial velocity of the ego vehicle model in m/s, which can differ from the actual ego vehicle initial velocity.

This value is used to configure the initial conditions of the model predictive controller. For more information, see "Initial Conditions" on page 3-131.

## Transport lag between model inputs and outputs — Total transport lag in ego vehicle model

0 (default) | nonnegative scalar

Total transport lag,  $\tau$ , in the ego vehicle model in seconds. This lag includes actuator, sensor, and communication lags. For each input-output channel, the transport lag model is:

$$\frac{1}{\tau s + 1}$$

#### **Spacing Control**

## Maintain safe distance between lead vehicle and ego vehicle — Enable spacing control

on (default) | off

To configure the safe following distance, set the **Default spacing** parameter. For more information on the safe following distance used by the controller, see "Safe Following Distance" on page 3-131.

### Default spacing — Minimum spacing to lead vehicle

10 (default) | nonnegative scalar

Minimum spacing in meters between the lead vehicle and the ego vehicle. This value corresponds to the target relative distance between the ego and lead vehicles when the ego vehicle velocity is zero.

This value is used to calculate the:

- Minimum safe following distance. For more information, see "Safe Following Distance" on page 3-131.
- Controller initial conditions. For more information, see "Initial Conditions" on page 3-131.

### **Dependencies**

To enable this parameter, select the **Maintain safe distance between lead vehicle and ego vehicle** parameter.

#### Controller Tab

### **Path Following Controller Constraints**

### Minimum steering angle — Minimum front steering angle

-0.26 (default) | scalar between -pi/2 and pi/2

Minimum front steering angle constraint in radians.

If the minimum steering angle varies over time, add the **Minimum steering angle** input port to the block by selecting **Use external source**.

#### **Dependencies**

This parameter must be less than the **Maximum steering angle** parameter.

### Maximum steering angle — Maximum front steering angle

0.26 (default) | scalar between -pi/2 and pi/2

Maximum front steering angle constraint in radians.

If the maximum steering angle varies over time, add the **Maximum steering angle** input port to the block by selecting **Use external source**.

### **Dependencies**

This parameter must be greater than the **Minimum steering angle** parameter.

## Minimum longitudinal acceleration — Minimum ego vehicle acceleration -3 (default) | scalar

Minimum ego vehicle longitudinal acceleration constraint in m/s<sup>2</sup>.

If the minimum acceleration varies over time, add the **Minimum longitudinal acceleration** input port to the block by selecting **Use external source**.

## Maximum longitudinal acceleration — Maximum ego vehicle acceleration 2 (default) | scalar

Maximum ego vehicle longitudinal acceleration constraint in m/s<sup>2</sup>.

If the maximum acceleration varies over time, add the **Maximum longitudinal acceleration** input port to the block by selecting **Use external source**.

#### **Model Predictive Controller Settings**

#### Sample time — Controller sample time

0.1 (default) | positive scalar

Controller sample time in seconds.

### Prediction horizon — Controller prediction horizon

10 (default) | positive integer

Controller prediction horizon steps. The controller prediction time is the product of the sample time and the prediction horizon.

#### Control horizon — Controller control horizon

3 (default) | positive integer | vector of positive integers

Controller control horizon, specified as one of the following:

- Positive integer less than or equal to the **Prediction horizon** parameter. In this case, the controller computes m free control moves occurring at times k through k+m-1, and holds the controller output constant for the remaining prediction horizon steps from k+m through k+p-1. Here, k is the current control interval.
- Vector of positive integers,  $[m_1, m_2, ...]$ , where the sum of the integers equals the **Prediction horizon** parameter. In this case, the controller computes M blocks of free moves, where M is the length of the control horizon vector. The first free move applies to times k through  $k+m_1-1$ , the second free move applies from time  $k+m_1$  through k

 $+m_1+m_2-1$ , and so on. Using block moves can improve the robustness of your controller.

#### **Controller Behavior**

## Weight on velocity tracking — Tuning weight for longitudinal velocity tracking

0.1 (default) | positive scalar

Tuning weight for longitudinal velocity tracking. To produce smaller velocity-tracking errors, increase this weight.

