The software described in this document is furnished under a license agreement. The software may be used or copied only under the terms of the license agreement. No part of this manual may be photocopied or reproduced in any form without prior written consent from The MathWorks, Inc.

FEDERAL ACQUISITION: This provision applies to all acquisitions of the Program and Documentation by, for, or through the federal government of the United States. By accepting delivery of the Program or Documentation, the government hereby agrees that this software or documentation qualifies as commercial computer software or commercial computer software documentation as such terms are used or defined in FAR 12.212, DFARS Part 227.72, and DFARS 252.227-7014. Accordingly, the terms and conditions of this Agreement and only those rights specified in this Agreement, shall pertain to and govern the use, modification, reproduction, release, performance, display, and disclosure of the Program and Documentation by the federal government (or other entity acquiring for or through the federal government) and shall supersede any conflicting contractual terms or conditions. If this License fails to meet the government's needs or is inconsistent in any respect with federal procurement law, the government agrees to return the Program and Documentation, unused, to The MathWorks, Inc.

Trademarks

MATLAB and Simulink are registered trademarks of The MathWorks, Inc. See www.mathworks.com/trademarks for a list of additional trademarks. Other product or brand names may be trademarks or registered trademarks of their respective holders.

Patents

MathWorks products are protected by one or more U.S. patents. Please see www.mathworks.com/patents for more information.

Revision History

November 1990	First printing	New for Simulink 1
December 1996	Second printing	Revised for Simulink 2
January 1999	Third printing	Revised for Simulink 3 (Release 11)
November 2000	Fourth printing	Revised for Simulink 4 (Release 12)
July 2002	Fifth printing	Revised for Simulink 5 (Release 13)
April 2003	Online only	Revised for Simulink 5.1 (Release 13SP1)
April 2004	Online only	Revised for Simulink 5.1.1 (Release 13SP1+)
June 2004	Sixth printing	Revised for Simulink 5.0 (Release 14)
October 2004	Seventh printing	Revised for Simulink 6.1 (Release 14SP1)
March 2005	Online only	Revised for Simulink 6.2 (Release 14SP2)
September 2005	Eighth printing	Revised for Simulink 6.3 (Release 14SP3)
March 2006	Online only	Revised for Simulink 6.4 (Release 2006a)
March 2006	Ninth printing	Revised for Simulink 6.4 (Release 2006a)
September 2006	Online only	Revised for Simulink 6.5 (Release 2006b)
March 2007	Online only	Revised for Simulink 6.6 (Release 2007a)
September 2007	Online only	Revised for Simulink 7.0 (Release 2007b)
March 2008	Online only	Revised for Simulink 7.1 (Release 2008a)
October 2008	Online only	Revised for Simulink 7.2 (Release 2008b)
March 2009	Online only	Revised for Simulink 7.3 (Release 2009a)
September 2009	Online only	Revised for Simulink 7.4 (Release 2009b)
March 2010	Online only	Revised for Simulink 7.5 (Release 2010a)
September 2010	Online only	Revised for Simulink 7.6 (Release 2010b)
April 2011	Online only	Revised for Simulink 7.7 (Release 2011a)
September 2011	Online only	Revised for Simulink 7.8 (Release 2011b)
March 2012	Online only	Revised for Simulink 7.9 (Release 2012a)
September 2012	Online only	Revised for Simulink 8.0 (Release 2012b)
March 2013	Online only	Revised for Simulink 8.1 (Release 2013a)
September 2013	Online only	Revised for Simulink 8.2 (Release 2013b)
March 2014	Online only	Revised for Simulink 8.3 (Release 2014a)
October 2014	Online only	Revised for Simulink 8.4 (Release 2014b)
March 2015	Online only	Revised for Simulink 8.5 (Release 2015a)
September 2015	Online only	Revised for Simulink 8.6 (Release 2015b)
October 2015	Online only	Rereleased for Simulink 8.5.1 (Release 2015aSP1)
March 2016	Online only	Revised for Simulink 8.7 (Release 2016a)
September 2016	Online only	Revised for Simulink 8.8 (Release 2016b)
March 2017	Online only	Revised for Simulink 8.9 (Release 2017a)
September 2017	Online only	Revised for Simulink 9.0 (Release 2017b)
March 2018	Online only	Revised for Simulink 9.1 (Release 2018a)
September 2018	Online only	Revised for Simulink 9.2 (Release 2018b)
March 2019	Online only	Revised for Simulink 9.3 (Release 2019a)

Introduction to Simulink

1

Simulink Basics

Start the Simulink Software	1-2
Start the MATLAB Software	1-2
Open the Simulink Editor	1-2
Open the Library Browser	1-3
Create and Open Models	1-5
Create a Model	1-5
Use Customized Settings When Creating New Models ..	1-8
Open a Model	1-9
Load Variables When Opening a Model	1-10
Open a Model with Different Character Encoding	1-11
Simulink Model File Types	1-11
Programmatic Modeling Basics	1-13
Load a Model	1-13
Create a Model and Specify Parameter Settings	1-13
Programmatically Load Variables When Opening a Model	1-14
Programmatically Add and Connect Blocks	1-15
Name a Signal Programmatically	1-17
Arrange Model Layouts Automatically	1-17
Open the Same Model in Multiple Windows	1-18
Get a Simulink Identifier	1-18
Specify Colors Programmatically	1-22
Build and Edit a Model in the Simulink Editor	1-24
Start Simulink and Create a Model	1-24
Add Blocks to the Model	1-24

Align and Connect Blocks	1-26
Set Block Parameters	1-26
Add More Blocks	1-27
Branch a Connection	1-28
Organize Your Model Into Components	1-32
Simulate Model and View Results	1-34
Modify the Model	1-35
Save a Model	1-39
How to Tell If a Model Needs Saving	1-39
Save a Model	1-39
What Happens When You Save a Model?	1-40
Save Models in the SLX File Format	1-41
Save Models with Different Character Encodings	1-43
Export a Model to a Previous Simulink Version	1-45
Save from One Earlier Simulink Version to Another	1-46
Model Editing Environment	1-47
Simulink Editor	1-47
Interactive Model Building	1-49
Model Design Error Detection	1-50
Library Browser	1-50
Setting Properties and Parameters	1-52
Parts of a Model	1-55
About Blocks	1-55
Block Parameters and Properties in Simulink	1-56
Signals	1-58
Preview Content of Model Components	1-60
Use Viewmarks to Save Views of Models	1-62
What Are Viewmarks?	1-62
Create a Viewmark	1-63
Open and Navigate Viewmarks	1-64
Manage Viewmarks	1-64
Refresh a Viewmark	1-65
Update Diagram and Run Simulation	1-66
Updating the Diagram	1-66
Simulation Updates the Diagram	1-66
Update Diagram While Editing	1-66
Simulate a Model	1-67

Print Model Diagrams	1-69
Print Interactively or Programmatically	1-69
Printing Options	1-69
Canvas Color	1-69
Basic Printing	1-71
Print the vdp Model Using Default Settings	1-71
Print a Subsystem Hierarchy	1-73
Select the Systems to Print	1-75
Print Current System	1-75
Print Subsystems	1-75
Print a Model Referencing Hierarchy	1-76
Specify the Page Layout and Print Job	1-78
Page and Print Job Setup	1-78
Set Paper Size and Orientation Without Printing	1-78
Tiled Printing	1-79
Print Multiple Pages for Large Models	1-80
Add a Log of Printed Models	1-81
Add a Sample Time Legend	1-82
Print from the MATLAB Command Line	1-83
Printing Commands	1-83
Print Systems with Multiline Names or Names with Spaces	1-83
Set Paper Orientation and Type	1-84
Position and Size a System	1-84
Use Tiled Printing	1-85
Print to a PDF	1-87
Print Model Reports	1-88
Model Report Options	1-89
Print Models to Image File Formats	1-91
Copy Model Views to Third-Party Applications	1-91

Keyboard and Mouse Actions for Simulink Modeling . . .	1-92
Object Selection and Clipboard Operations	1-92
Block and Signal Line Shortcuts and Actions	1-93
Signal Name and Label Actions	1-95
Simulation Keyboard Shortcuts	1-96
Debugging and Breakpoints Keyboard Shortcuts	1-96
Zooming and Scrolling Shortcuts	1-96
Library Browser Shortcuts	1-97
File Operations	1-98

Simulation Stepping

2

How Simulation Stepper Helps With Model Analysis	2-2
How Stepping Through a Simulation Works	2-3
Simulation Snapshots	2-3
How Simulation Stepper Uses Snapshots	2-4
How Simulation Stepper Differs from Simulink Debugger	2-5
Use Simulation Stepper	2-8
Simulation Stepper Access	2-8
Simulation Stepper Pause Status	2-8
Tune Parameters	2-9
Referenced Models	2-10
Simulation Stepper and Interval Logging	2-10
Simulation Stepper and Stateflow Debugger	2-10
Simulation Stepper Limitations	2-12
Interface	2-12
Model Configuration	2-12
Blocks	2-12
Step Through a Simulation	2-15
Step Forward and Back	2-15
Set Conditional Breakpoints for Stepping a Simulation 	2-18
Add and Edit Conditional Breakpoints	2-18

Observe Conditional Breakpoint Values	2-20
Simulation Pacing	2-21
Using Simulation Pacing	2-21
Using Simulation Pacing with Dashboard library blocks	2-22
Limitations	2-24

How Simulink Works

3

How Simulink Works	3-2
Modeling Dynamic Systems	3-3
Block Diagram Semantics	3-3
Creating Models	3-4
Time	3-4
States	3-5
Block Parameters	3-8
Tunable Parameters	3-8
Block Sample Times	3-9
Custom Blocks	3-9
Systems and Subsystems	3-10
Signals	3-14
Block Methods	3-15
Model Methods	3-16
Simulation Phases in Dynamic Systems	3-17
Model Compilation	3-17
Link Phase	3-18
Simulation Loop Phase	3-18
Solvers	3-21
Fixed-Step Solvers Versus Variable-Step Solvers	3-21
Continuous Versus Discrete Solvers	3-21
Minor Time Steps	3-22
Shape Preservation	3-22

Zero-Crossing Detection	3-24
Demonstrating Effects of Excessive Zero-Crossing Detection	3-24
How the Simulator Can Miss Zero-Crossing Events	3-30
Preventing Excessive Zero Crossings	3-30
Zero-Crossing Algorithms	3-32
Understanding Signal Threshold	3-33
How Blocks Work with Zero-Crossing Detection	3-34
Algebraic Loop Concepts	3-38
Mathematical Interpretation	3-39
Physical Interpretation	3-40
Artificial Algebraic Loops	3-40
How the Algebraic Loop Solver Works	3-42
Why Algebraic Loops Are Undesirable	3-44
Identify Algebraic Loops in Your Model	3-45
Highlight Algebraic Loops in the Model	3-47
Use the Algebraic Loop Diagnostic	3-48
Remove Algebraic Loops	3-50
Introduce a Delay	3-50
Solve Algebraic Loops Manually	3-52
How Simulink Eliminates Artificial Algebraic Loops . . .	3-53
Eliminate Artificial Algebraic Loops Caused by Atomic Subsystems	3-59
Bundled Signals That Create Artificial Algebraic Loops	3-59
Model and Block Parameters to Diagnose and Eliminate Artificial Algebraic Loops	3-63
Block Reduction and Artificial Algebraic Loops	3-64
When Simulink Cannot Eliminate Artificial Algebraic Loops	3-67
Modeling Considerations with Algebraic Loops	3-70
Managing Large Models with Artificial Algebraic Loops	3-70
Model Blocks and Direct Feedthrough	3-70
Changing Block Priorities When Using Algebraic Loop Solver	3-72

4

Create a Template from a Model	4-2
Add or Read Notes for Model Layers	4-3
Manage Notes Files	4-3
Read and Edit Modes	4-3
Add and Edit Notes	4-3
Describe Models Using Annotations	4-5
Add a Text Annotation	4-5
Resize an Annotation	4-6
Make an Annotation Interactive	4-6
Add an Image Annotation	4-6
Add Equations in an Annotation	4-7
Associate Annotations with Blocks and Areas	4-8
Show or Hide Annotations	4-11
Configure an Annotation for Hiding	4-11
Hide Markup Annotations	4-11
Add an Annotation Callback	4-13
Annotation Callback Functions	4-13
Associate a Click Function with an Annotation	4-13
Select and Edit Click-Function Annotations	4-14
Create an Annotation Programmatically	4-15
Annotations API	4-15
Create Annotations Programmatically	4-15
Delete an Annotation Programmatically	4-16
Find Annotations in a Model	4-16
Show or Hide Annotations Programmatically	4-16
Use TeX Commands in an Annotation	4-18
TeX for Simulink Model Annotations	4-19

What is a Subsystem?	4-22
Advantages of Using Subsystems	4-22
Types of Subsystem	4-22
Create a Subsystem	4-24
Create a Subsystem Block	4-24
Create Subsystem from Selection	4-26
Configure a Subsystem	4-28
Subsystem Execution	4-28
Label Subsystem Ports	4-28
Control Access to Subsystems	4-28
Control Subsystem Behavior with Callbacks	4-29
Navigate Model Hierarchies	4-31
Open a Subsystem or Referenced Model	4-31
Subsystem Expansion	4-34
What Is Subsystem Expansion?	4-34
Why Expand a Subsystem?	4-35
Subsystems That You Can Expand	4-36
Results of Expanding a Subsystem	4-36
Data Stores	4-37
Expand Subsystem Contents	4-39
Expand a Subsystem	4-39
Expand a Subsystem from the Command Line	4-40
Use Control Flow Logic	4-41
What is a Control Flow Subsystem	4-41
Equivalent C Language Statements	4-41
Conditional Control Flow Logic	4-41
While and For Loops	4-44
Callbacks for Customized Model Behavior	4-50
Model, Block, and Port Callbacks	4-50
What You Can Do with Callbacks	4-50
Avoid run Commands in Callback Code	4-51
Model Callbacks	4-52
Create Model Callbacks	4-52
Model Callback Parameters	4-54

Block Callbacks	4-57
Specify Block Callbacks	4-57
Block Callback Parameters	4-57
Port Callbacks	4-65
Callback Tracing	4-66
Manage Model Versions and Specify Model Properties	4-67
How Simulink Helps You Manage Model Versions	4-67
Model File Change Notification	4-67
Manage Model Properties	4-68
Log Comments History	4-70
Version Information Properties	4-71
Model Discretizer	4-74
What Is the Model Discretizer?	4-74
Requirements	4-74
Discretize a Model with the Model Discretizer	4-75
View the Discretized Model	4-83
Discretize Blocks from the Simulink Model	4-86
Discretize a Model with the sldiscmdl Function	4-96

Model Advisor

5

Select and Run Model Advisor Checks	5-2
Model Advisor Overview	5-2
Run Model Advisor Checks	5-2
Display Check Results	5-4
Set Model Advisor Window Preferences	5-5
Display and Run Checks	5-5
Run the Same Set of Checks Consistently	5-6
Run Model Checks Programmatically	5-7
Access Other Advisors	5-7
Model Advisor Limitations	5-8
Save Model Analysis Time	5-9

Run Model Checks in Background	5-11
Address Model Check Results	5-13
Address Model Check Results with Highlighting	5-13
Fix a Model Check Warning or Failure	5-17
Revert Changes	5-18
Save and View Model Advisor Reports	5-20
Save Model Advisor Reports	5-20
View Model Advisor Reports	5-20

Upgrade Advisor

6

Consult the Upgrade Advisor	6-2
Upgrade Programmatically	6-3
Upgrade Advisor Checks	6-3

Working with Sample Times

7

What Is Sample Time?	7-2
Specify Sample Time	7-3
Designate Sample Times	7-3
Specify Block-Based Sample Times Interactively	7-5
Specify Port-Based Sample Times Interactively	7-6
Specify Block-Based Sample Times Programmatically ...	7-7
Specify Port-Based Sample Times Programmatically ...	7-8
Access Sample Time Information Programmatically ...	7-8
Specify Sample Times for a Custom Block	7-8
Determining Sample Time Units	7-8
Change the Sample Time After Simulation Start Time ...	7-8
View Sample Time Information	7-9
Inspect Sample Time Using Timing Legend	7-10
Inspect Sample Times Throughout a Model	7-14

Types of Sample Time	7-15
Discrete Sample Time	7-15
Continuous Sample Time	7-16
Fixed-in-Minor-Step	7-16
Inherited Sample Time	7-16
Constant Sample Time	7-17
Variable Sample Time	7-17
Controllable Sample Time	7-18
Triggered Sample Time	7-18
Asynchronous Sample Time	7-18
Blocks for Which Sample Time Is Not Recommended ..	7-20
Best Practice to Model Sample Times	7-20
Appropriate Blocks for the Sample Time Parameter ...	7-21
Specify Sample Time in Blocks Where Hidden	7-21
Block Compiled Sample Time	7-23
Sample Times in Subsystems	7-26
Sample Times in Systems	7-28
Purely Discrete Systems	7-28
Hybrid Systems	7-31
Resolve Rate Transitions	7-34
Automatic Rate Transition	7-34
Visualize Inserted Rate Transition Blocks	7-35
How Propagation Affects Inherited Sample Times	7-38
Process for Sample Time Propagation	7-38
Simulink Rules for Assigning Sample Times	7-38
Backpropagation in Sample Times	7-40
Specify Execution Domain	7-42
Domain Specification Badge	7-42
Types of Execution Domains	7-43
Set Execution Domain	7-44
Enforce Discrete Execution Domain for a Subsystem ..	7-46

Model Reference Basics	8-2
Model Reference Advantages	8-2
Model Hierarchies	8-3
Model Block and Referenced Model Interface	8-4
Model Workspaces and Data Dictionaries	8-5
Referenced Model Execution	8-6
Referenced Model Simulation	8-6
Referenced Model Code Generation	8-6
Model Reference Requirements and Limitations	8-8
Model Reuse	8-8
Model Masks	8-9
S-Functions in Referenced Models	8-9
Model Architecture Requirements and Limitations	8-11
Signal Requirements and Limitations	8-12
Simulation Requirements and Limitations	8-12
Tools Requirements and Limitations	8-15
Code Generation Requirements and Limitations	8-16
Reference Existing Models	8-17
Reference Protected Models from Third Parties	8-20
Reference a Protected Model	8-20
View Protected Model Contents	8-22
Convert Subsystems to Referenced Models	8-24
Update Subsystem Block Contents for Conversion	8-24
Convert Subsystem Blocks to Model Blocks	8-28
Conversion Results	8-30
Compare Simulation Results Before and After Conversion	8-31
Revert the Conversion	8-32
Integrate the Referenced Model into the Parent Model	8-32
Modify Referenced Models for Conditional Execution . .	8-33
Conditional Models	8-33
Requirements for Conditional Models	8-36
Modify a Referenced Model for Conditional Execution .	8-38

Inspect Model Hierarchies	8-41
Content Preview	8-41
Model Dependency Viewer	8-41
List of Model References	8-42
Model Version Numbers	8-42
Model Reference Interface	8-44
Refresh Model Blocks	8-46
Signal Propagation	8-46
Sample Time Requirements	8-47
Share Data Among Referenced Model Instances	8-47
Referenced Model Sample Times	8-49
How Sample-Time Inheritance Works for Model Blocks	8-49
Conditions for Inheriting Sample Times	8-49
Determining Sample Time of a Referenced Model	8-50
Blocks That Depend on Absolute Time	8-50
Blocks Whose Outputs Depend on Inherited Sample Time	8-51
Sample Time Consistency	8-52
Sample Rates and Solvers	8-53
Simulate Model Hierarchies	8-54
Simulate a Top Model	8-54
Referenced Model Simulation	8-54
Simulate Conditional Referenced Models	8-60
Log Signals in Referenced Models	8-61
Set Diagnostics and Debug Model Hierarchies	8-62
Index Information Propagation	8-62
Simulate Multiple Referenced Model Instances in Normal Mode	8-64
Normal Mode Visibility	8-64
Example Models with Multiple Referenced Model Instances	8-64
Configure Models with Multiple Referenced Model Instances	8-66
Specify the Instance Having Normal Mode Visibility ...	8-67
Model Reference Simulation Targets	8-72
Simulation Targets	8-72
Build Simulation Targets	8-73

Simulation Target Output File Control	8-74
Reduce Update Time for Referenced Models	8-76
Share Simulation Builds for Faster Simulations	8-81
Store Simulink Cache Files	8-81
Share Simulink Cache Files	8-82
Use Simulink Cache Files	8-82
Set Configuration Parameters for Model Referencing ..	8-84
Manage Configuration Parameters by Using Configuration References	8-84
Configuration Requirements for All Referenced Model Simulation	8-85
Diagnostics That Are Ignored in Accelerator Mode ...	8-87
Accelerated Simulation and Code Generation Changes Settings	8-88
Parameterize Instances of a Reusable Referenced Model	8-90
Specify a Different Value for Each Instance of a Reusable Model	8-90
Combine Multiple Arguments into a Structure	8-91
Parameterize a Referenced Model	8-91
Change Model Argument Name or Value	8-99
Customize User Interface for Reusable Components ...	8-99
Configure Instance-Specific Data for Lookup Tables ..	8-100
Parameterize a Referenced Model Programmatically .	8-104
Group Multiple Model Arguments into a Single Structure	8-107
Configure Instance-Specific Data for Lookup Tables Programmatically	8-111

Simulink Units

9

Unit Specification in Simulink Models	9-2
Specify Physical Quantities	9-4

Specify Units in Objects	9-4
Specify Units for Temperature Signals	9-6
Specify Units in MATLAB Function Blocks	9-6
Specify Units for Logging and Loading Signal Data	9-6
Restricting Unit Systems	9-6
Displaying Units	9-9
Unit Consistency Checking and Propagation	9-11
Unit Propagation Between Simulink and Simscape	9-14
Converting Units	9-16
Automatic Unit Conversion Limitations	9-16
Update an Existing Model to Use Units	9-18
Troubleshooting Units	9-27
Undefined Units	9-27
Overflow and Underflow Errors or Warning	9-27
Mismatched Units Detected	9-28
Mismatched Units Detected While Loading	9-28
Disallowed Unit Systems	9-28
Automatic Unit Conversions	9-28
Unsuccessful Automatic Unit Conversions	9-29
Simscape Unit Specification Incompatible with Simulink	9-29

Conditional Subsystems

10

Conditionally Executed Subsystems Overview	10-3
Model Examples	10-4
Ensure Output is Virtual	10-5
Conditional Output Signal	10-5
Partial Write Signals With a Merge Block	10-8
Using Enabled Subsystems	10-11
Create an Enabled Subsystem	10-12
Blocks in Enabled Subsystems	10-13

Alternately Executing Enabled Subsystems	10-15
Model Examples	10-19
Using Triggered Subsystems	10-21
Create a Triggered Subsystem	10-22
Triggering with Discrete Time Systems	10-24
Triggered Model Versus a Triggered Subsystem	10-24
Blocks in a Triggered Subsystem	10-25
Model Examples	10-25
Using Enabled and Triggered Subsystems	10-26
Creating an Enabled and Triggered Subsystem	10-27
Blocks in an Enabled and Triggered Subsystem	10-29
Model Examples	10-29
Select Subsystem Execution	10-30
Models with If-Else Structures	10-30
Models with Switch Case Structure	10-33
Model Examples	10-35
Iterate Subsystem Execution	10-36
Models with While Structures	10-36
Model with For Structures	10-39
Model Examples	10-43
Using Function-Call Subsystems	10-44
Creating a Function-Call Subsystem	10-45
Sample Time Propagation in a Function-Call Subsystem	10-45
Model Examples	10-46
Conditional Subsystem Initial Output Values	10-48
Inherit Initial Output Values from Input Signals	10-48
Specify Initial Output Values Using Dialog Parameters	10-49
Rate-Based Models Overview	10-50
Create A Rate-Based Model	10-51

Test Rate-Based Model Simulation Using Function-Call Generators	10-52
Create Test Model That References a Rate-Based Model	10-52
Simulate Rate-Based Model	10-54
Generate Code from Rate-Based Model	10-56
Sorting Rules for Explicitly Scheduled Model Components	10-58
Export-Function Models	10-58
Test Harness for Export Function Models with Strict Scheduling	10-60
Test Harness for Export-Function Models Without Strict Scheduling	10-62
Data Dependency Error Caused by Data Sorting Rules	10-63
Test Harness for Models with Initialize, Reset, and Terminate Function Blocks	10-65
Initiators for Model Block in Test Harness	10-65
Conditional Subsystem Output Values When Disabled	10-69
Simplified Initialization Mode	10-70
When to Use Simplified Initialization	10-70
Set Initialization Mode to Simplified	10-71
Classic Initialization Mode	10-72
When to Use Classic Initialization	10-72
Set Initialization Mode to Classic	10-72
Classic Initialization Issues	10-72
Identity Transformation Can Change Model Behavior	10-73
Inconsistent Output with Discrete-Time Integrator or S-Function Block	10-77
Sorted Order Affecting Merge Block Output	10-80
Convert from Classic to Simplified Initialization Mode	10-91
Blocks to Consider	10-91

Create Export-Function Model	10-93
Create Model Algorithms	10-93
Add Function-Call Inputs	10-94
Satisfy Export-Function Model Requirements	10-95
Test Export-Function Model Simulation Using Input Matrix	10-96
Create Function-Call Inputs and Data Inputs	10-96
Simulate Export-Function Model	10-97
Test Export-Function Model Simulation Using Function-Call Generators	10-101
Create Referenced Export-Function Model	10-101
Create Test Model (Harness) for Simulation	10-102
Simulate Export Function Model	10-104
Test Export-Function Model Simulation Using Stateflow Chart	10-106
Create Referenced Export-Function Model	10-106
Create Periodic Scheduler Using Stateflow Chart ...	10-107
Create Test Model (Harness) for Simulation	10-109
Simulate Export Function Model	10-110
Generate Code for Export-Function Model	10-112
Generate Code for Exported Functions	10-112
Generate Code for Export-Function Model with Rate-Based Model	10-116
Create Export-Function Model with Scheduled Subsystems	10-116
Generate Code for Exported Functions	10-118
Export-Function Models	10-120
Workflows for Export-Function Models	10-122
Allowed Blocks	10-122
Requirements for Export Function Models	10-123
Sample Time for Function-Call Subsystems	10-124
Execution Order for Root-Level Function-Call Inport Blocks	10-125
Latched Input Data for Function-Call Subsystems ...	10-127
Nested Export-Function Models	10-128
Export-Function Model with a Multi-Instanced Function-Call Model	10-129

Export-Function Models and Models with Asynchronous Function-Call Inputs	10-131
Use Resettable Subsystems	10-134
Behavior of Resettable Subsystems	10-134
Comparison of Resettable Subsystems and Enabled Subsystems	10-137
Model Examples	10-140
Simulink Functions Overview	10-141
What Are Simulink Functions?	10-141
What Are Simulink Function Callers?	10-141
Connect to Local Signals	10-142
Reusable Logic with Functions	10-142
Input/Output Argument Behavior	10-143
Shared Resources with Functions	10-144
How a Function Caller Identifies a Function	10-145
Reasons to Use a Simulink Function Block	10-146
Choose a Simulink Function or Reusable Subsystem	10-147
When Not to Use a Simulink Function Block	10-147
Tracing Simulink Functions	10-147
Using Simulink Function Blocks and Exported Stateflow Functions	10-152
Simulink Functions	10-152
Call Simulink Functions with a Function Caller Block	10-158
Call Simulink Functions from a MATLAB Function Block	10-162
Call Simulink Functions from a Stateflow Chart	10-164
Call a Simulink Function Block from Multiple Sites ..	10-166
Argument Specification for Simulink Function Blocks	10-170
Example Argument Specifications for Data Types	10-170
Input Argument Specification for Bus Data Type	10-171
Input Argument Specification for Enumerated Data Type	10-172
Input Argument Specification for an Alias Data Type	10-173
Simulink Function Blocks in Referenced Models	10-175
Simulink Function Block in Referenced Model	10-175
Function Caller Block in Referenced Model	10-178

Function and Function Caller in Separate Models . . .	10-180
Function and Function Caller in the Same Model . . .	10-181
Scoped and Global Simulink Function Blocks Overview	
.	10-184
Summary of Simulink Function Block Visibility and Access	
.	10-187
Scoped Simulink Function Blocks in Subsystems . . .	10-188
Resolve to a Function Hierarchically	10-188
Resolve to a Function by Qualification	10-190
Scoped Simulink Function Blocks in Models	10-196
Resolve to a Function Hierarchically	10-196
Resolve to a Function by Qualification	10-200
Multi-Instance Modeling with Simulink Functions . . .	10-204
Diagnostics Using a Client-Server Architecture	10-207
Diagnostic Messaging with Simulink Functions	10-207
Client-Server Architecture	10-207
Modifier Pattern	10-209
Observer Pattern	10-211
Using Initialize, Reset, and Terminate Functions	10-213
Create Model Component with State	10-213
Initialize Block State	10-215
Reset Block State	10-217
Read and Save Block State	10-220
Prepare Model Component for Testing	10-224
Create an Export-Function Model	10-225
Create Test Harness to Generate Function Calls	10-228
Reference the Export-Function Model	10-228
Model an Event Scheduler	10-231
Connect Chart to Test Model	10-233
Initialize and Reset Parameter Values	10-236
Using the Parameter Writer Block	10-236
Initialize, Reset, and Terminate Function Limitations	
.	10-240
Unsupported Blocks	10-240
Unsupported Features	10-240

Modeling Variant Systems

11

What Are Variants and When to Use Them	11-3
What Are Variants?	11-3
Advantages of Using Variants	11-5
When to Use Variants	11-6
Options for Representing Variants in Simulink	11-7
Mapping Inports and Outports of Variant Choices	11-8
Variant Badges	11-9
Comment Out and Comment Through	11-11
Variant Terminology	11-14
Command Line Parameters	11-15
Working with Variant Choices	11-27
Default Variant Choice	11-28
Active Variant Choice	11-29
Inactive Variant Choice	11-29
Empty Variant Choice	11-29
Open Active Variant	11-30
Introduction to Variant Controls	11-31
Variant control mode	11-31
Operands	11-33
Operators	11-34
Known Limitations	11-34
Approaches for Specifying Variant Controls	11-34
Viewing Variant Conditions	11-40
Operators and Operands in Variant Condition Expressions	11-41
Create a Simple Variant Model	11-44
Create Variant Controls Programmatically	11-49
Create and Export Variant Controls	11-49
Reuse Variant Conditions	11-49
Enumerated Types as Variant Controls	11-50

Define, Configure, and Activate Variants	11-52
Represent Variant Choices	11-52
Include Simulink Model as Variant Choice	11-56
Configure Variant Controls	11-58
Convert to Variants	11-59
Prepare Variant-Containing Model for Code Generation	11-61
Convert Variant Control Variables into Simulink.Parameter Objects	11-61
Configure Model for Generating Preprocessor Conditionals	11-63
Visualize Variant Implementations in a Single Layer ..	11-67
How Variant Sources and Sinks Work	11-67
Advantages of Using Variant Sources and Sinks	11-68
Limitations of Using Variant Sources and Sinks	11-68
Define and Configure Variant Sources and Sinks	11-69
Variant Condition Propagation with Variant Sources and Sinks	11-75
View Variant Condition Annotations	11-75
How Variant Condition Propagation Works	11-77
Condition Propagation with Subsystems	11-80
Condition Propagation with Other Simulink Blocks ...	11-82
Known Limitations	11-86
Create and Validate Variant Configurations	11-87
Step 1: Open Variant Manager	11-87
Step 2: Define Variant Configuration	11-88
Step 3: Activate and Validate Variant Configuration ..	11-89
Import Control Variables to Variant Configuration ...	11-91
Step 1: Open Variant Manager	11-91
Step 2: Import Variant Configuration	11-92
Step 3: View Referenced Model Configuration	11-93
Define Constraints	11-95
Reduce Models Containing Variant Blocks	11-98
Reduce Model Programmatically	11-106
Considerations and Limitations	11-107

Condition Propagation with Variant Subsystem	11-108
Propagate Conditions Without Generate Preprocessor Conditionals	11-109
Propagate Conditions with Generate Preprocessor Conditionals	11-111
Adaptive Interface for Variant Subsystems	11-114
Condition Propagation with Conditional Systems	11-116
Known Limitations	11-116
Propagate Conditions Programmatically	11-117
Code Generation with Conditional Systems	11-117
 Variant Systems with Conditional Systems	 11-121
 Convert Configurable Subsystem to Variant Subsystem	 11-125
Behavior of Configurable Subsystem on Loading	11-127
Changing Active Variant	11-129
 Variant Elements within Buses	 11-131
Create Buses with Variant Conditions	11-131
Variant Condition Propagation with Bus	11-131
Code Generation	11-132
Virtual and Nonvirtual Bus Behavior	11-132
Variant Bus with Model Reference Block	11-134
Known Limitations	11-134
 Initialization Function	 11-136
Model InitFcn	11-136
Block InitFcn	11-139
 Analyze Variant Configurations in Models Containing Variant Blocks	 11-142
View blocks	11-145
Show blocks activeness	11-145
 Variants Example Models	 11-146
 Propagating Variant Conditions to Subsystems	 11-150
 Variant Subsystems	 11-155
 Variant Source and Variant Sink Blocks	 11-164

Control Variant Condition Propagation	11-168
Propagate Variant Condition to Conditional Subsystem	11-173
Hierarchical Nesting of Variant Sources and Variant Sinks	11-176
Export-Function model with Variant Subsystem	11-179
Variant Subsystem with Enable Subsystem as Choice	11-182
Propagating Variant Conditions to Subsystems	11-185

Exploring, Searching, and Browsing Models

12

Search and Edit Using Model Explorer	12-2
What You Can Do Using the Model Explorer	12-2
Open the Model Explorer and Edit Object Properties ..	12-3
Search Bar Controls	12-4
Model Explorer Components	12-6
Add Objects to a Model, Chart, or Workspace	12-8
Focus on Specific Elements of a Model or Chart	12-8
Model Explorer: Model Hierarchy Pane	12-9
Model Explorer: Contents Pane	12-16
Organize Data Display in Model Explorer	12-21
Filter Objects in the Model Explorer	12-28
Model Explorer: Property Dialog Pane	12-33
Customize Model Explorer Views	12-36
Using Views	12-36
Customizing Views	12-39
Managing Views	12-40
Find Model Elements in Simulink Models	12-45
Explore the Model Hierarchy Using the Model Browser	12-45
Search for Model Elements Using Find	12-46
Search Using Model Explorer	12-50

Model Dependency Viewer	12-54
Model Dependency Views	12-54
View Model File and Library Dependencies	12-57
View Linked Requirements in Models and Blocks	12-59
Requirements Traceability in Simulink	12-59
Highlight Requirements in a Model	12-60
View Information About a Requirements Link	12-62
Navigate to Requirements from a Model	12-63
Filter Requirements in a Model	12-64
Trace Connections Using Interface Display	12-67
How Interface Display Works	12-67
Trace Connections in a Subsystem	12-67
Display Signal Attributes at Model Load Time	12-73
Find Attribute Mismatches Between Components	12-76

Managing Model Configurations

13

About Model Configurations	13-2
Multiple Configuration Sets in a Model	13-3
Share a Configuration for Multiple Models	13-4
Convert an Existing Configuration Set to a Configuration Reference	13-4
Create a Configuration Reference in Another Model ...	13-4
Share a Configuration Across Referenced Models	13-6
Manage a Configuration Set	13-11
Create a Configuration Set in a Model	13-11
Create a Configuration Set in the Base Workspace ...	13-11
Open a Configuration Set in the Configuration Parameters Dialog Box	13-12
Activate a Configuration Set	13-13
Copy, Delete, and Move a Configuration Set	13-13

Save a Configuration Set	13-14
Load a Saved Configuration Set	13-15
Copy Configuration Set Components	13-16
Compare Configuration Sets	13-16
Manage a Configuration Reference	13-18
Create and Attach a Configuration Reference	13-18
Resolve a Configuration Reference	13-19
Activate a Configuration Reference	13-20
Manage Configuration Reference Across Referenced Models	13-21
Change Parameter Values in a Referenced Configuration Set	13-22
Change Parameter Value in a Configuration Reference	13-22
Save a Referenced Configuration Set	13-24
Load a Saved Referenced Configuration Set	13-24
About Configuration Sets	13-26
What Is a Configuration Set?	13-26
What Is a Freestanding Configuration Set?	13-27
About Configuration References	13-29
Why Use Configuration References?	13-29
Unresolved Configuration References	13-30
Overriding Individual Configuration Parameters	13-30
Configuration Reference Limitations	13-31
Configuration References for Models with Older Simulation Target Settings	13-31
Model Configuration Command Line Interface	13-33
Overview	13-33
Load and Activate a Configuration Set at the Command Line	13-34
Save a Configuration Set at the Command Line	13-35
Create a Freestanding Configuration Set at the Command Line	13-35
Create and Attach a Configuration Reference at the Command Line	13-36
Attach a Configuration Reference to Multiple Models at the Command Line	13-37
Get Values from a Referenced Configuration Set	13-38
Change Values in a Referenced Configuration Set	13-38
Obtain a Configuration Reference Handle	13-39

Configuring Models for Targets with Multicore Processors

14

Concepts in Multicore Programming	14-2
Basics of Multicore Programming	14-2
Types of Parallelism	14-3
System Partitioning for Parallelism	14-6
Challenges in Multicore Programming	14-7

Basic Workflow	14-10
How Simulink Helps You to Overcome Challenges in Multicore Programming	14-11
Implement Data Parallelism in Simulink	14-14
Implement Task Parallelism in Simulink	14-18
Implement Pipelining in Simulink	14-21
Configure Your Model for Concurrent Execution	14-24
Specify a Target Architecture	14-25
Choose from Predefined Architectures	14-25
Define a Custom Architecture File	14-27
Partition Your Model Using Explicit Partitioning	14-31
Prerequisites for Explicit Partitioning	14-31
Add Periodic Triggers and Tasks	14-32
Add Aperiodic Triggers and Tasks	14-33
Map Blocks to Tasks, Triggers, and Nodes	14-34
Implicit and Explicit Partitioning of Models	14-37
Partitioning Guidelines	14-37
Configure Data Transfer Settings Between Concurrent Tasks	14-40
Optimize and Deploy on a Multicore Target	14-45
Generate Code	14-45
Build on Desktop	14-46

Profile and Evaluate Explicitly Partitioned Models on a Desktop	14-49
Customize the Generated C Code	14-52
Concurrent Execution Models	14-54
Programmatic Interface for Concurrent Execution ...	14-55
Map Blocks to Tasks	14-55
Supported Targets For Multicore Programming	14-57
Supported Multicore Targets	14-57
Supported Heterogeneous Targets	14-57
Limitations with Multicore Programming in Simulink	14-59

Modeling Best Practices

15

General Considerations when Building Simulink Models	15-2
Avoiding Invalid Loops	15-2
Shadowed Files	15-4
Model Building Tips	15-6
Model a Continuous System	15-8
Best-Form Mathematical Models	15-11
Series RLC Example	15-11
Solving Series RLC Using Resistor Voltage	15-11
Solving Series RLC Using Inductor Voltage	15-13
Model a Simple Equation	15-15
Model Differential Algebraic Equations	15-17
Overview of Robertson Reaction Example	15-17
Simulink Model from ODE Equations	15-17
Simulink Model from DAE Equations	15-20
Simulink Model from DAE Equations Using Algebraic Constraint Block	15-23

Capabilities of Model Components	15-29
Componentization	15-29
Componentization Techniques	15-29
General Componentization Guidelines	15-30
Summary of Componentization Techniques	15-31
Subsystems Summary	15-33
Libraries Summary	15-37
Model References Summary	15-40
Model Complex Logic	15-47
Model Physical Systems	15-48
Model Signal Processing Systems	15-49
Basic Modeling Workflow	15-50
Model a Mechanical System Algorithm	15-51
Create Virtual Model Components	15-54
Manage Signal Lines	15-58
Manage Model Data	15-65
Reuse Model Components from Files	15-67
Create Interchangeable Variations of Model Components	15-71
Set up a File Management System	15-73

Project Setup

16

Organize Large Modeling Projects	16-2
What Are Projects?	16-3

Explore Project Tools with the Airframe Project	16-5
Explore the Airframe Project	16-5
Set Up Project Files and Open the Project	16-6
View, Search, and Sort Project Files	16-6
Open and Run Frequently Used Files	16-7
Review Changes in Modified Files	16-8
Run Dependency Analysis	16-10
Run Project Integrity Checks	16-11
Commit Modified Files	16-12
View Project and Source Control Information	16-12
Create a Project from a Model	16-14
Create a New Project From a Folder	16-16
Add Files to the Project	16-22
Create a New Project from an Archived Project	16-24
Create a New Project Using Templates	16-25
Use Project Templates from R2014a or Before	16-25
Open Recent Projects	16-27
Specify Project Details, Startup Folder, and Derived Files Folders	16-29
Specify Project Path	16-30
What Can You Do With Project Shortcuts?	16-32
Automate Startup Tasks	16-33
Automate Shutdown Tasks	16-35
Create Shortcuts to Frequent Tasks	16-36
Create Shortcuts	16-36
Group Shortcuts	16-36
Annotate Shortcuts to Use Meaningful Names	16-37
Customize Shortcut Icons	16-37
Use Shortcuts to Find and Run Frequent Tasks	16-39

Create Templates for Standard Project Settings	16-40
Using Templates to Create Standard Project Settings	
.	16-40
Create a Template from the Current Project	16-40
Create a Template from a Project Under Version Control	
.	16-41
Edit a Template	16-41
Explore the Example Templates	16-42

Project File Management

17

Group and Sort File Views	17-2
Search Inside Project Files and Filter File Views	17-3
Project-Wide Search	17-3
Filter Project File Views	17-5
More Ways to Search	17-6
Work with Project Files	17-8
Manage Shadowed and Dirty Models and Other Project Files	17-10
Identify Shadowed Project Files When Opening a Project	
.	17-10
Find Models and Other Project Files With Unsaved Changes	17-11
Manage Open Models and Data Dictionaries When Closing a Project	17-11
Move, Rename, Copy, or Delete Project Files	17-12
Move or Add Files	17-12
Automatic Updates When Renaming, Deleting, or Removing Files	17-12
Back Out Changes	17-17
Upgrade Model Files to SLX and Preserve Revision History	17-18
Project Tools for Migrating Model Files to SLX	17-18

Upgrade the Model and Commit the Changes	17-18
Verify Changes After Upgrade to SLX	17-20
Create Labels	17-22
Add Labels to Files	17-24
View and Edit Label Data	17-25
Automate Simulink Project Tasks Using Scripts	17-27
Create a Custom Task Function	17-40
Run a Project Custom Task and Publish Report	17-41
Sharing Projects	17-44
Share Project by Email	17-46

Use the Model Manifest Report	18-41

Project Source Control

19

About Source Control with Projects	19-2
Classic and Distributed Source Control	19-3
Add a Project to Source Control	19-6
Add a Project to Git Source Control	19-6
Add a Project to SVN Source Control	19-7
Register Model Files with Source Control Tools	19-10

Set Up SVN Source Control	19-11
Set Up SVN Provided with Projects	19-11
Set Up Project SVN for SVN Version Already Installed	19-12
Set Up Project SVN for SVN Version Not Yet Provided with Projects	19-13
Register Model Files with Subversion	19-14
Enforce SVN Locking Model Files Before Editing	19-17
Share a Subversion Repository	19-17
Manage SVN Externals	19-18
Set Up Git Source Control	19-20
Use Git Source Control in Projects	19-20
About Git Source Control	19-21
Install Command-Line Git Client	19-22
Register Model Files with Git	19-23
Add Git Submodules	19-24
Disable Source Control	19-27
Change Source Control	19-28
Write a Source Control Integration with the SDK	19-29
Clone Git Repository or Check Out SVN Repository ...	19-30
Troubleshooting	19-31
Tag and Retrieve Versions of Project Files	19-33
Refresh Status of Project Files	19-35
Check for Modifications	19-36
Update Revisions of Project Files	19-37
Update Revisions with SVN	19-37
Update Revisions with Git	19-37
Update Selected Files	19-38
Get SVN File Locks	19-39
Manage SVN Repository Locks	19-39
View Modified Files	19-41
Project Definition Files	19-42

Compare Revisions	19-43
Run Project Checks	19-46
Commit Modified Files to Source Control	19-48
Revert Changes	19-50
Discard Local Changes	19-50
Revert a File to a Specified Revision	19-50
Revert the Project to a Specified Revision	19-51
Pull, Push, and Fetch Files with Git	19-53
Pull and Push	19-53
Pull, Fetch, and Merge	19-54
Push Empty Folders	19-57
Use Git Stashes	19-57
Branch and Merge Files with Git	19-59
Create a Branch	19-59
Switch Branch	19-61
Compare Branches and Save Copies	19-61
Merge Branches	19-61
Revert to Head	19-62
Delete Branches	19-62
Resolve Conflicts	19-64
Resolve Conflicts	19-64
Merge Text Files	19-66
Merge Models	19-67
Extract Conflict Markers	19-67
Work with Derived Files in Projects	19-70
Customize External Source Control to Use MATLAB for Diff and Merge	19-71

Project Reference

Componentization Using Referenced Projects	20-2
---	-------------

Add or Remove a Reference to Another Project	20-5
View, Edit, or Run Referenced Project Files	20-7
Extract a Folder to Create a Referenced Project	20-8
Manage Referenced Project Changes Using Checkpoints	20-10

Compare Simulink Models

21

About Simulink Model Comparison	21-2
Creating Model Comparison Reports	21-2
Examples of Model Comparison	21-3

Create Custom Block Libraries	43-138
When to Use MATLAB Function Block Libraries	43-138
How to Create Custom MATLAB Function Block Libraries	
.	43-138

Example: Creating a Custom Signal Processing Filter Block	
Library	43-139
Code Reuse with Library Blocks	43-150
Debugging MATLAB Function Library Blocks	43-155
Properties You Can Specialize Across Instances of Library	
Blocks	43-155
Use Traceability in MATLAB Function Blocks	43-157
Extent of Traceability in MATLAB Function Blocks ..	43-157
Traceability Requirements	43-157
Tutorial: Using Traceability in a MATLAB Function Block	
.....	43-157
Include MATLAB Code as Comments in Generated Code	
.....	43-160
How to Include MATLAB Code as Comments in the	
Generated Code	43-160
Location of Comments in Generated Code	43-161
Including MATLAB user comments in Generated Code	
.....	43-163
Limitations of MATLAB Source Code as Comments ..	43-164
Integrate C Code Using the MATLAB Function Block	43-165
Call C Code from a Simulink Model	43-165
Use coder.ceval in a MATLAB Function Block	43-166
Control Imported Bus and Enumeration Type Definitions	
.....	43-167
Enhance Code Readability for MATLAB Function Blocks	
.....	43-169
Requirements for Using Readability Optimizations ..	43-169
Converting If-Elseif-Else Code to Switch-Case Statements	
.....	43-169
Example of Converting Code for If-Elseif-Else Decision	
Logic to Switch-Case Statements	43-171
Control Run-Time Checks	43-177
Types of Run-Time Checks	43-177
When to Disable Run-Time Checks	43-177
How to Disable Run-Time Checks	43-178
Track Object Using MATLAB Code	43-179
Learning Objectives	43-179

Tutorial Prerequisites	43-179
Example: The Kalman Filter	43-180
Files for the Tutorial	43-183
Tutorial Steps	43-184
Best Practices Used in This Tutorial	43-201
Key Points to Remember	43-201
Filter Audio Signal Using MATLAB Code	43-203
Learning Objectives	43-203
Tutorial Prerequisites	43-203
Example: The LMS Filter	43-204
Files for the Tutorial	43-207
Tutorial Steps	43-208

Define New System Objects

44

Customize System Block Appearance	44-2
Specify Input and Output Names	44-2
Add Text to Block Icon	44-3
Add Image to Block Icon	44-5
Customize System Block Dialog Box	44-7
Add Header to MATLAB System Block	44-7
Add Data Types Tab to MATLAB System Block	44-8
Add Property Groups to System Object and MATLAB System Block	44-10
Control Simulation Type in MATLAB System Block	44-15
Add Button to MATLAB System Block	44-17
Specify Output	44-21
Set Output Size	44-21
Set Fixed- or Variable-Size Output	44-23
Set Output Data Type	44-25
Set Output Complexity	44-29
Set Discrete State Output Specification	44-31
Set Model Reference Discrete Sample Time Inheritance 	44-34

Use Update and Output for Nondirect Feedthrough . . .	44-36
Enable For Each Subsystem Support	44-39
Define System Object for Use in Simulink	44-41
Develop System Object for Use in MATLAB System Block	44-41
Define Block Dialog Box for Plot Ramp	44-42
Use Global Variables in System Objects	44-46
System Object Global Variables in MATLAB	44-46
System Object Global Variables in Simulink	44-46
Use System Objects in Simulink	44-50
System Objects in the MATLAB Function Block	44-50
System Objects in the MATLAB System Block	44-50
System Design in Simulink Using System Objects	44-51
System Design and Simulation in Simulink	44-51
Define New System Objects for Use in Simulink	44-51
Test New System Objects in MATLAB	44-57
Add System Objects to Your Simulink Model	44-57
Specify Sample Time for MATLAB System Block System Objects	44-58

System Objects in Simulink

45

MATLAB System Block	45-2
Why Use the MATLAB System Block?	45-2
Choosing the Right Block Type	45-2
System Objects	45-3
Interpreted Execution or Code Generation	45-3
Default Input Signal Attributes	45-4
MATLAB System Block Limitations	45-4
MATLAB System and System Objects Examples	45-5
Implement a MATLAB System Block	45-8
Understanding the MATLAB System Block	45-9

Change Blocks Implemented with System Objects	45-11
Call Simulink Functions from MATLAB System Block	
.	45-12
Create a Simulink Function Block	45-12
Create a MATLAB System Block and Define System Object	
.	45-13
Call a Simulink Function in a Subsystem from a MATLAB	
System Block	45-13
Call Simulink Functions from a MATLAB System Block	
.	45-14
Specify Sample Time for MATLAB System Block	45-17
Types of Sample Time for MATLAB System Block	45-17
Change Block Icon and Port Labels	45-19
Modify MATLAB System Block Dialog	45-19
Change the MATLAB System Block Icon to an Image .	45-20
Nonvirtual Buses and MATLAB System Block	45-21
Use System Objects in Feedback Loops	45-22
Simulation Modes	45-24
Interpreted Execution vs. Code Generation	45-24
Simulation Using Code Generation	45-25
Mapping System Objects to Block Dialog Box	45-27
System Object to Block Dialog Box Default Mapping . .	45-27
System Object to Block Dialog Box Custom Mapping .	45-29
Considerations for Using System Objects in Simulink	
.	45-32
System Objects in Simulink	45-32
System Objects in For Each Subsystems	45-33
Input Validation	45-33
Simulink Engine Interaction with System Object Methods	
.	45-35
Simulink Engine Phases Mapped to System Object	
Methods	45-35

Add and Implement Propagation Methods	45-38
When to Use Propagation Methods	45-38
Add Propagation Methods to System Objects	45-38
Implement Propagation Methods	45-39
Share Data with Other Blocks	45-42
Data Sharing with the MATLAB System Block	45-42
Choose How to Store Shared Data	45-43
How to Use Data Store Memory Blocks for the MATLAB System Block	45-44
How to Set Up Simulink.Signal Objects	45-46
Using Data Store Diagnostics to Detect Memory Access Issues	45-49
Limitations of Using Shared Data in MATLAB System Blocks	45-49
Use Shared Data with P-Coded System Objects	45-49
Troubleshoot System Objects in Simulink	45-51
Class Not Found	45-51
Error Invoking Object Method	45-51
Performance	45-52
Customize MATLAB System Block Dialog	45-53
Break Algebraic Loops	45-58
Customize MATLAB System Block Appearance	45-63
Implement Algorithm with Tunable Parameters	45-67
Implement a Simple Algorithm	45-71
Specify Output Characteristics of MATLAB System Block	45-74
Implement Algorithm that Calls External C Code	45-77

Import FMUs	46-2
FMU XML File Directives	46-2
Additional Support and Limitations	46-3
FMU Import Examples	46-4
Implement an FMU Block	46-6
Explore the FMU Block	46-6
Change Block Input, Output, and Parameter Structures	46-10
Timing Considerations	46-13
Troubleshooting FMUs	46-14
Export a Model as a Tool-Coupling FMU	46-15
Use the Exported Tool-Coupling FMU	46-16
Co-Simulation Execution and Numerical Compensation	46-19
Execution Timing	46-19
Numerical Compensation	46-20
Run Co-Simulation Components on Multiple Cores ...	46-30
Using the MultiThreadCoSim Parameter	46-31
Configuring S-Function Blocks to Run Single or Multithreaded	46-32
Co-Simulation on Multiple Threads Limitations	46-33
Simulink Community and Connection Partner Program	46-35

Design Considerations for C/C++ Code Generation

When to Generate Code from MATLAB Algorithms	47-2
When Not to Generate Code from MATLAB Algorithms	47-2

Which Code Generation Feature to Use	47-4
Prerequisites for C/C++ Code Generation from MATLAB	47-6
MATLAB Code Design Considerations for Code Generation	47-7
See Also	47-8
Differences Between Generated Code and MATLAB Code	47-9
Loop Index Overflow	47-9
Character Size	47-11
Order of Evaluation in Expressions	47-11
Termination Behavior	47-13
Size of Variable-Size N-D Arrays	47-13
Size of Empty Arrays	47-13
Size of Empty Array That Results from Deleting Elements of an Array	47-13
Floating-Point Numerical Results	47-14
NaN and Infinity	47-15
Negative Zero	47-15
Code Generation Target	47-15
MATLAB Class Property Initialization	47-16
MATLAB Class Property Access Methods That Modify Property Values	47-16
MATLAB Classes in Nested Property Assignments That Have Set Methods	47-17
MATLAB Handle Class Destructors	47-17
Variable-Size Data	47-18
Complex Numbers	47-18
Converting Strings with Consecutive Unary Operators to double	47-18
MATLAB Language Features Supported for C/C++ Code Generation	47-19
MATLAB Features That Code Generation Supports ...	47-19
MATLAB Language Features That Code Generation Does Not Support	47-20

Functions, Classes, and System Objects Supported for Code Generation

48

Functions and Objects Supported for C/C++ Code Generation — Alphabetical List	48-2
Functions and Objects Supported for C/C++ Code Generation — Category List	48-91
5G Toolbox	48-93
Aerospace Toolbox	48-96
Arithmetic Operations in MATLAB	48-96
Audio and Video in MATLAB	48-97
Audio Toolbox	48-97
Automated Driving Toolbox	48-100
Bit-Wise Operations MATLAB	48-102
Casting in MATLAB	48-102
Characters and Strings in MATLAB	48-102
Communications Toolbox	48-104
Complex Numbers in MATLAB	48-111
Computer Vision Toolbox	48-111
Control Flow in MATLAB	48-116
Control System Toolbox	48-116
Data and File Management in MATLAB	48-117
Data Type Conversion in MATLAB	48-117
Data Types in MATLAB	48-118
Deep Learning Toolbox	48-119
Descriptive Statistics in MATLAB	48-120
Desktop Environment in MATLAB	48-121
Discrete Math in MATLAB	48-121
DSP System Toolbox	48-121
Error Handling in MATLAB	48-127
Exponents in MATLAB	48-127
Filtering and Convolution in MATLAB	48-128
Fixed-Point Designer	48-128
Fuzzy Logic Toolbox	48-133
Histograms in MATLAB	48-133
Image Acquisition Toolbox	48-134
Image Processing in MATLAB	48-134
Image Processing Toolbox	48-134
Input and Output Arguments in MATLAB	48-138
Interpolation and Computational Geometry in MATLAB	48-138

Linear Algebra in MATLAB	48-139
Logical and Bit-Wise Operations in MATLAB	48-140
MATLAB Compiler	48-140
Matrices and Arrays in MATLAB	48-141
Model Predictive Control Toolbox	48-145
Numerical Integration and Differentiation in MATLAB	48-145
Optimization Functions in MATLAB	48-145
Optimization Toolbox	48-146
Performance and Memory in MATLAB	48-146
Phased Array System Toolbox	48-146
Polynomials in MATLAB	48-154
Preprocessing Data in MATLAB	48-155
Programming Utilities in MATLAB	48-155
Property Validation in MATLAB	48-155
Relational Operators in MATLAB	48-156
Robotics System Toolbox	48-156
Rounding and Remainder Functions in MATLAB	48-161
Sensor Fusion and Tracking Toolbox	48-161
SerDes Toolbox	48-168
Set Operations in MATLAB	48-169
Signal Processing in MATLAB	48-169
Signal Processing Toolbox	48-170
Special Values in MATLAB	48-174
Specialized Math in MATLAB	48-174
Statistics and Machine Learning Toolbox	48-175
System Identification Toolbox	48-182
System object Methods	48-183
Trigonometry in MATLAB	48-183
Wavelet Toolbox	48-185
WLAN Toolbox	48-186

System Objects Supported for Code Generation

49

Code Generation for System Objects	49-2
--	------

Defining MATLAB Variables for C/C++ Code Generation

50

Variables Definition for Code Generation	50-2
Best Practices for Defining Variables for C/C++ Code Generation	50-3
Define Variables By Assignment Before Using Them . . .	50-3
Use Caution When Reassigning Variables	50-5
Use Type Cast Operators in Variable Definitions	50-5
Define Matrices Before Assigning Indexed Variables . . .	50-6
Eliminate Redundant Copies of Variables in Generated Code	50-7
When Redundant Copies Occur	50-7
How to Eliminate Redundant Copies by Defining Uninitialized Variables	50-7
Defining Uninitialized Variables	50-8
Reassignment of Variable Properties	50-9
Reuse the Same Variable with Different Properties . . .	50-10
When You Can Reuse the Same Variable with Different Properties	50-10
When You Cannot Reuse Variables	50-10
Limitations of Variable Reuse	50-12
Supported Variable Types	50-13

Defining Data for Code Generation

51

Data Definition for Code Generation	51-2
Code Generation for Complex Data	51-4
Restrictions When Defining Complex Variables	51-4
Code Generation for Complex Data with Zero-Valued Imaginary Parts	51-4

Results of Expressions That Have Complex Operands	51-7
Results of Complex Multiplication with Nonfinite Values	51-7
Encoding of Characters in Code Generation	51-9
Array Size Restrictions for Code Generation	51-10
Code Generation for Constants in Structures and Arrays	51-11
Code Generation for Strings	51-13
Limitations	51-13
Differences from MATLAB	51-13
Code Generation for Sparse Matrices	51-15
Code Generation Guidelines	51-15
Code Generation Limitations	51-15

Code Generation for Variable-Size Data

52

Code Generation for Variable-Size Arrays	52-2
Memory Allocation for Variable-Size Arrays	52-3
Enabling and Disabling Support for Variable-Size Arrays	52-3
Variable-Size Arrays in a MATLAB Function Report	52-4
Specify Upper Bounds for Variable-Size Arrays	52-5
Specify Upper Bounds for MATLAB Function Block Inputs and Outputs	52-5
Specify Upper Bounds for Local Variables	52-5
Define Variable-Size Data for Code Generation	52-7
Use a Matrix Constructor with Nonconstant Dimensions	52-7
Assign Multiple Sizes to the Same Variable	52-8
Define Variable-Size Data Explicitly by Using <code>coder.varsize</code>	52-8

Diagnose and Fix Variable-Size Data Errors	52-13
Diagnosing and Fixing Size Mismatch Errors	52-13
Diagnosing and Fixing Errors in Detecting Upper Bounds	52-15
Incompatibilities with MATLAB in Variable-Size Support for Code Generation	52-17
Incompatibility with MATLAB for Scalar Expansion . . .	52-17
Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays	52-19
Incompatibility with MATLAB in Determining Size of Empty Arrays	52-19
Incompatibility with MATLAB in Determining Class of Empty Arrays	52-21
Incompatibility with MATLAB in Matrix-Matrix Indexing	52-21
Incompatibility with MATLAB in Vector-Vector Indexing	52-22
Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation	52-23
Incompatibility with MATLAB in Concatenating Variable- Size Matrices	52-24
Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements	52-24
Variable-Sizing Restrictions for Code Generation of Toolbox Functions	52-26
Common Restrictions	52-26
Toolbox Functions with Restrictions for Variable-Size Data	52-27

Code Generation for MATLAB Structures

53

Structure Definition for Code Generation	53-2
Structure Operations Allowed for Code Generation	53-3

Define Scalar Structures for Code Generation	53-4
Restrictions When Defining Scalar Structures by Assignment	53-4
Adding Fields in Consistent Order on Each Control Flow Path	53-4
Restriction on Adding New Fields After First Use	53-5
Define Arrays of Structures for Code Generation	53-6
Ensuring Consistency of Fields	53-6
Using repmat to Define an Array of Structures with Consistent Field Properties	53-6
Defining an Array of Structures by Using struct	53-7
Defining an Array of Structures Using Concatenation	53-7
Index Substructures and Fields	53-8
Assign Values to Structures and Fields	53-10
Pass Large Structures as Input Parameters	53-12

Code Generation for Cell Arrays

54

Code Generation for Cell Arrays	54-2
Homogeneous vs. Heterogeneous Cell Arrays	54-2
Controlling Whether a Cell Array Is Homogeneous or Heterogeneous	54-3
Cell Arrays in Reports	54-3
Control Whether a Cell Array Is Variable-Size	54-5
Cell Array Limitations for Code Generation	54-8
Cell Array Element Assignment	54-8
Variable-Size Cell Arrays	54-9
Definition of Variable-Size Cell Array by Using cell . . .	54-10
Cell Array Indexing	54-14
Growing a Cell Array by Using {end + 1}	54-15
Cell Array Contents	54-16
Passing Cell Arrays to External C/C++ Functions	54-16

Code Generation for Categorical Arrays

55

Code Generation for Categorical Arrays	55-2
Define Categorical Arrays for Code Generation	55-2
Allowed Operations on Categorical Arrays	55-2
MATLAB Toolbox Functions That Support Categorical Arrays	55-4
Define Categorical Array Inputs	55-6
Define Categorical Array Inputs at the Command Line	55-6
Categorical Array Limitations for Code Generation	55-7

Code Generation for MATLAB Classes

56

MATLAB Classes Definition for Code Generation	56-2
Language Limitations	56-2
Code Generation Features Not Compatible with Classes	56-3
Defining Class Properties for Code Generation	56-4
Calls to Base Class Constructor	56-6
Inheritance from Built-In MATLAB Classes Not Supported	56-8
Classes That Support Code Generation	56-9
Generate Code for MATLAB Value Classes	56-10
Generate Code for MATLAB Handle Classes and System Objects	56-15

Code Generation for Handle Class Destructors	56-18
Guidelines and Restrictions	56-18
Behavioral Differences of Objects in Generated Code and in MATLAB	56-19
Class Does Not Have Property	56-22
Solution	56-22
Passing By Reference Not Supported for Some Properties	56-24
Handle Object Limitations for Code Generation	56-25
A Variable Outside a Loop Cannot Refer to a Handle Object Created Inside a Loop	56-25
A Handle Object That a Persistent Variable Refers To Must Be a Singleton Object	56-26
References to Handle Objects Can Appear Undefined	56-27
System Objects in MATLAB Code Generation	56-29
Usage Rules and Limitations for System Objects for Generating Code	56-29
System Objects in codegen	56-32
System Objects in the MATLAB Function Block	56-32
System Objects in the MATLAB System Block	56-32
System Objects and MATLAB Compiler Software	56-32

Code Generation for Function Handles

57

Function Handle Limitations for Code Generation	57-2
--	-------------

Defining Functions for Code Generation

58

Code Generation for Variable Length Argument Lists	58-2
--	-------------

Code Generation for Anonymous Functions	58-3
Anonymous Function Limitations for Code Generation	58-3
Code Generation for Nested Functions	58-4
Nested Function Limitations for Code Generation	58-4

Calling Functions for Code Generation

59

Resolution of Function Calls for Code Generation	59-2
Key Points About Resolving Function Calls	59-4
Compile Path Search Order	59-4
When to Use the Code Generation Path	59-5
Resolution of File Types on Code Generation Path	59-6
Compilation Directive %#codegen	59-8
Extrinsic Functions	59-9
Declaring MATLAB Functions as Extrinsic Functions	59-10
Calling MATLAB Functions Using feval	59-14
Extrinsic Declaration for Nonstatic Methods	59-14
Resolution of Extrinsic Functions During Simulation	59-15
Working with mxArray's	59-16
Restrictions on Extrinsic Functions for Code Generation	59-18
Limit on Function Arguments	59-18
Code Generation for Recursive Functions	59-19
Compile-Time Recursion	59-19
Run-Time Recursion	59-19
Disallow Recursion	59-20
Disable Run-Time Recursion	59-20
Recursive Function Limitations for Code Generation	59-20
Force Code Generator to Use Run-Time Recursion	59-22
Treat the Input to the Recursive Function as a Nonconstant	59-22

Make the Input to the Recursive Function Variable-Size	59-24
Assign Output Variable Before the Recursive Call	59-24
Avoid Duplicate Functions in Generated Code	59-26
Issue	59-26
Cause	59-26
Solution	59-26

Improve Run-Time Performance of MATLAB Function Block

60

Eliminate Redundant Copies of Function Inputs	60-2
Inline Code	60-5
Unroll for-Loops	60-6
Force Loop Unrolling by Using <code>coder.unroll</code>	60-6
Generate Reusable Code	60-8
LAPACK Calls for Linear Algebra in a MATLAB Function Block	60-9
BLAS Calls for Matrix Operations in a MATLAB Function Block	60-10

Troubleshooting MATLAB Code in MATLAB Function Blocks

61

Compile-Time Recursion Limit Reached	61-2
Issue	61-2
Cause	61-2
Solutions	61-2

Force Run-Time Recursion	61-2
Increase the Compile-Time Recursion Limit	61-5
Output Variable Must Be Assigned Before Run-Time Recursive Call	61-7
Issue	61-7
Cause	61-7
Solution	61-7
Unable to Determine That Every Element of Cell Array Is Assigned	61-11
Issue	61-11
Cause	61-11
Solution	61-13
Nonconstant Index into varargin or varargout in a for-Loop	61-16
Issue	61-16
Cause	61-16
Solution	61-17
Unknown Output Type for coder.ceval	61-19
Issue	61-19
Cause	61-19
Solution	61-19

Managing Data

Working with Data

62

About Data Types in Simulink	62-3
About Data Types	62-3
Data Typing Guidelines	62-4
Data Type Propagation	62-4
Data Types Supported by Simulink	62-6
Block Support for Data and Signal Types	62-6

Control Signal Data Types	62-8
Entering Valid Data Type Values	62-9
Use the Model Data Editor for Batch Editing	62-12
Share a Data Type Between Separate Algorithms, Data Paths, Models, and Bus Elements	62-13
Reuse Custom C Data Types for Signal Data	62-14
Determine Data Type of Signal That Uses Inherited Setting	62-15
Data Types Remain double Despite Changing Settings	62-16
Validate a Floating-Point Embedded Model	62-17
Apply a Data Type Override to Floating-Point Data Types	62-17
Validate a Single-Precision Model	62-17
Blocks That Support Single Precision	62-20
Fixed-Point Numbers	62-21
Binary Point Interpretation	62-22
Signed Fixed-Point Numbers	62-23
Benefits of Using Fixed-Point Hardware	62-24
Scaling, Precision, and Range	62-26
Scaling	62-26
Precision	62-27
Range	62-27
Fixed-Point Data in MATLAB and Simulink	62-29
Fixed-Point Data in Simulink	62-29
Fixed-Point Data in MATLAB	62-31
Scaled Doubles	62-32
Share Fixed-Point Models	62-33
Control Fixed-Point Instrumentation and Data Type Override	62-34
Control Instrumentation Settings	62-34
Control Data Type Override	62-34
Specify Fixed-Point Data Types	62-36
Overriding Fixed-Point Specifications	62-36

Specify Data Types Using Data Type Assistant	62-38
Specify a Fixed-Point Data Type	62-41
Specify an Enumerated Data Type	62-48
Specify a Bus Object Data Type	62-48
 Data Types for Bus Signals	 62-51
 Simulink Strings	 62-52

Load Data with Interchangeable Scenarios	64-266
Load Data with Interchangeable Scenarios Using Signal Editor Block	64-266
Replace Signal Builder Block with Signal Editor Block	64-270
Get Number of Scenarios and Signals	64-271
Load Signal Data That Uses Units	64-272
Loading Bus Signals That Have Units	64-272
Load Data Using the From File Block	64-274
Data Loading	64-274
Sample Time	64-275
Simulation Time Hits Without Corresponding Time Data	64-275
Duplicate Timestamps	64-275
Detect Zero Crossings	64-276
Create Data for a From File Block	64-276
Load Data Using the From Workspace Block	64-280
Specify the Workspace Data	64-281
Use Data from a To File Block	64-284
Load Dataset Data	64-284
Specifying Variable-Size Signals	64-284
Store Data for Model Linked to Data Dictionary	64-284
Sample Time	64-285
Interpolate Missing Data Values	64-285
Specify Output After Final Data	64-285
Detect Zero Crossings	64-285

State Information	64-287
Simulation State Information	64-287
Types of State Information	64-287
Format for State Information Saved Without Operating Point	64-290
State Information for Referenced Models	64-291
Save State Information	64-293
Save State Information for Each Simulation Step ...	64-293
Save Partial Final State Information	64-293
Examine State Information Saved Without the SimState	64-294
Save Final State Information with SimState	64-296
Load State Information	64-297
Import Initial States	64-297
Initialize a State	64-297
Initialize States in Referenced Models	64-299

Working with Data Stores

65

Data Store Basics	65-2
When to Use a Data Store	65-2
Local and Global Data Stores	65-3
Data Store Diagnostics	65-3
Specify Initial Value for Data Store	65-11
Model Global Data by Creating Data Stores	65-13
Data Store Examples	65-13
Create and Apply Data Stores	65-15
Data Stores with Data Store Memory Blocks	65-17
Data Stores with Signal Objects	65-20
Access Data Stores with Simulink Blocks	65-22
Order Data Store Access	65-25
Data Stores with Buses and Arrays of Buses	65-31
Accessing Specific Bus and Matrix Elements	65-32
Rename Data Stores	65-37
Customized Data Store Access Functions in Generated Code	65-39

Log Data Stores	65-40
Logging Local and Global Data Store Values	65-40
Supported Data Types, Dimensions, and Complexity for Logging Data Stores	65-40
Data Store Logging Limitations	65-41
Logging Data Stores Created with a Data Store Memory Block	65-41
Logging Icon for the Data Store Memory Block	65-41
Logging Data Stores Created with a Simulink.Signal Object	65-42
Accessing Data Store Logging Data	65-42

Simulink Data Dictionary

66

What Is a Data Dictionary?	66-2
Dictionary Capabilities	66-2
Sections of a Dictionary	66-3
Dictionary Usage for Models Created with Different Versions of Simulink	66-4
Manage and Edit Entries in a Dictionary	66-5
Dictionary Referencing	66-6
Import and Export File Formats	66-6
Allow Access to Base Workspace	66-6
 Migrate Models to Use Simulink Data Dictionary	 66-7
Migrate Single Model to Use Dictionary	66-7
Migrate Model Reference Hierarchy to Use Dictionary	66-8
Considerations before Migrating to Data Dictionary . . .	66-9
Continue to Use Shared Data in the Base Workspace .	66-13
Migrate Complicated Model Hierarchy with Shared Data	66-14
 Enumerations in Data Dictionary	 66-15
Migrate Enumerated Types into Data Dictionary	66-15
Manipulate Enumerations in Data Dictionary	66-18
 Import and Export Dictionary Data	 66-20
Import Data to Dictionary from File	66-20

Export Design Data from Dictionary	66-25
View and Revert Changes to Dictionary Data	66-27
View and Revert Changes to Dictionary Entries	66-27
View and Revert Changes to Entire Dictionary	66-31
Partition Dictionary Data Using Referenced Dictionaries	66-34
Partition Data for Model Reference Hierarchy Using Data Dictionaries	66-37
Create a Dictionary for Each Component	66-37
Strategies to Discover Shared Data	66-45
Store Data in Dictionary Programmatically	66-47
Add Entry to Design Data Section of Data Dictionary .	66-48
Increment Value of Data Dictionary Entry	66-48
Data Dictionary Management	66-48
Dictionary Section Management	66-50
Dictionary Entry Manipulation	66-51
Transition to Using Data Dictionary	66-51
Programmatically Migrate Single Model to Use Dictionary	66-52
Import Directly From External File to Dictionary	66-53
Programmatically Partition Data Dictionary	66-55
Make Changes to Configuration Set Stored in Dictionary	66-56

Start the Simulink Software

To build models, use the Simulink Editor and the Library Browser.

Start the MATLAB Software

Before you start Simulink, start MATLAB®. See “Startup and Shutdown” (MATLAB).

Configure MATLAB to Start Simulink

The first model that you open in a MATLAB session takes longer to open than subsequent models because, by default, MATLAB starts Simulink when opening the first model. This just-in-time starting of Simulink reduces MATLAB startup time and avoids unnecessary system memory use.

To speed up opening the first model, you can configure MATLAB startup to also start Simulink. To start Simulink without opening models or the Library Browser, use `start_simulink`.

Depending on how you start MATLAB, use the command:

- In the MATLAB `startup.m` file
- At the operating system command line, with the `matlab` command and the `-r` switch

For example, to start Simulink when MATLAB starts on a computer running the Microsoft® Windows® operating system, create a desktop shortcut with this target:

```
matlabroot\bin\win64\matlab.exe -r start_simulink
```

On Macintosh and Linux® computers, use this command to start Simulink when you start MATLAB:

```
matlab -r start_simulink
```

Open the Simulink Editor

To open the Simulink Editor, you can:

- Create a model. On the MATLAB **Home** tab, click **Simulink** and choose a model template.

Alternatively, if you already have the Library Browser open, click the **New Model** button . For additional ways to create a model, see “Create a Model” on page 1-5.

- Open an existing model. To open recent models, on the MATLAB **Home** tab, click **Simulink**.

Alternatively, if you know the name of the model you want, at the MATLAB command prompt, enter the name, such as `vdp`. For additional ways to open a model, see “Open a Model” on page 1-9.

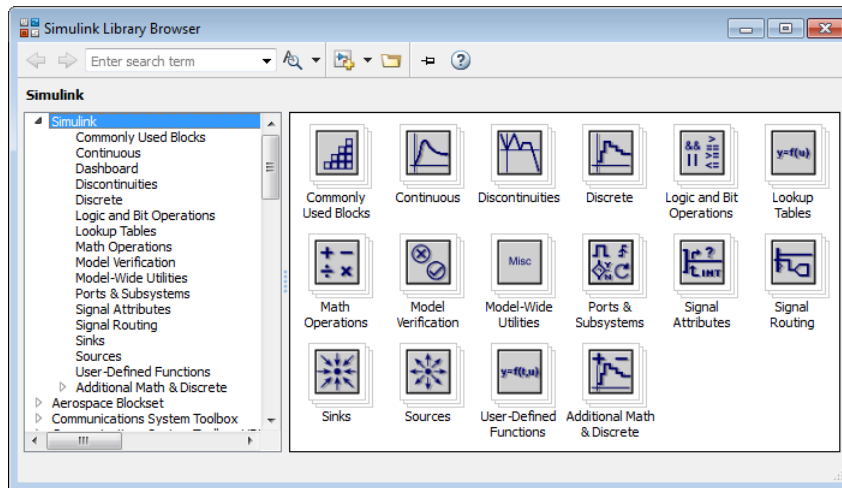

Tip The Simulink Editor opens on top of the MATLAB desktop. To move the MATLAB desktop on top, in the Simulink Editor, select **View > MATLAB Desktop**.

Open the Library Browser

Use any of these techniques to open the Simulink Library Browser from MATLAB:

- On the **Home** tab, click **Simulink**, and choose a model template. In the new model, click the **Library Browser** button .
- At the command prompt, enter `slLibraryBrowser`.

The Library Browser opens and displays a tree view of the Simulink block libraries on your system. As you click libraries in the tree, the contents of the library appear in the right pane.

Note Simulink comes with block libraries in addition to the Simulink library. These libraries support simulating supplied example models that contain blocks from those libraries. However, you can generate code or modify these blocks only with the relevant product licenses.

Create a Model

- 1 On the MATLAB **Home** tab, click **Simulink**.
- 2 In the Simulink start page, choose a template or search the templates.

Model templates are starting points to apply common modeling approaches. They help you reuse settings and block configurations and share knowledge. Use model and project templates to apply best practices and take advantage of previous modeling solutions.

Click the title of a template to read the description.

Digital Filter

By The MathWorks, Inc.

Create Model

Create a Simulink model to filter discrete-time signals. This model uses recommended configuration parameters for simulating discrete-time systems, including a discrete-time solver and no signal logging. This template shows how to use built-in Simulink blocks for very basic signal processing tasks, like filtering scalar signals using precomputed filter coefficients. To design signal processing systems in Simulink, use blocks from [DSP System Toolbox](#).

Search for templates by entering text in the search box. You can enter flexible search options including OR, AND, NOT, wildcards, fuzzy (~), etc. Use the Lucene search engine query parser syntax.

To locate templates that are not on the MATLAB search path, click **Open**. Model templates have the extension `.sltx`.

- 3 After selecting the template you want, click **Create Model**.

To use a template without reading the description, click the template image. Alternatively, press **Ctrl+N** to use your default template. To set a default template, see “Use Customized Settings When Creating New Models” on page 1-8.

A new model using the template settings and contents opens in the Simulink Editor. For next steps, see “Build and Edit a Model in the Simulink Editor” on page 1-24.

If the built-in templates do not meet your needs, try searching on the **Examples** tab, or you can create your own templates. See “Create a Template from a Model” on page 4-2. On the **Examples** tab, enter search terms to find examples titles and descriptions of interest, or open further examples on the web by clicking **View All** next to a product name.

Use Customized Settings When Creating New Models

You can specify a model template to use for all new models.

- 1 Create a model with the configuration settings and blocks you want, then export the model to a template. See “Create a Template from a Model” on page 4-2.
- 2 To reuse these settings in every new model, make the new template your default model template using the Simulink start page or the `Simulink.defaultModelTemplate` function.

In the start page, click the title of a template to expand the description, then click the down arrow next to **Create Model** and select **Set As Default**.

After you set a default model template, every new model uses that template, for example, when you press **Ctrl+N**, when you use new model buttons, or when you use `new_system`. In the Simulink Editor, your default template name is at the top of the list when you select **File > New > MyDefaultTemplateName**.

The default template shows a tick mark in the start page.

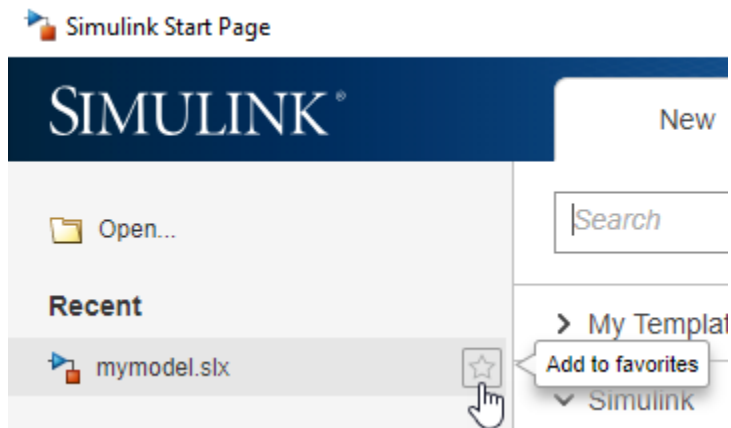

Open a Model

Opening a model loads the model into memory and displays it in the Simulink Editor. Use any of these techniques:

- On the MATLAB **Home** tab, click **Simulink**. In the Simulink Start Page, select a recent model or project from the list, or click **Open**.
- In the Simulink Editor, select **File > Open Recent** and choose a recent model.
- At the MATLAB command prompt, enter the name of the model without a file extension, for example, `vdp`. The model must be in the current folder or on the MATLAB search path.
- In the Simulink Library Browser, click the **Open model or library** button .
- Open the model using the Current Folder browser or your operating system file browser.

Tip Set favorites to easily get back to your favorite models and projects in the start page.

In the Simulink start page recent files list, you can add files to favorites. The Favorites list then appears above recent files in the start page, so that you can easily reopen your favorite models and projects.

To edit or clear the list of recent files in the start page, right-click a recent file and use the context menu.

Note To open a model created in a later version of Simulink software in an earlier version, first export the model to the earlier version. See “Export a Model to a Previous Simulink Version” on page 1-45.

Load Variables When Opening a Model

As you build models, you sometimes define variables for a model. For example, suppose that you have a model that contains a Gain block. You can specify the variable K as the gain rather than setting the value on the block. When you use this approach, you must define the variable K for the model to simulate.

You can use a model callback to load variables when you open a model.

- 1 In a model that uses the Gain block, set the block **Gain** value to K .
- 2 Define the variable in a MATLAB script. In MATLAB, select **New > Script**. In the script, enter your variable definitions:

```
K=27
```

- 3 Save the script as `loadvar.m`.

- 4 In the model, open the Property Inspector. Select **View > Property Inspector**. With no selection at the top level of a model, you can use the Property Inspector to set model properties. Otherwise, use **File > Model Properties**.
- 5 In the **Callbacks** section of the model properties, select `PreLoadFcn` as the callback that you want to define. In the pane, enter `loadvar`.
- 6 Save the model.

The next time that you open the model, the `PreLoadFcn` callback loads the variables into the MATLAB workspace.

To learn about callbacks, see “Callbacks for Customized Model Behavior” on page 4-50. To define a callback for loading variables programmatically, see “Programmatically Load Variables When Opening a Model” on page 1-14.

Open a Model with Different Character Encoding

If you open an MDL file that uses a particular character set encoding in a MATLAB session that uses a different encoding, a warning appears. For example, suppose that you create an MDL file in a MATLAB session configured for `Shift_JIS` and open it in a session configured for `US_ASCII`. The warning message shows the encoding of the current session and the encoding used to create the model.

SLX files do not warn because they can store characters from any encoding.

If you encounter any problems with corrupted characters, for example when using MATLAB files associated with the model, then try using the `slCharacterEncoding` function to change the character encoding of the current MATLAB session to match the model character encoding.

Simulink can check if models contain characters unsupported in the current locale. For more details, see “Check model for foreign characters” and “Save Models with Different Character Encodings” on page 1-43.

Simulink Model File Types

New models that you create have the `.slx` extension by default. Models created before R2012b have the extension `.mdl`. Models you can edit can have the `.slx` or `.mdl` extension, depending on when they were created or whether you converted them. See “Save Models in the SLX File Format” on page 1-41.

.slxp and .mdl extensions denote protected models that you cannot open and edit. See “Reference Protected Models from Third Parties” on page 8-20. Model templates have the extension .sltx.

Simulink libraries also use the .slx extension, but you cannot simulate them. To learn more, see “Create a Custom Library” on page 41-4.

“Open the Same Model in Multiple Windows” on page 1-18

“Get a Simulink Identifier” on page 1-18

“Specify Colors Programmatically” on page 1-22

You can perform most Simulink modeling basics programmatically at the MATLAB command prompt. The commands that correspond to basic modeling operations, such as creating models, adding blocks to models, and setting parameters, are listed in the Functions section of “Interactive Model Editing”. These examples show some of these commands and how you can use them.

Load a Model

Loading a model brings it into memory but does not open it in the Simulink Editor for editing. After you load a model, you can work with it programmatically. You can use the Simulink Editor to edit the model only if you open the model.

To load a system, use the `load_system` command. For example, to load the `vdp` model, at the MATLAB command prompt, enter:

```
load_system('vdp')
```

Create a Model and Specify Parameter Settings

You can write a function that creates a model and uses the settings that you prefer. For example, this function creates a model that has a green background and uses the `ode3` solver:

```
function new_model(modelname)
% NEW_MODEL Create a new, empty Simulink model
%   NEW_MODEL('MODELNAME') creates a new model with
%   the name 'MODELNAME'. Without the 'MODELNAME'
%   argument, the new model is named 'my_untitled'.

if nargin == 0
    modelname = 'my_untitled';
end

% create and open the model
open_system(new_system(modelname));

% set default screen color
set_param(modelname, 'ScreenColor', 'green');

% set default solver
set_param(modelname, 'Solver', 'ode3');

% save the model
save_system(modelname);
```

Programmatically Load Variables When Opening a Model

If you assign a variable as a block parameter value, you must define the value of the variable in the model. See “Load Variables When Opening a Model” on page 1-10. You can define the variable programmatically using the `PreloadFcn` callback with the `set_param` function. Use the function in this form:

```
set_param('mymodel', 'PreloadFcn', 'expression')
```

`expression` is a MATLAB command or a MATLAB script on your MATLAB search path. This command sets the model `PreloadFcn` callback to the value that you specify. Save the model to save the setting.

For example, when you define the variables in a MATLAB script `loadvar.m` for the model `modelname.slx`, use this command:

```
set_param('modelname', 'PreloadFcn', 'loadvar')
```

To assign the variable `K` the value `15`, use this command:

```
set_param('modelname', 'PreloadFcn', 'K=15')
```

After you save the model, the `PreloadFcn` callback executes when you next open the model.

Programmatically Add and Connect Blocks

This example shows how to use functions to add blocks and connect the blocks programmatically. Once you have added blocks to the model, you use three different approaches to connect them: routed lines, port handles, and port IDs. Routed lines allow you to specify the exact (x,y) coordinates of all connecting line segment endpoints. Port handles and port IDs allow connecting lines to block ports without having to know the port location coordinates.

Create and open a blank model named 'myModel'.

Add blocks, including a subsystem block. Use the `position` array in the `set_param` function to set the size and position of the blocks. Set the upper left and lower right block corners using (x,y) coordinates.

```
add_block('simulink/Sources/Sine Wave','myModel/Sine1');
set_param('myModel/Sine1','position',[140,80,180,120]);
add_block('simulink/Sources/Pulse Generator','myModel/Pulse1');
set_param('myModel/Pulse1','position',[140,200,180,240]);
add_block('simulink/Ports & Subsystems/Subsystem','myModel/Subsystem1');
set_param('myModel/Subsystem1','position',[315,120,395,200]);
add_block('simulink/Sinks/Scope','myModel/Scope1');
set_param('myModel/Scope1','position',[535,140,575,180]);
```

Inside `Subsystem1`, delete the default connection between `In1` and `Out1`. Also, add a second input port by copying and renaming `In1` from the block library.

```
delete_line('myModel/Subsystem1','In1/1','Out1/1');
add_block('simulink/Sources/In1','myModel/Subsystem1/In2');
```

Reposition the internal input and output port blocks inside `Subsystem1`.

```
set_param('myModel/Subsystem1/In1','position',[50,50,90,70]);
set_param('myModel/Subsystem1/In2','position',[50,130,90,150]);
set_param('myModel/Subsystem1/Out1','position',[500,80,540,100]);
```

Insert and position an `Add` block inside `Subsystem1`.

```
add_block('simulink/Math Operations/Add','myModel/Subsystem1/Add1');
set_param('myModel/Subsystem1/Add1','position',[250,80,290,120]);
```

Next, add lines to connect all the blocks in the model. Start by connecting the Sine1 and Pulse1 blocks using routed lines.

Find the (x,y) coordinates of the Sine1 output port.

```
Sine1_Port = get_param('mymodel/Sine1','PortConnectivity')
```

```
Sine1_Port =
```

```
    struct with fields:
```

```
        Type: '1'  
    Position: [185 100]  
    SrcBlock: []  
    SrcPort: []  
    DstBlock: [1x0 double]  
    DstPort: [1x0 double]
```

get_param shows that the port Position is [185 100].

Find the (x,y) coordinates of the Pulse1 output port.

```
Pulse1_Port = get_param('mymodel/Pulse1','PortConnectivity')
```

```
Pulse1_Port =
```

```
    struct with fields:
```

```
        Type: '1'  
    Position: [185 220]  
    SrcBlock: []  
    SrcPort: []  
    DstBlock: [1x0 double]  
    DstPort: [1x0 double]
```

get_param shows that the port position is [185 220].

Connect the output of Sine1 to the first input of Subsystem1 using three segments of routed line.

```
add_line('mymodel', [185 100; 275 100]);  
add_line('mymodel', [275 100; 275 140]);  
add_line('mymodel', [275 140; 310 140]);
```

Connect the output of `Pulse1` to the second input of `Subsystem1` using three segments of routed line.

```
add_line('mymodel', [185 220; 275 220]);
add_line('mymodel', [275 220; 275 180]);
add_line('mymodel', [275 180; 310 180]);
```

Use `get_param` to get the port handles of the blocks being connected. Then use the block port handles to connect the output of `Subsystem1` to the input of `Scope1`.

```
SubsysPortHandles = get_param('mymodel/Subsystem1', 'PortHandles');
ScopePortHandles = get_param('mymodel/Scope1', 'PortHandles');
add_line('mymodel', SubsysPortHandles.Output(1), ...
ScopePortHandles.Inport(1));
```

Use port names and IDs to connect the `Add1` block inside `Subsystem1` to the subsystem inputs and outputs. Simulink uses the most direct path to connect the ports.

```
add_line('mymodel/Subsystem1', 'In1/1', 'Add1/1');
add_line('mymodel/Subsystem1', 'In2/1', 'Add1/2');
add_line('mymodel/Subsystem1', 'Add1/1', 'Out1/1');
```

Name a Signal Programmatically

- 1 Select the block that is the source for the signal line.
- 2 Use `get_param` to assign the port handle of the currently selected block to the variable `p`. Use `get_param` to assign the name of the signal line from that port to the variable `l`. Then set the name of the signal line to `'s9'`.

```
p = get_param(gcf, 'PortHandles')
l = get_param(p.Output, 'Line')
set_param(l, 'Name', 's9')
```

Arrange Model Layouts Automatically

You can use the `Simulink.BlockDiagram.arrangeSystem` command to lay out your model. This command aligns input blocks on the left, output blocks on the right, and model elements in columns between the inputs and outputs. The command affects only one layer at a time.

You can use the `Simulink.BlockDiagram.routeLine` command to route existing lines of your model. Routing existing lines improves line route quality and avoids overlaps of a line with other lines and obstacles in the model.

While you can use these commands with any open model, they are particularly useful with models you build programmatically. For an example, see “Arrange a Programmatically Populated Model”.

Open the Same Model in Multiple Windows

When you open a model, the model appears in a Simulink Editor window. For example, if you have one model open and then you open a second model, the second model appears in a second window.

To open the same model in two Simulink Editor windows, at the MATLAB command prompt, enter the `open_system` command and use the `window` argument. For example, if you have the `vdp` model open, to open another instance of the `vdp` model, enter:

```
open_system('vdp','window')
```

Get a Simulink Identifier

Every block in your model has a Simulink Identifier (SID), a unique and unmodifiable identifier. The SID persists for the lifetime of the object and is saved with a model. If the name of the object changes, the SID stays the same. The SID has the form `model_name:number`.

Locate Diagram Components Using Simulink Identifiers

A Simulink Identifier (SID) is a unique designation automatically assigned to a Simulink block, model annotation, or Stateflow® object within a Stateflow chart. The SID helps to identify specific instances of these components in your diagram, especially when sharing models between people within a team.

To highlight a component visually within the model, get the SID and use it with the `Simulink.ID.hilite` function.

The SID has these characteristics:

- Persistent within the lifetime of a Simulink block, model annotation, or Stateflow object

- Saved in the model file
- Remains the same if the block or object name changes
- Cannot be modified

The SID format is:

```
model_name:sid_number
```

- `model_name` is the name of the model where the block, annotation, or Stateflow object resides.
- `sid_number` is a unique number within the model, assigned by Simulink.

The SID includes additional colons in certain cases, for example on an instance of a block from a user library.

Highlight Block

- 1** To open the model `vdp`, enter `vdp` at the MATLAB command prompt.
- 2** Get the SID of the Mu block.

```
Simulink.ID.getSID('vdp/Mu')
```

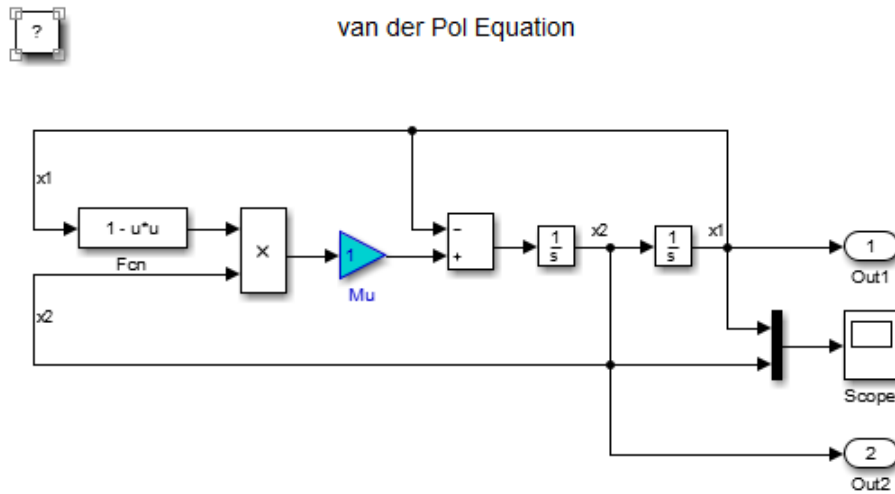

```
ans =
```

```
vdp:4
```

- 3** Use the SID to highlight the block.

```
Simulink.ID.hilite('vdp:4')
```

The block appears highlighted in the model:

Highlight Annotation

- 1 Open the model vdp.
- 2 Select the annotation at the top of the diagram.
- 3 Get the annotation object for the selected annotation.

```
ann = getSelectedAnnotations('vdp')
```

```
ann =
```

```
Simulink.Annotation
```

- 4 Get the SID of the annotation.

```
ann.SIDFullString
```

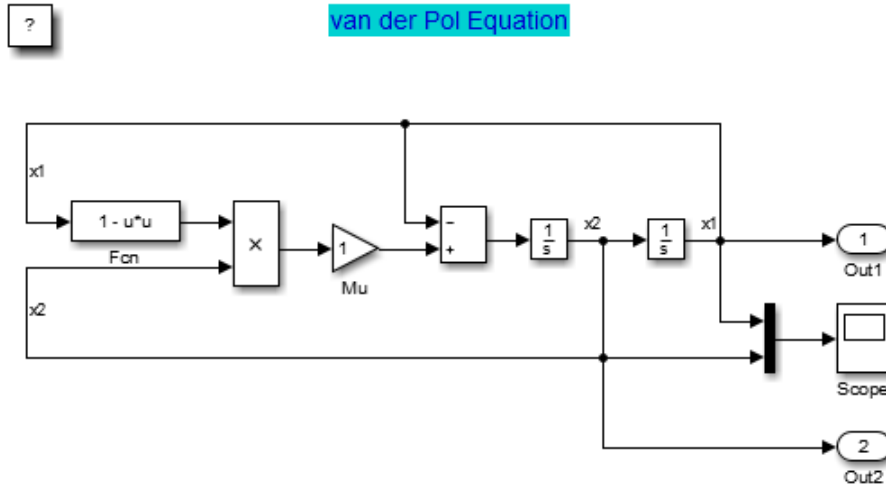

```
ans =
```

```
vdp:13
```

- 5 Use the SID to highlight the annotation.

```
Simulink.ID.hilite('vdp:13')
```

The annotation appears highlighted in the model:

Highlight Stateflow Object

- 1 Open the model `sf_resolve_signal_object`.
- 2 Get the SID of the Signal Object Chart Stateflow object:

```
Simulink.ID.getSID('sf_resolve_signal_object/Signal Object Chart')
```

```
ans =
```

```
sf_resolve_signal_object:1
```

- 3 Use the SID to highlight the object.

```
Simulink.ID.hilite('sf_resolve_signal_object:1')
```

The object appears highlighted in the model.

Resolve Signal Object

Specify Colors Programmatically

You can use the `set_param` command at the MATLAB command line or in a MATLAB program to set parameters that determine the background color of a diagram and the background color and foreground color of diagram elements. The following table summarizes the parameters that control block diagram colors.

Parameter	Determines
ScreenColor	Block diagram background
BackgroundColor	Block and annotation background
ForegroundColor	Block and annotation foreground

Set the color parameter to either a named color or an RGB value.

- Named color: 'automatic', 'black', 'white', 'red', 'green', 'blue', 'cyan', 'magenta', 'yellow', 'gray', 'lightBlue', 'orange', 'darkGreen'
- RGB value: '[r,g,b]'

where *r*, *g*, and *b* are the red, green, and blue components of the color normalized to the range 0.0 to 1.0.

For example, the following command sets the background color of the currently selected system or subsystem to a light green color:

```
set_param(gcs, 'ScreenColor', '[0.3, 0.9, 0.5]')
```

“Simulate Model and View Results” on page 1-34

“Modify the Model” on page 1-35

This example shows the basics of how to create a model, add blocks to it, connect blocks, and simulate the model. You also learn how to organize your model with subsystems, name parts of a model, and modify a model.

For a summary of mouse actions to connect blocks and add ports interactively, see “Block and Signal Line Shortcuts and Actions” on page 1-93.

Start Simulink and Create a Model

- 1 On the MATLAB **Home** tab, click **Simulink**.
- 2 In the Simulink Start Page, click the **Blank Model** template.

A new model based on the template opens in the Simulink Editor.

- 3 Open the Library Browser so that you can access the blocks you need to add to your model. In the Simulink Editor, click the **Library Browser** button .

Add Blocks to the Model

A minimal model takes an input signal, operates on it, and outputs the result. In the Library Browser, the Sources library contains blocks that represent input signals. The Sinks library has blocks for capturing and displaying outputs. The other libraries contain blocks you can use for a variety of purposes, such as math operations.

In this example of a basic model, the input is a sine wave, the operation is a gain (which increases the signal value by multiplying), and you output the result to a scope. Try different techniques to explore the library and to add blocks to your model.

- 1 Open the Sources library. In the tree view of the Library Browser, click the **Sources** library.
- 2 In the right pane, hover over the Sine Wave block to see a tooltip describing its purpose.
- 3 Add a block to your model using a context menu. Right-click the Sine Wave block and select **Add block to model untitled**. To learn more about the block, select **Help** from the context menu.
- 4 Add a block to your model by dragging. In the library tree view, click **Math Operations**. In the Math Operations library, locate the Gain block and drag it to your model to the right of the Sine Wave block.
- 5 In the library tree view, click **Simulink** to view the sublibraries as icons in the right pane. This view is an alternative way to navigate the library structure. Double-click the **Sinks** library icon.
- 6 In the Sinks library, locate the Scope block and add it to your model using the context menu or by dragging it.

The figure shows your model so far.

Note The editor names blocks as you add them. For example, it names the first Gain block that you add Gain, the next Gain1, and so on. By default, the Simulink Editor hides these names. However, you can see the name by selecting the block. You can also explicitly name a block so that the name appears. You can display all names given by the editor by selecting **Display** and clearing the **Hide Automatic Names** check box. For more information on displaying block names, see “Manage Block Names” on page 36-13.

Align and Connect Blocks

Connect the blocks to create the relationships between model elements that are needed to make the model operate. Reading the model is easier when you line up blocks according to how they interact with each other. Shortcuts help you to align and connect blocks.

- 1 Drag a Gain block so it lines up with a Sine Wave block. An alignment guide appears when the blocks line up horizontally.
- 2 Release the block, and a blue arrow appears as a preview of the suggested connection.

- 3 To make the connection, click the arrow. A solid line appears in place of the guide.
- 4 Line up and connect the Scope block to the Gain block using the same technique. Additional guides appear when multiple blocks are within range.

Tip Use the **Diagram > Arrange** menu for additional alignment options.

Set Block Parameters

You can set parameters on most blocks. Parameters help you to specify how a block operates in the model. You can use the default values or you can set values. Use the Property Inspector to set parameters. Alternatively, you can double-click most blocks to set the parameters using a block dialog box. To understand when to use each approach, see “Setting Properties and Parameters” on page 1-52.

In your model, set the sine wave amplitude and the gain value.

- 1 Display the Property Inspector. Select **View > Property Inspector**.
- 2 Select the Sine Wave block.
- 3 In the Property Inspector, set the **Amplitude** parameter to 2.
- 4 For blocks whose value appears on the icon, you can edit the parameter interactively. Select the Gain block. Hover over the block. A blue underline appears under the number.
- 5 Set the **Gain** parameter to 3. Click the underlined number, delete it, and type 3.

In a block dialog box or in the Property Inspector, when you set a block parameter value to a variable or function, Simulink provides a suggested list to select from based on the current text typed in the edit field. The suggestions include relevant variables or objects from every workspace (base, model, and mask), data dictionary, and referenced dictionary visible to the editable block parameter. Autocomplete is available for variables, fields of structures and objects, and functions on the MATLAB path.

Add More Blocks

Suppose that you want to perform another gain but on the absolute value of the output from the Sine Wave block. Add blocks for this purpose, trying different techniques for locating blocks in the library and adding them to your model.

- 1 If you know the name of the block that you want to add, you can use a shortcut. Click where you want to add the block, and type the block name, in this case Gain.

The list of suggestions shown are dynamically ranked based on your recent block usage history.

- 2 Click the block name or, with the block name highlighted, press **Enter**. You can use the arrow keys to highlight the block name if it is not first in the list.
- 3 Some blocks display a prompt for you to enter a value for one of the block parameters. The Gain block prompts you to enter the **Gain** value. Type 3 and press **Enter**.
- 4 To perform an absolute value, add an Abs block. Suppose you do not know the library a block is in or the full name of the block. You can search for it using the search box in the Library Browser. Enter **abs** in the search box and press **Enter**. When you find the Abs block, add it to the left of the new Gain block.
- 5 Add another Scope block. You can right-click the existing Scope block and drag to create the copy or use the **Copy** and **Paste** commands.

The figure shows the current state of the model.

Branch a Connection

The input to the second Gain block is the absolute value of the output from the Sine Wave block. To use a single Sine Wave block as the input to both gain operations, create a branch from the Sine Wave block output signal.

- 1 For the first set of blocks in your model, you used the horizontal alignment guides to help you align and connect them. You can also use guides to align blocks vertically. Drag the second Scope block so that it lines up under the first one. Release it when the vertical alignment guide shows that the blocks are aligned.

- 2 You can click two ports to connect them. After you click the first port, compatible ports appear highlighted. Click another port to connect.

Align and connect the blocks as shown.

- 3 Create a branch from the Sine Wave block output to the Abs block. Click the input port of the Abs block. Move the cursor toward the output signal line from the Sine Wave block. A preview line appears. Click to create the branch.

Alternatively, you can start the branch by clicking the line segment and then moving the cursor toward the port.

- 4 Name signals. Double-click the signal between the lower Gain block and the Scope block and type Scope. Double-click the line and not a blank area of the canvas. For other techniques that you can use with signal names, see “Signal Name and Label Actions” on page 1-95.

Try these methods to add or connect blocks:

- Drag from a block port and release so that a red, dotted line appears. Double-click the end of the line to use the block insertion shortcut. Suggested blocks for the current context appear on the menu. You can select one of the listed blocks.

To improve the menu suggestions based on your model designs, see “Improve Quick Block Insert Results” on page 70-27.

- Double-click and then type the name of a block to get a list of blocks that starts with the characters you typed. For custom library blocks, you can type the block keyword if

the library author assigned one. The list is ranked based on your recent block-usage history.

- After you click a port, hold **Shift** as you connect to another port. Holding **Shift** puts you in a mode in which you can make multiple, consecutive connections. For example, while holding **Shift**, you can branch a new signal line and connect it to another port or signal line with one click.
- Select the first block and **Ctrl+click** the block you want to connect it to. This technique is useful when you want to connect blocks that have multiple inputs and outputs, such as multiple blocks to a bus or two subsystems with multiple ports. As with clicking two ports, this technique is useful when you do not want to align blocks. The signal line bends as needed to make the connection.

To approximate a diagonal line from line segments, press **Shift** and drag a vertex.

Tip To improve the shape of a signal line, select the line and, from the action bar, select **Auto-route Line**. The line redraws if a better route between model elements is possible. You can select **Auto-route Lines** from the action bar to improve lines with a single block selected or with multiple model elements selected by dragging a selection box.

Organize Your Model Into Components

You can group blocks in subsystems and label blocks, subsystems, and signals. For more information about subsystems, see “Create a Subsystem” on page 4-24.

- 1 Drag a selection box around the Abs block and the Gain block next to it.
- 2 Move the cursor over the ellipses that appear at the corner of the box where you ended the selection. From the action bar, select **Create Subsystem**.

A subsystem block appears in the model in place of the selected blocks.

To resize the subsystem block for the best fit in your model, drag the block handles.

- 3 Give the subsystem a meaningful name. Select the block, double-click the name, and type **Absolute Value**. Naming a block causes the name to appear in the model.
- 4 Open the Absolute Value subsystem by double-clicking it.

Tip To use the Explorer Bar to navigate the model hierarchy, right-click the subsystem and select **Open in New Tab**.

The subsystem contains the blocks and signal that you selected as the basis of the subsystem. They are connected in sequence to two new blocks: an Inport block and an Outport block. Inport and Outport blocks correspond to the input and output ports on the subsystem. Creating the subsystem from a selection that includes a named signal adds the name of the signal to the corresponding Inport or Outport block.

- 5 Click the **Up to Parent** button  to return to the top level of the model.
- 6 The figure shows the model after you create the subsystem and name it.

Simulate Model and View Results

- 1 You can simulate a model using the **Simulation > Run** command (**Ctrl+T**) or the **Run** button . Simulate the model using the technique that you prefer.

In this example, simulation runs for 10 seconds, the default setting.

- 2 Double-click both Scope blocks to open them and view the results.

The figure shows the two results. In the second plot, as expected, the absolute value of the sine wave is always positive.

Modify the Model

You can add blocks to a signal, remove blocks from models, and redraw connections. To modify this model, add a bias to the input to both branches of your model. Also, replace one of the scopes with a different sink. Add more blocks to the subsystem and another output.

- 1 Add a Bias block to the model and set the **Bias** parameter to 2.
- 2 Drag the block onto the signal line after the Sine Wave block but before the branch. If you need to make room for the block, drag the Sine Wave block to the left or move the end of the branch by dragging it to the right.

When you drag the block onto the signal line, the block connects to the signal line at both ends. Release the block when you are satisfied with the position.

- 3 Remove the top Scope block. Press **Shift** and drag the block if you want to disconnect it from the model but do not want to delete it. Cut or delete it using the **Edit** menu commands or a keystroke. The broken connection appears as a red dotted line.

Tip When you delete a block that has one input and one output, a prompt appears between the broken connection lines. Click the prompt to connect the signals.

- 4 Add a To Workspace block to the model at the end of the broken connection. The To Workspace block outputs the results to a variable in the MATLAB workspace.
- 5 Add a Sine Wave block to the model and set the amplitude to 5. Place it to the left of the subsystem.
- 6 Add another input to the subsystem. Drag a line from the new Sine Wave block to the left side of the subsystem. A new port, In2, appears on the subsystem.

For certain blocks, dragging a line to it adds an input port or output port. For example, a port appears on a subsystem when you connect a line to it. Other blocks that add ports include the Bus Creator, Scope, and Add, Sum, and Product blocks.

- 7 Add an output to the subsystem. Add another To Workspace block to the model and place it to the right of the subsystem. Drag a line from its input port to the right side of the subsystem. A new port, Out2, appears on the subsystem.

- 8 Open the subsystem and rename the Out2 block Workspace. Add a Manual Switch block to the subsystem. Resize it and connect it as shown. Branch the signal after the Gain block to direct the output to the To Workspace block.

Then, return to the top level of the model. The figure shows the current model.

- 9 Simulate the model.

- The `simout` and `simout1` variables appear in the MATLAB workspace. Double-click each variable to explore the results.
- If you want to use the second sine wave as input to the subsystem algorithm, open the subsystem and double-click the switch. The input changes to In2. Simulate again.

Tip To toggle between simulating the model with and without the effects of the Bias block, right-click the Bias block and select **Comment Through**. The block stays in the model but does not affect the operation. Right-click the Bias block and select **Uncomment** to enable the block. The **Comment Out** command comments out the block's output signal, so signal data does not pass through. Try each of these commands to better understand their effects.

“Export a Model to a Previous Simulink Version” on page 1-45

“Save from One Earlier Simulink Version to Another” on page 1-46

How to Tell If a Model Needs Saving

To tell whether a model needs saving, look at the title bar in the Simulink Editor. If the model needs saving, an asterisk appears next to the model name in the title bar (known as the dirty flag: *).

To determine programmatically whether a model needs saving, use the model parameter `Dirty`. For example:

```
if strcmp(get_param(gcs,'Dirty'),'on')
    save_system;
end
```

Save a Model

To save a model for the first time, in the Simulink Editor, select **File > Save**. Provide a location and name for the model file. For name requirements, see “Model Names” on page 1-40.

To save a previously saved model:

- To replace the file contents, in the Simulink Editor, select **File > Save**.
- To save the model with a new name or location, or to change from MDL to SLX format, in the Simulink Editor, select **File > Save As**.

Note For details about the SLX format, see “Upgrade Models to SLX” on page 1-42.

- To save the model in a format compatible with the earlier version, select **File > Export Model to > Previous Version**. See “Export a Model to a Previous Simulink Version” on page 1-45.

Model Names

Model file names must start with a letter and can contain letters, numbers, and underscores. The file name must not be:

- A language keyword (e.g., `if`, `for`, `end`)
- A reserved name: `'simulink'`, `'sl'`, `'sf'`
- A MATLAB software command

The total number of characters in the model name must not be greater than a certain maximum, usually 63 characters. To find out whether the maximum for your system is greater than 63 characters, use the MATLAB `namelengthmax` command.

Note Copying and pasting blocks whose names follow numeric order (`Gain1`, `Gain2`, and so on) creates names that follow standard sorting order conventions for ASCII characters. This sorting order can result in a sequence of numbers on the block names that is hard to understand. If the numbering scheme is important to you, name your blocks explicitly such that copying and pasting them creates names that follow a typical reading order. To do so, use a leading zero in the block names, for example `Gain001`, `Gain002`, and so on.

To understand how MATLAB determines which function to call when you specify a model name, see “Function Precedence Order” (MATLAB).

What Happens When You Save a Model?

Simulink saves the model (block diagram) and block properties in the model file.

If you have any pre- or post-save functions, they execute in this order:

- 1 All block `PreSaveFcn` callback routines execute first, then the model `PreSaveFcn` callback routine executes.
- 2 Simulink writes the model file.
- 3 All block `PostSaveFcn` callback routines execute, then the model `PostSaveFcn` executes.

During the save process, Simulink maintains a temporary backup copy (named *modelName.bak*) for restoring in case of an error. If an error occurs during saving or during any callback during the save process, Simulink:

- Restores the original file
- Writes any content saved before the error occurred in a file named *modelName.err*
- Issues an error message

When saving a model loaded from an SLX file, the original SLX file must still be present. Simulink performs incremental loading and saving of SLX files, so if the original file is missing at save-time, Simulink warns that it cannot reconstruct the file fully.

Save Models in the SLX File Format

Save New Models as SLX

Simulink saves new models and libraries in the SLX format by default, with file extension `.slx`. SLX is a compressed package that conforms to the Open Packaging Conventions (OPC) interoperability standard. SLX stores model information using Unicode® UTF-8 in XML and other international formats. Saving Simulink models in the SLX format:

- Typically reduces file size compared to MDL. The file size reduction between MDL and SLX varies depending on the model.
- Solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters.
- Enables incremental loading and saving. Simulink optimizes performance and memory usage by loading only required parts of the model and saving only modified parts of the model.

You can specify your file format for saving new models and libraries with the Simulink preference “File format for new models and libraries”.

Upgrade Models to SLX

If you upgrade an MDL file to SLX file format, the file contains the same information as the MDL file, and you always have a backup file. All functionality and APIs that currently exist for working with models, such as the `get_param` and `set_param` commands, are also available when using the SLX file format. If you upgrade an MDL file to SLX file format without changing the model name or location, then Simulink creates a backup file by renaming the MDL (if writable).

If you save an existing MDL file using **File > Save**, Simulink respects the file's current format and saves your model in MDL format.

To save an existing MDL file in the SLX file format:

- 1 Select **File > Save As**.
- 2 Leave the default **Save as type** as SLX, and click **Save**.

Simulink saves your model in SLX format, and creates a backup file by renaming the MDL (if writable) to `mymodel.mdl.releasename`, e.g., `mymodel.mdl.R2010b`.

Alternatively, use `save_system`:

```
save_system mymodel mymodel.slx
```

This command creates `mymodel.slx`, and if the existing file `mymodel.mdl` is writable it is renamed `mymodel.mdl.releasename`.

SLX files take precedence over MDL files, so if both exist with the same name and you do not specify a file extension, you load the SLX file.

Simulink Projects can help you migrate files to SLX. For an example, see “Upgrade Model Files to SLX and Preserve Revision History” on page 17-18.

Caution If you use third-party source control tools, be sure to register the model file extension `.slx` as a binary file format. If you do not, these third-party tools might corrupt SLX files when you submit them.

Operations with Possible Compatibility Considerations when using SLX	What Happens	Action
Hard-coded references to file names with extension <code>.mdl</code> .	Scripts cannot find or process models saved with new file extension <code>.slx</code> .	Make your code work with both the <code>.mdl</code> and <code>.slx</code> extension. Use functions like <code>which</code> and <code>what</code> instead of file names.
Third-party source control tools that assume a text format by default.	Binary format of SLX files can cause third-party tools to corrupt the files when you submit them.	Register <code>.slx</code> as a binary file format with third-party source control tools. Also recommended for <code>.mdl</code> files. See “Register Model Files with Source Control Tools” on page 19-10.
Changing character encoding.	Some cases are improved, e.g., SLX solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters. However, sharing models between different locales remains problematic.	See “SLX Files and Character Encodings” on page 1-44.

The format of content within MDL and SLX files is subject to change. To operate on model data, use documented APIs (such as `get_param`, `find_system`, and `Simulink.MDLInfo`).

Save Models with Different Character Encodings

- “MDL Files and Character Encodings” on page 1-44
- “SLX Files and Character Encodings” on page 1-44

MDL Files and Character Encodings

When you save a model, the current character encoding is used to encode the text stored in the model file. With MDL files, this can lead to model corruption if you save a model whose original encoding differs from current encoding.

If you change character encoding, it is possible to introduce characters that cannot be represented in the current encoding. If this is the case, the model is saved as *model.mdl.err*, where *model* is the model name, leaving the original model file unchanged. Simulink also displays an error message that specifies the line and column number of the first character which cannot be represented.

To recover from this error, either:

- Save the model in SLX format (see “Save Models in the SLX File Format” on page 1-41).
- Locate and remove characters one by one.
 - 1 Use a text editor to find the character in the *.err* file at the position specified by the save error message.
 - 2 Find and delete the corresponding character in the open model and resave the model.
 - 3 Repeat this process until you are able to save the model without error.

It's possible that your model's original encoding can represent all the text changes made in the current session, albeit incorrectly. For example, suppose you open a model whose original encoding is A in a session whose current encoding is B. Further suppose that you edit the model to include a character that has different encodings in A and B and then save the model. If in addition the encoding for x in B is the same as the encoding for y in A, and if you insert x in the model while B is in effect, save the model, and then reopen the model with A in effect the Simulink software will display x as y. To alert you to the possibility of such corruptions, a warning message appears whenever you save a model in which the current and original encoding differ but the original encoding can encode, possibly incorrectly, all of the characters to be saved in the model file.

SLX Files and Character Encodings

Saving Simulink models in the SLX format typically reduces file size and solves some problems in previous releases with loading and saving MDL files containing Korean and Chinese characters.

Considerations for choosing a model file format:

- Use SLX if you are loading and saving models with Korean or Chinese characters
- Use SLX if you would benefit from a compressed model file
- Whether you use SLX or MDL, Simulink can detect and warn if models contain characters unsupported in the current locale. For SLX, you can use the Model Advisor to help you, see “Check model for foreign characters”.

Export a Model to a Previous Simulink Version

You can export (save) a model created with the latest version of the Simulink software in a format used by an earlier version. For example, to share a model with colleagues who only have access to a previous version of the Simulink product.

To export a model in an earlier format:

- 1** In the Simulink Editor, select **File > Save**. This saves a copy in the latest version of Simulink. This step avoids compatibility problems.
- 2** Simulink Editor, select **File > Export Model to > Previous Version**.

The Export to Previous Version dialog box appears.

- 3** In the dialog box, from the **Save as type** list, select the previous version to which to export the model. The list supports 7 years of previous releases.
- 4** Click the **Save** button.

When you export a model to a previous version’s format, the model is saved in the earlier format, regardless of whether the model contains blocks and features that were introduced after that version. If the model does contain blocks or use features that postdate the earlier version, the model might not give correct results when you run it in the earlier version of Simulink software. In addition, Simulink converts blocks that postdate an earlier version into yellow empty masked Subsystem blocks. For example, if you use `save_system` to export a model to Release R2007b, and the model contains Polynomial blocks, Simulink converts the Polynomial blocks into yellow empty masked Subsystem blocks. Simulink also removes any unsupported functionality from the model. See `save_system`.

Save from One Earlier Simulink Version to Another

You can open a model created in an earlier version of Simulink and export that model to a different earlier version. To prevent compatibility problems, use the following procedure if you need to save a model from one earlier version to another earlier version.

- 1 Use the current version of Simulink to open the model created with the earlier version.
- 2 Before you make any changes, save the model in the current version by selecting **File > Save**.

After saving the model in the current version, you can change and resave it as needed.

- 3 Save the model in the earlier version of Simulink by selecting **File > Export Model to > Previous Version**.
- 4 Start the earlier Simulink version and use it to open the model that you exported to that earlier version.
- 5 Save the model in the earlier version by selecting **File > Save**.

You can now use the model in the earlier version of Simulink exactly as you could if it had been created in that version.

See also the Simulink preferences that can help you work with models from earlier versions:

- “Do not load models created with a newer version of Simulink”
- “Save backup when overwriting a file created in an older version of Simulink”

Model Editing Environment

In this section...

“Simulink Editor” on page 1-47

“Interactive Model Building” on page 1-49

“Model Design Error Detection” on page 1-50

“Library Browser” on page 1-50

“Setting Properties and Parameters” on page 1-52

The Simulink model editing environment consists of two main tools: the Simulink Editor and the Library Browser. You find the blocks for your model in the Library Browser and build the model by adding and connecting the blocks in the Simulink Editor.

Simulink Editor

The Simulink Editor is an intuitive tool for building models. In addition to providing standard methods for working with diagrams in a vector graphics editor, the editor provides shortcuts that help you to add and connect blocks. The Simulink Editor also gives you access to the tools you need for technical operations such as importing data, simulating your model, and analyzing model performance.

The figure shows the Simulink Editor with the example model vdp open.

The Simulink Editor has menus of commands and a toolbar of shortcuts for performing frequent operations or opening tools. Tooltips appear when you hover over the toolbar buttons. Commands also appear on context menus. Context menus appear when you right-click a model element or a blank area of the editor. For example, right-click a block, and the menus display the commands relevant for working on blocks, such as clipboard and alignment operations. Some commands appear only on a context menu.

Palette

The palette along the left side of the editor provides more shortcuts. The palette shortcuts have to do with the model appearance and how you navigate the model rather than how you build and operate it. For example, the palette includes a shortcut for adding annotations and other visuals, like boxed-in areas for labeling the model. It also provides a zoom button for zooming on a particular part of the model.

The **Hide/Show Explorer Bar** button displays a bar that shows where you are in the model hierarchy as you navigate. The **Hide/Show Model Browser** button displays a hierarchical view of the model that you can use to navigate. See “Explore the Model Hierarchy Using the Model Browser” on page 12-45.

Additional Model Views

The control in the lower-right corner opens additional views of the model. One such view is the interface view, which helps you to trace model interfaces. Click the control to see these views.

Interactive Model Building

When you build a model in the Simulink Editor, you use common techniques for working with graphics objects. Some of these actions include:

- Selection using click, shift-click, and dragging
- Resizing objects using handles and moving objects by dragging
- Clipboard operations, that is, cut, copy, and paste
- Undo/redo (up to 101 operations)

Note After you undo or redo block parameter changes, a visual cue appears that shows the current values of the affected parameters. Some parameter changes are not affected by the Undo or Redo commands. After you undo or redo changes to block parameters, use the cue to see the parameters affected.

A small subset of parameters do not support Undo. Changing these parameters clears the Undo history, whether you make the change in the Property Inspector or in the block dialog box.

You zoom and scroll the editing area using familiar methods, such as the commands on the **View > Zoom** menu. If you are using a supported touch display platform, you can pinch to zoom and swipe to scroll. The supported touch display devices include Microsoft

Windows platforms with a Windows 7 certified or Windows 8 certified touch display and Macintosh platforms with an Apple Magic Trackpad.

The editor supports additional shortcuts for scrolling that are unique to Simulink. Shortcuts and the other interactive model building techniques are summarized in “Keyboard and Mouse Actions for Simulink Modeling” on page 1-92. For a tutorial, see “Build and Edit a Model in the Simulink Editor” on page 1-24.

Model Design Error Detection

The Simulink Editor can provide you with visual cues for some model design issues. In the model editor, highlighted blocks alert you to issues while you edit. To see a description of the issue, hover over a highlighted block and click the error or warning symbol.

Similar to the Diagnostic Viewer, if an error or warning has a predefined fix, the notification dialog box can provide you with suggested actions along with corresponding **Fix** buttons.

Simulink can detect block errors and warnings, such as:

- Goto and From block mismatches.
- Duplicate data store blocks. The value of the Duplicate data store names parameter determines if there is a visual cue, and if the cue is an error or warning.

The **Errors and Warnings** option is enabled by default. To turn off this option, deselect **Display > Errors & Warnings**.

Library Browser

Use the Library Browser to locate blocks and visuals (annotations) to add to your model. Navigate the libraries using the tree structure in the left pane or by double-clicking

sublibraries in the right pane. Sublibraries, blocks, and text and image annotations can appear in the right pane. Hover over any item to see a description.

When you find the item you are looking for, you can drag it into your model, or you can select it and use the context menu to add it.

Tip The Recently Used Blocks structure at the bottom of the tree contains the blocks and libraries from the supplied libraries that you used most recently.

You can search for blocks and annotations using the search controls. To use regular expressions, whole word search, or case-sensitive search, use the **Search for subsystems, blocks, and annotations** button arrow . For annotations, you can search for any of the text in the annotation or any part of its description.

By default, library contents appear in alphabetical order. Subsystems appear first, then blocks, and then annotations. If you prefer to view the contents of the libraries in the

order set by the developer of the library, right-click the right pane and select **Sort in library model order**. This setting stays in effect from session to session.

To return to the alphabetical order, right-click and select **Sort in alphabetical order**. Depending on how the library designer set up the library, some items might not appear in alphabetical order. For example, in the **Simulink** library, the Additional Math & Discrete library appears as the last item regardless of the sorting option you choose.

You can create your own libraries and, optionally, have them appear in the Library Browser. See “Create a Custom Library” on page 41-4.

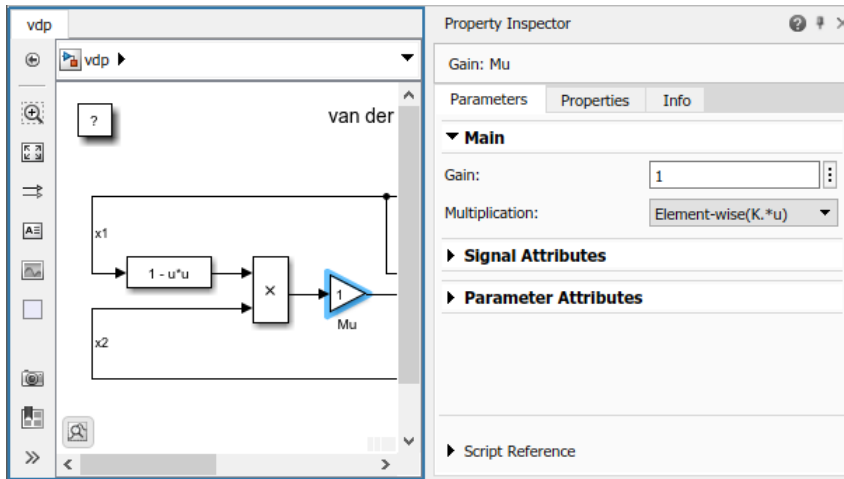

Setting Properties and Parameters

As you build a model, you can set parameters and properties on model elements. For example, you can set parameters and properties for blocks that affect how the block functions. You can also set properties on Stateflow charts, signal lines, visual elements such as annotations, and on the model.

Based on your workflow and goals, set parameters and properties using:

- The Property Inspector, which stays open in the editor as you work and updates based on the current selection
- A dialog box that is associated with an element, such as a specific block
- The Model Data Editor, which stays open and displays information about signals, states, and algorithmic block parameters (for instances, gains and filter coefficients) in a table
- For blocks whose parameter value appears on the block icon, you can select the block, hover over the value, and edit the value directly. For more information, see “Set Block Parameters” on page 1-26

When you select **View > Property Inspector**, the interface appears in the Simulink Editor on the right. You can drag the Property Inspector from the default location and dock it in another location in the editor. You can collapse the Property Inspector interface by clicking the pushpin. The figure shows a block selected with the Property Inspector displayed.

The Property Inspector is useful when you set parameters and properties as you work. It can stay open and available for setting values for the current selection. Values take effect when you set them. This workflow simplifies your interaction with the interface.

You can alternatively open a dialog box for a selected model element using an item on the **Diagram** menu, such as **Properties** and, for blocks, **Block Parameters**. You can also use the context menu. Double-clicking a block generally opens a block dialog box. (Use one of the menu commands on Subsystem and Model blocks.)

The Property Inspector and dialog boxes operate on a single selection. The main difference is that the Property Inspector updates with each selection and the dialog box shows settings for only the element you opened it from. For this reason, the dialog box is useful if:

- You are moving through the model hierarchy and want to see or set element parameters or properties as you navigate the model.
- You want to compare the parameters or properties of similar elements.
- The settings are advanced and appear only in the dialog box.

With the Model Data Editor (**View > Model Data Editor**), you can configure multiple signals, states, and algorithmic parameters at once. You can set only certain parameters and properties such as data types, initial values, and physical units. To work with one model element at a time, open the Property Inspector. To perform batch operations, open the Model Data Editor.

For more information about setting block properties and parameters, see “Specify Signal Properties” on page 67-4. To learn to use the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 62-179.

Parts of a Model

In this section...

“About Blocks” on page 1-55

“Block Parameters and Properties in Simulink” on page 1-56

“Signals” on page 1-58

You create a Simulink model by adding blocks, specifying block behavior, and using signal lines to connect the blocks to each other according to the dynamics of the system that you want to simulate.

About Blocks

Blocks are the main elements that you use to build models in Simulink. Generally, you add blocks from the supplied Simulink libraries to perform specific operations, such as math, as shown in “Build and Edit a Model in the Simulink Editor” on page 1-24.

You can further classify blocks in Simulink.

- Virtual blocks — These blocks help to organize a model and do not affect simulation. See “Nonvirtual and Virtual Blocks” on page 36-2.
- Subsystem blocks — Subsystems help you to organize your models hierarchically. You use a Subsystem block to encapsulate related parts of a model, that is, a representation of a system within the larger system that you are modeling. See “Design Model Architecture”.
- Masked blocks — You can add a mask to any block in a model. A mask is a custom interface that enables you to show only the block parameters and settings that you want the user of the block to have access to. A mask also provides an interface for setting parameters on blocks inside a subsystem without having to navigate the hierarchy. You can change the block appearance using a mask. See “Create Block Masks”.
- Referenced models — A model reference is a way to include a model in another model. You use a Model block to reference a model. See “Model References”.
- Linked blocks — A linked block is an instance of a block from a custom library that links to the library block. You can create a library of blocks that you configure for your specific purposes. For example, you can create subsystems and masked blocks and store them in a library for reuse. When you add a block to a model from a library that

you created, the block keeps a link to the library version, called a library link. You can modify a linked block only by disabling the link. See “Libraries”.

Block Parameters and Properties in Simulink

For most blocks, you can specify parameters that determine how the block works. For example, in the Trigonometric Function block, you specify the trigonometry function that you want the block to perform. For some blocks, you can specify the number of inputs or outputs. Whether the block has parameters that you can set and the nature of those parameters is specific to each block. For detailed information on parameter values, see “Set Block Parameter Values” on page 37-2.

You set block parameters in the Property Inspector or in a block dialog box.

- To open the Property Inspector, select **View > Property Inspector**. Select the block whose parameters you want to view or set. The parameters appear in the **Parameters** tab.
- To open the block dialog box, select **Diagram > Block Parameters** or, for most blocks, double-click the block. You can also use the context menu.
- To open the Model Data Editor, select **View > Model Data Editor**. Inspect the **Parameters** tab.
- For blocks whose parameter value appears on the block icon, you can select the block, hover over the value, and edit the value directly. For more information on setting block properties and parameters, see “Block Parameters and Properties in Simulink” on page 1-56.

To understand the differences between these approaches, see “Setting Properties and Parameters” on page 1-52. If you cannot access the block parameters from the Property Inspector or by double-clicking the block, select **Block Parameters** from the block context menu.

Tip You can edit some parameters on the block icon. For example, you can enter the **Gain** value on a Gain block on the icon. Select the block and then hover over it. When a blue underline appears, you can click and type.

Some block parameters do not appear in the Property Inspector or in the Model Data Editor. For example, some advanced parameters do not appear in the Property Inspector while the Model Data Editor shows only algorithmic parameters such as gains and coefficients. When the Property Inspector cannot display the parameters, an **Open** button appears in the Property Inspector. Click **Open** to open the block dialog box, where you can set the parameters.

See the documentation for your product to learn more about setting block parameters in the Property Inspector.

Blocks also have properties that are not specific to the block. Block properties enable you to configure the block to execute code when you perform actions such as opening the block or starting simulation. For example, you can set up a MATLAB script to perform tasks such as loading or defining variables for a block or any other callback functions. See “Callbacks for Customized Model Behavior” on page 4-50. Block properties also enable you to annotate the block and define callback functions. See “Specify Block Properties” on page 36-4.

You can set block properties on the **Properties** tab of the Property Inspector. Alternatively, you can use the Block Properties dialog box.

Additional Parameters and Properties

Simulink has these additional types of parameters and properties.

- Programmatically accessible parameters — Blocks and models have parameters whose value you do not set explicitly in the editor. For example, each block has a position parameter that is based on where you place the block in the model. There is no single interface to these parameters, but you can query and set any of them programmatically. You can also set any of the block-specific parameters programmatically. See “Common Block Properties” and “Model Parameters”.
- Model configuration parameters — Use configuration parameters (**Simulation > Model Configuration Parameters**) to specify simulation conditions, such as the

solver to use, the types of errors and warnings to display, and how you want to store simulation data. See “Configuration Parameters Dialog Box Overview”.

- Model properties — Model properties help you to define callbacks for the model. They also enable you to add a description and specify data to load or scripts to run, along with other settings. You can view and set model properties in the Property Inspector when there is no selection in the top level of a model. Otherwise, use **File > Model Properties**. See “Manage Model Properties” on page 4-68.

Note Simulink preferences (**File > Simulink Preferences**) help you to customize your model editing environment, such as how your scroll wheel functions and saving options. See “Set Simulink Preferences”.

Setting Parameter Values in Workspaces

Simulink gives you access to two workspaces where you can set values for parameters. Workspaces enable you to set parameters by using variables rather than setting every value on every block in a model. This approach is especially useful when your model is large and complex because you do not need to locate every block whose parameter value you want to set or change. Instead, assign a variable as the value of a parameter and define the variable in a workspace. This mechanism also allows you to use different sets of parameter values for the same model.

In the MATLAB base workspace, you can define parameters using any MATLAB mechanism for defining a variable. For example, you can use a MAT-file and load the variables when you open the model. Using the MATLAB base workspace or a Simulink data dictionary to define variables is useful when you are using the same set of parameters for more than one model.

You can also define parameters by assigning values to variables in a model workspace. You define a set of parameters that are specific to the model and save them with the model.

For more information about using workspace variables to set parameter values, see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-13.

Signals

As you can see in “Build and Edit a Model in the Simulink Editor” on page 1-24, you use signal lines to connect blocks in a model. At a minimum, a model takes an input signal,

operates on it, and outputs the result. In the Library Browser, the Sources library contains blocks that represent input signals. The Sinks library contains blocks for capturing and displaying outputs.

Simulink represents signals as lines. The line style varies with the type of signal. You create signals between the output port of one block and the input port of another block by drawing or using shortcuts.

For more on signals, see “Signals” and “Block and Signal Line Shortcuts and Actions” on page 1-93.

Preview Content of Model Components

Content preview displays a representation of the contents of a hierarchical model element, such as a subsystem, on the block. Content preview helps you to recognize the contents of the hierarchical element without navigating the hierarchy. Content preview shows blocks, signals, signal and block labels, and sample time color coding. It also shows signal highlighting and Stateflow animation.

Note For Model blocks, content preview appears only when the model is open.

By default, new hierarchical elements show content preview. You can change the default using the Simulink preference, **Content preview displays for new hierarchical elements**. Existing elements show content preview only if you enable preview for that element.

Content preview settings apply across Simulink sessions. Select the elements that you want to enable or disable content preview for, and select **Diagram > Format > Content Preview**.

The figure shows the Throttle & Manifold subsystem with content preview enabled.

Simulink scales the content preview to fit the size of the block. To improve the readability of the content preview, you can zoom or resize the block.

Elements that show content preview include:

- Subsystem blocks

Only masked subsystems whose **Icon transparency** property is set to Transparent and do not have an image show content preview.

- Model blocks, for referenced models
- Stateflow charts, subcharts, and graphical functions

Content preview does not appear for:

- Hierarchical block icons when they are smaller than their default size in the Library Browser
- Subsystem blocks when they have the **Read/Write permissions** block parameter set to `NoReadOrWrite`.
- Protected Model blocks
- Model blocks whose referenced models are not loaded
- Models that have the classic diagram theme enabled in Simulink Editor preferences.

Note A slight delay can occur in drawing models that contain many hierarchical items that enable content preview if those items contain many blocks.

Use Viewmarks to Save Views of Models

In this section...
“What Are Viewmarks?” on page 1-62
“Create a Viewmark” on page 1-63
“Open and Navigate Viewmarks” on page 1-64
“Manage Viewmarks” on page 1-64
“Refresh a Viewmark” on page 1-65

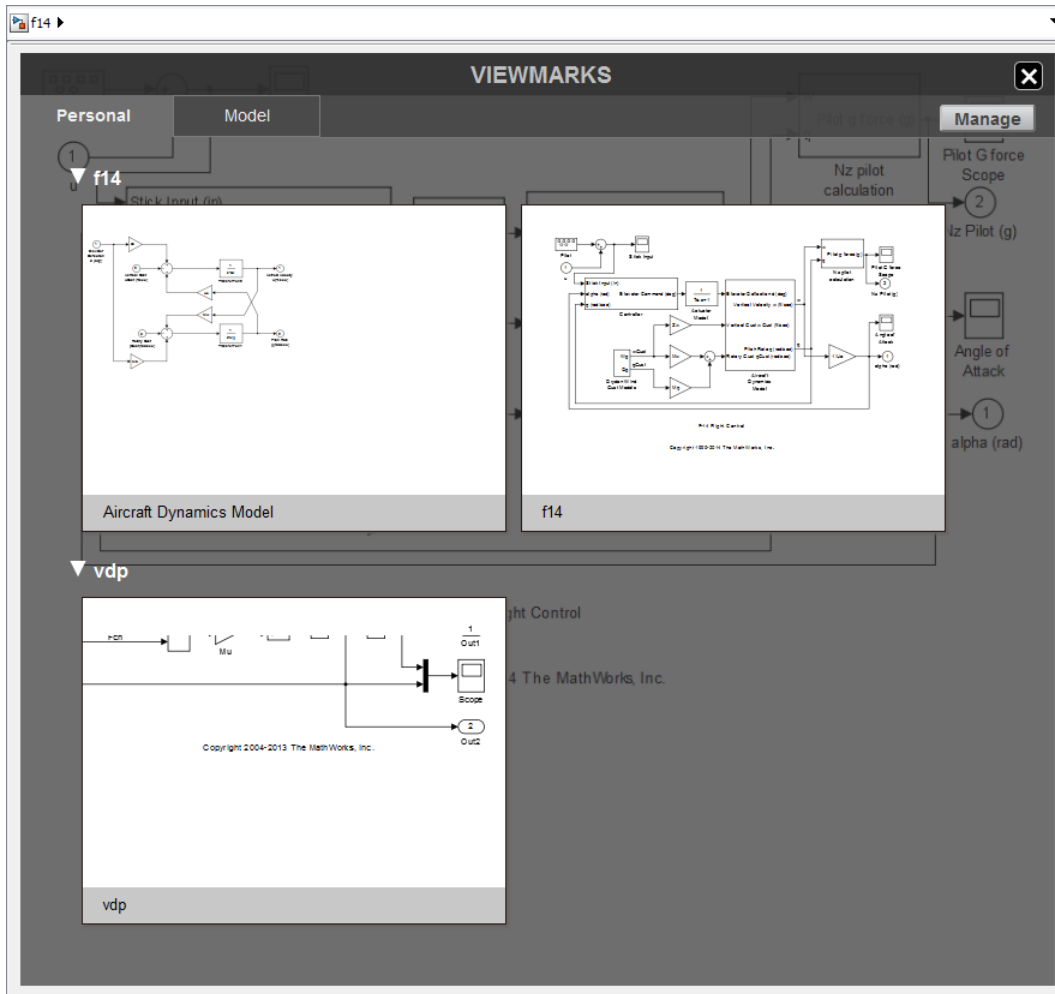

What Are Viewmarks?

Viewmarks are bookmarks to parts of a model. Use viewmarks to capture graphical views of a model so you can navigate directly to that view. You can capture viewmarks for specific levels in a model hierarchy. You can also pan and zoom to capture a point of interest.

Some examples of ways you can use viewmarks include:

- Navigate to specific locations in complex models without opening multiple Simulink Editor tabs or windows.
- Review model designs.
- Visually compare versions of a model.
- Share views of a model by storing viewmarks within the model.

You manage viewmarks in the viewmarks gallery. By default, viewmarks are stored locally on your computer. If you want to include a viewmark to share with a model, see “Save a Viewmark with the Model” on page 1-65. The figure shows the viewmark gallery.

Create a Viewmark

- 1 Navigate to the part of the model that you want to capture in a viewmark.
- 2 Pan and zoom to the part of the system that you want to capture.
- 3 Resize the Simulink Editor window so that it frames the part of the model you want to capture.

- 4 In the palette, click the **Viewmark This View** button .

The viewmark displays briefly and becomes part of the viewmarks gallery.

Open and Navigate Viewmarks

The viewmarks gallery has two tabs. The **Personal** tab consists of viewmarks that you created in a model and are stored locally on your computer. The **Model** tab consists of viewmarks that are saved in the Simulink model file.

- 1 In the Simulink Editor palette, click the **Viewmarks** button .
- 2 Select the tab (**Personal** or **Model**) that contains your viewmark, and then click the viewmark.

The Simulink Editor opens the model, if necessary, and displays the part of the model captured in the viewmark.

Manage Viewmarks

In the viewmarks gallery, you can rename viewmarks, add or edit a description for viewmark, and delete viewmarks. You also use the viewmarks gallery to save viewmarks with the model. You can manage viewmarks only in models saved in SLX format. In models saved in MDL format, the **Manage** button appears dimmed.

- To rename a viewmark, click the name and edit it.
- To add a description, click the viewmark Description button  and enter a description.
- To delete a viewmark, click the **Delete** button  on the viewmark. To delete all the viewmarks for a model, hover over the model name and click **Delete**.

You can replace the generated viewmark name.

- 1 Place the cursor in the viewmark name edit box.
- 2 Enter the new name.

You can also add a viewmark description. For example, you can add a description of the part of the model in the viewmark or add review comments.

- 1 Hover over the viewmark.
- 2 Click the **Description** button .
- 3 In the description edit box, enter the description.

Save a Viewmark with the Model

- 1 In the Simulink Editor palette, click the **Viewmarks** button .
- 2 In the viewmarks gallery, click **Manage**.
- 3 Select the check box in the viewmarks you want to copy to the model.
- 4 Click the **Add viewmarks to model** button .

These viewmarks become part of the model and are saved with the model.

Refresh a Viewmark

A viewmark is a static view of a part of a model. For currently loaded models, you can refresh a viewmark so that it reflects the current model. Open the viewmark gallery and click the **Refresh** button  on the viewmark.

If the viewmark shows a subsystem that has been removed, then the viewmark appears dimmed.

“Print to a PDF” on page 1-87

Update Diagram and Run Simulation

Updating the Diagram

You can leave many attributes of a block diagram, such as signal data types and sample times, unspecified. The Simulink software then infers the values of block diagram attributes, based on the block connectivity and attributes that you specify. The process that Simulink uses is known as *updating the diagram*.

Simulink attempts to infer the most appropriate values for attributes that you do not specify. If Simulink cannot infer an attribute, it halts the update and displays an error.

Simulation Updates the Diagram

Simulink updates the diagram at the start of a simulation. The updated diagram provides the simulation with the results of the latest changes that you have made to a model.

Update Diagram While Editing

As you create a model, at any point you can update the diagram. Updating the diagram periodically can help you to identify and fix potential simulation issues as you develop the model. This approach can make it easier to identify the sources of problems by focusing on a set of recent changes. Also, the update diagram processing takes less time than performing a simulation, so you can identify issues more efficiently.

To update the diagram select **Simulation > Update Diagram**, or press **Ctrl+D**.

This example shows the effects of updating the diagram.

- 1 Create the following model.

- 2 Select **Display > Signals & Ports > Port Data Types**.

The data types of the output ports of the Constant and Gain blocks appear. The data type of both ports is double, the default value.

- 3 In the Constant block dialog box, set **Output data type** to **single**.

The output port data type displays on the block diagram do not show this change.

- 4 Select **Simulation > Update Diagram**.

The updated block diagram shows the changes to the output data types of the Constant and Gain blocks.

When you update a block diagram, by default, a Gain block chooses an output data type based on the data types of the input signal and the **Gain** parameter. In this example, the block chooses the same data type as the input signal.

Simulate a Model

For any type of model you build in Simulink, you need to know how to simulate. Simulating performs the operations specified by the blocks in the model and its specific configuration and produces results. See “Simulation” for complete information, such as how to configure your model for simulation.

Use any of these methods to simulate a model:

- Select **Simulation > Run**.
- Press **Ctrl+T**.
- Click the **Run** button .

Print Model Diagrams

In this section...

“Print Interactively or Programmatically” on page 1-69

“Printing Options” on page 1-69

“Canvas Color” on page 1-69

Print Interactively or Programmatically

You can print a block diagram:

- Interactively in the Simulink Editor, by selecting **File > Print**
- Programmatically, by using the MATLAB `print` command

To control some additional aspects of printing a block diagram, use the `set_param` command with model parameters. You can use `set_param` with the interactive and programmatic printing interface.

Printing Options

In addition to printing a model using default settings, you can:

- “Select the Systems to Print” on page 1-75.
- “Specify the Page Layout and Print Job” on page 1-78
- “Print Multiple Pages for Large Models” on page 1-80
- “Print Using Print Frames” on page 71-13
- “Print to a PDF” on page 1-87
- “Add a Log of Printed Models” on page 1-81
- “Add a Sample Time Legend” on page 1-82
- “Print Models to Image File Formats” on page 1-91

Canvas Color

By default, the canvas (background) of the printed model is white. To match the color of the model, set the **Simulink Preferences > General > Print** preference.

Basic Printing

In this section...

“Print the vdp Model Using Default Settings” on page 1-71

“Print a Subsystem Hierarchy” on page 1-73

Print the vdp Model Using Default Settings

The default print settings produce good quality printed output for quickly capturing a model in printed form.

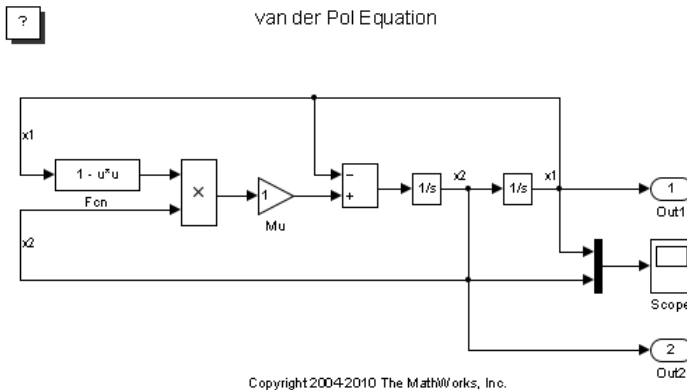

- 1 Open the vdp model.

- 2 In the Simulink Editor, select **File > Print > Print**.
- 3 In the Print Model dialog box, use the default settings. Click **Print**.

The output looks like this. The model, as it appears in the Simulink Editor, prints on a single page, using portrait orientation and not using a print frame.

Print a Subsystem Hierarchy

You can print levels in nested subsystems.

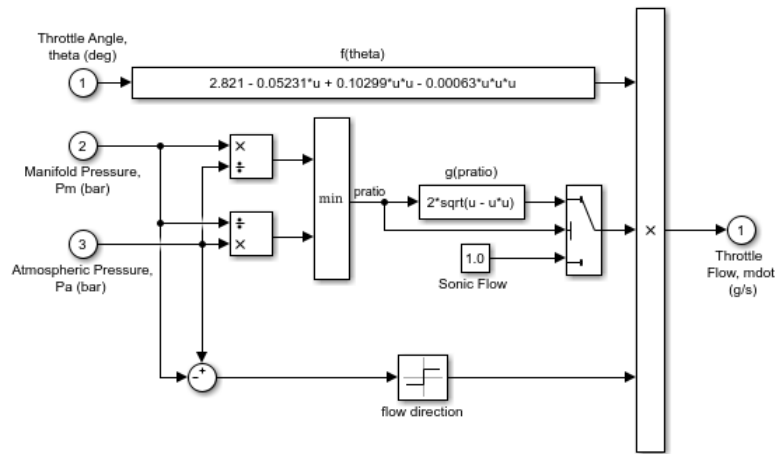

- 1 Open the `sldemo_enginewc` model.

- 2 Open the Throttle & Manifold subsystem.

- 3 Open the Throttle subsystem.

- 4 In the Simulink Editor, select **File > Print > Print**.
- 5 In the Print Model dialog box, click **Current system and above** and click **Print**.

The printed output shows the Throttle subsystem (the current system) and the two levels above it in the subsystem hierarchy.

Select the Systems to Print

In this section...

“Print Current System” on page 1-75

“Print Subsystems” on page 1-75

“Print a Model Referencing Hierarchy” on page 1-76

Print Current System

To select a specific system in a model to print, display that system in the currently open Simulink Editor tab and select **File > Print > Print**.

Print Subsystems

For models with subsystems, use the Simulink Editor and the Print Model dialog box to specify the systems in the model to print.

By default, Simulink does not print masked subsystems or library links. For information about masked subsystem and library link printing, see “Print Masked Subsystems and Library Links” on page 1-76.

Print All Subsystems in a Model

Use this procedure to print all of the subsystems in a model, including hierarchies of subsystems.

- 1 Display the top-level model in the currently open Simulink Editor tab.
- 2 In the Simulink Editor, select **File > Print > Print**.
- 3 In the Print Model dialog box, select **All systems**.
- 4 Click **Print**.

Print the Contents of a Specific Subsystem

In the currently open Simulink Editor tab, display the subsystem that you want to print and click **Print**.

Print a Subsystem Hierarchy

Use this procedure to print nested subsystems.

- 1 In the current tab of the Simulink Editor, display the subsystem level that you want to use as the starting point for printing the subsystem hierarchy.
- 2 In the Print Model dialog box, select one of the following:
 - **Current system and below**
 - **Current system and above**
- 3 Click **Print**.

Simulink prints the hierarchy for all of the subsystems in the current tab.

Print Masked Subsystems and Library Links

To print the contents of masked subsystems, in the Print Model dialog box, click **Look under mask dialog**.

To print the contents of library links, in the Print Model dialog box, click **Expand unique library links**. Simulink prints one copy, regardless of how many copies of the block the model contains.

If a subsystem is both a masked subsystem and a library link, Simulink uses the **Look under mask dialog** setting and ignores the **Expand unique library links** setting.

Print a Model Referencing Hierarchy

To print a model referencing hierarchy, open each level of the hierarchy and print that level.

Clicking **All systems** does not print different levels in the model referencing hierarchy.

You cannot print the contents of protected models.

- “Design Model Architecture”

Specify the Page Layout and Print Job

In this section...
“Page and Print Job Setup” on page 1-78
“Set Paper Size and Orientation Without Printing” on page 1-78

Page and Print Job Setup

Use the Print Model dialog box to specify the page orientation (portrait or landscape) for the current printing session.

To open the print dialog box for your operating system, in the Print Model dialog box, click **Print using system dialog**. The operating system print dialog box provides additional printing options for models, such as page range, copies, double-sided printing, printing in color (if your print driver supports color printing), and nonstandard paper sizes.

Set Paper Size and Orientation Without Printing

To specify paper size and orientation without printing, use the Page Setup dialog box. To open the dialog box, select **File > Print > Page Setup**.

Only the paper size and orientation are used.

- “Basic Printing” on page 1-71

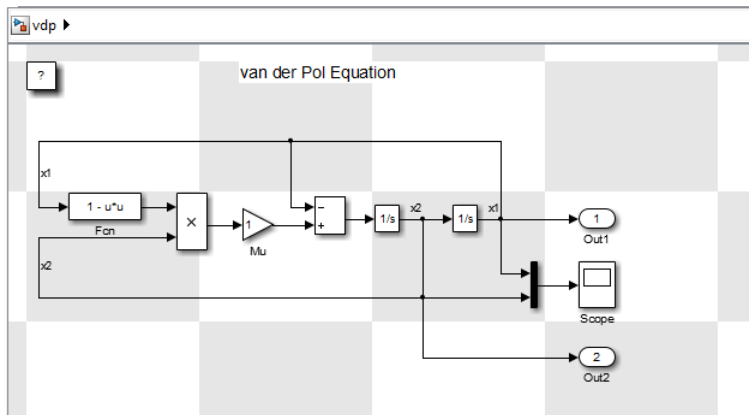

More About

- “Print Model Diagrams” on page 1-69

Tiled Printing

By default, each block diagram is scaled during the printing process so that it fits on a single page. In the case of a large diagram, this automatic scaling can make the printed image difficult to read.

Tiled printing enables you to print even the largest block diagrams without sacrificing clarity and detail. Tiled printing allows you to distribute a block diagram over multiple pages. For example, you can use tiling to divide a model as shown in the figure, with each white box and each gray box representing a separate printed page.

You can control the number of pages over which Simulink prints the block diagram.

Also, you can set different tiled-print settings for each of the systems in your model.

Note If you enable the print frame option, then Simulink does not use tiled printing.

Print Multiple Pages for Large Models

- 1 In the Simulink Editor, open the model in the current tab.
- 2 Select **File > Print > Print**.
- 3 In the Print Model dialog box, click **Enable tile printing**.

The default Enable tile printing setting in the Print Model dialog box is the same as the **File > Print > Enable Tiled Printing** setting. If you change the Print Model dialog box **Enable tile printing** setting, the Print Model dialog box setting takes precedence.

- 4 Confirm that tiling divides the model into separate pages the way you want it to appear in the printed pages. In the Simulink Editor, select **File > Print > Show Page Boundaries**. The gray and white squares indicate the page boundaries.
- 5 Optionally, from the MATLAB command line, specify the model scaling, tile margins, or both. See “Set Tiled Page Scaling and Margins” on page 1-85.
- 6 Optionally, specify a subset of pages to print. In the Print Model dialog box, specify the **Page Range**.
- 7 Click **Print**.

Add a Log of Printed Models

A print log lists the blocks and systems printed. To print the print log when you print a model:

- 1 In the Simulink Editor, open the model whose print job you want to log.
- 2 Select **File > Print > Print**.
- 3 In the Print Model dialog box, click **Include print log**.
- 4 Click **Print**.

The print log appears on the last page.

For example, here is the print log for the `sldemo_enginewc` model, with **All systems** enabled and **Enable tiled printing** cleared.

Page	System Name
1	sldemo_enginewc
2	sldemo_enginewc/Combustion
3	sldemo_enginewc/Compression
4	sldemo_enginewc/Controller
5	sldemo_enginewc/Engine Dynamics
6	sldemo_enginewc/More Info
7	sldemo_enginewc/Throttle & Manifold
8	sldemo_enginewc/Throttle & Manifold/Intake Manifold
9	sldemo_enginewc/Throttle & Manifold/Throttle
10	sldemo_enginewc/drag torque
11	sldemo_enginewc/valve timing
12	sldemo_enginewc/valve timing/TDC and BDC detection
13	sldemo_enginewc/valve timing/positive edge to dual edge conversion

Add a Sample Time Legend

You can print a legend that contains sample time information for your entire system, including any subsystems. The legend appears on a separate page from the model. To print a sample time legend:

- 1 In the Simulink Editor, select **Simulation > Update diagram**.
- 2 Select **File > Print > Print**.
- 3 In the Print Model dialog box, click **Print sample time legend**.
- 4 Click **Print**.

A sample time legend appears on the last page. For example, here is the sample time legend for the `sldemo_enginewc` model, with **All systems** enabled.

Sample Times for 'sldemo_enginewc'

Color	Description	Value
	Continuous	0
	Fixed in Minor Step [0,1]	
	Constant	Inf
	Triggered	Source: FIM

Print from the MATLAB Command Line

In this section...

“Printing Commands” on page 1-83

“Print Systems with Multiline Names or Names with Spaces” on page 1-83

“Set Paper Orientation and Type” on page 1-84

“Position and Size a System” on page 1-84

“Use Tiled Printing” on page 1-85

Printing Commands

The MATLAB `print` command provides several options for printing Simulink models. For example, print the `Compression` subsystem in the `sldemo_enginewc` model to your default printer:

```
open_system('sldemo_enginewc');  
print -sCompression
```

Tip When you use the `print` command, you can print only one system. To print multiple levels in a model, use multiple `print` commands, one for each system that you want to print. To print multiple systems in a model, consider using the Print Model dialog box in the Simulink Editor. For details, see “Select the Systems to Print” on page 1-75.

You can use `set_param` to specify printing options for models. For details, see “Model Parameters”.

You can use `orient` to control the paper orientation.

Print Systems with Multiline Names or Names with Spaces

To print a system whose name appears on multiple lines, assign the newline character to a variable and use that variable in the `print` command. This example shows how to print a subsystem whose name, `Aircraft Dynamics Model`, appears on three lines.

```
open_system('f14');  
open_system('f14/Aircraft Dynamics Model');
```

```
sys = sprintf('f14/Aircraft\nDynamics\nModel');  
print (['-s' sys])
```

To print a system whose name includes one or more spaces, specify the name as a character vector. For example, to print the Throttle & Manifold subsystem, enter:

```
open_system('sldemo_enginewc');  
open_system('sldemo_enginewc/Throttle & Manifold');  
print (['-sThrottle & Manifold'])
```

Set Paper Orientation and Type

To set just the paper orientation, use the MATLAB `orient` command.

You can also set the paper orientation by using `set_param` with the `PaperOrientation` model parameter. Set the paper type with the `PaperType` model parameter.

Position and Size a System

To position and size the model diagram on the printed page, use `set_param` command with the `PaperPositionMode` and `PaperPosition` model parameters.

The value of the `PaperPosition` parameter is a vector of form `[left bottom width height]`. The first two elements specify the bottom-left corner of a rectangular area on the page, measured from the bottom-left corner. The last two elements specify the width and height of the rectangle.

If you set the `PaperPositionMode` parameter to `manual`, Simulink positions (and scales, if necessary) the model to fit inside the specified print rectangle. If `PaperPositionMode` is `auto`, Simulink centers the model on the printed page, scaling the model, if necessary, to fit the page.

For example, to print the `vdp` model in the lower-left corner of a U.S. letter-size page in landscape orientation:

```
open_system('vdp');  
set_param('vdp', 'PaperType', 'usletter');  
set_param('vdp', 'PaperOrientation', 'landscape');  
set_param('vdp', 'PaperPositionMode', 'manual');  
set_param('vdp', 'PaperPosition', [0.5 0.5 4 4]);  
print -svdp
```

Use Tiled Printing

Enable Tiled Printing

- 1 Use `set_param` to set the `PaperPositionMode` parameter to `tiled`.
- 2 Use the `print` command with the `-tileall` argument.

For example, to enable tiled printing for the `Compression` subsystem in the `sldemo_enginewc` model:

```
open_system('sldemo_enginewc');
set_param('sldemo_enginewc/Compression', 'PaperPositionMode', ...
'tiled');
print('-ssldemo_enginewc/Compression', '-tileall')
```

Display Tiled Page Boundaries

To display the page boundaries programmatically, use the `set_param` command, with the model parameter `ShowPageBoundaries` set to `on`. For example:

```
open_system('sldemo_enginewc');
set_param('sldemo_enginewc', 'ShowPageBoundaries', 'on')
```

Set Tiled Page Scaling and Margins

To scale the block diagram so that more or less of it appears on a single tiled page, use `set_param` with the `TiledPageScale` parameter. By default, the value is 1. Values greater than 1 proportionally scale the model to use a smaller percentage of the tiled page, while values between 0 and 1 proportionally scale the model to use a larger percentage of the tiled page. For example, a `TiledPageScale` of 0.5 makes the printed diagram appear twice its size on a tiled page, while a `TiledPageScale` value of 2 makes the printed diagram appear half its size on a tiled page.

By decreasing the margin sizes, you can increase the printable area of the tiled pages. To specify the margin sizes associated with tiled pages, use `set_param` with the `TiledPaperMargins` parameter. Each margin is 0.5 inches by default. The value of `TiledPaperMargins` is a vector that specifies margins in this order: `[left top right bottom]`. Each element specifies the size of the margin at a particular edge of the page. The value of the `PaperUnits` parameter determines the units of measurement for the margins.

Specify Range of Tiled Pages to Print

To specify a range of tiled page numbers programmatically, use `print` with the `-tileall` argument and the `-pages` argument. Append to `-pages` a two-element vector that specifies the range.

Note Simulink uses a row-major scheme to number tiled pages. For example, the first page of the first row is 1, the second page of the first row is 2, and so on.

For example, to print the second, third, and fourth pages:

```
open_system('vdp');  
print('-svdp','-tileall','-pages[2 4]')
```

Print Model Reports

A model report is an HTML document that describes the structure and content of a model. The report includes block diagrams of the model and its subsystems and the settings of its block parameters.

Tip If you have the Simulink Report Generator™ installed, you can generate a detailed report about a system. To do so, in the Simulink Editor, select **File > Reports > System Design Description**. For more information, see “System Design Description” (Simulink Report Generator).

To generate a model report for the current model:

- 1 In the Simulink Editor, select **File > Print > Print Details**.
- 2 In the Print Details dialog box, select report options. For details, see “Model Report Options” on page 1-89.
- 3 Select **Print**.

The Simulink software generates the HTML report and displays the report in your default HTML browser.

While generating the report, Simulink displays status messages on a messages pane that replaces the options pane on the Print Details dialog box.

Select the detail level of the messages from the list at the top of the messages pane. When the report generation process begins, the **Print** button changes to a **Stop** button. To stop the report generation, click **Stop**. When the report generation process finishes, the **Stop** button changes to an **Options** button. Clicking this button redisplay the report generation options, allowing you to generate another report without having to reopen the Print Details dialog box.

Model Report Options

Use the Print Details dialog box allows you to specify the following report options.

Directory

The folder where the HTML report is stored. The options include your system's temporary folder (the default), your system's current folder, or another folder whose path you specify in the adjacent edit field.

Increment filename to prevent overwriting old files

Creates a unique report file name each time you generate a report for the same model in the current session. This preserves each report.

Current object

Include only the currently selected object in the report.

Current and above

Include the current object and all levels of the model above the current object in the report.

Current and below

Include the current object and all levels below the current object in the report.

Entire model

Include the entire model in the report.

Look under mask dialog

Include the contents of masked subsystems in the report.

Expand unique library links

Include the contents of library blocks that are subsystems. The report includes a library subsystem only once even if it occurs in more than one place in the model.

Print Models to Image File Formats

To print the current view of your model to an image file format such as `.png` or `.jpeg`, use the `-device` argument with the MATLAB `print` command. For example, to print the `vdp` model to a `.png` format, use this command:

```
print -dpng -svdp vdp_model.png
```

By default, the canvas (background) of the exported model matches the color of the model. To use a white or transparent canvas for model files that you export to another file format, set the **Simulink Preferences > Export** preference.

Copy Model Views to Third-Party Applications

On Microsoft Windows platforms, you can copy the current view of your model in either bitmap or metafile format. You can then paste the clipboard image to a third-party application such as word processing software.

On Macintosh platforms, when you copy a model view to the clipboard, Simulink saves the model in a scalable format, in addition to a bitmap format. When you paste from the clipboard to an application, the application selects the format that best meets its requirements.

By default, the canvas (background) of the copied model matches the color of the model. To use a white or transparent canvas for model files that you copy to another application, set the **Simulink Preferences > Clipboard** preference.

- 1 To copy a Simulink model to the operating system clipboard, in the Simulink Editor select **Edit > Copy Current View to Clipboard**.
- 2 Paste the model from the clipboard to a third-party application.

Object Selection and Clipboard Operations

Objects include blocks, signal lines, signal labels, and annotations.

Task	Action
Select an object	Click
Select additional objects	Shift+click
Select all objects	Ctrl+A
Copy object	Drag with right mouse button Ctrl+drag
Move any object, including signal labels	Drag
Delete selected object	Delete or Backspace Edit > Clear
Cut	Ctrl+X
Paste	Ctrl+V

Task	Action
Duplicate object	Ctrl+C, Ctrl+V
Undo	Ctrl+Z
Redo	Ctrl+Y

Block and Signal Line Shortcuts and Actions

Task	Action
Set the main parameter for selected block	Alt+Enter
Add a block at the current location from shortcut menu	Double-click and start typing the block name; select the block from the menu
Get prompted for suggested block based on context	Double-click at end of a line drawn from an existing block; select a suggestion from the list or start typing to select one from the library
Open or hide the Property Inspector	Ctrl+Shift+I
Copy block or model from another Simulink Editor window	Drag between windows
Move block	Arrow keys
Resize block, keeping same ratio of width and height	Shift+ drag handle
Resize block from the center	Ctrl+ drag handle
Rotate block clockwise	Ctrl+R
Rotate block counterclockwise	Ctrl+Shift+R
Flip block	Ctrl+I

Task	Action
Connect blocks	<p>Click a port, click the port you want connect to</p> <p>Select first block, Ctrl+click second block</p> <p>Drag from port to port</p> <p>Click a port and hold Shift as you connect to the next port; hold shift to make multiple, consecutive connections</p>
Draw branch line	<p>Click a port, move the cursor near the line you want to branch; click after you see the preview</p> <p>Select a line, move the cursor toward the element you want to connect with, and then click the port</p> <p>Ctrl+ drag line</p> <p>Right-mouse button+drag</p>
Route lines around blocks	Shift +drag while drawing
Interactively add ports to subsystems, buses, and other blocks that take multiple inputs	<p>Drag toward the port from a compatible block or signal line</p> <p>Drag from the edge of the block or bus that you want to add the port to</p> <p>Click the edge of the port, and then drag</p> <p>Click the edge of the port, move the cursor over the signal type—signal, bus, or connector—from the menu, and drag</p>
Disconnect block	Shift +drag block
Create subsystem from selected blocks	Ctrl + G
Open selected subsystem	Enter
Go to parent of selected subsystem	Esc

Task	Action
Find block	Ctrl+F
Mask subsystem	Ctrl+M
Look under block mask	Ctrl+U
Comment through a block	Ctrl+Shift+Y
Comment out/uncomment a block	Ctrl+Shift+X
Refresh Model blocks	Ctrl+K
For a linked block, go to the library of the parent block	Ctrl+L
Open Model Explorer	Ctrl+H

Signal Name and Label Actions

The signal name appears in a label on the signal line.

Task	Action
Name a signal line	Double-click signal and type name
Name a branch of a named signal line	Double-click the branch
Name every branch of a signal	Right-click the signal, select Properties , and use the dialog box
Delete signal label and name	Delete characters in label or delete name in Signal Properties dialog box.
Delete signal label only	Right-click label and select Delete Label .
Open signal label text box for edit	Double-click signal line Click label
Move signal label	Drag label to a new location on same signal line
Copy signal label	Ctrl +drag signal label
Change the label font	Select the signal line (not the label) and use Diagram > Format > Font Style

Simulation Keyboard Shortcuts

Task	Action
Open Configuration Parameters dialog box	Ctrl+E
Update diagram	Ctrl+D
Start simulation	Ctrl+T
Stop simulation	Ctrl+Shift+T
Build model (for code generation)	Ctrl+B

Debugging and Breakpoints Keyboard Shortcuts

Task	Action
Step	F10
Step in	F11
Step out	Shift + F11
Run	F5
Set/Clear breakpoint	F12

Zooming and Scrolling Shortcuts

Task	Action
Zoom in	Ctrl++
Zoom out	Ctrl+-
Zoom to normal (100%)	Ctrl+0 or Alt+1
Zoom with mouse	Scroll wheel Deselect the File > Simulink Preferences > Editor Preferences > Scroll wheel controls zooming preference to zoom using Ctrl +scroll wheel.
Zoom in on object	Drag the Zoom button  from the palette to the object

Task	Action
Fit diagram to screen	Spacebar
Scroll view	Arrow keys Shift +arrow for larger pans
Scroll with mouse	Spacebar +drag Hold the scroll wheel down and drag the mouse

Library Browser Shortcuts

Task	Shortcut
Open a model	Ctrl+O
Open Library Browser from a model	Ctrl+Shift+L
Move selection down in the Blocks or Libraries pane	Down arrow
Move selection up in the Blocks or Libraries pane	Up arrow
Expand a node in the Libraries pane	Right arrow
Collapse a node in the Libraries pane	Left arrow
Refresh Libraries pane	F5
Show parent library in Blocks pane	Esc
Select a block found with the search tool in the Blocks pane	Ctrl+R
Insert the selected block in a new model	Ctrl+I
Increase zoom in the Blocks pane	Ctrl++
Decrease zoom in the Blocks pane	Ctrl+-

Task	Shortcut
Reset zoom to default in the Blocks pane	Alt+1
Find a block	Ctrl+F
Close	Ctrl+W

File Operations

Task	Action
Open model	Ctrl+O
Create a model	Ctrl+N
Print	Ctrl+P
Save all modified models in active model hierarchy	Ctrl+S
Save active referenced model	Ctrl+Shift+S
Close model	Ctrl+W

How Simulation Stepper Helps With Model Analysis

Simulation Stepper enables you to step through major time steps of a simulation. Using discrete time steps, you can step forward or back to a particular instant in simulation time. At each time step, Stepper displays all of the simulation data the model produces.

Use Simulation Stepper to analyze your model in these ways:

- Step forward and back through a simulation.
- Pause a simulation in progress and step back.
- Continue running a simulation after stepping back.
- Analyze plotted data in your model at a particular moment in simulation time.
- Set conditions before and during simulation to pause a simulation.

How Stepping Through a Simulation Works

In this section...

“Simulation Snapshots” on page 2-3

“How Simulation Stepper Uses Snapshots” on page 2-4

“How Simulation Stepper Differs from Simulink Debugger” on page 2-5

These topics explain how Simulation Stepper steps through a simulation.

Simulation Snapshots

When you set up Simulation Stepper, you specify:

- The number of time steps where Stepper creates ‘snapshots’
- The number of steps to skip between snapshots
- The total number of snapshots stored

A simulation snapshot contains simulation state (SimState) and information related to logged data and visualization blocks. Simulation Stepper stores simulation states in snapshots at the specified interval of time steps when it steps forward through a simulation.

It is important to understand the difference between a Simulation Stepper step and a simulation time step. A simulation time step is the fixed amount of time by which the simulation advances. A Simulation Stepper step is where Simulation Stepper creates a snapshot. Each step (that Simulation Stepper takes) consists of one or more simulation time steps (that you specify).

When you step back through a simulation, the software uses simulation snapshots, stored as SimStates, to display previous states of the simulation. The model does not simulate in reverse when stepping back. Therefore, to enable the step back capability, you must first simulate the model or step it forward to save snapshots.

Keep in mind that snapshots for stepping back are available only during a single simulation. The Simulation Stepper does not save the steps from one simulation to the next.

How Simulation Stepper Uses Snapshots

A simulation snapshot captures all the information required to continue a simulation from that point. When you set up simulation stepping, you specify:

- The maximum number of snapshots to capture while simulating forward. The greater the number, the more memory the simulation uses and the longer the simulation takes to run.
- The number of time steps to skip between snapshots. This setting enables you to save snapshots of simulation state when stepping forward at periodic intervals, such as every three steps. This interval is independent of the number of forward or backward time steps taken. Because taking simulation snapshots affects simulation speed, saving snapshots less frequently can improve simulation speed.

The figure shows how you can step through a simulation depending on how you set the parameters in the Simulation Stepping Options dialog box. Because you can change the stepping parameters as you step through the simulation, you can step through a simulation as shown in this figure: sometimes by single steps and sometimes by two or more steps.

In the figure, the interval for snapshot captures is three.

This next figure shows the advantage of changing the stepping options while stepping forward. At the fourth step, the interval between stored steps changed the snapshot steps from three to one. This enables you to capture more snapshots around a simulation time of interest.

The next figure shows how the snapshot settings of Simulation Stepper can change what happens when stepping back. Suppose that the interval between snapshots is set to three, and starting at state six, the stepper **Move back/forward by** setting is set to one. The stepper first restores the simulation state to the last saved snapshot (state three), and then simulates two major time steps to arrive at the desired state (state five).

Thus, when you step back to a particular time step in a simulation, Simulation Stepper restores the last saved snapshot before that time step. Then, it steps forward to the time step you specify. This capability is helpful for memory usage and simulation performance.

How Simulation Stepper Differs from Simulink Debugger

Simulation Stepper and Simulink Debugger both enable you to start, stop, and step through a model simulation. Both tools allow you to use breakpoints as part of a debugging session. However, you use Simulation Stepper and Simulink Debugger for different purposes. The table shows the actions you can perform with each tool.

Action	Simulation Stepper	Simulink Debugger
Look at state of system after executing a major time step.	✓	✓

Action	Simulation Stepper	Simulink Debugger
Observe dynamics of the entire model from step to step.	✓	
Step simulation back.	✓	
Pause across major steps.	✓	
Control a Stateflow debugging session.	✓	
Step through simulation by major steps.	✓	
Monitor single block dynamics (for example, output and update) during a single major time step.		✓
Look at state of system while executing a major time step.		✓
Observe solver dynamics during a single major step.		✓
Show various stages of Simulink simulation.		✓
Pause within a major step.		✓
Step through a simulation block by block.		✓
Access via a command-line interface.		✓

Understanding the simulation process can help you to better understand the differences between Simulation Stepper and Simulink Debugger.

Use Simulation Stepper

In this section...

“Simulation Stepper Access” on page 2-8

“Simulation Stepper Pause Status” on page 2-8

“Tune Parameters” on page 2-9

“Referenced Models” on page 2-10

“Simulation Stepper and Interval Logging” on page 2-10

“Simulation Stepper and Stateflow Debugger” on page 2-10

Simulation Stepper Access

You run Simulation Stepper and access the settings from the Simulink Editor toolbar .

Click the Stepping Options button  to open the Simulation Stepping Options dialog box.

Use the dialog box to enable stepping back through a simulation. When stepping back is

enabled, after you start the simulation, the Stepping Options button changes to  , and then you can use it to step back. In that case, you can access the dialog box again only by using **Simulation > Stepping Options**.

If you clear the **Enable previous stepping** check box, the software clears the stored snapshot cache.

Simulation Stepper Pause Status

The status bar at the bottom of the Simulink Editor displays the simulation time of the last completed simulation step. While a simulation is running, the editor updates the time display to indicate the simulation progress. This display is approximate because the status

bar updates only at every major time step and not at every simulation time step. When you pause a simulation, the status bar display time catches up to the actual time of the last completed step.

The value (the time of the last completed step) that is displayed on the status bar is not always the same as the time of the solver. This happens because different solvers use different ways to propagate the simulation time in a single iteration of the simulation loop. Simulation Stepper pauses at a single position within the simulation loop. Some solvers perform their time advance before Simulation Stepper pauses. However, other solvers perform their time advance after Simulation Stepper pauses, and the time advance then becomes part of the next step. As a result, for continuous and discrete solvers, the solver time is always one major step ahead of the time of the last model output.

When this condition occurs, and the simulation is paused, the status bar time displays an asterisk. The asterisk indicates that the solver in this simulation has already advanced past the displayed time (which is the time of the last completed simulation step).

Tune Parameters

While using Simulation Stepper, when the simulation is paused, you can change tunable parameters, including some solver settings. However, changes to the solver step size take effect when the solver advances the simulation time. For some solvers, this occurs after the next simulation step is taken.

Simulation Stepper takes into account the size of a movement (**Move back/forward by**) and the frequency of saving steps (**Interval between stored back steps**). If you specify a frequency that is larger than the step size, Simulation Stepper first steps back to the last saved step and then simulates forward until the total step count difference reaches the size of the desired movement. Simulation Stepper applies values for tunable parameters when simulating forward. For this reason, if you change any tunable parameter before stepping back, the resulting simulation output might not match the previous simulation output at that step before the parameter change. This can cause unexpected results when stepping forward from the snapshot to the chosen time step.

For example, assume a snapshot save frequency of three and a step size of one. The stepper first steps back to the last saved step, up to three steps, and then simulates

forward until the total step count difference reaches one. If you change tunable parameters before stepping back, the resulting simulation output might not match the previous simulation output at that step.

Referenced Models

When using Simulation Stepper and the Model block, the referenced model shares the stepping options of the top model throughout a simulation. As a result, changing Simulation Stepper settings for the referenced model during simulation changes the Simulation Stepper settings of the top model. When the simulation ends, the settings of the referenced model revert to the original values; the Stepper settings of the top model stay at the changed settings.

- When the model is not simulating, the top model and referenced model retain their own independent stepping options.
- When the model is simulating and you change a referenced model stepping option, the top model stepping option changes to the same value.
- When the model is simulating and you change a top model stepping option, the referenced model stepping option changes to the same value.
- When the model stops simulating, the referenced model stepping options revert to how they were set before simulation started; the top model keeps the values set during simulation.

Simulation Stepper and Interval Logging

When you change the logging interval of a simulation before rolling back, Simulink does not log data for time steps that were outside the original logging interval until the first forward step after a rollback operation. For more information, see “Logging intervals”.

Simulation Stepper and Stateflow Debugger

When you debug a Stateflow chart (for example, when the simulation stops at a Stateflow breakpoint), Simulation Stepper adds buttons to control the Stateflow debugging session. When the Stateflow debugging session ends, the Simulation Stepper interface returns to the default. For more information about controlling the Stateflow debugger using the Simulink Editor toolbar, see “Control Chart Execution After a Breakpoint” (Stateflow).

- “Simulation Stepper Limitations” on page 2-12

Simulation Stepper Limitations

In this section...
“Interface” on page 2-12
“Model Configuration” on page 2-12
“Blocks” on page 2-12

Interface

- There is no command-line interface for Simulation Stepper.

Model Configuration

- Simulation stepping (forward and backward) is available only for Normal and Accelerator modes.
- The step back capability relies on SimState technology for saving and restoring the state of a simulation. As a result, the step back capability is available only for models that support SimState. For more information, see “Save and Restore Simulation Operating Point” on page 25-36.
- Simulation Stepper steps through the major time steps of a simulation without changing the course of a simulation. Choosing a refine factor greater than unity produces loggable outputs at times between the major time steps of the solver. These times are not major time steps, and you cannot step to a model state at those times.
- If you run a simulation with stepping back enabled, the Simulink software checks whether the model can step back. If it cannot, a warning appears at the MATLAB command prompt. For some simulations, Simulink cannot step back. The step back capability is then disabled until the end of that simulation. Then the setting resets to the value you requested.
- When you place custom code in **Configuration Parameters > Simulation Target > Custom Code > Initialize function** in the **Model Configuration Parameters** dialog box, this gets called only during the first simulation in Simulation Stepper.

Blocks

- Some blocks do not support stepping back for reasons other than SimState support. These blocks are:

- S-functions that have P-work vectors but do not declare their SimState compliance level or declare it to be unknown or disallowed (see “S-Function Compliance with the ModelOperatingPoint”)
- Simscape™ Multibody™ First Generation blocks
- Legacy (pre-R2016a) SimEvents® blocks
- MATLAB Function blocks generally support stepping back. However, the use of certain constructs in the MATLAB code of these blocks can prevent the block from supporting stepping back. These scenarios prevent the MATLAB Function blocks from stepping back:
 - Persistent variables of opaque data type. Attempts to step back under this condition cause an error message based on the specific variable type.
 - Extrinsic functions calls that can contain state (such as properties of objects or persistent data of functions). No warnings or error messages appear, but the result likely will be incorrect.
 - Calls to custom C code (through MEX function calls) that do not contain static variables. No warnings or error messages appear, but the result likely will be incorrect.
- Some visualization blocks do not support stepping back. Because these blocks are not critical to the state of the simulation, no errors or warnings appear when you step back in a model that contains these blocks:
 - XY Graph
 - Auto Correlator
 - Cross Correlator
 - Spectrum Analyzer
 - Averaging Spectrum Analyzer
 - Power Spectral Density
 - Averaging Power Spectral Density
 - Floating Bar Plot
 - 3Dof Animation
 - MATLAB Animation
 - VR Sink
 - Any blocks that implement custom visualization in their output method (for example, an S-function that outputs to a MATLAB figure) are not fully supported

for stepping back because the block method `Output` does not execute while stepping back. While the state of such blocks remains consistent with the simulation time (if the blocks comply with `SimState`), the visualization component is inconsistent until the next step forward in the simulation.

Because these blocks do not affect the numerical result of a simulation, stepping back is not disabled for these blocks. However, the values these blocks output are inaccurate until the simulation steps forward again.

Step Through a Simulation

Step Forward and Back

This example shows how to step forward and back through a simulation.

- 1 At the MATLAB prompt, type

vdp

- 2 In the Simulink Editor for the vdp model, click  to open the Simulation Stepping Options dialog box.

- 3 In the dialog box, select the **Enable stepping back** check box, and then click **OK**.

- 4

In the Simulation toolbar, click the **Step Forward** button  one time.

The simulation simulates one step, and the software stores a simulation snapshot for that step.

- 5 Click the Step Forward button again to step forward again and store simulation data. A total of 25 forward steps produces these simulation results:

- 6 You must step forward to create the simulation state that the step backward operation requires. This means you must first step forward before you can step backward through the same steps.

In the Simulation toolbar, click the **Step Back** button  four times to step backward to the simulation snapshot shown below.

Set Conditional Breakpoints for Stepping a Simulation

A conditional breakpoint is triggered based on a specified expression evaluated on a signal. When the breakpoint is triggered, the simulation pauses.

Set conditional breakpoints to stop Simulation Stepper when a specified condition is met. One example of a use for conditional breakpoints is when you want to examine results after a certain number of iterations in a loop.

Simulation Stepper allows you to set conditional breakpoints for scalar signals. These breakpoints appear for signals:

Breakpoint	Description
	Enabled breakpoint. Appears when you add the conditional breakpoint.
	Enabled breakpoint hit. Appears when the simulation reaches the condition specified and triggers the breakpoint.
	Disabled breakpoint. Appears when you disable a conditional breakpoint.
	Invalid breakpoint. Appears when the software determines that a breakpoint is invalid for the signal. An enabled breakpoint image changes to this one when, during simulation, the software determines that the conditional breakpoint is invalid.

When setting conditional breakpoints, keep in mind that:

- When simulation arrives at a conditional breakpoint, simulation does not stop when the block is executed. Instead, simulation stops after the current simulation step completes.
- You can add multiple conditional breakpoints to a signal line.

Add and Edit Conditional Breakpoints

- 1 In a model, right-click a signal and select **Add Conditional Breakpoint**.
- 2 In the **Add Conditional Breakpoint** dialog box, from the drop-down list, select the condition for the signal. For example, select greater than or less than.
- 3 Enter the signal value where you want simulation to pause and click **OK**. For the condition values:

- Use numeric values. Do not use expressions.
- Do not use NaN.

The affected signal line displays a conditional breakpoint icon: .

- 4 Click the breakpoint to view and edit all conditions set for the signal.

- 5 Simulate the model and notice that the model pauses as simulation steps through the conditional breakpoints.

Conditional Breakpoints Limitations

- You can set conditional breakpoints only on real scalar signals of these data types:
 - double
 - single
 - int
 - bool
 - fixed point (based on the converted double value)
- You cannot set conditional breakpoints (or port value display labels) on non-Simulink signals, such as Simscape or SimEvents signals.
- Conditional breakpoints also have the limitations that port value display have (“Port Value Display Limitations” on page 36-28).
- Conditional Breakpoints only work on the first iteration of For Each Subsystems

Observe Conditional Breakpoint Values

To observe a conditional breakpoint value of a block signal, use data tips to display block port values. You can add data tips before or after you add conditional breakpoints.

- 1 Enable the value display for a signal. Right-click the signal line that has a conditional breakpoint and select **Show Value Label of Selected Port**.

The data tip for the value display appears.

- 2 Simulate the model and observe the conditional breakpoint and data tip when the simulation triggers the breakpoint.

Simulation Pacing

Simulation pacing enables you to slow down a simulation to understand and observe the system's behavior. Visualizing simulations at a slower rate makes it easier to understand underlying system design, identify design issues and demonstrate near real-time behavior. You can view the results and inspect your system while the simulation is in progress. Slow down animations in scopes, to observe how and when the system changes state.

Simulation pacing is useful in scenarios where one simulation-second is completed in a few wall clock time milliseconds. You can also manually interact with the model while it is running at a slower rate, which can help you to explore how your changes affect the simulation behavior. Note that the simulation will run at an approximation of the specified pace.

To start, specify the rate of simulation. This rate is a ratio of elapsed simulation time to elapsed wall clock time.

Using Simulation Pacing

This example shows how to use simulation pacing during a simulation.

- 1 Open the vdp model.
vdp
- 2 In the Simulation menu, click **Pacing Options**

- 3 In the Simulation Pacing Options dialog, select the **Enable pacing to slow down simulation**. On enabling, the specified pace gets automatically applied to the simulation.
- 4 Select the pace at which the model should run by using the slider or entering the pace in the **Simulation time per wall clock second** field. This field also accepts values outside of the range on the slider. The value entered in the field can only be a finite positive number.
- 5 On simulating the model, you can watch the simulation progress at the specified pace in the scope. You can also change the pace through the dialog box and enable/disable pacing while your simulation is running.

To enable Pacing from the command line, use `set_param(model, 'EnablePacing', 'on')` command. To enter the value use `set_param(model, 'PacingRate', value)` where the value is a finite positive number.

The run button changes to , when a simulation is run with Pacing enabled. The status bar indicates if a simulation is running with pacing enabled. It also indicates if the simulation can not run at the specified pace.

Using Simulation Pacing with Dashboard library blocks

This example shows how to adjust simulation pacing while interacting with the simulation using Dashboard library blocks.

The example uses the `sldemo_househeat` model, which is a system that models the thermal characteristics of a house, its outdoor environment, and a house heating system. This model calculates heating costs for a generic house.

In this example, observe the effects of different outside temperatures on the heating cost. The goal of this example is to determine the outside temperature for which the heating cost stays stable at 15 dollars. Use the Knob block from the Dashboard library to change the outside temperatures while the simulation is running. This model is set up such that it simulates the system over a period of several days.

Open the model.

```
sldemo_househeat
```

Add the Knob block, from the Dashboard library. To control the temperature, connect it to the Average Outdoor Temperature block. To connect the blocks, double-click the Knob

block, then click on the Average Outdoor Temperature block and confirm your selection connect in the Knob block dialog box by selecting the **Connect** radio button in the Knob block dialog box.

In the Simulation menu, click **Pacing Options**. Set the pace to an approximation of 0.8 simulation time per wall clock second.

Simulate the model. Observe the simulation run in the scope.

While the simulation is running, change the Average Outdoor Temperature in the Knob block to observe the heat cost. On observing the simulation at a slower pace, you can see that the heat cost is 15 dollars at 61 degrees Fahrenheit.

Limitations

- Simulation pacing is not compatible with:
 - Simulation stepper
 - Profiler
- Simulation pacing is not supported in rapid accelerator mode

How Simulink Works

Simulink is a software package that enables you to model, simulate, and analyze systems whose outputs change over time. Such systems are often referred to as dynamic systems. The Simulink software can be used to explore the behavior of a wide range of real-world dynamic systems, including electrical circuits, shock absorbers, braking systems, and many other electrical, mechanical, and thermodynamic systems. This section explains how Simulink works.

Simulating a dynamic system is a two-step process. First, a user creates a block diagram, using the Simulink model editor, that graphically depicts time-dependent mathematical relationships among the system's inputs, states, and outputs. The user then commands the Simulink software to simulate the system represented by the model from a specified start time to a specified stop time.

Block Diagram Semantics

A classic block diagram model of a dynamic system graphically consists of blocks and lines (signals). The history of these block diagram models is derived from engineering areas such as Feedback Control Theory and Signal Processing. A block within a block diagram defines a dynamic system in itself. The relationships between each elementary dynamic system in a block diagram are illustrated by the use of signals connecting the blocks. Collectively the blocks and lines in a block diagram describe an overall dynamic system.

The Simulink product extends these classic block diagram models by introducing the notion of two classes of blocks, nonvirtual blocks and virtual blocks. Nonvirtual blocks represent elementary systems. Virtual blocks exist for graphical and organizational convenience only: they have no effect on the system of equations described by the block diagram model. You can use virtual blocks to improve the readability of your models.

In general, blocks and lines can be used to describe many “models of computations.” One example would be a flow chart. A flow chart consists of blocks and lines, but one cannot describe general dynamic systems using flow chart semantics.

The term “time-based block diagram” is used to distinguish block diagrams that describe dynamic systems from that of other forms of block diagrams, and the term block diagram (or model) is used to refer to a time-based block diagram unless the context requires explicit distinction.

To summarize the meaning of time-based block diagrams:

- Simulink block diagrams define time-based relationships between signals and state variables. The solution of a block diagram is obtained by evaluating these relationships over time, where time starts at a user specified “start time” and ends at a user specified “stop time.” Each evaluation of these relationships is referred to as a time step.
- Signals represent quantities that change over time and are defined for all points in time between the block diagram's start and stop time.
- The relationships between signals and state variables are defined by a set of equations represented by blocks. Each block consists of a set of equations (block methods). These equations define a relationship between the input signals, output signals and the state variables. Inherent in the definition of an equation is the notion of parameters, which are the coefficients found within the equation.

Creating Models

The Simulink product provides a graphical editor that allows you to create and connect instances of block types selected from libraries of block types (see “Block Libraries”) via a library browser. Libraries of blocks are provided representing elementary systems that can be used as building blocks. The blocks supplied with Simulink are called built-in blocks. Users can also create their own block types and use the Simulink editor to create instances of them in a diagram. User-defined blocks are called custom blocks.

Time

Time is an inherent component of block diagrams in that the results of a block diagram simulation change with time. Put another way, a block diagram represents the instantaneous behavior of a dynamic system. Determining a system's behavior over time thus entails repeatedly solving the model at intervals, called time steps, from the start of the time span to the end of the time span. The process of solving a model at successive time steps is referred to as *simulating* the system that the model represents.

States

Typically the current values of some system, and hence model, outputs are functions of the previous values of temporal variables. Such variables are called states. Computing a model's outputs from a block diagram hence entails saving the value of states at the current time step for use in computing the outputs at a subsequent time step. This task is performed during simulation for models that define states.

Two types of states can occur in a Simulink model: discrete and continuous states. A continuous state changes continuously. Examples of continuous states are the position and speed of a car. A discrete state is an approximation of a continuous state where the state is updated (recomputed) using finite (periodic or aperiodic) intervals. An example of a discrete state would be the position of a car shown on a digital odometer where it is updated every second as opposed to continuously. In the limit, as the discrete state time interval approaches zero, a discrete state becomes equivalent to a continuous state.

Blocks implicitly define a model's states. In particular, a block that needs some or all of its previous outputs to compute its current outputs implicitly defines a set of states that need to be saved between time steps. Such a block is said to have states.

The following is a graphical representation of a block that has states:

Blocks that define continuous states include the following standard Simulink blocks:

- Integrator
- State-Space
- Transfer Fcn
- Variable Transport Delay
- Zero-Pole

The total number of a model's states is the sum of all the states defined by all its blocks. Determining the number of states in a diagram requires parsing the diagram to determine the types of blocks that it contains and then aggregating the number of states defined by each instance of a block type that defines states. This task is performed during the Compilation phase of a simulation.

Working with States

The following facilities are provided for determining, initializing, and logging a model's states during simulation:

- The `model` command displays information about the states defined by a model, including the total number of states defined by the model, the block that defines each state, and the initial value of each state.
- The Simulink debugger displays the value of a state at each time step during a simulation, and the Simulink debugger's `states` command displays information about the model's current states (see “Simulink Debugger”).
- The **Data Import/Export** pane of a model's Configuration Parameters dialog box (see “State Information” on page 64-287) allows you to specify initial values for a model's states, and to record the values of the states at each time step during simulation as an array or structure variable in the MATLAB workspace.
- The Block Parameters dialog box (and the `ContinuousStateAttributes` parameter) allows you to give names to states for those blocks (such as the Integrator) that employ continuous states. This can simplify analyzing data logged for states, especially when a block has multiple states.

The Two Cylinder Model with Load Constraints model illustrates the logging of continuous states.

Continuous States

Computing a continuous state entails knowing its rate of change, or derivative. Since the rate of change of a continuous state typically itself changes continuously (i.e., is itself a state), computing the value of a continuous state at the current time step entails integration of its derivative from the start of a simulation. Thus modeling a continuous state entails representing the operation of integration and the process of computing the state's derivative at each point in time. Simulink block diagrams use Integrator blocks to indicate integration and a chain of blocks connected to an integrator block's input to represent the method for computing the state's derivative. The chain of blocks connected to the integrator block's input is the graphical counterpart to an ordinary differential equation (ODE).

In general, excluding simple dynamic systems, analytical methods do not exist for integrating the states of real-world dynamic systems represented by ordinary differential equations. Integrating the states requires the use of numerical methods called ODE solvers. These various methods trade computational accuracy for computational

workload. The Simulink product comes with computerized implementations of the most common ODE integration methods and allows a user to determine which it uses to integrate states represented by Integrator blocks when simulating a system.

Computing the value of a continuous state at the current time step entails integrating its values from the start of the simulation. The accuracy of numerical integration in turn depends on the size of the intervals between time steps. In general, the smaller the time step, the more accurate the simulation. Some ODE solvers, called variable time step solvers, can automatically vary the size of the time step, based on the rate of change of the state, to achieve a specified level of accuracy over the course of a simulation. The user can specify the size of the time step in the case of fixed-step solvers, or the solver can automatically determine the step size in the case of variable-step solvers. To minimize the computation workload, the variable-step solver chooses the largest step size consistent with achieving an overall level of precision specified by the user for the most rapidly changing model state. This ensures that all model states are computed to the accuracy specified by the user.

Discrete States

Computing a discrete state requires knowing the relationship between its value at the current time step and its value at the previous time step. This is referred to this relationship as the state's update function. A discrete state depends not only on its value at the previous time step but also on the values of a model's inputs. Modeling a discrete state thus entails modeling the state's dependency on the systems' inputs at the previous time step. Simulink block diagrams use specific types of blocks, called discrete blocks, to specify update functions and chains of blocks connected to the inputs of discrete blocks to model the dependency of a system's discrete states on its inputs.

As with continuous states, discrete states set a constraint on the simulation time step size. Specifically, the step size must ensure that all the sample times of the model's states are hit. This task is assigned to a component of the Simulink system called a discrete solver. Two discrete solvers are provided: a fixed-step discrete solver and a variable-step discrete solver. The fixed-step discrete solver determines a fixed step size that hits all the sample times of all the model's discrete states, regardless of whether the states actually change value at the sample time hits. By contrast, the variable-step discrete solver varies the step size to ensure that sample time hits occur only at times when the states change value.

Modeling Hybrid Systems

A hybrid system is a system that has both discrete and continuous states. Strictly speaking, any model that has both continuous and discrete sample times is treated as a

hybrid model, presuming that the model has both continuous and discrete states. Solving such a model entails choosing a step size that satisfies both the precision constraint on the continuous state integration and the sample time hit constraint on the discrete states. The Simulink software meets this requirement by passing the next sample time hit, as determined by the discrete solver, as an additional constraint on the continuous solver. The continuous solver must choose a step size that advances the simulation up to but not beyond the time of the next sample time hit. The continuous solver can take a time step short of the next sample time hit to meet its accuracy constraint but it cannot take a step beyond the next sample time hit even if its accuracy constraint allows it to.

You can simulate hybrid systems using any one of the integration methods, but certain methods are more effective than others. For most hybrid systems, `ode23` and `ode45` are superior to the other solvers in terms of efficiency. Because of discontinuities associated with the sample and hold of the discrete blocks, do not use the `ode15s` and `ode113` solvers for hybrid systems.

Block Parameters

Key properties of many standard blocks are parameterized. For example, the Constant value of the Simulink Constant block is a parameter. Each parameterized block has a block dialog that lets you set the values of the parameters. You can use MATLAB expressions to specify parameter values. Simulink evaluates the expressions before running a simulation. You can change the values of parameters during a simulation. This allows you to determine interactively the most suitable value for a parameter.

A parameterized block effectively represents a family of similar blocks. For example, when creating a model, you can set the Constant value parameter of each instance of the Constant block separately so that each instance behaves differently. Because it allows each standard block to represent a family of blocks, block parameterization greatly increases the modeling power of the standard Simulink libraries. See “Block Parameters” on page 3-8 and “Block Libraries” for more information.

Tunable Parameters

Many block parameters are tunable. A *tunable parameter* is a parameter whose value can be changed without recompiling the model (see “Model Compilation” on page 3-17 for more information on compiling a model). For example, the gain parameter of the Gain block is tunable. You can alter the block's gain while a simulation is running. If a parameter is not tunable and the simulation is running, the dialog box control that sets the parameter is disabled.

When you change the value of a tunable parameter, the change takes effect at the start of the next time step. See “Block Parameters” on page 3-8 and “Tune and Experiment with Block Parameter Values” on page 37-42 for more information.

Block Sample Times

Every Simulink block has a sample time which defines when the block will execute. Most blocks allow you to specify the sample time via a `SampleTime` parameter. Common choices include discrete, continuous, and inherited sample times.

Common Sample Time Types	Sample Time	Examples
Discrete	$[T_s, T_o]$	Unit Delay, Digital Filter
Continuous	$[0, 0]$	Integrator, Derivative
Inherited	$[-1, 0]$	Gain, Sum

For discrete blocks, the sample time is a vector $[T_s, T_o]$ where T_s is the time interval or period between consecutive sample times and T_o is an initial offset to the sample time. In contrast, the sample times for nondiscrete blocks are represented by ordered pairs that use zero, a negative integer, or infinity to represent a specific type of sample time (see “View Sample Time Information” on page 7-9). For example, continuous blocks have a nominal sample time of $[0, 0]$ and are used to model systems in which the states change continuously (e.g., a car accelerating). Whereas you indicate the sample time type of an inherited block symbolically as $[-1, 0]$ and Simulink then determines the actual value based upon the context of the inherited block within the model.

Note that not all blocks accept all types of sample times. For example, a discrete block cannot accept a continuous sample time.

For a visual aid, Simulink allows the optional color-coding and annotation of any block diagram to indicate the type and speed of the block sample times. You can capture all of the colors and the annotations within a legend (see “View Sample Time Information” on page 7-9).

For a more detailed discussion of sample times, see “Sample Time”

Custom Blocks

You can create libraries of custom blocks that you can then use in your models. You can create a custom block either graphically or programmatically. To create a custom block

graphically, you draw a block diagram representing the block's behavior, wrap this diagram in an instance of the Simulink Subsystem block, and provide the block with a parameter dialog, using the Simulink block mask facility. To create a block programmatically, you create a MATLAB file or a MEX-file that contains the block's system functions (see 1“C/C++ S-Function Basics”). The resulting file is called an S-function. You then associate the S-function with instances of the Simulink S-Function block in your model. You can add a parameter dialog to your S-Function block by wrapping it in a Subsystem block and adding the parameter dialog to the Subsystem block. See “Block Authoring and Simulation Integration” for more information.

Systems and Subsystems

A Simulink block diagram can consist of layers. Each layer is defined by a subsystem. A subsystem is part of the overall block diagram and ideally has no impact on the meaning of the block diagram. Subsystems are provided primarily to help with the organizational aspects of a block diagram. Subsystems do not define a separate block diagram.

The Simulink software differentiates between two different types of subsystems: virtual and nonvirtual. The primary difference is that nonvirtual subsystems provide the ability to control when the contents of the subsystem are evaluated.

Virtual Subsystems

Virtual subsystems provide graphical hierarchy in models. Virtual subsystems do not impact execution. During model execution, the Simulink engine flattens all virtual subsystems, i.e., Simulink expands the subsystem in place before execution. This expansion is very similar to the way macros work in a programming language such as C or C++. Roughly speaking, there will be one system for the top-level block diagram which is referred to as the root system, and several lower-level systems derived from nonvirtual subsystems and other elements in the block diagram. You will see these systems in the Simulink Debugger. The act of creating these internal systems is often referred to as *flattening the model hierarchy*.

Nonvirtual Subsystems

Nonvirtual subsystems, which are drawn with a bold border, provide execution and graphical hierarchy in models. Nonvirtual subsystems are executed as a single unit (atomic execution) by the Simulink engine. You can create conditionally executed subsystems that are executed only when a precondition—such as a trigger, an enable, a function-call, or an action— occurs (see “Conditionally Executed Subsystems and Models”). Simulink always computes all inputs used during the execution of a nonvirtual

subsystem before executing the subsystem. Simulink defines the following nonvirtual subsystems.

Atomic subsystems

The primary characteristic of an atomic subsystem is that blocks in an atomic subsystem execute as a single unit. This provides the advantage of grouping functional aspects of models at the execution level. Any Simulink block can be placed in an atomic subsystem, including blocks with different execution rates. You can create an atomic subsystem by selecting the **Treat as atomic unit** option on a virtual subsystem (see the Atomic Subsystem block for more information).

Enabled subsystems

An enabled subsystem behaves similarly to an atomic subsystem, except that it executes only when the signal driving the subsystem enable port is greater than zero. To create an enabled subsystem, place an Enable port block within a Subsystem block. You can configure an enabled subsystem to hold or reset the states of blocks within the enabled subsystem prior to a subsystem enabling action. Simply select the **States when enabling** parameter of the Enable port block. Similarly, you can configure each output port of an enabled subsystem to hold or reset its output prior to the subsystem disabling action. Select the **Output when disabled** parameter in the Output block.

Triggered subsystems

You create a triggered subsystem by placing a trigger port block within a subsystem. The resulting subsystem executes when a rising or falling edge with respect to zero is seen on the signal driving the subsystem trigger port. The direction of the triggering edge is defined by the **Trigger type** parameter on the trigger port block. Simulink limits the type of blocks placed in a triggered subsystem to blocks that do not have explicit sample times (i.e., blocks within the subsystem must have a sample time of -1) because the contents of a triggered subsystem execute in an aperiodic fashion. A Stateflow chart can also have a trigger port which is defined by using the Stateflow editor. Simulink does not distinguish between a triggered subsystem and a triggered chart.

Function-call subsystems

A function-call subsystem is a subsystem that another block can invoke directly during a simulation. It is analogous to a function in a procedural programming language. Invoking a function-call subsystem is equivalent to invoking the output and update methods of the blocks that the subsystem contains in sorted order. The block that invokes a function-call subsystem is called the function-call initiator. Stateflow, Function-Call Generator, and S-function blocks can all serve as function-call initiators. To create a function-call

subsystem, drag a Function-Call Subsystem block from the Ports & Subsystems library into your model and connect a function-call initiator to the function-call port displayed on top of the subsystem. You can also create a function-call subsystem from scratch by first creating a Subsystem block in your model and then creating a Trigger block in the subsystem and setting the Trigger block `Trigger type` to `function-call`.

You can configure a function-call subsystem to be triggered (the default) or periodic by setting its `Sample time type` to be `triggered` or `periodic`, respectively. A function-call initiator can invoke a triggered function-call subsystem zero, once, or multiple times per time step. The sample times of all the blocks in a triggered function-call subsystem must be set to inherited (-1).

A function-call initiator can invoke a periodic function-call subsystem only once per time step and must invoke the subsystem periodically. If the initiator invokes a periodic function-call subsystem aperiodically, Simulink halts the simulation and displays an error message. The blocks in a periodic function-call subsystem can specify a noninherited sample time or inherited (-1) sample time. All blocks that specify a noninherited sample time must specify the same sample time, that is, if one block specifies .1 as its sample time, all other blocks must specify a sample time of .1 or -1. If a function-call initiator invokes a periodic function-call subsystem at a rate that differs from the sample time specified by the blocks in the subsystem, Simulink halts the simulation and displays an error message.

Enabled and triggered subsystems

You can create an enabled and triggered subsystem by placing a Trigger Port block and an Enable port block within a Subsystem block. The resulting subsystem is essentially a triggered subsystem that executes when the subsystem is enabled and a rising or falling edge with respect to zero is seen on the signal driving the subsystem trigger port. The direction of the triggering edge is defined by the `Trigger type` parameter on the trigger port block. Because the contents of a triggered subsystem execute in an aperiodic fashion, Simulink limits the types of blocks placed in an enabled and triggered subsystem to blocks that do not have explicit sample times. In other words, blocks within the subsystem must have a sample time of -1.

Resettable subsystems

A resettable subsystem computes its outputs at every sample time hit but also resets the states of the subsystem on triggering. The resettable subsystem resets the states of all blocks within it, triggered by a rising or falling edge with respect to zero. On triggering, the resettable subsystem resets its states and also computes the outputs.

The resettable subsystem supports only single sample time for all the blocks it contains. Different sample times for different blocks within the subsystem result in an error. For more information, see Resettable Subsystem.

Action subsystems

Action subsystems can be thought of as an intersection of the properties of enabled subsystems and function-call subsystems. Action subsystems are restricted to a single sample time (e.g., a continuous, discrete, or inherited sample time). Action subsystems must be executed by an action subsystem initiator. This is either an If block or a Switch Case block. All action subsystems connected to a given action subsystem initiator must have the same sample time. An action subsystem is created by placing an Action Port block within a Subsystem block. The subsystem icon will automatically adapt to the type of block (i.e., If or Switch Case block) that is executing the action subsystem.

Action subsystems can be executed at most once by the action subsystem initiator. Action subsystems give you control over when the states reset via the **States when execution is resumed** parameter on the Action Port block. Action subsystems also give you control over whether or not to hold the output values via the **Output when disabled** parameter on the output block. This is analogous to enabled subsystems.

Action subsystems behave very similarly to function-call subsystems because they must be executed by an initiator block. *Function-call subsystems can be executed more than once at any given time step whereas action subsystems can be executed at most once.* This restriction means that a larger set of blocks (e.g., periodic blocks) can be placed in action subsystems as compared to function-call subsystems. This restriction also means that you can control how the states and outputs behave.

While iterator subsystems

A while iterator subsystem will run multiple iterations on each model time step. The number of iterations is controlled by the While Iterator block condition. A while iterator subsystem is created by placing a While Iterator block within a subsystem block.

A while iterator subsystem is very similar to a function-call subsystem in that it can run for any number of iterations at a given time step. The while iterator subsystem differs from a function-call subsystem in that there is no separate initiator (e.g., a Stateflow Chart). In addition, a while iterator subsystem has access to the current iteration number optionally produced by the While Iterator block. A while iterator subsystem also gives you control over whether or not to reset states when starting via the **States when starting** parameter on the While Iterator block.

For iterator subsystems

A for iterator subsystem will run a fixed number of iterations at each model time step. The number of iterations can be an external input to the for iterator subsystem or specified internally on the For Iterator block. A for iterator subsystem is created by placing a For Iterator block within a subsystem block.

A for iterator subsystem has access to the current iteration number that is optionally produced by the For Iterator block. A for iterator subsystem also gives you control over whether or not to reset states when starting via the **States when starting** parameter on the For Iterator block. A for iterator subsystem is very similar to a while iterator subsystem with the restriction that the number of iterations during any given time step is fixed.

For each subsystems

The for each subsystem allows you to repeat an algorithm for individual elements (or subarrays) of an input signal. Here, the algorithm is represented by the set of blocks in the subsystem and is applied to a single element (or subarray) of the signal. You can configure the decomposition of the subsystem inputs into elements (or subarrays) using the For Each block, which resides in the subsystem. The For Each block also allows you to configure the concatenation of individual results into output signals. An advantage of this subsystem is that it maintains separate sets of states for each element or subarray that it processes. In addition, for certain models, the for each subsystem improves the code reuse of the code generated by Simulink Coder™.

Signals

The term *signal* refers to a time varying quantity that has values at all points in time. You can specify a wide range of signal attributes, including signal name, data type (e.g., 8-bit, 16-bit, or 32-bit integer), numeric type (real or complex), and dimensionality (one-dimensional, two-dimensional, or multidimensional array). Many blocks can accept or output signals of any data or numeric type and dimensionality. Others impose restrictions on the attributes of the signals they can handle.

On the block diagram, signals are represented with lines that have an arrowhead. The source of the signal corresponds to the block that writes to the signal during evaluation of its block methods (equations). The destinations of the signal are blocks that read the signal during the evaluation of the block's methods (equations).

A good way to understand the definition of a signal is to consider a classroom. The teacher is the one responsible for writing on the white board and the students read what

is written on the white board when they choose to. This is also true of Simulink signals: a reader of the signal (a block method) can choose to read the signal as frequently or infrequently as so desired.

For more information about signals, see “Signals”.

Block Methods

Blocks represent multiple equations. These equations are represented as block methods. These block methods are evaluated (executed) during the execution of a block diagram. The evaluation of these block methods is performed within a simulation loop, where each cycle through the simulation loop represents the evaluation of the block diagram at a given point in time.

Method Types

Names are assigned to the types of functions performed by block methods. Common method types include:

- Outputs

Computes the outputs of a block given its inputs at the current time step and its states at the previous time step.

- Update

Computes the value of the block's discrete states at the current time step, given its inputs at the current time step and its discrete states at the previous time step.

- Derivatives

Computes the derivatives of the block's continuous states at the current time step, given the block's inputs and the values of the states at the previous time step.

Method Naming Convention

Block methods perform the same types of operations in different ways for different types of blocks. The Simulink user interface and documentation uses dot notation to indicate the specific function performed by a block method:

`BlockType.MethodType`

For example, the method that computes the outputs of a Gain block is referred to as

Gain.Outputs

The Simulink debugger takes the naming convention one step further and uses the instance name of a block to specify both the method type and the block instance on which the method is being invoked during simulation, e.g.,

g1.Outputs

Model Methods

In addition to block methods, a set of methods is provided that compute the model properties and its outputs. The Simulink software similarly invokes these methods during simulation to determine a model's properties and its outputs. The model methods generally perform their tasks by invoking block methods of the same type. For example, the model Outputs method invokes the Outputs methods of the blocks that it contains in the order specified by the model to compute its outputs. The model Derivatives method similarly invokes the Derivatives methods of the blocks that it contains to determine the derivatives of its states.

Simulation Phases in Dynamic Systems

In this section...

“Model Compilation” on page 3-17

“Link Phase” on page 3-18

“Simulation Loop Phase” on page 3-18

Model Compilation

The first phase of simulation occurs when the system’s model is open and you simulate the model. In the Simulink Editor, select **Simulation > Run**. Running the simulation causes the Simulink engine to invoke the model compiler. The model compiler converts the model to an executable form, a process called compilation. In particular, the compiler:

- Evaluates the model’s block parameter expressions to determine their values.
- Determines signal attributes, e.g., name, data type, numeric type, and dimensionality, not explicitly specified by the model and checks that each block can accept the signals connected to its inputs.
- A process called attribute propagation is used to determine unspecified attributes. This process entails propagating the attributes of a source signal to the inputs of the blocks that it drives.
- Performs block reduction optimizations.
- Flattens the model hierarchy by replacing virtual subsystems with the blocks that they contain (see “Solvers” on page 3-21).
- Determines the block sorted order (see “Control and Display the Sorted Order” on page 36-31 for more information).
- Determines the sample times of all blocks in the model whose sample times you did not explicitly specify (see “How Propagation Affects Inherited Sample Times” on page 7-38).

These events are essentially the same as what occurs when you update a diagram (“Update Diagram and Run Simulation” on page 1-66). The difference is that the Simulink software starts model compilation as part of model simulation, where compilation leads directly into the linking phase, as described in “Link Phase” on page 3-18. In contrast, you start an explicit model update as a standalone operation on a model.

Link Phase

In this phase, the Simulink engine allocates memory needed for working areas (signals, states, and run-time parameters) for execution of the block diagram. It also allocates and initializes memory for data structures that store run-time information for each block. For built-in blocks, the principal run-time data structure for a block is called the SimBlock. It stores pointers to a block's input and output buffers and state and work vectors.

Method Execution Lists

In the Link phase, the Simulink engine also creates method execution lists. These lists list the most efficient order in which to invoke a model's block methods to compute its outputs. The block sorted order lists generated during the model compilation phase is used to construct the method execution lists.

Block Priorities

You can assign update priorities to blocks (see “Assign Block Priorities” on page 36-45). The output methods of higher priority blocks are executed before those of lower priority blocks. The priorities are honored only if they are consistent with its block sorting rules.

Simulation Loop Phase

Once the Link Phase completes, the simulation enters the simulation loop phase. In this phase, the Simulink engine successively computes the states and outputs of the system at intervals from the simulation start time to the finish time, using information provided by the model. The successive time points at which the states and outputs are computed are called time steps. The length of time between steps is called the step size. The step size depends on the type of solver (see “Solvers” on page 3-21) used to compute the system's continuous states, the system's fundamental sample time (see “Sample Times in Systems” on page 7-28), and whether the system's continuous states have discontinuities (see “Zero-Crossing Detection” on page 3-24).

The Simulation Loop phase has two subphases: the Loop Initialization phase and the Loop Iteration phase. The initialization phase occurs once, at the start of the loop. The iteration phase is repeated once per time step from the simulation start time to the simulation stop time.

At the start of the simulation, the model specifies the initial states and outputs of the system to be simulated. At each step, new values for the system's inputs, states, and outputs are computed, and the model is updated to reflect the computed values. At the

end of the simulation, the model reflects the final values of the system's inputs, states, and outputs. The Simulink software provides data display and logging blocks. You can display and/or log intermediate results by including these blocks in your model.

Loop Iteration

At each time step, the Simulink engine:

1 Computes the model's outputs.

The Simulink engine initiates this step by invoking the Simulink model Outputs method. The model Outputs method in turn invokes the model system Outputs method, which invokes the Outputs methods of the blocks that the model contains in the order specified by the Outputs method execution lists generated in the Link phase of the simulation (see "Solvers" on page 3-21).

The system Outputs method passes the following arguments to each block Outputs method: a pointer to the block's data structure and to its SimBlock structure. The SimBlock data structures point to information that the Outputs method needs to compute the block's outputs, including the location of its input buffers and its output buffers.

2 Computes the model's states.

The Simulink engine computes a model's states by invoking a solver. Which solver it invokes depends on whether the model has no states, only discrete states, only continuous states, or both continuous and discrete states.

If the model has only discrete states, the Simulink engine invokes the discrete solver selected by the user. The solver computes the size of the time step needed to hit the model's sample times. It then invokes the Update method of the model. The model Update method invokes the Update method of its system, which invokes the Update methods of each of the blocks that the system contains in the order specified by the Update method lists generated in the Link phase.

If the model has only continuous states, the Simulink engine invokes the continuous solver specified by the model. Depending on the solver, the solver either in turn calls the Derivatives method of the model once or enters a subcycle of minor time steps where the solver repeatedly calls the model's Outputs methods and Derivatives methods to compute the model's outputs and derivatives at successive intervals within the major time step. This is done to increase the accuracy of the state computation. The model Outputs method and Derivatives methods in turn invoke

their corresponding system methods, which invoke the block Outputs and Derivatives in the order specified by the Outputs and Derivatives methods execution lists generated in the Link phase.

- 3 Optionally checks for discontinuities in the continuous states of blocks.

A technique called zero-crossing detection is used to detect discontinuities in continuous states. See “Zero-Crossing Detection” on page 3-24 for more information.

- 4 Computes the time for the next time step.

Steps 1 through 4 are repeated until the simulation stop time is reached.

Solvers

A dynamic system is simulated by computing its states at successive time steps over a specified time span, using information provided by the model. The process of computing the successive states of a system from its model is known as solving the model. No single method of solving a model suffices for all systems. Accordingly, a set of programs, known as *solvers*, are provided that each embody a particular approach to solving a model. The Configuration Parameters dialog box allows you to choose the solver most suitable for your model (see “Compare Solvers” on page 25-7).

Fixed-Step Solvers Versus Variable-Step Solvers

The solvers provided in the Simulink software fall into two basic categories: fixed-step and variable-step.

Fixed-step solvers solve the model at regular time intervals from the beginning to the end of the simulation. The size of the interval is known as the step size. You can specify the step size or let the solver choose the step size. Generally, decreasing the step size increases the accuracy of the results while increasing the time required to simulate the system.

Variable-step solvers vary the step size during the simulation, reducing the step size to increase accuracy when a model's states are changing rapidly and increasing the step size to avoid taking unnecessary steps when the model's states are changing slowly. Computing the step size adds to the computational overhead at each step but can reduce the total number of steps, and hence simulation time, required to maintain a specified level of accuracy for models with rapidly changing or piecewise continuous states.

Continuous Versus Discrete Solvers

The Simulink product provides both continuous and discrete solvers.

Continuous solvers use numerical integration to compute a model's continuous states at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on the individual blocks to compute the values of the model's discrete states at each time step.

Mathematicians have developed a wide variety of numerical integration techniques for solving the ordinary differential equations (ODEs) that represent the continuous states of dynamic systems. An extensive set of fixed-step and variable-step continuous solvers are

provided, each of which implements a specific ODE solution method (see “Compare Solvers” on page 25-7).

Discrete solvers exist primarily to solve purely discrete models. They compute the next simulation time step for a model and nothing else. In performing these computations, they rely on each block in the model to update its individual discrete states. They do not compute continuous states.

Note You must use a continuous solver to solve a model that contains both continuous and discrete states. You cannot use a discrete solver because discrete solvers cannot handle continuous states. If, on the other hand, you select a continuous solver for a model with no states or discrete states only, Simulink software uses a discrete solver.

Two discrete solvers are provided: A fixed-step discrete solver and a variable-step discrete solver. The fixed-step solver by default chooses a step size and hence simulation rate fast enough to track state changes in the fastest block in your model. The variable-step solver adjusts the simulation step size to keep pace with the actual rate of discrete state changes in your model. This can avoid unnecessary steps and hence shorten simulation time for multirate models (see “Sample Times in Systems” on page 7-28 for more information).

Minor Time Steps

Some continuous solvers subdivide the simulation time span into major and minor time steps, where a minor time step represents a subdivision of the major time step. The solver produces a result at each major time step. It uses results at the minor time steps to improve the accuracy of the result at the major time step.

Shape Preservation

Usually the integration step size is only related to the current step size and the current integration error. However, for signals whose derivative changes rapidly, you can obtain a more accurate integration results by including the derivative input information at each time step. To do so, enable the **Model Configuration Parameters > Solver > Shape Preservation** option.

“Simulation Phases in Dynamic Systems” on page 3-17

Zero-Crossing Detection

A variable-step solver dynamically adjusts the time step size, causing it to increase when a variable is changing slowly and to decrease when the variable changes rapidly. This behavior causes the solver to take many small steps in the vicinity of a discontinuity because the variable is rapidly changing in this region. This improves accuracy but can lead to excessive simulation times.

The Simulink software uses a technique known as *zero-crossing detection* to accurately locate a discontinuity without resorting to excessively small time steps. Usually this technique improves simulation run time, but it can cause some simulations to halt before the intended completion time.

Two algorithms are provided in the Simulink software: Nonadaptive and Adaptive. For information about these techniques, see “Zero-Crossing Algorithms” on page 3-32.

Demonstrating Effects of Excessive Zero-Crossing Detection

The Simulink software comes with three models that illustrate zero-crossing behavior: `sldemo_bounce_two_integrators`, `sldemo_doublebounce`, and `sldemo_bounce`.

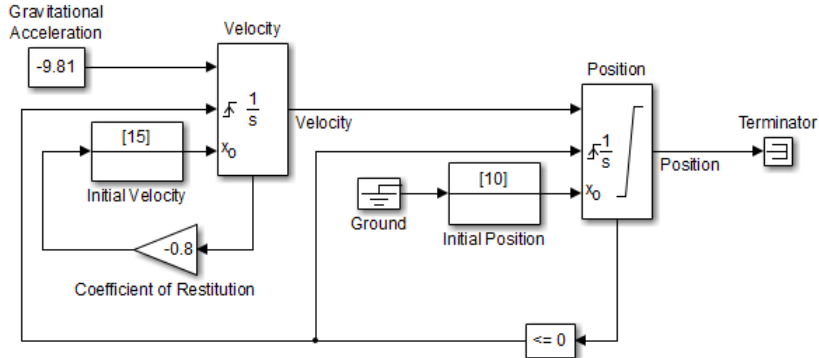

- The `sldemo_bounce_two_integrators` model demonstrates how excessive zero crossings can cause a simulation to halt before the intended completion time unless you use the adaptive algorithm.
- The `sldemo_bounce` model uses a better model design than `sldemo_bounce_two_integrators`.
- The `sldemo_doublebounce` model demonstrates how the adaptive algorithm successfully solves a complex system with two distinct zero-crossing requirements.

The Bounce Model with Two Integrators

Bouncing Ball Model

Two separate Integrators are less efficient than a single Second-Order Integrator for simulating a bouncing ball.
[Click here to see sldemo_bounce for the recommended modeling approach.](#)

- 1 At the MATLAB command prompt, type `sldemo_bounce_two_integrators` to load the example.
- 2 Once the block diagram appears, set the **Model Configuration Parameters** > **Solver** > **Algorithm** parameter to Nonadaptive.
- 3 Also in the **Solver** pane, set the **Stop time** parameter to 20 s.
- 4 Run the model. In the Simulink Editor, select **Simulation** > **Run**.
- 5 After the simulation completes, click the Scope block window to see the results.

You may need to click on **Autoscale** to view the results in their entirety.

- 6 Use the scope zoom controls to closely examine the last portion of the simulation. You can see that the velocity is hovering just above zero at the last time point.

- 7 Change the simulation **Stop time** edit box in the Simulink Editor toolbar to 25 seconds, and run the simulation again.
- 8 This time the simulation halts with an error shortly after it passes the simulated 20 second time point.

Excessive chattering as the ball repeatedly approaches zero velocity has caused the simulation to exceed the default limit of 1000 for the number of consecutive zero crossings allowed. Although you can increase this limit by adjusting the **Model Configuration Parameters > Solver > Number of consecutive zero crossings** parameter. In this case, making that change does not allow the simulation to simulate for 25 seconds.

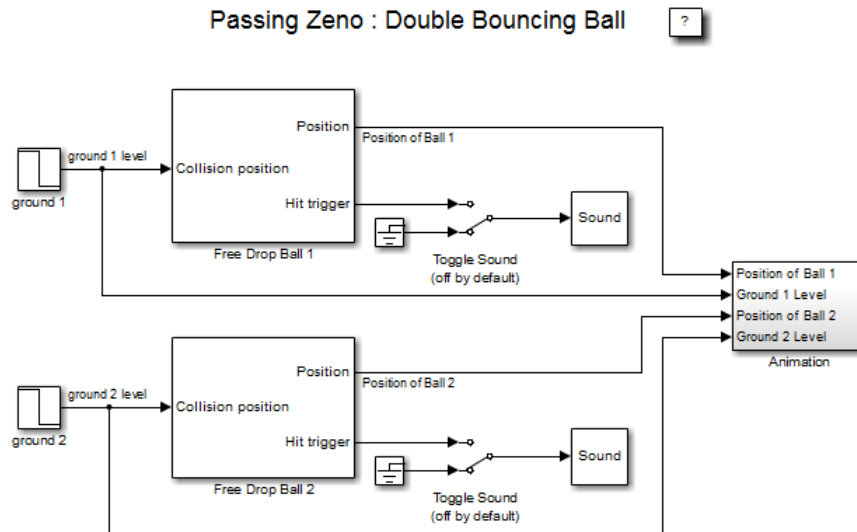

- 9 Also in the **Solver** pane, from the **Algorithm** pull down menu, select the **Adaptive** algorithm.
- 10 Run the simulation again.
- 11 This time the simulation runs to completion because the adaptive algorithm prevented an excessive number of zero crossings from occurring.

Bounce Model with a Second-Order Integrator

The Double-Bounce Model

- 1 At the MATLAB command prompt, type `sldemo_doublebounce` to load the example. The model and an animation window open. In the animation window, two balls are resting on two platforms.
- 2 In the animation window, click the **Nonadaptive** button to run the example using the nonadaptive algorithm. This is the default setting used by the Simulink software for all models.
- 3 The ball on the right is given a larger initial velocity. Consequently, the two balls hit the ground and recoil at different times.
- 4 The simulation halts after 14 seconds because the ball on the left exceeded the number of zero crossings limit. The ball on the right is left hanging in mid air.
- 5 An error message dialog opens. Click **OK** to close it.
- 6 Click on the **Adaptive** button to run the simulation with the adaptive algorithm.
- 7 Notice that this time the simulation runs to completion, even after the ground shifts out from underneath the ball on the left at 20 seconds.

How the Simulator Can Miss Zero-Crossing Events

The bounce and double-bounce models show that high-frequency fluctuations about a discontinuity ('chattering') can cause a simulation to prematurely halt.

It is also possible for the solver to entirely miss zero crossings if the solver error tolerances are too large. This is possible because the zero-crossing detection technique checks to see if the value of a signal has changed sign after a major time step. A sign change indicates that a zero crossing has occurred, and the zero-crossing algorithm will then hunt for the precise crossing time. However, if a zero crossing occurs within a time step, but the values at the beginning and end of the step do not indicate a sign change, the solver steps over the crossing without detecting it.

The following figure shows a signal that crosses zero. In the first instance, the integrator steps over the event because the sign has not changed between time steps. In the second, the solver detects change in sign and so detects the zero-crossing event.

Preventing Excessive Zero Crossings

Use the following table to prevent excessive zero-crossing errors in your model.

Make this change...	How to make this change...	Rationale for making this change...
Increase the number of allowed zero crossings	Increase the value of the Number of consecutive zero crossings . option on the Solver pane in the Configuration Parameters dialog box.	This may give your model enough time to resolve the zero crossing.

Make this change...	How to make this change...	Rationale for making this change...
Relax the Signal threshold	Select Adaptive from the Algorithm pull down and increase the value of the Signal threshold option on the Solver pane in the Configuration Parameters dialog box.	The solver requires less time to precisely locate the zero crossing. This can reduce simulation time and eliminate an excessive number of consecutive zero-crossing errors. However, relaxing the Signal threshold may reduce accuracy.
Use the Adaptive Algorithm	Select Adaptive from the Algorithm pull down on the Solver pane in the Configuration Parameters dialog box.	This algorithm dynamically adjusts the zero-crossing threshold, which improves accuracy and reduces the number of consecutive zero crossings detected. With this algorithm you have the option of specifying both the Time tolerance and the Signal threshold .
Disable zero-crossing detection for a specific block	<ol style="list-style-type: none"> 1 Clear the Enable zero-crossing detection check box on the block's parameter dialog box. 2 Select Use local settings from the Zero-crossing control pull down on the Solver pane of the Configuration Parameters dialog box. 	Locally disabling zero-crossing detection prevents a specific block from stopping the simulation because of excessive consecutive zero crossings. All other blocks continue to benefit from the increased accuracy that zero-crossing detection provides.
Disable zero-crossing detection for the entire model	Select Disable all from the Zero-crossing control pull down on the Solver pane of the Configuration Parameters dialog box.	This prevents zero crossings from being detected anywhere in your model. A consequence is that your model no longer benefits from the increased accuracy that zero-crossing detection provides.

Make this change...	How to make this change...	Rationale for making this change...
If using the ode15s solver, consider adjusting the order of the numerical differentiation formulas	Select a value from the Maximum order pull down on the Solver pane of the Configuration Parameters dialog box.	For more information, see "Maximum order".
Reduce the maximum step size	Enter a value for the Max step size option on the Solver pane of the Configuration Parameters dialog box.	This can insure the solver takes steps small enough to resolve the zero crossing. However, reducing the step size can increase simulation time, and is seldom necessary when using the Adaptive algorithm.

Zero-Crossing Algorithms

The Simulink software includes two zero-crossing detection algorithms: Nonadaptive and Adaptive.

To choose the algorithm, either use the **Algorithm** option in the Solver pane of the Configuration Parameter dialog box, or use the ZeroCrossAlgorithm command. The command can either be set to 'Nonadaptive' or 'Adaptive'.

The Nonadaptive algorithm is provided for backwards compatibility with older versions of Simulink and is the default. It brackets the zero-crossing event and uses increasingly smaller time steps to pinpoint when the zero crossing has occurred. Although adequate for many types of simulations, the Nonadaptive algorithm can result in very long simulation times when a high degree of 'chattering' (high frequency oscillation around the zero-crossing point) is present.

The Adaptive algorithm dynamically turns the bracketing on and off, and is a good choice when:

- The system contains a large amount of chattering.
- You wish to specify a guard band (tolerance) around which the zero crossing is detected.

The Adaptive algorithm turns off zero-crossing bracketing (stops iterating) if either of the following are satisfied:

- The zero crossing error is exceeded. This is determined by the value specified in the **Signal threshold** option in the Solver pane of the Configuration Parameters dialog box. This can also be set with the `ZCThreshold` command. The default is Auto, but you can enter any real number greater than zero for the tolerance.
- The system has exceeded the number of consecutive zero crossings specified in the **Number of consecutive zero crossings** option in the Solver pane of the Configuration Parameters dialog box. Alternatively, this can be set with the `MaxConsecutiveZCs` command.

Understanding Signal Threshold

The Adaptive algorithm automatically sets a tolerance for zero-crossing detection. Alternatively, you can set the tolerance by entering a real number greater than or equal to zero in the Configuration Parameters Solver pane, `Signal threshold` pull down. This option only becomes active when the zero-crossing algorithm is set to Adaptive.

This graphic shows how the Signal threshold sets a window region around the zero-crossing point. Signals falling within this window are considered as being at zero.

The zero-crossing event is bracketed by time steps T_{n-1} and T_n . The solver iteratively reduces the time steps until the state variable lies within the band defined by the signal threshold, or until the number of consecutive zero crossings equals or exceeds the value in the Configuration Parameters Solver pane, `Number of consecutive zero crossings` pull down.

It is evident from the figure that increasing the signal threshold increases the distance between the time steps which will be executed. This often results in faster simulation times, but might reduce accuracy.

How Blocks Work with Zero-Crossing Detection

A block can register a set of zero-crossing variables, each of which is a function of a state variable that can have a discontinuity. The zero-crossing function passes through zero from a positive or negative value when the corresponding discontinuity occurs. The registered zero-crossing variables are updated at the end of each simulation step, and any variable that has changed sign is identified as having had a zero-crossing event.

If any zero crossings are detected, the Simulink software interpolates between the previous and current values of each variable that changed sign to estimate the times of the zero crossings (that is, the discontinuities).

Note The Zero-Crossing detection algorithm can bracket zero-crossing events only for signals of data type double

Blocks That Register Zero Crossings

The following table lists blocks that register zero crossings and explains how the blocks use the zero crossings:

Block	Description of Zero Crossing
Abs	One: to detect when the input signal crosses zero in either the rising or falling direction.
Backlash	Two: one to detect when the upper threshold is engaged, and one to detect when the lower threshold is engaged.
Compare To Constant	One: to detect when the signal equals a constant.
Compare To Zero	One: to detect when the signal equals zero.
Dead Zone	Two: one to detect when the dead zone is entered (the input signal minus the lower limit), and one to detect when the dead zone is exited (the input signal minus the upper limit).

Block	Description of Zero Crossing
Enable	One: If an Enable port is inside of a Subsystem block, it provides the capability to detect zero crossings. See the Enable Subsystem block for details “Using Enabled Subsystems” on page 10-11.
From File	One: to detect when the input signal has a discontinuity in either the rising or falling direction
From Workspace	One: to detect when the input signal has a discontinuity in either the rising or falling direction
Hit Crossing	One or two. If there is no output port, there is only one zero crossing to detect when the input signal hit the threshold value. If there is an output port, the second zero crossing is used to bring the output back to 0 from 1 to create an impulse-like output.
If	One: to detect when the If condition is met.
Integrator	If the reset port is present, to detect when a reset occurs. If the output is limited, there are three zero crossings: one to detect when the upper saturation limit is reached, one to detect when the lower saturation limit is reached, and one to detect when saturation is left.
MinMax	One: for each element of the output vector, to detect when an input signal is the new minimum or maximum.
Relational Operator	One: to detect when the specified relation is true.
Relay	One: if the relay is off, to detect the switch-on point. If the relay is on, to detect the switch-off point.
Saturation	Two: one to detect when the upper limit is reached or left, and one to detect when the lower limit is reached or left.
Second-Order Integrator	Five: two to detect when the state x upper or lower limit is reached; two to detect when the state dx/dt upper or lower limit is reached; and one to detect when a state leaves saturation.
Sign	One: to detect when the input crosses through zero.
Signal Builder	One: to detect when the input signal has a discontinuity in either the rising or falling direction
Step	One: to detect the step time.

Block	Description of Zero Crossing
Switch	One: to detect when the switch condition occurs.
Switch Case	One: to detect when the case condition is met.
Trigger	One: If a Triggered port is inside of a Subsystem block, it provides the capability to detect zero crossings. See the Triggered Subsystem block for details: “Using Triggered Subsystems” on page 10-21.
Enabled and Triggered Subsystem	Two: one for the enable port and one for the trigger port. See the Enabled and Triggered Subsystem block for details: “Using Enabled and Triggered Subsystems” on page 10-26

Note Zero-crossing detection is also available for a Stateflow chart that uses continuous-time mode. See “Configure a Stateflow Chart for Continuous-Time Simulation” (Stateflow) for more information.

Implementation Example: Saturation Block

An example of a Simulink block that registers zero crossings is the Saturation block. Zero-crossing detection identifies these state events in the Saturation block:

- The input signal reaches the upper limit.
- The input signal leaves the upper limit.
- The input signal reaches the lower limit.
- The input signal leaves the lower limit.

Simulink blocks that define their own state events are considered to have *intrinsic zero crossings*. Use the Hit Crossing block to receive explicit notification of a zero-crossing event. See “Blocks That Register Zero Crossings” on page 3-34 for a list of blocks that incorporate zero crossings.

The detection of a state event depends on the construction of an internal zero-crossing signal. This signal is not accessible by the block diagram. For the Saturation block, the signal that is used to detect zero crossings for the upper limit is `zcSignal = UpperLimit - u`, where `u` is the input signal.

Zero-crossing signals have a direction attribute, which can have these values:

- *rising* — A zero crossing occurs when a signal rises to or through zero, or when a signal leaves zero and becomes positive.
- *falling* — A zero crossing occurs when a signal falls to or through zero, or when a signal leaves zero and becomes negative.
- *either* — A zero crossing occurs if either a rising or falling condition occurs.

For the Saturation block's upper limit, the direction of the zero crossing is *either*. This enables the entering and leaving saturation events to be detected using the same zero-crossing signal.

Algebraic Loop Concepts

In this section...
“Mathematical Interpretation” on page 3-39
“Physical Interpretation” on page 3-40
“Artificial Algebraic Loops” on page 3-40
“How the Algebraic Loop Solver Works” on page 3-42
“Why Algebraic Loops Are Undesirable” on page 3-44

In a Simulink model, an algebraic loop occurs when a signal loop exists with only direct feedthrough blocks within the loop. Direct feedthrough means that Simulink needs the value of the block’s input signal to compute its output at the current time step. Such a signal loop creates a circular dependency of block outputs and inputs in the same time-step. This results in an algebraic equation that needs solving at each time-step, adding computational cost to the simulation.

Some examples of blocks with direct feedthrough inputs are:

- Math Function
- Gain
- Product
- State-Space, when the D matrix coefficient is nonzero
- Sum
- Transfer Fcn, when the numerator and denominator are of the same order
- Zero-Pole, when the block has as many zeros as poles

Nondirect feedthrough blocks maintain a State variable. Two examples are Integrator and Unit Delay.

Tip To determine if a block has direct feedthrough, read the **Characteristics** section of the block reference page.

The figure shows an example of an algebraic loop. The Sum block is an algebraic variable x_a that is constrained to equal the first input u minus x_a (for example, $x_a = u - x_a$).

The solution of this simple loop is $x_a = u/2$.

Mathematical Interpretation

Simulink contains a suite of numerical solvers for simulating ordinary differential equations (ODEs), which are systems of equations that you can write as

$$\dot{\mathbf{x}} = \mathbf{f}(\mathbf{x}, t),$$

where \mathbf{x} is the state vector and t is the independent time variable.

Some systems of equations contain additional constraints that involve the independent variable and the state vector, but not the derivative of the state vector. Such systems are called differential algebraic equations (DAEs),

The term algebraic refers to equations that do not involve any derivatives. You can express DAEs that arise in engineering in the semi-explicit form

$$\begin{aligned} \dot{\mathbf{x}} &= \mathbf{f}(\mathbf{x}, \mathbf{x}_a, t) \\ 0 &= \mathbf{g}(\mathbf{x}, \mathbf{x}_a, t), \end{aligned}$$

where:

- \mathbf{f} and \mathbf{g} can be vector functions.
- The first equation is the differential equation.
- The second equation is the algebraic equation.
- The vector of differential variables is \mathbf{x} .
- The vector of algebraic variables is \mathbf{x}_a .

In Simulink models, algebraic loops are algebraic constraints. Models with algebraic loops define a system of differential algebraic equations. Simulink solves the algebraic equations (the algebraic loop) numerically for \mathbf{x}_a at each step of the ODE solver.

The model in the figure is equivalent to this system of equations in semi-explicit form:

$$\begin{aligned}\dot{x} &= f(x, x_a, t) = x_a \\ 0 &= g(x, x_a, t) = -x + u - 2x_a.\end{aligned}$$

At each step of the ODE solver, the algebraic loop solver must solve the algebraic constraint for x_a before calculating the derivative \dot{x} .

Physical Interpretation

Algebraic constraints:

- Occur when modeling physical systems, often due to conservation laws, such as conservation of mass and energy
- Occur when you choose a particular coordinate system for a model
- Help impose design constraints on system responses in a dynamic system

Use Simscape to model systems that span mechanical, electrical, hydraulic, and other physical domains as physical networks. Simscape constructs the DAEs that characterize the behavior of a model. The software integrates these equations with the rest of the model and then solves the DAEs directly. Simulink solves the variables for the components in the different physical domains simultaneously, avoiding problems with algebraic loops.

Artificial Algebraic Loops

An *artificial algebraic loop* occurs when an atomic subsystem or Model block causes Simulink to detect an algebraic loop, even though the contents of the subsystem do not contain a direct-feedthrough from the input to the output. When you create an atomic subsystem, all Inport blocks are direct feedthrough, resulting in an algebraic loop.

Start with the included model which represents a simple proportional control of the plant described by

$$G(s) = \frac{1}{s^2 + 2s + 1}$$

which can be rewritten in state-space form as

$$\dot{x} = \begin{bmatrix} -2 & -1 \\ 1 & 0 \end{bmatrix} x + \begin{pmatrix} 0 \\ 1 \end{pmatrix} u$$

$$y = \begin{bmatrix} 0 & 1 \end{bmatrix} x$$

The system has neither algebraic variables nor direct feedthrough and does not contain an algebraic loop.

Modify the model as described in the following steps:

- 1 Enclose the Controller and Plant blocks in a subsystem
- 2 In the subsystem dialog box, select **Treat as atomic unit** to make the subsystem atomic
- 3 In the **Diagnostics** pane of the the Model Configuration Parameters, set the **Algebraic Loop** parameter to error

When simulating this model, an algebraic loop occurs because the subsystem is direct feedthrough, even though the path within the atomic subsystem is not direct feedthrough. Simulation stops with an algebraic loop error.

How the Algebraic Loop Solver Works

When a model contains an algebraic loop, Simulink uses a nonlinear solver at each time step to solve the algebraic loop. The solver performs iterations to determine the solution to the algebraic constraint, if there is one. As a result, models with algebraic loops can run more slowly than models without algebraic loops.

Simulink uses a dogleg trust region algorithm to solve algebraic loops. The tolerance used is smaller than the ODE solver `RelTol` and `Abstol`. This is because Simulink uses the “explicit ODE method” to solve Index-1 differential algebraic equations (DAEs).

For the algebraic loop solver to work,

- There must be one block where the loop solver can break the loop and attempt to solve the loop.
- The model should have real double signals.
- The underlying algebraic constraint must be a smooth function

For example, suppose your model has a Sum block with two inputs—one additive, the other subtractive. If you feed the output of the Sum block to one of the inputs, you create an algebraic loop where all of the blocks include direct feedthrough.

The Sum block cannot compute the output without knowing the input. Simulink detects the algebraic loop, and the algebraic loop solver solves the loop using an iterative loop. In the Sum block example, the software computes the correct result this way:

$$x_a(t) = u(t) / 2. \quad (3-1)$$

The algebraic loop solver uses a gradient-based search method, which requires continuous first derivatives of the algebraic constraint that correspond to the algebraic

loop. As a result, if the algebraic loop contains discontinuities, the algebraic loop solver can fail.

For more information, see Solving Index-1 DAEs in MATLAB and Simulink ¹

Trust-Region and Line-Search Algorithms in the Algebraic Loop Solver

The Simulink algebraic loop solver uses one of two algorithms to solve algebraic loops:

- Trust-Region
- Line-Search

By default, the algebraic loop solver uses the trust-region algorithm.

If the algebraic loop solver cannot solve the algebraic loop with the trust-region algorithm, try simulating the model using the line-search algorithm.

To switch to the line-search algorithm, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'LineSearch');
```

To switch back to the trust-region algorithm, at the MATLAB command line, enter:

```
set_param(model_name, 'AlgebraicLoopSolver', 'TrustRegion');
```

Limitations of the Algebraic Loop Solver

Algebraic loop solving is an iterative process. The Simulink algebraic loop solver is successful only if the algebraic loop converges to a definite answer. When the loop fails to converge, or converges too slowly, the simulation exits with an error.

The algebraic loop solver cannot solve algebraic loops that contain any of the following:

- Blocks with discrete-valued outputs
- Blocks with nondouble or complex outputs
- Discontinuities
- Stateflow charts

Why Algebraic Loops Are Undesirable

If your model contains an algebraic loop:

- You cannot generate code for the model.
- The Simulink algebraic loop solver might not be able to solve the algebraic loop.
- While Simulink is trying to solve the algebraic loop, the simulation can execute slowly.

For most models, the algebraic loop solver is computationally expensive for the first time step. Simulink solves subsequent time steps rapidly because a good starting point for x_a is available from the previous time step.

- “Modeling Considerations with Algebraic Loops” on page 3-70

Identify Algebraic Loops in Your Model

If Simulink reports an algebraic loop in your model, the algebraic loop solver may be able to solve the loop. If Simulink cannot solve the loop, there are several techniques to eliminate the loop.

Use this workflow to decide how you want to eliminate an algebraic loop.

Highlight Algebraic Loops in the Model

Use `getAlgebraicLoops` to identify algebraic loops in a model and highlight them in the Simulink Editor. With this approach:

- You can traverse multiple layers of model hierarchy to locate algebraic loops.
- You can identify real and artificial algebraic loops.
- You can visualize all loops in your model simultaneously.
- You do not need to drill in and out of the model, across boundaries.
- You do not need to detect loops in serial order. Also, you do not need to compile the model every time you detect and solve a loop. Therefore you can solve loops quickly.

You perform algebraic loop highlighting on an entire model, not on specific subsystems.

- 1 Open the model.
- 2 In the **Diagnostics** pane of Model Configuration Parameters, set **Algebraic loop** to **none** or **warning**. Setting this parameter to **error** prevents the model from compiling.
- 3 Compile the model without any errors. The model must compile before you can highlight any algebraic loops.
- 4 At the MATLAB command prompt, enter:

```
Simulink.BlockDiagram.getAlgebraicLoops(bdroot)
```

The `getAlgebraicLoops` function highlights algebraic loops in the model, including algebraic loops in subsystems. It also creates a report with information about each loop:

- Solid lines represent real algebraic loops.
- Dotted lines represent artificial algebraic loops.
- A red highlight appears around a block assigned with an algebraic variable.
- The **Loop ID** helps you identify the system that contains a particular loop.

Customize the report by selecting or clearing the **Visible** checkbox for a loop.

Once you have identified algebraic loops in a model, you can remove them by editing the model. Close the highlight report and make changes to the model. You can edit the model only after you close the report.

Simulink does not save loop highlighting. Closing the model or exiting the display removes the loop highlighting.

Use the Algebraic Loop Diagnostic

Simulink detects algebraic loops during simulation initialization, for example, when you update your diagram. You can set the Algebraic loop diagnostic to report an error or warning if the software detects any algebraic loops in your model.

In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic loop** parameter:

- **none** -- Simulink tries to solve the algebraic loop; reports an error only if the algebraic loop cannot be solved.
- **warning** -- Algebraic loops result in warnings. Simulink tries to solve the algebraic loop; reports an error only if the algebraic loop cannot be solved.
- **error** -- Algebraic loops stop the initialization. Review the loop manually before Simulink tries to solve the loop.

This example shows how to use the algebraic loop diagnostic to highlight algebraic loops in the `sldemo_hydcyl` model.

- 1 Open the `sldemo_hydcyl` model
- 2 In the **Diagnostics** pane of the Model Configuration Parameters, set the **Algebraic loop** parameter to **error**.
- 3 Try to simulate the model

When Simulink detects an algebraic loop during initialization, the simulation stops. The Diagnostic Viewer displays an error message and lists all the blocks in the model that are part of that algebraic loop. In the model, red highlights show the blocks and signals that make up the loop.

Single Hydraulic Cylinder Simulation

Remove Algebraic Loops

Use these techniques to remove algebraic loops in a model.

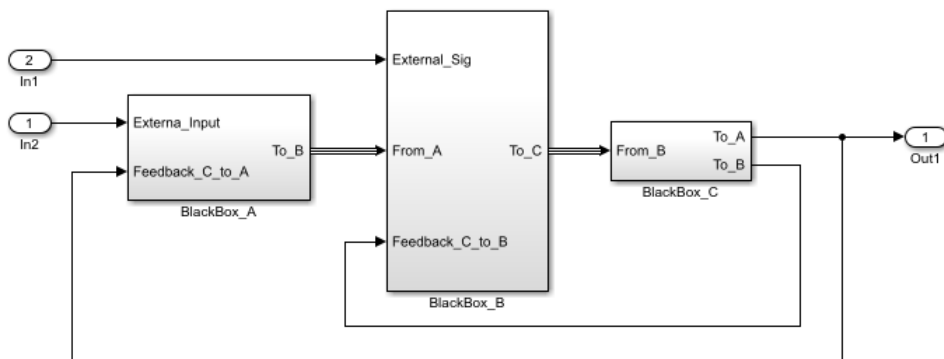

- “Introduce a Delay” on page 3-50
- “Solve Algebraic Loops Manually” on page 3-52
- “Create Initial Guesses Using the IC and Algebraic Constraint Blocks” on page 3-53

Introduce a Delay

Algebraic loops can occur in large models when atomic subsystems create feedback loops.

In the generic model here, there are two algebraic loops that involve subsystems.

- BlackBox_A → BlackBox_B → BlackBox_C → BlackBox_A
- BlackBox_B → BlackBox_C → BlackBox_B

When you update this model, Simulink detects the loop BlackBox_A → BlackBox_B → BlackBox_C → BlackBox_A.

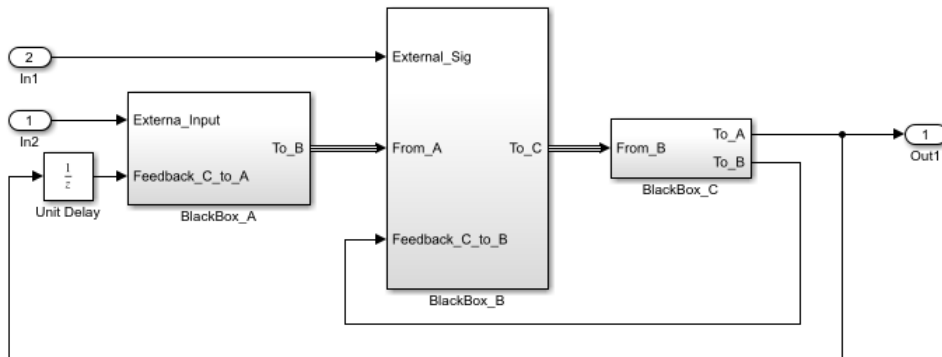

Since you do not know the contents of these subsystems, break the loops by adding a Unit Delay block outside the subsystems. There are three ways to use the Unit Delay block to break these loops:

- Add a Unit Delay between BlackBox_A and BlackBox_C.
- Add a Unit Delay between BlackBox_B and BlackBox_C.

- Add Unit Delay blocks to both algebraic loops.

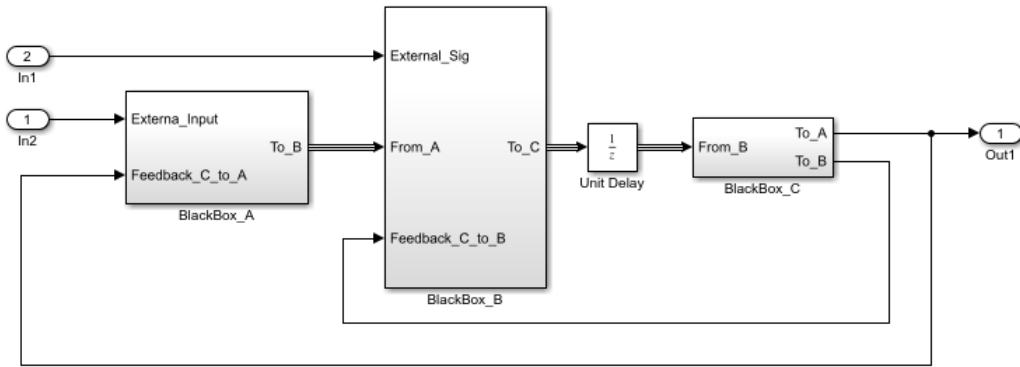

Add a unit delay between BlackBox_A and BlackBox_C

If you add a unit delay on the feedback signal between the subsystems BlackBox_A and BlackBox_C, you introduce the minimum number of unit delays (1) to the system. By introducing the delay before BlackBox_A, BlackBox_B and BlackBox_C use data from the current time step.

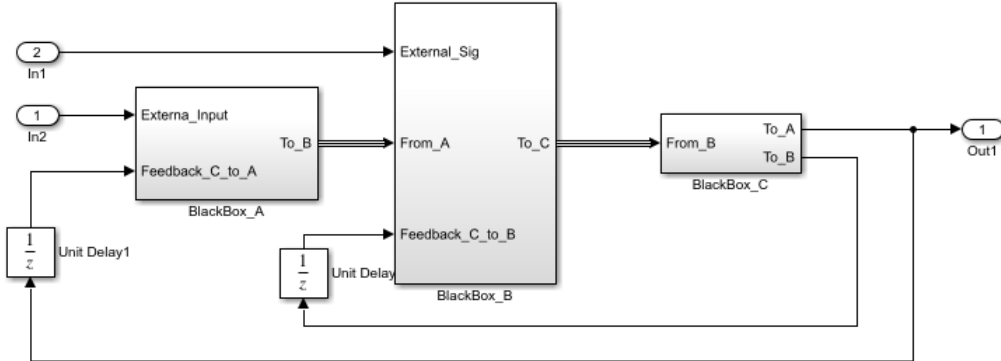

Add a unit delay between BlackBox_B and BlackBox_C

If you add a unit delay between the subsystems BlackBox_B and BlackBox_C, you break the algebraic loop between BlackBox_B and BlackBox_C. In addition, you break the loop between BlackBox_A and BlackBox_C, because that signal completes the algebraic loop. By inserting the Unit Delay block before BlackBox_C, BlackBox_C now works with data from the previous time step only.

Add unit delays to both algebraic loops

In the example here, you insert Unit Delay blocks to break both algebraic loops. In this model, BlackBox_A and BlackBox_B use data from the previous time step. BlackBox_C uses data from the current time step.

Solve Algebraic Loops Manually

If Simulink cannot solve the algebraic loop, the software reports an error. Use one of these techniques to solve the loop manually:

- Restructure the underlying DAEs using techniques such as differentiation or change of coordinates. These techniques put the DAEs in a form that is easier for the algebraic loop solver to solve.

- Convert the DAEs to ODEs, which eliminates any algebraic loops.
- “Create Initial Guesses Using the IC and Algebraic Constraint Blocks” on page 3-53

Create Initial Guesses Using the IC and Algebraic Constraint Blocks

Your model might contain loops for which the loop solver cannot converge without a good, initial guess for the algebraic states. You can specify an initial guess for the algebraic state variables, but use this technique only when you think the loop is legitimate.

There are two ways to specify an initial guess:

- Place an IC block in the algebraic loop.
- Specify an initial guess for a signal in an algebraic loop using an Algebraic Constraint block.

How Simulink Eliminates Artificial Algebraic Loops

When you enable **Minimize algebraic loop occurrences**, Simulink tries to eliminate artificial algebraic loops. In this example, the model contains an atomic subsystem that causes an artificial algebraic loop.

The contents of the atomic subsystem are not direct feedthrough, but Simulink identifies the atomic subsystem as direct feedthrough.

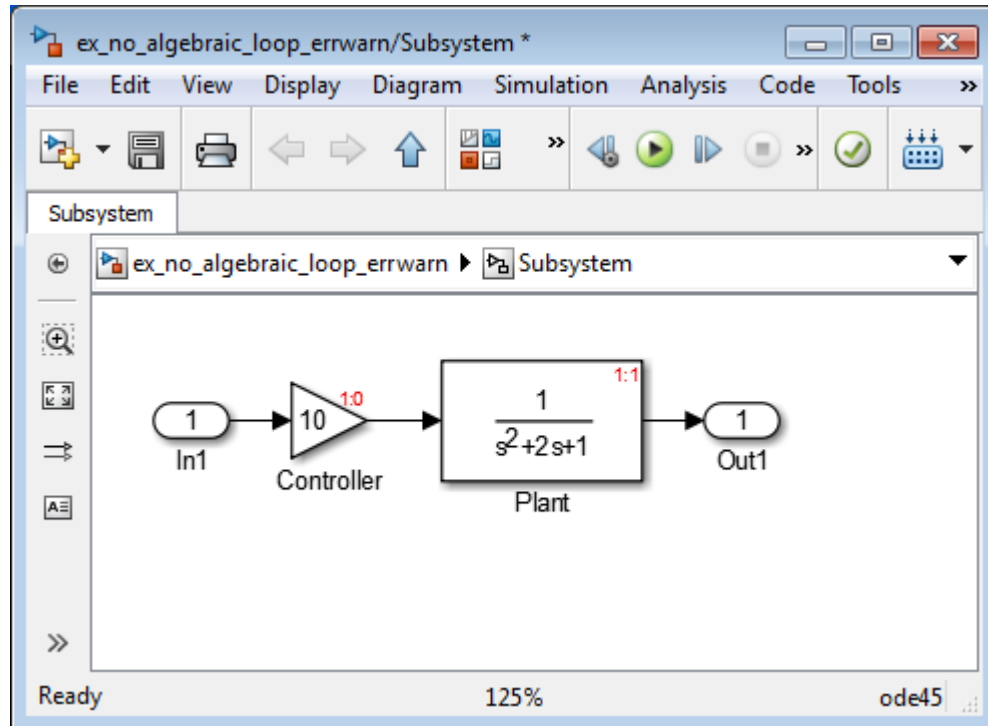

If the **Algebraic loop** diagnostic is set to **error**, simulating the model results in an error because the model contains an artificial algebraic loop involving its atomic subsystem.

To eliminate this algebraic loop,

- 1 Create the model from the preceding graphics, with the atomic subsystem that causes the artificial algebraic loop.
- 2 In the **Diagnostics** pane of Model Configuration Parameters, set the **Algebraic loop** parameter to **warning** or **none**.
- 3 In the **Data Import/Export** pane, make sure the **Signal logging** parameter is disabled. If signal logging is enabled, Simulink cannot eliminate artificial algebraic loops.
- 4 To display the sorted order for this model and the atomic subsystem, select **Display > Blocks > Sorted Execution Order**.

Reviewing the sorted order can help you understand how to eliminate the artificial algebraic loop.

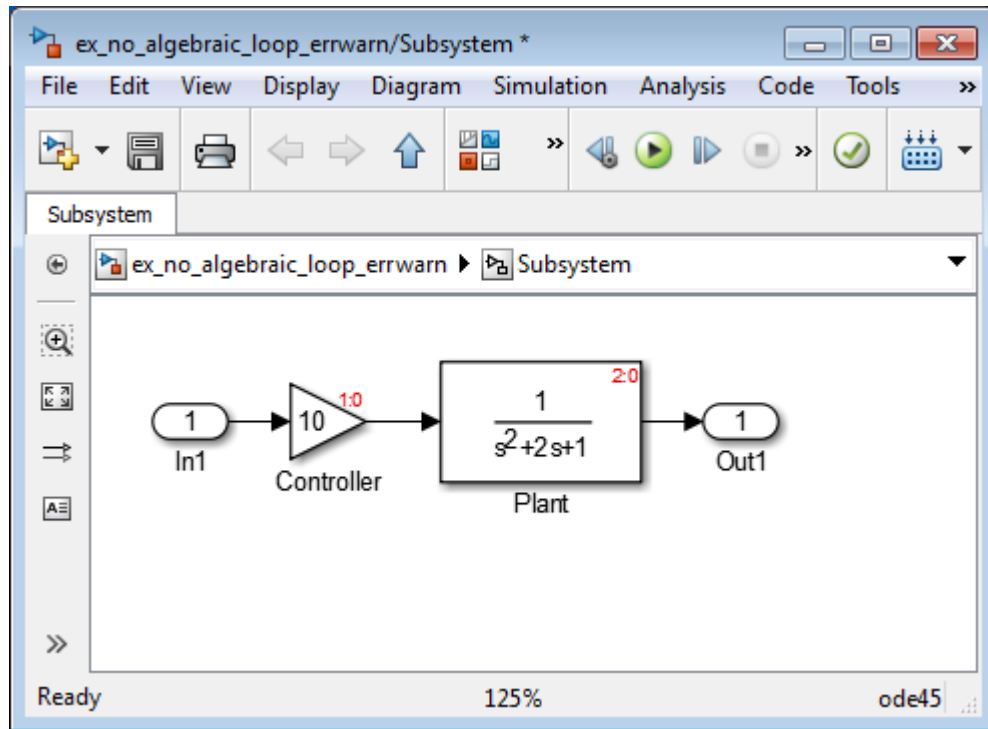

All the blocks in the subsystem execute at the same level: 1. (0 is the lowest level, indicating the first blocks to execute.)

Note For more information about sorted order, see “Control and Display the Sorted Order” on page 36-31.

- 5 In the top-level model’s **Subsystem Parameters** dialog box, select **Minimize algebraic loop occurrences**. This parameter directs Simulink to try to eliminate the algebraic loop that contains the atomic subsystem, when it simulates the model. Save the changes.
- 6 Click **Simulation > Update Diagram** to recalculate the sorted order.

Now there are two levels of sorted order inside the subsystem: 1 and 2.

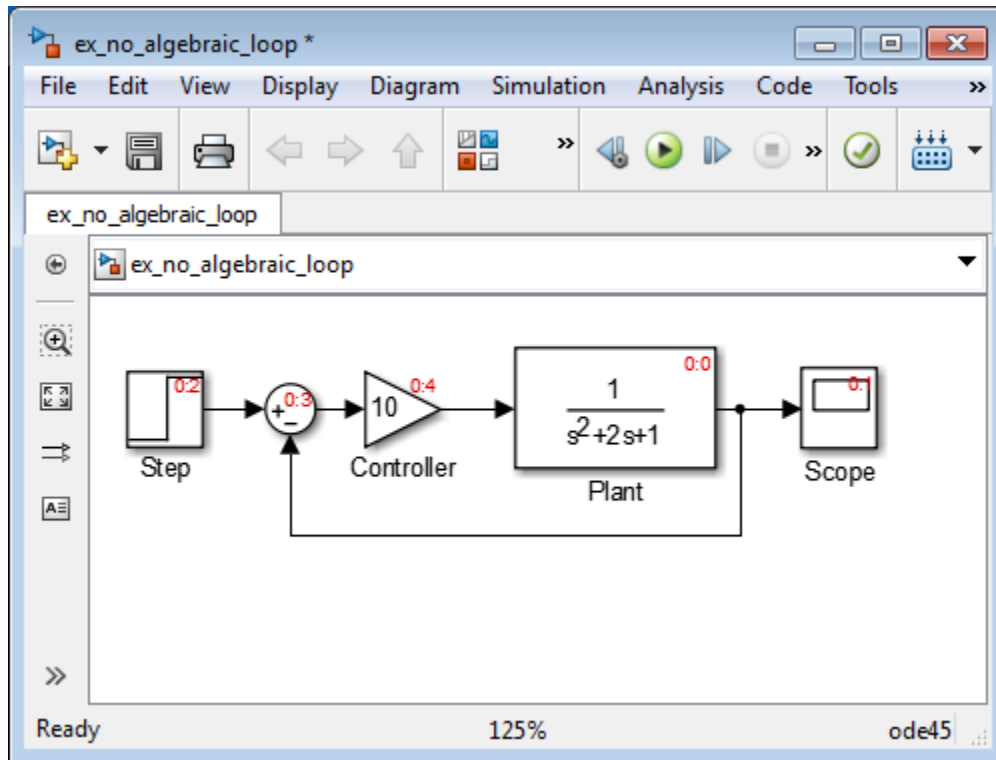

To eliminate the artificial algebraic loop, Simulink tries to make the input of the subsystem or referenced model non-direct feedthrough.

When you simulate a model, all blocks execute methods in this order:

- 1 mdlOutputs
- 2 mdlDerivatives
- 3 mdlUpdate

In the original version of this model, the execution of the `mdlOutputs` method starts with the Plant block because the Plant block is non-direct feedthrough. The execution finishes with the Controller block.

Note For more information about these methods, see “Block Methods” on page 3-15.

If you enable the **Minimize algebraic loop occurrences** parameter for the atomic subsystem, Simulink divides the subsystem into two atomic units.

These conditions are true:

- Atomic unit 2 is not direct feedthrough.
- Atomic unit 1 has only a `mdlOutputs` method.

Only the `mdlDerivatives` or `mdlUpdate` methods of Atomic unit 2 need the output of Atomic unit 1. Simulink can execute what normally would have been executed during the `mdlOutput` method of Atomic unit 1 in the `mdlDerivatives` methods of Atomic unit 2.

The new execution order for the model is:

- 1 `mdlOutputs` method of model
 - a `mdlOutputs` method of Atomic unit 2
 - b `mdlOutputs` methods of other blocks
- 2 `mdlDerivatives` method of model
 - a `mdlOutputs` method of Atomic unit 1
 - b `mdlDerivatives` method of Atomic unit 2
 - c `mdlDerivatives` method of other blocks

For the **Minimize algebraic loop occurrences** technique to be successful, the subsystem or referenced model must have a non-direct-feedthrough block connected directly to an Inport. Simulink can then set the `DirectFeedthrough` property of the block Inport to `false` to indicate that the input port does not have direct feedthrough.

Eliminate Artificial Algebraic Loops Caused by Atomic Subsystems

If an atomic subsystem causes an artificial algebraic loop, convert the atomic subsystem to a virtual subsystem. This change has no effect on the behavior of the model. When the subsystem is atomic and you simulate the model, Simulink invokes the algebraic loop solver. The solver terminates after one iteration. The algebraic loop is automatically solved because there is no algebraic constant. After you make the subsystem virtual, Simulink does not invoke the algebraic loop solver during simulation.

To convert an atomic subsystem to a virtual subsystem:

- 1 Open the model that contains the atomic subsystem.
- 2 Right-click the atomic subsystem and select **Subsystem Parameters**.
- 3 Clear the **Treat as atomic unit** parameter.
- 4 Save the changes.

If you replace the atomic subsystem with a virtual subsystem and the simulation still fails with an algebraic loop error, examine the model for one of these:

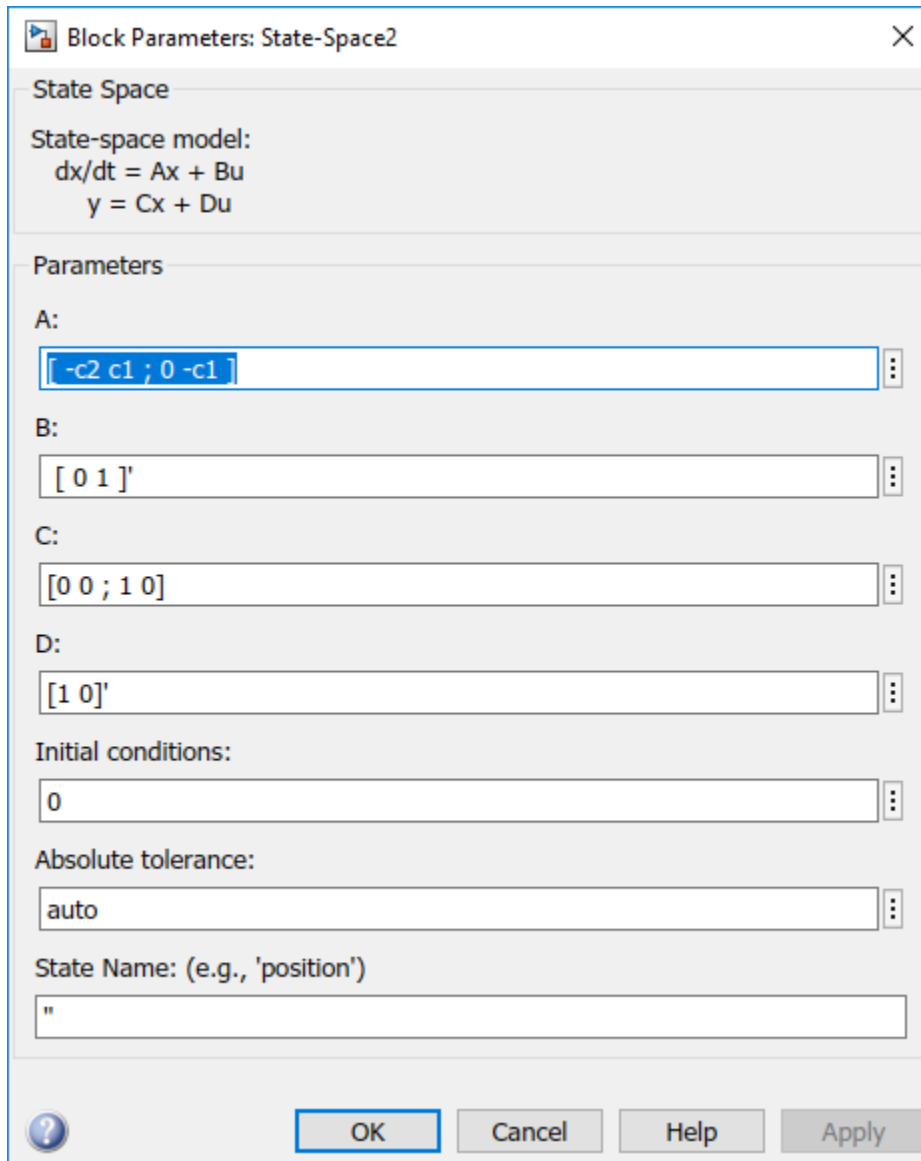

- An algebraic constraint
- An artificial algebraic loop that was not caused by this atomic subsystem

Bundled Signals That Create Artificial Algebraic Loops

Some models bundle signals together. This bundling can cause Simulink to detect an algebraic loop, even when an algebraic constraint does not exist. If you redirect one or more signals, you may be able to remove the artificial algebraic loop.

In this example, a linearized model simulates the dynamics of a two-tank system fed by a single pump. In this model:

- Output q1 is the rate of the fluid flow into the tank from the pump.
- Output h2 is the height of the fluid in the second tank.
- The State-Space block defines the dynamic response of the tank system to the pump operation:

- The output from the State-Space block is a vector that contains q1 and h2.

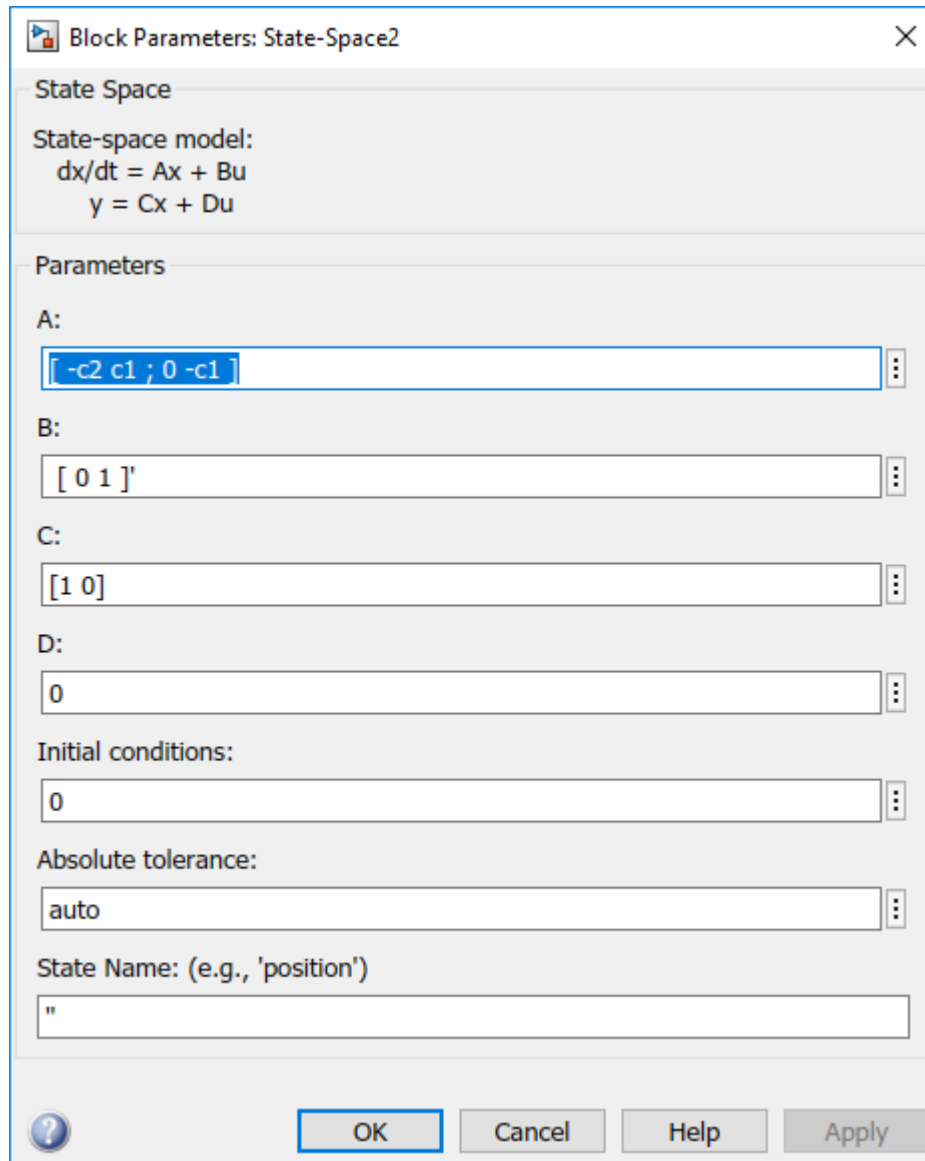

If you simulate this model with the **Algebraic loop** parameter set to warn or error, Simulink identifies the algebraic loop.

To eliminate this algebraic loop:

- 1 Change the C and D matrices as follows:

- 2 Pass q1 directly to the Scope instead of through the State-Space block.

Now, the input (q1) does not pass directly to the output (the D matrix is 0), so the State-Space block no longer has direct feedthrough. The feedback signal has only one element now, so the Selector block is no longer necessary, as you can see in the following model.

Model and Block Parameters to Diagnose and Eliminate Artificial Algebraic Loops

There are two parameters to consider when you think that your model has an artificial algebraic loop:

- **Minimize algebraic loop occurrences** parameter — Specify that Simulink try to eliminate any artificial algebraic loops for:
 - Atomic subsystems — In the Subsystem Parameters dialog box, select **Minimize algebraic loop occurrences**.
 - Model blocks — For the referenced model, in the **Model Referencing** pane of Configuration Parameters, select **Minimize algebraic loop occurrences**.
- **Minimize algebraic loop** parameter — Specifies what diagnostic action Simulink takes if the **Minimize algebraic loop occurrences** parameter has no effect.

The **Minimize algebraic loop** parameter is in the **Diagnostics** pane of Configuration Parameters. The diagnostic actions for this parameter are:

Setting	Simulation Response
none	Simulink takes no action.
warning	Simulink displays a warning that the Minimize algebraic loop occurrences parameter has no effect.

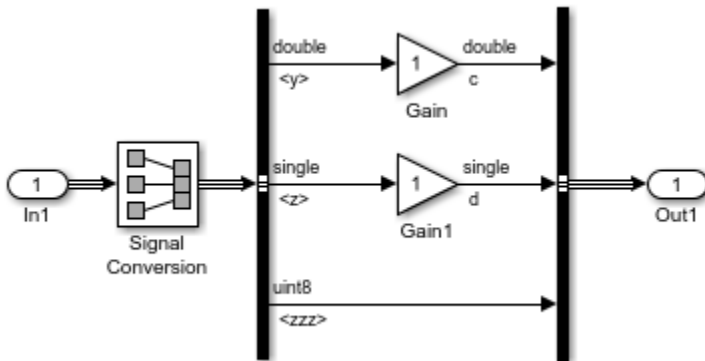

Setting	Simulation Response
error	Simulink terminates the simulation and displays an error that the Minimize algebraic loop occurrences parameter has no effect.

Block Reduction and Artificial Algebraic Loops

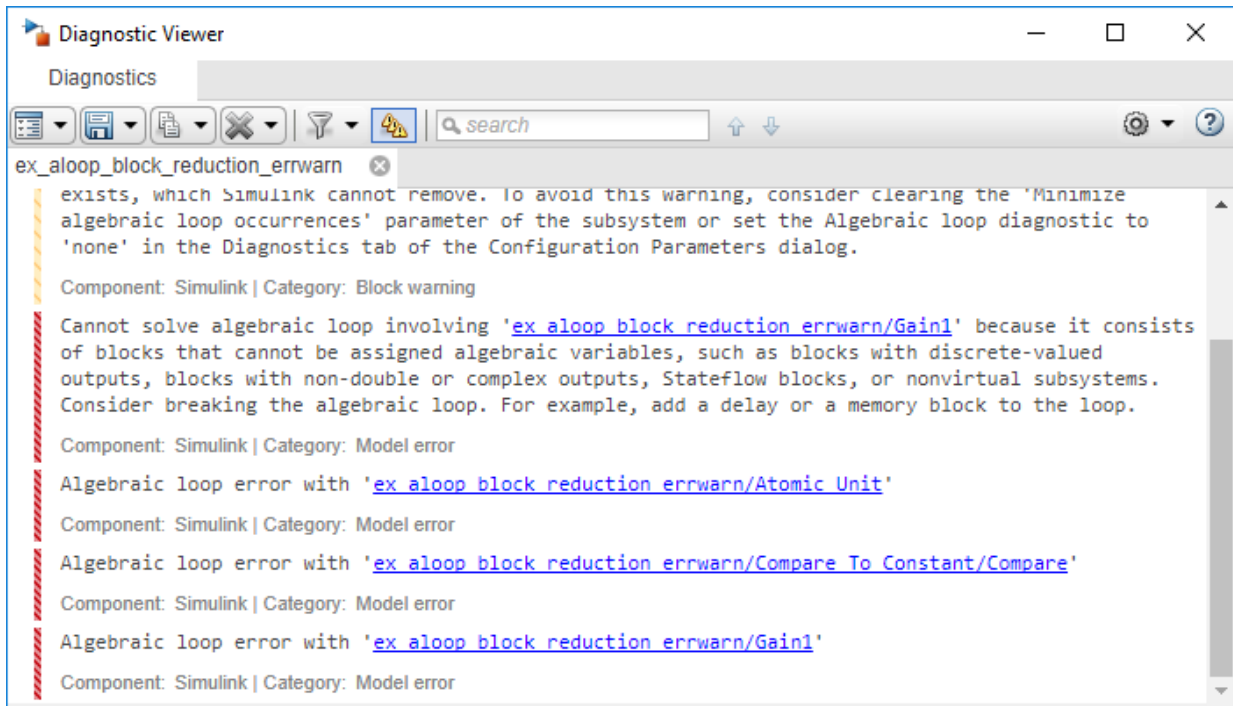

When you enable the **Block reduction** optimization in Model Configuration Parameters, Simulink collapses certain groups of blocks into a single, more efficient block, or removes them entirely. Enabling block reduction results in faster execution during model simulation and in generating code.

Enabling block reduction can also help Simulink solve artificial algebraic loops.

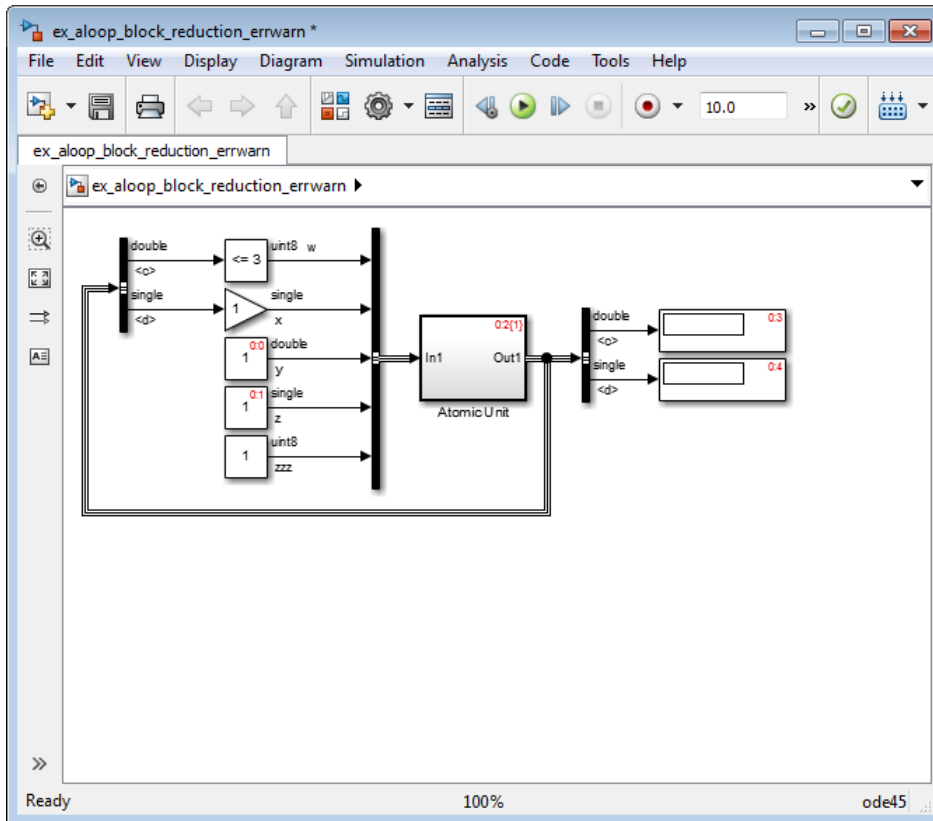

Consider the following example model.

Initially, block reduction is turned off. When you simulate this model, the Atomic Unit subsystem and Gain and Compare to Constant blocks are part of an algebraic loop that Simulink cannot solve.

If you enable block reduction and sorted order, and resimulate the model, Simulink does not display the sorted order for blocks that have been reduced. You can now quickly see which blocks have been reduced.

The Compare to Constant and Gain blocks have been eliminated from the model, so they no longer generate an algebraic loop error. The Atomic Unit subsystem generates a warning:

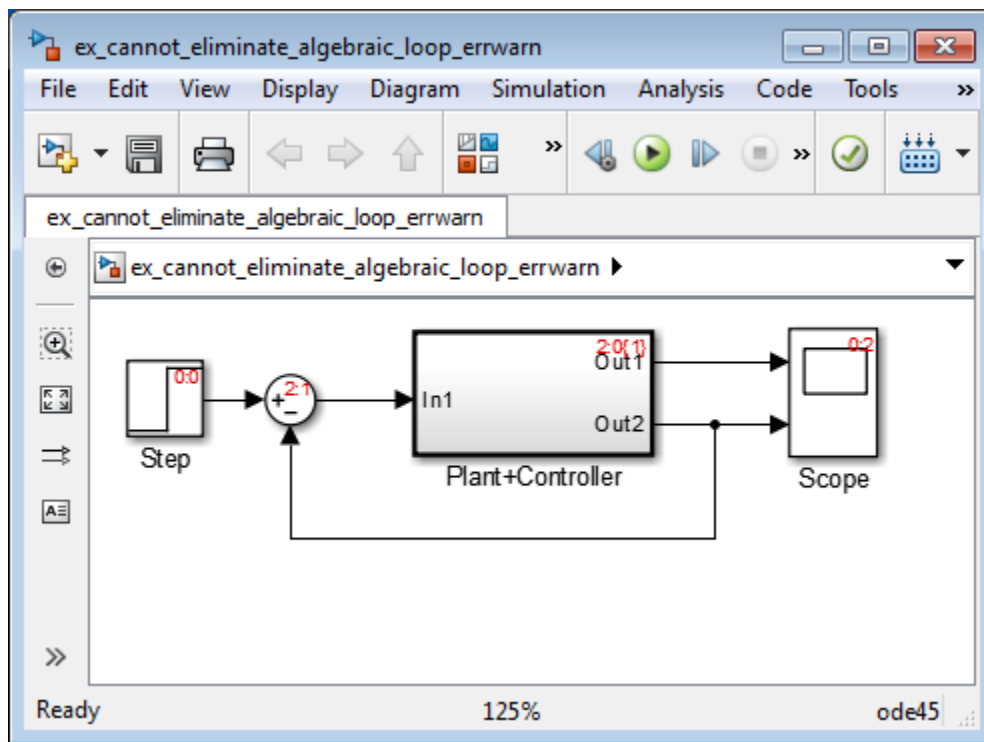

Warning: If the inport 'ex_aloop_block_reduction_errwarn/Atomic Unit/In1' of subsystem 'ex_aloop_block_reduction_errwarn/Atomic Unit' involves direct feedback, then an algebraic loop exists, which Simulink cannot remove. Consider clearing the 'Minimize algebraic loop occurrences' parameter to avoid this warning.

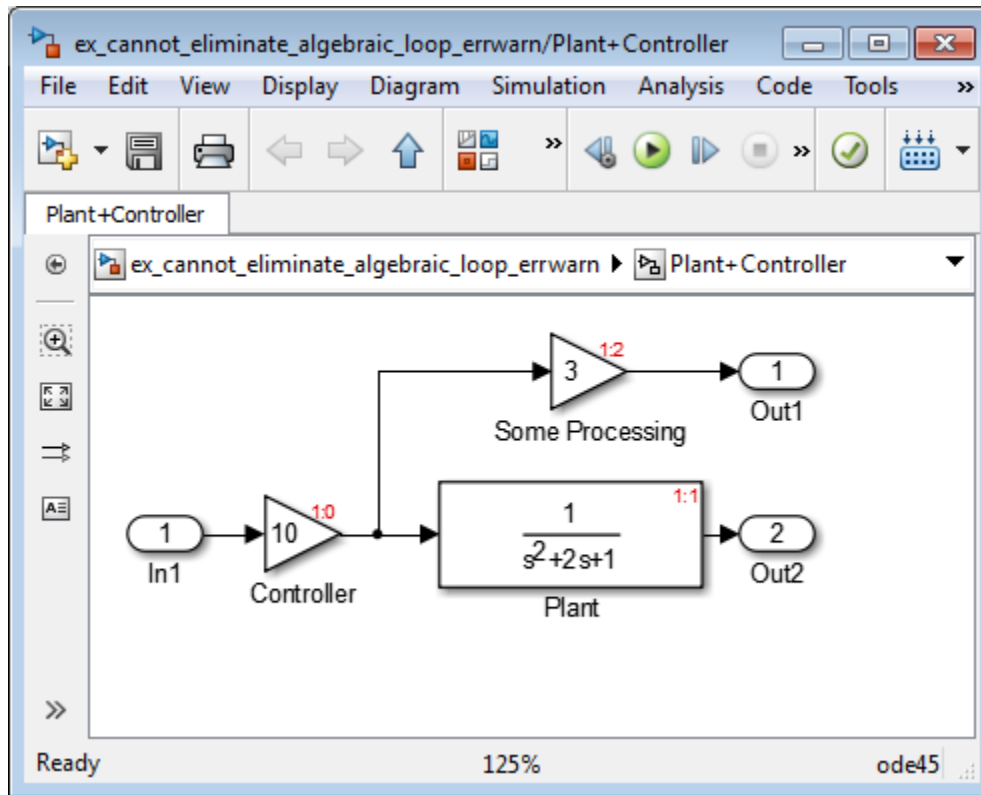

Tip Use Bus Selector blocks to pass only the required signals into atomic subsystems.

When Simulink Cannot Eliminate Artificial Algebraic Loops

Setting the **Minimize algebraic loop occurrences** parameter does not always work. Simulink cannot change the `DirectFeedthrough` property of an Inport for an atomic subsystem if the Inport is connected to an Outport only through direct-feedthrough blocks.

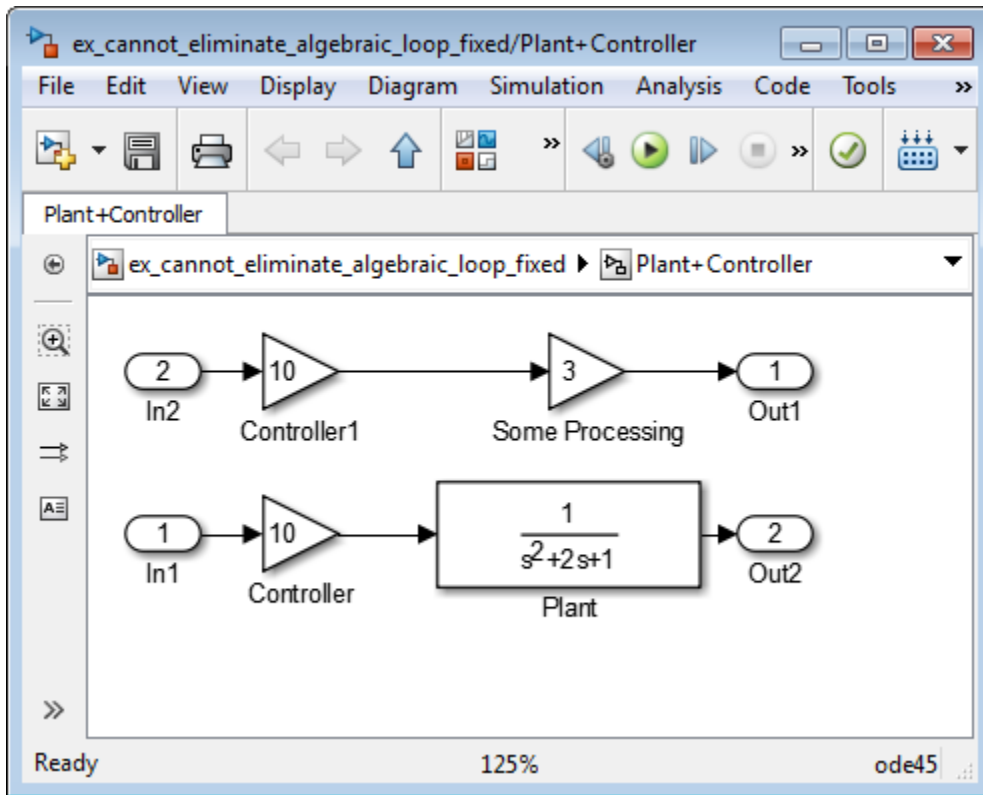

In this model, the subsystem `Plant+Controller` causes an algebraic loop, but it has an extra Gain block and an extra output.

Simulink cannot move the `mdlOutputs` method of the Controller block to the `mdlDerivative` method of an Atomic unit 1 because the output of the atomic subsystem depends on the output of the Controller block. You cannot make the subsystem non-direct-feedthrough.

You can modify this model to eliminate the artificial algebraic loop by redefining the atomic subsystem by adding additional Inport and Gain blocks, as you can see in the model here. Doing so makes In1 non-direct-feedthrough and In2 direct feedthrough, thus breaking the algebraic loop.

Modeling Considerations with Algebraic Loops

Managing Large Models with Artificial Algebraic Loops

Adopt these design techniques for large models with algebraic loops:

- Avoid creating loops that contain discontinuities or nondouble data types. The Simulink algebraic loop solver is gradient-based and must solve algebraic constraints to high precision.
- Develop a scheme for clearly identifying atomic subsystems as direct feedthrough or not direct feedthrough. Use a visual scheme such as coloring the blocks or defining a block-naming convention.
- If you plan to generate code for your model, enable the **Minimize algebraic loop occurrences** parameter for all atomic subsystems. When possible, make sure that the input ports for the atomic subsystems are connected directly to non-direct-feedthrough blocks.
- Avoid combining non-direct-feedthrough and direct-feedthrough paths using the Bus Creator or Mux blocks. Simulink may not be able to eliminate any resulting artificial algebraic loops. Instead, consider clustering the non-direct-feedthrough and direct-feedthrough objects in separate subsystems.

Use Bus Selector blocks to pass only the required signals into atomic subsystems.

Model Blocks and Direct Feedthrough

When a Model block is part of a cycle, and the block is a direct feed through block, an algebraic loop can result. An algebraic loop in a model is not necessarily an error, but it can give unexpected results. See:

- “Highlight Algebraic Loops in the Model” on page 3-47 for information about seeing algebraic loops graphically.
- “Display Algebraic Loop Information” on page 34-31 for information about tracing algebraic loops in the debugger.
- The “Model Configuration Parameters: Diagnostics” pane “Algebraic loop” option for information on detecting algebraic loops automatically.

Direct Model Block Feedthrough Caused by Referenced Model Structure

A Model block can be a direct feed through block due to the structure of the referenced model. Where direct feed through results from sub model structure, and causes an unwanted algebraic loop, you can:

- Automatically eliminate the algebraic loop using techniques described in:
 - “Minimize algebraic loop”
 - “Minimize algebraic loop occurrences”
 - “Remove Algebraic Loops” on page 3-50
- Manually insert the number of Unit Delay blocks needed to break the algebraic loop.

Direct Model Block Feedthrough Caused by Model Configuration

Generic Real Time (grt) and Embedded Real Time (ert) based targets provide the **Single output/update function** option on the **Configuration Parameters** dialog. This option controls whether generated code has separate output and update functions, or a combined output/update function. See:

- “Configure Code Generation for Model Entry-Point Functions” (Simulink Coder) for information about separate and combined output and update functions.
- “Single output/update function” (Simulink Coder) for information about specifying whether code has separate or combined functions.

When **Single output/update function** is enabled (default), a Model block has a combined output/update function. The function makes the block a direct feed through block for all inports, regardless of the structure of the referenced model. Where an unwanted algebraic loop results, you can:

- Disable **Single output/update function**. The code for the Model block then has separate output and update functions, eliminating the direct feed through and hence the algebraic loop.
- Automatically eliminate the algebraic loop using techniques described in:
 - “Minimize algebraic loop”
 - “Minimize algebraic loop occurrences”
 - “Remove Algebraic Loops” on page 3-50
- Manually insert one or more Unit Delay blocks as needed to break the algebraic loop.

Changing Block Priorities When Using Algebraic Loop Solver

During the updating phase of simulation, Simulink determines the simulation execution order of block methods. This block invocation ordering is the sorted order.

If you assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks, the algebraic loop solver does not honor these priorities when attempting to solve any algebraic loops.

Create a Template from a Model

Create a Simulink template from a model to reuse or share the settings and contents of the model without copying the model each time. Create templates only from models that do not have external file dependencies (for example, model references, data dictionary, scripts, S-functions, or other file dependencies). If you want to include other dependent files, use a project template instead. See “Using Templates to Create Standard Project Settings” on page 16-40.

- 1 In the model, select **File > Export Model to > Template**.
- 2 In the Export *modelName* to Model Template dialog box, edit the template title and enter a description of the template.

When you use the template, the Simulink start page displays this title and description.

- 3 In the **Template file** box, select a file name and location for the template SLTX file.

Tip Save the template on the MATLAB path to make it visible in the Simulink start page. If you save in a location that is not on the path, the new template is visible in the start page only in the current MATLAB session. Saving the template does not add the destination folder to the path.

- 4 (Optional) Specify a thumbnail image for the template by clicking **Change** and selecting an image file.
- 5 Click **Export**.

Add or Read Notes for Model Layers

You can describe your model with notes to help others to understand it. You can add notes to any system in the model hierarchy by entering text, showing website content, or inheriting note content from the parent system. For each system, you can also choose not to show any notes.

To get started, select **View > Notes**. If the model has notes associated with it, they appear in a pane to the right of the model. As you navigate the hierarchy, notes for each system appear. If the model does not have notes, you can add them.

Manage Notes Files

Notes are stored in a file with the extension `.mldatax`. If you want your model to have notes, first create the notes file. See “Add and Edit Notes” on page 4-3. After you create the file, the notes you add are saved automatically.

You can have multiple notes files associated with the same model, for example, for users with different roles. The person using the model can then select among notes files that match your model. Notes files contain model name and version information to ensure the notes file and model match.

The `.mldatax` file is saved separate from the model. If you move your model to a different folder, the `.mldatax` file does not also move, but the association remains if the file is on the MATLAB path.

Read and Edit Modes

Use the **Notes** pane to edit and read notes. Use the **Read/Edit Notes** toggle  to switch between modes. When you click **Edit Notes**, the editing features are enabled. When you click **Read Notes**, the editing features are not available. Instead, the content displays in read-only format. As you navigate the model, the **Notes** pane updates with the content for the current system.

Add and Edit Notes

- 1 In the model, select **View > Notes**. The notes interface appears to the right of the model and includes instructions to get started.

- 2 Click the **Create a notes file** button.
- 3 Enter a name for the notes file, or use the default name, and click **Save**.
- 4 The **Notes** pane is in editing mode. You can add notes in these ways:
 - Enter text in the text editor.
 - From the menu, select **Use URL for Notes** and enter a URL whose content you want to show as notes for the current system.
 - Navigate to a different system in the model and enter text, use a URL, or select **Show Parent Notes**.
 - Select **No Notes**.

- 5 When you have finished adding and editing, click the **Read Notes** toggle button  to put the notes in reading mode.

To edit notes from reading mode, navigate to the system whose content you want to edit and click the **Edit Notes** toggle button .

Describe Models Using Annotations

Annotations are visual elements that you can use to add descriptive notes and callouts to your model. You can also add annotations that perform an action when you click them.

Text annotations can contain any combination of:

- Text
- Images
- Equations using LaTeX and MathML commands
- Hyperlinks that open a website or perform MATLAB functions

Also, you can create an image-only annotation.

Add a Text Annotation

To create a text annotation, use one of these options:

- Double-click the canvas where you want to create the annotation and select **Create Annotation** from the menu.
- Click the annotation box  on the Simulink Editor palette and then click the canvas.
- Drag the annotation box to the canvas.

After you add the text annotation, you can:

- Apply formatting changes to text or insert an image, table, or equation using the formatting toolbar.
- Apply additional formatting, using the **Paragraph** menu on the context menu. For example, you can create bullet and numbered lists from this menu.
- Add hyperlinks using the context menu. You can use hyperlinks to open a website or make an annotation interactive using MATLAB commands.
- Apply properties using the Property Inspector. To view the Property Inspector, select **View > Property Inspector**.

Resize an Annotation

An annotation resizes as you enter content. You can also resize an annotation by dragging the corners. For example, you can hold **Shift** as you drag to resize proportionally.

After you resize an annotation, the annotation stays that size until you resize it again, regardless of the content size. To revert to the original height or width of the annotation, in the Property Inspector, under **Appearance**, clear the **Fixed height** or **Fixed width** check box.

Make an Annotation Interactive

To make the annotation interactive, use a hyperlink on any content of a text annotation.

- 1 In the annotation, select the content that you want to make interactive. To make the entire annotation interactive, select all the content.
- 2 Right-click and select **Hyperlink** from the context menu.
- 3 In the Hyperlink dialog box, either:
 - Select **URL Address** as the target and enter the web address in the **Code** box.
 - Select **MATLAB Code** as the target and enter MATLAB functions in the **Code** box.
- 4 Click **OK**.

For an alternative approach, see “Add an Annotation Callback” on page 4-13

Add an Image Annotation

When you want to resize or move an image independently from text, create an image annotation. For example, you can size and position your company logo at a particular location in the model. You can also invoke MATLAB functions with a click on the image. To add an annotation that contains an image, drag the image from your file system to the canvas.

Tip To include an image such as a logo in every new model, add the image to your default template. See “Create a Template from a Model” on page 4-2.

Alternatively, you can drag an **Image** box  from the palette onto the canvas. Then you can either:

- Double-click the image box and browse to an image.
- Paste an image from the clipboard. Right-click the image box and select **Paste Image**.

Tip If you resize an image, you can reset it to its original size. Right-click the image and select **Format > Restore Size**.

To associate an action with an image:

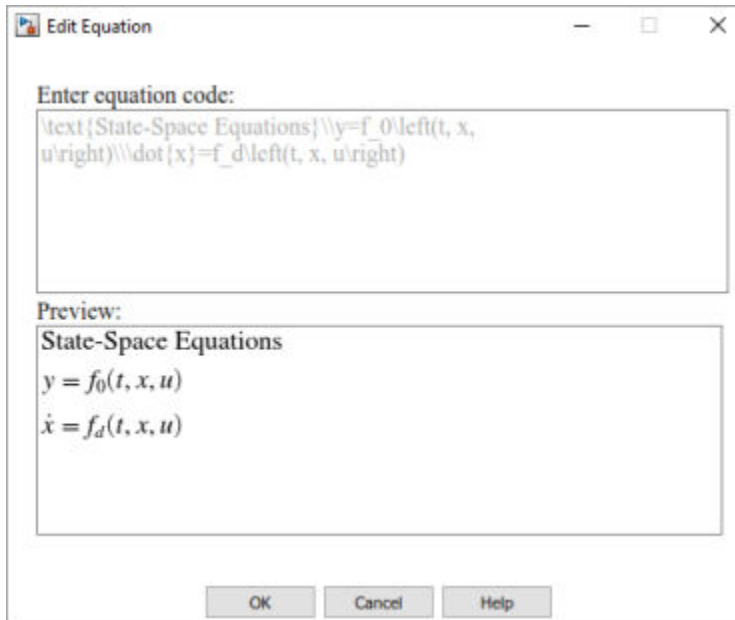

- 1 Select the image.
- 2 In the Property Inspector, under **ClickFcn**, add the MATLAB functions that you want to invoke with a click on the image.

Add Equations in an Annotation

You can add equations to your annotation by clicking the **Insert Equation** button in the annotation formatting toolbar.

In the Edit Equation dialog box, enter LaTeX or MathML code to generate equations. For LaTeX commands, see “Insert LaTeX Equation” (MATLAB).

To edit equation code, double-click the equation in the annotation. Similar to text in annotations, you can format equations in annotations by using the formatting toolbar. You can change the font color, text highlight color, font size, and location of equations in annotations.

Associate Annotations with Blocks and Areas

You can add a line between an annotation and a block or area in a model. These annotation connectors attach dynamically at both ends, so that they move and resize as necessary to maintain the connection.

- 1 Place the cursor over the annotation outline where you want the line to start.

- 2 When the cursor is a crosshair, drag the line to the block or area where you want the line to end.

Tip To specify the color or width of an annotation connector, right-click it and use the **Format** menu.

Show or Hide Annotations

In this section...

“Configure an Annotation for Hiding” on page 4-11

“Hide Markup Annotations” on page 4-11

By default, all annotations appear in the model. To hide an annotation, first configure it for hiding by converting it to markup. Then select **Display > Hide Markup**.

Configure an Annotation for Hiding

You can configure an annotation so that you can hide or display it.

- 1 Right-click the annotation.
- 2 From the context menu, select **Convert to Markup**.

A markup annotation has a light-blue background, regardless of the background color you set. If you change a markup annotation back to a regular annotation, the annotation returns to the background color you set.

To change a markup annotation to a regular annotation (one that you cannot hide), from the annotation context menu, select **Convert to Annotation**.

Hide Markup Annotations

To hide all markup annotations, select **Display > Hide Markup**.

To display hidden markup annotations, select **Display > Show Markup**.

Note In a model reference hierarchy, **Show Markup** and **Hide Markup** apply only to the current model reference level.

Add an Annotation Callback

In this section...

“Annotation Callback Functions” on page 4-13

“Associate a Click Function with an Annotation” on page 4-13

“Select and Edit Click-Function Annotations” on page 4-14

Annotation Callback Functions

You can associate these callback functions with annotations.

Click Function

You can make an annotation interactive using a link. Alternatively, you can make an annotation interactive by adding a click function callback. A click function is a MATLAB function that Simulink invokes when you click an annotation.

You can add a click function callback programmatically or interactively. To create a click function programmatically, see `Simulink.Annotation`. To create one interactively, see “Associate a Click Function with an Annotation” on page 4-13.

The text for annotations associated with a click function appears in blue.

Load Function

Simulink invokes a load function when you load the model that contains the associated annotation. To associate a load function with an annotation, set the `LoadFcn` property of the annotation to the desired function (see `Simulink.Annotation`).

Delete Function

A delete function is invoked before you delete an annotation. To associate a delete function with an annotation, set the `DeleteFcn` property of the annotation to the desired function (see `Simulink.Annotation`).

Associate a Click Function with an Annotation

You can interactively associate a click function with an annotation.

- 1 Add an annotation.
- 2 Open the Annotation Properties dialog box. Right-click the annotation and select **Properties**.
- 3 Open the **ClickFcn** tab. In the text box under **ClickFcn**, enter the MATLAB code that defines the click function, and click **OK**.

Tip Alternatively, you can use the annotation text as the click function. Then, in the Annotation Properties dialog box, select the **Use annotation text as click callback** check box.

Select and Edit Click-Function Annotations

If you associate an annotation with a click function, clicking invokes the function rather than selecting the annotation. To select it instead, drag a selection box around it. To edit it, right-click it and select **Edit Text** or **Properties**.

Create an Annotation Programmatically

In this section...

“Annotations API” on page 4-15

“Create Annotations Programmatically” on page 4-15

“Delete an Annotation Programmatically” on page 4-16

“Find Annotations in a Model” on page 4-16

“Show or Hide Annotations Programmatically” on page 4-16

Annotations API

Use MATLAB code to get and set the properties of annotations.

- `Simulink.Annotation` class
 - Set the properties of annotations.
- `getCallbackAnnotation` function

Get the `Simulink.Annotation` object for the annotation associated with the currently executing annotation callback function. Use this function to determine which annotation invoked the current callback. This function is also useful if you write a callback function in a separate MATLAB file that contains multiple callback calls.

Create Annotations Programmatically

You can use a `Simulink.Annotation` object to create an annotation. For example:

```
open_system('vdp')
note = Simulink.Annotation('vdp/This is an annotation');
note.position = [10,50]
```

To create an area, use the `add_block` function. You can position the area in the model using the `Position` parameter.

```
add_block('built-in/Area','vdp/This is an Area','Position',[120,100,230,200])
```

Delete an Annotation Programmatically

To delete an annotation programmatically, use the `find_system` function to get the annotation handle. Then use the `delete` function to delete the annotation. For example:

```
delete(find_system(gcs,'FindAll','on','type','annotation',...  
'text','programmatically created'));
```

Find Annotations in a Model

Use command such as this to find all of the annotations in a model.

```
open_system('vdp')  
annotations = find_system(gcs,'FindAll','on','Type','annotation')  
  
annotations =  
  
    34.0004  
    33.0009
```

See the `find_system` documentation for specifying levels of the model to search.

To identify the annotation handle of annotations, enter:

```
get_param(annotations,'Name')  
  
ans =  
  
    'Copyright 2004-2014 The MathWorks, Inc.'  
    'van der Pol Equation'
```

Show or Hide Annotations Programmatically

When you create an annotation, by default it appears in the model. You can configure an annotation to be a markup annotation, which you can hide.

To find out whether the first annotation is a markup annotation, use commands such as this:

```
open_system('vdp')  
annotations = find_system(gcs,'FindAll','on','Type','annotation')  
get_param(annotations(1),'MarkupType')
```

To configure the first annotation in a model so that it can be hidden, use a commands such as this:

```
set_param(annotations(1), 'MarkupType', 'markup')
```

To reconfigure that annotation to always appear, use this command:

```
set_param(annotations(1), 'MarkupType', 'model')
```

To find out whether a model is configured to show or hide markup annotations, use a command such as this for the vdp model:

```
get_param(vdp, 'ShowMarkup')
```

To configure a model to hide markup annotations, use a command such as this for the vdp model:

```
set_param(vdp, 'ShowMarkup', 'off')
```

Use TeX Commands in an Annotation

You can add TeX formatting commands to your annotation for mathematical and other symbols and Greek letters. For the supported TeX commands, see “TeX for Simulink Model Annotations” on page 4-19.

Alternatively, you can create an equation using an equations editor. See “Add Equations in an Annotation” on page 4-7.

- 1 Add supported TeX commands to your annotation. For example, add this text:

```
\sigma \kappa \mu
```

- 2 With the annotation selected, or with the text cursor in the annotation, in the Property Inspector, under **Appearance**, select **Enable TeX commands**.

When you click outside the annotation, the TeX commands appear as symbols in the annotation.

- “Describe Models Using Annotations” on page 4-5

What is a Subsystem?

A subsystem is a set of blocks that you replace with a single Subsystem block. As your model increases in size and complexity, you can simplify it by grouping blocks into subsystems.

When you make a copy of a subsystem, that copy is independent of the source subsystem. To reuse the contents of a subsystem across a model or across models, use subsystem referencing, model referencing, or a library.

Advantages of Using Subsystems

- Establishes a hierarchical block diagram, where a Subsystem block is on one layer and the blocks that make up the subsystem are on another.
- Keeps functionally related blocks together.
- Helps reduce the number of blocks displayed in your model window.

Types of Subsystem

A Subsystem can either be Virtual or Nonvirtual. A Virtual subsystem provides graphical hierarchy in models and does not impact the execution of a model. Whereas, a Nonvirtual subsystem provides execution and graphical hierarchy in models.

During model execution, Simulink Engine flattens all virtual subsystems while it executes nonvirtual subsystems as a single unit.

Simulink classifies nonvirtual subsystems into the following:

Type of Subsystem	Description
Subsystem, Atomic Subsystem, CodeReuse Subsystem	Subsystem that executes as a single unit
Enable	Subsystem whose execution is enabled by external input.
Triggered Subsystem	Subsystem whose execution is triggered by external input.
Function-Call Subsystem	Subsystem whose execution is controlled by an external function-call input.

Type of Subsystem	Description
Enabled and Triggered Subsystem	Subsystem whose execution is enabled and triggered by external inputs.
Resettable Subsystem	Subsystem whose block states reset with external trigger.
If Action Subsystem	Subsystem whose execution is enabled by an If block
While Iterator Subsystem	Subsystem that repeats execution during a simulation time step while a logical condition is true.
For Iterator Subsystem	Subsystem that repeats execution during a simulation time step for a specified number of iterations.
For Each Subsystem	Subsystem that repeats execution on each element or subarray of input signal and concatenates results.

Create a Subsystem

In this section...
“Create a Subsystem Block” on page 4-24
“Create Subsystem from Selection” on page 4-26

As your model increases in size and complexity, you can simplify it by grouping blocks into subsystems. Use subsystems to:

- Establish a hierarchical block diagram, where a Subsystem block is in one layer and the blocks that make up the subsystem are in another.
- Keep functionally related blocks together.
- Reduce the number of blocks displayed in your model window.

When you make a copy of a subsystem, that copy is independent of the source subsystem. To reuse the contents of a subsystem across a model or models, use either a model reference or library.

You can create a subsystem using these approaches:

- Add a Subsystem block to your model, and then open the block and add blocks to the subsystem window.
- Select blocks and enclose them in a subsystem.
- Copy a model to a subsystem. In the Simulink Editor, copy and paste the model into a subsystem window, or use `Simulink.BlockDiagram.copyContentsToSubsystem`.
- Copy an existing Subsystem block to a model.

Create a Subsystem Block

Add a Subsystem block to the model, and then add the blocks that make up the subsystem.

- 1** Create a Subsystem block from the Ports & Subsystems library.
- 2** Double-click the block to open it.
- 3** In the empty subsystem window, create the subsystem contents. Use Inport blocks to represent input from outside the subsystem and Outport blocks to represent external output.

For example, this subsystem includes a Sum block and Inport and Outport blocks to represent input to and output from the subsystem.

When you close the subsystem window, the Subsystem block includes a port for each Inport and Outport block.

You can alternatively create input and output ports by clicking the edge of the subsystem block or dragging to the edge from another block. The port appears on the block and the corresponding input or output block is added inside the subsystem.

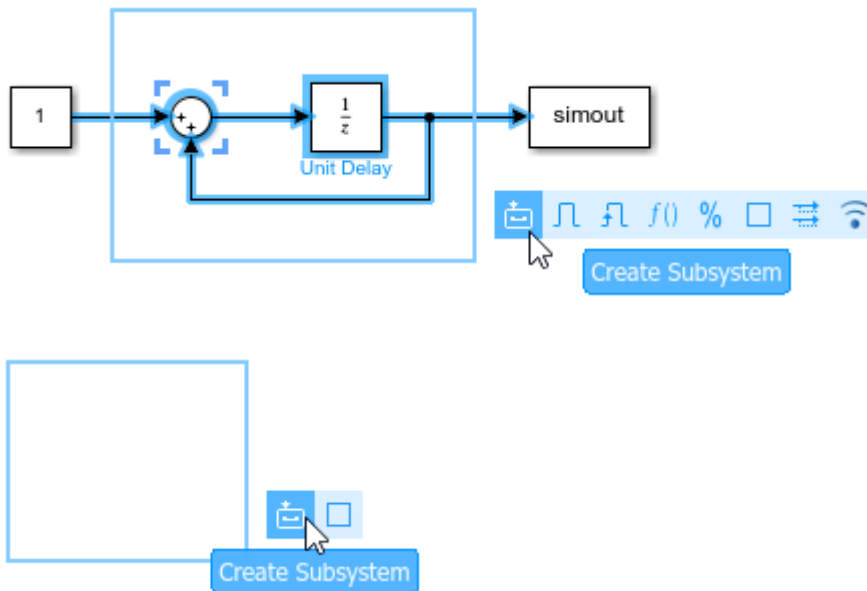

Create Subsystem from Selection

- 1 Drag a box to outline the subsystem that you want to create.

You can use the action bar with blocks selected or with no selection to create a subsystem. To select multiple blocks in one area of the model, drag a box around the blocks and connecting lines that you want to include in the subsystem.

- 2 From the action bar, select the subsystem that you want to create.

When your selection contains blocks, you can create virtual, enabled, triggered, and function-call subsystems.

Tip Resize the Subsystem block so that port labels are readable.

Creating the subsystem adds Inport and Outport blocks within the subsystem that represent the input and output ports of the Subsystem block.

You can change the name of the Subsystem block and modify the block the way that you do with any other block. For example, you can mask the subsystem.

Configure a Subsystem

In this section...
“Subsystem Execution” on page 4-28
“Label Subsystem Ports” on page 4-28
“Control Access to Subsystems” on page 4-28
“Control Subsystem Behavior with Callbacks” on page 4-29

Subsystem Execution

You can configure a subsystem to execute either conditionally or unconditionally.

- An unconditionally executed subsystem always executes.
- A conditionally executed subsystem executes based on the value of an input signal. For details, see “Conditionally Executed Subsystems and Models”.

Label Subsystem Ports

By default, Simulink labels ports on a Subsystem block. The labels are the names of the Inport and Outport blocks that connect the subsystem to blocks outside of the subsystem.

You can specify how Simulink labels the ports of a subsystem.

- 1 Select the Subsystem block.
- 2 Select one of the labeling options from **Diagram > Format > Port Labels** menu (for example, From Port Block Name).

Control Access to Subsystems

You can control user access to subsystems. For example, you can prevent a user from viewing or modifying the contents of a library subsystem while still allowing the user to employ the subsystem in a model.

Note This method does not necessarily prevent a user from changing the access restrictions. To hide proprietary information that is in a subsystem, consider using

protected model referencing models (see “Reference Protected Models from Third Parties” on page 8-20).

To restrict access to a library subsystem, open the subsystem parameter dialog box and set **Read/Write permissions** to one of these values:

- **ReadOnly**: A user can view the contents of the library subsystem but cannot modify the reference subsystem without disabling its library link or changing its **Read/Write permissions** to **ReadWrite**.
- **NoReadOrWrite**: A user cannot view the contents of the library subsystem, modify the reference subsystem, or change reference subsystem permissions.

Both options allow a user to use the library subsystem in models by creating links (see “Libraries”). For more information about subsystem access options, see the Subsystem block.

Note You do not receive a response if you attempt to view the contents of a subsystem whose **Read/Write permissions** parameter is set to **NoReadOrWrite**. For example, when double-clicking such a subsystem, Simulink does not open the subsystem and does not display any messages.

Control Subsystem Behavior with Callbacks

You can use block callbacks to perform actions in response to subsystem modeling actions such as:

- Handling an error
- Deleting a block or line in a subsystem
- Closing a subsystem

For details, see “Specify Block Callbacks” on page 36-5.

Navigate Model Hierarchies

Subsystems and model references allow you to create a hierarchical model comprising many layers. You can navigate this hierarchy using the Model Browser or with Simulink Editor model navigation commands.

Open a Subsystem or Referenced Model

To open a model component using the Simulink Editor context menu:

- 1 In the Simulink Editor, right-click the Subsystem block, Model block, or canvas.

- 2 From the context menu, select one of these options:
 - **Open** — Open the subsystem or referenced model in the same window and tab as used for the top model.

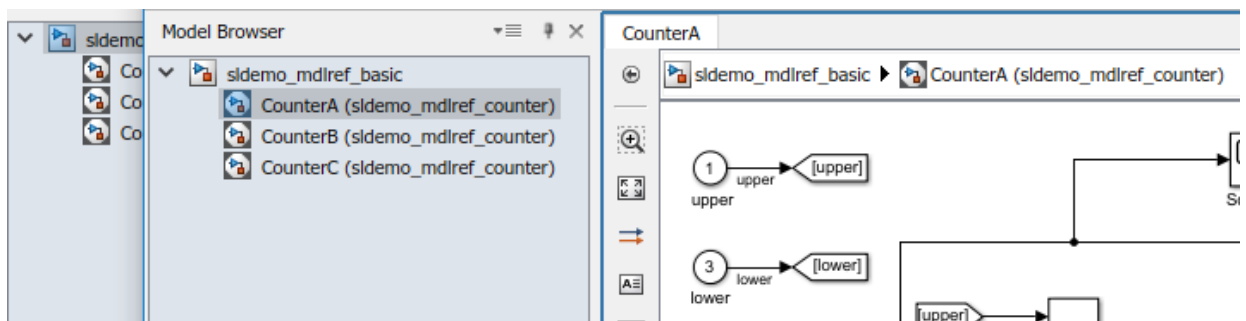

4 Creating a Model

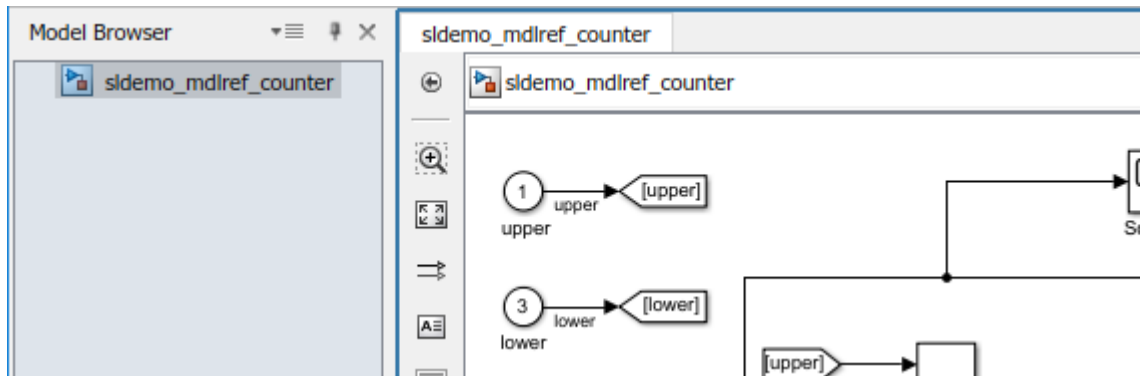

- **Open In New Tab** — Open the subsystem or referenced model in a new tab.

- **Open In New Window** — Open the subsystem or referenced model in a new Simulink Editor window.

- **Open As Top Model** — Open a referenced model as a top model in a new Simulink Editor window.

For any operation to open a subsystem or referenced model, you can use a keyboard shortcut to have it open in a new tab or window:

Where to Open the Subsystem or Referenced Model	Keyboard Shortcut
In a new tab	Hold the CTRL key while opening the subsystem or referenced model.
In a new window	Hold the SHIFT key while opening the subsystem or referenced model.

Tip To navigate up and out of a subsystem or referenced model, select **View > Navigate > Up to Parent**. The subsystem or referenced model you navigated from appears highlighted so that you can identify where you came from.

Subsystem Expansion

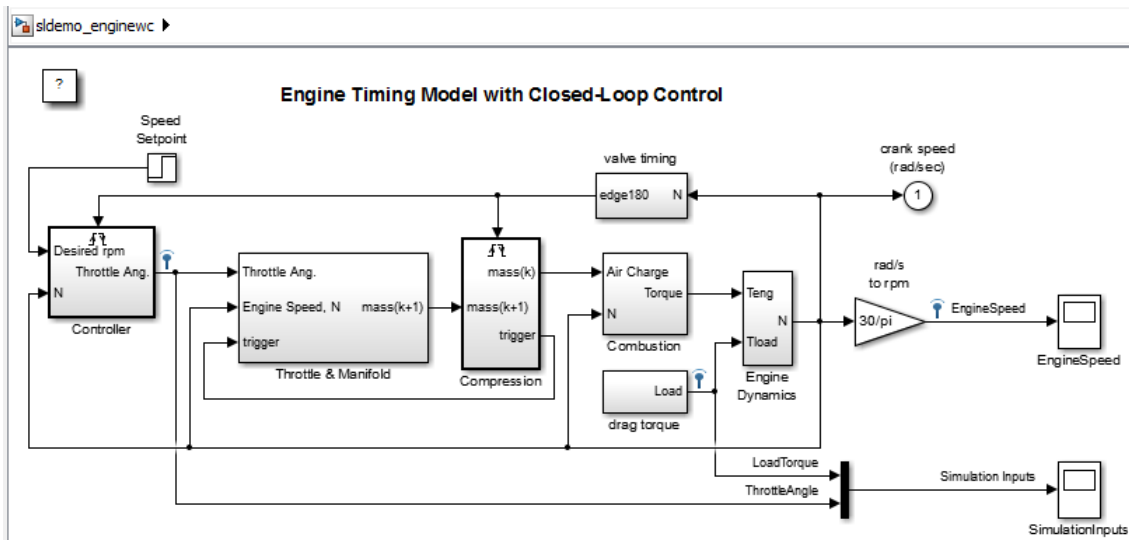

In this section...

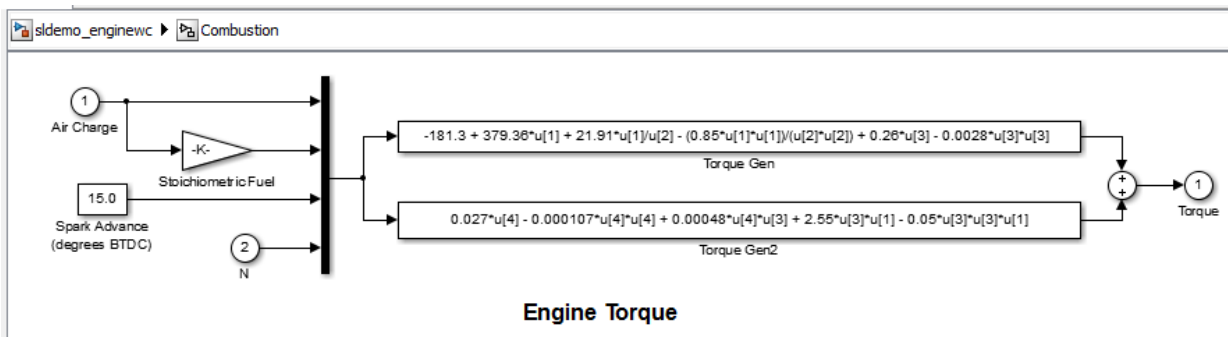

- “What Is Subsystem Expansion?” on page 4-34
- “Why Expand a Subsystem?” on page 4-35
- “Subsystems That You Can Expand” on page 4-36
- “Results of Expanding a Subsystem” on page 4-36
- “Data Stores” on page 4-37

What Is Subsystem Expansion?

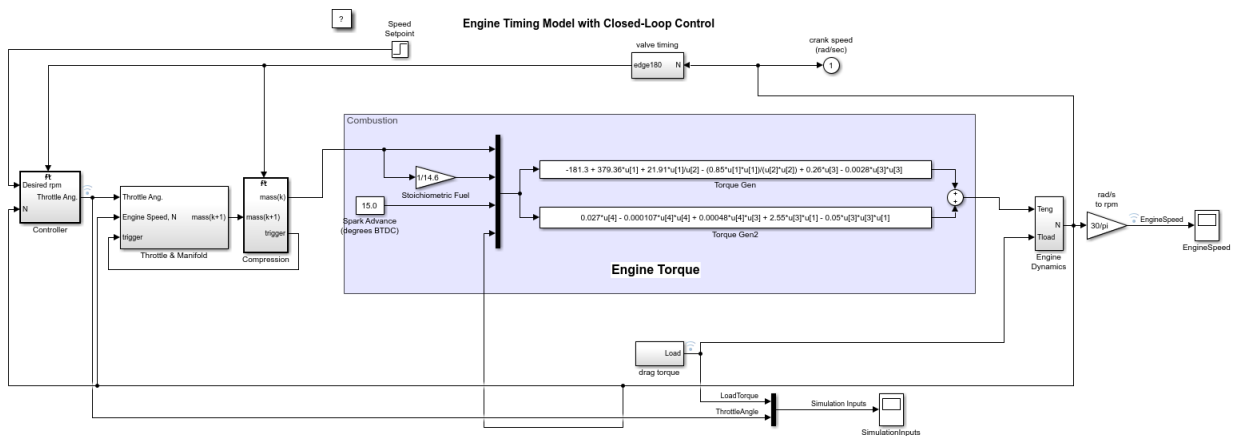

Subsystem expansion involves moving the contents of a virtual subsystem into the containing system.

For example, the `sldemo_enginewc` model includes the Combustion subsystem.

After you expand the Combustion subsystem, the top level of the `sldemo_enginewc` model includes the blocks and signals of the Combustion subsystem. The expansion removes the Subsystem block and the Inport and Outport blocks.

Why Expand a Subsystem?

Expand a subsystem if you want to flatten a model hierarchy by bringing the contents of a subsystem up one level.

Expanding a subsystem is useful when refactoring a model. Flattening a model hierarchy can be the end result, or just one step in refactoring. For example, you could pull a set of blocks up to the parent system by expanding the subsystem, deselect the blocks that you want to leave in the parent, and then create a subsystem from the remaining selected blocks.

Subsystems That You Can Expand

You can expand virtual subsystems that are not masked, linked, or commented.

Subsystems That You Can Automatically Modify to Enable Expansion

If you try to expand one of these subsystems using the Simulink Editor, a message gives you the option of having Simulink modify the subsystem so that you can then expand it.

Kind of Subsystem	Modification
Masked subsystem	Removes all masking information
Library links	Breaks the link
Commented-out subsystem	Removes the comment-out setting

Subsystems That You Cannot Expand

You cannot expand these subsystems:

- Atomic subsystems
- Conditional subsystems
- Configurable subsystems
- Variant subsystems
- Subsystems in a referenced model
- Subsystems with the **Read/Write permissions** parameter set to `ReadOnly` or `NoReadWrite`
- Subsystems with an `InitFcn`, `StartFcn`, `PauseFcn`, `ContinueFcn`, or `StopFcn` callback
- Subsystems with linked requirements (using Simulink Requirements™ software)

Results of Expanding a Subsystem

When you expand a subsystem, Simulink:

- Removes the Subsystem block
- Removes the root Inport, root Outport, and Simscape Connection Port blocks that were in the subsystem

- Connects the signal lines that went to the input and output ports of the subsystem directly to the ports of the blocks in the model that connected to the subsystem

Block Paths

The paths for blocks that were in the subsystem that you expanded change. After expansion, update scripts and test harnesses that rely on the hierarchical paths to blocks that were in the subsystem that you expanded.

Signal Names and Properties

If you expand a subsystem with a missing connection on the outside or inside of the subsystem, Simulink keeps the line labels, but uses the signal name and properties from just one of the lines. For lines corresponding to:

- A subsystem input port, Simulink uses the signal name and properties from the signal in the system in which the subsystem exists
- A subsystem output port, Simulink uses the signal name and properties from the subsystem

Display Layers

The display layers of blocks (in other words, which blocks appear in front or in back for overlapping blocks) does not change after expansion. Blocks in front of the Subsystem block remain above the expanded contents, and blocks below the Subsystem block remain under the expanded contents.

Sorted Order and Block Priorities

When you compile a model, Simulink sorts the blocks in terms of the order of block execution. Expanding a subsystem can change block path names, which, in rare cases, can impact the block execution order.

If you explicitly set block execution order by setting block priorities within a subsystem, Simulink removes those block priority settings when you expand that subsystem.

Data Stores

Expanding a subsystem that contains a Data Store Memory block that other subsystems read from or write to can change the required data store write and read sequence. You may need to restructure your model. For details, see “Order Data Store Access” on page 65-25.

See Also

Related Examples

- “Expand Subsystem Contents” on page 4-39

Expand Subsystem Contents

In this section...
“Expand a Subsystem” on page 4-39
“Expand a Subsystem from the Command Line” on page 4-40

Expand a subsystem to flatten a model hierarchy by bringing the contents of a subsystem up one level.

Expand a Subsystem

- 1 In the Simulink Editor, right-click the Subsystem block for the subsystem that you want to expand.
- 2 From the context menu, select **Subsystem & Model Reference > Expand Subsystem**.

Expand Subsystem is disabled for subsystems that you cannot convert. For some kinds of subsystems, you have the option of having Simulink modify the subsystem so that you can then expand it. For details, see “Subsystems That You Can Automatically Modify to Enable Expansion” on page 4-36.

- 3 If necessary, modify the model layout for readability.

Simulink distributes blocks and routes signals for readability, but you can refine the model layout to enhance readability. Also, you may want to modify the model to adjust for how the subsystem expansion handles aspects of the model such as signal naming. For details, see “Results of Expanding a Subsystem” on page 4-36.

- 4 Update scripts and test harnesses that rely on the hierarchical paths to blocks that were in the subsystem that you expanded.

Nested Subsystems

Subsystem expansion applies to the currently selected subsystem level. Simulink does not expand other subsystems in a nested subsystem hierarchy.

To improve readability when you expand nested subsystems, start by expanding the highest-level subsystem that you want to expand, and then work your way down the hierarchy as far as you want to expand.

Expand a Subsystem from the Command Line

To expand a subsystem programmatically, use the `Simulink.BlockDiagram.expandSubsystem` function.

Use Control Flow Logic

In this section...

“What is a Control Flow Subsystem” on page 4-41
 “Equivalent C Language Statements” on page 4-41
 “Conditional Control Flow Logic” on page 4-41
 “While and For Loops” on page 4-44

What is a Control Flow Subsystem

A *control flow subsystem* executes one or more times at the current time step when enabled by a control flow block. A control flow block implements control logic similar to that expressed by control flow statements of programming languages (e.g., *if-then*, *while-do*, *switch*, and *for*).

Equivalent C Language Statements

You can use block diagrams to model control flow logic equivalent to the following C programming language statements:

- `for`
- `if-else`
- `switch`
- `while`

Conditional Control Flow Logic

You can use the following blocks to perform conditional control flow logic.

C Statement	Equivalent Blocks
<code>if-else</code>	If, If Action Subsystem
<code>switch</code>	Switch Case, Switch Case Action Subsystem

If-Else Control Flow

The following diagram represents `if-else` control flow.

Construct an `if-else` control flow diagram as follows:

- 1 Provide data inputs to the If block for constructing if-else conditions.

In the If block parameters dialog box, set inputs to the If block. Internally, the inputs are designated as `u1`, `u2`, ..., `un` and are used to construct output conditions.

- 2 In the If block parameters dialog box, set output port if-else conditions for the If block.

In the If block parameters dialog box, set Output ports. Use the input values `u1`, `u2`, ..., `un` to express conditions for the if, elseif, and else condition fields in the dialog box. Of these, only the if field is required. You can enter multiple elseif conditions and select a check box to enable the else condition.

- 3 Connect each condition output port to an Action subsystem.

Connect each if, elseif, and else condition output port on the If block to a subsystem to be executed if the port's case is true.

Create these subsystems by placing an Action Port block in a subsystem. This creates an atomic Action subsystem with a port named Action, which you then connect to a condition on the If block.

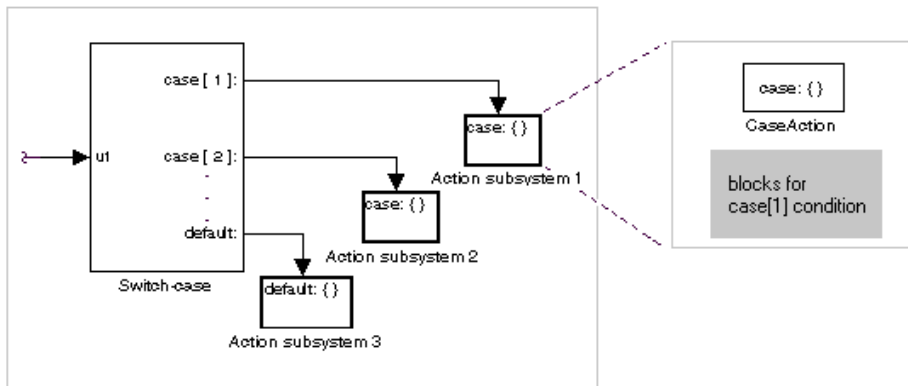

Once connected, the subsystem takes on the identity of the condition it is connected to and behaves like an enabled subsystem.

For more detailed information, see the If and Action Port blocks.

Note All blocks in an Action subsystem driven by an If or Switch Case block must run at the same rate as the driving block.

Switch Control Flow

The following diagram represents switch control flow.

Construct a switch control flow statement as follows:

- 1 Provide a data input to the argument input of the Switch Case block.

The input to the Switch Case block is the argument to the switch control flow statement. This value determines the appropriate case to execute. Noninteger inputs to this port are truncated.

- 2 Add cases to the Switch Case block based on the numeric value of the argument input.

Using the parameters dialog box of the Switch Case block, add cases to the Switch Case block. Cases can be single or multivalued. You can also add an optional default case, which is true if no other cases are true. Once added, these cases appear as output ports on the Switch Case block.

- 3 Connect each Switch Case block case output port to an Action subsystem.

Each case output of the Switch Case block is connected to a subsystem to be executed if the port's case is true. You create these subsystems by placing an Action Port block in a subsystem. This creates an atomic subsystem with a port named Action, which you then connect to a condition on the Switch Case block. Once

connected, the subsystem takes on the identity of the condition and behaves like an enabled subsystem. Place all the block programming executed for that case in this subsystem.

For more detailed information, see documentation for the Switch Case and Action Port blocks.

Note After the subsystem for a particular case executes, an implied break executes, which exits the switch control flow statement altogether. Simulink switch control flow statement implementations do not exhibit the “fall through” behavior of C switch statements.

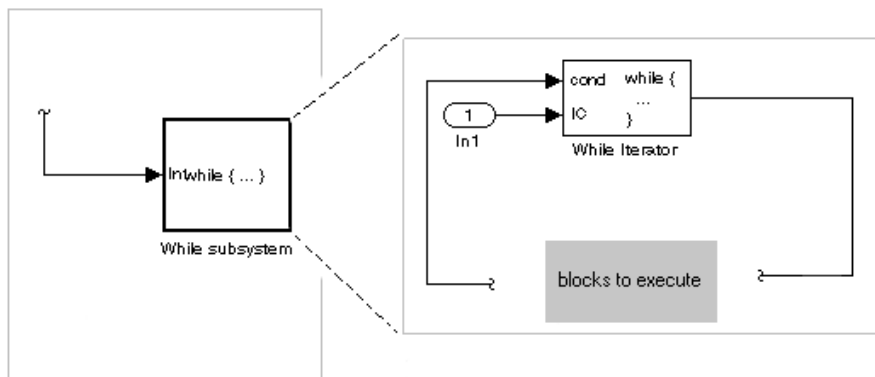

While and For Loops

Use the following blocks to perform while and for loops.

C Statement	Equivalent Blocks
do-while	While Iterator Subsystem
for	For Iterator Subsystem
while	While Iterator Subsystem

While Loops

The following diagram illustrates a while loop.

In this example, Simulink repeatedly executes the contents of the While subsystem at each time step until a condition specified by the While Iterator block is satisfied. In particular, for each iteration of the loop specified by the While Iterator block, Simulink invokes the update and output methods of all the blocks in the While subsystem in the same order that the methods would be invoked if they were in a noniterated atomic subsystem.

Note Simulation time does not advance during execution of a While subsystem's iterations. Nevertheless, blocks in a While subsystem treat each iteration as a time step. As a result, in a While subsystem, the output of a block with states (that is, a block whose output depends on its previous input), reflects the value of its input at the previous iteration of the `while` loop. The output does *not* reflect that block's input at the previous simulation time step. For example, a Unit Delay block in a While subsystem outputs the value of its input at the previous iteration of the `while` loop, not the value at the previous simulation time step.

Construct a `while` loop as follows:

- 1 Place a While Iterator block in a subsystem.

The host subsystem label changes to `while {...}`, to indicate that it is modeling a while loop. These subsystems behave like triggered subsystems. This subsystem is host to the block programming that you want to iterate with the While Iterator block.

- 2 Provide a data input for the initial condition data input port of the While Iterator block.

The While Iterator block requires an initial condition data input (labeled IC) for its first iteration. This must originate outside the While subsystem. If this value is nonzero, the first iteration takes place.

- 3 Provide data input for the conditions port of the While Iterator block.

Conditions for the remaining iterations are passed to the data input port labeled `cond`. Input for this port must originate inside the While subsystem.

- 4 (Optional) Set the While Iterator block to output its iterator value through its properties dialog.

The iterator value is 1 for the first iteration and is incremented by 1 for each succeeding iteration.

- (Optional) Change the iteration of the While Iterator block to `do-while` through its properties dialog.

This changes the label of the host subsystem to `do { ... } while`. With a `do-while` iteration, the While Iteration block no longer has an initial condition (IC) port, because all blocks in the subsystem are executed once before the condition port (labeled `cond`) is checked.

- Create a block diagram in the subsystem that defines the subsystem's outputs.

Note The diagram must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all the blocks must be either inherited (`-1`) or constant (`inf`).

For more information, see the While Iterator block.

Modeling For Loops

The following diagram represents a `for` loop:

In this example, Simulink executes the contents of the For subsystem multiples times at each time step. The input to the For Iterator block specifies the number of iterations. For each iteration of the `for` loop, Simulink invokes the update and output methods of all the blocks in the For subsystem in the same order that it invokes the methods if they are in a noniterated atomic subsystem.

Note Simulation time does not advance during execution of a For subsystem's iterations. Nevertheless, blocks in a For subsystem treat each iteration as a time step. As a result, in

a For subsystem, the output of a block with states (that is, a block whose output depends on its previous input) reflects the value of its input at the previous iteration of the `for` loop. The output does *not* reflect that block's input at the previous simulation time step. For example, a Unit Delay block in a For subsystem outputs the value of its input at the previous iteration of the `for` loop, not the value at the previous simulation time step.

Construct a `for` loop as follows:

- 1** Drag a For Iterator Subsystem block from the Library Browser or Library window into your model.
- 2** (Optional) Set the For Iterator block to take external or internal input for the number of iterations it executes.

Through the properties dialog of the For Iterator block you can set it to take input for the number of iterations through the port labeled `N`. This input must come from outside the For Iterator Subsystem.

You can also set the number of iterations directly in the properties dialog.

- 3** (Optional) Set the For Iterator block to output its iterator value for use in the block programming of the For Iterator Subsystem.

The iterator value is 1 for the first iteration and is incremented by 1 for each succeeding iteration.

- 4** Create a block diagram in the subsystem that defines the subsystem's outputs.

Note The diagram must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all the blocks must be either inherited (`-1`) or constant (`inf`).

The For Iterator block works well with the Assignment block to reassign values in a vector or matrix. The following example shows the use of a For Iterator block. Note the matrix dimensions in the data being passed.

4 Creating a Model

The above example outputs the sine value of an input 2-by-5 matrix (2 rows, 5 columns) using a For subsystem containing an Assignment block. The process is as follows.

- 1 A 2-by-5 matrix is input to the Selector block and the Assignment block.
- 2 The Selector block strips off a 2-by-1 matrix from the input matrix at the column value indicated by the current iteration value of the For Iterator block.
- 3 The sine of the 2-by-1 matrix is taken.
- 4 The sine value 2-by-1 matrix is passed to an Assignment block.
- 5 The Assignment block, which takes the original 2-by-5 matrix as one of its inputs, assigns the 2-by-1 matrix back into the original matrix at the column location indicated by the iteration value.

The rows specified for reassignment in the property dialog for the Assignment block in the above example are [1,2]. Because there are only two rows in the original matrix, you could also have specified -1 for the rows, (that is, all rows).

Note The Trigonometric Function block is already capable of taking the sine of a matrix. The above example uses the Trigonometric Function block only as an example of changing each element of a matrix with the collaboration of an Assignment block and a For Iterator block.

Callbacks for Customized Model Behavior

In this section...
“Model, Block, and Port Callbacks” on page 4-50
“What You Can Do with Callbacks” on page 4-50
“Avoid run Commands in Callback Code” on page 4-51

Model, Block, and Port Callbacks

Callbacks are commands you can define that execute in response to a specific modeling action, such as opening a model or stopping a simulation. Callbacks define MATLAB expressions that execute when the block diagram or a block is acted upon in a particular way.

Simulink provides model, block, and port callback parameters that identify specific kinds of model actions. You provide the code for a callback parameter. Simulink executes the callback code when the associated modeling action occurs.

For example, the code that you specify for the `PreLoadFcn` model callback parameter executes before the model loads. You can provide code for `PreLoadFcn` that loads the variables that model uses into the MATLAB workspace.

What You Can Do with Callbacks

Callbacks are a powerful way to customize your Simulink model. A callback executes when you perform actions on your model, such as double-clicking a block or starting a simulation. You can use callbacks to execute MATLAB code. You can use model, block, or port callbacks to perform common tasks, such as:

- “Load Variables When Opening a Model” on page 1-10
- “Specify Block Callbacks” on page 4-57
- “Automate Simulation Tasks Using Callbacks” on page 26-7

Avoid run Commands in Callback Code

Do not call the run command from within model or block callback code. Doing so can result in unexpected behavior (such as errors or incorrect results) if you load, compile, or simulate a Simulink model.

- “Fast Restart Methodology” on page 73-8

Model Callbacks

In this section...
“Create Model Callbacks” on page 4-52
“Model Callback Parameters” on page 4-54

Model callbacks execute at specified action points, for example after you load or save the model.

You can set most of the same callbacks for libraries. Only the callbacks that can execute for a library are available to set for a library. For example, you cannot set the `InitFcn` callback for a library, which is called as part of simulation, because you cannot simulate a library.

Create Model Callbacks

- 1 In the Simulink Editor, open the Property Inspector. Select **View > Property Inspector**.
- 2 With no selection at the top level of your model, in the **Properties** tab, in the **Callbacks** section, select the callback you want to set.
- 3 In the box, enter the functions you want the callback to perform.

To create a model callback programmatically, use the `set_param` function to assign MATLAB code to a model callback parameter. See “Model Callback Parameters” on page 4-54

Referenced Model Callbacks in Normal Mode

If a model references multiple instances of the same model in normal mode, callbacks execute for each instance.

Referenced Model Callbacks in Accelerator Mode

In accelerator mode, the execution of callbacks for model referencing reflects the order in which the top model and the models it references execute their callbacks. For example, suppose:

- Model A:

- References model B in accelerator mode.
- Has a `PostLoadFcn` callback that creates variables in the MATLAB workspace.
- Has the `Rebuild` configuration parameter set to `Always`, `If changes detected`, or `If any changes in known dependencies detected`.
- Model B:
 - Has a `CloseFcn` callback that clears the MATLAB workspace.
 - Has not been built or is out of date.

Simulating model A triggers rebuilding the referenced model B. When Simulink rebuilds model B, it opens and closes model B, which invokes the model B `CloseFcn` callback. `CloseFcn` clears the MATLAB workspace, including the variables created by the model A `OpenFcn` callback.

Instead of using a `CloseFcn` callback for model B, you can use a `StopFcn` callback in model A to clear the variables used by the model from the MATLAB workspace. Alternatively, you can use a data dictionary for the data to avoid the need to have variables in the base workspace.

Simulink does not call some callbacks of referenced models in accelerator mode. If everything is up to date and the `Rebuild` configuration parameter is set to `If any changes in known dependencies detected`, the referenced model does not compile and its `InitFcn` callbacks do not execute. Callbacks such as `StartFcn` and `StopFcn` do not execute because referenced models in accelerator mode use an S-function, which starts and stops instead of the referenced model.

Note Simulation outputs are not available in the `StopFcn` callbacks for command-line simulations.

Model Callback Parameters

Model Loading and Closing Callback Parameters

Model Callback Parameter	When Executed
PreLoadFcn	<p>This callback is executed before the model is loaded.</p> <p>Do not use model parameters in a PreLoadFcn model callback because parameters are loaded after the model is loaded. Instead, use a PostLoadFcn callback to work with model parameters when the model is loaded.</p> <p>Defining a callback code for this parameter is useful for loading variables that the model uses.</p> <p>If you want to call your model from a MATLAB file without opening your model, use the <code>load_system</code> function so that the PreLoadFcn executes.</p> <p>For examples, see:</p> <ul style="list-style-type: none"> • “Load Variables When Opening a Model” on page 1-10 • “Introduction to Managing Data with Model Reference” • “Model Reference Simulation Targets” on page 8-72 <p>Limitations include:</p> <ul style="list-style-type: none"> • For the PreLoadFcn callback, <code>get_param</code> does not return the model parameter values because the model is not yet loaded. Instead, <code>get_param</code> returns: <ul style="list-style-type: none"> • The default value for a standard model parameter such as <code>solver</code> • An error message for a model parameter added with <code>add_param</code> • Programmatic access to Scopes is not supported.

Model Callback Parameter	When Executed
PostLoadFcn	<p>After the model is loaded.</p> <p>Defining callback code for this parameter may be useful for generating an interface requiring a loaded model.</p> <p>Limitations include:</p> <ul style="list-style-type: none"> • If you make structural changes with PostLoadFcn, the function does not set the model Dirty flag to indicate unsaved changes. When you close the model, Simulink does not prompt you to save. • Programmatic access to Scopes is not supported. <p>Because the Simulink Editor opens after this callback executes, the PostLoadFcn callback is not suitable for setting up the model view, for example setting a zoom factor. Save zoom information with the model to open it with a particular zoom factor.</p>
CloseFcn	<p>Before the block diagram is closed.</p> <p>Any ModelCloseFcn and DeleteFcn callbacks set on blocks in the model are called prior to the model CloseFcn callback. The DestroyFcn callback of any blocks in the model is called after the model CloseFcn callback.</p>

Model Saving Callback Parameters

Model Callback Parameter	When Executed
PreSaveFcn	Before the model is saved.
PostSaveFcn	<p>After the model is saved.</p> <hr/> <p>Note If you make structural changes with PostSaveFcn, the function does not set the model Dirty flag to indicate unsaved changes. When you close the model, Simulink does not prompt you to save.</p>

Model Simulation Callback Parameters

Model Callback Parameter	When Executed
InitFcn	<p>Called during update phase before block parameters are evaluated. This is called during model update and simulation. For more information on InitFcn callback, see “Initialization Function” on page 11-136</p> <p>For examples, see:</p> <ul style="list-style-type: none"> • “Create Programmatic Hyperlinks” on page 25-69 • “Track Object Using MATLAB Code” on page 43-179
StartFcn	Called before the simulation phase. This is not called during model update.
PauseFcn	After the simulation pauses.
ContinueFcn	Before the simulation continues.
StopFcn	<p>After the simulation stops.</p> <p>Output is written to workspace variables and files before the StopFcn is executed.</p> <p>Simulation outputs are not available in the StopFcn callbacks for command-line simulations.</p>

Block Callbacks

In this section...
“Specify Block Callbacks” on page 4-57
“Block Callback Parameters” on page 4-57

Specify Block Callbacks

- 1 Open the Property Inspector. Select **View > Property Inspector**.
- 2 Select the block whose callback you want to specify. In the **Properties** tab of the Property Inspector, in the **Callbacks** section, select the callback you want to define.
- 3 In the box, enter the functions you want the callback to perform.

To specify a block callback programmatically, use `set_param` to assign MATLAB code to the block callback parameter.

Block Callback Parameters

If a block callback executes before or after a modeling action takes place, that callback occurs immediately before or after the action.

Block Opening Callback Parameters

Block Callback Parameter	When Executed
OpenFcn	<p>When the block is opened.</p> <p>Generally, use this parameter with Subsystem blocks.</p> <p>The callback executes when you double-click the block or when you use <code>open_system</code> with the block as an argument. The <code>OpenFcn</code> parameter overrides the normal behavior associated with opening a block, which is to display the block dialog box or to open the subsystem. Examples of tasks that you can use <code>OpenFcn</code> for include defining variables for a block, making a call to MATLAB to produce a plot of simulated data, or generating a graphical user interface.</p> <p>After you add an <code>OpenFcn</code> callback to a block, double-clicking the block does not open the block dialog box. Also, the block parameters do not appear in the Property Inspector when the block is selected. To set the block parameters, select Block Parameters from the block context menu.</p> <p>For examples of using <code>OpenFcn</code> with model referencing, see:</p> <ul style="list-style-type: none"> • In the Introduction to Managing Data with Model Reference example, click the question mark block at the top and then select Detailed Workflow for Managing Data with Model Reference. • “Model Reference Simulation Targets” on page 8-72
LoadFcn	<p>After the block diagram is loaded.</p> <p>For Subsystem blocks, the <code>LoadFcn</code> callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a <code>LoadFcn</code> callback defined.</p>

Block Editing Callback Parameters

Block Callback Parameter	When Executed
MoveFcn	When the block is moved or resized.
NameChangeFcn	<p>After a block name or path changes.</p> <p>When a Subsystem block path changes, the Subsystem block calls the NameChangeFcn callback of its descendant blocks and then calls the NameChangeFcn callback on itself.</p>
PreCopyFcn	<p>Before a block is copied. The PreCopyFcn is also executed if <code>add_block</code> is used to copy the block.</p> <p>If you copy a Subsystem block that contains a block for which the PreCopyFcn callback is defined, that callback executes also.</p> <p>The block CopyFcn callback is called after all PreCopyFcn callbacks are executed, unless PreCopyFcn invokes the error command, either explicitly or via a command used in any PreCopyFcn.</p>
CopyFcn	<p>After a block is copied. The callback is also executed if <code>add_block</code> is used to copy the block.</p> <p>If you copy a Subsystem block that contains a block for which the CopyFcn parameter is defined, the callback is also executed.</p>
ClipboardFcn	When the block is copied or cut to the system clipboard.
PreDeleteFcn	<p>Before a block is graphically deleted (for example, when you graphically delete the block or invoke <code>delete_block</code> on the block).</p> <p>The PreDeleteFcn is not called when the model containing the block is closed. The block's DeleteFcn is called after the PreDeleteFcn, unless the PreDeleteFcn invokes the error command, either explicitly or via a command used in the PreDeleteFcn.</p>

Block Callback Parameter	When Executed
DeleteFcn	<p>After a block is graphically deleted (for example, when you graphically delete the block, invoke <code>delete_block</code> on the block, or close the model containing the block).</p> <p>When the <code>DeleteFcn</code> is called, the block handle is still valid and can be accessed using <code>get_param</code>. If the block is graphically deleted by invoking <code>delete_block</code> or by closing the model, after deletion the block is destroyed from memory and the block's <code>DestroyFcn</code> is called.</p> <p>For Subsystem blocks, the <code>DeleteFcn</code> callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a <code>DeleteFcn</code> callback defined.</p>
DestroyFcn	<p>When the block has been destroyed from memory (for example, when you invoke <code>delete_block</code> on either the block or a subsystem containing the block or close the model containing the block).</p> <p>If the block was not previously graphically deleted, the <code>blockDeleteFcn</code> callback is called prior to the <code>DestroyFcn</code>. When the <code>DestroyFcn</code> is called, the block handle is no longer valid.</p>
UndoDeleteFcn	When a block deletion is undone.

Block Compilation and Simulation Callback Parameters

Block Callback Parameter	When Executed
InitFcn	Before the block diagram is compiled and before block parameters are evaluated. For more information on <code>InitFcn</code> callback, see "Initialization Function" on page 11-136.

Block Callback Parameter	When Executed
StartFcn	<p>After the block diagram is compiled and before the simulation starts.</p> <p>In the case of an S-Function block, StartFcn executes immediately before the first execution of the block's mdlProcessParameters function. For more information, see "S-Function Callback Methods".</p>
ContinueFcn	Before the simulation continues.
PauseFcn	After the simulation pauses.
StopFcn	<p>At any termination of the simulation.</p> <p>In the case of an S-Function block, StopFcn executes after the block's mdlTerminate function executes. For more information, see "S-Function Callback Methods".</p>

Block Saving and Closing Callback Parameters

Block Callback Parameter	When Executed
PreSaveFcn	<p>Before the block diagram is saved.</p> <p>For Subsystem blocks, the PreSaveFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a PreSaveFcn callback defined.</p>
PostSaveFcn	<p>After the block diagram is saved.</p> <p>For Subsystem blocks, the PostSaveFcn callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a PostSaveFcn callback defined.</p>

Block Callback Parameter	When Executed
CloseFcn	<p>When the block is closed using <code>close_system</code>.</p> <p>The <code>CloseFcn</code> is not called when you interactively close the block parameters dialog box, when you interactively close the subsystem or model containing the block, or when you close the subsystem or model containing a block using <code>close_system</code>.</p> <p>For example, to close all open MATLAB windows, use a command such as:</p> <pre>set_param('my_model','CloseFcn','close all')</pre>
ModelCloseFcn	<p>Before the block diagram is closed.</p> <p>When the model is closed, the block's <code>ModelCloseFcn</code> is called prior to its <code>DeleteFcn</code>.</p> <p>For Subsystem blocks, the <code>ModelCloseFcn</code> callback is performed for any blocks in the subsystem (including other Subsystem blocks) that have a <code>ModelCloseFcn</code> callback defined.</p>

Subsystem Block Callback Parameters

You can use the other block callback parameters with Subsystem blocks, but the callback parameters in this table are specific to Subsystem blocks.

Note A callback for a masked subsystem cannot directly reference the parameters of the masked subsystem (see “Create Block Masks”). Simulink evaluates block callbacks in the MATLAB base workspace, whereas the mask parameters reside in the masked subsystem's private workspace. A block callback, however, can use `get_param` to obtain the value of a mask parameter. For example, here `gain` is the name of a mask parameter of the current block:

```
get_param(gcb, 'gain')
```

Block Callback Parameter	When Executed
DeleteChildFcn	<p>After a block or line is deleted in a subsystem.</p> <p>If the block has a <code>DeleteFcn</code> or <code>DestroyFcn</code> callback, those callbacks execute prior to the <code>DeleteChildFcn</code> callback.</p>
ErrorFcn	<p>When an error has occurred in a subsystem.</p> <p>Use the following form for the callback code for the <code>ErrorFcn</code> parameter:</p> <pre>newException = errorHandler(subsys, ... errorType, originalException)</pre> <p>where</p> <ul style="list-style-type: none"> • <code>errorHandler</code> is the name of the function. • <code>subsys</code> is a handle to the subsystem in which the error occurred. • <code>errorType</code> is a character vector indicating the type of error that occurred. • <code>originalException</code> is an <code>MSLException</code> (see “Error Handling in Simulink Using <code>MSLException</code>” on page 26-25). • <code>newException</code> is an <code>MSLException</code> specifying the error message to be displayed to the user. <p>If you provide the original exception, then you do not need to specify the subsystem and the error type.</p> <p>The following command sets the <code>ErrorFcn</code> of the subsystem <code>subsys</code> to call the <code>errorHandler</code> callback:</p> <pre>set_param(subsys, 'ErrorFcn', 'errorHandler')</pre> <p>In such calls to <code>set_param</code>, do not include the input arguments of the callback code. Simulink displays the error message returned by the callback.</p>

Block Callback Parameter	When Executed
ParentCloseFcn	<p>Before closing a subsystem containing the block or when the block is made part of a new subsystem using either:</p> <ul style="list-style-type: none">• The <code>new_system</code> function• In the Simulink Editor, the Diagram > Subsystem & Model Reference > Create Subsystem from Selection option <p>When you close the model, Simulink does not call the ParentCloseFcn callbacks of blocks at the root model level.</p>

- “Port Callbacks” on page 4-65
- “Callback Tracing” on page 4-66
- “Fast Restart Methodology” on page 73-8

Port Callbacks

Block input and output ports have a single callback parameter, `ConnectionCallback`. This parameter allows you to set callbacks on ports that are triggered every time the connectivity of these ports changes. Examples of connectivity changes include adding a connection from the port to a block, deleting a block connected to the port, and deleting, disconnecting, or connecting branches or lines to the port.

Use `get_param` to get the port handle of a port and `set_param` to set the callback on the port. The callback code must have one input argument that represents the port handle. The input argument is not included in the call to `set_param`.

For example, suppose the currently selected block has a single input port. The following code sets `foo` as the connection callback on the input port:

```
phs = get_param(gcf, 'PortHandles');  
set_param(phs.Inport, 'ConnectionCallback', 'foo');
```

where, `foo` is defined as:

```
function foo(portHandle)
```

- “Fast Restart Methodology” on page 73-8

Callback Tracing

Use callback tracing to determine the callbacks that Simulink invokes and the order that it invokes them when you open, edit, or simulate a model.

To enable callback tracing, do one of the following:

- In the Simulink Preferences dialog box, select the **Callback tracing** preference.
- Execute `set_param(0, 'CallbackTracing', 'on')`.

The `CallbackTracing` parameter causes the callbacks to appear in the MATLAB Command Window as they are invoked. This option applies to all Simulink models, not just models that are open when you enable the preference.

Manage Model Versions and Specify Model Properties

In this section...

“How Simulink Helps You Manage Model Versions” on page 4-67

“Model File Change Notification” on page 4-67

“Manage Model Properties” on page 4-68

“Log Comments History” on page 4-70

“Version Information Properties” on page 4-71

How Simulink Helps You Manage Model Versions

In Simulink, you can manage multiple versions of a model using these techniques:

- Use Simulink Projects to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Use model file change notification to manage work with source control operations and multiple users. See “Model File Change Notification” on page 4-67.
- As you edit a model, Simulink generates version information about the model, including a version number, who created and last updated the model, and an optional comments history log. Simulink saves these version properties with the model.
 - View and edit some of the version information stored in the model and specify history logging in the model properties.
 - The Model Info block lets you display version information as an annotation block in a model diagram.
 - You can access Simulink version parameters programmatically.
- See `Simulink.MDLInfo` to extract information from a model file without loading the block diagram into memory. You can use `MDLInfo` to query model version and Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

Model File Change Notification

You can use a Simulink preference to specify whether to notify you if the model has changed on disk. You can receive this notification when updating or simulating the model,

first editing the model, or saving the model. The model can change on disk, for example, with source control operations and multiple users.

In the Simulink Editor, select **File > Simulink Preferences**. In the **Model File** pane, under **Change Notification**, select the appropriate action.

- If you select **First editing the model**, the file has changed on disk, and the block diagram is unmodified in Simulink:
 - Any interactive operation that modifies the block diagram (e.g., adding a block) causes a warning to appear.
 - Any command-line operation that modifies the block diagram (such as a call to `set_param`) causes a warning to appear.
- If you select **Saving the model**, and the file has changed on disk:
 - Saving the model in the Simulink Editor causes a message to appear.
 - The `save_system` function reports an error, unless you use the `OverwriteIfChangedOnDisk` option.

To programmatically check whether the model has changed on disk since it was loaded, use the function `slIsFileChangedOnDisk`.

For more options that help you work with source control and multiple users, see “Project Management”.

Manage Model Properties

You can use the Property Inspector to view and edit model version properties, description history, and callback functions. To open the Property Inspector, select **View > Property Inspector**. Model properties or, if you are in a library model, library properties, appear in the Property Inspector when nothing is selected at the top level of a model.

Specify the Current User

When you create or update a model, your name is logged in the model for version control purposes. Simulink assumes that your name is specified by at least one of the `USER`, `USERNAME`, `LOGIN`, or `LOGNAME` environment variables. If your system does not define any of these variables, Simulink does not update the user name in the model.

UNIX® systems define the **USER** environment variable and set its value to the name you use to log in to your system. Thus, if you are using a UNIX system, you do not have to take further action for Simulink to identify you as the current user.

Windows systems can define environment variables for user name that Simulink expects, depending on the version of Windows installed on your system and whether it is connected to a network. Use the MATLAB function `getenv` to determine which of the environment variables is defined. For example, at MATLAB command prompt, enter:

```
getenv('user')
```

This function determines whether the **USER** environment variable exists on your Windows system. If it does not, set it.

Model Information and History

The **Info** tab summarizes information about the current version of the model, such as modifications, version, and last saved date. You can view and edit model information and enable, view, and edit the model's change history.

Use the **Description** section to enter a description of the model. You can then view the model description by entering `help` followed by the model name at the MATLAB command prompt.

The **History** section displays model history information.

- **Model version**

Version number for this model, incremented by 1 each time you save the model.

- **Created by**

Name of the person who created this model based on the value of the **USER** environment variable when the model is created.

- **Created on**

Date and time this model was created. Do not change this value.

- **Last saved by**

Name of the person who last saved this model based on the value of the **USER** environment variable when the model is saved.

- **Last saved on**

Date that this model was last saved, based on the system date and time.

The **Model history** box displays the history of the model. For more information on updating model history, see “Log Comments History” on page 4-70.

Properties

You can view the source file location, specify where to save model design data, and define callbacks in the **Properties** tab of the model properties.

Note Library properties also enable you to specify the mapping from old library blocks to new library blocks. For information on using forwarding tables for this purpose, see “Forwarding Tables” on page 41-41.

Define Location of Design Data

Use the **Design Data** section to specify the location of the design data that your model uses. You can define design data in the base workspace or in a data dictionary. See “Migrate Single Model to Use Dictionary” on page 66-7.

Callbacks

Use the **Callbacks** section to specify functions to invoke at specific points in the simulation of the model. Select the callback from the list. In the box, enter the function you want to invoke for the selected callback. For information on these callbacks, see “Create Model Callbacks” on page 4-52.

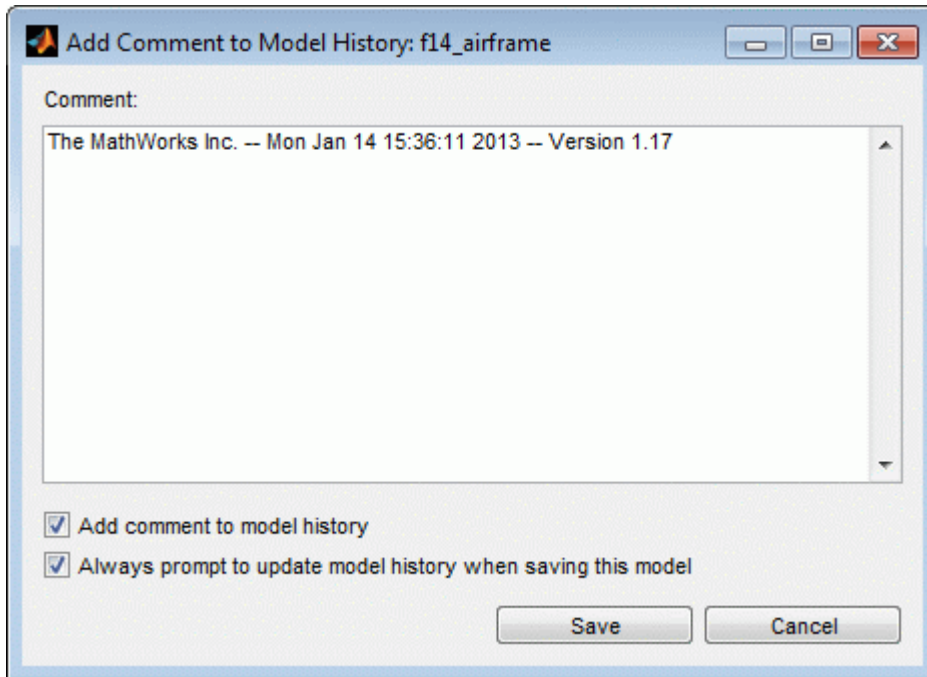

Log Comments History

You can create and store a record of changes with the model. Simulink compiles the history from comments that you or other users enter when saving changes to a model. For more flexibility adding labels and comments to models and submissions, see “Project Management”.

Logging Changes

To enable comment logging, in the **Info** tab of the model properties, in the **History** section, set **Prompt to update model history** to When saving model.

The next time you save the model, the Add Comment to Model History dialog box prompts you to enter a comment.

For example, describe the changes you have made to the model since the last time you saved it. To add an item to the model's change history, enter it in the **Comment** box and click **Save**. The information is stored in the model's change history log.

If you do not want to enter an item for this session, clear the **Add comment to model history** check box.

To discontinue change logging, you can either:

- Clear the **Always prompt to update model history when saving this model** check box.
- Change the **Prompt to update model history** model property to Never.

Version Information Properties

Some version information is stored as model parameters in a model. You can access this information programmatically using the Simulink `get_param` function.

The table describes the model parameters used by Simulink to store version information.

Property	Description
Created	Date created.
Creator	Name of the person who created this model.
Description	User-entered description of this model. Enter or edit a description on the Description tab of the Model Properties dialog box. You can view the model description by typing <code>help 'mymodelName'</code> at the MATLAB command prompt.
LastModifiedBy	Name of the user who last saved the model.
LastModifiedDate	Date when the model was last saved.
ModifiedByFormat	Format of the ModifiedBy parameter. The value can include the tag <code>%<Auto></code> . The Simulink software replaces the tag with the current value of the USER environment variable.
ModifiedDateFormat	Format used to generate the value of the LastModifiedDate parameter. The value can include the tag <code>%<Auto></code> . Simulink replaces the tag with the current date and time when saving the model.
ModifiedComment	Comment entered by user who last updated this model.
ModifiedHistory	History of changes to this model.
ModelVersion	Version number.
ModelVersionFormat	Format of model version number. The value can contain the tag <code>%<AutoIncrement:#></code> where # is an integer. Simulink replaces the tag with # when displaying the version number. It increments # when saving the model.

LibraryVersion is a block parameter for a linked block. LibraryVersion is the ModelVersion of the library at the time the link was created.

For source control version information, see instead “Project Management”.

Model Discretizer

In this section...
“What Is the Model Discretizer?” on page 4-74
“Requirements” on page 4-74
“Discretize a Model with the Model Discretizer” on page 4-75
“View the Discretized Model” on page 4-83
“Discretize Blocks from the Simulink Model” on page 4-86
“Discretize a Model with the sldiscmdl Function” on page 4-96

What Is the Model Discretizer?

Model Discretizer selectively replaces continuous Simulink blocks with discrete equivalents. Discretization is a critical step in digital controller design and for hardware in-the-loop simulations.

You can use the Model Discretizer to:

- Identify a model's continuous blocks
- Change a block's parameters from continuous to discrete
- Apply discretization settings to all continuous blocks in the model or selected blocks
- Create configurable subsystems that contain multiple discretization candidates along with the original continuous block(s)
- Switch among the different discretization candidates and evaluate the resulting model simulations

Requirements

To use Model Discretizer

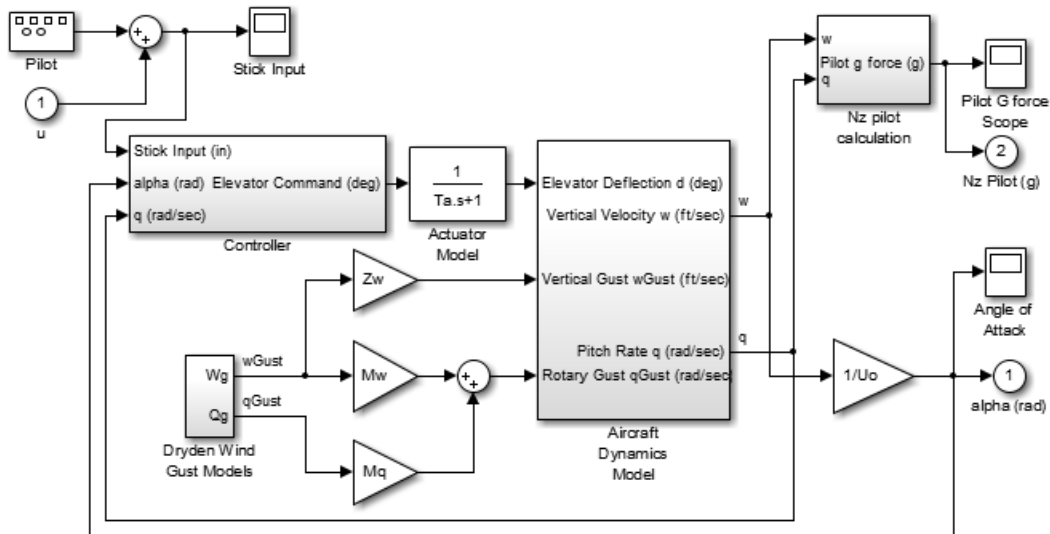

- You must have a Control System Toolbox™ license, Version 5.2 or later.
- Make sure your model does not contain any obsolete blocks and is upgraded to the current Simulink version. For more information, see “Model Upgrades”

Discretize a Model with the Model Discretizer

To discretize a model:

- Start the Model Discretizer
- Specify the Transform Method
- Specify the Sample Time
- Specify the Discretization Method
- Discretize the Blocks

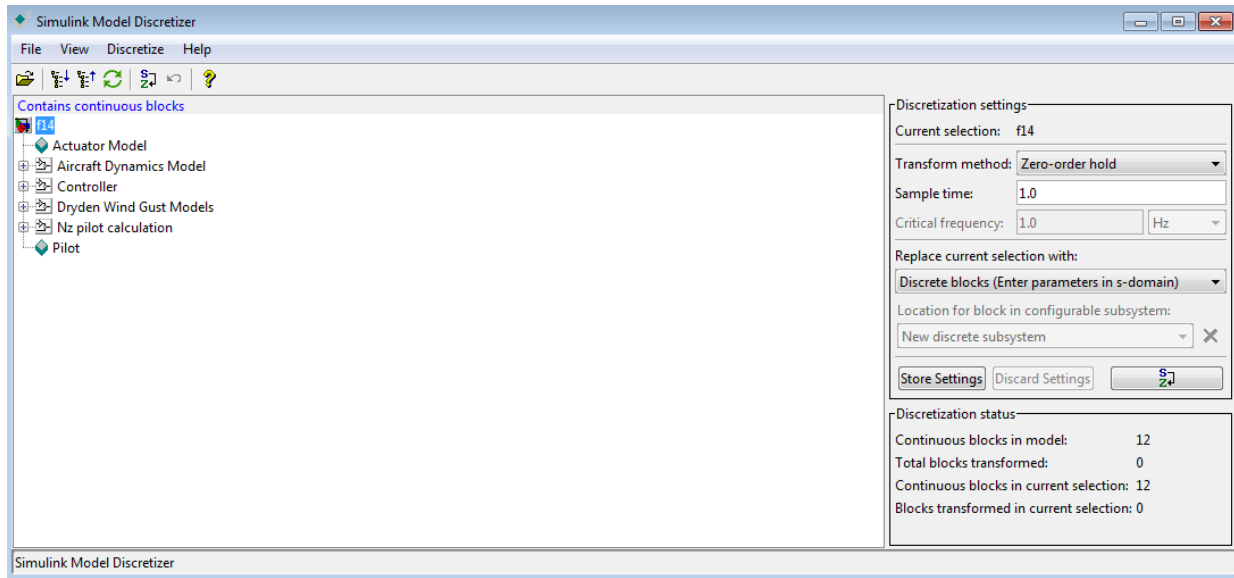

The f14 model shows the steps in discretizing a model.

Start Model Discretizer

To open the tool, in the Simulink Editor, select **Analysis > Control Design > Model Discretizer**.

The **Simulink Model Discretizer** opens.

Alternatively, you can open Model Discretizer from the MATLAB Command Window using the `slmdliscui` function.

The following command opens the **Simulink Model Discretizer** window with the `f14` model:

```
slmdliscui('f14')
```

To open a new model or library from Model Discretizer, select **File > Load model**.

Specify the Transform Method

The transform method specifies the type of algorithms used in the discretization. For more information on the different transform methods, see the Control System Toolbox.

The **Transform method** list contains the following options:

- Zero-order hold
Zero-order hold on the inputs.
- First-order hold
Linear interpolation of inputs.

- Tustin
Bilinear (Tustin) approximation.
- Tustin with prewarping
Tustin approximation with frequency prewarping.
- Matched pole-zero
Matched pole-zero method (for SISO systems only).

Specify the Sample Time

Enter the sample time in the **Sample time** field. For the Model Discretizer, this value must be numeric.

You can specify an offset time by entering a two-element vector for discrete blocks or configurable subsystems. The first element is the sample time and the second element is the offset time. For example, an entry of [1.0 0.1] would specify a 1.0 second sample time with a 0.1 second offset. If no offset is specified, the default is zero.

You can enter workspace variables when discretizing blocks in the s-domain. See “Discrete blocks (Enter parameters in s-domain)” on page 4-78.

Specify the Discretization Method

Specify the discretization method in the **Replace current selection with** field. The options are

- “Discrete blocks (Enter parameters in s-domain)” on page 4-78
Creates a discrete block whose parameters are retained from the corresponding continuous block.
- “Discrete blocks (Enter parameters in z-domain)” on page 4-79
Creates a discrete block whose parameters are “hard-coded” values placed directly into the block’s dialog.
- “Configurable subsystem (Enter parameters in s-domain)” on page 4-80
Create multiple discretization candidates using s-domain values for the current selection. A configurable subsystem can consist of one or more blocks.

- “Configurable subsystem (Enter parameters in z-domain)” on page 4-81

Create multiple discretization candidates in z-domain for the current selection. A configurable subsystem can consist of one or more blocks.

Discrete blocks (Enter parameters in s-domain)

Creates a discrete block whose parameters are retained from the corresponding continuous block. The sample time and the discretization parameters are also on the block's parameter dialog box.

The block is implemented as a masked discrete block that uses `c2d` to transform the continuous parameters to discrete parameters in the mask initialization code.

These blocks have the unique capability of reverting to continuous behavior if the sample time is changed to zero. Entering the sample time as a workspace variable ('Ts ' , for example) allows for easy changeover from continuous to discrete and back again. See “Specify the Sample Time” on page 4-77.

Note If you generated code from a model, parameters are not tunable when **Default parameter behavior** is set to **Inlined** in the model's Configuration Parameters dialog box.

The following figure shows a continuous Transfer Function block next to a Transfer Function block that has been discretized in the s-domain. The block parameters dialog box for each block appears below the block.

$$\frac{1}{s+1}$$

$$\frac{\text{tustin } 1}{s+1}$$

Block Parameters: Transfer Fcn

Transfer Fcn

The numerator coefficient can be a vector or matrix expression. The denominator coefficient must be a vector. The output width equals the number of rows in the numerator coefficient. You should specify the coefficients in descending order of powers of s.

Discrete blocks (Enter parameters in z-domain)

Creates a discrete block whose parameters are “hard-coded” values placed directly into the block's dialog box. Model Discretizer uses the c2d function to obtain the discretized parameters, if needed.

For more help on the c2d function, type the following in the Command Window:

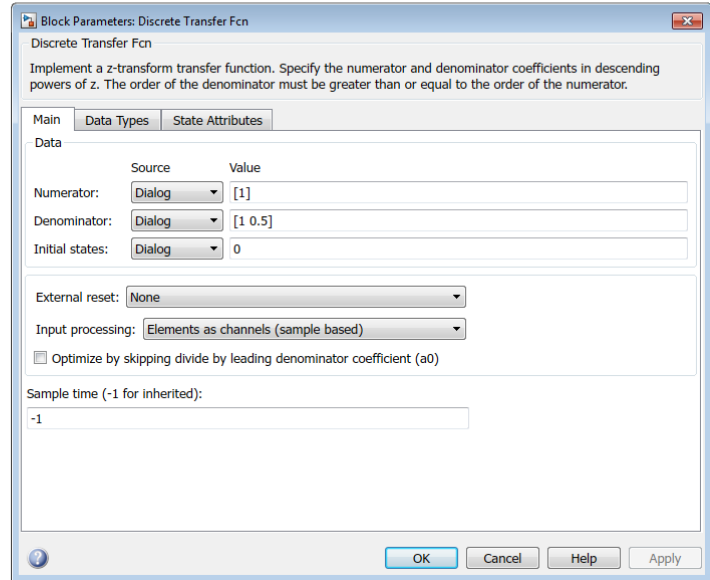

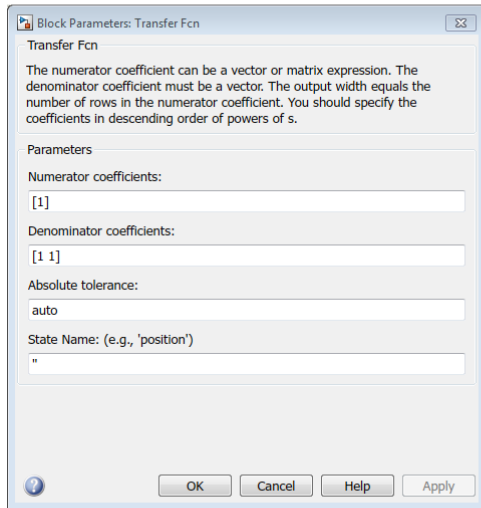

```
help c2d
```

The following figure shows a continuous Transfer Function block next to a Transfer Function block that has been discretized in the z-domain. The block parameters dialog box for each block appears below the block.

4 Creating a Model

$$\frac{1}{s+1}$$

$$\frac{1}{z+0.5}$$

Note If you want to recover exactly the original continuous parameter values after the Model Discretization session, you should enter parameters in the s-domain.

Configurable subsystem (Enter parameters in s-domain)

Create multiple discretization candidates using s-domain values for the current selection. A configurable subsystem can consist of one or more blocks.

The **Location for block in configurable subsystem** field becomes active when this option is selected. This option allows you to either create a new configurable subsystem or overwrite an existing one.

Note The current folder must be writable in order to save the library or libraries for the configurable subsystem option.

Configurable subsystem (Enter parameters in z-domain)

Create multiple discretization candidates in z-domain for the current selection. A configurable subsystem can consist of one or more blocks.

The **Location for block in configurable subsystem** field becomes active when this option is selected. This option allows you to either create a new configurable subsystem or overwrite an existing one.

Note The current folder must be writable in order to save the library or libraries for the configurable subsystem option.

Configurable subsystems are stored in a library containing the discretization candidates and the original continuous block. The library will be named <model name>_disc_lib and it will be stored in the current. For example a library containing a configurable subsystem created from the f14 model will be named f14_disc_lib.

If multiple libraries are created from the same model, then the filenames will increment accordingly. For example, the second configurable subsystem library created from the f14 model will be named f14_disc_lib2.

You can open a configurable subsystem library by right-clicking on the subsystem in the model and selecting **Library Link > Go to library block** from the context menu.

Discretize the Blocks

To discretize blocks that are linked to a library, you must either discretize the blocks in the library itself or disable the library links in the model window.

You can open the library from Model Discretizer by selecting **Load model** from the **File** menu.

You can disable the library links by right-clicking on the block and selecting **Library Link > Disable Link** from the context menu.

There are two methods for discretizing blocks.

Select Blocks and Discretize

- 1 Select a block or blocks in the Model Discretizer tree view pane.

To choose multiple blocks, press and hold the **Ctrl** button on the keyboard while selecting the blocks.

Note You must select blocks from the Model Discretizer tree view. Clicking blocks in the editor does not select them for discretization.

- 2 Select **Discretize current block** from the **Discretize** menu if a single block is selected or select **Discretize selected blocks** from the **Discretize** menu if multiple blocks are selected.

You can also discretize the current block by clicking the **Discretize** button, shown below.

Store the Discretization Settings and Apply Them to Selected Blocks in the Model

- 1 Enter the discretization settings for the current block.
- 2 Click **Store Settings**.

This adds the current block with its discretization settings to the group of preset blocks.

- 3 Repeat steps 1 and 2, as necessary.
- 4 Select **Discretize preset blocks** from the **Discretize** menu.

Deleting a Discretization Candidate from a Configurable Subsystem

You can delete a discretization candidate from a configurable subsystem by selecting it in the **Location for block in configurable subsystem** field and clicking the **Delete** button.

Undoing a Discretization

To undo a discretization, click the **Undo discretization** button.

Alternatively, you can select **Undo discretization** from the **Discretize** menu.

This operation undoes discretizations in the current selection and its children. For example, performing the undo operation on a subsystem will remove discretization from all blocks in all levels of the subsystem's hierarchy.

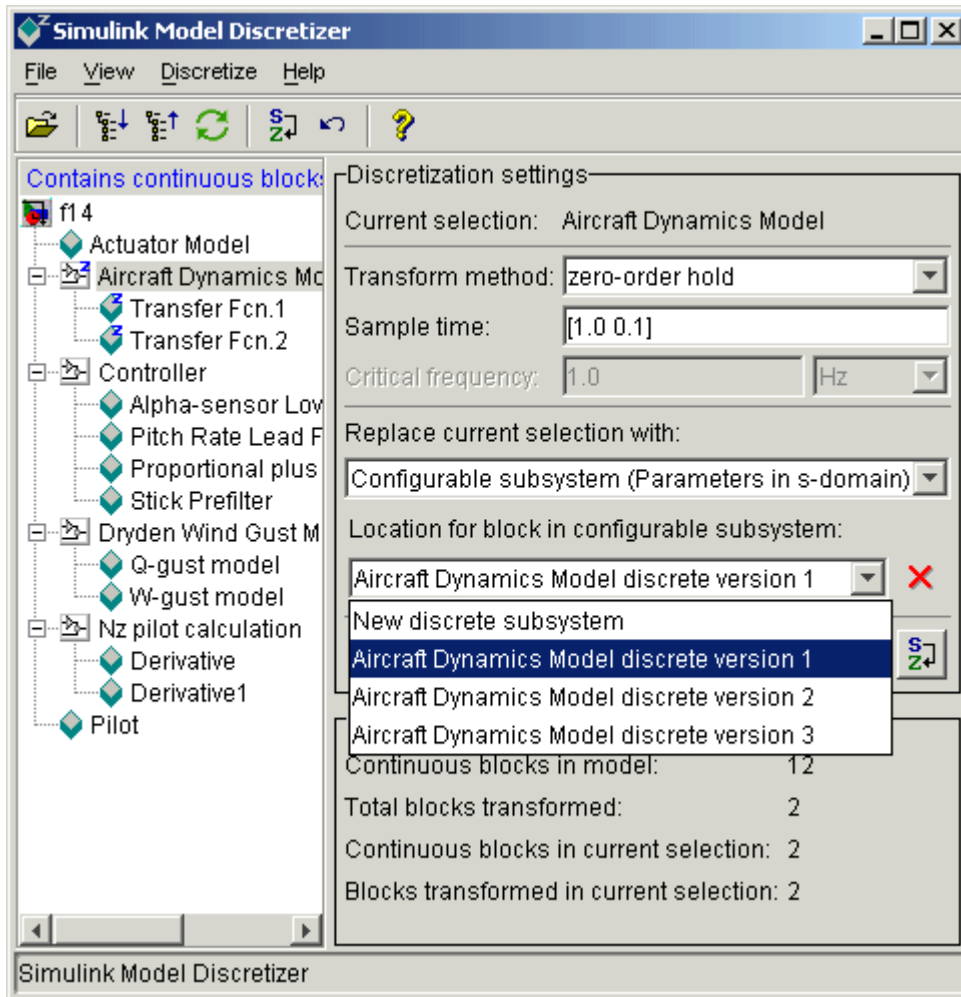

View the Discretized Model

Model Discretizer displays the model in a hierarchical tree view.

Viewing Discretized Blocks

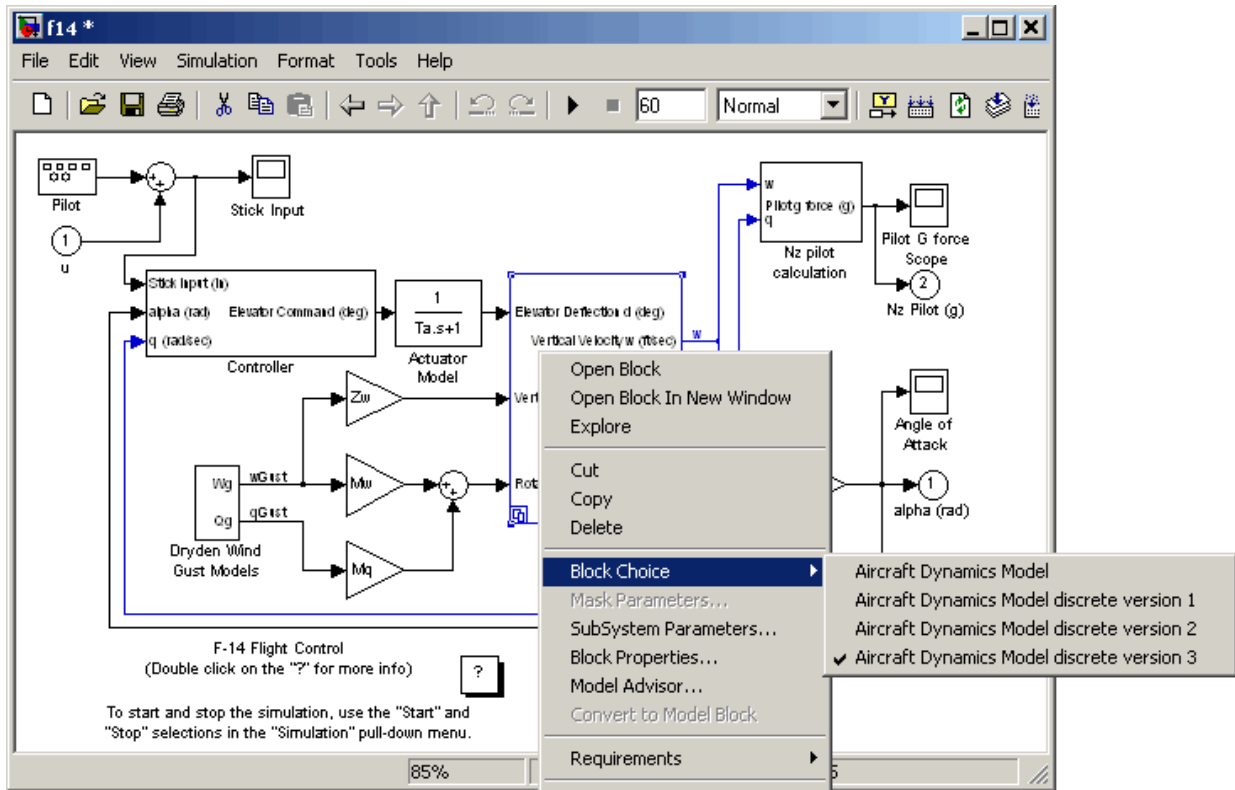

The block's icon in the tree view becomes highlighted with a “z” when the block has been discretized.

The following figure shows that the Aircraft Dynamics Model subsystem has been discretized into a configurable subsystem with three discretization candidates.

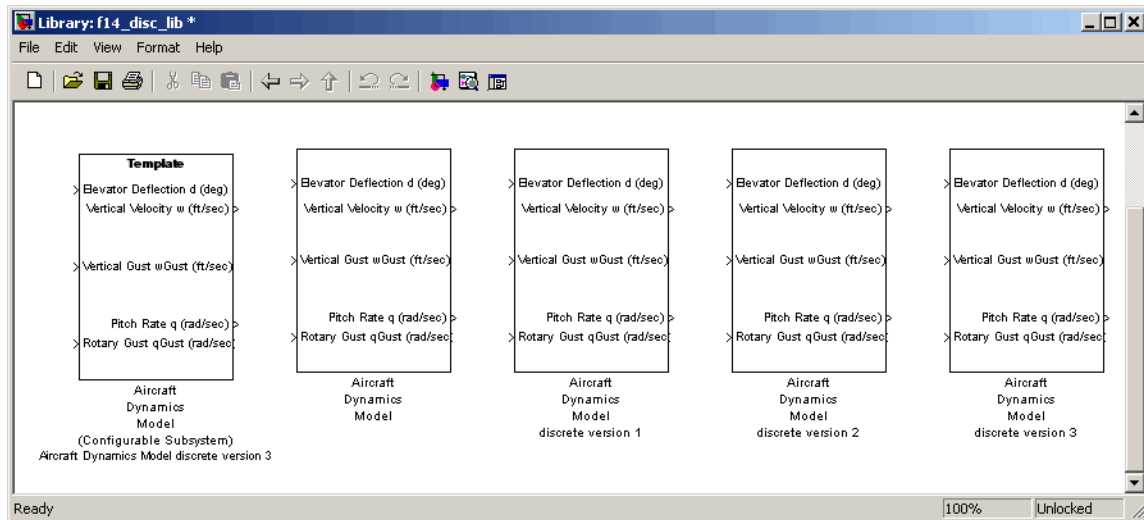

The other blocks in this f14 model have not been discretized.

The following figure shows the Aircraft Dynamics Model subsystem of the f14 example model after discretization into a configurable subsystem containing the original continuous model and three discretization candidates.

The following figure shows the library containing the Aircraft Dynamics Model configurable subsystem with the original continuous model and three discretization candidates.

Refreshing Model Discretizer View of the Model

To refresh Model Discretizer's tree view of the model when the model has been changed, click the **Refresh** button.

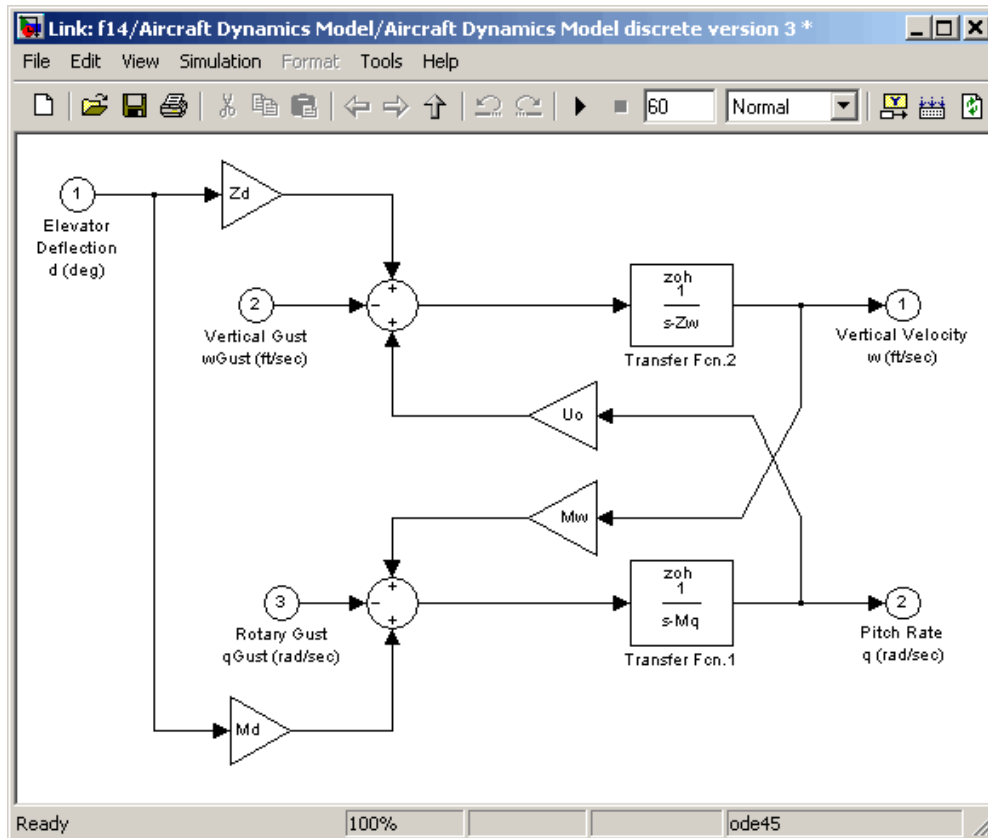

Alternatively, you can select **Refresh** from the **View** menu.

Discretize Blocks from the Simulink Model

You can replace continuous blocks in a Simulink software model with the equivalent blocks discretized in the s-domain using the Discretizing library.

The procedure below shows how to replace a continuous Transfer Fcn block in the Aircraft Dynamics Model subsystem of the f14 model with a discretized Transfer Fcn block from the Discretizing Library. The block is discretized in the s-domain with a zero-order hold transform method and a two second sample time.

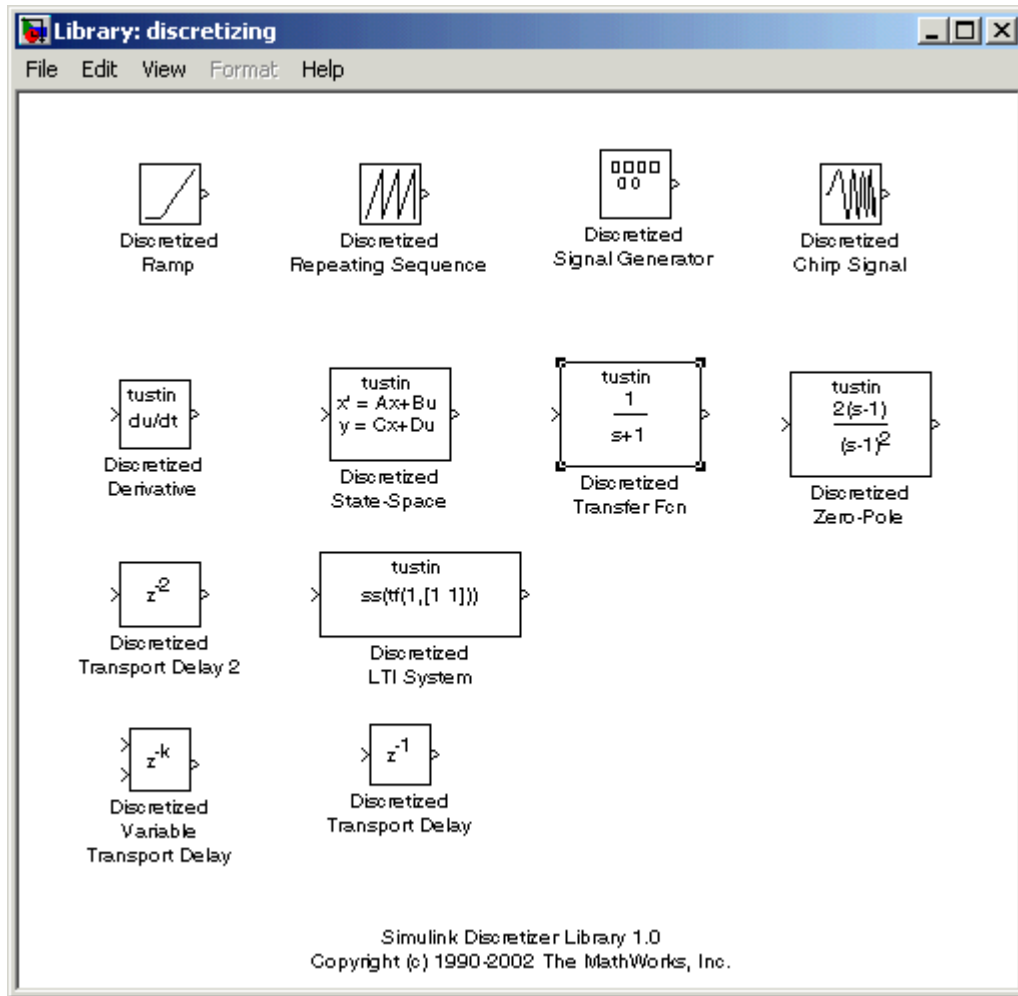

- 1 Open the f14 model.
- 2 Open the Aircraft Dynamics Model subsystem in the f14 model.

3 Open the Discretizing library window.

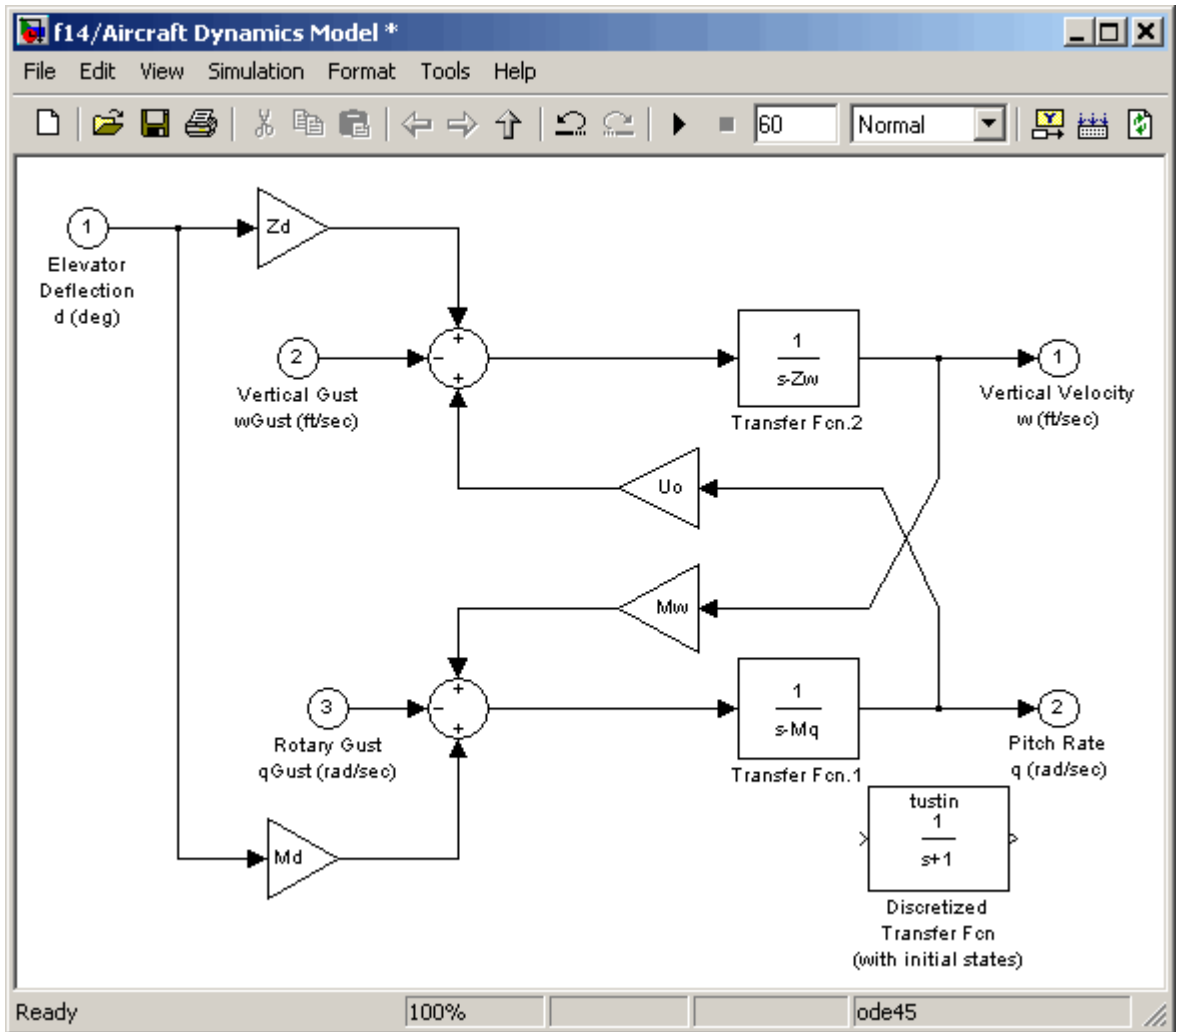

Enter discretizing at the MATLAB command prompt.

The **Library: discretizing** window opens.

This library contains s-domain discretized blocks.

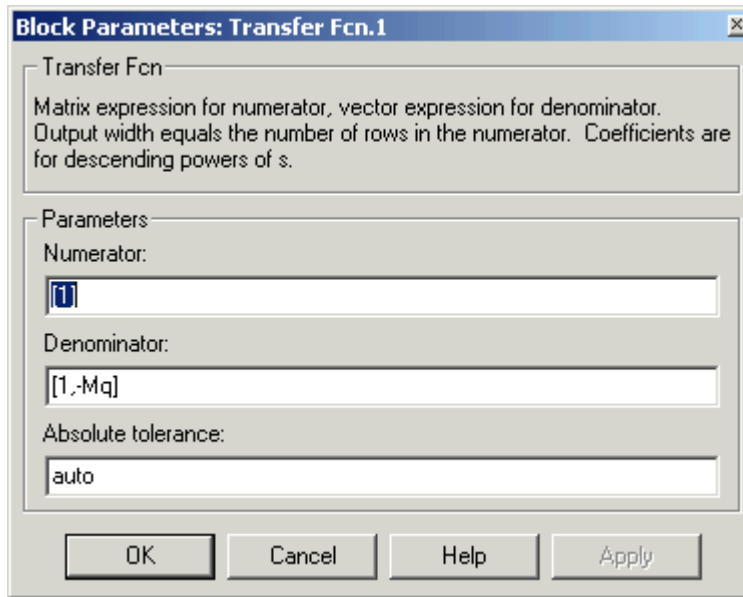

- 4 Add the Discretized Transfer Fcn (with initial states) block to the **f14/Aircraft Dynamics Model** window.
 - a Click the Discretized Transfer Fcn block in the **Library: discretizing** window.
 - b Drag it into the **f14/Aircraft Dynamics Model** window.

- 5 Open the parameter dialog box for the Transfer Fcn.1 block.

Double-click the Transfer Fcn.1 block in the **f14/Aircraft Dynamics Model** window.

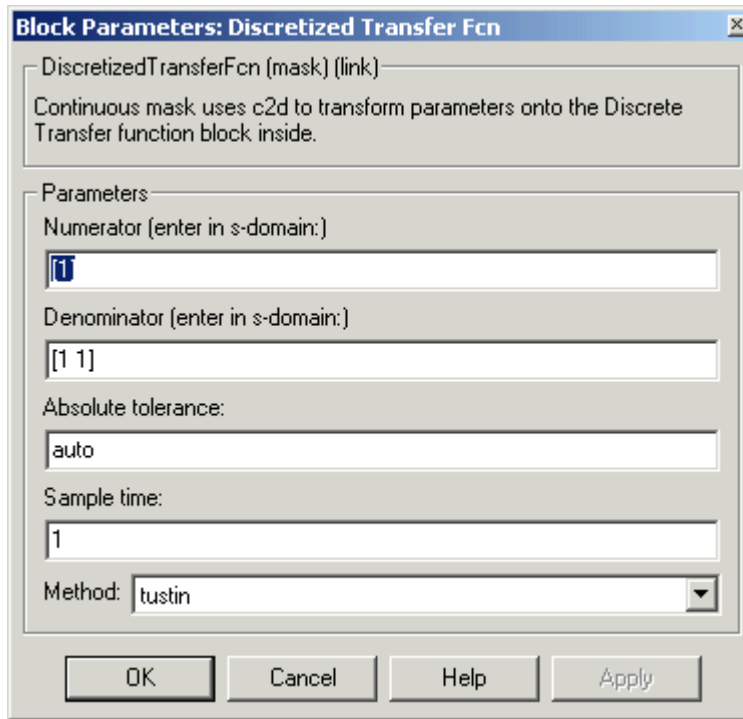

The Block Parameters: Transfer Fcn.1 dialog box opens.

- 6 Open the parameter dialog box for the Discretized Transfer Fcn block.

Double-click the Discretized Transfer Fcn block in the **f14/Aircraft Dynamics Model** window.

The Block Parameters: Discretized Transfer Fcn dialog box opens.

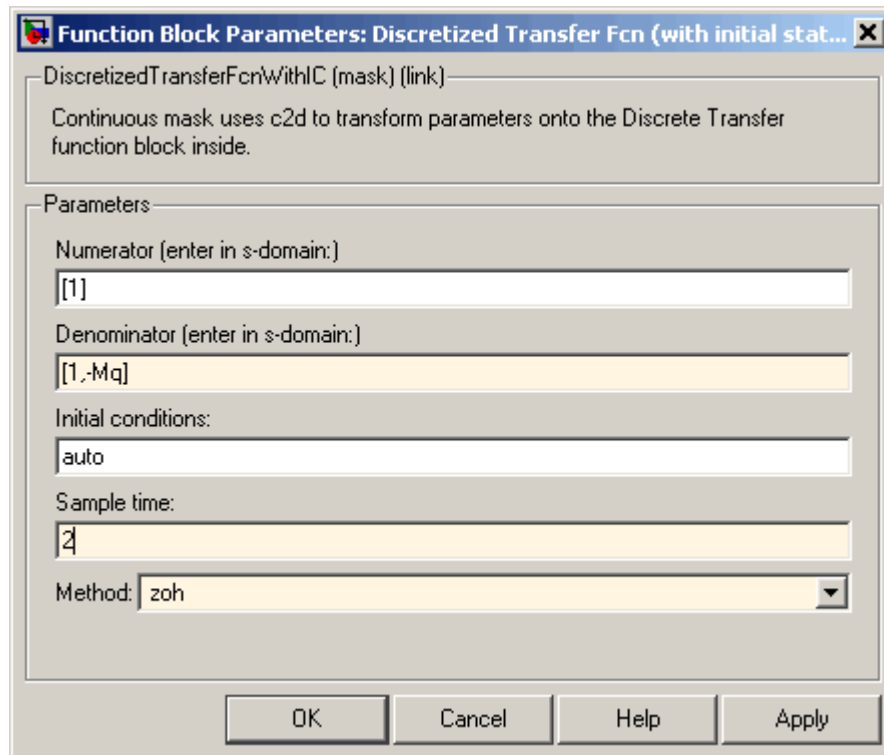

Copy the parameter information from the Transfer Fcn.1 block's dialog box to the Discretized Transfer Fcn block's dialog box.

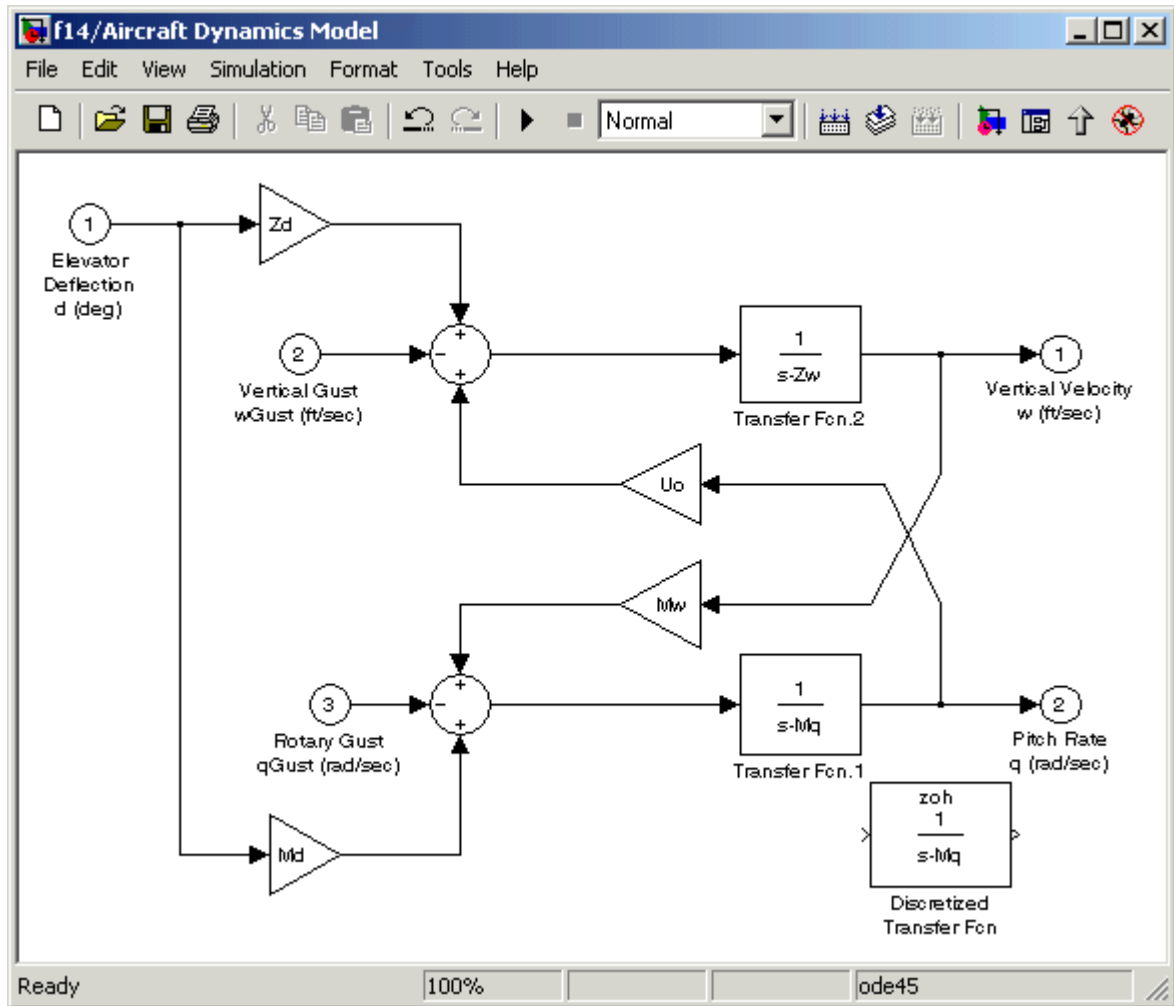

- 7 Enter 2 in the **Sample time** field.
- 8 Select **zoh** from the **Method** drop-down list.

The parameter dialog box for the Discretized Transfer Fcn now looks like this.

- 9 Click **OK**.

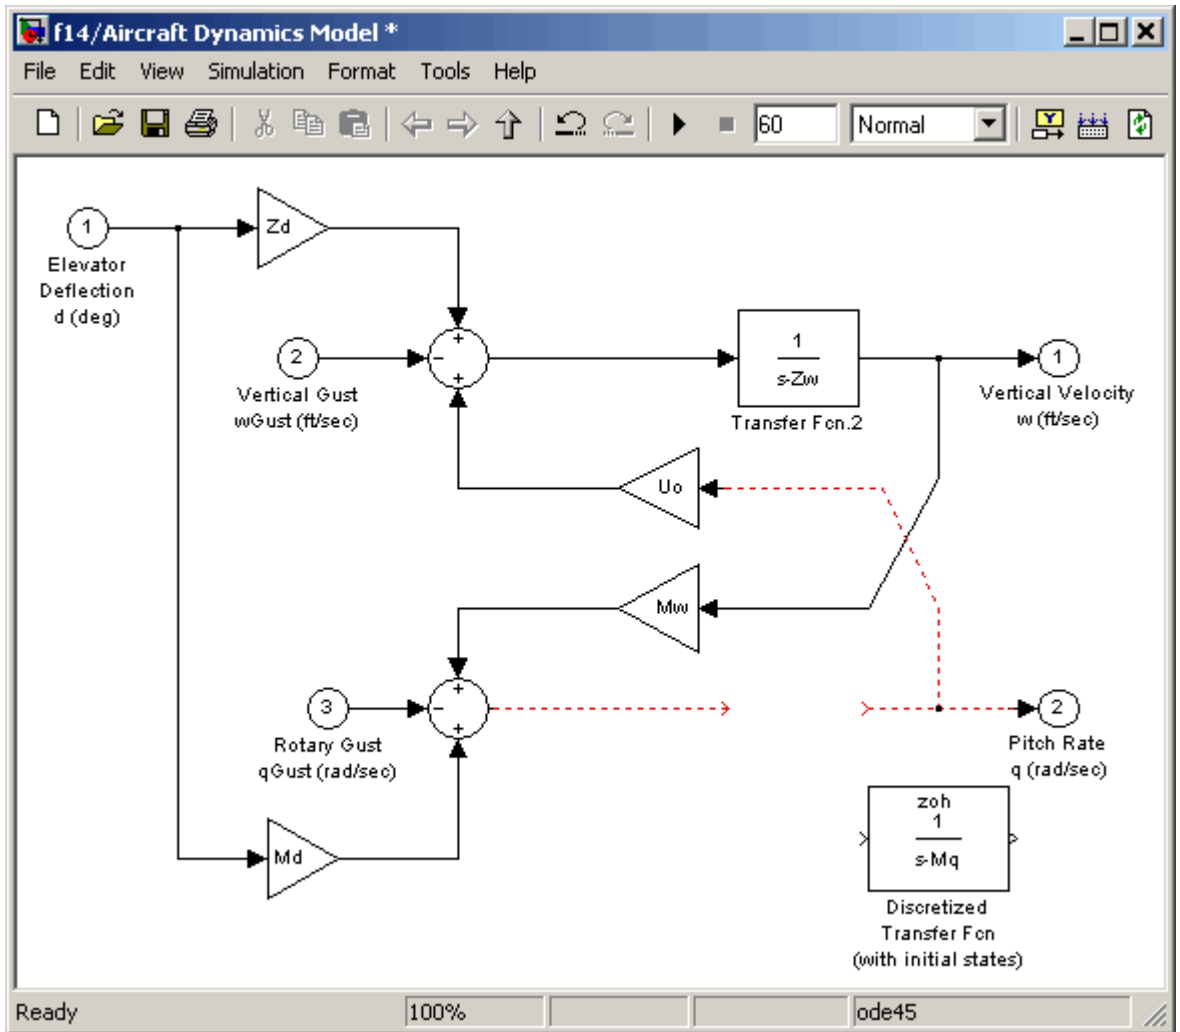

The **f14/Aircraft Dynamics Model** window now looks like this.

10 Delete the original Transfer Fcn.1 block.

- a Click the Transfer Fcn.1 block.
- b Press the **Delete** key.

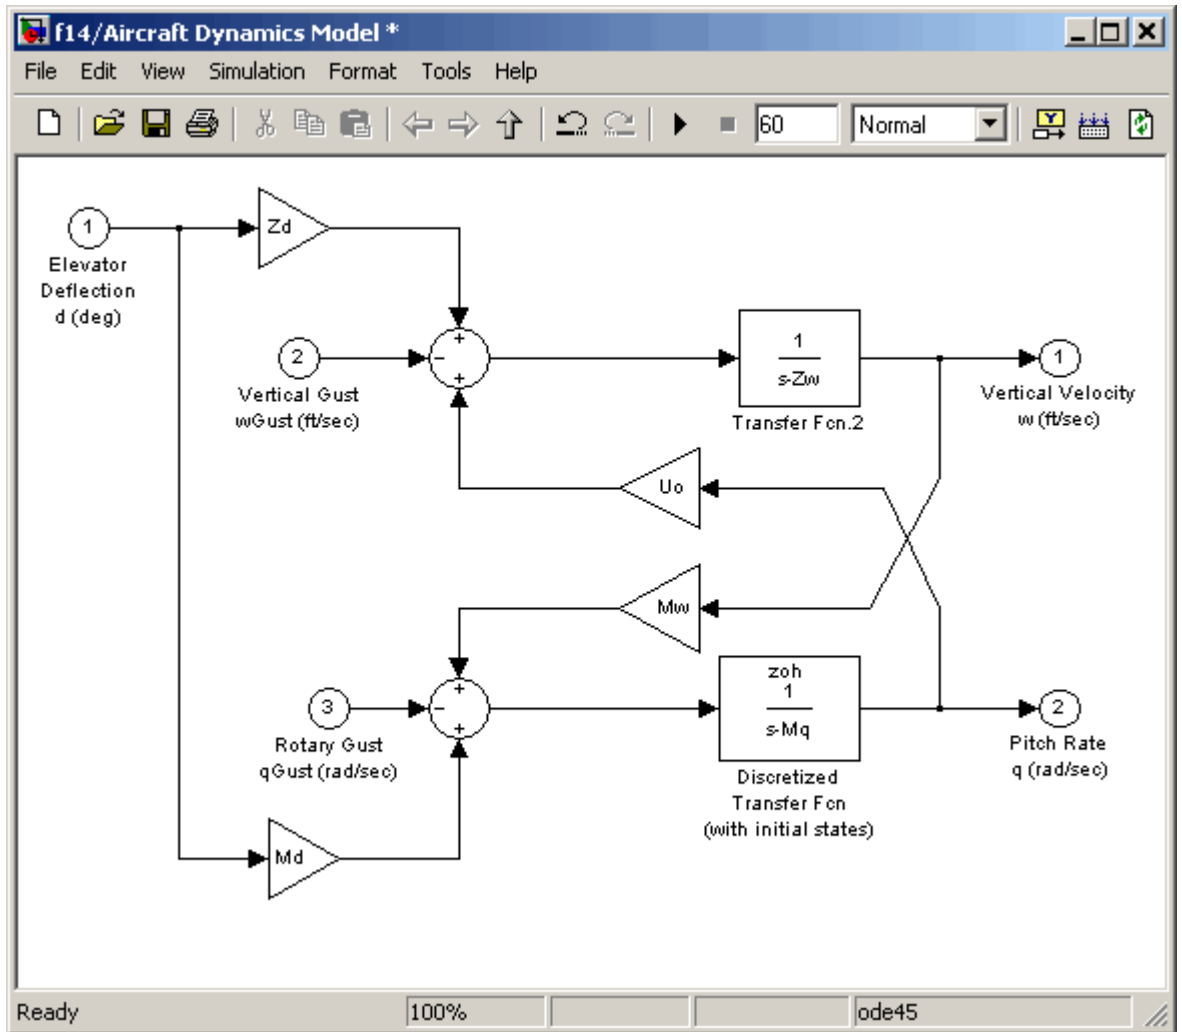

The f14/Aircraft Dynamics Model window now looks like this.

11 Add the Discretized Transfer Fcn block to the model.

- a** Click the Discretized Transfer Fcn block.
- b** Drag the Discretized Transfer Fcn block into position to complete the model.

The **f14/Aircraft Dynamics Model** window now looks like this.

Discretize a Model with the sldiscmdl Function

Use the `sldiscmdl` function to discretize Simulink software models from the MATLAB Command Window. You can specify the transform method, the sample time, and the discretization method with the `sldiscmdl` function.

For example, the following command discretizes the `f14` model in the s-domain with a 1-second sample time using a zero-order hold transform method:

```
sldiscmdl('f14',1.0,'zoh')
```

Model Advisor

Select and Run Model Advisor Checks

Model Advisor Overview

The Model Advisor checks a model or subsystem for conditions and configuration settings including conditions that cause inaccurate or inefficient simulation of the system that the model represents. If you have Simulink Coder or Simulink Check™, the Model Advisor can check for model settings that cause generation of inefficient code or code unsuitable for safety-critical applications. If you have Simulink Design Verifier™, the Model Advisor can check for design errors. If an error is reported, you can view a test case that reproduces the error.

The Model Advisor produces a report that lists the suboptimal conditions or settings that it finds, and proposes better model configuration settings where appropriate.

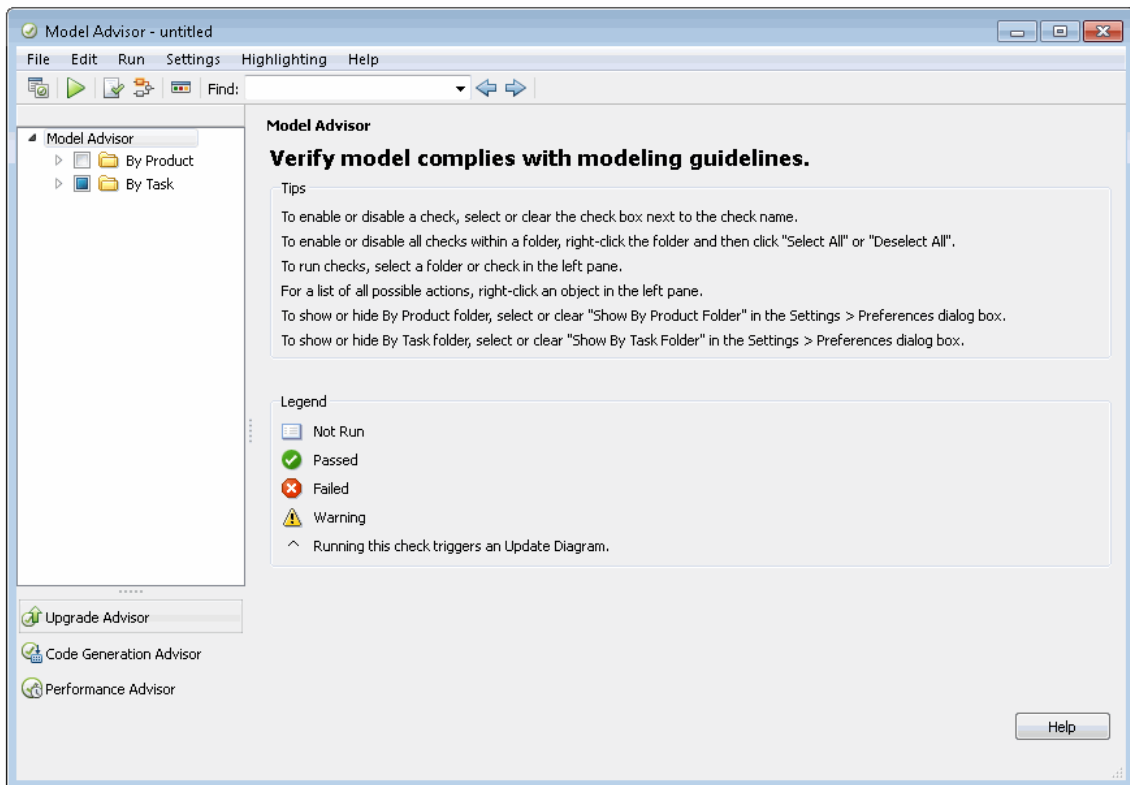

Software is inherently complex and may not be free of errors. Model Advisor checks might contain bugs. MathWorks® reports known bugs brought to its attention on its Bug Report system at <https://www.mathworks.com/support/bugreports/>. The bug reports are an integral part of the documentation for each release. Examine periodically all bug reports for a release as such reports may identify inconsistencies between the actual behavior of a release you are using and the behavior described in this documentation.

While applying Model Advisor checks to your model increases the likelihood that your model does not violate certain modeling standards or guidelines, their application cannot guarantee that the system being developed will be safe or error-free. It is ultimately your responsibility to verify, using multiple methods, that the system being developed provides its intended functionality and does not include any unintended functionality.

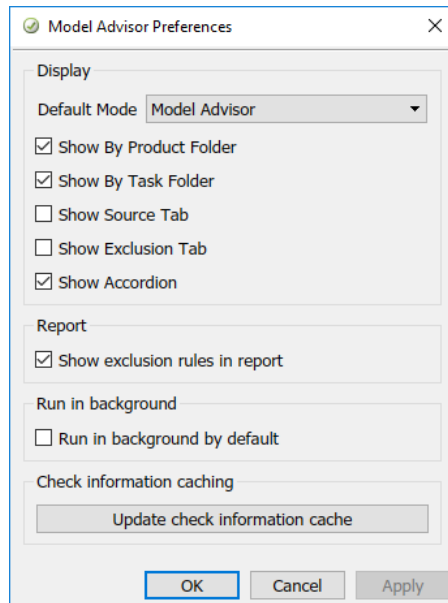

Run Model Advisor Checks

- 1 Open the Model Advisor example model `sldemo_mdladv`.
- 2 Start the Model Advisor. In the Model Editor, select **Analysis > Model Advisor > Model Advisor** or **Model Advisor Dashboard**. The dashboard preserves the checks used in the previous analysis. You can run these same checks without reloading them, saving analysis time.
- 3 In the Model Explorer, in the **Contents** pane, select **Advice for *model***. *model* is the name of the model that you want to check.
- 4 In the Model Editor, right-click the subsystem that you want to check, and in the context menu select **Model Advisor**.

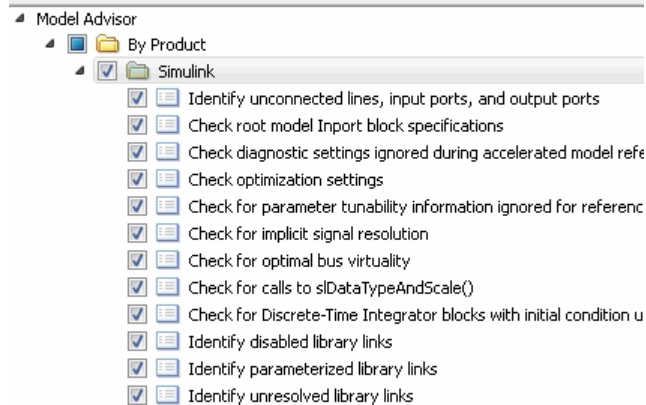

- 5 At the command prompt, enter `modeladvisor('sldemo_mdadv')`.
- 6 In the System Selector dialog box, select the model or system that you want to analyze, for example, `sldemo_mdadv`. Click **OK**.
- 7 In the left pane of the Model Advisor, expand the **By Product** and **By Task** folders to display the subfolders. The **By Task** folders display checks related to specific tasks. For example, to run checks to determine if your model is configured for simulation accuracy, select checks in the **Simulation Accuracy** folder.

- 8 The **By Product** folders display checks available with specific products.
- 9 Select **Settings > Preferences** to control the folders that are displayed.

- 10** In the left pane, select the checks to run on your model. For example, select the checks in the **By Product > Simulink** folder.

Display Check Results

To display an HTML report of check results:

- 1 In the right pane of the Model Advisor, select **Show report after run**.
- 2 On the toolbar, click **Run Selected Checks** or . After the Model Advisor runs the checks, the results appear in a browser if you selected the option to show the report.

Check status results include:

- Pass – Check did not identify issues.
 - D-Pass – Dependent on configuration parameter. Check did not identify issues.
 - Warn – Check has identified issues.
 - Fail – Check fails to execute.
- 3 Review the results and fix the warnings or failures as desired.

Set Model Advisor Window Preferences

To open the Model Advisor Preferences dialog box, on the toolbar, select **Settings > Preferences**.

Action	Select
Display the check available for each product.	Show By Product Folder
Display checks related to specific tasks.	Show By Task Folder
Display the check Title, TitleId, and location of the MATLAB source code for the check.	Show Source Tab. The Source tab displays check source information.
Display checks that are excluded from the Model Advisor analysis.	Show Exclusion tab. The Exclusions tab displays checks that are excluded from the Model Advisor analysis.

Display and Run Checks

Action	Model Advisor Options
Display checks related to specific tasks.	Select By Task .

Action	Model Advisor Options
Display the check available for each product.	Select By Product .
Find checks and folders.	In the Find: field, enter text and click the Find Next button (). The Model Advisor searches in check names, folder names, and analysis descriptions.
Reset the status of the checks to not run.	In the left pane, right-click Model Advisor and select Reset .
Select some or all of the checks.	Select the check and folder check boxes.
Run the selected checks.	On the toolbar of the Model Advisor window, click Run selected checks ().

Run the Same Set of Checks Consistently

To consistently run the same set of checks on your model, use the Model Advisor dashboard.

Action	Option
Select and view checks.	In the Model Advisor window, click the Switch to standard view toggle () button.
Run checks.	Click Run checks ().
View the report in a separate browser window.	Click Open Report .
View highlighted results.	Click the Enable highlighting toggle () button.

Run Model Checks Programmatically

If you have Simulink Check, you can create MATLAB scripts and functions so that you can run the Model Advisor programmatically. For example, you can create a `ModelAdvisor.run` function to check whether your model passes a specified set of the Model Advisor checks every time that you open the model and start a simulation. If you have Simulink Coder, the function can generate code from the model.

Access Other Advisors

You can use the Model Advisor window to access other Advisors.

Action	Select
Configure your model to meet code generation objectives.	Code Generation Advisor. See “Application Objectives Using Code Generation Advisor” (Simulink Coder).
Upgrade and improve models with the current release.	Upgrade Advisor. See “Consult the Upgrade Advisor” on page 6-2.
Improve the simulation performance of your model.	Performance Advisor. See “Improve Simulation Performance Using Performance Advisor” on page 32-2.

More About

- “Model Advisor Limitations” on page 5-8
- “Optimization Tools and Techniques” (Simulink Coder)
- “Create Model Advisor Checks” (Simulink Check)

Model Advisor Limitations

When you use the Model Advisor to check systems, these limitations apply:

- If you rename a system, you must restart the Model Advisor to check that system.
- In systems that contain a variant subsystem, the Model Advisor checks only the active subsystem.
- Model Advisor does not analyze commented blocks.
- Checks do not search in Model blocks or Subsystem blocks with the block parameter **Read/Write** set to **NoReadorWrite**. However, on a check-by-check basis, Model Advisor checks do search in library blocks and masked subsystems.
- Unless specified in the documentation for a check, the Model Advisor, by default, does not analyze the contents of a Model Reference block.

For limitations that apply to specific checks, see the “Capabilities and Limitations” section in the check documentation. For example, for capabilities that apply to the **Identify unconnected lines, input ports, and output ports** check, see “Capabilities and Limitations”.

More About

- “Model Advisor Overview” on page 5-2

Save Model Analysis Time

You can save analysis time by consistently running the same set of checks on your model by using the Model Advisor dashboard. When you use the dashboard, the Model Advisor does not reload the checks before executing them, saving analysis time.

- 1 Open your model. For example, open the Model Advisor model, `sldemo_mdadv`.
- 2 Open the Model Advisor dashboard.
 - a From the Simulink Editor, select **Analysis > Model Advisor > Model Advisor Dashboard**.

Alternatively, from the Simulink Editor toolbar  drop-down list, select **Model Advisor Dashboard**.

- b In the System Selector window, select the model or system that you want to review. For example, `sldemo_mdadv`. Click **OK**.
- 3 Optionally, to select or view checks to run on your model, click the **Switch to standard view** toggle () button.

- a In the Model Advisor window, open the **By Product** folder and select checks:
 - Identify unconnected lines, input ports, and output ports**
 - Check root model Inport block specifications**

If the **By Product** folder is not displayed in the Model Advisor window, select **Show By Product Folder** in the **Settings > Preferences** dialog box.

- b Return to the Model Advisor dashboard by clicking the **Switch to Model Advisor Dashboard** toggle () button.
- 4 On the Model Advisor dashboard, click **Run checks** ().

- 5 To view highlighted results, click the **Enable Highlighting** toggle ().

- In the model window, the blocks causing the **Identify unconnected lines, input ports, and output ports** check warning are highlighted in yellow.

- The Model Advisor Highlighting information window opens with a link to the Model Advisor window. In the Model Advisor window, you can find more information about the check results and how to fix the warning condition.

- 6 After reviewing the check results, you can choose to fix warnings or failures. For example, to fix the **Identify unconnected lines, input ports, and output ports** check warning:
 - a Connect model blocks Gain2 and Out4.
 - b On the Model Advisor dashboard, click **Run checks** (▶) to rerun the checks.

The **Identify unconnected lines, input ports, and output ports** check passes.

Run Model Checks in Background

If you have Parallel Computing Toolbox, you can run the Model Advisor in the background, so that you can continue working on your model during analysis. When you start a Model Advisor analysis run in the background, Model Advisor takes a snapshot of your model. The analysis does not reflect changes that you make to your model while Model Advisor is running in the background.

- 1 Open your model.
- 2 Start the Model Advisor.
 - a From the Simulink Editor, select **Analysis > Model Advisor > Model Advisor**.
 - b In the System Selector window, select the model or system that you want to review.
- 3 In the Model Advisor window, click the **Run checks in background** toggle ().
- 4 In the left pane of the Model Advisor window, select the checks that you want to run.
- 5 In the Model Advisor window, select **Run selected checks** () button.

Alternatively, you can use the Model Advisor dashboard to run the checks. In the Model Advisor window, switch to the Model Advisor dashboard by clicking the

Switch to Model Advisor Dashboard toggle (). On the Model Advisor dashboard, click **Run selected checks** (.

The Model Advisor starts an analysis on a parallel processor.

- 6 To stop running checks in the background, in the Model Advisor window, click **Stop background run** (). In the lower-left pane, you see a status of the analysis.

The **Explore Result** option is not available for checks that are run in the background.

See Also

Related Examples

- “Select and Run Model Advisor Checks” on page 5-2

- “Address Model Check Results” on page 5-13

Address Model Check Results

To find warnings or failures in your model:

- Open the model `sldemo_md1adv`. From the toolbar, select **Analysis > Model Advisor > Model Advisor**. Select checks **By Product > Simulink**.
- On the toolbar of the Model Advisor window, click **Run selected checks** (). The Model Advisor finds warnings or failures in the model.

Address Model Check Results with Highlighting

To indicate the analysis results for individual Model Advisor checks, use color highlighting on the model diagram. Highlighting is available for Simulink blocks and Stateflow charts. Blocks that pass a check, fail a check, or cause a check warning are highlighted in color in the model window. On the toolbar of the Model Advisor window, click **Enable**

highlighting () , select **Highlighting > Enable Highlighting**.

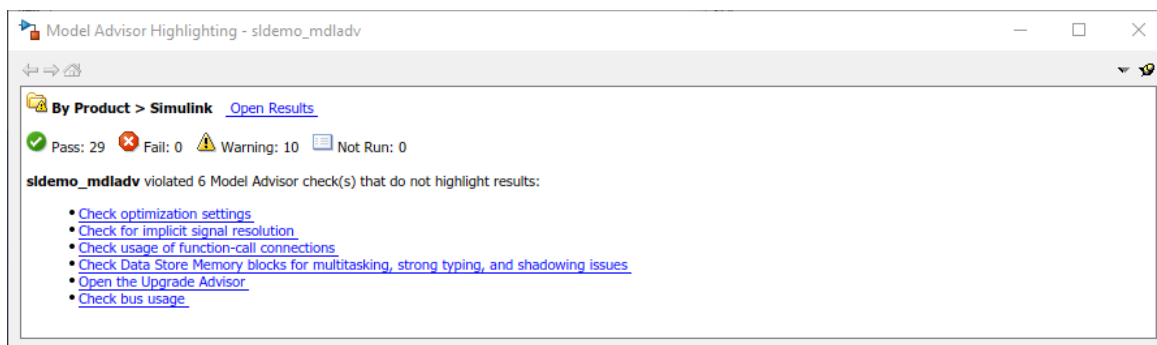

After selecting the highlighting feature, the model window and a Model Advisor Highlighting information window open. The Model Advisor Highlighting information window provides a link to the Model Advisor window where you can review the check results.

Yellow with orange border		Blocks that cause the check failure or warning.
White with orange border		Subsystem with blocks that cause the check warning or failure.
White with gray border		Blocks or subsystems without highlighting.
Gray with black border		Blocks that are excluded from the check.

White with black border		Subsystems that are excluded from the check.
-------------------------	---	--

If a check warns or fails, and the model window highlights blocks in gray, closely examine the results in the Model Advisor window. A Model Advisor check can fail or warn due to your parameter or diagnostic settings.

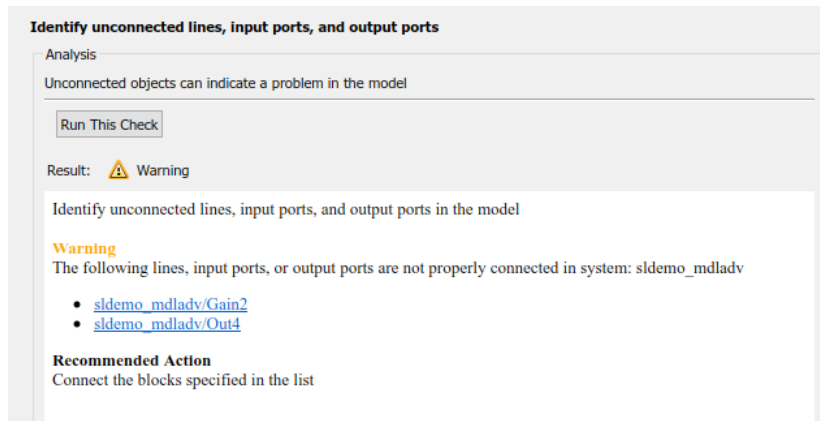

After you run a Model Advisor analysis and select the highlighting feature, checks with highlighted results are indicated with an  icon in the Model Advisor window. Highlighting is not available for some checks. Selecting **By Product > Simulink** displays Model Advisor checks in the Model Advisor Highlighting window that do not highlight results.

In the left pane of the Model Advisor window, select the highlighted check **Identify unconnected lines, input ports, and output ports**. In the model editor window, the Model Advisor highlights the blocks or components related to the warning. In this case, the Model Advisor finds a Gain block and an Output block not properly connected to the model.

In the right pane of the Model Advisor window, there is further information about the warning.

The **Recommended Action** suggests how to fix the warning or error. In this case, connect the disconnected blocks.

In the left pane of the Model Advisor window, select the highlighted check **Identify questionable operations for strict single-precision design**. In the model editor window, the Model Advisor highlights the blocks or components related to the warning. In this case, the Model Advisor finds an **Output** block that uses double precision due to a setting of the **Configuration Parameter Default for underspecified data type**.

In the right pane of the Model Advisor window, you see further detail on the single-precision warning.

Identify questionable operations for strict single-precision design

Analysis (^Triggers Update Diagram)

This check helps enforce a strict single-precision design by identifying double-precision operations and non-optimal model settings.

Result: Warning

Check model settings related to single-precision design
 This check verifies the status of model settings that will help you achieve a strict single-precision design.

Warning
 The following model settings are non-optimal to a single-precision design:

Model Name	Configuration Parameter	Current Value	Recommended Value
sldemo_mdldv	Implement logical signals as Boolean data (vs. double)	off	on
	Default for underspecified data type	double	single
	Standard math library	C89/C90 (ANSI)	C99 (ISO)

Check for double precision operations
 This check identifies blocks that introduce double-precision operations. For each block that the check identifies, make sure that its port data types and intermediate settings are set correctly.

Warning
 The following blocks use double-precision floating-point operations:

- [sldemo_mdldv/Out4](#)

The default input of the **Output** block is set to **double**. Model Advisor generates a warning because the **Output** block is not connected to another block. After reviewing the check results in the model window and the Model Advisor window, you can choose to fix warnings or failures.

To view model blocks that are excluded from the Model Advisor checks, on the Model Advisor window toolbar, select **Highlighting > Highlight Exclusions**. If you have Simulink Check, you can create or modify exclusions to the Model Advisor checks.

Fix a Model Check Warning or Failure

When a model or referenced model has a suboptimal condition, checks can fail. A warning result is informational. You can fix the reported issue or move on to the next task. For more information on why a specific check does not pass, see the documentation for that check.

Manually Fix Warnings or Failures

To manually fix warnings or failures, checks have an Analysis Result box that describes the recommended actions.

- 1 Optionally, save a model and data restore point so that you can undo your changes.
- 2 In the Analysis Result box, review the recommended actions to make changes to your model.
- 3 To verify that the check passes, rerun the check.

When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Automatically Fix Warnings or Failures

Some checks have an Action box that you can use to automatically fix failures. The action box applies all of the recommended actions listed in the Analysis Result box.

- 1 Optionally, save a model and data restore point so that you can undo your changes.
- 2 In the Action box, click **Modify All** or **Modify**.

The Action Result box displays a table of changes.

- 3 To verify that the check passes, rerun the check.

When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Batch-Fix Warnings or Failures

Some checks have an **Explore Result** button that opens the Model Advisor Result Explorer. With the Model Advisor Result Explorer, you can quickly locate, view, and change elements of a model.

The Model Advisor Result Explorer helps you to modify only the items that the Model Advisor is checking.

If a check does not pass and you want to explore the results and make batch changes:

- 1 Optionally, save a model and data restore point so that you can undo your changes.
- 2 In the Analysis box, click **Explore Result**.
- 3 In the Model Advisor Result Explorer, you can modify block parameters.
- 4 In the Model Advisor window, rerun the check to verify that it passes.

When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Model Advisor can report an invalid check result.

Revert Changes

The Model Advisor provides a model and a data restore point capability for reverting changes that you made in response to recommendations from the Model Advisor. You can also restore the default configuration of the Model Advisor. A restore point is a snapshot in time of the model, base workspace, and Model Advisor. The Model Advisor maintains restore points for the model or subsystem through multiple sessions of MATLAB.

Note A restore point saves only the current working model, base workspace variables, and the Model Advisor tree. It does not save other items, such as libraries and referenced models.

Restore Default Configuration

In the Model Advisor window, select **Settings > Restore Default Configuration**.

Save a Restore Point

You can save a restore point and give it a name and description. Or, the Model Advisor can name the restore point.

- 1 In the Model Advisor window, select **File > Save Restore Point As**.
- 2 In the **Name** field, enter a name for the restore point.
- 3 In the **Description** field, you can optionally add a description to help identify the restore point.
- 4 Click **Save**.

The Model Advisor saves a restore point of the current model, base workspace, and Model Advisor status.

To quickly save a restore point, in the Model Advisor window, select **File > Save Restore Point**. The Model Advisor saves a restore point with the name `autosaven`. *n* is the sequential number of the restore point. If you use this method, you cannot change the name of, or add a description to, the restore point.

Load a Restore Point

- 1 Optionally, save a model and data restore point so that you can undo your changes.
- 2 Select **File > Load Restore Point**.
- 3 In the Load Model and Data Restore Point dialog box, select the restore point that you want.
- 4 Click **Load**.

The Model Advisor issues a warning that the restoration removes changes that you made after saving the restore point.

- 5 To load the restore point that you selected, click **Load**.

The Model Advisor reverts the model, base workspace, and Model Advisor status.

- “Save Model Advisor Reports” on page 5-20
- “Check Your Model Interactively by Using Model Advisor Checks” (Simulink Check)

Save and View Model Advisor Reports

When the Model Advisor runs checks, it generates an HTML report of check results. By default, the HTML report is in the `s\prj\modeladvisor\model_name` folder.

If you have Simulink Check, you can generate reports in Adobe® PDF and Microsoft Word .docx formats.

Save Model Advisor Reports

The Model Advisor uses the `s\prj` folder in the code generation folder to store reports and other information. If the `s\prj` folder does not exist in the code generation folder, the Model Advisor creates it.

You can save a Model Advisor report to a new location.

- 1 In the Model Advisor window, navigate to the folder with the checks that you ran.
- 2 Select the folder. The right pane of the Model Advisor window displays information about that folder. The pane includes a **Report** box.
- 3 In the Report box, click **Generate Report**.
- 4 In the Generate Model Advisor Report dialog box, enter the path to the folder where you want to generate the report. Provide a file name.
- 5 Click **OK**. The Model Advisor saves the report in HTML format to the location that you specified.

If you rerun the Model Advisor, the report is updated in the working folder, not in the location where you archived the original report.

The full path to the report is in the title bar of the report window.

View Model Advisor Reports

Access a report by selecting a folder and clicking the link in the **Report** box. Or, before a Model Advisor analysis, in the right pane of the Model Advisor window, select **Show report after run**.

Tip Use the options in the Model Advisor window to interactively fix warnings and failures. Model Advisor reports are best for viewing a summary of checks.

As you run checks, the Model Advisor updates the reports with the latest information for each check in the folder. When you run the checks at different times, an informational message appears in the report. Timestamps indicate when checks have been run. The time of the current run appears at the top right of the report. Checks that occurred during previous runs have a timestamp following the check name.

Goal	Action
Display results for checks that pass, warn, or fail.	Use the Filter checks check boxes. For example, to display results for only checks that warn, in the left pane of the report, select the Warning check box. Clear the Passed , Failed , and Not Run check boxes.
Display results for checks with keywords or phrases in the check title.	Use the Keywords field. Results for checks without the keyword in the check title are not displayed in the report. For example, to display results for checks with only “setting” in the check title, in the Keywords field, enter “setting”.
Quickly navigate to sections of the report.	Select the links in the table-of-contents navigation pane.
Expand and collapse content in the check results.	Click Show/Hide check details .
Scroll to the top of the report.	Click Scroll to top .
Minimize folder results in the report.	Click the minus sign next to the folder name.

Printed versions of the report do not contain:

- Filtering checks, Navigation, or View panes.
- Content hidden due to filtering or keyword searching.

Some checks have input parameters specified in the right pane of the Model Advisor. For example, **Check Merge block usage** has an input parameter for **Maximum analysis time (seconds)**. When you run checks with input parameters, the Model Advisor displays the values of the input parameters in the HTML report. For more information, see the `EmitInputParametersToReport` property of the `Simulink.ModelAdvisor` class.

Upgrade Advisor

Consult the Upgrade Advisor

Use the Upgrade Advisor to help you upgrade and improve models with the current release. The Upgrade Advisor can identify cases where you can benefit by changing your model to use new features and settings in Simulink. The Advisor provides advice for transitioning to new technologies, and upgrading a model hierarchy.

The Upgrade Advisor can also help identify cases when a model will not work because changes and improvements in Simulink require changes to a model.

The Upgrade Advisor offers options to perform recommended actions automatically or instructions for manual fixes.

You can open the Upgrade Advisor in the following ways:

- From the Model Editor, select **Analysis > Model Advisor > Upgrade Advisor**
- From the MATLAB command line, use the `upgradeadvisor` function:

```
upgradeadvisor modelname
```
- Alternatively, from the Model Advisor, click **Upgrade Advisor**. This action closes the Model Advisor and opens the Upgrade Advisor.

In the Upgrade Advisor, you create reports and run checks in the same way as when using the Model Advisor.

- Select the top Upgrade Advisor node in the left pane to run all selected checks and create a report.
- Select each individual check to open a detailed view of the results in the right pane. View the analysis results for recommended actions to manually fix warnings or failures. In some cases, the Upgrade Advisor provides mechanisms for automatically fixing warnings and failures.

Caution When you fix a warning or failure, rerun all checks to update the results of all checks. If you do not rerun all checks, the Upgrade Advisor might report an invalid check result.

You must run upgrade checks in this order: first the checks that do not require compile time information and do not trigger an Update Diagram, then the compile checks. To guide you through upgrade checks to run both non-compile and compile checks, run the

check **Analyze model hierarchy and continue upgrade sequence**. See “Analyze model hierarchy and continue upgrade sequence”.

For more information on individual checks, see

- “Model Upgrades” for upgrade checks only
- “Simulink Checks” for all upgrade and advisor checks

Upgrade Programmatically

To analyze and upgrade models programmatically, use the `upgradeadvisor` function.

Tip For an example showing how to upgrade a whole project programmatically, see “Upgrade Simulink Models Using a Project”.

Upgrade Advisor Checks

For advice on upgrading and improving models with the current release, use the following Model Advisor checks in the Upgrade Advisor.

- “Check model for block upgrade issues”
- “Check usage of function-call connections”
- “Identify Model Info blocks that can interact with external source control tools”
- “Check for calls to `slDataTypeAndScale`”
- “Identify masked blocks that specify tabs in mask dialog using `MaskTabNames` parameter”
- “Identify Variant blocks using Variant objects with empty conditions”
- “Check that the model is saved in SLX format”
- “Check model for SB2SL blocks”
- “Check Model History properties”
- “Identify Model Info blocks that use the Configuration Manager”
- “Identify configurable subsystem blocks for converting to variant subsystem blocks”
- “Check and update masked blocks in library to use promoted parameters”
- “Check and update mask image display commands with unnecessary `imread()` function calls”

- “Check Rapid accelerator signal logging” “Check get_param calls for block CompiledSampleTime”
- “Check model for parameter initialization and tuning issues”
- “Check model for block upgrade issues requiring compile time information”
- “Check usage of Merge blocks”

What Is Sample Time?

The sample time of a block is a parameter that indicates when, during simulation, the block produces outputs and if appropriate, updates its internal state. The internal state includes but is not limited to continuous and discrete states that are logged.

Note Do not confuse the Simulink usage of the term sample time with the engineering sense of the term. In engineering, sample time refers to the rate at which a discrete system samples its inputs. Simulink allows you to model single-rate and multirate discrete systems and hybrid continuous-discrete systems through the appropriate setting of block sample times that control the rate of block execution (calculations).

For many engineering applications, you need to control the rate of block execution. In general, Simulink provides this capability by allowing you to specify an explicit `SampleTime` parameter in the block dialog or at the command line. Blocks that do not have a `SampleTime` parameter have an implicit sample time. You cannot specify implicit sample times. Simulink determines them based upon the context of the block in the system. The Integrator block is an example of a block that has an implicit sample time. Simulink automatically sets its sample time to 0.

Sample times can be port based or block based. For block-based sample times, all of the inputs and outputs of the block run at the same rate. For port-based sample times, the input and output ports can run at different rates. To learn more about rates of execution, see “Types of Sample Time” on page 7-15.

“Specify Sample Times for a Custom Block” on page 7-8

“Determining Sample Time Units” on page 7-8

“Change the Sample Time After Simulation Start Time” on page 7-8

Designate Sample Times

Simulink allows you to specify a block sample time directly as a numerical value or symbolically by defining a sample time vector. In the case of a discrete sample time, the vector is $[T_s, T_o]$ where T_s is the sampling period and T_o is the initial time offset. For example, consider a discrete model that produces its outputs every two seconds. If your base time unit is seconds, you can directly set the discrete sample time by specifying the numerical value of 2 as the `SampleTime` parameter. Because the offset value is zero, you do not need to specify it; however, you can enter $[2, 0]$ in the **Sample time** field.

For nondiscrete blocks, the components of the vector are symbolic values that represent one of the types in “Types of Sample Time” on page 7-15. The following table summarizes these types and the corresponding sample time values. The table also defines the explicit nature of each sample time type and designates the associated color and annotation. Because an *inherited sample time* is explicit, you can specify it as $[-1, 0]$ or as -1 . Whereas, a triggered sample time is implicit; only Simulink can assign the sample time of $[-1, -1]$. (For more information about colors and annotations, see “View Sample Time Information” on page 7-9.)

Designations of Sample Time Information

Sample Time Type	Sample Time	Color	Annotation	Explicit
Discrete	$[T_s, T_0]$	In descending order of speed: red, green, blue, light blue, dark green, orange	D1, D2, D3, D4, D5, D6, D7,... Di	Yes
Continuous	$[0, 0]$	black	Cont	Yes
Fixed in minor step	$[0, 1]$	gray	FiM	Yes
Inherited	$[-1, 0]$	N/A	N/A	Yes
Constant	$[\text{Inf}, 0]$	magenta	Inf	Yes
Variable	$[-2, T_{v0}]$	brown	V1, V2,... Vi	No
Controllable	$[\text{base}, -2i], i = 0, 1, 2, \dots,$	brown	Ctrl1, Ctrl2, Ctrl3, Ctrli	Yes
Hybrid	N/A	yellow	N/A	No
Triggered	Source: D1, Source: D2, ...Source: Di	cyan	T1, T2,... Ti	No
Asynchronous	$[-1, -n]$	purple	A1, A2,... Ai	No
Dataflow	N/A	light purple	N/A	No

The color that is assigned to each block depends on its sample time relative to other sample times in the model. This means that the same sample time may be assigned different colors in a parent model and in models that it references. (See “Model References”.)

For example, suppose that a model defines three sample times: 1, 2, and 3. Further, suppose that it references a model that defines two sample times: 2 and 3. In this case, blocks operating at the 2 sample rate appear as green in the parent model and as red in the referenced model.

It is important to note that Mux and Demux blocks are simply grouping operators; signals passing through them retain their timing information. For this reason, the lines emanating from a Demux block can have different colors if they are driven by sources having different sample times. In this case, the Mux and Demux blocks are color coded as hybrids (yellow) to indicate that they handle signals with multiple rates.

Similarly, Subsystem blocks that contain blocks with differing sample times are also colored as hybrids, because there is no single rate associated with them. If all the blocks within a subsystem run at a single rate, the Subsystem block is colored according to that rate.

You can use the explicit sample time values in this table to specify sample times interactively or programmatically for either block-based or port-based sample times.

The following model, `ex_specify_sample_time`, serves as a reference for this section.

`ex_specify_sample_time`

In this example, set the sample time of the input sine wave signal to 0.1 . The goal is to achieve an output sample time of 0.2 . The Rate Transition block serves as a zero-order hold. The resulting block diagram after setting the sample times and simulating the model is shown in the following figure. (The colors and annotations indicate that this is a discrete model.)

`ex_specify_sample_time` after Setting Sample Times

Specify Block-Based Sample Times Interactively

To set the sample time of a block interactively:

- 1 In the Simulink model window, double-click the block. The block parameter dialog box opens.
- 2 Enter the sample time in the **Sample time** field.

- 3 Click **OK**.

Following is a figure of a parameters dialog box for the Sine Wave block after entering 0.1 in the **Sample time** field.

The image shows a 'Parameters' dialog box for a Sine Wave block. The dialog has several fields and a checkbox:

- Sine type:** Time based (dropdown)
- Time (t):** Use simulation time (dropdown)
- Amplitude:** 1 (text field)
- Bias:** 0 (text field)
- Frequency:** 1 (text field)
- Phase (rad):** 0 (text field)
- Sample time:** 0.1 (text field, highlighted with a callout arrow pointing to it from the text 'Enter the sample time value in this field')
- Interpret vector parameters as 1-D

At the bottom of the dialog are four buttons: **OK**, **Cancel**, **Help**, and **Apply**.

To specify and inspect block-based sample times throughout a model, consider using the Model Data Editor (**View > Model Data Editor**). On the **Imports/Outputs, Signals,** and **Data Stores** tabs, set the **Change view** drop-down list to **Design** and use the **Sample Time** column. For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 62-179.

Specify Port-Based Sample Times Interactively

The Rate Transition block has port-based sample times. You can set the output port sample time interactively by completing the following steps:

- 1 Double-click the Rate Transition block. The parameters dialog box opens.

- 2 Leave the drop-down menu choice of the **Output port sample time options** as **Specify**.
- 3 Replace the **-1** in the **Output port sample time** field with **0.2**.

Enter sample time
in Output port
sample time field

- 4 Click **OK**.

For more information about the sample time options in the Rate Transition parameters dialog box, see the Rate Transition reference page.

Specify Block-Based Sample Times Programmatically

To set a block sample time programmatically, set its `SampleTime` parameter to the desired sample time using the `set_param` command. For example, to set the sample time of the Gain block in the “Specify_Sample_Time” model to inherited (-1), enter the following command:

```
set_param('Specify_Sample_Time/Gain','SampleTime','[-1, 0]')
```

As with interactive specification, you can enter just the first vector component if the second component is zero.

```
set_param('Specify_Sample_Time/Gain','SampleTime','-1')
```

Specify Port-Based Sample Times Programmatically

To set the output port sample time of the Rate Transition block to 0.2, use the `set_param` command with the parameter `OutPortSampleTime`:

```
set_param('Specify_Sample_Time/Rate Transition',...  
'OutPortSampleTime', '0.2')
```

Access Sample Time Information Programmatically

To access all sample times associated with a model, use the API `Simulink.BlockDiagram.getSampleTimes`.

To access the sample time of a single block, use the API `Simulink.Block.getSampleTimes`.

Specify Sample Times for a Custom Block

You can design custom blocks so that the input and output ports operate at different sample time rates. For information on specifying block-based and port-based sample times for S-functions, see “Specify S-Function Sample Times” in *Writing S-Functions* of the Simulink documentation.

Determining Sample Time Units

Since the execution of a Simulink model is not dependent on a specific set of units, you must determine the appropriate base time unit for your application and set the sample time values accordingly. For example, if your base time unit is second, then you would represent a sample time of 0.5 second by setting the sample time to 0.5.

Change the Sample Time After Simulation Start Time

To change a sample time after simulation begins, you must stop the simulation, reset the `SampleTime` parameter, and then restart execution.

View Sample Time Information

In this section...
“Inspect Sample Time Using Timing Legend” on page 7-10
“Inspect Sample Times Throughout a Model” on page 7-14

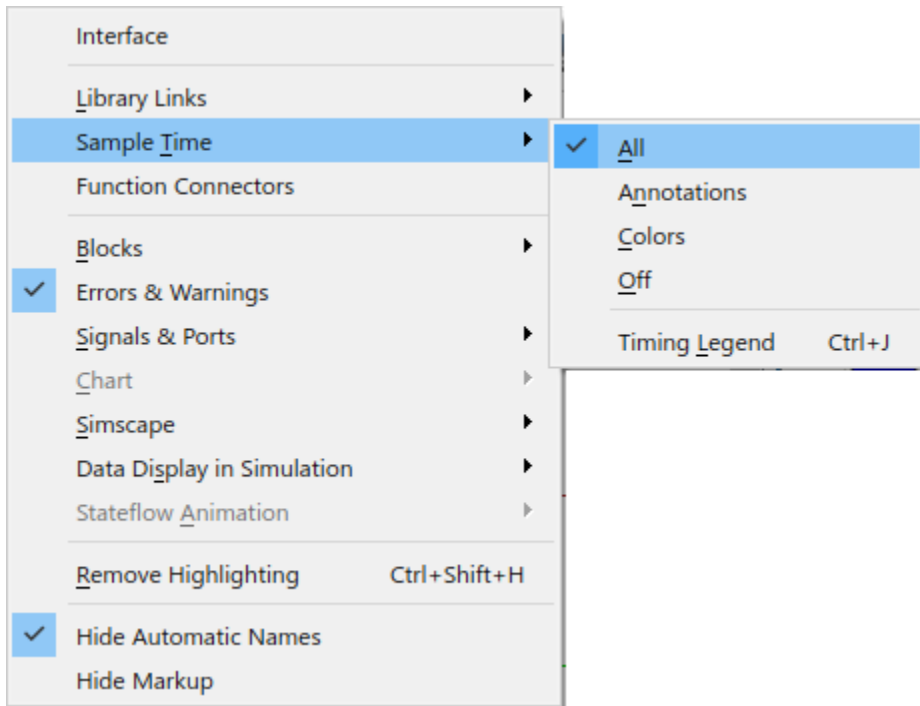

Simulink models can display color coding and annotations that represent specific sample times. Each sample time type has one or more colors associated with it. You can display the blocks and signal lines in color, the annotations in black, or both. To select one of these options:

- 1 In the Simulink model window, select **Display > Sample Time**.
- 2 Select **Colors, Annotations, or All**.

Selecting **All** results in the display of both the colors and the annotations. Regardless of your choice, Simulink performs an **Update Diagram** automatically. To turn off the colors and annotations:

- 1 Select **Display > Sample Time**.
- 2 Select **Off**.

Simulink performs another **Update Diagram** automatically.

Your Sample Time Display choices directly control the information that the Timing Legend displays.

Note The discrete sample times in the table Designations of Sample Time Information represent a special case. Five colors indicate the speed through the fifth fastest discrete rate. A sixth color, orange, represents all rates that are slower than the fifth discrete rate. You can distinguish between these slower rates by looking at the annotations on their respective signal lines.

Inspect Sample Time Using Timing Legend

You can view the Timing Legend for an individual model or for multiple models. Additionally, you can prevent the legend from automatically opening when you select options on the **Sample Time** menu.

To assist you with interpreting a block diagram, the Timing Legend contains the sample time color, annotation, and value for each sample time in the model. To view the legend:

- 1 In the Simulink model window, select **Simulation > Update Diagram**.
- 2 Select **Display > Sample Time > Timing Legend** or press **Ctrl + J** OR Select **All** from the **Sample Time** menu

In addition, when you select **Colors** or **Annotations**, Simulink updates the model diagram and opens the legend by default. The legend contents reflect your **Sample Time Display** choices. If you turn colors on, the legend displays the color and the value of the sample time. Similarly, if you turn annotations on, the annotations appear in the legend.

The legend displays sample times present in the model, classified by the type of the sample time.

The screenshot shows a Simulink model window titled "Sine_sampletimes". The model contains two discrete-time paths. The top path is red and consists of a block labeled "D1", a gain block labeled "2", and a scope block labeled "1". The bottom path is green and consists of a block labeled "D2", a gain block labeled "2", and a scope block labeled "2". To the right of the model is the "Timing Legend" panel. The legend has a "Highlight" dropdown set to "All" and a "1/p" button. Below the legend title is the text: "This rate is introduced by Simulink and not visible on any blocks." The legend contains a table with two columns: "Discrete" and "Period".

Discrete	Period
■ D1	1
■ D2	3

The legend provides two types of highlighting options:

- Highlighting the blocks and signals that the sample time originates from.
- Highlighting all the blocks and signals that contain the selected sample time.

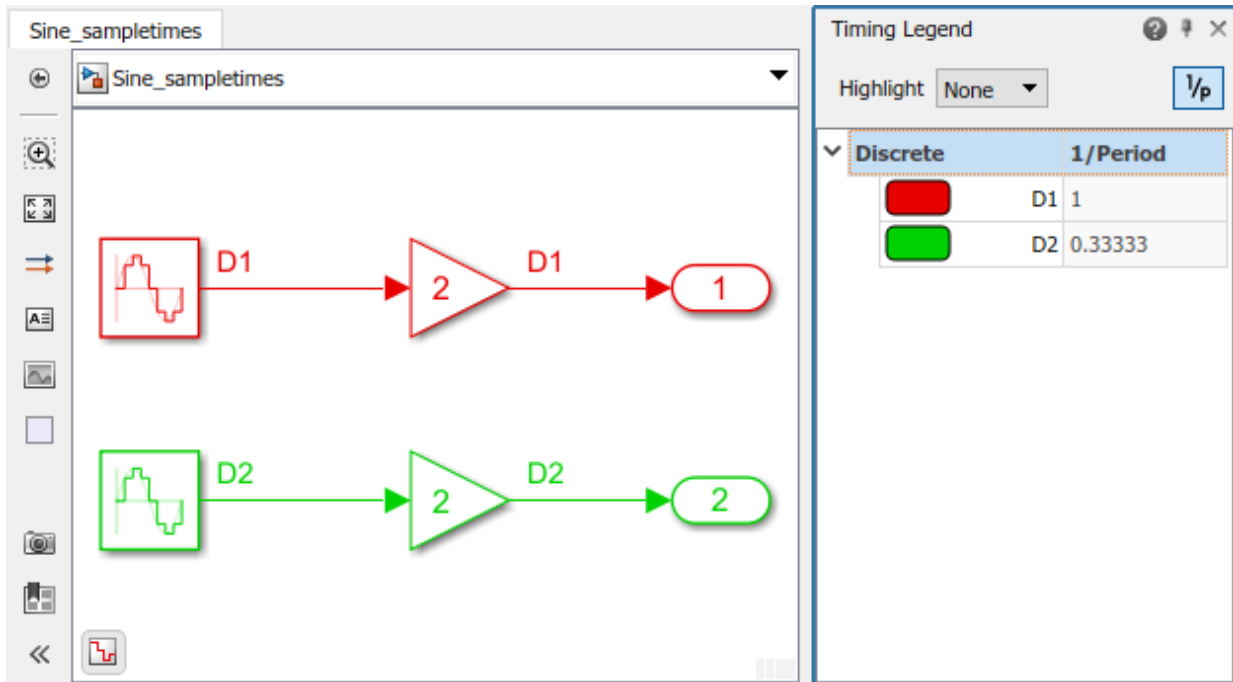

To enable highlighting of the origin of the sample times, click the **Origin** option from the **Highlight** menu. You can also click the type of the sample time to highlight all sources of a particular type of sample time.

To enable highlighting of all the blocks that contain a selected sample time, click the **All** option from the **Highlight** menu. You can also click the type of the sample time to highlight all the blocks and signals that contain the select type of sample time.

The **None** option from the **Highlight** menu clears current highlighting.

The button  shows discrete value as 1/period when the discrete sample time is present. When clicked, the discrete period is displayed as 1/period; for a nonzero offset, it displays as offset/period. The image shows 1/period values and the corresponding highlighted block in the model.

Note The Timing Legend displays all of the sample times in the model, including those that are not associated with any block. For example, if the fixed step size is 0.1 and all of the blocks have a sample time of 0.2, then both rates (0.1 and 0.2) appear in the legend.

For subsequent viewings of the legend, update the diagram to access the latest known information.

If you do not want to view the legend upon selecting **Sample Time Display**:

- 1 In the Simulink Editor, select **File > Simulink Preferences**
- 2 In the **General** pane, clear **Open the timing legend when the sample time display is changed** and click **Apply**.

Inspect Sample Times Throughout a Model

The Model Data Editor (**View > Model Data Editor**) shows information about model data (signals, parameters, and states) in a sortable, searchable table. The **Sample Time** column shows the sample time specified for each signal in a model. After you update the block diagram, the column also shows the specific sample that each signal uses (for example, for signals for which you specify inherited sample time, -1). You can also use this column to specify sample times.

For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 62-179.

“What Is Sample Time?” on page 7-2 | “Specify the Sample Time” on page 4-77 | “Types of Sample Time” on page 7-15

Types of Sample Time

In this section...

“Discrete Sample Time” on page 7-15
 “Continuous Sample Time” on page 7-16
 “Fixed-in-Minor-Step” on page 7-16
 “Inherited Sample Time” on page 7-16
 “Constant Sample Time” on page 7-17
 “Variable Sample Time” on page 7-17
 “Controllable Sample Time” on page 7-18
 “Triggered Sample Time” on page 7-18
 “Asynchronous Sample Time” on page 7-18

Discrete Sample Time

Given a block with a discrete sample time, Simulink executes the block output or update method at times

$$t_n = nT_s + |T_o|$$

where the sample time period T_s is always greater than zero and less than the simulation time, T_{sim} . The number of periods (n) is an integer that must satisfy:

$$0 \leq n \leq \frac{T_{sim}}{T_s}$$

As simulation progresses, Simulink computes block outputs only once at each of these fixed time intervals of t_n . These simulation times, at which Simulink executes the output method of a block for a given sample time, are referred to as *sample time hits*. Discrete sample times are the only type for which sample time hits are known *a priori*.

If you need to delay the initial sample hit time, you can define an offset, T_o .

The Unit Delay block is an example of a block with a discrete sample time.

Continuous Sample Time

Unlike the discrete sample time, continuous sample hit times are divided into major time steps and minor time steps, where the minor steps represent subdivisions of the major steps (see “Minor Time Steps” on page 3-22). The ODE solver you choose integrates all continuous states from the simulation start time to a given major or minor time step. The solver determines the times of the minor steps and uses the results at the minor time steps to improve the accuracy of the results at the major time steps. However, you see the block output only at the major time steps.

To specify that a block, such as the Derivative block, is continuous, enter $[0, 0]$ or 0 in the **Sample time** field of the block dialog.

Fixed-in-Minor-Step

If the sample time of a block is set to $[0, 1]$, the block becomes *fixed-in-minor-step*. For this setting, Simulink does not execute the block at the minor time steps; updates occur only at the major time steps. This process eliminates unnecessary computations of blocks whose output cannot change between major steps.

While you can explicitly set a block to be fixed-in-minor-step, more typically Simulink sets this condition as either an inherited sample time or as an alteration to a user specification of 0 (continuous). This setting is equivalent to, and therefore converted to, the fastest discrete rate when you use a fixed-step solver.

Inherited Sample Time

If a block sample time is set to $[-1, 0]$ or -1 , the sample time is *inherited* and Simulink determines the best sample time for the block based on the block context within the model. Simulink performs this task during the compilation stage; the original inherited setting never appears in a compiled model. Therefore, you never see inherited ($[-1, 0]$) in the Sample Time Legend. (See “View Sample Time Information” on page 7-9.)

There are some blocks in which the sample time is inherited (-1) by default. For these blocks, the parameter is not visible on the block dialog box unless it is set to a noninherited value. Examples of these blocks include the Gain and Rounding Function blocks. As a good modeling practice, do not change the **Sample time** parameter for these blocks. For more information, see “Blocks for Which Sample Time Is Not Recommended” on page 7-20.

All inherited blocks are subject to the process of sample time propagation, as discussed in “How Propagation Affects Inherited Sample Times” on page 7-38

Constant Sample Time

In Simulink, a constant is a symbolic name or expression whose value you can change only outside the algorithm or through supervisory control. Blocks, like the constant block, whose outputs do not change during normal execution of the model, are always considered to be constant.

Simulink assigns constant sample time to these blocks. They run their block output method:

- At the start of a simulation.
- In response to runtime changes in the environment, such as tuning a parameter.

For constant sample time, the block sample time assignment is $[\text{inf}, 0]$ or $[\text{inf}]$.

For a block to allow constant sample time, these conditions hold:

- The block has no continuous or discrete states.
- The block does not drive an output port of a conditionally executed subsystem (see “Using Enabled Subsystems” on page 10-11).

S-Function Blocks

The Simulink block library includes several blocks, such as the MATLAB S-Function block, the Level-2 MATLAB S-Function block, and the C S-Function block, whose ports can produce outputs at different sample rates. It is possible for some of the ports of these blocks to have a constant sample time.

Variable Sample Time

Blocks that use a variable sample time have an implicit `SampleTime` parameter that the block specifies; the block tells Simulink when to run it. The compiled sample time is $[-2, T_{vo}]$ where T_{vo} is a unique variable offset.

The Pulse Generator block is an example of a block that has a variable sample time. Since Simulink supports variable sample times for variable-step solvers only, the Pulse Generator block specifies a discrete sample time if you use a fixed-step solver.

To learn how to write your own block that uses a variable sample time, see “C MEX S-Function Examples”.

Controllable Sample Time

A block can be configured to use a controllable sample time with a resolution T_{base} . T_{base} is the smallest allowable time interval between block executions. To set T_{base} in your own C S-Function block, use `ssSetControllableSampleTime`.

A block using controllable sample time can be dynamically set to execute at n multiples of T_{base} . The time of the block's next execution is

$$T_{next} = n T_{base} + T$$

You can set n in your C S-Function block using `ssSetNumTicksToNextHitForControllableSampleTime`.

Triggered Sample Time

If a block is inside of a triggered-type (e.g., function-call, enabled and triggered, or iterator) subsystem, the block may be constant or have a triggered sample time. You cannot specify the triggered sample time type explicitly. However, to achieve a triggered type during compilation, you must set the block sample time to inherited (-1). Simulink then determines the specific times at which the block computes its output during simulation. One exception is if the subsystem is an asynchronous function call, as discussed in the following section.

Asynchronous Sample Time

An asynchronous sample time is similar to a triggered sample time. In both cases, it is necessary to specify an inherited sample time because the Simulink engine does not regularly execute the block. Instead, a run-time condition determines when the block executes. For the case of an asynchronous sample time, an S-function makes an asynchronous function call.

The differences between these sample time types are:

- Only a function-call subsystem can have an asynchronous sample time. (See “Using Function-Call Subsystems” on page 10-44.)

- The source of the function-call signal is an S-function having the option `SS_OPTION_ASYNCHRONOUS`.
- The asynchronous sample time can also occur when a virtual block is connected to an asynchronous S-function or an asynchronous function-call subsystem.
- The asynchronous sample time is important to certain code-generation applications. (See “Asynchronous Events” (Simulink Coder) in the *Simulink Coder User's Guide*.)
- The sample time is $[-1, -n]$.

For an explanation of how to use blocks to model and generate code for asynchronous event handling, see “Rate Transitions and Asynchronous Blocks” (Simulink Coder) in the *Simulink Coder User's Guide*.

Blocks for Which Sample Time Is Not Recommended

In this section...

“Best Practice to Model Sample Times” on page 7-20

“Appropriate Blocks for the Sample Time Parameter” on page 7-21

“Specify Sample Time in Blocks Where Hidden” on page 7-21

Some blocks do not enable you to set the **Sample Time** parameter by default. However, you can see and set the **Sample Time** parameter for these blocks in an existing model if the sample time is set to a value other than the default of -1 (inherited sample time). The **Sample Time** parameter is not available on certain blocks because specifying a sample time that is not -1 on blocks such as the Gain, Sum, and n-D Lookup Table causes sample rate transition to be implicitly mixed with block algorithms. This mixing can often lead to ambiguity and confusion in Simulink models.

In most modeling applications, you specify rates for a model on the boundary of your system instead of on a block within the subsystem. You specify the system rate from incoming signals or the rate of sampling the output. You can also decide rates for events you are modeling that enter the subsystem as trigger, function-call, or enable/disable signals. Some global variables (such as Data Store Memory blocks) might need additional sample time specification. If you want to change rate within a system, use a Rate Transition block, which is designed specifically to model rate transitions.

In a future release, you might not be able see or set this parameter on blocks where it is not appropriate.

Best Practice to Model Sample Times

Use these approaches instead of setting the **Sample Time** parameter in the blocks where it is not appropriate:

- Adjust your model by specifying **Sample Time** only in the blocks listed in “Appropriate Blocks for the Sample Time Parameter” on page 7-21, and set **Sample Time** to -1 for all other blocks. To change the sample time for multiple blocks simultaneously, use Model Explorer. For more information, see “Editing Object Properties” on page 12-20.
- Use the Rate Transition block to model rate transitions in your model.
- Use the Signal Specification block to specify sample time in models that don’t have source blocks, such as algebraic loops.

- Specify the simulation rate independently from the block sample times, using the Model Parameter dialog box.

Once you have completed these changes, verify whether your model gives the same outputs as before.

Appropriate Blocks for the Sample Time Parameter

Specify sample time on the boundary of a model or subsystem, or in blocks designed to model rate transitions. Examples include:

- Blocks in the Sources library
- Blocks in the Sinks library
- Trigger ports (if **Trigger type** is set to **function-call**) and Enable ports
- Data Store Read and Data Store Write blocks, as the Data Store Memory block they link to might be outside the boundary of the subsystem
- Rate Transition block
- Signal Specification block
- Blocks in the Discrete library
- Message Receive block
- Function Caller block

Specify Sample Time in Blocks Where Hidden

You can specify sample time in the blocks that do not display the parameter on the block dialog box. If you specify value other than -1 in these blocks, no error occurs when you simulate the model. However, a message appears on the block dialog box advising to set this parameter to -1 (inherited sample time). If you promote the sample time block parameter to a mask, this parameter is always visible on the mask dialog box.

To change the sample time in this case, use the `set_param` command. For example, select a block in the Simulink Editor and, at the command prompt, enter:

```
set_param(gcb, 'SampleTime', '2');
```

“Sample Times in Subsystems” on page 7-26 | “Sample Times in Systems” on page 7-28

Block Compiled Sample Time

During the compilation phase of a simulation, Simulink determines the sample time of a block from the `SampleTime` parameter (if the block has an explicit sample time), the block type (if it has an implicit sample time), or by the model content. This compiled sample time determines the sample rate of a block during simulation. You can determine the compiled sample time of any block in a model by first updating the model and then getting the block `CompiledSampleTime` parameter, using the `get_param` command.

For example, consider the model `ex_compiled_sample_new`.

Use `get_param` to obtain the block `CompiledSampleTime` parameter for each of the blocks in this example.

```
get_param('model_name/block_name','CompiledSampleTime');
```

For the Sine Wave3 block,

```
get_param('ex_compiled_sample_new/Sine Wave3','CompiledSampleTime');
```

displays

```
0.5000  0
```

The atomic subsystem contains sine wave blocks with sample times of 3 and 4.

When calculating the block `CompiledSampleTime` for this subsystem, Simulink returns a cell array of the sample times present in the subsystem.

```
3    0
4    0
```

The greatest common divisor (GCD) of the two rates is 1. However, this is not necessarily one of the rates in the model.

The Rate Transition block in this model serves as a Zero-Order Hold. Since the `Sample Time Multiple` parameter is set to 3, the input to the rate transition block has a sample rate of 0.5 while the output has a rate of 1.5.

```
rt=get_param('ex_compiled_sample_new/Rate Transition',...
'CompiledSampleTime');
rt{:}
```

```
0.5000    0
1.5000    0
```

The Sample Time Legend shows all of the sample rates present in the model.

To inspect compiled sample times throughout a model, you can use the Model Data Editor (**View > Model Data Editor**). After you update the block diagram, the right side of the **Sample Time** column shows compiled sample times for signals and data stores. For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 62-179.

Sample Times in Subsystems

Subsystems fall into two categories: triggered and non-triggered. For triggered subsystems, in general, the subsystem gets its sample time from the triggering signal. One exception occurs when you use a Trigger block to create a triggered subsystem. If you set the block **Trigger type** to **function-call** and the **Sample time type** to **periodic**, the `SampleTime` parameter becomes active. In this case, *you* specify the sample time of the Trigger block, which in turn, establishes the sample time of the subsystem.

There are four non-triggered subsystems:

- Virtual
- Enabled
- Atomic
- Action

Simulink calculates the sample times of virtual and enabled subsystems based on the respective sample times of their contents.

The atomic subsystem is a special case in that the subsystem block has a `SystemSampleTime` parameter. Moreover, for a sample time other than the default value of `-1`, the blocks inside the atomic subsystem can have only a value of `Inf`, `-1`, or the identical (discrete) value of the subsystem `SampleTime` parameter. If the atomic subsystem is left as inherited, Simulink calculates the block sample time in the same manner as the virtual and enabled subsystems. However, the main purpose of the subsystem `SampleTime` parameter is to allow for the simultaneous specification of a large number of blocks, within an atomic subsystem, that are all set to inherited. To obtain the sample time set on an atomic subsystem, use this command at the command prompt:

```
get_param(AtomicSubsystemBlock, 'SystemSampleTime');
```

Finally, the sample time of the action subsystem is set by the If block or the Switch Case block.

For non-triggered subsystems where blocks have different sample rates, Simulink returns the Compiled Sample Time for the subsystem as a cell array of all the sample rates present in the subsystem. To see this, use the `get_param` command at MATLAB prompt.

```
get_param(subsystemBlock, 'CompiledSampleTime')
```

Sample Times in Systems

In this section...
“Purely Discrete Systems” on page 7-28
“Hybrid Systems” on page 7-31

Purely Discrete Systems

A purely discrete system is composed solely of discrete blocks and can be modeled using either a fixed-step or a variable-step solver. Simulating a discrete system requires that the simulator take a simulation step at every sample time hit. For a *multirate discrete system*—a system whose blocks Simulink samples at different rates—the steps must occur at integer multiples of each of the system sample times. Otherwise, the simulator might miss key transitions in the states of the system. The step size that the Simulink software chooses depends on the type of solver you use to simulate the multirate system and on the fundamental sample time.

The *fundamental sample time* of a multirate discrete system is the largest double that is an integer divisor of the actual sample times of the system. For example, suppose that a system has sample times of 0.25 and 0.50 seconds. The fundamental sample time in this case is 0.25 seconds. Suppose, instead, the sample times are 0.50 and 0.75 seconds. The fundamental sample time is again 0.25 seconds.

The importance of the fundamental sample time directly relates to whether you direct the Simulink software to use a fixed-step or a variable-step discrete solver to solve your multirate discrete system. A fixed-step solver sets the simulation step size equal to the fundamental sample time of the discrete system. In contrast, a variable-step solver varies the step size to equal the distance between actual sample time hits.

The following diagram illustrates the difference between a fixed-step and a variable-step solver.

Fixed-Step Solver

Variable-Step Solver

In the diagram, the arrows indicate simulation steps and circles represent sample time hits. As the diagram illustrates, a variable-step solver requires fewer simulation steps to simulate a system, if the fundamental sample time is less than any of the actual sample times of the system being simulated. On the other hand, a fixed-step solver requires less memory to implement and is faster if one of the system sample times is fundamental. This can be an advantage in applications that entail generating code from a Simulink model (using Simulink Coder). In either case, the discrete solver provided by Simulink is optimized for discrete systems; however, you can simulate a purely discrete system with any one of the solvers and obtain equivalent results.

Consider the following example of a simple multirate system. For this example, the DTF1 Discrete Transfer Fcn block's **Sample time** is set to $[1 \ 0.1] []$, which gives it an offset of 0.1 . The **Sample time** of the DTF2 Discrete Transfer Fcn block is set to 0.7 , with no offset. The solver is set to a variable-step discrete solver.

Running the simulation and plotting the outputs using the `stairs` function

```

set_param(bdroot,'SolverType','Variable-Step','SolverName','VariableStepDiscrete','Save
simOut = sim(bdroot,'Stoptime','3');
stairs(simOut.tout,simOut.yout,'-*','LineWidth',1.2);
xlabel('Time (t)');
ylabel('Outputs (out1,out2)');
legend('t_s = [1, 0.1]','t_s = 0.7','location','best')

```

produces the following plot.

(For information on the `sim` command, see “Run Simulations Programmatically” on page 26-2.)

As the figure demonstrates, because the DTF1 block has a 0.1 offset, the DTF1 block has no output until $t = 0.1$. Similarly, the initial conditions of the transfer functions are zero; therefore, the output of DTF1, $y(1)$, is zero before this time.

Hybrid Systems

Hybrid systems contain both discrete and continuous blocks and thus have both discrete and continuous states. However, Simulink solvers treat any system that has both continuous and discrete sample times as a hybrid system. For information on modeling hybrid systems, see “Modeling Hybrid Systems” on page 3-7.

In block diagrams, the term hybrid applies to both hybrid systems (mixed continuous-discrete systems) and systems with multiple sample times (multirate systems). Such systems turn yellow in color when you perform an **Update Diagram** with Sample Time Display **Colors** turned 'on'. As an example, consider the following model that contains an atomic subsystem, “Discrete Cruise Controller”, and a virtual subsystem, “Car Dynamics”. (See `ex_execution_order`.)

Car Model

With the **Sample Time** option set to **All**, an **Update Diagram** turns the virtual subsystem yellow, indicating that it is a hybrid subsystem. In this case, the subsystem is a true hybrid system since it has both continuous and discrete sample times. As shown below, the discrete input signal, D1, combines with the continuous velocity signal, v , to produce a continuous input to the integrator.

Car Model after an Update Diagram

Car Dynamics Subsystem after an Update Diagram

Now consider a multirate subsystem that contains three Sine Wave source blocks, each of which has a unique sample time — 0.2, 0.3, and 0.4, respectively.

Multirate Subsystem after an Update Diagram

An **Update Diagram** turns the subsystem yellow because the subsystem contains more than one sample time. As shown in the block diagram, the Sine Wave blocks have discrete sample times D1, D2, and D3 and the output signal is fixed in minor step.

In assessing a system for multiple sample times, Simulink does not consider either constant $[\text{inf}, 0]$ or asynchronous $[-1, -n]$ sample times. Thus a subsystem consisting of one block that outputs constant value and one block with a discrete sample time will not be designated as hybrid.

The hybrid annotation and coloring are very useful for evaluating whether or not the subsystems in your model have inherited the correct or expected sample times.

“Blocks for Which Sample Time Is Not Recommended” on page 7-20 | “View Sample Time Information” on page 7-9

Resolve Rate Transitions

In general, a rate transition exists between two blocks if their sample times differ, that is, if either of their sample-time vector components are different. The exceptions are:

- Blocks that output constant value never have a rate transition with any other rate.
- A continuous sample time (black) and the fastest discrete rate (red) never has a rate transition if you use a fixed-step solver.
- A variable sample time and fixed in minor step do not have a rate transition.

You can resolve rate transitions manually by inserting rate transition blocks and by using two diagnostic tools. For the single-tasking execution mode, the **Single task rate transition** diagnostic allows you to set the level of Simulink rate transition messages. The **Multitask rate transition** diagnostic serves the same function for multitasking execution mode. These execution modes directly relate to the type of solver in use: Variable-step solvers are always single-tasking; fixed-step solvers may be explicitly set as single-tasking or multitasking.

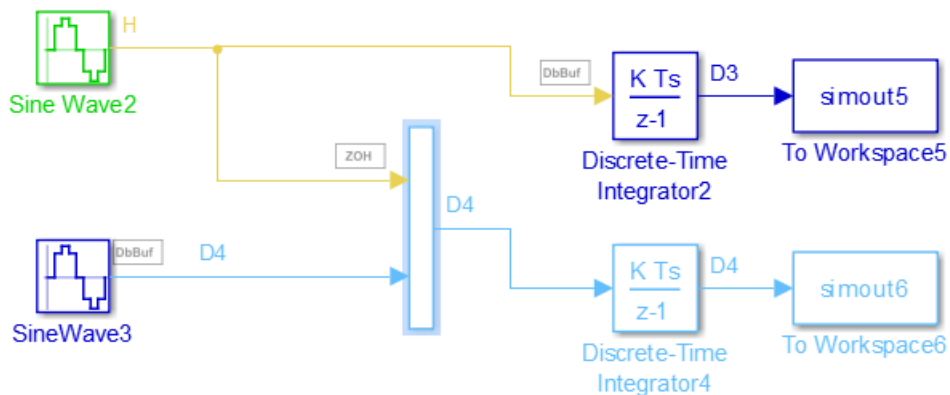

Automatic Rate Transition

Simulink can detect mismatched rate transitions in a multitasking model during an update diagram and automatically insert Rate Transition blocks to handle them. To enable this, in the **Solver** pane of model configuration parameters, select **Automatically handle rate transition for data transfer**. The default setting for this option is off. When you select this option:

- Simulink handles transitions between periodic sample times and asynchronous tasks.
- Simulink inserts hidden Rate Transition blocks in the block diagram.
- Automatically inserted Rate Transition blocks operate in protected mode for periodic tasks and asynchronous tasks. You cannot alter this behavior. For periodic tasks, automatically inserted Rate Transition blocks operate with the level of determinism specified by the **Deterministic data transfer** parameter in the **Solver** pane. The default setting is **Whenever possible**, which enables determinism for data transfers between periodic sample-times that are related by an integer multiple. For more information, see “Deterministic data transfer”. To use other modes, you must insert Rate Transition blocks and set their modes manually.

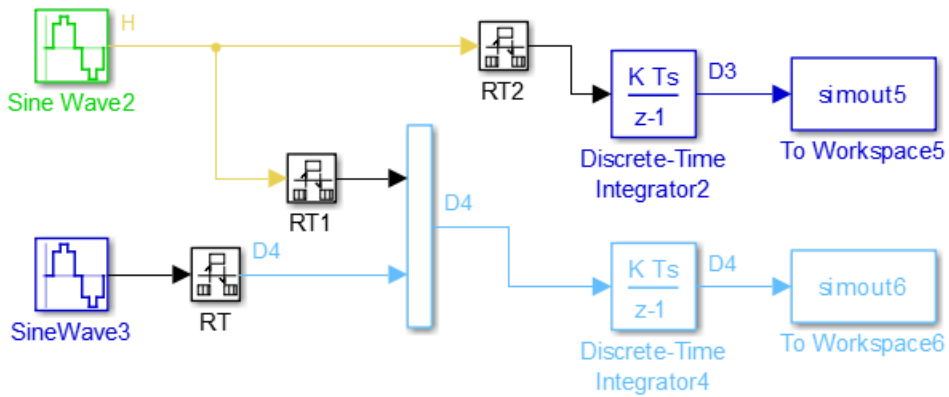

Visualize Inserted Rate Transition Blocks

When you select the **Automatically handle rate transition for data transfer** option, Simulink inserts Rate Transition blocks in the paths that have mismatched transition rates. These blocks are hidden by default. To visualize the inserted blocks, update the diagram. Badge labels appear in the model and indicate where Simulink inserted Rate Transition blocks during the compilation phase. For example, in this model, three Rate Transition blocks were inserted between the two Sine Wave blocks and the Multiplexer and Integrator when the model compiled. The ZOH and DbBuf badge labels indicate these blocks.

You can show or hide badge labels using the **Display > Signals and Ports > Hidden Rate Transition Block Indicators** setting.

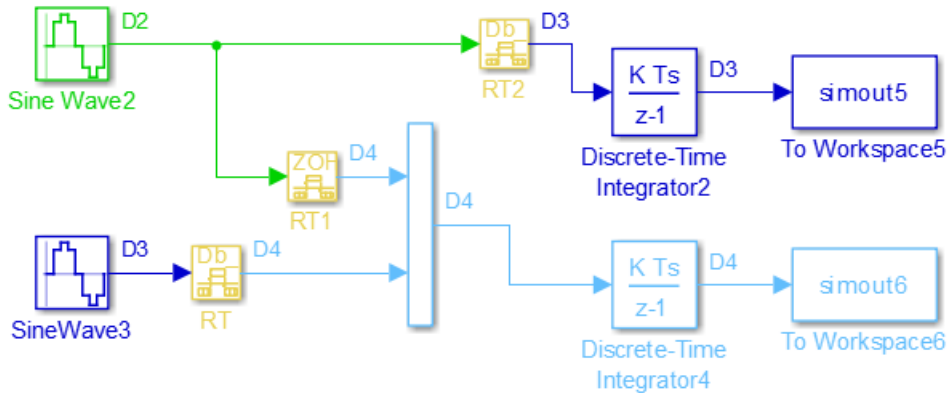

To configure the hidden Rate Transition blocks, right click on a badge label and click on **Insert rate transition block** to make the block visible.

When you make hidden Rate Transition blocks visible:

- You can see the type of Rate Transition block inserted as well as the location in the model.
- You can set the **Initial Conditions** of these blocks.
- You can change data transfer and sample time block parameters.

Validate the changes to your model by updating your diagram.

Displaying inserted Rate Transition blocks is not compatible with:

- Concurrent execution environment
- Export-function models

To learn more about the types of Rate Transition blocks, see [Rate Transition](#).

Note Suppose you automatically insert rate transition blocks and there is a virtual block specifying sample time upstream of the block you insert. You cannot click the badge of the inserted block to configure the block and make it visible because the sample time on the virtual block causes a rate transition as well. In this case, manually insert a rate transition block before the virtual block. To learn more about virtual blocks, see “Nonvirtual and Virtual Blocks” on page 36-2.

How Propagation Affects Inherited Sample Times

During a model update, for example at the beginning of a simulation, Simulink uses a process called sample time propagation to determine the sample times of blocks that inherit their sample times. The figure below illustrates a Discrete Filter block with a sample time period T_s driving a Gain block.

Because the output of the Gain block is the input multiplied by a constant, its output changes at the same rate as the filter. In other words, the Gain block has an effective sample rate equal to the sample rate of the filter. The establishment of such effective rates is the fundamental mechanism behind sample time propagation in Simulink.

Process for Sample Time Propagation

Simulink uses the following basic process to assign sample times to blocks that inherit their sample times:

- 1 Propagate known sample time information forward.
- 2 Propagate known sample time information backward.
- 3 Apply a set of heuristics to determine additional sample times.
- 4 Repeat until all sample times are known.

Simulink Rules for Assigning Sample Times

A block having a block-based sample time inherits a sample time based on the sample times of the blocks connected to its inputs, and in accordance with the following rules:

Rule	Action
All of the inputs have the same sample time and the block can accept that sample time	Simulink assigns the sample time to the block

Rule	Action
The inputs have different discrete sample times and all of the input sample times are integer multiples of the fastest input sample time	Simulink assigns the sample time of the fastest input to the block . (This assignment assumes that the block can accept the fastest sample time.)
The inputs have different discrete sample times, some of the input sample times are not integer multiples of the fastest sample time, and the model uses a variable-step solver	Simulink assigns a fixed-in-minor-step sample time to the block.
The inputs have different discrete sample times, some of the input sample times are not integer multiples of the fastest sample time, the model uses a fixed-step solver, and Simulink can compute the greatest common integer divisor (GCD) of the sample times coming into the block	Simulink assigns the GCD sample time to the block. Otherwise, Simulink assigns the fixed step size of the model to the block.
The sample times of some of the inputs are unknown, or if the block cannot accept the sample time	Simulink determines a sample time for the block based on a set of heuristics.

“Blocks for Which Sample Time Is Not Recommended” on page 7-20

More About

- “Backpropagation in Sample Times” on page 7-40

Backpropagation in Sample Times

When you update or simulate a model that specifies the sample time of a source block as inherited (-1), the sample time of the source block may be backpropagated; Simulink may set the sample time of the source block to be identical to the sample time specified by or inherited by the block connected to the source block. For example, in the model below, the Simulink software recognizes that the Sine Wave block is driving a Discrete-Time Integrator block whose sample time is 1; so it assigns the Sine Wave block a sample time of 1.

You can verify this sample time setting by selecting **Sample Time > Colors** from the Simulink **Display** menu and noting that both blocks are red. Because the Discrete-Time Integrator block looks at its input only during its sample hit times, this change does not affect the results of the simulation, but does improve the simulation performance.

Now replacing the Discrete-Time Integrator block with a continuous Integrator block, as shown in the model below, causes the Sine Wave and Gain blocks to change to continuous blocks. You can test this change by selecting **Simulation > Update Diagram** to update the colors; both blocks now appear black.

Note Backpropagation makes the sample times of model sources dependent on block connectivity. If you change the connectivity of a model whose sources inherit sample times, you can inadvertently change the source sample times. For this reason, when you update or simulate a model, by default, Simulink displays warnings at the command line if the model contains sources that inherit their sample times.

Specify Execution Domain

Execution domain specification allows you to set a model and its subsystems and referenced models to simulate as discrete-time or data-driven systems. Use this setting to separate the discrete dynamics from the rest of its dynamics, for example, in the design of a deployable controller for a plant that is modeled with continuous-time dynamics.

To simulate a computationally intensive signal processing or multirate signal processing system, you can also assign a dataflow domain. Dataflow domains simulate using a model of computation synchronous dataflow, which is data-driven and statically scheduled. For more information, see “Dataflow Domain” (DSP System Toolbox).

You can create subsystems that maintain their discrete execution domain irrespective of their environment. By constraining a subsystem to be discrete, you can increase reusability of your subsystem as a component. To improve code generation, this specification reduces unnecessary update methods, reduces major time step checks, and increases reusability of generated code.

Domain Specification Badge

The domain specification badge indicates the execution domain computed to a model or subsystem when you update the model diagram. You can toggle the visibility of the domain specification badge by turning on the **Sample Time Display**. For more information on visualizing sample time, see “View Sample Time Information” on page 7-9. The badge is visible at the bottom left corner of the Simulink Editor.

The model below shows a discrete Sine Wave block whose rate is reduced by the Rate Transition block before driving the Gain block.

Observe that the model receives the *Discrete* execution domain because its contents are all discrete.

You can also toggle the visibility of the badge by enabling or disabling the **Set Domain Specification** parameter in the **Execution** tab of the **Property Inspector**.

Types of Execution Domains

You can instruct Simulink to assign the execution domain (along with the allowed sample times) via the **Property Inspector**.

Specification	Discrete	Other	Dataflow
Deduce from contents	X	X	-
Discrete	X	-	-
Dataflow	-	-	X

-  **Deduce from contents** Let Simulink assign the execution domain based on the contents of the subsystem.
-  **Discrete** Constrain all blocks in a subsystem to be discrete.
-  **Dataflow** Simulate a computationally-intensive signal processing or multi-rate signal processing system. This setting requires the DSP System Toolbox™.

When you update the model diagram or simulate the model, the badge displays the computed execution domain for the model component. There are three execution domains in Simulink:

-  **Discrete** Blocks have discrete states and sample times. Allowed sample times include “Discrete Sample Time” on page 7-15, “Controllable Sample Time” on page 7-18, and “Asynchronous Sample Time” on page 7-18.
-  **Dataflow** Dataflow domains simulate using computation synchronous dataflow, which is data-driven and statically scheduled. This execution domain requires the DSP System Toolbox. For more information, see “Specifying Dataflow Domains” (DSP System Toolbox).
-  **Other** Blocks are not strictly discrete.

Subsystems that receive the **Other** execution domain include:

- Subsystems whose blocks have continuous states and sample times, including “Continuous Sample Time” on page 7-16, “Fixed-in-Minor-Step” on page 7-16, and “Variable Sample Time” on page 7-17

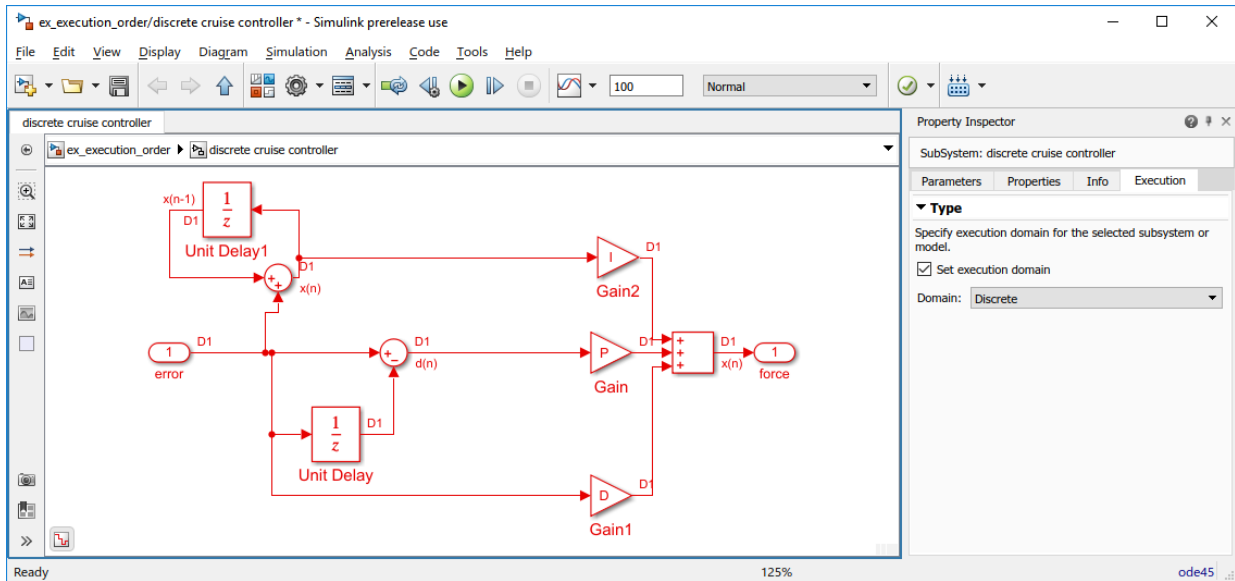

- Subsystems with a mixture of continuous and discrete sample times.
- Subsystems with “Asynchronous Sample Time” on page 7-18.
- Triggered Subsystem
- Function-Call Subsystem
- Enabled and Triggered Subsystem
- Initialize Function
- Reset Function
- Terminate Function
- “Action subsystems” on page 3-13

If a subsystem has continuous, variable, fixed-in-minor step, “Constant Sample Time” on page 7-17, or a mixture of sample times, you can use the badge to enable or disable domain specification. The subsystem still receives the **Other** time domain.

The domain specification badge is not actionable when the currently selected subsystem or model is a linked block, inside a library block, or a conditionally executed subsystem that receives the **Other** domain. To change the execution domain of a linked library block, break the link to the parent library block. See “Disable or Break Links to Library Blocks” on page 41-27.

Set Execution Domain

You can set the domain specification per subsystem and at the root level of the model using the **Execution** tab of the **Property Inspector**. Enable the **Property Inspector** for the model via **View > Property Inspector** or by pressing the **Ctrl+Shift+I** key combination on your keyboard. If the domain specification badge is displayed, you can also open the **Execution** settings in the **Property Inspector** by clicking the badge. See “Domain Specification Badge” on page 7-42.

Select the **Set Execution Domain** check box. You can now specify the **Domain**.

Note Changing the domain specification at the root level of the model does not change the setting for its child subsystems.

You can also enable this setting from the command line using `set_param` to set the `SetExecutionDomain` parameter 'on' or 'off'.

Once enabled, the default setting for the **Domain** parameter is **Deduce from contents**. When you update the diagram, the execution domain is deduced from the characteristics of the blocks in the currently open subsystem. For example, a system that has only discrete blocks is in the **Discrete** execution domain. See "Types of Execution Domains" on page 7-43.

The badge shows the current specification setting. If you set the subsystem domain to **Deduce from contents**, the badge text displays **Deduce** until you update the diagram. Once you update the model diagram, the badge shows the computed execution domain, as described in "Types of Execution Domains" on page 7-43. When you enable **Set domain specification** and **Domain** is set to **Deduce from Contents**, Simulink computes the

execution domain of the currently focused subsystem based on the blocks and sample times inside the subsystem.

To set the **Domain** parameter from the command line, use `set_param` to change `ExecutionDomainType` to either `'DeduceFromContents'` or `'Discrete'`. You can also get the computed execution domain after you update the diagram using the `CompiledExecutionDomain` parameter of the subsystem.

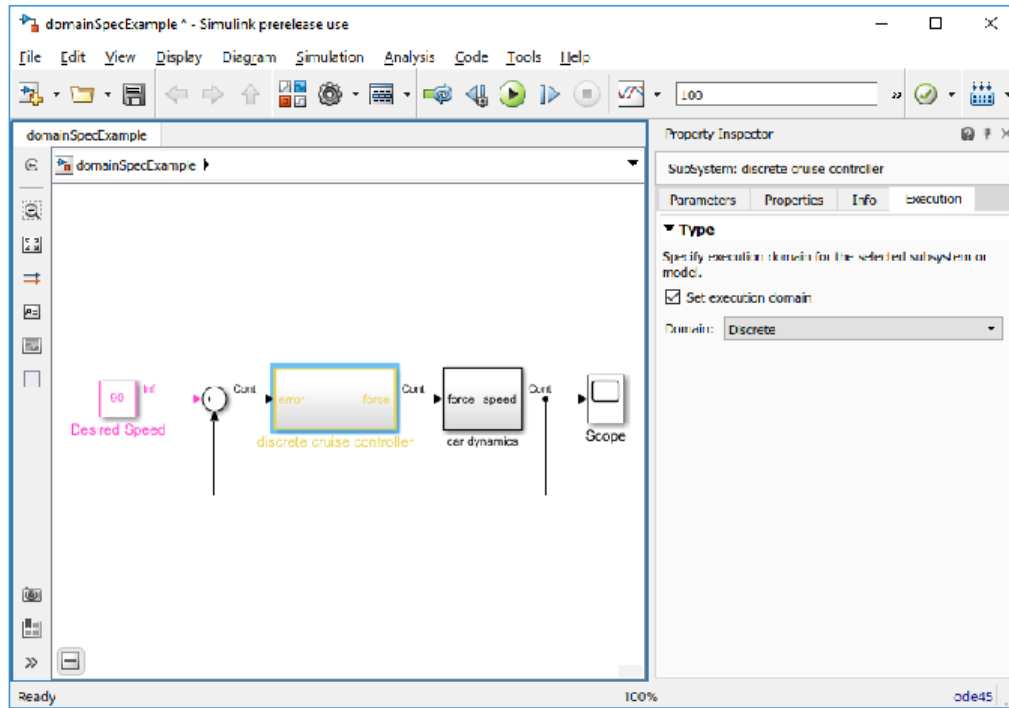

Enforce Discrete Execution Domain for a Subsystem

This model shows how to specify execution domains for the constituent subsystems of a model. The model has a discrete cruise controller subsystem that tracks the reference speed set in the Desired Speed block. A car dynamics subsystem models the continuous-time dynamics of the car.

Notice that the discrete cruise controller of the model has a hybrid sample time due to the presence of a continuous-time signal from the output of the car dynamics at the input port of the controller.

To enforce discrete-time execution of the controller, select the subsystem and open the **Execution** tab of the **Property Inspector** by clicking on the Domain badge at the bottom-left corner of the Simulink Editor.

Enable the **Set execution domain** parameter and set **Domain** to Discrete. Update the model diagram or simulate the model.

Note that the discrete cruise controller subsystem is now discrete.

You can also set the execution domain of the car dynamics to **Deduce** from **Contents**. The car dynamics subsystem receives the Hybrid sample time and the **Other** execution domain. If you wish, set the **Sample Time** parameter of the Inport block in this subsystem to 0.

Referencing a Model

Model Reference Basics

You can include one model in another by using a Model block. Each instance of a Model block is a model reference. For simulation and code generation, blocks within a referenced model execute together as a unit. The model that contains a referenced model is a parent model. A collection of parent and referenced models constitutes a model hierarchy.

A model can function as both a standalone model and a referenced model, without changing the model or any entities derived from it. To use a referenced model as a standalone model, the referenced model cannot depend on data that is available only from a higher-level model.

Model Reference Advantages

Like subsystems, model references allow you to organize large models hierarchically. Like libraries, model references allow you to define a set of blocks once and use it repeatedly. Model references provide several advantages that are unavailable with subsystems and libraries. Several of these advantages result from referenced models compiling independent from the context of the Model block, including:

- **Modular development**

You can develop a referenced model independently from the models that use it.

- **Model protection**

With a Simulink Coder license, you can obscure the contents of a referenced model, allowing you to distribute the model without revealing its intellectual property.

With a Simulink license, you can reference a protected model provided by a third party. Depending on the granted protected-model permissions, you can view, simulate, and generate code for the protected model.

- **Inclusion by reference**

You can reference a model multiple times without making redundant copies, and multiple models can reference the same model.

- **Incremental loading**

Simulink software loads a referenced model when it is needed, which speeds up model loading.

- **Accelerated simulation**

Simulink software can convert a referenced model to code and simulate the model by running the code, which is faster than interactive simulation.

- **Incremental code generation**

Accelerated simulation generates code only if the model has changed since the code was previously generated.

- **Independent configuration sets**

The configuration set used by a referenced model can differ from the configuration set of its parent or other referenced models.

For a video summarizing model reference advantages, see [Modular Design Using Model Referencing](#).

To compare model references, subsystems, and libraries, see “Capabilities of Model Components” on page 15-29. You can use multiple componentization techniques in the same model.

Model Hierarchies

Referenced models can contain Model blocks that reference lower-level models. The top model is the topmost model in a hierarchy of referenced models. Where only one level of model reference exists, the parent model and top model are the same. To prevent cyclic inheritance, a Model block cannot refer directly or indirectly to a model that is superior to it in the model hierarchy. This figure shows cyclic inheritance.

A parent model can contain multiple Model blocks that reference the same referenced model, as long as the referenced model does not define global data. For example, the

`sldemo_mdref_basic` model includes Model blocks that reference three instances of the same referenced model, `sldemo_mdref_counter`.

Component-Based Modeling with Model Reference

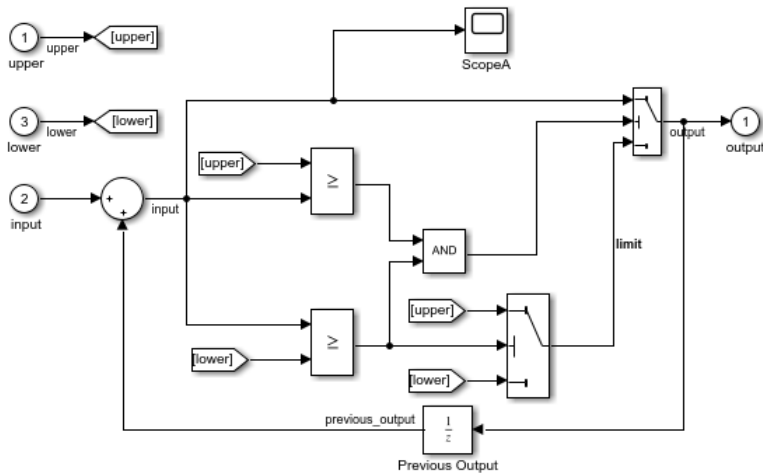

The referenced model can also appear in other parent models at any level.

Model Block and Referenced Model Interface

A Model block displays input, output, and control ports that correspond to root-level input, output, and control ports of the model it references. To connect the referenced model to other elements of the parent model, use these Model block ports. Connecting a signal to a Model block port connects the signal to the corresponding port in the referenced model.

In model `sldemo_mdref_basic`, each Model block has three inputs: two Constant blocks and a Pulse Generator block. Each Model block has one output signal logged to a scope. Because the input signal from each Pulse Generator block uses a different sample time, the output signal from each Model block differs for each model instance.

To connect to the parent model, referenced model `sldemo_mdref_counter` includes three Inport blocks (**upper**, **lower**, and **input**) and one Outport block (**output**). If you change the ports in the referenced model, refresh the Model block to reflect these changes.

Signal attributes in the referenced model are independent from the context of the Model block. For example, signal dimensions and data types do not propagate across the Model block boundary. To define signal attributes in the referenced model, define block parameters for root-level Inport and In Bus Element blocks.

For more information, see “Model Reference Interface” on page 8-44.

Model Workspaces and Data Dictionaries

Each model has its own workspace for storing variable values. In a model hierarchy, each model workspace acts as a unique namespace. Therefore, you can use the same variable name in multiple model workspaces. To share data among models, you can use a data dictionary.

Duplicate data definitions can exist in a model reference hierarchy under these conditions:

- Each model in the hierarchy can see only one definition.
- Definitions must be the same across models in the hierarchy.

For more information on where you can store variables and objects, see “Determine Where to Store Variables and Objects for Simulink Models” on page 62-134.

Referenced Model Execution

To use an external signal to control whether a Model block executes during simulation, see “Modify Referenced Models for Conditional Execution” on page 8-33.

Variant Subsystem blocks can contain Model blocks as variant systems. For information on variant systems, see “What Are Variants and When to Use Them” on page 11-3.

By default, a block parameter has the same value in each Model block instance of a reusable referenced model. To specify a different block parameter value for each instance of a reusable referenced model, create model arguments. For example, if you add a Gain block to model `sldemo_mdref_counter`, model arguments allow each of the three instances of this model to use different gain values. See “Parameterize Instances of a Reusable Referenced Model” on page 8-90.

With a model mask, you can control the appearance of Model blocks and customize the way the blocks display model arguments. For model mask requirements, see “Model Masks” on page 8-9.

Referenced Model Simulation

You can simulate a referenced model either interpretively (in normal mode) or by compiling the referenced model to code and executing the code (in accelerator mode). For details, see “Simulate Model Hierarchies” on page 8-54.

Faster Simulations Using Simulink Cache Files

The first time that you simulate or update the diagram for a model that builds a model reference simulation (SIM) target, the build process creates a Simulink cache file. The cache file stores build artifacts and speeds up successive model builds. For additional benefits and an example workflow, see “Share Simulation Builds for Faster Simulations” on page 8-81.

Referenced Model Code Generation

To learn about considerations when generating code for a referenced model, see “Code Generation of Referenced Models” (Simulink Coder).

Model Reference Requirements and Limitations

In this section...
“Model Reuse” on page 8-8
“Model Masks” on page 8-9
“S-Functions in Referenced Models” on page 8-9
“Model Architecture Requirements and Limitations” on page 8-11
“Signal Requirements and Limitations” on page 8-12
“Simulation Requirements and Limitations” on page 8-12
“Tools Requirements and Limitations” on page 8-15
“Code Generation Requirements and Limitations” on page 8-16

To successfully implement Model blocks, before organizing your model into components, consider their requirements and limitations. By understanding requirements and limitations upfront, you are better prepared to use Model blocks.

Model Reuse

You can reference a model more than once in a model hierarchy unless the referenced model has any of these properties:

- The model contains To File blocks.
- The model references another model that is set to single instance.
- The model contains an internal signal or state with a storage class that is not supported for multi-instance models. Internal signals and states must have the storage class set to `Auto` or `Model default` and the default storage class for internal data must be a multi-instance storage class.
- The model uses any of these Stateflow constructs:
 - Stateflow graphical functions
 - Machine-parented data
- The referenced model executes in accelerator mode and contains:
 - A subsystem that is marked as a function
 - An S-function that is either not inlined or is inlined but does not set the option `SS_OPTION_WORKS_WITH_CODE_REUSE`

- The model contains a function-call subsystem that:
 - Simulink forces to be a function
 - Is called by a wide signal

If the referenced model has any of these properties, only one instance of the model can appear in the model hierarchy. The model must have **Total number of instances allowed per top model** set to One.

Model Masks

You can use masked blocks in a referenced model. Also, you can mask a referenced model (see “Create and Reference a Masked Model” on page 39-62).

To successfully use masks, consider these requirements and limitations:

- If a mask specifies the name of a referenced model, the mask must provide the name of the referenced model directly. You cannot use a workspace variable to provide the name.
- The mask workspace of a Model block is not available to the referenced model. Any variable that the referenced model uses must resolve to either of these workspaces:
 - A workspace that the referenced model defines
 - The MATLAB base workspace
- Mask callbacks cannot add Model blocks, change the Model block name, or change the Model block simulation mode.

S-Functions in Referenced Models

Different types of S-functions provide different levels of support for model references.

Type of S-Function	Support for Model References
Level-1 MATLAB S-function	Not supported
Level-2 MATLAB S-function	<ul style="list-style-type: none"> • Supports normal and accelerator mode • Accelerator mode requires a TLC file
Handwritten C MEX S-function	<ul style="list-style-type: none"> • Supports normal and accelerator mode • Can be inlined with TLC file

The S-Function Builder and Legacy Code Tool both support normal and accelerator modes for model references.

For information on how to use S-functions in models, see “Use S-Functions in Models”.

S-Function Sample Time

If an S-function depends on an inherited sample time, the S-function must explicitly declare a dependence on the inherited sample time. To control sample-time inheritance, use `ssSetModelReferenceSampleTimeInheritanceRule` differently based on whether an S-function permits or precludes inheritance. For details, see “Inherited Sample Time for Referenced Models” (Simulink Coder).

S-Functions in Accelerator Mode Referenced Models

For a referenced model that executes in accelerator mode, set **Total number of instances allowed per top model** to One if the model contains an S-function that is either:

- Inlined, but has not set the `SS_OPTION_WORKS_WITH_CODE_REUSE` flag
- Not inlined

For accelerator mode referenced models that contain an S-function that requires inlining using a Target Language Compiler file, the S-function must use the `ssSetOptions` macro to set the `SS_OPTION_USE_TLC_WITH_ACCELERATOR` option in its `mdlInitializeSizes` method. The simulation target does not inline the S-function unless the S-function sets this option.

A referenced model cannot use noninlined S-functions in these cases:

- The model uses a variable-step solver.
- The S-function supports use of fixed-point numbers as inputs, outputs, or parameters.
- The model is referenced more than once in the model reference hierarchy. To work around this limitation, use normal mode or:
 - 1 Make copies of the referenced model.
 - 2 Assign different names to the copies.
 - 3 Reference a different copy at each location that needs the model.
- The S-function uses character vector parameters.

A referenced model in accelerator mode cannot use S-functions generated by the Simulink Coder software.

C S-Functions in Normal Mode Referenced Models

Under certain conditions, when a C S-function appears in a referenced model that executes in normal mode, successful execution is impossible. For details, see “S-Functions in Normal Mode Referenced Models”.

To specify whether an S-function can be used in a normal mode referenced model, use the `ssSetModelReferenceNormalModeSupport` SimStruct function.

For an S-function to work with multiple instances of referenced models in normal mode, the S-function must indicate explicitly that it supports multiple `exec` instances. For details, see “Supporting the Use of Multiple Instances of Referenced Models That Are in Normal Mode”.

Protected Models

A protected model cannot use noninlined S-functions directly or indirectly.

Model Architecture Requirements and Limitations

Element	Requirements and Limitations
Goto and From blocks	Goto and From blocks cannot cross model reference boundaries.
Iterator subsystems	If the referenced model contains Assignment blocks, you can place the Model block in an iterator subsystem only if the Assignment blocks are also in an iterator subsystem.
Configurable subsystems	In a configurable subsystem with a Model block, during model update, do not change the subsystem that the configurable subsystem selects.
InitFcn callback	An InitFcn callback in a top model cannot change parameters used by referenced models.
MATLAB Function block	A MATLAB Function block in a referenced model that executes in accelerator mode cannot call MATLAB functions that are declared extrinsic for code generation.

Signal Requirements and Limitations

Signal	Requirements and Limitations
0-based or 1-based indexing information propagation	See “Index Information Propagation” on page 8-62.
Asynchronous rates	Referenced models can only use asynchronous rates if the model meets <i>both</i> of these conditions: <ul style="list-style-type: none"> • An external source drives the asynchronous rate through a root-level Inport block. • The root-level Inport block outputs a function-call signal. See Asynchronous Task Specification.
User-defined data type input or output	A referenced model can input or output only the user-defined data types that are fixed point or that <code>Simulink.DataType</code> or <code>Simulink.Bus</code> objects define.
Buses	If you use a virtual bus as an input or an output for a referenced model, the bus cannot contain a variable-size signal element. See “Model Reference Requirements for Nonvirtual Buses” on page 68-161.
Signal objects	A signal that connects to a Model block is functionally the same signal outside and inside the block. Therefore, that signal is subject to the restriction that a given signal can have at most one associated signal object. See <code>Simulink.Signal</code> for more information.

Simulation Requirements and Limitations

Simulation Property	Requirements and Limitations
Continuous sample time propagation	A continuous sample time cannot be propagated to a Model block that is sample-time independent.
Sample times and solvers	The solver of the topmost model controls all continuous sample times in a model hierarchy. For example, for a fixed-step solver, all continuous rates in referenced models run at the fixed-step size of the topmost model. For information about how sample times impact solvers, see “Types of Sample Time” on page 7-15.

Simulation Property	Requirements and Limitations
State initialization	To initialize the states of a model that references other models with states, specify the initial states in structure or structure with time format. For more information, see “State Information for Referenced Models” on page 64-291.
Parameter tunability	When you simulate a model that references other models, under some circumstances, you lose some tunability of block parameters (for example, the Gain parameter of a Gain block). For more information, see “Tunability Considerations and Limitations for Other Modeling Goals” on page 37-49.
Normal mode visibility for multiple instances of referenced model	<p>You can simulate a model that has multiple instances of a referenced model that are in normal mode. All the instances of the referenced model are part of the simulation. However, Simulink displays only one of the instances in a model window. The normal mode visibility setting determines which instance Simulink displays. Normal mode visibility includes the display of Scope blocks and data port values.</p> <p>To control which instance of a referenced model in normal mode has visibility and to ensure proper simulation of the model, see “Configure Models with Multiple Referenced Model Instances” on page 8-66.</p>
Save before using accelerator mode	When you create a model, you cannot use that model as an accelerator mode referenced model until you have saved the model to disk. You can work around this limitation by setting the model to normal mode. See “Simulate Model Hierarchies” on page 8-54.
Diagnostic configuration parameters in accelerator mode	For models referenced in accelerator mode, Simulink ignores certain runtime diagnostics that you set to a value other than none or Disable all . For details, see “Diagnostic Configuration Parameters Ignored in Accelerator Mode” on page 8-58.

Simulation Property	Requirements and Limitations
Blocks with runtime checks in accelerator mode	Some blocks include runtime checks that are disabled when you include the block in a referenced model in accelerator mode. Examples of these blocks include Assignment, Selector, and MATLAB Function blocks.
sim command in accelerator mode	When the sim command executes a referenced model in accelerator mode, the source workspace is always the MATLAB base workspace.
Data logging and visualization in accelerator mode	These logging methods have limitations when specified for referenced models executing in accelerator mode. <ul style="list-style-type: none"> • To Workspace blocks — Data is logged only if you use Timeseries format. • Scope, Floating Scope, and Scope Viewer blocks — No data is displayed. • Runtime display — Simulation data values, such as port values, do not display.
Linearization of discrete states in accelerator mode	In accelerator mode, discrete states of model references are not exposed to linearization. These discrete states are not perturbed during linearization and, therefore, are not truly free in the trimming process.
Trimming in accelerator mode	The outputs of random blocks are not kept constant during trimming. Outputs that are not kept constant can affect the optimization process.
External mode in accelerator mode	Accelerator mode does not support the External mode option. If you enable the External mode option, accelerator mode ignores it.
Sim viewing device in rapid accelerator mode	In rapid accelerator mode, Simulink does not update a Model block with a sim viewing device.
SIL and PIL mode	See “Simulation Mode Override Behavior in Model Reference Hierarchy” (Embedded Coder).

Simulation Property	Requirements and Limitations
Custom C code for referenced model simulation (SIM) target build for accelerator mode	<p>To use custom C code in accelerator mode, enable the Include custom code for referenced models configuration parameter.</p> <hr/> <p>Caution Using custom C code for referenced models in accelerator mode can produce different results than when you simulate the model without using the custom code. If the custom code includes declarations of structures for buses or enumerations, the SIM target generation fails if the build results in duplicate declarations of those structures. Also, if custom code uses a structure representing a bus or enumeration, you can get unexpected simulation results.</p>

Tools Requirements and Limitations

Tool	Requirements and Limitations
Simulink Debugger breakpoints	Working with the Simulink Debugger in a parent model, you can set breakpoints at Model block boundaries. Setting the breakpoints allows you to look at the input and output values of the Model block. You can set a breakpoint inside the referenced model in normal mode. However, you cannot set a breakpoint inside the referenced model in accelerator mode. See “Simulink Debugger” for more information.
Simulink Profiler	In normal mode, enabling the Simulink Profiler on a parent model does not enable profiling for referenced models. Enable profiling separately for each referenced model. See “How Profiler Captures Performance Data” on page 31-5.

Tool	Requirements and Limitations
Simulink tools that access internal data or model configurations	Simulink tools that require access to the internal data or the configuration of a model have no effect on referenced models executing in accelerator mode. Specifications made and actions taken by such tools are ignored. Examples of tools that require access to model internal data or configuration include: <ul style="list-style-type: none">• Model Coverage• Simulink Report Generator• Simulink Debugger• Simulink Profiler
Printing referenced models	You cannot print a referenced model from a top model.

Code Generation Requirements and Limitations

By understanding code generation requirements and limitations upfront, you are better prepared to properly set up the model hierarchy for code generation. See “Code Generation Model Referencing Limitations” (Simulink Coder).

Reference Existing Models

A model becomes a referenced model when a Model block in another model references it. Any model can function as a referenced model, and can continue to function as a separate model.

For a video explaining how to create model references, see [Getting Started with Model Referencing](#).

To reference an existing model in another model, follow these steps.

- 1 If the folder containing the model you want to reference is not on the MATLAB path, add the folder to the MATLAB path.
- 2 In the referenced model, set **Total number of instances allowed per top model** to:
 - **One** to use the model at most once in a model hierarchy.
 - **Multiple** to use the model more than once in a model hierarchy. To reduce overhead, specify **Multiple** only when necessary.
 - **Zero** to preclude referencing the model.
- 3 Create an instance of the Model block in the parent model. The new block is initially unresolved because it does not specify a referenced model.

- 4 To open the block parameters dialog box, double-click the Model block.

- 5 Enter the name of the referenced model in the **Model name** field. This name must contain fewer than 60 characters, exclusive of the `.slx` or `.mdl` suffix.
- 6 Click **OK**. If the referenced model contains root-level inputs or outputs, the Model block displays corresponding input and output ports.
- 7 Use the Model block ports to connect referenced model signals to ports in the parent model. See “Model Reference Interface” on page 8-44.

Reference Protected Models from Third Parties

To deliver a model without revealing its intellectual property, third parties can protect the model before delivery. A protected model is a referenced model that does not support editing. The protected model author chooses whether to enable read-only view, simulation, code generation, and password protection. When an operation is password protected, the AES-256 encryption technology protects the supporting file contents. Creating a protected model requires a Simulink Coder license.

To locate protected models, look for:

- Files in the MATLAB Folder Browser with a badge icon.

- Model blocks with a badge icon in the lower left corner.

- Files with an `.slxp` extension.

Note Protected models do not appear in the model hierarchy in the Model Explorer.

Reference a Protected Model

To reference a protected model, complete this workflow:

- 1 Check whether the protected model supports the desired functionality.

For example, check that the protected model supports simulation. If available, the protected model report shows the supported functionality. To open the report, right-click the protected-model badge icon and select **Display Report**.

- 2 Check that the Simulink release you are using supports the protected model.

If available, the protected model report shows the release versions used to create the protected model. Use the same Simulink release that was used to create the

protected model unless the protected model also supports later releases, as described by this table.

Use Models Protected in Previous Releases

Goal	Cross-Release Support
Read-only view	Models protected in R2018
Simulation in normal mode	Models protected in R2018
Simulation in accelerator mode	None
Simulation in SIL or PIL mode	None
Simulation in rapid accelerator mode	None
Code generation	None

- 3 Confirm that you have access to the licenses used in the protected model.
If available, the protected model report shows the required licenses.
- 4 If you plan to simulate the protected model, use the same platform used to create the protected model. The software stores the protected model as a compiled MEX binary.
- 5 If you received a protected model package, unpack files according to accompanying directions.
- 6 Ensure that the protected model is on the MATLAB path.
- 7 If you received a harness model, copy the Model block from the harness model into your model. Otherwise, reference the protected model in a Model block.

When you set a Model block to reference a protected model, the **Simulation mode** of the block becomes **Accelerator**. You cannot change this mode or use this Model block in **External** mode.

- 8 If the protected model is password protected, right-click the protected model badge icon and select **Authorize**. In the **Model view** box, enter the password, then click **OK**.
- 9 Connect signal lines to the Model block that match its input and output port requirements. See “Model Reference Interface” on page 8-44.

Note that the protected model cannot use noninlined S-functions directly or indirectly.

- 10 Provide any needed model argument values. See “Parameterize a Referenced Model” on page 8-91.

Protected Model Supporting Files

Protected models can require supporting files. If you received a MAT-file, load the MAT-file containing workspace definitions. You can configure a callback function, such as **LoadFcn**, to load the MAT-file automatically. See “Callbacks for Customized Model Behavior” on page 4-50.

View Protected Model Contents

Web view allows you to view this protected model information:

- System contents
- Block parameters
- Signal properties

To access the read-only view, you must have access to the licenses used in the protected model. If available, the protected model report shows the required licenses.

To open the read-only view, you can double-click the Model block referencing the protected model or the `.slxp` file in the Current Folder browser. If the read-only view is password protected, right-click the protected-model badge icon and select **Authorize**. In the **Model view** box, enter the password, then click **OK**.

You can navigate the model hierarchy by double-clicking Model or Subsystem blocks. Alternatively, you can navigate to the **View All** tab and select the system that you want to view. You cannot view the content of protected referenced models in the protected model.

To view block parameters and signal properties, select a block or signal line respectively.

To search in Web view, click the search button then enter the name or value that you want to search in the box that appears. The elements of the model that the search returns appear highlighted. The search results include the name and parent of each returned element.

Convert Subsystems to Referenced Models

Model reference offers benefits for modeling large, complex systems and for team-based development. Many large models use a combination of subsystems and referenced models. To decide whether to convert a subsystem to a referenced model, see “Capabilities of Model Components” on page 15-29 and “Guidelines for Component Size and Functionality” on page 22-4.

The Model Reference Conversion Advisor does not support conversion for some types of subsystems.

- You cannot convert a Subsystem block with Simscape Multibody components to a Model block.
- To convert a masked Subsystem block, use the `Simulink.SubSystem.convertToModelReference` function.
- To convert an asynchronous subsystem to a referenced model that accepts asynchronous function calls, see “Asynchronous Support Limitations” (Simulink Coder).

Update Subsystem Block Contents for Conversion

The Model Reference Conversion Advisor helps you review and fix issues. Preparing the contents of a Subsystem block can eliminate or reduce the number of issues that the advisor identifies. Addressing these issues in the model editing environment can be more efficient than switching repeatedly between the advisor and the Simulink Editor.

To convert the Subsystem block without preparing its contents, see “Convert Subsystem Blocks to Model Blocks” on page 8-28. Otherwise, take these steps to prepare Subsystem block contents:

- 1** Set the **Signal resolution** parameter to `Explicit only` or `None`.

You can use the Model Reference Conversion Advisor **Fix** option to address this issue.

- 2** Configure the Subsystem block interface.

Subsystem Block Interface	What to Look For	Model Modification
Goto or From blocks	Goto or From blocks crossing the subsystem boundary	<p>Replace From blocks that have a corresponding Goto block that crosses the subsystem boundary with an Inport block.</p> <p>Replace each Goto block that has corresponding From blocks that cross the subsystem boundary with an Output block.</p> <p>Connect the Inport and Output blocks to the corresponding subsystem ports.</p> <p>You can use the Model Reference Conversion Advisor Fix option to address this issue.</p>
Data stores	Data Store Memory blocks accessed by Data Store Read or Data Store Write blocks from outside of the subsystem	<p>Replace the Data Store Memory block with a global data store. Define a global data store using a <code>Simulink.Signal</code> object. For details, see “Data Stores with Signal Objects” on page 65-20.</p> <p>You can use the Model Reference Conversion Advisor Fix option to address this issue.</p>

Subsystem Block Interface	What to Look For	Model Modification
Tunable parameters	Global tunable parameters in the dialog box opened using the Configuration Parameters > Optimization > Configure button	<p>To create a <code>Simulink.Parameter</code> object for each tunable parameter, use <code>tunablevars2parameterobjects</code>.</p> <p>The <code>Simulink.Parameter</code> objects must have a storage class other than <code>Auto</code>.</p> <p>For more information, see “Parameterize Instances of a Reusable Referenced Model” on page 8-90 and “Tunable Parameters” on page 3-8.</p> <p>You can use the Model Reference Conversion Advisor Fix option to address this issue.</p>

3 Configure the Subsystem block contents.

Subsystem Configuration	What to Look For	Model Modification
Function calls	Function-call signals that cross virtual subsystem boundaries	<p>Move the Function-Call Generator block into the subsystem that you want to convert.</p> <hr/> <p>Note If you convert an export-function subsystem, then you do not need to move the Function-Call Generator block.</p>
	Function-call outputs	Change the function-call outputs to data triggers.
	Wide function-call ports	Eliminate wide signals for function-call subsystems.

Subsystem Configuration	What to Look For	Model Modification
Sample times	An Inport block sample time that does not match the sample time of the block driving the Inport block	Insert Rate Transition blocks where appropriate.
Inport blocks	Merged Inport blocks	Configure the model to avoid merged Inport blocks. See the Merge block documentation.
Constant blocks	Constant blocks that provide input for subsystems	Move Constant blocks into the subsystem.
Buses	Bus signals that enter and exit a subsystem	Match signal names and bus element names for blocks inside the subsystem. To find signal names that do not match bus element names, use the Signal label mismatch diagnostic.
	Duplicate signal names in buses	Make signal names of bus elements unique.

Subsystem Configuration	What to Look For	Model Modification
	<p>Signal names that are not valid MATLAB identifiers. A valid identifier is a character vector that meets these conditions:</p> <ul style="list-style-type: none"> • The name contains letters, digits, or underscores. • The first character is a letter. • The length of the name is less than or equal to the value returned by the <code>namelengthmax</code> function. 	<p>Change any invalid signal names to be valid MATLAB identifiers.</p>

Convert Subsystem Blocks to Model Blocks

To convert a Subsystem block to a Model block, use the Model Reference Conversion Advisor.

- 1 Make sure that the model containing the subsystem that you want to convert compiles successfully.
- 2 For improved conversion performance, close any open Scope block windows.
- 3 To open the Model Reference Conversion Advisor, right-click the Subsystem block and select **Subsystem & Model Reference > Convert to > Referenced Model**.

- 4 Review the default settings under **Input Parameters**. Modify the parameters as needed, then click **Apply**.
- The advisor can fix some conversion issues automatically. Select **Fix errors automatically (if possible)**. This option can make the conversion process faster, but you do not control the fixes that the advisor makes.
 - The advisor can leave the Subsystem block in place and create a separate model from the contents of the Subsystem block. Clear **Replace the content of a subsystem with a Model block**.
 - The advisor can compare top-model simulation results before and after conversion. To compare simulation results:
 - Enable signal logging for output signals of interest
 - Select **Check simulation results after conversion** and **Replace the content of a subsystem with a Model block**

- Set the **Stop time**, **Absolute tolerance**, and **Relative tolerance**
 - Set the **Model block simulation mode** option in the advisor to the same simulation mode as the original model
- 5 Click **Convert**. For information about the checks, right-click the check (such as **Check conversion input parameters**) and select **What's This?**
 - 6 Address any issues that the advisor reports. For some issues, the advisor provides a **Fix** button to address an issue.
 - 7 After you address each issue, click **Continue** until the advisor reports no remaining issues.

Alternatively, you can use the `Simulink.SubSystem.convertToModelReference` function. You can convert multiple Subsystem blocks using one `Simulink.SubSystem.convertToModelReference` command. However, you cannot convert a parent subsystem and a child of that subsystem at the same time.

Conversion Results

After the Model Reference Conversion Advisor runs all checks successfully, it:

- Creates a referenced model from the subsystem.
- Creates the bus objects, signal objects, and tunable parameters that the referenced model requires.
- By default, replaces the Subsystem block with a Model block that contains the referenced model.
- Inserts the Model block in a Subsystem block if the automatic fixes added ports to the Model block interface.
- Creates an HTML conversion summary report in the `slprj` folder. This report summarizes the results of the conversion process, including the results of the fixes that the advisor performed. This report also describes the elements that it copies.
- Optionally checks the consistency of simulation results before and after conversion.

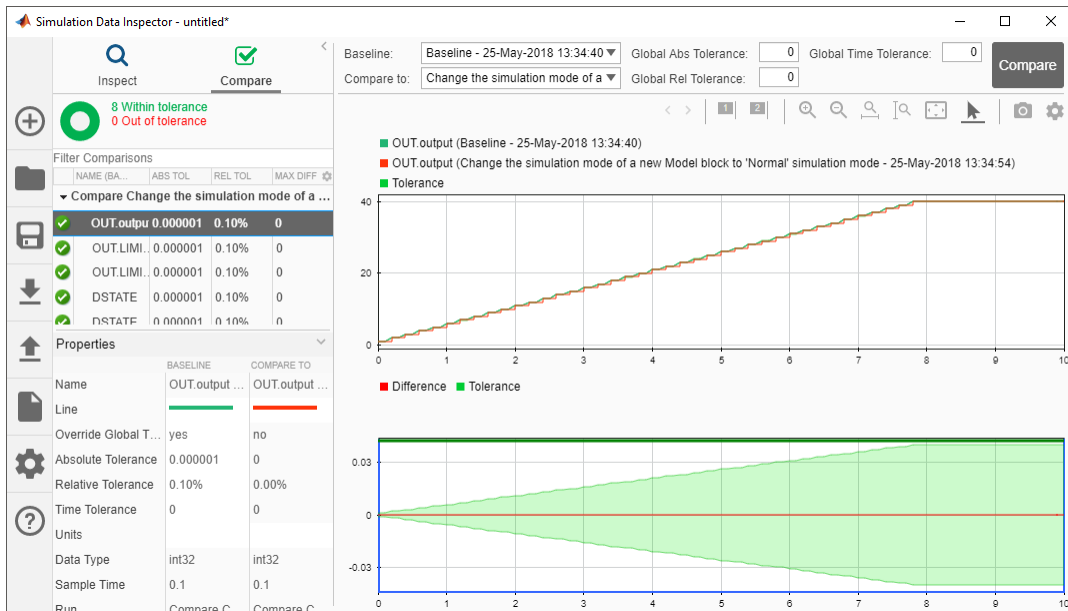

The advisor copies the following elements from the original model to the new referenced model.

- **Configuration set** — If the parent model uses:
 - A configuration set that is not a referenced configuration set, the advisor copies the entire configuration set to the referenced model

- A referenced configuration set, then both the parent and referenced models use the same referenced configuration set
- **Variables** — The advisor copies only the model workspace variables that the subsystem used in the original model to the model workspace of the referenced model. If the model that contained the subsystem uses a data dictionary, then the referenced model uses the same data dictionary.
- **Requirements links** — The advisor copies requirements links created with Simulink Requirements software to the Model block from the original Subsystem block.

Compare Simulation Results Before and After Conversion

The Model Reference Conversion Advisor can compare simulation results before and after the conversion. After you successfully run the **Complete conversion** check, select **Click here to view the comparison results**. The results display in the Simulation Data Inspector. A green check mark indicates that simulation results are within tolerance between the baseline model and the model with the new referenced model.

For more information about the Simulation Data Inspector, see “View and Analyze Simulation Results”.

Revert the Conversion

If you are not satisfied with the conversion results, you can restore the model to its initial state. Use one of these approaches:

- At any point during the conversion, select **File > Load Restore Point**.
- After you successfully run the **Complete conversion** check, select **Click here to restore the original model**.

Integrate the Referenced Model into the Parent Model

After you complete the conversion, update the model as necessary to meet your modeling requirements. For example, you can manually replace a Subsystem block with a Model block that references the created referenced model.

If you want to simulate the model with external data, check that the root Inport blocks in the new referenced model have the appropriate **Interpolate data** parameter setting. See the documentation for the **Interpolate data** parameter of the Inport block.

Modify Referenced Models for Conditional Execution

A conditionally executed referenced model, or conditional model, allows you to control its execution with an external signal. The external signal, called the control signal, is attached to the control input port. Conditional models are useful when you create complex model hierarchies that contain components whose execution depends on other components.

Conditional Models

You can set up referenced models so that they execute conditionally, similar to conditional subsystems. For information about conditional subsystems, see “Conditionally Executed Subsystems Overview” on page 10-3.

Simulink software supports these conditional model types:

Conditional Model	Description
Enabled	<p>An enable port executes a referenced model at each simulation step for which the control signal has a positive value. To add an enable port to a Model block, insert an Enable block in the referenced model.</p> <p>This image displays the contents of a simple enabled referenced model.</p>  <p>To see an example of an enabled <i>subsystem</i>, see <code>enablesub</code>. A corresponding enabled referenced model uses the same blocks as are in the enabled subsystem.</p>

Conditional Model	Description
<p>Triggered</p>	<p>A trigger port executes a referenced model each time a trigger event occurs. To add a trigger port to a Model block, insert a Trigger block in the referenced model.</p> <p>This image displays the contents of a simple triggered referenced model.</p> <div data-bbox="516 517 1080 876" data-label="Diagram"> </div> <p>For an example of a triggered model, see model <code>sldemo_mdref_datamngt</code>.</p>
<p>Triggered and Enabled</p>	<p>A Model block can have both trigger and enable ports. If the enable control signal has a positive value at the time step for which a trigger event occurs, a triggered and enabled model executes once.</p>

Conditional Model	Description
Function-Call	<p>A function-call port executes a referenced model each time a function-call event occurs. To add a function-call port to a Model block, insert a Trigger block in the referenced model. Then, open the Block Parameters dialog box and set the Trigger type to <code>function-call</code>.</p> <p>A Stateflow chart, Function-Call Generator block, or an appropriately configured custom S-function can provide function-call events. See “Using Function-Call Subsystems” on page 10-44.</p> <p>This image displays the contents of a simple function-call referenced model.</p>  <p>For an example of a function-call model, see model <code>sldemo_mdref_fcncall</code>.</p>

Requirements for Conditional Models

Conditional models must meet the requirements for:

- Conditional subsystems (see “Conditionally Executed Subsystems and Models”)
- Referenced models (see “Reference Existing Models” on page 8-17)

Conditional models must also meet the requirements specific to each type of conditional model.

Conditional Model	Requirements
Enabled	<ul style="list-style-type: none"> • Multi-rate enabled models cannot use multi-tasking solvers. Use single-tasking. • For models with enable ports at the root, if the model uses a fixed-step solver, the fixed-step size of the model must not exceed the rate for any block in the model. • Signal attributes of the enable port in the referenced model must be consistent with the input that the Model block provides to that enable port.
Triggered	Signal attributes of the trigger port in the referenced model must be consistent with the input that the Model block provides to that trigger port.
Triggered and Enabled	See requirements for triggered models and enabled models.

Conditional Model	Requirements
Function-Call	<ul style="list-style-type: none"> • A function-call model cannot have an output driven only by Ground blocks, including hidden Ground blocks inserted by Simulink. To meet this requirement, do the following: <ol style="list-style-type: none"> 1 Insert a Signal Conversion block into the signal connected to the output. 2 Enable the Exclude this block from 'Block reduction' optimization option of the inserted block. • The parent model must trigger the function-call model at the rate specified by the Configuration Parameters > Solver 'Fixed-step size' option if the function-call model meets both these conditions: <ul style="list-style-type: none"> • It specifies a fixed-step solver. • It contains one or more blocks that use absolute or elapsed time. <p>Otherwise, the parent model can trigger the function-call model at any rate.</p> • A function-call model must not have direct internal connections between its root-level input and output ports. Simulink does not honor the None and Warning settings for the Invalid root Inport/Outport block connection diagnostic for a referenced function-call model. It reports all invalid root port connections as errors. • If the Sample time type is periodic, the sample-time period must not contain an offset. • The signal connected to a function-call port of a Model block must be scalar.

Modify a Referenced Model for Conditional Execution

- 1 At the root level of the referenced model, insert one of the following blocks:

Type of Model	Blocks to Insert
Enabled	Enable

Type of Model	Blocks to Insert
Triggered	Trigger
Triggered and Enabled	Trigger and Enable
Function-Call	Trigger

For an enabled model, go to Step 3.

- For the Trigger block, set the **Trigger type** parameter:

Type of Model	Trigger Type Parameter Setting
Triggered	One of the following:
Triggered and enabled	<ul style="list-style-type: none"> rising falling either
Function-Call	function-call

- Use the Model block ports to connect the referenced model to other ports in the parent model.
 - The top of the Model block displays an icon that corresponds to the control signal type expected by the referenced model. For a triggered model, the top of the Model block displays this icon.

- “Conditionally Executed Subsystems Overview” on page 10-3
- “Export-Function Models” on page 10-120

Inspect Model Hierarchies

To better understand a model hierarchy, you can use Simulink tools, functions, parameters, or preferences to:

- Preview model contents
- Visualize the model hierarchy
- List referenced models and Model blocks
- Display model version numbers

Content Preview

Content preview displays a representation of the contents of a referenced model on the Model block. This preview helps you to understand at a glance the kind of processing performed by the referenced model without opening the referenced model. See “Preview Content of Model Components” on page 1-60.

Model Dependency Viewer

The Model Dependency Viewer shows the structure of the model hierarchy and lets you open constituent models. The **Model Instances** view displays Model blocks differently to indicate Normal, Accelerator, SIL, and PIL modes. See “Model Dependency Viewer” on page 12-54.

The depview function opens the Model Dependency Viewer.

List of Model References

The `find_mdirefs` function lists all models that are directly or indirectly referenced by a given model. This function also provides the paths to the related Model blocks.

Find Referenced Models in Model Hierarchy

Find referenced models and Model blocks for all models referenced by the specified model.

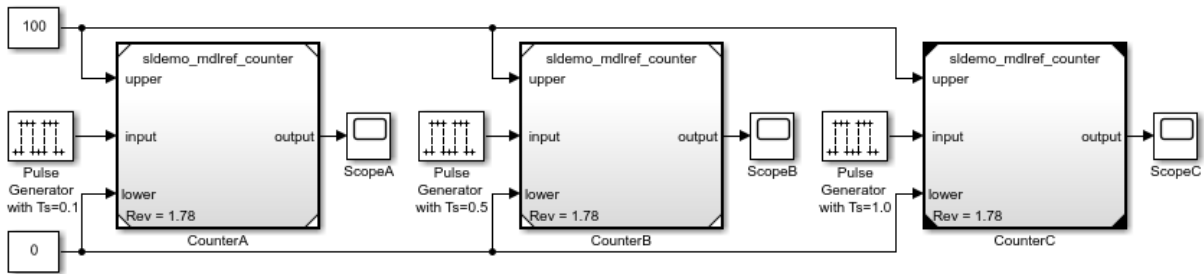

```
load_system('sldemo_mdiref_basic');
[myModels,myModelBlks] = find_mdirefs('sldemo_mdiref_basic')
```

```
myModels = 2x1 cell array
    {'sldemo_mdiref_counter'}
    {'sldemo_mdiref_basic' }
```

```
myModelBlks = 3x1 cell array
    {'sldemo_mdiref_basic/CounterA'}
    {'sldemo_mdiref_basic/CounterB'}
    {'sldemo_mdiref_basic/CounterC'}
```

Model Version Numbers

To display the version numbers of the referenced models, in the parent model, choose **Display > Blocks > Block Version for Referenced Models**. The version of each Model block instance appears on each Model block.

For information on model versions, see “Manage Model Versions and Specify Model Properties” on page 4-67.

Model Reference Interface

In this section...

“Refresh Model Blocks” on page 8-46

“Signal Propagation” on page 8-46

“Sample Time Requirements” on page 8-47

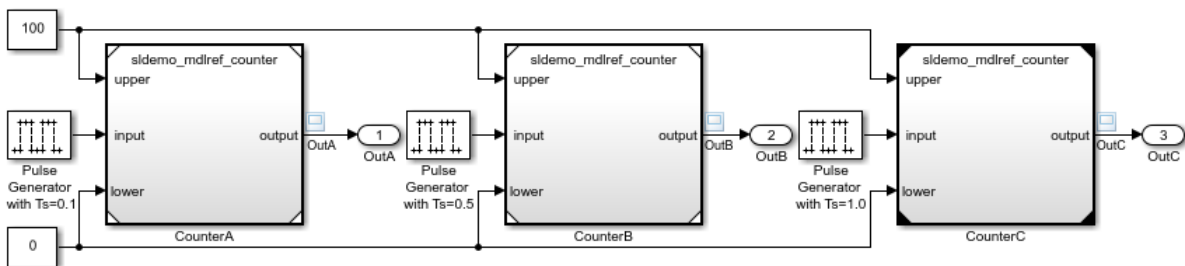

“Share Data Among Referenced Model Instances” on page 8-47

A Model block has input, output, and control ports that correspond to root-level input, output, and control ports of the model it references. A referenced model can include Inport, Outport, In Bus Element, Out Bus Element, Trigger, and Enable blocks to get input from the parent model and to provide output to the parent model. The input signals for the Model block must be valid for the corresponding input blocks of the referenced model. The output signals for the Model block are the referenced model root-level output block signals.

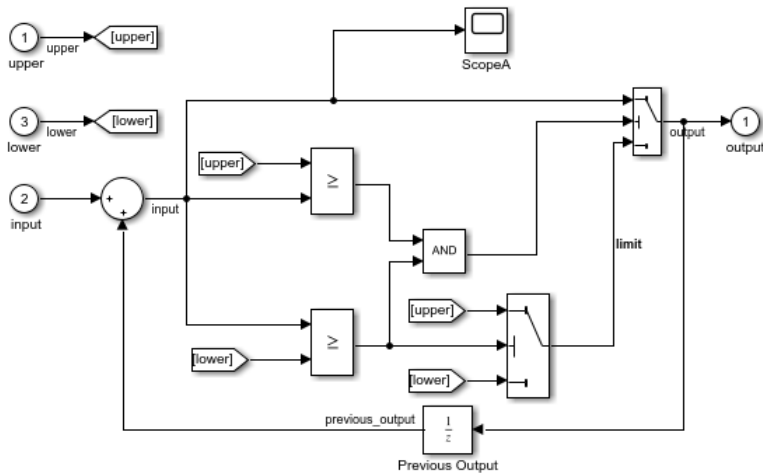

In `sldemo_mdref_basic`, each Model block has three inputs: two Constant blocks and a Pulse Generator block. Each Model block has one output signal logged to a scope. Because the input signal from each Pulse Generator block uses a different sample time, the output signal from each Model block differs for each model instance.

Component-Based Modeling with Model Reference

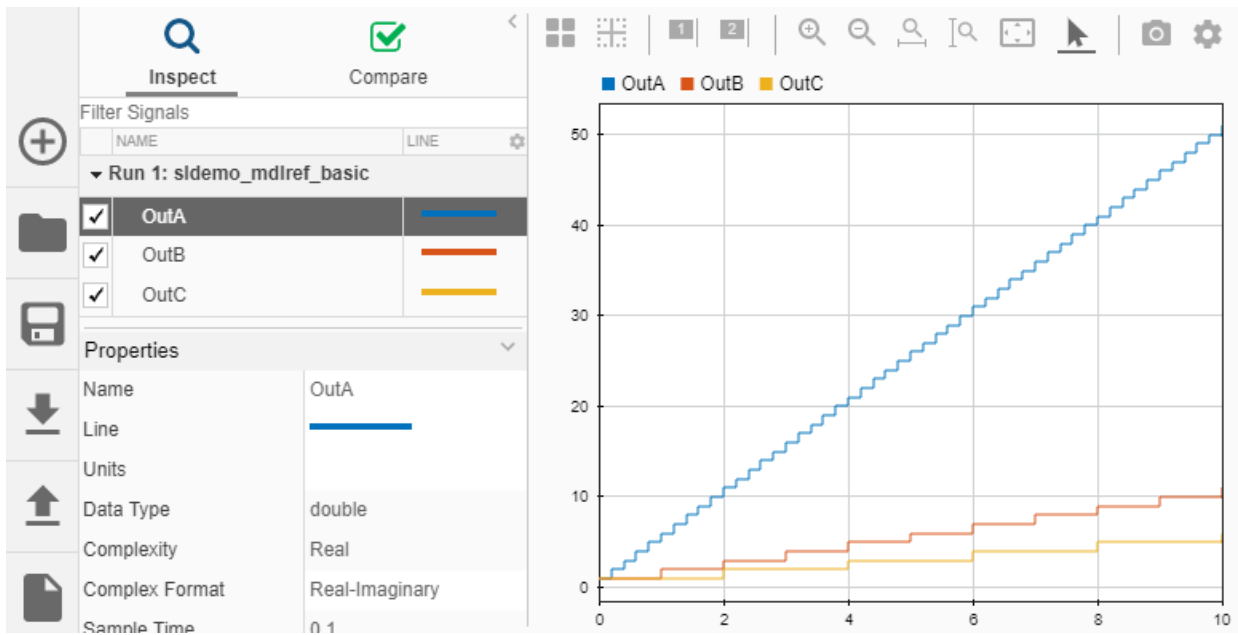

?

To connect to the parent model, referenced model `sldemo_mdref_counter` includes three Inport blocks (**upper**, **lower**, and **input**) and one Outport block (**output**). If you change the ports in the referenced model, refresh the Model block to reflect these changes.

To compare the output signals of each Model block, you can use the Simulation Data Inspector. In a referenced model, you can log any signal marked for signal logging.

To set up signal logging, see “Export Signal Data Using Signal Logging” on page 64-69. To log a subset of the signals marked for logging in a model hierarchy, see “Override Signal Logging Settings” on page 64-93. For an example that uses the Simulation Data Inspector with referenced models, see “Viewing Signals in Model Reference Instances”.

Refresh Model Blocks

Refreshing a Model block updates its internal representation to reflect changes to the interface of the referenced model. For example, when the referenced model gains or loses a port, refresh the Model block to update its ports.

To detect changes in referenced model interfaces that could require refreshing the related Model blocks, use Simulink diagnostics. These diagnostics include:

- **Model block version mismatch**
- **Port and parameter mismatch**

If changes to a referenced model interface do not affect how the referenced model interfaces to its parent, you do not need to refresh the Model block.

To refresh a specific Model block, from the context menu of the Model block, select **Subsystem & Model Reference > Refresh Selected Model Block**.

To refresh all Model blocks in a model (including linked blocks in a library or model), in the Simulink Editor, select **Diagram > Refresh Blocks**. Simulating or generating code for a model also refreshes all Model blocks in the model.

Signal Propagation

Signal attributes in a referenced model are independent from the context of the Model block. For example, signal dimensions and data types do not propagate across the Model block boundary. To define signal attributes in a referenced model, define block parameters for root-level Inport and In Bus Element blocks.

For signals that connect to Outport blocks to propagate out of a referenced model to the parent model, the signal names must explicitly appear on the signal lines.

For virtual buses that cross model reference boundaries, use In Bus Element and Out Bus Element blocks.

For nonvirtual buses that cross model reference boundaries, use Inport and Outport blocks that specify the same bus object as the related buses in the parent model. See “Bus Data Crossing Model Reference Boundaries” on page 68-161.

For an example of a model hierarchy that uses buses, see `sldemo_mderef_bus`.

A referenced model can only provide input or get output for user-defined data types that are fixed point or that `Simulink.DataType` or `Simulink.Bus` objects define.

Sample Time Requirements

The first nonvirtual block that connects to a referenced model root-level input or output block must have the same sample time as the related port. If the sample times are different, use Rate Transition blocks to match input and output sample times, as shown in this diagram.

Share Data Among Referenced Model Instances

By default, each Model block instance reads from and writes to a separate copy of the signals and block states in the model. Therefore, the instances do not interact with each other through shared signal or state data.

To share a piece of data between all of the instances (for example, an accumulator or a fault indicator), model the data as a data store.

- To restrict access to data so that only the blocks in the referenced model can read from and write to it, use a Data Store Memory block in the model and select the **Share across model instances** parameter. For an example, see “Share Data Store Between Instances of a Reusable Algorithm”.

- To allow access to data outside the referenced model, use a global data store, which is a `Simulink.Signal` object in the base workspace or a data dictionary. Data outside the referenced model can be in the parent model or in other referenced models.

For more information about data stores, see “Model Global Data by Creating Data Stores” on page 65-13.

Referenced Model Sample Times

In this section...

“How Sample-Time Inheritance Works for Model Blocks” on page 8-49

“Conditions for Inheriting Sample Times” on page 8-49

“Determining Sample Time of a Referenced Model” on page 8-50

“Blocks That Depend on Absolute Time” on page 8-50

“Blocks Whose Outputs Depend on Inherited Sample Time” on page 8-51

“Sample Time Consistency” on page 8-52

“Sample Rates and Solvers” on page 8-53

How Sample-Time Inheritance Works for Model Blocks

The sample times of a Model block are the sample times of the model that it references. If the referenced model must run at specific rates, the model specifies the required rates. Otherwise, the referenced model inherits its sample time from the parent model.

Placing a Model block in a triggered, function call, or iterator subsystem relies on the ability to inherit sample times. Also, allowing a Model block to inherit sample time maximizes its reuse potential. For example, a model can fix the data types and dimensions of all its input and output signals. You could reuse the model with different sample times (for example, discrete at 0.1 or discrete at 0.2, triggered).

Conditions for Inheriting Sample Times

A referenced model inherits its sample time if the model:

- Does not have any continuous states
- Specifies a fixed-step solver and the **Fixed-step size** is auto
- Contains no blocks that specify sample times (other than inherited or constant)
- Does not contain any S-functions that use their specific sample time internally
- Has only one sample time (not counting constant and triggered sample time) after sample time propagation
- Does not contain any blocks, including Stateflow charts, that use absolute time, as listed in “Blocks That Depend on Absolute Time” on page 8-50

- Does not contain any blocks whose outputs depend on inherited sample time, as listed in “Blocks Whose Outputs Depend on Inherited Sample Time” on page 8-51.

You can use a referenced model that inherits its sample time anywhere in a parent model. By contrast, you cannot use a referenced model that has intrinsic sample times in a triggered, function call, or iterator subsystem. To avoid rate transition errors, ensure that blocks connected to a referenced model with intrinsic samples times operate at the same rates as the referenced model.

Note A continuous sample time cannot be propagated to a Model block that is sample-time independent.

For more information, see “Blocks Whose Outputs Depend on Inherited Sample Time” on page 8-51.

Determining Sample Time of a Referenced Model

To determine whether a referenced model can inherit its sample time, set the **Periodic sample time constraint** configuration parameter to `Ensure sample time independent`. If the model is unable to inherit sample times, this setting causes Simulink to display an error message when building the model. See “Periodic sample time constraint” for more about this option.

To determine the intrinsic sample time of a referenced model, or the fastest intrinsic sample time for multirate referenced models:

- 1 Update the model that references the model
- 2 Select a Model block within the parent model
- 3 Enter the following at the MATLAB command line:

```
get_param(gcf, 'CompiledSampleTime')
```

Blocks That Depend on Absolute Time

The following Simulink blocks depend on absolute time, and therefore preclude a referenced model from inheriting sample time:

- Backlash (only when the model uses a variable-step solver and the block uses a continuous sample time)

- Chirp Signal
- Clock
- Derivative
- Digital Clock
- Discrete-Time Integrator (only when used in triggered subsystems)
- From File
- From Workspace
- Pulse Generator
- Ramp
- Rate Limiter
- Repeating Sequence
- Signal Generator
- Sine Wave (only when the **Sine type** parameter is Time-based)
- `stateflow` (when the chart uses absolute-time temporal logic, or the reserved word `t` to reference time)
- Step
- To File
- To Workspace (only when logging to Timeseries or Structure With Time format)
- Transport Delay
- Variable Time Delay
- Variable Transport Delay

Some blocks other than Simulink blocks depend on absolute time. See the documentation for the blocksets that you use.

Blocks Whose Outputs Depend on Inherited Sample Time

Using a block whose output depends on an inherited sample time in a referenced model can cause simulation to produce unexpected or erroneous results. When building a referenced model that does not need a specified rate, Simulink checks for blocks whose outputs are functions of the inherited sample time. This checking includes examining S-Function blocks. If Simulink finds any such blocks, it specifies a default sample time. If you have set the **Configuration Parameters > Solver > Periodic sample time**

constraint to Ensure sample time independent, Simulink displays an error. See “Periodic sample time constraint” for more about this option.

The outputs of the following built-in blocks depend on inherited sample time. The outputs of these blocks preclude a referenced model from inheriting its sample time from the parent model:

- Discrete-Time Integrator
- From Workspace (if it has input data that contains time)
- Probe (if probing sample time)
- Rate Limiter
- Sine Wave

Simulink assumes that the output of an S-function does not depend on inherited sample time unless the S-function explicitly declares the contrary. See “Specify S-Function Sample Times” for information on how to create S-functions that declare whether their output depends on their inherited sample time.

In referenced models that inherit their sample time, avoid S-functions in referenced models that fail to declare whether output depends on inherited sample time. Excluding those kinds of S-functions helps to avoid simulation errors. By default, Simulink warns you if your model contains such blocks when you update or simulate the model. See “Unspecified inheritability of sample time” for details.

Sample Time Consistency

Use consistent sample time rates to promote the reliable use of a model referenced by another model. Make the rates of root Inport and Outport blocks in a referenced model consistent with the rates of blocks reading from and writing to those blocks. Simulink generates an error when there are sample time mismatches between:

- The sample times of root Inport blocks and the sample times of blocks to which the Inport block inputs.
- The sample times of root Outport blocks and the sample times of blocks that input to the Outport block.

To address an error that flags a sample time inconsistency in a referenced model, you can use one of these approaches.

Root Inport or Output Block Sample Time is Different From	Possible Solution
All the blocks to which it connects, and those blocks all have the same sample time as each other	Set the sample time of the Inport or Output block so that it matches the sample time of the block to which it connects.
One or more blocks and the same as one or more blocks	For blocks that do not match the Inport or Output block, insert Rate Transition blocks on the signal that connects to the Inport or Output block.

Sample Rates and Solvers

The solver of the topmost model controls all continuous sample times in a model hierarchy. For example, for a fixed-step solver, all continuous rates in referenced models run at the fixed-step size of the topmost model. For information about how sample times impact solvers, see “Types of Sample Time” on page 7-15.

Simulate Model Hierarchies

In this section...
“Simulate a Top Model” on page 8-54
“Referenced Model Simulation” on page 8-54
“Simulate Conditional Referenced Models” on page 8-60
“Log Signals in Referenced Models” on page 8-61
“Set Diagnostics and Debug Model Hierarchies” on page 8-62
“Index Information Propagation” on page 8-62

Simulating a model that uses model reference differs in some ways from simulating a standalone model that does not use model reference.

There are some limitations for simulating model hierarchies. For details, see “Simulation Requirements and Limitations” on page 8-12 and “Signal Requirements and Limitations” on page 8-12.

Simulate a Top Model

The top model in a model hierarchy executes the same way that models without model references execute. The top model supports all Simulink simulation modes. To speed up execution of a top model in a model hierarchy, you can use Simulink accelerator or rapid accelerator mode. For information about accelerator mode, see “Acceleration”. For information about rapid accelerator mode, see “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” (Simulink Coder).

When you execute a top model in accelerator or rapid accelerator mode, all referenced models execute in accelerator mode.

Referenced Model Simulation

You can simulate a referenced model in one of these modes:

- Normal
- Accelerator
- Software-in-the-loop (SIL)

- Processor-in-the-loop (PIL)

For more information about using these simulation modes for referenced models, see “Comparison of Simulation Modes for Referenced Models” on page 8-55.

The simulation modes used for referenced models depend on the simulation mode of the parent model. For details, see “Parent and Referenced Model Simulation Modes” on page 8-59.

Specify the Simulation Mode for Referenced Models

The Model block for each instance of a referenced model controls the simulation mode of the instance. To set or change the simulation mode for a referenced model:

- 1** Access the block parameter dialog box for the Model block.
- 2** Set the **Simulation mode** parameter.
- 3** Click **OK** or **Apply**.

Comparison of Simulation Modes for Referenced Models

You can use rapid accelerator mode for the top model in a model hierarchy, but not for Model blocks. You can set referenced models to rapid accelerator mode, but the simulation mode of the top model, parent Model block, or referenced model Model block overrides the referenced model simulation mode.

The different simulation modes for referenced models share many capabilities and techniques, but they have different implementations, requirements, and limitations.

Tip Accelerator mode execution of a referenced model is different from:

- Accelerator mode execution of a freestanding or top model, as described in “Acceleration”.
- Rapid Accelerator mode execution of a freestanding or top model, as described in “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” (Simulink Coder).

For more information about Accelerator mode execution of a referenced model, see “Model Reference Simulation Targets” on page 8-72.

Simulation Mode	Description	When to Use
Normal	Executes referenced model interpretively.	<p>Compared to other simulation modes, normal mode:</p> <ul style="list-style-type: none"> • Executes slower. • Requires no delay for code generation or compilation. • Works with more Simulink and Stateflow tools, supporting tools such as: <ul style="list-style-type: none"> • Scopes, port value display, and other output viewing tools. • Model coverage analysis. • Stateflow debugging and animation. • Provides more accurate linearization analysis. • Supports more S-functions than accelerator mode does. <p>When you simulate multiple instances of a referenced model in normal mode, Simulink software displays results for only one of the normal-mode instances. For details, see “Simulate Multiple Referenced Model Instances in Normal Mode” on page 8-64.</p>

Simulation Mode	Description	When to Use
Accelerator	<p>Executes the referenced model by creating a MEX-file (a simulation target) for the referenced model, then running the MEX-file.</p> <p>For more information, see “Model Reference Simulation Targets” on page 8-72.</p>	<ul style="list-style-type: none"> • Executes faster than normal mode. • Takes time for code generation and code compilation. • Does not fully support some Simulink tools, such as Model Coverage and the Simulink Debugger. • Supports Scope blocks, but requires using the Signal & Scope Manager and adding test points to signals. Adding or removing a test point requires rebuilding the SIM target for a model.
SIL	<p>Executes referenced model by generating production code. This code is compiled for, and executed on, the host platform.</p> <p>Requires Embedded Coder® software. For more information, see “SIL and PIL Limitations” (Embedded Coder) and “Numerical Equivalence Testing” (Embedded Coder).</p>	<ul style="list-style-type: none"> • Verifies generated source code without modifying the original model. • Supports the reuse of test harnesses for the original model with the generated source code. <p>SIL mode provides a convenient alternative to PIL simulation when the target hardware is not available.</p>

Simulation Mode	Description	When to Use
PIL	<p>Executes referenced model by generating production code. This code is cross-compiled for, and executed on, a target processor or an equivalent instruction set simulator.</p> <p>Requires Embedded Coder software. For more information, see “SIL and PIL Limitations” (Embedded Coder) and “Numerical Equivalence Testing” (Embedded Coder).</p>	<ul style="list-style-type: none"> • Verifies deployment object code on target processors without modifying the original model. • Supports the reuse of test harnesses for the original model with the generated source code.

Note Simulation results for a given model are nearly identical in normal and accelerator modes. Trivial differences can occur, depending on differences in the optimizations and libraries that you use.

Configuration parameter setting requirements and behavior can vary depending on the simulation mode. For details, see “Accelerated Simulation and Code Generation Changes Settings” on page 8-88 and “Diagnostics That Are Ignored in Accelerator Mode” on page 8-87.

Diagnostic Configuration Parameters Ignored in Accelerator Mode

For models referenced in accelerator mode, Simulink ignores the values of these configuration parameter settings if you set them to a value other than **None**:

- **Array bounds exceeded** (ArrayBoundsChecking)
- **Inf or NaN block output** (SignalInfNanChecking)
- **Simulation range checking** (SignalRangeChecking)
- **Division by singular matrix** (CheckMatrixSingularityMsg)

- **Wrap on overflow** (IntegerOverflowMsg)

Also, for models referenced in accelerator mode, Simulink ignores these configuration parameters when you set them to a value other than `Disable all`. For details, see “Data Store Diagnostics” on page 65-3.

- **Detect read before write** (ReadBeforeWriteMsg)
- **Detect write after read** (WriteAfterReadMsg)
- **Detect write after write** (WriteAfterWriteMsg)

You can use the Model Advisor to identify models referenced in accelerator mode for which Simulink ignores these configuration parameters.

- 1 In the Simulink Editor, select **Analysis > Model Advisor**.
- 2 Select **By Task**.
- 3 Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

To see the results of running the identified diagnostics with settings to produce warnings or errors, simulate the model in normal mode. Inspect the diagnostic warnings and then simulate in accelerator mode.

Parent and Referenced Model Simulation Modes

The simulation modes you can use for a referenced model depend on the simulation mode of its parent model.

Parent Model Simulation Mode	Referenced Model Simulation Modes
Normal	<ul style="list-style-type: none"> • Referenced models can use normal, accelerator, SIL, or PIL mode. • If every model that is superior to a referenced model in the model hierarchy also executes in normal mode, that referenced model can execute in normal mode.

Parent Model Simulation Mode	Referenced Model Simulation Modes
Accelerator	<ul style="list-style-type: none"> • All subordinate models must also execute in accelerator mode. • When a normal mode model is subordinate to an accelerator mode model, Simulink returns a warning and temporarily overrides the normal mode specification. • When a SIL-mode or PIL-mode model is subordinate to an accelerator mode model that is not the top model, an error occurs.
SIL	<ul style="list-style-type: none"> • If their simulation modes are normal, accelerator, or SIL, all subordinate models also execute in SIL mode. Otherwise, an error occurs. See “Simulation Mode Override Behavior in Model Reference Hierarchy” (Embedded Coder). • Multiple Model blocks, starting at the top of a model hierarchy, can execute in SIL mode. However, if code coverage or code execution profiling is enabled, only one Model block can execute at a time in SIL mode.
PIL	<ul style="list-style-type: none"> • If their simulation modes are normal, accelerator, or PIL, all subordinate models also execute in PIL mode. Otherwise, an error occurs. See “Simulation Mode Override Behavior in Model Reference Hierarchy” (Embedded Coder). • Multiple Model blocks, starting at the top of a model hierarchy, can execute in PIL mode. However, if code coverage or code execution profiling is enabled, only one Model block can execute at a time in PIL mode.

Simulate Conditional Referenced Models

- “Triggered, Enabled, and Triggered and Enabled Models” on page 8-61
- “Function-Call Models” on page 8-61

You can run a standalone simulation of a conditional referenced model. A standalone simulation is useful for unit testing because it provides consistent data across simulations

in terms of data type, dimension, and sample time. Use normal, accelerator, or rapid accelerator mode to simulate a conditional model.

Triggered, Enabled, and Triggered and Enabled Models

Triggered, enabled, and triggered and enabled models require an external input to drive the Trigger or Enable blocks. In the **Signal Attributes** pane of the Trigger or Enable block dialog box, specify values for the signal data type, dimension, and sample time.

To run a standalone simulation, specify the inputs using the **Input** parameter. For details about how to specify the input, see “Comparison of Signal Loading Techniques” on page 64-125. The following conditions apply when you use the “Input” parameter for trigger and enable block inputs:

- Use the last data input for the trigger or enable input. For a triggered and enabled model, use the last data input for the trigger input.
- If you do not provide any input values, the simulation uses zero as the default values.

You can log data to determine which signal caused the model to run. For the Trigger or Enable block, in the **Main** pane of the Block Parameters dialog box, select **Show output port**.

Function-Call Models

When you simulate a function-call model, it simulates as if a function call at the fastest rate for the system drives the function-call block. You can also configure the model to calculate output at specific times using a variable-step solver (see “Samples to Export for Variable-Step Solvers” on page 64-65).

Log Signals in Referenced Models

In a referenced model, you can log any signal configured for signal logging. Use the Signal Logging Selector to select a subset or all the signals configured for signal logging in a model hierarchy. For details, see “Models with Model Referencing: Overriding Signal Logging Settings” on page 64-97.

You can use the Simulation Data Inspector to view and analyze signals logged in referenced models. You can view signals on multiple plots, zoom, and use data cursors to understand and evaluate the data. Also, you can compare signal data from multiple simulations. For an example of viewing signals with referenced models, see “Viewing Signals in Model Reference Instances”.

Set Diagnostics and Debug Model Hierarchies

You can enable or suppress warning messages about mismatches between a Model block and its referenced model by setting diagnostics on the **Diagnostics Pane: Model Referencing**.

Working with the Simulink Debugger in a parent model, you can set breakpoints at Model block boundaries. Setting breakpoints allows you to look at the input and output values of the Model block. However, you cannot set a breakpoint inside the model that the Model block references. See “Simulink Debugger” for more information.

Index Information Propagation

In two cases, Simulink does not propagate 0-based or 1-based indexing information to referenced model root-level ports connected to blocks that:

- Accept indexes (such as the Assignment block)
- Produce indexes (such as the For Iterator block)

An example of a block that accepts indexes is the Assignment block. An example of a block that produces indexes is the For Iterator block.

The two cases result in a lack of propagation that can cause Simulink to fail to detect incompatible index connections. These two cases are:

- If a root-level input port of the referenced model connects to index inputs in the model that have different 0-based or 1-based indexing settings, Simulink does not set the 0-based or 1-based indexing property of the root-level Inport block.
- If a root-level output port of the referenced model connects to index outputs in the model that have different 0-based or 1-based indexing settings, Simulink does not set the 0-based or 1-based indexing property of the root-level Outport block.

Simulate Multiple Referenced Model Instances in Normal Mode

In this section...
“Normal Mode Visibility” on page 8-64
“Example Models with Multiple Referenced Model Instances” on page 8-64
“Configure Models with Multiple Referenced Model Instances” on page 8-66
“Specify the Instance Having Normal Mode Visibility” on page 8-67

Normal Mode Visibility

All instances of a normal-mode referenced model are part of the simulation. However, Simulink software displays only one instance in a model window. Normal mode visibility includes the display of Scope blocks and data port values.

Set normal mode visibility by selecting in the top model the **Diagram > Subsystem & Model Reference > Model Block Normal Mode Visibility**. This setting determines the instance that Simulink software displays. If you do not specify normal mode visibility for a specific instance of a referenced model, Simulink software selects one instance of the referenced model to display.

After a simulation, if you try to open a referenced model from a Model block that does not have normal mode visibility, Simulink software displays a warning.

To set up your model to control which instance of a referenced model in normal mode has visibility and to ensure proper simulation of the model, see “Specify the Instance Having Normal Mode Visibility” on page 8-67.

Example Models with Multiple Referenced Model Instances

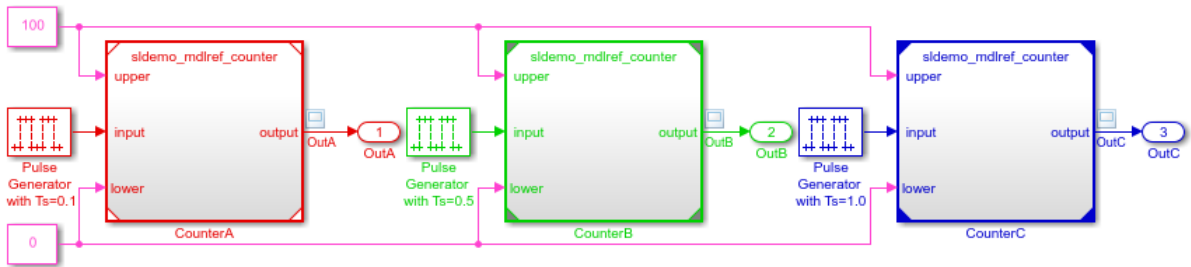

The `sldemo_mdhref_basic` model and the “Visualizing Model Reference Architectures” featured example show the use of models containing multiple instances of a referenced model.

`sldemo_mdhref_basic`

The `sldemo_mdhref_basic` model has three Model blocks (CounterA, CounterB, and CounterC) that each reference the `sldemo_mdhref_counter` model.

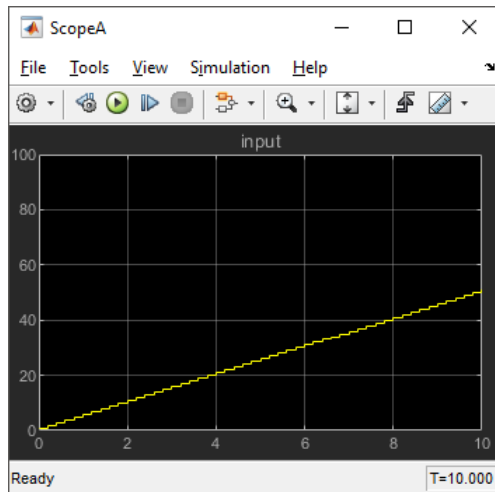

If you update the diagram, the `sldemo_mdref_basic` displays different icons for each of the three Model blocks that reference `sldemo_mdref_counter`.

Component-Based Modeling with Model Reference

Model Block	Icon Corners	Simulation Mode and Normal Mode Visibility Setting
CounterA	White	Normal mode, with normal mode visibility enabled
CounterB	Gray corners	Normal mode, with normal mode visibility disabled
CounterC	Black corner	Accelerator mode (normal mode visibility is not applicable)

Open and simulate `sldemo_mdref_basic`. Double-click the CounterA model and open the ScopeA block.

That ScopeA block reflects the results of simulating the CounterA Model block, which has normal mode visibility enabled.

If you try to open mdlref_counter model by double-clicking the CounterB Model block, ScopeA in mdlref_counter still shows the results of the CounterA Model block because that block has normal mode visibility enabled.

Visualizing Model Reference Architectures

The featured example Visualizing Model Reference Architectures shows the use of the Model Dependency Viewer for a model (sldemo_mdref_depgraph) that references multiple instances of a referenced model in normal mode. The example shows how to set up a model with multiple referenced instances in normal mode.

Configure Models with Multiple Referenced Model Instances

- 1 Set the **Total number of instances allowed per top model** parameter to **Multiple**.
- 2 Set each instance of the referenced model so that it uses normal mode. In the block parameters dialog box for the Model block that references the instance, set the **Simulation Mode** parameter to **Normal**. Ensure that all the ancestors in the hierarchy for that Model block are in normal mode.

The corners of icons for Model blocks that are in normal mode can be white (empty). The corners turn gray after you update the diagram or simulate the model.

- 3 If necessary, modify S-functions used by the model so that they work with multiple instances of referenced models in normal mode. For details, see “Supporting the Use of Multiple Instances of Referenced Models That Are in Normal Mode”.

By default, Simulink assigns normal mode visibility to one of the instances. After you complete the configuration steps, you can specify a non-default instance to have normal mode visibility.

For more information about encapsulating a reusable algorithm in a referenced model, see “Model Reuse” on page 8-8.

Specify the Instance Having Normal Mode Visibility

Determine Which Instance Has Normal Mode Visibility

To determine which instance currently has normal mode visibility:

- 1 To apply the normal mode visibility setting, update the diagram and make no other changes to the model.
- 2 Examine the Model blocks that reference the model that you are interested in. The Model block that has white corners has normal mode visibility enabled, navigate through the model hierarchy.

When you are editing a model or during compilation, after updating the diagram, use the `ModelReferenceNormalModeVisibilityBlockPath` parameter. The result is a `Simulink.BlockPath` object that is the block path for the Model block that references the model that has normal mode visibility enabled. For example:

```
get_param('sldemo mdlref_basic',...
'ModelReferenceNormalModeVisibilityBlockPath')
```

```
ans =
```

```
Simulink.BlockPath
Package: Simulink
```

```
Block Path:
'sldemo mdlref_basic/CounterA'
```

For a top model that you are simulating or that is in a compiled state, you can use the `CompiledModelBlockInstancesBlockPath` parameter. For example:

```
a = get_param('sldemo_mdhref_depgraph', ...  
            'CompiledModelBlockInstancesBlockPath')  
  
a =  
  
            sldemo_mdhref_F2C: [1x1 Simulink.BlockPath]  
            sldemo_mdhref_heater: [1x1 Simulink.BlockPath]  
sldemo_mdhref_outdoor_temp: [1x1 Simulink.BlockPath]
```

Enable Normal Mode Visibility for an Instance

Note You cannot change normal mode visibility during simulation.

To enable normal mode visibility for a different instance of the referenced model than the instance that currently has normal mode visibility:

- 1 Navigate to the top model.
- 2 In the Simulink Editor, select the **Diagram > Subsystem & Model Reference > Model Block Normal Mode Visibility**.

The Model Block Normal Mode Visibility dialog box appears. For example, here is the dialog box for the `sldemo_mdhref_basic` model, with the hierarchy pane expanded:

The model hierarchy pane shows a partial model hierarchy for the model from which you opened the dialog box. The hierarchy stops at the first Model block that is not in normal mode. The model hierarchy pane does not display Model blocks that reference protected models.

The dialog box shows the complete model block hierarchy for the top model. The normal mode instances of referenced models have check boxes.

Tip To have the model hierarchy pane of the Model Block Normal Mode Visibility dialog box reflect the current model hierarchy, click **Refresh**.

- 3 Select the instance of the model that you want to have normal mode visibility.

Simulink selects all ancestors of the model and clears all other instances of that model. When a model is cleared, Simulink clears all children of that model.

Tip To open a model from the Model Block Normal Mode Visibility dialog box, right-click the model in the model hierarchy pane and then click **Open**.

- 4 To apply the normal mode visibility setting, simulate the top model in the model hierarchy.

As an alternative to using the Model Block Normal Mode Visibility dialog box, at the MATLAB command line you can use the `ModelBlockNormalModeVisibility` parameter. For input, you can specify one of these values:

- An array of `Simulink.BlockPath` objects. For example:

```
bp1 = Simulink.BlockPath({'mVisibility_top/Model', ...
    'mVisibility_mid_A/Model'});
bp2 = Simulink.BlockPath({'mVisibility_top/Model1', ...
    'mVisibility_mid_B/Model1'});
bps = [bp1, bp2];
set_param(topMdl, 'ModelBlockNormalModeVisibility', bps);
```

- A cell array of cell arrays of character vectors, with the character vectors being paths to individual blocks and models. This example produces the same effect as the object array example:

```
p1 = {'mVisibility_top/Model', 'mVisibility_mid_A/Model'};  
p2 = {'mVisibility_top/Model1', 'mVisibility_mid_B/Model1'};  
set_param(topMdl, 'ModelBlockNormalModeVisibility', {p1, p2});
```

- An empty array, to specify the use of the Simulink default selection of the instance that has normal mode visibility. For example:

```
set_param(topMdl, 'ModelBlockNormalModeVisibility', []);
```

Using an empty array is equivalent to clearing all the check boxes in the Model Block Normal Mode Visibility dialog box.

“Build Simulation Targets” on page 8-73
“Simulation Target Output File Control” on page 8-74
“Reduce Update Time for Referenced Models” on page 8-76

Simulation Targets

A simulation target, or SIM target, is a MEX-file that implements a referenced model that executes in accelerator mode. Simulink invokes the simulation target as needed during simulation to compute the behavior and outputs of the referenced model. Simulink uses the same simulation target for all accelerator mode instances of a given referenced model anywhere in a reference hierarchy.

If you have a Simulink Coder license, be careful not to confuse the simulation target of a referenced model with any of these other types of target:

- Hardware target — A platform for which Simulink Coder generates code
- System target — A file that tells Simulink Coder how to generate code for particular purpose
- Rapid Simulation target (RSim) — A system target file supplied with Simulink Coder
- Model reference target — A library module that contains Simulink Coder code for a referenced model

Simulink creates a simulation target only for a referenced model that has one or more accelerator mode instances in a reference hierarchy. A referenced model that executes only in normal mode always executes interpretively and does not use a simulation target. When one or more instances of a referenced model executes in normal mode, and one or more instances executes in accelerator mode:

- Simulink creates a simulation target for the accelerator mode instances.
- The normal mode instances do not use that simulation target.

Because accelerator mode requires code generation, it imposes some requirements and limitations that do not apply to normal mode. Aside from these constraints, you can

generally ignore simulation targets and their details when you execute a referenced model in accelerator mode. See “Simulation Requirements and Limitations” on page 8-12 for details.

Build Simulation Targets

Simulink by default generates the needed target from the referenced model:

- If a simulation target does not exist at the beginning of a simulation
- When you perform an update diagram for a parent model

If the simulation target exists, then by default Simulink checks whether the referenced model has structural changes since the target was last generated. If so, Simulink regenerates the target to reflect changes in the model. For details about how Simulink detects whether to rebuild a model reference target, see the “Rebuild” parameter documentation.

You can change this default behavior to modify the rebuild criteria or specify that Simulink always or never rebuilds targets. See “Rebuild” for details.

To generate simulation targets interactively for accelerator mode referenced models, do one of these steps:

- Update the diagram on a model that directly or indirectly references the model that is in accelerator mode
- Execute the `slbuild` command with appropriate arguments at the MATLAB command line

While generating a simulation target, Simulink displays status messages at the MATLAB command line to enable you to monitor the target generation process. Target generation entails generating and compiling code and linking the compiled target code with compiled code from standard code libraries to create an executable file.

Reduce Change Checking Time

You can reduce the time that Simulink spends checking whether any or all simulation targets require rebuilding by setting configuration parameter values as follows:

- In all referenced models throughout the hierarchy, set the **Signal resolution** configuration parameter to `Explicit only` or `None`. (See “Signal resolution”.)

- To minimize change detection time, consider setting the **Rebuild options** configuration parameter to `If any changes in known dependencies detected on the top model`. See “Rebuild”.

These parameter values exist in the configuration set of a referenced model, not in the individual Model block. Setting either value for any instance of a referenced model sets it for all instances of that model.

Simulation Target Output File Control

Simulink creates simulation targets in the `s\prj` subfolder of the working folder. If `s\prj` does not exist, Simulink creates it.

Note Simulink Coder code generation also uses the `s\prj` folder. Subfolders in `s\prj` provide separate places for simulation code, Simulink Coder code, and other files. For details, see “Manage Build Process Folders” (Simulink Coder).

By default, files generated by Simulink diagram updates and model builds are placed in a build folder, the root of which is the current working folder (`pwd`). You can place generated files in a root folder outside the current working folder. This option allows you to:

- Store generated files separate from the models and other source materials used to generate them.
- Reuse or share previously built simulation targets without having to set the current working folder back to a previous working folder.

You can separate generated simulation artifacts from generated production code.

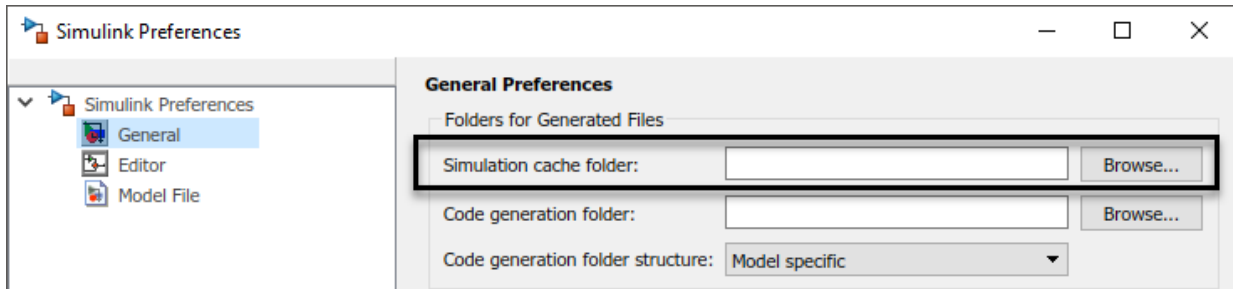

To control the output locations for files generated by diagram updates and model builds, specify the build folder for these files separately. The simulation cache folder is the root folder in which to place artifacts used for simulation.

To specify the simulation cache folder, use *one* of these approaches:

- Use the `CacheFolder` MATLAB session parameter.
- In the **Simulink Preferences > General** dialog box, use the **Simulation cache folder** preference. This preference provides the initial defaults for the MATLAB session parameters.

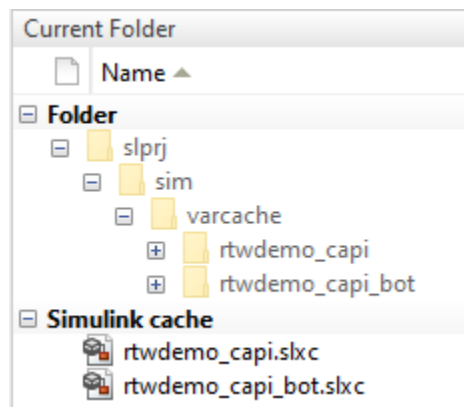

Control Output Location for Model Simulation Build Artifacts

To control the output location for files generated by Simulink diagram updates, in the **Simulink Preferences > General** dialog box, use the **Simulation cache folder** preference. To specify the root folder location for files generated by Simulink diagram updates, set the preference value by entering or browsing to a folder path, for example:

The folder path that you specify provides the initial default for the MATLAB session parameter `CacheFolder`. When you initiate a Simulink diagram update, generated files are placed in a build folder at the root location specified by `CacheFolder`, rather than in the current working folder (`pwd`).

For example, using a 32-bit (Windows trademark) host platform, if you set the **Simulation cache folder** to 'C:\Work\mymodelsimcache' and then simulate the model `rtwdemo_capi`, files are generated into the specified folder as follows:

As an alternative to using the Simulink preferences to set **Simulation cache folder**, you also can get and set the preference value from the command line using `get_param` and `set_param`. For example,

```
>> get_param(0, 'CacheFolder')  
  
ans =  
  
    ''  
  
>> set_param(0, 'CacheFolder', fullfile('C:', 'Work', 'mymodelsimcache'))  
>> get_param(0, 'CacheFolder')  
  
ans =  
  
C:\Work\mymodelsimcache
```

Also, you can choose to override the **Simulation cache folder** preference value for the current MATLAB session.

Override Build Folder Settings

The Simulink preferences **Simulation cache folder** and **Code generation folder** provide the initial defaults for the MATLAB session parameters `CacheFolder` and `CodeGenFolder`, which determine where files generated by Simulink diagram updates and model builds are placed. However, you can override these build folder settings during the current MATLAB session, using the `Simulink.fileGenControl` function. This function allows you to manipulate the MATLAB session parameters (for example, overriding or restoring the initial default values) directly. The values you set using `Simulink.fileGenControl` expire at the end of the current MATLAB session.

Reduce Update Time for Referenced Models

- “Parallel Building for Large Model Reference Hierarchies” on page 8-76
- “Parallel Building Configuration Requirements” on page 8-77
- “Update Models in a Parallel Computing Environment” on page 8-78
- “Locate Parallel Build Logs” on page 8-79

Parallel Building for Large Model Reference Hierarchies

In a parallel computing environment, you can increase the speed of diagram updates for models containing large model reference hierarchies by building referenced models that are configured in accelerator mode in parallel whenever conditions allow. For example, if

you have Parallel Computing Toolbox software, updating of each referenced model can be distributed across the cores of a multicore host computer. Also, if you have MATLAB Parallel Server™ software, updating of each referenced model can be distributed across remote workers in your MATLAB Parallel Server configuration.

The performance gain realized by using parallel builds for updating referenced models depends on several factors, including:

- How many models can be built in parallel for a given model referencing hierarchy
- The size of the referenced models
- The parallel computing resources, such as number of local or remote workers available and the hardware attributes of the local and remote machines (amount of RAM, number of cores, and so on)

For configuration requirements that can apply to your parallel computing environment, see “Parallel Building Configuration Requirements” on page 8-77.

For a description of the general workflow for building referenced models in parallel whenever conditions allow, see “Update Models in a Parallel Computing Environment” on page 8-78.

Parallel Building Configuration Requirements

These requirements apply to using parallel builds for updating model reference hierarchies:

- For local pools, the host machine needs an appropriate amount of RAM available for supporting the number of local workers (MATLAB sessions) that you plan to use. For example, using `parpool(4)` to create a parallel pool with four workers results in five MATLAB sessions on your machine, each using approximately 120 MB of memory at startup.
- Remote MATLAB Parallel Server workers participating in a parallel build must use a common platform and compiler.
- Set up a consistent MATLAB environment for each MATLAB worker session and the MATLAB client session. For example, use consistent shared base workspace variables, MATLAB path settings, and so forth. One approach is to use the `PreLoadFcn` callback of the top model. If you configure your model to load the top model with each MATLAB worker session, its preload function can be used for any MATLAB worker session setup.

Update Models in a Parallel Computing Environment

To take advantage of parallel building for a model reference hierarchy:

- 1 Set up a pool of local and/or remote MATLAB workers in your parallel computing environment.
 - a Make sure that Parallel Computing Toolbox software is licensed and installed.
 - b To use remote workers, make sure that MATLAB Parallel Server software is licensed and installed.
 - c Issue MATLAB commands to set up the worker pool, for example, `parpool(4)`.
- 2 From the top model of the model reference hierarchy, open the Configuration Parameters dialog box. Go to the **Model Referencing** pane and select the **Enable parallel model reference builds** option. This selection enables the parameter **MATLAB worker initialization for builds**.

For **MATLAB worker initialization for builds**, select one of the following values:

- **None** - The software performs no special worker initialization. Specify this value if the child models in the model reference hierarchy do not rely on anything in the base workspace beyond what they explicitly set up (for example, with a model load function).
- **Copy base workspace** - The software attempts to copy the base workspace to each worker. Specify this value if you use a setup script to prepare the base workspace for multiple models to use.
- **Load top model** - The software loads the top model on each worker. Specify this value if the top model in the model reference hierarchy handles all the base workspace setup (for example, with a model load function).

Note Set **Enable parallel model reference builds** only for the top model of the model reference hierarchy to which it applies.

- 3 Optionally, turn on verbose messages for simulation builds. If you select verbose builds, the build messages report the progress of each parallel build with the name of the model.

To turn on verbose messages for simulation target builds, go to the Configuration Parameters dialog box and select **Verbose accelerator builds**.

The **Verbose accelerator builds** option controls the verbosity of build messages both in the MATLAB Command Window and in parallel build log files.

- 4 Optionally, inspect the model reference hierarchy to determine, based on model dependencies, which models will build in parallel. For example, you can use the Model Dependency Viewer from the Simulink **Analysis > Model Dependencies** menu.
- 5 Update your model. Messages in the MATLAB command window record when each parallel or serial build starts and finishes.

If you need more information about a parallel build, for example, if a build fails, see “Locate Parallel Build Logs” on page 8-79.

Locate Parallel Build Logs

When you update a model for which referenced models are built in parallel, if verbose builds are turned on, messages in the MATLAB Command Window record when each parallel or serial build starts and finishes. For example,

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model001'
### Starting parallel model reference SIM build for 'bot_model002'
### Starting parallel model reference SIM build for 'bot_model003'
### Starting parallel model reference SIM build for 'bot_model004'
### Finished parallel model reference SIM build for 'bot_model001'
### Finished parallel model reference SIM build for 'bot_model002'
### Finished parallel model reference SIM build for 'bot_model003'
### Finished parallel model reference SIM build for 'bot_model004'
```

To obtain more detailed information about a parallel build, you can examine the parallel build log. For each referenced model built in parallel, the build process generates a file named *model_buildlog.txt*, where *model* is the name of the referenced model. This file contains the full build log for that model.

If a parallel build completes, you can find the build log file in the build subfolder corresponding to the referenced model. For example, for a build of referenced model *bot_model004*, look for the build log file *bot_model004_buildlog.txt* in the referenced model subfolder *build_folder/slprj/sim/bot_model004*.

If a parallel builds fails, you can see output similar to the following:

```
### Initializing parallel workers for parallel model reference build.
### Parallel worker initialization complete.
### Starting parallel model reference SIM build for 'bot_model002'
### Starting parallel model reference SIM build for 'bot_model003'
### Finished parallel model reference SIM build for 'bot_model002'
```

```
### Finished parallel model reference SIM build for 'bot_model003'  
### Starting parallel model reference SIM build for 'bot_model001'  
### Starting parallel model reference SIM build for 'bot_model004'  
### Finished parallel model reference SIM build for 'bot_model004'  
### The following error occurred during the parallel model reference SIM build for  
'bot_model001':  
  
Error(s) encountered while building model "bot_model001"  
  
### Cleaning up parallel workers.
```

If a parallel build fails, you can find the build log file in a referenced model subfolder under the build subfolder `/par_md1_ref/model`. For example, for a failed parallel build of model `bot_model001`, look for the build log file `bot_model001_buildlog.txt` in the subfolder `build_folder/par_md1_ref/bot_model001/slprj/sim/bot_model001`.

Share Simulation Builds for Faster Simulations

In this section...

“Store Simulink Cache Files” on page 8-81

“Share Simulink Cache Files” on page 8-82

“Use Simulink Cache Files” on page 8-82

You can reuse a simulation build for a model that builds a Simulink accelerator, rapid accelerator, or referenced model simulation (SIM) target. The first time that you simulate this model or update the diagram for this model, the build process creates a Simulink cache file to store build artifacts. Simulink creates:

- A Simulink accelerator target for the top model
- A rapid accelerator target for the top model
- A SIM target for a referenced model that has one or more accelerator mode instances in a model hierarchy

For a model hierarchy, each referenced model that generates these targets has an associated cache file. The cache file name is the name of the model with an `.slxc` file extension. You can use the same cache file on different platforms after creating the cache file on each platform. Use cache files to:

- Speed up first-time builds for later use by yourself or others.
- Speed up parallel simulations.
- Avoid manual updates associated with setting the **Rebuild** configuration parameter to **Never**. That setting prevents SIM target builds and cache file updates.

When you modify a model and then update the diagram or simulate, Simulink determines whether to rebuild based on the **Rebuild** setting for the model. For a rebuild, Simulink updates the build artifacts on disk and the cache file.

Store Simulink Cache Files

Simulink stores cache files in the folder specified by the **Simulation cache folder** preference. You can change the default location. To use the cache file with the model, store the cache file on the MATLAB path. To preserve a version of the cache file:

- Manually move the cache file outside the folder specified by the **Simulation cache folder** preference.
- Specify a different folder by the **Simulation cache folder** preference before a rebuild.

Share Simulink Cache Files

Sharing Simulink cache files with team members saves them the first-time build overhead when they use your model. If you use a project, you can:

- Identify out-of-date targets and include cache files in the share operation by using the **Project** tab **Share** button.
- Display cache files and highlight missing cache files in the project tree by clicking the **Dependency Analysis** node.

When you create a project from a top model, the project includes associated cache files for the model and its referenced models.

If you do not use a project, you can save the cache files in a shared location or attach the cache files to an email. If you share an out-of-date cache file with someone, when that person simulates the model, Simulink detects that it must rebuild.

Use Simulink Cache Files

For team development of large models that reference other models, Simulink cache files are useful for a synchronize and design workflow. For example, assume that in this model development environment:

- A team of 20 people is working on a model hierarchy containing 100 models.
- All the referenced models simulate in accelerator mode.
- The team uses one platform for development.
- The team uses a source control system for their models.

The team uses Simulink cache files in this workflow:

- 1 A pool of parallel worker machines updates the diagram for the model hierarchy using the latest version of the models.
- 2 Your team member fetches the latest version of all models from the source control system.

- 3 Your team member fetches the latest version of all Simulink cache files from the build archive.
- 4 Your team member opens the top model and simulates it. During simulation, Simulink extracts the necessary artifacts from the cache files. The simulation begins without any builds.
- 5 Your team member changes some models in the hierarchy and simulates, which rebuilds models as needed. While updating the diagram, Simulink locally updates the cache files for those models as needed.
- 6 Your team member commits the changes to the source control system by submitting the changed models.
- 7 The pool of parallel worker machines builds the latest version of the model hierarchy.
- 8 You fetch the latest version of all models and cache files.
- 9 You simulate the top model. Simulink extracts the necessary artifacts from the cache files without building.

Set Configuration Parameters for Model Referencing

In this section...
“Manage Configuration Parameters by Using Configuration References” on page 8-84
“Configuration Requirements for All Referenced Model Simulation” on page 8-85
“Diagnostics That Are Ignored in Accelerator Mode” on page 8-87
“Accelerated Simulation and Code Generation Changes Settings” on page 8-88

A referenced model uses a configuration set in the same way that any other model does, as described in “Manage a Configuration Set” on page 13-11. By default, every model in a hierarchy has its own configuration set. Each model uses its configuration set the same way that it would if the model executed independently.

Because each model can have its own configuration set, configuration parameter values can be different in different models. Furthermore, some parameter values are intrinsically incompatible with model referencing. The Simulink response to an inconsistent or unusable configuration parameter depends on the parameter:

- Where an inconsistency has no significance, or a trivial resolution without risk exists, Simulink ignores or resolves the inconsistency without posting a warning.
- Where a nontrivial and possibly acceptable solution exists, Simulink resolves the conflict silently, resolves it with a warning, or generates an error. See “Diagnostics That Are Ignored in Accelerator Mode” on page 8-87 for details.
- Where no acceptable resolution is possible, Simulink generates an error. Change some or all parameter values to eliminate the problem.

Manage Configuration Parameters by Using Configuration References

Manually eliminating all configuration parameter incompatibilities can be tedious when:

- A model hierarchy contains many referenced models that have incompatible parameter values
- A changed parameter value must propagate to many referenced models

You can control or eliminate such overhead by using configuration references to assign an externally stored configuration set to multiple models. See “Manage a Configuration Reference” on page 13-18 for details.

Configuration Requirements for All Referenced Model Simulation

Some configuration parameter options can cause problems if set:

- In certain ways, as indicated in the tables
- Differently in a referenced model than in a parent model

Where possible, Simulink resolves violations of these requirements automatically, but most cases require changes to the parameters in some or all models.

Dialog Box Pane	Option	Requirement
Solver	Start time	The start time of the top model and all referenced models must be the same, but need not be zero.
	Stop time	Simulink uses Stop time of the top model for simulation, overriding any differing Stop time in a referenced model.
	Type Solver	The Type and Solver of the top model apply throughout the hierarchy. See “Solver Settings” on page 8-86.
Data Import/Export	Initial state	Can be on for the top model, but must be off for a referenced model.
Math and Data Types	Default parameter behavior	If the parent model has this option set to Inlined , then the referenced model cannot be set to Tunable .

Dialog Box Pane	Option	Requirement
	Application lifespan (days)	For code generation, must be the same for parent and referenced models. For simulation, the setting can be different for the parent and referenced models.
Model Referencing	Total number of instances allowed per top model	Must not be Zero in a referenced model. Specifying One rather than Multiple is preferable or required sometimes. See “Number of Model Instances Setting” on page 8-87.

Solver Settings

Model referencing works with both fixed-step and variable-step solvers. All models in a model hierarchy use the same solver, which is always the solver specified by the top model. An error occurs if the solver type specified by the top model is incompatible with the solver type specified by any referenced model.

Top Model Solver Type	Referenced Model Solver Type	Compatibility
Fixed step	Fixed step	Allowed
Variable step	Variable Step	Allowed
Variable step	Fixed step	Allowed unless the referenced model is multirate and specifies both a discrete sample time and a continuous sample time
Fixed Step	Variable step	Error

If an incompatibility exists between the top model solver and any referenced model solver, one or both models must change to use compatible solvers. For information about solvers, see “Solvers” on page 3-21 and “Solver Types” on page 25-6.

Number of Model Instances Setting

A referenced model must specify that it is available to be referenced, and whether it can be referenced at most once or can have multiple instances. The **Total number of instances allowed per top model** parameter provides this specification. The possible values for this parameter are:

- **Zero** — A model cannot reference this model. An error occurs if a reference to the model occurs in another model.
- **One** — A model hierarchy can reference the model at most once. An error occurs if more than one instance of the model exists. This value is sometimes preferable or required.
- **Multiple** — A model hierarchy can reference the model more than once, if it contains no constructs that preclude multiple references. An error occurs if the model cannot be multiply referenced, even if only one reference exists.

Setting **Total number of instances allowed per top model** to **Multiple** for a model that is referenced only once can reduce execution efficiency slightly. However, this setting does not affect data values that result from simulation or from executing code Simulink Coder generates. Specifying **Multiple** when only one model instance exists avoids having to change or rebuild the model when reusing the model:

- In the same hierarchy
- Multiple times in a different hierarchy

Some model properties and constructs require setting **Total number of instances allowed per top model** to **One**. For details, see “Model Reuse” on page 8-8.

Diagnostics That Are Ignored in Accelerator Mode

For models referenced in accelerator mode, Simulink ignores the values of these configuration parameter settings if you set them to a value other than **None**:

- **Array bounds exceeded** (ArrayBoundsChecking)
- **Inf or NaN block output** (SignalInfNanChecking)
- **Simulation range checking** (SignalRangeChecking)
- **Division by singular matrix** (CheckMatrixSingularityMsg)
- **Wrap on overflow** (IntegerOverflowMsg)

Also, for models referenced in accelerator mode, Simulink ignores these **Configuration Parameters > Diagnostics > Data Validity > Data Store Memory block** parameters if you set them to a value other than `Disable all`. For details, see “Data Store Diagnostics” on page 65-3.

- **Detect read before write** (`ReadBeforeWriteMsg`)
- **Detect write after read** (`WriteAfterReadMsg`)
- **Detect write after write** (`WriteAfterWriteMsg`)

You can use the Model Advisor to identify models referenced in accelerator mode for which Simulink ignores the configuration parameters listed above.

- 1 In the Simulink Editor, select **Analysis > Model Advisor**.
- 2 Select **By Task**.
- 3 Run the **Check diagnostic settings ignored during accelerated model reference simulation** check.

To see the results of running the identified diagnostics with settings to produce warnings or errors, simulate the model in normal mode. Inspect the diagnostic warnings and then simulate in accelerator mode.

Accelerated Simulation and Code Generation Changes Settings

Note Configuration parameters on the **Code Generation** pane of the Configuration Parameters dialog box do not affect simulation in either normal or accelerator mode. **Code Generation** parameters affect only code generation by Simulink Coder itself. Accelerated mode simulation requires code generation to create a simulation target. Simulink uses default values for all **Code Generation** parameters when generating the target, and restores the original parameter values after code generation is complete.

During model referencing simulation in accelerator and rapid accelerator mode, Simulink temporarily sets several **Configuration Parameters > Diagnostics > Data Validity** parameter settings to `None`, if they are set to `Warning` or `Error`. You can use the Model Advisor to check for parameters that change. For details, see “Diagnostic Configuration Parameters Ignored in Accelerator Mode” on page 8-58.

If the **Configuration Parameters > Code Generation > Symbols** parameters hold identifier information about the name of a referenced model and do not use a \$R token, code generation prepends the \$R token to the name of the model. You can use the Model Advisor to check for changed model names. See “Simulink Coder Model Referencing Requirements” (Simulink Coder).

Parameterize Instances of a Reusable Referenced Model

When you reference the same model using multiple Model blocks, you can configure a block parameter to use either the same value or a different value for each instance of the model. For example, you can configure the **Gain** parameter of a Gain block. To use different values, create and use a model argument to set the value of the block parameter. For some applications, you can reuse a referenced model only if you can configure each instance to use a different value for a block parameter (such as the setpoint of a controller or a filter coefficient).

Specify a Different Value for Each Instance of a Reusable Model

For a block parameter in a reusable referenced model, to specify a different value for each instance of the model:

- 1 Create a MATLAB variable or `Simulink.Parameter` object in the model workspace of the referenced model.
 - Use a MATLAB variable for ease of maintenance.
 - Use a `Simulink.Parameter` object for greater control over the minimum and maximum value, the data type, and other properties of the model argument.
- 2 Set the block parameter value in the model by using the variable or parameter object. Optionally, use the same variable or object to set other block parameter values.
- 3 Configure the variable or object as a model argument.

When you simulate this model directly, the block parameters use the value that the variable or object stores in the model workspace. When this model is simulated as a referenced model, a parameter that is configured as a model argument gets its value from its parent model.

- 4 In each Model block that refers to the reusable model, specify an instance-specific value for the block parameter.
- 5 In intermediate models, in addition to specifying an instance-specific value for the block parameter, you can specify if the parameter can be overridden at the next level of the hierarchy.

Combine Multiple Arguments into a Structure

When you configure a model to use multiple model arguments, consider using a structure instead of separate variables in the model workspace. This technique reduces the effort of maintenance when you want to add, rename, or delete arguments. Instead of manually synchronizing the arguments in the model workspace with the argument values in Model blocks, you modify structures by using the Variable Editor or the command prompt.

If you have a Simulink Coder license, this technique can also reduce the ROM consumed by the formal parameters of the referenced model functions, such as the output (`step`) function.

To create and use structures to set block parameter values, see “Organize Related Block Parameter Definitions in Structures” on page 37-26.

Parameterize a Referenced Model

This example shows how to configure multiple instances of a referenced model to use different values for the same block parameter interactively. For an example that parameterizes a referenced model using only the command prompt, see “Parameterize a Referenced Model Programmatically” on page 8-104. For an example that involves code generation, see “Specify Instance-Specific Parameter Values for Reusable Referenced Model” (Simulink Coder).

Configure Referenced Model to Use Model Arguments

When you simulate a referenced model by itself, the parameter objects in the model workspace use the values that you specify for the `Simulink.Parameter` objects or MATLAB variables. The block parameters also use these values.

To configure the **Gain** parameter of a Gain block and the **Numerator** parameter of a Discrete Filter block as model arguments, follow these steps:

- 1 Create a 3-layer hierarchical model by opening a new Simulink model.
- 2 Add a Model block to the model and set the **Model name** to `ex_model_arg`.
- 3 Save the model as `ex_model_arg_top`.
- 4 Open `ex_model_arg_ref`. This model represents a reusable algorithm.