### Weight on lateral error — Tuning weight for lateral error

1 (default) | positive scalar

Tuning weight for lateral error. To produce smaller lateral errors, increase this weight.

## Weight on change of longitudinal acceleration — Tuning weight for change in longitudinal acceleration

0.1 (default) | positive scalar

Tuning weight for changes in longitudinal acceleration. To produce less-aggressive vehicle acceleration, increase this weight.

## Weight on change of steering angle — Tuning weight for change in steering angle

0.1 (default) | positive scalar

Tuning weight for changes in steering angle. To produce less-aggressive steering angle changes, increase this weight.

### **Block Tab**

## Use suboptimal solution — Apply suboptimal solution after specified number of iterations

off (default) | on

Configure the controller to apply a suboptimal solution after a specified maximum number of iterations, which quarantees the worst-case execution time for your controller.

For more information, see "Suboptimal QP Solution".

#### **Dependencies**

After selecting this parameter, specify the **Maximum iteration number** parameter.

## **Maximum iteration number — Maximum optimization iterations** 10 (default) | positive integer

Maximum number of controller optimization iterations.

#### **Dependencies**

To enable this parameter, select the **Use suboptimal solution** parameter.

## Use external signal to enable or disable optimization — Add port for enabling optimization

off (default) | on

To add the **Enable optimization** input port to the block, select this parameter.

# Use external signal for bumpless transfer between PFC and other controllers — Add external control signal input port off (default) | on

To add the **External control signal** input port to the block, select this parameter.

## **Create PFC subsystem — Create custom controller** button

Generate a custom PFC subsystem, which you can modify for your application. The configuration data for the custom controller is exported to the MATLAB workspace as a structure.

You can modify the custom controller subsystem to:

- Modify default MPC settings or use advanced MPC features.
- Modify the default controller initial conditions.
- Use different application settings, such as a custom safe following distance definition.

## **Algorithms**

### **Ego Vehicle Predictive Model**

The default ego vehicle predictive model for path-following control is the combination of two state-space models, one for adaptive cruise control and one for lane keeping.

### **Adaptive Cruise Control Predictive Model**

The predictive state-space model for adaptive cruise control is:

$$A_{1} = \begin{bmatrix} -1/\tau & 0 \\ 1 & 0 \end{bmatrix}$$

$$B_{1} = \begin{bmatrix} 1/\tau \\ 0 \end{bmatrix}$$

$$C_{1} = \begin{bmatrix} 0 & 1 \end{bmatrix}$$

$$D_{1} = 0$$

Here,  $\tau$  is the **Longitudinal acceleration tracking time constant** parameter.

The input to this model is the longitudinal acceleration in  $m/s^2$ , and the output is the longitudinal velocity in meters per second.

### **Lane-Keeping Predictive Model**

The predictive state-space model for lane keeping is:

$$A_2 = \begin{bmatrix} -2(C_F + C_R)/m/V_X & -V_X - 2(C_F L_F - C_R L_R)/m/V_X \\ -2(C_F L_F - C_R L_R)/I_Z/V_X & -2\left(C_F L_F^2 + C_R L_R^2\right)/I_Z/V_X \end{bmatrix}$$

$$B_2 = 2C_F \begin{bmatrix} 1/m \\ L_F/I_Z \end{bmatrix}$$

$$C_2 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$D_2 = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Here:

- $V_X$  is the longitudinal velocity of the car. At the start of the simulation, this velocity is equal to the **Initial condition for longitudinal velocity** parameter. At run time, this velocity is equal to the **Longitudinal velocity** input signal.
- *m* is the **Total mass** parameter.
- $I_Z$  is the **Yaw moment of inertia** parameter.
- L<sub>F</sub> is the **Longitudinal distance from center of gravity to front tires** parameter.
- $L_R$  is the Longitudinal distance from center of gravity to rear tires parameter.
- $C_F$  is the **Cornering stiffness of front tires** parameter.
- $C_R$  is the **Cornering stiffness of rear tires** parameter.

The input to this model is the steering angle in radians. The outputs are the lateral velocity in meters per second and yaw angle rate in radians per second.