- 5 In the model, select **View > Model Data Editor**.
- 6 In the Model Data Editor, select the **Parameters** tab.
- 7 Use the **Value** column to set the value of the **Gain** parameter to a variable, for example, `gainArg`.
- 8 Next to `gainArg`, click the action button  and select **Create**.
- 9 In the Create New Data dialog box, set **Value** to `Simulink.Parameter` and **Location** to `Model Workspace`. Click **Create**.
- 10 In the `Simulink.Parameter` property dialog box, set **Value** to a number, for example, `3.17`. Click **OK**.
- 11 Using the Model Data Editor, set the **Numerator** parameter of the Discrete Filter block.
 - Use a `Simulink.Parameter` object named `coeffArg`.
 - Store `coeffArg` in the model workspace.
 - Assign a value of `1.05` to `coeffArg`.
- 12 In the Model Data Editor, click the **Show/refresh additional information** button.
- 13 For each object, select the check box in the **Argument** column.

Model Data Editor									
Inports/Outports Signals Data Stores States Parameters									
Design  									
 model workspace x									
Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument	
Model Workspace	<code>coeffArg</code>	<code>1.05</code>	<code>double (auto)</code>			<code>[1 1]</code>		<input checked="" type="checkbox"/>	
Model Workspace	<code>gainArg</code>	<code>3.17</code>	<code>auto</code>	<code>[]</code>	<code>[]</code>	<code>[1 1]</code>		<input checked="" type="checkbox"/>	

For models with many parameters, you can use the **Filter contents** box to find specific parameters quicker.

14 Save `ex_model_arg_ref`.

Set Model Argument Values in Parent Model

When you simulate a parent model, each instance of a reusable referenced model uses the parameter values that you specify in the parent model. This example shows how you can expose a model argument as a tunable parameter on the Model block at each level of the model hierarchy.

- 1 Open `ex_model_arg`. This model represents a system model that uses multiple instances of the reusable algorithm.

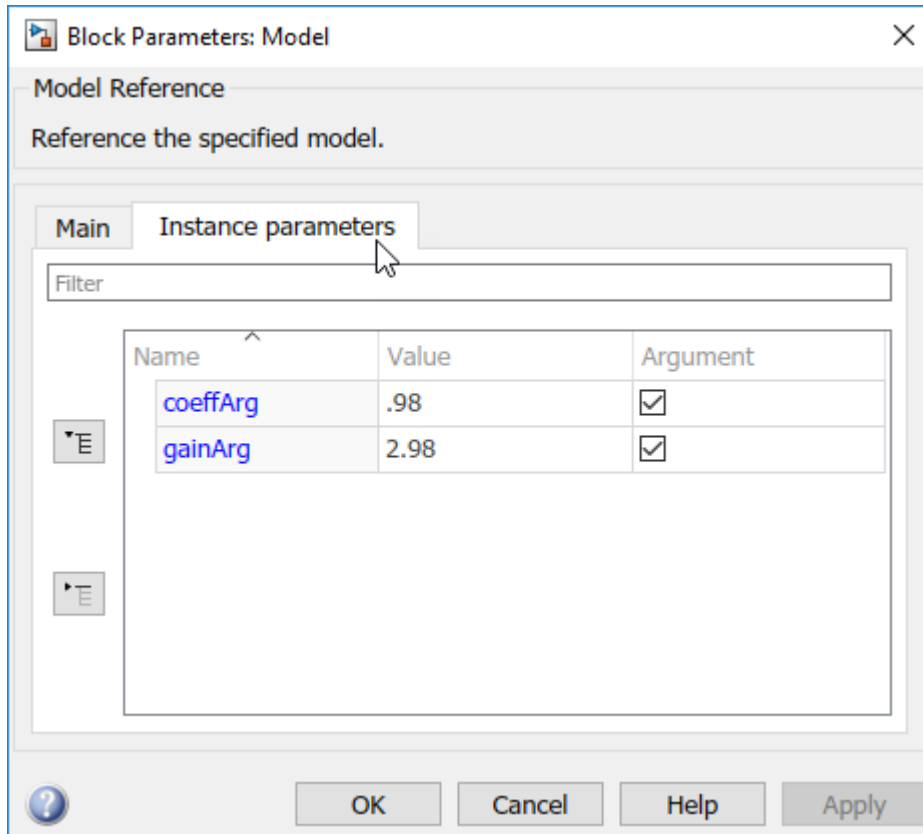

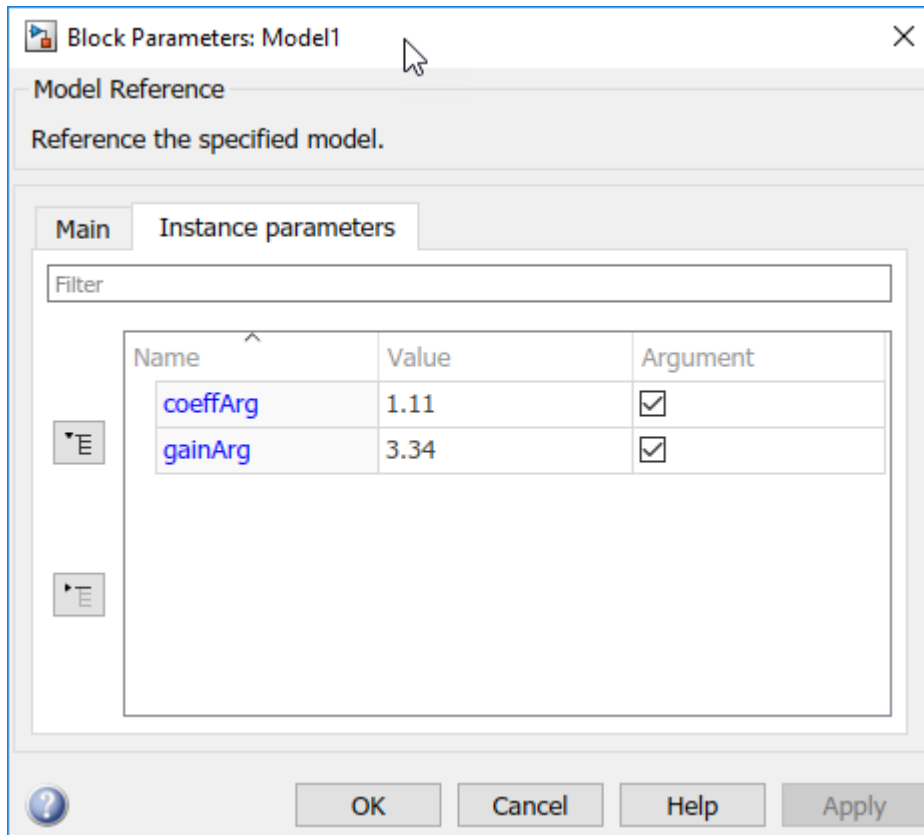

- 2 In the model, select **View > Model Data Editor**.
- 3 In the Model Data Editor, select the **Parameters** tab. The Model Data Editor shows four rows that correspond to the instance-specific parameters that you can specify for the two Model blocks.
- 4 Use the Model Data Editor to set values for the parameters. For example, use the values in this figure.

Model Data Editor									
Imports/Outputs									
Signals									
Data Stores									
States									
Parameters									
Design	Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument
	Model	coeffArg	.98						<input type="checkbox"/>
	Model	gainArg	2.98						<input type="checkbox"/>
	Model1	coeffArg	1.11						<input type="checkbox"/>
	Model1	gainArg	3.34						<input type="checkbox"/>

- 5 To override the value of these parameters at the next level of the model hierarchy, select the check box in the **Argument** column. By default, the check box is not selected.

You can also configure instance-specific parameters at each Model block. In the block dialog box, select the **Instance parameters** tab.

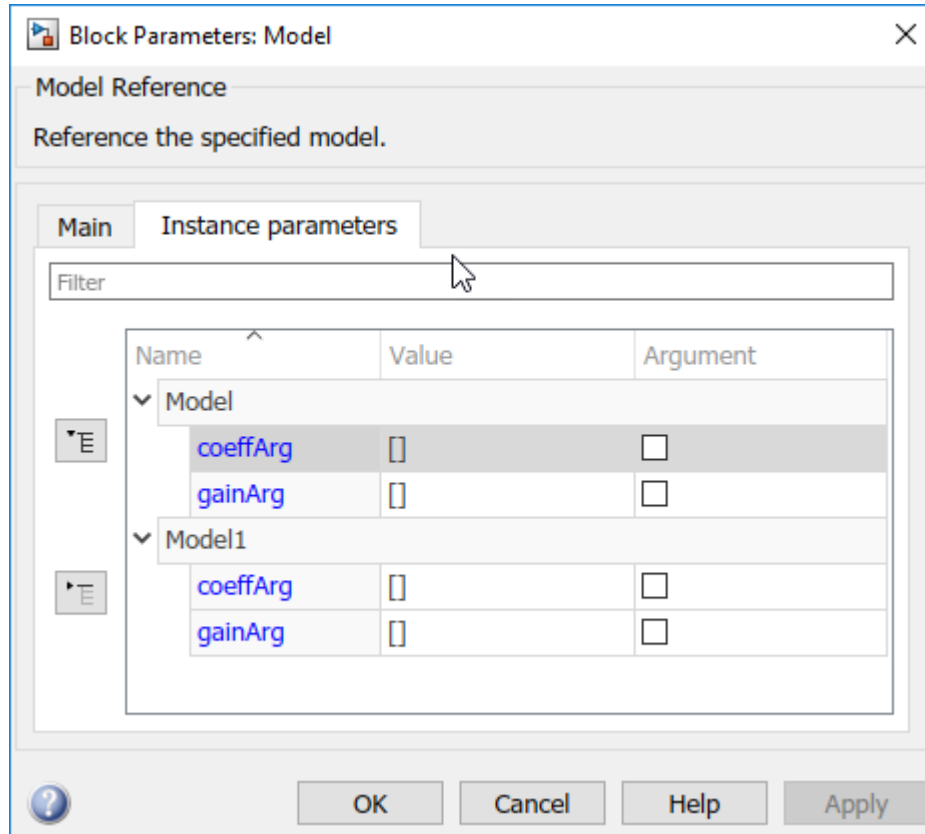

- Open `ex_model_arg_top`. This model contains a Model block that references `ex_model_arg`.

- Open the block parameter dialog box for Model and select the **Instance parameters** tab. In this tab you can see each instance-specific parameter that was exposed as a tunable parameter in the model `ex_model_arg`. From here you can create a parameter value set for all instances of the `coeffArg` and `gainArg` parameters in the model hierarchy.

Group Multiple Model Arguments into Single Structure

You can use structures to reduce the effort of maintenance when you want to add, rename, or delete arguments. With structures, the mathematical functionality of the models is the same.

To replace the parameter values with structures for `ex_model_arg_ref` and `ex_model_arg`, follow these steps:

- 1 At the command prompt, create a structure. Add one field for each of the parameter objects in the `ex_model_arg_ref` workspace.

```
structForInst1.gain = 3.17;
structForInst1.coeff = 1.05;
```

- 2 Store the structure in a `Simulink.Parameter` object.

```
structForInst1 = Simulink.Parameter(structForInst1);
```

- 3 Open the Model Explorer. In the referenced model, `ex_model_arg_ref`, select **View > Model Explorer > Model Explorer**.
- 4 Use the Model Explorer to copy the parameter object from the base workspace into the `ex_model_arg_ref` model workspace.
- 5 In the model workspace, rename `structForInst1` as `structArg`.
- 6 In the **Contents** pane, configure `structArg` as the only model argument.

Name	Value	Argument	DataType	Dimension
coeffArg	1.05	<input type="checkbox"/>	auto	[1 1]
gainArg	3.17	<input type="checkbox"/>	auto	[1 1]
structArg	<1x1 struct>	<input checked="" type="checkbox"/>	struct	[1 1]

- 7 In the `ex_model_arg_ref` model, in the Model Data Editor **Parameters** tab, set the value of the **Gain** parameter to `structArg.gain` and the value of the **Numerator** parameter to `structArg.coeff`.
- 8 Save the model.
- 9 At the command prompt, copy the existing structure in the base workspace as `structForInst2`.

```
structForInst2 = copy(structForInst1);
```

- 10 Set the field values in the two structures by using the same numbers that you used to set the model argument values in the Model blocks.

```
structForInst1.Value.gain = 2.98;
structForInst1.Value.coeff = 0.98;
```

```
structForInst2.Value.gain = 3.34;
structForInst2.Value.coeff = 1.11;
```

- 11 In the top model, `ex_model_arg`, use the Model Data Editor to set the argument values as shown in this figure.

Model Data				
Inports/Outports	Signals	Data Stores	States	Parameters
Design  				
Source	Name	Value		
 Model	structArg	structForInst1		
 Model1	structArg	structForInst2		

Use Bus Object as Data Type of Structures

You can use a `Simulink.Bus` object as the data type of the structures. The object ensures that the characteristics of the instance-specific structures, such as the names and order of fields, match the characteristics of the structure in the model workspace.

- 1 At the command prompt, use the function `Simulink.Bus.createObject` to create a `Simulink.Bus` object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1.Value);
```

- 2 Rename the bus object as `myParamStructType` by copying it.

```
myParamStructType = copy(slBus1);
```

- 3 In the Model Data Editor for `ex_model_arg`, click the **Show/refresh additional information** button. The Model Data Editor now contains rows that correspond to the parameter objects in the base workspace, `structForInst1` and `structForInst2`.
- 4 Use the **Data Type** column to set the data type of `structForInst1` and `structForInst2` to `Bus: myParamStructType`.
- 5 In the Model Data Editor for `ex_model_arg_ref`, use the Model Data Editor to set the data type of `structArg` to `Bus: myParamStructType`.

Source	Name	Value	Data Type	Min	Max	Dimensions	Unit	Argument
Model Workspace	structArg	<1x1 struct>	Bus: myParamStructType	[]	[]	[1 1]		<input checked="" type="checkbox"/>

Change Model Argument Name or Value

To rename a model argument in the context of the referenced model:

- Find all Model blocks that refer to the model and save the instance-specific parameter values that each block specifies. Use the `get_param` function to query the `InstanceParameters` parameter of each block, which is a structure array. The structure contains four fields: `Name`, `Value`, `Path`, and `Argument`.

You must save the instant-specific parameter values because the renaming operation discards the values in the Model blocks.

- In the Model Data Editor, right-click the variable or object in the model workspace of the referenced model and select **Rename All**. The renaming operation changes the name of the variable or object and changes references to it throughout the model. For more information, see “Create, Edit, and Manage Workspace Variables” on page 62-143.
- Reapply the argument values to the Model blocks by using the new name of the argument. To programmatically set argument values in a Model block, see “Instance parameters”.

Customize User Interface for Reusable Components

When you design a reusable referenced model for use by other members of a team, you can apply a mask to the entire referenced model. You can then customize the way that your users interact with Model blocks, including setting instance-specific values.

Using this technique also makes it easier to programmatically specify instance-specific values. If you create and use a mask parameter named `gainMask` to programmatically set the value to `0.98` for an instance of the model named `myModelBlock`, your users can use this command at the command prompt:

```
set_param('myModelBlock', 'gainMask', '0.98')
```

If you apply a mask to the referenced model, the model mask shows only the instance-specific parameters from the direct child model. It does not show instance-specific parameters promoted up from descendant models.

If you do not mask the model, to set the instance-specific value, use the `InstanceParameters` parameter of the block. For more information, see “Parameterize a Referenced Model Programmatically” on page 8-104.

For information about masking models, see “Introduction to Model Mask” on page 39-61.

Configure Instance-Specific Data for Lookup Tables

When you use `Simulink.LookupTable` objects to store and configure lookup table data for ASAP2 or AUTOSAR code generation (for example, `STD_AXIS` or `CURVE`), you can configure the objects as model arguments. You can then specify unique table data and breakpoint data for each instance of a component.

You cannot use `Simulink.Breakpoint` objects or `Simulink.LookupTable` objects that refer to `Simulink.Breakpoint` objects as model arguments.

For an example that parameterizes a referenced model by using lookup tables and the command prompt, see “Configure Instance-Specific Data for Lookup Tables Programmatically” on page 8-111.

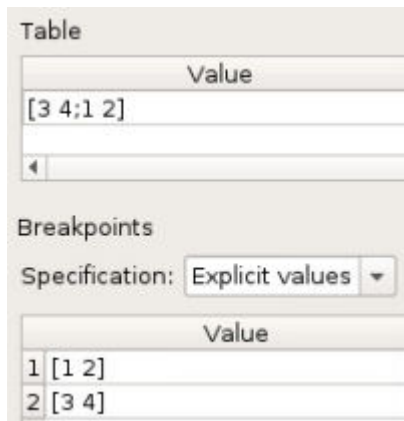

Configure Model Arguments in a Referenced Model

- 1 Open the example model `ex_arg_LUT_ref`, which represents a reusable algorithm.

```
open_system('ex_arg_LUT_ref')
```

- 2 Using the Model Explorer, add a Simulink.LookupTable object in the model workspace. You can use the Add Simulink LookupTable button . Name the object LUTArg.
- 3 Set **Number of table dimensions** to 2. Under **Table** and **Breakpoints**, specify values for the table and breakpoint data. For example, use the values in this figure.

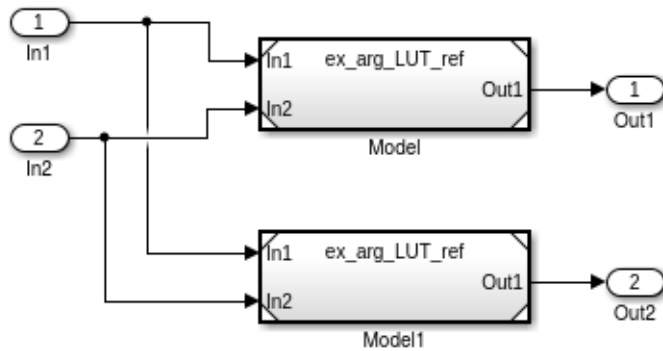

When you simulate or generate code directly from `ex_arg_LUT_ref`, the model uses these values.

- 4 Under **Struct Type definition**, set **Name** to `LUTArg_Type`.
- 5 Click **Apply**.
- 6 In the **Contents** pane, for LUTArg, select the check box in the **Argument** column.
- 7 In the referenced model, in the n-D Lookup Table block, set **Data specification** to Lookup table object. Set **Name** to LUTArg.
- 8 Save the model.

Create Instance-Specific Argument Values

- 1 Open the example model `ex_arg_LUT`, which uses the reusable algorithm twice.

```
open_system('ex_arg_LUT')
```

- At the command prompt, create two `Simulink.LookupTable` objects in the base workspace. Alternatively, you can create the `Simulink.LookupTable` objects in a data dictionary.

```
LUTForInst1 = Simulink.LookupTable;
LUTForInst2 = Simulink.LookupTable;
```

- Specify breakpoint and table data for each object.

```
LUTForInst1.Table.Value = [8 7; 6 5];
LUTForInst1.Breakpoints(1).Value = [5 6];
LUTForInst1.Breakpoints(2).Value = [3 4];
```

```
LUTForInst2.Table.Value = [9 8; 7 7];
LUTForInst2.Breakpoints(1).Value = [3 4];
LUTForInst2.Breakpoints(2).Value = [5 6];
```

- Specify a structure type name. Match this name to the name specified by the object in the referenced model workspace.

```
LUTForInst1.StructTypeInfo.Name = 'LUTArg_Type';
LUTForInst2.StructTypeInfo.Name = 'LUTArg_Type';
```

- In the `ex_arg_LUT` model, in the top Model block, on the **Instance parameters** tab, set the value of **LUTArg** to `LUTForInst1`.
- In the bottom Model block, set **LUTArg** to `LUTForInst2`.

Each instance of `ex_arg_LUT_ref` uses the table and breakpoint data stored in one of the `Simulink.LookupTable` objects in the base workspace.

Parameterize a Referenced Model Programmatically

This example shows how to programmatically configure multiple instances of a referenced model to use different values for the same block parameter.

Configure Referenced Model to Use Model Arguments

When you simulate a model, the parameter objects in the model workspace use the values that you specify for the `Simulink.Parameter` objects, `Simulink.LookupTable` objects, or MATLAB® variables. The block parameters also use these values.

To configure the **Gain** parameter of a Gain block and the **Numerator** parameter of a Discrete Filter block as model arguments, follow these steps.

Open model `ex_model_arg_ref`. This model represents a reusable algorithm.

```
open_system('ex_model_arg_ref')
```

For the Gain block, set the value of the **Gain** parameter to a `Simulink.Parameter` object in the model workspace with a numeric value. For this example, name the `Simulink.Parameter` object `gainArg` and assign a value of 3.17.

```
set_param('ex_model_arg_ref/Gain', 'Gain', 'gainArg')
modelWorkspace = get_param('ex_model_arg_ref', 'ModelWorkspace');
assignin(modelWorkspace, 'gainArg', Simulink.Parameter(3.17));
```

For the Discrete Filter block, set the value of the **Numerator** parameter to a `Simulink.Parameter` object in the model workspace with a numeric value. For this example, name the `Simulink.Parameter` object `coeffArg` and assign a value of 1.05.

```
set_param('ex_model_arg_ref/Discrete Filter', 'Numerator', 'coeffArg')
assignin(modelWorkspace, 'coeffArg', Simulink.Parameter(1.05));
```

Specify gainArg and coeffArg as model arguments.

```
set_param('ex_model_arg_ref', 'ParameterArgumentNames', 'coeffArg, gainArg')
```

Set Model Argument Values in Parent Model

When you simulate a parent model, each instance of a reusable referenced model uses the argument values that you specify in the parent model. In this example, in the upper instance of `ex_model_arg_ref`, the parameter object `gainArg` uses the value `2.98`.

Model `ex_model_arg` contains two Model blocks that reference `ex_model_arg_ref`. To set different parameter values for the two instances of the model, follow these steps.

Open model `ex_model_arg`. This model represents a system model that uses multiple instances of the reusable algorithm.

```
open_system('ex_model_arg')
```

For both instances of model `ex_model_arg`, set values for the model arguments. If you decide to re-promote these arguments, set the `Argument` field to `true`. By default, the `Argument` field is `false`.

```
instSpecParams = get_param('ex_model_arg/Model', 'InstanceParameters');
instSpecParams1 = get_param('ex_model_arg/Model1', 'InstanceParameters');
```

```
instSpecParams(1).Value = '.98';
instSpecParams(2).Value = '2.98';
instSpecParams1(1).Value = '1.11';
```

```
instSpecParams1(2).Value = '3.34';
instSpecParams(1).Argument = true;
instSpecParams(2).Argument = true;
instSpecParams1(1).Argument = true;
instSpecParams1(2).Argument = true;

set_param('ex_model_arg/Model', 'InstanceParameters', instSpecParams);
set_param('ex_model_arg/Model1', 'InstanceParameters', instSpecParams1);
```

Group Multiple Model Arguments into a Single Structure

This example shows how to programmatically configure multiple instances of a referenced model to use different values for the same block parameter by using structures.

Configure Referenced Model to Use Model Arguments Grouped Into Structure

You can use structures to reduce the effort of maintenance when you want to add, rename, or delete arguments. With structures, the mathematical functionality of the models is the same.

To replace the parameter values with structures for `ex_model_arg_ref` and `ex_model_arg`, follow these steps.

Open model `ex_model_arg_ref`. This model represents a reusable algorithm.

```
open_system('ex_model_arg_ref')
```

Create a structure that contains one field for each of the parameter objects that exist in the `ex_model_arg_ref` workspace. Specify a value for each field.

```
structForInst1.gain = 3.17;  
structForInst1.coeff = 1.05;
```

Store the structure in a `Simulink.Parameter` object.

```
structForInst1Param = Simulink.Parameter(structForInst1);
```

Copy the `Simulink.Parameter` object into the `ex_model_arg_ref` model workspace. For this example, name the copy of the object `structArg`.

```
modelWorkspace = get_param('ex_model_arg_ref','ModelWorkspace');
assignin(modelWorkspace,'structArg',copy(structForInst1Param));
```

Configure structArg as the only model argument.

```
set_param('ex_model_arg_ref','ParameterArgumentNames','structArg')
```

In the `ex_model_arg_ref` model, set the **Gain** parameter of the Gain block to `structArg.gain` and set the **Numerator** parameter of the Discrete Filter block to `structArg.coeff`.

```
set_param('ex_model_arg_ref/Gain','Gain','structArg.gain')
set_param('ex_model_arg_ref/Discrete Filter',...
    'Numerator','structArg.coeff')
```

Copy the existing structure as `structForInst2Param`.

```
structForInst2Param = copy(structForInst1Param);
```

Set the field values in the two structures to the same numbers that you used to set the model argument values in the Model blocks.

```
structForInst1Param.Value.coeff = 0.98;
structForInst1Param.Value.gain = 2.98;
structForInst2Param.Value.coeff = 1.11;
structForInst2Param.Value.gain = 3.34;
```

Open model `ex_model_arg`. This model represents a system model that uses multiple instances of the reusable algorithm.

```
open_system('ex_model_arg')
```

For model instance `Model`, set **structArg** to `structForInst1Param`. For model instance `Model1`, set **structArg** to `structForInst2Param`.

```
instSpecParamsStruct = get_param('ex_model_arg/Model', 'InstanceParameters');  
instSpecParamsStruct1 = get_param('ex_model_arg/Model1', 'InstanceParameters');  
  
instSpecParamsStruct(1).Value = 'structForInst1Param';  
instSpecParamsStruct1(1).Value = 'structForInst2Param';  
  
set_param('ex_model_arg/Model', 'InstanceParameters', instSpecParamsStruct);  
set_param('ex_model_arg/Model1', 'InstanceParameters', instSpecParamsStruct1);
```

Use Bus Object as Data Type of Structures

You can use a `Simulink.Bus` object as the data type of the structures. The bus object makes sure that the characteristics of the instance-specific structures, such as the names and order of fields, match the characteristics of the structure in the model workspace.

To set the data type of the structures to bus objects, follow these steps.

Use the `Simulink.Bus.createObject` function to create the bus object. The hierarchy of elements in the object matches the hierarchy of the structure fields. The default name of the object is `slBus1`.

```
Simulink.Bus.createObject(structForInst1Param.Value);
```

Rename the bus object by copying it.

```
myParamStructType = copy(slBus1);
```

Set the data type of the parameter objects in the base workspace by using the bus object.

```
structForInst1Param.DataType = 'Bus: myParamStructType';  
structForInst2Param.DataType = 'Bus: myParamStructType';
```

For the `structArg` object, set `DataType` to `Bus: myParamStructType`.

```
temp = getVariable(modelWorkspace, 'structArg');  
temp = copy(temp);  
temp.DataType = 'Bus: myParamStructType';  
assignin(modelWorkspace, 'structArg', copy(temp));
```

```
close_system('ex_model_arg_ref',0)  
close_system('ex_model_arg',0)
```

Configure Instance-Specific Data for Lookup Tables Programmatically

When you use `Simulink.LookupTable` objects to store and configure lookup table data for ASAP2 or AUTOSAR code generation (for example, `STD_AXIS` or `CURVE`), you can configure the objects as model arguments. You can then specify unique table data and breakpoint data for each instance of a component.

This example shows how to configure multiple instances of a referenced model to use different values for the same block parameter by using lookup tables and the command prompt.

Configure Model Arguments in Referenced Model

Open model `ex_arg_LUT_ref`, which represents a reusable algorithm.

```
open_system('ex_arg_LUT_ref')
```

Create a `Simulink.LookupTable` object in the base workspace. For this example, name the object `LUTArg`.

```
temp = Simulink.LookupTable;
```

Specify values for the table and breakpoint data. When you simulate or generate code directly from `ex_arg_LUT_ref`, the model uses these values.

```
temp.Table.Value = [3 4; 1 2];
temp.Breakpoints(1).Value = [1 2];
temp.Breakpoints(2).Value = [3 4];
```

Set the structure name to `LUTArg_Type`.

```
temp.StructTypeInfo.Name = 'LUTArg_Type';
```

Copy the structure to the model workspace.

```
mdlwks = get_param('ex_arg_LUT_ref','ModelWorkspace');
assignin(mdlwks,'LUTArg',copy(temp))
```

Specify LUTArg as a model argument.

```
set_param('ex_arg_LUT_ref','ParameterArgumentNames','LUTArg')
```

For the n-D Lookup Table block, set 'Data specification' to 'Lookup table object' and set the name to LUTArg.

```
set_param('ex_arg_LUT_ref/n-D Lookup Table',...
    'DataSpecification','Lookup table object','LookupTableObject','LUTArg')
```

Create Instance-Specific Argument Values

Open model ex_arg_LUT, which uses the reusable algorithm twice.

```
open_system('ex_arg_LUT')
```

Create two Simulink.LookupTable objects in the base workspace.

```
LUTForInst1 = Simulink.LookupTable;
LUTForInst2 = Simulink.LookupTable;
```

Specify table and breakpoint data for each object.

```
LUTForInst1.Table.Value = [8 7; 6 5];
LUTForInst1.Breakpoints(1).Value = [5 6];
LUTForInst1.Breakpoints(2).Value = [3 4];
```

```
LUTForInst2.Table.Value = [9 8; 7 7];  
LUTForInst2.Breakpoints(1).Value = [3 4];  
LUTForInst2.Breakpoints(2).Value = [5 6];
```

Specify the structure name to match the name specified by the object in the referenced model workspace.

```
LUTForInst1.StructTypeInfo.Name = 'LUTArg_Type';  
LUTForInst2.StructTypeInfo.Name = 'LUTArg_Type';
```

In the `ex_arg_LUT` model, for model instance `Model`, set the value of `LUTArg` to `LUTForInst1`. For model instance `Model1`, set the value of `LUTArg` to `LUTForInst2`.

```
set_param('ex_arg_LUT/Model', 'ParameterArgumentValues', ...  
    struct('LUTArg', 'LUTForInst1'))  
set_param('ex_arg_LUT/Model1', 'ParameterArgumentValues', ...  
    struct('LUTArg', 'LUTForInst2'))
```

Each instance of `ex_arg_LUT_ref` uses the table and breakpoint data stored in one of the `Simulink.LookupTable` objects in the base workspace.

Simulink Units

Unit Specification in Simulink Models

Simulink enables you to specify physical units as attributes on signals at the boundaries of model components. Such components can be:

- Subsystems
- Referenced Simulink models
- Simulink-PS Converter and PS-Simulink Converter blocks that interface between Simulink and components developed in Simscape and its associated physical modeling products
- Stateflow charts, state transition tables, or truth tables
- MATLAB Function blocks

By specifying, controlling, and visualizing signal units, you can ensure the consistency of calculations across the various components of your model. For example, this added degree of consistency checking is useful if you are integrating many separately developed components into a large, overall system model.

In Simulink models, you specify units from a unit database. The unit database comprises units from the following unit systems:

- SI — International System of Units
- SI (extended) — International System of Units (extended)
- English — English System of Units
- CGS — Centimetre-gram-second System of Units

Based on the type of system you are modeling, you can use any combination of units from these supported unit systems. For more information about supported unit systems and the units they contain, see [Allowed Units](#).

You can assign units to signals through these blocks:

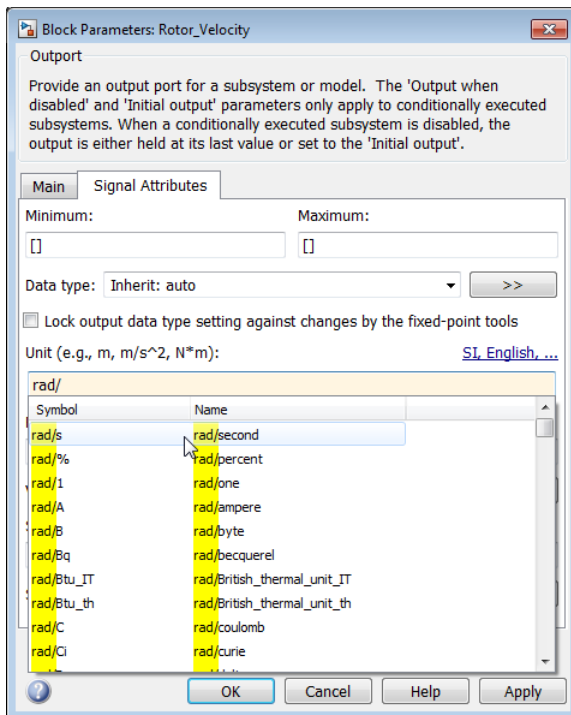

- Inport
- Outport
- Signal Specification
- MATLAB Function
- Stateflow Chart

and these objects:

- `Simulink.Signal`
- `Simulink.BusElement`
- `Simulink.Parameter`

When you add a supported block to your model, the **Unit** parameter on the block is set to **inherit** by default. This setting means that the block inherits the unit from a connecting signal that has an explicitly specified unit.

You can explicitly specify units for signals using the **Unit** parameter of a supported block. For this parameter, the dialog box provides matching suggestions to help you:

If you do not provide a correctly formed unit expression, you get an error. Correctly formed unit expressions are a combination of unit names or symbols with properly balanced parentheses and `*`, `/`, and `^` characters. Special characters such as `[`, `]`, `{`, `}`, `<`, `>`, `\`, `"`, `&`, and so forth are not supported.

By default, a block port has an empty (that is, unspecified) unit and the **Unit** parameter is set to `inherit`. When you specify a unit for one port, Simulink checks the unit setting of any port connected to it. If a port has an empty unit, you can connect it to another port that has any supported unit. If a port unit parameter is set to `inherit`, it inherits the unit from a connected port that has a specified unit.

Specify Physical Quantities

When you model a physical system, it is possible to use the same unit expression for two or more signals that represent different physical quantities. For example, a unit expression of $N*m$ can represent either torque or energy. To prevent mistaken connection of two ports with the same unit but representing different physical quantities, you can add a physical quantity to the unit expression. For example, for the same unit of $N*m$, you can specify different physical quantities of $N*m@torque$ and $N*m@energy$. Similar to units, the dialog box provides suggestions as you type the names of physical quantities.

Physical quantities help you to enforce an extra degree of unit consistency checking between connected ports. When you attempt to connect ports with different physical quantities, the model displays a warning.

Specify Units in Objects

By default, `Simulink.Signal`, `Simulink.BusElement`, and `Simulink.Parameter` objects have empty units. In the case of a:

- `Simulink.Signal` object, the empty unit means that the corresponding signal can inherit a unit from an upstream or downstream port.
- `Simulink.BusElement` object, the empty unit means that the corresponding bus element signal also has an empty unit. You can connect the signal to a port with any unit, but the signal does not inherit a unit from the port.
- `Simulink.Parameter` object, the object does not attach a unit to the corresponding parameter value.

If you specify a unit in a `Simulink.Signal` or `Simulink.BusElement` object, Simulink applies the attribute to the corresponding signal line when:

- The `Simulink.Signal` object resolves to a signal in the model
- You use a bus element signal that is associated with a `Simulink.Bus` object with a Bus Creator, Bus Selector, or Bus Assignment block.

If you use either of these objects with a Data Store block, Simulink does not display any unit attribute.

For the `Simulink.Parameter` object, Simulink does not apply any attribute. For all objects, if the **Unit** parameter has a value that is not formed correctly, you see an error. If the unit is formed correctly but is undefined, you see a warning when you compile the model. If the unit expression contains special characters such as `[,], {, }, <, >, \, ", &`, and so forth, Simulink replaces them with underscores (`_`).

Custom Unit Properties

Notes on the `Unit` and `DocUnits` properties starting in R2016a:

- The `DocUnits` property is now `Unit` for `Simulink.Parameter` or `Simulink.Signal` objects. If, in a previous release, you used the `DocUnits` parameter of a `Simulink.Parameter` or `Simulink.Signal` object to contain text that does not now comply with units specifications, simulation returns a warning when the model simulates.

To suppress these warnings, set the configuration parameter “Units inconsistency messages” to none. This setting suppresses all units inconsistency check warnings.

- If you have a class that derives from `Simulink.Parameter`, `Simulink.Signal`, or `Simulink.BusElement` with a previously defined `Unit` property, Simulink returns an error like the following:

```
Cannot define property 'Unit' in class 'classname' because
the property has already been defined in the superclass 'superclass'.
```

If you use this property to represent the physical unit of the signal, delete the `Unit` property from the derived class in the R2016a or later release. Existing scripts continue to work, unless you are assigning incorrectly formed unit expressions to the `Unit` field. In this case, replace the use of `Unit` with `DocUnits` to continue to be able to assign the unit expression.

Note If you store existing data in a MAT- or `.sldd` file, in a release prior to R2016a, copy the contents of the `Unit` property to the `DocUnits` first. Then, save the file in the earlier release before loading the model in R2016a or later release.

Specify Units for Temperature Signals

When modeling absolute temperature quantities, use units such as K, degC, degF, and degR. When modeling temperature *difference* quantities, use units such as deltaK, deltadegC, deltadegF, and deltadegR. If you connect a signal that has a temperature difference unit to a block that specifies an *absolute* temperature unit, Simulink detects the mismatch.

Specify Units in MATLAB Function Blocks

You can specify units for input and output data of MATLAB Function blocks by using the **Unit** parameter on the Ports and Data Manager.

During model update, Simulink checks for inconsistencies in units between input or output data ports and the corresponding signals.

Specify Units for Logging and Loading Signal Data

You can include units in signal data that you log or load.

You specify units for logging and loading using `Simulink.SimulationData.Unit` objects. When you log using `Dataset` or `Timeseries` format, Simulink stores the unit information using `Simulink.SimulationData.Unit` objects. If you create MATLAB timeseries data to load, you can specify `Simulink.SimulationData.Unit` object for the `Units` property of the `timeseries` object.

For details, see “Log Signal Data That Uses Units” on page 64-38 and “Load Signal Data That Uses Units” on page 64-272.

Restricting Unit Systems

By default, you can specify units from any of the supported unit systems. However, in large modeling projects, to enforce consistency, you might want to restrict the unit systems that certain components of your model can use. To specify available unit systems for a model, in the configuration parameter **Allowed unit systems**, enter `all` or a comma-separated list containing one or more of `SI`, `SI (extended)`, `CGS`, and `English`. Do not use quotation marks. If your model contains referenced models, you can use the **Allowed unit systems** to restrict units in each of those referenced models. If your model contains subsystems, you can use the Unit System Configuration block to restrict units in

the subsystems. You can also optionally use a Unit System Configuration block in a model. In this case, the settings in the Unit System Configuration block override whatever you specify in **Allowed unit systems**.

To restrict unit systems in a model:

- 1 In the **Unit** parameter of the Inport, Output, or Signal Specification block, click the link.

If a Unit System Configuration block exists in your model, this link opens the block dialog box. Otherwise, the link opens the **Allowed unit systems** configuration parameter.

- 2 Specify one or more the desired unit systems, SI, SI (extended), English, or CGS, in a comma-delimited list, or all, without quotation marks.

In a parent-child relationship (for example, a top model with a referenced model or subsystem), you can specify different unit systems for each component. However, if a child propagates a unit into a parent that is not in the unit systems specified for the parent, you get a warning.

To check whether there are unit mismatches caused by restricted unit systems in your model hierarchy:

- Press **Ctrl+D** and visually inspect the model for warning badges.
- Use the Model Advisor check **Identify disallowed unit systems**.

Displaying Units

To display signal units in your model, select **Display > Signals & Ports > Port Units**. To select this option programmatically, use the command-line property `ShowPortUnits`.

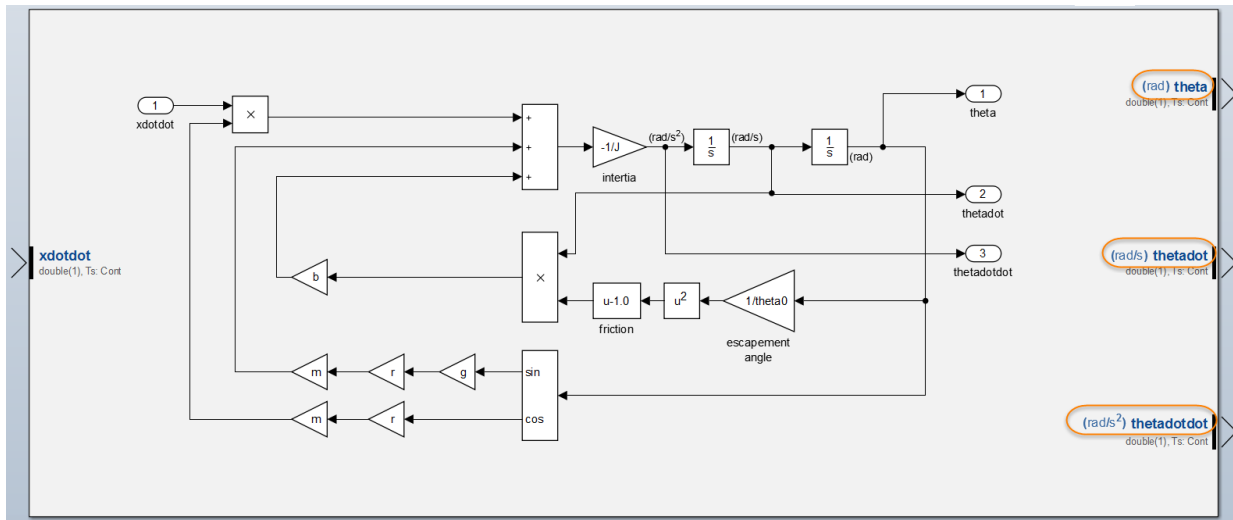

With this option selected, the model dynamically updates port and signal labels to show any changes that you make to units. You do not need to press **Ctrl+D** to update the model. When you simulate your model, the Scope block displays units for connected signals as *y*-axis labels.

Note When you explicitly specify units on inport or outport blocks, block port labels and signal lines display those units. If a port is set to inherit units or has empty units, port labels and signal lines do not show labels.

Note With the option to display units cleared, you do not see port and signal labels, even when you press **Ctrl+D** to update your model. However, you do see warning or error badges for any unit inconsistency problems that exist in the model.

You can also see units in the interface view of your model. Select **Display > Interface**.

Unit Consistency Checking and Propagation

Simulink performs unit consistency checking between components. Ports that you connect together — sometimes via intermediate blocks that propagate units — must have the same units. For example, you cannot connect a port with unit ft/s to a port with unit m/s^2 .

By default, Simulink shows the mismatch warning  when it detects a mismatch in units between two connected ports. You can press **Ctrl+D** to show mismatched units in your model.

To make this connection valid, you can:

- Explicitly set both port units to the same unit.
- Set the **Unit** parameter of one of the connecting ports to `inherit`.
- Insert a Unit Conversion block between the mismatched units if they are separated by a scaling factor or offset, or if they are inverse units. These units are convertible. For more information, see “Converting Units” on page 9-16.
- Select the **Allow automatic unit conversions** configuration parameter. For more information, see “Converting Units” on page 9-16.

Note Simulink supports variations on unit expressions. For example, one port can have a unit of m/s^2 and a connected port can have a unit of $m/s/s$. In these cases, Simulink does not display a warning for mismatched units.

When Simulink detects one of these conditions, it displays the inconsistency warning :

- Disallowed unit system
- Undefined unit

Simulink checks the consistency of unit settings and propagates units across component boundaries. In a model that contains a referenced model, Simulink compiles the referenced model independently of the top model. This independent compilation means that the referenced model cannot inherit units from the top model.

If a port in a referenced model has **Unit** set to `inherit`, it can inherit a unit from any upstream or downstream block in the referenced model. If the port does not inherit a unit from an upstream or downstream block, you can connect it to a port in the top model with any unit.

Simulink passes units through the following blocks that do not change data, known as noncomputation blocks:

- Bus Creator
- Bus Selector
- Bus to Vector
- Data Type Conversion
- Demux
- From
- Goto
- Inport
- Merge
- Model
- Mux
- Outport
- Rate Transition
- Signal Conversion
- Signal Specification
- Subsystem
- Variant Sink
- Variant Source

Note If you supply two or more signals with different units to a Mux block, Simulink applies empty units to the vector signal that the Mux block outputs. Vector signals must have a common unit.

Note If you have a nonvirtual bus in your model (see “Virtual and Nonvirtual Buses” on page 68-4), Simulink sets the unit of the bus to empty. A nonvirtual bus cannot have a unit. However, if the bus element signals themselves have units, Simulink does not change these.

Simulink does not propagate units through blocks that produce new data as output. When signals with units pass through these blocks, the units of these signals become empty. Examples of blocks that do not preserve units because they produce new data as an output include:

- Sum
- Gain
- Filter
- Product

Unit Propagation Between Simulink and Simscape

When modeling physical systems, you might want to integrate components developed in Simulink with components developed in Simscape and its associated physical modeling products. Simscape components use physical signals instead of regular Simulink signals. Therefore, you need Simulink-PS Converter and PS-Simulink Converter converter blocks to connect signals between Simulink and Simscape components.

To specify units for the input and output signals of your Simscape component, you can explicitly specify the units on the converter blocks. When you specify units on a PS-Simulink Converter block that converts a signal from Simscape to Simulink, Simulink propagates the unit settings to the connected Simulink port. However, Simulink cannot propagate a signal unit from Simulink into your Simscape component. To do that, you must explicitly specify the unit on the Simulink-PS Converter block. For more information, see “Physical Units” (Simscape).

Converting Units

Simulink can convert units between ports when it detects discrepancies that have known mathematical relationships such as:

- Scaling factors
- Conversion factors and offsets, such as F (Fahrenheit) to C (Celsius)
- Scaled, inverse units, such as mpg (miles per gallon) and L/km (liters per kilometer).

For example, if you connect one port with a unit of cm to one with a unit of mm, Simulink can automatically scale one unit to work with the other.

To enable Simulink to convert unit mismatches in your model automatically, select the **Allow automatic unit conversions** configuration parameter.

- When Simulink successfully converts signal units at a block port, it displays .
- When Simulink detects that an automatic conversion is not possible, it displays .

To manually convert units separated by a conversion factor or offset:

- 1 Clear the **Allow automatic unit conversions** configuration parameter.
- 2 Insert a Unit Conversion block between the ports whose units you want to convert.

Tip Automatic conversion of units is a convenience. For better control of units, when Simulink detects a mismatch, consider modifying the units specified at one or the other of the two connected ports.

Automatic Unit Conversion Limitations

Simulink does not support automatic conversion:

- At the boundaries of virtual subsystems. Virtual subsystems have the **Treat as atomic unit** parameter cleared. For more information, see “Nonvirtual and Virtual Blocks” on page 36-2.
- At the root level of models configured for concurrent execution or export-function models. For more information, see “Configure Your Model for Concurrent Execution” on page 14-24 and “Export-Function Models” on page 10-120.

- For fixed-point and integer signals.
- At an input port of a Merge block.
- At any port of an asynchronous Rate Transition block.
- At an input port of a function-call subsystem.
- For bus signals.

Update an Existing Model to Use Units

This example shows how to add units to an existing model. You see how to:

- Use an incremental workflow to add units to components in your model
- Integrate components that use different unit systems
- Specify units for individual elements of a bus object
- Troubleshoot unit mismatch problems

The model in the example is a fuel control system. The controller (Fuel Rate Controller) and plant (Engine Gas Dynamics) components of the model are nonvirtual subsystems. Nonvirtual subsystems have the **Treat as atomic unit** parameter selected. You introduce units to the plant before introducing units to the controller and connecting signals. You also specify units for the individual elements of a bus object in the model.

Open the `ex_units_fuelsys` example model.

For the top model, the **Allowed unit systems** configuration parameter determines the unit systems the model can use. For each of the plant and controller subsystems, a Unit System Configuration block determines the allowed unit systems.

Component	Allowed Unit Systems
Top model	SI
Fuel Rate Controller subsystem (controller)	all

Component	Allowed Unit Systems
Engine Gas Dynamics subsystem (plant)	all

In the plant subsystem, on the **Signal Attributes** tab of each inport block dialog box, set the **Unit** parameter to a value appropriate for the connected physical signal.

Block	Physical Signal	Unit Parameter Setting
1	engine speed	rad/s (radians per second)
2	throttle angle	deg (degrees)
3	fuel rate	g/s (grams per second)

To display units on ports and signals in the model, select **Display > Signals & Ports > Port Units**.

In the plant subsystem, you see units on the inport blocks and connected signals.

Navigate back to the top model. To compile the model, press **Ctrl+D**, which also performs unit consistency checking.

The model displays a warning to indicate that there is a disallowed unit for the throttle angle signal. Clicking the warning icon displays a link to a Model Advisor report that gives you more detail.

The model also displays the warning at the bottom of the model editing window.

In the plant subsystem, you specified a unit of deg (degrees) for the throttle angle signal. However, the warning message indicates that degrees are not in the SI unit system. As determined by the **Allowed unit systems** configuration parameter, SI is the only unit system that the top model currently allows. To resolve this warning, you have two options:

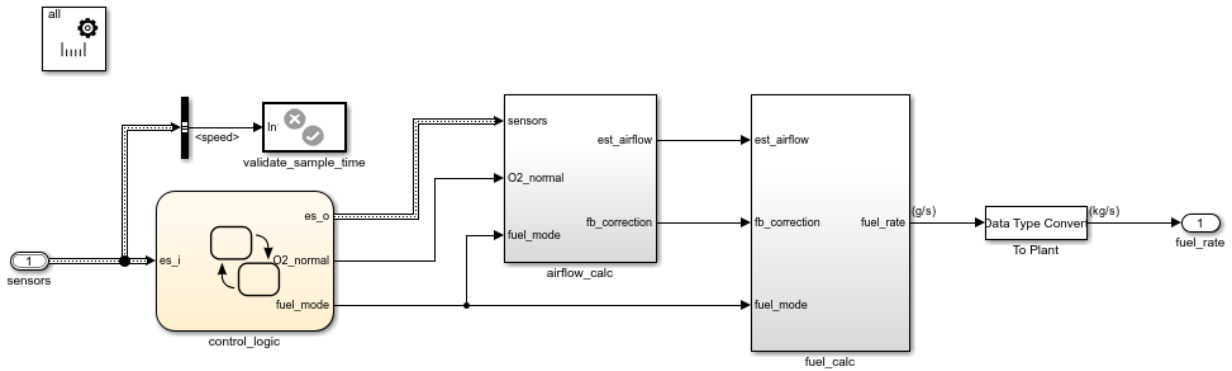

- In the plant subsystem, specify a unit for the `throttle` angle signal that the SI unit system supports. For more information about supported unit systems and the units they contain, see Allowed Units.
- In the top model, change the **Allowed unit systems** configuration parameter to expand the set of allowed unit systems.

In this case, a unit of `deg` for the `throttle` angle signal is appropriate. Instead, to resolve the warning, expand the set of allowed unit systems for the top model. Set the **Allowed unit systems** configuration parameter of the top model to `all`. To recompile the model, press **Ctrl+D**.

The top model no longer displays warnings.

Now that you have introduced units to the plant and successfully resolved unit inconsistency problems, you can add units to the controller. In the Fuel Rate Controller subsystem, set the **Unit** parameter of the `fuel_rate` outport block to `kg/s` (kilograms per second).

Navigate back to the top model. To recompile it, press **Ctrl+D**.

The top model now shows a warning for mismatched units between the controller and plant. To resolve this error, you can:

- Explicitly insert a Unit Conversion block between the two components.
- Select the **Allow automatic unit conversions** configuration parameter.

Both options convert units in the same way. A situation in which you might disallow automatic conversions and insert conversion blocks instead is when you are integrating many components in a large system model. In that case, manually inserting conversion blocks can give you an added degree of control of unit conversions in the model. Also, with a conversion block, you can control the data type of the converted signal. This is useful, for instance, when you are modeling for fixed-point precision.

In this case, to enable Simulink to resolve the unit mismatch automatically, select **Allow automatic unit conversions**. To recompile the model, press **Ctrl+D**.

Simulink automatically converts units between the controller and the plant. An automatic conversion icon replaces the warning.

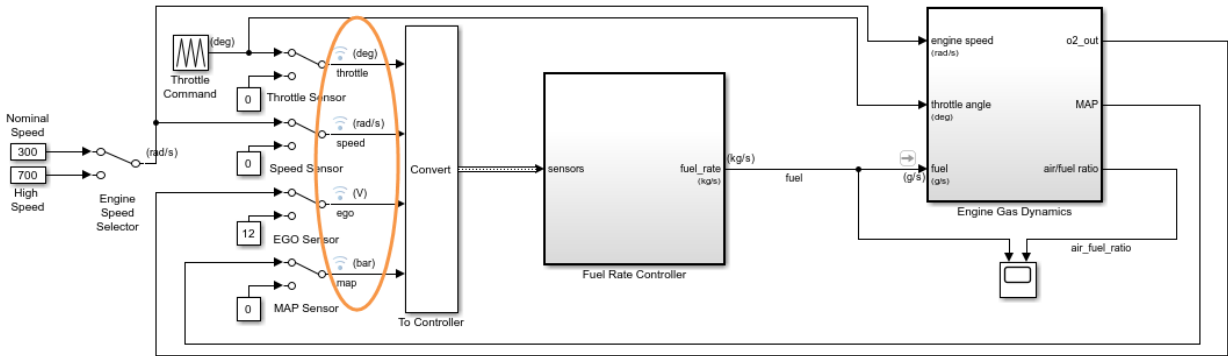

The top model includes a **EngSensors** bus object that passes various sensor signals as a composite signal to the controller. To use the **Bus Editor** to add units to individual elements of the bus object, select **Edit > Bus Editor**.

For the EngSensors bus object, set the **Unit** parameter of each element.

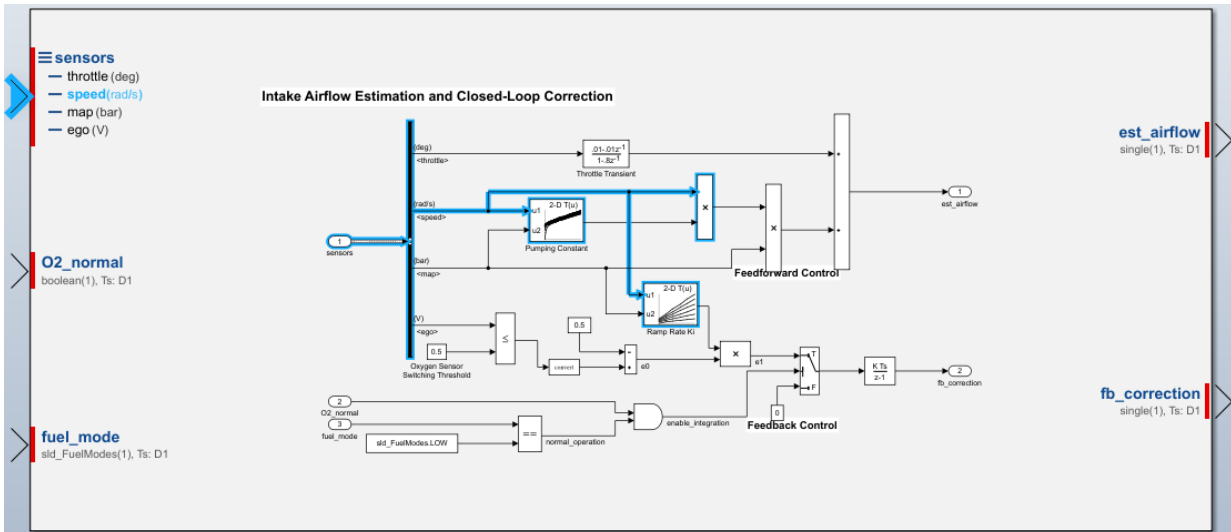

Signal	Unit Parameter Setting
throttle	deg (degrees)
speed	rad/s (radians per second)
ego	V (volts)
map	bar (bars)

To recompile the model, press **Ctrl+D**.

The model shows units on the individual elements of the bus object.

You can also see the units in the interface view of your model. Select **Display > Interface**.

The `airflow_calc` block of the controller subsystem displays units on the individual elements of the bus object, both at the component interface and within the component.

After you introduce units incrementally and resolve inconsistency and mismatch issues, you can simulate the model.

For the fuel signal that is connected to the scope, the plot window displays the associated units of kg/s as a y-axis label.

“Automatic Unit Conversions” on page 9-28

“Unsuccessful Automatic Unit Conversions” on page 9-29

“Simscape Unit Specification Incompatible with Simulink” on page 9-29

To help you troubleshoot issues with unit settings, Simulink uses Model Advisor checks to generate a report useful for larger models.

By default, Simulink flags unit usage issues, such as mismatched units, with warnings. Warnings enable you to continue working despite mismatched units. You can reduce the number of warnings you see by setting the configuration parameter **Units inconsistency messages** to none.

Undefined Units

Simulink does not support custom unit specifications. For more information about supported unit systems and the units they contain, see Allowed Units.

The Model Advisor check “Identify undefined units in the model” identifies undefined units.

Overflow and Underflow Errors or Warning

You can get overflow and underflow errors or warnings when using the Unit Conversion block. If you get:

- Overflow messages, change the data type at the output port to one with a better range
- Underflow messages, change the data type at the output port to one with better precision

Mismatched Units Detected

At the boundary of a component, Simulink detects if the units of two ports do not match. To see the tooltip, hover over the warning badge. If the unit is convertible, Simulink displays advice on fixing the issue.

The Model Advisor check “Identify unit mismatches in the model” identifies mismatched units.

Mismatched Units Detected While Loading

At the boundary of a component, Simulink detects if the units of two ports do not match. To see the tooltip, hover the warning badge. When possible, Simulink displays advice on fixing the issue.

The Model Advisor check “Identify unit mismatches in the model” identifies mismatched units.

Disallowed Unit Systems

Simulink supports only the unit systems listed in the tables of allowed units.

The Model Advisor check “Identify disallowed unit systems in the model” identifies unit systems that are not allowed in the configured units systems.

Automatic Unit Conversions

If the **Allow automatic unit conversions** configuration parameter is set, Simulink supports the automatic conversion of units. Simulink flags automatically converted units with the  badge.

For a list of the automatic unit conversions, use the Model Advisor check “Identify automatic unit conversions in the model”.

Unsuccessful Automatic Unit Conversions

If the **Allow automatic unit conversions** configuration parameter is set, Simulink supports the automatic conversion of units. If Simulink cannot perform the automatic unit conversion, Simulink returns a warning (). In such cases, consider manually specifying the unit.

Tip Automatic unit conversion is a convenience. For better control of units, you can manually set the units for two connecting ports.

Simscape Unit Specification Incompatible with Simulink

If these are true:

- You define a new unit to your unit registry by using the `pm_addunit` function.
- You use the new unit with the Simulink-PS Converter or PS-Simulink Converter block.
- Your new unit conflicts with an existing one in the Simulink database.

Simulink returns a warning about a potential incorrect calculation ().

Models with While Structures

Conditionally Executed Subsystems Overview

A conditionally executed subsystem is an atomic subsystem that allows you to control its execution with an external signal. The external signal, called the control signal, is attached to the control input port. Conditional subsystems are useful when you create complex models that contain components whose execution depends on other components.

Simulink supports these types of conditional subsystems:

- **Enabled Subsystem** — Executes at each time step while the control signal is positive. Execution starts at the time step when the control signal crosses zero from the negative to the positive direction. See “Using Enabled Subsystems” on page 10-11.
- **Triggered Subsystem** — Executes at each time step when the control signal rises or falls to zero or crosses zero. See “Using Triggered Subsystems” on page 10-21.
- **Enabled and Triggered Subsystem** — Executes at the time step when the enable control signal has a positive value and the trigger control signal rises or falls to zero. See “Using Enabled and Triggered Subsystems” on page 10-26.
- **Function-Call subsystem** — Executes when the control signal receives a function-call event. Events can occur one or more time during a time step. A Stateflow chart, Function-Call Generator block, or an S-function block can provide function call events. See “Using Function-Call Subsystems” on page 10-44.

Ensure Output is Virtual

Simulink can add a hidden signal buffer before the Outport block in a conditional subsystem or before an Outport block at the root-level of a model. This buffer ensures consistent initialization of the Outport block signal.

In a few cases, adding a signal buffer with a conditional output signal or partial write signal can cause a different simulation result. The parameter **Ensure output is virtual** is an option on an Outport block to remove the buffer. Select this option when you are concerned with conditional or partial write signals.

Conditional Output Signal

Consider the following model.

The Merge block combines its inputs into a single signal whose value at any time is equal to the most recently computed output of its driving blocks.

For the case with most models, clear (uncheck) the **Ensure output is virtual** check box on the Output block connected to Enabled Subsystem C.

- The output block follows non-virtual semantics. A hidden buffer is inserted if needed before the Output block.
- The buffer provides consistent initialization of the Output block signal.

Time 0: A runs, C does not run, but because the buffer is in A, it runs and copies the initial value of zero to the Output block. B does not run. The merge signal is zero from the output from A.

Time 0.5: A does not run. B runs and outputs a sine wave. The merge signal is the sine wave from B.

Time 1. A runs, C does not run, but the buffer again runs and copies over the initial value of zero to the Output block. B does not run. The merge signal is again the initial value of A, not the last value from B.

Simulating the model with a fixed-step, produces the following result.

For the case where you are concerned with conditional and partial writes, select (check) the **Ensure output is virtual** check box for the Output block connected to Enabled Subsystem C.

- The Output block follows virtual semantics.
- A hidden buffer is not inserted before the Output block of the Subsystem.
- If Simulink determines a buffer is needed, an error is displayed.

Time 0: A runs, C does not run. B does not run. Merge signal is the initial value of the signal.

Time 0.5 sec: A does not run. B runs and outputs a sine wave. The merge signal is the value of the sine wave from B.

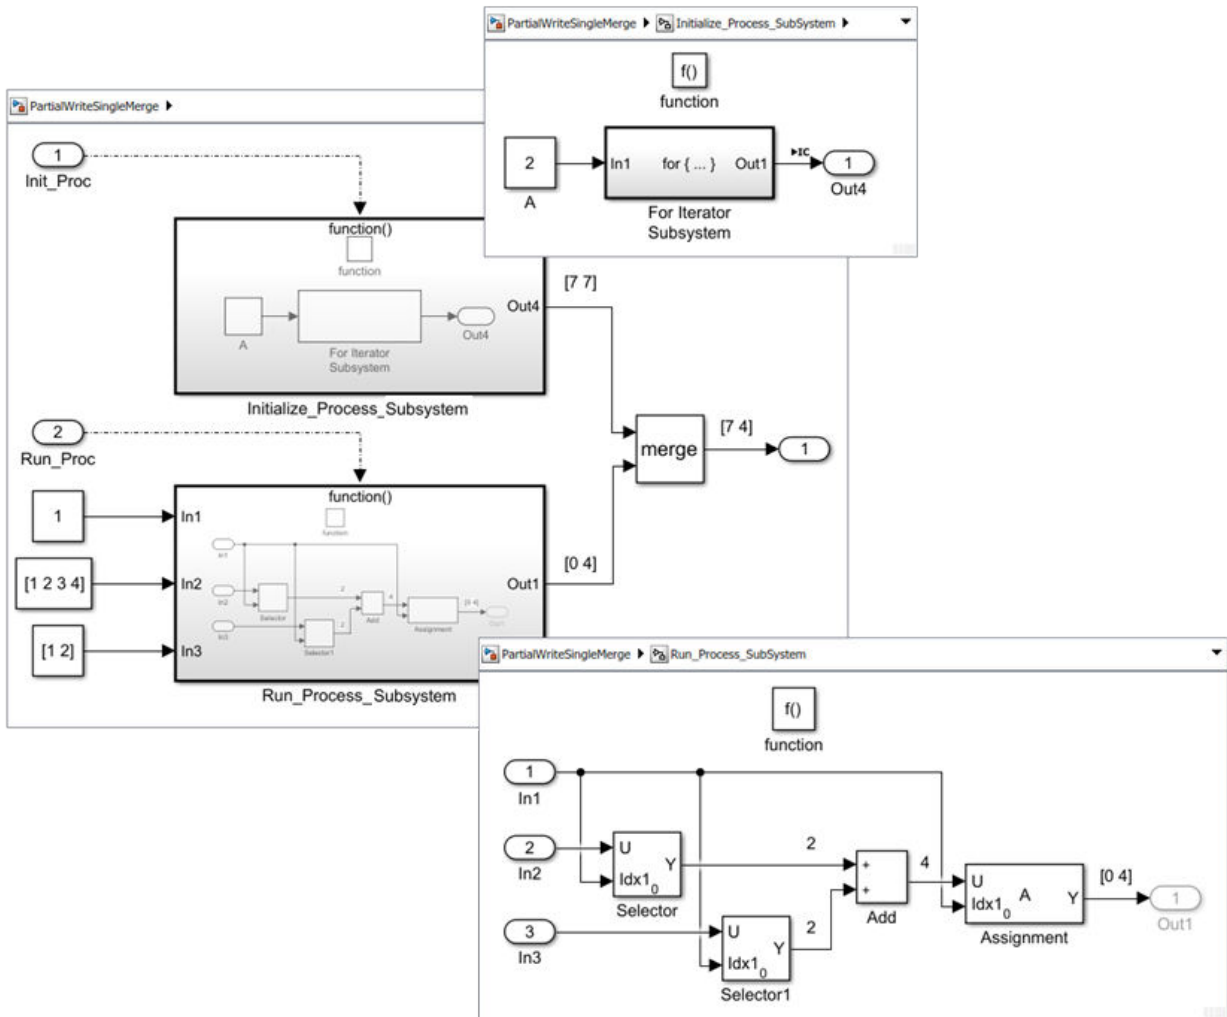

Time 1: A runs, C does not run. B does not run. The merge signal is the most recently computed output which was the sine wave from B.

Partial Write Signals With a Merge Block

A typical modeling pattern is where you want to initialize a vector signal and then periodically update partial elements of the signal based upon certain conditions or inputs. One way of modeling this pattern is to use a Merge block whose inputs are from two Function-Call Subsystem blocks. One subsystem is the initialize task while the other subsystem is a periodic write task.

The model below demonstrates this pattern. The Initialize_Process_Subsystem is called once at the beginning of a simulation to initialize a vector signal. The Run_Process_Subsystem is called to partially write to elements of the vector. However, the output from the Assignment block needs a path where hidden buffers do not make copies of the vector. Selecting the **Ensure output is virtual** check box on the Outputport block removes a hidden buffer. If Simulink determines the buffer is needed an error is displayed.

The Initialize_Process_SubSystem

- Initializes each element of a 2 element vector with a value of 7.
- Outputs the vector [7 7].

The Run_Process_Subsystem

- Inputs an index value of 1, but because the **Index mode** parameter for the Selector blocks is set to **Zero-based**, they select the 2nd elements from the input vectors.
- Adds the output scalar values from the Selector blocks for a result of 4.
- Because the Assignment block **Index mode** parameter is set to **Zero-based** and the input index Idx1 is 1, the output signal needs to be a vector with length 2. After setting the **Output size** parameter to 2, the Assignment block is able to write to the 2nd element.
- Selecting the **Ensure output is virtual** check box removes the hidden buffer.

Code generated from this model includes two functions. Init_Proc and Run_Proc.

```
/* Model step function */
void Init_Proc(void)
{
    int32_T s3_iter;

    /* Initialize signal vector elements with 7.0 */
    for (s3_iter = 0; s3_iter < 2; s3_iter++) {
        PartialWriteSingleMerge_DW.Assignment[s3_iter] = 7.0;
    }

    for (s3_iter = 0; s3_iter < 2; s3_iter++) {
        PartialWriteSingleMerge_Y.Out4[s3_iter] =
            PartialWriteSingleMerge_DW.Assignment[s3_iter];
    }
}

/* Model step function */
void Run_Proc(void)
{
    /* Write to element 1 of the output signal vector */
    PartialWriteSingleMerge_Y.Out4[1] = 4.0;
}
```

Using Enabled Subsystems

In this section...

“Create an Enabled Subsystem” on page 10-12

“Blocks in Enabled Subsystems” on page 10-13

“Alternately Executing Enabled Subsystems” on page 10-15

“Model Examples” on page 10-19

An enabled subsystem is a conditionally executed subsystem that runs once at each major time step while the control signal has a positive value. If the signal crosses zero during a minor time step, the subsystem is not enabled or disabled until the next major time step.

The control signal can be either a scalar or a vector.

- If a scalar value is greater than zero, the subsystem executes.
- If any one of the vector element values is greater than zero, the subsystem executes.

Create an Enabled Subsystem

To create an enabled subsystem:

- 1 Add an Enabled Subsystem block to your model.
 - Copy a block from the Simulink Ports & Subsystems library to your model.
 - Click the model diagram, start typing `enabled`, and then select Enabled Subsystem.

- 2 Set initial and disabled values for the Output blocks. See “Conditional Subsystem Initial Output Values” on page 10-48 and “Conditional Subsystem Output Values When Disabled” on page 10-69.
- 3 Specify how subsystem states are handled when the subsystem is enabled.

Open the subsystem block, and then open the parameter dialog box for the Enable port block. From the **States when enabling** drop-down list, select:

- `held` — States maintain their most recent values.
- `reset` — If the subsystem is disabled for at least one time step, states revert to their initial conditions.

In simplified initialization mode (default), the subsystem elapsed time is always reset during the first execution after becoming enabled. This reset happens regardless of whether the subsystem is configured to reset on being enabled. See “Underspecified initialization detection”.

For nested subsystems whose Enable blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem.

- 4 Output the control signal from the Enable block.

In the parameter dialog box for the Enable Block, select the **Show output port** check box.

Selecting this parameter allows you to pass the control signal into the enabled subsystem. You can use this signal with an algorithm that depends on the value of the control signal.

Blocks in Enabled Subsystems

Discrete Blocks

Discrete blocks in an enabled subsystem execute only when the subsystem executes, and only when their sample times are synchronized with the simulation sample time.

Consider the `ex_enabled_subsys_1` model, which contains four discrete blocks and a control signal. The discrete blocks are:

- Block A, with the sample time of 0.25 seconds
- Block B, with the sample time of 0.5 seconds

Signal E is the enable control signal generated by a Pulse Generator with a sample time of 0.125. Its output changes value from 0 to 1 at 0.375 seconds and returns to 0 at 0.875 seconds.

The discrete blocks in the enabled subsystem are:

- Block C, within the enabled subsystem, with the sample time of 0.125 seconds
- Block D, also within the enabled subsystem, with the sample time of 0.25 seconds

Discrete blocks execute at sample times shown.

Blocks A and B execute independently of the enable control signal because they are not part of the enabled subsystem. When the enable control signal becomes positive, blocks C and D execute at their assigned sample rates until the enable control signal becomes zero again. Block C does not execute at 0.875 seconds when the enable control signal changes to zero.

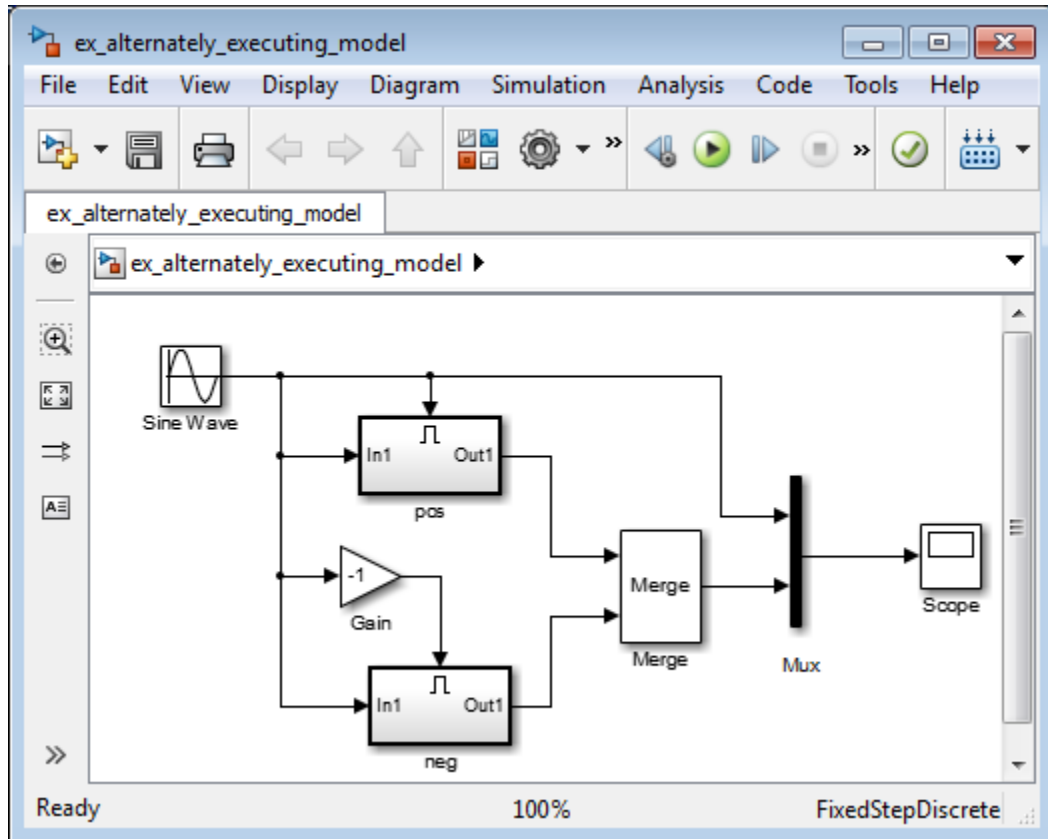

Goto Blocks

Enabled subsystems can contain Goto blocks. However, only output ports for blocks with state can connect to Goto blocks. See the Locked subsystem in the model `sldemo_clutch`, for an example of using Goto blocks in an enabled subsystem.

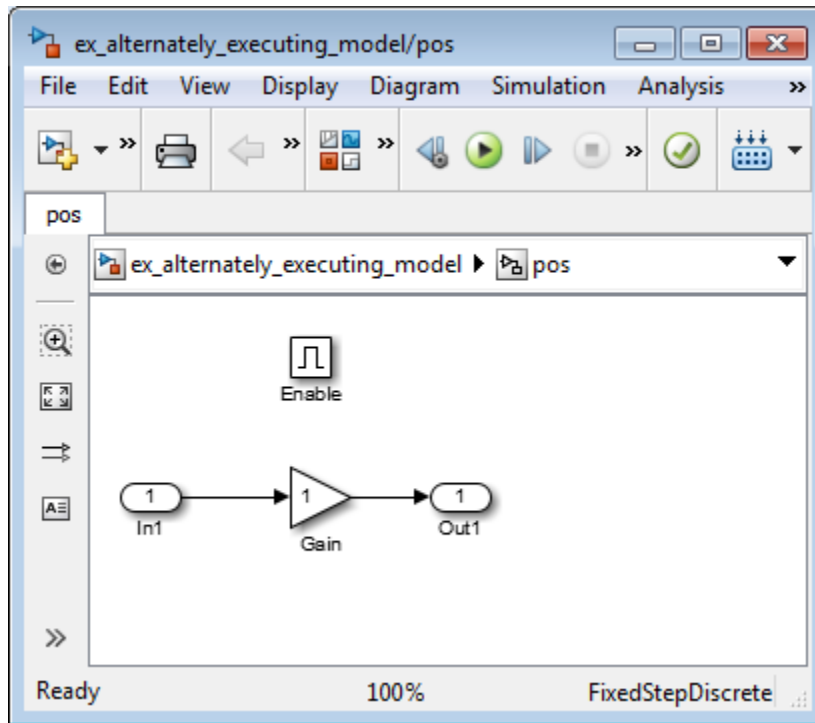

Alternately Executing Enabled Subsystems

You can use conditional subsystems with Merge blocks to create sets of subsystems that execute alternately, depending on the current state of the model.

Consider a model that uses two Enabled Subsystem blocks and a Merge block to model a full-wave rectifier (a device that converts AC current to pulsating DC current).

Open the `pos` subsystem. The subsystem is enabled when the AC waveform is positive and passes the waveform unchanged to its output.

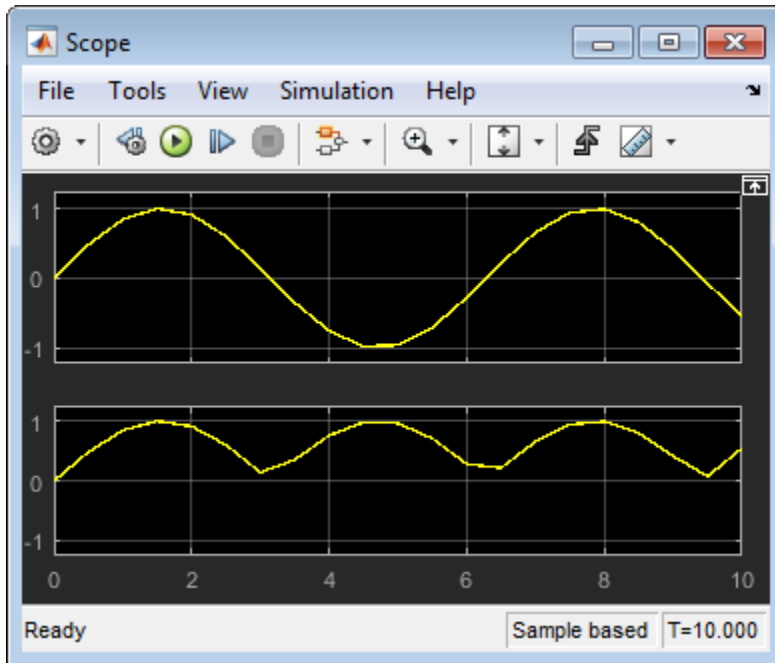

Open the `neg` subsystem. The subsystem is enabled when the waveform is negative and inverts the waveform.

The Merge block passes the output of the currently enabled subsystem along with the original waveform to the Scope block.

Running a simulation and then open the Scope block.

Using Triggered Subsystems

In this section...

“Create a Triggered Subsystem” on page 10-22

“Triggering with Discrete Time Systems” on page 10-24

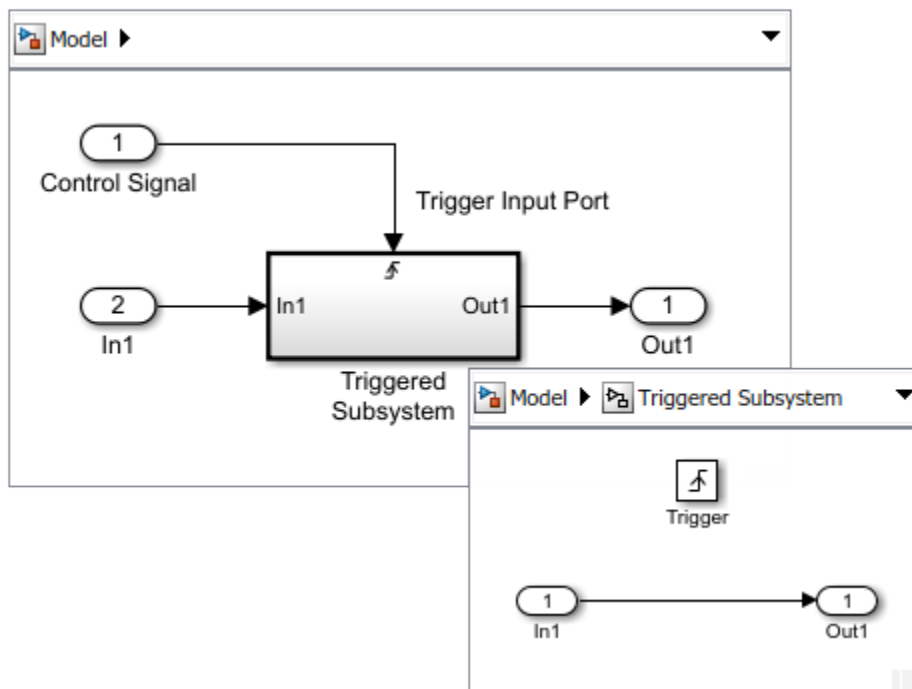

“Triggered Model Versus a Triggered Subsystem” on page 10-24

“Blocks in a Triggered Subsystem” on page 10-25

“Model Examples” on page 10-25

A triggered subsystem is a conditionally executed atomic subsystem that runs each time the control signal (trigger signal):

- Either rises from a negative value to a positive value or zero, or rises from a zero value to a positive value.
- Either falls from a positive value to a negative value or zero, or falls from a zero value to a negative value.
- Rises or falls through or to a zero value.

Unlike an Enabled Subsystem block, a Triggered Subsystem block always holds its outputs at the last value between triggers. Also, triggered subsystems cannot reset block states when executed; the states of any discrete block are held between triggers.

Create a Triggered Subsystem

To create a triggered subsystem:

- 1 Add a Triggered Subsystem block to your model.
 - Copy a block from the Simulink Ports & Subsystems library to your model.
 - Click the model diagram, start typing `trigger`, and then select Triggered Subsystem.

- 2 Set initial and disabled values for the Output blocks. See “Conditional Subsystem Initial Output Values” on page 10-48 and “Conditional Subsystem Output Values When Disabled” on page 10-69.
- 3 Set how the control signal triggers execution.

Open the subsystem block, and then open the parameter dialog box for the Trigger port block. From the **Trigger type** drop-down list, select:

- **rising** — Trigger execution of the subsystem when the control signal rises from a negative or zero value to a positive value.
- **falling** — Trigger execution of the subsystem when the control signal falls from a positive or zero value to a negative value.
- **either** — Trigger execution of the subsystem with either a rising or falling control signal.

Different symbols appear on the Trigger and Subsystem blocks to indicate rising and falling triggers.

- 4 Output the enable control signal from the Trigger port block. Open the Trigger port block. Select the **Show output port** check box to pass the control signal into the triggered subsystem.

You can use this signal with an algorithm that depends on the value of the control signal.

- 5 From the **Output data type** drop-down list, select auto, int8, or double.

The auto option causes the data type of the output signal to be the data type (either `int8` or `double`) of the block port connected to the signal.

Triggering with Discrete Time Systems

For a discrete time system, the trigger control signal must remain at zero for more than one time step. This triggering strategy eliminates false triggers caused by control signal sampling.

In the following timing diagram for a discrete system, a rising trigger signal (R) does not occur at time step 3. The trigger signal remains at zero for only one time step before the signal increases from zero.

Triggered Model Versus a Triggered Subsystem

You can place a Trigger port block in a Model block (referenced model) to simplify your model design instead of using one of these blocks:

- A Triggered Subsystem block in a Model block.
- A Model block in a Triggered Subsystem block.

For information about using Trigger port blocks in referenced models, see “Modify Referenced Models for Conditional Execution” on page 8-33.

To convert a subsystem to use model referencing, see “Convert Subsystems to Referenced Models” on page 8-24.

Blocks in a Triggered Subsystem

All blocks in a triggered subsystem must have **Sample time** set to inherited (-1) or constant (inf). This requirement allows the blocks in a triggered subsystem to run only when the triggered subsystem itself runs. This requirement also means that a triggered subsystem cannot contain continuous blocks, such as an Integrator block.

Using Enabled and Triggered Subsystems

In this section...

“Creating an Enabled and Triggered Subsystem” on page 10-27

“Blocks in an Enabled and Triggered Subsystem” on page 10-29

“Model Examples” on page 10-29

An Enabled and Triggered Subsystem is a conditionally executed subsystem that runs once at each simulation time step when both these conditions apply:

- Enabled control signal has a positive value.
- Trigger control signal rises or falls through zero.

An Enabled and Triggered Subsystem block contains both an Enable port block and a Trigger port block. When a trigger signal rises or falls through zero, the enable input port is checked to evaluate the enable control signal. If its value is greater than zero, the subsystem is executed. When both inputs are vectors, the subsystem executes if at least one element of each vector is nonzero.

Creating an Enabled and Triggered Subsystem

To create an enabled and triggered subsystem:

- 1 Add an Enabled and Triggered Subsystem block to your model.
 - Copy a block from the Simulink Ports & Subsystems library to your model.
 - Click the model diagram, start typing `enabled`, and then select Enabled and Triggered Subsystem.

- 2 Set initial and disabled values for the Outport blocks. See “Conditional Subsystem Initial Output Values” on page 10-48 and “Conditional Subsystem Output Values When Disabled” on page 10-69.
- 3 Set how the control signal triggers execution.

Open the subsystem block, and then open the block parameters dialog box for the Trigger port block. From the **Trigger type** drop-down list, select:

- **rising** — Trigger execution of the subsystem when the control signal rises from a negative or zero value to a positive value.
- **falling** — Trigger execution of the subsystem when the control signal falls from a positive or zero value to a negative value.
- **either** — Trigger execution of the subsystem with either a rising or falling control signal.

Different symbols appear on the Trigger and Subsystem blocks to indicate rising and falling triggers.

- 4 Specify how subsystem states are handled when enabled.

Open the subsystem block, and then open the Enable port block. From the **States when enabling** drop-down list, select:

- **held** — States maintain their most recent values.
- **reset** — States revert to their initial conditions if the subsystem is disabled for at least one time step.

In simplified initialization mode, the subsystem elapsed time is always reset during the first execution after becoming enabled. This reset happens regardless of whether the subsystem is configured to reset when enabled. See “Underspecified initialization detection”.

For nested subsystems whose Enable blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem.

Blocks in an Enabled and Triggered Subsystem

All blocks in an enabled and triggered subsystem must have **Sample time** set to inherited (-1 or constant (`inf`)). This requirement allows the blocks in a triggered subsystem to run only when the triggered subsystem itself runs. This requirement also means that a triggered subsystem cannot contain continuous blocks, such as an Integrator block.

Select Subsystem Execution

In this section...
“Models with If-Else Structures” on page 10-30
“Models with Switch Case Structure” on page 10-33
“Model Examples” on page 10-35

A logically executed subsystem block runs one or more times at the current time step when enabled by a control block. A control block implements control logic similar to that expressed by a programming language statement (e.g., if-then, switch, while, for).

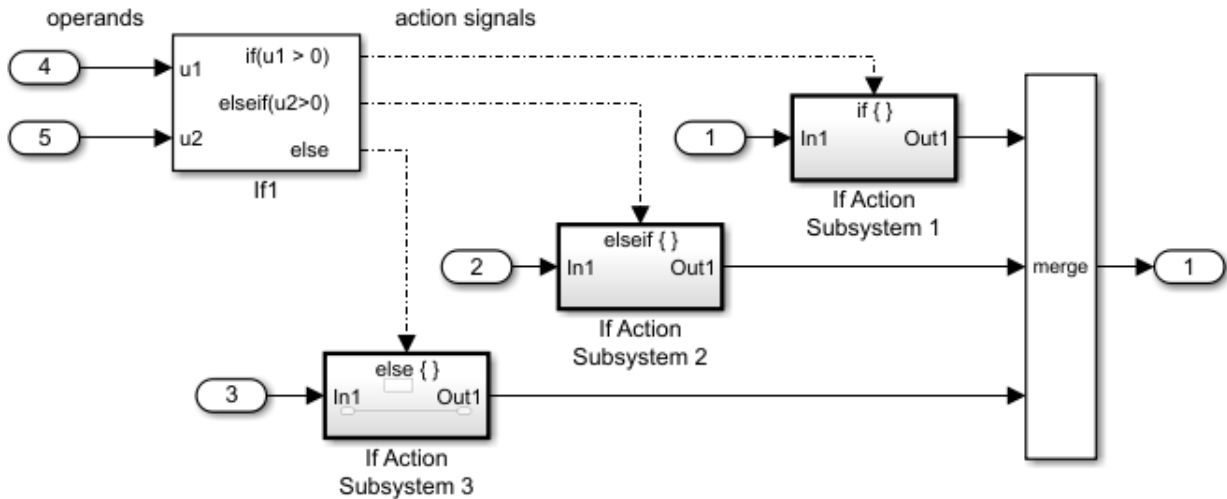

Selector subsystems are one type of logically executed subsystem that execute once during a time step in response to an action signal from a control block located external to the subsystem. Simulink supports two selector subsystem structures, if-else and switch-case.

Models with If-Else Structures

The If Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is enabled by an If block.

An external If block controls execution. The If block evaluates a logical expression and then, depending on the result of the evaluation, outputs an action signal to a If Action Subsystem block.

Consider the following model.

In this model, the inputs to the If block provide the operand values for the logical expressions represented as output ports. Each output port is attached to an If Action Subsystem block. The expressions in the If block are evaluated top down starting with the `if` expression. When an expression evaluates to true, its corresponding If Action Subsystem is executed and the remaining expressions are not evaluated.

The *if-else* structure in the model can be represented with the following pseudo code.

```
IF u1 > 0 THEN
    Subsystem 1
ELSEIF u2 > 0
    Subsystem 2
ELSE
    Subsystem 3
END IF
```

Create Model with If-Else Structure

To create the example model, use the following procedure.

- 1 Place an If block in the Simulink Editor. Double-click the block to open the block parameters dialog box.
- 2 In the **Number of inputs** box, enter 2.

Two input ports are added to the block. The inputs ports are for signals containing operand values, not necessary the number of operands. An input signal can be a vector. For example, you could specify the fifth element of a vector u in an expression as $u(5) > 0$.

- 3** In the **If expression** text box, enter $u1 > 0$.

An output port is added to the block with the label $if(u1 > 0)$. This port is the only required output for an If block.

- 4** In the **Elseif expressions** text box, enter $u2 > 0$.

You can enter multiple elseif expressions with a comma separating the expressions. Each expression adds an output port to the If block with a label of the form `elseif(expression)`.

- 5** Check the **Show else condition** check box.

An output port is added to the block with the label `else`.

- 6** Add three If Action Subsystem blocks.

These blocks are Subsystem blocks with an Action Port block. When you place an Action Port block inside a subsystem, an input port named Action is added to the block.

- 7** Connect each output port from the If block to the action port of an If Action Subsystem block.

When you make the connection, the icon for the If Action Subsystem block is renamed to the type of expression that attached to it.

- 8** In each If Action Subsystem block, enter the Simulink blocks to be executed for the condition it handles.

- 9** Connect outputs from If Action Subsystem blocks to a Merge block.

- 10** Run a simulation.

The action signal lines between the If block and the If Action Subsystem blocks change from a solid to a dashed line.

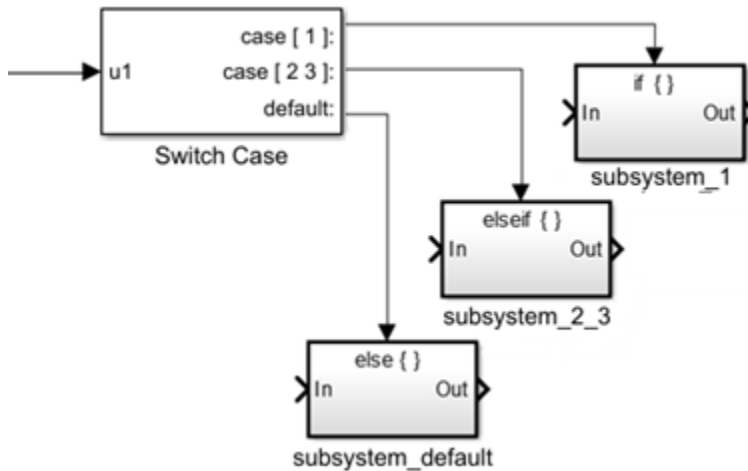

Note All blocks in an If Action Subsystem block driven by an If block must run at the same rate as the driving block.

Models with Switch Case Structure

The Switch Case Action Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem whose execution is enabled by a Switch Case block.

An external Switch Case block controls execution. The Switch Case block evaluates a case index and then, depending on the selected case, outputs an action signal to a Switch Case Action Subsystem block.

Consider the following model with a *switch* structure.

In this model, the input to the Switch Case block provides the index value for selecting a case represented as output ports. Each output port is attached to an If Action Subsystem block. When a case is selected, its corresponding If Action Subsystem is executed.

The *switch* structure in the model can be represented with the following pseudo code.

```

CASE u1
  u1 = 1:
    subsystem_1
    break
  u1 = 2 or 3:
    subsystem_2_3
    break
  u1 = OTHER VALUES:
    subsystem_default

```

```
        break
    END CASE
```

Create Model with Switch Case Structure

To create the example model, use the following procedure.

- 1 Place a Switch Case block in the Simulink Editor. Double-click the block to open the block parameters dialog box.
- 2 In the **Case conditions** box, enter {1, [2,3]}.

Two cases are defined. The first case when the input value is 1, and the second case when the input value is 2 or 3. Cases can be single or multivalued and appear as output ports on the Switch Case block. Non-integer input values are truncated to integers.

- 3 Select the **Show default case** check box.

An output port labeled `default` is added to the block. This port sends an action signal if no other cases are selected.

- 4 Add three Switch Case Action Subsystem blocks.

These blocks are Subsystem blocks with an Action Port block. When you place an Action Port block inside a subsystem, an input port named Action is added to the block.

- 5 Connect each output port from the Switch Case block to the action port of an Switch Case Action Subsystem block.

When you make the connection, the icon for the Switch Case Action Subsystem block is renamed to the type of expression attached to it.

- 6 In each Switch Case Action Subsystem block, enter the Simulink blocks to be executed for the case it handles.
- 7 Run a simulation.

The action signal lines between the Switch Case block and the Switch Case Action Subsystem blocks change from a solid to a dashed line.

Note After the subsystem for a particular case executes, an implied break terminates the execution of the Switch Case block. Simulink Switch Case blocks do not exhibit the fall-through behavior of C `switch` statements.

Iterate Subsystem Execution

In this section...
“Models with While Structures” on page 10-36
“Model with For Structures” on page 10-39
“Model Examples” on page 10-43

A logically executed subsystem block runs one or more times at the current time step when enabled by a control block. A control block implements control logic similar to that expressed by a programming language statement (e.g., if-then, switch, while, for).

Iterator subsystems are one type of logically executed subsystem that execute one or more times during a time step in response to a control block internal to the subsystem block.

Note The While Iterator Subsystem and For Iterator Subsystem blocks must not contain blocks with continuous states (for example, blocks from the Continuous block library). The sample times of all blocks within the subsystem must be either inherited (-1) or constant (inf).

Models with While Structures

The While Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step while a logical (Boolean) expression is true.

Consider the following model.

An input of 1 (true) to the While Iterator block activates the subsystem. At each time step, the current iterative number is added to a running total until a maximum sum is reached.

The *while* structure in the model can be represented with the following pseudo code.

```

maximum_sum = 10;
sum = 0;
iteration_number = 0

condition = (maximum_sum > 0)
WHILE condition NOT EQUAL 0
    iteration_number = iteration_number + 1
    sum = sum + iteration_number
    IF (sum > maximum_sum OR iteration_number > maximum_iterations) THEN
        condition = 0
    END WHILE

```

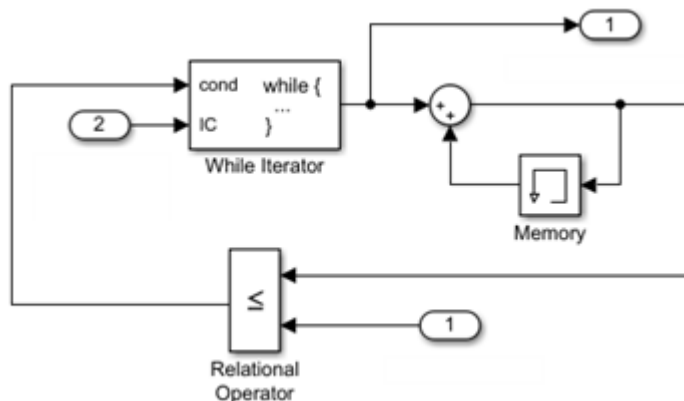

Create Model with While Structure

To create the example model, use the following procedure.

- 1 Place a While Iterator Subsystem block in the Simulink Editor. Double-click the subsystem block to display its contents.

- 2 Double-click the While Iterator block to open its block parameters dialog box. Set the **Maximum number of iterations** to 20 and **States when starting** to reset. Select the **Show iteration number** port check box.
- 3 Add Memory, Relational Operator, and Sum blocks. Connect blocks as shown. For the Memory block, select the **Inherit sample time** check box.

The iteration number from the output of the While Iterator block is added to its previous value until the sum is greater or equal to the maximum sum from Inport block 1.

- 4 Navigate to the top level of the model.
- 5 Connect a Constant block to input port 2. This block provides the *initial logical condition* value for the While Iterator block. Set the **Constant value** to any non-zero number.

The While Iterator block requires an initial logical condition (input port labeled IC) for its first iteration. This signal enables the While Iterator Subsystem block and must originate from outside the subsystem. If this value is nonzero, the first iteration takes place.

- 6 Connect a second Constant block to input port 1. This block provides a maximum value for the iterative algorithm. The algorithm adds successive integers until a maximum value is reached.
- 7 Connect a Display block to output port 1. This block shows the number of iterations from the While Integrator block output port.
- 8 Run a simulation.

During a single time step, the first four iteration numbers are added for a total sum (10). With the fifth iteration, the sum (15) is greater than the maximum sum (10), the iterations stop, and the block waits for the next time step.

Note Simulation time does not advance during iterative executions of a While Iteration Subsystem block. Nevertheless, blocks in the subsystem treat each iteration as a time step. As a result, in a While Iterator Subsystem block, the output of a block with states (that is, a block whose output depends on its previous input), reflects the value of its input at the previous iteration of the `while` loop. The output does *not* reflect the block input at the previous simulation time step. For example, a Unit Delay block in a While subsystem outputs the value of its input at the previous iteration of the `while` loop, not the value at the previous simulation time step.

Model with For Structures

The For Iterator Subsystem block is a Subsystem block preconfigured as a starting point for creating a subsystem that repeats execution during a simulation time step for a specified number of iterations.

Consider the following model.

The input to the For Iterator block specifies the number of iterations. At each time step, the current iterative number is added to a running total for 5 iterations.

The *for* structure in the model can be represented with the following pseudo code.

```

number_of_iterations = 5
sum = 0;
iteration_number = 0

FOR iteration_number = 0 TO number_of_iterations
    iteration_number = iteration_number + 1
    sum = sum + iteration_number
END FOR
    
```

Create Model With For Structure

To create the example model, use the following procedure.

- 1 Place a For Iterator Subsystem block in the Simulink Editor. Double-click the subsystem block to display its contents.

- 2 Double-click the For Iterator block to open its block parameters dialog box. Set **States when starting** to reset and **Iteration limit source** to external.
- 3 Add Memory, Sum, and Outport blocks. Connect blocks as shown. For the Memory block, select the **Inherit sample time** check box.

The iteration number from the output of the For Iterator block is added to its previous value for the specified number of iterations from Inport block 1.

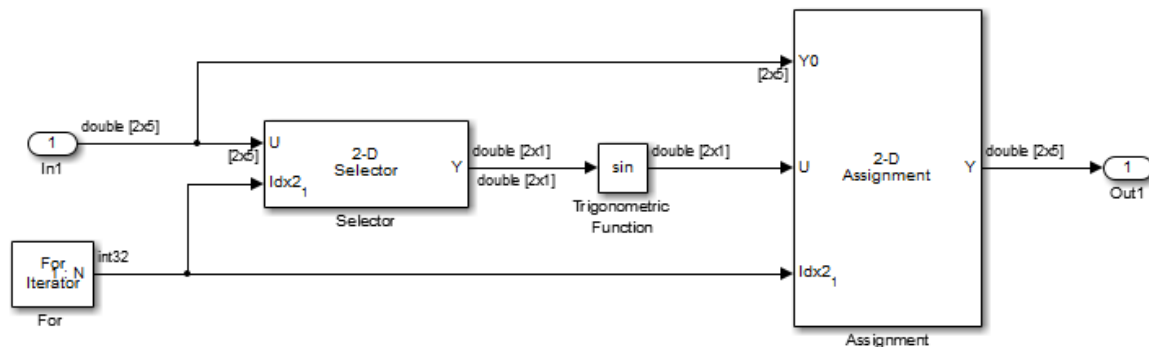

- 4 Navigate to the top level of the model.
- 5 Connect a Constant block to input port 1. This block provides the number of iterations for the For Iterator block. Set the **Constant value** to 5.
- 6 Connect Display blocks to output ports 1 and 2. These blocks show the number of iterations from the For Iterator block output port and the sum from the Memory block.
- 7 Run a simulation.

During each time step, the first five iteration numbers are added for a total sum (15).

Using Assignment Blocks

The For Iterator block works well with the Assignment block to reassign values in a vector or matrix. The following example shows the use of a For Iterator block. Note the matrix dimensions in the data being passed.

The example outputs the sine value of an input 2-by-5 matrix (2 rows, 5 columns) using a For subsystem containing an Assignment block. The process is as follows.

- A 2-by-5 matrix is input to the Selector block and the Assignment block.
- The Selector block strips off a 2-by-1 matrix from the input matrix at the column value indicated by the current iteration value of the For Iterator block.
- The sine of the 2-by-1 matrix is taken.
- The sine value 2-by-1 matrix is passed to an Assignment block.
- The Assignment block, which takes the original 2-by-5 matrix as one of its inputs, assigns the 2-by-1 matrix back into the original matrix at the column location indicated by the iteration value.

The rows specified for reassignment in the parameter dialog box for the Assignment block in the example are [1,2]. Because there are only two rows in the original matrix, you could also have specified -1 for the rows (that is, all rows).

Note The Trigonometric Function block is already capable of taking the sine of a matrix. The example uses the Trigonometric Function block only as an example for changing each element of a matrix with the collaboration of an Assignment block and a For Iterator block.

Using Function-Call Subsystems

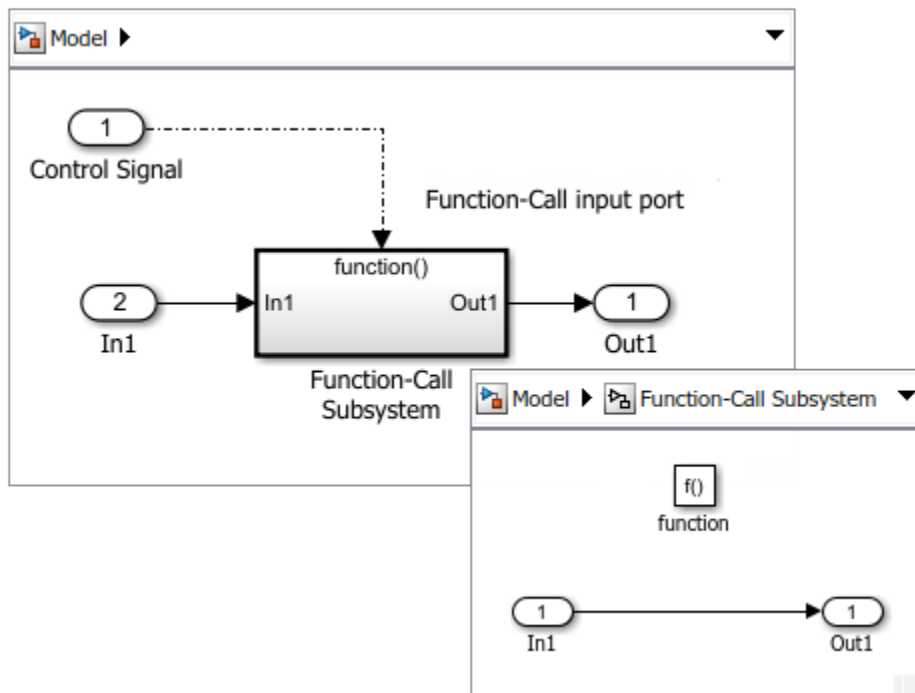

In this section...

“Creating a Function-Call Subsystem” on page 10-45

“Sample Time Propagation in a Function-Call Subsystem” on page 10-45

“Model Examples” on page 10-46

A Function-Call Subsystem block is a conditionally executed subsystem that runs each time the control signal receives a function-call event. A Stateflow chart, Function-Call Generator block, or an S-function block can provide function call events.

A function-call subsystem is analogous to a function in a procedural programming language. Invoking a function-call subsystem executes the output methods of the blocks within the subsystem in sorted order. For an explanation of Function-Call Subsystem blocks parameters, see [Subsystem](#), [Atomic Subsystem](#), [Nonvirtual Subsystem](#), [CodeReuse Subsystem](#)

Creating a Function-Call Subsystem

To create a function-call subsystem:

- 1 Add a Function-Call Subsystem block to your model.
- 2 Open the subsystem block. Add a block diagram defining the algorithm that is executed when the subsystem receives a function-call event.
- 3 Set initial and disabled values for the Output blocks. See “Conditional Subsystem Initial Output Values” on page 10-48 and “Conditional Subsystem Output Values When Disabled” on page 10-69.
- 4 Set how subsystem states are handled when subsystem is executed.

Open the subsystem block, and then open the block parameters dialog box for the Trigger block. From the **States when enabling** drop-down list, select:

- **held** — States maintain their most recent values.
- **reset** — States set to their initial conditions.
- **inherit** — Use the held or reset setting from the parent subsystem initiating the function-call.

For nested subsystems whose Function-Call Subsystem blocks have different parameter settings, the settings for the child subsystem override the settings inherited from the parent subsystem.

- 5 Attach a function-call initiator to the function-call input port.

If you attach an Inport block, open the block, select the Signal Attributes pane, and then select the **Output function call** check box.

Sample Time Propagation in a Function-Call Subsystem

Configure a Function-Call Subsystem block by setting the **Sample time type** of its Trigger port block to **triggered** or **periodic**.

- A triggered (aperiodic) function-call subsystem can execute zero, one, or multiple times during a time step.

If a function-call subsystem is executed by a root-level function-call Inport block with a discrete sample time, multiple function-calls during a time step are not allowed. To allow multiple function-calls, set **Sample time** to **-1** (inherited), and set the sample time for all blocks in the function-call subsystem to **-1** (inherited).

- A periodic function-call subsystem executes once during a time step and must receive periodic function-calls. If the function-calls are aperiodic, the simulation stops and an error message is displayed. Set the sample time for all blocks in the function-call subsystem to -1 (inherited).

Note During range checking, the minimum and maximum parameter settings are back-propagated to the actual source port of the function-call subsystem, even when the function-call subsystem is not enabled.

To prevent this back propagation:

- 1 Add a Signal Conversion block and a Signal Specification block after the source port.
 - 2 Set the **Output** of the Signal Conversion block to `Signal copy`.
 - 3 Specify the minimum and maximum values for the Signal Specification block instead of specifying them on the source port.
-

Conditional Subsystem Initial Output Values

In this section...
“Inherit Initial Output Values from Input Signals” on page 10-48
“Specify Initial Output Values Using Dialog Parameters” on page 10-49

To initialize the output values for a conditional subsystem, initialize Output blocks within the subsystem by using one of these methods:

- Inherit initial output values from input signals connected to the Output blocks.
- Specify initial output values using Output block parameters.

Note If the conditional subsystem is driving a Merge block in the same model, you do not need to specify an initial condition for the subsystem Output block.

Inherit Initial Output Values from Input Signals

Simulink attempts to use input signals connected to conditional subsystem Output blocks to initialize output values. This behavior is seen after setting the Output block parameter **Source of initial output value** to `Input signal`. The exact same behavior is seen when **Source of initial output value** is set to `Dialog` and **Initial output** is set to `[]`.

Valid input signals for setting initial output values are:

- Output ports from another conditionally executed subsystem
- Output ports from a Model block with a Trigger block set to function-call
- Merge blocks
- Constant blocks
- IC (initial condition) blocks
- Simulink signal object attached to the signal line connected to the Output block. If the `InitialValue` parameter is defined, Simulink uses this value.
- Stateflow chart

If the input signal is from a block that is not listed here, the Output block uses the default initial value of the output data type.

Note If you are using classic initialization mode, selecting `Input signal` causes an error. To inherit the initial output value from an input signal, set the **Source of initial output value** parameter to `Dialog`, set **Output when disabled** to `held`, and set **Initial output** to the empty matrix `[]`.

Specify Initial Output Values Using Dialog Parameters

Explicitly set the initial output values in cases where you want to:

- Test the behavior of a model with various initial values.
- Set initial values to steady state and reduce simulation time.
- Eliminate having to trace input signals to determine the initial output values.

To specify initial output values

- 1 Open the dialog box for an Output block within a conditional subsystem.
- 2 From the **Source of initial output value** drop-down list, select `Dialog`.
- 3 In the **Initial output** box, enter the initial value.

Rate-Based Models Overview

You can control the execution of model components (Subsystem and Model blocks) by using export-function models or rate-based models. Benefits of scheduling components are:

- Full control over scheduling of model components rather than letting Simulink implicitly schedule the components.
- No need to deal with data dependency issues between components. That is, there are only data transfers.

See Also

More About

- “Sorting Rules for Explicitly Scheduled Model Components” on page 10-58

Create A Rate-Based Model

A rate-based model is a model with explicitly scheduled subsystems. You can schedule a subsystem with a periodic execution rate by specifying the **Sample time** parameter for an Inport block connected to the Subsystem block, the Subsystem block, or a block within the Subsystem block where Sample time can be specified (for example, a Delay block).

Note Using Continuous time blocks such as Integrator blocks are not allowed. Instead use discrete time equivalent blocks

Consider the following model with two atomic Subsystem blocks. Subsystem1 multiplies its input by 2 while Subsystem2 multiplies its input by 4.

- 1 Open the Inport 1 dialog box. On the Signal Attributes tab, set the **Sample time** to 0.2.
- 2 Open the Inport 2 dialog box. On the Signal Attributes tab, set the **Sample time** to 0.4.
- 3 If a rate-based model has multiple rates, single tasking is not allowed. Select the Configuration Parameter check box for **Treat each discrete rate as a separate task**.

Test Rate-Based Model Simulation Using Function-Call Generators

In this section...
“Create Test Model That References a Rate-Based Model” on page 10-52
“Simulate Rate-Based Model” on page 10-54

This topic describes how to reference a rate-based model in a test mode, and then add periodic function-call event ports to the test model for simulation.

Create Test Model That References a Rate-Based Model

Testing a rate-based model includes referencing the model from a Model block in a test model, adding periodic function-call event ports to the Model block, and then connecting function-calls to the ports.

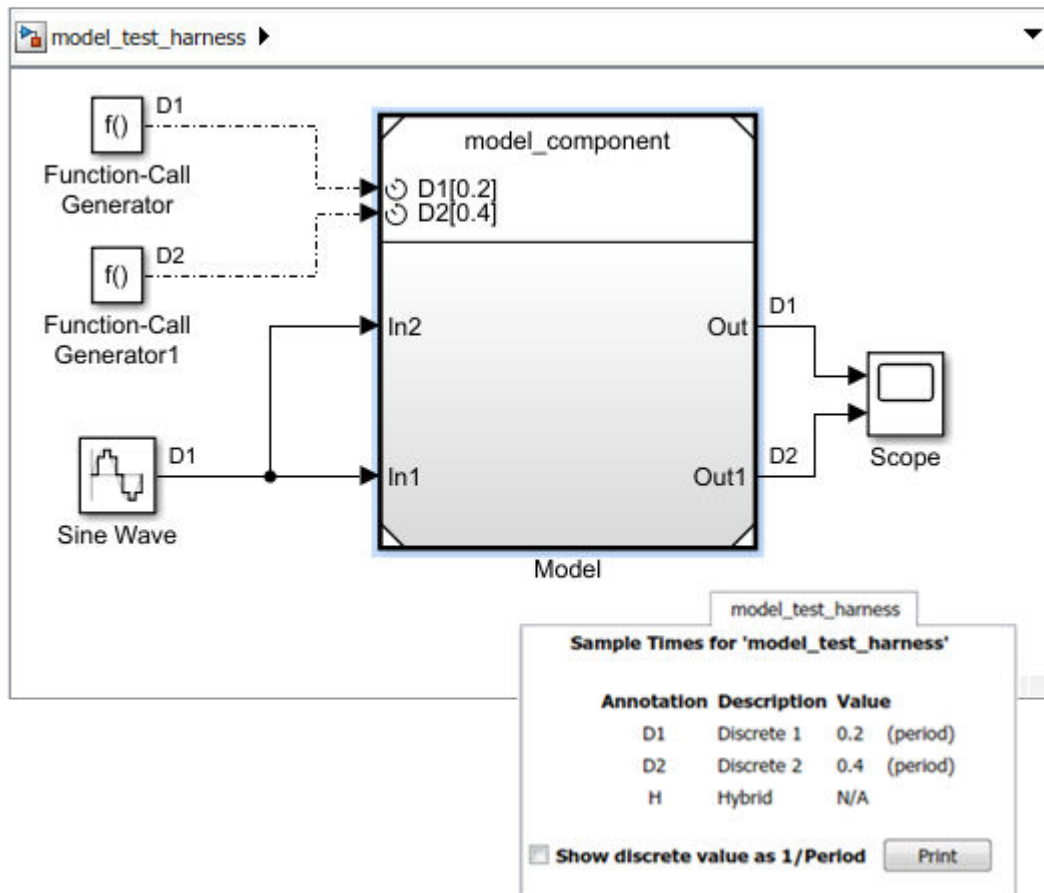

- 1 Create a new Simulink model.
- 2 Add a Model block and open the block parameters dialog box.
- 3 In the **Model name** box, enter the file name for the rate-based model.
- 4 Select the **Schedule rates** check box.

Periodic function-call event ports are added to the Model block with the **Sample times** you specified for the Inport blocks connected to the Subsystem blocks.

- 5 Specify the execution rate using function-call initiators (Function-Call Generator blocks or Stateflow charts). The function-call events and scheduling of the events are located outside of the Model block referencing the rate-based model.

In this example, add Function-Call Generator blocks. Open the block dialog box for the blocks and specify **Sample time**.

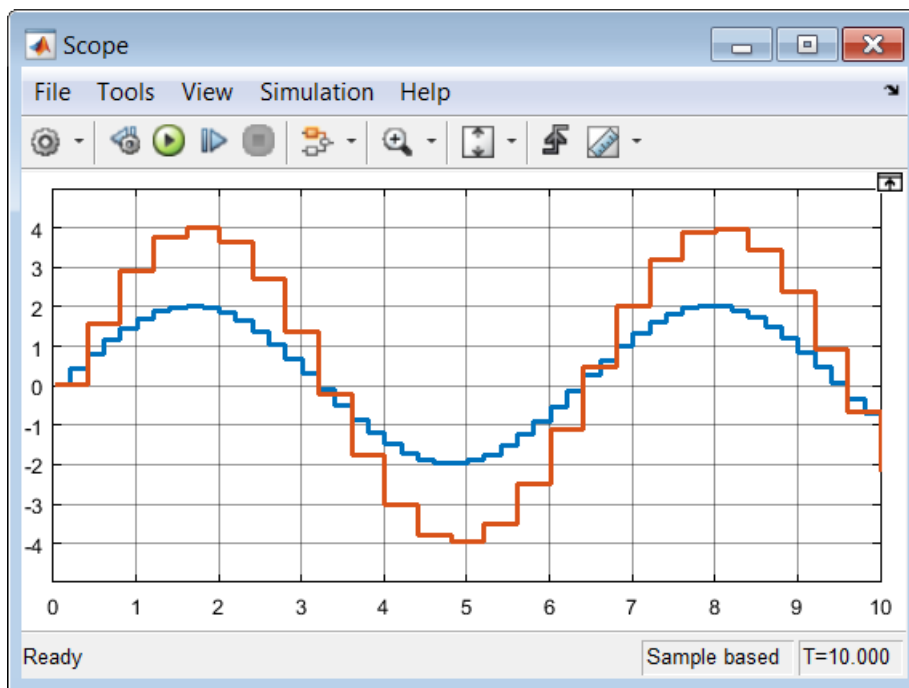

Subsystems or referenced models in a rate-based model with the same sample time must have a common rate initiator. This requirement includes periodic scheduled subsystems and event-driven Function-Call Subsystem blocks with the same rate.

- Use a fixed-step solver for simulation. Set the Configuration Parameters **Type** to Fixed-step, Solver to auto, and **Fixed-step size** to auto.

Simulate Rate-Based Model

Simulate the behavior of a rate-based model from the test model.

- 1 Run a simulation. Some common compile and run-time errors are caused by:
 - A periodic event port that is not connected to a function-call initiator with the same specified sample time.
 - A scheduled Inport block (**Sample time** parameter set to a value) in the referenced component model that does not specify one of the periodic function-call event port rates (sample times specified in the **Port discrete rates** table).
- 2 Observe the behavior of the component model. Open the Scope block.

Generate Code from Rate-Based Model

Generate code from the rate-based model, not from the model test harness. For scheduled subsystems with different discrete rates, multi-tasking is required and the resulting code has separate entry points.

- 1 Generate code for the component model. From the menu, select **Code > C/C++ Code > Build Model**.
- 2 Open the code generation report. From the menu, select **Code > C/C++ Code > Code Generation Report > Open Model Report**.

Function: [model_component_step](#)

Sorting Rules for Explicitly Scheduled Model Components

Simulink determines the sorted order for model components (subsystems and referenced models).

Export-Function Models

Export-function models include Function-Call Subsystem blocks, function-call Model blocks, Simulink Function blocks at the root level, and S-Function blocks invoked by function-call root Inport blocks.

Root function-call Inport blocks are sorted with the following rules:

- First compare block priorities. The block with the highest priority (a small value) is sorted before the others.

- If block priorities are the same, compare their sample times. The block with a faster rate (a smaller sample time value) is sorted before the other.
- If the sample times are the same, compare the input port numbers. The block with the smaller port number is sorted before the other.

Root Simulink Function blocks are sorted after root function-call Inport blocks.

Test Harness for Export Function Models with Strict Scheduling

Reference the export-function model in a test harness and connect ports to Function Generator blocks.

If you select the Configuration Parameter **Enable strict scheduling checks for referenced models**, both compile time and run-time checks ensure initiators will invoke function-calls based on the pre-defined scheduling order. Initiators are sorted based on their sample time priorities. For this example, the scheduling order and the sample time priorities do not match. The model `mHarness_ExpFcnMdl` displays an error.

The Model block '[mHarness_ExpFcnMdl/Model](#)' requires that function-call input port 'fcIn2' execute before function-call input port 'fcIn3'. However, this execution order cannot be honored because the task priority of the sample time for function-call input port 'fcIn2' is lower than that of function-call input port 'fcIn3'. The two function-call input ports are driven by the function-call initiator blocks, '[mHarness_ExpFcnMdl/FcnCallGenOp4](#)' and '[mHarness_ExpFcnMdl/FcnCallGenOp3](#)', respectively. Consider using a function-call initiator with faster sample time (higher priority) or higher asynchronous task priority for function-call input port 'fcIn2'.

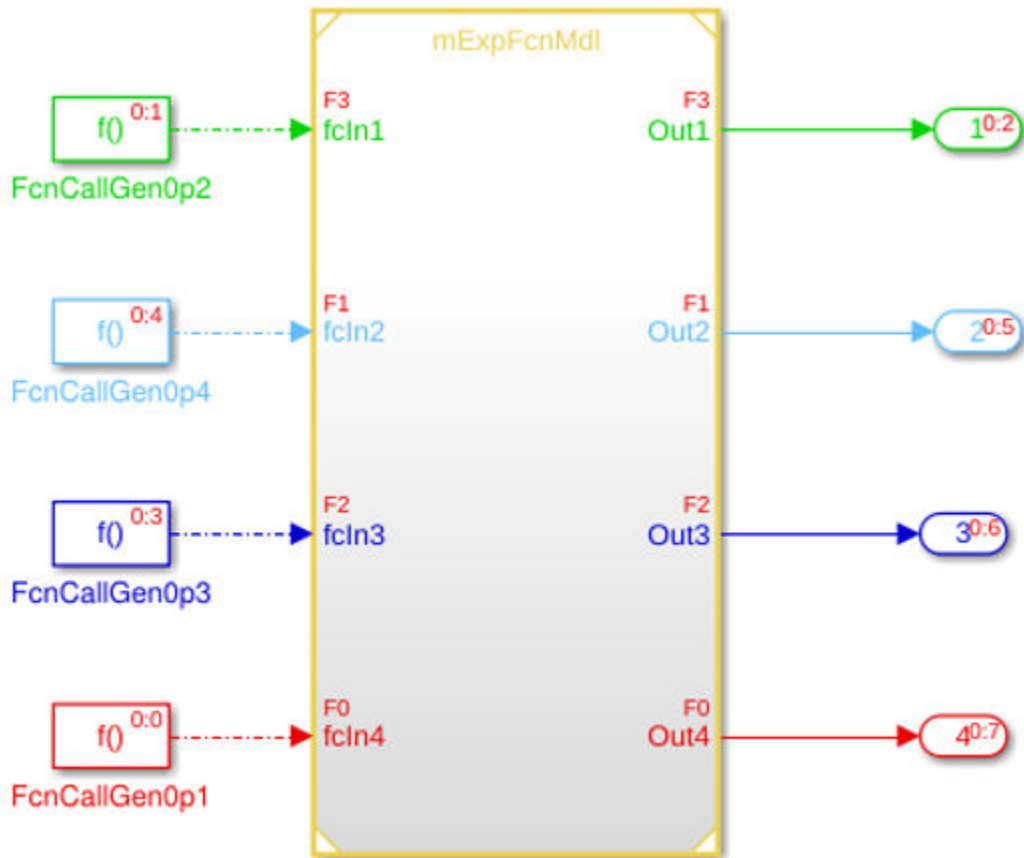

▼ **Suggested Actions**

- To disable this error message, clear the parameter 'Enable strict scheduling checks for referenced models' in the Model Referencing page of the Configuration Parameters dialog.
- Alternatively, consider using a Function-Call Split block or a common function-call initiator block such as a Stateflow chart to schedule function-calls for these two input ports in the required order.

Fix

Test Harness for Export-Function Models Without Strict Scheduling

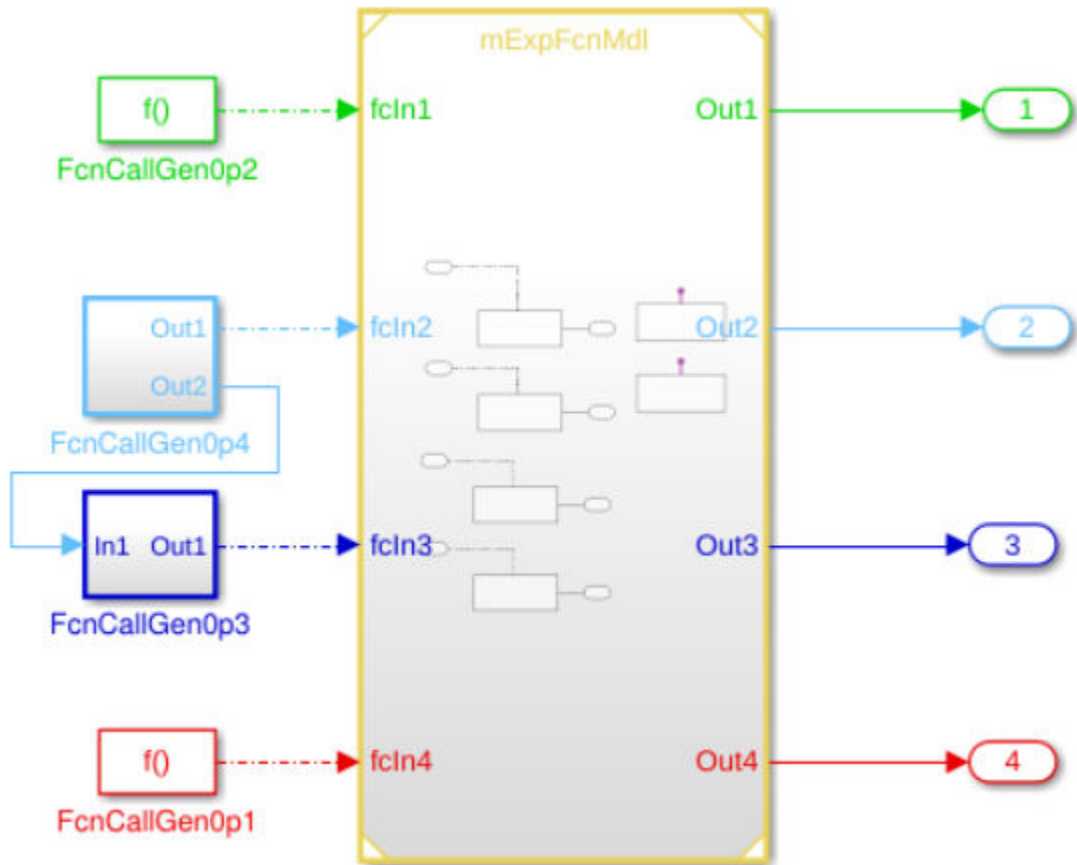

Reference the export-function model in a test harness and connect ports to Function Generator blocks.

If you clear the Configuration Parameter **Enable struct scheduling checks for a referenced model** and the test harness model is in signal taking mode. The function-call initiators are sorted based on their sample time priorities. For this example, the sorted order is FcnCallGen0p1 > FcnCallGen0p2 > FcnCallGen0p3 > FcnCallGen0p1.

Data Dependency Error Caused by Data Sorting Rules

Consider a model where the output from one function-call initiator is the input to another.

The function-call initiator FcnCallGen0p3 should be sorted before FcnCallGen0p4. However, because FcnCallGen0p4 is also a source for FcnCallGen0p3 a data dependency occurs and Simulink displays an error.

▼ Update Diagram 4

11:24 PM Elapsed: 0.441sec

The function-call initiators invoking the export-function model referenced by Model block '[mHarness_ExpFcnMdl_Loop/Model](#)' must execute in the order of their sample times or task priorities. In a model with a single task, this implies that '[mHarness_ExpFcnMdl_Loop/FcnCallGen0p3](#)' must execute before '[mHarness_ExpFcnMdl_Loop/FcnCallGen0p4](#)'. However, applying this rule caused a data dependency violation. Consider clearing the 'Configuration Parameters' > 'Solver' > 'Treat each discrete rate as a separate task' option or tracing the data connections between the blocks listed below to resolve the data dependency loop.

Component: Simulink | Category: Model error

Block '[mHarness_ExpFcnMdl_Loop/FcnCallGen0p3](#)' is involved in the loop.

Component: Simulink | Category: Model error

Block '[mHarness_ExpFcnMdl_Loop/FcnCallGen0p4](#)' is involved in the loop.

Component: Simulink | Category: Model error

Block '[mHarness_ExpFcnMdl_Loop/Model](#)' is involved in the loop.

Test Harness for Models with Initialize, Reset, and Terminate Function Blocks

If a Model block references a model that has an initialize, reset, or terminate ports, the function-call initiators connected to these ports have a higher priority than other function-call input ports. For example, export-function models, rate-based models, and JMAAB-B models can have other function-call input ports. Simulink sorts function-call initiators in the follow order:

- Initialize, reset, and then terminate ports.
- If there is more than one reset port, initiators to those reset ports are not sorted. For example, if a model has one initialize port driven by block A, two reset ports driven by blocks B and C, and one terminate port driven by block D, then Simulink sorts in the order A, B or C, and then D. B and C are sorted using general sorting rules.

Initiators for Model Block in Test Harness

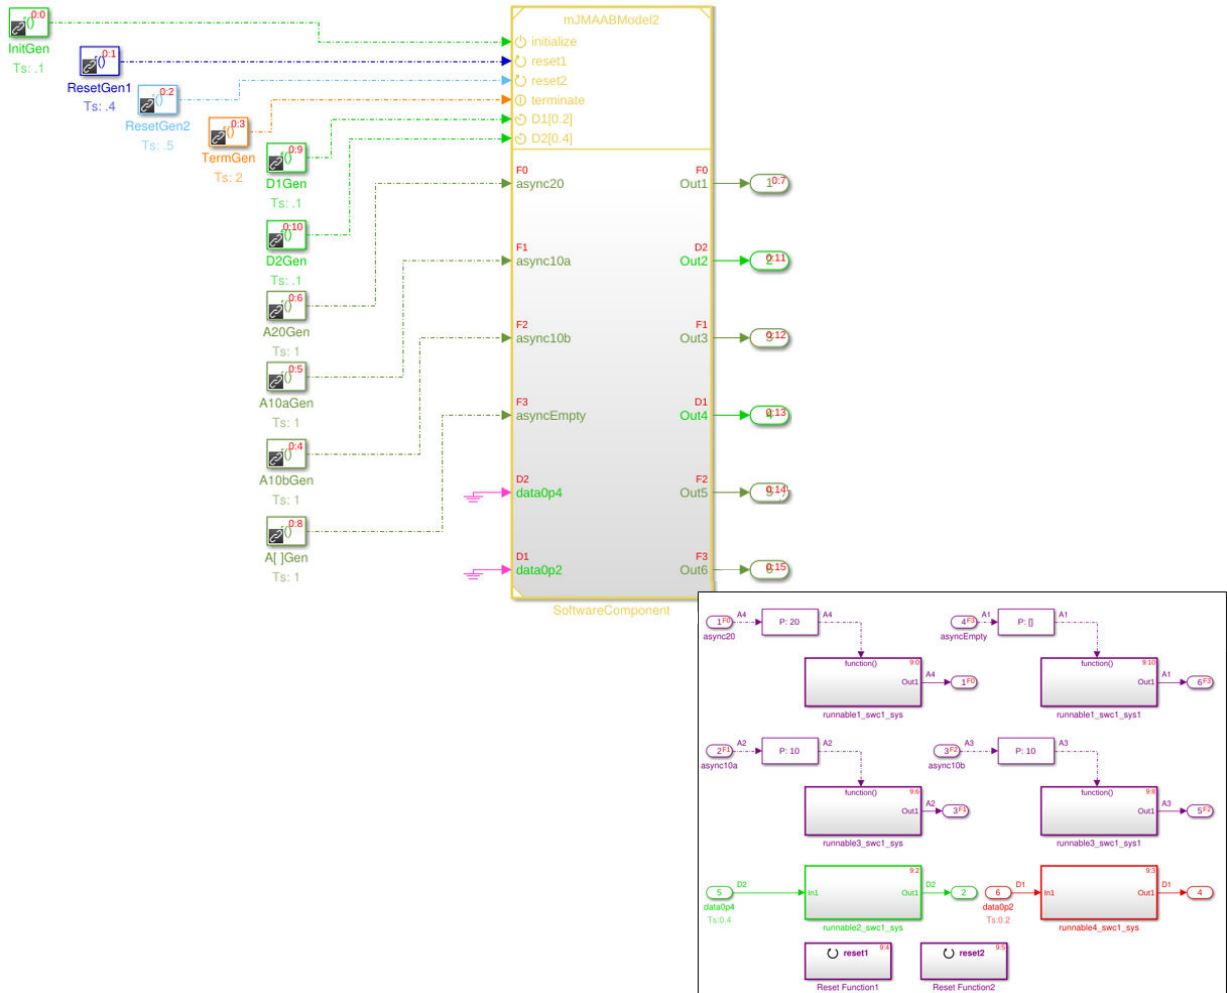

Add function-call event ports to a Model block in a test harness that references a rate-based model or JMAAB-B model by selecting the Model block parameter **Schedule rates**.

In a single tasking model, all discrete rates are in the same task. In a multi-tasking model, discrete rates with the same value execute in the same task. Simulink sorts test harness initiators in the same task in the following order:

- Initialize, reset, and then terminate ports.
- Function-call input ports mapped to asynchronous function-call root Inport blocks if adapted model is a JMAAB-B model. Among those "async" function-call input ports, use the task priorities specified by the Asynchronous Task Specification block connected to the function-call root Inport block inside the referenced model to compare ports. In the follow cases, do not compare ports:
 - For two "async" function-call input ports with the same task priorities.
 - For "async" function-call input ports with an empty (unspecified) task priority
- Periodic function-call event input ports mapped to discrete rates. Use rate monotonic scheduling (RMS) rules to compare.

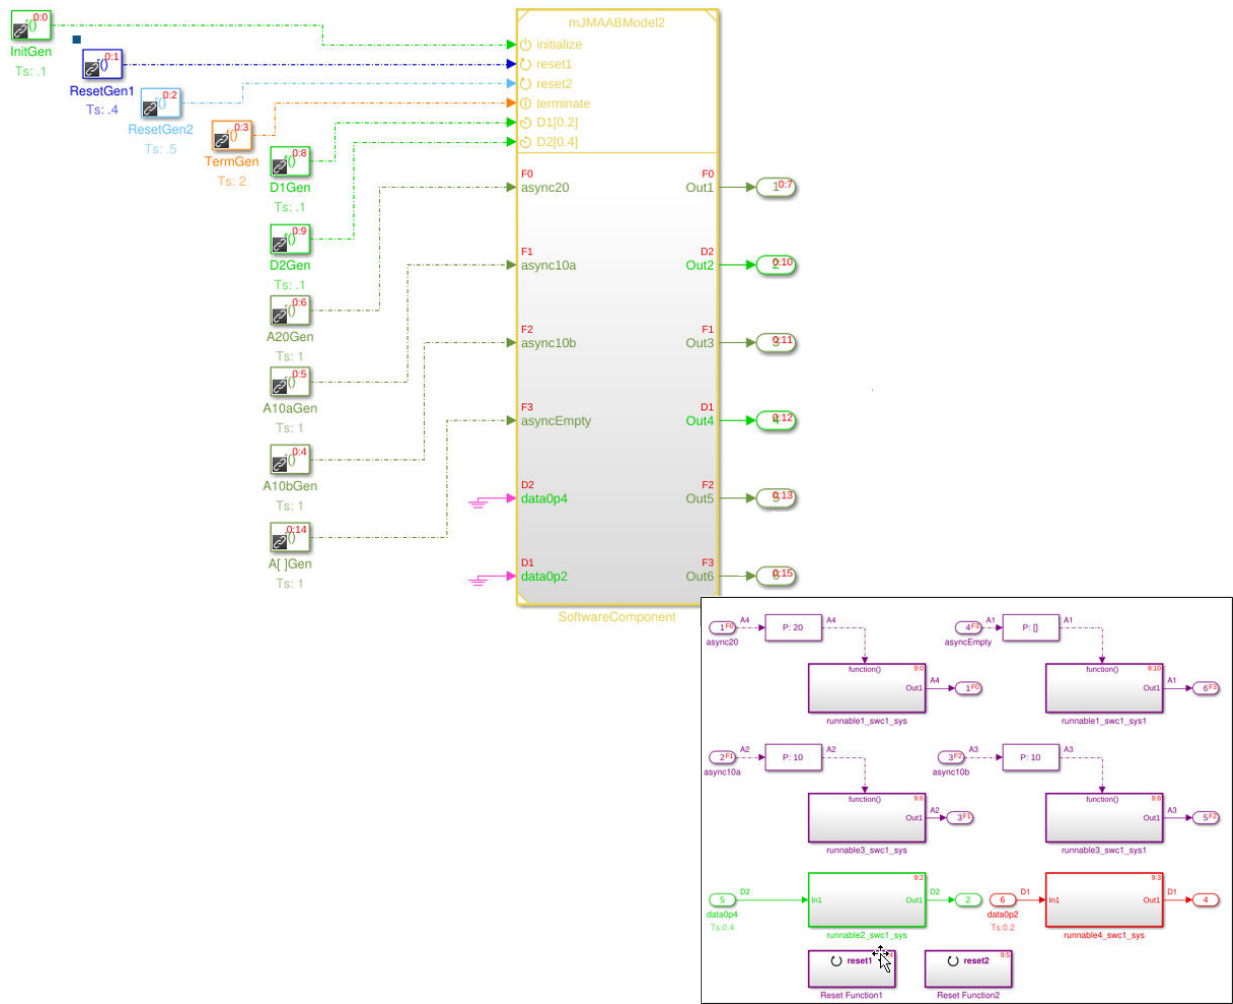

In a single tasking model, all initiators are in the same task:

- InitGen > ResetGen1 or ResetGen2 > TermGen > A10aGen or A10bGen or A[]Gen > D1Gen > D2Gen
- A10aGen or A10bGen > A20Gen
- Could swap relative ordering of (ResetGen1, ResetGen2) or (A10aGen, A10bGen), or (A[]Gen, A20Gen), etc.

In a multi-tasking model, initiators of the same color are in the same task.

- `InitGen` > `D1Gen` > `D2Gen`
- `A10aGen` or `A10bGen` > `A20Gen`

Conditional Subsystem Output Values When Disabled

Although a conditional subsystem does not execute while it is disabled, the output signal is still available to other blocks. When a conditional subsystem is disabled and you have specified not to inherit initial conditions from an input signal, you can hold the subsystem outputs at their previous values or reset them to their initial conditions.

To specify output values when disabled:

- 1 Open the dialog box for an Outport block in a conditional subsystem.
- 2 From the **Source of initial output value** drop-down list, select **Dialog**.
- 3 From the **Output when disabled** drop-down list, select one of these options:
 - **held** — Maintain the most recent value.
 - **reset** — Use the initial condition when enabled.

Note If you are connecting the output of a conditionally executed subsystem to a Merge block, set **Output when disabled** to **held** to ensure consistent simulation results.

If you are using simplified initialization mode, you must select **held** when connecting a conditionally executed subsystem to a Merge block. For more information, see “Underspecified initialization detection”.

- 4 In the **Initial output** box, enter the initial value.

Note If an Outport block in an Enabled Subsystem resets its output when disabled at a different rate from the execution of the subsystem contents, both the disabled and execution outputs write to the subsystem output. This behavior can cause unexpected results.

Simplified Initialization Mode

In this section...
“When to Use Simplified Initialization” on page 10-70
“Set Initialization Mode to Simplified” on page 10-71

Initialization mode controls how Simulink handles:

- Initialization values for conditionally executed subsystems.
- Initial values for Merge blocks.
- Discrete-Time Integrator blocks.
- Subsystem elapsed time.

The default initialization mode for a model is simplified. This mode uses enhanced processing to improve consistency of simulation results and helps to:

- Attain the same simulation results with the same inputs when using the same blocks in a different model.
- Avoid unexpected changes to simulation results as you modify a model.

When to Use Simplified Initialization

Use simplified initialization mode for models that contain one or more of the following blocks:

- Conditional subsystem blocks.
- Merge blocks. If a root Merge block has an empty matrix ([]) for its initial output value, simplified mode uses the default ground value of the output data type.
- Discrete-Time Integrator blocks. Simplified mode always uses the initial value as both the initial and reset value for output from a Discrete-Time Integrator block.

Use simplified mode if your model uses features that require simplified initialization mode, such as:

- Specify a structure to initialize a bus.
- Branch merged signals inside a conditional subsystem.

Set Initialization Mode to Simplified

Simplified mode is the default initialization mode when creating a new Simulink model. If your model is using classic mode, you might need to make changes after you select simplified mode. See “Convert from Classic to Simplified Initialization Mode” on page 10-91.

- 1 Open the Configuration Parameters dialog box.
- 2 In the search box, enter **Underspecified initialization detection**.
- 3 From the drop-down list, select Simplified.

Classic Initialization Mode

In this section...
“When to Use Classic Initialization” on page 10-72
“Set Initialization Mode to Classic” on page 10-72
“Classic Initialization Issues” on page 10-72
“Identity Transformation Can Change Model Behavior” on page 10-73
“Inconsistent Output with Discrete-Time Integrator or S-Function Block” on page 10-77
“Sorted Order Affecting Merge Block Output” on page 10-80

When to Use Classic Initialization

Initialization mode controls how Simulink handles the initialization values for conditionally executed subsystems.

Classic mode was the default initialization mode for Simulink models created in R2013b or before. You can continue to use classic mode if:

- The model does not include any modeling elements affected by simplified mode.
- The behavior and requirements of simplified mode do not meet your modeling goals.
- The work involved in converting to simplified mode is greater than the benefits of simplified mode. See “Convert from Classic to Simplified Initialization Mode” on page 10-91.

Set Initialization Mode to Classic

To set classic initialization mode:

- 1 Open the Configuration Parameters dialog box.
- 2 In the search box, enter **Underspecified initialization detection**.
- 3 From the drop-down list, select **Classic**.

Classic Initialization Issues

Using classic initialization mode can result in one or more of the following issues. You can address these issues by using simplified mode. The description of each issue includes an

example of the behavior in classic mode, the behavior when you use simplified mode, and a summary of the changes you must make to use simplified mode.

- “Identity Transformation Can Change Model Behavior” on page 10-73.

Conditional subsystems that include identical subsystems can display different initial values before the first execution if both of the following apply:

- The model uses classic initialization mode.
- One or more of the identical subsystems outputs to an identity transformation block.
- “Inconsistent Output with Discrete-Time Integrator or S-Function Block” on page 10-77

Conditional subsystems that use classic initialization mode and whose output connects to a Discrete-Time Integrator block or S-Function block can produce inconsistent output.

- “Sorted Order Affecting Merge Block Output” on page 10-80

The sorted order of conditional subsystems that used classic mode initialization, when connected to a Merge block, can affect the output of that Merge block. A change in block execution order can produce unexpected results.

- When you rename the Merge block source subsystem blocks, the initial output of the Merge block can change.

When two or more subsystems are feeding different initial output values to a Merge block that does not specify its own initial output value, renaming one of the subsystems can affect the initial output of the Merge block in classic initialization mode.

For additional information about the tasks involved to convert a model from classic to simplified mode, see “Convert from Classic to Simplified Initialization Mode” on page 10-91.

Identity Transformation Can Change Model Behavior

Conditional subsystems that include identical subsystems can display different initial values before the first execution if both of the following apply:

- The model uses classic initialization mode.

- One or more of the identical subsystems outputs to an identity transformation block.

An identity transformation block is a block that does not change the value of its input signal. Examples of identity transform blocks are a Signal Conversion block or a Gain block with a value of 1.

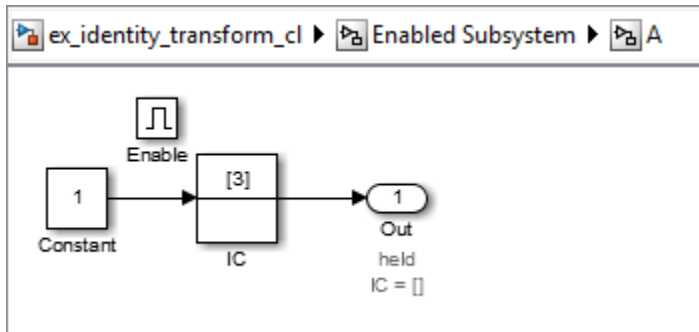

In the `ex_identity_transform_cl` model, subsystems A and B are identical, but B outputs to a Gain block, which in turn outputs to an Output block.

`ex_identity_transform_cl` ▶

`ex_identity_transform_cl` ▶ `Enabled Subsystem` ▶

When you simulate the model, the initial value for A (the top signal in the Scope block) is 2, but the initial value of B is 0, even though the subsystems are identical.

If you update the model to use simplified initialization mode (see `ex_identity_transform_simpl`), the model looks the same. The steps required to convert `ex_identity_transform_cl` to `ex_identity_transform_simpl` are:

- 1 Set **Underspecified initialization detection** to Simplified.
- 2 For the Output blocks in subsystems A and B, set the **Source of initial output value** parameter to Input signal.

You can also get the same behavior by setting the **Source of initial output value** parameter to Dialog and the **Initial output** parameter to 3.

When you simulate the updated model, the connection of an identity transformation does not change the result. The output is consistent in both cases.

Inconsistent Output with Discrete-Time Integrator or S-Function Block

Conditional subsystems that use classic initialization mode and whose output connects to a Discrete-Time Integrator block or S-Function block can produce inconsistent output.

In the `ex_discrete_time_cl` model, the enabled subsystem includes two Constant blocks and outputs to a Discrete-Time Integrator block. The enabled subsystem outputs to two Display blocks.

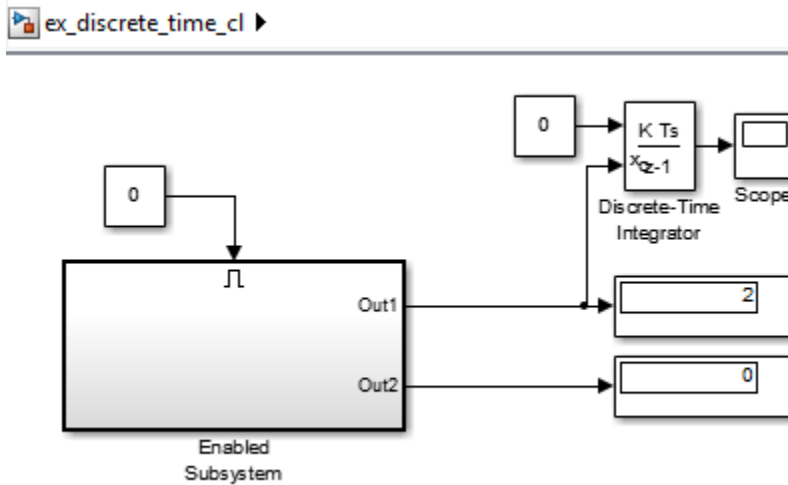

ex_discrete_time_cl ▶

ex_discrete_time_cl ▶ Enabled Subsystem

When you simulate the model, the two display blocks show different values.

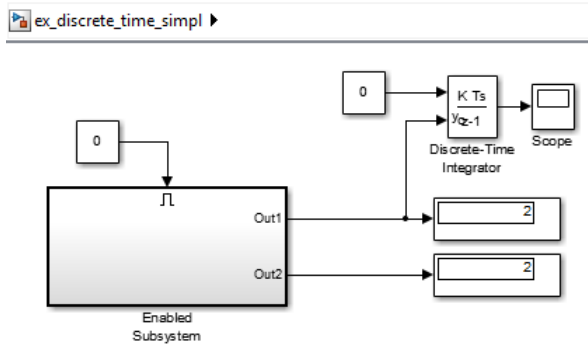

The Constant1 block, which is connected to the Discrete-Time Integrator block, executes, even though the conditional subsystem is disabled. The top Display block shows a value of 2, which is the value of the Constant1 block. The Constant2 block does not execute, so the bottom Display block shows a value of 0.

If you update the model to use simplified initialization mode (see `ex_discrete_time_simpl`), the model looks the same. The updated model corrects the inconsistent output issue by using simplified mode. The steps required to convert `ex_discrete_time_cl` to `ex_discrete_time_simpl` are:

- 1 Set **Underspecified initialization detection** to Simplified.
- 2 For the Output blocks Out1 and Out2, set the **Source of initial output value** parameter to `Input signal`. This setting explicitly inherits the initial value, which in this case is 2.

You can also get the same behavior by setting the **Source of initial output value** parameter to `Dialog` and the **Initial output** parameter to 2.

When you simulate the updated model, the Display blocks show the same output. The output value is 2 because both Output blocks inherit their initial value.

Sorted Order Affecting Merge Block Output

The sorted order of conditional subsystems that use classic mode initialization, when connected to a Merge block, can affect the output of that Merge block. A change in block execution order can produce unexpected results. The behavior depends on how you set the **Output When Disabled** parameter.

The `ex_basic_merge_sorted_order_1_cl` model has two identical enabled subsystems (Enable A and Enable B) that connect to a Merge block. When you simulate the model, the red numbers show the sorted execution order of the blocks.

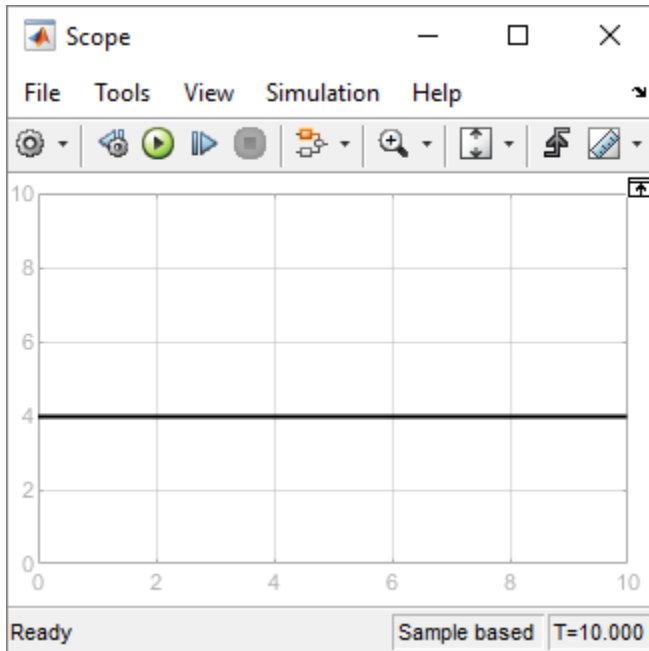

ex_basic_merge_sorted_order_1_cl ▶ Enable A

ex_basic_merge_sorted_order_1_cl ▶ Enable B

When you simulate the model, the Scope block looks like the following:

The `ex_basic_merge_sorted_order_2_cl` model is the same as `ex_merge_sorted_1_cl`, except that the block execution order is the reverse of the default execution order. To change the execution order:

- 1 Open the Properties dialog box for the Enable A subsystem and set the **Priority** parameter to 2.
- 2 Set the **Priority** of the Enable B subsystem to 1.

ex_basic_merge_sorted_order_2_cl ▶

When you simulate the model using the different execution order, the Scope block looks like the following:

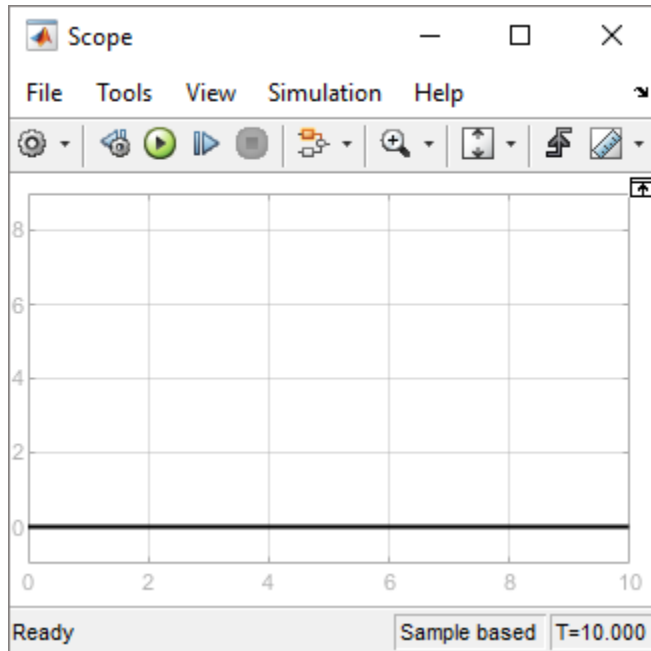

The change in sorted order produces different results from identical conditional subsystems.

To update the models to use simplified initialization mode (see `ex_basic_merge_sorted_order_1_simpl` and `ex_basic_merge_sorted_order_2_simpl`):

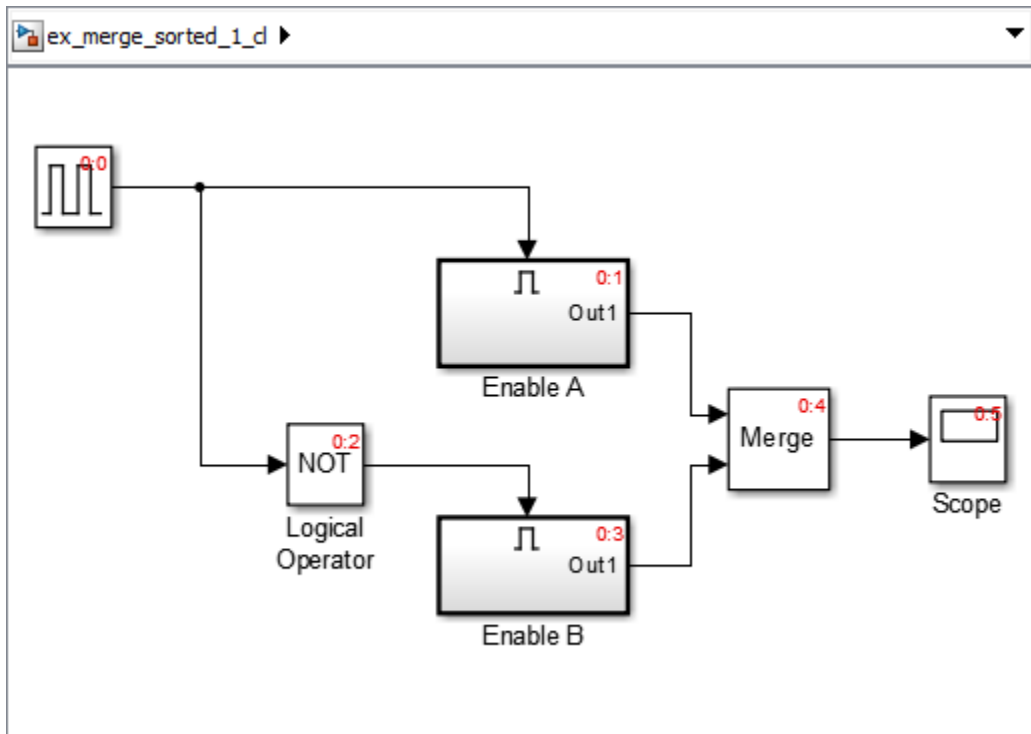

- 1 Set **Underspecified initialization detection** to Simplified.

The **Initial Output** parameter of the Merge block is an empty matrix, `[]`, by default. Hence, the initial output value is set to the default initial value for this data type, which is 0. For information on default initial value, see “Initializing Signal Values” on page 67-15. When you simulate each simplified mode model, both models produce the same results.

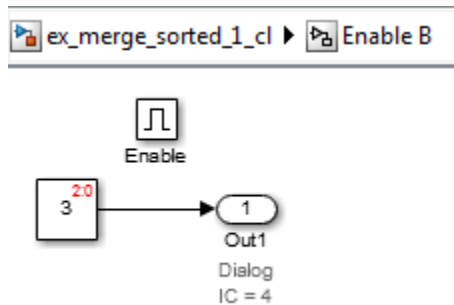

Using Output When Disabled Parameter Set to Reset

The `ex_merge_sorted_1_cl` model has two enabled subsystems (Enable A and Enable B) that connect to a Merge block. When you simulate the model, the red numbers show the sorted execution order of the blocks.

ex_merge_sorted_1_cl ▸ Enable A

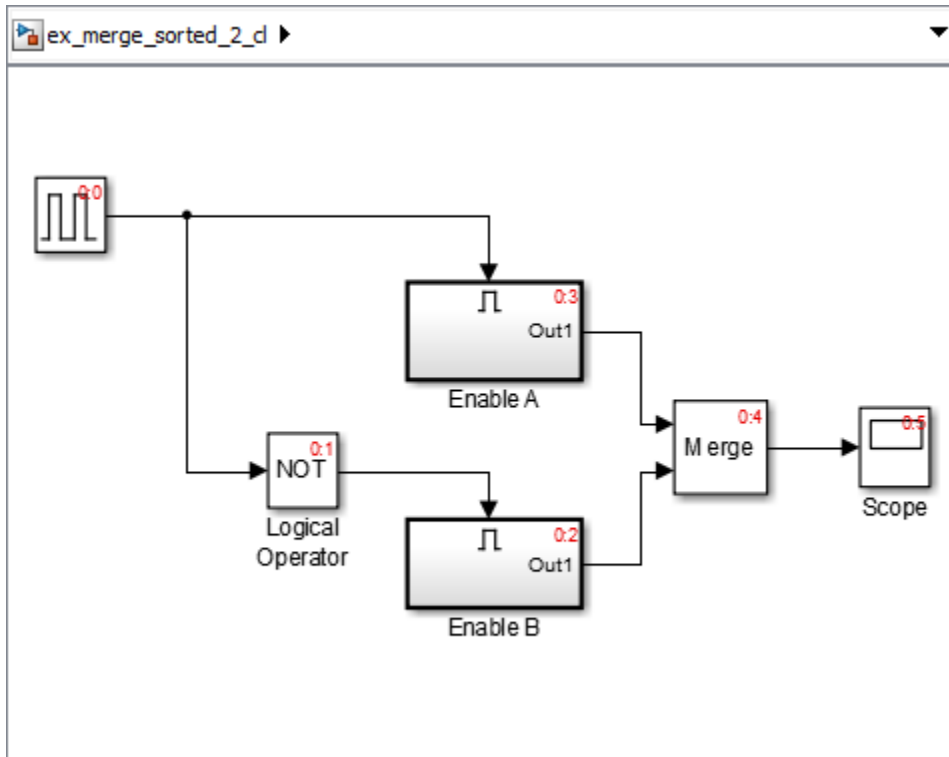

When you simulate the model, the Scope block looks like the following:

The `ex_merge_sorted_2_cl` model is the same as `ex_merge_sorted_1_cl`, except that the block execution order is the reverse of the default execution order. To change the execution order:

- 1 Open the Properties dialog box for the Enable A subsystem and set the **Priority** parameter to 2.
- 2 Set the **Priority** of the Enable B subsystem to 1.

When you simulate the model using the different execution order, the Scope block looks like:

The change in sorted order produces different results from identical conditional subsystems.

To update the models to use simplified initialization mode (see `ex_merge_sorted_1_simpl` and `ex_merge_sorted_2_simpl`):

- 1 Set **Underspecified initialization detection** to Simplified.
- 2 For the Output blocks in Enable A and Enable B, set the **Output when disabled** parameter to `held`. Simplified mode does not support `reset` for output ports of conditional subsystems driving Merge blocks.

When you simulate each simplified mode model, both models produce the same results.

Convert from Classic to Simplified Initialization Mode

If you switch the initialization mode from classic to simplified mode, you can encounter several issues that you must fix. For most models, the following approach helps you to address conversion issues more efficiently.

- 1 Save the existing model and simulation results for the model.
- 2 Simulate the model and address any warnings.
- 3 In the Model Advisor, in the Simulink checks section, run the checks in the folder “Migrating to Simplified Initialization Mode Overview”.
- 4 Address the issues that Model Advisor identifies.
- 5 Simulate the model to make sure that there are no errors.
- 6 Rerun the Model Advisor checks in the folder “Migrating to Simplified Initialization Mode Overview” check to confirm that the modified model addresses the issues related to initialization.

For examples of models that have been converted from classic initialization mode to simplified initialization mode, see “Classic Initialization Issues” on page 10-72.

Blocks to Consider

Discrete-Time Integrator Blocks

Discrete-Time Integrator block behaves differently in simplified mode than it does in classic mode. The changes for simplified mode promote more robust and consistent model behavior. For details, see “Behavior in Simplified Initialization Mode” in the Discrete-Time Integrator block reference documentation.

Library Blocks

Simulink creates a library assuming that classic mode is in effect. If you use a library block that is affected by simplified mode in a model that uses simplified mode, then use the Model Advisor to identify changes you must make so that the library block works with simplified mode.

Create Export-Function Model

The first step for creating independent functions in the generated code from a Simulink model is to define the functions in the context of an export-function model. See “Export-Function Models” on page 10-120.

Create Model Algorithms

At the root-level of an export-function model, functions are modeled within Function-Call Subsystem, function-call Model, Simulink Function, and S-Function blocks. This example uses Function-Call Subsystem blocks to model two functions.

- 1 Add two Function-Call Subsystem blocks.
- 2 In the first subsystem, model a unit delay that increments by 0.05 at each time step.

- 3 In the second subsystem, model the square of an input signal.

- 4 Add Inport and Outport blocks.

Add Function-Call Inputs

Inport blocks configured to output function-call signals control the execution of Function-Call Subsystem blocks during a simulation. The function-call Inport blocks also create an entry point function in the generated code.

- 1 Attach Inport blocks to the `function()` input ports on the Function-Call Subsystem blocks.
- 2 Specify sample times. Open the Inport block dialogs and select the **Signal Attributes** tab. Select the **Output function call** check box. Set **Sample time** for the delay function to `0.1` (100 ms), and the square function to `0.01` (10 ms).

Setting the sample time is only for simulation testing. Sample time values do not affect the generated code. However, comments are added in the code identifying the rate you should call the functions.

You could set the sample times to `-1` and allow any function-call rate (periodic or aperiodic) during simulation. By setting sample times, Simulink checks the calling rate with the specified rate and displays an error if there is a mismatch.

- 3 Rename blocks. The names help to identify signals in the generated code.
- 4 Update the model (Ctrl-D). Dotted-and-dashed lines identify function-call signals.

Satisfy Export-Function Model Requirements

- 1 Open the Configuration Parameters dialog. From the menu, select **Simulation > Model Configuration Parameters**.
- 2 In the Solver pane, set Solver selection **Type** to Fixed-step, **Solver** to auto, and Fixed-step size to auto.
- 3 In the Code generation pane, set **System target file** to `ert.tlc`. This step requires an Embedded Coder license.

After you create an export-function model, you can test it with simulations. Choose one of the following simulation testing methods: “Test Export-Function Model Simulation Using Input Matrix” on page 10-96, “Test Export-Function Model Simulation Using Function-Call Generators” on page 10-101, and “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-106.

Test Export-Function Model Simulation Using Input Matrix

When function-call sequencing is simple enough to be specified as a model input, simulation using an input matrix is the preferred method for testing an export-function model.

- Create time vectors that specify function-call times.
- Create a matrix that adds input data to the time vectors.
- Run simulation.

To create the model in this example, see “Create Export-Function Model” on page 10-93.

Create Function-Call Inputs and Data Inputs

Create time-vectors indicating when events occur for root-level function-call Inport blocks and data-vectors for root-level data Inport blocks.

- 1 For Inport 1 and Inport 2 blocks, create column vectors with time steps of 0.1 and 0.01. In the MATLAB Command window, enter

```
t1 = [0:0.1:10]'  
t2 = [0:0.01:10]'
```

- The time vector data type must be double and monotonically increasing.
 - If Sample time for a function-call Inport block is specified, the time vector must be a periodic series increasing with the specified value.
 - To specify multiple function-calls at a given time step, repeat the time value accordingly. For example, to specify three events at $t = 0.1$ and 2 events at $t = 0.5$, list 0.1 three times and 0.5 twice in your time vector, $t = [0.1 \ 0.1 \ 0.1 \ 0.5 \ 0.5]'$.
 - If you want to use a nonperiodic time vector, set the Inport block **Sample time** to -1 and provide a nonperiodic time vector, $t1 = [0, 0.1, 0.2, 0.4, 0.8]$
- 2 Create a matrix with time steps and data values for Inport block 3.

```
sine_data = sin(0:0.01:10)'  
d3 =[t2,sine_data]
```

The data input can use any supported format as described in “Forms of Input Data” on page 64-154.

The following table provides additional information for specifying the time vector t .

Sample time type for internal Trigger Port block set to:	Root-level Function-Call Inport block with inherited sample time (-1)	Root-level Function-Call Inport block with discrete sample time
Triggered	<p>Nondecreasing column vector.</p> <p>The function-call subsystem executes at the times specified by the column vector. The sample times can be periodic or aperiodic.</p> <p>If you specify an empty matrix (<code>[]</code>), the function-call subsystem does not execute.</p>	<p>Nondecreasing column vector. Each element in the column vector must be an integer multiple of the sample time specified by the Inport block.</p> <p>The function-call subsystem executes at the times specified by the column vector.</p> <p>Alternatively, specify an empty matrix (<code>[]</code>) and the function-call subsystem executes at every sample time specified by the Inport block.</p>
Periodic	Configuration not allowed.	<p>Empty matrix(<code>[]</code>).</p> <p>The the function-call subsystem executes at the times specified by the Inport block calling it.</p>

Simulate Export-Function Model

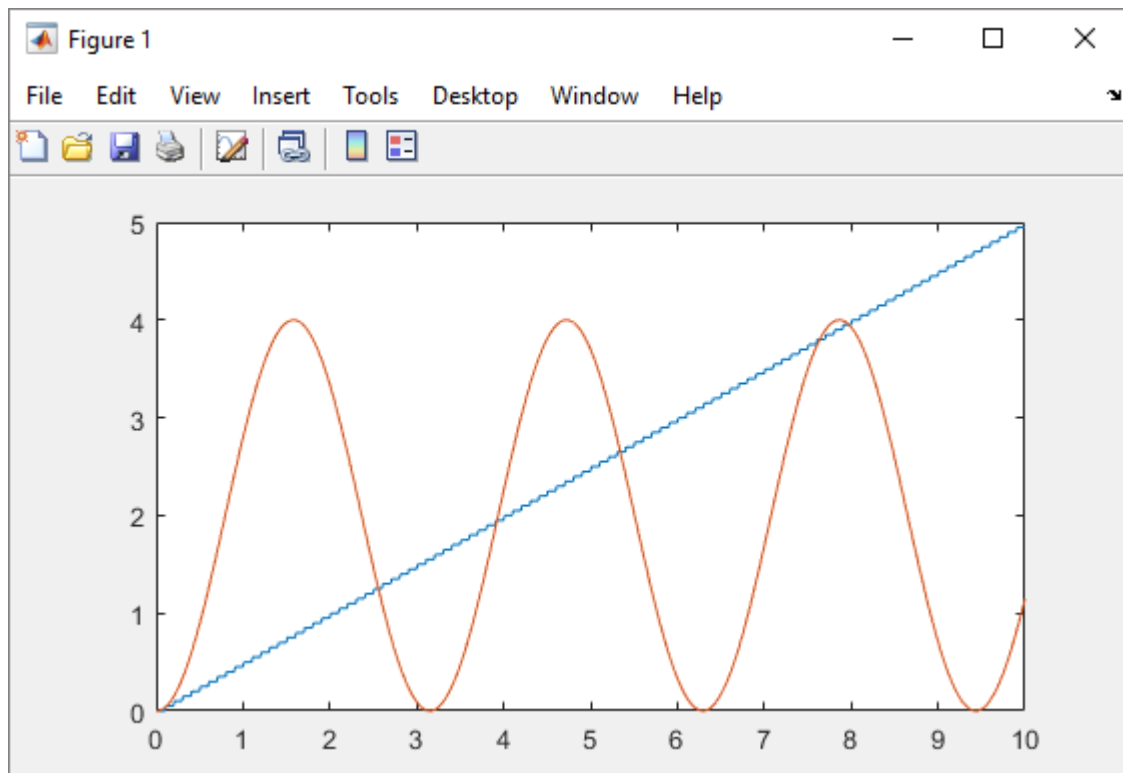

Simulate the export-function model to test and observe its behavior before generating code.

- 1 Import time and data from MATLAB workspace. In the **Configuration Parameters > Data Import/Export** pane, set the **Input** parameter to `t1`, `t2`, `d3`.

`t1` and `t2` are column vectors containing event times for the function-call Import blocks 1 and 2. `d3` is a table of input values versus time for the data Import block 3.

- 2 Run simulation.
- 3 Plot results. In the MATLAB Command Window, enter:

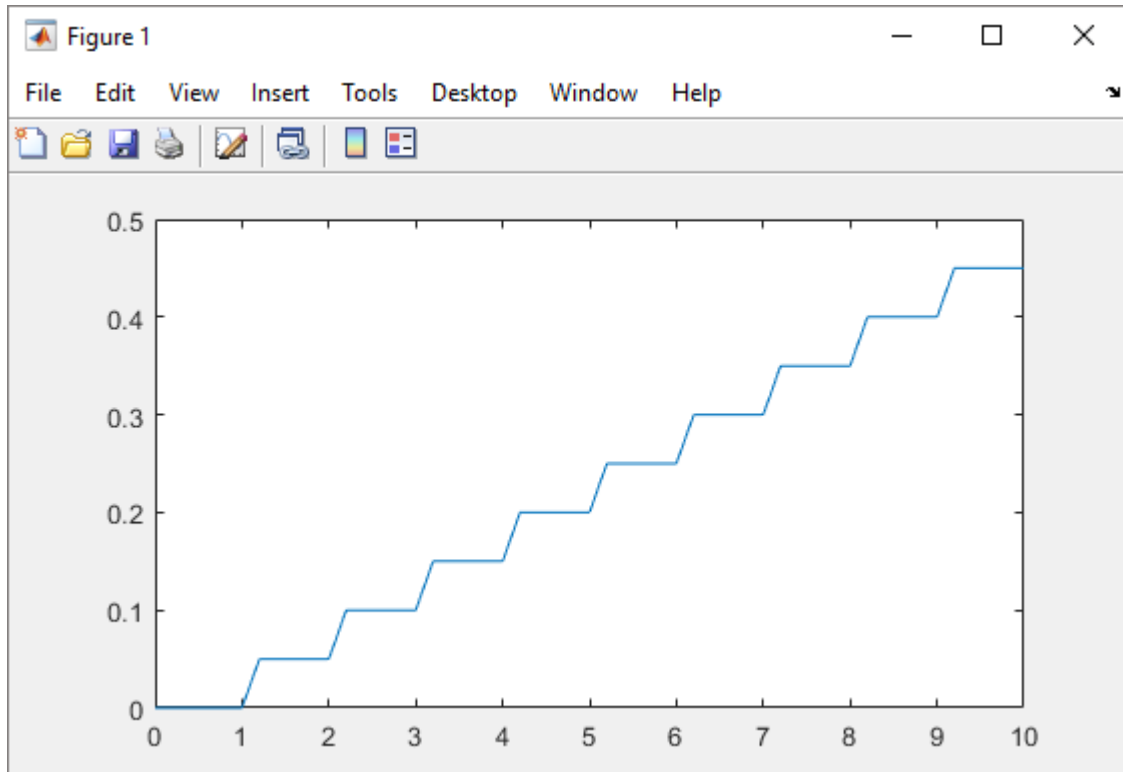

```
plot(yout.time, yout.signals(1).values)
hold
plot(yout.time, yout.signals(2).values)
```

- 4 Change `t1` to provide events every 0.5 seconds. 0.5 is an integer multiple of 0.1 specified in the Import block 1.

```
t1 = [0:0.5:10]'
```

5 Rerun simulation.

After you test your model, you can generate code for the functions. See “Generate Code for Export-Function Model” on page 10-112.

- “Generate Code for Export-Function Model” on page 10-112

Test Export-Function Model Simulation Using Function-Call Generators

Use multiple Function-Call Generator blocks with distinct sample times and let Simulink schedule the function-call components for simulation. This strategy is useful when the rate-monotonic scheduling behavior in Simulink is similar to the target OS behavior.

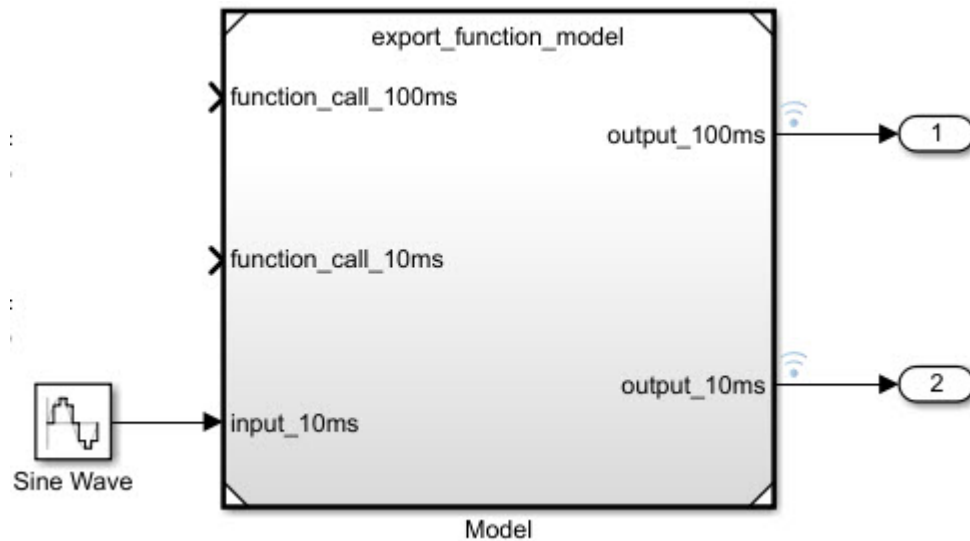

- Create a new Simulink model.
- Add a Model block that references the export-function model.
- Specify function-call events using Function-Call Generator blocks.
- Specify data inputs.
- Run simulation.

To create the model for this example, see “Create Export-Function Model” on page 10-93.

Create Referenced Export-Function Model

Referencing an export-function model from a Model block allows the addition of function-call signals and logging of signals without changing the model itself.

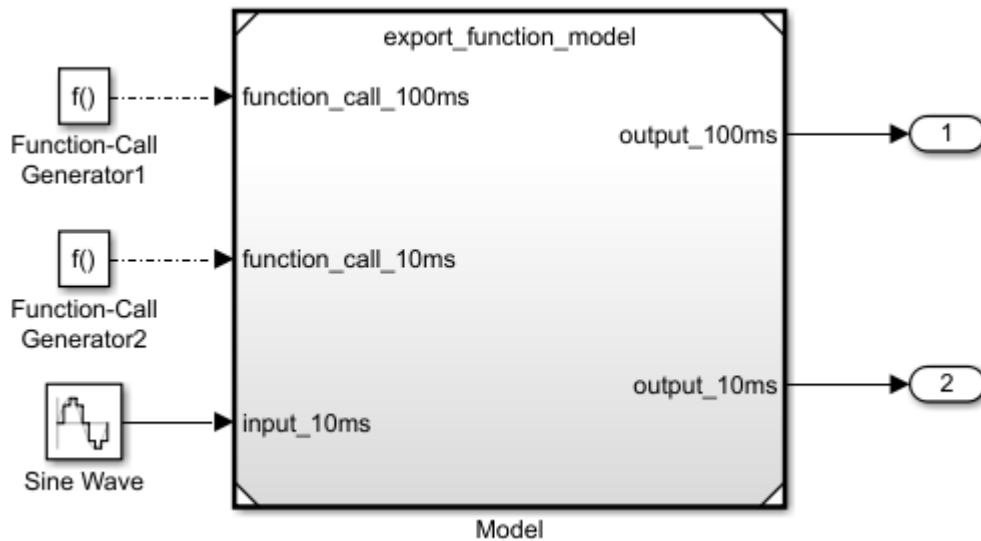

- 1** Add a Model block to a new Simulink model. In the **Model name** box, enter `export_function_model`.
- 2** Add Outport blocks to the **output_100ms** and **output_10ms** ports on the Model block.
- 3** Add a Sine Wave block to provide data input. Set **Amplitude** to 2 and **Sample time** to 0.01. Connect the block to the **input_10ms** input port on the Model block.

Create Test Model (Harness) for Simulation

You use a Simulink test model only for simulation. After simulation testing, generate code from the export-function model, and then integrate exported function code with an externally coded scheduler.

- 1 Add a Function-Call Generator block. Set **Sample time** to 0.1 . Connect the block to the **function_call_100ms** input port.
- 2 Add a second Function-Call Generator block. Set **Sample time** to 0.01 . Connect the block to the **function_call_10ms** input port.

Scheduling Restrictions for Referenced Export-Function Models

If a test model references an export-function model, there are some restrictions to ensure consistency with simulation results.

For the test model:

- You cannot use two Function-Call Generator blocks with the same sample time.
- Function-calls to the input ports on the Model block must follow the execution order of the root-level function-call Inport blocks in the referenced export-function model. Function-Call Generator blocks with smaller sample times execute first.

If the test model calls the referenced model functions out of order at any time step, Simulink displays an error. For information on sorted execution order, see “Control and Display the Sorted Order” on page 36-31. To disable this restriction, clear the check box **Model Configuration Parameters > Model Referencing > Enable strict scheduling checks for referenced models**.

- You can use a Mux block to connect signals from the Function-Call Generator blocks with different sample times before connecting them to the referenced export-function model. In the Configuration Parameters dialog box, clear the **Treat each discrete rate as a separate task** check box.

For the export-function model:

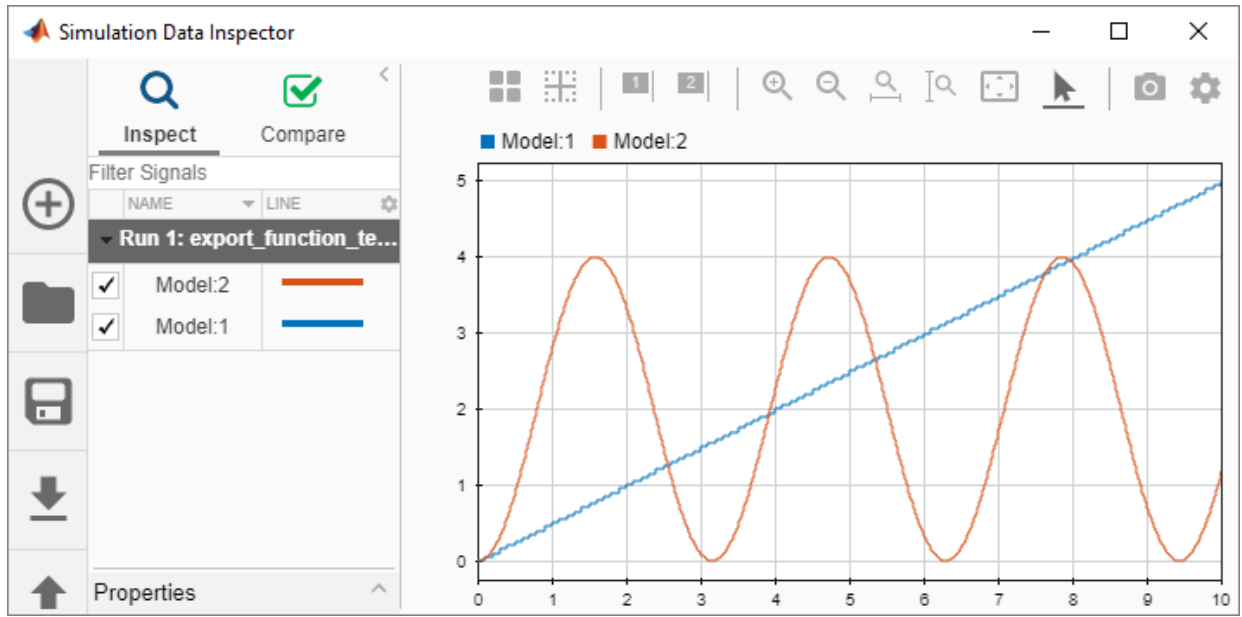

- The sample times for the root-level function-call Inport blocks must be set to inherited (-1) or match the sample time of the Function-Call Generator blocks that drive them.

Simulate Export Function Model

Simulate the export-function model to test and observe its behavior before generating code.

Note Simulink does not simulate preempting function-calls.

- 1 Clear the configuration parameter **Enable strict scheduling check for referenced models**.
- 2 Verify the configuration parameters for Solver Type is set to **Fixed-step**, Solver set to **discrete (no continuous states)**, and Fixed-step size (fundamental sample time) set to **auto**.
- 3 Set up logging of signals. Right-click output port signals and select **Log selected signal**.
- 4 Run simulation.
- 5 Open the Simulation Data Inspector by clicking the toolbar icon  .

After you test your model, you can generate code for the functions. See “Generate Code for Export-Function Model” on page 10-112.

- “Test Export-Function Model Simulation Using Input Matrix” on page 10-96
- “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-106
- “Generate Code for Export-Function Model” on page 10-112

Test Export-Function Model Simulation Using Stateflow Chart

Use a Stateflow chart to provide a function-call scheduler where you can fully control the scheduling process for periodic (synchronous) or aperiodic (asynchronous) call sequences.

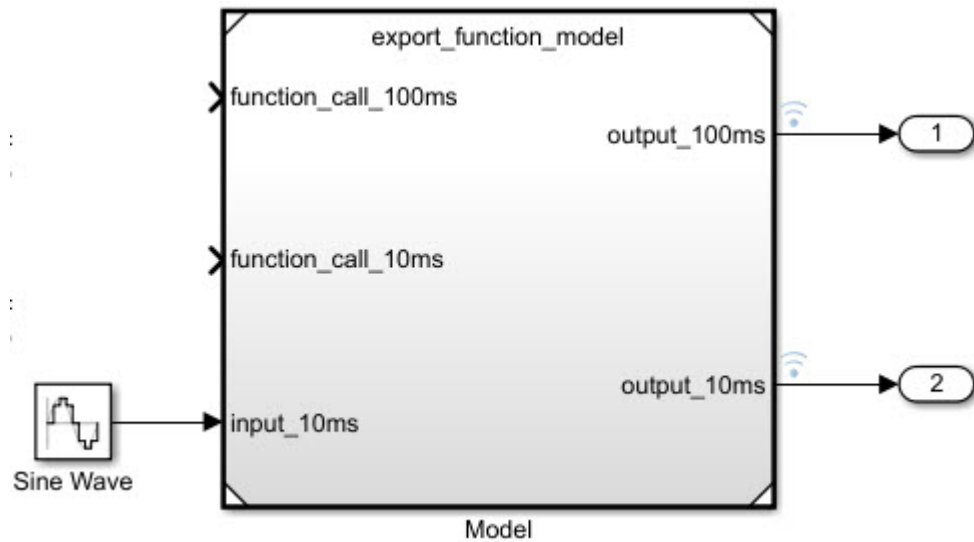

- Create a new Simulink model.
- Add a Model block that references the export-function model.
- Specify function-call Inputs using a Stateflow chart.
- Specify data inputs.
- Run simulation.

To create the model for this example, see “Create Export-Function Model” on page 10-93.

Create Referenced Export-Function Model

Referencing an export-function model from a Model block allows the addition of function-calls signals from a Stateflow chart and the logging of signals without changing the model itself.

- 1** Add a Model block to a new Simulink model. In the **Model name** box, enter `export_function_model`.
- 2** Add Outport blocks to the **output_100ms** and **output_10ms** ports for saving simulation data to MATLAB.
- 3** Add a Sine Wave block to provide data input. Set **Amplitude** to 2 and **Sample time** to `0.01`. Connect the block to the **input_10ms** input port on the Model block.

Create Periodic Scheduler Using Stateflow Chart

- 1 Create a new Stateflow chart. This step requires a Stateflow license.
- 2 From the menu, select **View > Model Explorer > Model Explorer**. In the **Model Hierarchy** pane, select Chart.
- 3 Add function-call events with output ports to the chart. From the menu, select **Add > Event**. In the **Name** box, enter `out_100ms`. From the **Scope** list, select **Output** to Simulink. Repeat step to create a function-call event and output port for `out_10ms`.

- 4 Open the chart by double-clicking the block. Add a State block and a Default transition arrow.

- 5 Rename the state to `function_call_scheduler`.
- 6 Add periodic function-calls every 10 and 100 milliseconds. In the state block, enter the following commands.

```
on every(10, tick):send(out_10ms);  
on every(100, tick):send(out_100ms);
```

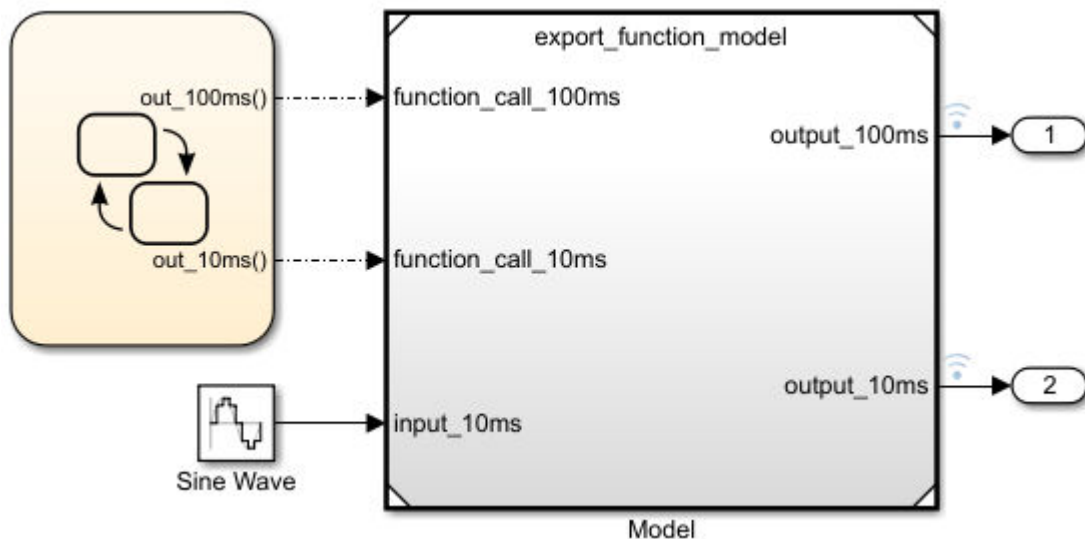

The keyword `tick` is an implicit event that counts the number of simulation steps while `send` is an explicit event that outputs a function-call event to the output ports.

Create Test Model (Harness) for Simulation

You use a Simulink test model only for simulation. After simulation testing, generate code from the export-function model, and then integrate exported function code with an externally coded scheduler.

- 1 Drag the Stateflow chart to your test model.
- 2 Connect Stateflow Chart outputs to Model block inputs.

Scheduling Restrictions for Referenced Export-Function Models

If a test model references an export-function model, there are some restrictions to ensure consistency with simulation results.

For the test model:

- Function-calls to the input ports on the Model block must follow the execution order of the root-level function-call Inport blocks in the referenced export-function model.

If the test model calls the referenced model functions out of order at any time step, Simulink displays an error. For information on sorted execution order, see “Control and Display the Sorted Order” on page 36-31. To disable this restriction, clear the

check box **Model Configuration Parameters > Model Referencing > Enable strict scheduling checks for referenced models.**

For the export-function model:

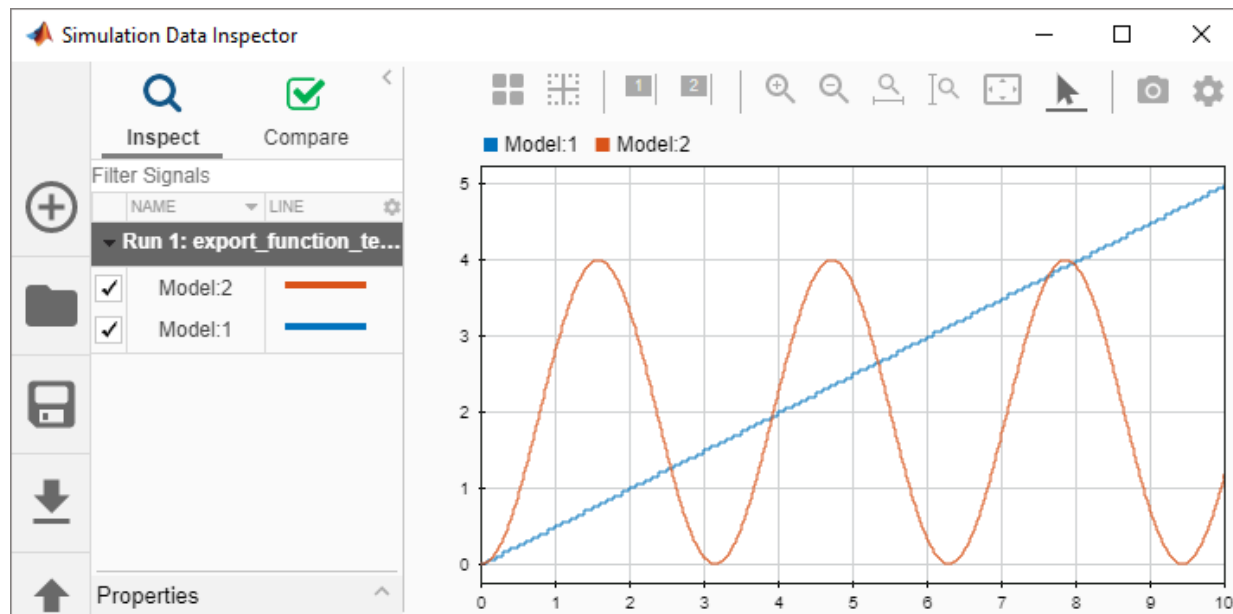

- The sample times for the root-level function-call Inport blocks must be set to inherited (-1) or match the sample time of the function-calls from the Stateflow chart that drives them.

Simulate Export Function Model

Simulate the export-function model to test and observe its behavior before generating code.

Note When using export-function models in top-model simulations, do not change the enable/disable status of the model during simulation. Enable it at the start of simulation and use function-calls to call it.

- 1 Clear the configuration parameter **Enable strict scheduling check for referenced models.**
- 2 Verify the configuration parameters **Solver Type** is set to Fixed-step, **Solver** set to discrete (no continuous states), and Fixed-step size (fundamental sample time) set to auto.
- 3 Right-click output port signals on the Model block and select **Log selected signal.**
- 4 Run simulation.
- 5 Open the Simulation Data Inspector by clicking the icon .

After you test your model, you can generate code for the functions. See “Generate Code for Export-Function Model” on page 10-112.

Generate Code for Export-Function Model

You generate code for independent functions from an export-function model, not the simulation test model (harness). After generating the function code, you can integrate the functions with a scheduler that you hand-code externally from Simulink.

To create the model for this example, see “Create Export-Function Model” on page 10-93.

Generate Code for Exported Functions

Generate code from the model that contains the functions.

- 1 Open the export-function model.
- 2 From the menu, select **Simulation > Model Configuration Parameters**.
- 3 In the Solver pane, set **Solver Type** to Fixed-step.
- 4 In the Code generation pane, set **System target file** to `ert.tlc`. Requires an Embedded Coder license.
- 5 From the Simulink menu, Select **Code > C/C++ Code > Build Model**. Wait for the code building process to complete.
- 6 Select **Code > C/C++ Code > Code Generation Report**

Entry-Point Functions

Function: [function_call_100ms](#)

Prototype	void function_call_100ms(void)
Description	Exported function: <Root>/function_call_100ms
Timing	Must be called periodically, every 0.1 seconds
Arguments	None
Return value	None
Header file	export_function_model.h

Function: [function_call_10ms](#)

Prototype	void function_call_10ms(void)
Description	Exported function: <Root>/function_call_10ms
Timing	Must be called periodically, every 0.01 seconds
Arguments	None
Return value	None
Header file	export_function_model.h

In the generated code, each root-level function-call Inport block generates a void-void function. The function name is the name of the output signal from the block. If there is no signal name, then the function name is derived from the name of the block. In this example, the function name was derived from the block name.

File: export_function_model.c

```

36 /* Model step function for TID1 */
37 void function_call_10ms(void)          /* Sample time: [0.01s, 0.0s]
38 {
39   /* RootInportFunctionCallGenerator: '<Root>/RootFcnCall_InsertedFor
40    * SubSystem: '<Root>/Function-Call Subsystem_2'
41    */
42   /* Output: '<Root>/output_10ms' incorporates:
43    * Inport: '<Root>/input_10ms'
44    * Math: '<S2>/Square'
45    */
46   export_function_model_Y.output_10ms = export_function_model_U.input
47     export_function_model_U.input_10ms;
48
49   /* End of Outputs for RootInportFunctionCallGenerator: '<Root>/Root
50  }
51
52 /* Model step function for TID2 */
53 void function_call_100ms(void)         /* Sample time: [0.1s, 0.0s] *
54 {
55   /* RootInportFunctionCallGenerator: '<Root>/RootFcnCall_InsertedFor
56    * SubSystem: '<Root>/Function-Call Subsystem_1'
57    */
58   /* Output: '<Root>/output_100ms' incorporates:
59    * UnitDelay: '<S1>/Unit Delay'
60    */
61   export_function_model_Y.output_100ms =
62     export_function_model_DW.UnitDelay_DSTATE;
63
64   /* Bias: '<S1>/Bias' incorporates:
65    * Output: '<Root>/output_100ms'
66    * UnitDelay: '<S1>/Unit Delay'
67    */
68   export_function_model_DW.UnitDelay_DSTATE =
69     export_function_model_Y.output_100ms + 0.05;
70

```

Generate Code for Export-Function Model with Rate-Based Model

You can generate code from a model that includes both function-call subsystems and scheduled subsystems. Create a rate-based model with scheduled subsystems, and then add the model to an export-function model by reference from a Model block.

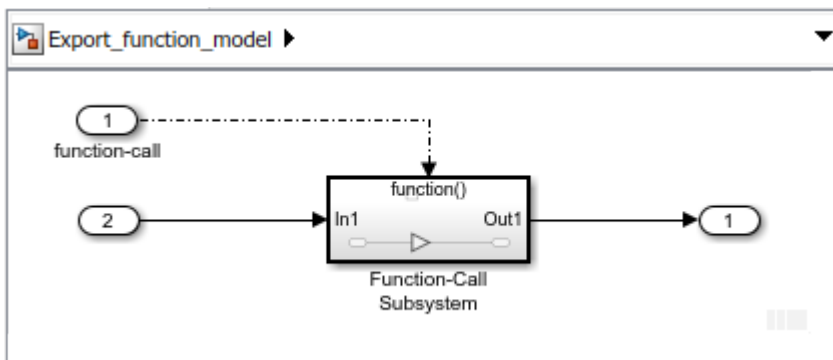

Create Export-Function Model with Scheduled Subsystems

Create a model with function-call and scheduled subsystems.

- 1 Begin by creating a rate-based model with scheduled subsystems. In this example, the **Sample time** for the Scheduled Subsystem is set to 0.01 . See “Create A Rate-Based Model” on page 10-51.

- 2 Create an export-function model with function-call subsystems. See “Create Export-Function Model” on page 10-93.

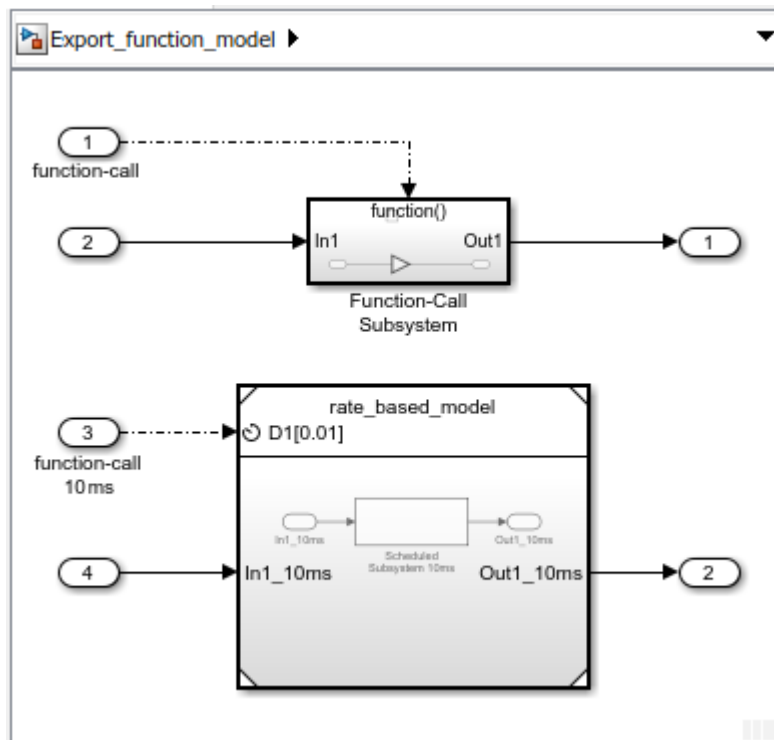

- 3 Include the rate-based model in the export-function model by reference from a Model block.

- 4 Display periodic event ports on the Model block by selecting the **Schedule rates** check box.

Connect Inport blocks to the periodic event ports.

- 5 In the Inport block dialog box, select the **Output function-call** parameter check box and specify the Sample time with the same sample time from the scheduled subsystem. In this example, the **Sample time** for the function-call 10ms Inport block is set to 0.01

Generate Code for Exported Functions

Generate code from the model that contains the functions.

- 1 From the menu, select **Simulation > Model Configuration Parameters**.
- 2 In the Solver pane, set **Solver Type** to Fixed-step.
- 3 In the Code generation pane, set **System target file** to `ert.tlc`. Requires an Embedded Coder license.
- 4 From the Simulink menu, Select **Code > C/C++ Code > Build Model**. Wait for the code building process to complete.
- 5 Select **Code > C/C++ Code > Code Generation Report**

In the generated code, each root-level function-call Inport block generates a void-void function. The function name is the name of the output signal from the block. If there is no

signal name, then the function name is derived from the name of the block. In this example, the function name was derived from the block name.

File: [Export_function_model.c](#)

```

36 /* Model step function for TID1 */
37 void function_call_10ms(void)          /* Explicit Task: function_call_10ms */
38 {

“Export-Function Model with a Multi-Instanced Function-Call Model” on page 10-129

“Export-Function Models and Models with Asynchronous Function-Call Inputs” on page 10-131

Export-function models are Simulink models that generate code for independent functions that can be integrated with an external environment and scheduler. Functions are defined using Function-Call Subsystem, function-call Model, Simulink Function, and S-Function blocks..

The following export-function model contains two functions defined with Function-Call Subsystem blocks. For a step-by-step procedure to create this model, see “Create Export-Function Model” on page 10-93

Code generated from this model has two independent functions, one for a delay function and the other for a square function.

```

/*
 * File: export_function_model.c
 * Code generated for Simulink model 'export_function_model'.
 */

void function_call_100ms(void)      /* Sample time: [0.1s, 0.0s] */
{
    export_function_model_Y.output_100ms =
        export_function_model_DW.UnitDelay_DSTATE;

    export_function_model_DW.UnitDelay_DSTATE =
        export_function_model_Y.output_100ms + 1.0;
}

void function_call_10ms(void)      /* Sample time: [0.01s, 0.0s] */
{
    export_function_model_Y.output_10ms = export_function_model_U.input_10ms *
        export_function_model_U.input_10ms;
}

```

Workflows for Export-Function Models

Three common workflows for creating export-function models differ in how you simulate and test your model before generating code for the functions.

When function-call sequencing is simple enough to be specified as a model input, simulation using an input matrix is the preferred method for testing an export-function model. See “Test Export-Function Model Simulation Using Input Matrix” on page 10-96.

When function-call sequencing is too complicated to specify with an input matrix, create a test model (harness) to mimic the target environment behavior. Use this test model to provide function-call inputs to the export-function model. See “Test Export-Function Model Simulation Using Function-Call Generators” on page 10-101 and “Test Export-Function Model Simulation Using Stateflow Chart” on page 10-106, “Schedule an Export-Function Model Using the Schedule Editor”.

Allowed Blocks

At the root-level, an export-function model is limited to the following blocks:

- Inport

- Outport
- Goto
- From
- Function-Call Subsystem
- Function-call Model
- Function-Call Split
- Simulink Function
- Initialize Function
- Reset Function
- Terminate Function
- Data Store Memory
- Bus Creator
- Bus Selector
- Mux
- Demux
- Merge
- Signal Specification
- S-Function

Requirements for Export Function Models

For an export-function model to successfully generate function code, the following requirements must be met.

Model Configuration Parameters:

- Solver **Type** set to Fixed-step.
- **Solver** set to auto or discrete.
- Code Generation **System target file** set to `ert.tlc`. Selecting `ert.tlc` requires an Embedded Coder license.
- For function-call Model blocks, **Periodic sample time constraint** for the referenced model is set to `Ensure sample time independent`.

Root-level function-call Inport blocks:

- **Output function call** check box selected.
- Cannot receive a signal from an Asynchronous Task Specification block.

Root-level data Inport and Outport blocks cannot connect to virtual bus data signals.

Root-level Function-Call Subsystem blocks and function-call Model blocks:

- All internal blocks within the block must support code generation.
- If the Trigger block **Sample time type** is set to:
 - `triggered`, internal blocks must have **Sample time** set to `-1`.
 - `periodic`, the root-level function-call Inport block must have its **Sample time** set to a specified discrete time and all internal blocks must have **Sample time** set to `-1` or the specified discrete time.

Data logging and signal viewer blocks are not allowed at the root-level or within Subsystem and Model blocks.

Sample Time for Function-Call Subsystems

In an export-function model, you can specify sample time for root-level function-call Inport blocks and the Trigger block inside a root-level Function-Call Subsystem block or function-call Model block. The following table shows how to specify these sample times.

Trigger block Sample time type	Trigger block Sample time	Inport block Sample time	Function-call rate during simulation
Triggered	Not specified, parameter is inactive.	-1 (inherited)	For simulation, the function-call initiator connected to the Inport block sets the rate of simulation.

		Specified discrete time	<p>Function-call initiator, in test model, connected to Inport block must have a sample time equal to the specified discrete time for the Inport block.</p> <p>For simulation, component executes at the specified discrete rate. If a function-call source uses a different sample, Simulink displays an error message.</p>
<p>Periodic</p> <p>Periodic function-call run-time checks apply if the export-function model is referenced from a Model block.</p>	<p>-1 (inherited) or the specified discrete time for the Inport block.</p>	-1 (inherited)	<p>This configuration is not allowed. Simulink displays an error message.</p>
		Specified discrete time.	<p>For simulation, component executes at the specified discrete sample time. If a function-call source uses a different sample time, Simulink displays an error message.</p>

Execution Order for Root-Level Function-Call Inport Blocks

Specifying sample time and priority for function-call Inport blocks gives you control over the execution order of Function-Call Subsystems and function-call Models.