### **Combined Path-Following Predictive Model**

The Path Following Control System block combines these models as follows:

$$A = \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix}$$

$$B = \begin{bmatrix} B_1 & 0 \\ 0 & B_2 \end{bmatrix}$$

$$C = \begin{bmatrix} C_1 & 0 \\ 0 & C_2 \end{bmatrix}$$

$$D = \begin{bmatrix} D_1 & 0 \\ 0 & D_2 \end{bmatrix}$$

The inputs to this combined model are the longitudinal acceleration in m/s<sup>2</sup> and steering angle in radians. The outputs are the longitudinal velocity in meters per second, lateral velocity in meters per second, and yaw angle rate in radians per second.

The controller creates its internal predictive model by augmenting the ego vehicle dynamic model. The augmented model includes the road curvature as a measured disturbance input signal.

#### **Define a Custom Model**

To define a different ego vehicle predictive model, select the **Use vehicle model** parameter, and specify the initial state-space model. Then, specify the run-time values of

the state-space matrices using the **Vehicle dynamics A**, **Vehicle dynamics B**, and **Vehicle dynamics C** input signals.

### **Safe Following Distance**

When the **Maintain safe distance between lead vehicle and ego vehicle** parameter is selected, the model predictive controller computes the safe following distance constraint; that is, the minimum relative distance between the lead and ego vehicle, as:

$$D_R = D_S + G_T * V_E$$

Here:

- $D_S$  is the **Default spacing** parameter.
- $G_T$  is the **Time gap** input signal.
- $V_E$  is the **Longitudinal velocity** input signal.

To define a different safe following distance constraint, create a custom path-following control system by, on the **Block** tab, clicking **Create PFC subsystem**.

### **Initial Conditions**

By default, the model predictive controller assumes the following initial conditions for the ego vehicle:

- Longitudinal velocity is equal to the Initial longitudinal velocity parameter.
- Longitudinal acceleration is zero.
- Lateral velocity is zero.
- · Steering angle is zero.
- Yaw angle rate is zero.

When the **Maintain safe distance between lead vehicle and ego vehicle** parameter is selected, the controller assumes the following additional initial conditions:

- The lead vehicle longitudinal velocity is equal to the **Initial longitudinal velocity** parameter.
- Relative distance between the lead vehicle and ego vehicle is:

$$D_R = D_S + G_T * V_E$$

#### Here:

- $D_S$  is the **Default spacing** parameter.
- $G_T$  is the time gap and is assumed to be 1.4.
- $V_E$  is the **Initial longitudinal velocity** parameter.

If the initial conditions in your model do not match these conditions, the **Steering angle** and **Longitudinal acceleration** outputs can exhibit initial bumps at the start of the simulation.

To modify the controller initial conditions to match your simulation, create a custom pathfollowing control system by, on the **Block** tab, clicking **Create PFC subsystem**.

- "Explicit MPC Controller Object" on page 4-23

## **MPC Controller Object**

All of the parameters defining the traditional (implicit) MPC control law are stored in an MPC object, whose properties are listed in the following table.

### **MPC Controller Object**

Property	Description
ManipulatedVariables (or MV or Manipulated or Input)	Scale factors, input bounds, input-rate bounds, corresponding ECR values, target values, signal names, and units.
OutputVariables (or OV or Controlled or Output)	Scale factors, input bounds, input-rate bounds, corresponding ECR values, target values, signal names, and units.
DisturbanceVariables (or DV or Disturbance)	Disturbance scale factors, names, and units
Weights	Weights used in computing the performance (cost) function
Model	Plant, input disturbance, and output noise models, and nominal conditions.
Ts	Controller sample time
Optimizer	Parameters controlling the QP solver
PredictionHorizon	Prediction horizon
ControlHorizon	Number of free control moves or vector of blocking moves
History	Creation time
Notes	Text or comments about the MPC controller object
UserData	Any additional data

### **ManipulatedVariables**

Manipulated Variables (or MV or Manipulated or Input) is an  $n_u$ -dimensional array of structures ( $n_u$  = number of manipulated variables), one per manipulated variable. Each structure has the fields described in the following table, where p denotes the prediction horizon. Unless indicated otherwise, numerical values are in engineering units.

### **Manipulated Variable Structure**

Field Name	Content	Default	
ScaleFactor	Nonnegative scale factor for this MV	1	
Min	1 to <i>p</i> length vector of lower bounds on this MV	-Inf	
Max	$\begin{bmatrix} 1 \text{ to } p \text{ length vector of upper bounds on this} \\ MV \end{bmatrix}$	Inf	
MinECR	1 to $p$ length vector of nonnegative parameters specifying the Min bound softness (0 = hard).	0 (dimensionless)	
MaxECR	1 to $p$ length vector of nonnegative parameters specifying the Max bound softness (0 = hard).	0 (dimensionless)	
Target	1 to $p$ length vector of target values for this MV	'nominal'	
RateMin	1 to <i>p</i> length vector of lower bounds on the interval-to-interval change for this MV	-Inf	
RateMax	1 to <i>p</i> length vector of upper bounds on the interval-to-interval change for this MV	Inf	
RateMinECR	1 to $p$ length vector of nonnegative parameters specifying the RateMin bound softness (0 = hard).	0 (dimensionless)	
RateMaxECR	1 to $p$ length vector of nonnegative parameters specifying the RateMax bound softness (0 = hard).	0 (dimensionless)	
Name	Read-only MV signal name (character vector)	InputName of LTI plant model	
Units	Read-only MV signal units (character vector)	InputUnit of LTI plant model	

**Note** Rates refer to the difference  $\Delta u(k) = u(k) - u(k-1)$ . Constraints and weights based on derivatives du/dt of continuous-time input signals must be properly reformulated for the discrete-time difference  $\Delta u(k)$ , using the approximation  $du/dt \cong \Delta u(k)/T_s$ .

### **OutputVariables**

OutputVariables (or OV or Controlled or Output) is an  $n_y$ -dimensional array of structures ( $n_y$  = number of outputs), one per output signal. Each structure has the fields described in the following table. p denotes the prediction horizon. Unless specified otherwise, values are in engineering units.

### **Output Variable Structure**

Field Name	Content	Default
ScaleFactor	Nonnegative scale factor for this OV	1
Min	1 to $p$ length vector of lower bounds on this OV	-Inf
Max	1 to <i>p</i> length vector of upper bounds on this OV	Inf
MinECR	1 to $p$ length vector of nonnegative parameters specifying the Min bound softness (0 = hard).	1 (dimensionless)
MaxECR	1 to $p$ length vector of nonnegative parameters specifying the Max bound softness (0 = hard).	1 (dimensionless)
Name	Read-only OV signal name (character vector)	OutputName of LTI plant model
Units	Read-only OV signal units (character vector)	OutputUnit of LTI plant model

In order to reject constant disturbances due, for instance, to gain nonlinearities, the default measured output disturbance model used in Model Predictive Control Toolbox software is integrated white noise (see "Output Disturbance Model").

### **DisturbanceVariables**

DisturbanceVariables (or DV or Disturbance) is an  $(n_v+n_d)$ -dimensional array of structures ( $n_v$  = number of measured input disturbances,  $n_d$  = number of unmeasured input disturbances). Each structure has the fields described in the following table.

#### **Disturbance Variable Structure**

Field Name	Content	Default
ScaleFactor	Nonnegative scale factor for this DV	1
Name	Read-only DV signal name (character vector)	InputName of LTI plant model
Units	Read-only DV signal units (character vector)	InputUnit of LTI plant model

The order of the disturbance signals within the array DV is the following: the first  $n_{\rm v}$  entries relate to measured input disturbances, the last  $n_{\rm d}$  entries relate to unmeasured input disturbances.

### Weights

Weights is the structure defining the QP weighting matrices. It contains four fields. The values of these fields depend on whether you are using the standard quadratic cost function (see "Standard Cost Function") or the alternative cost function (see "Alternative Cost Function").

#### **Standard Cost Function**

The table below lists the content of the four structure fields. In the table, p denotes the prediction horizon,  $n_u$  the number of manipulated variables, and  $n_y$  the number of output variables.