- 1 Specify sample time for simulation execution.. Right-click a function-call Inport block, and then select **Block parameters**.
- 2 Select the Signal Attributes tab. In the **Sample time** box, enter a discrete time.
- 3 Specify the block priority for simulation. Right-click a function-call Inport block, and then select **Properties**.
- 4 In the **Priority** box, enter a priority value.
- 5 Display sorted execution order for simulation. Select **Display > Blocks > Sorted Execution Order**. This display has no impact on the generated code.

In the following export-function model, Function-Call Subsystem 2 with **Sample time** for Inport block 2 set to 0.01 (10 ms) runs before Function-Call Subsystem 1 with **Sample time** for Inport block 1 set to 0.1 (100 ms).

Determine Relative Execution Order

Simulink compares function-call Inport block properties to determine their relative execution order using the following rules:

- 1 Priority - lower priority executes first
- 2 Sample time - smaller sample time executes first
- 3 Port number - smaller port number executes first

When two blocks have different values for the **Priority** parameter, the block with the lower priority executes first. If the **Priority** parameter is equal, the block with the faster rate (smaller sample time) executes first. If **Priority** and sample time are the same for both of the blocks, the block with the lower port number executes first.

Note When the simulation mode of the top model is Accelerator or Rapid Accelerator, Simulink does not perform run-time simulation checks for the execution order of root-level function-call Inport blocks inside referenced export-function models.

Suppose that an export function model has five root-level function-call Inport blocks, A to E, with block properties as shown in the table. To determine their relative execution order, Simulink compares their **Priority** parameters, sample times (if distinct and non-inherited), and port number.

root-level function-call Inport	A	B	C	D	E
Priority	10	30	40	40	30
Sample Time	-1	0.2	0.1	0.1	-1
Port Number	5	4	3	2	1

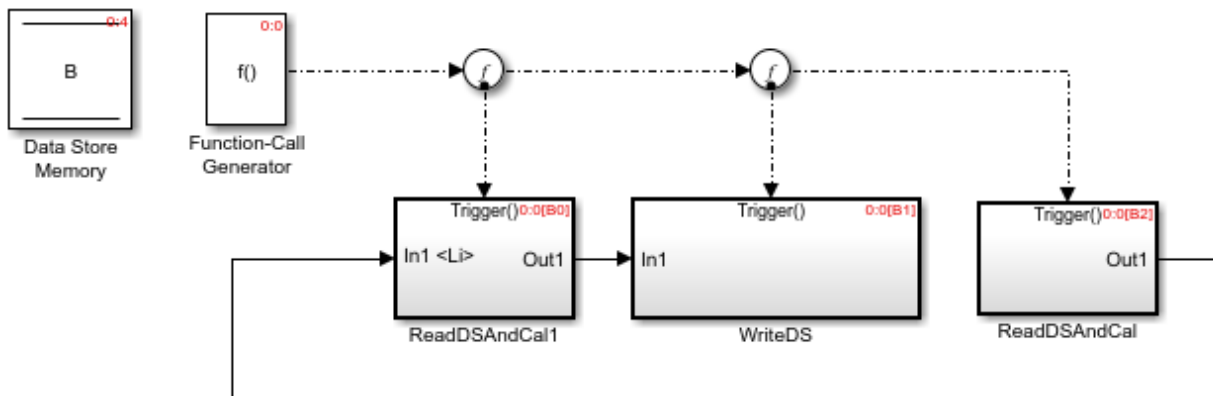

- Block A has the lowest priority of all five blocks. A executes first.
- B and E execute after A but before C and D. Since B and E have the same priority, Simulink compares their sample times to determine execution order. E has a sample time of -1 (inherited), which is smaller than 0.2, the sample time of B. E executes before B.
- C and D have the same priority and the same distinct, noninherited sample times. The port number for D (2) is smaller than C (3), D executes before C.

The relative execution order for these function-call Inport blocks is A, E, B, D, and C.

Latched Input Data for Function-Call Subsystems

You can latch input data for Inport blocks within Function-Call Subsystem blocks to ensure data integrity. To latch input data, select the **Latch input for feedback signals of function-call subsystem outputs** check box.

In the following model, input data for the Inport block in the function-call subsystem ReadDSAndCall is latched (indicated by) and cannot change during the execution of the subsystem. The Data Store Read and Data Store Write blocks are called within each function-call subsystem. The first and second function-calls write data and the last function-call reads data to the Data Store Memory block.

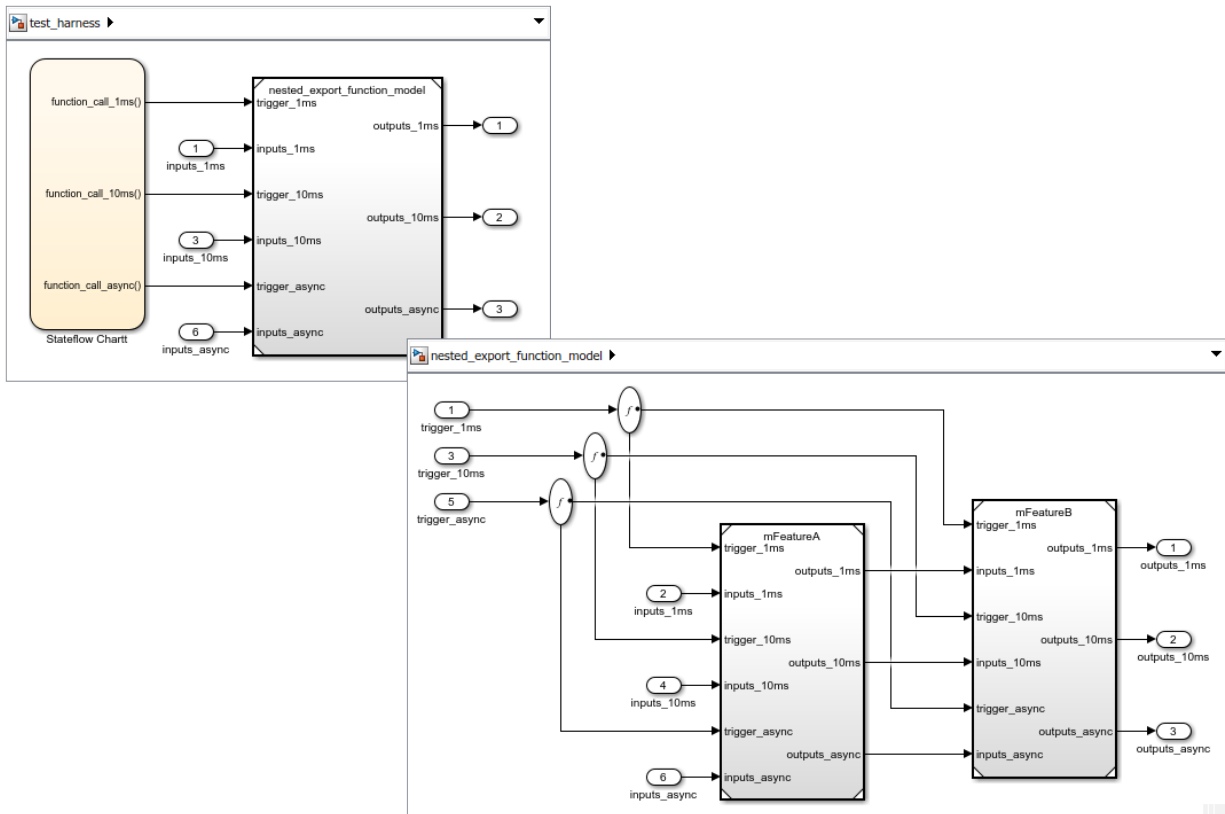

Note The root-level data Inport block connected to an internal Inport block is also latched if all of the blocks connected to the root-level block are latched. For more information, see “Latch input for feedback signals of function-call subsystem outputs”.

Note Data transfer signals are unprotected in the generated code by default. Use custom storage classes, to prevent data corruption in these signals due to preemption of the current task in the target environment.

Nested Export-Function Models

Nested export-function models provide an additional layer of organization. The following model has two referenced export-function models that are referenced from a Model block.

Note An export-function model cannot contain a referenced model with asynchronous function-call inputs, but can contain function-call subsystems and function-call models. A model with asynchronous function-call inputs can contain an export-function model, function-call subsystem, or a function-call model.

Export-Function Model with a Multi-Instanced Function-Call Model

You can use Function-Call Subsystem blocks or function-call Model blocks within an export-function model. If you use a function-call Model block, you can also create multiple instances of the model.

- 1 Define your algorithm with a model that contains a Trigger block. Set **Trigger type** to function-call.

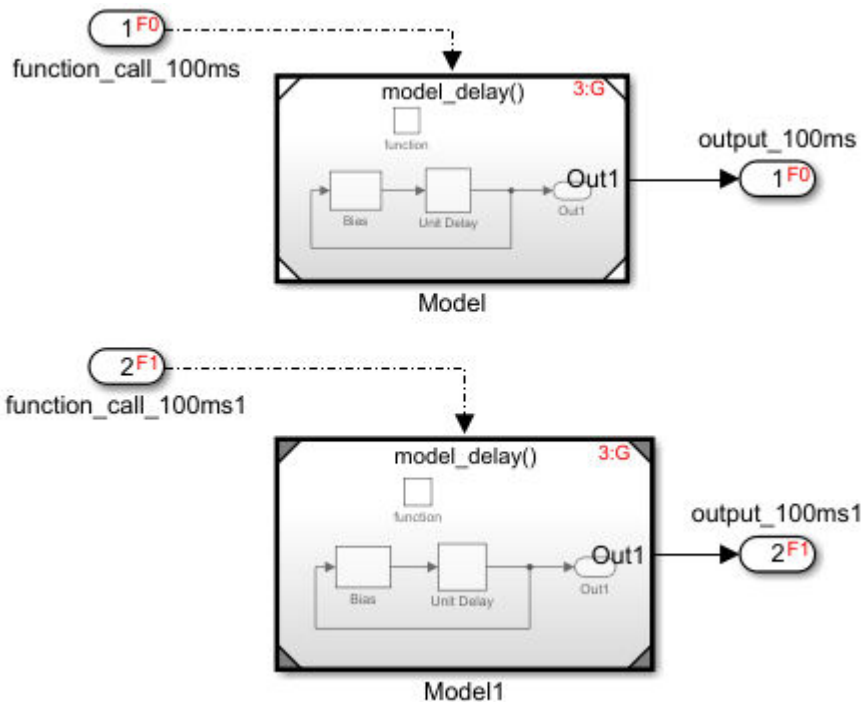

- 2 Reference the model from a Model block. The result is a function-call model.

- 3 Connect a function-call Inport block and select the **Output function call** check box. Add signal Inport and Outport blocks. Update the model (Ctrl-D). The result is an export-function model with a function-call model.

- 4 Copy the referenced model and port blocks to create a second instance of the model. Sorted order shows the first instance runs before the second instance.

Export-Function Models and Models with Asynchronous Function-Call Inputs

An export-function models capability is available for models with asynchronous function-call input ports. You use these models primarily in the Simulink environment where the Simulink scheduler calls the functions.

Comparison Characteristic	Export-Function Models	Models with Asynchronous Function-Call Inputs
Definition	These models have root-level function-call Inport blocks that are not connected to an Asynchronous Task Specification block. These Inport blocks trigger function-call subsystems or function-call models (Model block with Trigger block).	These models have root-level function-call Inport blocks connected to Asynchronous Task Specification blocks. These Inport blocks trigger function-call subsystems or function-call models.
Root-level blocks	Only blocks executing in a function-call context are allowed at the root level.	Blocks executing in a non-function-call context are also allowed.
Data transfer	Use data transfer indicators to interpret simulation results. Data transfer in export-function models is not protected by default in generated code. For more details, see “Latched Input Data for Function-Call Subsystems” on page 10-127.	Use Rate Transition blocks to protect data transferred between function-call subsystems running at different rates. For more information, see Rate Transition.
Simulation support	These models support standalone simulation and test model simulation in all simulation modes.	These models support test model simulation in all simulation modes and standalone simulation in Normal, Accelerator, and Rapid Accelerator modes.
Code generation support	Top-model and standalone code generation are supported.	Top-model and standalone code generation are supported.

Use Resettable Subsystems

In this section...

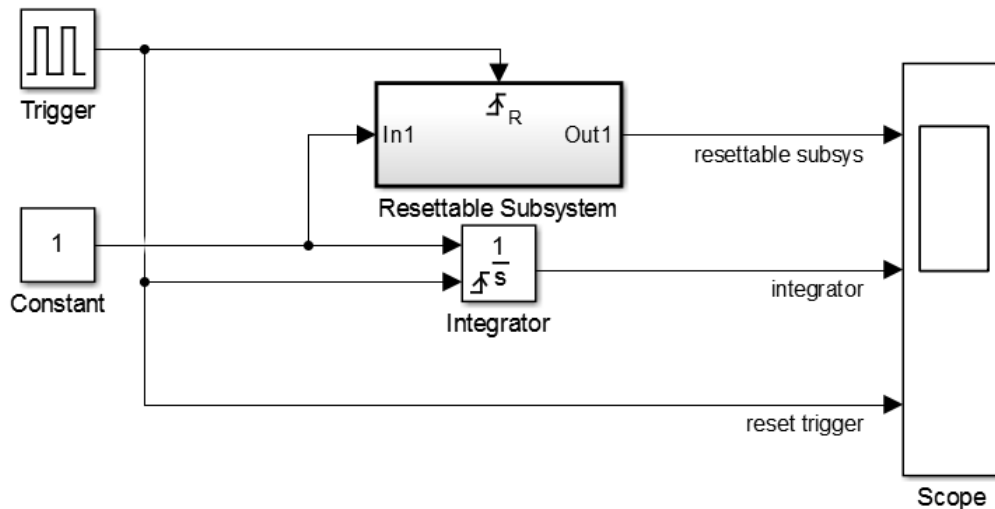

“Behavior of Resettable Subsystems” on page 10-134

“Comparison of Resettable Subsystems and Enabled Subsystems” on page 10-137

“Model Examples” on page 10-140

Behavior of Resettable Subsystems

Use resettable subsystems when you want to conditionally reset the states of all blocks within a subsystem to their initial condition. A resettable subsystem executes at every time step but conditionally resets the states of blocks within it when a trigger signal occurs at the reset port. This behavior is similar to the reset behavior of blocks with reset ports, except that a resettable subsystem resets the states of all blocks inside it.

Using resettable subsystems over other methods of resetting states of your block or subsystem has these advantages:

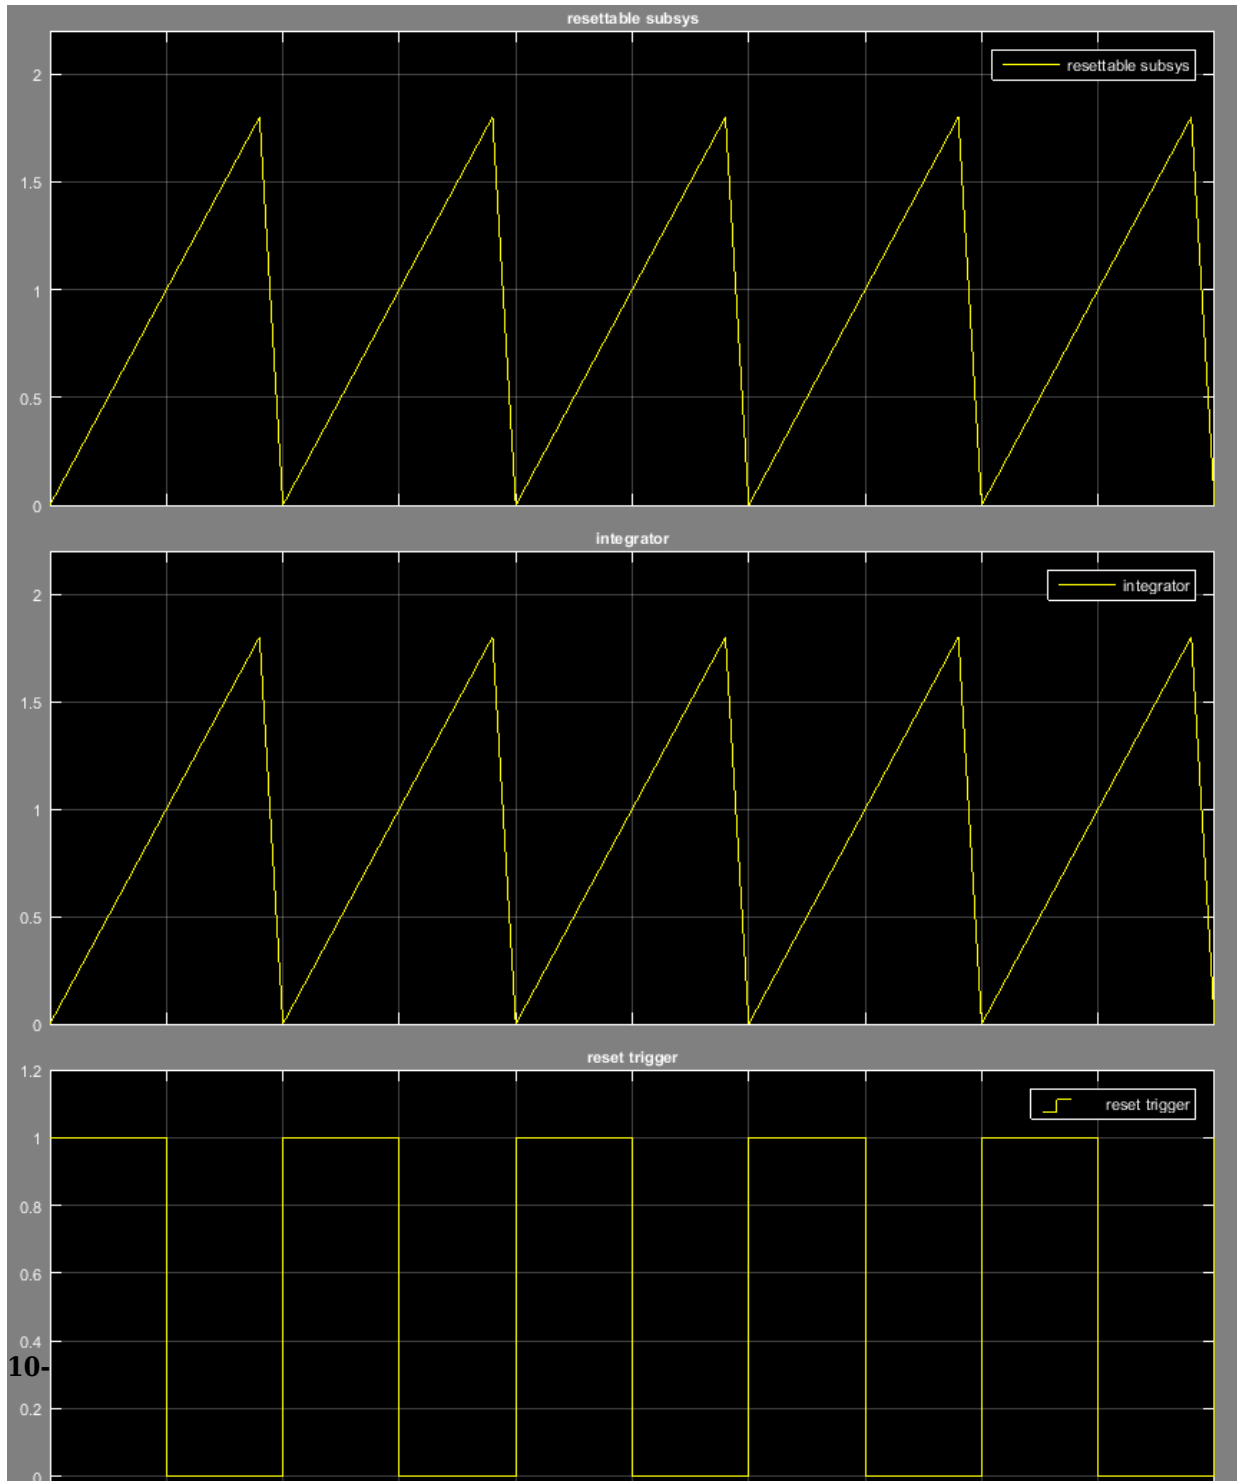

- When you want to reset the states of multiple blocks in a subsystem, displaying and connecting the reset port of each block is cumbersome and makes the block diagram

hard to read. Instead, place all the blocks in a resettable subsystem and configure the Reset block in the subsystem.

- Some blocks, such as the Discrete State-Space block, have states but do not have reset ports. You cannot reset these blocks individually, and you must reset the subsystem they are inside. In such cases, it is useful to place these blocks in a resettable subsystem.
- You can also reset blocks in enabled subsystems by setting the **States when enabling** parameter on the enable port to **reset**. However, for this behavior, you must disable the subsystem and then reenable it at a later time step. To reset your block states at the same time step, use resettable subsystems. For more information, see “Comparison of Resettable Subsystems and Enabled Subsystems” on page 10-137.

All blocks in a resettable subsystem must have the same sample time, and they execute at every sample time hit of the subsystem. Resettable subsystems and the model use a common clock.

This model shows that the behavior of block reset ports and resettable subsystems is the same. A resettable subsystem enables you to reset the states of all blocks inside it. The resettable subsystem contains an integrator block that is configured similar to the root-level Integrator block, but the block does not have a reset port. The subsystem resets the states of the integrator block inside it in the same manner as the reset port of the Integrator block. You can see this behavior by running the model and viewing the output in the scope.

Comparison of Resettable Subsystems and Enabled Subsystems

If you set **States when enabling** for the Enable block to **reset**, the enabled subsystem resets the states of all blocks in the subsystem. However, you must disable the subsystem for at least one time step and then reenable it for the states to reset.

In contrast, resettable subsystems always execute and reset the states of their blocks instantaneously.

This model shows the difference in the execution behavior of these subsystems. It contains an enabled subsystem and a resettable subsystem whose control ports are connected to pulse generator. The resettable subsystem is set to reset on the rising edge of the control signal, and the enabled subsystem has the **States when enabling** parameter set to **reset** in the enable port.

The subsystems contain identical Discrete-Time Integrator blocks, whose input is the Constant block at the root level of the model. The figure shows the contents of the resettable subsystem.

The figure shows the simulation output.

When the control signal is 0, the enabled subsystem is disabled and the integrator does not change its output while the resettable subsystem is executing. The rising edge of the control signal triggers the reset port of the resettable subsystem and enables the enabled subsystem. Both subsystems reset their states at this time step.

Notice that the enabled subsystem is disabled for at least one time step before its states can be reset. The resettable subsystem does not have this limitation.

What Are Simulink Functions?

A Simulink function is a computational unit that calculates a set of outputs when provided with a set of inputs. The function header uses a notation similar to programming languages such as MATLAB and C++. You can define and implement a Simulink function in several ways:

- **Simulink Function block** — Function defined using Simulink blocks within a Simulink Function block. See Simulink Function block reference.
- **Exported Stateflow graphical function** — Function defined with state transitions within a Stateflow chart, and then exported to a Simulink model.
- **Exported Stateflow MATLAB function** — Function defined with MATLAB language statements within a Stateflow chart, and then exported to a Simulink model.
- **S-function** — Function defined using an S-function block. For an example with an S-function, open `sfcndemo_simulinkfunction_getset`.

What Are Simulink Function Callers?

A Simulink function caller invokes the execution of a Simulink function from anywhere in a model or chart hierarchy.

- **Function Caller block** — Call a function defined in Simulink or exported from Stateflow. See Function Caller block reference.
- **Stateflow chart transition** — In a Stateflow chart, call a function defined in Simulink or exported from Stateflow.
- **MATLAB Function block** — Call a function from a MATLAB language script.
- **S-Function block** — Call a function using system methods. See `ssDeclareFunctionCaller` and `ssCallSimulinkFunction`.
- **MATLAB System block** — Call a function using a System Object and the MATLAB language.

Connect to Local Signals

In addition to Argument Inport and Argument Outport blocks, a Simulink Function block can interface to signals in the local environment of the block through Inport or Outport blocks. These signals are hidden from the caller. You can use port blocks to connect and communicate between two Simulink Function blocks or connect to root Inport and Outport blocks that represent external I/O.

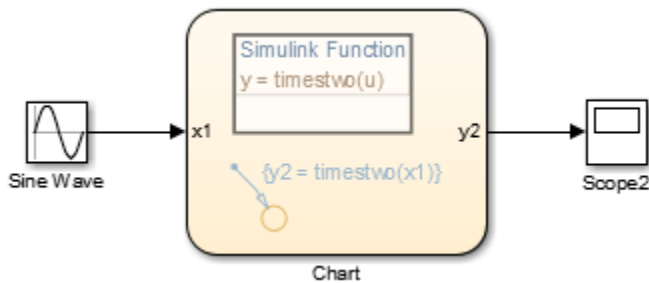

You can also connect the Outport blocks to sink blocks that include logging (To File, To Workspace) and viewing (Scope, Display) blocks. However, these blocks execute last after all other blocks.

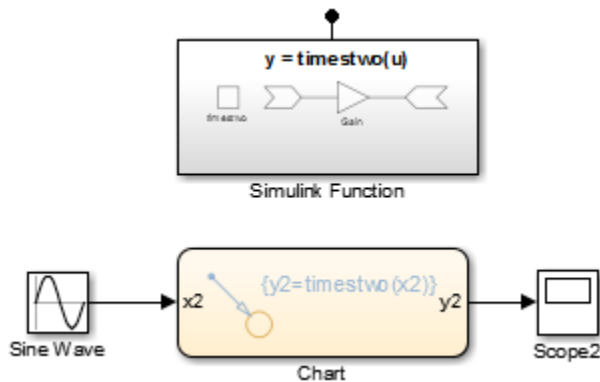

A Simulink Function block can output a function-call event to an Outport block.

Reusable Logic with Functions

Use functions when you need reusable logic across a model hierarchy. Consider an example where a Simulink Function with reusable logic is defined in a Stateflow chart.

You can move the reusable logic from inside the Stateflow chart to a Simulink Function block. The logic is then reusable by function callers in Simulink subsystems (Subsystem and Model blocks) and in Stateflow charts at any level in the model hierarchy.

The result is added flexibility for structuring your model for reuse.

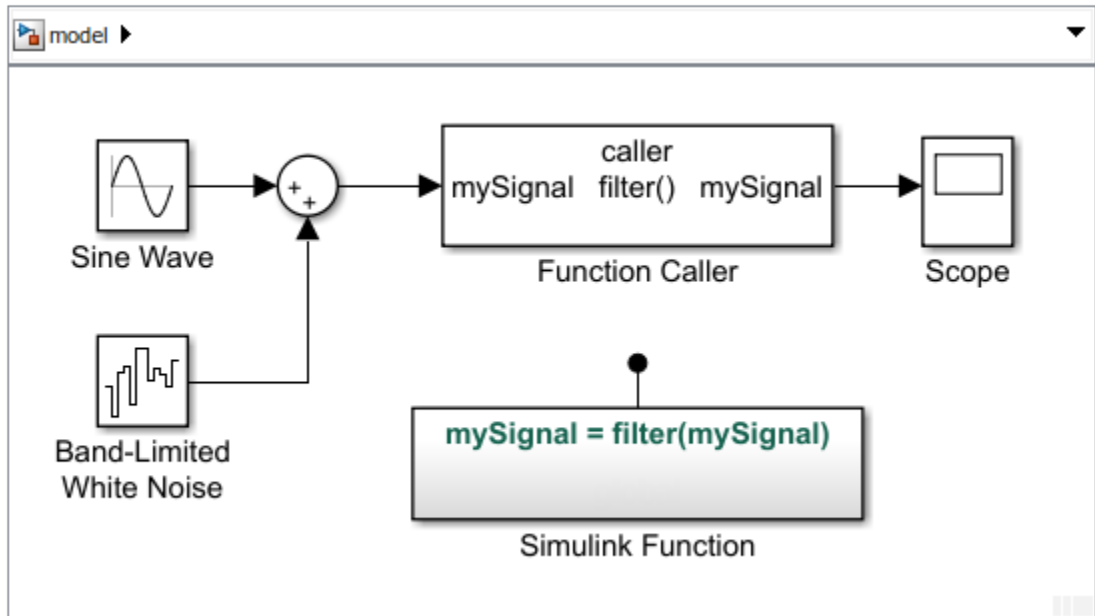

Note Input and output argument names (`x2`, `y2`) for calling a function from a Stateflow chart do not have to match the argument names (`u`, `y`) of a Simulink Function block.

Input/Output Argument Behavior

The function prototype for a Simulink Function block can have identical input and output arguments. For example, a function that filters noise could input a signal and then return the signal after filtering.

```
mySignal = filter(mySignal)
```

You can call the function with a Function Caller block and add noise to a test signal to verify the function algorithm.

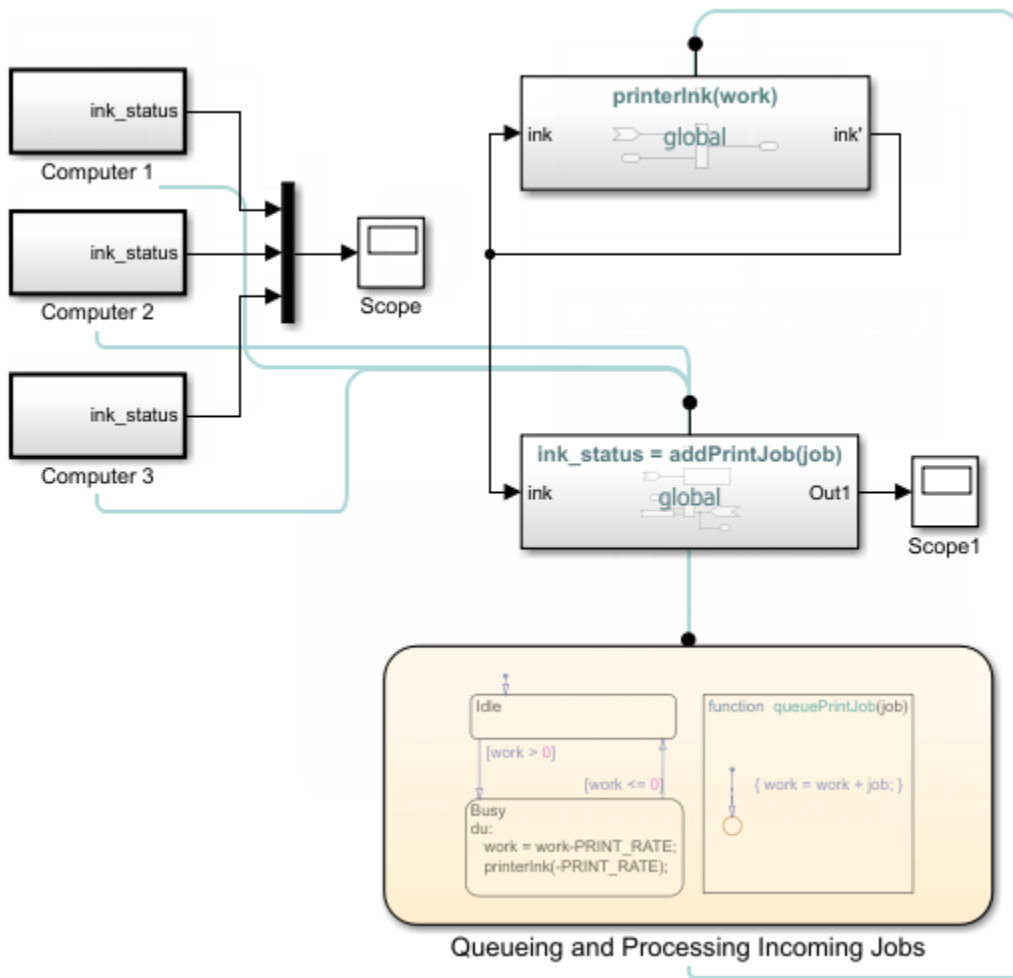

When generating code for this model, the input argument for the Simulink Function block passes a pointer to the signal, not a copy of the signal value.

```
void filter(real_T *rtuy_mySignal)
{
    . . .
    *rtuy_mySignal = model_P.DiscreteFilter_NumCoef * DiscreteFilter_tmp;
}
```

Shared Resources with Functions

Use functions when you model a shared resource, such as a printer. The model `slexPrinterExample` uses Simulink Function blocks as a common interface between multiple computers and a single Stateflow chart that models a printer process.

How a Function Caller Identifies a Function

The function interface uses MATLAB syntax to define the name of a function and its input and output arguments. The model hierarchy can contain only one function definition with the identified function name. Simulink verifies that:

- The arguments in the **Function prototype** parameter for a Function Caller block matches the arguments specified in the function. For example, a function with two input arguments and one output argument appears as:

```
y = MyFunction(u1, u2)
```

- The data type, dimension, and complexity of the arguments must agree. For a Function Caller block, you can set the **Input argument specifications** and **Output argument specifications** parameters, but usually you do not need to specify these parameters manually. Simulink derives the specification from the function.

The only case where you must specify the argument parameters is when the Function Caller block cannot find the function in the model or in any child model it references. This situation can happen when the Function Caller block and called function are in separate models that are referenced by a common parent model. See “Simulink Function Blocks in Referenced Models” on page 10-175 and “Argument Specification for Simulink Function Blocks” on page 10-170.

Reasons to Use a Simulink Function Block

Function-Call Subsystem blocks with direct signal connections for triggering provide better signal traceability than Simulink Function blocks, but Simulink Function blocks have other advantages.

- **Eliminate routing of signal lines.** The Function Caller block allows you to execute functions defined with a Simulink Function block without a connecting signal line. In addition, functions and their callers can reside in different models or subsystems. This approach eliminates signal routing problems through a hierarchical model structure and allows greater reuse of model components.
- **Use multiple callers to the same function.** Multiple Function Caller blocks or Stateflow charts can call the same function. If the function contains state (e.g., a Unit Delay block), the state is shared between the different callers.
- **Separate function interface from function definition.** Functions separate their interface (input and output arguments) from their implementation. Therefore, you can define a function using a Simulink Function block, an exported graphical function from Stateflow, or an exported MATLAB function from Stateflow. The caller does not need to know how or where the function was implemented.

Choose a Simulink Function or Reusable Subsystem

A consideration for using a Simulink Function block or a Subsystem block has to do with shared state between function calls. A Simulink Function block has shared state while a Subsystem block, even if specified as a reusable function, does not.

- For a Simulink Function block, when one block has multiple callers, code is always generated for one function. If the Simulink Function block contains blocks with state (for example, Delay or Memory), the state is persistent and shared between function callers. In this case, the order of calls is an important consideration.
- For a Subsystem block, when a block has multiple instances and is configured as a reusable function, code is usually generated for one function as an optimization. If the Subsystem block contains blocks with state, code is still generated for one function, but a different state variable is passed to the function. State is not shared between the instances.

When Not to Use a Simulink Function Block

Simulink Function blocks allow you to implement functions graphically, but sometimes using a Simulink Function block is not the best solution.

For example, when modeling a PID controller or a digital filter and you have to model the equations defining the dynamic system. Use an S-Function, Subsystem, or Model block to implement systems of equations, but do not use a Simulink Function block, because these conditions can occur:

- **Persistence of state between function calls.** If a Simulink Function block contains any blocks with state (for example, Unit Delay or Memory), then their state values are persistent between calls to the function. If there are multiple calls to that function, the state values are also persistent between the calls originating from different callers.
- **Inheriting continuous sample time.** A Simulink Function block cannot inherit a continuous sample time. Therefore, do not use this block in systems that use continuous sample times to model continuous system equations.

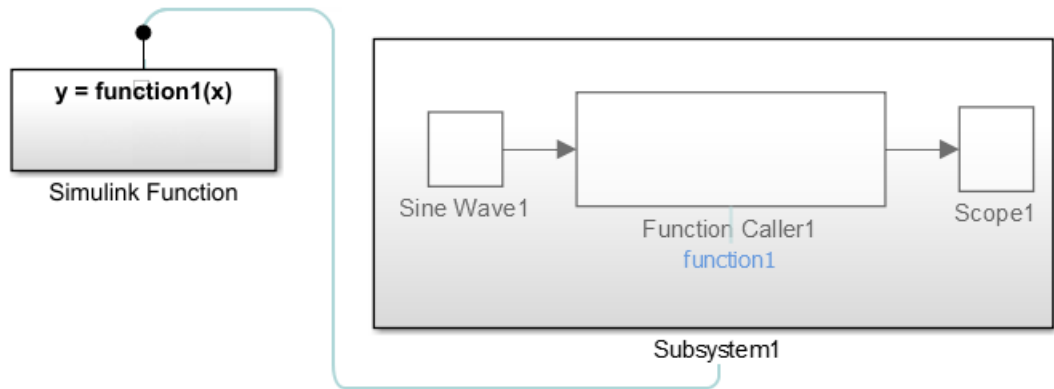

Tracing Simulink Functions

Visually display connections between a Simulink function and their callers with lines that connect callers to functions:

- Turning on/off tracing lines — From the Simulink Editor menu, select **Display > Function Connectors**.
- Direction of tracing lines — Lines connected at the bottom of a block are from a function caller. Lines connected at the top of a block are to a Simulink function or a subsystem containing the function.

- Navigation to functions — A function caller can be within a subsystem.

Navigate from a caller in a subsystem to a function by first opening the subsystem, and then clicking a link to the function.

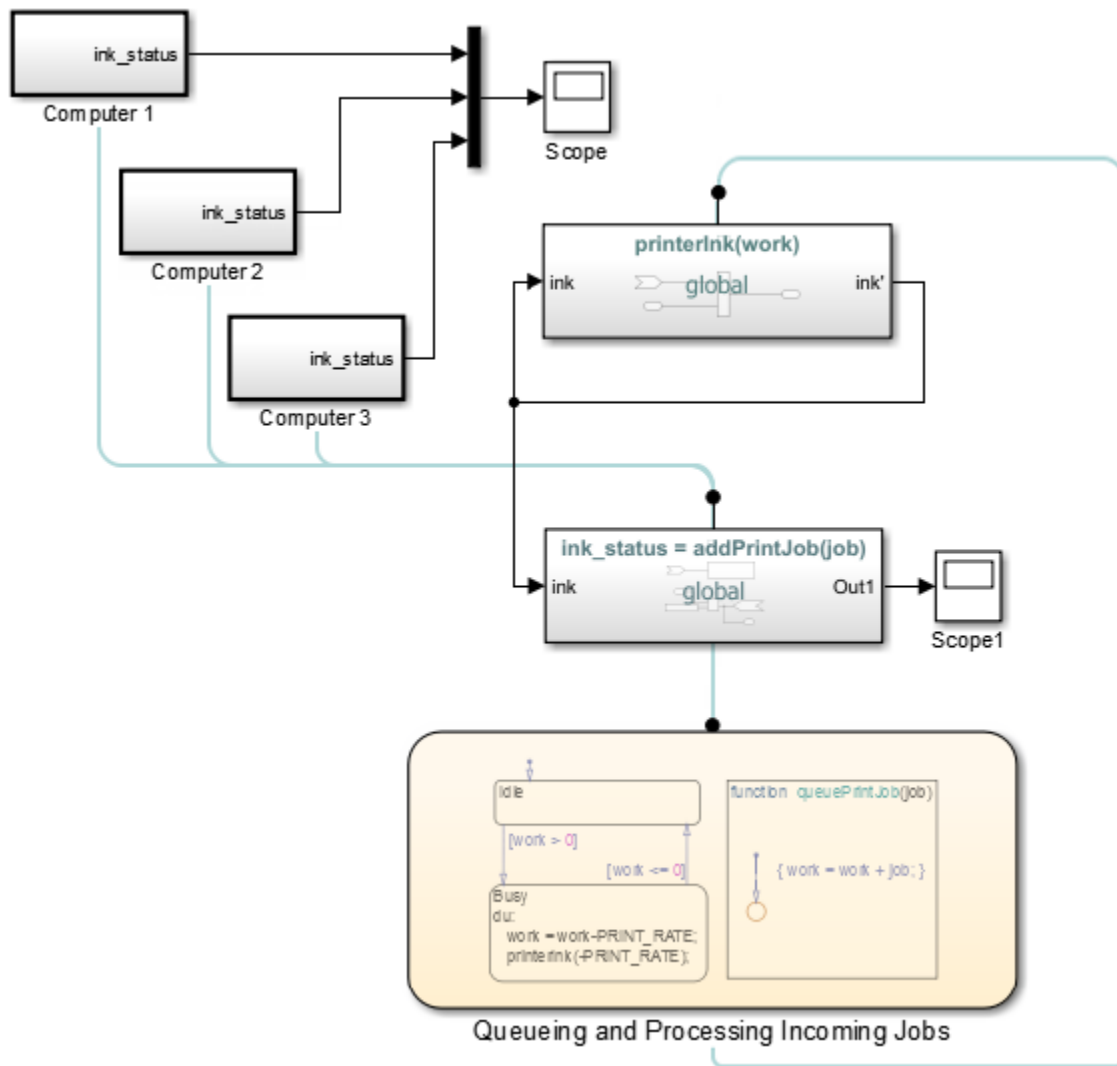

If the function is at the root level of a model, the function opens. If the function is within a subsystem, the subsystem containing the function opens.

Monitor Ink Status on a Shared Printer Using Simulink Functions

After selecting **Display > Function Connectors**, the model `slexPrinterExample` shows the relationships between callers and functions.

In this example, the Function Caller in the Simulink Function block `addPrintJob`, calls the exported Stateflow function `queuePrintJob`. The subchart `Busy` calls the Simulink Function block `printerInk`. Tracing lines are drawn into and out of the Stateflow chart.

“Call a Simulink Function Block from Multiple Sites” on page 10-166

Simulink Functions

Simulink functions have an interface with input and output arguments similar to programming languages. You create the function definitions:

- Graphically, using Simulink blocks in a Simulink Function block, or Stateflow state transitions in a graphical function exported from a Stateflow chart.
- Textually, using MATLAB code in a MATLAB function exported from a Stateflow chart.

Simulink Function Block

Set up a Simulink Function block to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument.

- 1 Add a Simulink Function block from the User-Defined Functions library into your model.

Open the Library Browser by selecting the Library Browser toolbar button .

- 2 On the block, enter this function prototype to set the function name to `timestwo`, the input argument to `u`, and the output argument to `y`:

```
y = timestwo(u)
```

- 3 Double-click the block to open the subsystem defining the function.
- 4 Add a Gain block and set the **Gain** parameter to 2.

Export Graphical Function from Stateflow Chart

Set up a graphical function in a Stateflow chart to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument. Set chart parameters to export the function to a Simulink model.

Define a Graphical Function

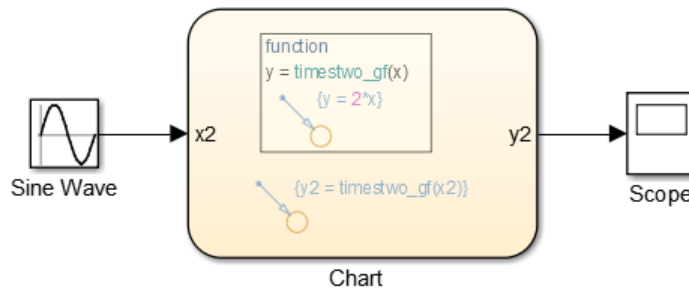

Create a graphical function in a Stateflow chart. Define the function interface and function definition.

- 1 Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File > New > Chart**.
- 2 Drag the new chart to your model. Double-click to open the chart.
- 3 Add a graphical function. From the left-side toolbar, click and drag the graphical function icon  onto the chart.
- 4 Define the function interface. In the function box, replace the ? with the function interface `y = timestwo_gf(x)`.

- Define the function. Click the transition arrow and replace the ? with the MATLAB code $\{y = 2*x\}$.

- Add a transition in the chart. Connect the chart input to a Sine Wave input and the output to a Scope.

- Run a simulation to test the function.

Set Argument Parameters for a Graphical Function

Specify the size, complexity, and type of the function input and output arguments. A chart can export only functions with fully specified prototypes.

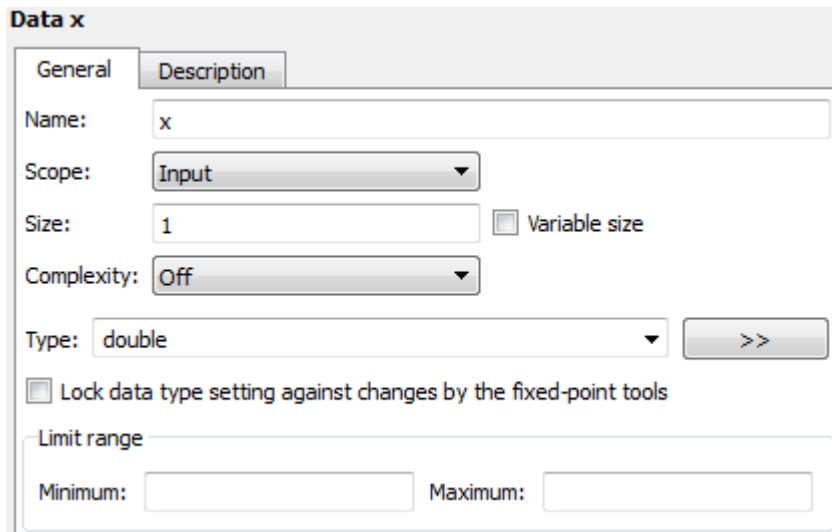

- Open Model Explorer. In the left pane, select the graphical function.

- From the **Column View** list in the middle pane, select Stateflow. Select the filter icon , and then select **All Stateflow Objects**. From the table at the bottom of the pane, select an input or output argument.

- 3 In the right pane, enter 1 (scaler) for Size, select Off (real number) for **Complexity**, and select double for **Type**.

- 4 Repeat steps 2 and 3 with the remaining function arguments.

Set Export Function Parameters for a Graphical Function

Set parameters to export the graphical function during a simulation.

- 1 From the left pane, select the chart containing the graphical function.

Alternatively, open the chart and from the menu, select **Chart > Properties**.

- 2 In the property dialog box, select **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** check boxes.

If you are calling the exported graphical function from another Stateflow chart (not the chart that exported the graphical function), you do not need to select the **Allow exported functions to be called by Simulink** check box.

Export MATLAB Function from Stateflow Chart

Set up a MATLAB function in a Stateflow chart to receive data through an input argument from a function caller. Multiply the input argument by 2, and then pass the calculated value back through an output argument. Set chart parameters to export the function to a Simulink model.

Define MATLAB Function

Create a graphical function in a Stateflow chart. Define the function interface and function definition.

- 1 Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File > New > Chart**. A new chart opens in a new model.
- 2 Drag the new chart to your model. Double-click the chart to open it.
- 3 Add a graphical function. From the left-side toolbar, click and drag the graphical

function icon  onto the chart.

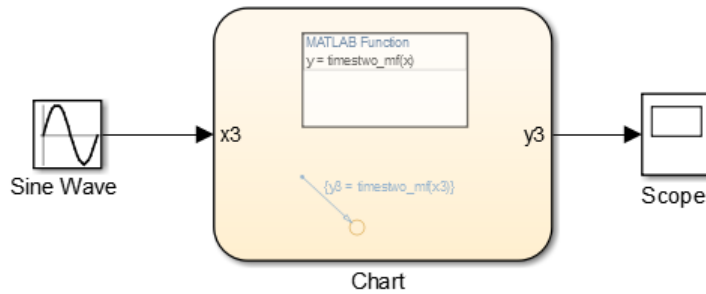

- 4 Define the function interface. In the function box, replace the ? with the function interface `y = timestwo_ml(x)`.

- 5 Double-click the function box to open the MATLAB code editor. Define the function with the MATLAB code.

- 6 Add a transition to test the MATLAB function. Add a Sine Wave input and connect the output to a Scope.

- 7 Run a simulation to test the function.

Set Argument Parameters

Specify the size, complexity, and type of the function input and output arguments. A chart can export only functions with fully specified prototypes.

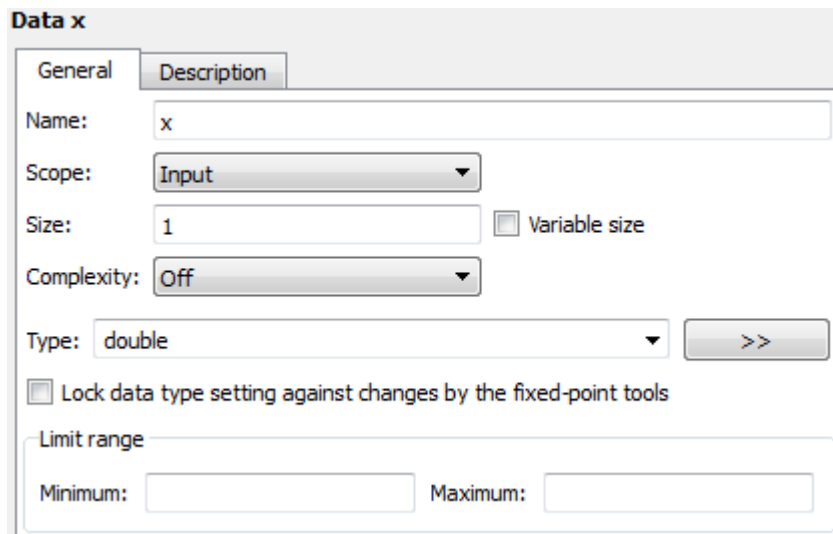

- 1 Open Model Explorer. In the left pane, select the MATLAB function.

- 2 In the middle pane, from the **Column View** list, select Stateflow. From the table, select an input or output argument.

- 3 In the right pane, enter 1 (scaler) for **Size**, select Off (real number) for **Complexity**, and select double for **Type**.

- 4 Repeat steps 2 and 3 with the remaining function arguments.

Set Export Function Parameters

Set parameters to export the MATLAB function during a simulation.

- 1 From the left pane, select the chart containing the graphical function.

Alternatively, open the chart and from the menu, select **Chart > Properties**.

- 2 In the property dialog box, select **Export Chart Level Function (Make Global)** and **Allow exported functions to be called by Simulink** check boxes.

If you are calling the exported graphical function from another Stateflow chart (not the chart that exported the graphical function), you do not need to select the **Allow exported functions to be called by Simulink** check box.

Call Simulink Functions with a Function Caller Block

The following examples show how to use a Function Caller block to call:

- Simulink Function block.
- Exported Graphical function from a Stateflow chart.
- Exported MATLAB function from a Stateflow chart.

The functions multiply a value from the caller by 2, and then send the calculated value back to the caller.

Because the Function Caller block cannot determine function arguments at compile time, you have to name the Function Caller block input and output arguments. The argument names in the **Function prototype** must match the function argument names.

Function Caller Block to Call Simulink Function Block

Set up a Function Caller block to send data through an input argument to a Simulink Function block. Receive data back from the function through an output argument. Points to consider:

- The input and output argument names for the Simulink Function block and the prototype for a Function Caller block must match exactly.
- If the Function Caller block is within a Model block (referenced model), you must define the **Input argument specification** and **Output argument specification**. See “Simulink Function Blocks in Referenced Models” on page 10-175 and “Argument Specification for Simulink Function Blocks” on page 10-170.

To add a Function Caller block.

- 1 Add a Function Caller block from the User-Defined Functions library into your model.
- 2 In the Function Caller dialog box, in the **Function prototype** box, enter `y = timestwo(u)`. This function prototype creates an input port `u` and output port `y` on the Function Caller block.

Note Typing in a blank text box displays a list of previously created function prototypes that match the text you are typing.

- 3 Add a Sine Wave block to the input and a Scope block to the output.

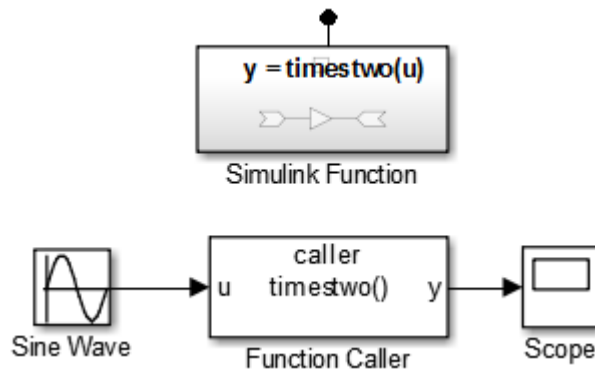

- 4 Set up a Simulink Function block as described in “Simulink Function Block” on page 10-152.

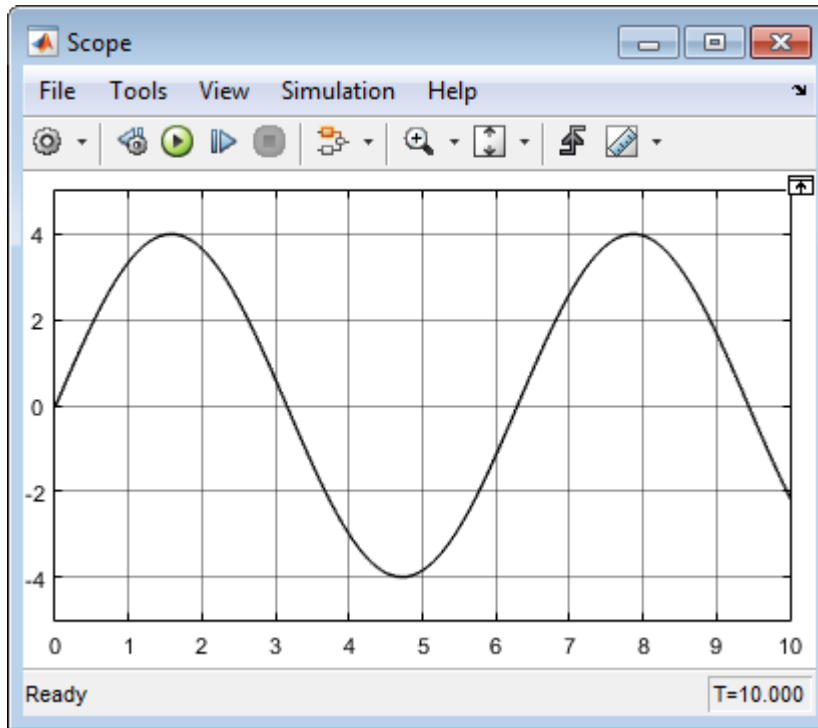

Simulate the Model

After you create a function using a Simulink Function block and setup a call to that function using a Function Caller block, you can simulate the model.

- 1 Return to the top level of the model.

- 2 Run a simulation.
- 3 To view the signal results, double-click the Scope block. The input sine wave with an amplitude of 2 is doubled.

Function Caller Block to Call Exported Graphical Function

Calling an exported graphical function from Stateflow is no different than calling a Simulink Function block. Points to consider:

- The input and output argument names for an exported function and the prototype for a Function Caller block must match exactly.
- If the Function Caller block is within a Model block (referenced model), you must define the **Input argument specification** and **Output argument specification**. See “Simulink Function Blocks in Referenced Models” on page 10-175 and “Argument Specification for Simulink Function Blocks” on page 10-170.

Function Caller Block to Call Exported MATLAB Functions

Calling an exported MATLAB function from Stateflow is no different than calling a Simulink Function block. Points to consider:

- The input and output argument names for an exported function and the prototype for a Function Caller block must match exactly.
- If the Function Caller block is within a Model block (referenced model), you must define the **Input argument specification** and **Output argument specification**. See “Simulink Function Blocks in Referenced Models” on page 10-175 and “Argument Specification for Simulink Function Blocks” on page 10-170.

Call Simulink Functions from a MATLAB Function Block

A MATLAB Function block can call another function. The following examples show how to use a MATLAB Function block to call:

- Simulink Function block.
- Exported Graphical function from a Stateflow chart.
- Exported MATLAB function from a Stateflow chart.

The functions multiply a value from the caller by 2, and then send the calculated value back to the caller.

MATLAB Function blocks only support discrete and fixed-in-minor sample times. When using a Sine Wave block as an input signal, setup the model and block parameters for a sample time compatible with the MATLAB Function block:

- Discrete — Open the model Configuration Parameters dialog box to the Solver pane. Set **Type** to Fixed-step and enter a value for **Fixed-step size** (fundamental sample time). Open the Sine Wave Block Parameters dialog box and set **Sample time** to the model sample time you entered.
- Fixed-In-Minor step — Open the Sine Wave Block Parameters dialog box. In the **Sample time** box, enter [0 1].

MATLAB Function Block to Call Simulink Function Block

Set up a MATLAB Function block to send data through an input argument to a Simulink Function block. Receive data back from the function through an output argument.

- 1 Add a MATLAB Function block to your model.
- 2 Double-click the block, which opens the MATLAB editor. Enter the function call `y1 = timestwo(u1)`.

```

1 function y1 = myFunction(u1)
2     %#codegen
3     y1 = timestwo(u1);

```

Note The argument names for the function you define in the MATLAB Function block do not have to match the argument names for the function that you define in the Simulink Function block. For a Function Caller block that calls a Simulink Function block, argument names must match.

- 3 Add a Sine Wave block for an input signal and a Scope block to view the output signal.

- 4 For the Sine Wave block, set the **Sample time** to 0.01. For the model, open the Configuration Parameters dialog box to the solver pane. Set **Type** to Fixed-step and **Fixed-step size** to 0.01.
- 5 Set up a Simulink Function block as described in “Simulink Function Block” on page 10-152.

MATLAB Function Block to Call Exported Graphical Function

Calling an exported graphical function from a MATLAB Function block is the same as calling a Simulink Function block.

MATLAB Function Block to Call Exported MATLAB Function

Calling an exported MATLAB function from a MATLAB Function block is the same as calling a Simulink Function block.

Call Simulink Functions from a Stateflow Chart

The following examples show how to use a Stateflow chart to call functions external to the chart but accessible in a Simulink model:

- Simulink Function block
- Exported Stateflow graphical function
- Exported Stateflow MATLAB function

There are no limitations to a function call from a Stateflow chart:

- Caller argument names can be different from the function argument names.
- Input signals to a Stateflow chart can be either continuous or discrete.

Create Stateflow Chart with a Transition

- 1 Add a Stateflow Chart to your Simulink model. From the Simulink Editor menu, select **File > New > Chart**. A new chart opens in a new model.
- 2 Drag the new chart to your model. Double-click the chart to open it.
- 3 Add a graphical function. From the left-side toolbar, click and drag the transition icon

onto the chart.

- 4 Add input port.
 - a From the menu, select **Chart > Add Inputs & Outputs > Data Input From Simulink**.
 - b In the Data dialog box, set **Name** to x1.
- 5 Add output port.
 - a From the menu, select **Chart > Add Inputs & Outputs > Data Output To Simulink**.
 - b In the Data dialog box, set **Name** to y1.
- 6 Add a Sine Wave block and connect signal output to the chart input port. Add a Scope block and connect input to the chart output port.
- 7 Edit transition code to call a function. For example, to call the Simulink Function block, enter:

```
{y1=timestwo_sf(x1);}
```

- 8 Set up a Simulink Function block as described in “Simulink Function Block” on page 10-152.

Stateflow Chart to Call Exported Graphical Function

Calling an exported graphical function from a Stateflow chart is the same as calling a Simulink Function block.

- 1 Open a Stateflow chart.
- 2 Click transition and enter

```
{y2=timestwo_gf(x2);}
```

Stateflow Chart to Call Exported MATLAB Functions

Calling an exported MATLAB function from a Stateflow chart is the same as calling a Simulink Function block.

- 1 Open Stateflow chart.
- 2 Click transition and enter:

```
{y3=timestwo_sf(x3);}
```

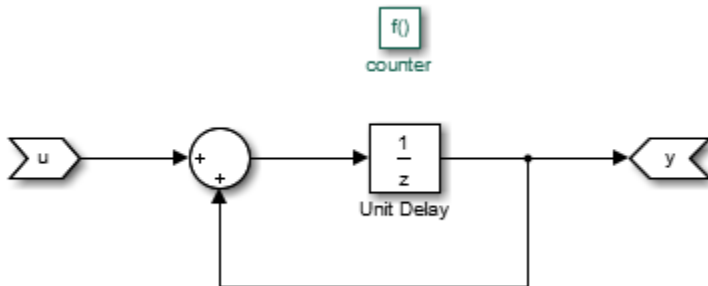

Call a Simulink Function Block from Multiple Sites

If you call a Simulink Function block from multiple sites, all call sites share the state of the function. For example, suppose that you have a Stateflow chart with two calls and two Function Caller blocks with calls to the same function.

A function defined with a Simulink Function block is a counter that increments by 1 each time it is called with an input of 1.

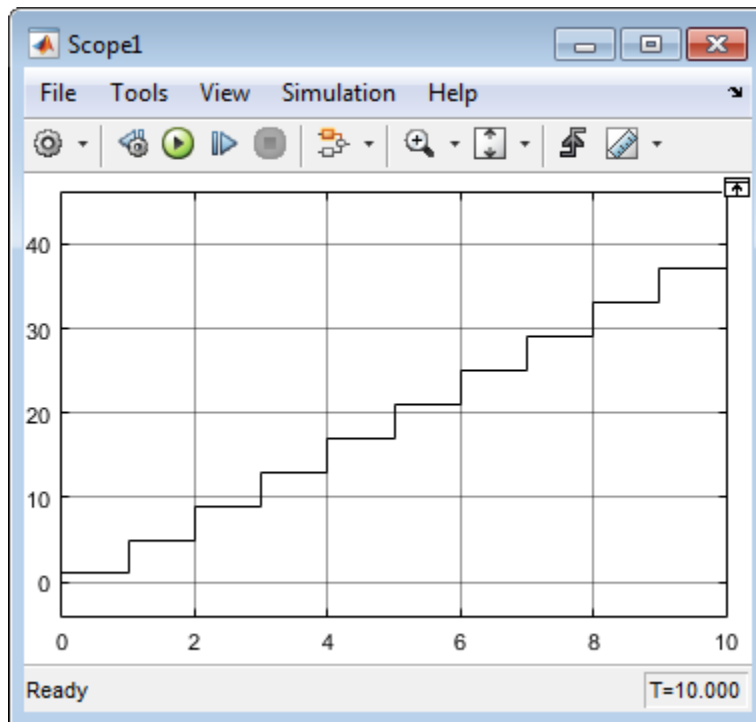

The Unit Delay block has state because the block value is persistent between calls from the two Function Caller blocks and the Stateflow chart. Conceptually, you can think of this function being implemented in MATLAB code:

```
function y = counter(u)
persistent state;
if isempty(state)
    state = 0;
end
y = state;
state = state + u;
```

Simulink initializes the state value of the Unit Delay block at the beginning of a simulation. After that, each time the function is called, the state value is updated.

In this example, the output observed in Scope1 increments by 4 at each time step. Scope2, Scope3, and Scope4 show a similar behavior. The only difference is a shift in the observed signal due to the execution sequence of the function calls.

Diagnostic Settings With Multiple Callers

For multiple callers that share a function and have different sample time rates, data integrity and consistency of real-time code might be a problem. Consider controlling the severity of diagnostics.

Select a **Fixed-step** solver. Set the **Treat each discrete rate as a separate task** to:

- Clear (single-tasking), and then set **Single task rate transition** parameter to none (default), warning, or error.
- Select (multi-tasking), and then set **Multitask rate transition** parameter to error (default) or warning.

Argument Specification for Simulink Function Blocks

In this section...

- “Example Argument Specifications for Data Types” on page 10-170
- “Input Argument Specification for Bus Data Type” on page 10-171
- “Input Argument Specification for Enumerated Data Type” on page 10-172
- “Input Argument Specification for an Alias Data Type” on page 10-173

When a Simulink Function block is within the scope of a Function Caller block, you do not have to specify the parameters. In such a case, the Function Caller block can determine the input and output argument specifications.

You specify arguments when a Simulink Function block is outside the scope of a Function Caller block. A Simulink Function block is considered to be out of scope of a Function Caller block when the two blocks are in separate models referenced by a common parent model.

Example Argument Specifications for Data Types

This table lists possible input and output argument specifications.

Simulink Function Block Data Type	Function Caller Block Expression	Description
double	double(1.0)	Double-precision scalar.
double	double(ones(12,1))	Double-precision column vector of length 12.
single	single(1.0)	Single-precision scalar.
int8, int16, int32	int8(1), int16(1), int32(1)	Integer scalars.
	int32([1 1 1])	Integer row vector of length 3.
	int32(1+1i)	Complex scalar whose real and imaginary parts are 32-bit integers.
uint8, int16, int32	uint8(1), uint16(1), uint32(1)	Unsigned integer scalars.

Simulink Function Block Data Type	Function Caller Block Expression	Description
boolean	boolean(true),boolean(false)	Boolean, initialized to true (1) or false (0).
fixdt(1,16) fixdt (signed, word_length)	fi(0,1,16) fi (value, signed, word_length)	16-bit fixed-point signed scalar with binary point set to zero. Fixed-point numbers can have a word size up to 128 bits.
fixdt(1,16,4)	fi(0,1,16,4)	16-bit fixed-point signed scalar with binary point set to 4.
fixdt(1,16,2^0,0)	fi(0,1,16,2^0,0)	16-bit fixed-point signed scalar with slope set to 2^0 and bias set to 0.
Bus: <object name>	parameter object name	Simulink.Parameter object with the Value parameter set to a MATLAB structure for the bus.
Enum: <class name>	parameter object name	Simulink.Parameter object with the Value parameter set to an enumerated value.
<alias name>	parameter object name	Simulink.Parameter object with the DataType parameter set to a Simulink.AliasType object and the Value parameter set to a value.

Input Argument Specification for Bus Data Type

Create a bus with two signals, and then specify the **Input argument specification** parameter for a Function Caller block. The Function Caller block calls a Simulink Function block that accepts the bus as input.

A bus input to a Function Caller block must be a non-virtual bus using a bus object.

- 1 Create a Simulink bus object myBus.

```
myBus = Simulink.Bus;
```

- 2 Add elements A and B.

```
myBus.Elements(1).Name = 'A';  
myBus.Elements(2).Name = 'B';
```

- 3 Create a MATLAB structure `myBus_MATLABstruct` with fields A and B.

```
myBus_MATLABstruct.A = 0;  
myBus_MATLABstruct.B = 0;
```

- 4 Create a Simulink parameter object `myBus_parameter` and assign the MATLAB structure to the `Value` parameter.

```
myBus_parameter = Simulink.Parameter;  
myBus_parameter.DataType = 'Bus: myBus';  
myBus_parameter.Value = myBus_MATLABstruct;
```

- 5 For the Function Caller block dialog box, set the **Input argument specification** parameter to `myBus_parameter`.
- 6 For the Argument In block dialog box of the Simulink Function block, set the **Data type** parameter to `Bus: myBus`.

Input Argument Specification for Enumerated Data Type

Create an enumerated data type for the three primary colors, and then specify the **Input argument specification** parameter for a Function Caller block. The Function Caller block calls a Simulink Function block that accepts a signal with the enumerated type as input.

- 1 Create a MATLAB file for saving the data type definition. On the MATLAB toolstrip, select **New > Class**.
- 2 In the MATLAB editor, define the elements of an enumerated data type. The class `BasicColors` is a subclass of the class `Simulink.IntEnumType`.

```
classdef BasicColors < Simulink.IntEnumType  
    enumeration  
        Red(0)  
        Yellow(1)  
        Blue(2)  
    end  
end
```

- 3 Save the class definition in a file named `BasicColors.m`.

- 4 Create a Simulink parameter object `myEnum_parameter` and assign one of the enumerated values to the `Value` parameter.

```
myEnum_parameter = Simulink.Parameter;  
myEnum_parameter.Value = BasicColors.Red;
```

- 5 For the Function Caller block dialog box, set the **Input argument specification** to `myEnum_parameter`.
- 6 For the Argument In block dialog box within a Simulink Function block, set the **Data type** parameter to `Enum: BasicColors`.

Input Argument Specification for an Alias Data Type

Create an alias name for the data type `single`, and then specify the **Input argument specification** parameter for a Function Caller block. The Simulink Function block called by the Function Caller block also uses the alias name to define the input data type.

- 1 Create a Simulink alias data type object `myAlias`.

```
myAlias = Simulink.AliasType;
```

- 2 Assign a data type.

```
myAlias.BaseType = 'single';
```

- 3 Create a Simulink parameter object `myAlias_parameter` and assign the alias name to the `Data Type` parameter.

```
myAlias_parameter = Simulink.Parameter;  
myAlias_parameter.DataType = 'myAlias';  
myAlias_parameter.Value = 1;
```

- 4 For the Function Caller block dialog box, set the **Input argument specification** parameter to `myAlias_parameter`.
- 5 For the Argument In block dialog box within a Simulink Function block, set the **Data type** parameter to `myAlias`.

Simulink Function Blocks in Referenced Models

In this section...

“Simulink Function Block in Referenced Model” on page 10-175

“Function Caller Block in Referenced Model” on page 10-178

“Function and Function Caller in Separate Models” on page 10-180

“Function and Function Caller in the Same Model” on page 10-181

You can place Simulink Function blocks and function callers (such as Function Caller blocks and Stateflow charts) in a referenced model, but doing so requires some special considerations:

- The referenced model must follow export-function model rules. See “Export-Function Models” on page 10-120.
- Sometimes, you must explicitly define the argument data types for a Function Caller block.

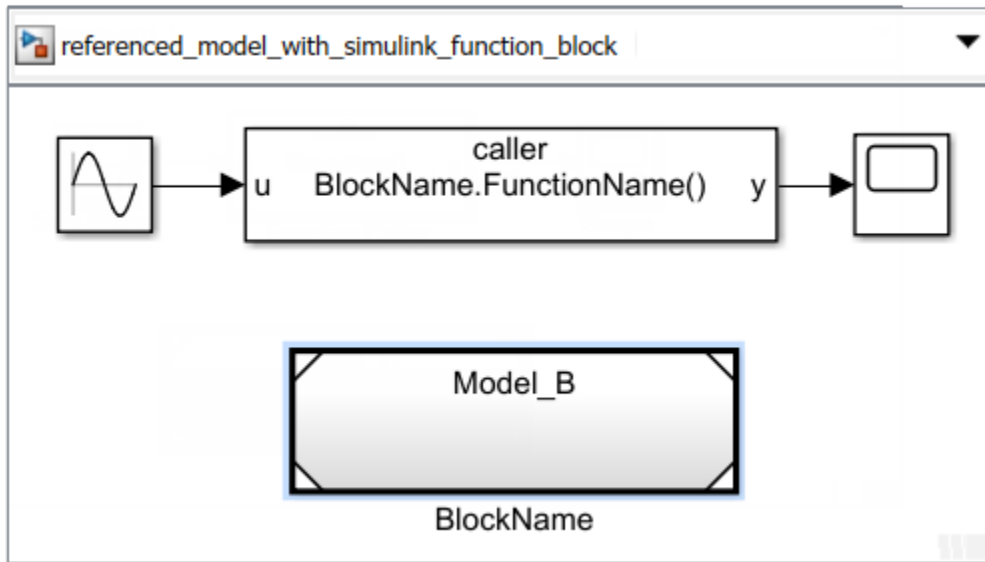

These examples show four relationships between Function Caller blocks, Simulink Function blocks, and referenced models.

Simulink Function Block in Referenced Model

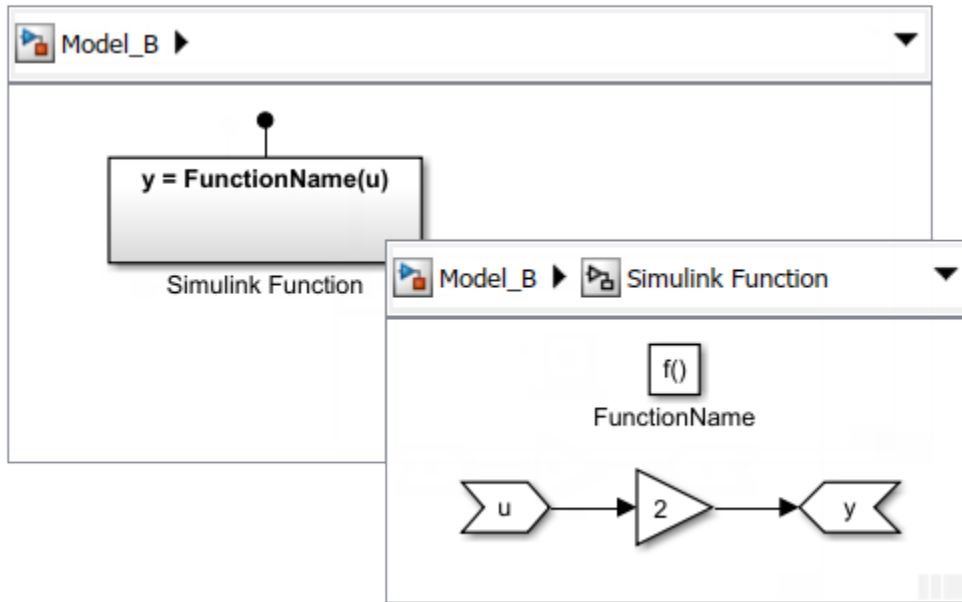

In this example, the parent model contains a Function Caller block, and the referenced model, `Model_B`, contains a Simulink Function block. `Model_B` must follow export-function model rules.

The Function Caller block can determine the argument data types of the function. In the Function Caller block, you do not need to define the **Input argument specification** and **Output argument specification** parameters.

But since, by default, the Simulink Function block is scoped to the model, you must qualify a call to the function name with the Model block name.

Model_B contains a Simulink Function block that defines a function for multiplying the input by 2. Because this model contains only a Simulink Function block, it satisfies export-function model rules. See “Export-Function Models” on page 10-120.

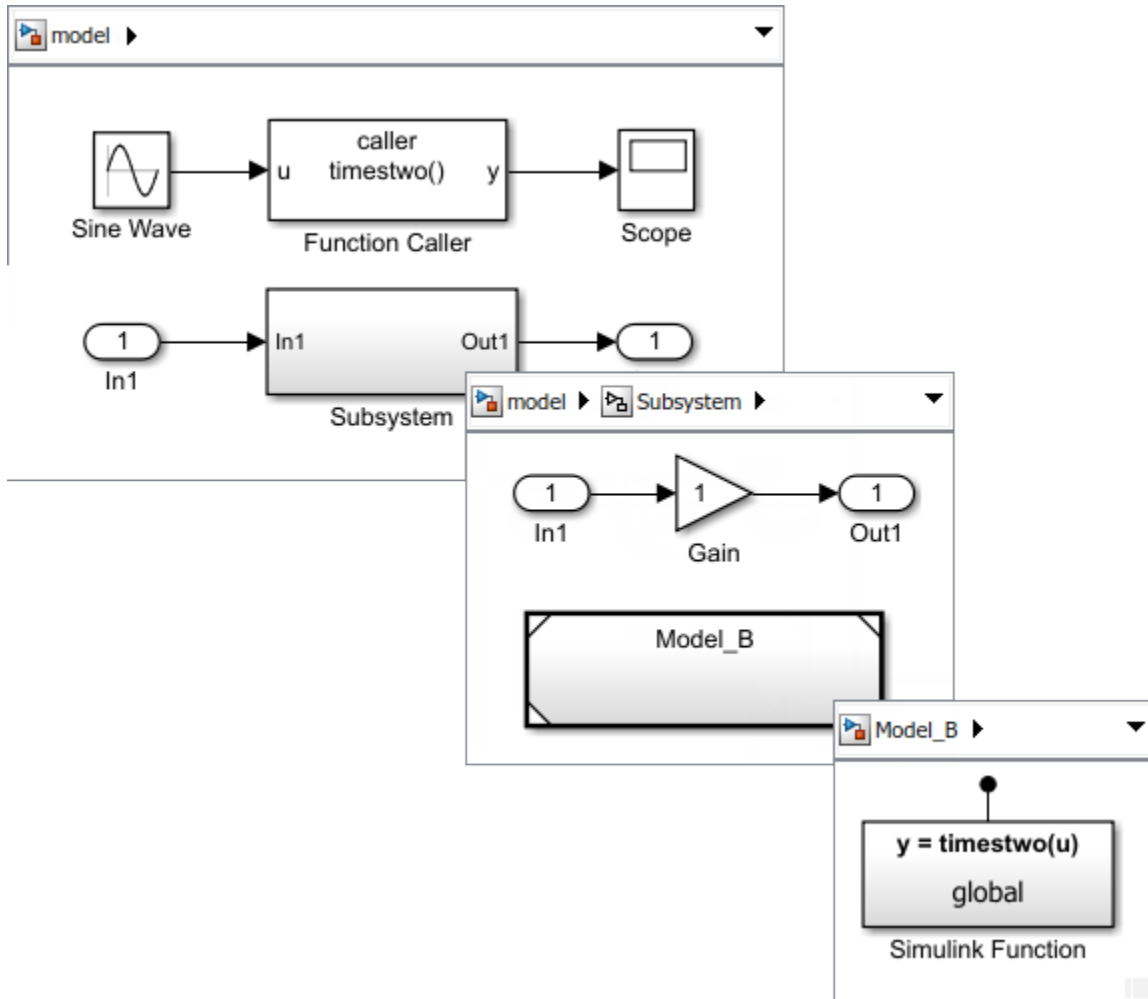

For Model_B, set the Configuration Parameters for the solver to satisfy export-function model rules:

- **Type:** Fixed-step.
- **Solver:** discrete (no continuous states).

Simulink Function in Referenced Model Placed in Subsystem

Once the Simulink Function block is identified as global by placing it at the root level of a referenced model, there are no limitations on where this referenced model can be placed.

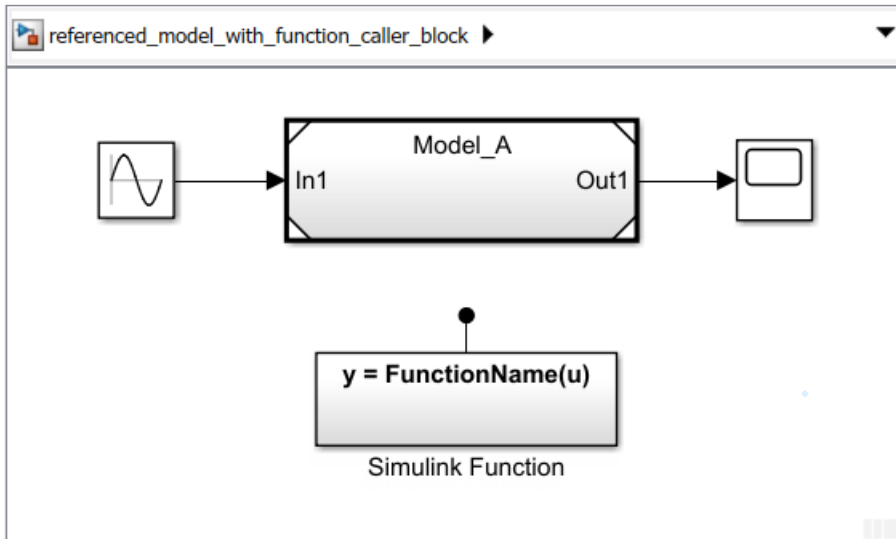

For example, you could place Model_B with a Simulink Function block in a Subsystem block.

Function Caller Block in Referenced Model

In this example, the parent model contains a Simulink Function block, and a referenced model, Model_A, contains a Function Caller block. If you want to use this modeling patterning, the **Function visibility** parameter for the Trigger port block in the Simulink Function block can be set to `scoped` or `global`.

For the parent model, set the solver type to Variable-step or Fixed-step.

Model_A contains a Function Caller block.

Since the Function Caller block cannot find the function in Model_A, you must provide the argument specification in one of two ways. Set the **Function visibility** parameter for the Trigger block to:

(1) **scoped** and qualify the function name in the Function Caller block **Function prototype** parameter. Add the name of the model file (not the Model block name) where the function is expected to be resolved. For example,

```
y = ModelFileName.FunctionName(u)
```

(2) **global** and specify the Function Caller block argument parameters:

- **Input argument specification:** Specify to match the Simulink Function block input argument data types, for example, `double(1.0)`.

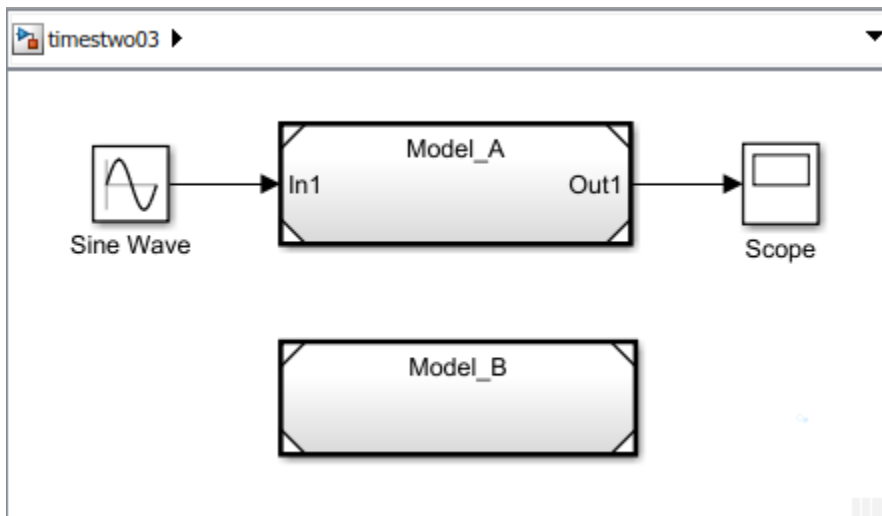

Specify the argument specification for a Simulink Function block with the **Data type** parameter in the Input Argument and Output Argument blocks.

- **Output argument specification:** Specify to match the Simulink Function block output argument data types, for example, `double(1.0)`.

Function and Function Caller in Separate Models

In this example, the parent model contains two referenced models. `Model_A` is a referenced model with a Function Caller block. `Model_B` is a referenced model with a scoped Simulink Function block. Only `Model_B` with a Simulink Function block must follow export-function rules.

For `Model_A`, provide the argument specification as you do for the referenced model in “Function Caller Block in Referenced Model” on page 10-178. For `Model_B`, specify parameters as you do for the referenced model in “Simulink Function Block in Referenced Model” on page 10-175.

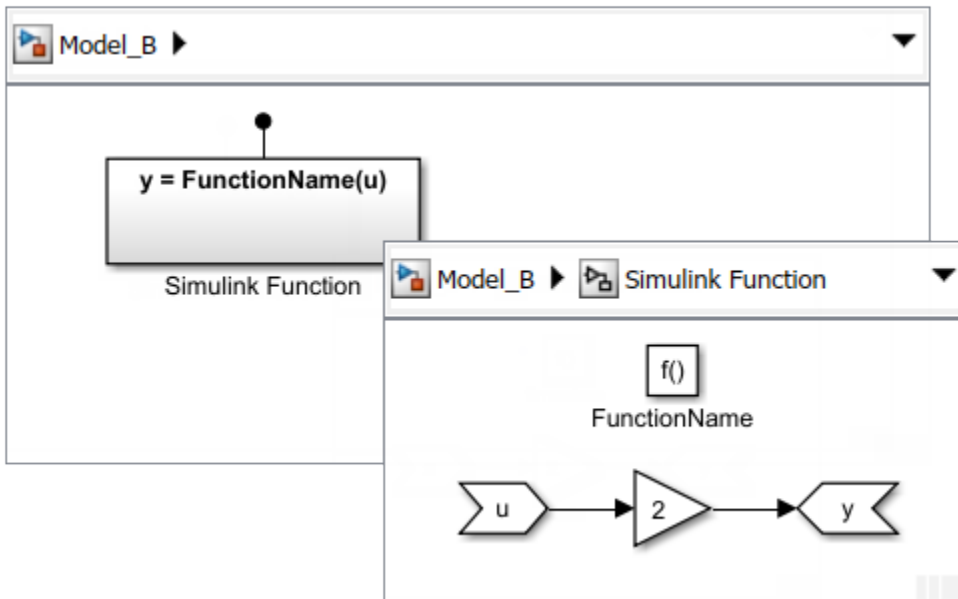

`Model_A` contains a Function Caller block. If the function is set to `global`, define the Input and Output Argument Specification parameters. If the function is set to `scoped`,

provide the file name of the model where the function is expected to be resolved to as `y = Model_B.FunctionName(u)`.

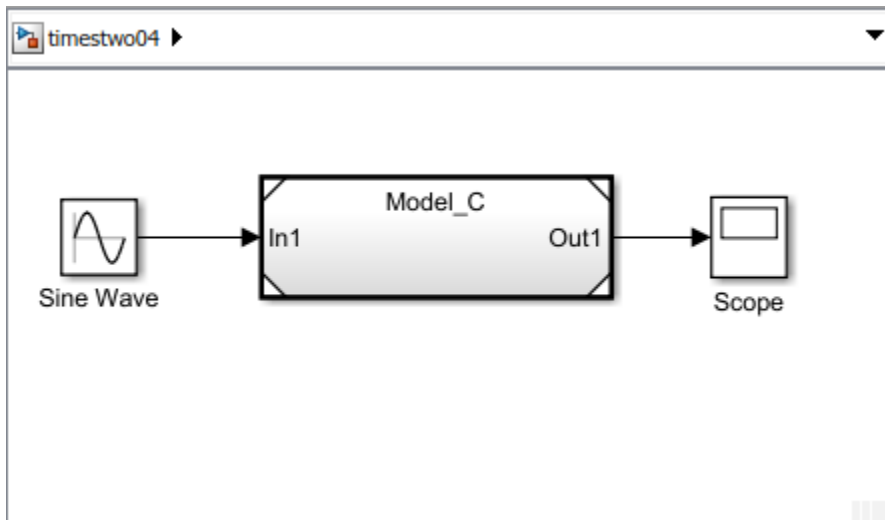

Model_B contains a Simulink Function block that defines a function for multiplying the input by 2. Because this model contains only a Simulink Function block, it satisfies export-function model rules. See "Export-Function Models" on page 10-120.

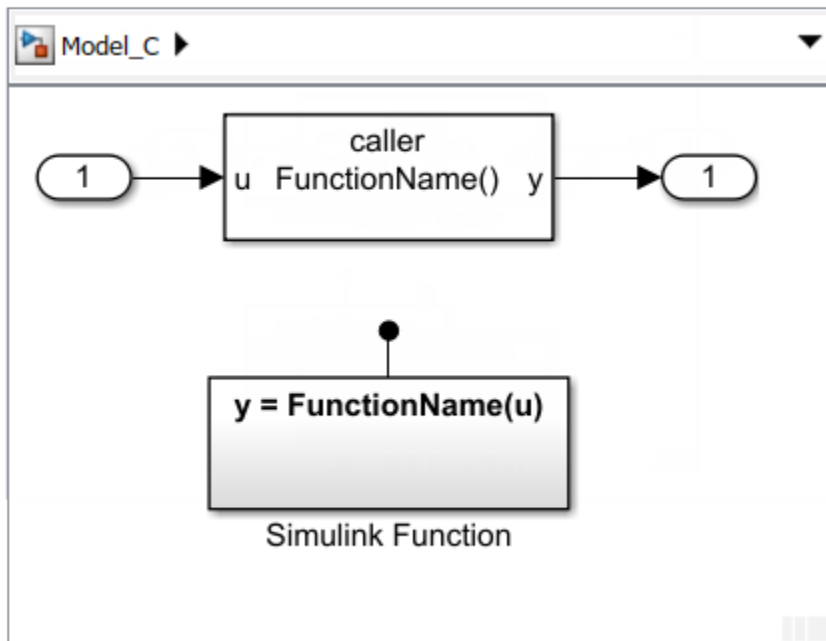

Function and Function Caller in the Same Model

In this example, the parent model contains one referenced model, Model_C, with both a Function Caller block and a scoped Simulink Function block.

- If there is only one instance of `Model_C`, and the Configuration Parameter **Total number of instances allowed per top model** is set to **One**, the parent model simulates without error. Since `Model_C` does not export the function, it does not need to follow export-function rules.
- If the Configuration Parameter **Total number of instances allowed per top model** is set to **Multiple**, `Model_C` exports the function regardless if there is a single instance or multiple instances of the model. In both cases, Simulink displays an error. The model needs to follow export-function rules, but it does not because a Function Caller block is not allowed at the root-level of an export-function model.

`Model_C` contains both a Function Caller block and a scoped Simulink Function block. If you want to use this modeling pattern, only one instance of `Model_C` is allowed in the parent model.

Scoped and Global Simulink Function Blocks Overview

Defining the visibility of functions can help you to avoid name space conflicts when integrating your referenced models. A Simulink Function block defines the visibility of its function in relationship to the subsystem or model containing the block as either scoped or global. By default, Simulink Function blocks are scoped.

- *Function Visibility.* A scoped function is visible in its hierarchy. A function caller located at the same level as the function, or one or more levels below can refer to the function. A global function is visible across a model hierarchy. This means that a function caller located anywhere in the current model or in the parent model hierarchy can refer to the function.
- *Function accessibility* is determined by the visibility of a function and the location of the function caller relative to the Simulink Function block. For function callers one hierarchical level above the function, qualify the function name with the virtual subsystem block name or model block name.
- *Function exporting* refers to functions exported from models. A function with global visibility, placed anywhere in an export function model, is exported to the top level of a model hierarchy in addition to the model interface. A function with scoped visibility at the root level of an export function model is exported to the model interface. In both these cases, you can access the exported function outside of the model.

Use the **Function visibility** parameter for the Trigger block within a Simulink Function block to set the function visibility to either `scoped` or `global`.

Summary of Simulink Function Block Visibility and Access

	Function visibility	Function accessibility	Function exporting
Virtual Subsystem	scoped Function name does not have to be unique	function caller inside hierarchy or at parent level. function caller inside Subsystem block hierarchy - unqualified, <code>fcn()</code> . See Resolve to a Function Hierarchically in “Scoped Simulink Function Blocks in Subsystems” on page 10-188. function caller at parent level - qualified with subsystem block name, <code>subsystem.fcn()</code> . See Resolve to a Function by Qualification in “Scoped Simulink Function Blocks in Subsystems” on page 10-188.	Does not apply
	global Function name must be unique	function caller at any level of hierarchy down or up. function caller at any level of hierarchy - unqualified, <code>fcn()</code>	Function at any level of model exported to the global name space of the top-level model

	Function visibility	Function accessibility	Function exporting
Atomic Subsystem	<p>scoped</p> <p>Function name does not have to be unique</p>	<p>function caller only inside hierarchy</p> <p>function caller inside Subsystem block hierarchy - unqualified, <code>fcn()</code>. Scoped Simulink Function Blocks in Subsystems

The scope of a Simulink function is defined in its parent subsystem within the context of a model. If you place a function in any Subsystem block, access to the function from outside the model is prohibited by default. In both cases, the Trigger block **Function visibility** parameter is set to `scoped`. The Simulink Function block can be located:

- In a virtual subsystem — Call the function from within the containing Subsystem block hierarchy without qualifying the function name, or call the function from outside the subsystem by qualifying the function name with the subsystem block name.
- In an atomic or non-virtual subsystem — Call the function from within the containing Subsystem block hierarchy without qualifying the function name. Accessing the function from outside of the subsystem is prohibited.

Resolve to a Function Hierarchically

Placing a scoped Simulink Function block within any Subsystem block (virtual or atomic) limits access to the function and removes the function name from the global name space. When a function caller resolves to a function hierarchically, it looks for the function using the following rules:

- Resolution Rule 1: Is the scoped Simulink Function block in the current Subsystem block with the function caller?
- Resolution Rule 2. If the scoped function is not in the current subsystem, is the scoped Simulink Function block in a parent or grandparent Subsystem block one or more levels above the function caller?

If a function caller resolves to a function hierarchically, you can call the function without qualifying the function name:

- Function caller located at the same hierarchic level as the function. In this case, the function caller finds the scoped function in the current subsystem (Resolution Rule 1).

- Function caller located in a Subsystem block one or more Subsystem block levels below the hierarchic level of the Simulink Function block. In this case, the function caller didn't find the scoped function in the current subsystem, but it found the function in the parent subsystem (Resolution Rule 2).

- You can also call a Simulink Function block in a Subsystem block without qualification from a MATLAB Function block or a Stateflow chart within the block.

Resolve to a Function by Qualification

When you place a Simulink Function block in a virtual Subsystem block, the function name is not visible outside of the subsystem. However, you can call the function by qualifying the function name with the Subsystem block name. When a function caller resolves to a qualified function hierarchically, it looks for the virtual Subsystem block containing the function using the following rules:

- Resolution Rule 1: Is the virtual Subsystem block in the current component with the function caller? A component can be a Subsystem block or Model.

- Resolution Rule 2. If the virtual Subsystem block is not in the current component, is the virtual Subsystem block in a parent or grandparent component one or more levels above the function caller?

If a function caller resolves to a virtual Subsystem block with a scoped function, you can call the function by qualifying the function name:

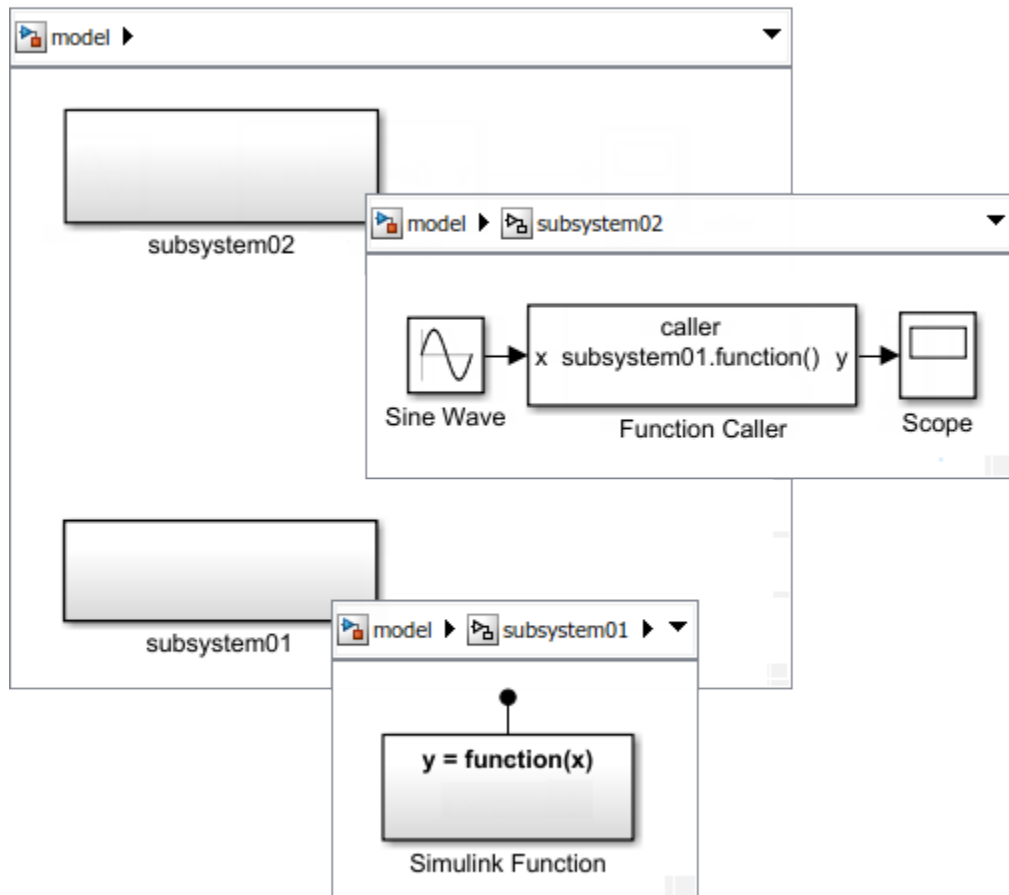

- Function caller located outside of the subsystem one hierarchic level above the function. In this case, the function caller finds the Subsystem block with the scoped function in the current model (Resolution Rule 1).

- Calling the function from a Stateflow chart outside the subsystem one hierarchic level above the function. In this case, the function caller finds the Subsystem block with the scoped function in the current model (Resolution Rule 1).

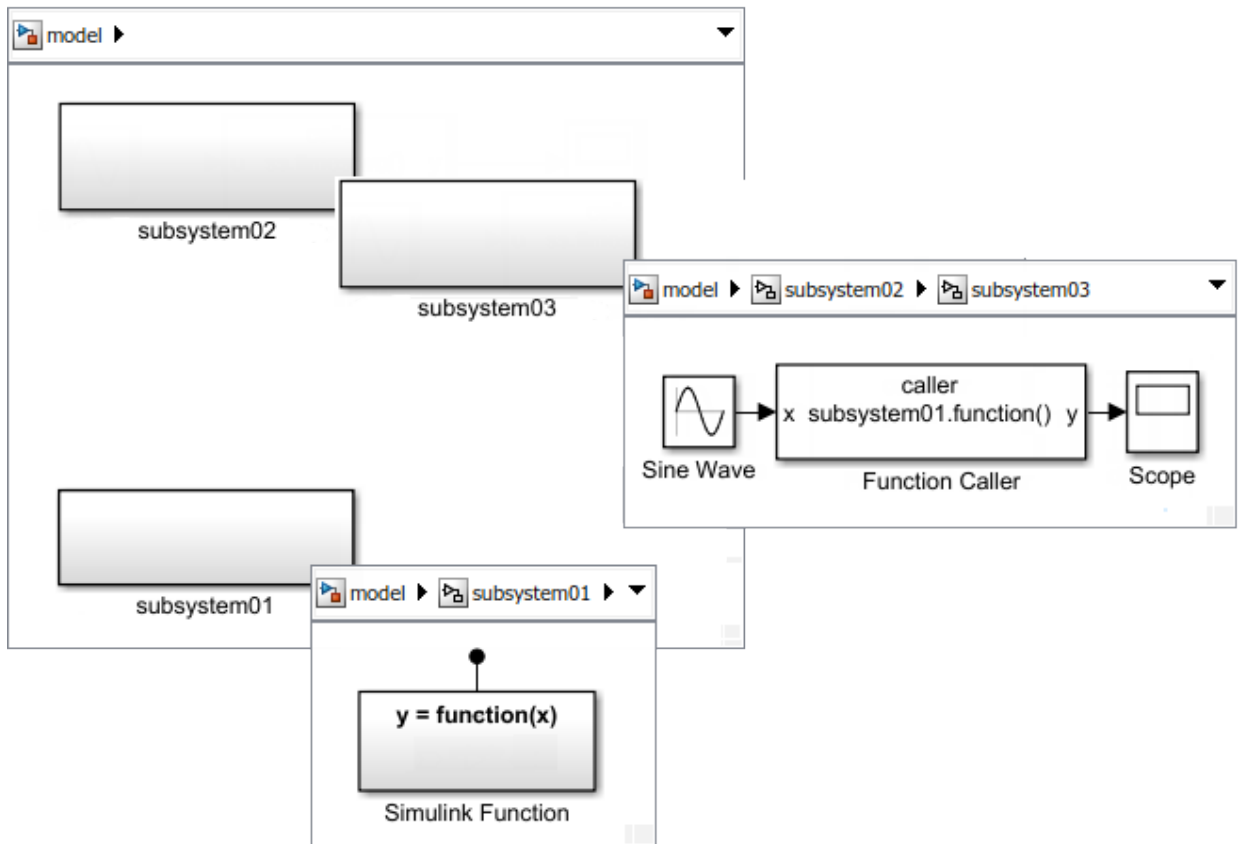

- Function caller is in another subsystem at the same hierarchic level as the function. In this case, the function caller didn't find the Subsystem block with the scoped function in the current subsystem, but it found the Subsystem block in the parent model (Resolution Rule 2).

- Function caller is in another subsystem one or more subsystem levels below the hierarchic level of the function. In this case, the function caller didn't find the Subsystem block with the scoped function in the current subsystem, but it found the Subsystem block in the grandparent model (Resolution Rule 2).

The function caller hierarchy cannot include a Model block since the function caller cannot cross model reference boundaries.

- “Diagnostics Using a Client-Server Architecture” on page 10-207

Scoped Simulink Function Blocks in Models

The scope of a Simulink function is defined in the context of a model. If you place a Simulink Function block in a model at the root level, the function is scoped to the model by default. The Trigger block **Function visibility** parameter is set to `scoped`. Access the function with a function caller located:

- Within the model hierarchy containing the function. Call the function without qualifying the function name.
- Outside the model. Call the function by qualifying the function name with the model block instance name, not the model file name.

Setting **Function visibility** for a Simulink Function block to `global` allows you to access the function from anywhere in the model or a parent model. As a result, models with a Simulink Function block set to `global` cannot be multi-instanced because function names must be unique.

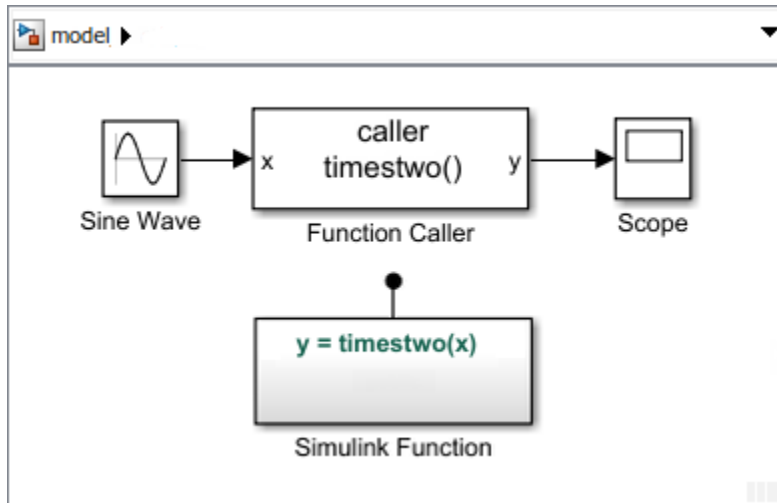

Resolve to a Function Hierarchically

Placing a scoped Simulink Function block within a model at the root level limits access to the function and removes the function name from the global name space. When a function caller resolves to a function hierarchically, it looks for the function using the following rules:

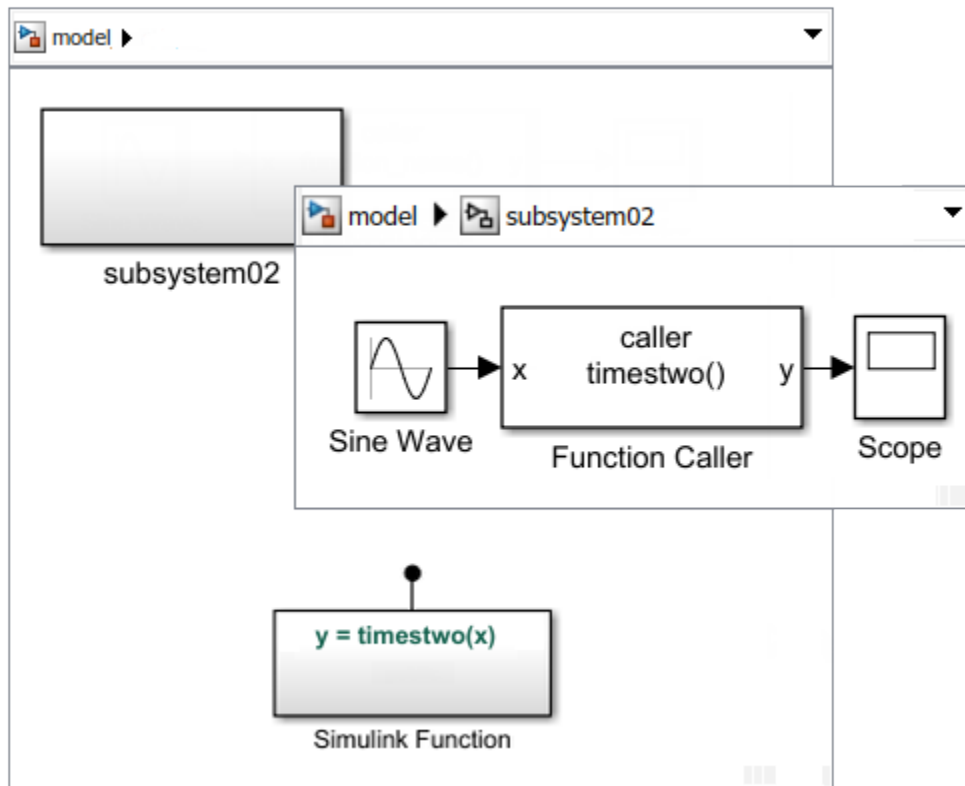

- Resolution Rule 1: Is the scoped Simulink Function block in the current model with the function caller?
- Resolution Rule 2: If the scoped function is not in the current model, is the scoped Simulink Function block in a parent or grandparent model one or more levels above the function caller?

If a function caller resolves to a function hierarchically, you can call the function without qualifying the function name.

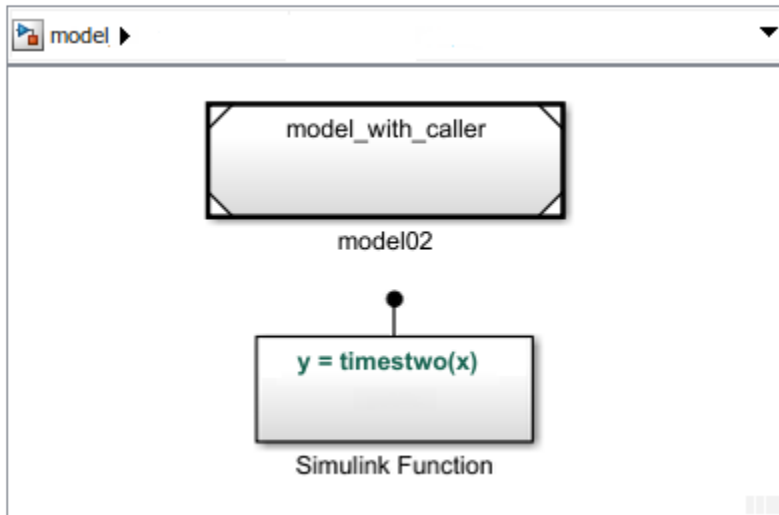

- Function caller located at the same hierarchic level as the function. In this case, the function caller finds the scoped function in the current model (Resolution Rule 1).

- Function caller located in a Subsystem block one or more subsystem levels below the hierarchic level of the function. The function caller hierarchy cannot include a Model block since the function caller cannot cross model reference boundaries. In this case, the function caller didn't find the scoped function in the current subsystem, but it found the function in the parent model (Resolution Rule 2).

- You cannot place a function caller inside a Model block and the Simulink Function block in the parent model,

If you place a function caller inside a Model block, Simulink displays an error. This error occurs because the model containing the caller does not know the name of the function. Function calls cannot cross model reference boundaries.

Resolve to a Function by Qualification

When you place a Simulink Function block in a Model block, the function name is not accessible outside the model. However, you can call a function by qualifying the function name with the Model block name. When a function caller resolves to a qualified function hierarchically, it looks for the Model block containing the function using the following rules:

- Resolution Rule 1: Is the Model block in the current model with the function caller?
- Resolution Rule 2: If the Model block is not in the current model or subsystem, is the Model block in a parent or grandparent model one or more levels above the function caller?

If a function caller resolves to a Model block with a scoped function, you can call the function by qualifying the function name:

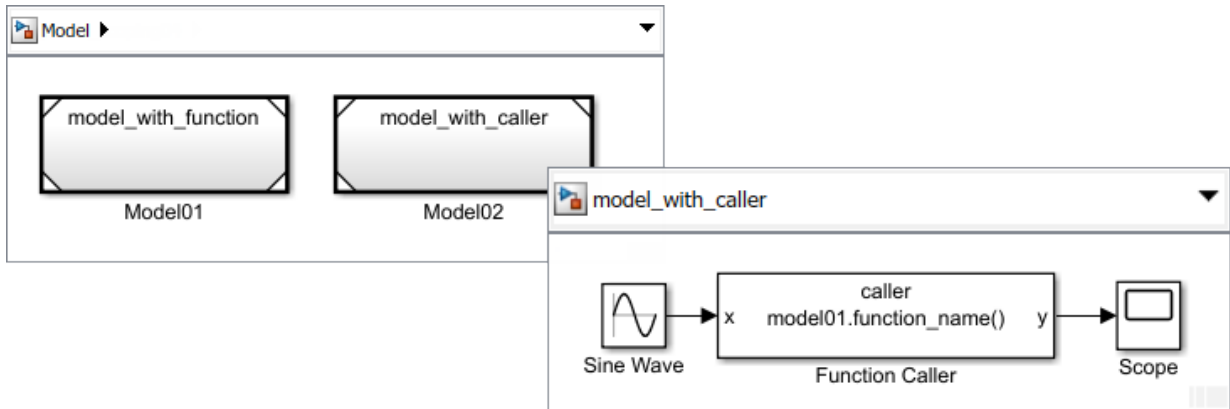

- Function caller located outside of the Model block one hierarchic level above the function. In this case, the function caller finds the Model block with the scoped function in the current model (Resolution Rule 1).

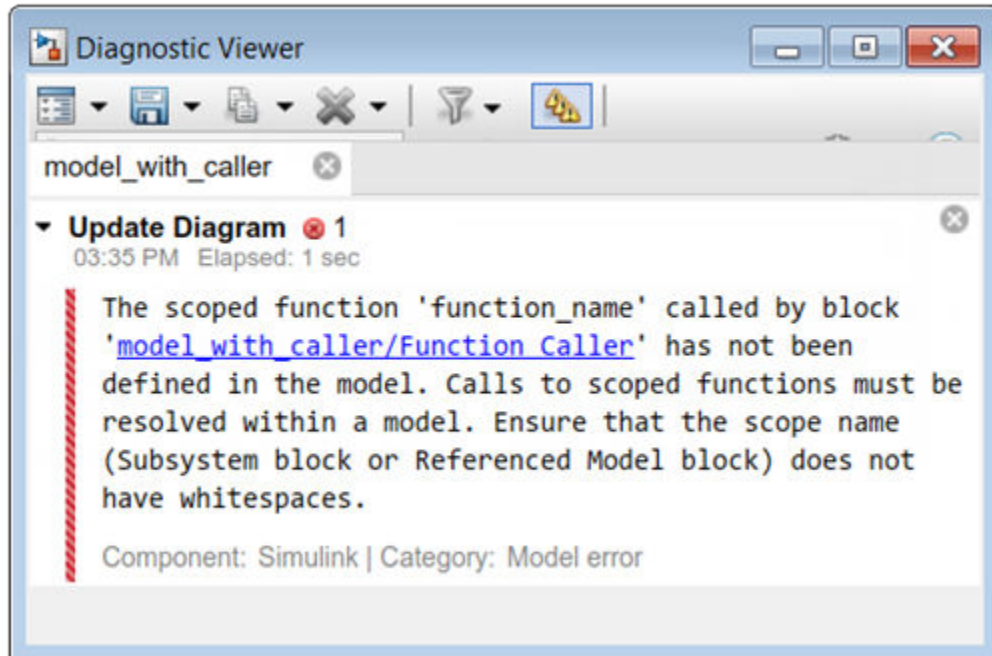

- Function caller in a subsystem at the same hierarchic level as the function. In this case, the function caller didn't find the Model block in the current subsystem, but it found the Model block in the parent model (Resolution Rule 2).

- You cannot place a Simulink Function block in one Model block and the function caller in another Model block.

If you place a Simulink Function block in a referenced model and a function caller in another referenced model, Simulink displays an error. This error occurs because the qualified function name using the Model block name is not visible to the model containing the caller.

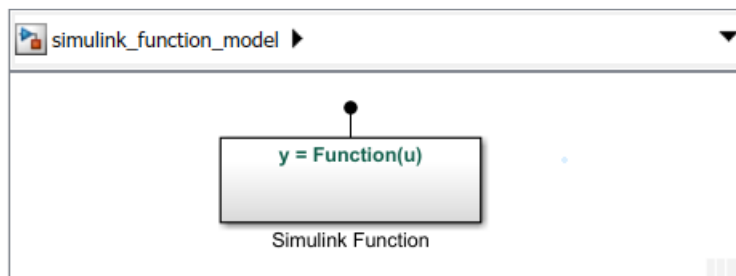

If you want to access the function using this modeling pattern, see the section Function Caller Block in Referenced Model and Function and the section Function Caller in Separate Models in the topic “Simulink Function Blocks in Referenced Models” on page 10-175.

Multi-Instance Modeling with Simulink Functions

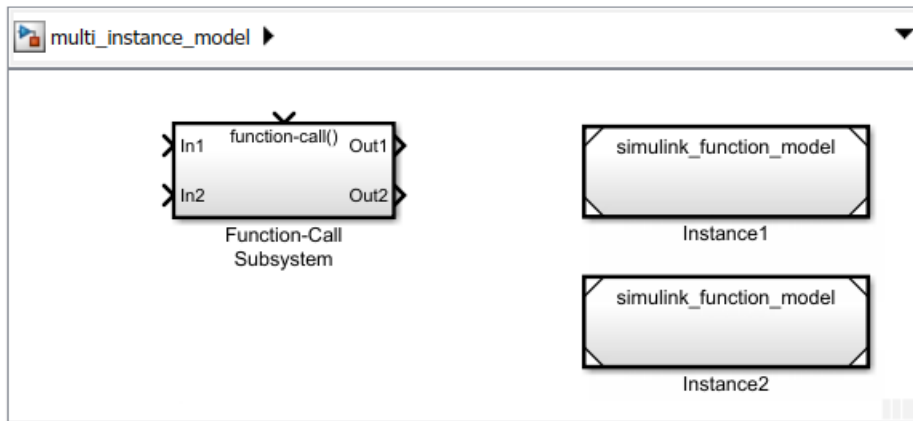

Setting **Function visibility** for a Simulink Function block to `scoped` encapsulates the function within the model, allowing you to multi-instance the model. Adding the model instance name to the function name creates a qualified function name that is unique within the parent model.

- 1 Create a model containing Simulink Function blocks.

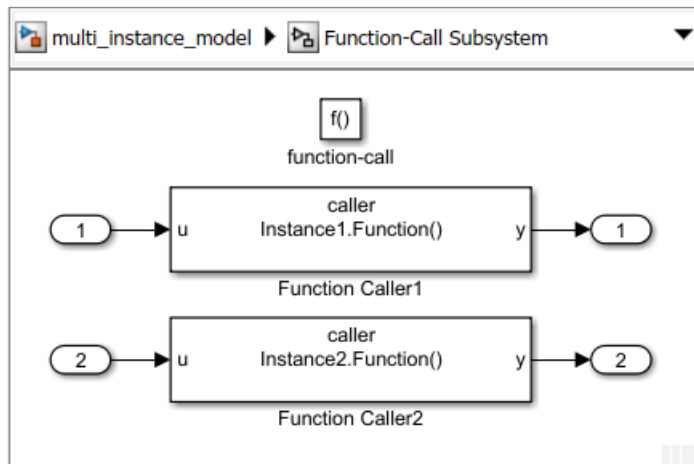

By default, the **Function visibility** parameter for the Trigger block within the Simulink Function block is set to `scoped`.

- 2 Reference the model with Simulink functions from multiple Model blocks. Add a Function-Call Subsystem block to schedule calls to the functions.

- 3 Add Function Caller blocks to the Function-Call Subsystem block. Access the function in separate model instances by qualifying the function name with the block name.

- 4 From the **Display** menu, select **Function Connectors**. Tracing lines are drawn to help you navigate from a function caller to the function.

For a model using Simulink Function blocks with multiple instances, see “Modeling Reusable Components Using Multiply Instanced Simulink Functions”.

“Client-Server Architecture” on page 10-207

“Modifier Pattern” on page 10-209

“Observer Pattern” on page 10-211

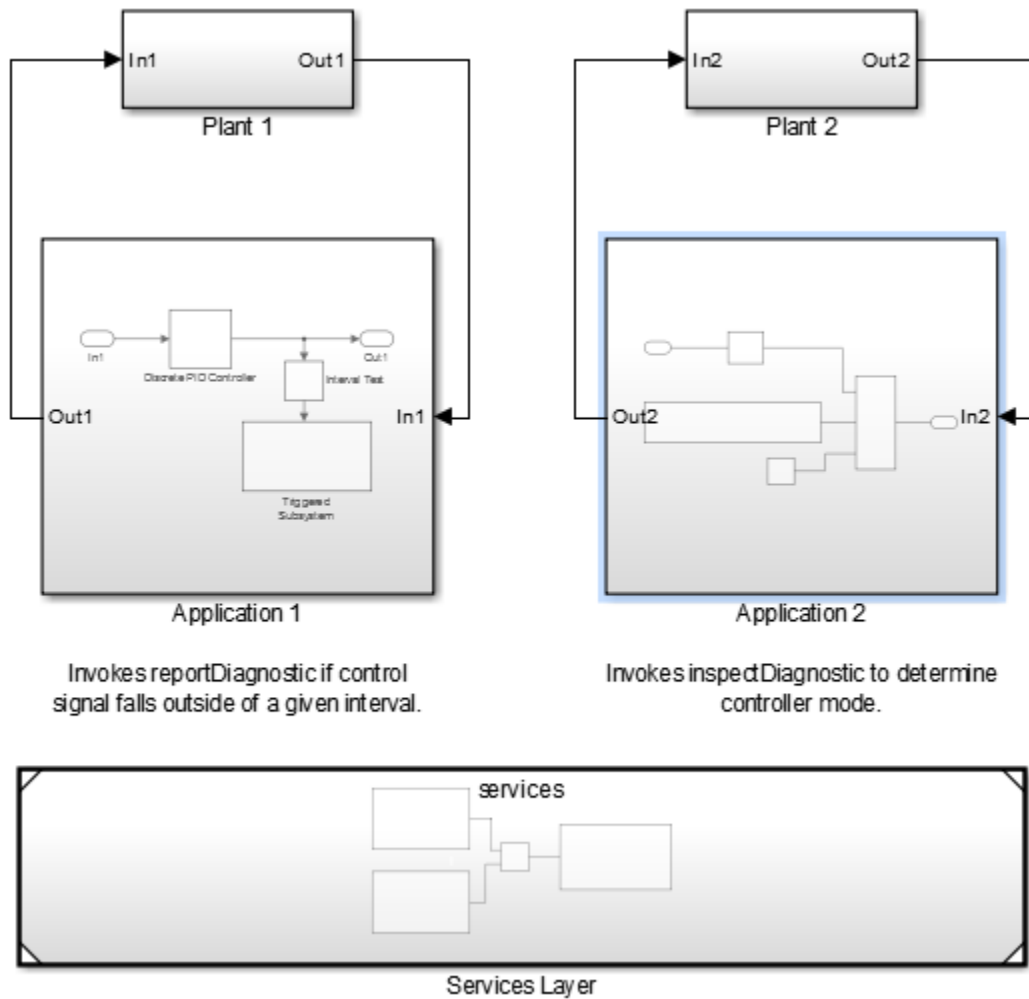

Diagnostic Messaging with Simulink Functions

Use Simulink functions when you define a diagnostic service where callers pass an error code. The service tracks error codes for all errors that occur. One way to implement this service is to use an indexed Data Store Memory block. A diagnostic monitoring system can then periodically check for the occurrence of specific errors and modify system behavior accordingly.

Client-Server Architecture

You can use Simulink Function blocks and Function Caller blocks to model client-server architectures. Uses for this architecture include memory storage and diagnostics.

As an example, create a model of a simple distributed system consisting of multiple control applications (clients), each of which can report diagnostics throughout execution. Since client-server architectures are typically constructed in layers, add a service layer to model the diagnostic interface.

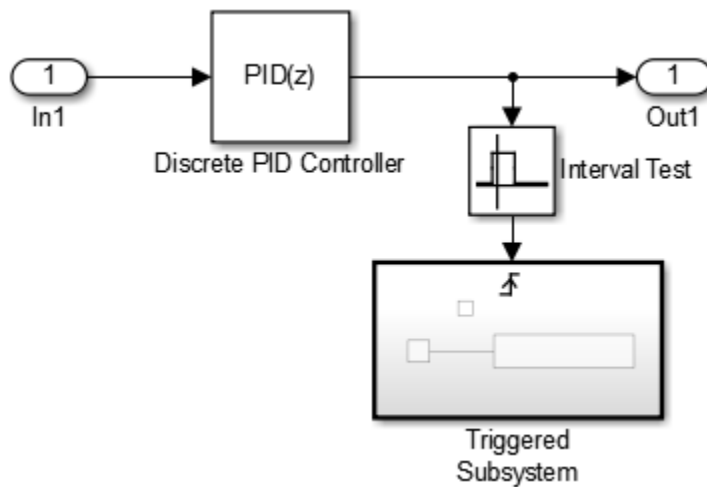

The services (servers), modeled using Simulink Function blocks, are in a separate model. Add the service model to your system model as a referenced model.

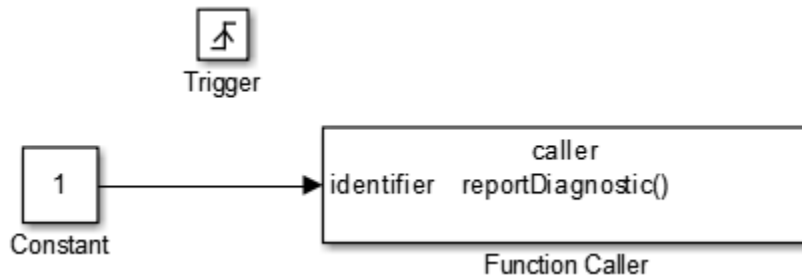

The control applications (clients) interact with the diagnostic interface using Function Caller blocks.

Modifier Pattern

Application 1 reports a diagnostic condition by invoking the `reportDiagnostic` interface within the service layer. The application calls this function while passing in a diagnostic identifier.

The interval test determines when to create a diagnostic identifier.

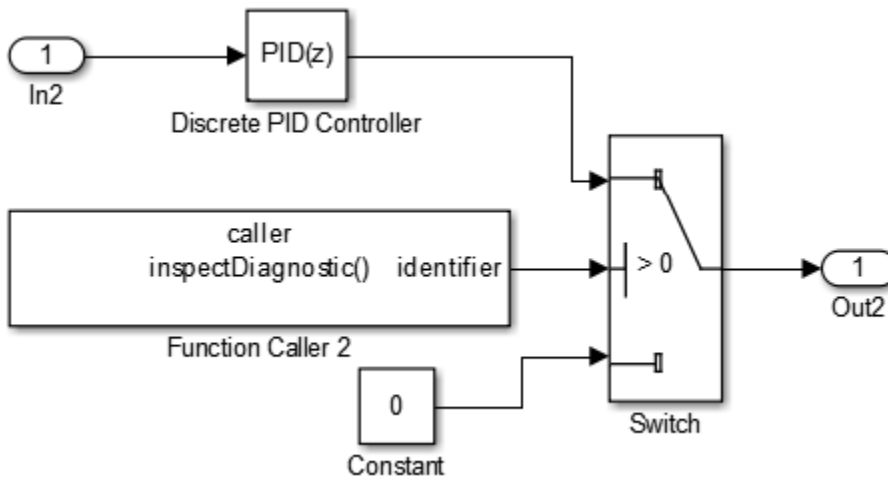

The implementation of the function (Simulink Function 1) tracks the passed-in identifier by transferring the value to a graphical output of the function. A graphical output is a server-side signal that is not part of the server interface but facilitates communication between service functions through function arguments. The value of graphical outputs is held between function invocations.

The `reportDiagnostic` function is an example of a modifier pattern. This pattern helps to communication of data from the caller to the function and later computations based on that data.

Observer Pattern

Application 2 invokes the `inspectDiagnostic` interface within the service layer to inspect whether diagnostics were reported.

The implementation of the function (Simulink Function) uses a graphical input (`id`) to observe the last reported diagnostic and transfer this value as an output argument (`identifier`) to the caller. A graphical input is a server-side signal that is not part of the server interface.

The `inspectDiagnostic` function is an example of an observer pattern. This pattern helps to communication of data from the function to the caller.

Using Initialize, Reset, and Terminate Functions

In this section...

“Create Model Component with State” on page 10-213

“Initialize Block State” on page 10-215

“Reset Block State” on page 10-217

“Read and Save Block State” on page 10-220

“Prepare Model Component for Testing” on page 10-224

“Create an Export-Function Model” on page 10-225

Some blocks maintain state information that they use during a simulation. For example, the Unit Delay block uses the current state of the block to calculate the output signal value for the next simulation time step.

Subsystem blocks have default initialize and termination routines. You can add custom routines to the default routines using Initialize Function and Terminate Function blocks to change or read block states. These function blocks contain:

- Event Listener blocks that execute the combined routines when receiving an initialize or terminate function-call event.
- State Writer blocks to initialize the block state and State Reader blocks to read the state.

Create Model Component with State

You can define model algorithms using Simulink blocks. In this example, a single Discrete-Time Integrator block defines the algorithm for integrating an input signal.

- 1 Open a new Simulink model. Save this model with the name `Model01`.
- 2 Add a Discrete-Time Integrator block. Verify the default parameter values are `1.0` for **Gain value**, `0` for **Initial condition**, `State` (most efficient) for **Initial condition setting**, and `-1` for **Sample time**.
- 3 Connect a Constant block to the input of the Discrete-Time Integrator block to model an input signal. Connect a Scope block to the output signal.

- 4 Open the Configuration Parameters dialog box. Set the simulation parameters for the Solver **Type** to Fixed-step, **Solver** to auto, and **Fixed-step size** to 1.
- 5 Open the Scope block, and then run simulation. The output signal increases by 1 at each time step.

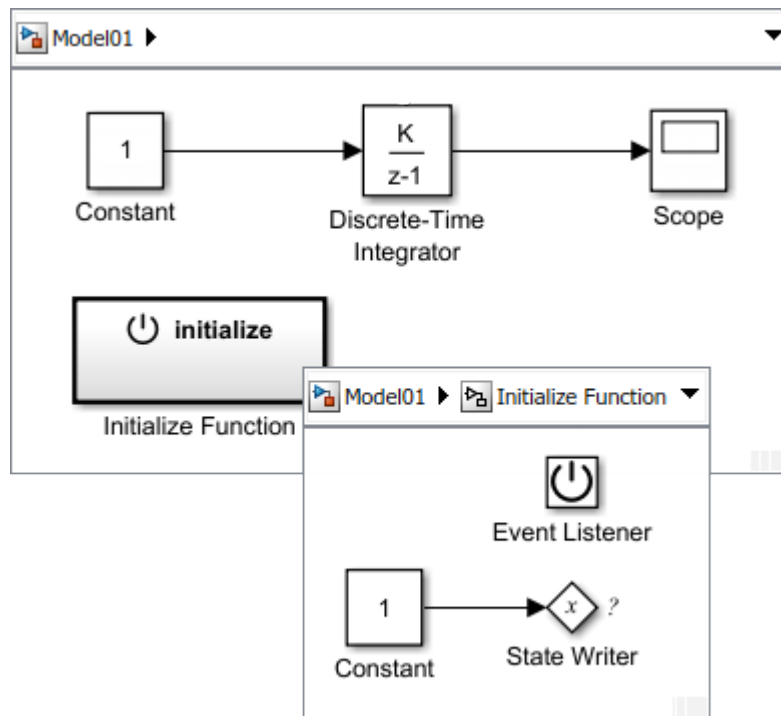

Initialize Block State

Some model algorithms contain states that you can initialize. For example, with an algorithm that reads a sensor value, you can perform a computation to set the initial sensor state.

At the beginning of a simulation, initialize the state of a block using a State Writer block. To control when initialization occurs, use an Initialize Function block that includes the State Writer block.

- 1 Add an Initialize Function block.

By default, the Initialize Function block includes an Event Listener block with the **Event type** parameter set to **Initialize**. The block also includes a State Writer block, and a Constant block as a placeholder for the source of the initial state value.

- 2 Model initial conditions. In this example, set the **Constant value** parameter for the Constant block to 4.

- 3 Connect the state writer with the state owner. Open the State Writer dialog box. Expand the State Owner Selector Tree, select Discrete-Time Integrator, and then click **Apply**.

The State Writer block displays the name of the state owner block. The state owner block displays a tag indicating a link to a State Writer block. If you click the label above the tag, a list opens with a link for navigating to the State Writer block.

- 4 Run simulation to confirm that your model simulates without errors.

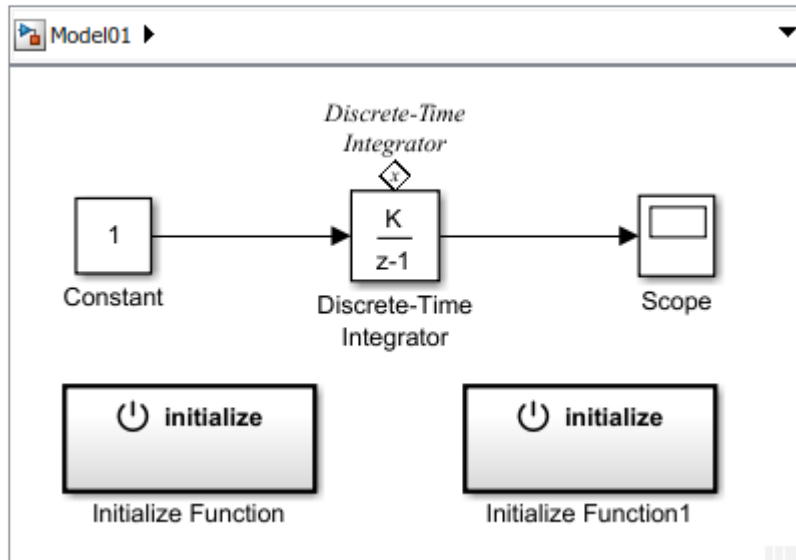

The Initialize Function block executes at the beginning of a simulation. The output signal starts with an initial value of 4 and then increases by 1 until the end of the simulation.

Reset Block State

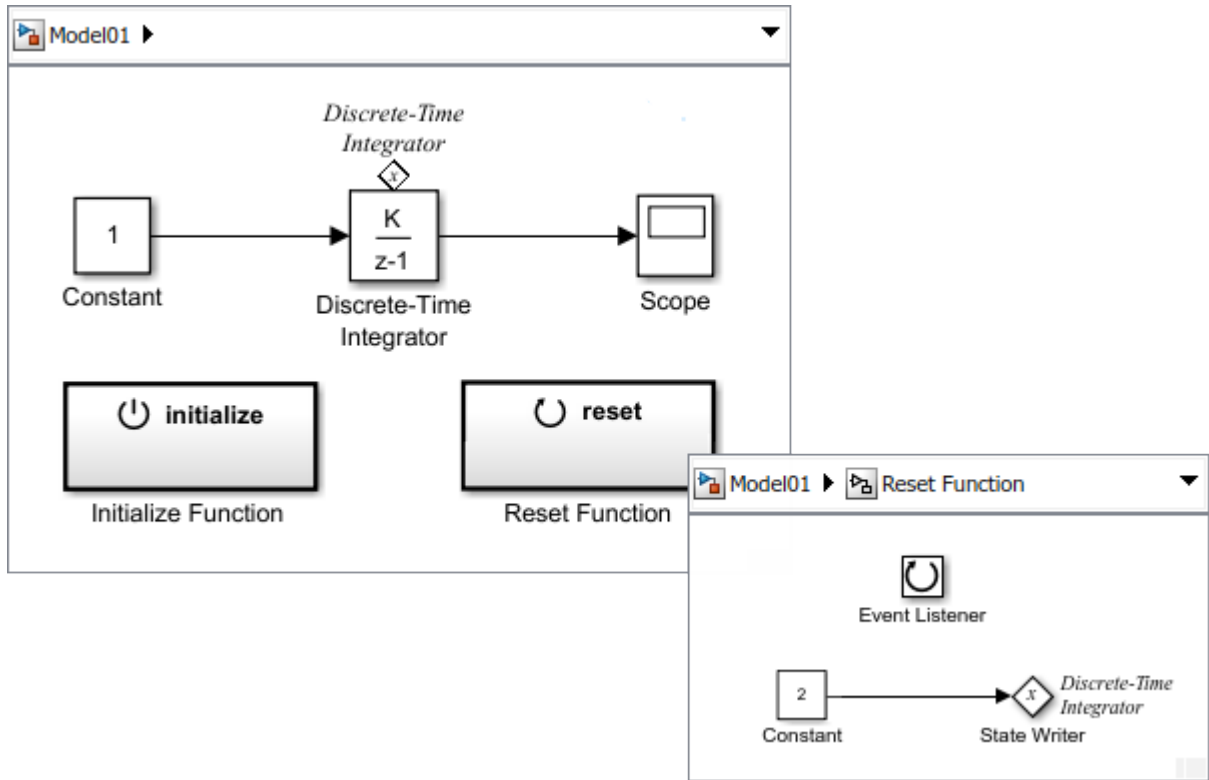

During a simulation, you can reset the state of a block using a State Writer block. To control when reset occurs, use an Initialize Function block that you reconfigure to a Reset Function block.

- 1 Add an Initialize Function block.

- 2 Open the new Initialize Function block.
- 3 Configure block for reset. Open the Block Parameter dialog box for the Event Listener block. From the **Event type** drop-down list, select Reset. In the **Event name** box, enter an event name. For example, enter reset. Close the dialog box.
- 4 Model reset conditions. In this example, set the **Constant value** parameter for the Constant block to 2.
- 5 Connect state writer with the state owner. Open the State Writer dialog box. Expand the State Owner Selector Tree, select Discrete-Time Integrator, and then click **Apply**.
- 6 Navigate to the top level of Model01. Rename the block from Initialize Function1 to Reset Function.

After updating your model, the event name for the Reset Function block is displayed on the face of the block.

If you click above the tag, a list opens with a link for navigating to the State Writer blocks located in the Initialize Function block and the Reset Function block.

- 7 Run a simulation to confirm that your model simulates without errors.

The Reset Function block does not execute during the simulation. It needs an function-call event signal.

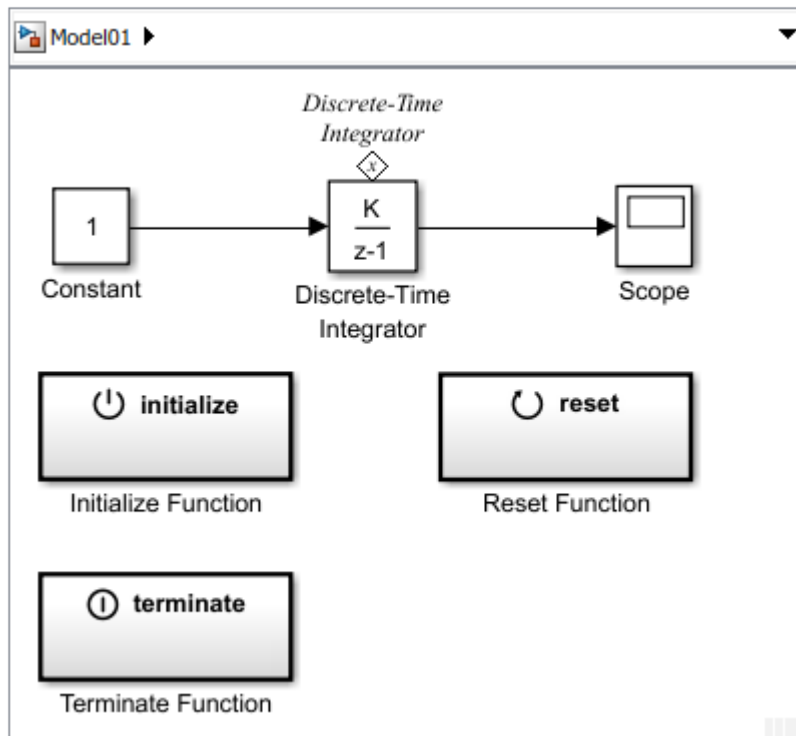

To create an function-call event signal for the Reset Function block, see “Create Test Harness to Generate Function Calls” on page 10-228.

Read and Save Block State

At the end of a simulation, you can read the state of a block, and save that state.

- 1 Add a Terminate Function block.

By default, the Terminate Function block includes an Event Listener block with the parameter **Event type** set to **Terminate**. The block also includes a State Reader block, and a Terminator block as a placeholder for saving the state value.

- 2 Connect the state reader with the state owner. Open the State Reader dialog box. From the State Owner Selector Tree, select Discrete-Time Integrator, and then click **Apply**.

- 3 Run a simulation to confirm that your model simulates without errors. The Terminate Function block executes at the end of a simulation.

- 4 Delete the blocks that you added for testing. Replace the Constant block with an Inport block and the Scope block with an Outport block.

Prepare Model Component for Testing

Make the following changes to avoid simulation errors when the component model is placed in an export-function model for simulation testing.

- 1 Open the Block Parameters dialog box for the Discrete-Time Integrator block. Set **Integrator method** to Accumulation:Forward Euler.
- 2 Open the Model Configuration Parameters dialog box. Confirm the solver **Type** is set to Fixed-step and **Solver** is set to auto. Change the **Fixed-step size** from 1 to auto.

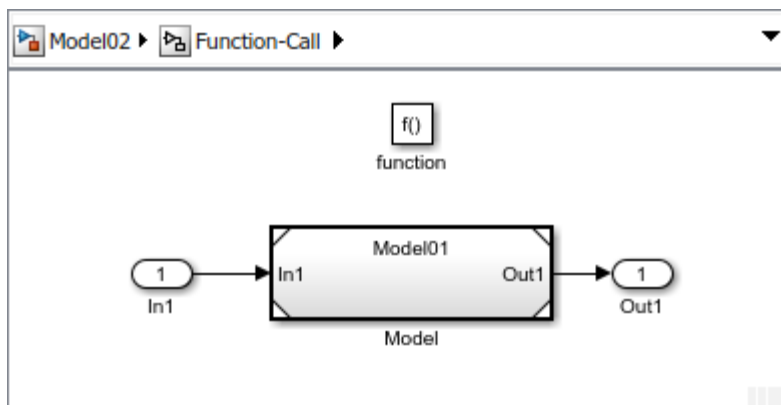

This change avoids a simulation error caused by having multiple sample times in a Function-Call Subsystem.

Create an Export-Function Model

Placing a model component in a test harness for testing the initialize, reset, and terminate functions requires the model to follow export-function rules. See “Export-Function Models” on page 10-120 and “Create Test Harness to Generate Function Calls” on page 10-228.

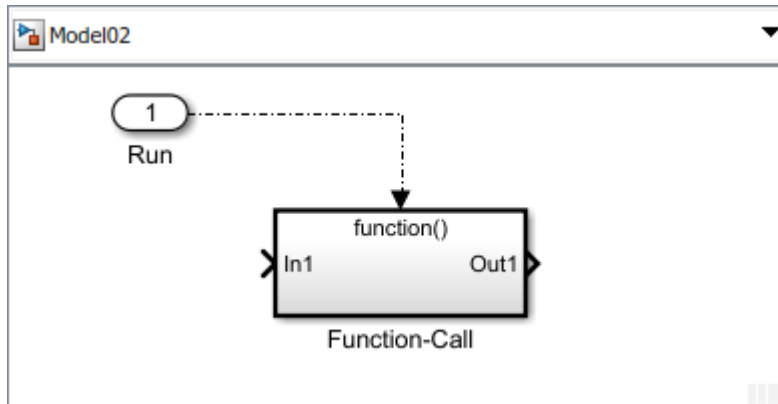

To create an export-function model, place the model component in a Function-Call Subsystem block using a Model block. Connect input and output ports from the model to the subsystem input and output ports.

- 1 Create a Simulink model. Save this model with the name `Model02`.
- 2 Open the Configuration Parameters dialog box. Set the simulation parameter for the Solver **Type** to `Fixed-step`. Confirm **Solver** is set to `auto` and **Fixed-step size** is set to `auto`.
- 3 Add a Function-Call Subsystem block. Open the subsystem by double-clicking the block.
- 4 Add a Model block to the subsystem and set **Model name** to `Model01`. Add Inport and Outport blocks.

- 5 Navigate to the top level of the model.
- 6 Add an Inport block. This block is the control signal for executing the subsystem. Change the block name to `Run` and connect it to the `function()` port.

Open the Inport block dialog box and on the Signal Attributes tab, select the **Output function call** check box.

- 7 Add a second Inport block and rename it to `Signal In`. Connect it to the `In1` port of the subsystem. This block is the signal for the integration algorithm.

Add an Outport block, rename it to `Signal Out`, and then connect it to the `Out1` port of the subsystem. This block is the integrated signal.

- 8 Open the Configuration Parameters dialog box. On the Model Referencing pane, set the **Total number of instances allowed per top model** to one.

Since logging root-level Outport blocks or signals in `Dataset` format are not supported, on the Data Import/Export pane, clear the **Time** and **Output** check boxes.

- 9 Update your model and confirm that there are no errors by pressing **Ctrl-D**.

The next step is create a test harness. See “Create Test Harness to Generate Function Calls” on page 10-228.

Create Test Harness to Generate Function Calls

In this section...
“Reference the Export-Function Model” on page 10-228
“Model an Event Scheduler” on page 10-231
“Connect Chart to Test Model” on page 10-233

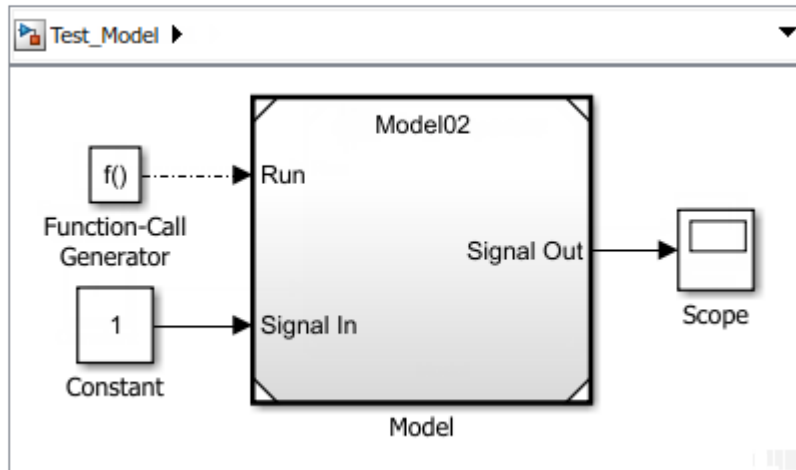

After you create a model component to initialize, reset, and terminate the state of blocks (see “Using Initialize, Reset, and Terminate Functions” on page 10-213), you can place the model in a simulation test harness. A test harness is a Simulink model that you use to develop, test, and debug a model component.

To create the test harness, reference the export-function model containing the model component in a new model, and then add a Stateflow chart to model a function-call event scheduler.

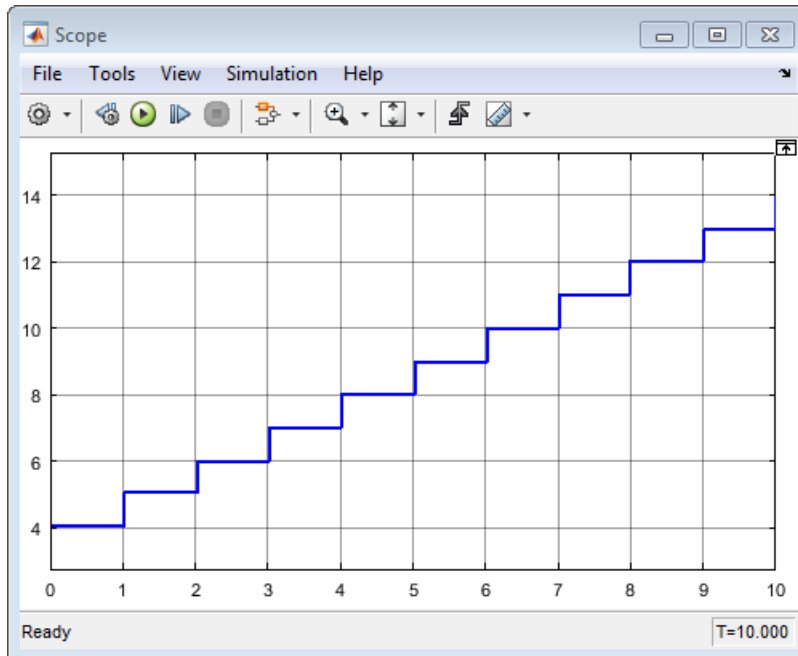

Reference the Export-Function Model

The export-function model contains the model component for testing. To create the export function model, see “Create an Export-Function Model” on page 10-225.

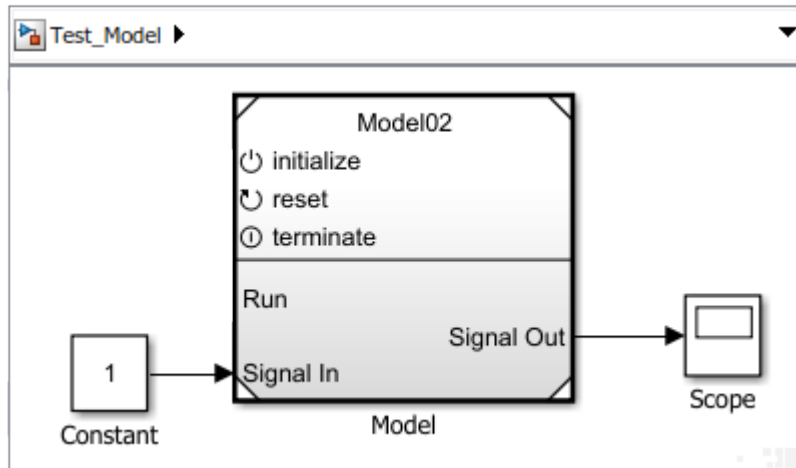

- 1 Create a new Simulink model. Save this model with the name `Test_Model`.
- 2 Set Model Configuration Parameters for solver **Type** to Fixed-step, Solver to auto, and **Fixed-step size** to 1.
- 3 Add a Model block. Open the Block Parameters dialog box. In the **Model name** text box, enter the name of your export-function model. In this example, enter `Model02`.
- 4 Test the referenced model component by connecting a Function-Call Generator block to the Run port. Connect a Constant block to the `Signal In` port and a Scope block to the `Signal Out` port.

- 5 Run simulation to verify your model simulates correctly from the parent model. When the model is simulated without function-call event ports, the Initialize Function block executes at the beginning of a simulation and the Terminate Function block executes at the end of the simulation.

- 6 Expose function-call input ports on the model block. Right-click the Model block and select **Block Parameters**. In the Block Parameters dialog box, select the **Show model initialize port**, **Show model reset port**, and **Show model terminate port** check boxes.
- 7 Delete the Function-Call Generator block and update the model by pressing **Ctrl-D**.

When you activate the initialize function-call input port on a Model block, the model has to receive an initialize function call on the `initialize` port before it can execute. The reception of a function call triggers the execution of the default model initialize routine, and then the execution of the Initialize Function block contents.

The reception of a function call on the Reset port triggers the execution of the Reset Function block contents.

The reception of a function call on the Terminate port triggers the execution of the Terminate Function block contents, and then the execution of the default model terminate routine. The model then stops running. To execute the model again, you have to reinitialize the model by sending an function-call event to the `initialize` port.

Model an Event Scheduler

Use a Stateflow chart to model an event schedule and generate the initialize and terminate function call signals.

- 1 Add a Stateflow Chart. Click the model diagram and start typing `Chart`. From the search list, select .
- 2 Open the chart and add two state blocks, one above the other.

- 3 Add a default transition and connect it to the top state block. Edit the label:

```
{step = 0}
```

- 4 Add a transition from the top block to the bottom block. Edit the label:

```
[step == 2]/{Initialize}
```

- 5 Add a transition from the bottom block and back to the bottom block. Edit the label:

```
[step == 5]/{Reset}
```

- 6 Add a transition from the bottom block to top block. Edit the label:

```
[step == 9]/{Terminate}
```

- 7 Edit the content of the top block:

```
Inactive
entry: step = step + 1;
during: step = step + 1;
```

- 8 Edit the content of the bottom block:

```
Running
entry: step = step + 1; Run;
during: step = step + 1; Run;
```

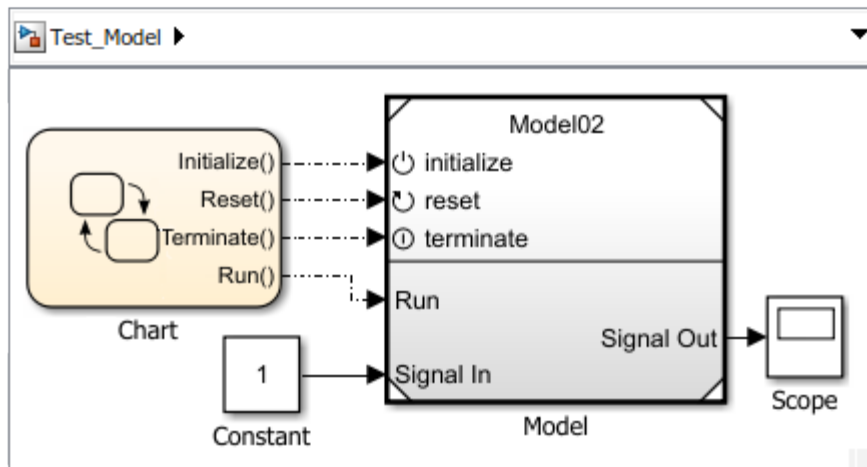

Connect Chart to Test Model

Create function-call output ports on the chart to control and run the model component.

- 1 Open Model Explorer. **View > Model Explorer > Model Explorer.**
- 2 Create index variable. From the menu, select **Add > Data**. In the Data dialog box, enter Step for the **Name**.
- 3 Create function-call output ports. For each function-call event you create, select **Add > Event** and in the Event dialog box, enter, and select the following values.

Enter in Event Text Box	Set Scope	Set Trigger
Initialize	Output to Simulink	Function call
Reset	Output to Simulink	Function call
Terminate	Output to Simulink	Function call
Run	Output to Simulink	Function call

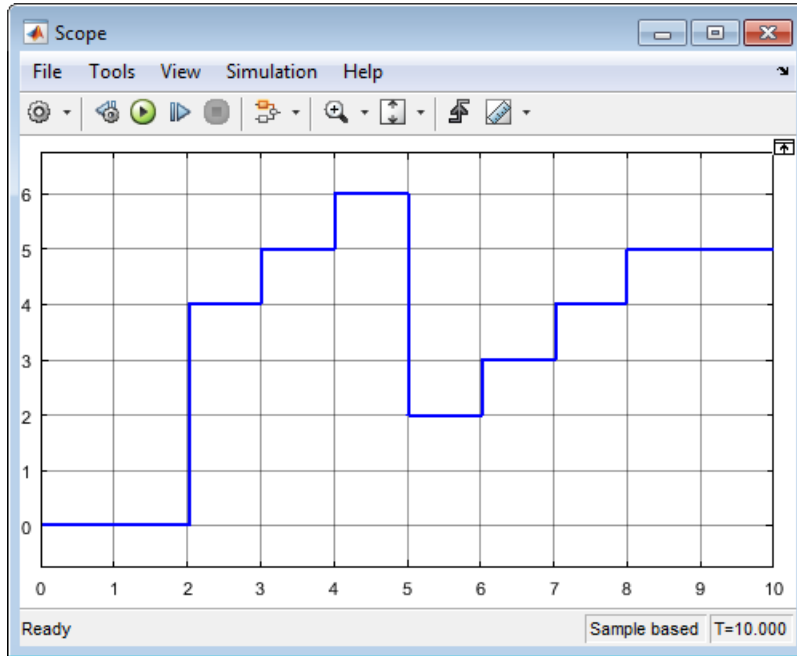

- 4 Navigate to the top level of the model. Connect the Initialize, Reset, Terminate, and Run ports on the chart to the initialize, reset, terminate, and Run input ports on the Model block.

- 5 Run simulation.

The model cannot execute until the second time step, when the block state is initialized to 4. At the fifth time step, a reset function call to the reset port triggers

the Reset Function block to execute. At the ninth time step, the subsystem stops executing, and the block state remains constant.

If the model receives a function call to run before an initialize function call, a simulation error occurs.

Initialize and Reset Parameter Values

During a simulation, you can respond to an event such as reading an environment sensor value, and then update an algorithm with a new parameter value.

The Initialize Function and Reset Function blocks can respond to events while the Parameter Writer block can change parameter values. The Parameter Writer block does not write directly to block parameter values. Instead, it changes block parameter values in a referenced model by writing to instance parameters belonging to the Model block.

Using the Parameter Writer Block

The following example shows how to use the Parameter Writer block to change a parameter value for a Gain block.

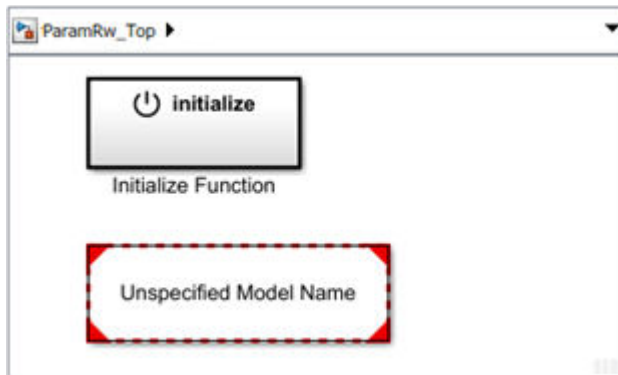

- 1 Create a model with a writable parameter, that is a block parameter you can define with a model parameter. In the example, add a Constant, Gain, and Outport block to a new model. Connect blocks. Save the model with the name ParamRw_Sub.

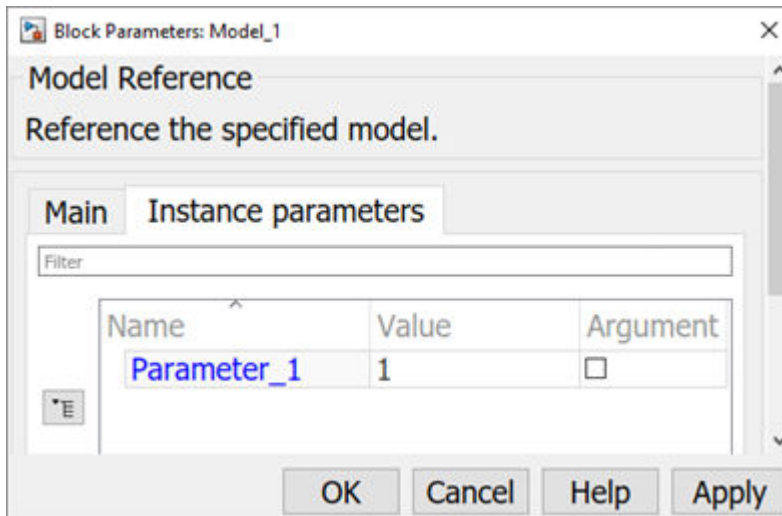

- 2 Add a Simulink parameter to the Model Workspace. From the Simulink Editor menu, select **View > Model Explorer > Model Workspace**. From the Model Explorer menu, select **Add > Simulink Parameter**. Set **Name** to Parameter_1 and **Value** to 1. Select the **Argument** check box. Click **Apply**.

- 3 Open the Gain block parameter dialog. Set **Gain** to Parameter_1.
- 4 Create a model that initializes the parameter. Add an Initialize Function and Model block to a new model. Save the model with the name ParamRw_Top.

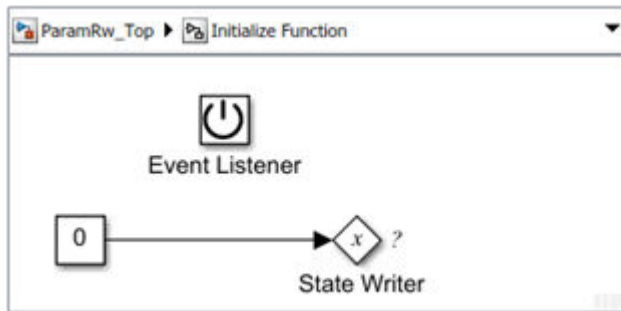

- 5 Rename the Model block to `Model_1`. Open the Model block parameter dialog box. In the **Model name** box, enter `ParamRw_Sub`. Select the Instance parameters tab. Set the **Value** for `Parameter_1` to 1. This is the default value the model uses before the Parameter Writer block updates this parameter with a new value.

If the Model block is at a lower hierarchical level than the Parameter Writer block, select the **Argument** check box to promote the parameter to a higher level and make it visible to the Parameter Writer block.

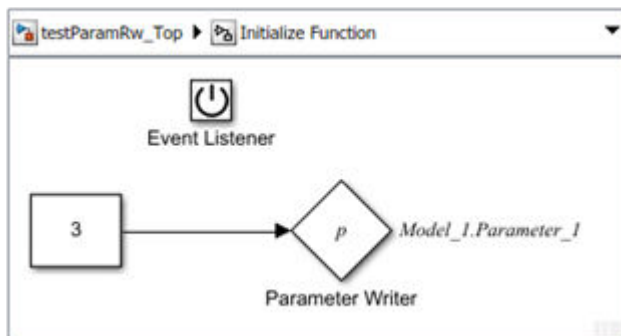

- 6 Double-click the Initialize Function block. The block is preconfigured with a State Writer block.

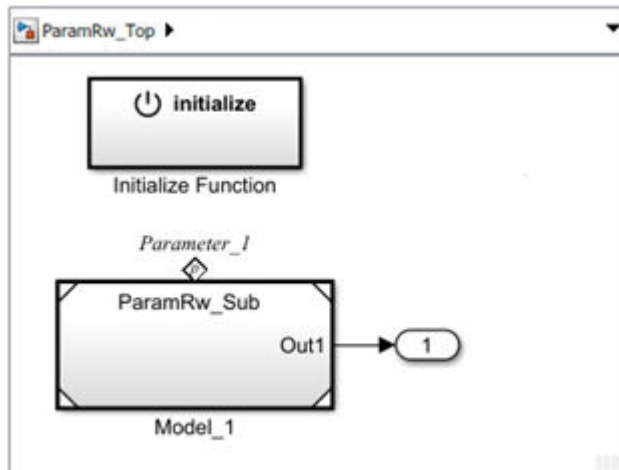

- 7 Replace the State Writer block with a Parameter Writer block. Open the Parameter Writer block parameter dialog box. From the **Parameter Owner Selector Tree**, select **Parameter_1**.

- 8 Open the Constant block parameter dialog box. Set **Constant value** to 3. This is the value for setting the gain with the Parameter Writer block.
- 9 Click **OK** to close the dialog. The Parameter Writer block displays a label indicating it writes to the model instance parameter **Parameter_1** for **Model_1**.

- 10 Click the **ParamRw_Top** tab. The Model block displays a badge  indicating a value is written to **Parameter_1**.

Initialize, Reset, and Terminate Function Limitations

In this section...
“Unsupported Blocks” on page 10-240
“Unsupported Features” on page 10-240
“Component I/O Blocks” on page 10-241

Unsupported Blocks

Initialize, Reset, and Terminate Function blocks do not support:

- Model blocks
- Custom code blocks
- Stateflow charts
- Resettable Subsystem blocks
- Blocks with state, for example, Unit Delay blocks
- Blocks with absolute time, for example, Clock blocks
- MATLAB System blocks
- MATLAB Function blocks which use persistent or global data. However, MATLAB Function blocks without persistent or global data are supported.

Initialize, Reset, and Terminate Function blocks cannot call Simulink Function blocks with:

- Input or output ports
- An Initialize Function, Reset Function, or Terminate Function block
- Unsupported blocks

Unsupported Features

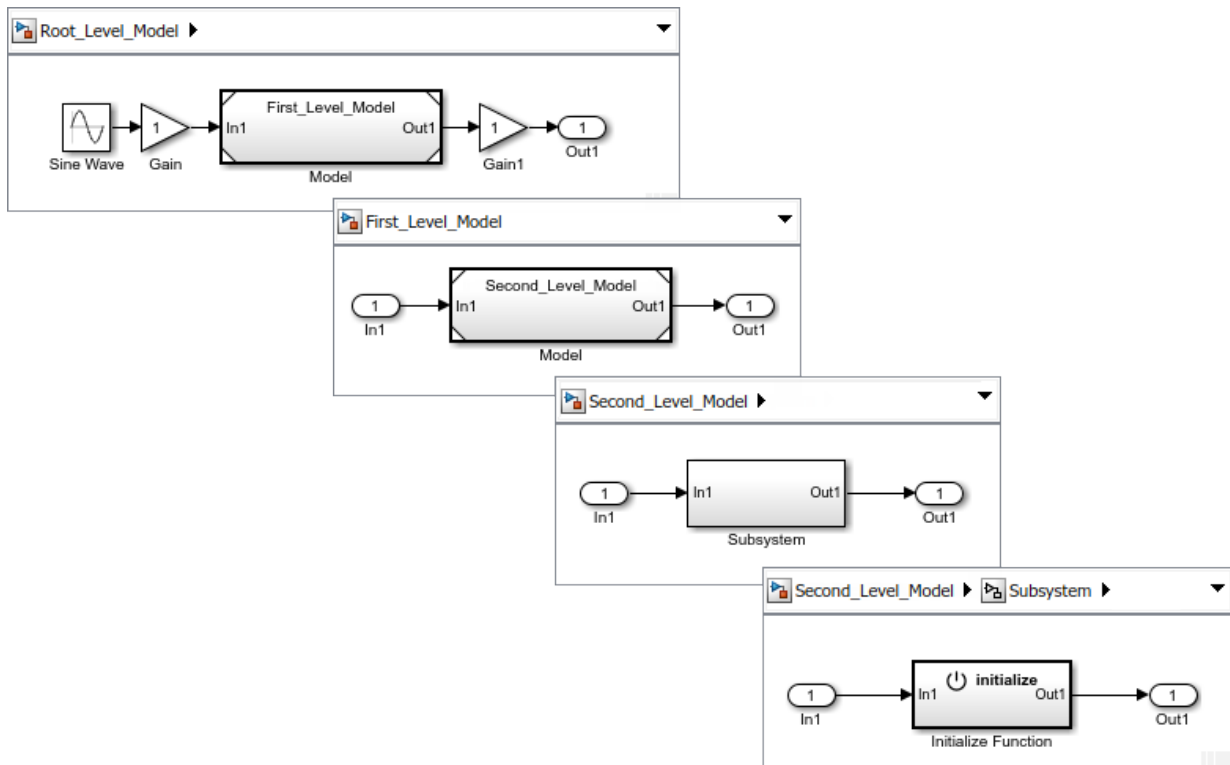

Initialize, Reset, and Terminate Function blocks do not support:

- Using variable-size signals

Component I/O Blocks

The input and output ports of a model component containing Initialize Function, Reset Function, or Terminate Function blocks must connect to root Inport and Outport blocks without intervening blocks.

In this example, an Initialize Function block is placed in a Subsystem block. The model containing the Subsystem block is referenced from a model that is referenced from the root level model. Only the root level model with the **Show model initialize port** parameter selected can have blocks between the input and output ports.

What Are Variants?

In Simulink, you can use the variant blocks to create a single model that caters to multiple variant requirements. Such models have a fixed common structure and a finite set of variable components. The variable components are activated depending on the variant choice that you select. Thus, the resultant active model is a combination of the fixed structure and the variable components based on the variant choice.

The use of variant blocks in a model helps in reusability of the model for different conditional expressions called variant choices. This approach helps you to meet diverse customer requirements based on application, cost, or operational considerations.

You can use these variant blocks depending on the model design:

- Variant Subsystem: For hierarchical model structure. The block is a template with two Subsystem blocks to use as variant systems. You can add Subsystem blocks, as well as Model blocks, for variants.
- Variant Model: For hierarchical model structure. The block is a template with two Model blocks to use as variant systems. You can add Model blocks, as well as Subsystem blocks, for variants.
- Inline Variants: For flat model structure.
 - Variant Source
 - Variant Sink
 - Manual Variant Source

- Manual Variant Sink

Note Sample time for single input Variant Source / Variant Sink blocks can differ with multiple input Variant Source / Variant Sink blocks. For more information on sample time, see “What Is Sample Time?” on page 7-2

Use of a Variant Subsystem block provides these advantages:

- Allows you to mix Model and Subsystem blocks as variant systems
- Supports flexible I/O, so that all variants do not need to have the same number of input and output ports

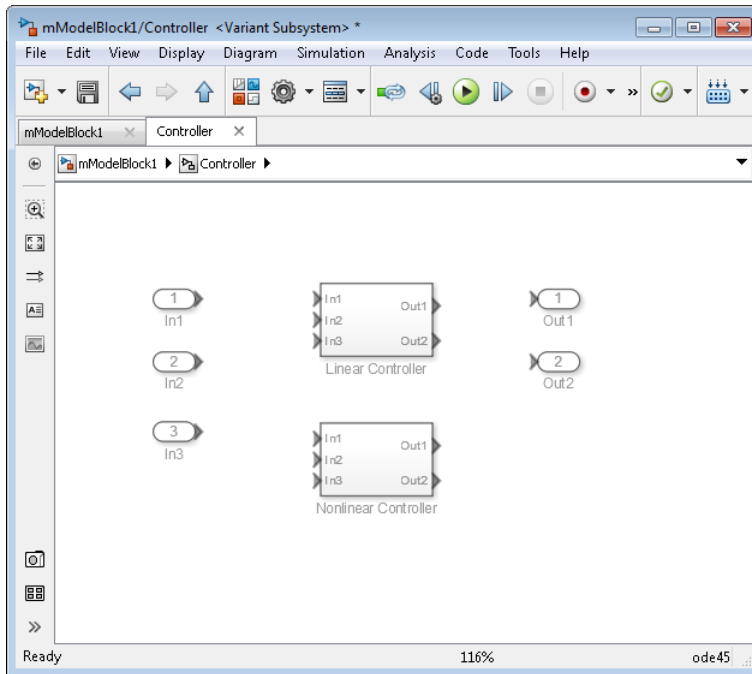

To convert a Model block that contains variant models to a Variant Subsystem block that contains Model blocks that reference the variant models, right-click the Model block and select **Subsystems & Model Reference > Convert to > Variant Subsystem**.

Alternatively, you can use the `Simulink.VariantManager.convertToVariant` function. Specify the Model block name or block handle. The converted model produces the same results as the original model.

If you want to simulate a model that represents an automobile with several configurations. These configurations, although similar in several aspects, can differ in properties such as fuel consumption, engine size, or emission standard. Instead of designing multiple models that together represent all possible configurations, you can use variants to model only the varying configurations. This approach keeps the common components fixed.

This model contains two variant choices inside a single Variant Subsystem block. Variant choices are two or more configurations of a component in your model.

Advantages of Using Variants

Using variants in Model-Based Design provides several advantages:

- Variants provide you a way to design one model for many systems.
- You can rapidly prototype design possibilities as variants without having to comment out sections of your model.
- Variants help you develop modular design platforms that facilitate reuse and customization. This approach improves workflow speed by reducing complexity.
- If a model component has several alternative configurations, you can efficiently explore these varying alternatives without altering the fixed, unvarying components.
- You can use different variant configurations for simulation or code generation from the same model.
- You can simulate every design possibility in a combinatorial fashion for a given test suite.

- If you are working with large-scale designs, you can distribute the process of testing these designs on a cluster of multicore computers. Alternatively, you can map different test suites to design alternatives for efficiently managing design-specific tests.
- You can generate a reduced model with a subset of configuration from a master model with many variants.

When to Use Variants

Variants help you specify multiple implementations of a model in a single, unified block diagram. Here are three scenarios where you can use variants:

- Models that represent multiple simulation, code generation, or testing workflows.

Figure 1. Model of an ideal actuator for basic simulation.

Figure 2. Detailed actuator for simulating customizations.

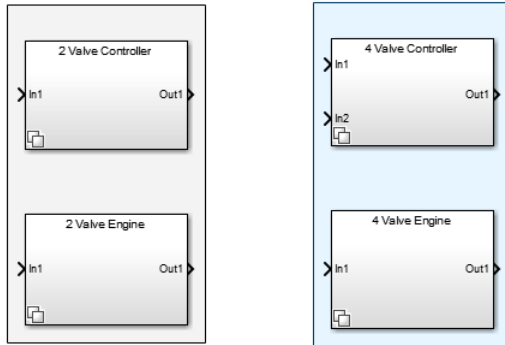

Figure 3. Model that is configured for Hardware-in-the-Loop simulation.

- Models that contain multiple design choices at the component level.

Subsystem blocks representing variant choices can have inports and outports that differ in number from the inports and outports in the parent Variant Subsystem block. See “Mapping Inports and Outports of Variant Choices” on page 11-8.

- Models that are mostly similar but have slight variations, such as in cases where you want to separate a test model from a debugging model.

The test model on the left has a fixed design. On the right, the same test model includes a variant that is introduced for debugging purposes.

Simulink selects the active variant during update diagram time and during code compile time.

Options for Representing Variants in Simulink

You can represent one or more variants as variant choices inside these blocks.

	Variant Source and Variant Sink blocks	Variant Subsystem and Variant Model blocks
Variant choice representation	Number of ports	Subsystem or Model block
Allows choice hierarchy	No	Yes
Mismatched number of inports and outports among variant choices	Simulink disables inactive ports	Simulink disables inactive ports
Option to specify default variant	Yes	Yes
Supports control ports	No	Yes
Can be saved as standalone file	No	No
Supports physical modeling connection ports	No	Partially
Comment choice (%)	No	No

In addition, you can represent variant choices using Variant Source and Variant Sink block. These blocks enable the propagation of variant conditions throughout the model and can propagate conditions through model reference hierarchy.

You can create variants at several levels inside your model hierarchy.

Mapping Inports and Outports of Variant Choices

A Variant Subsystem is a container of variants choices that are represented as Subsystem or Model blocks. The inputs that the Variant Subsystem block receives from upstream models components map to the inports and outports of the variant choices.

Subsystem and Model blocks representing variant choices can have inports and outports that differ in number from the inports and outports in the parent Variant Subsystem block. However, the following conditions must be satisfied:

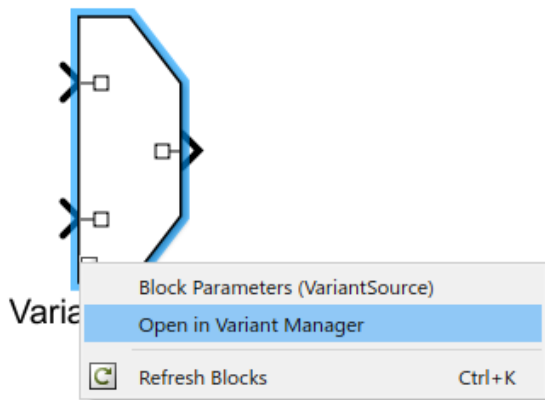

- The names of the inports of a variant choice are a subset of the inport names used by the parent variant subsystem.
- The names of the outports of a variant choice are a subset of the outport names used by the parent variant subsystem.

- If variant choices have control port, the name of data input port must match with control port name.

During simulation, Simulink disables the inactive ports in a Variant Subsystem block.

Variant Badges

Each Variant block has a badge associated with it. The color and icon of a Variant badge indicate the status of the Variant block. It also provides quick access to few Variant commands. You can right-click the Variant badge to access these commands.

Variant Badge	Variant Source	Variant Sink	Variant Subsystem
Default Variant badge when no option is selected.			

Variant Badge	Variant Source	Variant Sink	Variant Subsystem
<p>Variant block with Label selected as Variant control mode and an active variant choice is selected from Label mode active choice option.</p>			
<p>Variant block with Allow zero active variant controls option selected.</p>			
<p>Variant block with Analyze all choices during update diagram and generate preprocessor conditionals option selected.</p>			
<p>Variant block with Propagate conditions outside of variant subsystem option selected.</p>	<p>Not applicable</p>	<p>Not applicable</p>	

Variant Badge	Variant Source	Variant Sink	Variant Subsystem

Variant block with Analyze all choices during update diagram and generate preprocessor conditionals and Propagate conditions outside of variant subsystem option selected.	Not applicable	Not applicable	
Variant block with Allow zero active variant controls and Propagate conditions outside of variant subsystem option selected.	Not applicable	Not applicable	

Comment Out and Comment Through

Consider when you want to simulate a Simulink model by excluding some of its blocks from simulation and without physically removing the blocks from the model. The **Comment Out** and **Comment Through** commands in Simulink provide you with an

option to exclude blocks from simulation. Depending on your modeling requirement, you can use these options:

- **Comment Out:** Excludes the selected block from simulation. The signals are terminated and grounded.
- **Comment Through:** Excludes the selected block from simulation. The signals are passed through. To comment through a block, the number of input ports and the output ports for the block must be same.

To access the **Comment Out** or the **Comment Through** options, right-click the block and in the context menu either select **Comment Out** or **Comment Through** based on your modeling requirement.

Alternatively, you can also select the block and press **Ctrl+Shift+X** to comment out or press **Ctrl+Shift+Y** to comment through.

You can use `get_param` and `set_param` commands to view or change the commented state of a block programmatically. For example,

- `get_param(gcf,'commented');` % To view the commented state of the block
- `set_param(gcf,'commented','on');` % To comment out a block
- `set_param(gcf,'commented','through');` % To comment through a block
- `set_param(gcf,'commented','off');` % To uncomment a block

When you comment out a block, the signal names at the output port of the block are ignored. To include such signals during simulation, the signal name must be added at the input port of the block.

Comment Out and **Comment Through** are not supported with these blocks: Inport, Outport, Duplicate Port, Connection ports, Argument Inport, Argument Outport, Data Store Memory, Signal Generator, Goto Tag Visibility, For, and While blocks.

Variant Terminology

The Simulink Variant terminology helps you to understand various parameters and terms used in Variant documentation.

Variant Terminology	Description
Variant Subsystem, Variant Model	Contains one or more choices where each choice is a Subsystem or Model block.
Variant Source	Provides variation on the source of a signal.
Variant Sink	Provides variation on the sink (destination) of a signal.
Variant Model	Variant Subsystem block containing Model block as variant choices.
Active choice on page 11-29	Variant choice associated with a variant control that evaluates to <code>true</code> .
Variant control expression on page 11-32	Boolean expression or a <code>Simulink.Variant</code> object containing a boolean expression or (<code>default</code>). Used as Variant control mode.
Variant control label on page 11-33	String that is not evaluated and the choice used in simulation is determined by the Label mode active choice parameter. Used as Variant control mode.
Variant control variable	Normal MATLAB variable, <code>Simulink.Variant</code> object, or a <code>Simulink.Parameter</code> object.
Variant object	Container of variant control expression.
Variant Manager	Central tool that allows you to manage various variation points that are modeled using variant blocks in a system model.
Variant Reducer on page 11-98	Reduces variant models to simplified, standalone model depending on the selected variant configurations.

Command Line Parameters

Variant Subsystem Parameters

Parameter name	Description
Variant	<p>Used to check if the subsystem is a Variant Subsystem. Returns on if the subsystem is a Variant Subsystem, else it returns off. Example: <code>get_param(gcb, 'Variant')</code></p> <p>This is a read-only parameter.</p>
VariantControl	<p>Subsystem block and Model block parameter, which applies to a choice block of a Variant Subsystem and returns the variant control for the choice block.</p> <ul style="list-style-type: none"> • <code>get_param</code> behavior: Returns variant controls for choice block of a Variant Subsystem block. Example: <code>get_param(gcb, 'VariantControl')</code> • <code>set_param</code> behavior: Sets variant control for current block. Example: <code>set_param(gcb, 'VariantControl', 'A==1')</code>

Parameter name	Description
VariantControlMode	<p>Specifies the mode for modeling Variant blocks, which can be either Expression or Label.</p> <ul style="list-style-type: none">• <code>get_param</code> behavior: Returns the mode set for modeling Variant blocks. Example: <code>get_param(gcb, 'VariantControlMode')</code>• <code>set_param</code> behavior: Sets the mode for modeling Variant blocks. Example: <code>set_param(gcb, 'VariantControlMode', 'Label')</code>

Parameter name	Description
LabelModeActiveChoice	<p>Returns the variant control label of the selected choice for the Variant Subsystem block when <code>VariantControlMode</code> is specified as <code>Label</code>. If <code>VariantControlMode</code> is specified as <code>Expression</code>, this parameter returns empty (<code>''</code>).</p> <ul style="list-style-type: none"><li data-bbox="798 552 1338 835">• <code>get_param</code> behavior: Returns the variant control label of the selected choice for the Variant Subsystem when <code>VariantControlMode</code> is set to <code>Label</code>. If <code>VariantControlMode</code> is set to <code>Expression</code>, this parameter returns empty (<code>''</code>).<li data-bbox="798 847 1338 1095">• <code>set_param</code> behavior: When <code>VariantControlMode</code> is specified as <code>Expression</code>, <code>set_param</code> makes the label selected as the active choice. When <code>VariantControlMode</code> is <code>Label</code>, <code>set_param</code> switches between specified labels.

Parameter name	Description
TreatAsGroupedWhenPropagatingVariantConditions on page 11-150	<p>Returns on if the Subsystem is treated as a group when propagating variant conditions else returns off.</p> <ul style="list-style-type: none">• get_param behavior: Indicates if the subsystem is treated as a group when propagating Variant conditions or not by returning on or off. Example: <code>get_param(gcb, 'TreatAsGroupedWhenPropagatingVariantConditions')</code>• set_param behavior: Enables or disables treating subsystem as a group when propagating variant conditions. Example: <code>set_param(gcb, 'TreatAsGroupedWhenPropagatingVariantConditions', 'on')</code>

Parameter name	Description
GeneratePreprocessorConditionals	<p>Indicates if all the choices are to be analyzed and preprocessor conditionals to be generated by returning on or off.</p> <ul style="list-style-type: none"> • <code>get_param</code> behavior: Indicates if all the choices are to be analyzed and preprocessor conditionals be generated by returning on or off. Example: <code>get_param(gcb, 'GeneratePreprocessorConditionals')</code> • <code>set_param</code> behavior: Enables or disables analyzing all the choices and generating preprocessor conditionals. Example: <code>set_param(gcb, 'GeneratePreprocessorConditionals', 'on')</code>
CompiledActiveChoiceControl	<p>Returns the variant control corresponding to the active choice of the Variant Subsystem and returns empty (' ') when no choice is active. When the block is commented or is inside a commented subsystem, this parameter returns empty (' '). Example: <code>get_param(gcb, 'CompiledActiveChoiceControl')</code>.</p> <p>This is a read-only parameter.</p>

Parameter name	Description
CompiledActiveChoiceBlock	<p>Returns the full block path name of the active Variant Subsystem choice and returns empty (' ') when no choice is active. When the block is commented or is inside a commented Subsystem, the value is returned as empty(' '). Example: <code>get_param(gcb, 'CompiledActiveChoiceBlock')</code>.</p> <p>This is a read-only parameter.</p>
PropagateVariantConditions	<p>Indicates if conditions on ports inside the Variant Subsystem block are to be propagated outside the block.</p> <ul style="list-style-type: none"> • <code>get_param</code> behavior: <p>Indicates if conditions on ports inside the Variant Subsystem block are to be propagated outside the block.</p> • <code>set_param</code> behavior: <p>Enables or disables propagating conditions outside Variant Subsystem block. Example: <code>set_param(gcb, 'PropagateVariantConditions', 'on')</code></p>

Parameter name	Description
AllowZeroVariantControls	<p data-bbox="793 302 1332 361">Indicates if the Variant Subsystem block is allowed to have no active choices.</p> <ul data-bbox="793 392 1332 743" style="list-style-type: none"><li data-bbox="793 392 1332 517">• <code>get_param</code> behavior: Indicates if the Variant Subsystem block is allowed to have no active choices.<li data-bbox="793 527 1332 743">• <code>set_param</code> behavior: Enables or disables having active choices in Variant Subsystem block. Example: <code>set_param(gcb, 'AllowZeroVariantControls', 'on')</code>

Variant Source and Variant Sink Parameters

Parameter name	Description
VariantControls	<p>Returns a 1-by-N cell array of variant control expressions corresponding to each of the N ports of the Variant Source or Variant Sink blocks.</p> <ul style="list-style-type: none"> • get_param behavior: Returns a cell array of variant control expressions corresponding to each ports of the Variant Source or Variant Sink blocks. Example: <code>get_param(gcb, 'VariantControls')</code> • set_param behavior: Sets the cell array of Variant control expressions corresponding to each of ports of Variant Source or Variant Sink blocks. Example: <code>set_param(gcb, 'VariantControls', ({A==1}, '4'))</code>
VariantControlMode	<p>Specifies the mode for modeling variant blocks, which can be either Expression or Label.</p> <ul style="list-style-type: none"> • get_param behavior: Returns the mode set for modeling Variant blocks. Example: <code>get_param(gcb, 'VariantControlMode')</code> • set_param behavior: Sets the mode for modeling Variant blocks. Example: <code>set_param(gcb, 'VariantControlMode', 'Label')</code>

Parameter name	Description
LabelModeActiveChoice	<p>Returns the variant control label of the selected choice for Variant Source or Variant Sink block when VariantControlMode is specified as Label. If VariantControlMode is specified as Expression, this parameter returns empty ('').</p> <ul style="list-style-type: none">• get_param behavior: Returns the variant control label of the selected choice for the Variant Subsystem when VariantControlMode is set to Label. If VariantControlMode is set to Expression, this parameter returns empty ('').• set_param behavior: When VariantControlMode is specified as Expression, set_param makes the label selected as the active choice. When VariantControlMode is Label, set_param switches between specified labels.

Parameter name	Description
GeneratePreprocessorConditionals	<p>Indicates if all the choices are to be analyzed and preprocessor conditionals to be generated by returning on or off.</p> <ul style="list-style-type: none"> • <code>get_param</code> behavior: Indicates if all the choices are to be analyzed and preprocessor conditionals to be generated by returning on or off. Example: <code>get_param(gcb, 'GeneratePreprocessorConditionals')</code> • <code>set_param</code> behavior: Enables or disables analyzing all the choices and generating preprocessor conditionals. Example: <code>set_param(gcb, 'GeneratePreprocessorConditionals', 'on')</code>
ShowConditionOnBlock	<p>Indicates if the <code>VariantControlExpression</code> is to be displayed on the block by returning on or off.</p> <ul style="list-style-type: none"> • <code>get_param</code> behavior: Indicates if the <code>VariantControlExpression</code> is to be displayed on the block or not. • <code>set_param</code> behavior: Enables or disables the displaying of <code>VariantControlExpression</code> on the block. Example: <code>set_param(gcb, 'ShowConditionOnBlock', 'on')</code>

Parameter name	Description
AllowZeroVariantControls	<p>Indicates if the block is allowed to have no active ports by returning on or off.</p> <ul style="list-style-type: none"> • <code>get_param</code> behavior: Indicates if the Variant Source or Variant Sink block is allowed to have no active choices. • <code>set_param</code> behavior: Enables or disables having active choices in Variant Source or Variant Sink block. Example: <code>set_param(gcb, 'AllowZeroVariantControls', 'on')</code>
CompiledActiveVariantControl	<p>Returns the variant control corresponding to the active port from the last compilation instance. If no port is active, returns empty (' '). If the block is commented or inside a commented Subsystem or inside an inactive choice of a Variant Subsystem, the value is not computed and returns empty (' '). Example: <code>get_param(gcb, 'CompiledActiveVariantControl')</code></p> <p>This is a read-only parameter.</p>
CompiledActiveVariantPort	<p>Returns the "index" of the active port from the last compilation instance or returns -1 when no port is active. If the block is commented or inside a commented Subsystem or inside an inactive choice of a Variant Subsystem (with generate preprocessor conditionals Off), the value is not computed, and returns empty (' '). Example: <code>get_param(gcb, 'CompiledActiveVariantPort')</code></p> <p>This is a read-only parameter.</p>

Working with Variant Choices

In this section...

“Default Variant Choice” on page 11-28

“Active Variant Choice” on page 11-29

“Inactive Variant Choice” on page 11-29

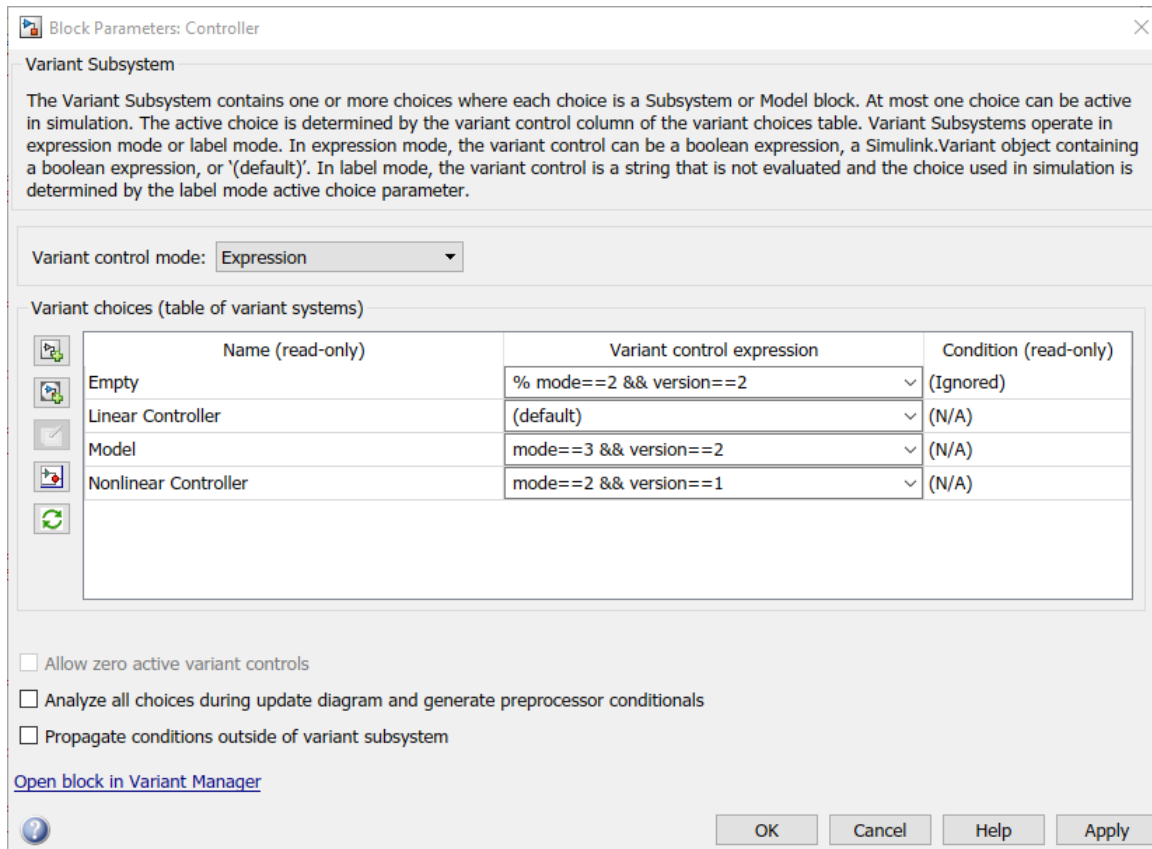

“Empty Variant Choice” on page 11-29

“Open Active Variant” on page 11-30

Each variant choice in your model is associated with a conditional expression called variant control. The way you specify your variant controls determines the active variant choice. **Variant control mode** parameter available in the block parameters dialog box allows you to select **Expression** or **Label** mode for modeling Variant blocks.

This image shows the block parameters dialog box of a Variant Subsystem block that contains four variant choices:

- The first choice is commented out by adding the % symbol before the variant control.
- The second choice is the (default) and is activated when no variant control evaluates to true.
- The third choice is activated when the expression `mode==3 && version==2` evaluates to true.
- The fourth choice is activated when the expression `mode==2 && version==1` evaluates to true.

Default Variant Choice

You can specify at most one variant choice as the default for the model. As shown in the image above, the **Linear Controller** subsystem is defined as the default variant choice. During model compilation, if Simulink finds that no variant control evaluates to true, it uses the default choice.

In the dialog box, select the variant choice and change its **Variant control** property to (default).

Active Variant Choice

While each variant choice is associated with a variant control, only one variant control can evaluate to `true` at a time. When a variant control evaluates to `true`, Simulink activates the variant choice that corresponds to that variant control. At most one variant choice can be active. The active variant cannot be changed once model is compiled.

In this example, you can activate either the `Model` variant choice or the `Nonlinear Controller` variant choice by specifying appropriate values for `mode` and `version`.

Value of mode	Value of version	Active variant choice
2	1	Nonlinear Controller
3	2	Model

You can specify the values of `mode` and `version` at the MATLAB Command Window.

Inactive Variant Choice

When a variant control activates one variant choice, Simulink considers the other variant choices to be inactive. Simulink ignores inactive variant choices during simulation. However, Simulink continues to execute block callbacks inside the inactive variant choices.

Empty Variant Choice

When you are prototyping variant choices, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which that subsystem is inactive without the need for completely modeling the variant choice.

For an empty variant choice, you can either specify a variant activation condition or comment out the variant condition by placing a `%` symbol before the condition.

If this variant choice is active during simulation, Simulink ignores the empty variant choice. However, Simulink continues to execute block callbacks inside the empty variant choices.

Open Active Variant

When you open a model, variant blocks display the name of the variant that was active the last time that you saved your model. Use the **Variant** menu to open the active variant. Right-click the block and select **Variant > Open**. Then select the active variant.

Use this command to find the current active choice:

```
get_param(gcb, 'CompiledActiveChoiceControl')
```

Use this command to find the path to the current active choice:

```
get_param(gcb, 'CompiledActiveChoiceBlock')
```

Note

- The `CompiledActiveChoiceBlock` parameter is supported only for the Variant Subsystem block.
 - Active variant cannot be changed once the model is compiled.

Introduction to Variant Controls

In this section...

“Variant control mode” on page 11-31

“Operands” on page 11-33

“Operators” on page 11-34

“Known Limitations” on page 11-34

“Approaches for Specifying Variant Controls” on page 11-34

“Viewing Variant Conditions” on page 11-40

“Operators and Operands in Variant Condition Expressions” on page 11-41

The components of a Simulink model that contain Variants are activated or deactivated based on the variant choice that you select.

Each variant choice in your model is associated with a conditional expression called variant control. Variant controls determine which variant choice is active. By changing the value of a variant control, you can switch the active variant choice.

While each variant choice is associated with a variant control, only one variant control can evaluate to true. When a variant control evaluates to true, Simulink activates the variant choice that corresponds to that variant control.

A variant control is a Boolean expression that activates a specific variant choice when it evaluates to `true`.

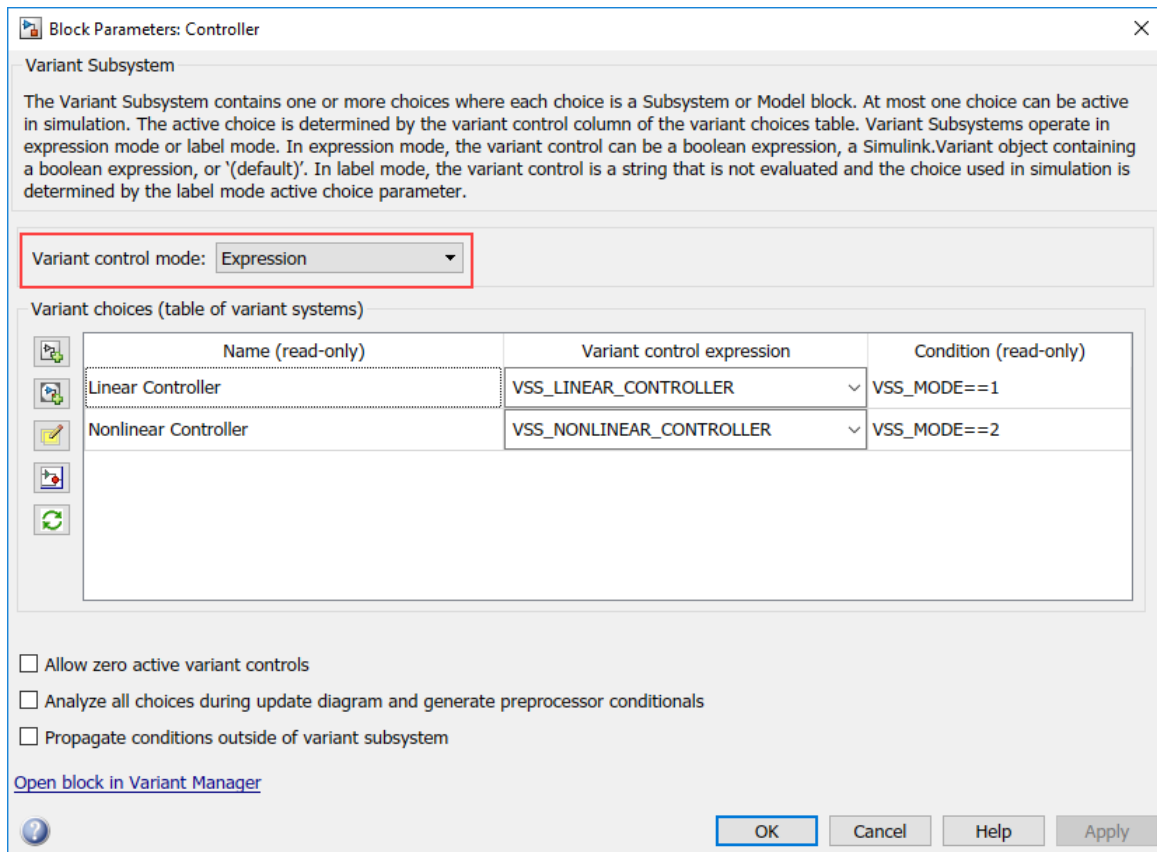

Note You can specify variant controls in the MATLAB global workspace or a data dictionary.

You can specify variant controls as `Simulink.Variant` objects, MATLAB expressions (including structures) or as expressions that contain one or more of these operands and operators.

Variant control mode

Variant control mode parameter available in the block parameters dialog box allows you to select `Expression` or `Label` mode for modeling Variant blocks.

- **Expression**: Specifies the active Variant based on the evaluation of the Variant conditions.

Variant control mode: Expression

- **Label**: Specifies the name based Variant controls (Label mode active choice). In Label mode, Variant control need not be created in the global workspace. Alternatively, you can select the Label mode active choice from the command line. For example, `set_param(block, 'LabelModeActiveChoice', 'Choice_1')`.

Variant control mode: Label

Operands

- Variable names that resolve to MATLAB variables or Simulink.Parameter objects with integer or enumerated data type and scalar literal values
- Variable names that resolve to Simulink.Variant objects
- Scalar literal values that represent integer or enumerated values

Operators

- Parentheses for grouping
- Arithmetic, relational, logical, or bitwise operators

For more information, see “Operators and Operands in Variant Condition Expressions” on page 11-41.

When you compile the model, Simulink determines that a variant choice is active if its variant control evaluates to `true`. The evaluation of active variant happens in the early stages of compilation and the active variant cannot be changed once model is compiled.

Known Limitations

- Simulink variant objects within structures are not allowed.
- Simulink parameters within structures are not allowed.

Approaches for Specifying Variant Controls

You can use many approaches for switching between variant choices—from options to use while prototyping to options required for generating code from your model.

Specification	Purpose	Example
Scalar variable	Rapid prototyping	<code>A == 1</code>
<code>Simulink.Variant</code> object	Reuse variant conditions	<code>LinearController = Simulink.Variant('FUE L==2 && EMIS==1');</code>
<code>Simulink.Parameter</code> object or MATLAB variables	Generate preprocessor conditionals for code generation	<code>mode == 1</code> , where <code>mode</code> can be <code>Simulink.Parameter</code> object or MATLAB variables
Enumerated type	Improved code readability because condition values are represented as meaningful names instead of integers	<code>LEVEL == Level.Advanced</code>

You can find control variables using the function `Simulink.VariantManager.findVariantControlVars`.

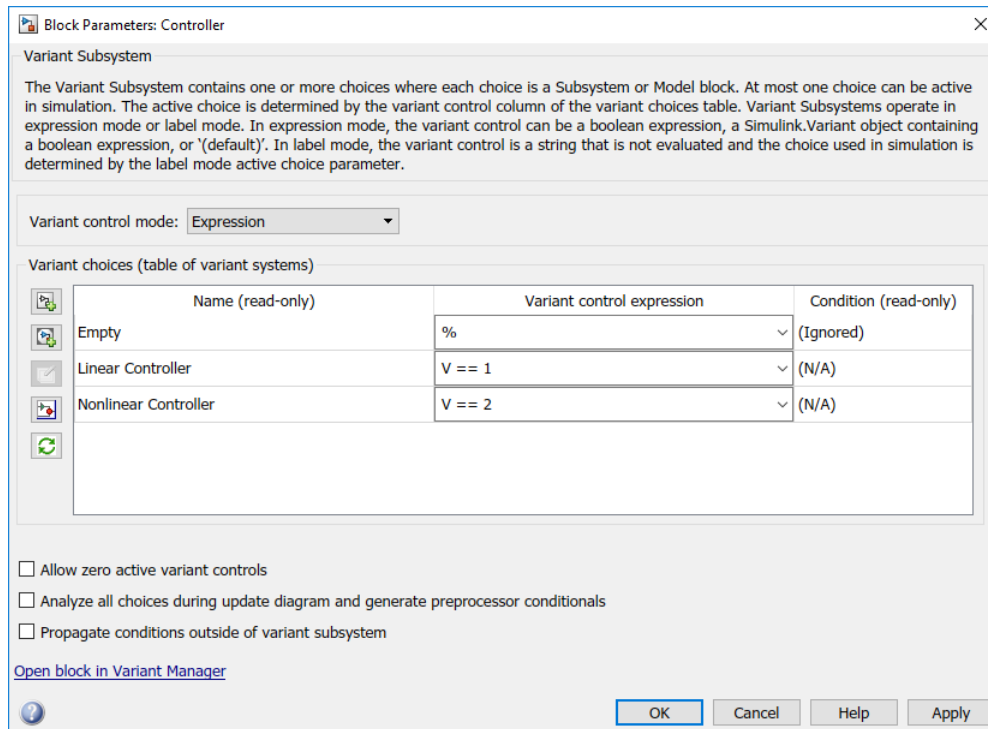

Scalar Variables for Rapid Prototyping

Scalar MATLAB variables allow you to rapidly prototype variant choices when you are still building your model. They help you focus more on building your variant choices than on developing the expressions that activate those choices.

Consider a model that contains two variant choices, each represented by a Variant Subsystem block.

You can specify variant controls in their simplest form as scalar variables in the block parameters dialog box of the Variant Subsystem block.

The **Condition** field for both the **Linear Controller** and **Nonlinear Controller** are N/A, because the variant control itself is the condition.

You can activate one of the variant choices by defining a scalar variable *V* and setting its value to 1 at the MATLAB Command Window.

```
V = 1;
```

This condition activates the **Linear Controller** variant choice. Variant controls are ignored when % symbol is used. Similarly, if variant control is empty, the choice is ignored.

Similarly, if you change the value of V to 2, Simulink activates the NonLinear Controller variant choice.

Simulink.Variant Objects for Variant Condition Reuse

After identifying the variant choices that your model requires, you can construct complex variant conditions to control the activation of your variant choices. Define variant conditions as `Simulink.Variant` objects.

`Simulink.Variant` objects enable you to reuse common variant conditions across models and help you encapsulate complex variant condition expressions.

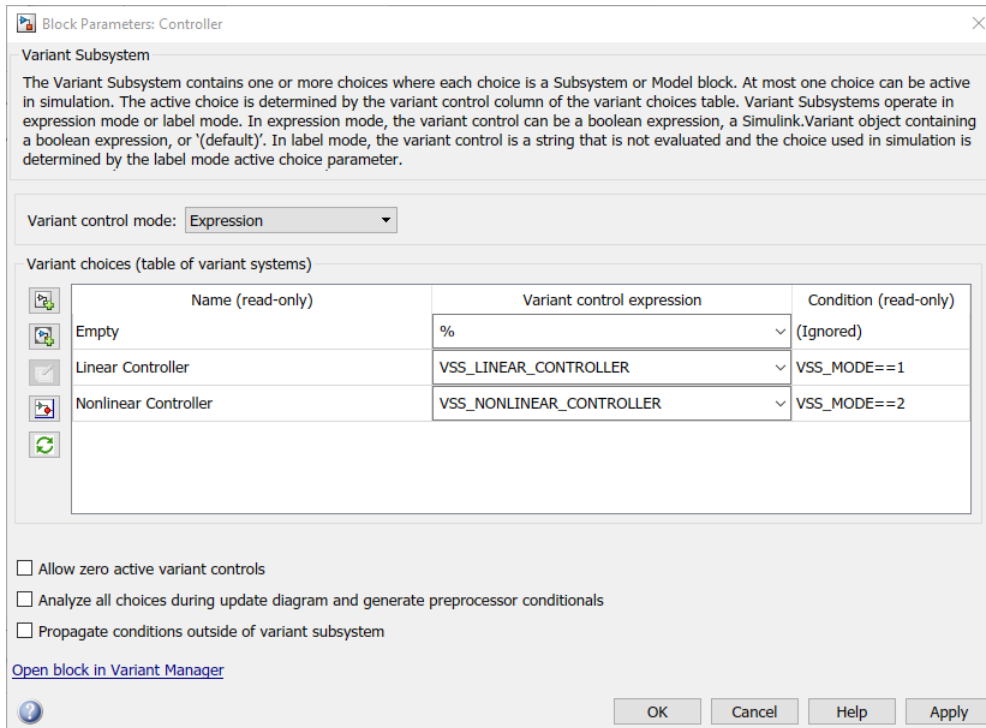

Consider an example where variant controls are already defined in the global workspace.

```
V=1;
V=2;
```

You can convert these controls into condition expressions encapsulated as `Simulink.Variant` objects.

```
LinearController=Simulink.Variant('V==1');
NonLinearController=Simulink.Variant('V==2');
```

You can then specify these `Simulink.Variant` objects as the variant controls in the block parameters dialog box of the Variant Subsystem block.