For the MV, MVRate and OV weights, if you specify fewer than p rows, the last row repeats automatically to form a matrix containing p rows.

### **Weights for the Standard Cost Function**

Field Name (Abbreviations)	Content	Default (dimensionless)
ManipulatedVariables (or MV or Manipulated or Input)	(1 to $p$ )-by- $n_u$ dimensional array of nonnegative MV weights	zeros(1,nu)
ManipulatedVariablesRate (or MVRate or ManipulatedRate or InputRate)	(1 to $p$ )-by- $n_{\rm u}$ dimensional array of MV-increment weights	0.1*ones(1,nu)
OutputVariables (or OV or Controlled or Output)	(1 to $p$ )-by- $n_y$ dimensional array of OV weights	1 (The default for output weights is the following: if $n_u \ge n_y$ , all outputs are weighted with unit weight; if $n_u < n_y$ , $n_u$ outputs default to 1, with preference given to measured outputs, and the rest default to 0.)
ECR	Scalar weight on the slack variable $\varepsilon$ used for constraint softening	1e5*(max weight)

**Note** If all MVRate weights are strictly positive, the resulting QP problem is strictly convex. If some MVRate weights are zero, the QP Hessian might be positive semidefinite. In order to keep the QP problem strictly convex, when the condition number of the Hessian matrix  $K_{\Delta U}$  is larger than  $10^{12}$ , the quantity 10\*sqrt(eps) is added to each diagonal term. See "Cost Function".

#### **Alternative Cost Function**

You can specify off-diagonal Q and R weight matrices in the cost function. To do so, define the fields ManipulatedVariables, ManipulatedVariablesRate, and OutputVariables as cell arrays, each containing a single positive-semi-definite matrix of the appropriate size. Specifically, OutputVariables must be a cell array containing the  $n_y$ -by- $n_y$  Q matrix, ManipulatedVariables must be a cell array containing the  $n_u$ -by- $n_u$   $R_{u}$  matrix, and ManipulatedVariablesRate must be a cell array containing the  $n_u$ -by- $n_u$   $R_{u}$  matrix (see "Alternative Cost Function" and the mpcweightsdemo example). You can use diagonal weight matrices for one or more of these fields. If you omit a field, the MPC controller uses the defaults shown in the table above.

For example, you can specify off-diagonal weights, as follows

```
MPCobj.Weights.OutputVariables = {Q}; MPCobj.Weights.ManipulatedVariables = {Ru}; MPCobj.Weights.ManipulatedVariablesRate = {Rdu}; where Q = Q. Ru = R_{\rm u}, and Rdu = R_{\rm Au} are positive semidefinite matrices.
```

**Note** You cannot specify non-diagonal weights that vary at each prediction horizon step. The same Q, Ru, and Rdu weights apply at each step.

### Model

The property Model specifies plant, input disturbance, and output noise models, and nominal conditions, according to the model setup described in "Controller State Estimation". It is a 1-D structure containing the following fields.

### **Models Used by MPC**

Field Name	Content	Default
Plant	LTI model or identified linear model of the plant	No default
Disturbance	LTI model describing expected unmeasured input disturbances	[ ] (By default, input disturbances are expected to be integrated white noise. To model the signal, an integrator with dimensionless unity gain is added for each unmeasured input disturbance, unless the addition causes the controller to lose state observability. In that case, the disturbance is expected to be white noise, and so, a dimensionless unity gain is added to that channel instead.)
Noise	LTI model describing expected noise for output measurements	[ ] (By default, measurement noise is expected to be white noise with unit variance. To model the signal, a dimensionless unity gain is added for each measured channel.)

Field Name	Content	Defa	Default	
Nominal Structure containing the state, input, and output values where Model.Plant is linearized		The default values of the fields are shown in the following table:		
	Fiel d	Description	Defa ult	
		Х	Plant state at operating point	[]
		U	Plant input at operating point, including manipulated variables and measured and unmeasured disturbances	[]
		Υ	Plant output at operating point	[]
	DX	For continuous-time models, DX is the state derivative at operating point: $DX=f(X,U)$ . For discrete-time models, $DX=x(k+1)-x(k)=f(X,U)-X$ .	[]	

**Note** Direct feedthrough from manipulated variables to any output in Model.Plant is not allowed. See "MPC Modeling".

Specify input and output signal types via the InputGroup and OutputGroup properties of Model.Plant, or, more conveniently, use the setmpcsignals command. Valid signal types are listed in the following tables.

### **Input Groups in Plant Model**

Name (Abbreviations)	Value
	Indices of manipulated variables in Model.Plant
MeasuredDisturbances (or MD or Measured)	Indices of measured disturbances in Model.Plant
UnmeasuredDisturbances (or UD or Unmeasured)	Indices of unmeasured disturbances in Model.Plant

### **Output Groups in Plant Model**

Name (Abbreviations)	Value
	Indices of measured outputs in Model.Plant
·	Indices of unmeasured outputs in Model.Plant

By default, all  ${\tt Model.Plant}$  inputs are manipulated variables, and all outputs are measured.

The structure Nominal contains the values (in engineering units) for states, inputs, outputs, and state derivatives/differences at the operating point where Model.Plant applies. This point is typically a linearization point. The fields are reported in the following table (see also "MPC Modeling").

### **Nominal Values at Operating Point**

Field	Description	Default
X	Plant state at operating point	[]
U	Plant input at operating point, including manipulated variables and measured and unmeasured disturbances	[]
Υ	Plant output at operating point	[]
DX	For continuous-time models, DX is the state derivative at operating point: $DX = f(X,U)$ . For discrete-time models, $DX = x(k+1)-x(k)=f(X,U)-X$ .	[]

#### Ts

Sample time of the MPC controller. By default, if Model.Plant is a discrete-time model, Ts = Model.Plant.ts. For continuous-time plant models, you must specify a controller Ts. Its measurement unit is inherited from Model.Plant.TimeUnit.

## **Optimizer**

Optimizer is a structure with fields that contain parameters for the QP optimization.

## **Optimizer Properties**

Field	Description	Default
MaxIter	Maximum number of iterations allowed in the QP solver, specified as one of the following:	'Default'
	'Default' — The MPC controller automatically computes the maximum number of QP solver iterations as:	
	$MaxIter = 4(n_C + n_V)$	
	where	
	• $n_{cy}$ is the total number of constraints across the prediction horizon.	
	• $n_{v}$ is the total number of optimization variables across the control horizon.	
	The default MaxIter value has a lower bound of 120.	
	Positive integer — The QP solver stops after MaxIter iterations. If the solver fails to converge in the final iteration, the controller:	
	<ul> <li>Freezes the controller movement if UseSuboptimalSolution is false.</li> </ul>	
	<ul> <li>Applies the suboptimal solution reached after the final iteration if UseSuboptimalSolution is true.</li> </ul>	
	If CustomSolver or CustomSolverCodeGen is true, the controller does not require the custom solver to honor MaxIter.	

Field	Description	Default
MinOutputECR	Minimum value allowed for OutputMinECR and OutputMaxECR, specified as a nonnegative scalar. A value of 0 indicates that hard output constraints are allowed. If either of the OutputVariables.MinECR or OutputVariables.MaxECR properties of an MPC controller are less than MinOutputECR, a warning is displayed and the value is raised to MinOutputECR during computation.	0
UseSuboptimalSol ution	Flag indicating whether to apply a suboptimal solution after the number of optimization iterations exceeds MaxIter, specified as a logical value.	false
UseWarmStart	Flag indicating whether to warm start each QP solver iteration by passing in a list of active inequalities from the previous iteration, specified as a logical value. Inequalities are active when their equal portion is true.  If CustomSolver or CustomSolverCodeGen is true, the controller does not require the custom solver to honor UseWarmStart.	true