The **Condition** field now reflects the encapsulated variant condition. Using this approach, you can develop complex variant condition expressions that are reusable.

Simulink.Parameter Objects or MATLAB variables for Code Generation

If you intend to generate code for a model containing variant choices, specify variant control variables as MATLAB variables or `Simulink.Parameter` objects. `Simulink.Parameter` objects allow you to specify other attributes (such as data type) that are required for generating code.

```
VSSMODE = Simulink.Parameter;
VSSMODE.Value = 1;
```

```
VSSMODE.DataType = 'int32';
VSSMODE.CoderInfo.StorageClass = 'Custom';
VSSMODE.CoderInfo.CustomStorageClass = 'ImportedDefine';
VSSMODE.CoderInfo.CustomAttributes.HeaderFile = ...
'rtwdemo_importedmacros.h';
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes:

- Define or ImportedDefine with header file specified
- CompilerFlag
- SystemConstant (AUTOSAR)
- Your own custom storage class that defines data as a macro

You can also convert a scalar variant control variable into a `Simulink.Parameter` object. See “Convert Variant Control Variables into Simulink.Parameter Objects” on page 11-61.

Enumerated Types for Improving Code Readability

Use enumerated types to give meaningful names to integers used as variant control values.

- 1 In the MATLAB Editor, define the classes that map enumerated values to meaningful names.

```
classdef sldemo_mrv_CONTROLLER_TYPE < Simulink.IntEnumType
    enumeration
        NONLINEAR (1)
        SECOND_ORDER (2)
    end
end

classdef sldemo_mrv_BUILD_TYPE < Simulink.IntEnumType
    enumeration
        PROTOTYPE (1)
        PRODUCTION (2)
    end
end
```

- 2 Define `Simulink.Variant` objects for these classes in the global workspace.

```
VE_NONLINEAR_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.NONLINEAR')
```

```

VE_SECOND_ORDER_CONTROLLER =Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.SECOND_ORDER')
VE_PROTOTYPE =Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PROTOTYPE')
VE_PRODUCTION =Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PRODUCTION')
    
```

Using enumerated types simplifies the generated code because it contains the names of the values rather than integers.

Viewing Variant Conditions

The **Variant Condition Legend** helps you visualize the variant conditions associated with a model. To view the **Variant Condition Legend**, click **Display > Blocks > Variant Condition Legend**.

Note The **Variant Condition Legend** is available only when **Display > Blocks > Variant Condition** is active.

Annotation	Simulation	Code Generation
v:0	V == 1	V == 1
v:1	V == 1	<i>unconditional</i>
v:2	V == 2	V == 2
v:3	V == 2	false
v:4	V == 3	V == 3
v:5	V == 3	false
v:6	V == 4	false
v:7	false	false

By default, the **Variant Condition Legend** displays the variant condition annotation and the variant condition during simulation. To view the variant condition in the generated code, select the **Show generated code conditions** option on the **Variant Condition Legend**.

In the **Variant Condition Legend**, the variant conditions on the blocks are annotated as $v : c$, where v is the variant semantic indicator and c represents the variant condition index. You can click through the hyperlinked variant annotations to observe which parts of the model the condition corresponds to.

When you hover over a block that has a variant condition, the tooltip displays the variant annotation and the related variant condition for the block. To view the variant condition annotation tooltip, the **Variant Condition** option must be selected.

To view the **Variant Condition Legend** programmatically, use the `Simulink.VariantManager.VariantLegend` function in the MATLAB command window.

Operators and Operands in Variant Condition Expressions

Simulink evaluates condition expressions within variant controls to determine the active variant choice. You can include the following operands in a condition expression:

- Scalar variables
- `Simulink.Parameter` objects that are not structures and that have data types other than `Simulink.Bus` objects
- Enumerated types
- Parentheses for grouping

Variant condition expressions can contain MATLAB operators, provided the expression evaluates to a boolean value. In these examples, A and B are expressions that evaluate to an integer, and x is a constant integer literal.

MATLAB Expressions That Support Generation of Preprocessor Conditionals	Equivalent Expression in C Preprocessor Conditional
Arithmetic	
<ul style="list-style-type: none"> • $A + B$ • $+A$ 	<ul style="list-style-type: none"> • $A + B$ • A
<ul style="list-style-type: none"> • $A - B$ • $-A$ 	<ul style="list-style-type: none"> • $A - B$ • $-A$
$A * B$	$A * B$

MATLAB Expressions That Support Generation of Preprocessor Conditionals	Equivalent Expression in C Preprocessor Conditional
<code>idivide(A,B)</code>	<code>A / B</code> If the value of the second operand (B) is 0, the behavior is undefined.
<code>rem(A,B)</code>	<code>A % B</code> If the value of the second operand (B) is 0, the behavior is undefined.
Relational	
<code>A == B</code>	<code>A == B</code>
<code>A ~= B</code>	<code>A != B</code>
<code>A < B</code>	<code>A < B</code>
<code>A > B</code>	<code>A > B</code>
<code>A <= B</code>	<code>A <= B</code>
<code>A >= B</code>	<code>A >= B</code>
Logical	
<code>~A</code>	<code>!A</code> , where A is not an integer
<code>A && B</code>	<code>A && B</code>
<code>A B</code>	<code>A B</code>
Bitwise (A and B cannot both be constant integer literals)	
<code>bitand(A,B)</code>	<code>A & B</code>
<code>bitor(A,B)</code>	<code>A B</code>
<code>bitxor(A,B)</code>	<code>A ^ B</code>
<code>bitcmp(A)</code>	<code>~A</code>
<code>bitshift(A,x)</code>	<code>A << x</code>
<code>bitshift(A,-x)</code>	<code>A >> x</code>

More About

- “Create a Simple Variant Model” on page 11-44

Create a Simple Variant Model

- 1 Create a model that contains variant blocks. For example, see “Variant Subsystems” on page 11-155 that contains a Variant Subsystem block (Controller).

Components of 'Controller' block

- 2 Define variant control variables that determine the condition under which a variant choice is active.
 - a Right-click the variant block and click **Block Parameters**. The Block Parameters dialog box for the variant block opens.
 - b To choose the active Variant based on the evaluation of the Variant conditions, use the Expression mode else select Label mode. When you select the **Variant control mode** as Label, the **Label mode active choice** option is available. In Label mode, Variant control need not be created in the global workspace. You can select an active Variant choice from **Label mode active choice** options.
 - c Use the options available on the Block Parameter dialog box to add variant controls and its corresponding variant condition.

A sample screenshot for Expression mode:

A sample screenshot for Label mode:

Note The variables used to specify the variant control and variant condition must be defined in the global workspace or data dictionary for the model.

- 3 Specify a default variant condition to be used when there is no active variant choice. Use the **Variant control** dropdown menu to specify the default.

Variant choices (table of variant systems)

	Name (read-only)	Variant control	Condition (read-only)
	Linear Controller	VSS_LINEAR_CONTROLLER	VSS_MODE==1
	Nonlinear Controller	VSS_NONLINEAR_CONTROLLER	VSS_MODE==2
		VSS_NONLINEAR_CONTROLLER (default)	

- 4 To activate a variant choice, type the variant choice in MATLAB command window. For example, type `VSS_MODE = 2`.
- 5 To simulate the model, click **Simulation > Run**. The model simulates for the specified active choice.
- 6 Modify the active choice and simulate the model again, if necessary.
- 7 Generate code for the variants model with preprocessor conditionals.

Note You must have an Embedded Coder license to generate code.

- a In the Block Parameters dialog box, select the **Analyze all choices during update diagram and generate preprocessor conditionals** check box.
 - b Open the Subsystem Block Parameters dialog boxes. Select the **Treat as atomic unit** parameter.
 - c In the **Code Generation** section of Configuration Parameters dialog box, specify the **System target file** as `ert.tlc`.
 - d In Model Explorer, define the variables used to specify the variant choice as a MATLAB variable or as a `Simulink.Parameter`. The data type of the `Simulink.Parameter` can be of type Integer, Boolean, or Enumerated and the storage class can be either `importedDefine(Custom)`, `Define(Custom)`, or `CompilerFlag`.
- 8 For the variants that are defined in the global workspace, export the control variables to a MAT-file. For example, type the following in the MATLAB command window:
 - a `save <MAT-File Name> <Variable Name>`
 - b `PostLoadCallback > load <MAT-File Name>`

Note To update or refresh active models that contain Variant Subsystem blocks, click **Diagram > Refresh Blocks** (Ctrl + K) or **Simulink > Update Diagram** (Ctrl + D) in Simulink.

Create Variant Controls Programmatically

In this section...

“Create and Export Variant Controls” on page 11-49

“Reuse Variant Conditions” on page 11-49

“Enumerated Types as Variant Controls” on page 11-50

Create and Export Variant Controls

Create control variables, define variant conditions, and export control variables.

- 1 Create control variables in the global workspace or a data dictionary.

```
FUEL=2;  
EMIS=1;
```

- 2 Use the control variables to define the control condition using a `Simulink.Variant` object.

```
LinearController=Simulink.Variant('FUEL==2 && EMIS==1');
```

Note Before each simulation, define `Simulink.Variant` objects representing the variant conditions.

- 3 If you saved the variables in the global workspace, select the control variables to export. Right-click and click **Save As** to specify the name of a MAT-file.

Reuse Variant Conditions

If you want to reuse common variant conditions across models, specify variant control conditions using `Simulink.Variant` objects.

Reuse `Simulink.Variant` objects to change the model hierarchy dynamically to reflect variant conditions by changing the values of the control variables that define the condition expression.

The example model `AutoSSVar` shows the use of `Simulink.Variant` objects to define variant control conditions.

Note You must use `Simulink.Variant` objects to define variant control conditions for AUTOSAR workflows.

Enumerated Types as Variant Controls

Use enumerated types to give meaningful names to integers used as variant control values.

- 1 In the MATLAB Editor, define the classes that map enumerated values to meaningful names.

```
classdef sldemo_mrv_CONTROLLER_TYPE < Simulink.IntEnumType
    enumeration
        NONLINEAR (1)
        SECOND_ORDER (2)
    end
end
```

```
classdef sldemo_mrv_BUILD_TYPE < Simulink.IntEnumType
    enumeration
        PROTOTYPE (1)
        PRODUCTION (2)
    end
end
```

- 2 Define `Simulink.Variant` objects for these classes in the global workspace.

```
VE_NONLINEAR_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.NONLINEAR')
VE_SECOND_ORDER_CONTROLLER = Simulink.Variant...
('E_CTRL==sldemo_mrv_CONTROLLER_TYPE.SECOND_ORDER')
VE_PROTOTYPE = Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PROTOTYPE')
VE_PRODUCTION = Simulink.Variant...
('E_CURRENT_BUILD==sldemo_mrv_BUILD_TYPE.PRODUCTION')
```

Using enumerated types simplifies the generated code because it contains the names of the values rather than integers.

Define, Configure, and Activate Variants

In this section...

“Represent Variant Choices” on page 11-52

“Include Simulink Model as Variant Choice” on page 11-56

“Configure Variant Controls” on page 11-58

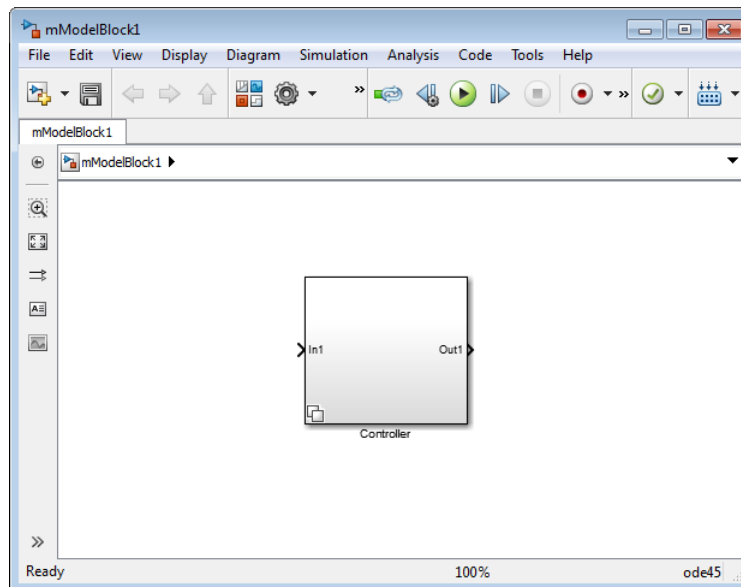

“Convert to Variants” on page 11-59

Represent Variant Choices

Variant choices are two or more configurations of a component in your model. This example shows how to represent variant choices inside a Variant Subsystem block in your model. For other ways to represent design variants, see “Options for Representing Variants in Simulink” on page 11-7.

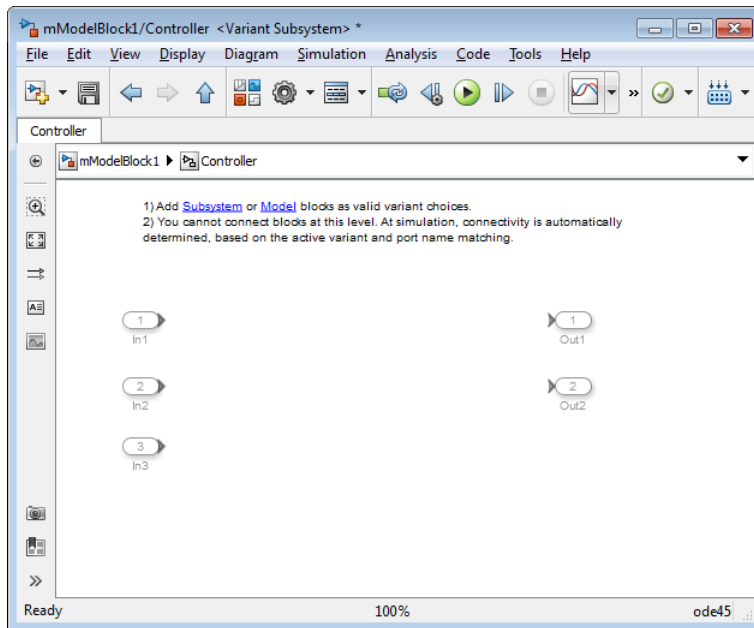

- 1 Add a Variant Subsystem block to your model and name it.

This block serves as the container for the variant choices.

- 2 Double-click the Variant Subsystem block. Add inport and output blocks so that they match the inputs into and outputs from this block.

Note You can add only Inport, Outport, Subsystem, and Model blocks inside a Variant Subsystem block. You can pass control signals through data ports.

- 3 Right-click the badge on the Variant Subsystem block and select **Block Parameters (Subsystem)**.
- 4 In the block parameters dialog box, click the  button for each variant subsystem choice you want to add.

Simulink creates empty Subsystem blocks inside the Variant Subsystem block. The new blocks have the same number of inports and outports as the containing Variant Subsystem block.

Tip (If your variant choices have different numbers of inports and outports, see “Mapping Inports and Outports of Variant Choices” on page 11-8.)

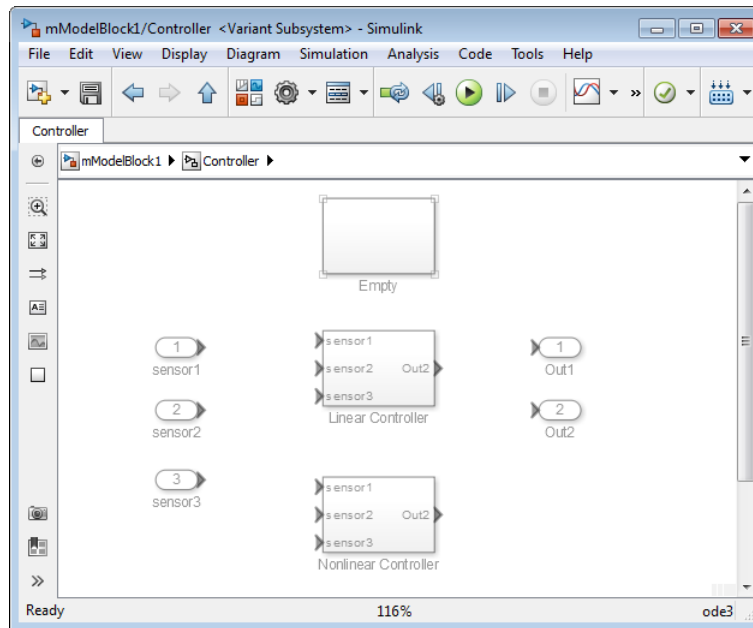

- 5 Open each Subsystem block and create the model that represents a variant choice.

- 6 When you are prototyping variants, you can create empty Subsystem blocks with no inputs or outputs inside the Variant Subsystem block. The empty subsystem recreates the situation in which a subsystem is inactive without the need for completely modeling the variant. For an empty variant choice, either specify a variant activation condition or comment out the variant condition by placing a % symbol before the condition.

If the empty variant choice is active during compilation, Simulink ignores it.

Include Simulink Model as Variant Choice

You can include a Simulink model as a variant choice inside a Variant Subsystem block.

- 1 Create a model that you want to include as a variant choice. Make sure that it has the same number of inports and outports as the containing Variant Subsystem block.

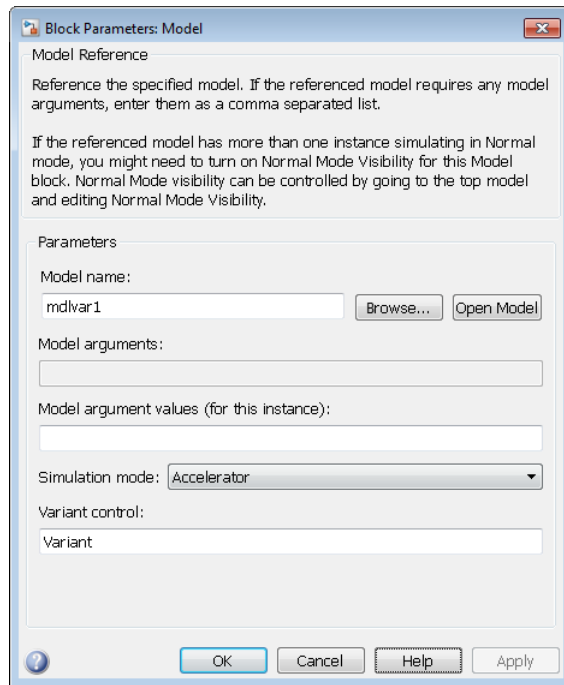

Note If your model has different numbers of inports and outports, see “Mapping Inports and Outports of Variant Choices” on page 11-8.

- 2 In your model, right-click the Variant Subsystem block that contains variant choices and select **Block Parameters (Subsystem)**.
- 3 In the block parameters dialog box, click the  button to add a Model block as variant choice.

Simulink creates an unresolved model reference block in the Variant Subsystem block.

- 4 Double-click the unresolved model block. In the **Model name** box, enter the name of the model you want to use as a model variant choice and click **OK**.

Configure Variant Controls

You can specify the conditions for activating a variant choice using variant controls. You can also specify at most one variant choice as the default.

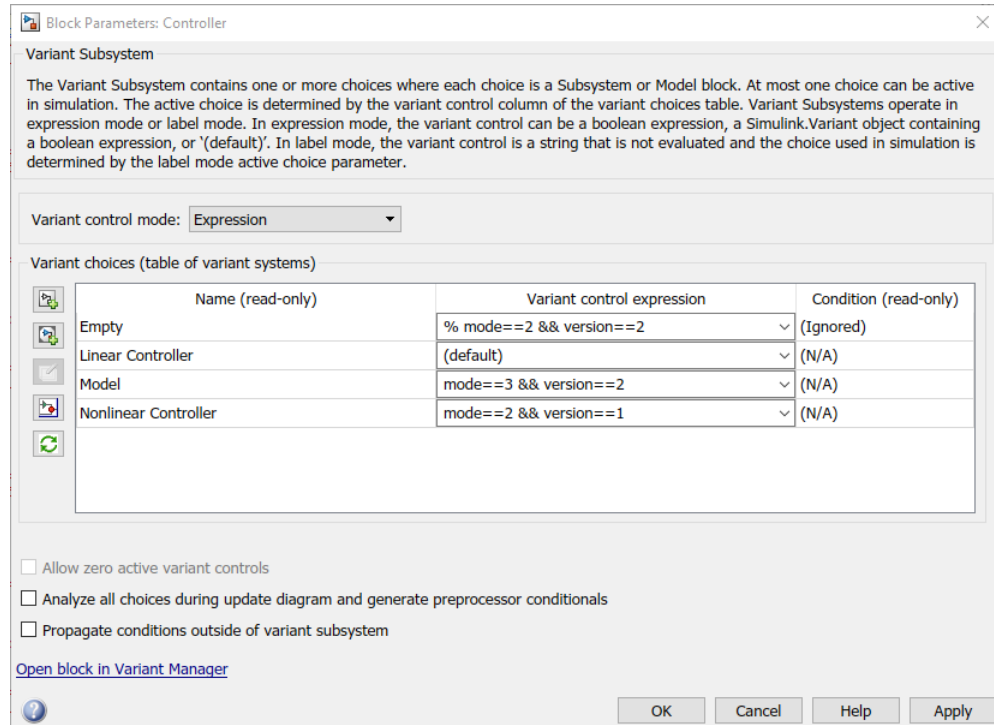

- 1 At the MATLAB command prompt, specify the control variables that create an activation condition when combined.

```
mode = 3;  
version = 2;
```

- 2 Right-click the Variant Subsystem block that is the container for variant choices in your model and select **Block Parameters (Subsystem)**.
- 3 In the block parameters dialog box, in the **Variant control** column, select (default) next to one of the choices.

Simulink verifies that only one variant choice is active for simulation. If **Allow zero active variant controls** is selected, you can have zero variant choice. When the

control condition does not activate a variant, Simulink uses the default variant for simulation and code generation.

- 4 Specify a variant condition each of the other choices. If you are using an empty variant choice, specify a variant condition for the choice. You can also comment out an existing activation condition by prefixing it with a % symbol.
- 5 Click **Apply**; otherwise, your changes are not saved.

Convert to Variants

In the Simulink Editor, you can convert these blocks to a Variant Subsystem block:

- Subsystem block
- Model block
- Variant Model block (for models created in versions earlier than R2017b)

- Conditionally executed subsystems

To do so, right-click the block, then in the context menu, click **Subsystem & Model Reference > Convert to > Variant Subsystem**.

You can also convert these block to Variant Subsystem block programmatically. To do so, use any of these syntaxes:

- `Simulink.VariantManager.convertToVariant(gcb)`
- `Simulink.VariantManager.convertToVariant(gcbh)`

For example,

```
open_system('sldemo_variant_subsystems');  
Simulink.VariantManager.convertToVariant('sldemo_variant_subsystems/Controller');
```

If you convert variant models to variant subsystem, note that the behavior of the Model block parameter **Generate preprocessor conditionals** is different than the Variant Subsystem block parameter **Analyze all choices during update diagram and generate preprocessor conditionals**. For variant models, enabling the parameter causes simulation and update diagram to compile the active variant only. For variant subsystem, enabling the parameter compiles all the variants, which can make simulation and updates slower.

Converting variant models to variant subsystems can require that you update scripts that use the `Variants` command-line parameter.

Prepare Variant-Containing Model for Code Generation

In this section...

“Convert Variant Control Variables into Simulink.Parameter Objects” on page 11-61

“Configure Model for Generating Preprocessor Conditionals” on page 11-63

Using Embedded Coder, you can generate code from Simulink models containing one or more variant choices. The generated code contains preprocessor conditionals that control the activation of each variant choice.

Note Simulink supports using multi-instance referenced models with variant Simulink Functions for code generation.

For information on using `STF_make_rtw_hook` file to customize build process, see “Customize Build Process with `STF_make_rtw_hook` File” (Simulink Coder)

Convert Variant Control Variables into Simulink.Parameter Objects

MATLAB variables allow you to rapidly prototype variant control expressions when you are building your model and generate preprocessor conditionals for code generation. However, if you want to specify other code generation attributes (such as data type), you can convert MATLAB variables into `Simulink.Parameter` objects.

- 1 Specify the model in which you want to replace MATLAB variant control variables with `Simulink.Parameter` objects.

```
model = 'my_model_containing_variant_choices';
open_system(model);
```

- 2 Get the variables that are referenced in variant control expressions.

```
vars = Simulink.VariantManager.findVariantControlVars(model)
```

```
vars =
```

```
4x1 struct array with fields:
```

```
    Name
```

```
Value
Exists
Source
SourceType
```

- 3 Create an external header file for specifying variant control values so that the variable definitions are imported when the code runs.

```
headerFileName = [model '_importedDefines.h'];
headerPreamble = strep(upper(headerFileName), '.', '_');

fid = fopen(headerFileName, 'w+');
fidErr = (fid == -1);
if (fidErr)
    fprintf('There was an error creating header file %s:...
\n', headerFileName);
else
    fprintf('+++ Creating header file ''%s'' with variant control...
variable definitions.\n\n', headerFileName);
    fprintf(fid, '#ifndef %s\n', headerPreamble);
    fprintf(fid, '#define %s\n', headerPreamble);
end
```

Variant control variables defined as `Simulink.Parameter` objects can have one of these storage classes.

- Define or ImportedDefine with header file specified
 - CompilerFlag
 - SystemConstant (AUTOSAR)
 - Your own custom storage class that defines data as a macro
- 4 Loop through all the MATLAB variables to convert them into `Simulink.Parameter` objects.

```
count = 0;
for countVars = 1:length(vars)
    var = vars(countVars).Name;
    val = vars(countVars).Value;
    if isa(val, 'Simulink.Parameter')
        % Do nothing
        continue;
    end
    count = count+1;

% Create and configure Simulink.Parameter objects
```

```
% corresponding to the control variable names.
% Specify the custom storage class as Define (Custom).
newVal = Simulink.Parameter(val);
newVal.DataType = 'int16';
newVal.CoderInfo.StorageClass = 'Custom';
newVal.CoderInfo.CustomStorageClass = 'Define (Custom)';
newVal.CoderInfo.CustomAttributes.HeaderFile = headerFileName;

    Simulink.data.assigninGlobal(model, var, newVal);

    if ~fidErr
        fprintf(fid, '#endif\n');
        fclose(fid);
    end
end
```

Note The header file can be empty for the Define custom storage class.

Configure Model for Generating Preprocessor Conditionals

If you represent variant choices inside a Variant Subsystem block or a Variant Model block, code generated for each variant choice is enclosed within C preprocessor conditionals `#if`, `#else`, `#elif`, and `#endif`.

If you represent variant choices using a Variant Source block or a Variant Sink block, code generated for each variant choice is enclosed within C preprocessor conditionals `#if` and `#endif`.

Therefore, the active variant is selected at compile time and the preprocessor conditionals determine which sections of the code to execute.

Note You must have an Embedded Coder® license to generate code.

- 1 In the Simulink editor, select **Simulation > Model Configuration Parameters**.
- 2 Select the **Code Generation** pane, and set **System target file** to `ert.tlc`.
- 3 In the **Report** pane, select **Create code generation report**.

Note In the **Code Placement** pane, if Compact option is selected from **File packaging format** drop-down list, `model_types.h` file is not generated and contents of `model_types.h` file are moved to `model.h` file.

- 4 Select the **Code Generation** pane, and clear **Ignore custom storage classes** and **Apply**.
- 5 In your model, right-click the block containing the variant choices (Variant Subsystem, Variant Source, Variant Sink, or Variant Model) and select **Block Parameters**.
- 6 Ensure that Expression (default option) is selected for **Variant control mode** parameter .
- 7 Select the option **Analyze all choices during update diagram and generate preprocessor conditionals**.

Simulink analyzes all variant choices during an update diagram or simulation. This analysis provides early validation of the code generation readiness for all variant choices.

- 8 Build the model.

Visualize Variant Implementations in a Single Layer

Simulink provides two blocks that you can use to propagate conditions throughout the model and visualize all possible implementations of variant choices in a model. These blocks are called Variant Source and Variant Sink.

When you compile the model, Simulink determines which variant control evaluates to true. Simulink then deactivates blocks that are not tied to the variant control being true and visualizes the active connections.

How Variant Sources and Sinks Work

The Variant Source block has one or more input ports and one output port. You can define variant choices as blocks that are connected to the input port so that, at most, one choice is active. The active choice is connected directly to the output port of the Variant Source and the inactive choices are eliminated during simulation.

The Variant Sink block has one input port and one or more output ports. You can define variant choices as blocks that are connected to the output port so that, at most, one choice is active. The active choice is connected directly to the input port of the Variant Sink, and the inactive choices are eliminated during simulation.

Variant Conditions Legend: iv_01_basic

Show generated code conditions

Annotation	Simulation	Code Generation
v:0	V == 1	V == 1
v:1	V == 1	<i>unconditional</i>
v:2	V == 2	V == 2
v:3	V == 2	false
v:4	W == 1	W == 1
v:5	W == 1	<i>unconditional</i>
v:6	W == 2	W == 2
v:7	W == 2	false

Print Help

Connect one or more blocks to the input port of the Variant Source block or the output port of the Variant Sink block. Then, you define variant controls for each variant choice entering the Variant Source block and exiting the Variant Sink block. For more information, see “Variant Condition Propagation with Variant Sources and Sinks” on page 11-75.

Advantages of Using Variant Sources and Sinks

Using Variant Source and Variant Sink blocks in Model-Based Design provides these advantages:

- The blocks enable the propagation of variant conditions throughout the model and allow you to visualize variant choices in a single layer of your model.
- By visualizing all possible implementations of variant choices, you can improve the readability of your model.
- During model compilation, Simulink eliminates inactive blocks throughout the model, improving the runtime performance of your model.
- Variant sources and sinks provide variant component interfaces that you can use to quickly model variant choices.

Limitations of Using Variant Sources and Sinks

- Variant Source and Variant Sink blocks work with time-based, function-call, or action signals. You cannot use SimEvents, Simscape Multibody, or other non-time-based signals with these blocks.
- The code generation variant report does not contain Variant Source and Variant Sink blocks.

Define and Configure Variant Sources and Sinks

Simulink provides two blocks that you can use to visualize all possible implementations of variant choices in a model graphically. These blocks are called Variant Source and Variant Sink.

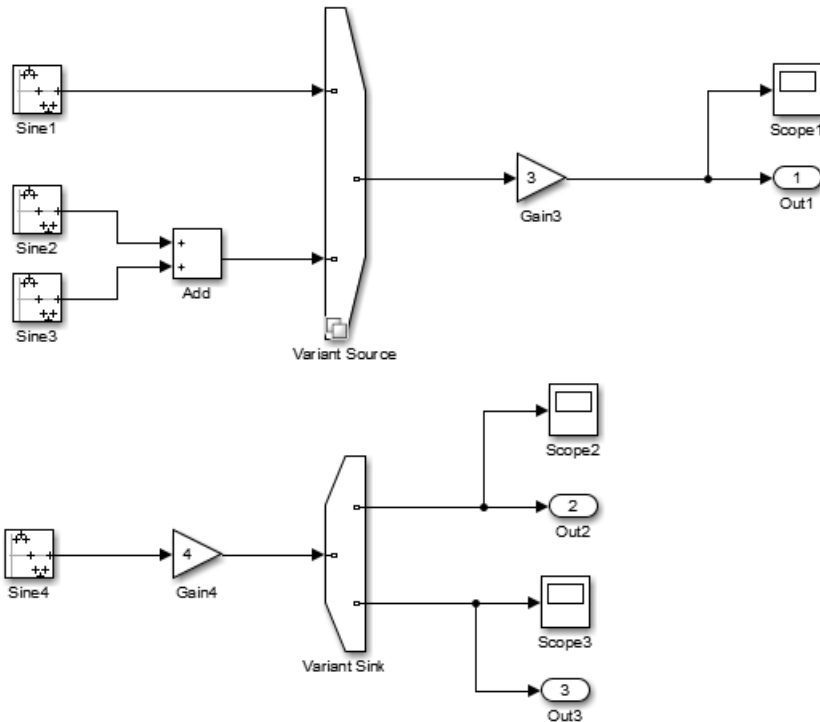

When you compile the model, Simulink determines which variant control evaluates to `true`. The active variant determination happens early stages of compilation. Simulink then deactivates blocks that are not tied to the variant control being `true` and visualizes the active connections.

- 1 Add Variant Source and Variant Sink blocks to your model.

These blocks enable ports that activate variant choices.

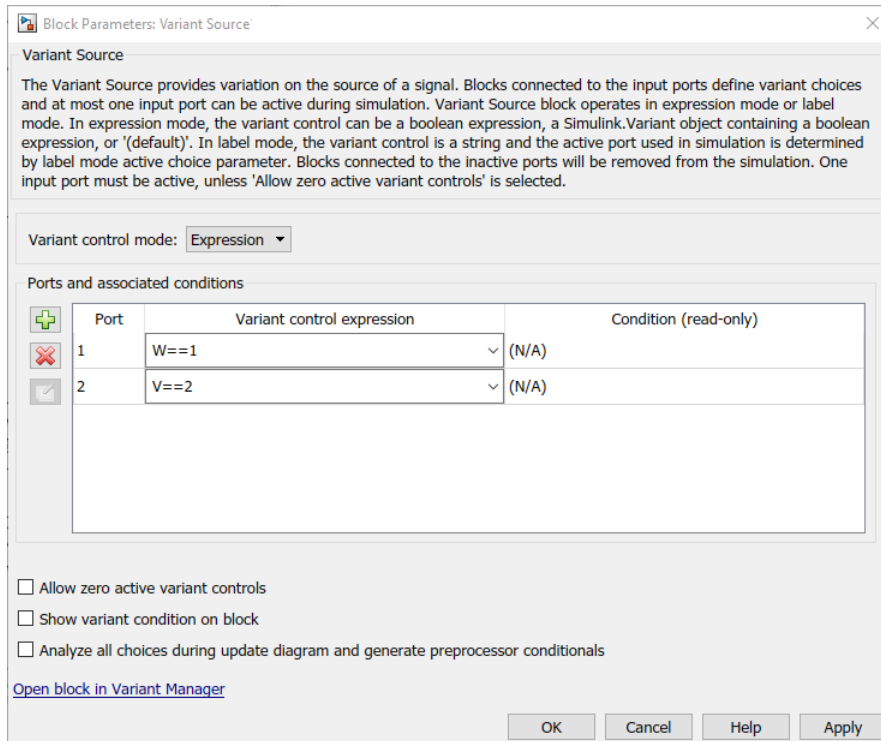

- 2 Using blocks from the Simulink Library Browser, create sources and sinks that represent variant choices. Connect choices to the input and output ports of the Variant Source and Variant Sink blocks.

- 3 At the MATLAB command prompt, specify the control variable that creates an activation condition for the variant source.

```
V = Simulink.Parameter(1);
```
- 4 Right-click the Variant Source block and select **Block Parameters (VariantSource)**.
- 5 In the block parameters dialog box, in the **Variant control** column, type $V==1$ next to one of the choices and $V==2$ next to the other. Click **Apply**; otherwise, your changes are not saved.

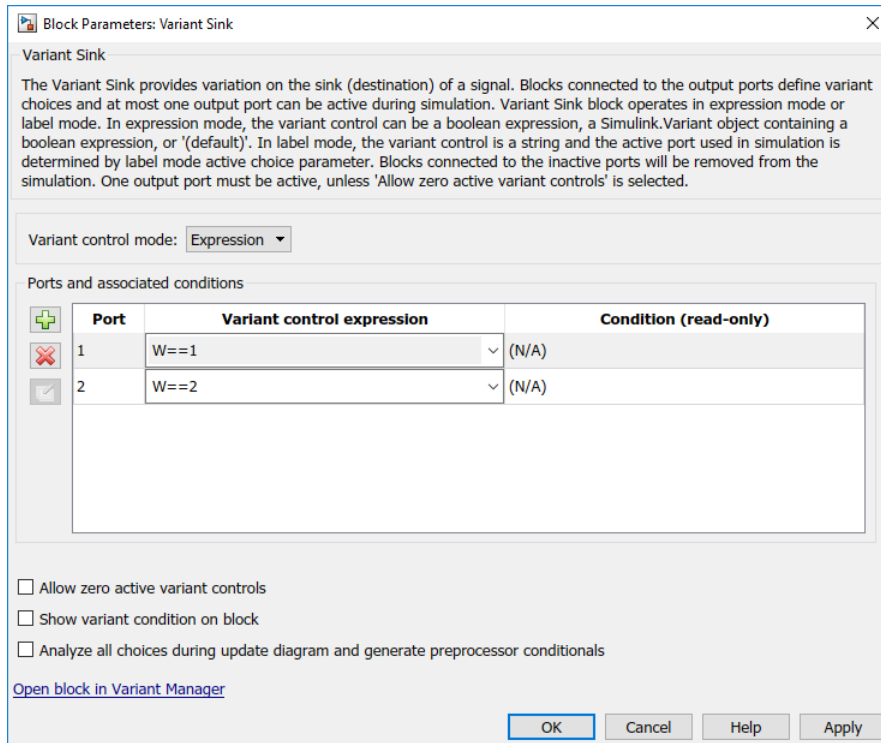

Simulink verifies that only one variant is active for simulation. When the control condition does not activate a variant, Simulink uses the default variant for simulation.

- 6 At the MATLAB command prompt, specify the control variable that creates an activation condition for the variant sink.

```
W = Simulink.Parameter(2);
```

- 7 Double-click the Variant Sink. In the block parameters dialog box, in the **Variant control** column, type **W==1** next to one of the choices and **W==2** next to the other.

- 8 Click **Apply**; otherwise, your changes are not saved.
- 9 Simulate the model. Simulink propagates the variant conditions to identify which model components to activate.

10 You can visualize the conditions that activate each variant choice by selecting **Display > Blocks > Variant Conditions**.

Variant Conditions Legend: iv_01_basic

Variant Condition Propagation with Variant Sources and Sinks

When you specify variant conditions in models containing Variant Source and Variant Sink blocks, Simulink propagates these conditions to determine which components of the model are active during simulation.

In this section...

“View Variant Condition Annotations” on page 11-75

“How Variant Condition Propagation Works” on page 11-77

“Condition Propagation with Subsystems” on page 11-80

“Condition Propagation with Other Simulink Blocks” on page 11-82

“Known Limitations” on page 11-86

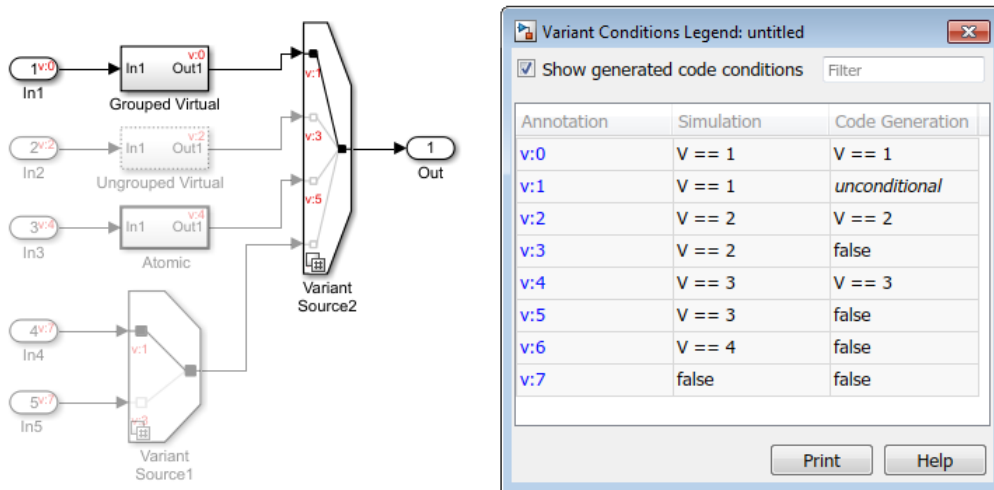

View Variant Condition Annotations

When you create a model that contains Variant Source or Variant Sink blocks, you can visualize the conditions that activate each variant choice. Simulink annotates these blocks in the model with their corresponding variant conditions.

Consider this model containing multiple variant choices feeding into Variant Source blocks. A specific variant condition activates each variant choice.

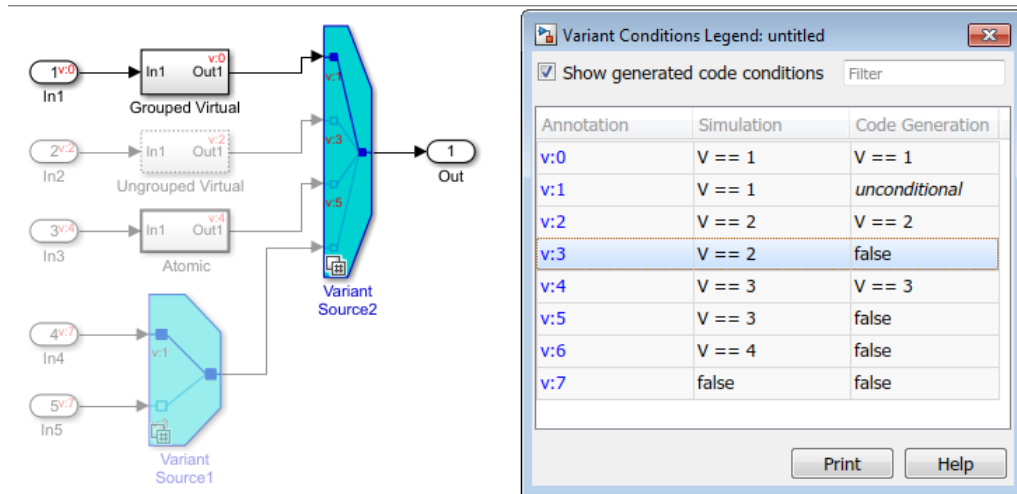

To visualize the variant conditions, select **Display > Blocks > Variant Conditions**.

The **Variant Condition Legend** dialog box appears. Variant conditions on blocks are annotated as $v:C$, where v is the variant semantic indicator and C represents the variant condition index. The dialog box also shows the expression associated with each condition.

In the **Variant Condition Legend** dialog box, you can click through the hyperlinked variant annotations to observe which parts of the model each condition activates. For example, if you click $v:3$, Simulink highlights the parts of the model that are activated when the condition $V==3$ evaluates to true.

Variant condition annotations have these properties:

- There are no annotations on unconditional blocks. Therefore, the Out block is not annotated.
- To reduce clutter, the legend only displays the final computed conditions. For example, if you enter a variant condition in a Variant Source block, that condition appears in the annotations only when you apply your changes.
- The conditions in the legend are sorted during display.
- In the legend, a condition is set to `false` if Simulink assesses that the blocks associated with that condition are never active.

For example, the In4 block is connected to the Variant Source1 block, whose condition is $V==1$. Variant Source1 is connected to the Variant Source2 block, which activates Variant Source1 only when $V==4$. Therefore, In4 can only be active when $V==1 \ \&\& \ V==4$, a condition that is always false.

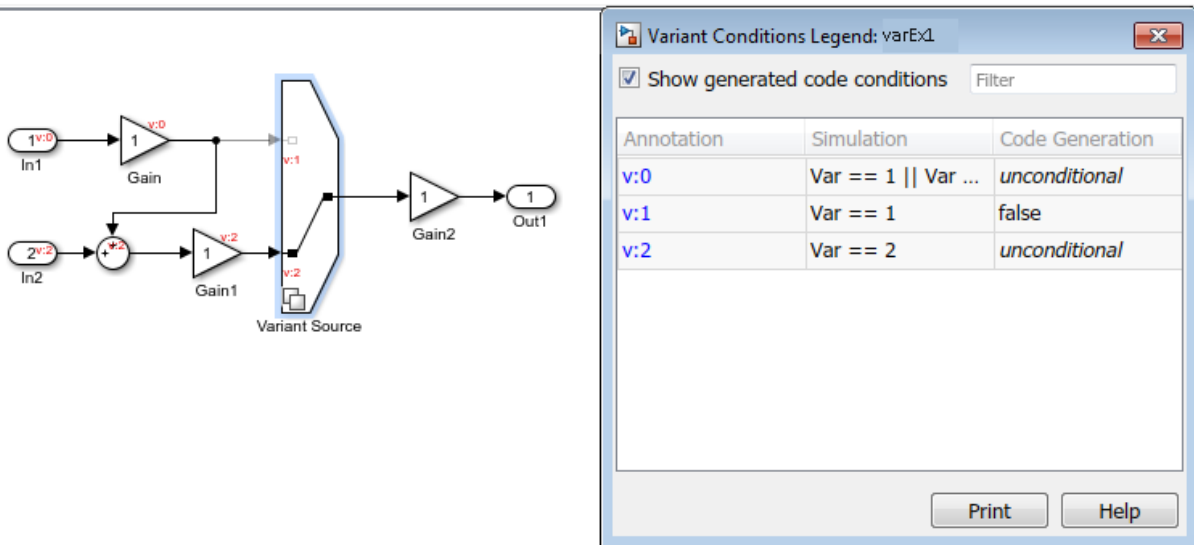

- In the legend, the (default) keyword is displayed as negated condition.

How Variant Condition Propagation Works

When you compile a model containing Variant Source or Variant Sink blocks, Simulink determines which variant control evaluates to `true`. The active variant determination happens in the early stage of compilation. Simulink then deactivates blocks that are not tied to the variant control being `true` and visualizes the active connections.

Cross-Coupling of Inputs and Outputs

In this model, two inputs feed the Variant Source block. The first input is active when $\text{Var} == 1$, and it branches into the second input before connecting to the Variant Source block. The second input is the default variant choice.

During simulation, this model exhibits three modes of operation:

- When $\text{Var} == 1$, the first input is active and its branch into the second input is inactive.
- When $\text{Var} == 1 \ || \ \text{Var} == 2$, the second input is active and the branch of the first input is active.
- When $\text{Var} == 2$, the second input is active and the output is active.

Cascading Blocks and Compounding Conditions

In this model, two Variant Source blocks, each fed by two input ports, are connected in a cascading manner. The inputs to Variant Source are active when $\text{Var1} == 1$ or $\text{Var1} == 2$. The output of Variant Source branches into one of the inputs of Variant Source1. The inputs to Variant Source1 are active when $\text{Var2} == 1$ or $\text{Var2} == 2$.

During simulation, this model exhibits eight modes of operation:

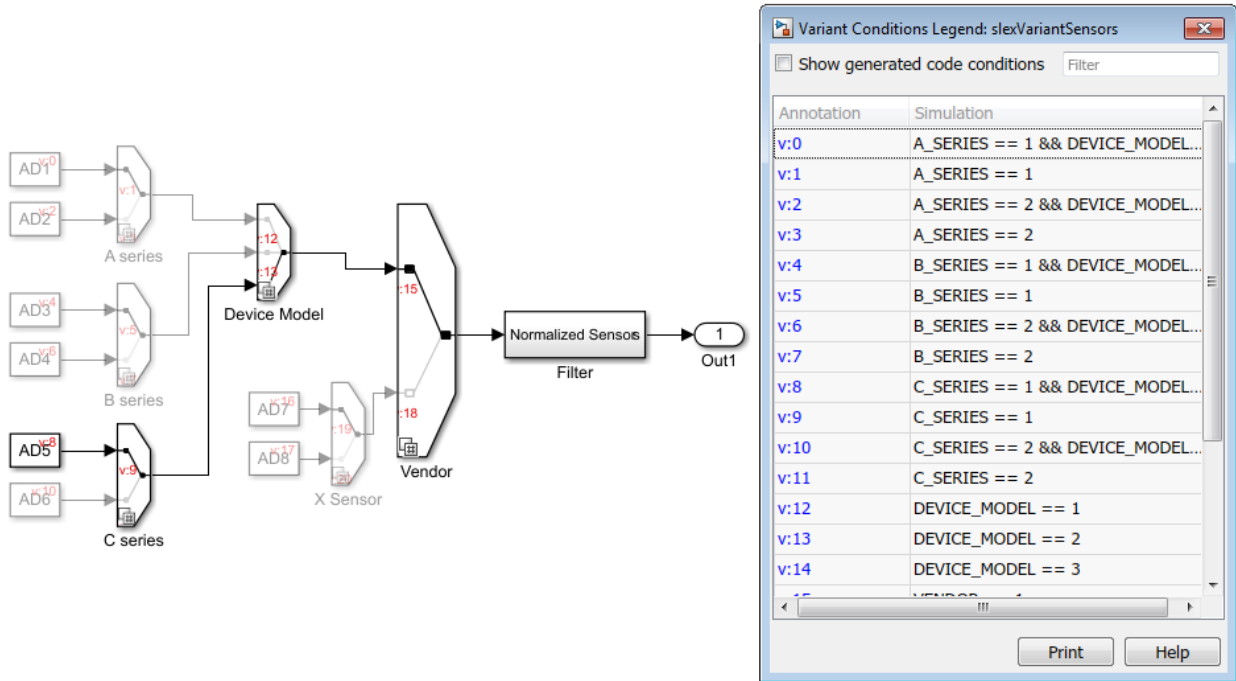

- When $\text{Var1} == 1$ && $\text{Var2} == 1$, the first inputs of Variant Source and Variant Source1 are active.
- When $\text{Var1} == 1$ && $\text{Var2} == 2$, the first input of Variant Source and the second input of Variant Source1 are active.
- When $\text{Var1} == 2$ && $\text{Var2} == 1$, the second input of Variant Source and the first input of Variant Source1 are active.
- When $\text{Var1} == 2$ && $\text{Var2} == 2$, the second inputs of Variant Source and Variant Source1 are active.
- When $\text{Var1} == 1$ && $\text{Var2} != (1,2)$, only the first input of Variant Source is active.
- When $\text{Var1} == 2$ && $\text{Var2} != (1,2)$, only the second input of Variant Source is active.
- When $\text{Var1} != (1,2)$ && $\text{Var2} == 1$, none of the inputs or outputs is active.
- When $\text{Var1} != (1,2)$ && $\text{Var2} == 2$, only the second input of Variant Source1 is active.
- When $\text{Var1} != (1,2)$ && $\text{Var2} != (1,2)$, none of the inputs or outputs is active.

Hierarchical Nesting of Sources or Sinks

In this model, multiple Variant Source blocks are used to create hierarchical nesting of variant choices. Choices are first grouped by series: A Series, B Series, and C

Series. A combination of one or more series is provided as input for a device model. The resulting device model is provided as input to the vendor by including or excluding a sensor selection.

Simulink propagates complex variant control conditions to determine which model components are active during compilation.

For more information, see Variant Sensors.

Condition Propagation with Subsystems

A subsystem can either be a virtual (grouped or ungrouped) or an atomic subsystem depending on the selections made in its **Block Parameters** dialog box. For,

- Grouped Virtual: Select the **Treat as grouped when propagating variant conditions** check box. A grouped virtual subsystem has a continuous line.
- Ungrouped Virtual: Clear the **Treat as grouped when propagating variant conditions** check box. An ungrouped virtual subsystem has a dotted line.

- Atomic: Select the **Treat as atomic unit** check box. An atomic virtual subsystem has a solid line.

Simulink propagates variant conditions differently to these Subsystem types.

In this model, three types of subsystems are provided as input to the block `Variant Source2`.

- The grouped virtual subsystem is activated when $V == 1$. Simulink propagates the variant activation condition to all the blocks in the subsystem.
- The ungrouped virtual subsystem is activated when $V == 2$. Simulink propagates the variant activation condition to the blocks that were available in the subsystem while marking the subsystem virtual.
- The atomic subsystem is activated when $V == 3$. Simulink does not propagate the variant activation condition into this subsystem.

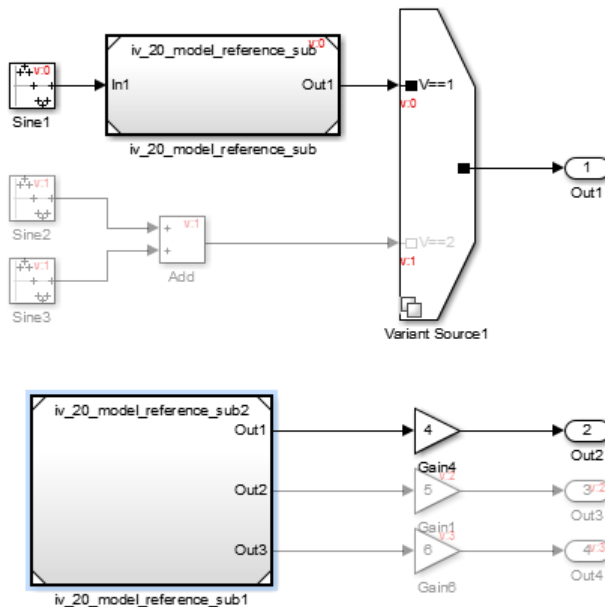

For more information, see “Propagating Variant Conditions to Subsystems” on page 11-150.

Condition Propagation with Other Simulink Blocks

Variant Condition Propagation with Model Block

Simulink compiles referenced models before propagating variant conditions. A variant condition can activate or deactivate a Model block, but variant conditions cannot propagate into the referenced model. A Model block can propagate variant conditions from its interface (inport, outport, or control port), if that variant condition originates at a port inside the model.

In this example, variant condition $V==1$ activates the model block `iv_20_model_reference_sub`. However, the condition does not propagate into the model referenced by the block. Model block `iv_20_model_reference_sub2` propagates the same variant condition from its output port.

Variant Condition Propagation with Simulink Function block

Argument Inport and Argument Outport blocks interfacing with Simulink Function blocks cannot be connected to Variant Source or Variant Sink blocks. One variant condition must control the entire Simulink Function.

Consider the model `slexVariantSimulinkFunction`.

In this example, the function-call port block within the Simulink Function block has the **Enable variant condition** option selected. The (`inherit`) keyword is used to specify the value for the **Variant control** parameter. As a result, the Simulink Function block inherits the variant condition from the corresponding Function Caller blocks in the model. The **Generate preprocessor conditionals** parameter value is also inherited.

Note Use the Configure C Step Function Interface dialog box to customize the generated C entry-point step function interface for a model. If the inport and the outport share an argument name and have propagated variant conditions, this level of interface control is not supported.

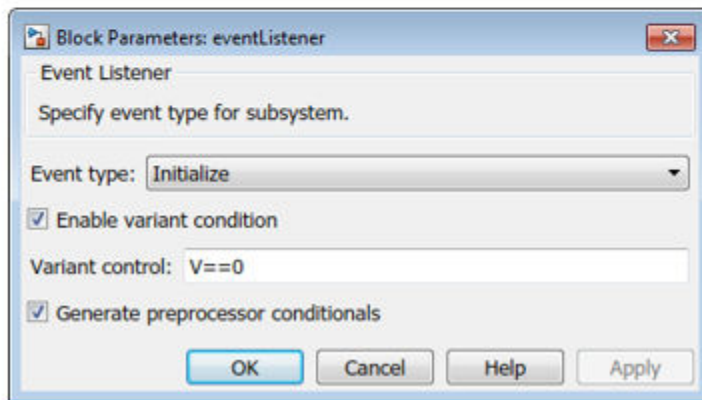

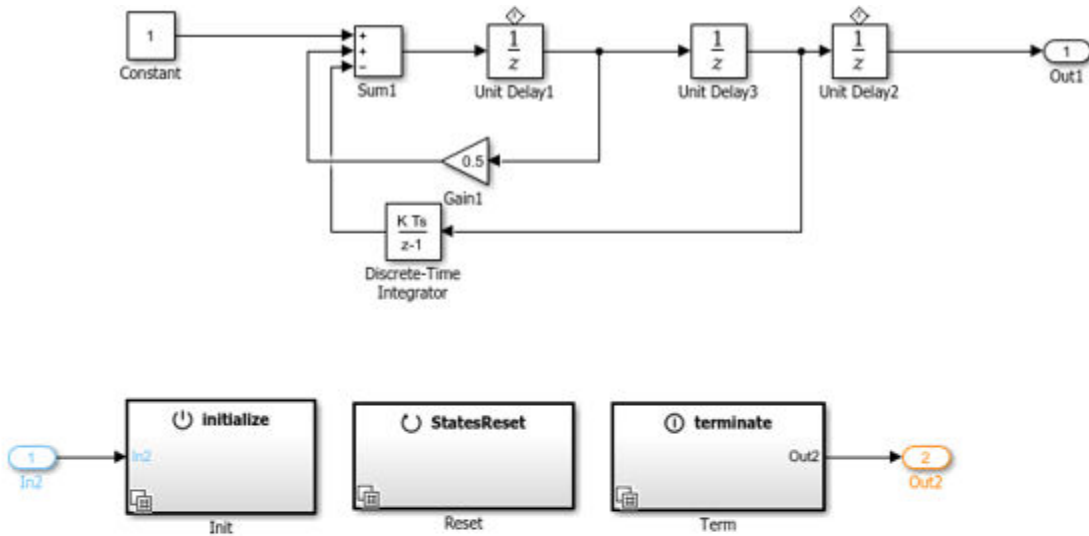

Variant Condition Propagation with Initialize, Reset, and Terminate Blocks

The Initialize, Reset, and Terminate function blocks are pre-configured subsystem blocks that execute during model initialize, reset, and terminate events. Similar to a Simulink Function block these blocks support variant condition propagation. You can propagate Variant conditions in Model blocks that have Reset Event ports. This results in optimized existence of blocks connected to the Reset Event ports. Models with inactive Variant Reset Event functions (in reference models) also supports Variant condition propagation.

Note

- Initialize and Terminate event ports are always unconditional because they control both the model default and block-specific initialize and terminate events of the referenced model. If you define an Initialize function block in the referenced model, it corresponds to an explicit initialize event.
-

In this example, the Event Listener block within the Init, Reset, and Term blocks have the **Enable variant condition** option selected. The **Variant control** parameter of the Event Listener block is specified as $V==0$. If you change the value of V to any value other than 0, the Init, Reset, and Term blocks become inactive.

Variant Condition Propagation with Subsystem Block

A variant condition can activate or deactivate a Subsystem block, but variant conditions cannot propagate into the subsystem. A Subsystem block can propagate variant conditions from its output port if that variant condition originates at a port inside the subsystem.

For more information, see “Propagating Variant Conditions to Subsystems” on page 11-150.

Variant Condition Propagation with Bus

A Variant Source block can accept either virtual or nonvirtual bus inputs. When generating code with preprocessor conditionals, the bus types and hierarchies of all bus inputs must be the same.

However, all elements of a Mux, Demux, or a Vector Concatenate block signal must have the same variant condition.

For more information, see “Variant Condition Propagation with Bus” on page 11-131.

Known Limitations

- Variant condition propagation from Simulink Function inside Stateflow block is not supported.
- When you simulate an Inline variants model with Simscape blocks, the Simscape blocks become unconditional.
- C++ code generation is not supported for models that contain propagated variant conditions.
- Variant condition propagation is not supported with root bus element ports.

Create and Validate Variant Configurations

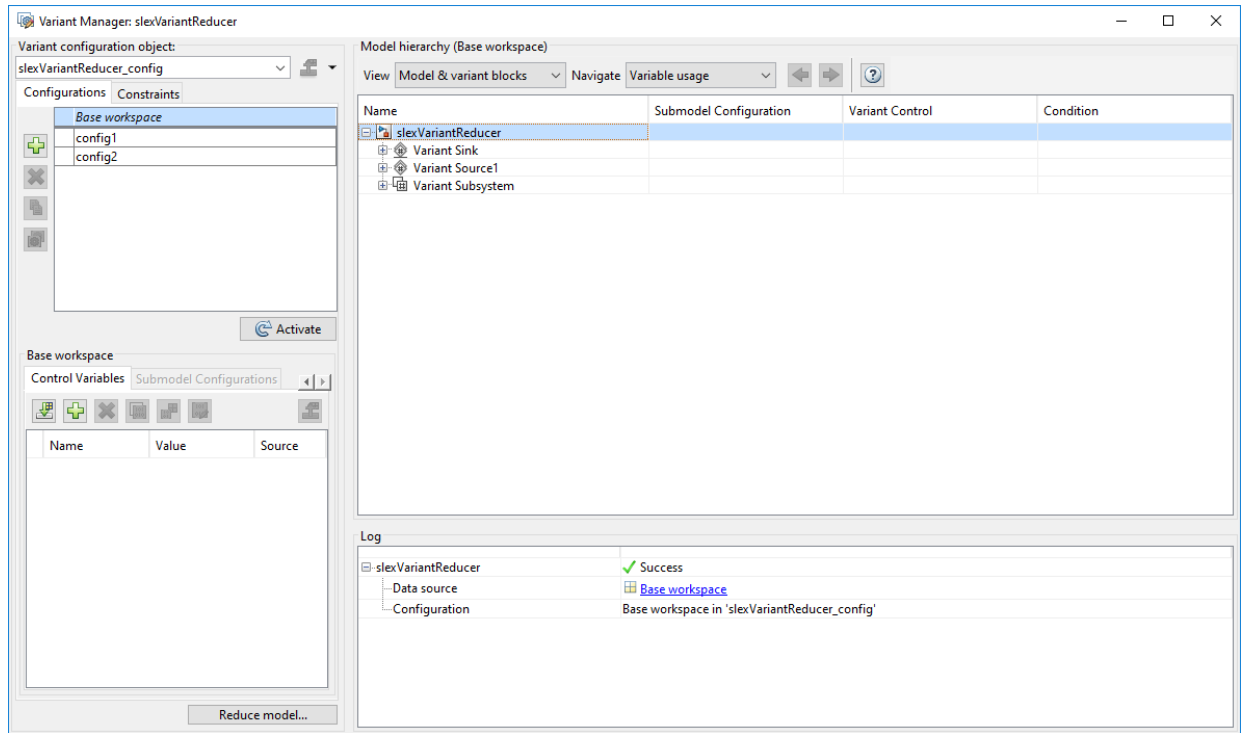

This example shows how to create and validate variant configurations for a model.

Step 1: Open Variant Manager

- 1 Open the model in which you want to create variant configurations. For example, consider a model containing a Variant Source, Variant Sink, and a Variant Subsystem block.

- 2 Right-click the variant badge and select **Open in Variant Manager**.

Step 2: Define Variant Configuration

You can use the **Variant configuration data** pane to define and store a variant configuration. For detailed information on each pane, see “Variant Manager Overview”.

- 1 In the variant configuration data pane, click the **Configurations** tab.
- 2 Click . A variant configuration is added. Type a name for this configuration in the **Name** column.
- 3 Click the **Control Variables** tab in the controls section of the **Configurations** pane.
- 4 To import the control variables for the variant configuration from the global workspace, click  or  to add new control variables to the model.
- 5 Type a name for the variant configuration in the **Name** box available at the top-left of Variant Manager.

6

To export the variant configuration information to the global workspace, click . The variant configuration for the model is now created.

Step 3: Activate and Validate Variant Configuration

To activate a variant configuration, select a configuration from the **Configurations** section and click the **Activate** button. The **Activate** button validates and applies the selected configuration on the model.

Note To reduce a model based on a variant condition, click **Reduce model**. For more information, see “Reduce Models Containing Variant Blocks” on page 11-98

Import Control Variables to Variant Configuration

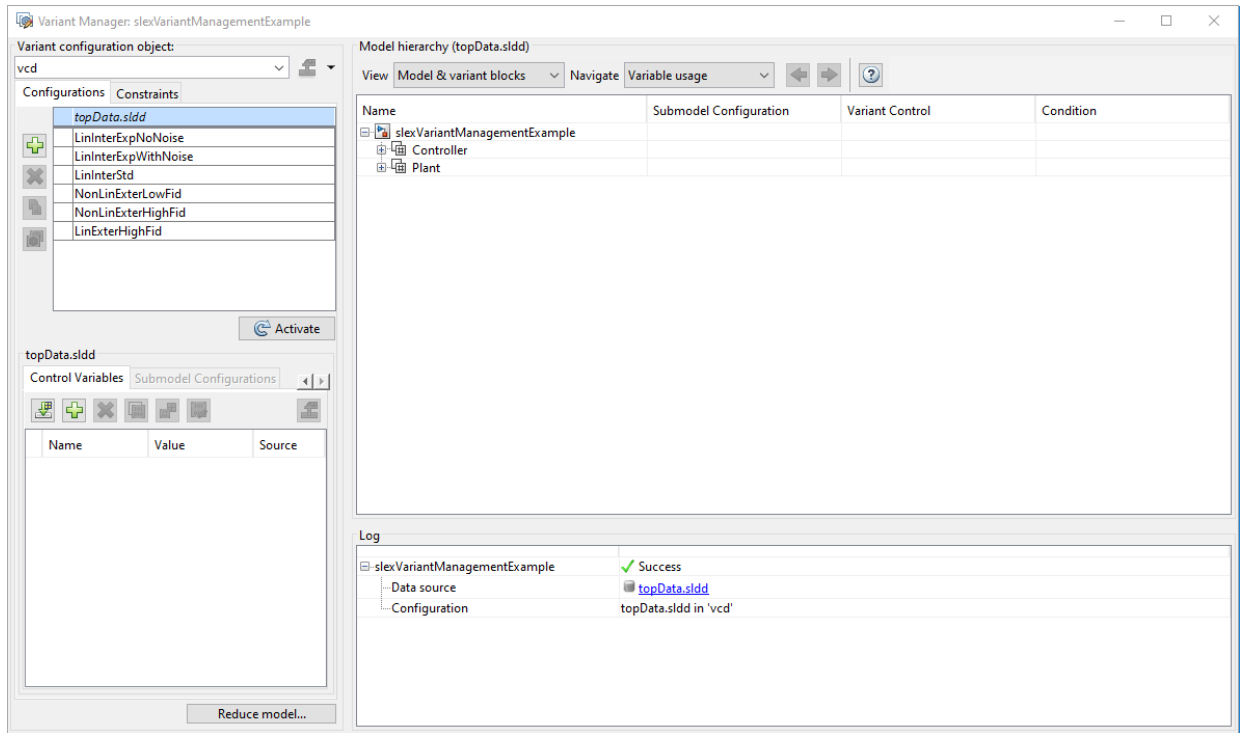

This example shows how to import control variables to a variant configuration and associate a configuration with a referenced model.

Step 1: Open Variant Manager

- 1 Open `slexVariantManagementExample`, which contains the variant configurations.

- 2 Double-click the blue block at the top to associate variant configuration data with the model.
- 3 Select **View > Variant Manager**.

Variant configuration data vcd is associated with the model.

Step 2: Import Variant Configuration

- 1 In the Variant Manager, in the **Configurations** tab, select **LinExterHighFid**.
- 2 In the **Control Variables** tab, click .

The variables are imported.

The screenshot shows a window titled "LinExterHighFid" with two tabs: "Control Variables" (selected) and "Submodel Configurations". Below the tabs are several icons for file operations. The main area contains a table with the following data:

Name	Value	Source
Ctrl	int32(1)	topData.slidd
PlantLocation	int32(1)	topData.slidd
SimType	int32(1)	topData.slidd
SmartSensorMod	int32(1)	topData.slidd
FidType	int32(1)	plantData.s...
Noise	int32(0)	topData.slidd

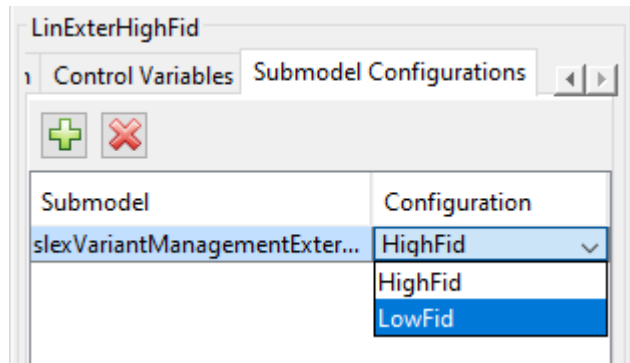

Note You can specify variant controls in the MATLAB® global workspace or a data dictionary.

Step 3: View Referenced Model Configuration

- 1 Open the referenced model `slexVariantManagementExternalPlantMdlRef`.

- 2 Double-click the blue block at the top to associate variant configuration data with the referenced model.
- 3 In the Variant Manager that is opened from `slexVariantManagementExample`, select `slexVariantManagementExternalPlantMdlRef` under the **Submodel Configurations** tab.
- 4 Select the `LowFid` configuration from the dropdown menu.

- 5 To validate the model using the LinExterHighFid variant configuration, select LinExterHighFid from the **Configurations** list and click **Activate**.

Simulink validates the new configuration against the model and returns the validation results.

Define Constraints

This example shows how to define model-wide constraints that must evaluate to true for a variant configuration to become active.

- 1 Open `slexVariantManagementExample`.

- 2 Select **View > Variant Manager**.

- 3 In the Variant Manager, in the **Constraints** tab, click .
- 4 Enter **LinNotExtern** as the **Name** and **(Ctrl~=1) || (PlantLocation ~=1)** as the **Condition** for the constraint.

This constraint activates variants that do not use the Linear Controller and External Plant Controller configurations.

- 5 To activate and validate the constraint, click the **Activate** button.

Reduce Models Containing Variant Blocks

Note You require a Simulink Design Verifier license to reduce your model.

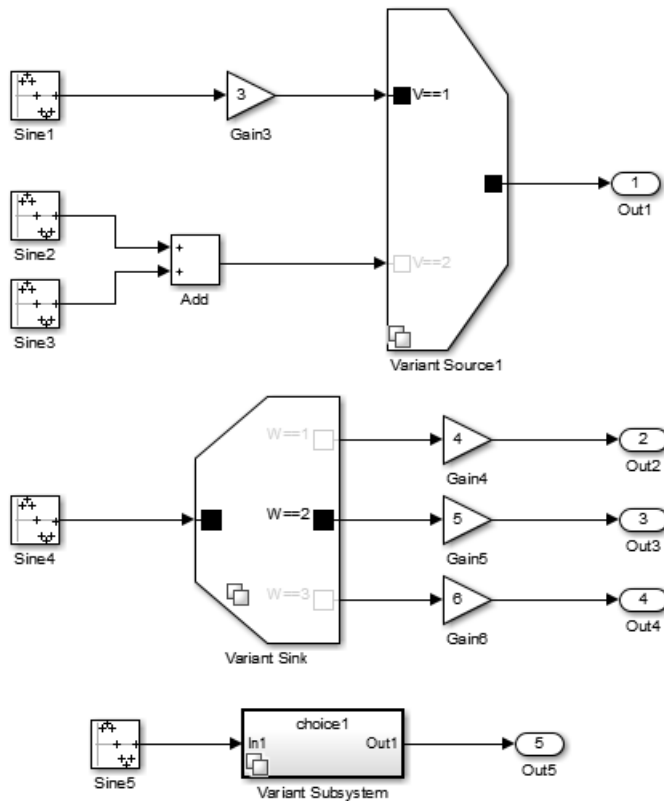

A variant model can contain multiple variable structures and a single fixed structure. The combination of a variable structure and the fixed structure to create a model depends on different combinations of the variant choices that you select. Each combination of the variant choices can be stored as a variant configuration.

Variant models can be reduced to simplified, standalone model depending on the selected variant configurations. Additionally, all related files and variable dependencies are also reduced. These reduced artifacts are packaged into a user-specified output folder.

Consider the model Variant Reducer. The model contains a Variant Source block, a Variant Sink block, and a Variant Subsystem block with these variant choices:

- Variant Source: $V==1$ and $V==2$
- Variant Sink: $W==1$, $W==2$, and $W==3$
- Variant Subsystem: $V==1$ and $V==2$

Assume that the model has two predefined variant configurations, named `config1` ($V==1$ && $W==2$) and `config2` ($V==2$ && $W==2$). These configurations are saved in a variant configuration data object, `varConfig`.

To reduce the model, perform the following steps:

- 1 Right-click the variant badge, and select **Open in Variant Manager**. The Variant Manager opens displaying the predefined configurations.

2 Click **Reduce model**. The Variant Reducer dialog box opens.

- 3 In the **Reduction mode** section, select:
- **Current variant control values** : To reduce the model based on its variant control variable values in the global workspace.

Reduction mode:

Current variant control values
 Specify variant configurations
 Specify variant control values

Name (read-only)	Value (read-only)
W	1
V	1

Preserve signal attributes

 Open reduced model (pwd changes to output folder)

Model suffix:

Output folder:

- **Specify variant configurations:** To reduce the model that is associated with a variant configuration data object and configurations to be retained in the reduced model.

Reduction mode:

Current variant control values

Specify variant configurations

Specify variant control values

Named configurations

config1

Name (read-only)	Value (read-only)
V	1
W	2

Preserve signal attributes

Generate detailed summary

Open reduced model (pwd changes to output folder)

Model suffix:

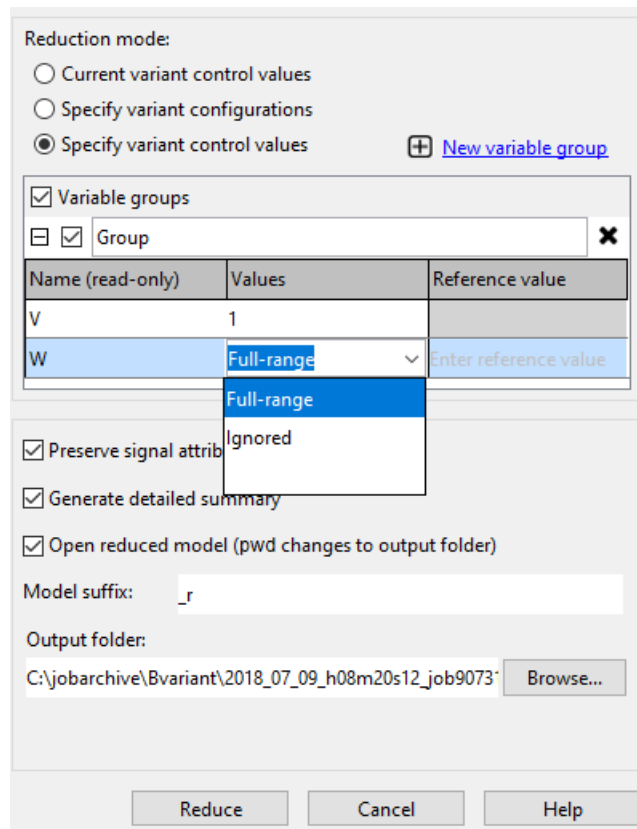

Output folder:

Note During reduction, the control variable values from the last selected configuration are stored in the global workspace.

- **Specify variant control values:** To reduce the model based on the variant control variable values. You can create multiple variable groups corresponding to different configurations. Click **New variable group** to set the values for variant control variables. You can either specify a variant control value or select **Full-range** or **Ignored** from the drop-down list. Specifying a variant control value as a vector also allows you to reduce a model for all combinations of that variable. For example, if you specify values $V = 1$ and $W = [1, 2]$, then the model is reduced for the configurations $\{V==1, W==1\}$ and $\{V==1, W==2\}$. If you select **Full-range** as a variant control value, **Reference Value** column is activated to enter a reference value required for successful model compilation. The model is

reduced for all valid values of the specified variant control variable. If you select **Ignored** as a variant control value, then that variant control variable is not considered while reducing the model.

Note To use a full-range variant control variable, **Analyze all choices during update diagram and generate preprocessor conditional** option has to be selected in the block parameters dialog of the blocks which uses that Variant control variable.

- 4 Select **Preserve signal attributes** to preserve the compiled signal attributes between the original and reduced model. When this option is selected, the Variant Reducer tries to preserve the compiled signal attributes between the original and

reduced models by adding signal specification blocks at appropriate block ports in the reduced model. Compiled signal attributes include signal data types, signal dimensions, compiled sample times, and so on.

- 5 Select **Generate detailed summary** to generate the Variant Reducer summary in the output folder. The Variant Reducer summary contains summary of **Variant Reducer Options, Original and Reduced Model Differences, Dependent Artifacts, Callbacks** and **Warnings**.

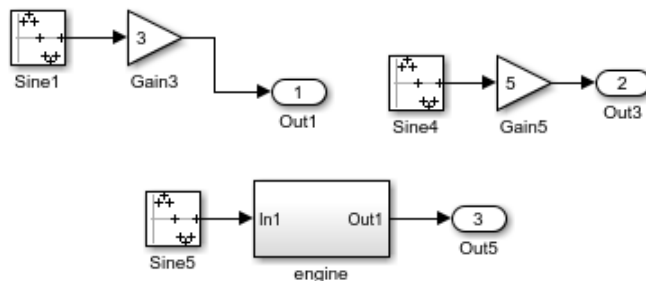

The detailed summary can be used to get traceability information between the original and reduced model. It also helps in identifying artifacts which cannot be handled automatically and need manual intervention. For example, callback codes that may need to be modified.

Note To generate detailed summary, you must have **Simulink Report Generator** license.

- 6 Specify a value as the suffix in the **Model suffix** field. The model suffix value is appended to the reduced models, data dictionaries, and the related artifacts. By default, `_r` is the suffix.
- 7 Specify the output folder to store the reduced model.

Note Selecting the **Open reduced model** check box changes the current working folder to the output folder.

- 8 Click **Reduce**. The reduced model for the required configurations are now created. If the model contains resolved library links or referenced models, the corresponding parent is reduced for the specified configuration and is referenced in the model. The reduced model, reduced referenced model, and the reduced library get their names from the corresponding model, referenced model, or the library with `_r` (**Model suffix**) appended to it.

Consider a Variant model that contains a Simulink Function block with Variant condition on the Simulink Function block as `V==1 || V==2 || V==3 || V==4`. If the model is reduced for any or a combination of the available Variant conditions, the Simulink Function block in the reduced model is unconditional. For example, if the model is reduced for Variant condition, `V=1`, `V=2`, and `V=3`, the Simulink Function block in the reduced model is unconditional. Whereas, if the model is reduced for Variant condition, `V=1`, `V=2`, and `V=5`, the Simulink Function block in the reduced model remains conditional with `V==1 || V==2` as the Variant condition.

Reduce Model Programmatically

To reduce a model programmatically, use the syntax:

```
Simulink.VariantManager.reduceModel(model,<Name>,<Value>)
```

For example,

- To reduce the model based on its variant control variable values in the global workspace.

```
Simulink.VariantManager.reduceModel('sldemo_variant_subsystems')
```

- To reduce the model based on its variant control variable values in the global workspace to a specified folder.

```
Simulink.VariantManager.reduceModel('sldemo_variant_subsystems', 'OutputFolder', 'outdir')
```

- To reduce the model that is associated with a variant configuration data object and configurations to be retained in the reduced model.

```
Simulink.VariantManager.reduceModel('sldemo_variant_subsystems', 'NamedConfigurations')
```

- To reduce the model by specifying configurations in the form of a structure of variant control variables.

```
Simulink.VariantManager.reduceModel('iv_model', 'VariableConfigurations', {'V',1,'W',[1 2]})
```

Here, two configurations are specified corresponding to `{V=1, W=1}` and `{V=1, W=2}`, respectively.

- To reduce the model by specifying variant control values where 'w' is a full-range variant control value.

```
Simulink.VariantManager.reduceModel('slexVariantReducer', 'VariableConfigurations', {'V',1,'W',0})
```

Here, four configurations are computed corresponding to `{V==1, W==1}`, `{V==1, W==2}`, `{V==1, W==3}` and `{V==1, W==0}` respectively.

For more information on reducing model programmatically, see `reduceModel`.

Considerations and Limitations

- The output folder to store the reduced model must not be under `matlabroot`.
- If a model has dependencies on files that are located under `matlabroot`, these files are not modified or copied to the output folder during model reduction. File dependency can include files from the Simulink libraries, `.m` files, `.mat` files, `.sldd` files.
- If the output folder contains the `variant_reducer.log` file from the previous model reduction, the reducer overwrites all the files available in that output for any subsequent reduction.
- Callback code (For example, model callbacks, mask initialization code and mask parameter callback codes) are not modified during model reduction and must be modified manually.
- Additional blocks are added automatically to the reduced model to ensure consistent simulation semantics. Additional blocks can include Signal Specification blocks for consistent signal attributes (data type, dimensions, complexity) or the Ground and the Terminator blocks for unconnected signals.
- During model reduction, commented blocks present on the active path are retained while the commented blocks present on an inactive path are deleted.
- During model reduction, Stateflow charts present on the active path are retained while the Stateflow charts present on an inactive path are deleted. However, they are not reduced.

Condition Propagation with Variant Subsystem

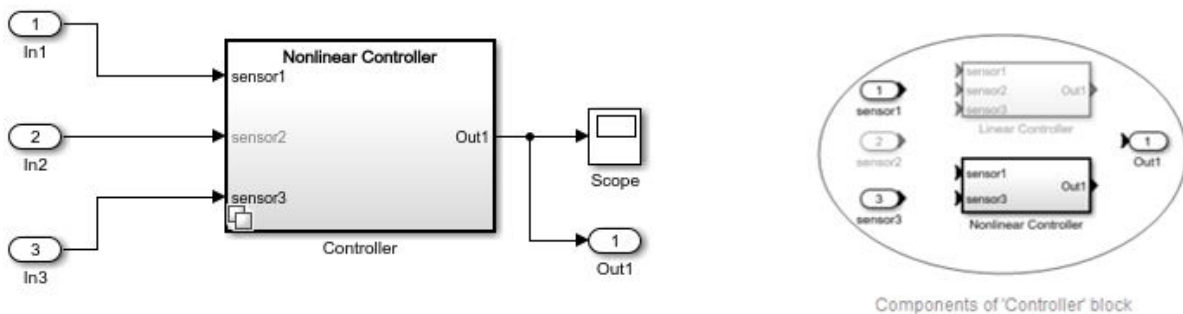

When you specify variant conditions in models containing Variant Subsystem blocks, Simulink propagates these conditions to determine which components of the model are active during simulation. A variant condition can be a condition expression or a variant object.

The variant condition annotations help you visualize the propagated conditions. To view the variant condition annotations, click **Display > Blocks > Variant Condition Legend**.

Note The **Variant Condition Legend** option is available only when **Display > Blocks > Variant Condition** is active.

In the legend, the (default) keyword is displayed as negated condition.

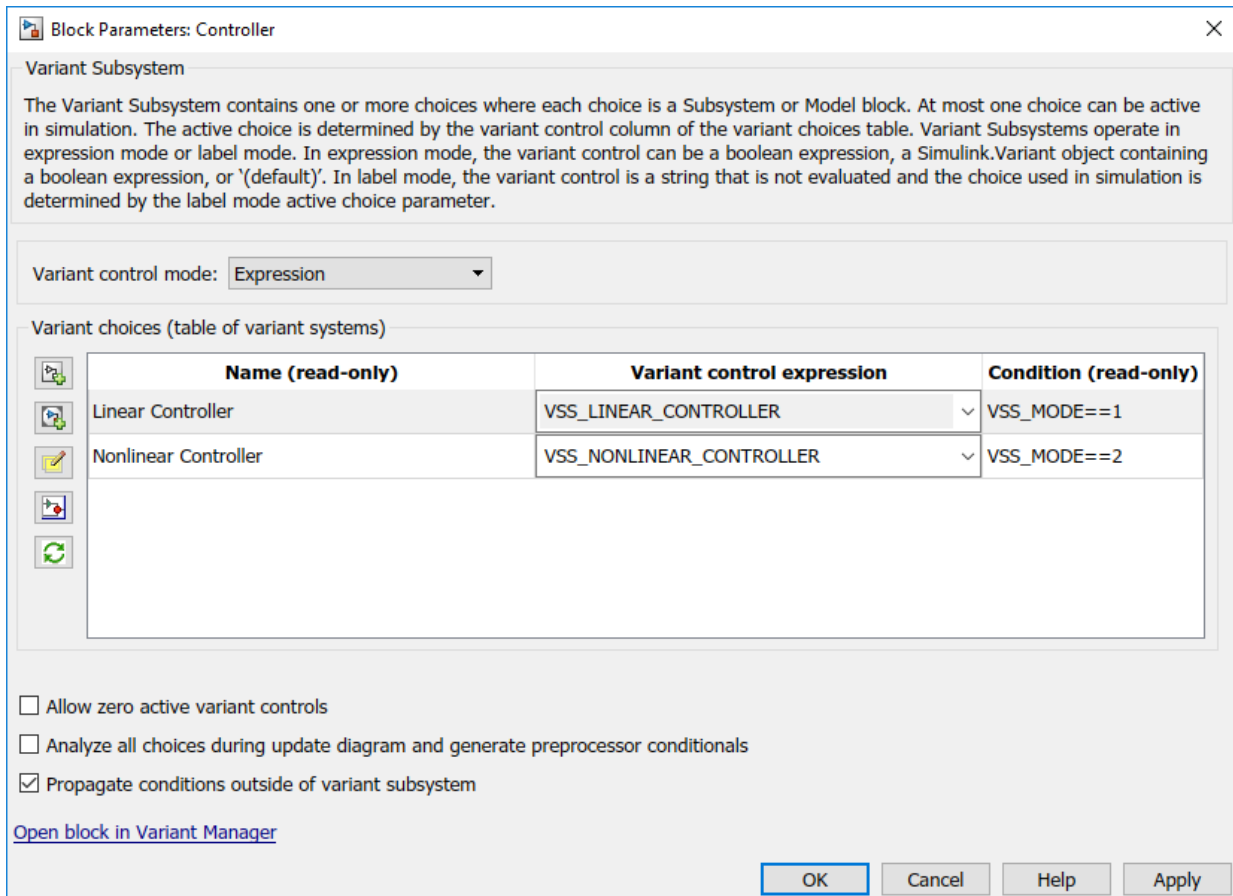

Consider this model containing a Variant Subsystem block with variant choices. A specific variant condition activates each block.

In the Variant Subsystem (Controller), sensor1 and sensor3 are used both in the Linear Controller and Nonlinear Controllers but sensor2 is used only in the Linear Controller. Hence, the sensor2 block is executed only when the Linear Controller choice is active and is not executed for any other choice. To ensure that the components outside of the Variant Subsystem (Controller) are aware of the active or inactive state of blocks with the Variant Subsystem, the block condition must propagate outside of the Variant Subsystem.

Propagate Conditions Without Generate Preprocessor Conditionals

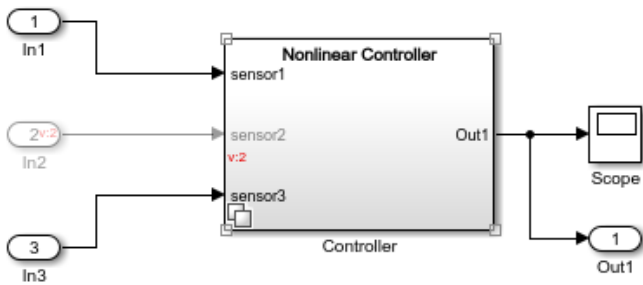

To propagate conditions outside of Variant Subsystems without generate preprocessor conditionals, select the **Propagate conditions outside of variant subsystem** check box in the **Block Parameter** dialog box of the Variant Subsystem block. By default, **Propagate conditions outside of variant subsystem** is not selected.

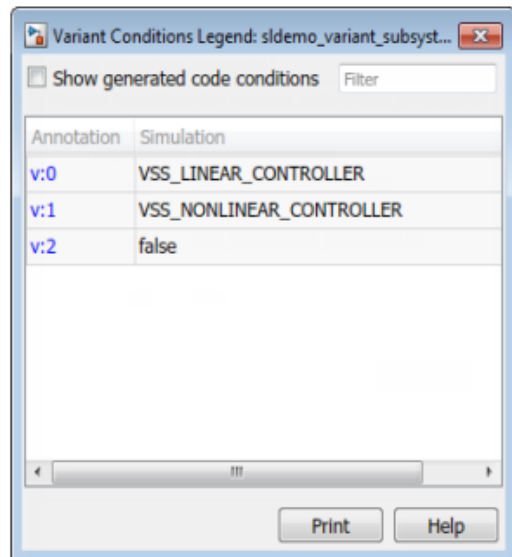

When you simulate the model with the active choice as Nonlinear Controller and the **Propagate condition outside of variant subsystem** selected, only the active choice is

analyzed. Notice that the **Analyze all choices during update diagram and generate preprocessor conditional** check box is not selected.

The **Variant Condition Legend** displays the inactive conditions as false. Here, sensor2 is inactive with variant choice as Nonlinear Controller and is marked as false. The annotations are displayed on the sensor2 port and the inactive block that is connected to sensor2.

Components of 'Controller' block

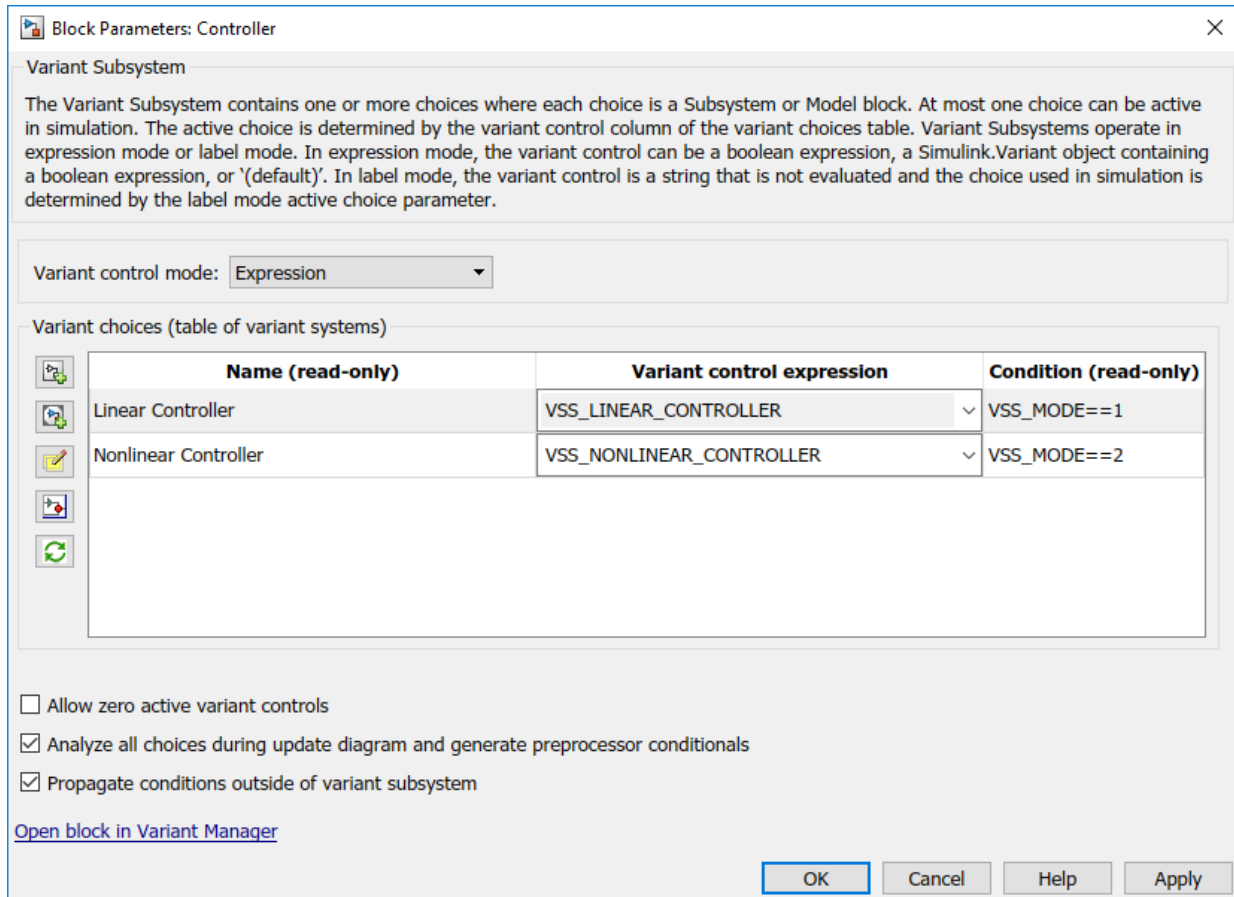

When you generate code for condition propagation without generate preprocessor conditionals, the inactive blocks are ignored. In this example, the input port In2 is not shown in the generated code.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
    real_T In1;          /* '<Root>/In1' */
    real_T In3;          /* '<Root>/In3' */
} EXTU_variant_subsystem_propagate_T;
```

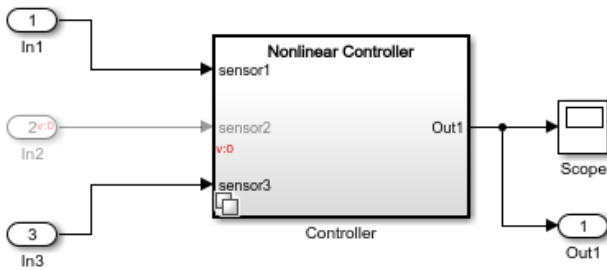

Propagate Conditions with Generate Preprocessor Conditionals

To propagate conditions outside of Variant Subsystem with generate preprocessor conditionals, select the **Propagate conditions outside of variant subsystem** check box and the **Analyze all choices during update diagram and generate preprocessor conditionals** check box in the **Block Parameters** dialog box of the Variant Subsystem.

Note **Analyze all choices during update diagram and generate preprocessor conditionals** is available only when you specify **Variant control mode** as Expression.

When you simulate the model with active choice as Nonlinear Controller and **Propagate conditions outside of variant subsystem** check box and the **Analyze all choices during update diagram and generate preprocessor conditionals** check box selected, all the variant choices are analyzed. The **Variant Condition Legend** displays the variant conditions associated with the model.

Components of 'Controller' block

Variant Conditions Legend: sldemo_variant_subsystems

Show generated code conditions Filter

Annotation	Simulation	Code Generation
v:0	VSS_LINEAR_CONTR...	VSS_LINEAR_CONTR...
v:1	VSS_LINEAR_CONTR...	false
v:2	VSS_NONLINEAR_CO...	<i>unconditional</i>

Print Help

When you generate code for condition propagation with generate preprocessor conditionals, the model is analyzed for all the choices. In this example, the input port In2 is guarded with necessary conditions.

```
/* External inputs (root inport signals with auto storage) */
typedef struct {
    real_T In1;                                /* '<Root>/In1' */

#ifdef VSS_LINEAR_CONTROLLER

    real_T In2;                                /* '<Root>/In2' */

#define EXTU_VARIANT_SUBSYSTEM_PROPAGATE_T_VARIANT_EXISTS
#endif

    real_T In3;                                /* '<Root>/In3' */
} EXTU_variant_subsystem_propagate_T;
```

Note To propagate variant conditions outside a Variant Subsystem block for zero or one active variant control specified, select **Allow zero active variant controls**.

Adaptive Interface for Variant Subsystems

When you select the **Propagate conditions outside of variant subsystem** check box in the **Block Parameters** dialog box, the Variant Subsystem adapts its interface to the connected blocks. Consider this model.

Adaptive Interfaces for Variant Subsystems

Copyright 2016 The MathWorks, Inc.

The Controller block is a Variant Subsystem that provides a Linear and a Nonlinear choice. The Linear choice is active when $V = 1$, and the Nonlinear choice is active when $V = 2$. Here, V is a variant control variable of the Simulink Parameter type. Select the Controller block and, in Simulink click **Diagram > Block Parameters** (Subsystem). Verify that the **Propagate condition outside of variant subsystem** check box is selected.

To change the value of the variant control variable, in the MATLAB command window, type $V.Value = 1$ or $V.Value = 2$.

Double-click the Controller block to view its contents. The Linear choice is using sensor1 and sensor3 inputs of the Controller (Variant Subsystem block). It is not using sensor2 and, therefore, does not produce a saturate output.

When you simulate this model, the Variant Subsystem block adapts its interface such that the condition $V = 2$ ($v:1 \ V=2$) propagates the In2, the filter, and the saturation logger blocks.

Condition Propagation with Conditional Systems

When you propagate a condition to a conditional system, the same condition is set to all ports. For more information, see “Propagate Variant Condition to Conditional Subsystem” on page 11-173.

Consider this model. Here, when condition is propagated to the Inport block (fcn), the same condition propagates to all the inports and outputs (as shown in the Variant Legend) and makes the Variant Subsystem block conditional.

Propagation behavior on Variant Subsystem with conditionally executing choices

Annotation	Simulation
v:0	A == 1
v:1	VSSMODE == 0
v:2	VSSMODE == 1

Known Limitations

- Propagated variant conditions from variant subsystems cannot be set on blocks in Simscape domain or Stateflow based blocks.
- C++ code generation is not supported for models that contain propagated conditions outside of a Variant Subsystem.
- Variant condition propagation is not supported in models with root bus element ports.

Note All elements of a Mux, Demux, or a Vector Concatenate block signal must have the same variant condition.

Propagate Conditions Programmatically

To propagate conditions outside of Variant Subsystem programmatically, use one of these syntaxes:

- Propagate conditions without generate preprocessor conditionals:

```
set_param(VariantSubsystemName, 'PropagateVariantConditions', 'on')
```

For example,

```
set_param('sldemo_variant_subsystems/Controller', 'PropagateVariantConditions', 'on')
```

- Propagate conditions with generate preprocessor conditionals:

```
set_param(VariantSubsystemName, 'PropagateVariantConditions', ...  
'on', 'GeneratePreprocessorConditionals', 'on')
```

For example,

```
set_param('sldemo_variant_subsystems/Controller', 'PropagateVariantConditions', 'on', ...  
'GeneratePreprocessorConditionals', 'on')
```

Code Generation with Conditional Systems

You can generate code for the model by selecting **Code > C/C++ Code > Build Model**. For more information on configuring model to generate code, see “Prepare Variant-Containing Model for Code Generation” on page 11-61.

Consider a variant model containing a Variant Subsystem block for generating code.

In the generated code, the code inside fcn definition is guarded by C preprocessor conditionals #if and #endif.

```

void fcn(void)
{
    /* RootInportFunctionCallGenerator: '<Root>/RootFcncall_InsertedFor_fcn_at_outport_1
    #if VSSMODE == 0

        rtDWork.Linear.DiscreteFilter = rtU.In1 - 0.5 *
        rtDWork.Linear.DiscreteFilter_states;

        rtDWork.Linear.DiscreteFilter_states = rtDWork.Linear.DiscreteFilter;
    #endif                                     /* VSSMODE == 0 */

    #if VSSMODE == 1

        rtDWork.Nonlinear.DiscreteFilter = look1_binlpxw(rtU.In1,
        rtCP_LookupTable_bp01Data, rtCP_LookupTable_tableData, 4U) - 0.5 *
        rtDWork.Nonlinear.DiscreteFilter_states;

        rtDWork.Nonlinear.DiscreteFilter_states = rtDWork.Nonlinear.DiscreteFilter;
    #endif                                     /* VSSMODE == 1 */

```

```

#if VSSMODE == 0
    rtY.Out1 = rtDWork.Linear.DiscreteFilter;
#endif
/* VSSMODE == 0 */
#if VSSMODE == 1
    rtY.Out1 = rtDWork.Nonlinear.DiscreteFilter;
#endif
/* VSSMODE == 1 */
}

```

Note

- Configuring model as AUTOSAR component with runnable as Variant Subsystem choices is not supported.
-

Guarding the Function-Call Definition

To guard the whole definition of Function-Call (fcn), use a variant source as shown below.

Annotation	Simulation
v:0	A == 1
v:1	VSSMODE == 0
v:2	VSSMODE == 1

In the generated code `fcn()` definition is guarded with `A==1`.

```
#if A == 1
void fcn(void)
{
...
}
#endif
```

This function can be referred using a code snippet similar to as shown below.

```
...
#if A==1
fcn()
#endif
.....
```

- Masking Variant Model

Variant Systems with Conditional Systems

You can use the conditionally executed systems (control ports) such as Enable, Trigger, Reset, and the Function-Call Subsystems within the Variant Subsystem block. When the **Analyze all choices during update diagram and generate preprocessor conditionals** check box is selected in the Block Parameters dialog box, a mix of control ports in a Variant Subsystem block as variant choice is not supported. Also, all control port types must have the same names. For more information on conditionally executed systems, see “Conditionally Executed Subsystems Overview” on page 10-3.

Export-Function model with Variant Subsystem

Consider a Variant model containing a Variant Subsystem block. If you use Function-Call system as a variant choice for the Linear Subsystem block then the other Subsystem block (Nonlinear) within the Variant Subsystem must also be Function-Call system. Additionally, the control ports in Linear and Nonlinear blocks and the corresponding inport block must have the same name (fcn).

In the generated code, the code inside fcn definition is guarded by C preprocessor conditionals inside export function.

```
fcn() {
#if VSSMODE==0
// code for Linear choice
.....
#endif
#if VSSMODE==1
```

```
// code for Nonlinear choice
.....
#endif
```

You can also have a similar modeling pattern with multi-point entry function using Model reference block. An example is as follows:

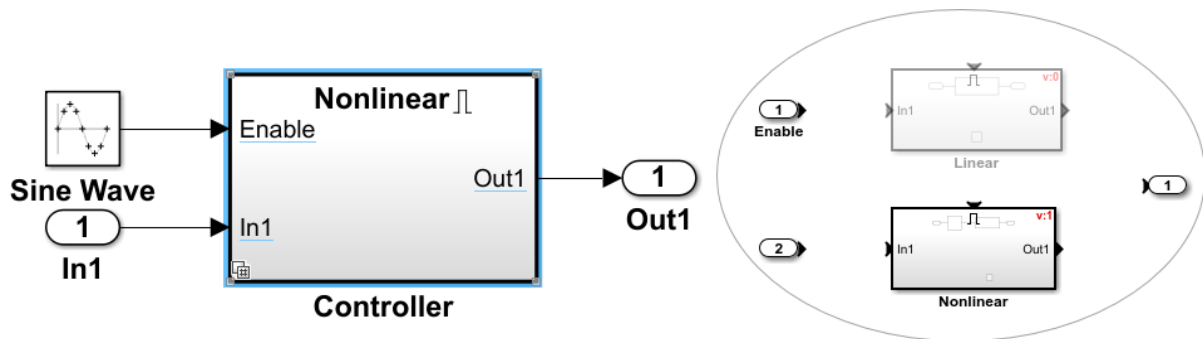

In the above example, fcln1, fcln2, and fcln3 are routed through the Variant Subsystem using Model reference block as variant choices.

These conditions are not supported when using conditionally executed systems within a Variant Subsystem block as variant choice:

- Action ports as Variant choices
- Variant choices containing Iterator port with generate preprocessor conditionals set to ON
- Models with Initialize, Reset, Terminate, and Simulink functions

Variant Subsystem with Enable Subsystem as Choice

Consider a Variant model containing a Variant Subsystem block. If you use Enable Subsystem as a variant choice for the Linear Subsystem block then the other Subsystem block (Nonlinear) within the Variant Subsystem must also be Enable Subsystem.

This model simulates and generates code based on VSSMODE value.

Snippet of the generated code is as shown below.

```
step() {
#if VSSMODE==0
// code for Linear choice
.....
#elif VSSMODE==1
// code for Nonlinear choice
.....
#endif
```

Convert Configurable Subsystem to Variant Subsystem

Note Configurable Subsystem will be removed in a future release. The Configurable Subsystem blocks in existing models must be converted to Variant Subsystem blocks.

Variant Subsystems offer more capabilities than Configurable Subsystems, with these advantages:

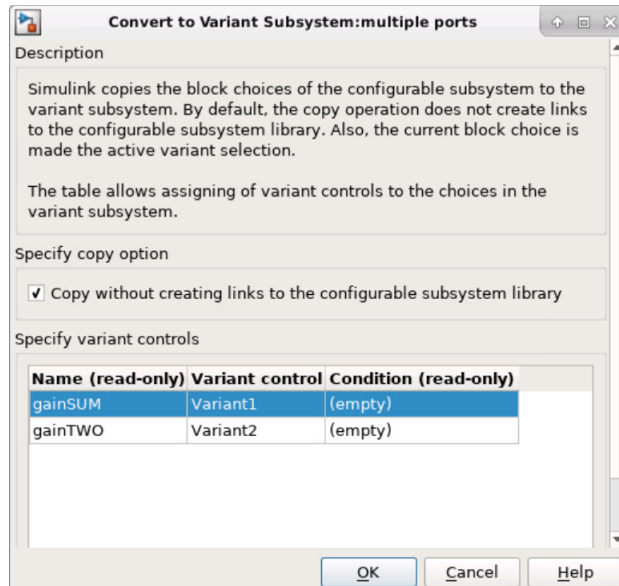

- You can mix Model blocks and Subsystem blocks as variant choices.
- You can specify variants that have different numbers of input and output ports.

Perform these steps to convert Configurable Subsystem block to a Variant Subsystem block:

- 1 Open a model containing Configurable Subsystem block.

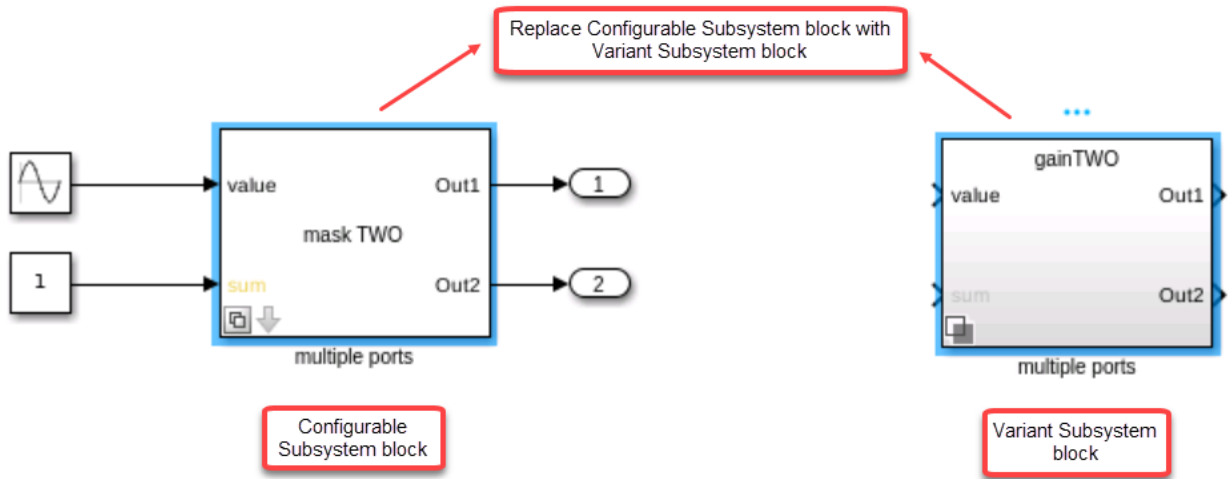

- 2 Right-click the Configurable Subsystem block and in the context menu, select **Subsystem & Model Reference > Convert to > Variant Subsystem**.

- 3 By default, the **Copy without creating links to the configurable subsystem library** check box is selected. This creates Variant choices without creating links to library.
- 4 Click **OK**. The Configurable Subsystem block is converted to Variant Subsystem block and is displayed in a new window.

Note When Configurable Subsystem block is converted to a Variant Subsystem block, the Block Choice of Configurable Subsystem block is changed to LabelModeActiveChoice in Variant Subsystem block.

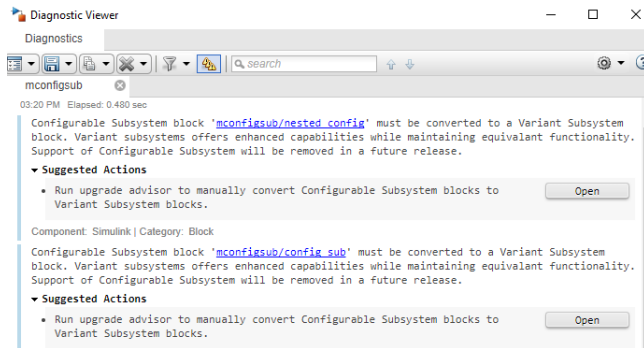

- 5 Manually replace the Configurable Subsystem block with the converted Variant Subsystem block in the original model.

Behavior of Configurable Subsystem on Loading

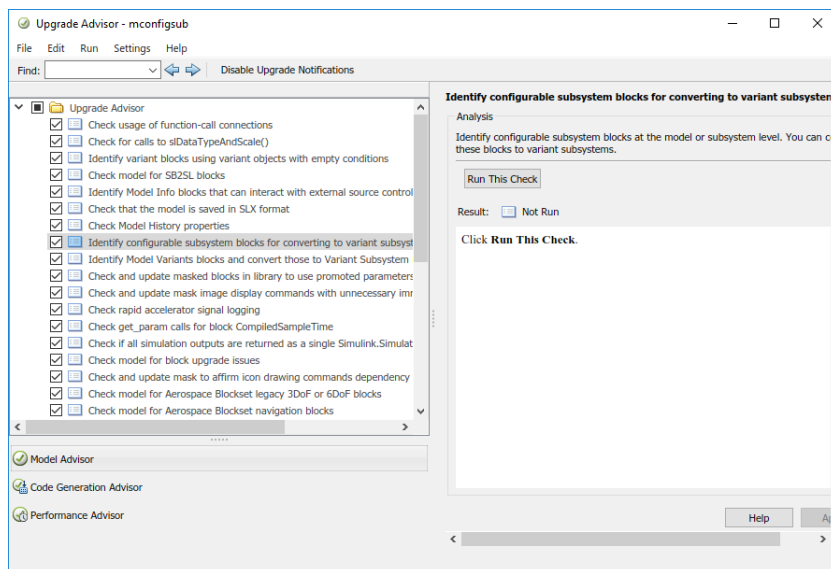

When you load a model containing Configurable Subsystem blocks, a warning is displayed which will instruct you to convert the Configurable Subsystem block to a Variant Subsystem block.

- 1 Consider a model with Configurable Subsystem block. When you load this model, a warning is displayed in the **Diagnostic Viewer**.

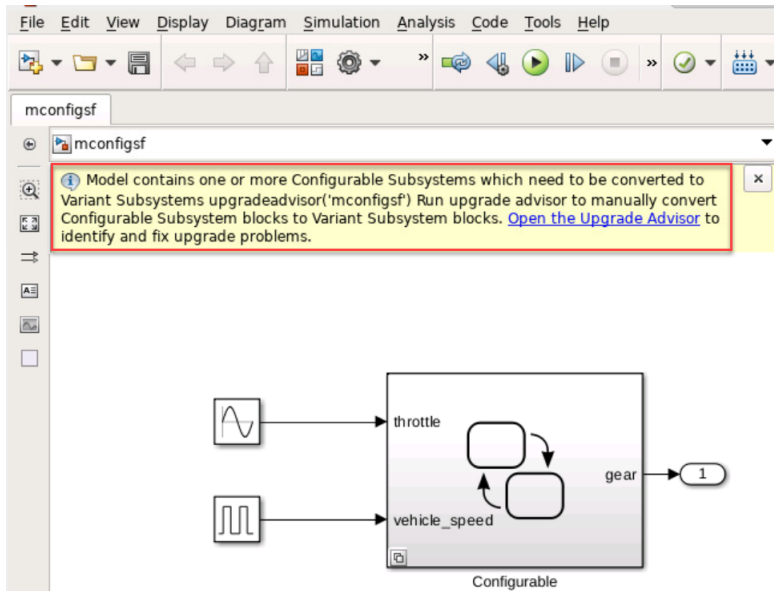

Note When you create a new Configurable Subsystem block, an upgrade advisor alert is displayed to convert the Configurable Subsystem block to Variant Subsystem block.

- 2 In the **Diagnostic Viewer**, click **Open** in the **Suggested Actions** section.
- 3 In the Upgrade Advisor, select **Identify configurable subsystem blocks for converting to variant subsystem blocks** and then click **Run This Check**. A list of all the Configurable Subsystem blocks in the model and recommend action to be performed is displayed.

Also, when you simulate the model containing Configurable Subsystem blocks, Upgrade Advisor warning is displayed in the editor. A sample screenshot is as shown below.

Changing Active Variant

When Configurable Subsystem block is converted to a Variant Subsystem block, the Block Choice of Configurable Subsystem block is changed to Label mode active choice in Variant Subsystem block.

To change the active variant, perform one of these steps:

- Right-click the badge on the Variant Subsystem block and select **Block Parameters (Subsystem)**. In the block parameters dialog box, select the active variant from Label mode active choice drop-down list.
- Right-click the badge on the Variant Subsystem block and select **Label Mode Active Choice**.

Note When a Configurable Subsystem block with a mask is converted to Variant Subsystem block, the Label mode active choice option and all other parameters in block parameters dialog box is disabled. To change the active variant, right-click the badge on the Variant Subsystem block and select **Label Mode Active Choice**.

Variant Elements within Buses

Create Buses with Variant Conditions

This example shows how to create bus signals with elements having different variant conditions. This model has two signals ('a', 'b') that are merged to create a bus signal. These two signals have different variant conditions, $V==1$ and $W==1$.

The bus selector is fed by two signals having two different variant conditions ($V==1$ and $W==1$). When this bus signal is fed into a bus selector and when you select the individual signals from the bus, the variant condition is also selected.

Note Variant bus supports using Composite ports as inports and outports.

To see the completed model, open the `slexVariantBus` model.

Variant Condition Propagation with Bus

A Variant Source block can accept either virtual or nonvirtual bus inputs.

Consider this model.

Bus is created with variant conditions $V = 1$ and $W = 1$. When conditions V and W are propagated through the bus and when individual elements are selected from the bus, conditions are also selected.

Code Generation

You can generate code for the model by selecting **Code > C/C++ Code > Build Model**. For more information on configuring model to generate code, see “Prepare Variant-Containing Model for Code Generation” on page 11-61.

When generating code with preprocessor conditionals, the bus types and hierarchies of all bus inputs must be the same.

Virtual and Nonvirtual Bus Behavior

Virtual buses provide the simplest approach for using buses to reduce signal clutter in a block diagram. Nonvirtual buses support modeling components (such as S-functions or MATLAB Function blocks) that require explicitly specified interfaces. There is no change in the propagation behavior of variant conditions when variant conditions are propagated through a virtual or nonvirtual bus.

Code generated for a virtual bus is as shown below.

```
/* Block states (default storage) for system '<Root>' */
typedef struct {
```

```

#if V == 1

real_T UnitDelay_1_DSTATE;          /* '<Root>/Unit Delay' */

#define D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS
#endif                               /* V == 1 */
#if W == 1

int32_T UnitDelay_2_DSTATE;        /* '<Root>/Unit Delay' */

#define D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS
#endif                               /* W == 1 */

#ifndef D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS

char _rt_unused;

#endif
} D_Work_ex_bus_var_cond;

```

Code generated for a nonvirtual bus is as shown below.

```

/* Block states (default storage) for system '<Root>' */
typedef struct {

#if V == 1 || W == 1

myBus UnitDelay_DSTATE;            /* '<Root>/Unit Delay' */

#define D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS
#endif                               /* V == 1 || W == 1 */

#ifndef D_WORK_EX_BUS_VAR_COND_VARIANT_EXISTS

char _rt_unused;

#endif

} D_Work_ex_bus_var_cond;

```

You must have an associated bus object in the bus, which provides properties that Simulink uses to validate the bus signal. For more information on bus objects, see “When

to Use Bus Objects” on page 68-64. The bus object used in the bus is unconditional and it generates unguarded code as shown below.

```
typedef struct {
    real_T a;
    int32_T b;
} myBus;
```

Variant Bus with Model Reference Block

Consider this model containing a Model Reference block.

This model has two signals ('a', 'b') which have different variant conditions, $V==1$ and $V==2$.

From the Model Reference block, the bus selector is fed two signals having two different variant conditions ($V==1$ and $V==2$). When you select the individual signals from the bus, the variant conditions are also selected.

Known Limitations

- Root bus element ports are not supported with variant elements.
- Bus objects do not support variant elements.
- State logging is not supported for a block (for example, Unit Delay) that takes in a bus in which some elements are removed.

- “Getting Started with Buses” on page 68-17
- “Variant Condition Propagation with Variant Sources and Sinks” on page 11-75

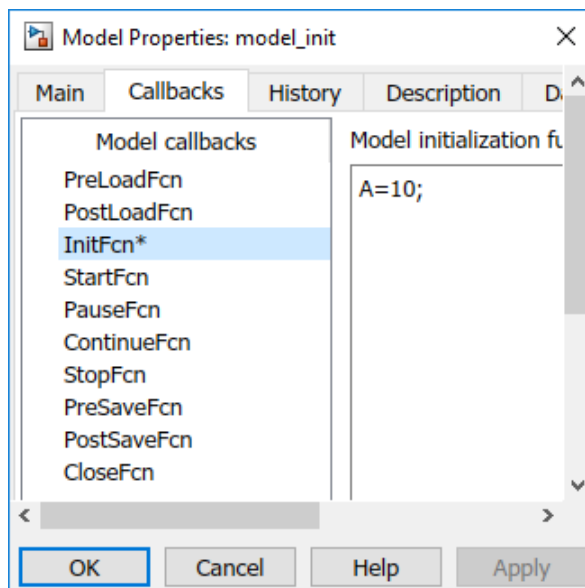

Initialization Function

Initialization function (`InitFcn`) is a type of callback that is executed or evaluated at the beginning of model compilation. You can use `InitFcn` in a model (`model InitFcn`) or a block (`blockInitFcn`).

Note Variant controls can be defined only in model `InitFcn` callback.

Model `InitFcn`

The model `InitFcn` callback is used to initialize parameters and environment settings that are specific to the model used.

Note It is not recommended to use the model `InitFcn` callback to get the simulation status. If you simulate a model in `rtwbuild`, or `SIL`(software-in-the-loop), or `Rapid Accelerator` mode, the model `InitFcn` callback status may show as 'stopped'. The model `InitFcn` callback must be used only to initialize parameters and environment settings that are specific to the model used.

Best practices for using Model InitFcn

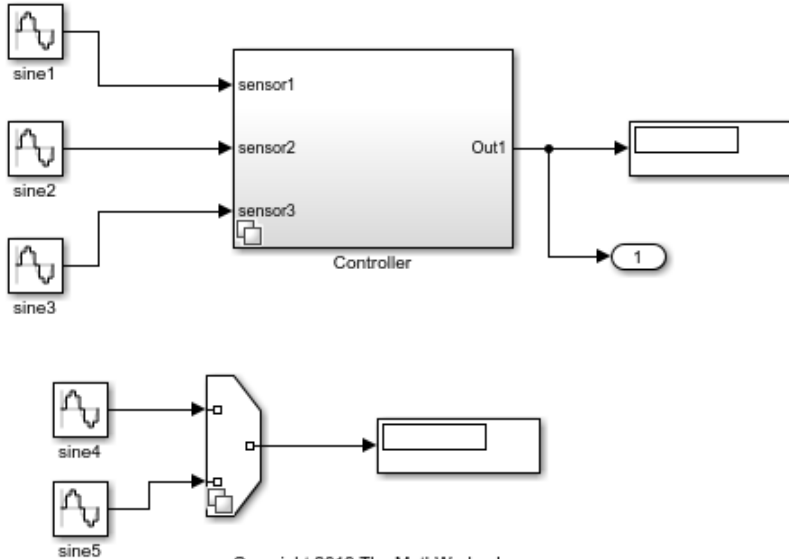

- Do use model `InitFcn` to initialize data required for the model. For example, to initialize:
 - Variables used in model parameters
 - License checks for the required software
- Do not use model `InitFcn` to modify models other than self. This also means that the block `InitFcn` of Model block must not modify the parameters (and structure) of the referenced model.
- Do not use model `InitFcn` in the top model to overwrite any variable used in the referenced model. For example, if top and the referenced models use the variable 'k', the model `InitFcn` of the top model must not modify 'k' of the referenced model. In such modeling patterns, it is recommended that you use different variable names. Alternatively, you can use data dictionary.
- Do not use simulation commands in model `InitFcn`. For example, using commands like `set_param(ModelName, 'SimulationCommand', 'start')` or `set_param(ModelName, 'SimulationCommand', 'update')` in the model `InitFcn` are not recommended.

Variants with Model InitFcn

You can use model properties to define the callbacks for a model. For example, `PreLoadFcn`, `PostLoadFcn`, `InitFcn` callbacks. Model properties is used to view the model information, description, history, and callback functions. You can use the Property Inspector to view and edit model version properties, description history, and callback functions. For more information on Model properties, see “Manage Model Properties” on page 4-68.

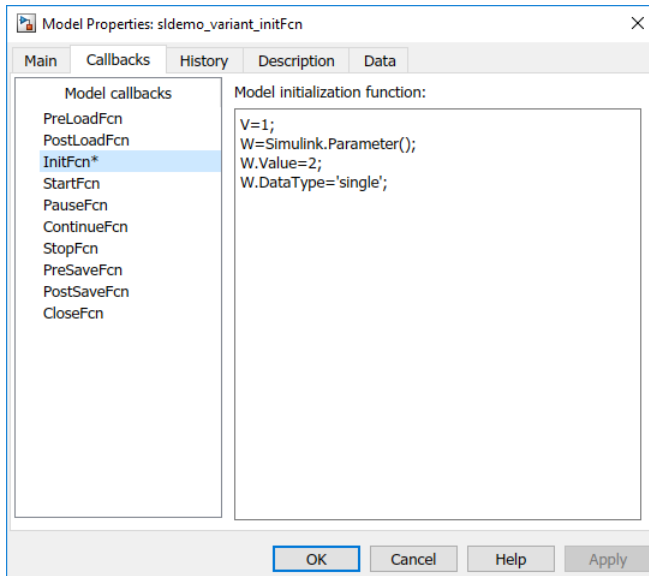

Consider a model with Variant Subsystem and Variant Source blocks. For example, Variant - `InitFcn`.

Variants with Model InitFcn

Copyright 2019 The MathWorks, Inc.

In this model, the model InitFcn is used to initialize parameters for the model.

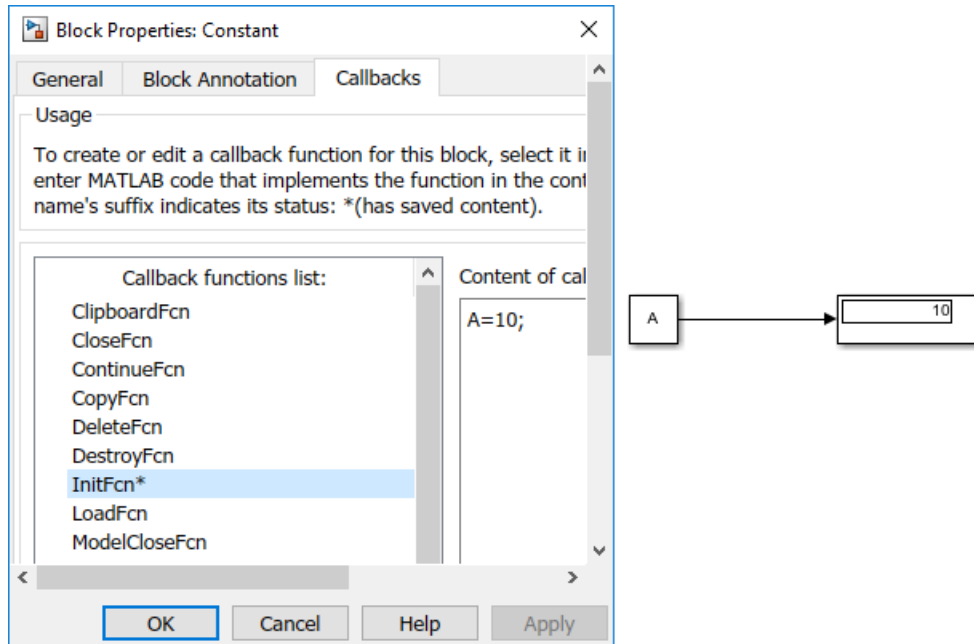

Similarly, these parameters can also be defined in PreLoadFcn or PostLoadFcn.

However, when the parameters are defined in InitFcn callback and if MATLAB workspace is cleared using the `Clear` command, the items in the workspace are cleared and they are re-created when you simulate the model. The items cleared will not be recreated when parameters are defined in PreLoadFcn or PostLoadFcn.

Block InitFcn

The block InitFcn callback is used to initialize block specific parameters and settings.

Best practices for using Block InitFcn

- Do not use block `InitFcn` to modify the parameters (or variables) of blocks other than self.
- Do not use block `InitFcn` on a child block to modify the parameters of the parent subsystem block or other child blocks. However, you can use block `InitFcn` on a parent subsystem block to modify the parameters of the direct child blocks.
- Do not use block `InitFcn` to make structural changes like adding or deleting block (`add_block` or `delete_block`).
- Do not use block `InitFcn` in the Model Reference block to modify the parameters (and structure) of the referenced model.

Analyze Variant Configurations in Models Containing Variant Blocks

A variant model can have single or multiple variant configuration associated with it. You can use the **Analyze** option in the Variant Manager to compare different variant configurations for a model. Additionally, you can also get information on model references and libraries used for a particular variant configuration. For information on getting information on model references and libraries, see `Simulink.VariantConfigurationAnalysis`.

To analyze variant configurations, perform these steps:

- 1 Open the model containing variant blocks. For example, Variant Management .
- 2 Right-click the variant badge and select **Open in Variant Manager**. The Variant Manager opens displaying the predefined configurations.

The screenshot shows the Variant Manager interface for a model named 'slexVariantManagementExample'. The 'Variant configuration object' is set to 'vcd'. The 'Model hierarchy (topData.sldd)' is displayed with the following structure:

- slexVariantManagementExample
 - Controller
 - Linear Controller
 - Nonlinear Controller
 - Smart Controller
 - Plant

The 'Variable usage' table is as follows:

Name	Submodel Configuration	Variant Control	Condition
slexVariantManagementExample			
Controller			
Linear Controller		LINEAR_CONTROL	Ctrl==1
Nonlinear Controller		NON_LINEAR_CONTROL	Ctrl==2
Smart Controller		SMART_CONTROL	Ctrl==3
Plant			

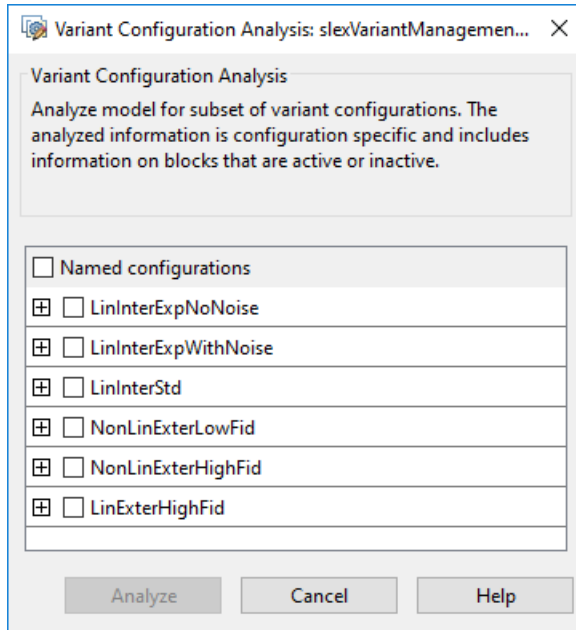

The 'Log' section shows a successful analysis:

```

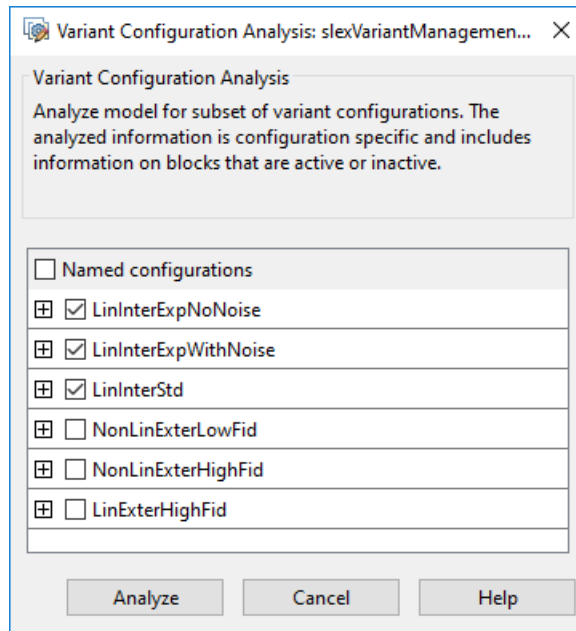

slexVariantManagementExample
├── Data source
│   └── topData.sldd
└── Configuration
    └── topData.sldd in 'vcd'
  
```

Buttons at the bottom include 'Analyze...' and 'Reduce model...'. The 'Control Variables' table is currently empty.

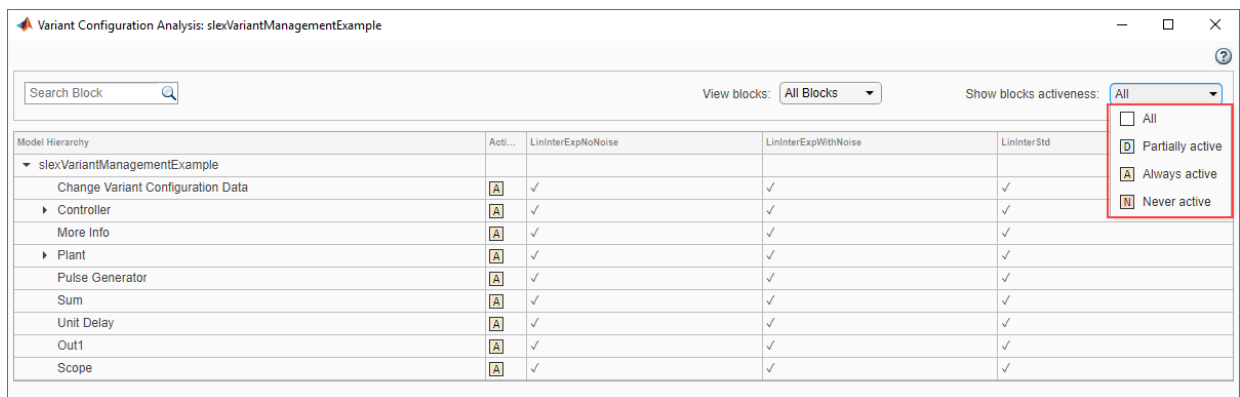

- 3 Click **Analyze**. The Variant Configuration Analysis dialog box opens and displays the associated variant configuration.

- 4 Select the required Variant Configurations. For example, `LinInterExpNoNoise`, `LinInterExpWithNoise`, and `LinInterStd`.

- 5 Click **Analyze**. The **Variant Configuration Analysis** dialog box opens and displays the associated variant configuration.

Note Variant configuration analysis screen displays an info message when the model and configuration analysis page are not in sync.

The controls on the **Variant Configuration Analysis** window allows you to perform the following actions:

- Search blocks .
- Filter the results to selectively display blocks.
- Selectively display analyzed blocks.

View blocks

Selectively display blocks in the **Variant Configuration Analysis** window:

- Select **Variant** to display all variant blocks in the model.
- Select **Hierarchical** to display all hierarchical blocks (for example, Subsystems, Model blocks) in the model.
- Select **All blocks** to display all blocks in the model.

Show blocks activeness

Selectively display blocks in the **Variant Configuration Analysis** window:

- Select **All** to display all analyzed blocks in the model.
- Select **Partially active** to display blocks that are active in some configurations and inactive in others amongst the selected configurations.
- Select **Always active** to display blocks that are always active in the model.
- Select **Never active** to display blocks which are never active in the model.

Propagating Variant Conditions to Subsystems

A Subsystem can be virtual or atomic. Simulink propagates variant conditions differently to such Subsystems. This example shows the propagation of variant conditions from Inline variants to Subsystem blocks. Consider a model as shown:

Variant Condition Propagation to Subsystems

Copyright 2016 The MathWorks, Inc.

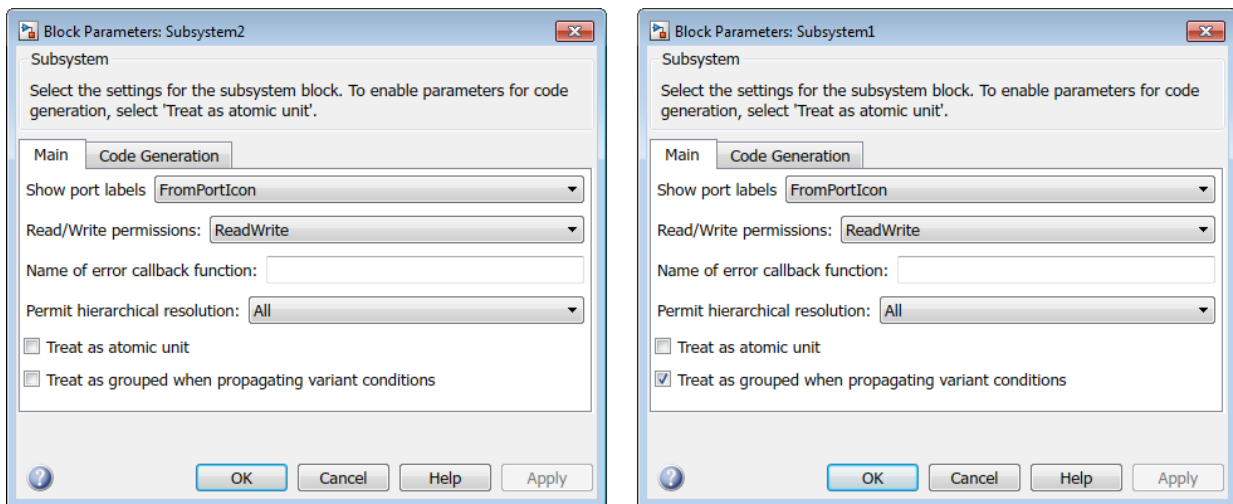

Click **Simulation > Run** to simulate this model and see the variant conditions being propagated from the Variant Source blocks to the blocks connected to it.

The variant condition annotation helps you visualize the propagated conditions. To be able to view the variant condition annotation, click **Display > Blocks > Variant Condition Legend**.

The model contains three Variant Source blocks: Variant Source1, Variant Source2, and Variant Source3, respectively.

Variant Source1 contains conditions $V = 1$ and $V = 2$ at inport. The variant condition $V = 1$ propagates to GainA1 while $V = 2$ propagates to Sine2. The Sine1 block does not get any propagated variant conditions because it is connected to a block, which is always consumed irrespective of the variant condition. If the To Workspace block1 did not exist or was commented-out before simulating the model, variant condition $V = 1$ propagates to Sine1.

Variant Source2 is connected to virtual subsystems Subsystem1 and Subsystem2 that have identical contents, a Sine Wave block connected to a To Workspace and an Output blocks. Subsystem1 is a grouped virtual subsystem (**Treat as grouped when propagating variant conditions** is selected) while Subsystem2 (**Treat as grouped when propagating variant conditions** is clear) is an ungrouped virtual subsystem.

A Subsystem block becomes a grouped virtual subsystem when you select the **Treat as grouped when propagating variant conditions** checkbox in the block parameters

dialog box. When the **Treat as grouped when propagating variant conditions** checkbox is clear, the Subsystem is an ungrouped virtual subsystem.

A grouped subsystem represents a system of equation and hence the propagated conditions also apply to the blocks within this system. A grouped subsystem has a continuous boundary line. An ungrouped subsystem does not represent a system of equation and the blocks within it have ungrouped semantics. An ungrouped subsystem has a dotted boundary line and the conditions are propagated into the subsystem.

The variant condition $V = 1$ propagates to Subsystem1 and further to the blocks within it as Subsystem1 is a grouped virtual subsystem (represents a system of equation). Since Subsystem1 is a system, the condition also applies the blocks within the system.

Subsystem2 that is an ungrouped virtual subsystem (does not represent a system of equation) also receives $V = 1$ as the propagated condition, and the propagated variant condition $V = 1$ propagates into Subsystem 2 as if the subsystem were expanded. The dotted lines on the Subsystem 2 icon indicates that it is flattened during Simulink compilation and hence you can see variant condition for those blocks inside it.

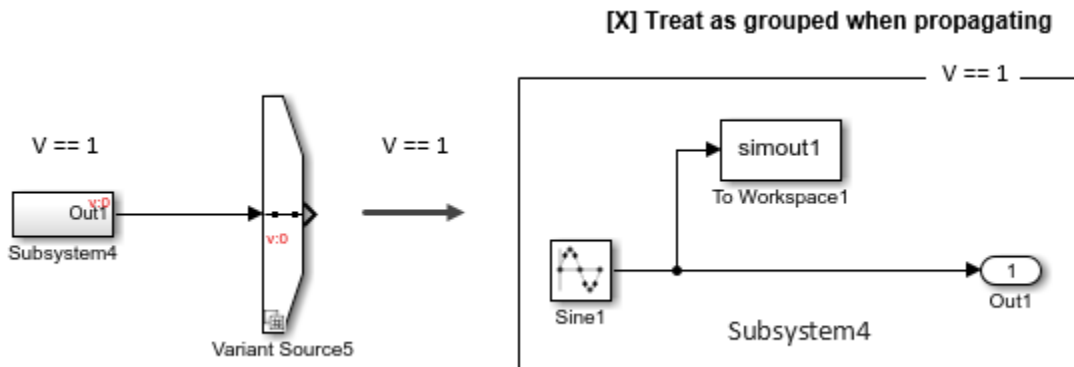

Variant Source3 is connected to a nonvirtual (atomic) subsystem with $V = 1$ as the propagated variant condition. A nonvirtual (atomic) subsystem always represents a system of equations. An atomic subsystem has a continuous solid boundary line. The variant condition does not propagate inside the nonvirtual subsystem. Instead, it stays on the boundary. However, all blocks inside that subsystem get same variant condition as the Subsystem. The nonvirtual subsystem behaves as an entity.

Virtual subsystems by default works like a grouped collection of blocks where all the blocks contained inside the subsystem have the same variant condition. This is true when the **Treat as grouped when propagating variant conditions** parameter is selected. Virtual subsystems behave like an ungrouped collection of blocks when the **Treat as grouped when propagating variant conditions** parameter is cleared. In this example, the behavior of the Subsystem2 (Ungrouped) may not be as expected as the block never becomes conditional. Nonvirtual subsystems always behave like an entity and the contents only execute when the condition assigned to the subsystem is satisfied. Nonvirtual subsystems, Model blocks, and grouped virtual subsystems behave the same.

Difference in behavior of Virtual Subsystems with Treat as grouped when propagating variant conditions is On or Off

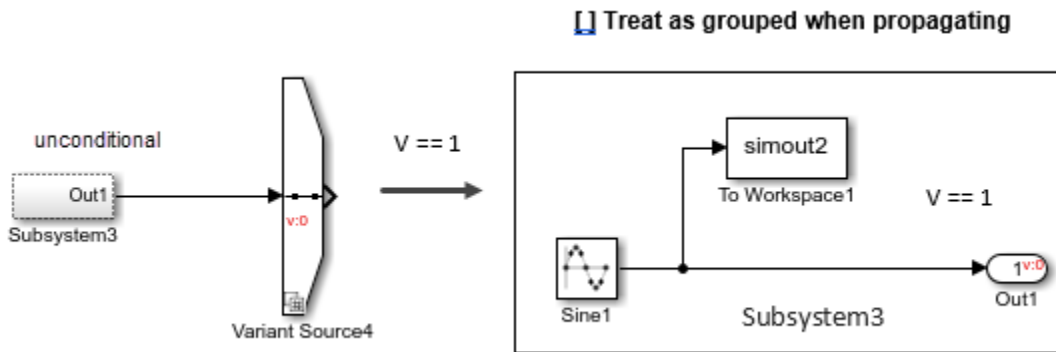

Treat as grouped when propagating variant conditions option is On: Consider an example with Variant Source block: Variant Source5 and a virtual subsystem

Subsystem4. The Variant Source5 has a condition $V = 1$. Subsystem4 has a Sine Wave connected to a To Workspace1 and Output blocks.

Subsystem4 gets condition $V = 1$ as $V = 1$ is propagated from Variant Source5. The blocks inside Subsystem4 indirectly inherits the condition from Subsystem4. Subsystem4 is conditional as its inports/outputs are conditional. To make the Subsystem4 as unconditional, add a new output or clear the **Treat as grouped when propagating variant conditions** option.

Treat as grouped when propagating variant conditions option is Off: Consider an example with a Variant Source block: Variant Source4 and a virtual subsystem Subsystem3. The Variant Source4 has condition $V = 1$. Subsystem3 has a Sine Wave connected to a To Workspace and Output blocks.

Subsystem3 gets the condition $V = 1$ as $V = 1$ propagates from Variant Source4. However due to unconditional block To Workspace1, the propagation stops and the condition $V = 1$ is set only to the Out1 port. Now the Subsystem3 is also unconditional due to presence of unconditional blocks within.

Variant Subsystems

This model illustrates Simulink® variant subsystems. Variant subsystems let you provide multiple implementations for a subsystem where only one implementation is active during simulation. You can programmatically swap out the active implementation and replace it with one of the other implementations without modifying the model.

Overview of Variant Subsystems

A Variant Subsystem block contains two or more child subsystems where one child is active during model execution. The active child subsystem is referred to as the *active variant*. You can programmatically switch the active variant of the Variant Subsystem block by changing values of variables in the global workspace, or by manually overriding variant selection using the Variant Subsystem block dialog. The *active variant* is programmatically wired to the Inport and Outport blocks of the Variant Subsystem by Simulink during model compilation.

To programmatically control variant selection, a `Simulink.Variant` object is associated with each child subsystem in the Variant Subsystem block dialog. `Simulink.Variant` objects are created in the MATLAB® global workspace. These objects have a property named `Condition`, which is an expression, that evaluates to a boolean value and is used to determine the active variant child subsystem.

Note: You can specify variant controls in the MATLAB® global workspace or a data dictionary.

For example, defining

```
VSS_LINEAR_CONTROLLER=Simulink.Variant('VSS_MODE==1');
```

in the global workspace creates a `Simulink.Variant` object where the constructor argument (`'VSS_MODE==1'`) defines when the variant is active. Using the Variant Subsystem dialog, you then associate `VSS_LINEAR_CONTROLLER` with one of the child subsystems within the Variant Subsystem. Defining

```
VSS_MODE=1
```

in the global workspace, activates the `VSS_LINEAR_CONTROLLER` variant. The condition argument can be a *simple expression* consisting of scalar variables, enumerations, equality, inequality, `&&`, `,` and `~`. Parenthesis `()` can be used for precedence grouping.

Using Variant Subsystems

The model in this example uses the following variant objects and variant control variable, which are defined in the MATLAB global workspace:

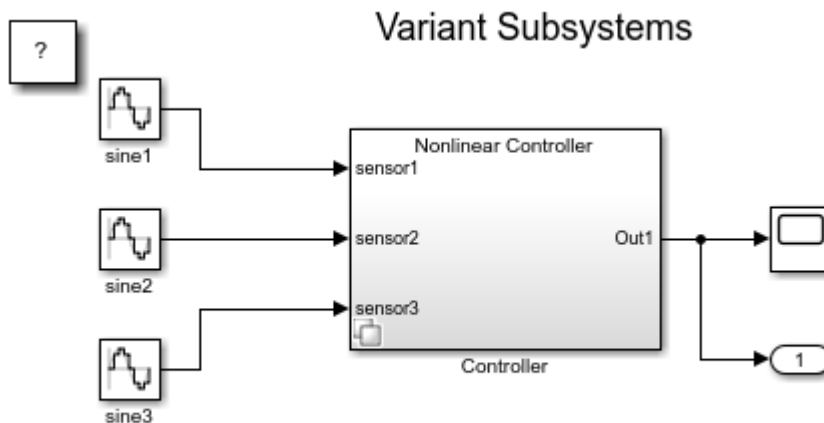

```
VSS_LINEAR_CONTROLLER=Simulink.Variant('VSS_MODE==1');
```

```
VSS_NONLINEAR_CONTROLLER=Simulink.Variant('VSS_MODE==2');
```

```
VSS_MODE=2;
```

Opening the example model `sldemo_variant_subsystems` runs the **PreLoadFcn** defined in File -> ModelProperties -> Callbacks. This populates the global workspace with the variables for the Variant Subsystem block named Controller:

```
open_system('sldemo_variant_subsystems')
```

Copyright 2010-2013 The MathWorks, Inc.

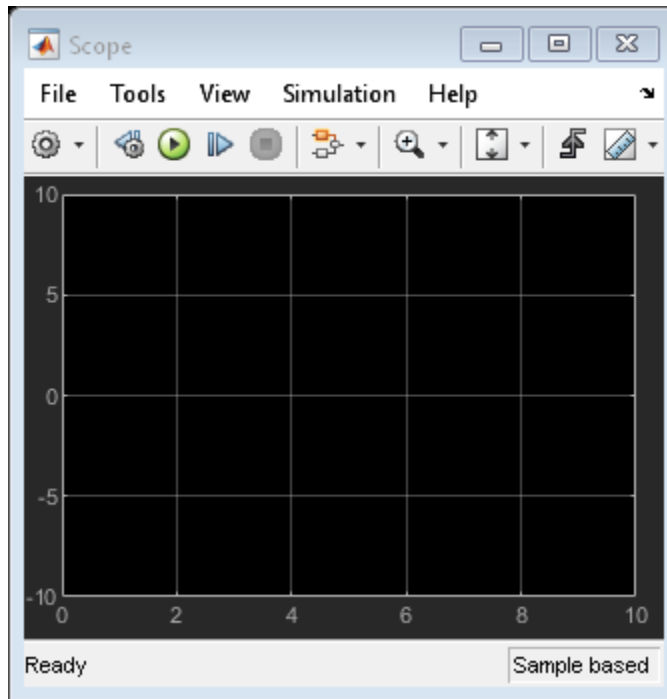

Figure 1: The example model, `sldemo_variant_subsystems`

To specify the `Simulink.Variant` objects association for the Controller subsystem, right-click on the Controller subsystem and select `Subsystem Parameters`, which will open the Controller subsystem block dialog.

The Controller subsystem block dialog specifies two potential variants. The two variants are in turn associated with the two `Simulink.Variant` objects `VSS_LINEAR_CONTROLLER` and `VSS_NONLINEAR_CONTROLLER`, which exist in the global workspace. These objects have a property named **Condition**, an expression that evaluates to a boolean and that determines which variant is active. The condition is also shown in the Variant Subsystem block dialog. In this example, the Condition properties of `VSS_LINEAR_CONTROLLER` and `VSS_NONLINEAR_CONTROLLER` are `VSS_MODE == 1` and `VSS_MODE == 2`, respectively. The variable `VSS_MODE` resides in the global workspace, and can be a standard MATLAB variable or a `Simulink.Parameter`.

If there is no associated variant object or a '%' (comment) character prefixes the variant object in the Variant Subsystem parameters dialog box, then the child subsystem is considered commented out and is not used during model execution.

```
open_system('sldemo_variant_subsystems/Controller');
```

Figure 2: Contents of the Controller subsystem block

Within a Variant Subsystem block, you can place Inport, Outport, and Subsystem blocks. In this example, the Linear Controller Subsystem block is associated with the variant object, VSS_LINEAR_CONTROLLER, and the Nonlinear Controller Subsystem block is associated with the variant object, VSS_NONLINEAR_CONTROLLER.

Signal connections are not allowed in the Variant Subsystem. Simulink programmatically wires up the Inport and Outport blocks to the active variant when simulating the model.

Switching Active Variants

To simulate using the Linear Controller variant, define:

```
VSS_MODE=1
```

in the global workspace and then simulate the model.

```
open_system('sldemo_variant_subsystems/Controller','parameter');
close_system('sldemo_variant_subsystems/Controller')
VSS_MODE=1; %#ok (used by sldemo_variant_subsystems)
sim sldemo_variant_subsystems;
```

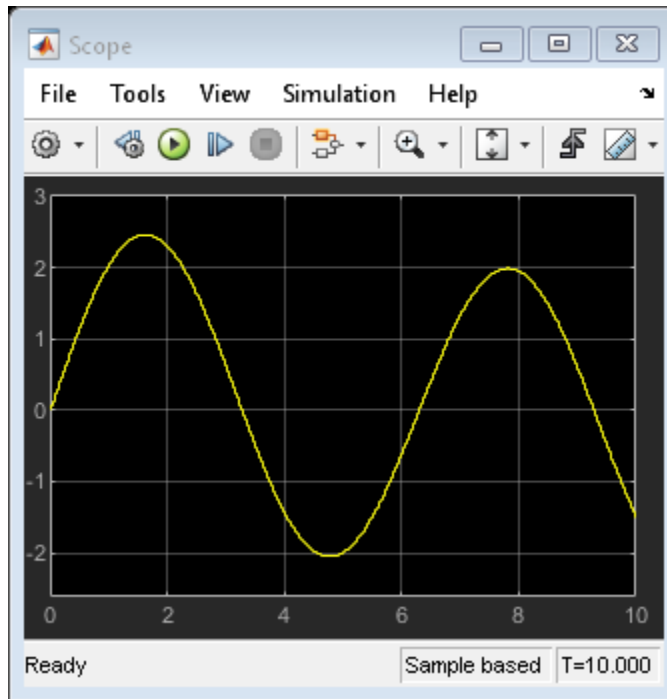

Figure 3: Simulation using the Linear Controller variant

To simulate using the Nonlinear Controller, define

```
VSS_MODE=2
```

in the global workspace and then simulate the model.

```
VSS_MODE=2; %#ok (used by sldemo_variant_subsystems)  
sim sldemo_variant_subsystems;
```

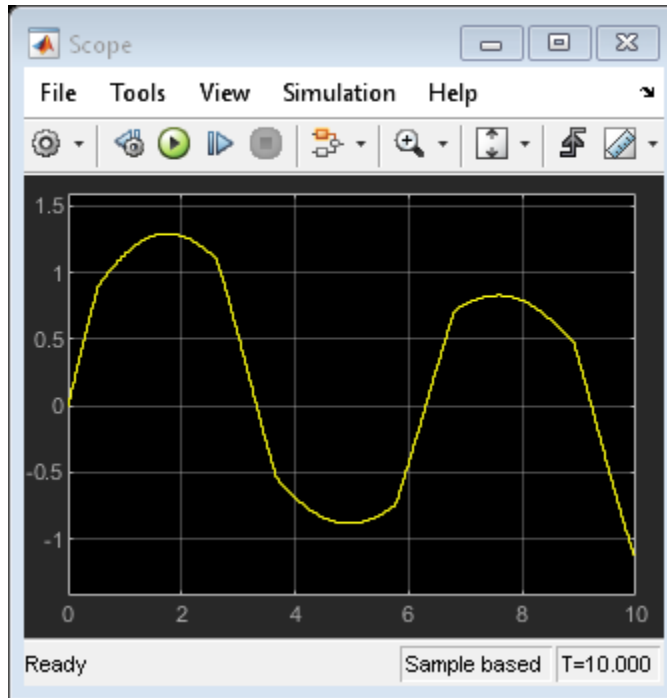

Figure 4: Simulation using the Nonlinear Controller variant

Enumerations and Reuse

The `sldemo_variant_subsystems_enum` model illustrates the following Simulink.Variant capabilities:

1. **Enumerations:** MATLAB enumeration classes can be used to improve readability in the conditions of the variant object.
2. **Reuse:** Simulink.Variant objects can be reused in different Variant Subsystem blocks.

This example uses the following variables which are defined in the MATLAB global workspace:

```
VSSE_LINEAR_CONTROLLER=Simulink.Variant( ...
'VSSE_MODE==sldemo_vss_CONTROLLER_TYPE.LINEAR')
```

```
VSSE_NONLINEAR_CONTROLLER=Simulink.Variant( ...  
'VSSE_MODE==sldemo_vss_CONTROLLER_TYPE.NONLINEAR')  
  
VSSE_MODE=sldemo_vss_CONTROLLER_TYPE.LINEAR  
  
VSSE_PROTOTYPE=Simulink.Variant( ...  
'VSSE_MODE_BUILD==sldemo_vss_BUILD_TYPE.PROTOTYPE')  
  
VSSE_PRODUCTION=Simulink.Variant( ...  
'VSSE_MODE_BUILD==sldemo_vss_BUILD_TYPE.PRODUCTION')  
  
VSSE_MODE_BUILD=sldemo_vss_BUILD_TYPE.PRODUCTION
```

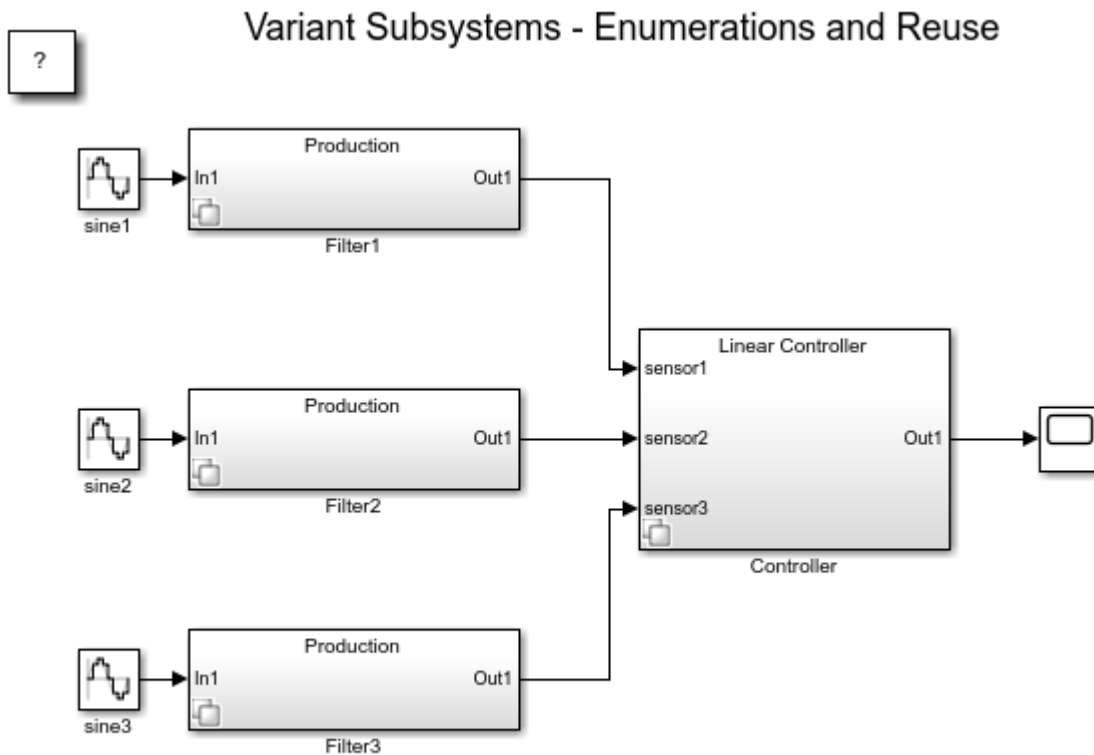

In these `Simulink.Variant` objects, we use the enumeration classes, `sldemo_vss_BUILD_TYPE.m`, and `sldemo_vss_CONTROLLER_TYPE.m` to define the `Simulink.Variant` **Condition** parameters which improves readability.

The three filter Variant Subsystems blocks, `Filter1`, `Filter2`, and `Filter3` all use the `VSSE_PROTOTYPE` and `VSSE_PRODUCTION` `Simulink.Variant` objects.

Note: The name of the enumeration class must be unique among data type names and global workspace variable names, and is case-sensitive.

Opening the example model `sldemo_variant_subsystems_enum` runs the **PreLoadFcn** defined in `File -> ModelProperties -> Callbacks`. This populates the global workspace with variables for the Variant Subsystem blocks:

```
open_system('sldemo_variant_subsystems_enum')
```

Copyright 2010-2013 The MathWorks, Inc.

Figure 5: The example model, `sldemo_variant_subsystems_enum`

Code Generation

You can use the Simulink® Coder™ to generate code from a model containing Variant Subsystem blocks. By default the generated code contains only the active variant. Alternatively, you can generate code for all variants guarded by C preprocessor conditionals (`#if`, `#elif`, `#endif`) when using the Embedded Coder™.

During the code generation process, one Merge block is placed at the input of each Outputport block within the variant subsystem and connected to the child subsystems within the variant subsystem. Thus, the restrictions placed on Merge blocks apply to the

contents of Variant Subsystem blocks. The restriction checks are only performed when generating code. In addition, the child subsystems of the Variant Subsystem block must be Atomic subsystems, which are created by selecting the **Treat as atomic unit** parameter of the Subsystem parameters dialog box.

Code generation of preprocessor conditionals is active when

- 1 Embedded Coder target is selected on the Code Generation pane of the Configuration Parameters dialog box.
- 2 The **Override variant conditions and use following variant** is *not* selected on the Variant Subsystem block parameter dialog box.

When code generation of preprocessor conditionals is active, the generated code contains all child subsystems of the Variant Subsystem blocks protected by C preprocessor conditionals. In this case, the selection of the active variants is deferred until compile-time of the generated code. Only one variant object which is encoded in C macros, must evaluate to true (be active).

In addition, the variant control variables (such as VSS_MODE and VSSE_MODE above) must be MATLAB variables or Simulink.Parameter objects that specify how the #define's for the variant control variables are managed in the generated code. For the sldemo_variant_subsystems, you can clear the VSS_MODE double from the global workspace. Use Model Explorer -> Simulink Root -> Global Workspace to add a new Simulink.Parameter named VSS_MODE. Specify the parameter **Value** as 1 or 2, the **Data Type** as int32, and **Storage class** as ImportedDefine with **Custom attributes Header file** as sldemo_variant_subsystems_vdef.h. You should then create this header in the current working directory:

```
/* File: sldemo_variant_subsystems_vdef.h */
#ifndef SLDEMO_VARIANT_SUBSYSTEM_VDEF_H
#define SLDEMO_VARIANT_SUBSYSTEM_VDEF_H
#define VSS_MODE 1
#endif
```

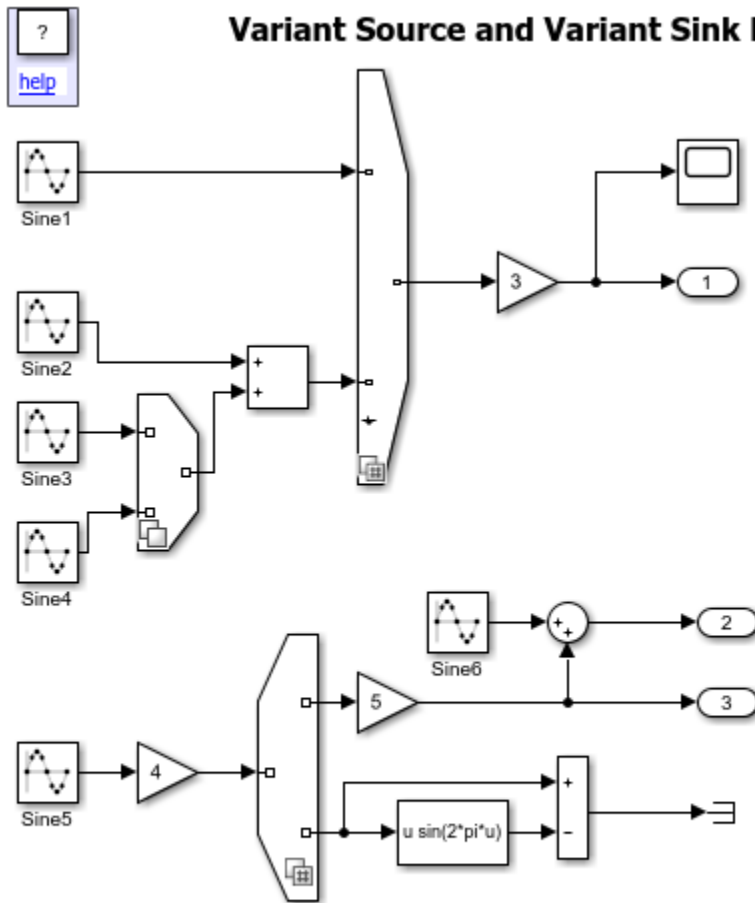

See the Embedded Coder documentation for more information on code generation for variant subsystems.

Variant Source and Variant Sink Blocks

Define variant choice regions in the Variant Source and Sink blocks based on the block connectivity. The variant choice regions are computed by Simulink when you update diagram (**Simulation > Update Diagram**).

The process of computing the variant choice regions is called `variant condition propagation`. The Variant Source block provides variation on the source of a signal, and the Variant Sink blocks provides variation on the destination (sink) of a signal.

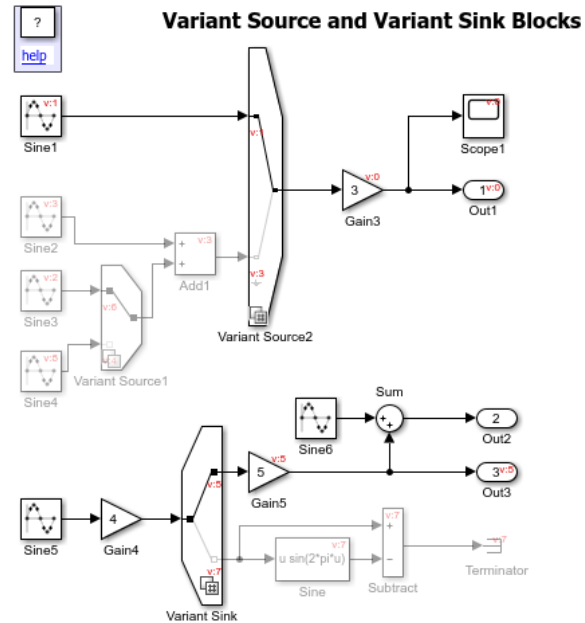

Consider a model containing two Variant Source blocks (`Variant Source1` , `Variant Source2`) and a Sink block (`Variant Sink`).

Copyright 2016 The MathWorks, Inc.

The variant conditions at the inports and outports of Variant Source and Sink blocks, respectively, determine the activation and deactivation of the blocks connected to them. To view the annotations and the variant conditions, click **Display > Blocks > Variant Conditions**.

Annotation	Simulation
v:0	$V == 1 \ \ V == 2$
v:1	$V == 1$
v:2	$V == 2 \ \&\& \ W == 1$
v:3	$V == 2$
v:4	$V == 4$
v:5	$W == 1$
v:6	$W == 1$
v:7	$W == 2$
v:8	false

Let's analyze the variant conditions and the block activation state.

- In Variant Source1, when $W==1$, the Sine3 block is active, and when $V==4$, the Sine4 block is active.
- In Variant Source2, when $V==1$, the Sine1 block is active, and when $V==2$, the Add1 block is active.
- At Add1 block the condition propagation continues making Variant Source1 block to be active only when the $V==2$. This further propagates to Sine3 block and Sine4 block, making the Sine3 block active at $V==2 \ \&\& \ W==1$ and the Sine4 block active at $V==2 \ \&\& \ W==2$, respectively.
- The Gain3 block is active when either $V==1$ or $V==2$, and hence the condition $V==2 \ || \ V==1$. The variant condition is further propagated to Scope1 and Out1.
- The blocks connected to the output of Variant Sink are active when $W==1$ (Gain5), or $W==2$ (Sine, Subtract, Terminator).
- The Sum block illustrates two key concepts in variant condition propagation: Signals are only variant if explicitly marked or when all paths can be proven to be variant. To make the Sine6, Sum, Out2 variant, place a Single-Input Single-Output Variant Source

before Out2 (or after the Sine6). Reading an inactive signal is equivalent to reading ground. When $W \neq 1$, then the bottom input to the Sum block is inactive and $Out2 = Sine6 + ground$.

If you select the **Analyze all choices during update diagram and generate preprocessor conditionals** parameter for the Variant Source and Variant Sink block, the generated code contains the code for the active and the inactive (`#if COND`). If this parameter is not selected, then code is generated only for the active choices.

If you select the **Allow zero active variant controls** parameter for the Variant Source and Variant Sink block, you can simulate the variant model without an active variant. In such cases, Simulink disables the blocks connected to the input and output stream of Variant Source and Variant Sink. These disabled blocks are ignored from update diagram or simulation.

More About

- “Define and Configure Variant Sources and Sinks” on page 11-69

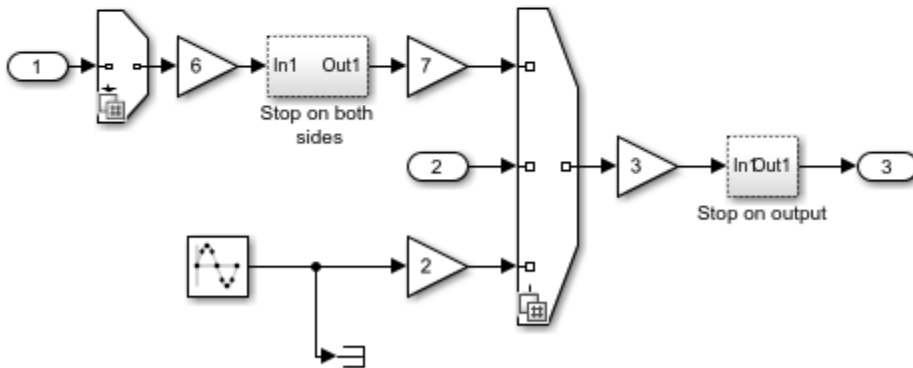

Control Variant Condition Propagation

During variant condition propagation, Simulink automatically assigns conditions to blocks. You can control how the variant condition propagates upstream and downstream in a model.

Consider this model.

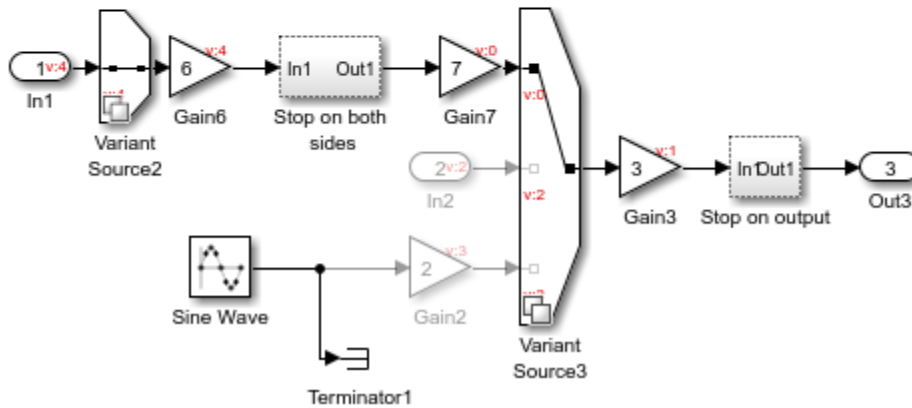

Controlling and Stopping Variant Condition Propagation

Copyright 2016 The MathWorks, Inc.

In Simulink, click **Simulation** > **Run** to view the variant condition propagation to blocks.

The Variant Source1 block has the $A==1$ condition, which propagates backward and forward to the blocks connected to Variant Source1 block. The variant condition propagates to Gain4 block but does not propagate to the Sine Wave1 block.

The Scope block is unconditional and receives its inputs from the Sine Wave1 block. Therefore, the Sine Wave1 block is unconditional. If you remove the Scope block, the variant condition propagates to the Sine Wave1 block.

If you replace the Scope block with any other block (including the Terminator block), the Sine Wave1 block remains unconditional.

A block is unconditional if at least one of its inputs is unconditional. The input side of the Sum block is connected to Gain5 (conditional) block and to the Sine Wave2 (unconditional) block. Therefore, the Sum block is unconditional.

You can use these concepts to create a Subsystem block that controls the propagation of variant conditions to both sides or to one side.

Stop Propagation of Variant Condition Upstream and Downstream

Consider the section of the model that is connected to the Variant Source2 and Variant Source3 blocks. When you simulate the model, the Variant condition from the Variant Source2 block and the Variant Source3 blocks propagates upstream and downstream.

The Stop on both sides block between Gain6 and the Gain7 block prevents the Variant condition from propagating upstream or downstream. Double-click the Stop on both sides block to view its components.

The Stop on both sides block uses a Terminator to stop the variant condition propagation on upstream of the Subsystem block. To stop the condition propagation on the downstream side of the Subsystem block, one of the inports is connected to Ground (unconditional). Therefore, this arrangement stops the variant condition propagation upstream and downstream. Similarly, you can selectively stop the condition propagation of variant condition at upstream or downstream for a model. For example, if you remove the Terminator block, variant condition propagates upstream but is stopped downstream.

Stop Propagation of Variant Condition Downstream

Here, one input port of the Subsystem block is unconditional making the Subsystem block unconditional at input side and thus stopping the propagation of variant condition downstream.

More About

- “Define and Configure Variant Sources and Sinks” on page 11-69

Propagate Variant Condition to Conditional Subsystem

A conditional subsystem (also known as a conditionally executed subsystem) is a type of subsystem where you can control the execution using an external signal.

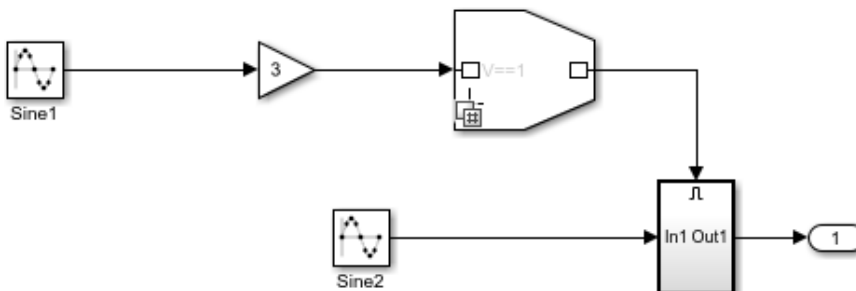

Enabled, Triggered, and Function-Call Subsystems are examples of conditional subsystems. The signal that controls a conditional subsystem is called the *control signal* and the port from which the signal enters the block is called the *control port*. For more information on conditional subsystems, see “Conditionally Executed Subsystems Overview” on page 10-3.

You can use a Variant block to control the execution of a conditional subsystem blocks.

Consider this model.

Variant Condition Propagation to Conditionally Executed Subsystems

Copyright 2016 The MathWorks, Inc.

Variant Source1 is a single-input/single-output Variant Source block with variant condition as $V==1$. When you simulate this model, the variant condition from the Variant Source1 block propagates to the control port of the Subsystem block and then to the blocks connected to its inports and outports.

For example, when $V=1$, Variant Source1 is active and the Variant condition propagates to the control port of the Subsystem block. Therefore, the Subsystem block is also active and the variant condition propagates to the blocks connected to the input and output ports of the Subsystem block.

Propagate Variant Condition to Function-Call Subsystem

A Function-Call Subsystem block is a subsystem that another block can invoke directly during simulation. The Function-Call Subsystem block is analogous to a function in procedural programming language. For more information, see “Using Function-Call Subsystems” on page 10-44.

You can use a single-input/single-output variant block to make the Function-Call Subsystem block conditional.

The Variant Source block has condition $V==1$, where V is a `Simulink.Parameter`.

When you simulate this model, the variant condition from the Variant Source block propagates to the control port of the SubA subsystem block and further propagates to the blocks connected to its inports and outports.

For example, when $V=1$, the SubA block is active and the variant condition propagates backward and forward to the blocks connected to the input (In1) and output (Out1) ports.

When $V\sim=1$ (for example, $V=0$), SubA becomes inactive, making Out1 to be inactive. In2 remains active as it is connected to SubB, which is active.

If In2 is not connected to SubB, In2 becomes inactive when $V\sim=1$.

Note: If the Function-Call Subsystem is placed inside a virtual grouped subsystem, the variant condition triggering the Function-Call Subsystem must match the corresponding condition on the input of the higher level subsystem block.

- “Define and Configure Variant Sources and Sinks” on page 11-69

Hierarchical Nesting of Variant Sources and Variant Sinks

This example shows how to use Variant Source blocks to provide Variant selection on sensors.

This model illustrates how you can use multiple Variant Source blocks to provide variant selection on sensors. In this model, multiple Variant Source blocks are used to create hierarchical nesting of variant choices. Choices are first grouped by series: A Series, B Series, and C Series. A combination of one or more series is provided as input for a device model. The resulting device model is provided as input to the vendor by including or excluding a sensor selection. In this model, a constant block is masked as a place holder for analog-to-digital converter (A/D) blocks. This model shows variation of sensor inputs. Alternatively, you may use Variant Sink blocks to create variation of actuator outputs. The variant control variables that parameterize the Variant Source blocks are defined in the PostLoadFcn of "File > Model Properties > Callbacks".

Consider this model with Variant Source blocks.

In this model, the Variant Source block "Vendor" gets inputs from Variant Source blocks "X Sensor" and "Device Model" blocks. The "X Sensor" block gets inputs from constants AD7 and AD8. The "Device Model" block gets inputs from Variant Source blocks "A Series", "B Series", and "C Series". The Variant Source blocks "A Series", "B Series", and "C Series" get inputs from constant blocks.

Now simulate the model,

When you simulate the model, the constant block AD5 is active. The Variant Source block "Vendor" selects between two vendors, `VENDOR==1` or `VENDOR==2` and in the base workspace, `VENDOR` is a Simulink.Parameter with `VENDOR.Value=1`. The Variant Source block "Device Model" selects between `DEVICE_MODEL==1`, `DEVICE_MODEL==2`, or `DEVICE_MODEL==3` and in the base workspace, `DEVICE_MODEL.Value=3`. The Variant Source block "C Series" selects between `C_SERIES==1` and `C_SERIES==2` and in the base workspace, `C_SERIES.Value=2`.

Code Generation

You can use the Simulink Coder to generate code from a model containing Variant Subsystem blocks. By default, the generated code contains only the active variant.

Alternatively, you can generate code for all variants guarded by C preprocessor conditionals (`#if`, `#elif`, `#endif`) when using the Embedded Coder.

More about

Export-Function model with Variant Subsystem

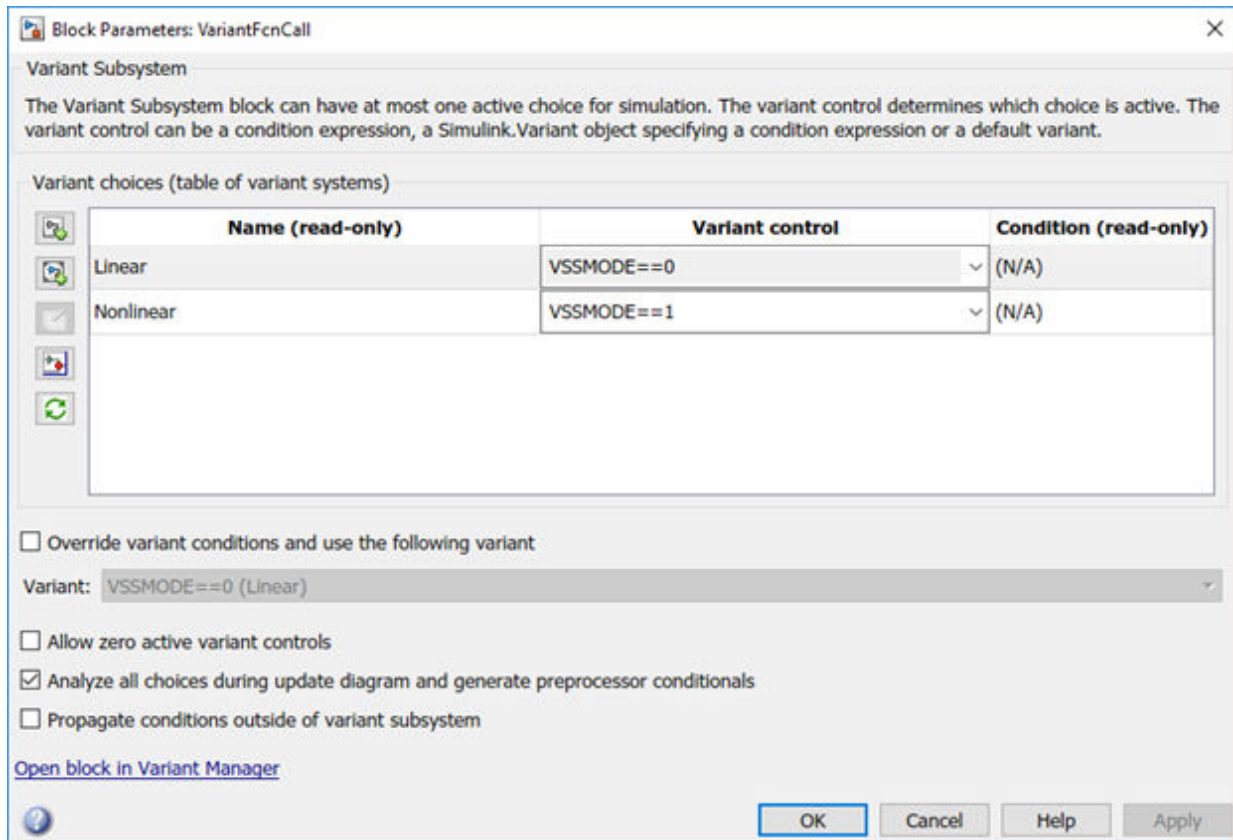

This example shows how to use Variant Subsystem model with Function-Call blocks as choice.

Consider this model containing a Variant Subsystem block.

Note: If you use Function-Call system as a variant choice for the Linear Subsystem block, then the other Subsystem block (Nonlinear) within the Variant Subsystem must also be Function-Call system. Additionally, the control ports in Linear and Nonlinear blocks and the corresponding inport block must have the same name (fcn).

The Variant Subsystem "VariantFcnCall" gets the inputs from two inport blocks. The "VariantFcnCall" block has two variant choices, Linear and Nonlinear governed by conditions $VSSMODE==0$ and $VSSMODE==1$. Root inport(fcn) is a function-call inport connecting variant subsystem making this model as export function model.

You can simulate the model `slexVariantSubsystemEnableChoice` and verify the behavior of the counters by examining the results.

Code Generation

You can use the Simulink Coder to generate code from a model containing Variant Subsystem blocks. By default the generated code contains only the active variant. Alternatively, you can generate code for all variants guarded by C preprocessor conditionals (`#if`, `#elif`, `#endif`) when using the Embedded Coder. In the generated code, the code inside `fcn` definition is guarded by C preprocessor conditionals inside `export` function.

```
% fcn() {
% #if VSSMODE==0
```

```
% // code for Linear choice  
% .....  
% #endif  
% #if VSSMODE==1  
% // code for Nonlinear choice  
% .....  
% #endif
```

More about

- “Variant Systems with Conditional Systems” on page 11-121

Variant Subsystem with Enable Subsystem as Choice

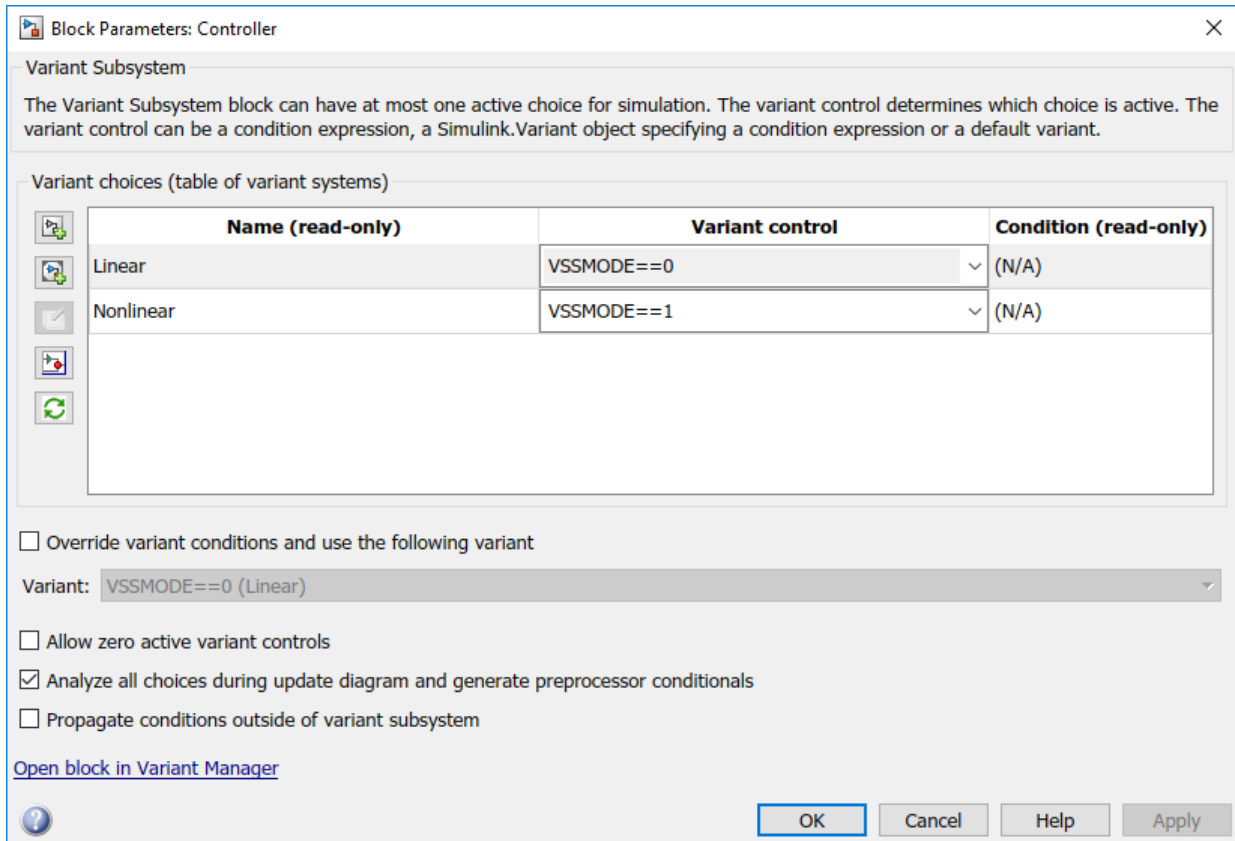

This example shows how to use Variant Subsystem model with Enable Subsystem as choice.

Consider this model with a Variant Subsystem block.

Note: If you use Enable Subsystem as a variant choice for the Linear Subsystem block then the other Subsystem block (Nonlinear) within the Variant Subsystem must also be Enable Subsystem.

The Variant Subsystem block "Controller" gets the input from Sine Wave and Inport blocks. The "Controller" block has two Variant choices, Linear and Nonlinear. The Variant choices are governed by conditions $VSSMODE==0$ and $VSSMODE==1$. This model can simulate and generate code based on $VSSMODE$ value.

You can simulate the model `slexVariantSubsystemEnableChoice` and verify the behavior of the counters by examining the results.

Code Generation

You can use the Simulink Coder to generate code from a model containing Variant Subsystem blocks. By default the generated code contains only the active variant. Alternatively, you can generate code for all variants guarded by C preprocessor conditionals (`#if`, `#elif`, `#endif`) when using the Embedded Coder. In the generated code, the code inside fcn definition is guarded by C preprocessor conditionals inside export function.

```
%step() {
% #if VSSMODE==0
```

```
% // code for Linear choice
% .....
% #elif VSSMODE==1
% // code for Nonlinear choice
% .....
% #endif
```

Propagating Variant Conditions to Subsystems

A Subsystem can be virtual or atomic. Simulink propagates variant conditions differently to such Subsystems. This example shows the propagation of variant conditions from Inline variants to Subsystem blocks. Consider a model as shown:

Variant Condition Propagation to Subsystems

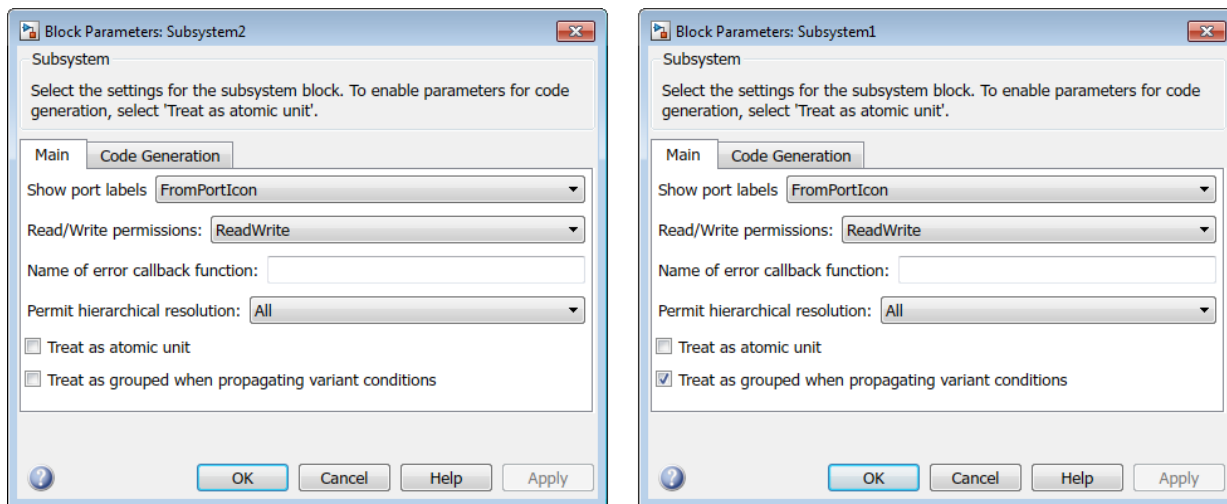

Click **Simulation > Run** to simulate this model and see the variant conditions being propagated from the Variant Source blocks to the blocks connected to it.

The variant condition annotation helps you visualize the propagated conditions. To be able to view the variant condition annotation, click **Display > Blocks > Variant Condition Legend**.

The model contains three Variant Source blocks: Variant Source1, Variant Source2, and Variant Source3, respectively.

Variant Source1 contains conditions $V = 1$ and $V = 2$ at inport. The variant condition $V = 1$ propagates to GainA1 while $V = 2$ propagates to Sine2. The Sine1 block does not get any propagated variant conditions because it is connected to a block, which is always consumed irrespective of the variant condition. If the To Workspace block1 did not exist or was commented-out before simulating the model, variant condition $V = 1$ propagates to Sine1.

Variant Source2 is connected to virtual subsystems Subsystem1 and Subsystem2 that have identical contents, a Sine Wave block connected to a To Workspace and an Output blocks. Subsystem1 is a grouped virtual subsystem (**Treat as grouped when propagating variant conditions** is selected) while Subsystem2 (**Treat as grouped when propagating variant conditions** is clear) is an ungrouped virtual subsystem.

A Subsystem block becomes a grouped virtual subsystem when you select the **Treat as grouped when propagating variant conditions** checkbox in the block parameters

dialog box. When the **Treat as grouped when propagating variant conditions** checkbox is clear, the Subsystem is an ungrouped virtual subsystem.

A grouped subsystem represents a system of equation and hence the propagated conditions also apply to the blocks within this system. A grouped subsystem has a continuous boundary line. An ungrouped subsystem does not represent a system of equation and the blocks within it have ungrouped semantics. An ungrouped subsystem has a dotted boundary line and the conditions are propagated into the subsystem.

The variant condition $V = 1$ propagates to Subsystem1 and further to the blocks within it as Subsystem1 is a grouped virtual subsystem (represents a system of equation). Since Subsystem1 is a system, the condition also applies the blocks within the system.

Subsystem2 that is an ungrouped virtual subsystem (does not represent a system of equation) also receives $V = 1$ as the propagated condition, and the propagated variant condition $V = 1$ propagates into Subsystem 2 as if the subsystem were expanded. The dotted lines on the Subsystem 2 icon indicates that it is flattened during Simulink compilation and hence you can see variant condition for those blocks inside it.

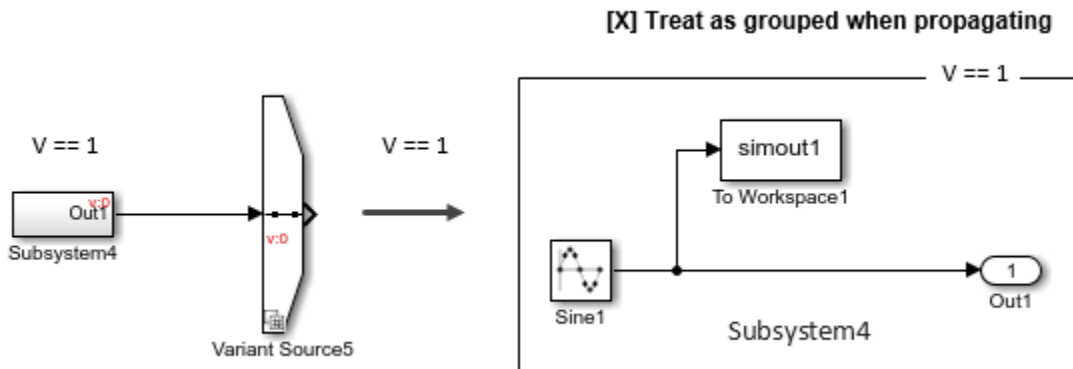

Variant Source3 is connected to a nonvirtual (atomic) subsystem with $V = 1$ as the propagated variant condition. A nonvirtual (atomic) subsystem always represents a system of equations. An atomic subsystem has a continuous solid boundary line. The variant condition does not propagate inside the nonvirtual subsystem. Instead, it stays on the boundary. However, all blocks inside that subsystem get same variant condition as the Subsystem. The nonvirtual subsystem behaves as an entity.

Virtual subsystems by default works like a grouped collection of blocks where all the blocks contained inside the subsystem have the same variant condition. This is true when the **Treat as grouped when propagating variant conditions** parameter is selected. Virtual subsystems behave like an ungrouped collection of blocks when the **Treat as grouped when propagating variant conditions** parameter is cleared. In this example, the behavior of the Subsystem2 (Ungrouped) may not be as expected as the block never becomes conditional. Nonvirtual subsystems always behave like an entity and the contents only execute when the condition assigned to the subsystem is satisfied. Nonvirtual subsystems, Model blocks, and grouped virtual subsystems behave the same.

Difference in behavior of Virtual Subsystems with Treat as grouped when propagating variant conditions is On or Off

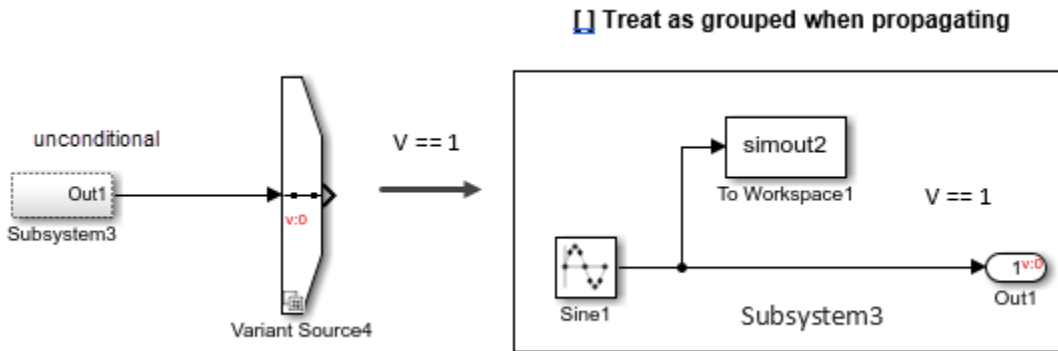

Treat as grouped when propagating variant conditions option is On: Consider an example with Variant Source block: Variant Source5 and a virtual subsystem

Subsystem4. The Variant Source5 has a condition $V = 1$. Subsystem4 has a Sine Wave connected to a To Workspace1 and Output blocks.

Subsystem4 gets condition $V = 1$ as $V = 1$ is propagated from Variant Source5. The blocks inside Subsystem4 indirectly inherits the condition from Subsystem4. Subsystem4 is conditional as its inports/outputs are conditional. To make the Subsystem4 as unconditional, add a new output or clear the **Treat as grouped when propagating variant conditions** option.

Treat as grouped when propagating variant conditions option is Off: Consider an example with a Variant Source block: Variant Source4 and a virtual subsystem Subsystem3. The Variant Source4 has condition $V = 1$. Subsystem3 has a Sine Wave connected to a To Workspace and Output blocks.

Subsystem3 gets the condition $V = 1$ as $V = 1$ propagates from Variant Source4. However due to unconditional block To Workspace1, the propagation stops and the condition $V = 1$ is set only to the Out1 port. Now the Subsystem3 is also unconditional due to presence of unconditional blocks within.

“Model Explorer: Property Dialog Pane” on page 12-33

What You Can Do Using the Model Explorer

Use the Model Explorer to view, modify, and add elements of Simulink models, Stateflow charts, and workspace variables. The Model Explorer lets you focus on specific elements (for example, blocks, signals, and properties) without navigating through the model or chart.

Use the Model Explorer to search for:

- Variables in workspaces and data dictionaries
- Variable usage in a model
- Instances of a type of block
- Block parameters and parameter values

You can combine search criteria and iteratively refine the results. Search in Model Explorer for model elements, starting with the node you select in the model hierarchy. You can search the entire model, in a particular system, or in a system and all the systems below it in the hierarchy. For details on the options, see “Search Bar Controls” on page 12-4.

For an example showing how to search for a parameter, see “Search Using Model Explorer” on page 12-50.

Using your search results, you can apply changes to multiple elements at once.

To manipulate model data (block parameters, signals, and states) in a searchable, sortable table, consider using the Model Data Editor. You can specify data attributes such as parameter values, signal names, and initial values for states. See “Configure Data Properties by Using the Model Data Editor” on page 62-179.

To create, modify, and view the entries in a data dictionary, use the Model Explorer. See “Edit and Manage Workspace Variables by Using Model Explorer” on page 62-149 and “View and Revert Changes to Dictionary Data” on page 66-27.

Open the Model Explorer and Edit Object Properties

To open the Model Explorer, use one of these approaches:

- From the Simulink Editor **View** menu, select **Model Explorer** or select the Model Explorer icon  from the toolbar.
- In an open model in the Simulink Editor, right-click a block and from the context menu, select **Explore**.
- In an open Stateflow chart, right-click in the drawing area and from the context menu, select **Explore**.
- At the MATLAB command line, enter `daexplr`.

Use this workflow to view and edit object properties:

- 1 To specify whether to display only the current system or the whole system hierarchy, select the model in the **Model Hierarchy** pane.
- 2 Control the model information the **Contents** pane displays:
 - Control which property columns to display using the **View > Column View** option.
 - Control which types of objects to display using the **View > Row Filter** option.
 - Directly manipulate column headings
- 3 Identify model elements with specific values using the search bar.

- 4 Edit the values for model elements, in either the **Contents** pane or the **Dialog** pane. To edit workspace variables, you can use the Variable Editor.

Search Bar Controls

Open the search bar using the **View > Toolbars > Search Bar** option. The search bar includes these controls:

Search Type

Use the **Search Type** control to specify the type of objects or properties to include in the search.

Search Type Option	Description
by Name	Searches a model or chart for all objects that have the specified string in the name of the object. See “Search Strings” on page 12-6.
by Property Name	Searches for objects that have a specified property. Specify the target property name from a list of properties that objects in the search domain can have.
by Property Value	Searches for objects with a property value that matches the value you specify. Specify the name of the property, the value to be matched, and the type of match (for example, equals, less than, or greater than). See “Search Strings” on page 12-6.
by Block Type	Searches for blocks of a specified block type. Select the target block type from the list of types contained in the currently selected model.
by Stateflow Type	Searches for Stateflow objects of a specified type.

Search Type Option	Description
for Variable Usage	Searches for blocks that use variables defined in a workspace. Select the base workspace or a model workspace (model name) and, optionally, the name of a variable. See “Search Strings” on page 12-6.
for Referenced Variables	Searches for variables that a model or block uses. Specify the name of the model or block in the by System field. The model or block must be in the Model Hierarchy pane.
for Unused Variables	Searches for variables that are defined in a workspace but not used by any model or block. Select the name of the workspace from the drop-down list for the in Workspace field.
for Library Links	Searches for library links in the current model.
by Class	Searches for Simulink objects of a specified class.
for Fixed Point Capable	Searches a model for all blocks that support fixed-point computations.
for Model References	Searches a model for references to other models.
by Dialog Prompt	Searches a model for all objects whose dialogs contain the prompt you specify. See “Search Strings” on page 12-6.
by String	Searches a model for all objects in which the string you specify occurs. See “Search Strings” on page 12-6.

Search Options

Use the **Search Options** control to specify the scope and how to apply search strings.

Search Option	Description
Match Whole String	Do not allow partial string matches (for example, do not allow sub to match substring).
Match Case	Considers case when matching strings (for example, Gain does not match gain).

Search Option	Description
Regular Expression	Considers a string to be matched as a regular expression.
Evaluate Property Values During Search	Applies only for searches by property value. If enabled, Model Explorer evaluates the value of each property as a MATLAB expression and compares the result to the search value. If this option is disabled (the default), the Model Explorer compares the unevaluated property value to the search value.
Refine Search	Initiates a secondary search that provides additional search criteria to refine the initial search results. The second search operation searches for objects that meet both the original and the new search criteria.

For an example showing how to search for a parameter, see “Search Using Model Explorer” on page 12-50.

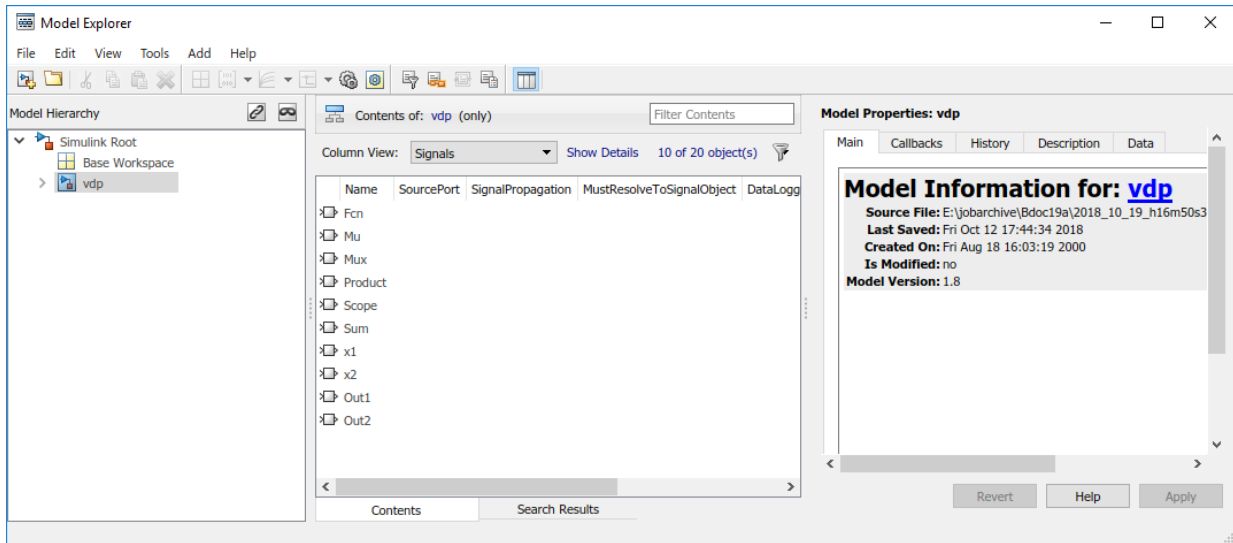

Search Strings

By default, search strings are case-insensitive and are treated as regular expressions.

By default, the search allows partial string matches. You cannot use wildcard characters in search strings. For example, if you enter *1 as a name search string, you get no search results unless there is an item whose name starts with the two characters *1. If there is an out1 item, the search results do not include that item.

Model Explorer Components

By default, the Model Explorer opens with three panes (**Model Hierarchy**, **Contents**, and **Dialog**), and a main toolbar. Open the search bar using the **View > Toolbars > Search Bar** option.