Field	Description	Default
CustomSolver	Flag indicating whether to use a custom QP solver for simulation, specified as a logical value. If CustomSolver is true, the user must provide an mpcCustomSolver function on the MATLAB path.	false
	This custom solver is not used for code generation. To generate code for a controller with a custom solver, use CustomSolverCodeGen.	
	If CustomSolver is true, the controller does not require the custom solver to honor MaxIter and UseWarmStart.	
	For more information on specifying custom solvers, see "Custom QP Solver".	
CustomSolverCode Gen	Flag indicating whether to use a custom QP solver for code generation, specified as a logical value. If CustomSolverCodeGen is true, the user must provide an mpcCustomSolverCodeGen function on the MATLAB path.	false
	This custom solver is not used for simulation. To simulate a controller with a custom solver, use CustomSolver.	
	If CustomSolverCodeGen is true, the controller does not require the custom solver to honor MaxIter and UseWarmStart.	
	For more information on specifying custom solvers, see "Custom QP Solver".	

**Note** The default MaxIter value can be very large for some controller configurations, such as those with large prediction and control horizons. When simulating such

controllers, if the QP solver cannot find a feasible solution, the simulation can appear to stop responding, since the solver continues searching for MaxIter iterations.

#### **PredictionHorizon**

PredictionHorizon is the integer number of prediction horizon steps. The control interval, Ts, determines the duration of each step. The default value is 10 + maximum intervals of delay (if any).

#### **ControlHorizon**

ControlHorizon is either a number of free control moves, or a vector of blocking moves (see "Optimization Variables"). The default value is 2.

### **History**

History stores the time the MPC controller was created (read only).

#### Notes

Notes stores text or comments as a cell array of character vectors.

#### **UserData**

Any additional data stored within the MPC controller object.

### **Construction and Initialization**

To minimize computational overhead, Model Predictive Controller creation occurs in two phases. The first happens at construction when you invoke the mpc command, or when you change a controller property. Construction involves simple validity and consistency checks, such as signal dimensions and non-negativity of weights.

The second phase is initialization, which occurs when you use the object for the first time in a simulation or analytical procedure. Initialization computes all constant properties required for efficient numerical performance, such as matrices defining the optimal control problem and state estimator gains. Additional, diagnostic checks occur during initialization, such as verification that the controller states are observable.

By default, both phases display informative messages in the command window. You can turn these messages on or off using the mpcverbosity command.

# **MPC Simulation Options Object**

The mpcsimopt object type contains various simulation options for simulating an MPC controller with the command sim. Its properties are listed in the following table.

## **MPC Simulation Options Properties**

Property	Description
PlantInitialState	Initial state vector of the plant model generating the data.
ControllerInitialState	Initial condition of the MPC controller. This must be a valid mpcstate object.
	Note Nonzero values of ControllerInitialState.LastMove are only meaningful if there are constraints on the increments of the manipulated variables.
UnmeasuredDisturbance	Unmeasured disturbance signal entering the plant.
	An array with as many rows as simulation steps, and as many columns as unmeasured disturbances.  Default: 0
InputNoise	Noise on manipulated variables.
	An array with as many rows as simulation steps, and as many columns as manipulated variables. The last sample of the array is extended constantly over the horizon to obtain the correct size. Default: 0
OutputNoise	Noise on measured outputs.
	An array with as many rows as simulation steps, and as many columns as measured outputs. The last sample of the array is extended constantly over the horizon to obtain the correct size. Default: 0
RefLookAhead	Preview on reference signal ('on' or 'off'). Default: 'off'
MDLookAhead	Preview on measured disturbance signal ('on' or 'off').
Constraints	Use MPC constraints ('on' or 'off'). Default: 'on'

Property	Description
Model	Model used in simulation for generating the data.
	This property is useful for simulating the MPC controller under model mismatch. The LTI object specified in Model can be either a replacement for Model.Plant, or a structure with fields Plant and Nominal. By default, Model is equal to MPCobj.Model (no model mismatch). If Model is specified, then PlantInitialState refers to the initial state of Model.Plant and is defaulted to Model.Nominal.x.
	If Model.Nominal is empty, Model.Nominal.U and Model.Nominal.Y are inherited from MPCobj.Model.Nominal.Model.Nominal.X/DX is only inherited if both plants are state-space objects with the same state dimension.
StatusBar	Display the wait bar ('on' or 'off'). Default: 'off'
MVSignal	Sequence of manipulated variables (with offsets) for open-loop simulation (no MPC action).  An array with as many rows as simulation steps, and
	as many columns as manipulated variables. Default:
OpenLoop	Perform open-loop simulation ('on' or 'off'). Default: 'off'

The property Model is useful for simulating an MPC controller with "model mismatch", i.e., when the controller's prediction model only approximates the true plant behavior (inevitable in practice).