Component	Purpose	Documentation
Main toolbar	Execute Model Explorer commands	Most toolbar buttons perform actions that you can also perform using Model Explorer menu items, except to bring MATLAB to the front or open the Simulink Library Browser. If you have Simulink Requirements installed, you can use additional toolbar buttons relating to requirements links.
Search bar	Perform a search within the context of the selected node in Model Hierarchy pane.	“Search Bar Controls” on page 12-4
Model Hierarchy pane	Navigate and explore model, chart, and workspace nodes	“Model Explorer: Model Hierarchy Pane” on page 12-9
Contents pane	Display and modify model or chart objects	“Model Explorer: Contents Pane” on page 12-16

Component	Purpose	Documentation
Dialog pane	View and change the details of object properties	"Model Explorer: Property Dialog Pane" on page 12-33

Add Objects to a Model, Chart, or Workspace

You can use the Model Explorer to add many kinds of objects to a model, chart, or workspace. The types of objects that you can add depend on the node that you select in the **Model Hierarchy** pane. Use toolbar buttons or the **Add** menu to add objects. The **Add** menu lists the types of objects you can add.

Focus on Specific Elements of a Model or Chart

As you explore a model or chart, you might want to narrow the contents that you see in the Model Explorer to particular elements of a model or chart. You can use several different techniques. The table summarizes techniques for controlling the content the Model Explorer displays and how the contents appear.

Technique	When to Use	Documentation
Show partial or whole model hierarchy contents	To control how much of a hierarchical model to display	"Display Partial or Whole Model Hierarchy Contents" on page 12-11
Use the Row Filter option	To focus on, or hide, a specific kind of a model object, such as signals	"Use the Row Filter Option" on page 12-29
Search	To find objects that might not be currently displayed	"Search Using Model Explorer" on page 12-50
Filter contents	To focus on specific objects in the Contents pane, based on a search string	"Filtering Contents" on page 12-31

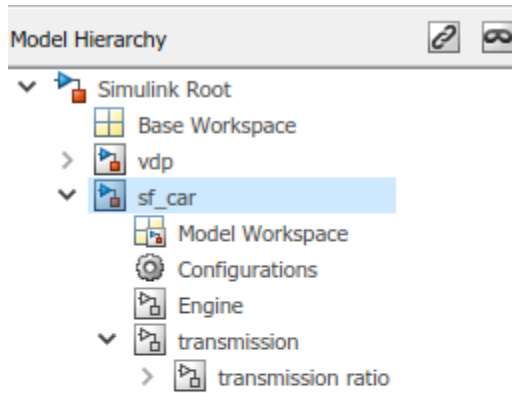

Once you have the general set of data that you are interested in, you can use the following techniques to organize the display of contents.

Technique	When to Use	Documentation
Sort	To quickly organize data for a property in ascending or descending order	“Sort Column Contents” on page 12-21
Group by property column	To logically group data based on values for a property	“How to Group by a Property Column” on page 12-23
Use column views	To display a named subset of property columns to apply to different kinds of nodes in the Model Hierarchy pane	“Customize Model Explorer Views” on page 12-36
Add, delete, or rearrange property table columns	To customize property columns	“Organize Data Display in Model Explorer” on page 12-21

Model Explorer: Model Hierarchy Pane

- “Simulink Root” on page 12-10
- “Base Workspace” on page 12-10
- “Work With Model Workspace Variables and Configuration Sets” on page 12-11
- “Display Partial or Whole Model Hierarchy Contents” on page 12-11
- “Display Linked Library Subsystems and Masked Subsystems” on page 12-12
- “Navigating to the Block Diagram” on page 12-13
- “Expand and Edit Model References” on page 12-13
- “Cut, Copy, and Paste Objects Between Workspaces” on page 12-16

The **Model Hierarchy** pane displays a tree-structured view of the Simulink model and Stateflow chart hierarchy. Use the **Model Hierarchy** pane to navigate to the part of the model and chart hierarchy that you want to explore.

Select the object in the **Model Hierarchy** pane whose contents you want to display in the **Contents** pane.

Simulink Root

The first node in the hierarchy represents the Simulink root. Expand the root node to display nodes representing the MATLAB workspace, Simulink models, and Stateflow charts that are in the current session.

Base Workspace

This node represents the MATLAB workspace. The MATLAB workspace is the base workspace for Simulink models and Stateflow charts. Variables defined in this workspace are visible to all open models and charts.

For information about exporting and importing workspace variables, see “Export Workspace Variables” on page 62-158 and “Importing Workspace Variables” on page 62-160.

Work With Model Workspace Variables and Configuration Sets

Expanding a model or chart node in the **Model Hierarchy** pane displays nodes representing the following elements, as applicable for the models and charts you have open.

Node	Description
Model workspace	For information about how to use the Model Explorer to work with model workspace variables, see the following sections: <ul style="list-style-type: none"> • “Finding Variables That Are Used by a Model or Block” on page 62-149 • “Finding Blocks That Use a Specific Variable” on page 62-151 • “Editing Workspace Variables” on page 62-154 • “Export Workspace Variables” on page 62-158 • “Importing Workspace Variables” on page 62-160 • “Model Workspaces” on page 62-162
Configurations	Select the Configurations node to show the model's configuration sets and configuration references in the Contents pane. For information about adding, deleting, saving, and moving configuration sets, see “Manage a Configuration Set” on page 13-11.
Top-level subsystems	Expand a node representing a subsystem to display underlying subsystems, if any.
Model blocks	Expand model blocks to show contents of referenced models (see “Expand and Edit Model References” on page 12-13).
Stateflow charts	<ul style="list-style-type: none"> • Expand a node representing a Stateflow chart to display the top-level states of the chart. • Expand a node representing a state to display its substates.

Display Partial or Whole Model Hierarchy Contents

By default, the Model Explorer displays objects for the system that you select in the **Model Hierarchy** pane. It does not display data for child systems. You can override that default, so that the Model Explorer displays objects for the whole hierarchy of the currently selected system. To toggle between displaying only the current system and displaying the whole system hierarchy of the current system, use one of these techniques:

- Select **View > Show Current System and Below**.
- Click the **Show Current System and Below** button  at the top of the **Contents** pane.

When you select the **Show Current System and Below** option:

- The **Model Hierarchy** pane highlights in pale blue the current system and its child systems.
- After the path in the **Contents of** field, the text (and below) appears.
- The appearance of the **Show Current System and Below** button at the top of the **Contents** pane and in the **View** menu changes.
- The status bar indicates the scope of the displayed objects when you hover over the **Show Current System and Below** button.

Loading very large models for the current system and below can be slow. To stop the loading process at any time, either click the **Show Current System and Below** button or click another node in the tree hierarchy.

If you show the current system and below, you might want to change the view to better reflect the displayed system contents. For details about views, see “Customize Model Explorer Views” on page 12-36.

The setting for the **Show Current System and Below** option is persistent across Simulink sessions.

Display Linked Library Subsystems and Masked Subsystems

By default, the Model Explorer does not display the contents of linked library subsystems or masked subsystems in the **Model Hierarchy** pane. To display the contents of linked library subsystems, use one of these approaches:

- At the top of the **Model Hierarchy** pane, click the **Show/Hide Library Links** button  or the **Show/Hide Masked Subsystems** button .
- From the **View** menu, select **Show Library Links** or **Show Masked Subsystems**.

Library-linked subsystems and masked subsystems are visible in the **Contents** pane, regardless of how you configure the **Model Hierarchy** pane.

Note Search does not find elements in linked library or masked subsystems that are not displayed in the **Model Hierarchy** pane.

For subsystems that are both library-linked and masked, how you set the linked library subsystems and masked subsystems options affects which subsystems appear in the **Model Hierarchy** pane, as described in the following table.

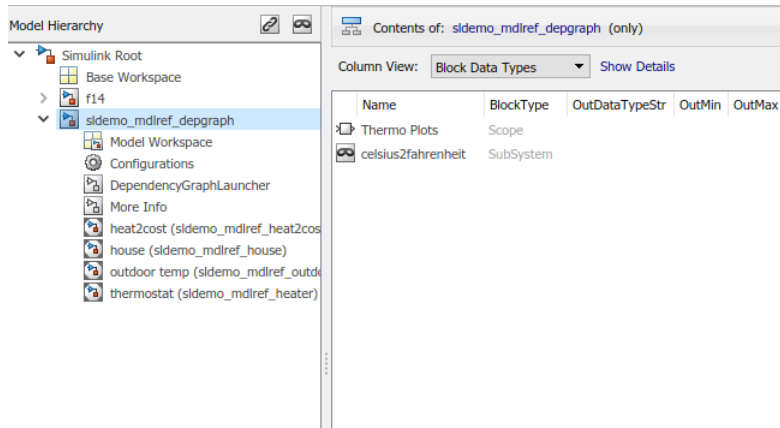

Settings	Subsystems Displayed in the Model Hierarchy Pane
Show Library Links Hide Masked Subsystems	Only library-linked, unmasked subsystems
Hide Library Links Show Masked Subsystems	Only masked subsystems that are not library-linked subsystems
Show Library Links Show Masked Subsystems	All library-linked or masked subsystems

Navigating to the Block Diagram

To open a graphical object (for example, a model, subsystem, or chart) in an editor window, right-click the object in the **Model Hierarchy** pane. From the context menu, select **Open**.

Expand and Edit Model References

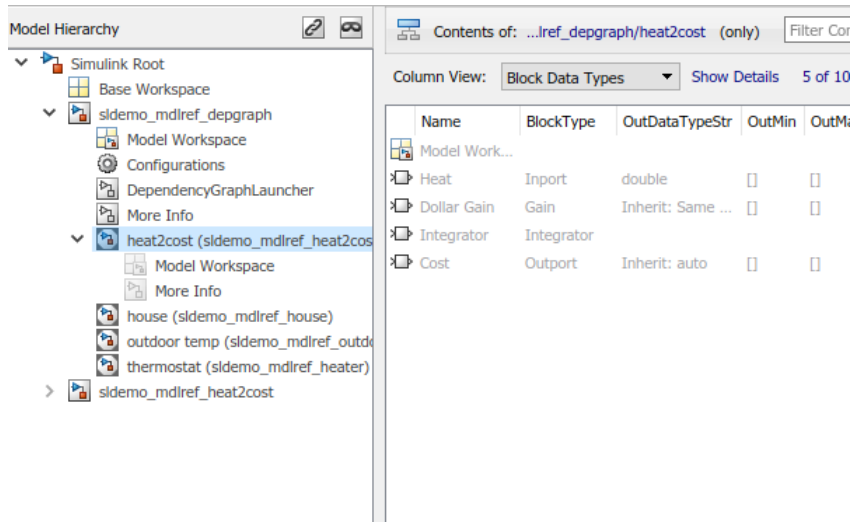

To browse a model that includes Model blocks, you can expand the **Model Hierarchy** pane nodes of the Model blocks. For example, the `sldemo_mdref_depgraph` model includes Model blocks that reference other models. If you open the `sldemo_mdref_depgraph` model and expand that model node in the **Model Hierarchy** pane, you see that the model contains several Model blocks, including `heat2cost`.

To browse a model referenced by a Model block:

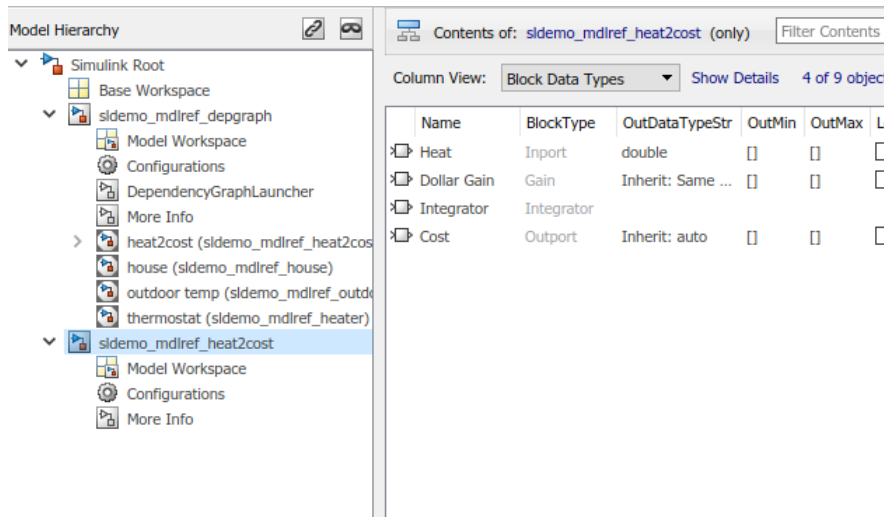

- 1 Right-click the referenced model node in the **Model Hierarchy** pane.
- 2 From the context menu, choose **Open Model**.
 - The referenced model opens.
 - The **Model Hierarchy** pane indicates that you can expand the Model block node.
 - The **Model Hierarchy** pane displays a separate expandable node for the referenced model (read-only).
 - The **Contents** pane displays objects corresponding to the Model block node (read-only).

For example, if you right-click the `heat2cost` Model block node and select the **Open Model** option, the **Contents** pane displays the objects corresponding to the `heat2cost` Model block. You can expand the `heat2cost` node.

You can browse the contents of the referenced model, but you cannot edit the model objects that are inside the Model block.

To edit the referenced model, expand the referenced model node in the **Model Hierarchy** pane, and then you access the properties of objects in the referenced model. For example, expand the `sldemo_mdhref_heat2cost` node.

For information about referenced models, see “Model References”.

Cut, Copy, and Paste Objects Between Workspaces

To cut, copy, and paste workspace objects from one workspace into another workspace:

- 1 In the **Contents** pane, right-click on the workspace object you want to cut or copy.
- 2 From the context menu, select **Cut** or **Copy**.
 - You can also cut a workspace object by selecting in the **Contents** pane **Edit > Cut** or by clicking the **Cut** button ()
 - You can also copy a workspace object by selecting **Edit > Copy** or by clicking the **Copy** button ()
- 3 If you want to paste the workspace object that you cut or copied, in the **Model Hierarchy** pane, right-click the workspace into which you want to paste the object, and select **Paste**.
 - You can also paste the object by selecting **Edit > Paste** or by clicking the **Paste** button ()
 - When you copy and paste (or drag and drop), you can manage the resolution of name conflicts. In the dialog box, choose an action for each item whose name conflicts with an existing item.
 - **Skip** — Default action when the conflicting items have the same value.
 - **Replace** — Default action when the conflicting items have different values.
 - **Keep both** — Preserve both copies. The name given to the copied item follows the naming rules that are used in the MATLAB workspace.

If the source and destination are the same, the software resolves the name conflict by following the naming rules that are used in the MATLAB workspace.

You can also cut, copy, and paste by selecting an object and performing drag and drop operations.

Model Explorer: Contents Pane

- “Contents Pane Tabs” on page 12-17
- “Data Displayed in the Contents Pane” on page 12-18

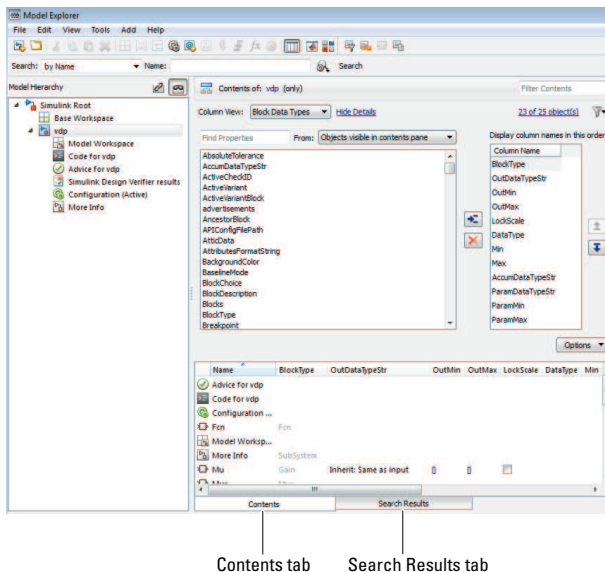

- “Link to the Currently Selected Node” on page 12-19
- “Working with the Contents Pane” on page 12-19
- “Editing Object Properties” on page 12-20

Contents Pane Tabs

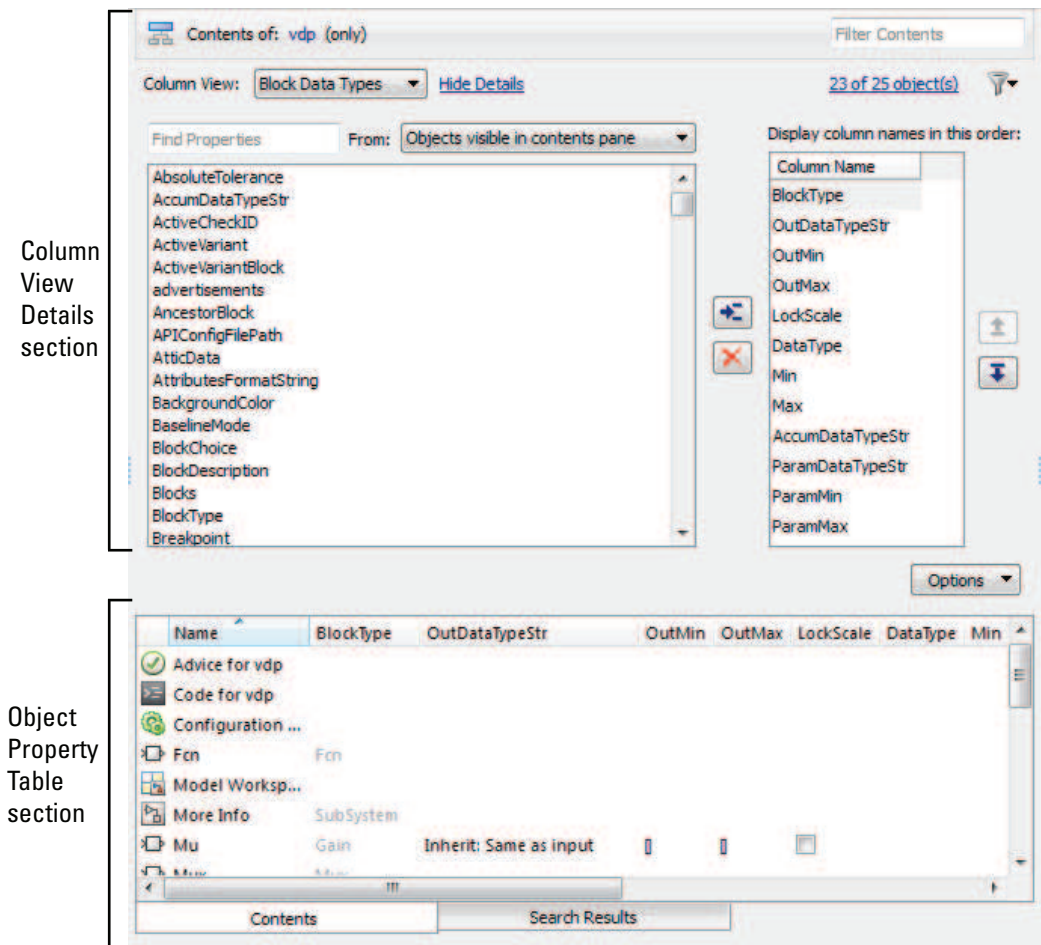

The **Contents** pane displays one of two tables containing information about models and charts, depending on the tab that you select:

- The **Contents** tab displays an object property table for the node that you select in the **Model Hierarchy** pane.
- The **Search Results** tab displays the search results table (see “Search Using Model Explorer” on page 12-50).

Optionally, you can also open a column view details section in the **Contents** pane. This graphic shows the **Contents** pane with the column view details section opened.

To open the column view details section, click **Show Details**, at the top of the **Contents** pane.

The **Column view details** section provides an interface for customizing the column view (hidden by default).

The **Object property table** section displays a table of model and chart object data (open by default).

Data Displayed in the Contents Pane

In the object property table section of the **Contents** tab and in the **Search Results** tab:

- Table columns correspond to object properties (for example, Name and BlockType).

The object property table displays the first two columns (the object icon and the Name property) persistently, so that these columns remain visible regardless of how far you scroll to the right.

- Table rows correspond to objects (for example, blocks, and states).

The objects and properties displayed in the **Contents** pane depend on:

- The column view that you select in the **Contents** pane
- The node that you select in the **Model Hierarchy** pane
- The kind of object (for example, subsystem or chart) that you select in the **Model Hierarchy** pane
- The **View > Row Filter** options that you select

For more information about controlling which objects and properties to display in the **Contents** pane, see:

- “Customize Model Explorer Views” on page 12-36
- “Organize Data Display in Model Explorer” on page 12-21
- “Filter Objects in the Model Explorer” on page 12-28

Link to the Currently Selected Node

The **Contents of** link at the top left side of the **Contents** pane links to the currently selected node in the **Model Hierarchy** pane. The model data displayed in the Contents pane reflects the setting of the **Current System and Below** option. In this example, **Contents of** links to the vdp model, which is the currently selected node.

Working with the Contents Pane

The table summarizes the key tasks to control what is displayed in the **Contents**.

Task	Documentation
Control which kinds of objects to display.	“Use the Row Filter Option” on page 12-29
Search within the selected set of objects.	“Search Using Model Explorer” on page 12-50
Specify a set of properties to display based on the kind of node.	“Customize Model Explorer Views” on page 12-36
Group data based on unique values in a property column.	“Group by a Property” on page 12-22
Manage views (for example, save and export a view).	“Managing Views” on page 12-40
Add, remove, or rearrange columns.	“Organize Data Display in Model Explorer” on page 12-21
Edit object property values.	“Editing Object Properties” on page 12-20

Editing Object Properties

To open a properties dialog box for an object in the **Model Hierarchy** pane, right-click the object, and from the context menu, select **Properties**. Alternatively, click an object and from the **Edit** menu, select **Properties**.

You can change modifiable properties in the **Contents** pane (for example, a block name) by editing the displayed value. To edit a value, first select the row that contains the value, and then click the value. An edit control replaces the value (for example, an edit field for text values or a list for a range of values). For workspace variables that are arrays or structures, you can use the Variable Editor. Use the edit control to change the value of the selected property.

To assign the same property value to multiple objects in the **Contents** pane, select the objects and then change one of the selected objects to have the new property value. An edit control replaces the value with `<edit>`, indicating that you are doing batch editing. The Model Explorer assigns the new property value to the other selected objects, as well.

You can also change property values using the **Dialog** pane. See “Model Explorer: Property Dialog Pane” on page 12-33.

Organize Data Display in Model Explorer

- “Sort Column Contents” on page 12-21
- “Group by a Property” on page 12-22
- “Change the Order of Property Columns” on page 12-25
- “Add Property Columns” on page 12-25
- “Hide or Remove Property Columns” on page 12-26
- “Mark Nonexistent Properties” on page 12-28

You can control how the object property table and **Search Results** pane organize the layout of property information by:

- Sorting column contents
- Grouping by a property
- Changing the order of property columns
- Adding a property column
- Hiding and removing property columns

Sort Column Contents

To sort the column contents in ascending order, click the heading of the property column. A triangle pointing up appears in the column heading. To change the order from ascending to descending, or from descending to ascending, click the heading of the column again.

For example, if properties are in ascending order, based on the **Name** property (the default), click the heading of the **Name** column to display objects by name, in descending order.

By default, the **Contents** pane displays its contents in ascending order, based on the name of the object. Objects that have no values in any property columns appear at the end of the object property table.

Note When you group by property, the Model Explorer applies sorting of column contents within each group.

Group by a Property

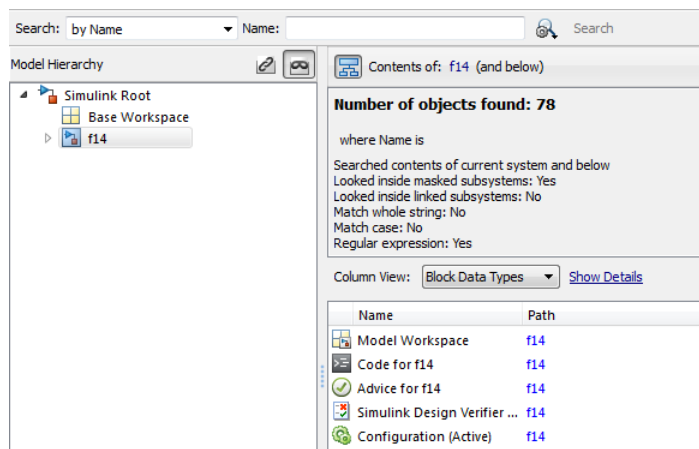

Organizing Contents by Property Values

When you explore a model, you might want to focus on all objects with the same property value. One approach is to group data by a property column.

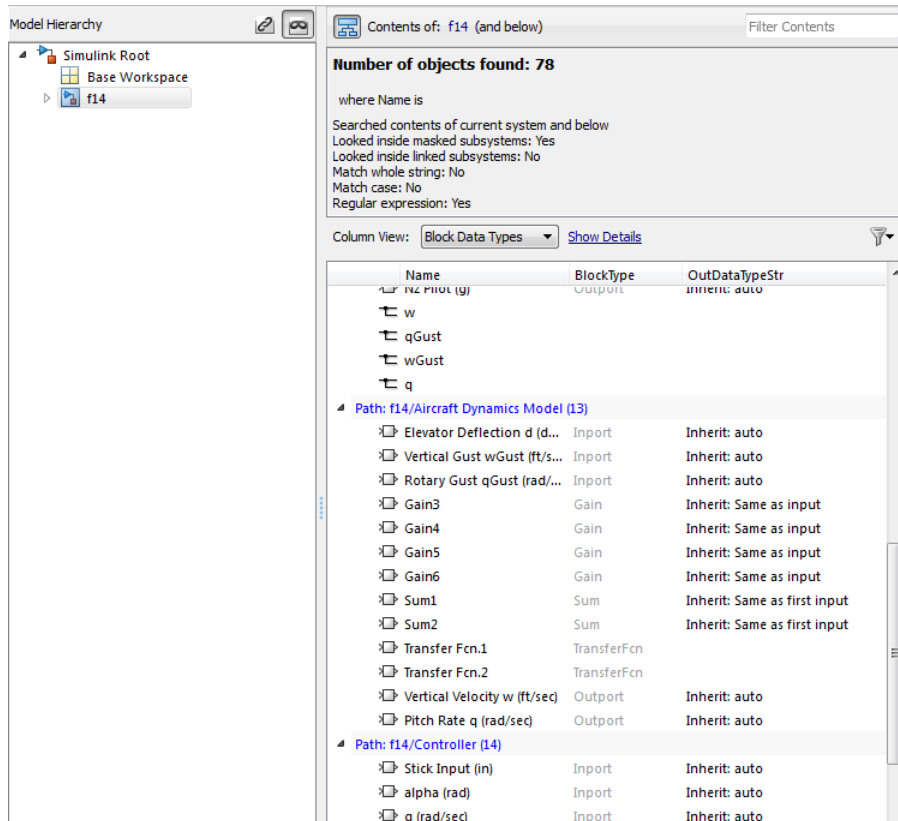

For example, suppose that you want to see all of the blocks in the f14 model. You could perform the following search.

The search results obscure the whole path name for lower-level nodes:

By grouping on the Path property column, you see the whole path for lower-level nodes.

You can also collapse groups to focus on specific parts of a model.

How to Group by a Property Column

To group by a property:

- 1 In the object property table, right-click the column heading of the property by which you want to group contents.

You can group by object icons, such as a block icon (□), which represents a type of object. Right-click the empty column heading in the first column.

- 2 From the context menu, select the **Group By This Column** menu item.

Sorting with Grouped Data

When you group by property, the Model Explorer applies sorting of column contents within each group.

Expanding and Collapsing Grouped Data

By default, Model Explorer displays groups in expanded form. That is, all the objects in each group are visible. You can collapse and expand groups.

- To collapse the contents of a group, click the minus sign icon for that group.
- To expand a group, click the plus sign.
- To collapse or expand all the groups, right-click the column heading and select either the **Collapse All Groups** menu item (**Shift+C**) or **Expand All Groups** menu item (**Shift+E**).

Hiding the Group Column

By default, the property column that you use for grouping appears in the property table. That property also appears in the top row for each group.

To hide the group column in the property table, use one of the following approaches:

- From the **View** menu, clear the **Show Group Column** check box.
- Right-click a column heading in the property table and clear the **Show Group Column** check box.

Persistence of Grouped Data Settings

If you group by a property, that grouping is saved as part of the view definition.

When you select a different node in the **Model Hierarchy** pane, the contents for the new node are grouped by that same property. However, all groups are expanded, even if you had collapsed all groups before switching nodes.

Group Search Results

You can use grouping to organize the **Search Results** pane. The grouping that you apply to the **Search Results** pane also applies to the object property table, if that property is in the table. If the search results include a property that is not in the object property table, and you group on that property, then the Model Explorer removes the grouping setting that was in effect in the object property table.

Change the Order of Property Columns

Object Icon and Name Columns Are Always First

The first two columns of every object property table are the object icon column (the column with a blank column heading) and the Name property column. You cannot hide, remove, or change the location of the first two columns.

How to Change the Order of Property Columns

To change the order of property columns in the object property table, use one of these approaches:

- In the object property table, select a column heading and drag it to a new location in the table.

This approach avoids opening the column view details section and makes it easier to move a column a short distance to the right or left.

- In the column view details section, select one or more property columns and move them up or down in the list, using the arrow buttons to the right of the list.

This approach allows you to move several property columns in one step, but it moves the selected columns right or left by only one column at a time.

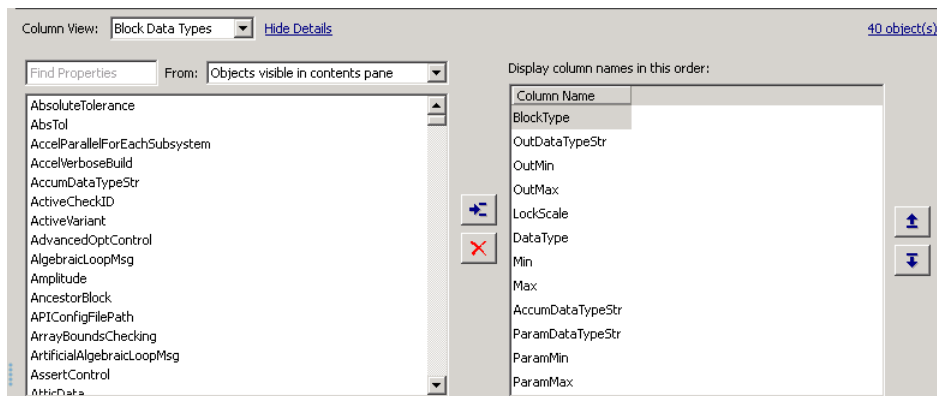

To move a property column by using the view details interface:

- 1 In the **Display column names in this order** list on the right side of the column view details section, select one or more property columns that you want to move.
- 2 Click the **Move column left in view** button  or the **Move column right in view** button .

Add Property Columns

To add property columns to a view:

- 1 If you do not have the column view details section of the **Contents** pane already open, then at the top of the **Contents** pane, select **Show Details**.

- 2 In the list of properties on left side of the column view details section, select one or more properties that you want to add.
 - The list displays property names in alphabetical order. You can use the **Find Properties** search box in the column view details section to search for properties that contain the text string that you enter. You can specify the scope of the search with the **From** list to the right of the search box.
- 3 In the list of column names on the right side, select the property column that you want to be to the left of the property columns you insert.
- 4 Click the **Display property as column in view** button ()

Adding a Path Property Column

The Model Explorer provides a shortcut for adding a Path property column to a view. To add a Path property column:

- 1 Right-click the column heading in the object property table to the right of which you want to insert a Path column.
- 2 From the context menu, select **Insert Path**.

Hide or Remove Property Columns

You can choose between two approaches to hide (remove) a property column from the object property table. Hiding and removing a column both have the same result. You can:

- Hide a column using the context menu for a column heading. This approach avoids needing to open the column view details section.

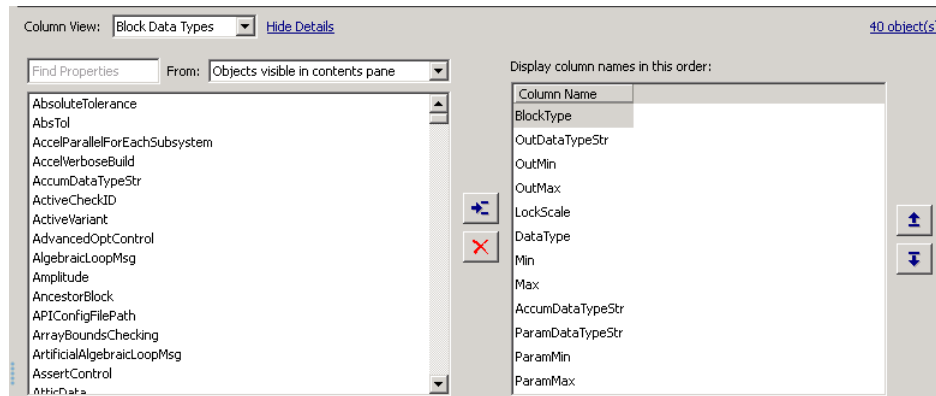

- Remove a column using the column view details interface. This approach allows you to delete several properties in one step.

Hiding a Column Using the Column Heading Context Menu

- 1 Right-click the column heading of the column that you want to remove.
- 2 From the context menu, select **Hide**.

Removing a Column Using the Column View Details Interface

- 1 If you do not have the column view details section of the **Contents** pane already open, then at the top of the **Contents** pane, select **Show Details**.

- 2 In the column view details section of the **Contents** pane, in the **Display column names in this order** list, select one or more properties that you want to remove.
- 3 Click the **Remove column from view** button () or the **Delete** key.

Inserting Recently Hidden or Removed Columns

The Model Explorer maintains a list of columns you hide or remove for each view during a Simulink session.

To add a recently hidden or removed column back into a view:

- 1 Right-click the column heading of the column to the right of which you want to insert a recently hidden column.
- 2 From the context menu, select **Insert Recently Hidden Columns**.

- 3 Select the column that you want to insert.

See “Hide or Remove Property Columns” on page 12-26.

Mark Nonexistent Properties

Usually, some of the properties that the **Contents** pane displays do not apply to all the displayed objects (in other words, some objects do not have values set). By default, the Model Explorer displays a dash (-) to mark properties that do not have a value.

If you want the Model Explorer to display a blank (instead of the default dash) in property cells that have no values, clear the **View > Show Nonexistent Properties as “-”** option. The **Contents** pane looks similar to the following graphic:

Name	BlockType	OutDataTypeStr	OutMin	OutMax	LockScale
u	Inport	Inherit: auto	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Actuator Model	TransferFcn				
Aircraft Dynamics Model	SubSystem				
Angle of Attack	Scope				
Controller	SubSystem				
Dryden Wind Gust Models	SubSystem				
Gain	Gain	Inherit: Same as input	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Gain1	Gain	Inherit: Same as input	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Gain2	Gain	Inherit: Same as input	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Gain5	Gain	Inherit: Same as input	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Nz pilot calculation	SubSystem				
Pilot	SignalGenerator				
Pilot G force Scope	Scope				
Stick Input	Scope				
Sum	Sum	Inherit: Same as first input	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Sum1	Sum	Inherit: Same as first input	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Filter Objects in the Model Explorer

- “Use the Row Filter Option” on page 12-29
- “Filtering Contents” on page 12-31

Two techniques that you can use to control the set of objects that the **Contents** pane displays are:

- Using the Row Filter option

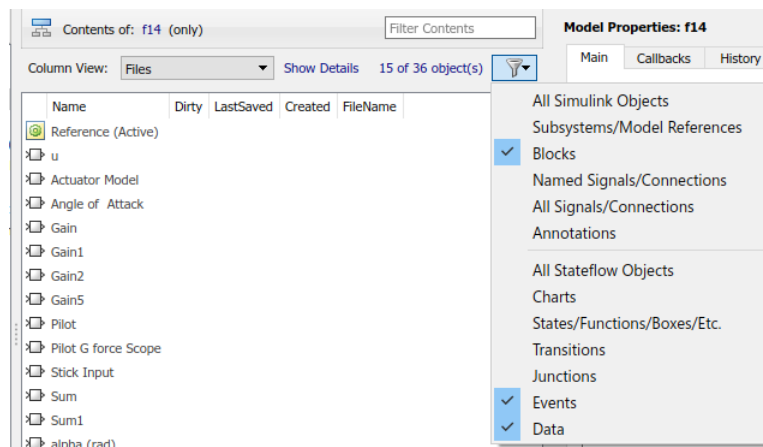

- Filtering contents

For a summary of other techniques, see “Focus on Specific Elements of a Model or Chart” on page 12-8.

Use the Row Filter Option

You can filter the kinds of objects that the **Contents** pane displays:

- 1 Open the **Row Filter** options menu. In the Model Explorer, at the top-right corner of the **Contents** pane, click the **Row Filter** button.

An alternative way to open the Row Filter menu is to select **View > Row Filter**.

By default, the **Contents** pane displays these kinds of objects for the selected node:

- Blocks
 - Stateflow events
 - Stateflow data
- 2 Clear the kinds of objects that you do not want to display in the **Contents** pane, or enable any cleared options to display more kinds of objects. For example, clear **Events** to prevent the display of Stateflow events in the **Contents** pane.

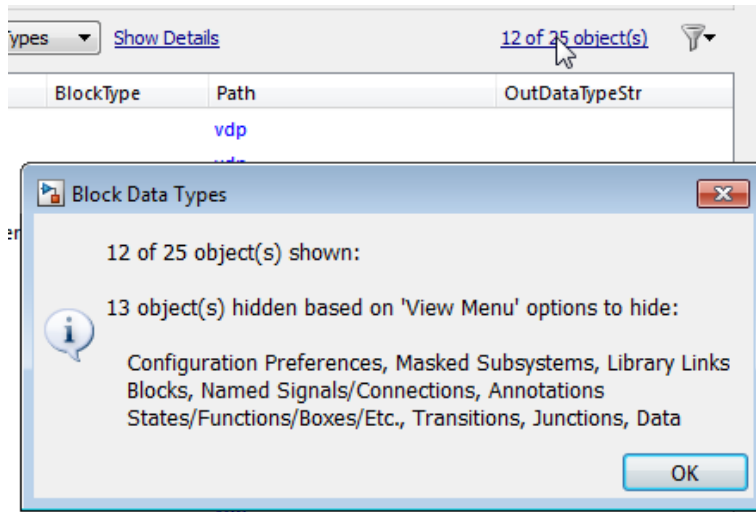

Object Count

The top-right portion of the **Contents** pane includes an object counter, indicating how many objects the **Contents** pane is displaying.

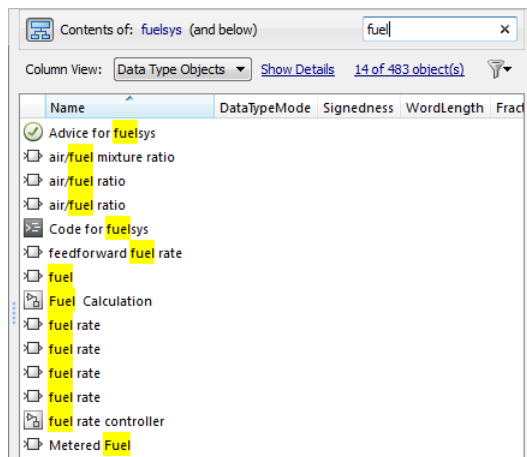

When you use the **Row Filter** option to filter objects, the object count indicator reflects that the **Contents** pane displays a subset of all the model and chart objects.

To view an explanation of the current object count, click the object count link (for example, [12 of 25 objects](#)).

Filtering Contents

To refine the display of objects that are currently displayed in the **Contents** pane, you can use the **Filter Contents** text box at the top of the **Contents** pane to specify search strings for filtering a subset of objects.

Using the **Filter Contents** text box can help you to find specific objects within the set of objects, based on a particular object name, property value, or property that is of interest

to you. For example, if you enter the text string `fuel` in the **Filter Contents** edit box, the Model Explorer displays results similar to those shown above.

Specifying Filter Text Strings

As you enter text in the **Filter Contents** text box, the Model Explorer performs a dynamic search, displaying results that reflect the text as you enter it.

The text strings you enter must be in the format consistent with the guidelines described in the following sections.

Case Sensitivity — By default, the Model Explorer ignores case as it performs the filtering.

To specify that you want the Model Explorer to respect case sensitivity for a text string that you enter, put that text string in quotation marks.

Specifying Properties and Property Values — To restrict the filtering to apply to objects with a specific property, specify the property name followed by a colon. The **Contents** pane displays objects that have that property.

To filter for objects for which a specific property has a specific value, specify the property name followed by a colon (:) and then the value. For example, to filter the contents to display only the objects whose `OutDataTypeStr` property has a value that includes `Inherit`, enter `OutDataTypeStr: Inherit` (alternatively, you could put the whole string in quotation marks to enforce case sensitivity).

Name	BlockType	OutDataTypeStr
Constant2	Constant	Inherit: Inherit from 'Constant v
Constant3	Constant	Inherit: Inherit from 'Constant v
Constant4	Constant	Inherit: Inherit from 'Constant v
Constant5	Constant	Inherit: Inherit from 'Constant v
High Speed (rad./Sec.)	Constant	Inherit: Inherit from 'Constant v
Nominal Speed	Constant	Inherit: Inherit from 'Constant v
engine speed	Inport	Inherit: auto
throttle angle	Inport	Inherit: auto
fuel	Inport	Inherit: auto

Wildcards and MATLAB Expressions Not Supported — The Model Explorer does not recognize wildcard characters, such as an asterisk (*), as having any special meaning. For example, if you enter `fuel*` in the **Filter Contents** text box, you get no results, even if several objects contain the text string `fuel`.

Also, if you specify a MATLAB expression, in the **Filter Contents** text box, the Model Explorer interprets that string as literal text, not as a MATLAB expression.

Clearing the Filtered Contents

To redisplay the object property table as it appears before you filter the contents, click **X** in the **Filter Contents** text box.

Filtering Removes Grouping

If you have set up grouping on a column, then when you filtering contents, the Model Explorer does not retain that grouping.

Model Explorer: Property Dialog Pane

- “Showing and Hiding the Dialog Pane” on page 12-34
- “Editing Properties in the Dialog Pane” on page 12-34
- “Argument Check Box” on page 12-35

Use the **Dialog** pane to view and change properties of objects that you select in the **Model Hierarchy** pane or in the **Contents** pane.

Showing and Hiding the Dialog Pane

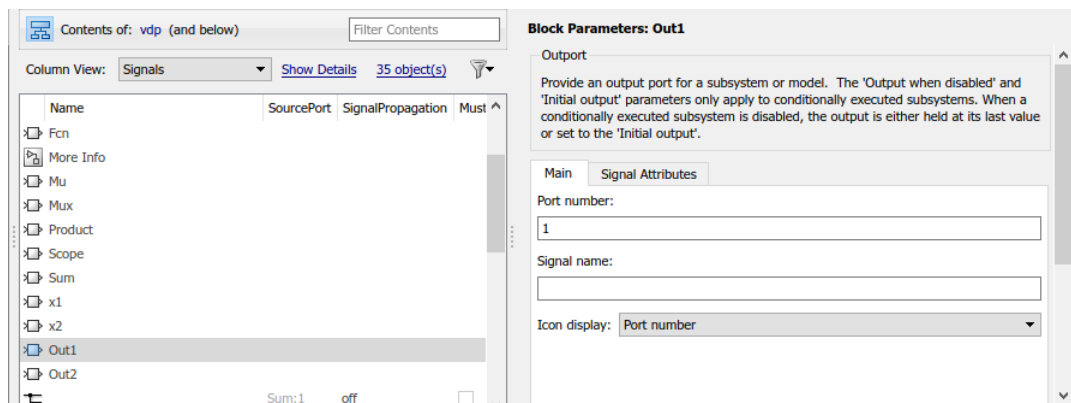

By default, the **Dialog** pane appears in the Model Explorer, to the right of the **Contents** pane. To show or hide the **Dialog** pane, use one of these approaches:

- From the **View** menu, select **Show Dialog Pane**.
- From the main toolbar, click the **Dialog View** button (.

Editing Properties in the Dialog Pane

To edit property values using the **Dialog** pane:

- 1 In the **Contents** pane, select an object (such as a block or signal). The **Dialog** pane displays the properties of the object you selected.

- 2 Change a property (for example, the port number of an Outport block) in the **Dialog** pane.
- 3 Click **Apply** to accept the change, or click **Revert** to return to the original value.

By default, clicking outside a dialog box with unapplied changes causes the Apply Changes dialog box to appear:

Click **Apply** to accept the changes or **Ignore** to revert to the original settings.

To prevent display of the **Apply Changes** dialog box:

- 1 In the dialog box, click the **In the future Apply or Ignore (whichever I select) without asking** check box.
- 2 If you want Simulink to apply changes without warning you, press **Apply**. If you want Simulink to ignore changes without warning you, press **Ignore**.

To restore display of the **Apply Changes** dialog box, from the **Tools** menu, select **Prompt if dialog has unapplied changes**.

Argument Check Box

When you select a numeric MATLAB variable or a Simulink.Parameter object in a model workspace, the **Argument** check box appears in the Dialog pane. This check box configures the variable or object as a model argument. See “Parameterize Instances of a Reusable Referenced Model” on page 8-90.

Customize Model Explorer Views

In this section...
“Using Views” on page 12-36
“Customizing Views” on page 12-39
“Managing Views” on page 12-40

Using Views

What Is a Column View?

A view in the Model Explorer is a named set of properties.

The Model Explorer uses views to specify sets of property columns to display in the **Contents** pane.

For each kind of node in the **Model Hierarchy** pane, certain properties are most relevant for the objects displayed in the **Contents** pane. For example, for a Simulink model node, such as a model or subsystem, some properties that are useful to display include:

- `BlockType` (block type)
- `OutDataTypeStr` (output data type)
- `OutMin` (minimum value for the block output)

Generally, a column view does not contain the total set of properties for all the objects in a node. Specifying a subset of properties to display can streamline the task of exploring and editing model and chart object properties and increase the density of the data displayed in the **Contents** pane.

What You Can Capture in a View

You can use a view to capture the following characteristics of the model information to show in the Model Explorer:

- Properties that you want to display in the **Contents** pane (see “Customizing Views” on page 12-39)
- Layout of the **Contents** pane (for example, grouping by property, the order of property columns, and sorting), as described in “Organize Data Display in Model Explorer” on page 12-21.

Use Standard Views or Customized Views

You can use views in the following ways:

- Use the standard views shipped with the Model Explorer
- Customize the standard views
- Create your own views

Automatically Applied Views

The first time you open the Model Explorer, the software automatically applies one of the standard views to the node you select in the **Model Hierarchy** pane. The Model Explorer applies a view based on the kind of node you select.

The Model Explorer assigns one of four categories of nodes in the **Model Hierarchy** pane. The Model Explorer initially associates a default view with each node category. The four node categories are:

Node Category	Kinds of Hierarchy Nodes Included	Initial Associated View
Simulink	Models, subsystems, and root level models	Block Data Types
Workspace	Base and model workspace objects	Data Objects
Stateflow	Stateflow charts and states	Stateflow
Configurations	Configurations section node	Configurations
Other	Objects that do not fit into one of the first three categories; for example, configuration sets	Default

The **Column View** field at the top of the **Contents** pane displays the view that the Model Explorer is currently using.

If you select a view

In the **Contents** pane, from the **Column View** list, you can select a different view. If you select a different view, then the Model Explorer associates that view with the category of the current node. For example, suppose the selected node in the **Model Hierarchy** pane

is a Simulink model, and the current view is **Data Objects**. If you change the view to **Signals**, then when you select another Simulink model node, the Model Explorer uses the **Signals** view. See “Selecting a View Manually” on page 12-38.

Selecting a View Manually

By default, the Model Explorer automatically applies a view, based on the category of node that you select and the last view used for that node. You can manually select a view from the **Column View** list that better meets your current task.

You can shift from the default mode of having the Model Explorer automatically apply views to a mode in which you must manually select a view to change views.

To enable the manual view selection mode:

- 1 Select **View > Column View > Manage Views**.

The View Manager dialog box opens.

- 2 In the View Manager dialog box, click the **Options** button and clear **Change View Automatically**.

In the manual view selection mode, if you switch to a different kind of node in the **Model Hierarchy** pane that has a different view associated with it, the **Contents** pane displays a yellow informational bar suggesting a view to use.

Tip interface

The tip interface appears immediately above the object property table.

The tip does not appear if you use automatic view selection.

To hide the currently displayed tip, from the menu button on the right-hand side of the tip bar, select **Hide This Tip**.

The tip interface displays a link for changing the current view to a suggested view. To choose the suggested view displayed in the tip bar, click the link.

Initially, the suggested view is the default view associated with a node. If you associate a different view with a node category, then the tip suggests the most recently selected view when you select similar nodes.

To change from manual specification of views to automatic specification, from the tip interface, select the down arrow and then the **Change View Automatically** menu item.

Customizing Views

If a standard view does not meet your needs, you can either modify the view or create a new view.

You can customize the object property table represented by the current view in several ways, as described in these sections:

- “Add Property Columns” on page 12-25
- “Hide or Remove Property Columns” on page 12-26
- “Change the Order of Property Columns” on page 12-25

How the Model Explorer Saves Your Customizations

As you modify the object property table, you change the current view definition.

The Model Explorer saves the following changes to the object property table as part of the column view definition:

- Grouping by property
- Sorting in a column
- Changing the order of property columns
- Adding a property column
- Hiding and removing property columns

When you change from one view to another view, the Model Explorer saves any customizations that you have made to the previous view.

For example, suppose you use the **Block Data Types** view and you remove the **LockScale** property column. If you then switch to use the **Data Objects** view, and later

use the **Block Data Types** view again, the **Block Data Types** view no longer includes the **LockScale** column that you deleted.

At the end of a Simulink session, the Model Explorer saves the view customizations that you made during that session. When you reopen the Model Explorer, Simulink uses the customized view, reflecting any changes that you made to the view in the previous session.

Controlling the Font Size

You can change the font size in the Model Explorer panes:

- To increase the font size, press the **Ctrl + Plus Sign (+)**.

Alternatively, from the Model Explorer **View** menu, select **Increase Font Size**.

- To decrease the font size, press the **Ctrl + Minus Sign (-)**.

Alternatively, from the Model Explorer **View** menu, select **Decrease Font Size**.

Note The changes remain in effect for the Model Explorer and in the Simulink dialog boxes across Simulink sessions.

Managing Views

If a standard view does not meet your needs, you can either modify the view or create a new view. See “Customizing Views” on page 12-39.

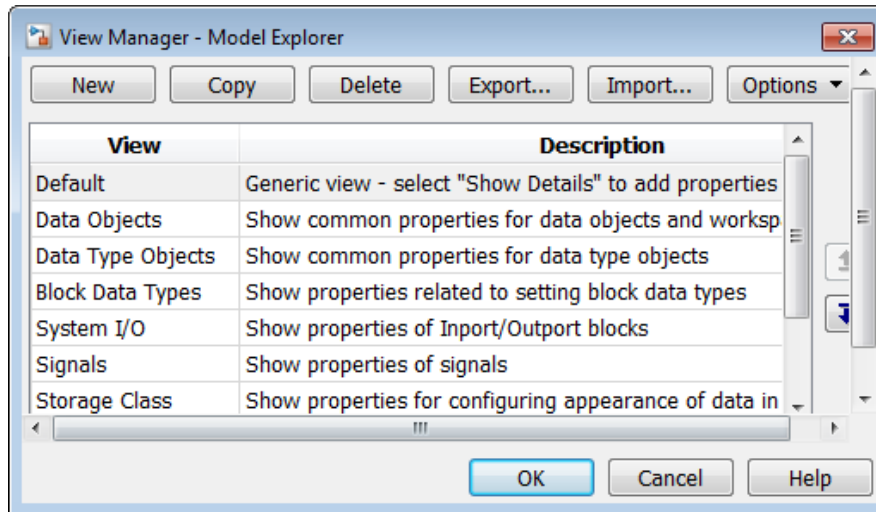

You can manage views (for example, create a new view or export a view) using the View Manager dialog box.

Opening the View Manager Dialog Box

To open the View Manager dialog box, select the **Manage Views** option from either:

- The **View > Column View** menu
- The options listed when you click the **Options** button in the column view details section

The View Manager dialog box displays a list of defined views and provides tools for you to manage views.

You can manage views in several ways, including:

- “Creating a New View” on page 12-41
- “Deleting Views” on page 12-42
- “Reordering Views” on page 12-42
- “Exporting Views” on page 12-43
- “Importing Views” on page 12-43
- “Resetting Views to Factory Settings” on page 12-44

Creating a New View

To create a new view that has a new name, you can use one of these approaches:

- Copy an existing view, rename it, and customize the view.
- Create a completely new view.

After you create a new view, you can customize the view as described in “Customizing Views” on page 12-39.

Copying and renaming an existing view

You can build a new view by copying an existing view, renaming it, and optionally customizing the renamed view. In the View Manager dialog box:

- 1 Select the view that you want to use as the starting point for your new view.
- 2 Click the **Copy** button.

A new row appears at the bottom of the View Manager table of views. The new row contains the name of the view you copied, followed by a number in parentheses. For example, if you copy the `Stateflow` view, the initial name of the copied view is `Stateflow (1)`.

Creating a completely new view

To create a completely view, in the View Manager dialog box, click the **New** button. A new view row appears at the bottom of the View Manager dialog box list of views.

Naming and describing a new view

Once you create a view, you can name the view and provide a description of the view:

- 1 Double-click `New View` in the left column of the table of views and replace the text with a name for the view.
- 2 Double-click `Description` in the table and replace the text with a description of the view.
- 3 Click **OK**.

Deleting Views

To delete a view from the **Column View** list of views:

- 1 In the View Manager dialog box, select one or more views that you want to remove from the list.
- 2 Click the **Delete** button or the **Delete** key.
- 3 Click **OK**.

Deleting a view using the View Manager dialog box permanently deletes that view from the Model Explorer interface.

If you think you or someone else might want to use a view again, consider exporting the view before you delete it (see “Exporting Views” on page 12-43).

Reordering Views

To change the position of a view in the **Column View** list, in the View Manager dialog box:

- 1 Select one or more views that you wish to move up or down one row in the table of views.
- 2 Click the up or down arrow buttons to the right of the table of views. Repeat this step until the view appears where you want it to be in the table.
- 3 Click **OK**.

Exporting Views

To export views that you or others can then import, in the View Manager dialog box:

- 1 In the View Manager dialog box, select one or more views that you want to export.
- 2 Click the **Export** button.

An Export Views dialog box opens, with check marks next to the views that you selected.

- 3 Click **OK**.

An Export to File Name dialog box opens.

- 4 Navigate to the folder to which you want to export the view.

By default, the Model Explorer exports views to the MATLAB current folder.

- 5 Specify the file name for the exported view.

The file format is `.mat`.

- 6 Click **OK**.

Importing Views

To import view files from another location for use by the Model Explorer:

- 1 In the View Manager dialog box, click the **Import** button.

The Select `.mat` File to Import dialog box opens.

- 2 Navigate to the folder from which you want to import the view.
- 3 Select the MAT-file containing the view that you want to import and then click **Open**.

A confirmation dialog box opens. Click **OK** to import the view.

The imported view appears at the bottom of the **Column View** list of views.

The Model Explorer automatically renames the view if a name conflict occurs.

Resetting Views to Factory Settings

You can reset (restore) the original definition of a specific standard view (that is, a view shipped with the Model Explorer) if that view is the current view. To do so, click the **Options** button in the column view details section and select **Reset This View to Factory Settings**.

To reset the factory settings for *all* standard views in one step, in the View Manager dialog box, click the **Options** button and select **Reset All Views to Factory Settings**.

Note When you reset all views, the Model Explorer removes all the custom views you have created. Before you reset views to factory settings, export any views that you will want to use in the future.

More About

- “Search and Edit Using Model Explorer” on page 12-2

Find Model Elements in Simulink Models

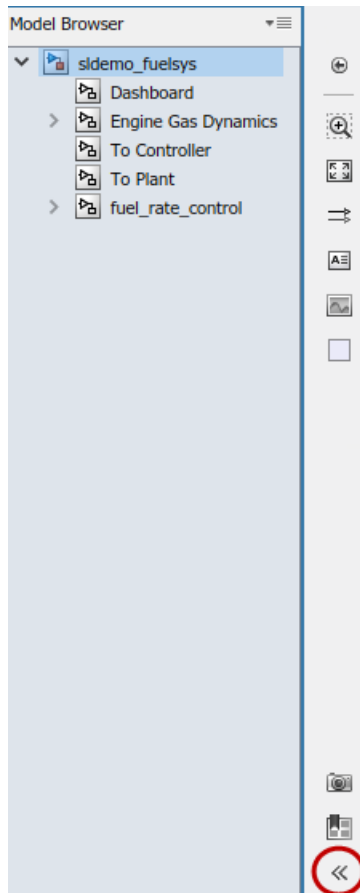

As you build and modify your model, it helps when you can understand your model structure and locate specific model elements. Simulink Editor tools simplify these tasks. Use the tool that is appropriate for your model size and complexity.

- Use the model browser to view and navigate the structure of your model. You can find an element using the model browser by navigating to it through the model hierarchy. This approach works well for a small model whose structure you are familiar with. See “Explore the Model Hierarchy Using the Model Browser” on page 12-45.
- Use **Edit > Find** to locate model elements that match search criteria. You can search in a selected system and optionally include all systems below it. You can also narrow your results based on search criteria. See “Search for Model Elements Using Find” on page 12-46.
- Use the Model Explorer to search the model hierarchy using advanced criteria. You can use it to search the model hierarchy and search for variables. The Model Explorer also enables you to search in and apply a change to multiple model elements at once. See “Search Using Model Explorer” on page 12-50.
- Use project-wide search to search across all your models and supporting files in one place. You can find matches inside model files, MATLAB files, and other project files such as PDF and Microsoft Word files. See “Project-Wide Search” on page 17-3.

Explore the Model Hierarchy Using the Model Browser

Use the model browser to navigate a model hierarchy using a tree structure. The browser helps you to understand the organization of your model and explore systems within systems.

To display the model browser, in the Simulink Editor, select **View > Model Browser > Show Model Browser**. You can also use the **Hide/Show Model Browser** control on the palette to toggle the browser display.

You can use the commands on the **View > Model Browser** menu to specify whether to include in the browser blocks that are linked to a library and masked subsystems. For information on these types of blocks, see “Linked Blocks” on page 41-15 and “Masking Fundamentals” on page 39-2.

Search for Model Elements Using Find

You can search in Simulink models using **Edit > Find**. Use Find and the Finder interface to locate, navigate to, and select any element that matches the search string that you enter. Searching can match the string anywhere in the element, such as in the name and

in parameter values. You can customize the search to look only in certain types of elements or when specific parameters are set a certain way.

Default Search	Search Options
In the current system	Specify to search the current system and all systems below it in the model hierarchy.
In all model elements, including all types of Simulink and Stateflow objects	Narrow your search to include only the elements you are interested in, such as blocks, annotations, or signals.
In parameters	Specify to omit parameter values from the search.
Case-insensitive, partial matches	Search for an exact match and use regular expressions.
In referenced models but not in linked blocks or masked systems	You can turn each of these options off and on.

Perform a Basic Search

Search in the current level of the model `sldemo_fuelsys` for any model element that contains the number 2.

Tip Open the Property Inspector to see the properties and parameters of the current selection. Select **View > Property Inspector**.

- 1 Open the model `sldemo_fuelsys`.
- 2 Select **Edit > Find**.
- 3 In the search box, enter 2 and press **Enter**.

Nine model elements appear highlighted. The first element found, the copyright annotation, has a stronger highlight to show that it is the current match.

- 4 To move to the next element, click the search box down arrow. In this example, the current selection highlight moves to a Constant block. The block name does not appear in the model. Look in the Property Inspector to see the block name, Constant2.
- 5 Use the up and down arrows to move through the rest of the elements found.

Perform an Advanced Search

You can narrow your search by specifying search criteria. For an example, see “Specify Search Criteria and Sort Results” on page 12-49.

- 1 Select **Edit > Find**.
- 2 Enter the search string. Alternatively, you can add the search string later.
- 3 Click **View Details**.

- 4 Click the **Configure advanced search settings** button .
- 5 In the Advanced Search Settings dialog box, for each criterion you want to set, click the **Add property and value** button. Select the property and enter the value for each criterion.
- 6 Set any other advanced search settings, and then click **OK**.
- 7 If you entered a search string, the search executes. Alternatively, you can enter the search string after you specify the criteria, or enter an asterisk (*) to search for any model element that matches the advanced criteria.

Tip You can cancel a search and view partial search results. In the Finder interface, click the **Stop Search** button.

Search for a Property Value

Using the search box, you can specify a property and value to search for. Enter the search string in the form `Property:Value`. For example, to search for all **Constant value** parameters whose value is `throttle_sw`, type `Value:throttle_sw` and press **Enter**. To search for all Constant blocks, enter `BlockType:Constant`. To search for text that appears in the description of the block, use the form `Description:textstring`.

- Search using the programmatic name of the property. To find the programmatic name, in the Property Inspector, hover over the property.

- Enter the full property name, case insensitive. You cannot use regular expressions or partial matches for the property name.
- By default, the value search is case insensitive and finds partial matches. Use the advanced search settings to make the search case sensitive, specify verbatim matches, or search using regular expressions.

To search for a string that has a colon and prevent the text before the colon from being treated as a property, use one of these approaches:

- Escape the colon using a backslash, for example, `Earth\ : a planet`.
- Use single or double quotes around the expression, for example, `'Earth: a planet'` or `"Earth: a planet"`.

Specify Search Criteria and Sort Results

You can specify criteria for your search and sort the results using the Finder interface. In this example, you search for all elements that contain the string `fuel`. You then use the Finder interface to narrow your results. You can interact with search results while the search runs. However, you can sort the results only after the search is complete.

Tip Use the model browser with the Finder interface to select the starting point for your search.

- 1 Open the model `sldemo_fuelsys`.
- 2 Select **Edit > Find**. Next to the search box, click **View Details**.

- 3 To expand the scope of the search, in the Finder interface, click the **Click to search in current system and below** button .
- 4 Search for any elements that include the string `fuel`. In the search box, enter `fuel` and press **Enter**.

The model has many elements with `fuel` in the name or in a parameter or property value, including blocks, annotations, signals (data), and Stateflow charts.

Use the Finder interface to make your results more meaningful. For example, you can sort by any of the headings and double-click an item in the list to go to and select the element in the model. Click an item in the list to make it the current match in the model if it is displayed.

- 5 When a search returns too many results, use the advanced search settings. Next to the search box, click the **Configure advanced search settings** button .
- 6 Search only for blocks. In the Advanced Search Settings dialog box, under **Object Type**, clear the **Stateflow** check box. Expand the **Simulink** list and clear the **Annotations** and **Signals** check boxes.
- 7 Narrow the search further to look only in blocks whose description contains the word input. Under **Property : Value**, from the property list, select **BlockDescription**. In the value box, enter input, and then click the **Add property and value** button. Click **OK**.
- 8 Searching returns fewer blocks. You can add more property values to narrow the search further. For example, you can specify the type of blocks to search in. Open the Advanced Search Settings dialog box. Under **Property : Value**, add another property-value pair. Set the property to **BlockType** and the value to **MultiPortSwitch**. Click the **Add property and value** button and click **OK**.

One block appears in the list.

- 9 Clear the advanced search criteria. Click the arrow on the **Configure advanced search settings** button and select **Clear advanced settings**.

Search Using Model Explorer

Model Explorer helps you to explore and modify your model using advanced techniques. Use the Model Explorer for to search for:

- Variables in workspaces and data dictionaries
- Variable usage in a model
- Instances of a type of block
- Block parameters and parameter values

You can combine search criteria and iteratively refine the results. Search in Model Explorer for model elements, starting with the node you select in the model hierarchy. You can search the entire model, in a particular system, or in a system and all the systems below it in the hierarchy. For details on the options, see “Search Bar Controls” on page 12-4.

Using your search results, you can apply changes to multiple elements at once.

To modify algorithmic block parameters such as the **Gain** parameter of a Gain block, consider using the Model Data Editor. See “Configure Data Properties by Using the Model Data Editor” on page 62-179.

Search for a Parameter and Refine Results

In this example, you search for model elements that have an **Integer rounding mode** parameter. You then refine the results to include only n-D Lookup table blocks. You can use the search results to find out more about how these values are set or make batch changes to the model elements found by the search.

- 1 Open the model `sldemo_fuelsys`.
- 2 Open Model Explorer. Select **View > Model Explorer > Model Explorer**.

By default, the Model Explorer searches the current system and below. You can use the model hierarchy tree in combination with the **Show contents** button  to specify the scope of the search. For example, you can select a node and set the search to **current system only** to keep the search only at that level. Set the search to **current system and below** to search the current system and all the subsystems within it.

- 3 For this example, leave the search scope set to search the current system and below, starting with the top level of the model. Specify your search criteria. In the search bar, set:

- **Search** to by Property Name
- **Property** to Rounding

Rounding is the programmatic name for the **Integer rounding mode** parameter. For a list of these names, see “Block-Specific Parameters”.

- 4 Click **Search**. In the **Search Results** box, 43 results appear. You can go to an item by clicking the link to the path.
- 5 Refine the search. In the search bar, click **Search Options** and select **Refine Search**.

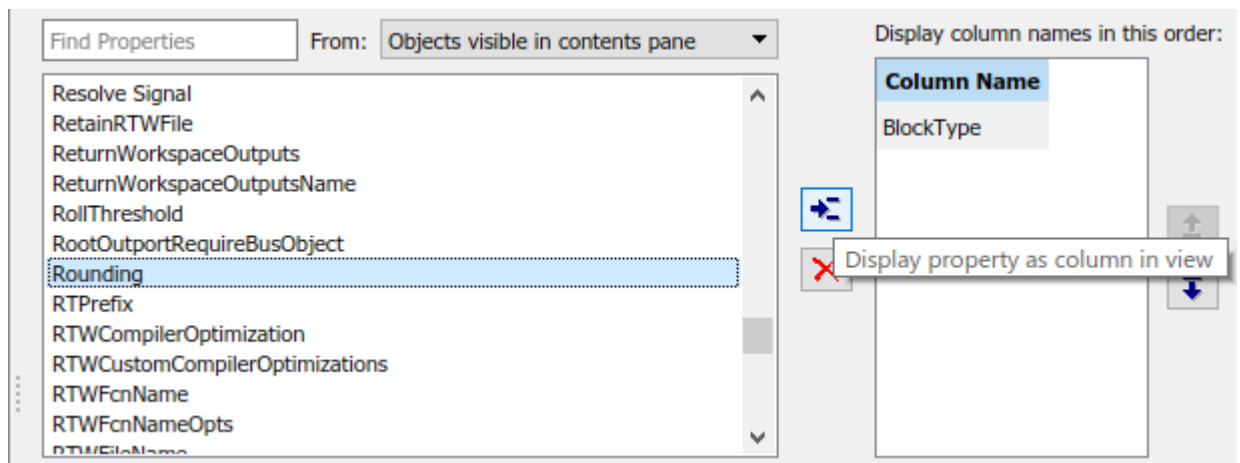

The search button label changes to **Refine**. With this label in effect, additional search criteria act on the previous set of results.

- 6 Set **Search** to by Block Type and set **Type** to Lookup_n-D. Click **Refine**.

The search returns 5 items.

- 7 To work further with the values, click **Show Details**.
- 8 The property you are interested in learning more about or acting on is **Rounding**. First add a column for it in the search results. Select **Rounding** from the list (you can enter it in the **Find Properties** box to locate it quickly), and click the **Display property as column in view** button.

A column for **Rounding** appears in the search results. For any parameter or property that appears in a column, you can view, sort, and change values for multiple items. For example, to change the **Rounding** values on all n-D Lookup Table blocks you find by searching, select all the items in the list. In the **Rounding** column, click one cell and select a new value from the list (for example, **Floor**).

Tip To view a summary of the search options that you used, expand the **Number of objects found** box by clicking the **Show Search Details** button .

- To create, modify, and view the entries in a data dictionary, use the Model Explorer. See “Edit and Manage Workspace Variables by Using Model Explorer” on page 62-149 and “View and Revert Changes to Dictionary Data” on page 66-27.
- For general information about Model Explorer and its uses, see “Search and Edit Using Model Explorer” on page 12-2.

Model Dependency Viewer

In this section...

“Model Dependency Views” on page 12-54

“View Model File and Library Dependencies” on page 12-57

Model Dependency Views

The Model Dependency Viewer displays a dependency view of a model. The dependency view is a graph of all the models and libraries referenced directly or indirectly by the model. You can use the dependency view to find and open referenced libraries and models. To identify and package all required files instead, see “Analyze Model Dependencies” on page 18-23.

The Model Dependency Viewer allows you to choose between the file dependency view and the model instances view.

File Dependency View

The file dependency view shows the model and library files referenced by a top model. A referenced model or library appears only once in the view even if it is referenced more than once in the model. The figure shows a dependency view. Gray blocks represent model files and blue boxes represent libraries. Arrows represent dependencies. For example, the arrows in this view indicate that the `aero_guidance` model references two libraries: `aerospace` and `simulink_need_slupdate`.

An arrow from a library that points to itself indicates that the library references itself. Blocks in the library reference other blocks in that same library. The example view shows that the `aerospace` library references itself.

A file dependency view can include a legend that identifies the model in the view and the date and time the view was created.

Model Instances View

The model instances view shows every reference to a model in a model reference hierarchy (see “Model References”) with the top model at the root of the hierarchy. If a model hierarchy references the same model more than once, the referenced model appears multiple times in the instance view, once for each reference. For example, this view indicates that the model reference hierarchy for `sldemo_mdhref_depgraph` contains two references to the model `sldemo_mdhref_F2C`.

In an instance view, boxes represent a top model and model references. Boxes representing accelerated-mode instances (see “Simulate Model Hierarchies” on page 8-54) have filled triangles in their corners; boxes representing normal-mode instances have empty triangles in their corners. For example, the previous diagram shows that one of the

references to `sldemo_md\ref_F2C` operates in normal mode, and the other operates in accelerated mode.

Boxes representing protected referenced models on page 8-20 show the protected models `.slxp` extension. You cannot expand protected reference models.

An instance view displays information icons  on instance boxes to indicate an override in simulation mode for that instance. For example, if a referenced model is configured to run in normal mode and it runs in accelerator mode, its simulation mode is overridden. This override occurs because another referenced model that runs in accelerator mode directly or indirectly references it.

Processor-in-the-Loop Mode Indicator

An instance view appends PIL to the names of models that run in processor-in-the-loop mode (see “Simulate Model Hierarchies” on page 8-54). For example, this dependency instance view indicates one instance of the referenced model `ModDepViewerSub` runs in processor-in-the-loop mode.

View Model File and Library Dependencies

This example shows how to use Model Dependency Viewer to view model file and library dependencies of the model. To identify and package all required files instead, see “Analyze Model Dependencies” on page 18-23.

- 1 Open the model `sldemo_mdref_depgraph`.
- 2 To open the Model Dependency Viewer in file dependency view, select **Analysis > Model Dependencies > Model Dependency Viewer > Models Only**.
- 3 Select the **User-Defined Libraries** check box. The viewer shows dependencies on user-defined libraries, if such dependencies exist.

You can open this view directly from the Simulink Editor by selecting **Analysis > Model Dependencies > Model Dependency Viewer > Models & Libraries**.

- 4 Select the **Built-In Libraries** check box to show dependencies on MathWorks built-in libraries.
- 5 To view the dependencies laid out horizontally, click **Options** and, under **Layout**, select **Horizontal**.
- 6 Collapse the dependencies of `sldemo_mdref_outdoor_temp`. Click - on the box for `sldemo_mdref_outdoor_temp`.
- 7 Hide the dependency viewer legend. Click **Options** and, under **Display**, select the **Legend** check box.
- 8 Click **Model Instances** to open the model instance view.

You can open this view directly from the Simulink editor by selecting **Analysis > Model Dependencies > Model Dependency Viewer > Referenced Model Instances**.

- 9 To display full paths in the boxes representing the instances, click **Options** and, under **Display**, select the **Full path** check box. Each box in the instance view displays the path of the Model block corresponding to the instance. The name of the referenced model appears in parentheses.
- 10 Select the box for `sldemo_mdref_heat2cost` and click **Highlight Block**. The corresponding block in the `sldemo_mdref_depgraph` model appears highlighted.
- 11 In the dependency viewer, double-click the `sldemo_mdref_heat2cost` box to open the model in the Simulink Editor.

View Linked Requirements in Models and Blocks

In this section...

“Requirements Traceability in Simulink” on page 12-59

“Highlight Requirements in a Model” on page 12-60

“View Information About a Requirements Link” on page 12-62

“Navigate to Requirements from a Model” on page 12-63

“Filter Requirements in a Model” on page 12-64

Requirements Traceability in Simulink

If your Simulink model has links to requirements in external documents, you can review these links. To identify which model objects satisfy certain design requirements, use the following requirements features available in Simulink software:

- Highlighting objects in your model that have links to external requirements
- Viewing information about a requirements link
- Navigating from a model object to its associated requirement
- Filtering requirements highlighting based on specified keywords

Having a Simulink Requirements license enables you to perform the following additional tasks, using the Requirements Management Interface (RMI):

- Adding new requirements
- Changing existing requirements
- Deleting existing requirements
- Applying user tags to requirements
- Creating reports about requirements links in your model
- Checking the validity of the links between the model objects and the requirements documents

Highlight Requirements in a Model

You can highlight a model to identify which objects in the model have links to requirements in external documents. Both the Simulink Editor and the Model Explorer provide this capability.

- “Highlight a Model Using the Simulink Editor” on page 12-60
- “Highlight a Model Using the Model Explorer” on page 12-61

Note If your model contains a Model block whose referenced model contains requirements, those requirements are not highlighted. If you have Simulink Requirements, you can view this information only in requirements reports. To generate requirements information for referenced models and then see highlighted snapshots of those requirements, follow the steps in “Report for Requirements in Model Blocks” (Simulink Requirements).

Highlight a Model Using the Simulink Editor

If you are working in the Simulink Editor and want to see which model objects in the `slvndemo_fuelsys_officereq` model have requirements, follow these steps:

- 1 Open the example model:

```
slvndemo_fuelsys_officereq
```

- 2 Select **Analysis > Requirements > Highlight Model**.

Two types of highlighting indicate model objects with requirements:

- Yellow highlighting indicates objects that have requirements links for the object itself.

- Orange outline indicates objects, such as subsystems, whose child objects have requirements links.

Objects that do not have requirements are colored gray.

- 3 To remove the highlighting from the model, select **Analysis > Requirements > Unhighlight Model**. Alternatively, you can right-click anywhere in the model, and select **Remove Highlighting**.

While a model is highlighted, you can still manage the model and its contents.

Highlight a Model Using the Model Explorer

If you are working in Model Explorer and want to see which model objects have requirements, follow these steps:

- 1 Open the example model:
`slvndemo_fuelsys_officereq`

- 2 Select **View > Model Explorer**.
- 3 To highlight all model objects with requirements, click the **Highlight items with requirements on model** icon ().

The Simulink Editor window opens, and all objects in the model with requirements are highlighted.

Note If you are running a 64-bit version of MATLAB, when you navigate to a requirement in a PDF file, the file opens at the beginning of the document, not at the specified location.

View Information About a Requirements Link

Using Simulink, you can view detailed information about a requirements link, such as identifying the location and type of document that contains the requirement.

Note You can modify the requirements information only if you have a Simulink Requirements license.

For example, to view information about the requirements link from the MAP Sensor block in the `slvndemo_fuelsys_officereq` example model, follow these steps:

- 1 Open the example model:
`slvndemo_fuelsys_officereq`
- 2 Right-click the MAP sensor block, and select **Requirements > Edit/Add Links**.

The Requirements dialog box opens and displays the following information about the requirements link:

- The description of the link (which is the actual text of the requirement).
- The Microsoft Excel® workbook named `slvndemo_FuelSys_TestScenarios.xlsx`, which contains the linked requirement.
- The requirements text, which appears in the named cell `Simulink_requirement_item_2` in the workbook.

- The user tag `test`, which is associated with this requirement.

Navigate to Requirements from a Model

Navigate from the Model Object

You can navigate directly from a model object to that object's associated requirement. When you take these steps, the external requirements document opens in the application, with the requirements text highlighted.

- 1 Open the example model:
`slvndemo_fuelsys_officereq`
- 2 Open the fuel rate controller subsystem.
- 3 To open the linked requirement, right-click the Airflow calculation subsystem and select **Requirements > 1. "Mass airflow estimation"**.

The Microsoft Word document `slvndemo_FuelSys_DesignDescription.docx`, opens with the section **2.1 Mass airflow estimation** selected.

Note If you are running a 64-bit version of MATLAB, when you navigate to a requirement in a PDF file, the file opens at the top of the page, not at the bookmark location.

Navigate from a System Requirements Block

Sometimes you want to see all the requirements links at a given level of the model hierarchy. In such cases, you can insert a System Requirements block to collect all requirements links in a model or subsystem. The System Requirements block lists requirements links for the model or subsystem in which it resides; it does not list requirements links for model objects inside that model or subsystem, because those are at a different level of the model hierarchy.

In the following example, you insert a System Requirements block at the top level of the `slvndemo_fuelsys_officereq` model, and navigate to the requirements using the links inside the block.

- 1 Open the example model:
`slvndemo_fuelsys_officereq`

- 2 In the Simulink Editor, select **Analysis > Requirements > Highlight Model**.
- 3 Open the fuel rate controller subsystem.

The Airflow calculation subsystem has a requirements link.

- 4 Open the Airflow calculation subsystem.
- 5 In the Simulink Editor, select **View > Library Browser**.
- 6 On the **Libraries** pane, select **Simulink Requirements**.

This library contains only one block—the System Requirements block.

- 7 Drag a System Requirements block into the Airflow calculation subsystem.

The RMI software collects and displays any requirements links for that subsystem in the System Requirements block.

- 8 In the System Requirements block, double-click **1. “Mass airflow subsystem”**.

The Microsoft Word document, `slvndemo_FuelSys_DesignDescription.docx`, opens, with the section **2.1 Mass airflow estimation** selected.

Filter Requirements in a Model

- “Filtering Requirements Highlighting by User Tag” on page 12-64
- “Filtering Options for Highlighting Requirements” on page 12-65

Filtering Requirements Highlighting by User Tag

Some requirements links in your model can have one or more associated user tags. User tags are keywords that you create to categorize a requirement, for example, `design` or `test`.

For example, in the `slvndemo_fuelsys_officereq` model, the requirements link from the MAP sensor block has the user tag `test`.

To highlight only all the blocks that have a requirement with the user tag `test`:

- 1 Open the example model:
`slvndemo_fuelsys_officereq`
- 2 In the Simulink Editor, select **Analysis > Requirements > Settings**.

The Requirements Settings dialog box opens. If you do not have a Simulink Requirements license, the **Filters** tab is the only option available.

By default, your model has no requirements filtering enabled.

- 3 Select **Filter links by user tags when highlighting and reporting requirements**.
- 4 In the **Include links with any of these tags** text box, delete design, and enter test.
- 5 Press **Enter**.
- 6 Highlight the `slvndemo_fuelsys_officereq` model for requirements. Select **Analysis > Requirements > Highlight Model**.

In the top-level model, only the MAP sensor block and the Test inputs block are highlighted.

- 7 To disable the filtering by user tag, select **Analysis > Requirements > Settings**, and clear **Filter links by user tags when highlighting and reporting requirements**.

The model highlighting updates immediately.

Filtering Options for Highlighting Requirements

On the **Filters** tab, you select options that designate which objects with requirements are highlighted. The following table describes these settings, which apply to all requirements in your model for the duration of your MATLAB session.

Option	Description
Filter links by user tags when highlighting and reporting requirements	Enables filtering for highlighting and reporting, based on specified user tags.
Include links with any of these tags	Highlights all objects whose requirements match at least one of the specified user tags. The tag names must match exactly. Separate multiple user tags with commas or spaces.

Option	Description
Exclude links with any of these tags	Excludes from the highlighting all objects whose requirements match at least one of the specified user tags. The tag names must match exactly. Separate multiple user tags with commas or spaces.
Apply same filters in context menus	Disables navigation links in context menus for all objects whose requirements do not match at least one of the specified user tags.
Under Link type filters, Disable DOORS surrogate item links in context menus	Disables links to IBM® Rational® DOORS® surrogate items from the context menus when you right-click a model object. This option does not depend on current user tag filters.

Trace Connections Using Interface Display

In this section...

“How Interface Display Works” on page 12-67

“Trace Connections in a Subsystem” on page 12-67

How Interface Display Works

In the Simulink Editor, you can turn on and off the display of interfaces in a model. When you are building large, complex models, you can connect or add signal lines between blocks or buses that are at different levels. The interface view allows you to trace signals through the nested levels. This capability helps you to:

- Identify inputs and outputs.
- Trace signal lines and bus elements to sources and terminations.
- Annotate signal characteristics such as data type, dimensions, and sample time.
- View units associated with signals, where applicable.

When you build a model, transition block pairs such as Inport and Outport and From and Goto help you to simplify connections of the crossovers among many signal lines. The interface view enables you to trace the hand-off and receipt between such blocks by way of colored highlights.

Trace Connections in a Subsystem

This example shows how to use the display of model interfaces to examine, trace, and understand the flow of signals and buses. This model propagates bus signals into referenced models.

- 1 Open the model `sldemo_mdhref_counter_bus`.

The `counter_bus_input` port channels the data and saturation limits of the counter to count and sets the upper and lower limit values. The `increment_bus_input` port channels a bus signal to change the increment and reset the counter.

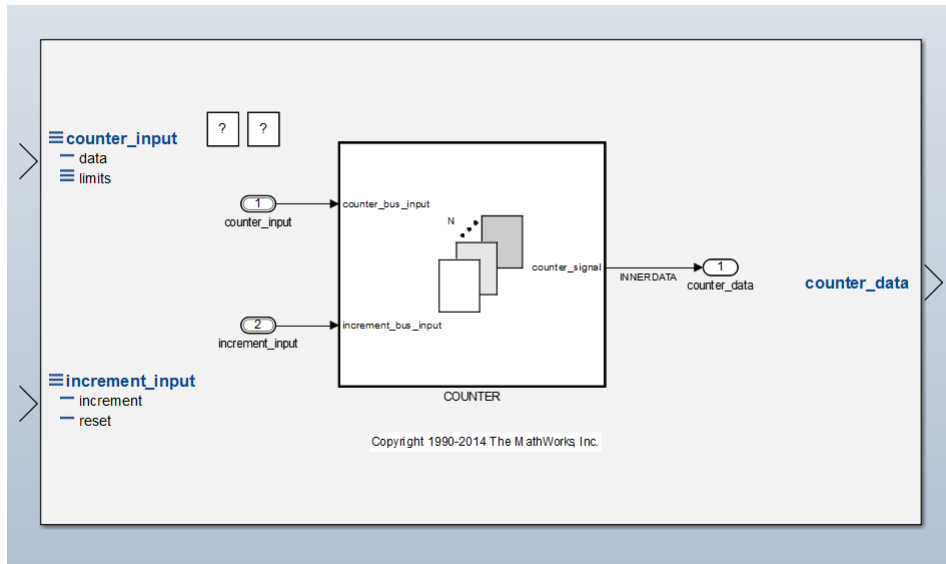

- 2 Select **Display > Interface** to enable the interface view.

Tip Use the perspectives control in the lower-right corner of the model to toggle the display of interfaces.

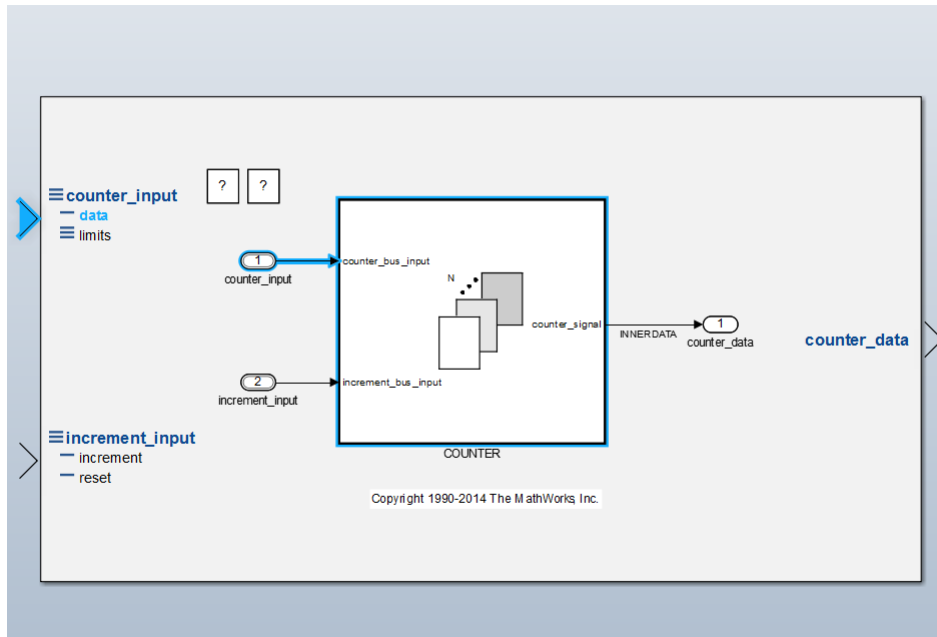

The three bars next to the `counter_input` and `increment_input` interfaces indicate the bus input signals. The single bars indicate data lines, such as counts per second, or command lines, such as reset, to start a new counting sequence. The three bars next to `limits` indicate that bus signals are nested inside the `COUNTER` subsystem.

- 3 Under `counter_input`, click `data`.

The path for the data appears in blue. The COUNTER subsystem is highlighted, indicating the path continues within it.

4 Double-click the COUNTER subsystem.

The continuation of the path for the data signal appears in blue.

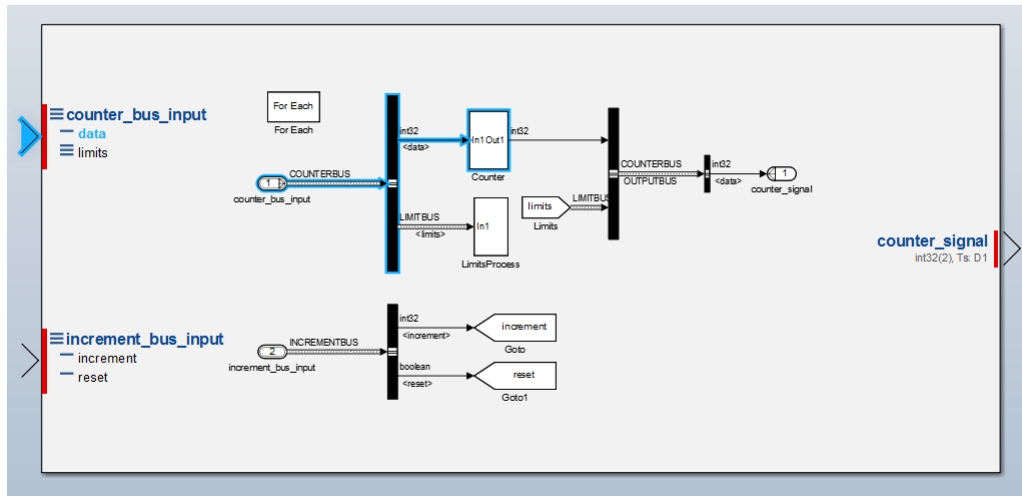

5 Select **Simulation > Update Diagram**.

Note This model requires values from a parent model to simulate completely.

The `counter_signal` interface displays these signal attributes, which help you to synchronize signals between blocks during simulation:

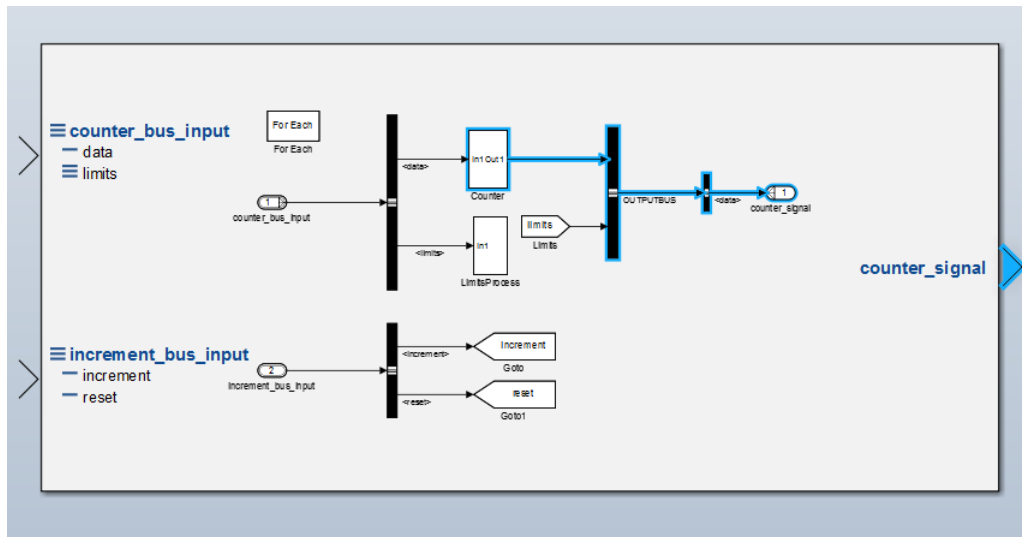

- Data type: int32 (signed 32-bit integer)
- Dimensions: (2) (a 1-D Simulink representation of a scalar)
- Sample time: Ts:D1 (a discrete sample time of D1, which is the highest speed)

In addition, when you update the diagram with interfaces displayed, the model displays the color code for sample time at each interface. For example, this model displays a red bar at each interface to indicate a sample time of D1.

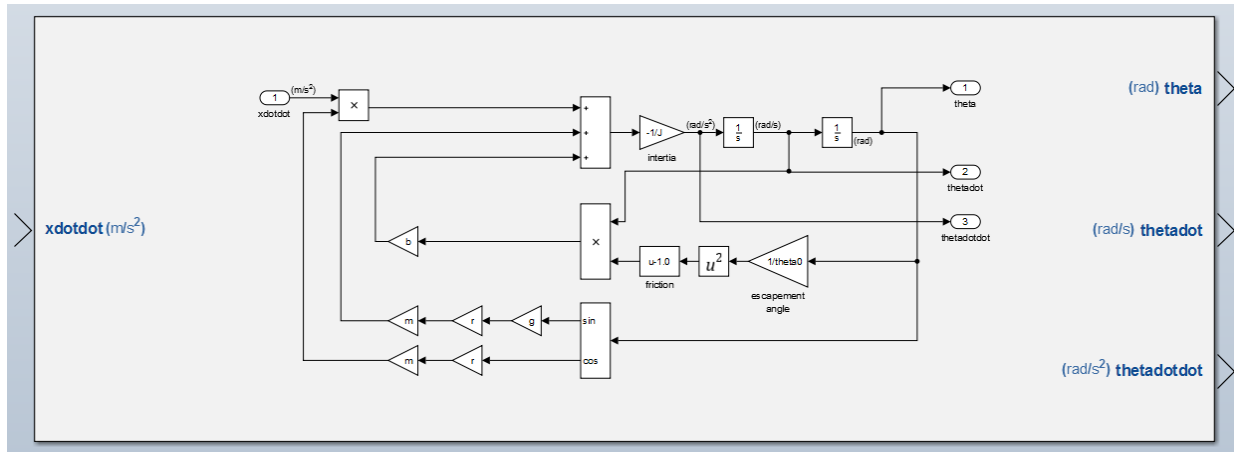

Tip To display a legend of the meaning of sample time colors, select **Display > Sample Time > Colors**.

- Click the `counter_signal` output interface to see the output of the bus outlined in blue, where the path ends.

- 7 If you want to print this diagram with the interfaces displayed, select **File > Print > Print**.

When signals in your model have units associated with them, you see the units in the interface view. For example, in the model `sldemo_metro`, the `Metronome1` subsystem shows units for inputs and outputs of the subsystem in the interface view.

To modify the attributes of the existing interface (such as signal names, data types, and dimensions), consider using the Model Data Editor (**View > Model Data Editor**). For information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 62-179.

Display Signal Attributes at Model Load Time

When working with multiple model components in large models, consider displaying signal attributes at load time without compiling the model. To enable the display, select **Display > Signals & Ports > Port Data Types** and save the model. The next time you load the model, it displays the data type and complexity signal attributes.

You can use the `ShowPortDataTypes` property to toggle the display of the data type and complexity signal attributes:

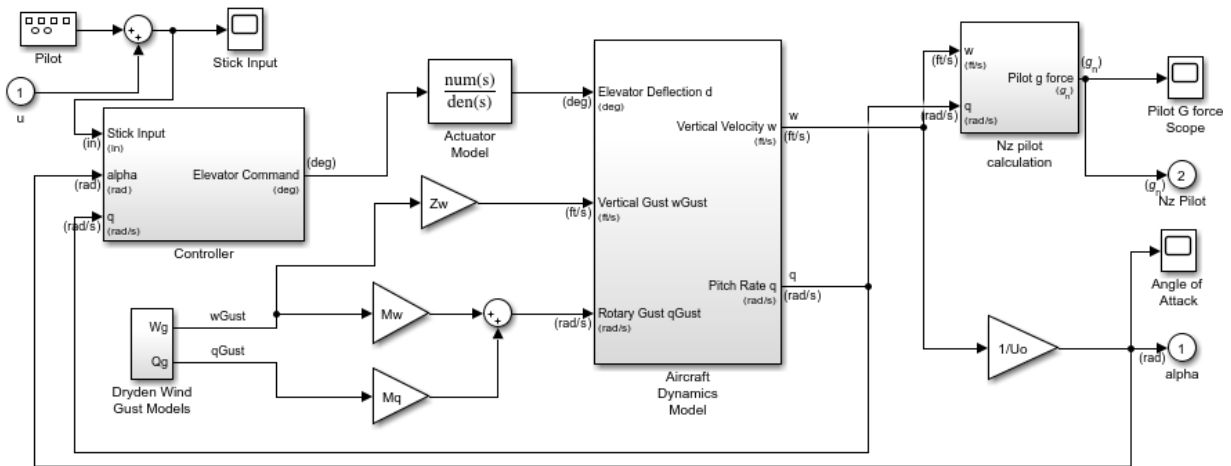

```
set_param(bdroot, 'ShowPortDataTypes', 'on')
set_param(bdroot, 'ShowPortDataTypes', 'off')
```

The `ShowLineDimensions` and `ShowPortUnits` properties then display dimensions and units at load time.

These blocks are a subset of the blocks that support the display of signal attributes:

- Inport
- Outport
- In Bus Element
- Out Bus Element
- Subsystem
- Model
- Signal Specification
- Bus Creator

For example, this model has the display of port data types disabled.

And this is the same model after enabling the display of port data types.

Tip To display port dimensions and values for a compiled model, you can use the `CompiledPortDimensions` parameter. For details, see “Get Compiled Port Dimensions” on page 67-36.

Bus Creator | Inport | Model | Outport | Signal Specification | Subsystem

More About

- “Find Attribute Mismatches Between Components” on page 12-76

Find Attribute Mismatches Between Components

When working with multiple model components in large models, consider checking signal attributes in the interface display. To enable the check, select the **Display > Errors & Warnings** check box. You do not compile the model first.

These blocks support the signal attribute mismatch check:

- Inport
- Outport
- Subsystem
- Model
- Signal Specification
- Bus Creator

When Simulink detects a mismatch, it flags the issue.

Managing Model Configurations

- “About Model Configurations” on page 13-2
- “Multiple Configuration Sets in a Model” on page 13-3
- “Share a Configuration for Multiple Models” on page 13-4
- “Share a Configuration Across Referenced Models” on page 13-6
- “Manage a Configuration Set” on page 13-11
- “Manage a Configuration Reference” on page 13-18
- “About Configuration Sets” on page 13-26
- “About Configuration References” on page 13-29
- “Model Configuration Command Line Interface” on page 13-33

About Model Configurations

A model configuration is a named set of values for the parameters of a model. It is referred to as a *configuration set* on page 13-26. Every new model is created with a default configuration set, called **Configuration**, that initially specifies default values for the model parameters. You can change the default values for new models by setting the Model Configuration Preferences. For more information, see “Model Configuration Pane”.

You can subsequently create and modify additional configuration sets and associate them with the model. The configuration sets associated with a model can specify different values for any or all configuration parameters. For more information, see “About Configuration Sets” on page 13-26. For examples on how to use configuration sets, see:

- “Multiple Configuration Sets in a Model” on page 13-3
- “Manage a Configuration Set” on page 13-11

By default, a configuration set resides within a single model so that only that model can use it. Alternatively, you can store a configuration set independently, so that other models can use it. A configuration set that exists outside any model is a freestanding configuration set on page 13-27. Each model that uses a freestanding configuration set defines a configuration reference on page 13-29 that points to the freestanding configuration set. A freestanding configuration set allows you to single-source a configuration set for several models. For more information, see “About Configuration References” on page 13-29. For examples on how to use configuration references, see:

- “Share a Configuration for Multiple Models” on page 13-4
- “Share a Configuration Across Referenced Models” on page 13-6
- “Manage a Configuration Reference” on page 13-18

More About

- “Configuration Parameters Dialog Box Overview”
- “Solver Pane”

Multiple Configuration Sets in a Model

A model can include many different configuration sets. This capability is useful if you want to compare the difference in simulation output after changing the values of several parameters. Attaching additional configuration sets allows you to quickly switch the active configuration.

- 1 To create additional configuration sets in your model, in the Model Explorer, select your model node in the Model Hierarchy pane and do one of the following:
 - Right-click the model node and select **Configuration > Add Configuration**.
 - Expand the model node and select the Configurations node. In the **Contents** pane, right-click an existing configuration set. In the context menu, select **Copy**. Right-click the Configurations node or right-click in the **Contents** pane, and select **Paste**.
- 2 To import a previously saved configuration set, right-click the model node and select **Configuration > Import**. In the Import Configuration From File dialog box, select a configuration file.
- 3 To modify the newly added configuration set, in the **Model Hierarchy** pane, select the Configurations node. In the **Contents** pane, right-click the configuration and select **Open**. Modify any parameters in the Configuration Parameters dialog box.
- 4 To make the new configuration set the active configuration, in the configuration set context menu, select **Activate**. In the **Contents** pane, the new configuration set name is now displayed as (Active).
- 5 To simulate your model using a different configuration set, switch the active configuration by repeating step 4.

- “Manage a Configuration Set” on page 13-11
- “Model Configuration Command Line Interface” on page 13-33

Share a Configuration for Multiple Models

With configuration references, multiple models can share a configuration set. To share a configuration set between models, store the configuration set as a configuration set object in the base workspace or data dictionary. Then create a configuration reference in your model that references the configuration set object. You can create configuration references in other models that also point to the same configuration set object.

Note Before saving and closing your models, follow the instructions to “Save a Referenced Configuration Set” on page 13-24. If you do not save the referenced configuration set from the base workspace, when you reopen your model, the configuration reference is unresolved.

Convert an Existing Configuration Set to a Configuration Reference

To convert an existing configuration set in your model to a configuration reference:

- 1 Open the Model Explorer.
- 2 In the **Model Hierarchy** pane, select the Configurations node.
- 3 In the **Contents** pane, right-click the active configuration set to share.
- 4 In the configuration set context menu, select **Convert to Configuration Reference**, which opens a dialog box. Alternatively, you can right-click the model node and select **Configuration > Convert Active Configuration to Reference**.
- 5 In the Convert Active Configuration to Reference dialog box, use the default configuration set object name, `Configuration`, or type a name.
- 6 Click **OK**, which creates a configuration reference in the model and a configuration set object in the base workspace or data dictionary. The configuration reference points to the configuration set object, which has the same values as the original active configuration set. The configuration reference name in the **Contents** pane is now marked as (Active).

Create a Configuration Reference in Another Model

To share the preceding configuration set, which is stored as `Configuration` in the base workspace, create a configuration reference in another model:

- 1 In the **Model Hierarchy** pane, right-click the model node.
- 2 In the context menu, select **Configuration > Add Configuration Reference**.
- 3 A new configuration reference appears in the **Contents** pane. The default name of the new reference is **Reference**. Specify the name of the configuration set object, **Configuration**, in the base workspace.
- 4 To make the new configuration reference the active configuration, in the **Contents** pane, right-click the configuration reference. In the context menu, select **Activate**.

Both models now contain a configuration reference that points to the same configuration set object in the base workspace. Alternatively, you can store the configuration set object in the data dictionary. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-50.

More About

- “About Configuration References” on page 13-29

Share a Configuration Across Referenced Models

This example shows how to share the same configuration set for the top model and referenced models in a model reference hierarchy. You can use a configuration reference in each of the models to reference the same configuration set object in the base workspace.

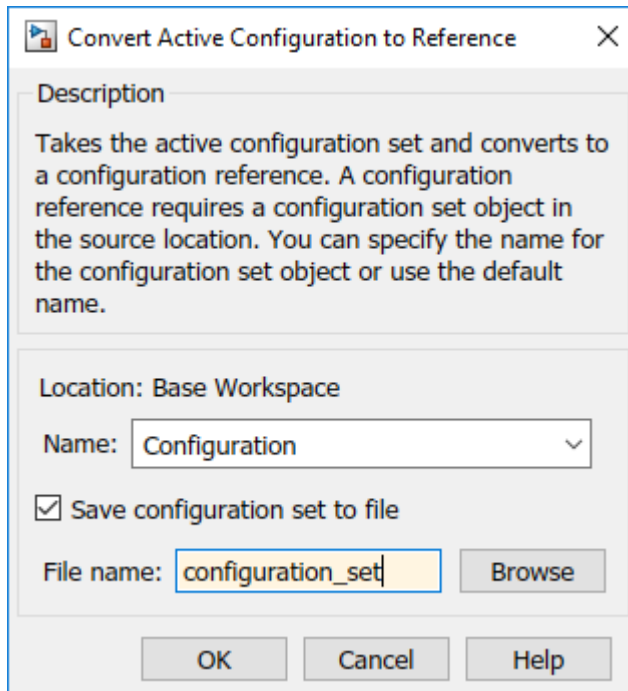

In the diagram, each model shown in the Model Dependency Viewer specifies the configuration reference, `my_configuration`, as its active configuration set. `my_configuration` points to the freestanding configuration set, `Configuration`. Therefore, the parameter values in `Configuration` apply to all four models. Any parameter change in `Configuration` applies to all four models.

Convert Configuration Set to Configuration Reference

In the top model, you must convert the active configuration set to a configuration reference:

- 1 Open the `sldemo_mdhref_depgraph` model and the Model Explorer.
- 2 In the **Model Hierarchy** pane, expand the top model, `sldemo_mdhref_depgraph`. In the list, select the Configurations node, and right-click Configuration (Active) in the **Contents** pane. In the context menu, select **Convert to Configuration Reference**.
- 3 In the **Configuration set name** field, specify a name for the configuration set object, or use the default name, Configuration. This configuration set object is stored in the base workspace.
- 4 Optionally, you can save the configuration set to a MAT-file. Select **Save configuration set to file**. This enables the **File name** parameter.
- 5 In the **File name** field, specify a name for the MAT-file.

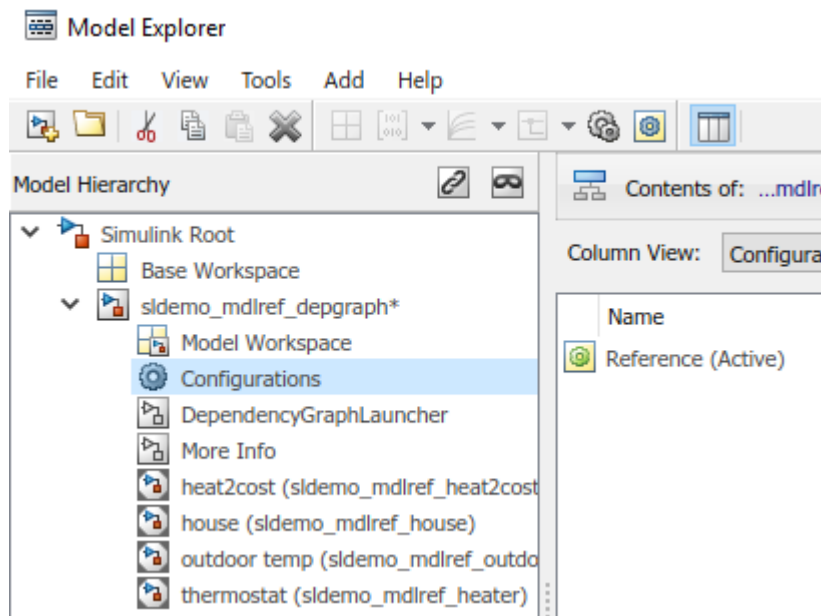

- 6 Click **OK**.

The original configuration set is now stored as a configuration set object, `Configuration`, in the base workspace. The configuration set is also stored in a MAT-file, `configuration_set.mat`. The active configuration for the top model is now a configuration reference. This configuration reference points to the configuration set object in the base workspace.

Propagate a Configuration Reference

Now that the top model contains an active configuration reference, you can propagate this configuration reference to all of the child models. Propagation creates a copy of the top model configuration reference in each referenced model. For each referenced model, the configuration reference is now the active configuration. The configuration references point to the configuration set object, `Configuration`, in the base workspace.

- 1 In the Model Explorer, in the **Model Hierarchy** pane, expand the `sldemo_mdhref_depgraph` node and select the **Configurations** node.

- 2 In the **Contents** pane, right-click the active configuration reference, **Reference (Active)**. In the context menu, select **Propagate to Referenced Models**.

- 3 In the Configuration Reference Propagation dialog box, select the check box for each referenced model. In this example, they are already selected.
- 4 Verify that your current folder is a writable folder. The propagation mechanism saves the original configuration parameters for each referenced model so that you can undo the propagation. Click **Propagate**.
- 5 In the Propagation Confirmation dialog box, click **OK**.
- 6 In the Configuration Reference Propagation dialog box, the Propagation Report is updated and the **Status** for each referenced model is marked as **Converted**.

Undo a Configuration Reference Propagation

After propagating a configuration reference from a top model to the referenced models, you can undo the propagation for all referenced models by clicking **Restore All**. If you want to undo the propagation for individual referenced models, in the **Undo/Redo** column, click the **Undo** button. The Propagation Report is updated and the **Status** for the referenced model is set to **Restored**.

Manage a Configuration Set

In this section...

- “Create a Configuration Set in a Model” on page 13-11
- “Create a Configuration Set in the Base Workspace” on page 13-11
- “Open a Configuration Set in the Configuration Parameters Dialog Box” on page 13-12
- “Activate a Configuration Set” on page 13-13
- “Copy, Delete, and Move a Configuration Set” on page 13-13
- “Save a Configuration Set” on page 13-14
- “Load a Saved Configuration Set” on page 13-15
- “Copy Configuration Set Components” on page 13-16
- “Compare Configuration Sets” on page 13-16

Create a Configuration Set in a Model

- 1 Open the Model Explorer.
- 2 In the **Model Hierarchy** pane, select the model name.
- 3 You can create a new configuration set in any of these ways:
 - From the **Add** menu, select **Configuration**.
 - On the toolbar, click the **Add Configuration** button .
 - Select the Configurations node below the model node. In the **Contents** pane, right-click an existing configuration set and copy and paste the configuration set.

Create a Configuration Set in the Base Workspace

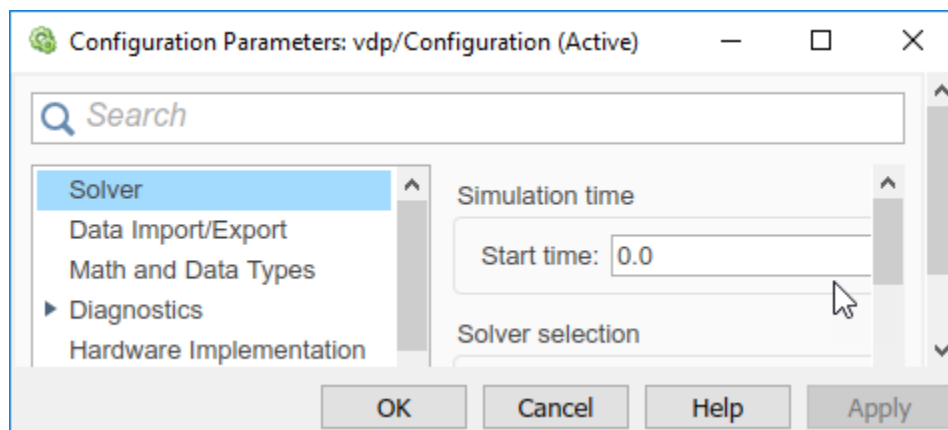

- 1 Open the Model Explorer.
- 2 In the **Model Hierarchy** pane, select **Base Workspace**.
- 3 You can create a new configuration set object in these ways:
 - From the **Add** menu, select **Configuration**
 - In the toolbar, click the **Add Configuration** button .

- 4 The configuration set object appears in the **Contents** pane, with the default name, Configuration.

Open a Configuration Set in the Configuration Parameters Dialog Box

In the Model Explorer, to open the Configuration Parameters dialog box for a configuration set, right-click the configuration set's node to display the context menu, then select **Open**. You can open the Configuration Parameters dialog box for any configuration set, whether or not it is active. To set the value of a parameter in a configuration set, use the Configuration Parameters dialog box.

The title bar of the dialog box indicates whether the configuration set is active or inactive.

Note Every configuration set has its own Configuration Parameters dialog box. As you change the state of a configuration set, the title bar of the dialog box changes to reflect the state.

Activate a Configuration Set

Only one configuration set associated with a model is active at any given time. The active set determines the current values of the model parameters. You can change the active or inactive set at any time (except when executing the model). In this way, you can quickly reconfigure a model for different purposes, for example, testing and production, or apply standard configuration settings to new models.

To activate a configuration set, right-click the configuration set node to display the context menu, then select **Activate**.

Copy, Delete, and Move a Configuration Set

You can use edit commands on the Model Explorer **Edit** or context menus or object drag-and-drop operations to delete, copy, and move configuration sets among models displayed in the **Model Hierarchy** pane.

For example, to copy a configuration set from one model to another:

- 1 In the **Model Hierarchy** pane, expand the node of the model with the configuration set and select the Configurations node below it.
- 2 In the **Contents** pane, right-click the configuration set that you want to copy.
- 3 Select **Copy** in the configuration set context menu.
- 4 Expand the model node in which you want to create the copy.
- 5 Right-click the Configurations node and select **Paste** from the context menu.

To copy the configuration set using object drag-and-drop, hold down the right mouse button and drag the configuration set to the Configurations node of the model in which you want to create the copy.

To move a configuration set from one model to another using drag-and-drop, hold the left mouse button down and drag the configuration set to the Configurations node of the destination model.

Note You cannot move or delete an active configuration set from a model.

Save a Configuration Set

You can save the settings of configuration sets as MATLAB functions or scripts. Using the MATLAB function or script, you can share and archive model configuration sets. You can also compare the settings in different configuration sets by comparing the MATLAB functions or scripts of the configuration sets.

To save an active or inactive configuration set from the Model Explorer:

- 1 Open the model.
- 2 Open the Model Explorer.
- 3 Save the configuration set:
 - a In the **Model Hierarchy** pane:
 - Right-click the model node and select **Configuration > Export Active Configuration Set**.
 - Select the Configurations node under the model node. In the **Contents** pane, right-click a configuration set and select **Export**.
 - b In the Export Configuration Set to File dialog box, specify the name of the file and the file type. If you specify a `.m` extension, the file contains a function that

creates a configuration set object. If you specify a `.mat` extension, the file contains a configuration set object.

Note Do not specify the name of the file to be the same as a model name. If the file and model have the same name, the software cannot determine which file contains the configuration set object when loading the file.

- c Click **Save**. The Simulink software saves the configuration set.

Load a Saved Configuration Set

You can load configuration sets that you previously saved as MATLAB functions or scripts.

To load a configuration set from the Model Explorer:

- 1 Open the model.
- 2 Open the Model Explorer.
- 3 In the **Model Hierarchy** pane, right-click the model and select **Configuration > Import**.
- 4 In the Import Configuration Set From File dialog box, select the `.m` file that contains the function to create the configuration set object, or the `.mat` file that contains the configuration set object.
- 5 Click **Open**. The Simulink software loads the configuration set.

Note

- If you load a configuration set object that contains an invalid custom target, the software sets the “System target file” (Simulink Coder) parameter to `ert.tlc`.
- If you load a configuration set that contains a component that is not available on your system, the parameters in the missing component are reset to their default values.

-
- 6 Optionally, activate the configuration set. For more information, see “Activate a Configuration Set” on page 13-13.

Copy Configuration Set Components

You can copy a configuration set component from one configuration to another using the `copy` and `attachComponent` functions.

- 1 Get the configuration set that has the component you want to copy.

```
cs1 = getConfigSet('model_name', 'config_set_1_name');
```

- 2 Get the configuration component that you want to copy.

```
cc1 = getComponent(cs1, 'component_name');
```

- 3 Copy the configuration component.

```
cc2 = copy(cc1);
```

- 4 Get the destination configuration set.

```
cs2 = getConfigSet('model_name', 'config_set_2_name');
```

- 5 Attach the component copy to the destination configuration set.

```
attachComponent(cs2, cc2);
```

Note The copy replaces the component of the same name in the destination configuration set. For example, if you copy the Solver component of configuration set A and paste it into configuration set B, the copy replaces the existing Solver component in B.

Compare Configuration Sets

You can visually compare two configuration sets using the `visdiff` function. This function opens the Comparison Tool and presents the differences between the two files. Alternatively, you can select a pair of models to compare. See “Compare Simulink Models” on page 21-7.

- 1 Get the first configuration set for a model. By default, the configuration set name is `Configuration`.

```
cs = getConfigSet('model_name', 'config_set_1_name');
```

- 2 Save the configuration set to a MAT-file.

```
save('configSet1.mat', 'cs');
```

- 3 Get the second configuration set for the model. By default, the configuration set name is Configuration.

```
cs = getConfigSet('model_name','config_set_2_name');
```

- 4 Save the second configuration set to a MAT-file.

```
save('configSet2.mat','cs');
```

- 5 Compare the files.

```
visdiff('configSet1.mat','configSet2.mat');
```

For more information on using the Comparison Tool to compare MAT-files, see “Compare and Merge MAT-Files” (MATLAB).

“Change Parameter Value in a Configuration Reference” on page 13-22

“Save a Referenced Configuration Set” on page 13-24

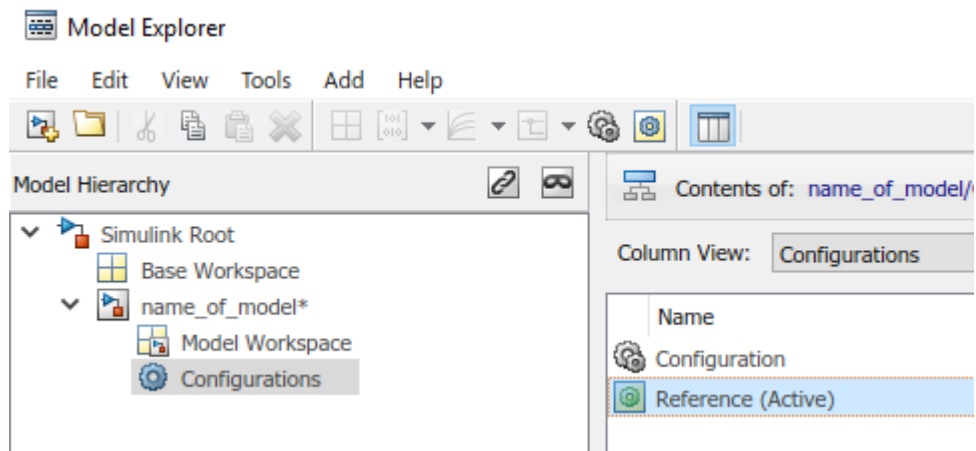

“Load a Saved Referenced Configuration Set” on page 13-24

Create and Attach a Configuration Reference

To be used, a configuration reference on page 13-29 must point to freestanding configuration set on page 13-27. To create a freestanding configuration set before creating a configuration reference, see “Create a Configuration Set in the Base Workspace” on page 13-11.

To create a configuration reference:

- 1 In the Model Explorer, in the **Model Hierarchy** pane, select the model.
- 2 Select **Add > Configuration Reference** or click the **Add Configuration Reference** tool .
- 3 In the right panel, specify the **Name** of the configuration set object in the base workspace to be referenced.
- 4 If you chose to create a configuration reference without first creating a configuration set object, a warning indicates that your configuration reference cannot be found. In this case, an unresolved configuration reference is created. For more information, see “Unresolved Configuration References” on page 13-30. Follow the instructions in “Resolve a Configuration Reference” on page 13-19.
- 5 A new configuration reference appears in the **Contents** pane of the Configurations node for the selected model. The default name of the new reference is **Reference**.

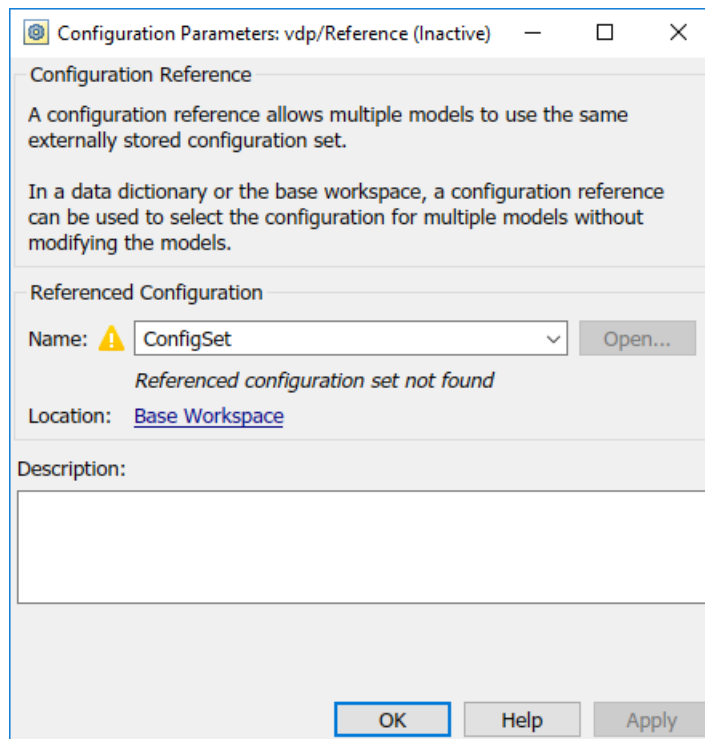

Resolve a Configuration Reference

An unresolved configuration reference on page 13-30 is a configuration reference that is not pointing to a valid configuration set object.

To resolve a configuration reference:

- 1 In the **Model Hierarchy** pane, select the Configurations node. In the **Contents** pane, select the unresolved configuration reference.

The Configuration Reference dialog box opens in the Dialog pane.

- 2 Specify the **Referenced configuration** set to be a configuration set object already in the base workspace or data dictionary. If one does not exist, see “Create a Configuration Set in the Base Workspace” on page 13-11.

Tip You can specify the name of a configuration reference. But, nesting of a configuration reference beyond this depth results in an error.

- 3 Click **OK** or **Apply**. The warning icon disappears.

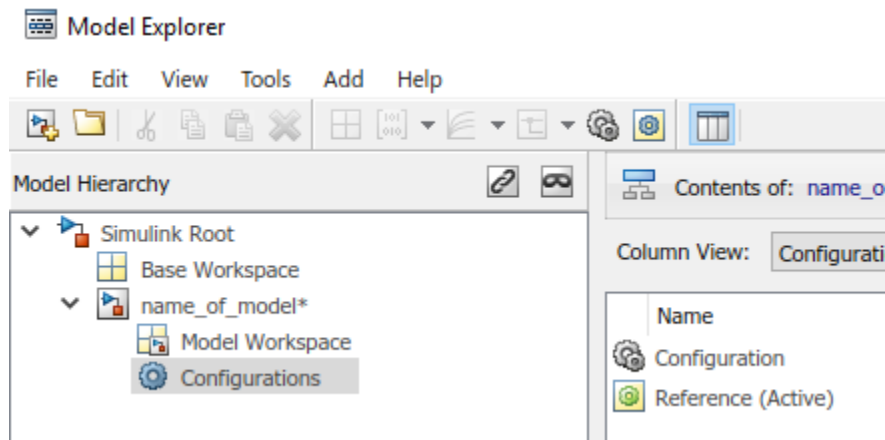

Activate a Configuration Reference

After you create a configuration reference and attach it to a model, you can activate it so that it is the active configuration.

- From the context menu of the configuration reference, select **Activate**.

- From the command line, execute `setActiveConfigSet`, specifying the configuration reference as the second argument.

When a configuration reference is active, the **Is Active** field of the Configuration Reference dialog box changes to yes. Also, the Model Explorer shows the name of the reference with the suffix (Active).

The freestanding configuration set of the active reference now provides the configuration parameters for the model.

Manage Configuration Reference Across Referenced Models

In a model hierarchy, you can share a configuration reference across referenced models. Using the Configuration Reference Propagation dialog box, you can propagate a configuration reference of a top model to an individual referenced model or to all referenced models in the model hierarchy. The dialog box provides:

- A list of referenced models in the top model.
- The ability to select only specific referenced models for propagation.
- After propagation, the status for the converted configuration for each referenced model.
- A view of the changed parameters after the propagation.
- The ability to undo the configuration reference and restore the previous configuration settings for a referenced model.

To open the dialog box, in the Model Explorer, in the **Model Hierarchy** pane, select the Configurations node. In the **Contents** pane, right-click the configuration reference of a model. In the context menu, select **Propagate to Referenced Models**. For an example, see “Share a Configuration Across Referenced Models” on page 13-6.

Change Parameter Values in a Referenced Configuration Set

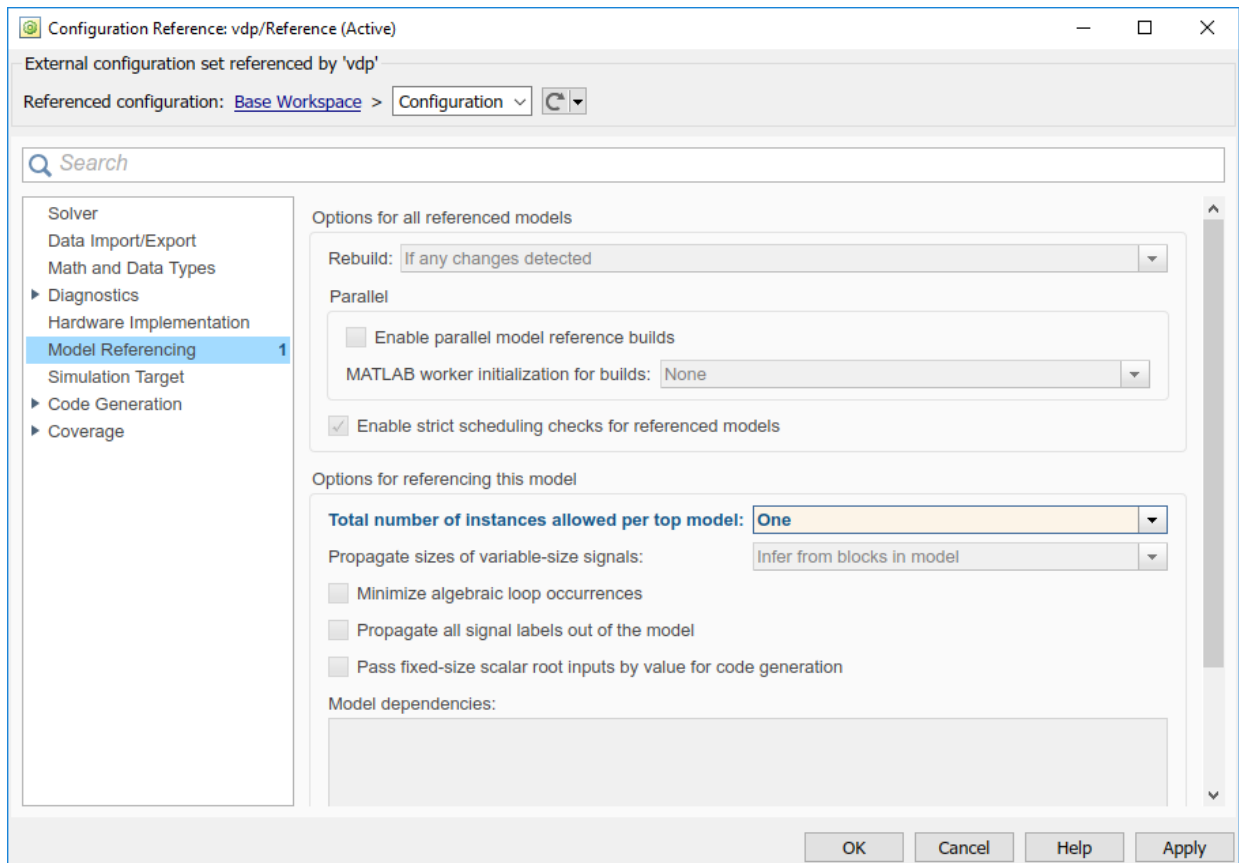

From the Configuration Reference dialog box, you can open the referenced configuration set to change parameter values. Making changes to the standalone configuration set affects configuration references that refer to it, except for parameters that are overridden in those references. To obtain a referenced configuration set:

- 1** Click the Model Configuration Parameters button  on the Simulink Editor toolbar to open the Configuration Reference dialog box. The Configuration Reference dialog box displays a read-only view of the referenced configuration. In the dialog box you can browse, search, and get context-sensitive help for the parameters in the same way you do in the Configuration Parameters dialog box.
- 2** At the top of the Configuration Reference dialog box, expand the drop-down list to the right of the Refresh icon and select **Open referenced configuration**. The Configuration Parameters dialog box opens. You can now change and apply parameter values as you would for any configuration set.
- 3** To see your applied changes in the Configuration Reference dialog box, click the Refresh icon.

Change Parameter Value in a Configuration Reference

When one reference to a standalone configuration requires a different value for a parameter, you can override that parameter in the configuration reference. Override a parameter to change its value in the reference without changing the standalone configuration. For an overridden parameter, the reference uses the value you assign locally instead of the value in the referenced configuration set. For example, the models of a hierarchy may reference a standalone configuration in which the parameter **Model Referencing > Total number of instances allowed per top model** is set to **Multiple**. If you want to reference a model only once in the hierarchy, you can override the parameter for the configuration reference of only that model and set the value to **One**. Simulink detects a violation if the hierarchy references that model more than one time.

- 1 Click the Model Configuration Parameters button  on the Simulink Editor toolbar to open the Configuration Reference dialog box.
- 2 Right-click the parameter you want to change and select **Override** from the context menu. You can now change the parameter value as you would for any configuration set. In the left pane, each component displays the number of overridden parameters it contains.

- 3 Click **Apply** to keep the changes or **Cancel** to restore the parameter to the referenced value. Changes you make to a parameter value apply only to the configuration reference in which you override and edit the parameter. They do not affect other references to the referenced configuration set.

- 4 To restore an overridden parameter to its value from the referenced configuration set, right-click the overridden parameter and select **Restore** from the context menu. The overridden parameter resets to the value in the referenced configuration and becomes read-only again.

Save a Referenced Configuration Set

If your model uses a configuration reference to specify the model configuration, before closing your model, you need to save the referenced configuration set to a MAT-file or MATLAB script.

- 1 In the Model Explorer, in the Model Hierarchy, select **Base Workspace**.
- 2 In the Contents pane, right-click the name of the referenced configuration set object.
- 3 From the context menu, select **Export Selected**.
- 4 Specify the filename for saving the configuration set as either a MAT-file or a MATLAB script.

Tip When you reopen the model you must load the saved configuration set, otherwise the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-50.

Load a Saved Referenced Configuration Set

If your model uses a configuration reference to specify the model configuration, you need to load the referenced configuration set from a MAT-file or MATLAB script to the base workspace.

- 1 In the Model Explorer, in the Model Hierarchy, right-click **Base Workspace**.
- 2 From the context menu, select **Import**.
- 3 Specify the filename for the saved configuration set and select OK. The configuration set object appears in the base workspace.

Tip When you reopen the model, you must load the saved configuration set, otherwise the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-50.

About Configuration Sets

In this section...
“What Is a Configuration Set?” on page 13-26
“What Is a Freestanding Configuration Set?” on page 13-27

What Is a Configuration Set?

A configuration set comprises groups of related parameters called components. Every configuration set includes the following components:

- Solver
- Data Import/Export
- Optimization
- Diagnostics
- Hardware Implementation
- Model Referencing
- Simulation Target

Some MathWorks products that work with Simulink, such as Simulink Coder, define additional components. If such a product is installed on your system, the configuration set also contains the components that the product defines.

When you select any model configuration, the Model Configuration dialog appears in the Model Explorer **Dialog** pane. In this location, you can edit the name and description of your configuration.

Configuration Parameters: vdp/Configuration (Active)

Model Configuration

The Configuration is a set of 'Configuration Components' that individually define specific settings for a particular model's execution (simulation) and/or deployment (code generation). A given model can have more than one Configuration associated with it. Different Configurations can be customized for the different phases of model development. The 'Active' Configuration is used for current operation (simulation or code generation) on the model. Only one Configuration is active at a time.

Configuration Name: 'Configuration'
Associated Model: [vdp](#)
Is Active: [yes](#)

Name:

Description:

Tip If you want to reuse the same configuration settings in new models, use a model template. See “Use Customized Settings When Creating New Models” on page 1-8.

What Is a Freestanding Configuration Set?

A freestanding configuration set is a configuration set object, `Simulink.ConfigSet`, stored in the base workspace. To use a freestanding configuration set as the configuration for a model, you must create a configuration reference in the model that references it. You can create a freestanding configuration set in the base workspace in these ways:

- Create a new configuration set object.
- Copy a configuration set that resides within a model to the base workspace.
- Load a configuration set from a MAT-file.

You can store any number of configuration sets in the base workspace by assigning each set to a different MATLAB variable.

Note Although you can store a configuration set in a model and point to it with a base workspace variable, such a configuration set is not freestanding. Using it in a configuration reference causes an error.

About Configuration References

In this section...

“Why Use Configuration References?” on page 13-29

“Unresolved Configuration References” on page 13-30

“Overriding Individual Configuration Parameters” on page 13-30

“Configuration Reference Limitations” on page 13-31

“Configuration References for Models with Older Simulation Target Settings” on page 13-31

A configuration reference in a model is a reference to a configuration set object in the base workspace or data dictionary. A model that has a configuration reference that points to a freestanding configuration set on page 13-27 uses that configuration set when configuration reference is active. The model then has the same configuration parameters as if the referenced configuration set resides directly in the model.

You can attach any number of configuration references to a model. Each reference must have a unique name. For an example on how to use configuration references, see “Share a Configuration for Multiple Models” on page 13-4 or “Create and Attach a Configuration Reference” on page 13-18.

Tip Save or export the configuration set object. Otherwise, when you reopen your model, the configuration reference is unresolved. To set up your model to automatically load the configuration set object, see “Callbacks for Customized Model Behavior” on page 4-50.

Why Use Configuration References?

You can use configuration references and freestanding configuration sets to achieve these goals.

- Assign the same configuration set to any number of models

Each model that uses a given configuration set contains a configuration reference that points to a MATLAB variable. The value of that variable is a freestanding configuration set. All the models share that configuration set. Changing the value of any parameter in the set changes it for every model that uses the set. Use this feature to reconfigure many referenced models quickly and ensure consistent configuration of parent models

and referenced models. If one model requires a different value for an individual parameter, you can override that parameter to change the value locally in the configuration reference. For more information, see “Overriding Individual Configuration Parameters” on page 13-30.

- Replace the configuration sets of any number of models without changing the model files

When multiple models use configuration references to access a freestanding configuration set, assigning a different set to the MATLAB variable assigns that set to all models. Use this feature to maintain a library of configuration sets and assign them to any number of models in a single operation.

- Use different configuration sets for a referenced model used in different contexts without changing the model file

A referenced model that uses different configuration sets in different contexts contains a configuration reference that specifies the referenced model configuration set as a variable.

Unresolved Configuration References

When a configuration reference does not reference a valid configuration set, a warning indicates that the referenced configuration set cannot be found. If you activate an unresolved configuration reference, no warning or error appears. However, an unresolved configuration reference that is active provides no configuration parameter values to the model. Therefore, trying to build the model, simulate it, generate code for it, or otherwise require it to access configuration parameter values results in an error.

For more information, see “Resolve a Configuration Reference” on page 13-19.

Overriding Individual Configuration Parameters

When you reference the same configuration set from many models, there may be a model that requires a different value for an individual parameter. When you use a configuration reference, you can override an individual parameter to specify a setting that is different from the referenced configuration. The local setting affects only the configuration reference in which you override the parameter and does not affect the referenced configuration set or other configuration references.

If you have overridden a parameter, you can restore its value from the referenced configuration set. When you restore a parameter, it reflects the value in the referenced

configuration and is no longer overridden. For more information, see “Change Parameter Value in a Configuration Reference” on page 13-22.

Configuration Reference Limitations

- A configuration reference can link to another configuration reference, but you cannot nest a configuration reference beyond that depth.
- If you activate a configuration reference when using a custom target, the `ActivateCallback` function does not trigger to notify the corresponding freestanding configuration set. Likewise, if a freestanding configuration set switches from one target to another, the `ActivateCallback` function does not trigger to notify the new target. This behavior occurs, even if an active configuration reference points to that target. For more information about `ActivateCallback` functions, see “`rtwgensettings` Structure” (Simulink Coder).
- Not all parameters in a reference can be overridden, for example, parameters that must be consistent in a model reference hierarchy.

Configuration References for Models with Older Simulation Target Settings

Suppose that you have a nonlibrary model that contains one of these blocks:

- MATLAB Function
- Chart
- Truth Table
- Attribute Function

In R2008a and earlier, this type of nonlibrary model does not store simulation target (or `sfun`) settings in the configuration parameters. Instead, the model stores the settings outside any configuration set.

When you load this older type of model, the simulation target settings migrate to parameters in the active configuration set.

- If the active configuration set resides internally with the model, the migration happens automatically.
- If the model uses an active configuration reference to point to a configuration set in the base workspace, the migration process is different.

Default Migration Process That Disables the Configuration Reference

Because multiple models can share a configuration set in the base workspace, loading a nonlibrary model cannot automatically change any parameter values in that configuration set. By default, these actions occur while a model is loading to ensure that simulation results are the same, no matter which version of the software that you use:

- A copy of the configuration set in the base workspace attaches to the model.
- The simulation target settings migrate to the corresponding parameters in this new configuration set.
- The new configuration set becomes active.
- The old configuration reference becomes inactive.

A warning message appears in the MATLAB Command Window to describe those actions. Although this process ensures consistent simulation results for the model, it disables the configuration reference that links to the configuration set in the base workspace.

Overview

An application programming interface (API) lets you create and manipulate configuration sets at the command line or in a script. The API includes the `Simulink.ConfigSet` and `Simulink.ConfigSetRef` classes and the following functions:

- `attachConfigSet`
- `attachConfigSetCopy`
- `detachConfigSet`
- `getConfigSet`
- `getConfigSets`
- `setActiveConfigSet`
- `getActiveConfigSet`
- `openDialog`
- `closeDialog`
- `Simulink.BlockDiagram.saveActiveConfigSet`
- `Simulink.BlockDiagram.loadActiveConfigSet`

These functions, along with the methods and properties of `Simulink.ConfigSet` class, allow you to create a script to:

- Create and modify configuration sets.
- Attach configuration sets to a model.
- Set the active configuration set for a model.
- Open and close configuration sets.
- Detach configuration sets from a model.
- Save configuration sets.
- Load configuration sets.

For examples using the preceding functions and the `Simulink.ConfigSet` class, see the function and class reference pages.

Load and Activate a Configuration Set at the Command Line

To load a configuration set from a MATLAB function or script:

- 1 Use the `getActiveConfigSet` or `getConfigSet` function to get a handle to the configuration set that you want to update.
- 2 Call the MATLAB function or execute the MATLAB script to load the saved configuration set.
- 3 Optionally, use the `attachConfigSet` function to attach the configuration set to the model. To avoid configuration set naming conflicts, set `allowRename` to `true`.
- 4 Optionally, use the `setActiveConfigSet` function to activate the configuration set.

Alternatively, to load a configuration set at the command line and make it the active configuration set:

- 1 Open the model.
- 2 Use the `Simulink.BlockDiagram.loadActiveConfigSet` function to load the configuration set and make it active.

Note If you load a configuration set with the same name as the:

- Active configuration set, the software overwrites the active configuration set.
 - Inactive configuration set that is associated with the model, the software detaches the inactive configuration from the model.
-

Save a Configuration Set at the Command Line

To save an active or inactive configuration set as a MATLAB function or script:

- 1 Use the `getActiveConfigSet` or `getConfigSet` function to get a handle to the configuration set.
- 2 Use the `saveAs` method of the `Simulink.Configset` class to save the configuration set as a function or script.

Alternatively, to save the active configuration set:

- 1 Open the model.
- 2 Use the `Simulink.BlockDiagram.saveActiveConfigSet` function to save the active configuration set.

Create a Freestanding Configuration Set at the Command Line

Copy a Configuration Set Stored in a Model

Create a freestanding configuration set on page 13-27 to be referenced by a configuration reference in several models. You must copy any configuration set obtained from an existing model, otherwise, `cset` refers to the existing configuration set stored in the model, rather than a new freestanding configuration set in the base workspace. For example, use one of the following:

- `cset = copy (getActiveConfigSet(model))`
- `cset = copy (getConfigSet(model, ConfigSetName))`

`model` is any open model, and `ConfigSetName` is the name of any configuration set attached to the model.

Read a Configuration Set from a MAT-File

To use a freestanding configuration set across multiple MATLAB sessions, you can save it to a MAT-file. To create the MAT-file, you first copy the configuration set to a base workspace variable, then save the variable to the MAT-file:

```
save (workfolder/ConfigSetName.mat, cset)
```

workfolder is a working folder, *ConfigSetName.mat* is the MAT-file name, and *cset* is a base workspace variable whose value is the configuration set to save. When you later reopen your model, you can reload the configuration set into the variable:

```
load (workfolder/ConfigSetName.mat)
```

To execute code that reads configuration sets from MAT-files, use one of these techniques:

- The preload function of a top model
- The MATLAB startup script
- Interactive entry of load statements

Create and Attach a Configuration Reference at the Command Line

To create and populate a configuration reference, `Simulink.ConfigSetRef`, using the API:

- 1 Create the reference:

```
cref = Simulink.ConfigSetRef
```

- 2 Change the default name if desired:

```
cref.Name = 'ConfigSetRefName'
```

- 3 Specify the referenced configuration set:

```
cref.SourceName = 'cset'
```

Tip Do not specify the name of a configuration reference. If you nest a configuration reference, an error occurs.

- 4 Attach the reference to a model:

```
attachConfigSet(model, cref, true)
```

The third argument is optional and authorizes renaming to avoid a name conflict.

Using a configuration reference with an invalid configuration set, `SourceName`, generates an error and is called an unresolved configuration reference. The GUI equivalent of `SourceName` is **Referenced configuration**. You can later use the API or GUI to provide

the name of a freestanding configuration set. For more information, see “Unresolved Configuration References” on page 13-30.

Note A `Simulink.ConfigSetRef` object cannot be saved to a MATLAB file. To save the configuration, call the `Simulink.ConfigSetRef.getRefConfigSet` method. Then save the `Simulink.ConfigSet` object that the method returns. For more information, see “Save a Configuration Set at the Command Line” on page 13-35.

Attach a Configuration Reference to Multiple Models at the Command Line

After you create a configuration reference and attach it to a model, you can attach copies of the reference to any other models. Each model has its own copy of any configuration reference attached to it, just as each model has its own copy of any attached configuration set.

If you use the GUI, attaching an existing configuration reference to another model automatically attaches a distinct copy to the model. If necessary to prevent name conflict, the GUI adds or increments a digit at the end of the name of the copied reference. If you use the API, be sure to copy the configuration reference explicitly before attaching it, with statements like:

```
cref = copy (getConfigSet(model, ConfigSetRefName))
attachConfigSet (model, cref, true)
```

If you omit the `copy` operation, `cref` becomes a handle to the original configuration reference, rather than a copy of the reference. Any attempt to use `cref` causes an error. If you omit the argument `true` to `attachConfigSet`, the operation fails if a name conflict exists.

The following example shows code for obtaining a freestanding configuration set and attaching references to it from two models. After the code executes, one of the models contains an internal configuration set and a configuration reference that points to a freestanding copy of that set. If the internal copy is an extra copy, you can remove it with `detachConfigSet`, as shown in the last line of the example.

```
open_system('modell')
% Get handle to local cset
cset = getConfigSet('modell', 'Configuration')
```

```
% Create freestanding copy; original remains in model
cset1 = copy(cset)

% In the original model, create a configuration
% reference to the cset copy
cref1 = Simulink.ConfigSetRef
cref1.SourceName = 'cset1'

% Attach the configuration reference to the model
attachConfigSet('model1', cref1, true)

% In a second model, create a configuration
% reference to the same cset
open_system('model2')
% Rename if name conflict occurs
attachConfigSetCopy('model2', cref1, true)

% Delete original cset from first model
detachConfigSet('model1', 'Configuration')
```

Get Values from a Referenced Configuration Set

You can use `get_param` on a configuration reference to obtain parameter values from the linked configuration set, as if the reference object were the configuration set itself. Simulink software retrieves the referenced configuration set and performs the indicated `get_param` on it.

For example, if configuration reference `cref` links to configuration set `cset`, the following operations give identical results:

```
get_param (cset, 'StopTime')
get_param (cref, 'StopTime')
```

Change Values in a Referenced Configuration Set

By operating on only a configuration reference, you cannot change the referenced configuration set parameter values. If you execute:

```
set_param (cset, 'StopTime', '300')
set_param (cref, 'StopTime', '300')           % ILLEGAL
```

the first operation succeeds, but the second causes an error. Instead, you must obtain the configuration set itself and change it directly, using the GUI or the API.

To obtain a referenced configuration set using the API:

- 1 Follow the instructions in “Obtain a Configuration Reference Handle” on page 13-39.
- 2 Obtain the configuration set *cset* from the configuration reference *cref*:

```
cset = cref.getRefConfigSet
```

You can now use `set_param` on *cset* to change parameter values. For example:

```
set_param (cset, 'StopTime', '300')
```

Tip If you want to change parameter values through the GUI, execute:

```
cset.openDialog
```

The Configuration Parameters dialog box opens on the specified configuration set.

Obtain a Configuration Reference Handle

Most functions and methods that operate on a configuration reference take a handle to the reference. When you create a configuration reference:

```
cref = Simulink.ConfigSetRef
```

the variable *cref* contains a handle to the reference. If you do not already have a handle, you can obtain one by executing:

```
cref = getConfigSet(model, 'ConfigSetRefName')
```

ConfigSetRefName is the name of the configuration reference as it appears in the Model Explorer, for example, Reference. You specify this name by setting the **Name** field in the Configuration Reference dialog box or executing:

```
cref.Name = 'ConfigSetRefName'
```

The technique for obtaining a configuration reference handle is the same technique you use to obtain a configuration set handle. Wherever the same operation applies to both configuration sets and configuration references, applicable functions and methods overload to perform correctly with either class.

Concepts in Multicore Programming

In this section...
“Basics of Multicore Programming” on page 14-2
“Types of Parallelism” on page 14-3
“System Partitioning for Parallelism” on page 14-6
“Challenges in Multicore Programming” on page 14-7

Basics of Multicore Programming

Multicore programming helps you create concurrent systems for deployment on multicore processor and multiprocessor systems. A *multicore processor system* is a single processor with multiple execution cores in one chip. By contrast, a *multiprocessor system* has multiple processors on the motherboard or chip. A multiprocessor system might include a Field-Programmable Gate Array (FPGA). An FPGA is an integrated circuit containing an array of programmable logic blocks and a hierarchy of reconfigurable interconnects. A *processing node* processes input data to produce outputs. It can be a processor in a multicore or multiprocessor system, or an FPGA.

The multicore programming approach can help when:

- You want to take advantage of multicore and FPGA processing to increase the performance of an embedded system.
- You want to achieve scalability so your deployed system can take advantage of increasing numbers of cores and FPGA processing power over time.

Concurrent systems that you create using multicore programming have multiple tasks executing in parallel. This is known as *concurrent execution*. When a processor executes multiple parallel tasks, it is known as *multitasking*. A CPU has firmware called a scheduler, which handles the tasks that execute in parallel. The CPU implements tasks using operating system threads. Your tasks can execute independently but have some data transfer between them, such as data transfer between a data acquisition module and controller for the system. Data transfer between tasks means that there is a *data dependency*.

Multicore programming is commonly used in signal processing and plant-control systems. In signal processing, you can have a concurrent system that processes multiple frames in parallel. In plant-control systems, the controller and the plant can execute as two

separate tasks. Using multicore programming helps to split your system into multiple parallel tasks, which run simultaneously, speeding up the overall execution time.

To model a concurrently executing system, see “Partitioning Guidelines” on page 14-37.

Types of Parallelism

The concept of multicore programming is to have multiple system tasks executing in parallel. Types of parallelism include:

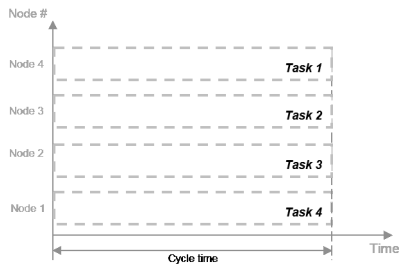

- Data parallelism
- Task parallelism
- Pipelining

Data Parallelism

Data parallelism involves processing multiple pieces of data independently in parallel. The processor performs the same operation on each piece of data. You achieve parallelism by feeding the data in parallel.

The figure shows the timing diagram for this parallelism. The input is divided into four chunks, A, B, C, and D. The same operation $F()$ is applied to each of these pieces and the output is O_A , O_B , O_C , and O_D respectively. All four tasks are identical, and they run in parallel.

The time taken per processor cycle, known as cycle time, is

$$t = tF.$$

The total processing time is also tF , since all four tasks run simultaneously. In the absence of parallelism, all four pieces of data are processed by one processing node. The cycle time is tF for each task but the total processing time is $4 * tF$, since the pieces are processed in succession.

You can use data parallelism in scenarios where it is possible to process each piece of input data independently. For example, a web database with independent data sets for processing or processing frames of a video independently are good candidates for data parallelism.

Task Parallelism

In contrast to data parallelism, task parallelism doesn't split up the input data. Instead, it achieves parallelism by splitting up an application into multiple tasks. Task parallelism involves distributing tasks within an application across multiple processing nodes. Some tasks can have data dependency on others, so all tasks do not run at exactly the same time.

Consider a system that involves four functions. Functions $F2a()$ and $F2b()$ are in parallel, that is, they can run simultaneously. In task parallelism, you can divide your computation into two tasks. Function $F2b()$ runs on a separate processing node after it gets data $Out1$ from Task 1, and it outputs back to $F3()$ in Task 1.

The figure shows the timing diagram for this parallelism. Task 2 does not run until it gets data Out1 from Task 1. Hence, these tasks do not run completely in parallel. The time taken per processor cycle, known as cycle time, is

$$t = t_{F1} + \max(t_{F2a}, t_{F2b}) + t_{F3}.$$

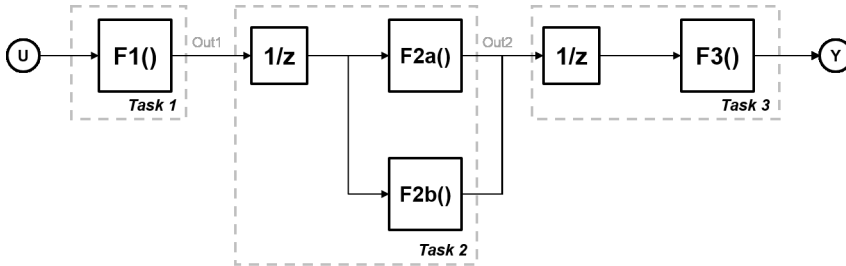

You can use task parallelism in scenarios such as a factory where the plant and controller run in parallel.

Model Pipeline Execution (Pipelining)

Use model pipeline execution, or pipelining, to work around the problem of task parallelism where threads do not run completely in parallel. This approach involves modifying your system model to introduce delays between tasks where there is a data dependency.

In this figure, the system is divided into three tasks to run on three different processing nodes, with delays introduced between functions. At each time step, each task takes in the value from the previous time step by way of the delay.

Each task can start processing at the same time, as this timing diagram shows. These tasks are truly parallel and they are no longer serially dependent on each other in one processor cycle. The cycle time does not have any additions but is the maximum processing time of all the tasks.

$$t = \max(\text{Task1}, \text{Task2}, \text{Task3}) = \max(t_{F1}, t_{F2a}, t_{F2b}, t_{F3}).$$

You can use pipelining wherever you can introduce delays artificially in your concurrently executing system. The resulting overhead due to this introduction must not exceed the time saved by pipelining.

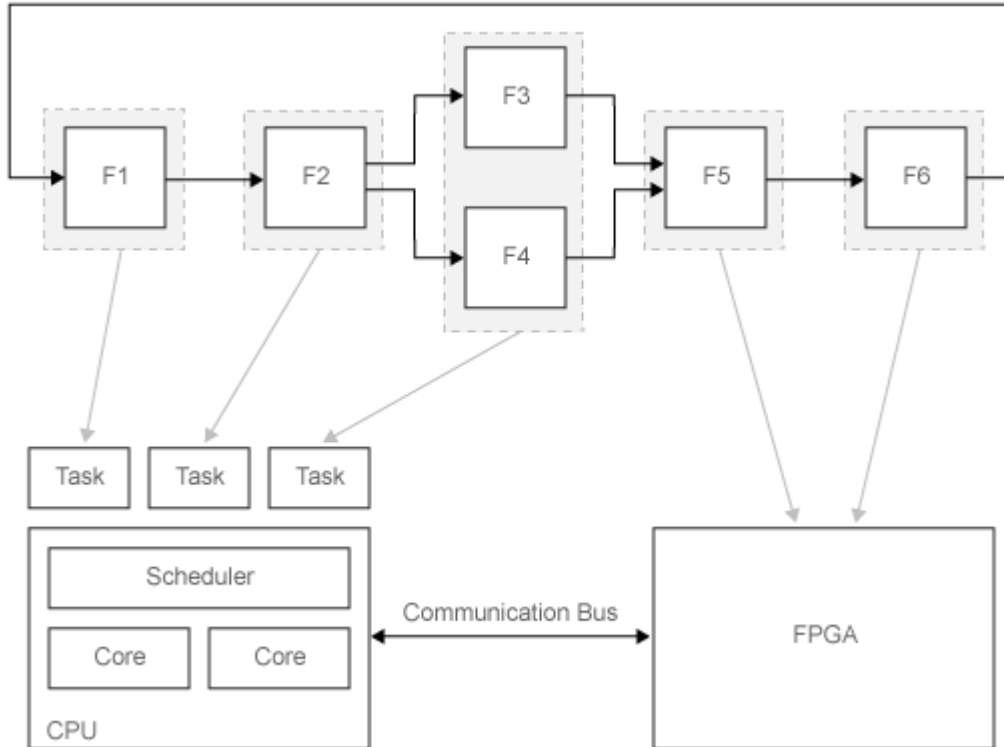

System Partitioning for Parallelism

Partitioning methods help you to designate areas of your system for concurrent execution. Partitioning allows you to create tasks independently of the specifics of the target system on which the application is deployed.

Consider this system. F1-F6 are functions of the system that can be executed independently. An arrow between two functions indicates a data dependency. For example, the execution of F5 has a data dependency on F3.

Execution of these functions is assigned to the different processor nodes in the target system. The gray arrows indicate assignment of the functions to be deployed on the CPU

or the FPGA. The CPU scheduler determines when individual tasks run. The CPU and FPGA communicate via a common communication bus.

The figure shows one possible configuration for partitioning. In general, you test different configurations and iteratively improve until you get the optimal distribution of tasks for your application.

Challenges in Multicore Programming

Manually coding your application onto a multicore processor or an FPGA poses challenges beyond the problems caused by manual coding. In concurrent execution, you must track:

- Scheduling of the tasks that execute on the embedded processing system multicore processor

- Data transfers to and from the different processing nodes

Simulink manages the implementation of tasks and data transfer between tasks. It also generates the code that is deployed for the application. For more information, see “Multicore Programming with Simulink” on page 14-10.

In addition to these challenges, there are challenges when you want to deploy your application to different architectures and when you want to improve the performance of the deployed application.

Portability: Deployment to Different Architectures

The hardware configuration that runs the deployed application is known as the architecture. It can contain multicore processors, multiprocessor systems, FPGAs, or a combination of these. Deployment of the same application to different architectures can require effort due to:

- Different number and types of processor nodes on the architecture
- Communication and data transfer standards for the architecture
- Standards for certain events, synchronization, and data protection in each architecture

To deploy the application manually, you must reassign tasks to different processing nodes for each architecture. You might also need to reimplement your application if each architecture uses different standards.

Simulink helps overcome these problems by offering portability across architectures. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-11.

Deployment Efficiency

You can improve the performance of your deployed application by balancing the load of the different processing nodes in the multicore processing environment. You must iterate and improve upon your distribution of tasks during partitioning, as mentioned in “System Partitioning for Parallelism” on page 14-6. This process involves moving tasks between different processing nodes and testing the resulting performance. Since it is an iterative process, it takes time to find the most efficient distribution.

Simulink helps you to overcome these problems using profiling. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-11.

Cyclic Data Dependency

Some tasks of a system depend on the output of other tasks. The data dependency between tasks determines their processing order. Two or more partitions containing data dependencies in a cycle creates a data dependency loop, also known as an *algebraic loop*.

Simulink identifies loops in your system before deployment. For more information, see “How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-11.

Multicore Programming with Simulink

In this section...

“Basic Workflow” on page 14-10

“How Simulink Helps You to Overcome Challenges in Multicore Programming” on page 14-11
--

Using the process of partitioning, mapping, and profiling in Simulink, you can address common challenges of designing systems for concurrent execution.

Partitioning enables you to designate regions of your model as tasks, independent of the details of the embedded multicore processing hardware. This independence enables you to arrange the content and hierarchy of your model to best suit the needs of your application.

In a partitioned system, mapping enables you to assign partitions to processing elements in your embedded processing system. Use the Simulink mapping tool to represent and manage the details of executing threads, HDL code on FPGAs, and the work that these threads or FPGAs perform. While creating your model, you do not need to track the partitions or data transfer between them because the tool does this work. Also, you can reuse your model across multiple architectures.

Profiling simulates deployment of your application under typical computational loads. It enables you to determine the partitioning and mapping for your model that gives the best performance, before you deploy to your hardware.

Basic Workflow

To deploy your model to the target.

- 1 Set up your model for concurrent execution.

For more information about configuring your model for concurrent execution, see “Configure Your Model for Concurrent Execution” on page 14-24. With these settings, Simulink partitions your model based on the sample time of blocks at the root level, with each sample time in your model corresponding to a partition, and all blocks of a single rate or sample time belonging to the same partition.

If you want to specify how to partition your model, use explicit partitioning. With explicit partitioning, you must specify a target architecture, and then explicitly

partition your model. For more information, see “Specify a Target Architecture” on page 14-25, and “Partition Your Model Using Explicit Partitioning” on page 14-31.

- 2 Generate code and deploy it to your target. You can choose to deploy onto multiple targets.
 - To build and deploy on a desktop target, see “Build on Desktop” on page 14-46.
 - To deploy onto embedded targets using Embedded Coder, see “Deployment” (Embedded Coder).
 - To build and deploy on a real-time target using Simulink Real-Time™, see “Standalone Operation” (Simulink Real-Time).
 - To deploy onto FPGAs using HDL Coder™, see “Deployment” (HDL Coder).

Note Deployment onto FPGAs is supported only for explicitly partitioned models.

- 3 Optimize your design. This step is optional, and includes iterating over the design of your model and mapping to get the best performance, based on your metrics. One way to evaluate your model is to profile it and get execution times.

Product	Information
Desktop target	“Profile and Evaluate Explicitly Partitioned Models on a Desktop” on page 14-49
Simulink Real-Time	“Execution Profiling for Real-Time Applications” (Simulink Real-Time)
Embedded Coder	“Code Execution Profiling” (Embedded Coder)
HDL Coder	“Speed and Area Optimization” (HDL Coder)

How Simulink Helps You to Overcome Challenges in Multicore Programming

Manually programming your application for concurrent execution poses challenges beyond the typical challenges with manual coding. With Simulink, you can overcome the challenges of portability across multiple architectures, efficiency of deployment for an architecture, and cyclic data dependencies between application components. For more information on these challenges, see “Challenges in Multicore Programming” on page 14-7

Portability

Simulink enables you to determine the content and hierarchical needs of the modeled system without considering the target system. While creating model content, you do not need to keep track of the number of cores in your target system. Instead, you select the partitioning methods that enable you to create model content. Simulink generates code for the architecture you specify.

You can select an architecture from the available supported architectures or add a custom architecture. When you change your architecture, Simulink generates only the code that needs to change for the second architecture. The new architecture reuses blocks and functions. For more information, see “Supported Targets For Multicore Programming” on page 14-57 and “Specify a Target Architecture” on page 14-25.

Deployment Efficiency

To improve the performance of the deployed application, Simulink allows you to simulate it under typical computational loads and try multiple configurations of partitioning and mapping the application. Simulink compares the performance of each of these configurations to provide the optimal configuration for deployment. This is known as profiling. Profiling helps you to determine the optimum partition configuration before you deploy your system to the desired hardware.

You can create a mapping for your application in which Simulink maps the application components across different processing nodes. You can also manually assign components to processing nodes. For any mapping, you can see the data dependencies between components and remap accordingly. You can also introduce and remove data dependencies between different components.

Cyclic Data Dependency

Some tasks of a system depend on the output of other tasks. The data dependency between tasks determines their processing order. Two or more partitions containing data dependencies in a cycle creates a data dependency loop, also known as an *algebraic loop*. Simulink does not allow algebraic loops to occur across potentially parallel partitions because of the high cost of solving the loop using parallel algorithms.

In some cases, the algebraic loop is artificial. For example, you can have an artificial algebraic loop because of Model-block-based partitioning. An algebraic loop involving Model blocks is artificial if removing the use of Model partitioning eliminates the loop. You can minimize the occurrence of artificial loops. In the Configuration Parameter dialog

boxes for the models involved in the algebraic loop, select **Model Referencing > Minimize algebraic loop occurrences**.

Additionally, if the model is configured for the Generic Real-Time target (`grt.tlc`) or the Embedded Real-Time target (`ert.tlc`) in the Configuration Parameters dialog box, clear the **Single output/update function** check box.

If the algebraic loop is a true algebraic condition, you must either contain all the blocks in the loop in one Model partition, or eliminate the loop by introducing a delay element in the loop.

The following examples show how to implement different types of parallelism in Simulink. These examples contain models that are partitioned and mapped to a simple architecture with one CPU and one FPGA.

Implement Data Parallelism in Simulink

This example shows how to implement data parallelism for a system in a Simulink model. The model consists of an input, a functional component that applies to each input, and a concatenated output. For more information on data parallelism, see “Types of Parallelism” on page 14-3.

Set up this model for concurrent execution. To see the completed model, open `ex_data_parallelism_top`.

- 1 Convert areas in this model to referenced models. Use the same referenced model to replace each of the functional components that process the input. The figure shows a sample configuration.

- 2 Open the model configuration parameters for the top level model. Clear the **MAT-file logging** check box.
- 3 On the **Solver** pane, set **Type** to Fixed-step and click **Apply**. Also ensure that the **Periodic sample time constraint** is set to Unconstrained. Under **Additional options**, select **Allow tasks to execute concurrently on target** and click **Configure Tasks**.
- 4 In the Concurrent Execution dialog box, in the right pane, select the **Enable explicit model partitioning for concurrent behavior** check box. With explicit partitioning, you can partition your model manually.
- 5 In the selection pane, select **CPU**. Click **Add task**  four times to add four new tasks.
- 6 In the selection pane, select **Tasks and Mapping**. On the **Map block to tasks** pane:
 - Under **Block: Input**, click **select task** and select **Periodic: Task**.
 - Under **Block: Function 1**, select **Periodic: Task1**.
 - Under **Block: Function 2**, select **Periodic: Task2**.
 - Under **Block: Function 3**, select **Periodic: Task3**.
 - Under **Block: Output**, select **Periodic: Task**.

This maps your partitions to the tasks you created. The Input and Output model blocks are on one task. Each functional component is assigned a separate task.

- 7 In the selection pane, select **Data transfer**. In the **Data Transfer Options** pane, set the parameter **Periodic signals** to Ensure deterministic transfer (minimum delay). Click **Apply** and close the Concurrent Execution dialog box.
- 8 Apply these configuration parameters to all referenced models. For more information, see “Share a Configuration for Multiple Models” on page 13-4.

Update your model to see the tasks mapped to individual model blocks.

 - Under **Block: Input**, click **select task** and select **Periodic: Task**.
 - Under **Block: Function 1**, select **Periodic: Task1**.
 - Under **Block: Function 2**, select **Periodic: Task2**.
 - Under **Block: Output**, select **Periodic: Task**.

This maps your partitions to the tasks you created. The Input and Output model blocks are on one task. Each functional component is assigned a separate task.

- 7 Close the Concurrent Execution dialog box.
- 8 Apply these configuration parameters to all referenced models. For more information, see “Share a Configuration for Multiple Models” on page 13-4.

Update your model to see the tasks mapped to individual model blocks.

Note Notice that delays are introduced between different tasks, indicated by the z-1 badge. Introducing these delays may cause different model outputs in Simulink. Ensure that your model has an expected output on simulating the parallelized model.

Configure Your Model for Concurrent Execution

Follow these steps to configure your Simulink model to take advantage of concurrent execution.

- 1 Open your model.
- 2 Open the **Simulation** menu and select **Model Configuration Parameters**.
- 3 In **Configuration Parameters > Solver > Solver selection**, choose Fixed-step for the **Type** and auto (Automatic solver selection) for the **Solver**.
- 4 Select the **Allow tasks to execute concurrently on target** check box in the **Solver** pane under **Solver details**. Selecting this check box is optional for models referenced in the model hierarchy. When you select this option for a referenced model, Simulink allows each rate in the referenced model to execute as an independent concurrent task on the target processor.
- 5 In **Configuration Parameters > Code Generation > Interface > Advanced parameters**, clear the **MAT-file logging** check box.

Once you have a model that executes concurrently on your computer, you can further configure your model in the following ways:

- “Specify a Target Architecture” on page 14-25
- “Partition Your Model Using Explicit Partitioning” on page 14-31.
- “Configure Data Transfer Settings Between Concurrent Tasks” on page 14-40

Specify a Target Architecture

In this section...

“Choose from Predefined Architectures” on page 14-25

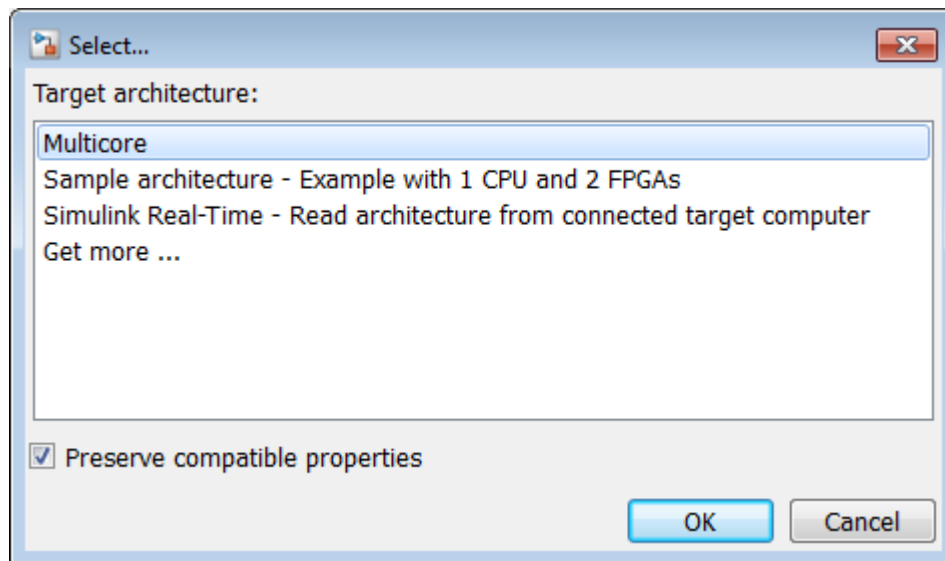

“Define a Custom Architecture File” on page 14-27

For models configured for concurrent execution, you can choose the architecture to which you want to deploy your model. Choose from a set of predefined architectures in Simulink, or you can create an interface for a custom architecture. After selecting your architecture, you can use explicit partitioning to specify which tasks run on it. For more information, see “Partition Your Model Using Explicit Partitioning” on page 14-31.

Choose from Predefined Architectures

You can choose from the predefined architectures available in Simulink, or you can download support packages for different available architectures.

- 1 In the Concurrent Execution dialog box, in the **Concurrent Execution** pane, click **Select**. The concurrent execution target architecture selector appears.

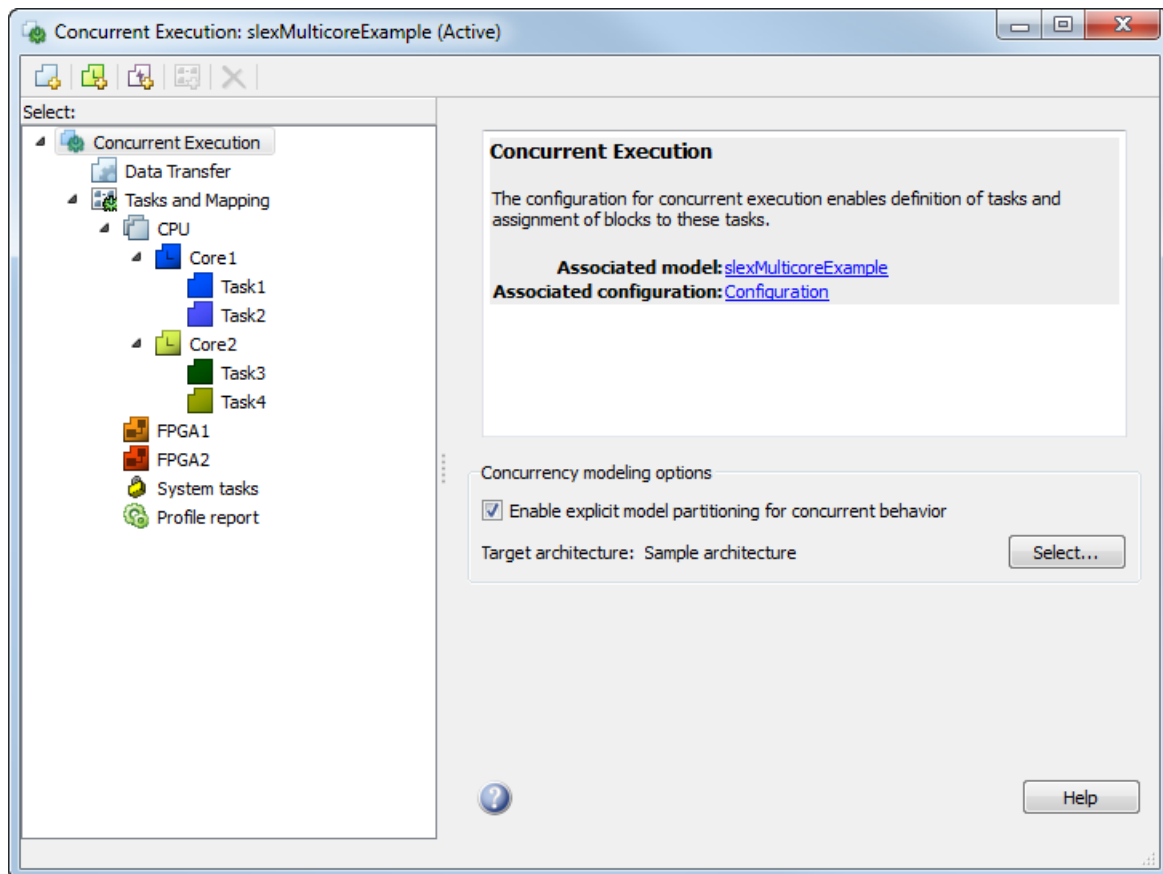

- 2 Select your target.

Property	Description
Multicore	Single CPU with multiple cores.
Sample Architecture	Single CPU with multiple cores and two FPGAs.
Simulink Real-Time	Simulink Real-Time target.
Get more ...	Click OK to start the Support Package Installer. From the list, select the target and follow the instructions.

- 3 In the Target architecture window, clear the **Preserve compatible properties** check box to reset existing target property settings to their default. Alternatively, select the **Preserve compatible properties** check box to preserve existing target property settings.
- 4 Click **OK**.

Simulink adds the corresponding software and hardware nodes to the configuration tree hierarchy. For example, the following illustrates one software node and two hardware nodes added to the configuration tree when you select Sample architecture as the target architecture.

Define a Custom Architecture File

A custom architecture file is an XML file that allows you to define custom target properties for tasks and triggers. For example, you may want to define custom properties to represent threading APIs. Threading APIs are necessary to take advantage of concurrency on your target processor.

The following is an example custom architecture file:

```
<architecture brief="Multicore with custom threading API"
  format="1.1" revision="1.1"
  uuid="MulticoreCustomAPI" name="MulticoreCustomAPI">
<configurationSet>
```

```
<parameter name="SystemTargetFile" value="ert.tlc"/>
<parameter name="SystemTargetFile" value="grt.tlc"/>
</configurationSet>
<node name="MulticoreProcessor" type="SoftwareNode" uuid="MulticoreProcessor"/>
<template name="CustomTask" type="Task" uuid="CustomTask">
  <property name="affinity" prompt="Affinity:" value="1" evaluate="true"/>
  <property name="schedulingPolicy" prompt="Scheduling policy:" value="Rate-monotonic">
    <allowedValue>Rate-monotonic</allowedValue>
    <allowedValue>Round-robin</allowedValue>
  </property>
</template>
</architecture>
```

An architecture file must contain:

- The architecture element that defines basic information used by Simulink to identify the architecture.
- A `configurationSet` element that lists the system target files for which this architecture is valid.
- One node element that Simulink uses to identify the multicore processing element.

Note The architecture must contain exactly one node element that identifies a multicore processing element. You cannot create multiple nodes identifying multiple processing elements or an architecture with no multicore processing element.

- One or more template elements that list custom properties for tasks and triggers.
 - The type attribute can be `Task`, `PeriodicTrigger`, or `AperiodicTrigger`.
 - Each property is editable and has the default value specified in the `value` attribute.
 - Each property can be a text box, check box, or combo box. A check box is one where you can set the `value` attribute to on or off. A combo box is one where you can optionally list `allowedValue` elements as part of the property.
 - Each text box property can also optionally define an `evaluate` attribute. This lets you place MATLAB variable names as the value of the property.

Assuming that you have saved the custom target architecture file in `C:\custom_arch.xml`, register this file with Simulink using the `Simulink.architecture.register` function.

For example:

- 1 Save the contents of the listed XML file in `custom_arch.xml`.

- 2 In the MATLAB Command Window, type:
`Simulink.architecture.register('custom_arch.xml')`
- 3 In the MATLAB Command Window, type:
`slexMulticoreSolverExample`
- 4 In the Simulink editor, open the **Configuration Parameters** > **Solver** pane and click **Configure Tasks**. The Concurrent Execution dialog box displays.
- 5 In the **Concurrent Execution** pane, click **Select...** under **Target Architecture**. The Target architecture window displays.
- 6 Select **MulticoreCustomAPI** and click **OK**.

Your Concurrent Execution dialog box updates to contain Code Generation properties for the tasks as shown. These are the properties defined in the XML file.

- "Partition Your Model Using Explicit Partitioning" on page 14-31
- "Implicit and Explicit Partitioning of Models" on page 14-37

Partition Your Model Using Explicit Partitioning

When you have a model that is configured for concurrent execution, you can add tasks, create partitions, and map individual tasks to partitions using explicit partitioning. This enables you to execute different parts of your model to different parts of your architecture. For more information, see “Implicit and Explicit Partitioning of Models” on page 14-37.

Prerequisites for Explicit Partitioning

To use explicit partitioning, you must meet the following prerequisites:

- 1 Set up your model for concurrent execution. For more information, see “Configure Your Model for Concurrent Execution” on page 14-24.
- 2 Convert all blocks at the root level of your model into one of the following types of blocks.
 - Models that are referenced using Model blocks
 - Subsystem blocks
 - MATLAB System blocks
 - MATLAB Function blocks
 - Stateflow charts

For more information, see “Implicit and Explicit Partitioning of Models” on page 14-37.

Note When using referenced models, replicate the model configuration parameters of the top model to the referenced models. Consider using a single configuration reference to use for all of your referenced models. For more information, see “Configuration Reuse”.

- 3 Select the target architecture on which to deploy your model. For more information, see “Specify a Target Architecture” on page 14-25.

Add Periodic Triggers and Tasks

Add periodic tasks for components in your model that you want to execute periodically. To add aperiodic tasks whose execution is trigger based, see “Add Aperiodic Triggers and Tasks” on page 14-33.

If you want to explore the effects of increasing the concurrency on your model execution, you can create additional periodic tasks in your model.

- 1 In the Concurrent Execution dialog box, right-click the **Periodic** node and select **Add task**.

A task node appears in the Configuration Execution hierarchy.

- 2 Select the task node and enter a name and period for the task, then click **Apply**.

The task node is renamed to the name you enter.

- 3 Optionally, specify a color for the task. The color illustrates the block-to-task mapping. If you do not assign a color, Simulink chooses a default color. If you enable sample time colors for your model, the software honors the setting.
- 4 Click **Apply** as necessary.

To create more periodic triggers, click the **Add periodic trigger** symbol. You can also create multiple periodic triggers with their own trigger sources.

Note Periodic triggers let you represent multiple periodic interrupt sources such as multiple timers. The periodicity of the trigger is either the base rate of the tasks that the trigger schedules, or the period of the trigger. Data transfers between triggers can only be **Ensure Data Integrity Only** types. With blocks mapped to periodic triggers, you can only generate code for `ert.tlc` and `grt.tlc` system target files.

To delete tasks and triggers, right-click them in the pane and select **Delete**.

When the periodic tasks and trigger configurations are complete, configure the aperiodic (interrupt) tasks as necessary. If you do not need aperiodic tasks, continue to “Map Blocks to Tasks, Triggers, and Nodes” on page 14-34.

Add Aperiodic Triggers and Tasks

Add aperiodic tasks for components in your model whose execution is interrupt-based. To add periodic tasks whose execution is periodic, see “Add Periodic Triggers and Tasks” on page 14-32.

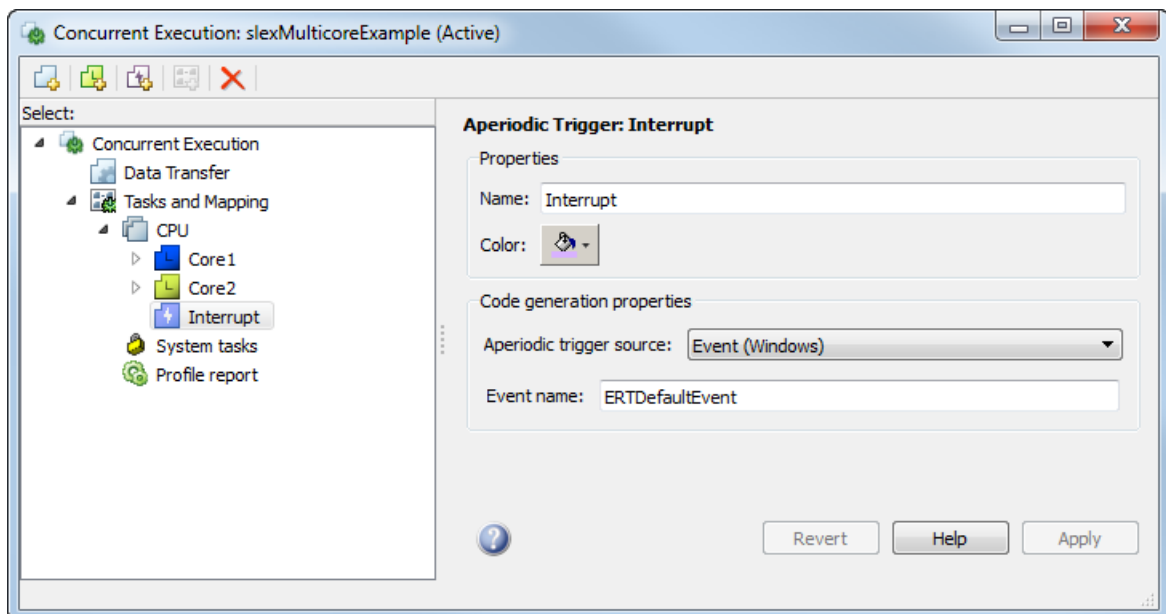

- 1 To create an aperiodic trigger, in the Concurrent Execution dialog box, right-click the **Concurrent Execution** node and click the **Add aperiodic trigger** symbol.

A node named **Interrupt N** appears in the configuration tree hierarchy, where N is an integer.

- 2 Select **Interrupt**.

This node represents an aperiodic trigger for your system.

- 3 Specify the name of the trigger and configure the aperiodic trigger source. Depending on your deployment target, choose either **Posix Signal (Linux/VxWorks 6.x)** or **Event (Windows)**. For POSIX® signals, specify the signal number to use for delivering the aperiodic event. For Windows events, specify the name of the event.

- 4 Click **Apply**.

The software services aperiodic triggers as soon as possible. If you want to process the trigger response using a task:

- 1 Right-click the **Interrupt** node and select **Add task**.

A new task node appears under the **Interrupt** node.

- 2 Specify the name of the new task node.
- 3 Optionally, specify a color for the task. The color illustrates the block-to-task mapping. If you do not assign a color, Simulink chooses a default color.
- 4 Click **Apply**.

To delete tasks and triggers, right-click them in the pane and select **Delete**.

Once you have created your tasks and triggers, map your execution components to these tasks. For more information, see “Map Blocks to Tasks, Triggers, and Nodes” on page 14-34.

Map Blocks to Tasks, Triggers, and Nodes

After you create the tasks and triggers, you can explicitly assign partitions to these execution elements.

- 1 In the Concurrent Execution dialog box, click the **Tasks and Mapping** node.

The **Tasks and Mapping** pane appears. If you add a Model block to your model, the new block appears in the table with a **select task** entry under it.

- 2 If you want to add a task to a block, in the **Name** column, right-click a task under the block and select **Add new entry**.
- 3 To assign a task for the entry, click the box in the **Name** column and select an entry from the list. For example:

The block-to-task mapping symbol appears on the top-left corner of the Model block. For example:

If you assign a Model block to multiple tasks, multiple task symbols are displayed in the top-left corner.

To display the Concurrent Execution dialog box from the block, click the block-to-task mapping symbol.

- 4 Click **Apply**.

Note

- System tasks allow you to perform mapping incrementally. This means that if there is only one periodic trigger, Simulink assigns any Model blocks, subsystem blocks, or MATLAB System blocks that you have not explicitly mapped to a task, trigger, or hardware node to a task created by the system. Simulink creates at most one system task for each rate in the model. If there are multiple periodic triggers created, explicitly map the Model block partitions, subsystems, or MATLAB System blocks to a task, trigger, or hardware node.
 - Map Model block partitions that contain continuous blocks to the same periodic trigger.
 - You can map only Model blocks to hardware nodes. Also, if you map the Model block to a hardware node, and the Model block contains multiple periodic sample times, clear the **Allow tasks to execute concurrently on target** check box in the **Solver** pane of the Configuration Parameters dialog box.
-

When the mapping is complete, simulate the model again.

Implicit and Explicit Partitioning of Models

When implementing multicore programming for your application in Simulink, there are two ways to partition your model for running on individual processing nodes. If you are new to multicore programming in Simulink, use the default (implicit partitioning) for your first iteration of implementing multicore programming.

The automated way of creating tasks and mapping them to your processing nodes is called implicit partitioning. Simulink partitions your model based on the sample time of blocks at the root level. Each sample time in your model corresponds to a partition, and all blocks of a single rate or sample time belong to the same partition. Simulink maps these partitions to tasks that run on your processor. Implicit partitioning assumes your architecture to be a single multicore CPU. The CPU task scheduler handles all the partitioned tasks.

If you want to specify how to partition your model, use explicit partitioning. In explicit partitioning, you create partitions in the root-level model by using referenced models, MATLAB system blocks, MATLAB Function blocks, Stateflow charts, and Simulink subsystems. For example, if your model has data acquisition and a controller, partition your model by putting these components in two referenced models at the model root-level. Each sample time of the blocks in the model corresponds to a partition. You can add tasks to run on processing nodes in the Concurrent Execution dialog box and assign your partitions to these tasks. If some partitions are left unassigned, Simulink automatically assigns them to tasks.

In explicit partitioning, you can specify your own architecture. The default architecture is a multicore CPU, the same as the assumed architecture in implicit partitioning. Explicit partitioning has more restrictions on your root-level model than implicit partitioning. For more information, see “Limitations with Multicore Programming in Simulink” on page 14-59.

Partitioning Guidelines

There are multiple ways to partition your model for concurrent execution in Simulink. Rate-based and model-based approaches give you primarily graphical means to represent concurrency for systems that are represented using Simulink and Stateflow blocks. You can partition MATLAB code using the MATLAB System block and the MATLAB Function block. You can also partition models of physical systems using multisolver methods.

Each method has additional considerations to help you decide which to use.

Goal	Valid Partitioning Methods	Considerations
Increase the performance of a simulation on the host computer.	No partitioning method	Simulink tries to optimize the host computer performance regardless of the modeling method you use. For more information on the ways that Simulink helps you to improve performance, see “Optimize Performance”.
Increase the performance of a plant simulation in a multicore HIL (hardware-in-the-loop) system.	You can use any of the partitioning methods and their combinations.	The processing characteristics of the HIL system and the embedded processing system can vary greatly. Consider partitioning your system into more units of work than there are number of processing elements in the HIL or embedded system. This convention allows flexibility in the mapping process.
Create a valid model of a multirate concurrent system to take advantage of a multicore processing system.	You can use any of the partitioning methods and their combinations.	Partitioning can introduce signal delays to represent the data transfer requirements for concurrent execution. For more information, see “Configure Data Transfer Settings Between Concurrent Tasks” on page 14-40.
Create a valid model of a heterogeneous system to take advantage of multicore and FPGA processing.	<ul style="list-style-type: none"> • Multicore processing: Use any of the partitioning methods. • FPGA processing: Partition your model using Model blocks. 	Consider partitioning for FPGA processing where your computations have bottlenecks that could be reduced using fine-grained hardware parallelism.

Configure Data Transfer Settings Between Concurrent Tasks

Data dependencies arise when a signal originates from one block in one partition and is connected to a block in another partition. To create opportunities for parallelism, Simulink provides multiple options for handling data transfers between concurrently executing partitions. These options help you trade off computational latency for numerical signal delays.

Use the **Data Transfer Options** pane to define communications between tasks. Set the values for the `Use global setting` option of the Data Transfer tab in the Signal Properties dialog box. The table provides the model-level options that you can apply to each signal that requires data transfer in the system.

Data Transfer Options

Goal	Data Transfer Type	Simulation	Deployment
<ul style="list-style-type: none"> • Create opportunity for parallelism. • Reduce signal latency. 	<p>Ensure data integrity only.</p>	<p>Data transfer is simulated using a one-step delay.</p>	<p>Simulink Coder ensures data integrity during data transfer. Simulink generates code to operate with maximum responsiveness and data integrity. However, the implementation is interruptible, which can lead to loss of data during data transfer.</p> <p>Use a deterministic execution schedule to achieve determinism in the deployment environment.</p>
<ul style="list-style-type: none"> • Create opportunity for parallelism. • Produce numeric results that are repeatable with each run of the generated code. 	<p>Ensure deterministic transfer (maximum delay).</p>	<p>Data transfer is simulated using a one-step delay, which can have impact on the numeric results. To compensate, you might need to specify an initial condition for these delay elements.</p>	<p>Simulink Coder ensures data integrity during data transfer. In addition, Simulink Coder ensures that data transfer is identical with simulation.</p>

Goal	Data Transfer Type	Simulation	Deployment
<ul style="list-style-type: none"> Enforce data dependency. Produce numeric results that are repeatable with each run of the generated code. 	Ensure deterministic transfer (minimum delay).	Data transfer occurs within the same step.	

You can also override these options for each signal from the **Data Transfer** pane of the Signal Properties dialog box. For more information, see “Data Transfer Options for Concurrent Execution”.

For example, consider a control application in which a controller that reads sensory data at time T must produce the control signals to the actuator at time $T+\Delta$.

- If the sequential algorithm meets the timing deadlines, consider using option 3.
- If the embedded system provides deterministic scheduling, consider using option 2.
- Otherwise, use option 1 to create opportunities for parallelism by introducing signal delays.

For continuous signals, Simulink uses extrapolation methods to compensate for numerical errors that were introduced due to delays and discontinuities in data transfer.

To avoid numerical errors in signals configured for **Ensure Data Integrity Only** and **Ensure deterministic transfer (maximum delay)** data transfers, you may need to provide an initial condition. You can specify this initial condition in the **Data Transfer** tab of the Signal Properties dialog box. To access this dialog box, right-click the signal line and select **Properties** from the context menu. A dialog box like the following is displayed.

- 1 From the Data Transfer Options table, determine how you want your tasks to communicate.
- 2 In the Concurrent Execution dialog box, select Data Transfer defaults and apply the settings from step 1.

3 Apply your changes.

- “Implicit and Explicit Partitioning of Models” on page 14-37

Optimize and Deploy on a Multicore Target

In this section...

“Generate Code” on page 14-45

“Build on Desktop” on page 14-46

“Profile and Evaluate Explicitly Partitioned Models on a Desktop” on page 14-49

“Customize the Generated C Code” on page 14-52

This topic shows you how to use a model that is configured for concurrent execution using explicit partitioning and deploy it onto a target. To set up your model for concurrent execution, see “Configure Your Model for Concurrent Execution” on page 14-24. To specify the target architecture, see “Specify a Target Architecture” on page 14-25. To use explicit partitioning in a model that is set up for concurrent execution, see “Partition Your Model Using Explicit Partitioning” on page 14-31.

Generate Code

To generate code for a model that is configured for concurrent execution, in the Simulink editor window, select **Code > C/C++ Code > Build Model**. The resulting code includes:

- C code for parts of the model that are mapped to tasks and triggers in the Concurrent Execution dialog box. C code generation requires a Simulink Coder license. For more information, see “Code Generation” (Simulink Coder) and “Code Generation from Simulink Models” (Embedded Coder).
- HDL code for parts of the model that are mapped to hardware nodes in the Concurrent Execution dialog box. HDL code generation requires an HDL Coder license. For more information, see “HDL Code Generation from Simulink” (HDL Coder).
- Code to handle data transfer between the concurrent tasks and triggers and to interface with the hardware and software components.

The generated C code contains one function for each task or trigger defined in the system. The task and trigger determines the name of the function:

```
void <TriggerName>_TaskName(void);
```

The content for each such function consists of target-independent C code, except for:

- Code corresponding to blocks that implement target-specific functionality

- Customizations, including those derived from custom storage classes (see “Apply Custom Storage Classes to Individual Signal, State, and Parameter Data Elements” (Embedded Coder)) or “Code Replacement Libraries” (Simulink Coder)
- Code that is generated to handle how data is transferred between tasks. In particular, Simulink Coder uses target-specific implementations of mutual exclusion primitives and data synchronization semaphores to implement the data transfer as described in the following table of pseudocode.

Data Transfer	Initialization	Reader	Writer
Data Integrity Only	BufferIndex = 0; Initialize Buffer[1] with IC	Begin mutual exclusion Tmp = 1 - BufferIndex; End mutual exclusiton Read Buffer[Tmp];	Write Buffer[BufferIndex]; Begin mutual exclusion BufferIndex = 1 - BufferIndex; End mutual exclusion
Ensure Determinism (Maximum Delay)	WriterIndex = 0; ReaderIndex = 1; Initialize Buffer[1] with IC	Read Buffer[ReaderIndex]; ReaderIndex = 1 - ReaderIndex;	Write Buffer[WriterIndex] WriterIndex = 1 - WriterIndex;
Ensure Determinism (Minimum Delay)	N/A	Wait dataReady; Read data; Post readDone;	Wait readDone; Write data; Post dataReady;
Data Integrity Only C-HDL interface	The Simulink Coder and HDL Coder products both take advantage of target-specific communication implementations and devices to handle the data transfer between hardware and software components.		

The generated HDL code contains one HDL project for each hardware node.

Build on Desktop

Simulink Coder and Embedded Coder targets provide an example target to generate code for Windows, Linux and Mac OS operating systems. It is known as the native threads example, which is used to deploy your model to a desktop target. The desktop may not be your final target, but can help to profile and optimize your model before you deploy it on another target.

If you have specified an Embedded Coder target, make the following changes in the Configuration Parameters dialog box.

- 1 Select the **Code Generation > Templates > Generate an example main program** check box.
- 2 From the **Code Generation > Templates > Target Operating System** list, select **NativeThreadsExample**.
- 3 Click **OK** to save your changes and close the Configuration Parameters dialog box.
- 4 Apply these settings to all referenced models in your model.

Once you have set up your model, press **Ctrl-B** to build and deploy it to your desktop. The native threads example illustrates how Simulink Coder and Embedded Coder use target-specific threading APIs and data management primitives, as shown in “Threading APIs Used by Native Threads Example” on page 14-47. The data transfer between concurrently executing tasks behaves as described in Data Transfer Options. The coder products use the APIs on supported targets for this behavior, as described in “Data Protection and Synchronization APIs Used by Native Threads Example” on page 14-48.

Threading APIs Used by Native Threads Example

Aspect of Concurrent Execution	Linux Implementation	Windows Implementation	Mac OS Implementation
Periodic triggering event	POSIX timer	Windows timer	Not applicable
Aperiodic triggering event	POSIX real-time signal	Windows event	POSIX non-real-time signal
Aperiodic trigger	For blocks mapped to an aperiodic task: thread waiting for a signal For blocks mapped to an aperiodic trigger: signal action	Thread waiting for an event	For blocks mapped to an aperiodic task: thread waiting for a signal For blocks mapped to an aperiodic trigger: signal action
Threads	POSIX	Windows	POSIX

Aspect of Concurrent Execution	Linux Implementation	Windows Implementation	Mac OS Implementation
Threads priority	Assigned based on sample time: fastest task has highest priority	Priority class inherited from the parent process. Assigned based on sample time: fastest task has highest priority for the first three fastest tasks. The rest of the tasks share the lowest priority.	Assigned based on sample time: fastest task has highest priority
Example of overrun detection	Yes	Yes	No

Data Protection and Synchronization APIs Used by Native Threads Example

API	Linux Implementation	Windows Implementation	Mac OS Implementation
Data protection API	<ul style="list-style-type: none"> • pthread_mutex_init • pthread_mutex_destroy • pthread_mutex_lock • pthread_mutex_unlock 	<ul style="list-style-type: none"> • CreateMutex • CloseHandle • WaitForSingleObject • ReleaseMutex 	<ul style="list-style-type: none"> • pthread_mutex_init • pthread_mutex_destroy • pthread_mutex_lock • pthread_mutex_unlock
Synchronization API	<ul style="list-style-type: none"> • sem_init • sem_destroy • sem_wait • sem_post 	<ul style="list-style-type: none"> • CreateSemaphore • CloseHandle • WaitForSingleObject • ReleaseSemaphore 	<ul style="list-style-type: none"> • sem_open • sem_unlink • sem_wait • sem_post

Profile and Evaluate Explicitly Partitioned Models on a Desktop

Profile the execution of your code on the multicore target using the **Profile Report** pane of the Concurrent Execution dialog box. You can profile using Simulink Coder (GRT) and Embedded Coder (ERT) targets. Profiling helps you identify the areas in your model that are execution bottlenecks. You can analyze the execution time of each task and find the task that takes most of the execution time. For example, you can compare the average execution times of the tasks. If a task is computation intensive, or does not satisfy real-time requirements and overruns, you can break it into tasks that are less computation intensive and that can run concurrently.

When you generate a profile report, the software:

- 1 Builds the model.
- 2 Generates code for the model.
- 3 Adds tooling to the generated code to collect data.
- 4 Executes the generated code on the target and collects data.
- 5 Collates the data, generates an HTML file (*model_name_ProfileReport.html*) in the current folder, and displays that HTML file in the **Profile Report** pane of the Concurrent Execution dialog box.

Note If an HTML profile report exists for the model, the **Profile Report** pane

displays that file. To generate a new profile report, click .

Section	Description
Summary	Summarizes model execution statistics, such as total execution time and profile report creation time. It also lists the total number of cores on the host machine.
Task Execution Time	Displays the execution time, in microseconds, for each task in a pie chart color coded by task. Visible for Windows, Linux, and Mac OS platforms.

Section	Description
Task Affinitization to Processor Cores	<p>Platform-dependent. For each time step and task, Simulink displays the processor core number the task started executing on at that time step, color coded by processor.</p> <p>If there is no task scheduled for a particular time step, NR is displayed.</p> <p>Visible for Windows and Linux platforms.</p>

After you analyze the profile report, consider changing the mapping of Model blocks to efficiently use the concurrency available on your multicore system (see “Map Blocks to Tasks, Triggers, and Nodes” on page 14-34).

Generate Profile Report

This topic assumes a previously configured model ready to be profiled for concurrent execution. For more information, see “Configure Your Model for Concurrent Execution” on page 14-24.

- 1 In the Concurrent Execution dialog box, click the **Profile report** node.

The profile tool looks for a file named *model_name_ProfileReport.html*. If such a file does not exist for the current model, the **Profile Report** pane displays the following.

Note If an HTML profile report exists for the model, the **Profile Report** pane displays that file. To generate a new profile report, click .

- 2 Enter the number of time steps for which you want the profiler to collect data for the model execution.
- 3 Click the **Generate task execution profile report** button.

This action builds the model, generates code, adds data collection tooling to the code, and executes it on the target, which also generates an HTML profile report. This process can take several minutes. When the process is complete, the contents of the profile report appear in the **Profile Report** pane. For example:

Task Execution Profiling Report for slxMulticoreExample

1. Summary

Total simulation time [seconds]	9.9
Profile data created	Thu Nov 12 16:47:52 2015
Model name	slxMulticoreExample
Number of processor cores on the host machine	12

2. Task Execution Time

3. Task Affinitization to Processor Cores

Legend

NR - Not scheduled to run

The profiling report shows the summary, execution time for each task, and the mapping of each task to processor cores. We see that tasks 1 and 2 run on core 0, where tasks 3 and 4 run on core 1. The **Task Execution Time** section of the report

indicates that task 1 and task 3 take the most amount of time to run. Note that the period of task 3 is twice that of tasks 1 and 2, and the period of task 4 is twice that of task 3.

- 4 Analyze the profile report. Create and modify your model or task mapping if needed, and regenerate the profile report.

Generate Profile Report at Command Line

Alternatively, you can generate a profile report for a model configured for concurrent execution at the command line. Use the `Simulink.architecture.profile` function.

For example, to create a profile report for the model `slexMulticoreSolverExample`:

```
Simulink.architecture.profile('slexMulticoreSolverExample');
```

To create a profile report with a specific number of samples (100) for the model `slexMulticoreSolverExample`:

```
Simulink.architecture.profile('slexMulticoreSolverExample',120);
```

The function creates a profile report named `slexMulticoreSolverExample_ProfileReport.html` in your current folder.

Customize the Generated C Code

The generated code is suitable for many different applications and development environments. To meet your needs, you can customize the generated C code as described in “Target Development” (Embedded Coder). In addition to those customization capabilities, for multicore and heterogeneous targets you can further customize the generated code as follows:

- You can register your preferred implementation of mutual exclusion and data synchronization primitives using the code replacement library.
- You can define a custom target architecture file that allows you to specify target specific properties for tasks and triggers in the Concurrent Execution dialog box. For more information, see “Define a Custom Architecture File” on page 14-27.

Programmatic Interface for Concurrent Execution

Use these functions to configure models for concurrent execution.

To	Use
Create or convert configuration for concurrent execution.	<code>Simulink.architecture.config</code>
Add triggers to the software node or add tasks to triggers.	<code>Simulink.architecture.add</code>
Delete triggers or tasks.	<code>Simulink.architecture.delete</code>
Find objects with specified parameter values.	<code>Simulink.architecture.find_system</code>
Get configuration parameters for target architecture.	<code>Simulink.architecture.get_param</code>
Import and select architecture.	<code>Simulink.architecture.importAndSelect</code>
Generate profile report for model configured for concurrent execution.	<code>Simulink.architecture.profile</code>
Add custom target architecture.	<code>Simulink.architecture.register</code>
Set properties for a concurrent execution object (such as task, trigger, or hardware node).	<code>Simulink.architecture.set_param</code>
Configure concurrent execution data transfers.	<code>Simulink.GlobalDataTransfer</code>

Map Blocks to Tasks

To map blocks to tasks, use the `set_param` function.

Map a block to one task:

```
set_param(block, 'TargetArchitectureMapping', [bdroot 'CPU/PeriodicTrigger1/Task1']);
```

Map a block to multiple tasks:

```
set_param(block, 'TargetArchitectureMapping', ...  
{[bdroot 'CPU/PeriodicTrigger1/Task1']; ...  
[bdroot 'CPU/PeriodicTrigger1/Task2']});
```

Get the current mapping of a block:

```
get_param(block, 'TargetArchitectureMapping');
```

Supported Targets For Multicore Programming

Supported Multicore Targets

You can build and download models that are implicitly or explicitly partitioned for the following multicore targets using system target files:

- Linux, Windows, and Mac OS using `ert.tlc` and `grt.tlc`.
- Simulink Real-Time using `slrt.tlc`.
- `idelink_ert.tlc`, `idelink_grt.tlc`, and `ert.tlc`, if it is supported for your hardware board.

Note

- To build and download your model, you must have Simulink Coder software installed.
 - To build and download your model to a Simulink Real-Time system, you must have Simulink Real-Time software installed. You must also have a multicore target system supported by the Simulink Real-Time product.
 - Deploying to an embedded processor that runs Linux and VxWorks® operating systems requires the Embedded Coder product.
-

Supported Heterogeneous Targets

In addition to multicore targets, Simulink also supports building and downloading partitions of an explicitly partitioned model to heterogeneous targets that contain a multicore target and one or more field-programmable gate arrays (FPGAs).

Select the heterogeneous architecture using the Target architecture option in the Concurrent Execution dialog box **Concurrent Execution** pane:

Item	Description
Sample Architecture	Example architecture consisting of single CPU with multiple cores and two FPGAs. You can use this architecture to model for concurrent execution.

Item	Description
Simulink Real-Time	Simulink Real-Time target containing FPGA boards.
Xilinx Zynq ZC702 evaluation kit	Xilinx® Zynq® ZC702 evaluation kit target.
Xilinx Zynq ZC706 evaluation kit	Xilinx Zynq ZC706 evaluation kit target.
Xilinx Zynq Zedboard	Xilinx Zynq ZedBoard™ target.
Altera Cyclone V SoC development kit Rev. C	Altera® Cyclone® SoC Rev. C development kit target.
Altera Cyclone V SoC development kit Rev. D	Altera Cyclone SoC Rev. D development kit target.
Arrow SoCKit development board	Arrow® SoCKit development board target.

Note Building HDL code and downloading it to FPGAs requires the HDL Coder product. You can generate HDL code if:

- You have an HDL Coder license
- You are building on Windows or Linux operating systems

You cannot generate HDL code on Macintosh systems.