By default, Model is equal to MPCobj.Model (no model mismatch). If Model is specified, then PlantInitialState refers to the initial state of Model.Plant and defaults to Model.Nominal.x.

If Model.Nominal is empty, Model.Nominal.U and Model.Nominal.Y are inherited from MPCobj.Model.Nominal.Model.Nominal.X/DX is only inherited if both plants are state-space objects with the same state dimension.

# **MPC State Object**

The mpcstate object type contains the state of an MPC controller. Create the MPC state object using mpcstate. Its properties are as follows.

Property	Description
Plant	Vector of state estimates for the controller's plant model. Values are in engineering units and are absolute, i.e., they include state offsets.
	If the controller's plant model includes delays, the Plant field of the MPC state object includes states that model the delays.  Therefore length(Plant) > order of undelayed controller plant model.
	Default: controller's Model.Nominal.X property.
Disturbance	Vector of unmeasured disturbance model state estimates. This comprises the states of the input disturbance model followed by the states of the output disturbances model.
	Disturbance models may be created by default. Use the getindistand getoutdistcommands to view the two disturbance model structures.
	Default: zero, or empty if there are no disturbance model states.
Noise	Vector of output measurement noise model state estimates.
	Default: zero, or empty if there are no noise model states.
LastMove	Vector of manipulated variables used in the previous control interval, $u(k-1)$ . Values are absolute, i.e., they include manipulated variable offsets.
	Default: nominal values of the manipulated variables.

Property	Description
Covariance	<i>n</i> -by- <i>n</i> symmetrical covariance matrix for the controller state estimates, where <i>n</i> is the dimension of the extended controller state, i.e., the sum of the number states contained in the Plant, Disturbance, and Noise fields.
	Default: If the controller is employing default state estimation the default is the steady-state covariance computed according to the assumptions in "Controller State Estimation". See also the description of the P matrix in the Control System Toolbox kalmd command. If the controller is employing custom state estimation, this field is empty (not used).

## **Explicit MPC Controller Object**

An explicit MPC object contains the explicit control law equivalent to the traditional (implicit) MPC controller object from which it derives. Use an explicit MPC controller to implement MPC in applications requiring very rapid computations, i.e., a short control interval. Use the <code>generateExplicitMPC</code> command to create the object. Its properties are as follows:

## **Properties**

Property	Description
MPC	Traditional (implicit) controller object used to generate the explicit MPC controller. You create this MPC controller using is the mpc command. It is the first argument to generateExplicitMPC when you create the explicit MPC controller. See "MPC Controller Object" on page 4-2 or type mpcprops for details regarding the properties of the MPC controller.
Range	1-D structure containing the parameter bounds used to generate the explicit MPC controller. These determine the resulting controller's valid operating range. This property is automatically populated by the range input argument to generateExplicitMPC when you create the explicit MPC controller. See generateExplicitRange for details about this structure.

Property	Description
OptimizationOptions	1-D structure containing user-modifiable options used to generate the explicit MPC controller. This property is automatically populated by the opt argument to generateExplicitMPC when you create the explicit MPC controller. See generateExplicitOptions for details about this structure.
PiecewiseAffineSolution	$n_r$ -dimensional structure, where $n_r$ is the number of piecewise affine (PWA) regions required to represent the control law. The $i$ th element contains the details needed to compute the optimal manipulated variables when the solution lies within the $i$ th region. See "Implementation".
IsSimplified	Logical switch indicating whether the explicit control law has been modified using the simplify command such that the explicit control law approximates the base (implicit) MPC controller. If the control law has not been modified, the explicit controller should reproduce the base controller's behavior exactly, provided both operate within the bounds described by the Range property.