Limitations with Multicore Programming in Simulink

The following limitations apply when partitioning a model for concurrent execution.

- Configure the model to use the fixed-step solver.
- Do not use the following modes of simulation for models in the concurrent execution environment:
 - External mode for desktop targets
 - Logging to MAT-files (**MAT-file logging** check box selected). However, you can use the To Workspace and To File blocks.
 - If you are simulating your model using Rapid Accelerator mode, the top-level model cannot contain a root level Inport block that outputs function calls.
 - In the Configuration Parameters dialog box, set the **Diagnostics > Sample Time > Multitask conditionally executed subsystem** and **Diagnostics > Data Validity > Multitask data store** parameters to error.
 - In addition, use the model-level control to handle data transfer for rate transition or if you use Rate Transition blocks, then:
 - Select the **Ensure data integrity during data transfer** check box.
 - Clear the **Ensure deterministic data transfer (maximum delay)** check box.
- If you want to use explicit partitioning, at the root level of your model, the model must consist entirely of
 - Models that are referenced using Model blocks
 - Subsystem blocks
 - MATLAB System blocks
 - MATLABFunction blocks
 - Stateflow charts
 - Rate Transition blocks
 - Virtual connectivity blocks

The following are valid virtual connectivity blocks:

- Goto and From blocks
- Ground and Terminator blocks

- Inport and Outport blocks
- Virtual subsystem blocks that contain permitted blocks

General Considerations when Building Simulink Models

In this section...

“Avoiding Invalid Loops” on page 15-2

“Shadowed Files” on page 15-4

“Model Building Tips” on page 15-6

Avoiding Invalid Loops

You can connect the output of a block directly or indirectly (i.e., via other blocks) to its input, thereby, creating a loop. Loops can be very useful. For example, you can use loops to solve differential equations diagrammatically (see “Model a Continuous System” on page 15-8) or model feedback control systems. However, it is also possible to create loops that cannot be simulated. Common types of invalid loops include:

- Loops that create invalid function-call connections or an attempt to modify the input/output arguments of a function call (see “Using Function-Call Subsystems” on page 10-44 for a description of function-call subsystems)
- Self-triggering subsystems and loops containing non-latched triggered subsystems (see “Using Triggered Subsystems” on page 10-21 in the Using Simulink documentation for a description of triggered subsystems and Inport in the Simulink reference documentation for a description of latched input)
- Loops containing action subsystems

The Subsystem Examples block library in the Ports & Subsystems library contains models that illustrates examples of valid and invalid loops involving triggered and function-call subsystems. Examples of invalid loops include the following models:

- `simulink/Ports&Subsystems/sl_subsys_semantics/Triggered subsystem/sl_subsys_trigerr1(sl_subsys_trigerr1)`
- `simulink/Ports&Subsystems/sl_subsys_semantics/Triggered subsystem/sl_subsys_trigerr2(sl_subsys_trigerr2)`
- `simulink/Ports&Subsystems/sl_subsys_semantics/Function-call systems/sl_subsys_fcncallerr3(sl_subsys_fcncallerr3)`

You might find it useful to study these examples to avoid creating invalid loops in your own models.

Detecting Invalid Loops

To detect whether your model contains invalid loops, select **Update Diagram** from the model's **Simulation** menu. If the model contains invalid loops, the invalid loops are highlighted. This is illustrated in the following model ,

and displays an error message in the Diagnostic Viewer.

Shadowed Files

If there are two Model files with the same name (e.g. `mylibrary.slx`) on the MATLAB path, the one higher on the path is loaded, and the one lower on the path is said to be "shadowed".

Tip To help avoid problems with shadowed files, turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See "Do not load models that are shadowed on the MATLAB path".

The rules Simulink software uses to find Model files are similar to those used by MATLAB software. See "What Is the MATLAB Search Path?" (MATLAB) in the MATLAB documentation. However, there is an important difference between how Simulink block

diagrams and MATLAB functions are handled: a loaded block diagram takes precedence over any unloaded ones, regardless of its position on the MATLAB path. This is done for performance reasons, as part of the Simulink software's incremental loading methodology.

The precedence of a loaded block diagram over any others can have important implications, particularly since a block diagram can be loaded without the corresponding Simulink window being visible.

Making Sure the Correct Block Diagram Is Loaded

When using libraries and referenced models, you can load a block diagram without showing its window. If the MATLAB path or the current MATLAB folder changes while block diagrams are in memory, these block diagrams can interfere with the use of other files of the same name.

For example, open a model with a library called `mylib`, change to another folder, and then open another model with a library also called `mylib`. When you run the first model, it uses the library associated with the second model.

This can lead to problems including:

- Simulation errors
- "Unresolved Link" icons on blocks that are library links
- Wrong results

Detecting and Fixing Problems

To help avoid problems with shadowed files, you can turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See "Do not load models that are shadowed on the MATLAB path".

When updating a block diagram, the Simulink software checks the position of its file on the MATLAB path and will issue a warning if it detects that another file of the same name exists and is higher on the MATLAB path. The warning reads:

```
The file containing block diagram 'mylibrary' is shadowed
by a file of the same name higher on the MATLAB path.
```

This may indicate that the wrong file called `mylibrary.slx` is being used. To see which file called `mylibrary.slx` is loaded into memory, enter:

```
which mylibrary
```

```
C:\work\Model1\mylibrary.slx
```

To see all the files called `mylibrary` which are on the MATLAB path, including MATLAB scripts, enter:

```
which -all mylibrary
```

```
C:\work\Model1\mylibrary.slx
```

```
C:\work\Model2\mylibrary.slx % Shadowed
```

To close the block diagram called `mylibrary` and let the Simulink software load the file which is highest on the MATLAB path, enter:

```
close_system('mylibrary')
```

Model Building Tips

Here are some model-building hints you might find useful:

- Memory issues

In general, more memory will increase performance.

- Using hierarchy

More complex models often benefit from adding the hierarchy of subsystems to the model. Grouping blocks simplifies the top level of the model and can make it easier to read and understand the model. For more information, see “Create a Subsystem” on page 4-24. The Model Browser provides useful information about complex models (see “Explore the Model Hierarchy Using the Model Browser” on page 12-45).

- Cleaning up models

Well organized and documented models are easier to read and understand. Signal labels and model annotations can help describe what is happening in a model. For more information, see “Signal Names and Labels” on page 67-4 and “Describe Models Using Annotations” on page 4-5.

- Modeling strategies

If several of your models tend to use the same blocks, you might find it easier to save these blocks in a model. Then, when you build new models, just open this model and

copy the commonly used blocks from it. You can create a block library by placing a collection of blocks into a system and saving the system. You can then access the system by typing its name in the MATLAB Command Window.

Generally, when building a model, design it first on paper, then build it using the computer. Then, when you start putting the blocks together into a model, add the blocks to the model window before adding the lines that connect them. This way, you can reduce how often you need to open block libraries.

Model a Continuous System

To model the differential equation

$$\dot{x} = -2x(t) + u(t),$$

where $u(t)$ is a square wave with an amplitude of 1 and a frequency of 1 rad/sec, use an integrator block and a gain block. The Integrator block integrates its input \dot{x} to produce x . Other blocks needed in this model include a Gain block and a Sum block. To generate a square wave, use a Signal Generator block and select the Square Wave form but change the default units to radians/sec. Again, view the output using a Scope block. Gather the blocks and define the gain.

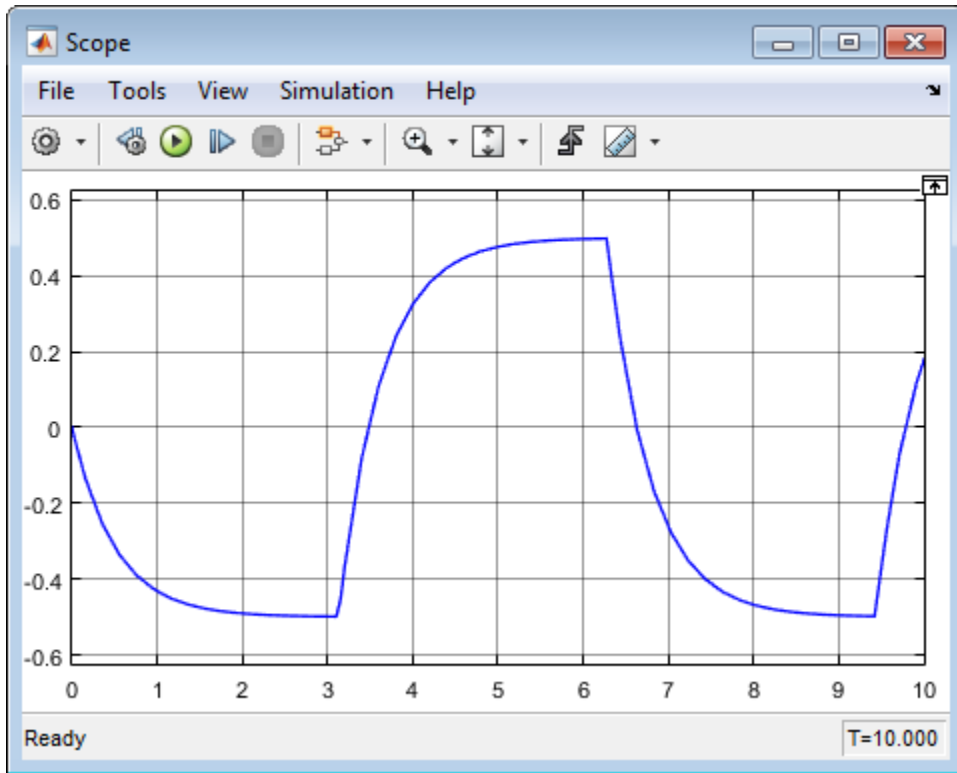

In this model, to reverse the direction of the Gain block, select the block, then use the **Diagram > Rotate & Flip > Flip Block** command. To create the branch line from the output of the Integrator block to the Gain block, hold down the **Ctrl** key while drawing the line. For more information, see “Branch a Connection” on page 1-28.

Now you can connect all the blocks.

An important concept in this model is the loop that includes the Sum block, the Integrator block, and the Gain block. In this equation, x is the output of the Integrator block. It is also the input to the blocks that compute \dot{x} , on which it is based. This relationship is implemented using a loop.

The Scope displays x at each time step. For a simulation lasting 10 seconds, the output looks like this:

The equation you modeled in this example can also be expressed as a transfer function. The model uses the Transfer Fcn block, which accepts u as input and outputs x . So, the block implements x/u . If you substitute sx for x' in the above equation, you get

$$sx = -2x + u.$$

Solving for x gives

$$x = u/(s + 2).$$

or,

$$x/u = 1/(s + 2).$$

The Transfer Fcn block uses parameters to specify the numerator and denominator coefficients. In this case, the numerator is 1 and the denominator is $s+2$. Specify both terms as vectors of coefficients of successively decreasing powers of s .

In this case the numerator is [1] (or just 1) and the denominator is [1 2].

The results of this simulation are identical to those of the previous model.

Best-Form Mathematical Models

In this section...

“Series RLC Example” on page 15-11

“Solving Series RLC Using Resistor Voltage” on page 15-11

“Solving Series RLC Using Inductor Voltage” on page 15-13

Series RLC Example

You can often formulate the mathematical system you are modeling in several ways. Choosing the best-form mathematical model allows the simulation to execute faster and more accurately. For example, consider a simple series RLC circuit.

According to Kirchoff's voltage law, the voltage drop across this circuit is equal to the sum of the voltage drop across each element of the circuit.

$$V_{AC} = V_R + V_L + V_C$$

Using Ohm's law to solve for the voltage across each element of the circuit, the equation for this circuit can be written as

$$V_{AC} = Ri + L \frac{di}{dt} + \frac{1}{C} \int_{-\infty}^t i(t) dt$$

You can model this system in Simulink by solving for either the resistor voltage or inductor voltage. Which you choose to solve for affects the structure of the model and its performance.

Solving Series RLC Using Resistor Voltage

Solving the RLC circuit for the resistor voltage yields

$$V_R = Ri$$

$$Ri = V_{AC} - L \frac{di}{dt} - \frac{1}{C} \int_{-\infty}^t i(t) dt$$

Circuit Model

The following diagram shows this equation modeled in Simulink where R is 70, C is 0.00003, and L is 0.04. The resistor voltage is the sum of the voltage source, the capacitor voltage, and the inductor voltage. You need the current in the circuit to calculate the capacitor and inductor voltages. To calculate the current, multiply the resistor voltage by a gain of $1/R$. Calculate the capacitor voltage by integrating the current and multiplying by a gain of $1/C$. Calculate the inductor voltage by taking the derivative of the current and multiplying by a gain of L .

Series RLC Circuit: Formulated to solve for resistor current

This formulation contains a Derivative block associated with the inductor. Whenever possible, you should avoid mathematical formulations that require Derivative blocks as they introduce discontinuities into your system. Numerical integration is used to solve the model dynamics through time. These integration solvers take small steps through time to satisfy an accuracy constraint on the solution. If the discontinuity introduced by the Derivative block is too large, it is not possible for the solver to step across it.

In addition, in this model the Derivative, Sum, and two Gain blocks create an algebraic loop. Algebraic loops slow down the model's execution and can produce less accurate simulation results. See “Algebraic Loop Concepts” on page 3-38 for more information.

Solving Series RLC Using Inductor Voltage

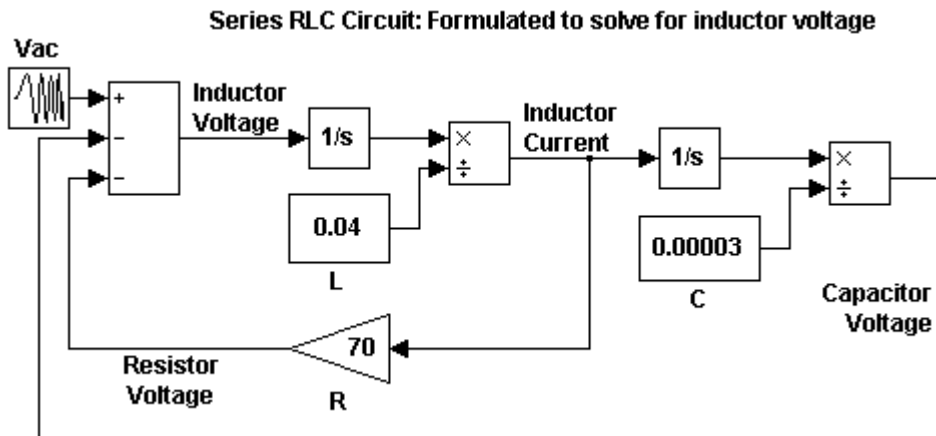

To avoid using a Derivative block, formulate the equation to solve for the inductor voltage.

$$V_L = L \frac{di}{dt}$$

$$L \frac{di}{dt} = V_{AC} - Ri - \frac{1}{C} \int_{-\infty}^t i(t) dt$$

Circuit Model

The following diagram shows this equation modeled in Simulink. The inductor voltage is the sum of the voltage source, the resistor voltage, and the capacitor voltage. You need the current in the circuit to calculate the resistor and capacitor voltages. To calculate the current, integrate the inductor voltage and divide by L . Calculate the capacitor voltage by integrating the current and dividing by C . Calculate the resistor voltage by multiplying the current by a gain of R .

This model contains only integrator blocks and no algebraic loops. As a result, the model simulates faster and more accurately.

Model a Simple Equation

To model the equation that converts Celsius temperature to Fahrenheit

$$T_F = 9/5(T_C) + 32$$

First, consider the blocks needed to build the model:

- A Ramp block to input the temperature signal, from the Sources library
- A Constant block to define a constant of 32, also from the Sources library
- A Gain block to multiply the input signal by 9/5, from the Math Operations library
- A Sum block to add the two quantities, also from the Math Operations library
- A Scope block to display the output, from the Sinks library

Next, gather the blocks into your model window.

Assign parameter values to the Gain and Constant blocks by opening (double-clicking) each block and entering the appropriate value. Then, click the **OK** button to apply the value and close the dialog box.

Now, connect the blocks.

The Ramp block inputs Celsius temperature. Open that block and change the **Initial output** parameter to 0. The Gain block multiplies that temperature by the constant 9/5. The Sum block adds the value 32 to the result and outputs the Fahrenheit temperature.

Open the Scope block to view the output. Now, choose **Run** from the **Simulation** menu to run the simulation. The simulation runs for 10 seconds.

Model Differential Algebraic Equations

In this section...

“Overview of Robertson Reaction Example” on page 15-17

“Simulink Model from ODE Equations” on page 15-17

“Simulink Model from DAE Equations” on page 15-20

“Simulink Model from DAE Equations Using Algebraic Constraint Block” on page 15-23

Overview of Robertson Reaction Example

Robertson [1] on page 15-27 created a system of autocatalytic chemical reactions to test and compare numerical solvers for stiff systems. The reactions, rate constants (k), and reaction rates (V) for the system are given as follows:

Because there are large differences between the reaction rates, the numerical solvers see the differential equations as stiff. For stiff differential equations, some numerical solvers cannot converge on a solution unless the step size is extremely small. If the step size is extremely small, the simulation time can be unacceptably long. In this case, you need to use a numerical solver designed to solve stiff equations.

Simulink Model from ODE Equations

A system of ordinary differential equations (ODE) has the following characteristics:

- All of the equations are ordinary differential equations.
- Each equation is the derivative of a dependent variable with respect to one independent variable, usually time.
- The number of equations is equal to the number of dependent variables in the system.

Using the reaction rates, you can create a set of differential equations describing the rate of change for each chemical species. Since there are three species, there are three differential equations in the mathematical model.

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

$$C' = 3 \cdot 10^7 B^2$$

Initial conditions: $A = 1$, $B = 0$, and $C = 0$.

Build the Model

Create a model, or open the model `ex_hb1ode`.

- 1 Add three Integrator blocks to your model. Label the inputs A' , B' , and C' , and the outputs A , B , and C respectively.
- 2 Add Sum, Product, and Gain blocks to solve each differential variable. For example, to model the signal C' ,
 - a Add a Math Function block and connect the input to signal B . Set the **Function** parameter to `square`.
 - b Connect the output from the Math Function block to a Gain block. Set the **Gain** parameter to `3e7`.
 - c Continue to add the remaining differential equation terms to your model.
- 3 Model the initial condition of A by setting the **Initial condition** parameter for the A Integrator block to `1`.
- 4 Add Out blocks to save the signals A , B , and C to the MATLAB variable `yout`.

Simulate the Model

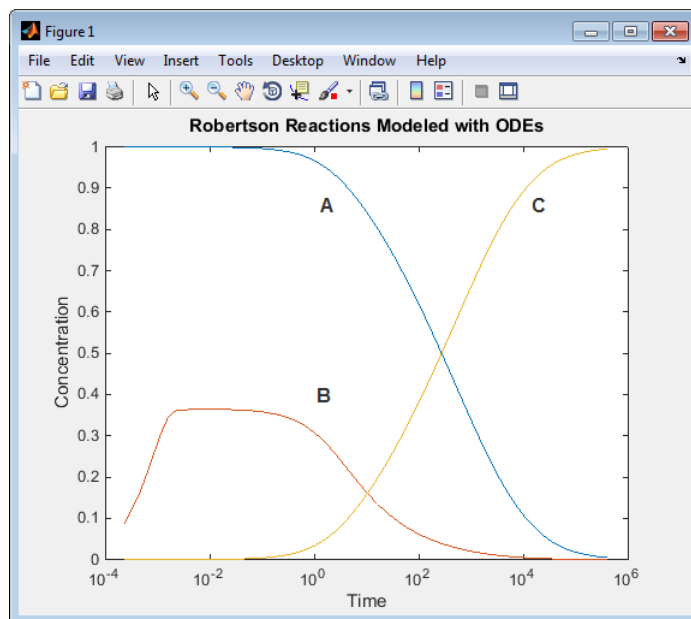

Create a script that uses the `sim` command to simulate your model. This script saves the simulation results in the MATLAB variable `yout`. Since the simulation has a long time interval and `B` initially changes very fast, plotting values on a logarithmic scale helps to visually compare the results. Also, since the value of `B` is small relative to the values of `A` and `C`, multiply `B` by $1 \cdot 10^4$ before plotting the values.

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hb1ode` with the name of your model.

```
sim('ex_hb1ode')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with ODEs')
```

- 2 From the Simulink Editor menu, select **Simulation > Model Configuration Parameters**:

- In the Solver pane, set the **Stop time** to $4e5$ and the **Solver** to `ode15s` (`stiff/NDF`).
 - In the Data Import pane, select the **Time** and **Output** check boxes.
- 3 Run the script. Observe that all of A is converted to C.

Simulink Model from DAE Equations

A system of differential algebraic equations (DAE) has the following characteristics:

- It contains both ordinary differential equations and algebraic equations. Algebraic equations do not have any derivatives.
- Only some of the equations are differential equations defining the derivatives of some of the dependent variables. The other dependent variables are defined with algebraic equations.
- The number of equations is equal to the number of dependent variables in the system.

Some systems contain constraints due to conservation laws, such as conservation of mass and energy. If you set the initial concentrations to $A = 1$, $B = 0$, and $C = 0$, the total

concentration of the three species is always equal to 1 since $A + B + C = 1$. You can replace the differential equation for C with the following algebraic equation to create a set of differential algebraic equations (DAEs).

$$C = 1 - A - B$$

The differential variables A and B uniquely determine the algebraic variable C .

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

$$C = 1 - A - B$$

Initial conditions: $A = 1$ and $B = 0$.

Build the Model

Make these changes to your model or to the model `ex_hb1ode`, or open the model `ex_hb1dae`.

- 1 Delete the Integrator block for calculating C .
- 2 Add a Sum block and set the **List of signs** parameter to `+ - -`.
- 3 Connect the signals A and B to the minus inputs of the Sum block.
- 4 Model the initial concentration of A with a Constant block connected to the plus input of the Sum block. Set the **Constant value** parameter to `1`.
- 5 Connect the output of the Sum block to the branched line connected to the Product and Out blocks.

Simulate the Model

Create a script that uses the `sim` command to simulate your model.

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hb1dae` with the name of your model.

```
sim('ex_hb1dae')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);
xlabel('Time');
ylabel('Concentration');
title('Robertson Reactions Modeled with DAEs')
```

- 2 From the Simulink Editor menu, select **Simulation > Model Configuration Parameters**:

- In the Solver pane, set the **Stop time** to $4e5$ and the **Solver** to `ode15s` (`stiff/NDF`).
 - In the Data Import pane, select the **Time** and **Output** check boxes.
- 3** Run the script. The simulation results when you use an algebraic equation are the same as for the model simulation using only differential equations.

Simulink Model from DAE Equations Using Algebraic Constraint Block

Some systems contain constraints due to conservation laws, such as conservation of mass and energy. If you set the initial concentrations to $A = 1$, $B = 0$, and $C = 0$, the total concentration of the three species is always equal to 1 since $A + B + C = 1$.

You can replace the differential equation for C with an algebraic equation modeled using an Algebraic Constraint block and a Sum block. The Algebraic Constraint block constrains its input signal $F(z)$ to zero and outputs an algebraic state z . In other words, the block output is a value needed to produce a zero at the input. Use the following algebraic equation for input to the block.

$$0 = A + B + C - 1$$

The differential variables A and B uniquely determine the algebraic variable C .

$$A' = -0.04A + 1 \cdot 10^4 BC$$

$$B' = 0.04A - 1 \cdot 10^4 BC - 3 \cdot 10^7 B^2$$

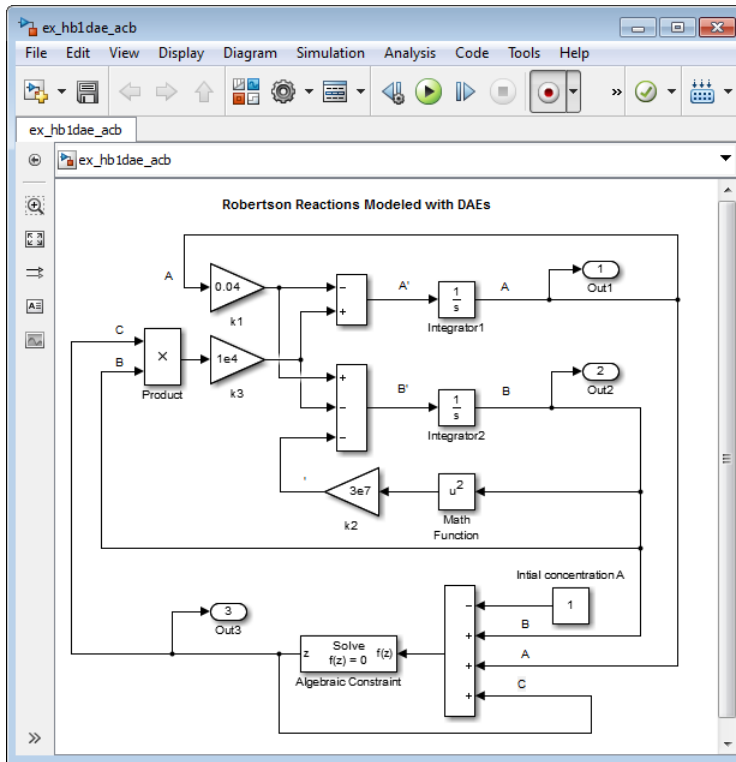

$$C = 1 - A - B$$

Initial conditions: $A = 1$, $B = 0$, and $C = 1 \cdot 10^{-3}$.

Build the Model

Make these changes to your model or to the model `ex_hb1ode`, or open the model `ex_hb1dae_acb`.

- 1 Delete the Integrator block for calculating C .
- 2 Add an Algebraic Constraint block. Set the **Initial guess** parameter to `1e-3`.
- 3 Add a Sum block. Set the **List of signs** parameter to `-+++`.
- 4 Connect the signals A and B to plus inputs of the Sum block.
- 5 Model the initial concentration of A with a Constant block connected to the minus input of the Sum block. Set the **Constant value** parameter to `1`.
- 6 Connect the output of the Algebraic Constraint block to the branched line connected to the Product and Out block inputs.
- 7 Create a branch line from the output of the Algebraic Constraint block to the final plus input of the Sum block.

Simulate the Model

Create a script that uses the `sim` command to simulate your model.

- 1 Enter the following statements in a MATLAB script. If you built your own model, replace `ex_hb1dae_acb` with the name of your model.

```
sim('ex_hb1dae_acb')
yout(:,2) = 1e4*yout(:,2);
figure;
semilogx(tout,yout);

title('Robertson Reactions Modeled with DAEs and Algebraic Constraint Block')
```

- 2 From the Simulink Editor menu, select **Simulation > Model Configuration Parameters**:

- In the Solver pane, set the **Stop time** to $4e5$ and the **Solver** to `ode15s` (`stiff/NDF`).
 - In the Data Import pane, select the **Time** and **Output** check boxes.
- 3 Run the script. The simulation results when you use an Algebraic Constraint block are the same as for the model simulation using only differential equations.

Using an Algebraic Constraint block creates an algebraic loop in a model. If you set the **Algebraic Loop** parameter to `warning` (**Simulation > Model Configuration Parameters > Diagnostics > Algebraic Loop**), the following message displays in the Diagnostic Viewer during simulation.

For this model, the algebraic loop solver was able to find a solution for the simulation, but algebraic loops don't always have a solution, and they are not supported for code generation. For more information about algebraic loops in Simulink models and how to remove them, see "Algebraic Loop Concepts" on page 3-38.

Capabilities of Model Components

Componentization

A component is a piece of your design, a unit level item, or a subassembly, that you can work on without needing the higher level parts of the model.

Componentization involves organizing your model into components. Componentization provides many benefits for organizations that develop large Simulink models that consist of many functional pieces. The benefits include:

- Meeting development process requirements, such as:
 - Component reuse
 - Team-based development
 - Intellectual property protection
 - Unit testing
- Improving performance for:
 - Model loading
 - Simulation speed
 - Memory usage

Componentization Techniques

Key componentization techniques that you can use with Simulink include:

- Subsystems
- Libraries
- Model references

These componentization techniques support a wide range of modeling requirements for models that vary in size and complexity. Most large models use a combination of componentization techniques. For example, you can include subsystems in referenced models, and include referenced models in subsystems. As another example, a large model might use model reference Accelerator blocks at the top level component partitions and blend model reference Accelerator and atomic subsystem libraries at lower levels.

Simulink provides tools to convert from subsystems to model references. Because of the differences between subsystems and model references, switching from subsystems to model references can involve several steps (see *Converting a Subsystem to a Referenced Model* on page 8-24). Consider scalability and support for anticipated future modeling requirements, such as how a model is likely to grow in size and complexity and possible code generation requirements. Designing a scalable architecture can avoid later conversion costs.

General Componentization Guidelines

This table provides high-level guidelines about the kinds of modeling goals and models for which subsystems, libraries, and model references are each particularly well suited.

Componentization Technique	Modeling Goals for Which the Technique Is Well Suited
Subsystems	<ul style="list-style-type: none">• Add hierarchy to organize and visually simplify a model.• Maximize design reuse with inherited attributes for context-dependent behavior.
Libraries	<ul style="list-style-type: none">• Provide a frequently used, and infrequently changed, modeling utility.• Reuse components repeatedly in a model or in multiple models.

Componentization Technique	Modeling Goals for Which the Technique Is Well Suited
Model references	<ul style="list-style-type: none"> • Develop a referenced model independently from the models that use it. • Obscure the contents of a referenced model, allowing you to distribute it without revealing the intellectual property that it embodies. • Reference a model multiple times without having to make redundant copies. • Facilitate changes by multiple people, with defined interfaces for top-level components. • Improve the overall performance by using incremental model loading, update diagram, simulation, and code generation for large models (for example, a model with 10,000 blocks). • Perform unit testing. • Simplify debugging for large models. • Generate code that reflects the model structure.

For a more detailed comparison of these modeling techniques, see “Summary of Componentization Techniques” on page 15-31.

Summary of Componentization Techniques

This section compares subsystems, libraries, and model references. The table includes recommendations and notes about a range of modeling requirements and features.

To see more information about a specific requirement or feature, click a link in a table cell.

Modeling Requirement or Feature	Subsystems	Libraries	Model References
Development Process			
Component reuse	Not supported	Well suited	Well suited

- “Libraries Summary” on page 15-37
- “Model References Summary” on page 15-40

Subsystems Summary

This section provides guidelines for using subsystems for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about subsystems, see:

- Creating Subsystems on page 4-24
- “Conditionally Executed Subsystems and Models”

Modeling Requirement or Feature	Guidelines for Subsystems
Development Process	

Modeling Requirement or Feature	Guidelines for Subsystems
Component reuse	<p>Not supported</p> <ul style="list-style-type: none"> • Copy a subsystem to reuse it in a model. • Subsystem copies are independent of each other. • Save a subsystem by saving the model that contains the subsystem. • Configuration management for subsystems is difficult.
Team-based development	<p>Not supported</p> <ul style="list-style-type: none"> • For subsystems in a model, Simulink provides no direct interface with source control tools. • To create or change a subsystem, you need to open the parent model's file. This can lead to file contention when multiple people want to work on multiple subsystems in a model.
Intellectual property protection	<p>Not supported</p> <p>Use protected referenced models instead.</p>
Unit testing	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • For coverage testing, use Signal Builder and source blocks. • Each time a subsystem changes, you need to copy the subsystem to a harness model. • The test harness may have different Simulink sort orders, due to virtual boundaries. • Test harness files require configuration management overhead.
Performance	
Model loading speed	<p>Supported, with limitations</p> <p>Loading a model loads all subsystems at one time. There is no incremental loading.</p>

Modeling Requirement or Feature	Guidelines for Subsystems
Simulation speed for large models	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To speed simulation, use Accelerator or Rapid Accelerator simulation mode. • Simulation mode applies to the whole model. Model references provide a finer level of control for simulation modes.
Memory	<p>Supported, with limitations</p> <p>Memory use for simulation and code generation is comparable for subsystems and libraries. For models with over 500 blocks, model reference Accelerator mode can significantly reduce memory usage for simulation and code generation.</p>
Artificial algebraic loop avoidance	<p>Well suited</p> <ul style="list-style-type: none"> • Virtual subsystems avoid artificial algebraic loops. • For nonvirtual subsystems, consider enabling the Subsystem block parameter Minimize algebraic loop occurrences.
Features	
Signal property inheritance	<p>Well suited</p> <ul style="list-style-type: none"> • Inheriting signal properties from outside the subsystem boundary avoids your having to specify properties for every signal. • Propagation of signal properties can lead to Simulink using signal properties that you did not anticipate.
State initialization	<p>Well suited</p> <p>You can initialize states of subsystems.</p>

Modeling Requirement or Feature	Guidelines for Subsystems
Tunability	<p>Well suited</p> <ul style="list-style-type: none"> • Tune subsystems using a block parameterization or masked subsystems. • Control tunability in generated code using Configuration Parameters > Optimization > Default parameter behavior.
Buses	<p>Well suited</p> <p>Subsystems do not require the use of bus objects for virtual buses.</p>
S-functions	<p>Well suited</p> <p>Subsystems support inlined or noninlined S-functions.</p>
Model configuration settings	<p>Well suited</p> <p>A subsystem uses the model configuration settings of the model that contains the subsystem.</p>
Tools	<p>Well suited</p> <p>Subsystems provide extensive support for Simulink tools.</p>
Code generation	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To generate code for a subsystem by itself, right-click the Subsystem block and select a code generation option. • As an optimization, Simulink attempts to recognize identical subsystems. For detected identical subsystems, the generated code includes only one copy of code for the multiple subsystems. • For virtual subsystems, you cannot specify file or function code partitions for code generation.

Libraries Summary

This section provides guidelines for using libraries for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about libraries, see “Libraries”.

Modeling Requirement or Feature	Guidelines for Libraries
Development Process	
Component reuse	<p>Well suited</p> <ul style="list-style-type: none"> • Access a collection of well-defined utility blocks. • Create a component once and reuse it in models. • Link to the same library block multiple times without creating multiple copies. • Link to the same library block from multiple models. • Restrict write access to library components. • Maintain one truth: propagate changes from a single library block to all blocks that link to that library. • Disable a link to allow independent changes to a linked block. • Managing library links adds some overhead. • Save library in a file similar to a Simulink model, but you cannot simulate the file contents. • Share data between instances by defining the data outside the component (for example, a data store in a common parent subsystem).

Modeling Requirement or Feature	Guidelines for Libraries
Team-based development	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • Place library files in source control for version control and configuration management. • Maintain one truth: propagate changes from a single library block to all blocks that link to that library. • To reduce file contention, use one subsystem per library. • Link to the same library block from multiple models. • Restrict write access to library component.
Intellectual property protection	<p>Not supported</p> <p>Use protected referenced models instead.</p>
Unit testing	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • For coverage testing, use Signal Builder and source blocks. • Test harness may have different Simulink sort orders, due to virtual boundaries. • Test harness files require configuration management overhead.
Performance	
Model loading speed	<p>Well suited</p> <p>Simulink incrementally loads a library at the point needed during editing, updating a diagram, or simulating a model.</p>
Simulation speed for large models	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To speed simulation, use Accelerator or Rapid Accelerator simulation mode. • Simulation mode applies to the whole model. Model references provide a finer level of control for simulation modes.

Modeling Requirement or Feature	Guidelines for Libraries
Memory	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • Simulink incrementally loads libraries at the point needed during editing, updating a diagram, or simulating a model. • Simulink duplicates library block instances during block update. • Memory usage for simulation and code generation is comparable for subsystems and libraries. For models with over 500 blocks, model reference Accelerator mode can significantly reduce memory usage for simulation and code generation.
Artificial algebraic loop avoidance	<p>Well suited</p> <ul style="list-style-type: none"> • Virtual subsystems avoid artificial algebraic loops. • For nonvirtual subsystems, consider enabling the Subsystem block parameter Minimize algebraic loop occurrences.
Features	
Signal property inheritance	<p>Well suited</p> <ul style="list-style-type: none"> • Inheriting signal properties from outside the library block boundary avoids your having to specify properties for every signal. • Propagation of signal properties can lead to Simulink using signal properties that you did not anticipate.
State initialization	<p>Well suited</p> <p>You can initialize states of library blocks.</p>
Tunability	<p>Well suited</p> <ul style="list-style-type: none"> • Tune library blocks using block parameterization or masked subsystems. • Control tunability in generated code using Configuration Parameters > Optimization > Default parameter behavior.

Modeling Requirement or Feature	Guidelines for Libraries
Buses	<p>Well suited</p> <p>Libraries do not require the use of bus objects for virtual buses.</p>
S-functions	<p>Well suited</p> <p>Libraries support inlined and noninlined S-functions.</p>
Model configuration settings	<p>Well suited</p> <ul style="list-style-type: none"> • Library models do not have model configuration settings. • A referenced library block uses the model configuration setting of the model that contains that block.
Tools	<p>Supported, with limitations</p> <p>There are some limitations for using some Simulink tools, such as the Model Advisor, with libraries.</p>
Code generation	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • As an optimization, Simulink attempts to recognize identical subsystems. For detected identical subsystems, the generated code includes only one copy of code for the multiple subsystems. • For virtual subsystems, you cannot specify file or function code partitions for code generation.

Model References Summary

This section provides guidelines for using model references for each of the modeling requirements and features highlighted in the “Summary of Componentization Techniques” on page 15-31.

For additional information about model references, see:

- “Model References”
- “Reference Existing Models” on page 8-17

- Model Referencing Limitations on page 8-8

Modeling Requirement or Feature	Guidelines for Model References
Development Process Requirements	
Component reuse	<p>Well suited</p> <ul style="list-style-type: none"> • Create a standalone component once and reuse it in multiple models. • Reference the same model multiple times without creating multiple copies. See “Model Reuse” on page 8-8. • Reference the same model from multiple models. • Model references use specified boundaries for preserving component integrity. • Share data between instances (Model blocks) by creating a data store inside the model. See “Share Data Among Referenced Model Instances” on page 8-47.
Team-based development	<p>Well suited</p> <ul style="list-style-type: none"> • For version control and configuration management, you can place model reference files in a source control system. • Design, create, simulate, and test a referenced model independently from the model that references it. • Link to the same model reference from multiple models. • Changes made to a referenced model apply to all instances of that referenced model. • Simulink does not limit access for changing a model reference. • You save a referenced model in a separate file from the model that references it. Using separate files helps to avoid file contention.

Modeling Requirement or Feature	Guidelines for Model References
Intellectual property protection	<p>Well suited</p> <ul style="list-style-type: none"> • Use the protected model feature to obscure contents of a referenced model in a distributed model. • Creating a protected model feature requires a Simulink Coder license. Using a protected model does <i>not</i> require a Simulink Coder license.
Unit testing	<p>Well suited</p> <ul style="list-style-type: none"> • Test components independently to isolate behaviors, by simulating them standalone. • You can eliminate unit retest for unchanged components. • Use a data-defined test harness, with MATLAB test vectors and direct coverage collection. • For coverage testing, use root inports and outports.
Performance	
Model loading speed	<p>Well suited</p> <ul style="list-style-type: none"> • Simulink incrementally loads a referenced model at the point needed during editing, updating a diagram, or simulating a model. • If a simulation target build is required, first-time loading can be slow.

Modeling Requirement or Feature	Guidelines for Model References
Simulation speed for large models	<p>Well suited</p> <ul style="list-style-type: none"> • Simulate a referenced model standalone. • The Model block has an option for specifying the simulation mode. • You can improve rebuild performance by selecting the appropriate setting for the Configuration Parameters > Model Referencing > Rebuild parameter. • Simulation through code generation can have a slow start-up time, which might be undesirable during prototyping. • See “Simulation Requirements and Limitations” on page 8-12.
Memory	<p>Well suited</p> <ul style="list-style-type: none"> • Simulink loads a referenced model at the point that model is needed for navigation during editing, updating a diagram, or simulating a model. • Use model reference Accelerator mode to reduce memory usage, incrementally loading a compiled version of a referenced model.
Artificial algebraic loop avoidance	<p>Supported, with limitations</p> <p>Consider enabling Configuration Parameters > Model Referencing > Minimize algebraic loop occurrences.</p>
Features	

Modeling Requirement or Feature	Guidelines for Model References
Signal property inheritance	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • Inherit sample time when the referenced model is sample-time independent. You cannot propagate a continuous sample time to a Model block that is sample-time independent. • Model block is context-independent, so it cannot inherit signal properties. Explicitly set input and output signal properties. • Use a bus object to define the signal data type of a bus signal that is passed into a referenced model. • Goto and From block lines cannot cross model reference boundaries. • See Index Base Limitations on page 8-62.
State initialization	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • You can initialize states from the top model. • Use either the structure format or structure with time format to initialize the states of a top model and the models that it references. • To use the <code>SimState</code> (simulation state) feature with model references, simulate all Model blocks in Normal mode. • See “State Information for Referenced Models” on page 64-291.
Tunability	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To have each instance of a referenced model use different values, use model arguments in the Model block. • To have each instance of a referenced model use the same values, use <code>Simulink.Parameter</code> objects. • By default, all other parameters are inlined in generated code.

Modeling Requirement or Feature	Guidelines for Model References
Buses	<p>Supported, with limitations</p> <p>You must use bus objects for bus signals that cross referenced model boundaries (for example, global data stores, root inports, root outports).</p>
S-functions	<p>Supported, with limitations</p> <p>Model references generally support inlined or noninlined S-functions. See “S-Functions in Referenced Models” on page 8-9.</p>
Model configuration settings	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • To apply the same model configuration settings to all models in a model hierarchy, use a referenced configuration set. • Configuration settings for the root model and referenced models must be consistent. However, not all configuration settings need to be the same across the model hierarchy.
Tools	<p>Supported, with limitations</p> <ul style="list-style-type: none"> • There are some limitations for using some Simulink tools, such as the Simulink Debugger, with model references. • For details, see “Tools Requirements and Limitations” on page 8-15.
Code generation	<p>Well suited</p> <ul style="list-style-type: none"> • By default, model references generate code incrementally. • You can improve rebuild performance by selecting the appropriate setting for the Configuration Parameters > Model Referencing > Rebuild parameter.

Model Complex Logic

To model complex logic in a Simulink model, consider using Stateflow software.

Stateflow extends Simulink with a design environment for developing state transition diagrams and flow charts. Stateflow provides the language elements required to describe complex logic in a natural, readable, and understandable form. It is tightly integrated with MATLAB and Simulink products, providing an efficient environment for designing embedded systems that contain control, supervisory, and mode logic.

For more information on Stateflow software, see “Stateflow”.

Model Physical Systems

To model physical systems in the Simulink environment, consider using Simscape software.

Simscape extends Simulink with tools for modeling systems spanning mechanical, electrical, hydraulic, and other physical domains as physical networks. It provides fundamental building blocks from these domains to let you create models of custom components. The MATLAB based Simscape language enables text-based authoring of physical modeling components, domains, and libraries.

For more information on Simscape software, see “Simscape”.

Model Signal Processing Systems

To model signal processing systems in the Simulink environment, consider using DSP System Toolbox software.

DSP System Toolbox provides algorithms and tools for the design and simulation of signal processing systems. These capabilities are provided as MATLAB functions, MATLAB System objects, and Simulink blocks. The system toolbox includes design methods for specialized FIR and IIR filters, FFTs, multirate processing, and DSP techniques for processing streaming data and creating real-time prototypes. You can design adaptive and multirate filters, implement filters using computationally efficient architectures, and simulate floating-point digital filters. Tools for signal I/O from files and devices, signal generation, spectral analysis, and interactive visualization enable you to analyze system behavior and performance. For rapid prototyping and embedded system design, the system toolbox supports fixed-point arithmetic and C or HDL code generation.

For more information on DSP System Toolbox software, see “DSP System Toolbox”.

Basic Modeling Workflow

In large, well-defined projects, you define file management and model architecture upfront. In other words, your predefined requirements drive components and interfaces.

To understand how to create such projects, you must know how to create scalable models that represent system equations. This example shows how, as model size and complexity increases, file storage and model architecture change to satisfy evolving project requirements.

- 1 “Model a Mechanical System Algorithm” on page 15-51
- 2 “Create Virtual Model Components” on page 15-54
- 3 “Manage Signal Lines” on page 15-58
- 4 “Manage Model Data” on page 15-65
- 5 “Reuse Model Components from Files” on page 15-67
- 6 “Create Interchangeable Variations of Model Components” on page 15-71
- 7 “Set up a File Management System” on page 15-73

You can use the files provided at any of these steps as starting points for your design. The final example helps you create a project that contains the model components and supporting files developed in this example set.

Model a Mechanical System Algorithm

When incomplete system requirements and a developing system design prevent you from defining file management and model architecture upfront, you can still model fundamental system algorithms. By organizing the model into inputs, outputs, and systems, you create a general framework for model components as the model grows.

To show the first stage of a modeling workflow that begins with limited information, this example uses a simple mechanical system composed of a mass, spring, and damper.

This second-order differential equation characterizes the system:

$$m\ddot{x} + c\dot{x} + kx = F$$

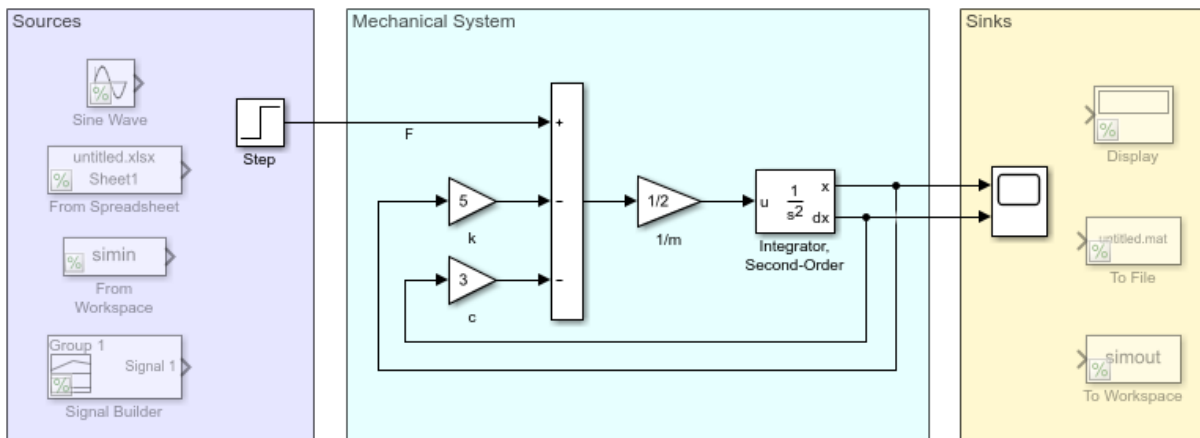

where

- m is mass
- c is the damping coefficient
- k is the spring constant
- \ddot{x} is acceleration
- \dot{x} is velocity
- x is displacement
- F is force

Solving for \ddot{x} provides a form of this equation that maps more clearly to a Simulink® model.

$$\ddot{x} = \frac{1}{m}(F - c\dot{x} - kx)$$

In model `ex_modeling_simple_system`, a Sum block computes the forces applied to the mass, the Gain block labeled $1/m$ computes the acceleration of the mass, and the Second-Order Integrator block solves for the velocity and position of the mass.

Copyright 2018 The MathWorks, Inc.

These blocks, which represent the mechanical system, are grouped in an area. The two other areas contain system inputs and outputs. By organizing the model upfront, you create a general framework for model components as the model grows.

Since this example shows a model in the preliminary stages of development, the actual input force is unknown and can be represented by a variety of standard source blocks. Model `ex_modeling_simple_system` uses a Step block connected as input to the mechanical system. Some alternative source blocks are shown, but commented out. For example, you can use the From Spreadsheet block to load empirical data if it were available.

Similarly, a variety of sink blocks can accept the output displacement. To check whether simulation results meet expectations, model `ex_modeling_simple_system` uses a Scope block to visualize the signals.

Create Virtual Model Components

As you gather requirements for a system, you can identify specific model components within the higher-level organization of inputs, outputs, and systems. To identify model components, the requirements and design can be only partially defined. For example, you might know where the interface among components will exist despite having an incomplete specification to describe that interface. To define model components without affecting simulation results and without investing time specifying an ambiguous interface, you can use Subsystem blocks to visually organize the model.

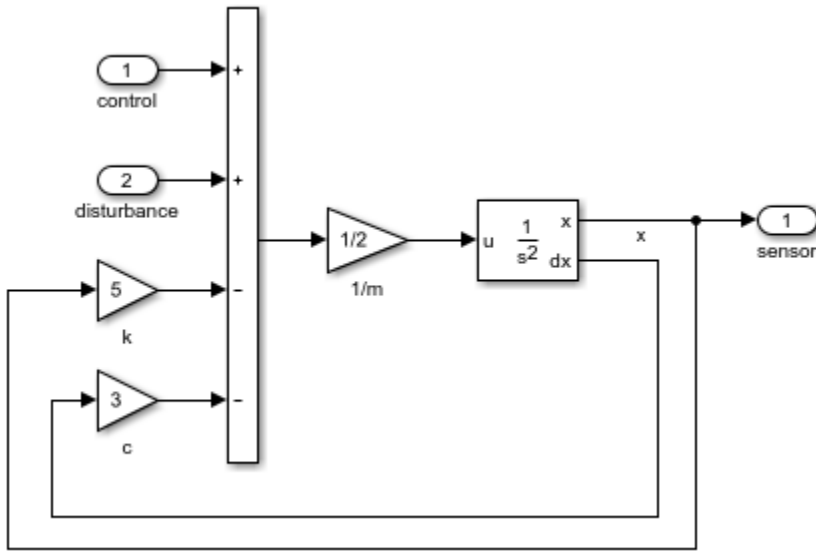

Model `ex_modeling_components` contains four common model components.

- Mechanical System — a mass separated from a surface by a spring and damper
- Controller — algorithm that controls the motion of the physical system
- Operator — logic that defines the commands sent to the controller
- Environment — external disturbances that affect the mechanical system

Copyright 2018 The MathWorks, Inc.

The ports on each of the Subsystem blocks correspond to input and output blocks within the subsystem. The block label shows the name of the corresponding port. For example, the Inport block labeled `disturbance` corresponds with the `disturbance` port of the mechanical system Subsystem block.

The four model components interact to determine the position of the mass.

The controller computes the force required to move the mechanical system to its goal position.

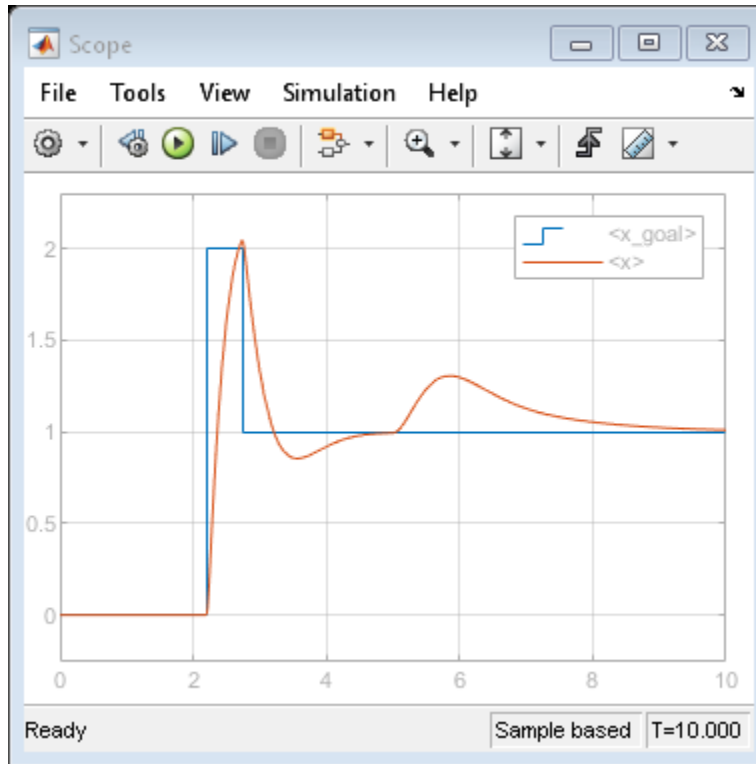

The operator determines the goal position of the mass and implements the related procedural logic with a Stateflow® chart.

The environment generates a disturbance force that affects the mechanical system.

During simulation, the operator tells the controller to wait 2 seconds, then move the mass up 2 meters. When the mass overshoots the goal position, the operator tells the controller to position the mass 1 meter above its original position. After 5 seconds, an environmental disturbance applies a steady force to the physical system and the controller reacts to stabilize the mass at the goal position.

Manage Signal Lines

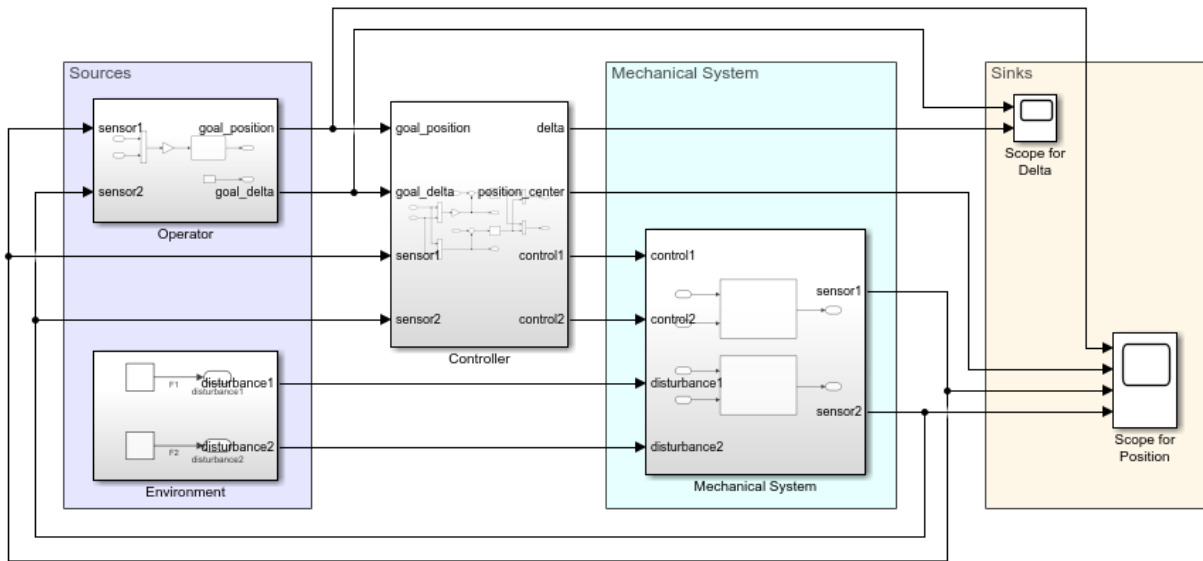

As a model grows, model components help functionally and visually organize blocks in the model. To similarly organize signal lines in the model, you can apply a variety of strategies, such as grouping signals into buses.

To demonstrate how to reduce signal line clutter, this example implements a model with multiple sensors and actuators. The system has two springs, dampers, and masses. A beam connects the two masses, as shown in this image.

Sensors read the displacement of the masses. The controller regulates the height at the center of the beam x and levels the beam by computing the force the actuators must apply to the masses. The controller uses the height difference between the beam ends, *delta*, to level the beam.

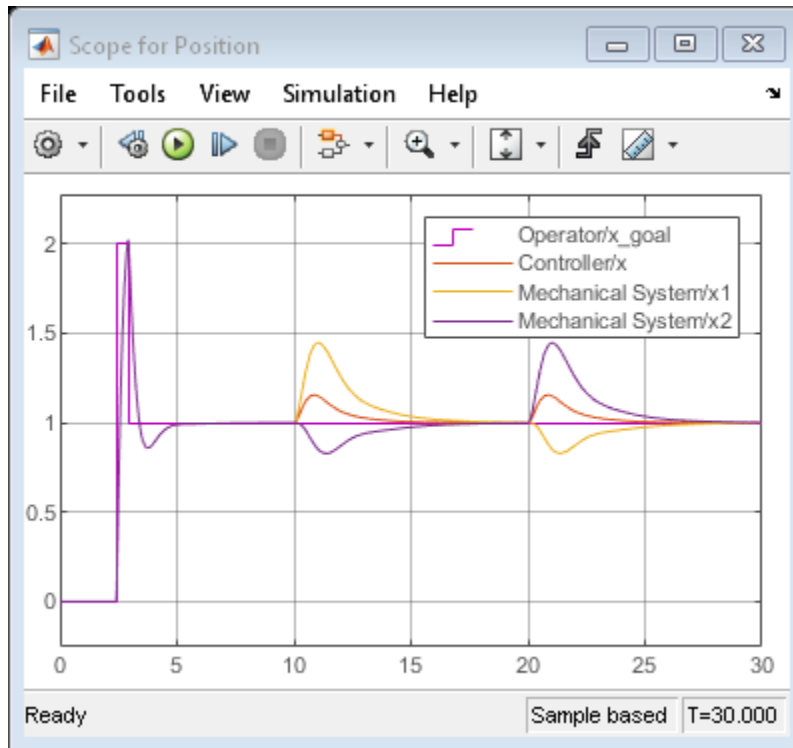

Model `ex_modeling_signals` represents the system.

Copyright 2018 The MathWorks, Inc.

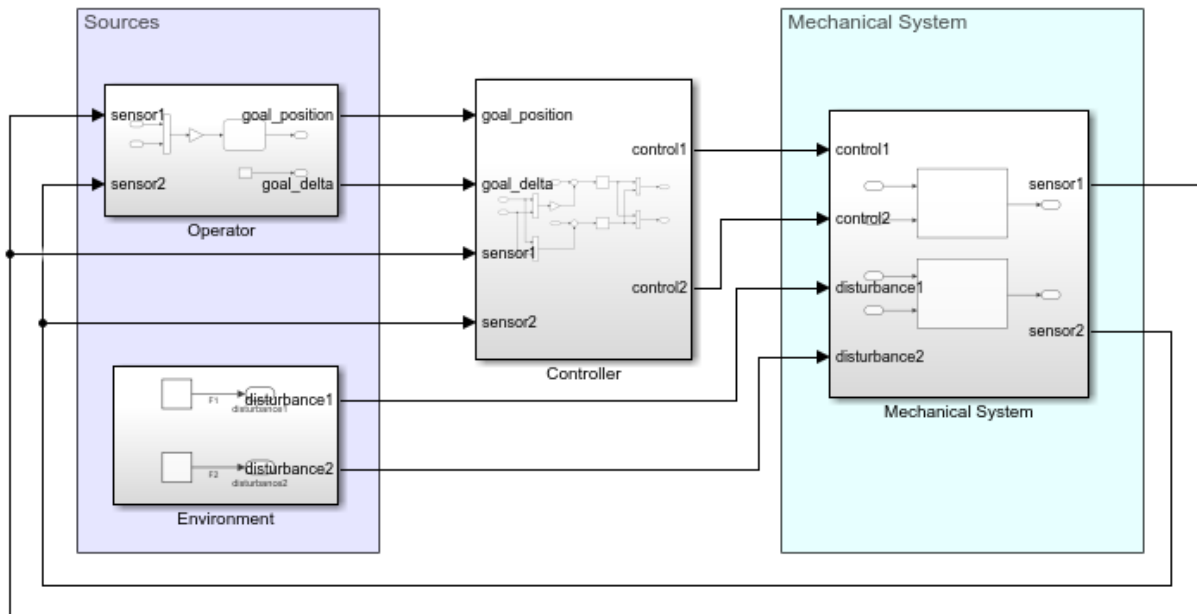

To display signals, the model uses two Scope blocks. One Scope block shows the goal and actual beam levelness. The other Scope block shows the goal and actual position of the beam at its center, along with the actual beam position at both ends.

To reduce the number of signal lines, you can connect a viewer directly to signal lines or enable data logging for signal lines. By choosing a way to visualize simulation data without using a sink block, you can avoid extra signal lines.

Model `ex_modeling_simulation_data_inspector` removes the Scope blocks and related signal lines, then enables data logging for those signals.

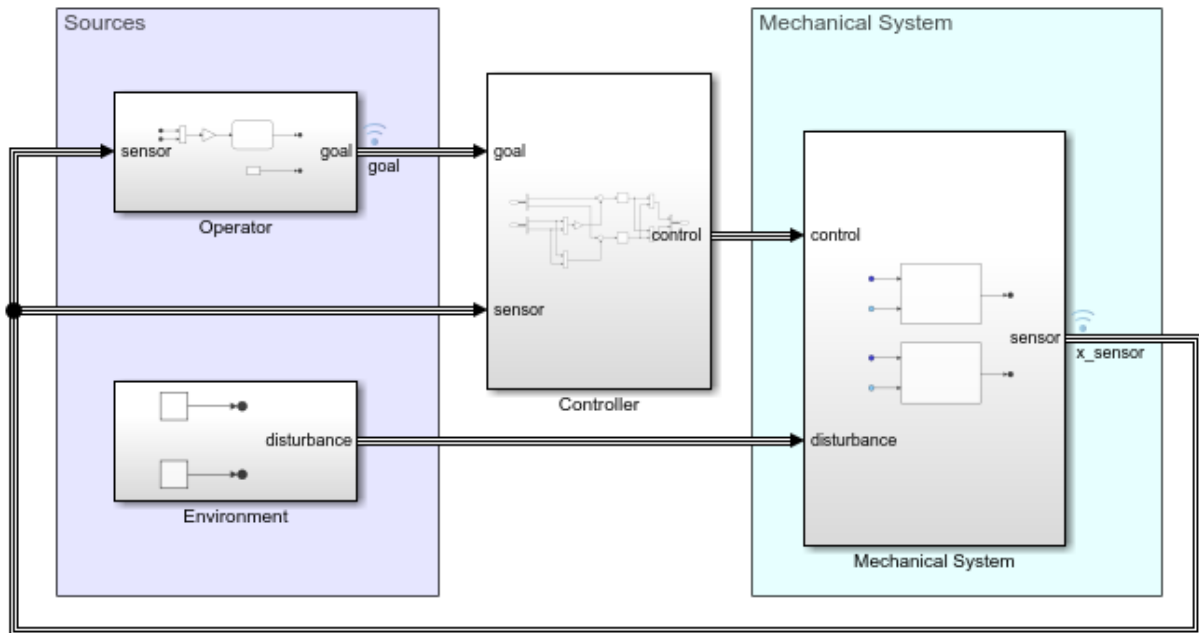

Copyright 2018 The MathWorks, Inc.

To view the logged signals, open the Simulation Data Inspector by clicking the highlighted **Simulation Data Inspector** button.

To further reduce the number of signal lines, you can group signal lines into a bus by using a Bus Creator block. You can also create buses at the output of subsystems and models by using Out Bus Element blocks. All signal lines retain their identities when grouped in a bus and can be separated downstream from the bus.

By creating buses, model `ex_modeling_composite_signals` provides an even more readable system representation.

Copyright 2018 The MathWorks, Inc.

The simulation results remain the same after signals are grouped in buses. This example enables data logging for signal lines associated with buses `x_sensor` and `goal` instead of logging data individually for each of the signals in these buses.

Manage Model Data

To define a parameter value that multiple blocks or models use, you can use variables. Separately updating numerical parameter values at each instance of the parameter can be inefficient and error prone. You can update the value of a variable in the workspace or source file that defines it. Having a single source for this information facilitates scalability and reusability of model components.

To specify value ranges, data types, tunability, and other characteristics of signals, states, and block parameters, you can use the `Simulink.Parameter` and `Simulink.Signal` objects. While you can use variables or objects to specify parameter values, this example uses variables for simplicity.

You can define variables by using these supporting file types:

- MAT-file
- MATLAB file
- Data dictionary

To load data for small models, you can use model callbacks. For large model hierarchies, different loading methods are more efficient.

In model `ex_modeling_data`, a `PreLoadFcn` model callback evaluates MATLAB file `ex_modeling_data_variables.m`, which defines variables k , c , and m in the base workspace. Gain blocks in the mechanical system and PID Controller blocks in the controller use these variables.

You can interactively change variable values at the MATLAB® command prompt. You can also use tools like the Model Data Editor to edit values.

Reuse Model Components from Files

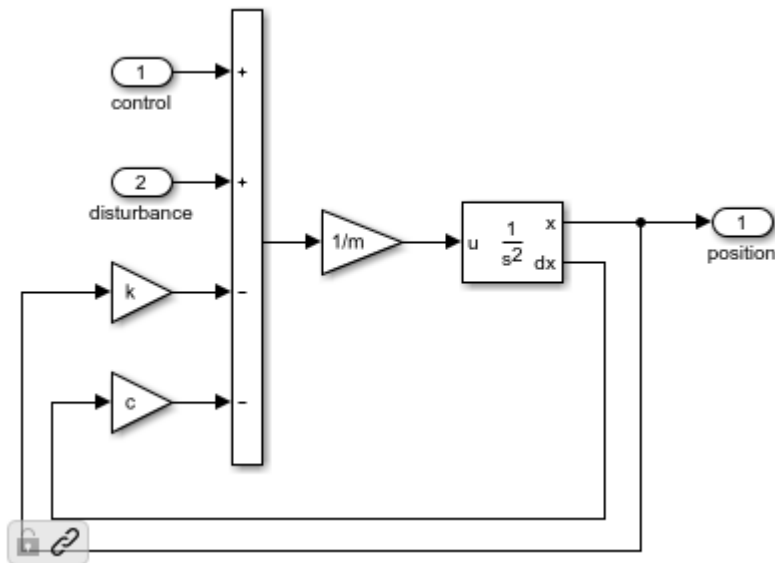

When working on a large model, you can separate it into multiple files so that team members can develop different model components at the same time. You can reuse these components multiple times in a model and in other models.

Model and library files provide a single source for multiple instances of the same model component. You can reference a model to execute it as an independent unit within the parent model. You can also add linked blocks to your model that derive their contents from the source block in a library. To learn when you should use each of these componentization methods, see “Component-Based Modeling Guidelines” on page 22-2.

Model `ex_modeling_component_reuse` uses two linked blocks to represent identical mechanical subsystems.

When you navigate into a linked block, you see a read-only view of its contents.

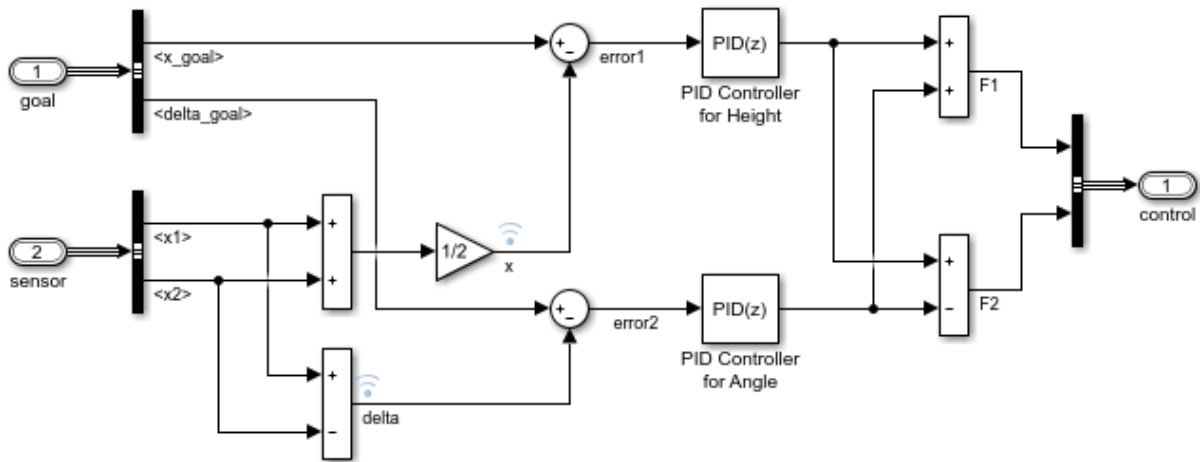

Each of these linked blocks derives its content from a single block in library file `ex_modeling_library.slx`. To edit the contents, you must either disable the link to the source block or edit the contents directly in the source library.

Copyright 2018 The MathWorks, Inc.

In addition to using blocks linked to a library file, model `ex_modeling_component_reuse` references model file `ex_modeling_controller.slx`. Controller code is often deployed on embedded systems, so having a standalone controller model is useful.

Copyright 2018 The MathWorks, Inc.

An embedded processor might not support default properties for the controller. Since a controller model might be used to generate code for an embedded processor, these constraints apply to the referenced controller model and the interface with its parent model:

- Fixed Signal Attributes — To require that buses at model interfaces share the same signal attributes, bus objects specify signal attributes at the three sets of input and output ports.
- Discrete Sample Time — To specify a discrete sample time, model `ex_modeling_controller` specifies a discrete execution domain and script `ex_modeling_data_controller.m` specifies discrete PID controller values.

- Fixed Data Type — To apply the single-precision data type required by the embedded processor, Data Type Conversion blocks convert the bus element data types before they reach the model interface.

Create Interchangeable Variations of Model Components

To add flexibility to a model so that it can cater to different requirements, you can use variant subsystems and models. Variants allow you to choose among multiple variations of a component within a single model. You can change the active variant without modifying the model by changing the values of variant control variables at the MATLAB® command prompt.

Model `ex_modeling_variants` includes three variant choices for the operator subsystem.

Operator 1 is the active variant defined by script `ex_modeling_variant_choice.m`. To determine the goal position for the mechanical system, this operator implements procedural logic with a Stateflow® chart.

Inactive variants and their contents are grayed out. To define the goal position for the mechanical system position, inactive variant subsystem Operator 2 uses a Waveform Generator block.

Variant choice Operator 3 is an inactive variant model. Variant Subsystem blocks allow both subsystems and models as variant choices.

- “What Are Variants and When to Use Them” on page 11-3
- “Working with Variant Choices” on page 11-27

Set up a File Management System

As a model grows, managing referenced files and dependencies becomes more complicated. To reduce the complexity of managing large models, you can use projects. Projects in Simulink help to organize large model hierarchies by finding required files, managing and sharing files and settings, and interacting with source control.

MATLAB® script `ex_modeling_project_setup.m` creates a project that contains these files:

- Model `ex_modeling_variants.slx`
- Model `ex_modeling_controller.slx`
- Model `ex_modeling_operator_variant.slx`
- Library `ex_modeling_library.slx`
- MATLAB script `ex_modeling_data_mechanical_system.m`
- MATLAB script `ex_modeling_data_controller.m`
- MATLAB script `ex_modeling_variant_choice.m`
- MATLAB function `ex_modeling_bus_objects.m`

To open this script, enter this command in the MATLAB command prompt:

```
openExample('simulink/SetupAFileManagementSystemExample')
```

Run the script to create the project.

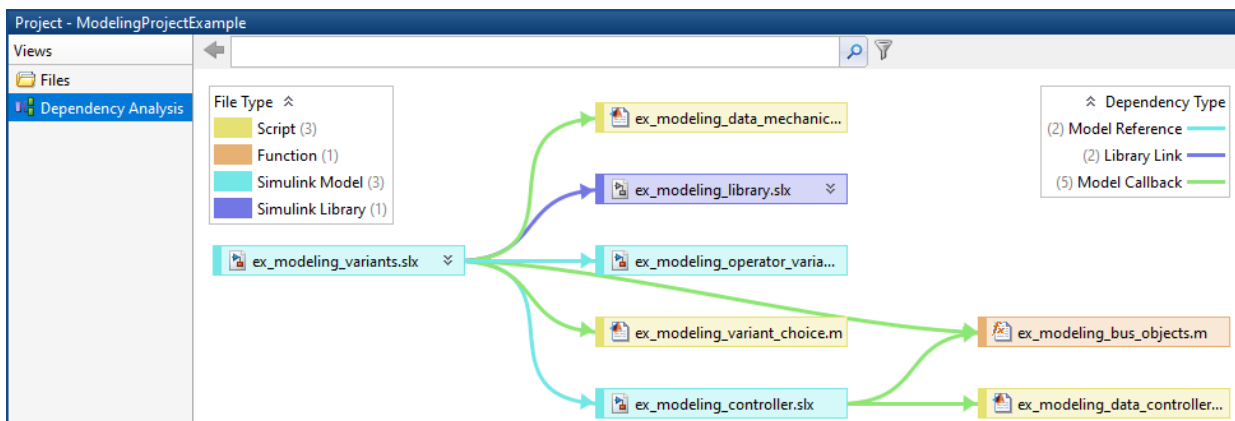

Project - ModelingProjectExample			
Views	All	Project (8)	
Files			
Dependency Analysis			
Name	Status	Type	
 <code>ex_modeling_variants.slx</code>	✓	Simulink Model	
 <code>ex_modeling_operator_variant.slx</code>	✓	Simulink Model	
 <code>ex_modeling_controller.slx</code>	✓	Simulink Model	
 <code>ex_modeling_library.slx</code>	✓	Simulink Library	
 <code>ex_modeling_variant_choice.m</code>	✓ 	Script	
 <code>ex_modeling_data_mechanical_system.m</code>	✓ 	Script	
 <code>ex_modeling_data_controller.m</code>	✓ 	Script	
 <code>ex_modeling_bus_objects.m</code>	✓ 	Function	

The MATLAB scripts and function are configured to **Run at Startup**.

Using this project, you can explore project capabilities, such as these capabilities:

- Automate tasks
- Create shortcuts for common actions
- Analyze file dependencies
- Analyze the impact of changing files
- Compare model files

Performing a dependency analysis shows that the MATLAB scripts and function are being run by model callbacks.

Since these files now run at startup, the model callbacks are redundant and can be removed.

The dependency analysis also shows the two-level model hierarchy, in which the top model depends on a library and referenced model.

Organize Large Modeling Projects

You can use projects to help you organize your work. To get started with managing your files in a project:

- 1 Try an example project to see how the tools can help you organize your work. See “Explore Project Tools with the Airframe Project” on page 16-5.
- 2 Create a new project. See “Create a New Project From a Folder” on page 16-16.
- 3 Use the Dependency Analysis view to analyze your project and check required files. See “Run Dependency Analysis” on page 18-4.
- 4 Explore views of your files. See “Work with Project Files” on page 17-8.
- 5 Create shortcuts to save and run frequent tasks. See “Use Shortcuts to Find and Run Frequent Tasks” on page 16-39.
- 6 Run custom task operations on batches of files. See “Run a Project Custom Task and Publish Report” on page 17-41.
- 7 If you use a source control integration, you can use the **Modified** files view to review changes, compare revisions, and commit modified files. If you want to use source control with your project, see “About Source Control with Projects” on page 19-2.

For guidelines on structuring projects, see “Capabilities of Model Components” on page 15-29.

What Are Projects?

You can use projects to help you organize your work. Find all your required files; manage and share files, settings, and user-defined tasks; and interact with source control.

If your work involves any of the following:

- More than one model file
- More than one model developer
- More than one model version

— then a project can help you organize your work. You can manage all the files you need in one place — all MATLAB and Simulink files, and any other file types you need such as data, requirements, reports, spreadsheets, tests, or generated files.

Projects can promote more efficient team work and individual productivity by helping you:

- Find all the files that belong with your project.
- Create standard ways to initialize and shut down a project.
- Create, store, and easily access common operations.
- View and label modified files for peer review workflows.
- Share projects using built-in integration with Subversion® (SVN) or Git™, external source control tools.

Starting in R2019a, you can use projects in MATLAB, with or without Simulink. You can share projects with users who do not have Simulink.

For information on basic project workflows in MATLAB, see “Projects” (MATLAB).

Projects provide additional tools to help with Simulink workflows. For example:

- Opening models and running customizations on startup
- Checking for shadowed model files
- Dependency analysis of models, subsystems, libraries and library blocks, data files, requirements, and generated code
- Automatic refactoring help for models, libraries, library links, model references, model callbacks, S-functions, busses and bus elements
- Comparing and merging differences in models.

For help on project workflows in Simulink, see “Project Management”.

See the Web page <https://uk.mathworks.com/products/simulink/projects.html> for the latest information, downloads, and videos.

To get started with managing your files in a project:

- 1** Try an example project to see how the tools can help you organize your work. See “Explore Project Tools with the Airframe Project” on page 16-5.
- 2** Create a new project. See “Create a New Project From a Folder” on page 16-16.
- 3** Analyze your project and check required files by using the Dependency Analysis view. See “Run Dependency Analysis” on page 18-4.
- 4** Explore views of your files. See “Work with Project Files” on page 17-8.
- 5** Create shortcuts to save and run frequent tasks. See “Use Shortcuts to Find and Run Frequent Tasks” on page 16-39.
- 6** Run custom task operations on batches of files. See “Run a Project Custom Task and Publish Report” on page 17-41.
- 7** If you use a source control integration, you can use the **Modified** files view to review changes, compare revisions, and commit modified files. If you want to use source control with your project, see “About Source Control with Projects” on page 19-2.

For guidelines on structuring projects, see “Large-Scale Modeling”.

Explore Project Tools with the Airframe Project

In this section...

- “Explore the Airframe Project” on page 16-5
- “Set Up Project Files and Open the Project” on page 16-6
- “View, Search, and Sort Project Files” on page 16-6
- “Open and Run Frequently Used Files” on page 16-7
- “Review Changes in Modified Files” on page 16-8
- “Run Dependency Analysis” on page 16-10
- “Run Project Integrity Checks” on page 16-11
- “Commit Modified Files” on page 16-12
- “View Project and Source Control Information” on page 16-12

Explore the Airframe Project

Try an example project to see how the tools can help you organize your work. Projects can help you manage:

- Your design (model and library files, `.m`, `.mat`, and other files, source code for S-functions, and data)
- A set of actions to use with your project (run setup code, open models, simulate, build, and run shutdown code)
- Working with files under source control (check out, compare revisions, tag or label, and check in)

The Airframe example shows how to:

- 1 Set up and browse some example project files under source control.
- 2 Examine project shortcuts to access frequently used files and tasks.
- 3 Analyze dependencies in the example project and locate required files that are not yet in the project.
- 4 Modify some project files, find and review modified files, compare to an ancestor version, and commit modified files to source control.
- 5 Explore views of project files only, modified files, and all files under the project root folder.

Set Up Project Files and Open the Project

Run this command to create a working copy of the project files and open the project:

```
sldemo_slproject_airframe
```

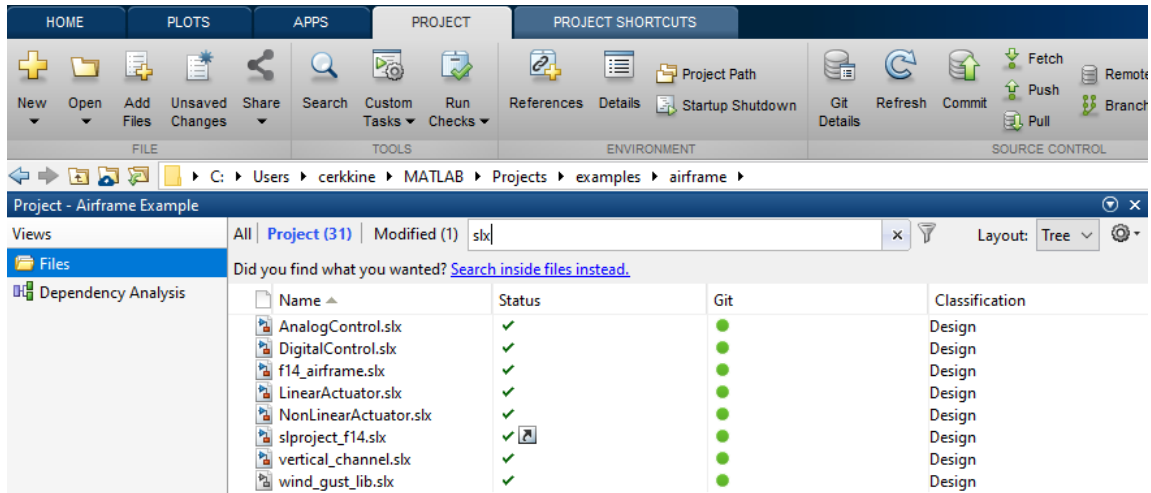

The project example copies files to your temporary folder so that you can edit them and put them under Git source control.

The Project window opens and loads the project. The project is configured to run some startup tasks, including changing the current working folder to the project root folder.

Note Alternatively, you can try this example project using SVN source control, by specifying `sldemo_slproject_airframe_svn`. The following example shows the options when using Git.

View, Search, and Sort Project Files

- 1 In a Project, examine the **Files** view to manage the files within your project. When the **Project (*number of files*)** view is selected, only the files in your project are shown.
- 2 To see all the files in your sandbox, click **All**. This view shows all the files that are under the project root, not just the files that are in the project. This view is useful for adding files to the project from your sandbox.
- 3 To find particular files or file types, in any file view, type in the search box or click the Filter button. You can also search inside files.

Click the x to clear the search.

- 4 To view files as a list instead of a tree, use the Layout control.
- 5 To sort files and to customize the columns, click the Organize view button at the far right of the search box.
- 6 You can dock and undock the Project into the MATLAB Desktop. If you want to maximize space for viewing your project files, undock the Project. Drag the title bar to undock it.

Open and Run Frequently Used Files

You can use shortcuts to make scripts easier to find in a large project. View and run shortcuts on the Project Shortcuts toolstrip. You can organize the shortcuts into groups.

In this example, the script that regenerates S-functions is set as a shortcut so that a new user of the project can easily find it. You can also make the top-level model, or models, within a project easier to find. In this example, the top-level model, `slproject_f14.mdl`, is a shortcut.

Regenerate the S-functions.

- 1 On the Project Shortcuts tab in the toolstrip, click the shortcut **Rebuild Project's S-functions**.

The shortcut file builds a MEX-file. If you do not have a compiler set up, follow the instructions to choose a compiler.

- 2 Open the `rebuild_s_functions.m` file to explore how it works.

Open the top model.

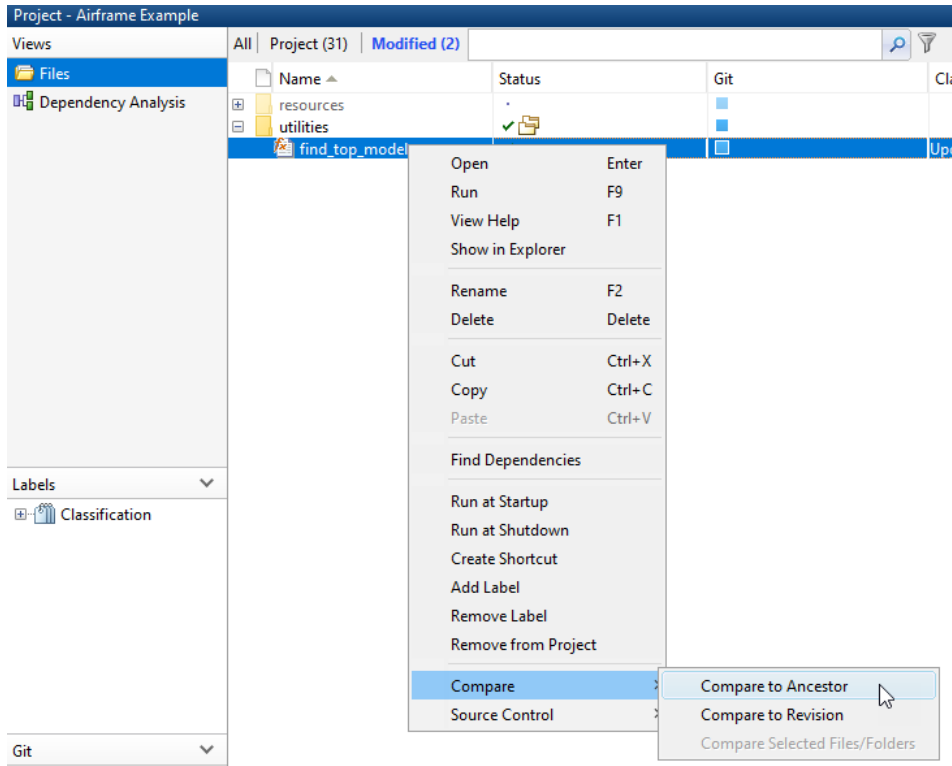

- On the Project Shortcuts tab, click the shortcut **F14 Model** to open the root model for this project.
- To create shortcuts to access frequently used files, select the **Files** view, right-click a file, and select **Create Shortcut**.

You can also specify files to run at startup and shutdown. See “Automate Startup Tasks” on page 16-33.

Review Changes in Modified Files

Open and make changes to files and review changes.

- 1 Select the Files view. View folders using the tree layout, and then expand the `utilities` folder.
- 2 Either double-click to open the `find_top_models` file for editing from the project, or right-click and select **Open**.
- 3 Make a change in the Editor, such as adding a comment, and save the file.
- 4 In the project Files view, select the tab **Modified (number of files)**. After editing the file, you see **Modified (2)**. The files you changed appear in the list. You edited a file in the `utilities` folder. Observe that the Modified files list also includes a `resources` folder. The files stored in the `resources` folder are internal project definition files generated by your changes. The project definition files allow you to add metadata to files, for example, by creating shortcuts, adding labels, and adding a project description. Project definition files also define the files that are added to your project. You can review changes in revisions of project definition files like any other project files. See “Project Definition Files” on page 19-42.
- 5 To review changes, right-click the `find_top_models` file in the **Modified** files view and select **Compare > Compare to Ancestor**.

The MATLAB Comparison Tool opens a report comparing the modified version of the file in your sandbox against its ancestor stored in the version control tool. The comparison report type can differ depending on the file you select. If you select a Simulink model to **Compare > Compare to Ancestor**, this command runs a Simulink model comparison.

To compare models, try the following example.

- 1 In the Files view, select the **Project (number of files)** tab, and expand the models folder.
- 2 Either double-click to open the AnalogControl file for editing from the project, or right-click and select **Open**.
- 3 Make a change in the model, such as opening a block and changing some parameters, and then save the model.

- To review changes, select the **Modified (number of files)** tab. Right-click the modified model file and select **Compare > Compare to Ancestor**.

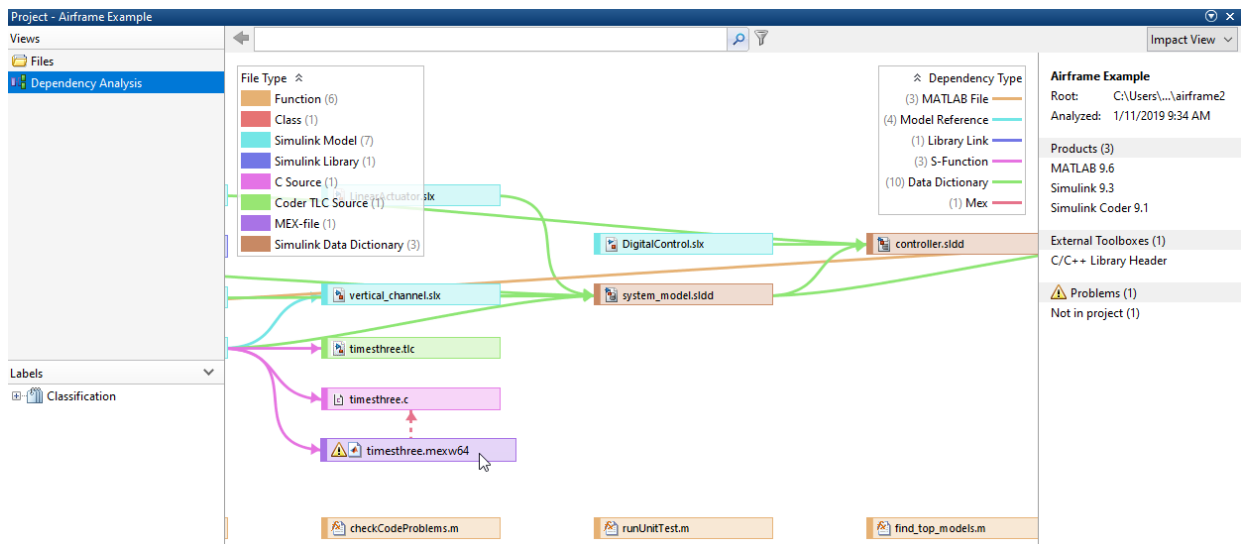

The Comparison Tool opens a report.

Run Dependency Analysis

To check that all required files are in the project, run a file dependency analysis on the modified files in your project.

- In the Views pane, select **Dependency Analysis**.
- Click **Analyze**.

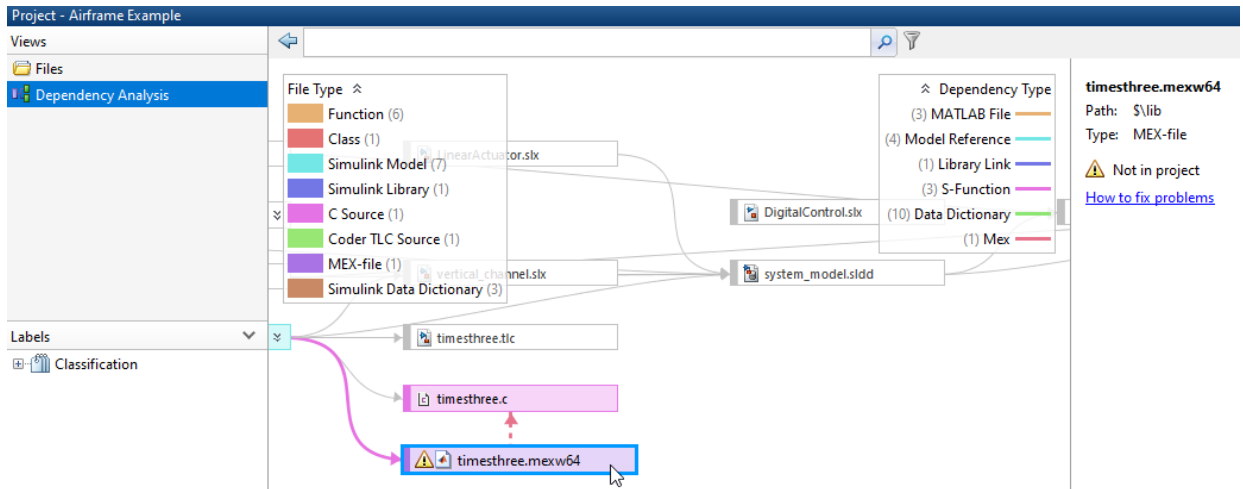

The Impact graph displays the structure of all analyzed dependencies in the project. The right pane lists required toolboxes and any problem files.

- To view the files that use a problem file, hover over the messages under **Problems** and click **Find All**.

The graph updates to display only the problem file, and the problem message in the right panel. The file is not in the project. To view the dependencies of the problem file, on the Dependency Analysis tab, in the Impact Analysis section, select **Find > All Dependencies of Selection**.

- Observe that `timesthree.mex64` is an S-function binary file required by `f14_airframe.slx`. You can add binary files to your project or, as in this project, provide a utility script that regenerates them from the source code that is part of the project.

- To remove the file from the problem files list, right-click the file and select **Add External File**. The next time you run a dependency analysis, the file does not appear as a problem file.

In this example, you do not want to add the binary file to the project, but instead use the script to regenerate the binary file from the source code in the project. Use **Add External File** to stop such files being marked as problems.

- On the **Dependency Analysis** tab, in the **Impact Analysis** section, select **Find > All Files**.
- In the **Impact Analysis** section, choose **Select > Modified Files**.
- To view dependencies of the modified files, in the **Impact Analysis** section, select **Find > All Dependencies of Selection**.

Run Project Integrity Checks

To make sure that your changes are ready to commit, check your project. On the Project tab in the toolstrip, click **Run Checks** to run the project integrity checks. The checks look for missing files, files to add to source control or retrieve from source control, and other

issues. The checks dialog box can offer automatic fixes to problems found. When you click a **Details** button in the Checks dialog box, you can view recommended actions and decide whether to make the changes.

For an example using the project checks to fix issues, see “Upgrade Model Files to SLX and Preserve Revision History” on page 17-18.

Commit Modified Files

After you modify files and you are satisfied with the results of the checks, you can commit your changes to the source control repository.

- 1 In the Files view, select the **Modified (number of files)** tab. The files you changed appear in the list.
- 2 To commit your changes to source control, on the Project tab, in the Source Control section, click **Commit**.
- 3 Enter a comment for your submission, and click **Submit**.

Watch the messages in the status bar as the source control commits your changes. Git commits to your local repository. To commit to the remote repository, use **Push** in the Source Control section. See “Pull, Push, and Fetch Files with Git” on page 19-53

View Project and Source Control Information

- To view and edit project details, on the **Project** tab, in the **Environment** section, click **Details**. View and edit details such as the name, description, project root, startup folder, and generated files folders such as the `slprj` folder.
- To view details about the source control integration and repository location, on the Project tab, in the Source Control section, click **Git Details**. This Airframe example project uses Git source control.

Alternatively, use the project API to get the current project:

```
project = currentProject;
```

You can use the project API to get all the project details and manipulate the project at the command line. See `currentProject`.

For next steps, see “Project Management”.

- “About Source Control with Projects” on page 19-2

Create a Project from a Model

Create a project to organize your model and any dependent files. Use **Create Project from Model** to run a dependency analysis on your top model to identify required files.

Tip For a simpler option that automates more steps for you, see instead “Create a New Project From a Folder” on page 16-16.

Projects can help you organize your work and collaborate in teams. The project can help you to:

- Find all your required files
- Manage and share files, settings, and user-defined tasks
- Interact with source control.

1 In a Simulink model, select **File > Project > Create Project from Model**.

Simulink runs dependency analysis on your model to identify required files and a project root location that contains all dependencies.

2 In the New Project dialog box, edit any settings you want to change:

- **Project name** — By default, the name of the suggested project root folder. Edit if desired.
- **Project folder** — A folder that dependency analysis identified to contain all dependencies. If you want, click to select a different folder in the file system hierarchy between the file system root and the model folder.
- **Files to include** — Files to include in the project. Files with selected check boxes are identified by dependency analysis. Select check boxes to specify all the files you want to include.

Any external dependencies are listed. If required files are outside your project root, then you cannot add these files to your project. An external dependency might not indicate a problem if the file is on your path and is a utility or other resource that is not part of your project.

- If you do not want to make a shortcut to the top-level file, or add all the folders to the project path, under **More Options**, clear the check boxes. Alternatively, you can edit these project settings later.

- 3 Click **Create** to create the project containing your model and any other specified files.

For an example showing what you can do with projects, see “Explore Project Tools with the Airframe Project” on page 16-5.

- “About Source Control with Projects” on page 19-2

Create a New Project From a Folder

If you have many files that you want to organize into a project, with or without source control, use the following steps to create a new project.

Note If you want to retrieve a project from a source control repository, see instead “Clone Git Repository or Check Out SVN Repository” on page 19-30.

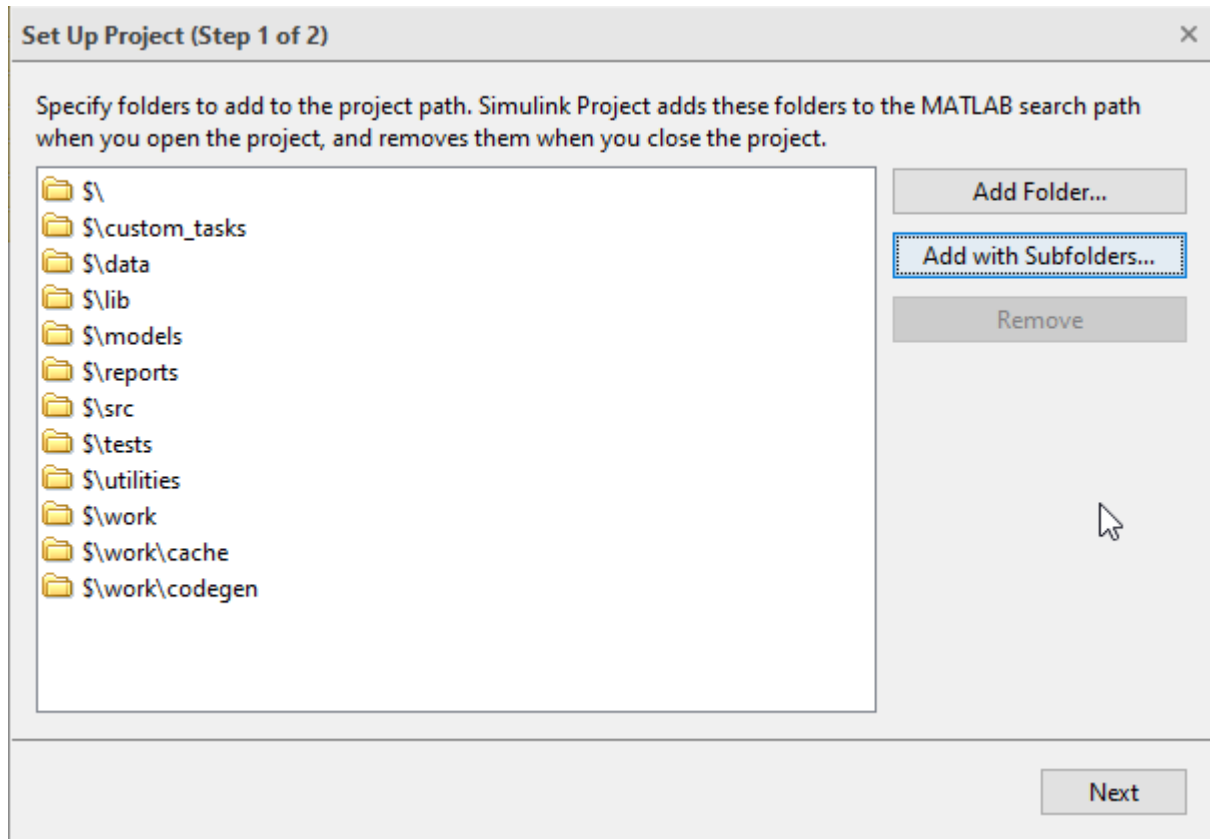

Easily convert a folder of files into a project by using the **Folder to Project** template in the Simulink start page. The template automatically adds your files to the project and prompts you to set up the path and startup files. This simple, quick process sets up your project to manage your files and introduces you to project features. When you open the project, it automatically puts the folders you need on the path, and runs any setup operations to configure your environment. Startup files automatically run (.m and .p files), load (.mat files), and open (Simulink models) when you open the project.

To create a new project to manage your files:

- On the MATLAB **Home** tab, select **New > Project > From Folder**.
 - Alternatively, in the Simulink start page, click the **Folder to Project** template. You can also select **File > New > Project** from the Model Editor.
- 1** In the New Project dialog box, enter a project name, browse to select the folder containing your files, and click **OK**.
 - 2** In the Welcome to your project dialog box, click **Set Up Project** to continue.

- 3** In the Set Up Project (Step 1 of 2) dialog box, optionally choose folders to add to the project path. When you open the project, it adds these folders to your MATLAB search path, and removes them when you close the project. Add project folders to ensure dependency analysis detects project files. To add all project folders, click **Add with Subfolders** and then select the project folder containing all your subfolders. Alternatively, you can set up the project path later. Click **Next**.

- 4 In the Set Up Project (Step 2 of 2) dialog box, optionally specify startup and shutdown files.
 - Use startup files to configure settings when you open the project. Startup files automatically run (.m and .p files), load (.mat files), or open (Simulink models) when you open the project.
 - Use shutdown files to specify MATLAB code to run as the project shuts down. You do not need to use shutdown files to close models when you close a project, because it automatically closes any project models that are open, unless they are dirty. The project prompts you to save or discard changes.

Click **Add** to specify startup or shutdown files. Alternatively, you can setup these files later.

- 5 Click **Finish** and your new project opens. The **Folder to Project** template automatically adds all your files to the project. The template does not add derived files to your project.

For next steps, try dependency analysis to visualize the structure of your project, or consider adding source control to help you manage versions. For details, see “Run Dependency Analysis” on page 18-4 or “Add a Project to Source Control” on page 19-6.

As alternatives to the **Folder to Project** template, you can:

- Create a project from a model by analyzing it for dependent files that you want to put in a project. See “Create a Project from a Model” on page 16-14

- Create projects manually, but then you need to add files to the project and configure the path, startup, and shutdown files. To examine the alternative templates, or to use your own templates:
 - 1** In the Simulink start page, click templates in the list to read the descriptions. If you selected a new project option to open the start page, the list shows only project templates, or you can filter the list for Project Templates using the list next to the Search box.
 - Select the **Blank Project** template if you are creating a project in a folder with existing files and want to set up the project manually. The **Blank Project** template creates a project in your selected folder and leaves any other files untouched. You must manually set up the project, for example by adding files to the project, configuring startup files, configuring the project path, etc.
 - Try the **Simple Project** template if you are creating a project in a new folder and want a blank model. The **Simple Project** template creates a simple project containing a blank model and some utilities. The model is a shortcut so you can open it from the toolstrip. The project manages your path and the location of the temporary files (slprj folder) when you open and close the project. You can modify any of these files, folders, and settings later.
 - You can create your own templates. See “Using Templates to Create Standard Project Settings” on page 16-40.
 - 2** In the start page, select a template and click **Create Project**.
 - 3** In the Create Project dialog box, specify your project folder and edit the project name, and click **Create Project**. You can control the default folder for new projects using the project preferences.

The Project displays the project files view for the specified project root. You need to add files to the project. See “Add Files to the Project” on page 16-22.

For next steps using your new project, try dependency analysis to visualize the structure of your files.

- “Add Files to the Project” on page 16-22
- “Work with Project Files” on page 17-8
- “Create Shortcuts to Frequent Tasks” on page 16-36
- “Add a Project to Source Control” on page 19-6

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Add Files to the Project

If you create a project from a folder, from a model, or with a Git or SVN template from the start page, then the project setup helps you add initial files to the project. If you create a new blank project, then the project files view is empty and you need to add files to the project.

To display all files in your project folder (or `projectroot`), in the **Files** view, click **All**. You might not want to include all files in your project. For example, you might want to exclude some files under `projectroot` from your project, such as SVN or CVS source control folders.

To add existing files to your project:

- 1 On the Project tab, in the File section, click **Add Files**.
- 2 Select from the list of unmanaged files in the project folder.

Use **Add Files** any time you want to check for new files not yet added to the project.

Alternatively, you can use these methods to add files:

- In the **All** files view, select files or folders, right-click, and select **Add to Project** or **Add to Project (including child files)**.
- To add files to your project, cut and paste or drag and drop files from a file browser or the Current Folder browser onto the **Project** files view. If you drag a file from outside the project root, this moves the file and adds it to your project. You can drag files within project root to move them.
- Add and remove project files at the command line using `addFile`.

To create new files or folders in the project, right-click a white space in the **Files** view and select **New Folder** or **New File**. The new files are added to the project.

To learn how to set up your project with all required files, see “Run Dependency Analysis” on page 18-4.

To add or remove project folders from the MATLAB search path, see “Specify Project Path” on page 16-30.

To configure your project to automatically run startup and shutdown tasks, see “Automate Startup Tasks” on page 16-33.

You can access your recent projects direct from MATLAB. See “Open Recent Projects” on page 16-27.

If you want to add source control, see “Add a Project to Source Control” on page 19-6.

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Create a New Project from an Archived Project

To create a new project from an archived project:

- 1 Locate and double-click the `m\proj` file in the Current Folder, Windows Explorer, or Apple Finder.

If you do not have a product that the project requires, you see a warning with a link to the Add-On Explorer to get missing products.

- 2 In the Extract Project to dialog box, specify the location of the new project and click **Select Folder**.

The new project opens. The current working folder is the location of the new project, which is a new subfolder of the extraction folder.

If you have a project archived in a zip file, double click or right click to extract the project. The current working folder, for example, `C:\myNewProject`, contains the imported project folders. If the zip project contains referenced projects, the project imports files into two subfolders, `main` and `refs`. The current working folder, for example, `C:\myNewProject\main` contains the project folders and `C:\myNewProject\refs` contains the referenced project folders. To open the project, navigate into `main` to locate and double-click the `prj` file.

Create a New Project Using Templates

In a project, you can use templates to create and reuse a standard project structure.

- 1 To browse for templates, click **Simulink** on the MATLAB Home tab, or on the Project tab, click **New**.
- 2 In the Simulink start page, click a template in the list to read the description. For example, click **Simple Project**.
- 3 The start page shows all project templates (*.sltx) on the MATLAB path. If your templates do not appear, locate them by clicking **Open**. In the Open dialog box, make *.sltx files visible by changing the file type list **Model Files** to **All MATLAB files**, and browse to your template.
- 4 In the start page, select a template and click **Create Project**.

Templates created in R2017b or later warn you if required products are missing. Click the links to open Add-On Explorer and install required products.

- 5 In the Create Project dialog box, specify your project folder and edit the project name, and click **Create Project**.

Use Project Templates from R2014a or Before

To use project templates created in R2014a or earlier (.zip files), upgrade them to .sltx files using `Simulink.exportToTemplate`.

After you upgrade the templates to .sltx and put them on the MATLAB path, you can use the templates from the start page.

Open Recent Projects

Note You can have one project open at a time, to avoid conflicts. If you open another project, any currently open project closes.

You can use any of these methods to open recent projects:

- On the MATLAB **Home** tab, click **Simulink**, and select your project in the recent list.
If you select a recent model that is part of a project, you can choose to also open the project.
- On the MATLAB **Home** tab, click the **Open** arrow and select your project under the **Recent Projects** list.
- From the Current Folder browser, double-click the `.prj` file.
- In the Simulink Editor, if an open model, library, or chart belongs to a project, you can select **File > Project > Open Project**.

Alternatively, open the project by entering `simulinkproject`, or in the Simulink Editor, select **View > Project**. When the Project is open, you can open projects with these methods:

- On the **Project** tab, click the **Open** arrow and select your project under the **Recent** list.
- Select **Open > Open**. Browse and select your project `.prj` file.

Tip Create a MATLAB shortcut for opening or giving focus to the Project by dragging this command to the toolstrip from the Command History or Command Window:

```
simulinkproject
```

When you open a project, you are prompted if loaded files shadow your project model files. To avoid working on the wrong files, close the shadowing files. See “Manage Shadowed and Dirty Models and Other Project Files” on page 17-10.

Specify Project Details, Startup Folder, and Derived Files Folders

On the Project tab, in the Environment section, click **Details**. Use the Project Details dialog box for the following tasks:

- Edit the project name or add a description.
- View the **Project root** folder. You can change your project root by moving your entire project on your file system, and reopening your project in its new location. All project file paths are stored as relative paths. To change the current working folder to your project root, click **Set As Current Folder**.
- View or edit the **Start Up** folder. By default, this is set to the project root. When you open the project, the current working folder changes to the project root folder. You can specify a different startup folder or click **Clear**.

You can also configure startup scripts that set the current folder and perform other setup tasks. If you configure startup files to set the current folder, your startup setting takes precedence over the startup folder at the Project Details dialog box. To set up startup files, see “Automate Startup Tasks” on page 16-33.

- View or edit the **Generated Files** folders. You can set the **Simulink cache folder** and **Code generation folder**. For details, see “Manage Build Process Folders” (Simulink Coder).
- If you edit any project details, then click **OK** to save your changes.

If you are looking for source control information for your project, see instead the details button for your source control in the Source Control section of the Project tab, e.g., **SVN Details**. See “Add a Project to Source Control” on page 19-6.

See Also

Related Examples

Specify Project Path

- When you open your project, it adds the project path to the MATLAB search path before applying startup shortcuts.
- When you close your project, it removes the project path from the MATLAB search path after applying shutdown shortcuts.

You can add or remove folders from the project path. Add project folders to ensure dependency analysis detects project files. On the **Project** tab, in the **Environment** section, click **Project Path**:

- To add a folder (without subfolders) to the project path, click **Add Folder**. If you want to add a folder and its subfolders, click **Add with Subfolders** instead. Then use the Open dialog box to add the new folder.
- To remove a folder from the project path, from the display list, select the folder. Then click **Remove**.

In the **Project > Files** view, you can use the context menu to add or remove folders from the project path. Right-click a folder and select **Project Path > Add to Project Path**, or **Add to the Project Path (Including Subfolders)**, or one of the options to remove the folder from the path.

Folders on the project path display the project path icon in the **Status** column.

Name ^	Status	SVN	Revision	Type	Classification
batch_jobs			2	Folder	None
data			2	Folder	None
models			2	Folder	None
reports			2	Folder	None
src			2	Folder	None
tests			2	Folder	None
utilities			2	Folder	None
work			2	Folder	None
src (Folder)					

If you want to set the startup folder, see the check box option at the root project node:
Change current folder to project root on start up.

- “What Can You Do With Project Shortcuts?” on page 16-32

What Can You Do With Project Shortcuts?

In a project, use shortcuts to make it easy for any project user to find and access important files and operations. You can use shortcuts to make top models or scripts easier to find in a large project. You can group shortcuts to organize them by type and annotate them to use meaningful names instead of cryptic file names.

Using the Project Shortcuts tab in the toolstrip, you can execute, group, or annotate shortcuts. Run shortcuts by clicking them in the Project Shortcuts tab or execute them manually from the context menu.

To automate tasks, use startup and shutdown files instead. You can use startup files to help you set up the environment for your project, and shutdown shortcuts to help you clean up the environment for the current project when you close it.

- “Automate Startup Tasks” on page 16-33
- “Automate Shutdown Tasks” on page 16-35
- “Specify Project Path” on page 16-30

Automate Startup Tasks

In a project, startup files help you set up the environment for your project.

Startup files are automatically run (.m and .p files), loaded (.mat files), and opened (Simulink models) when you open the project.

Note Startup scripts can have any name. You do not need to use `startup.m`

You can use a file named `startup.m` on the MATLAB path which runs when you start MATLAB. If your `startup.m` file calls the project with `simulinkproject`, an error appears because no project is loaded yet. To avoid the error, rename `startup.m` and use it as a project startup file instead.

Configure an existing file to run when you open your project.

- Right-click the file and select **Run at Startup** .
- Alternatively, on the Project tab, click **Startup Shutdown**. In the Manage Project Startup and Shutdown dialog box, you can add and remove startup and shutdown files. If execution order is important, change the order using the arrow buttons.

In the files view, the **Status** column displays an icon and tooltip indicating the file will run at startup.

Note Startup file settings are included when you commit modified files to source control. Any startup tasks you create run for all other project users.

To stop a file running at startup, change back by right-clicking it and selecting **Remove from Startup**.

On the Manage Project Startup and Shutdown dialog box, use the check boxes to specify environment options:

- **Start Simulink before this project starts**-This option starts Simulink when you open the project.
- **Refresh Simulink customizations**- This option runs `sl_customization` files on project startup and shutdown.

When you open the project, the startup files run. Also, the current working folder changes to the project startup folder. If you want to set the startup folder, on the Project tab, click **Details** and edit the **Start Up** folder. See “Specify Project Details, Startup Folder, and Derived Files Folders” on page 16-29.

You can create new startup and shutdown files interactively in the project or at the command line. For details, see `addStartupFile`.

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Automate Shutdown Tasks

In a project, shutdown files help you clean up the environment for the current project when you close it. Shutdown files should undo the settings applied in startup files.

Configure an existing file to run when you close your project.

- 1 Right-click the file and select **Run at Shutdown**.

The **Status** column displays an icon and tooltip indicating the file will run at shutdown.

Note Shutdown files are included when you commit modified files to source control. Any shutdown files you set run for all other project users.

To stop a file running at shutdown, change it back by right-clicking it and selecting **Remove from Shutdown**.

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Create Shortcuts to Frequent Tasks

In this section...
“Create Shortcuts” on page 16-36
“Group Shortcuts” on page 16-36
“Annotate Shortcuts to Use Meaningful Names” on page 16-37
“Customize Shortcut Icons” on page 16-37

Create Shortcuts

In a project, create shortcuts for common project tasks and to make it easy to find and access important files and operations. For example, find and open top models, run code (for example, to load data), and simulate models. To run startup or shutdown code, see instead “Automate Startup Tasks” on page 16-33.

To configure an existing project file as a shortcut, use any of the following methods:

- In the **Files** view, right-click the project file and select **Create Shortcut**. In the Create New Shortcut dialog box, you can edit the shortcut name, choose an icon, and select a group if you have created a shortcut group you want to use. You can change shortcut group later. Click **OK**.
- Click **New Shortcut** on the Project Shortcuts tab on the toolstrip and browse to select a file.

The shortcut appears on the Project Shortcuts tab on the toolstrip.

In the files view, the **Status** column displays an icon and tooltip indicating the file is a shortcut.

Note Shortcuts are included when you commit your modified files to source control, so you can share shortcuts with other project users.

Group Shortcuts

You can group shortcuts to organize them by type. For example, you can group shortcuts for loading data, opening models, generating code, and running tests.

You can select a shortcut group when creating shortcuts, or manage groups later on the Project Shortcuts toolbar tab.

Create new shortcut groups to organize your shortcuts:

- On the Project Shortcuts tab, click **Organize Groups**.
- Click **Create**, enter a name for the group and click **OK**.

The new shortcut group appears on the Project Shortcuts tab.

To organize your shortcuts by group, either:

- Select a group when creating a shortcut.
- In the **Project** files view, right-click a file and select **Edit Shortcut**.
- On the Project Shortcuts tab, right-click a file and select **Edit Shortcut**.

The shortcuts are organized by group in the Project Shortcuts toolbar tab.

Annotate Shortcuts to Use Meaningful Names

Annotating shortcuts makes their purpose visible, without changing the file name or location of the script or model the shortcut points to. For example, you can change a cryptic file name to a descriptive name for the shortcut. To put shortcuts in a workflow order on the toolbar, prefix the shortcut names with numbers.

When creating a shortcut, edit the **Name**. The shortcut name does not affect the file name or location.

Your specified shortcut name appears on the Project Shortcuts tab, to make it easier to find your shortcuts.

Customize Shortcut Icons

You can specify an icon to use for your shortcut buttons on the Project Shortcuts tab. Icons such as "build" can aid other project users to recognize frequent tasks.

- 1 When creating a shortcut, choose an icon.
- 2 Select an image file. Images must be exactly 16 pixels square, and a png or a gif file.

More About

- “What Can You Do With Project Shortcuts?” on page 16-32

Use Shortcuts to Find and Run Frequent Tasks

In a project, use shortcuts to make it easy for any project user to find and access important files and operations. You can use shortcuts to make top models or scripts easier to find in a large project. Shortcuts are available from any file view via the toolstrip.

If your project does not yet contain any shortcuts, see “Create Shortcuts to Frequent Tasks” on page 16-36.

To use shortcuts:

- In the Project Shortcuts toolstrip tab, click the shortcut. Clicking a shortcut in the toolstrip performs the default action for the file type, for example, run `.m` files, load `.mat` files, and open models. Hover over a shortcut to view the full path.

Choose which behavior you want when running shortcuts:

- If the script is not on the path, and you want to switch to the parent folder and run the script without being prompted, then click the shortcut in the Project Shortcuts toolstrip tab. If you use this option, the result of `pwd` in the script is the parent folder of the script.
- If you select **Run** in the **Files** view context menu, and the script is not on the path, then MATLAB asks if you want to change folder or add the folder to the path. This is the same behavior as running from the Current Folder browser. If you use this option, the result of `pwd` in the script is the current folder when you run the script.

Create Templates for Standard Project Settings

In this section...
“Using Templates to Create Standard Project Settings” on page 16-40
“Create a Template from the Current Project” on page 16-40
“Create a Template from a Project Under Version Control” on page 16-41
“Edit a Template” on page 16-41
“Explore the Example Templates” on page 16-42

Using Templates to Create Standard Project Settings

In a project, use templates to create and reuse a standard project structure. Templates help you make consistent projects across teams. You can use templates to create new projects that:

- Use a standard folder structure.
- Set up a company standard environment, for example, with company libraries on the path.
- Have access to tools such as company Model Advisor checks.
- Use company standard startup and shutdown scripts.
- Share labels and categories.

You can use templates to share information and best practices. You or your colleagues can create templates.

Create a template from a project when it is useful to reuse or share with others. You can use the template when creating new projects.

Create a Template from the Current Project

In a project, when you create a template, it contains the structure and all the contents of the current project, enabling you to reuse scripts and other files for your standard project setup. You can choose whether to include the contents of referenced projects in the template.

- 1 Before creating the template, create a copy of the project, and edit the copy to contain only the files you want to reuse. Use the copy as the basis for the template.

Note If the project is under version control, see instead “Create a Template from a Project Under Version Control” on page 16-41.

- 2 On the **Project** tab, in the **File** section, select **Share > Template**.
- 3 On the Create Project Template dialog box, edit the name and author, add a description to help template users.
- 4 If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
- 5 Click **Save As**. Choose a file location and click **Save**

Create a Template from a Project Under Version Control

- 1 Get a new working copy of the project. See “Clone Git Repository or Check Out SVN Repository” on page 19-30.
- 2 To avoid accidentally committing changes to your project meant only for the template, stop using source control with this sandbox as you work on the template. In the Source Control view, under **Available Source Control Integrations**, select **No Source Control Integration** and click **Reload**.
- 3 Remove the files that you do not want in the template. For example, you might want to reuse only the utility functions, startup and shutdown scripts, and labels. In the **Files** view, right-click unwanted files and select **Remove from Project**.
- 4 On the **Project** tab, in the **File** section, select **Share > Template** and use the dialog box to name and save the file.

To verify that your template behaves as you expect, create a new project that uses your new template. See “Create a New Project Using Templates” on page 16-25.

Edit a Template

- 1 Create a new project that uses the template you want to modify. See “Create a New Project Using Templates” on page 16-25.
- 2 Make the changes.
- 3 On the **Project** tab, in the **File** section, select **Share > Template**.

Use the dialog box to create a new template or overwrite the existing one.

Explore the Example Templates

You can use the example templates as example structures for a new project.

You can explore the templates using the Simulink start page. To search for templates, use the start page search box. See “Create a New Project Using Templates” on page 16-25 and “Create a New Project From a Folder” on page 16-16.

Group and Sort File Views

In a project, to group and sort the views in the Files view:

- Use the **List** or **Tree** options under **Layout** to switch between a flat list of files and a hierarchical tree of files.
- Click the Actions button  to specify display columns and sort order. For example, you can display columns for label categories that you created and sort files by label category.

Search Inside Project Files and Filter File Views

In this section...

“Project-Wide Search” on page 17-3

“Filter Project File Views” on page 17-5

“More Ways to Search” on page 17-6

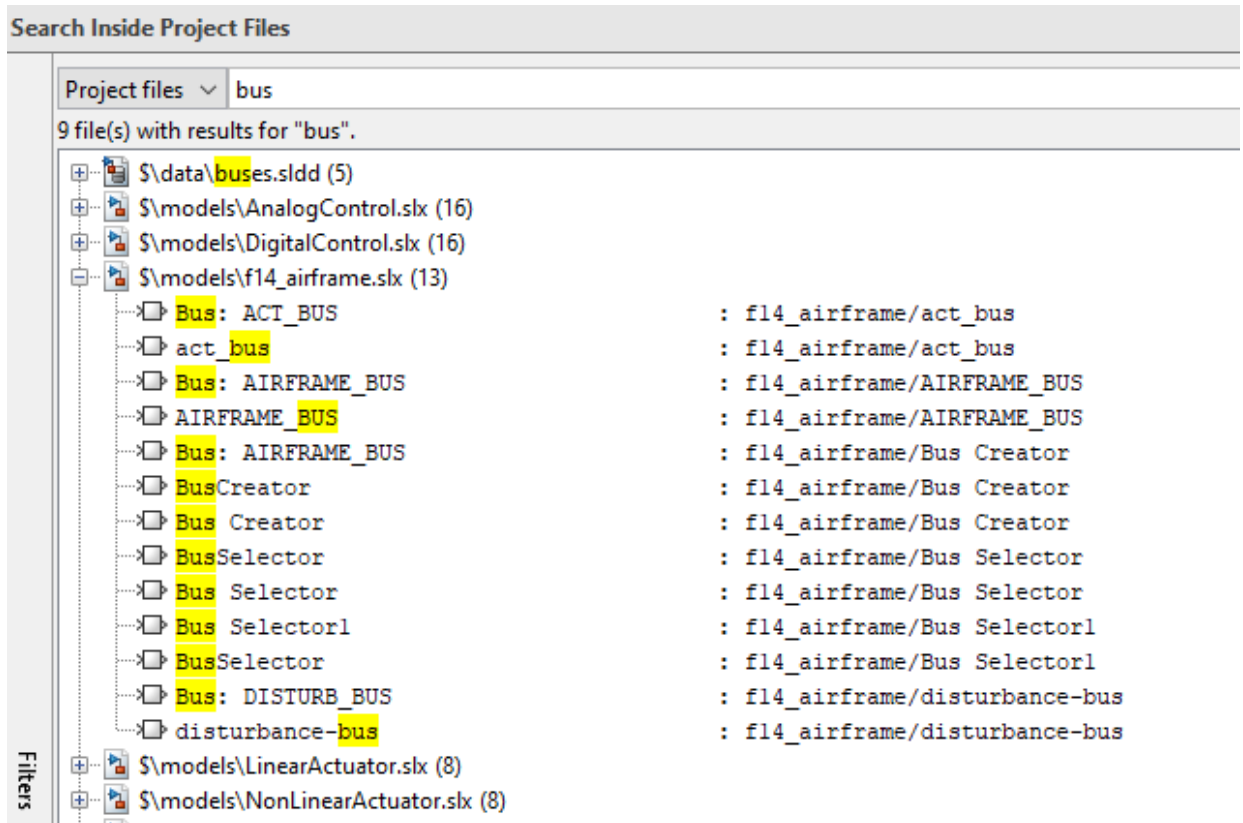

Project-Wide Search

In a project, you can search inside all your models and supporting files. You can find matches inside model files, MATLAB files, data dictionaries, and other project files such as PDF and Microsoft Word files. You search only the current project. If you want to search referenced project files, open the referenced project.

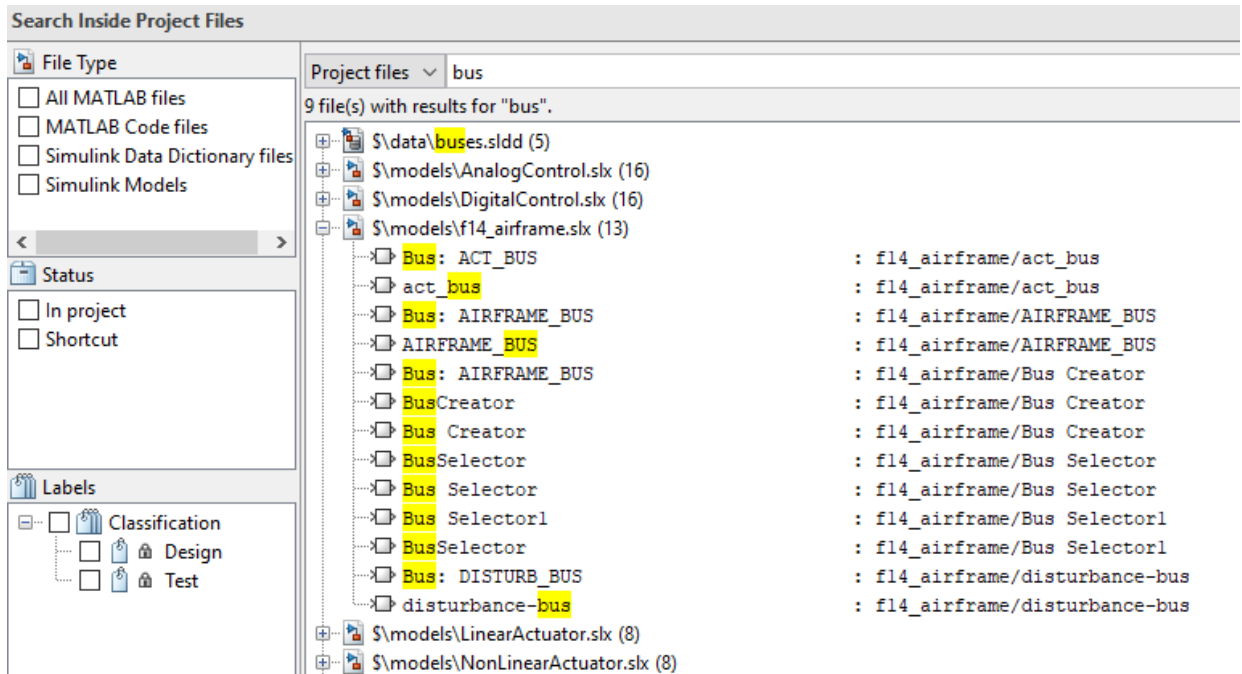

- 1 On the **Project** tab, click **Search**. Alternatively, type in the file filter box, and the project provides a link to try searching inside files instead.

- 2 In the Search Inside Project Files dialog box, enter some characters to search for. Do not use quotes around phrases, or hyphens.
- 3 Expand files in the list to see results inside the file. Double-click results to locate specific items, e.g., highlight blocks in Simulink models, or highlight specific lines in MATLAB files.

- 4 Click **Filters** to refine results by file type, status, or label.

Filter Project File Views

In a project, in the Files and Dependency Analysis views, and in the Custom Task dialog box, you can use the search box and filtering tools to specify file display.

- To view files, select the **Files** node. When the **Project (number of files)** view is selected, only the files in your project are shown. To see all the files in your sandbox, click **All**. This view shows all the files that are under the project root, not just the files that are in the project.
- To search, type a search term in the search box, for example, part of a file name or a file extension. You can use wildcards, for example, *.m, or *.m*.

Click **X** to clear the search.

- To build a filter for the current view, click the filter button .

In the Filter Builder dialog box you can select multiple filter criteria to apply using names, file types, project status, and labels.

The dialog box reports the resulting filter at the bottom, for example:

```
Filter = file type is 'Model files (*.slx, *.mdl)' AND project status  
is 'In project' AND has label 'Engine Type:Diesel'
```

When you click **Apply**, the search box shows the filter that you are applying.

More Ways to Search

You can also search:

- Model contents without loading the models into memory. On the MATLAB **Home** tab, in the **File** section, click **Find Files**. You can search a folder or the entire path. However, you cannot highlight results in models from the results in the Find Files dialog box the same way you do with project search. See “Advanced Search for Files” (MATLAB).
- A model hierarchy. In the Simulink Editor, select **Edit > Find**. Select options to look inside masks, links, and references. This search loads the models into memory. See “Find Model Elements in Simulink Models” on page 12-45
- For variables, block parameter values, or search a model hierarchy and contents using more options, using the Model Explorer. This search loads the models into memory. Use the Model Explorer to search for variables in workspaces and data dictionaries, and variable usage in a model. See “Edit and Manage Workspace Variables by Using Model Explorer” on page 62-149

Work with Project Files

In a project, in the **Files** view, use the context menus to perform actions on the files that you are viewing. Right-click a file (or selected multiple files) to perform project options such as:

- Open files.
- Add and remove files from the project.
- Add, change, and remove labels. See “Add Labels to Files” on page 17-24.
- Create entry point shortcuts (for example, code to run at startup or shutdown, open models, simulate, or generate code). See “Create Shortcuts to Frequent Tasks” on page 16-36.
- If a source control interface is enabled, you can also:
 - Refresh source control status.
 - Update from source control.
 - Check for modifications.
 - Revert.
 - Compare against revision (select a version to compare).

See “About Source Control with Projects” on page 19-2.

In the **Files** view, if you select, for example a model file, the bottom right-hand pane displays file information, a model preview, and file labels.

Manage Shadowed and Dirty Models and Other Project Files

In this section...

“Identify Shadowed Project Files When Opening a Project” on page 17-10

“Find Models and Other Project Files With Unsaved Changes” on page 17-11

“Manage Open Models and Data Dictionaries When Closing a Project” on page 17-11

Identify Shadowed Project Files When Opening a Project

If there are two model files with the same name on the MATLAB path, then the one higher on the path is loaded, and the one lower on the path is shadowed. This shadowing applies to all models and libraries (SLX and MDL files).

A loaded model always takes precedence over unloaded ones, regardless of its position on the MATLAB path. Loaded models can interfere when you try to use other files of the same name, especially when models are loaded but not visible. Simulink warns when you try to load a shadowed model, because the other model is already loaded and can cause conflicts. The project checks for shadowed files when you open a project.

- 1 When you open a project, it warns you if any models of the same names as your project models are already loaded. This check enables you to find and avoid shadowed files before opening any project models.

The Configuring Project Environment dialog box reports the **Identify shadowed project files** check fails. Click **Details**.

- 2 In the dialog box, you can choose to show or close individual files, or close all potentially shadowing files, by clicking the hyperlinks. To avoid working on the wrong files, close the loaded models.
- 3 After deciding whether to show or close the loaded models, click **OK** to return to the Configuring Project Environment dialog box.
- 4 Inspect the other project loading tasks, then click **Continue** to view the project.

Tip To help avoid problems with shadowed files, turn on the Simulink preference **Do not load models that are shadowed on the MATLAB path**. See “Do not load models that are shadowed on the MATLAB path”.

To learn more about shadowed files, see “Shadowed Files” on page 15-4.

Find Models and Other Project Files With Unsaved Changes

You can check your project for models, data dictionaries and MATLAB files with unsaved changes. On the **Project** tab, in the **File** section, click **Unsaved Changes**.

In the Unsaved Changes dialog box, you can see all dirty project models, data dictionaries, and MATLAB files. If you have referenced projects, files are grouped by project. You can save or discard all changes.

Manage Open Models and Data Dictionaries When Closing a Project

When you close a project, it closes any project models or data dictionaries, unless they are dirty.

When you close a project, if there are model files or data dictionaries with unsaved changes, a message prompts you to save or discard changes. You can see all dirty files, grouped by project if you have referenced projects. To avoid losing work, you can save or discard changes by file, by project, or globally.

Control this behavior using the project shutdown preferences.

Move, Rename, Copy, or Delete Project Files

In this section...
“Move or Add Files” on page 17-12
“Automatic Updates When Renaming, Deleting, or Removing Files” on page 17-12

Move or Add Files

To move or add project files, you can drag them to the project, or use clipboard operations.

- To add files to your project, you can paste files or drag them from your operating system file browser or the MATLAB Current Folder browser onto the **Project** files view in the project. When you drag a file to the **Project** files view, you add the file to the project. For projects under source control, you also add the file to source control.
- To move files within your project, cut and paste or drag files in the project.

See also “Add Files to the Project” on page 16-22.

Automatic Updates When Renaming, Deleting, or Removing Files

When you rename, delete, or remove files or folders in a project, the project checks for impact in other project files. You can find and fix impacts such as changed library links, model references, and model callbacks. You can avoid refactoring pain tracking down other affected files. Automatic renaming helps to prevent errors that result from changing names or paths manually and overlooking or mistyping one or more instances of the name.

For example:

- When renaming a library, the project offers to automatically update all library links to the renamed library.
- When renaming a class, the project offers to automatically update all classes that inherit from it. If you rename a `.m` or `.mlx` file, the project offers to automatically update any files and callbacks that call it.
- When deleting files or removing them from the project, the project prompts you if other files refer to them. You must decide how to fix the affected files manually.

- When renaming a C file, the project prompts you to update the S-function that uses it.
- When renaming buses or bus elements using the Simulink Bus Editor, the project prompts you to update all usages in the project.

To use automatic updates:

- 1 Rename a model, library, or MATLAB file in a project.

The project runs a dependency analysis to look for impacts in other files.

- 2 In the Rename dialog box, you can examine impacted files, choose to rename and update, just rename, or cancel renaming the file.
- 3 If you choose automatic updates, you can examine the results in updated files.

Automatic Renaming Using the Power Window Project

- 1 Open the power window example project by entering in MATLAB:

```
slexPowerWindowStart
```

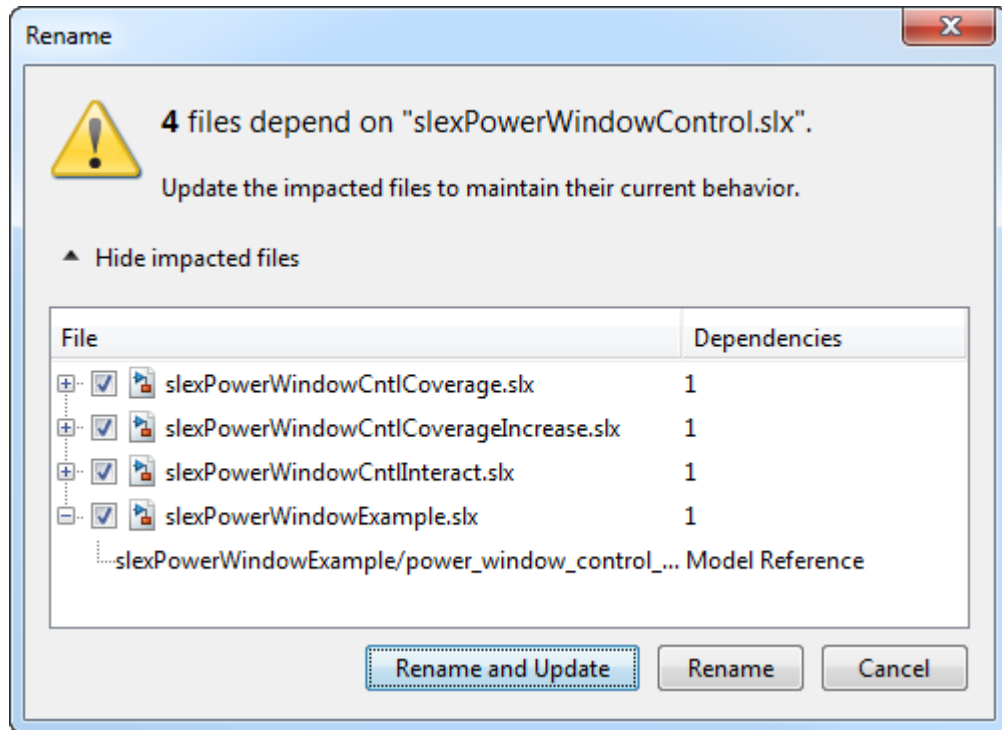

The project opens the top model, some scopes, and an animation window.

- 2 In a project, expand the model folder, and rename the `slexPowerWindowControl.slx` model to `slexPowerWindowControlSystem.slx`.

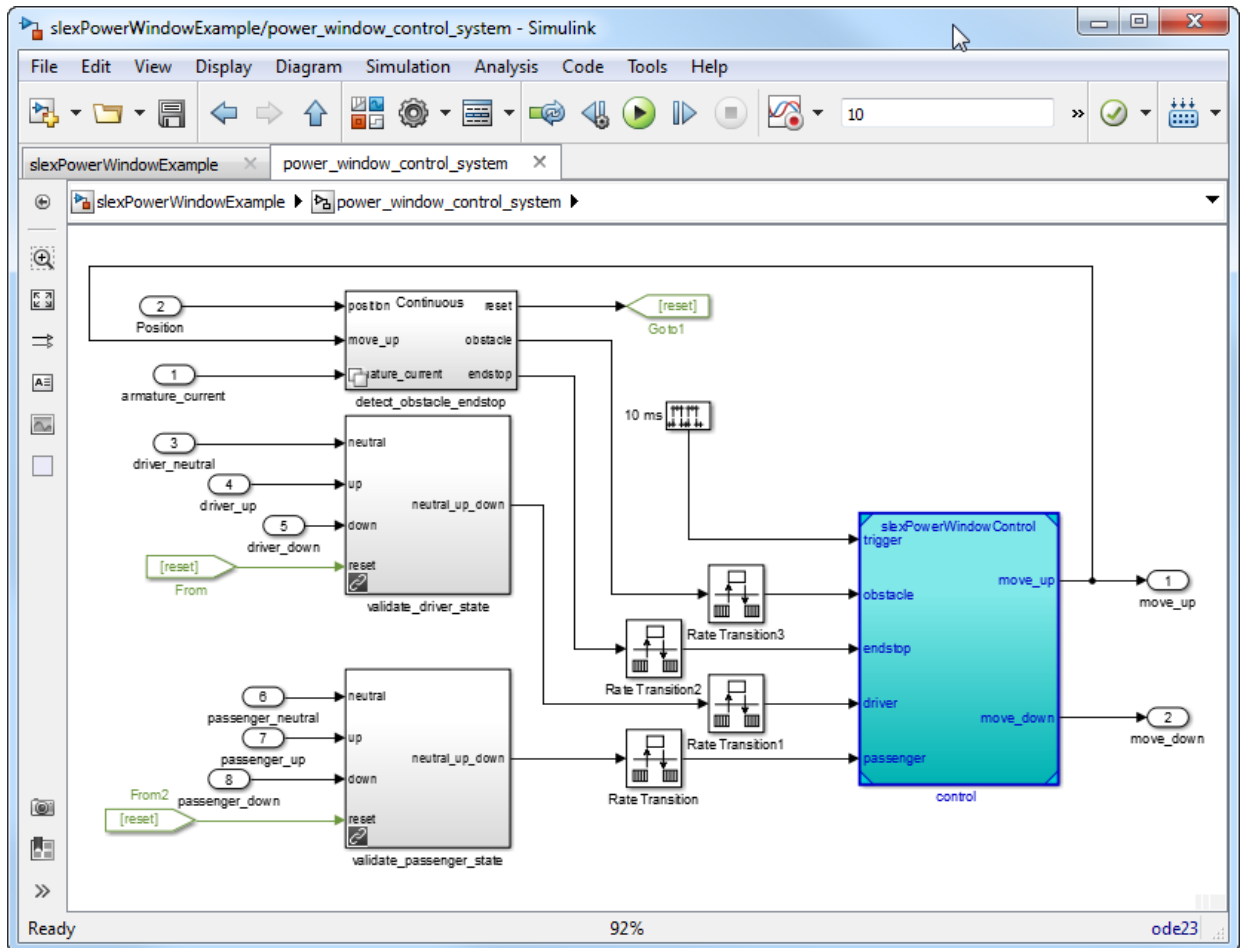

The project runs a dependency analysis to look for impacts in other files, and then the Rename dialog box reports impacted files.

- 3 In the Rename dialog box, click **Show impacted files**. Expand the last impacted file to view the dependency, which is a model reference.

- 4 To view the dependency highlighted in the model, double-click the last **Model Reference** line in the Rename dialog box. Observe the model name on the highlighted control block, `slxPowerWindowControl`.

- 5 In the Rename dialog box, click **Rename and Update**.

The project updates the impact files to use the new model name in model references. When the project can automatically rename items, it reports success with a check mark. With some impacts, you must decide how to fix the affected files manually.

- 6 Examine the results by double-clicking items in the Rename dialog box. Double-click the last **Model Reference** line. Check if the model name on the highlighted control block is updated to `slexPowerWindowControlSystem`.

Back Out Changes

Similar to many applications, the project enables you to Undo and Redo, to back out recent changes.

- 1 Click the arrow next to the Undo or Redo button.
- 2 Select the actions you want to undo or redo. You can select multiple actions. Hover over each action to view details in a tooltip.

If you are using source control, you can revert to particular versions of files or projects. See “Revert Changes” on page 19-50.

Upgrade Model Files to SLX and Preserve Revision History

In this section...

“Project Tools for Migrating Model Files to SLX” on page 17-18

“Upgrade the Model and Commit the Changes” on page 17-18

“Verify Changes After Upgrade to SLX” on page 17-20

Project Tools for Migrating Model Files to SLX

A project helps you upgrade model files from MDL format to SLX format. You can use the project integrity checks to automatically add the new SLX file to your project, remove the MDL file from the project, and preserve the revision history of your MDL file with the new SLX file. You can then commit your changes to source control and maintain the continuity of your model file history.

The following example shows how to use project checks to fix your project after manually saving a model as SLX.

Upgrade the Model and Commit the Changes

- 1 Open a new copy of the `airframe` project.
`sldemo_slproject_airframe`
- 2 In the project **Files** view, right-click the model file `AnalogControl.mdl`, and select **Open**.
- 3 Select **File > Save As**.
- 4 Ensure that **Save as type** is SLX, and click **Save**. SLX is the default unless you change your preferences.
- 5 To see the results, in the Files view, change the view from **Project (number of files)** to **All**. Expand the `models` folder.

Simulink saves the model in SLX format, and creates a backup file by renaming the MDL file to `AnalogControl.mdl.releasename`. The project also reports the original name of the MDL file as missing.

All Project (34) Modified (1)	
Name ▲	Status
custom_tasks	✓
data	✓
lib	✓
models	✓
AnalogControl.mdl	✗
AnalogControl.mdl.r2018b	·
AnalogControl.slx	·

- 6 To resolve these issues, on the Project tab, click **Run Checks** to run the project integrity checks. The checks look for MDL files converted to SLX, and offer automatic fixes if that check fails.
- 7 Click the **Fix** button to view recommended actions and decide whether to make the changes.

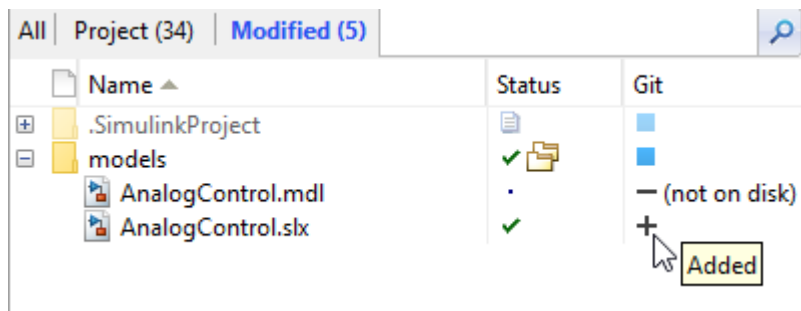

When you click **Fix**, the Missing Files dialog box offers to remove the missing MDL file from the project and add the new SLX file to the project.

- 8 Click **Yes** to perform the fix.

Project checks rerun after you click **Yes** to perform the fix. Close the Project Integrity Checks dialog box.

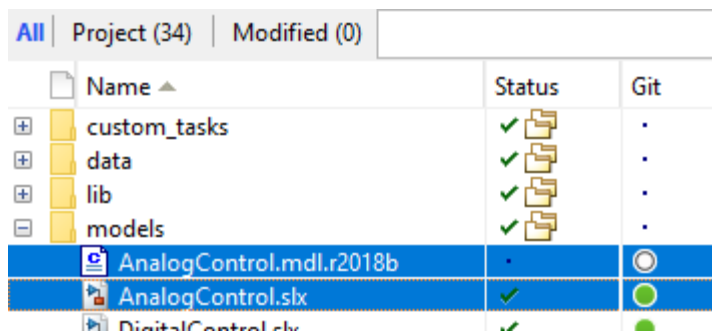

- 9 Select the **Modified** files view. Expand the `models` folder and check the Modifications column to see that the newly created SLX file has been added to the project, and the original MDL file is scheduled for removal.

- 10 On the Project tab, in the Source Control section, click **Commit**. Enter a comment for your submission in the dialog box, for example, Convert to SLX, and click **Submit**.

Verify Changes After Upgrade to SLX

- 1 In the Files view, select the **All** view. Check that the backup file, for example, `AnalogControl.mdl.r2018b` is still present, along with the new SLX file. Click the Actions button  to customize the columns to show, such as **Date Modified**.

- 2 In the Files view, select the **Project** files view. Check that only the new SLX file is included in the project, and the backup file is not included in the project.

All Project (34) Modified (0)		
Name ▲	Status	Git
custom_tasks	✓	•
data	✓	•
lib	✓	•
models	✓	•
AnalogControl.slx	✓	●
DigitalControl.slx	✓	●
f14_airframe.slx	✓	●

- 3 Right-click the model file `AnalogControl.slx` and select **Show Revisions**.
- 4 In the File Revisions dialog box, verify that the previous revision is `AnalogControl.mdl`. The revision history of the previous model file is preserved with the new SLX file.

For an example showing commands to find and upgrade all model files in the project to SLX, see “Converting from MDL to SLX Model File Format in a Project”.

Note For an example showing how to programmatically upgrade a whole project using `upgradeadvisor`, see instead:

```
sldemo_slproject_upgrade
```

Create Labels

In a project, use labels to organize files and communicate information to project users. You can create these types of label categories:

- Single-valued — You can attach only one label from the category to a file.
- Multi-valued — You can attach multiple labels from the category to a file.

The **Labels** tree has built-in labels in the single-valued **Classification** category:

- You cannot rename or delete **Artifact**, **Convenience**, **Derived**, **Design**, **None**, **Test**, and **Other**.
- You can rename or delete **Utility**.
- You cannot annotate built-in labels.

To create a label category:

- 1 In a project, right-click the **Labels** pane. Then select **Create New Category**.
- 2 In the Create Category dialog box, enter a name for the new category.
- 3 If you require a single-valued label category, select the **Single Valued** check box. The default is multi-valued.
- 4 If you want to specify a data type for the label other than `String`, from the **Type** list, select `Double`, `Integer`, `Logical`, or `None`.
- 5 Click **Create**.

To create a label in a category:

- 1 In the **Labels** pane, right-click the label category and select **Create New Label**.
- 2 In the Create Label dialog box, enter a name for the new label and click **OK**.

To rename or delete a category or label, right-click it and select **Rename** or **Remove**.

To create new labels at the command line, see “Automate Simulink Project Tasks Using Scripts” on page 17-27.

Related Examples

- “Add Labels to Files” on page 17-24
- “View and Edit Label Data” on page 17-25

Add Labels to Files

In a project, use labels to organize files and communicate information to project users.

To add a label to a file, use one of these methods:

- Drag the label from the **Labels** pane onto the file.
- In the Files view, select the file. Then, drag the label from the **Labels** pane into the label editor.

To add a label to multiple files, in the Files view or Impact graph, select the files that require the label. Then right-click and select **Add Label**. Use the dialog box to specify the label.

To add labels programmatically, for example, in custom task functions, see “Automate Simulink Project Tasks Using Scripts” on page 17-27.

Note After you add a label to a file, the label persists across file revisions.

After you add labels, you can organize files by label in the Files view and Impact graph. See “Group and Sort File Views” on page 17-2 and “Perform Impact Analysis” on page 18-6.

If the project is under SVN source control, adding tags to all your project files enables you to mark versions. See “Tag and Retrieve Versions of Project Files” on page 19-33.

View and Edit Label Data

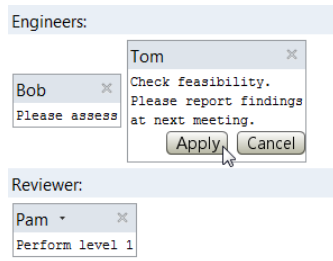

When you select a file in the project Files view, the file labels appear in the label editor view.

To change a label that belongs to a single-valued category, select the new value from the label list.

You can annotate labels from categories that you create. In the label, insert or modify text. Then, click **Apply**.

Automate Simulink Project Tasks Using Scripts

This example shows how to use the Simulink project API to automate project tasks manipulating files, including working with modified files, dependencies, shortcuts, and labels.

Get Simulink Project at the Command Line

Open the Airframe project and use `simulinkproject` to get a project object to manipulate the project at the command line. You must open a project in Simulink Project to perform command-line operations on the project.

```
sldemo_slproject_airframe
proj = simulinkproject
```

```
Creating sandbox for project.
Created example files in "C:\slexamples\airframe21"
Initializing: Project Path
Identifying shadowed project files
Running: C:\slexamples\airframe21\utilities\set_up_project.m
Building with 'MinGW64 Compiler C '.
MEX completed successfully.
```

```
proj =
```

```
  ProjectManager with properties:
```

```
      Name: 'Simulink Project Airframe Example'
      Information: [1x1 slproject.Information]
      Dependencies: [1x1 slproject.Dependencies]
      Shortcuts: [1x9 slproject.Shortcut]
      ProjectPath: [1x7 slproject.PathFolder]
      ProjectReferences: [1x0 slproject.ProjectReference]
      Categories: [1x1 slproject.Category]
      Files: [1x33 slproject.ProjectFile]
      RootFolder: 'C:\slexamples\airframe21'
```

Find Project Commands

Find out what you can do with your project.

```
methods(proj)
```

Methods for class `slproject.ProjectManager`:

```
addFile                isLoaded
addFolderIncludingChildFiles listModifiedFiles
close                 refreshSourceControl
createCategory        reload
export               removeCategory
findCategory         removeFile
findFile
getFilesRequiredBy
```

Examine Project Files

After you get a project object, you can examine project properties such as files.

```
files = proj.Files
```

```
files =
```

```
    1×33 ProjectFile array with properties:
```

```
    Path
    Labels
    Revision
    SourceControlStatus
```

Use indexing to access files in this list. The following command gets file number 14. Each file has properties describing its path and attached labels.

```
proj.Files(14)
```

```
ans =
```

```
    ProjectFile with properties:
```

```
                Path: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
                Labels: [1×1 slproject.Label]
                Revision: '2'
    SourceControlStatus: Unmodified
```

Examine the labels of the 14th file.

```
proj.Files(14).Labels
```

```
ans =
```

```
Label with properties:
```

```
    File: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
  DataType: 'none'
    Data: []
    Name: 'Design'
  CategoryName: 'Classification'
```

Get a particular file by name.

```
myfile = findFile(proj, 'models/AnalogControl.mdl')
```

```
myfile =
```

```
ProjectFile with properties:
```

```
    Path: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
  Labels: [1x1 slproject.Label]
  Revision: '2'
  SourceControlStatus: Unmodified
```

Find out what you can do with the file.

```
methods(myfile)
```

```
Methods for class slproject.ProjectFile:
```

```
addLabel    findLabel    removeLabel
```

Get Modified Files

Modify a project model file by adding an arbitrary block.

```

open_system('AnalogControl')
add_block('built-in/SubSystem', 'AnalogControl/test')
save_system('AnalogControl')

```

Get all the modified files in the project. Observe two modified files. Compare with the Modified Files view in Simulink Project, where you can see a modified model file, and the corresponding .SimulinkProject definition file.

```
modifiedfiles = listModifiedFiles(proj)
```

```
modifiedfiles =
```

```
1x2 ProjectFile array with properties:
```

```

Path
Labels
Revision
SourceControlStatus

```

Get the second modified file. Observe the file `SourceControlStatus` property is `Modified`. Similarly, `listModifiedFiles` returns any files that are added, conflicted, deleted, etc., that show up in the Modified Files view in Simulink Project.

```
modifiedfiles(2)
```

```
ans =
```

```
ProjectFile with properties:
```

```
    Path: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
    Labels: [1x1 slproject.Label]
    Revision: '2'
    SourceControlStatus: Modified
```

Refresh source control status before querying individual files. You do not need to do before using `listModifiedFiles`.

```
refreshSourceControl(proj)
```

Get all the project files with a particular source control status. For example, get the files that are `Unmodified`.

```
proj.Files(ismember([proj.Files.SourceControlStatus], matlab.sourcecontrol.Status.Unmodified))
```

```
ans =
```

```
1x32 ProjectFile array with properties:
```

```
    Path
    Labels
    Revision
    SourceControlStatus
```

Get File Dependencies

Update the file dependencies. The project runs a dependency analysis to update the known dependencies between project files.

```
update(proj.Dependencies)
```

Examine the dependencies in the project object. The dependencies property of the project object contains the graph of dependencies between project files in a MATLAB digraph object. You can view the same dependency analysis graph in the Impact view of Simulink Project. If you want to plot the graph, instead of working with the digraph object, save the impact view to an image file.

```
proj.Dependencies
```

```
ans =
```

```
Dependencies with properties:
```

```
Graph: [1x1 digraph]
```

Get the graph dependencies. You can use digraph methods to get information from the graph.

```
g = proj.Dependencies.Graph
```

```
g =
```

```
digraph with properties:
```

```
Edges: [24x1 table]
```

```
Nodes: [25x1 table]
```

Get the files required by a model.

```
requiredFiles = bfsearch(g, which('AnalogControl'))
```

```
requiredFiles =
```

```
3x1 cell array
```

```
'C:\slexamples\airframe21\models\AnalogControl.mdl'
```

```
'C:\slexamples\airframe21\data\controller.sldd'
```

```
'C:\slexamples\airframe21\data\buses.sldd'
```

Get the top-level files of all types in the graph.

```
top = g.Nodes.Name(indegree(g)==0);
```

Get the top-level files that have dependencies.

```
top = g.Nodes.Name(indegree(g)==0 & outdegree(g)>0)
```

```
top =
```

```
7×1 cell array
```

```
'C:\slexamples\airframe21\models\DigitalControl.slx'  
'C:\slexamples\airframe21\models\LinearActuator.slx'  
'C:\slexamples\airframe21\models\slproject_f14.slx'  
'C:\slexamples\airframe21\tests\f14_airframe_test.m'  
'C:\slexamples\airframe21\utilities\rebuild_s_functions.m'  
'C:\slexamples\airframe21\utilities\set_up_project.m'  
'C:\slexamples\airframe21\utilities\upgrade_project.m'
```

Find impacted (or "upstream") files by creating a transposed graph.

```
transposed = flippedge(g)
```

```
impacted = bfssearch(transposed, which('vertical_channel'))
```

```
transposed =
```

```
digraph with properties:
```

```
Edges: [24×1 table]
```

```
Nodes: [25×1 table]
```

```
impacted =
```

```
4×1 cell array
```

```
'C:\slexamples\airframe21\models\vertical_channel.slx'  
'C:\slexamples\airframe21\models\f14_airframe.slx'  
'C:\slexamples\airframe21\models\slproject_f14.slx'  
'C:\slexamples\airframe21\tests\f14_airframe_test.m'
```

Find files impacted by a data dictionary.

```
impacted2 = bfsearch(transposed, which('buses.sldd'))

impacted2 =

    11x1 cell array

    'C:\slexamples\airframe21\data\buses.sldd'
    'C:\slexamples\airframe21\data\controller.sldd'
    'C:\slexamples\airframe21\data\system_model.sldd'
    'C:\slexamples\airframe21\tests\f14_airframe_test.m'
    'C:\slexamples\airframe21\models\AnalogControl.mdl'
    'C:\slexamples\airframe21\models\DigitalControl.slx'
    'C:\slexamples\airframe21\models\f14_airframe.slx'
    'C:\slexamples\airframe21\models\LinearActuator.slx'
    'C:\slexamples\airframe21\models\NonLinearActuator.mdl'
    'C:\slexamples\airframe21\models\slproject_f14.slx'
    'C:\slexamples\airframe21\models\vertical_channel.slx'
```

Get information on your files, such as the number of dependencies and orphans.

```
averageNumDependencies = mean(outdegree(g));
numberOfOrphans = sum(indegree(g)+outdegree(g)==0);
```

If you want to make changes to a model hierarchy, starting from the bottom up, find the topological order.

```
ordered = g.Nodes.Name(flip(toposort(g)));
```

Query Shortcuts

Examine the project's Shortcuts property. You can automate startup and shutdown tasks using shortcuts, or use them to save frequent tasks and frequently accessed files.

```
shortcuts = proj.Shortcuts
```

```
shortcuts =
```

```
    1x9 Shortcut array with properties:
```

```
    File
    RunAtStartup
    RunAtShutdown
```

Examine a shortcut in the array.

```
shortcuts(9)
```

```
ans =
```

```
Shortcut with properties:
```

```
File: 'C:\slexamples\airframe21\utilities\set_up_project.m'
RunAtStartup: 1
RunAtShutdown: 0
```

The RunAtStartup property is set to 1, so this shortcut file is set to run at project startup. At the command line, you can view but not change the RunAtStartup and RunAtShutdown properties. To set these properties, use the shortcut tools Simulink Project. Get the file path of a shortcut.

```
shortcuts(6).File
```

```
ans =
```

```
1x50 char array
```

```
C:\slexamples\airframe21\reports\slproject_f14.pdf
```

Examine all the files in the shortcuts cell array.

```
{shortcuts.File}'
```

```
ans =
```

```
9x1 cell array
```

```
'C:\slexamples\airframe21\batch_jobs\billOfMaterials.m'
'C:\slexamples\airframe21\batch_jobs\checkCodeProblems.m'
'C:\slexamples\airframe21\batch_jobs\runUnitTest.m'
'C:\slexamples\airframe21\batch_jobs\saveModelFiles.m'
'C:\slexamples\airframe21\models\slproject_f14.slx'
'C:\slexamples\airframe21\reports\slproject_f14.pdf'
'C:\slexamples\airframe21\utilities\clean_up_project.m'
```

```
'C:\slexamples\airframe21\utilities\rebuild_s_functions.m'  
'C:\slexamples\airframe21\utilities\set_up_project.m'
```

Create a logical array that shows the shortcuts set to run at startup.

```
idx = [shortcuts.RunAtStartup]
```

```
idx =
```

```
1×9 logical array
```

```
0 0 0 0 0 0 0 0 1
```

Use the logical array to get only the startup shortcuts.

```
startupshortcuts = shortcuts(idx)
```

```
startupshortcuts =
```

```
Shortcut with properties:
```

```
File: 'C:\slexamples\airframe21\utilities\set_up_project.m'  
RunAtStartup: 1  
RunAtShutdown: 0
```

Get the path of the startup shortcut by accessing the File property.

```
startupshortcuts.File
```

```
ans =
```

```
1×51 char array
```

```
C:\slexamples\airframe21\utilities\set_up_project.m
```

Label files

Create a new category of labels, of type char. In Simulink Project, the new Engineers category appears in the Labels pane.

```
createCategory(proj, 'Engineers', 'char')
```

```
ans =
```

```
Category with properties:
```

```
        Name: 'Engineers'  
    SingleValued: 0  
        DataType: 'char'  
LabelDefinitions: [1x0 slproject.LabelDefinition]
```

Find out what you can do with the new category.

```
category = findCategory(proj, 'Engineers');  
methods(category)
```

```
Methods for class slproject.Category:
```

```
createLabel  findLabel  removeLabel
```

Define a new label in the new category.

```
createLabel(category, 'Bob');
```

Get a label definition.

```
ld = findLabel(category, 'Bob')
```

```
ld =
```

```
LabelDefinition with properties:
```

```
        Name: 'Bob'  
    CategoryName: 'Engineers'
```

Attach a label to the retrieved file, myfile. If you select the file in Simulink Project, you can see this label in the label editor pane.

```
addLabel(myfile, 'Engineers', 'Bob');
```

Get a particular label and attach data to it, for example, some text.

```
label = findLabel(myfile, 'Engineers', 'Bob');  
label.Data = 'Please assess'
```

```
label =
```

```
Label with properties:
```

```
File: 'C:\slexamples\airframe21\models\AnalogControl.mdl'  
DataType: 'char'  
Data: 'Please assess'  
Name: 'Bob'  
CategoryName: 'Engineers'
```

You can specify a variable for the label data, for example:

```
mydata = label.Data
```

```
mydata =
```

```
1×13 char array
```

```
Please assess
```

Create a new label category with numeric data type.

```
createCategory(proj, 'Assessors', 'double');  
category = findCategory(proj, 'Assessors');  
createLabel(category, 'Sam');
```

Attach the new label to a specified file and assign data value 2 to the label.

```
myfile = proj.Files(14);  
addLabel(myfile, 'Assessors', 'Sam', 2)
```

```
ans =
```

```
Label with properties:
```

```
File: 'C:\slexamples\airframe21\models\AnalogControl.mdl'
```

```
DataType: 'double'  
Data: 2  
Name: 'Sam'  
CategoryName: 'Assessors'
```

Close Project

Closing the project at the command line is the same as closing the project using the Simulink Project tool. For example, the project runs shutdown scripts and checks for unsaved models.

```
close(proj)
```

```
Running: C:\slexamples\airframe21\utilities\clean_up_project.m  
Closing Project Models  
Clearing: Project Path
```

More Information

For more details on using the API, enter: `doc simulinkproject`.

To automate start and shutdown tasks, see “Automate Startup Tasks” on page 16-33.

- Automate Label Management in a Simulink Project

Create a Custom Task Function

In a project, you can create functions and run them on selected project files.

For example custom task functions, see “Running Custom Tasks with a Project”.

To create a custom task function:

- 1 In a Project, select **Custom Tasks > Manage Custom Tasks**.
- 2 In the Manage Custom Tasks dialog box, select **Add > Add Using New Script** or **Add Using Existing Script**.

Either browse to an existing script, or name and save the new file on your MATLAB path. The file is added to the project.

- 3 The MATLAB Editor opens the new file containing a simple example custom task function for you to edit. Edit the function to perform the desired action on each file. The instructions guide you to create a custom task with the correct function signature. Save the file.
- 4 To run your task, in the project, click **Custom Tasks**. In the Custom Task dialog box, select project files to include using the check boxes, select your custom task in the list, and click **Run Task**.
- 5 After your custom task function runs, view the results in the Custom Task Report.
- 6 To save the results in a file, click **Publish Report**.

See Also

Related Examples

- “Run a Project Custom Task and Publish Report” on page 17-41

Run a Project Custom Task and Publish Report

- 1 In a project, click **Custom Tasks**, and then select the check boxes of project files you want to include in the custom task.

Tip If the function can identify the files to operate on, include all files. For example, the custom task function `saveModelFiles` in the `airframe` project checks that the file is a Simulink model and does nothing if it is not.

To select multiple files, **Shift** or **Ctrl**+click, and then right-click a file and select **Include** or **Exclude**.

- 2 Specify the custom task function to run in the **Custom task** box. Enter the name, or click **Browse**, or choose from a list of custom tasks.

If your project does not yet contain any custom task functions, see “Create a Custom Task Function” on page 17-40.

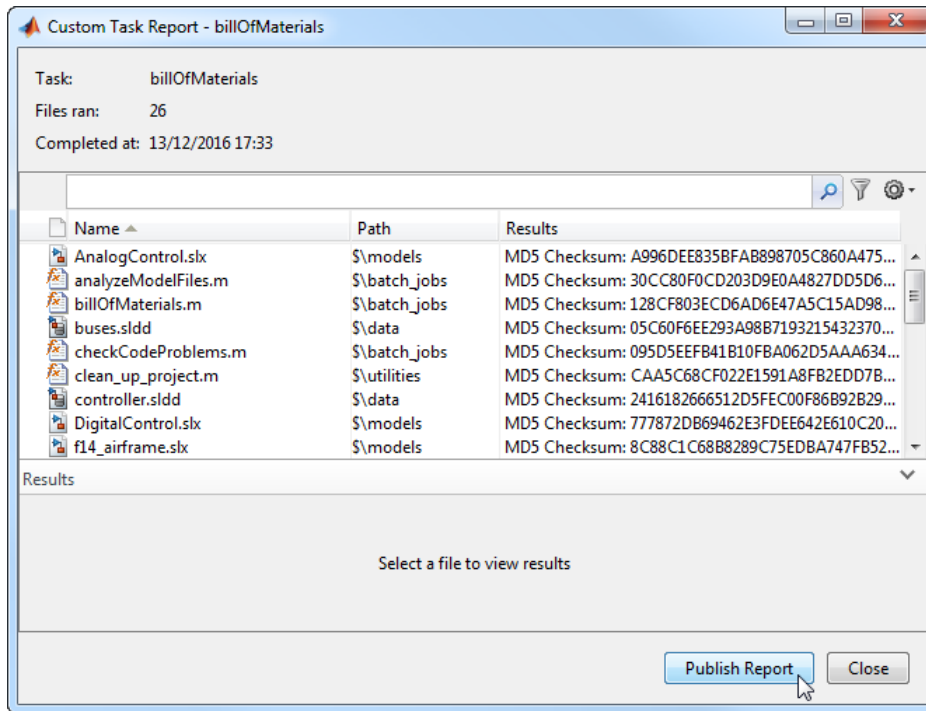

- 3 Click **Run Task**.

The project displays the results.

- 4 To view details of results for the currently selected file, click a file and check the Results pane.

You can publish a report of your custom task results. For example, try this custom task:

- 1 Open an example project by entering `sldemo_slproject_customtasks`.
- 2 In a Project, click **Custom Tasks**.
- 3 In the Custom Task dialog box, click the **Custom task** drop-down arrow to choose from a list of tasks, and select **Generate Bill of Materials Report**.
- 4 Click **Run Task**. Results appear.

- 5 Click **Publish Report**.
- 6 In the file browser, specify a name and location for the report, and choose a file type from HTML or Microsoft Word. If you have MATLAB Report Generator, you can also choose PDF.
- 7 View the results in the report.

The example custom task function **Generate Bill of Materials Report** creates a list of project files, their source control status, revision numbers, and MD5 checksums. You can view the code for this custom task in the file `billOfMaterials.m`.

- 8 To see the report file and add it to your project, switch to the **All** files view.

Tip To try example custom tasks in a project, see the example “Running Custom Tasks with a Project”.

Sharing Projects

Projects help you collaborate. Use the **Share** menu to share your project in these ways:

- Archive your project in a single file.
- Share your project by email (Windows only).
- Create a template from your project.
- Package your project as a MATLAB toolbox.
- Make your project publicly available on GitHub.

You can also collaborate by using source control within projects.

- “Share Project as a MATLAB Toolbox” on page 17-47
- “Share Project on GitHub” on page 17-48

More About

- “About Source Control with Projects” on page 19-2

Share Project by Email

To package and share project files on Windows, you can email your project as an archive file attachment. For example, you can share the project with people who do not have access to the connected source control tool.

- 1 With a project loaded, on the **Project** tab, select **Share > Email**.
- 2 (Optional) To export only the specified files, choose an **Export profile**. To exclude files with particular labels, select **Manage Export Profiles** and create an export profile.
- 3 If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
- 4 Click **Attach to Email**. The project opens a new email in your default email client with the project attached as an archive `.mlproj` file.
- 5 Edit and send the email.

More About

- “Sharing Projects” on page 17-44

Share Project as a MATLAB Toolbox

To package and share project files, you can create a MATLAB toolbox from your project.

- 1 With a project loaded, on the **Project** tab, select **Share > Toolbox**.

The packager adds all project files to the toolbox and opens the Package a Toolbox dialog box.

- 2 The **Toolbox Information** fields are populated with the project name, author, and description. Edit the information if needed.
- 3 If you want to include files not already included in the project files, edit the excluded files and folders.
- 4 Click **Package**.

More About

- “Sharing Projects” on page 17-44

Share Project on GitHub

To share your project, you can make your project publicly available on GitHub. First, create a login on GitHub.

You can share any project. Sharing adds Git source control to the open project. If your project is already under source control, sharing replaces the source control configuration with Git, and the project's remote repository is GitHub.

Note If you do not want to change your current source control in the open project, share a copy of the project instead. To create a copy to share, see “Archive Projects” on page 17-50.

- 1 With a project loaded, on the Project tab, select **Share > Change Share Options**.
- 2 Add the **GitHub** option to your **Share** menu. In the Manage Sharing dialog box, select **GitHub** and click **Close**.
- 3 Select **Share > GitHub**.
- 4 In the Create GitHub Repository dialog box, enter your GitHub user name and password, and edit the name for the new repository. Click **Create**.

A warning prompts you to confirm that you want to create a public repository and modify the current project's remote repository location. To continue, click **Yes**.

- 5 The Create GitHub Repository dialog box displays the URL address for your new repository. Click the link to view the new repository on the GitHub website. The repository contains the initial check-in of your project files.
- 6 The source control in your current project now references the new repository on GitHub as the remote repository. To use the project with the new repository, in the Create GitHub Repository dialog box, click **Reload Project**.

In the project, you can find the URL address for your remote repository on the Project tab, under **Source Control**, using the **SVN Details** or **Git Details** button.

If you have not already set up Git, you need some additional setup steps before you can merge branches. You can use other Git functionality without any additional installation. See “Set Up Git Source Control” on page 19-20.

More About

- “Sharing Projects” on page 17-44

Archive Projects

To package and share project files, you can export all project files to an archive file. For example, you can share a archived project with people who do not have access to the connected source control tool.

- 1 With a project loaded, on the **Project** tab, select **Share > Archive**.
- 2 (Optional) To export only the specified files, choose an **Export profile**.
- 3 If you have referenced projects and want to export the referenced project files, then select the **Include referenced projects** check box.
- 4 Click **Save As**.
- 5 Use the file browser to specify a file path in the **File name** field. By default, the file *myProjectName.mlproj* is created in the current working folder. You can choose the file type project archive (.mlproj) or zip file.

If you want to exclude files from the archive, create an export profile to exclude files with particular labels.

- 1 Create labels and add them to the project files you want to exclude. See “Create Labels” on page 17-22.
- 2 Specify an export profile. On the **Project** tab, select **Share > Manage Export Profiles**.
 - a Click **+** and specify a name for the export profile.
 - b In the Files pane, click **+** and select the labels for the files you do not want to export, and click **OK**. You can also choose not to export custom labels.
 - c Click **Apply** and close the Manage Export Profiles dialog box.
- 3 When you share the project to an archive, in the **Export profile** list, select the name of your export profile to export only the specified files.

Before sharing projects with other users, it can be useful to examine the required toolboxes for your project. See “Find Required Toolboxes” on page 18-8.

Upgrade All Project Models, Libraries, and MATLAB Code Files

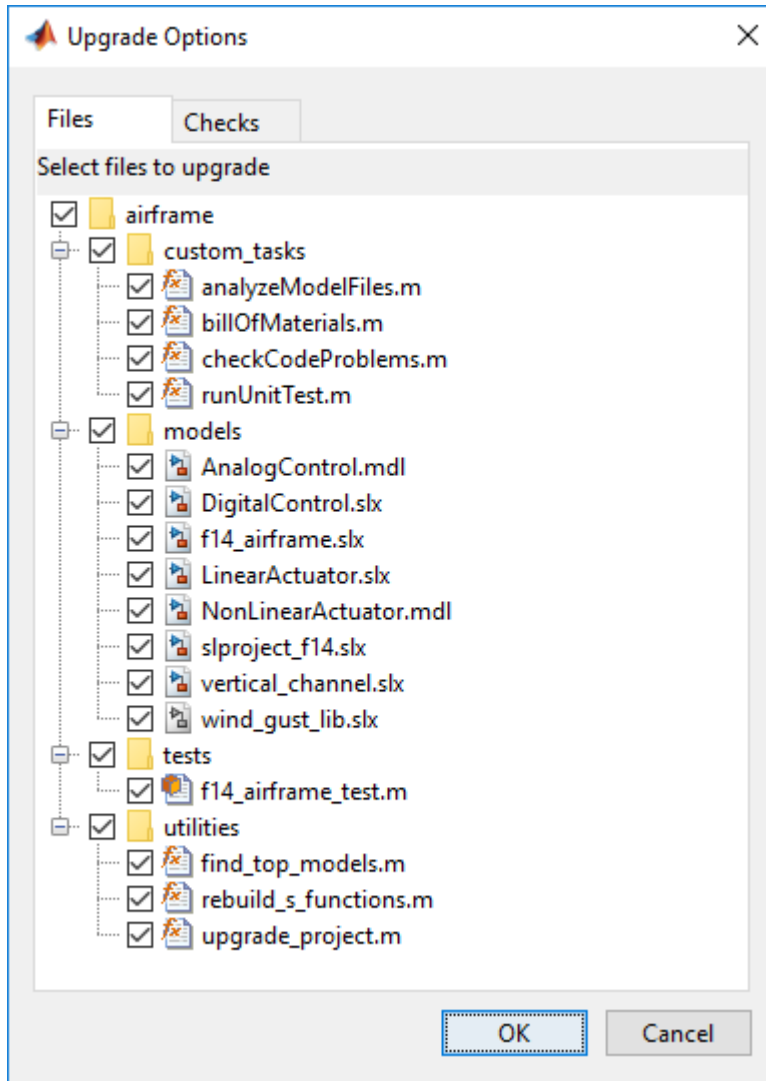

Tip Before upgrading, if you put your project under source control, you can easily revert changes later if you want. See “Add a Project to Source Control” on page 19-6.

Upgrade all models, libraries, and MATLAB code files in your project to the latest release using a simple workflow. The Upgrade Project tool can apply all fixes automatically when possible, upgrade all model hierarchies in the project at once, and produce a report. You do not need to open the Upgrade Advisor.

- 1 On the Project tab, select **Run Checks > Upgrade**.

- 2 In the Upgrade Project dialog box, to upgrade all files, run all checks, and apply fixes automatically where possible, click **Upgrade**. If you want to change the settings, use these options before clicking **Upgrade**:
 - If you want to run upgrade checks but not apply fixes automatically where possible, clear the check box **Apply upgrades automatically**.
 - If you want to change which files to upgrade and which checks to run, click **Change Options**. In the Upgrade Options dialog box, clear check boxes for models and checks you want to exclude from the upgrade. For example, you might want to exclude checks that require an **Update Diagram**.

When you click **Upgrade**, the tool runs the checks and applies fixes if specified. Upgrading can take several minutes.

- 3 Examine the Upgrade Project Report. The summary at the top shows how many files passed and how many files require attention.

The screenshot shows the 'Upgrade Project Report' window. At the top, a large green circle indicates '100% Passed'. To the right, a summary table shows the status of Models, Libraries, and MATLAB Code.

	Models	Libraries	MATLAB Code
Passed	7	1	7
Need attention	-	-	-

Report: S:\Airframe Example.html Refresh

Below the summary, there are two dropdown menus: 'Show: All Files' and 'All Results'. The main area is divided into two panes. The left pane lists files, with 'AnalogControl.slx' selected. The right pane shows the check results for 'AnalogControl.slx', including a table of check names and their results.

Check Name	Result
Check model settings for migration to simplified initialization mode	✓
Check usage of function-call connections	✓
Check and set embedded target model to use ert.tlc system target file	✓
Check and update masked blocks in library to use promoted parameters	✓
Check and update mask image display commands with unnecessary imread() function calls	✓
Check and update mask to affirm icon drawing commands dependency on mask workspace	✓
Check and update model to use toolchain approach to build generated code	✓
Check Delay, Unit Delay and Zero-Order Hold blocks for rate transition	✓

Below the table, there is a section for 'Check model settings for migration to simplified initialization mode' with a 'Learn more' link. It includes a 'Check for model level messages' section and a 'See Also' section with links to 'Check model settings for migration to simplified initialization mode' and 'Underspecified initialization detection'.

At the bottom left, it says 'Checks run on 04/07/2018 09:33'. At the bottom right, there is a 'Close' button.

- Select files in the left list to view check results on the right. By default, the left list shows any files that need attention. Show instead all files, files types, all results, files that passed, or files that passed with fixes, by using the **Show** controls.
- Select checks in the right list to read details of results and any applied fixes in the lower pane. Examine checks marked as needing attention, with an orange

circle in the **Result** column. For details of upgrading libraries, see “Upgrade Libraries” on page 17-55.

- c** If your project is under source control, you can examine the upgrade changes in your files using a comparison report. To see the differences before and after upgrade, in the Upgrade Project Report, click **View Changes**.
- 4** The project saves an HTML report of the upgrade results in the project root folder. To open the published report, click the **Report** link at the top of the Upgrade Project Report.
- 5** To close the interactive report, click **Close**.

Upgrade Libraries

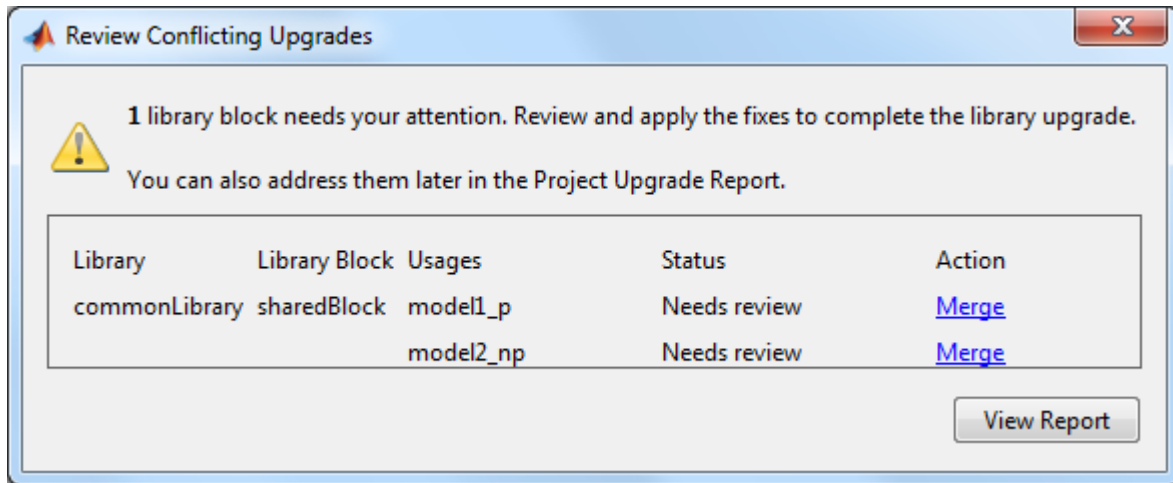

The project automatically runs all upgrade checks on multiple libraries, including any checks that require an Update Diagram.

You cannot run Update Diagram on a library, so project upgrade runs the Update Diagram checks in the models where the library blocks are used. This means that project upgrade can only fully upgrade library blocks that are used in a model. If the library block is used in a model, project upgrade automatically runs all checks, including Update Diagram checks, and then upgrades the block in the library.

If a library block is not used in any project model, then the check **Run checks that require Update Diagram on library blocks** is marked as needing attention, with an orange circle in the **Result** column. Select the check and in the details pane you see the message **Unable to upgrade blocks unused by a model**.

- To upgrade unused library blocks, use the blocks in a model and then upgrade.
- If you want to upgrade library blocks that use forwarding tables, disable the library link and save the model before upgrading, upgrade and then restore the link.

The upgrade of library blocks depends on the model context. The same library block might be used in multiple models. Linked library blocks inherit attributes from the surrounding models, such as data types and sample rate. The blocks' behavior can differ depending on the context where they are used, and this can lead to conflicting upgrades for Update Diagram checks. If models require a different upgrade of the same library block, you are prompted to view and resolve the upgrade conflict.

If you need to review conflicting upgrades, click **Merge**. Alternatively you can review conflicting upgrades later from the report. Review changes in the comparison report and choose which upgrades to save.

Project Dependency Analysis

- “What Is Dependency Analysis?” on page 18-2
- “Run Dependency Analysis” on page 18-4
- “Perform Impact Analysis” on page 18-6
- “Check Dependency Results and Resolve Problems” on page 18-15
- “Find Requirements Documents in a Project” on page 18-20
- “Save, Open, and Compare Dependency Analysis Results” on page 18-21
- “Analyze Model Dependencies” on page 18-23

What Is Dependency Analysis?

Project Dependency Analysis

In a project, you can analyze project structure and discover files required by your project in the Dependency Analysis view.

- To help you set up your project with all required files, you can use dependency analysis.

In a Simulink model, select **File > Project > Create Project from Model**.

Simulink runs dependency analysis on your model to identify required files and a project root location that contains all dependencies. See “Create a Project from a Model” on page 16-14.

Alternatively, you can manually add models to your project, analyze the model dependencies, and then add all dependent files to your project. See “Run Dependency Analysis” on page 18-4.

- You can use the Impact graph view of a dependency analysis to analyze the structure of a project visually. You can perform impact analysis to find the impact of changing particular files. In the graph, you can examine your project structure; find required toolboxes for the whole project or for selected files; open, edit, and run files; add labels and export files. See “Perform Impact Analysis” on page 18-6.

Impact analysis can show you how a change affects other files before you make the change. For example:

- Investigate the potential impact of a change in requirements by finding the design files linked to the requirements document.
- Investigate change set impact by finding upstream and downstream dependencies of modified files before committing the changes. Finding these dependencies can help you identify design and test files that need modification and help you find the tests you need to run.
- You can run dependency analysis at any point in your workflow when you want to check that the project has all required files. For example, check dependencies before submitting a version of your project to source control. To work with results, see “Check Dependency Results and Resolve Problems” on page 18-15.
- You can search for requirements documents in a project. See “Find Requirements Documents in a Project” on page 18-20.

- After performing dependency analysis, you can open or label the files, export the results as workspace variables, images, or reloadable files, or send files for custom task processing. Exporting the results enables further processing or archiving of impact analysis results. You can add the exported list of files to reports or artifacts that describe the impact of a change. See “Save, Open, and Compare Dependency Analysis Results” on page 18-21.

Tip For an example showing how to perform file-level impact analysis to find and run the tests affected by modified files, see “Perform Impact Analysis with a Project”.

Model Dependency Analysis

Use a project to analyze file dependencies for your entire project. For detailed dependency analysis of a *specific* model, use the manifest tools to control more options. Use the manifest tools if you want to:

- Analyze a model that is not in a project.
- Save the list of the model dependencies to a manifest file.
- Create a report to identify where dependencies arise.
- Control the scope of dependency analysis.

See “Analyze Model Dependencies” on page 18-23.

See Also

Related Examples

- “Run Dependency Analysis” on page 18-4
- “Check Dependency Results and Resolve Problems” on page 18-15
- “Perform Impact Analysis” on page 18-6
- “Find Requirements Documents in a Project” on page 18-20
- “Analyze Model Dependencies” on page 18-23

Run Dependency Analysis

Note You can analyze only files that are in your project. If your project is new, add files to the project before running a dependency analysis. See “Add Files to the Project” on page 16-22.

- 1 In the project **Views** pane, select **Dependency Analysis**.
- 2 If you want to analyze the dependencies of external toolboxes, select **Options > Analyze External Toolboxes**.

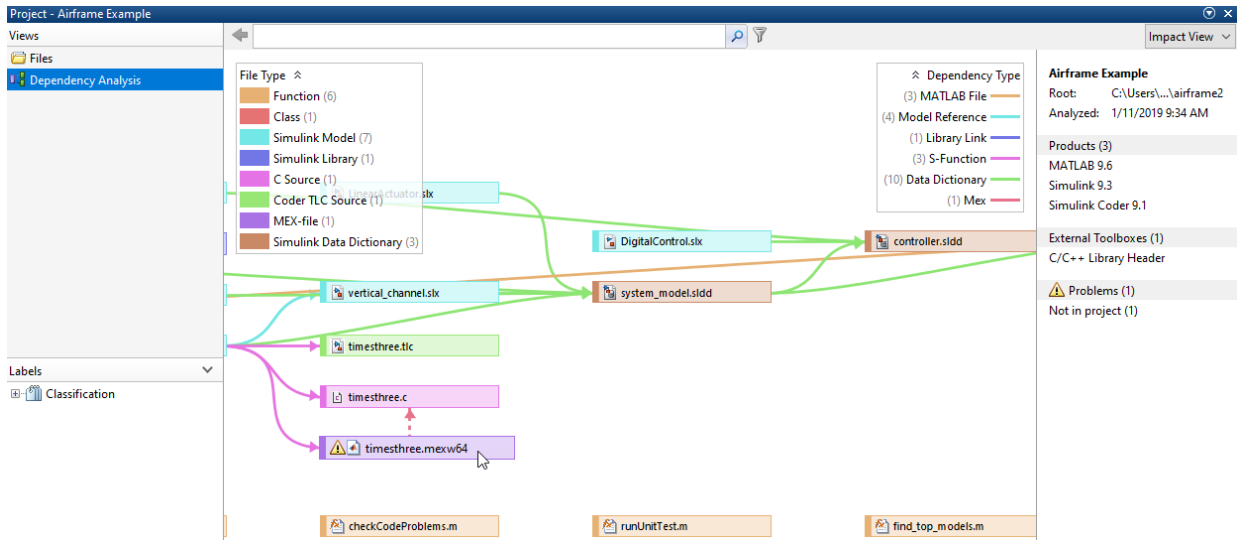

After you run the first dependency analysis of your project, subsequent analyses are incremental updates. However, if you update external toolboxes and want to discover dependency changes in them, you must perform a complete analysis. In this case, turn off **Options > Perform Incremental Updates** before running the dependency analysis.

- 3 To analyze all files in your project, on the **Dependency Analysis** tab or view, select **Analyze**.

If you want to analyze specific files, on the **Dependency Analysis** tab, click **Analyze > Select Files to Analyze**. In the Dependency Analysis dialog box, select files for analysis, and click **Analyze**.

Note In the Simulink Editor, if an open model, library, or chart belongs to a project, you can find file dependencies. Select **File > Project > Find Dependencies**. Simulink analyzes the whole project and shows upstream and downstream dependencies for the file.

For next steps, see:

- “Find Required Toolboxes” on page 18-8
- “Find Dependencies of Selected Files” on page 18-10
- “Select, Edit, and Export File Dependencies” on page 18-12
- “Check Dependency Results and Resolve Problems” on page 18-15

Tip To try a dependency analysis on example files, see “Perform Impact Analysis with a Project”.

Perform Impact Analysis

In this section...
“About Impact Analysis” on page 18-6
“Run Dependency Analysis” on page 18-6
“Find Required Toolboxes” on page 18-8
“Find Dependencies of Selected Files” on page 18-10
“Select, Edit, and Export File Dependencies” on page 18-12

About Impact Analysis

In a project, you can use impact analysis to find out the impact of changing particular files. Investigate dependencies visually and explore the structure of your project. Analyze selected or modified files to find their required files and the files they affect. Impact analysis can show you how a change affects other files before you make the change. For example, you can:

- Investigate the potential impact of a change in requirements by finding the design files linked to the requirements document.
- Investigate change set impact by finding upstream and downstream dependencies of modified files before committing the changes. Finding these dependencies can help you identify design and test files that need modification, and help you find the tests you need to run.

After performing dependency analysis, you can open or label the files, export the results as workspace variables, images, or reloadable files, or send files for custom task processing. Exporting the results enables further processing or archiving of impact analysis results. You can add the exported list of files to reports or artifacts that describe the impact of a change.

Tip For an example showing how to perform file-level impact analysis to find and run the tests affected by modified files, see “Perform Impact Analysis with a Project”.

Run Dependency Analysis

To investigate dependencies, run a dependency analysis on your project.

- 1 In the project, in the **Views** pane, select **Dependency Analysis**. If you want to analyze the dependencies of external toolboxes, select **Options > Analyze External Toolboxes**.
- 2 Click **Analyze**.

The **Impact View** graph displays the structure of all analyzed dependencies in the project. Project files that are not detectable dependencies of the analyzed files do not appear on the graph.

After you run the first dependency analysis of your project, clicking **Analyze** again produces incremental updates. If you want to analyze changes in external toolboxes, turn off the incremental update option.

After performing dependency analysis, the Impact view shows:

- A graph of your project structure and its file dependencies, showing how files such as models, libraries, functions, data files, and source and derived files relate to each other.

- Required products and toolboxes.
- Relationships between source and derived files (such as .m and .p files, .slx and .slxp, .ssc and .sscp, .c and .mex files), and between C/C++ source and header files. You can see what code is generated by each model, and find what code needs to be regenerated if you modify a model.
- Warnings about problem files, such as missing files, files not in the project, unsaved changes, and out-of-date derived files.

For next steps:

- “Find Required Toolboxes” on page 18-8
- “Find Dependencies of Selected Files” on page 18-10
- “Select, Edit, and Export File Dependencies” on page 18-12
- “Check Dependency Results and Resolve Problems” on page 18-15

Tip To try a dependency analysis on example files, see “Perform Impact Analysis with a Project”.

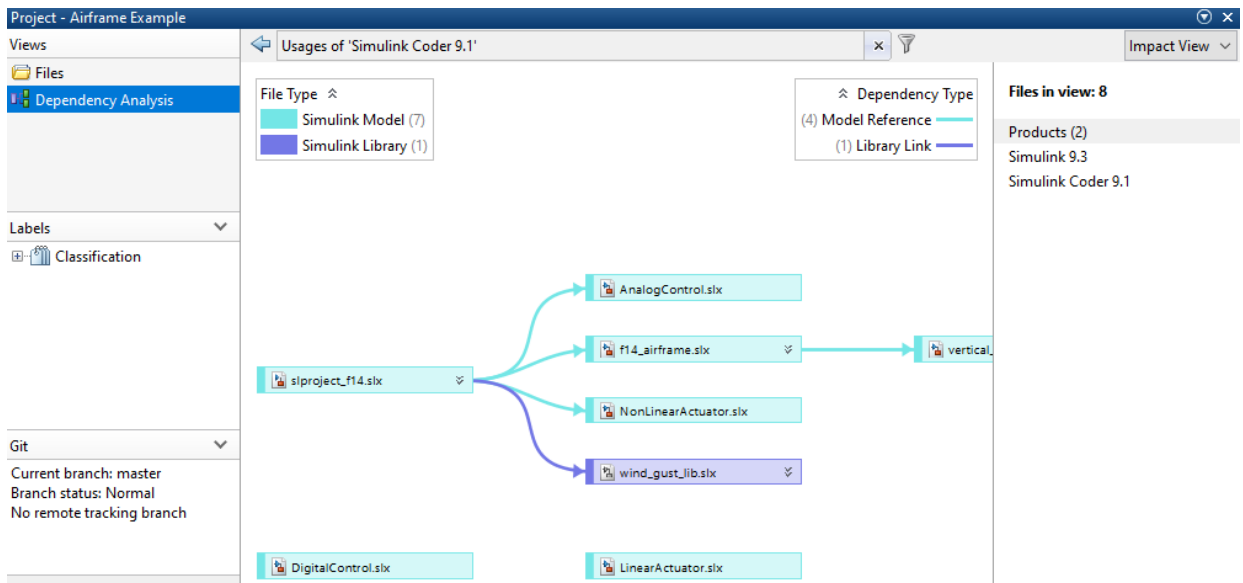

Find Required Toolboxes

After running dependency analysis in a project, the Impact view shows the required toolboxes for the whole project or for selected files. You can see which products a new team member requires to use the project, or find which file is introducing a product dependency.

- 1 After running dependency analysis, view the required products for the whole project listed in the right pane.
- 2 To find which file is introducing a product dependency, hover over the product name and click **Find Usages**.

The graph updates to show only the files using the selected product.

To return to the full project view, click the arrow to undo the filtering and return to the previous view. Alternatively, clear the filter in the search box (e.g., **Usages of "productname"**).

- 3 To view required products of selected files, select some files by clicking the graph or a legend.

If a required product is missing, the product list labels it **Missing**. See “Check Dependency Results and Resolve Problems” on page 18-15.

Find Dependencies of Selected Files

After a dependency analysis, to find out the impact of particular files, in the **Impact View** use the context menu, or use controls in the **View** and **Impact Analysis** sections of the **Dependency Analysis** tab. You can simplify the graph by investigating dependencies of particular files.

- 1 Select files to investigate using one of these methods:
 - Select files in the graph or select groups of files by clicking the legend. For example, select all model files by clicking **Simulink Model** in the **File Type** legend. Change the legend, in the **View** section of the toolbar, using the **Group By** menu, for example to show problem types, status, or labels.
 - To select modified files, problem files or external files, use the **Select** menu in the **Impact Analysis** section of the toolbar.
- 2 To find dependencies, right-click selected files and use the context menu. Select **Find All Dependencies**, **Find Impacted Files**, or **Find Required Files**.

Alternatively, select files and then use the **Dependency Analysis** tab. In the **Impact Analysis** section, select **Find** and then specify the range of dependencies you want to display: **All Dependencies of Selection**, **Files Impacted by Selection**, or **Files Required by Selection**.

The graph shows the selected files and their file dependencies.

Tip To reset the graph to show all analyzed dependencies in the project, on the **Dependency Analysis** tab, in the **Impact Analysis** section, select **Find > All Files**. Alternatively, if you filter files, click the arrow to undo filtering and return to previous views.

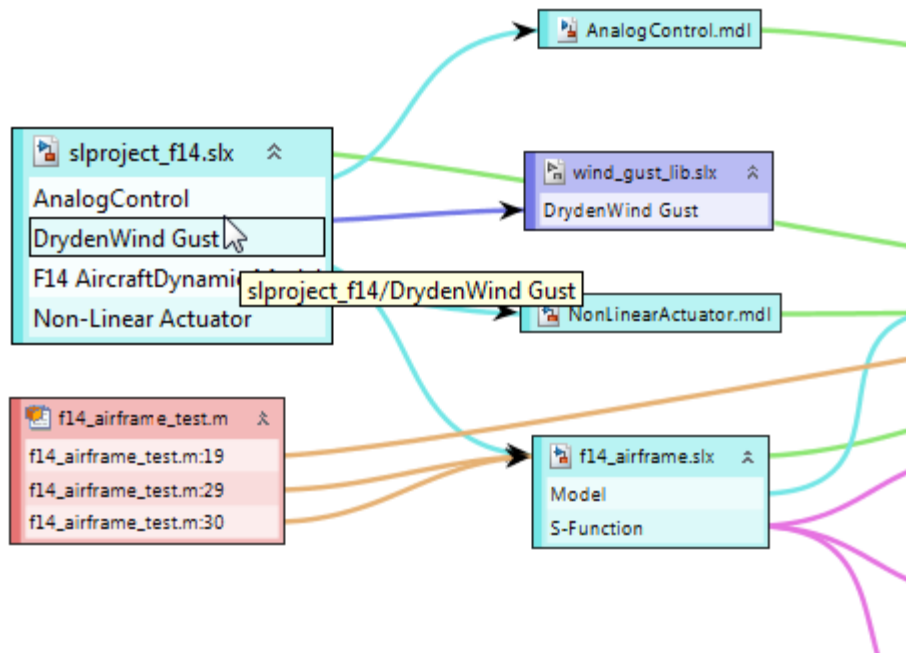

- 3 To see the blocks that have dependencies, expand individual files in the graph by clicking the arrows next to the file names.

The Impact graph expands the dependent file. You can see the subsystems that have dependencies. You can view dependent blocks, models, libraries, library blocks and requirements.

To highlight a dependent block in the model, double-click the block name in the expanded file.

To expand all files in the graph, in the **View** section, click **Expand All**.

- 4 You can find impacted files for a single block in a library, or for a single requirement. To find specific upstream or downstream dependencies at the block or requirement level, right-click a block or requirement and use the context menu. Select **Find All Dependencies**, **Find Impacted Files**, or **Find Required Files**.
- 5 To investigate changes in modified files, right-click and select **Compare to Ancestor** or **Compare to Revision**. See “Compare Revisions” on page 19-43.

- For large projects, viewing the results in a table can be easier to navigate. Click **Impact View** to switch to **Table View**. See “Investigate Problem Files in Table View” on page 18-19.

Select, Edit, and Export File Dependencies

To highlight or select groups of files:

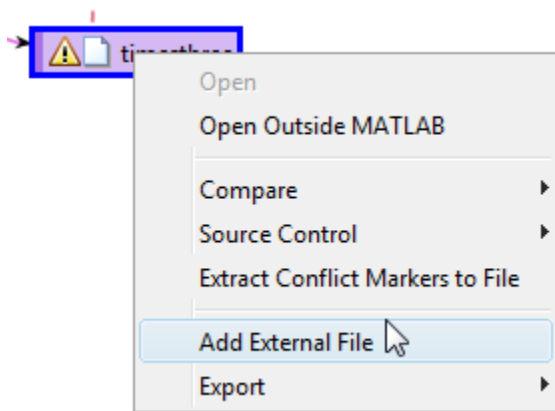

- Click a legend item to select all files of that type. For example, to select all model files, in the **File Type** legend, click **Simulink Model**. Selected files display a blue box.
- To choose a legend, on the **Dependency Analysis** tab, in the **View** section, use the **Group By** control. Choose a category such as file type, project status, source control status, labels, project, and problem type. Files in the graph are colored to indicate the legend category on each file.

For example:

- If your project is under source control, to show modified files, select **Group By > SVN** (or **Git**).
- To identify whether files are in your project or a referenced project, select **Group By > Project**.

To perform file operations:

- Take actions to resolve problem files. For example, right-click a problem file and select **Add to Project** or **Add External File**. For advice on resolving problem files, see “Check Dependency Results and Resolve Problems” on page 18-15.

- Hover over a file to read the file name in the tooltip at any zoom level. Double-click to open the file. Expand or collapse files in the graph by clicking the arrows next to the file names. View dependent blocks under an expanded file, and double-click a dependent block to highlight it in the model.
- Right-click files in the graph to use commands such as **Open**, **Compare**, or **Source Control** operations.

You can perform file operations on multiple files. To fit the view to the currently selected files, press **F**.

- Export selected files using the **Export** menu. You can switch to the files or custom task views with the files selected, or send the file paths to a workspace variable. You can also save and reload graph layouts, and save the graph as an image file, using **Save As**. Your graph layout is saved with the project. See “Save, Open, and Compare Dependency Analysis Results” on page 18-21.

Alternatively, you can work with the graph information programmatically. See “Automate Simulink Project Tasks Using Scripts” on page 17-27.

Check Dependency Results and Resolve Problems

In a project, under **Views**, select **Dependency Analysis**. If you have not yet run an analysis, click **Analyze**. After you run a dependency analysis, you see the Impact graph for the whole project in **Impact View**. The project dependency analysis identifies problems, such as missing files, files not in the project, unsaved changes, and out-of-date derived files. You can examine problem files and resolve issues using the **Impact View** or the **Table View**.

To show only problem files, hover over the **Problems** heading in the right pane of the Impact view and click **Find All**.

Problem Message	Description	Fix
Not in project	The file is not in the project.	<p>Add it to the project.</p> <p>You do not need to add all required files to the project. For example, you can exclude derived S-Function binary files that the source code in your project generates. “Work with Derived Files in Projects” on page 19-70.</p> <p>To remove a file from the problem list without adding it to the project, right-click the file and select Add External File.</p>
Missing project file	The file is in the project but does not exist on disk.	Create the file, or recover it using source control.

Problem Message	Description	Fix
Outside project root	The file is outside the project root folder.	<p>If this is OK, set the file as an external file. Otherwise move it under the project root.</p> <p>If you need a file that is outside the project root to be in your project, copy or move the file within the project root, and add it to the project and the path. Remove the original location from the path.</p> <p>If required files are outside your project, you cannot add these files to your project. This dependency might not indicate a problem if the file is on your path and is a utility or resource that is not part of your project. Use dependency analysis to ensure that you understand the design dependencies.</p>
In unreferenced project	The file is within a project that is not referenced by the current project.	Add the project containing the file as a project reference.
Missing file	The file or variable could not be found.	If this status is acceptable, set the file as an external file.
Unsaved changes	The file has unsaved changes in the MATLAB or Simulink editors	Save the file.
Derived file out of date	The derived file is older than the source file it was derived from.	<p>Regenerate the derived file. If it is a P-Block, you can regenerate automatically by running the project checks.</p> <p>On the Project tab, click Check Project and follow prompts to rebuild files.</p> <p>If you rename a source file, the project detects impact in the derived file and prompts you to update it.</p>

Problem Message	Description	Fix
Missing product	The project has a dependency on a missing product.	<p>Fix models by installing missing products.</p> <p>If you open a model that contains built-in blocks or library links from missing products, you see labels and links to help you fix the problem.</p> <ul style="list-style-type: none"> • Blocks are labeled with missing product names (for example, SimEvents not installed). • Tooltips include the name of the missing product. • Messages provide links to open Add-On Explorer and install the missing product. <p>To find a link to open Add-On Explorer and install the product:</p> <ul style="list-style-type: none"> • For built-in blocks, open the Diagnostic Viewer, and click the link in the warning message. • For unresolved library links, double-click the block to view details and click the link to install the product. <p>Product dependencies can occur in many other ways, for example in callbacks, so in this case you cannot easily see where the missing product is referenced. Fix models by installing missing products.</p>

Investigate Problem Files in Impact View

Use the **Impact View** to investigate your project dependencies graphically.

- 1 In the Impact view, to see problem files for the whole project, clear any file selections by clicking a blank area of the graph. View any problem files listed in the right panel.
- 2 To view the files that use a problem file, hover over the problem file and click **Find Dependencies**.

The graph updates to display only the problem file and its dependencies, and the problem message in the right panel.

- 3 Take actions to resolve the problem file. For example, right-click the file and select **Add to Project** or **Add External File**.
- 4 Click a problem file and check the path shown on the right. Check if required files are outside your project root.
- 5 Examine or edit dependencies by opening referencing components (such as a block or line of MATLAB code that references a problem file). To open a referencing component, expand a file in the graph, and double-click an item in the list.

MATLAB files open in the MATLAB Editor, and Simulink models open in the Simulink Editor with the referencing component block highlighted.
- 6 To return to the full project view, clear the filter in the search box (e.g., **Dependencies of "filename"**).

For more ways to work with the Impact view, see "Perform Impact Analysis" on page 18-6.

Investigate Problem Files in Table View

- 1 Select **Table View** and sort by the Problem Description column.
- 2 Click each file in the problem list.

Use the lower pane to display the files that use the selected file. You can view **Directly Impacted Files** or switch to **Directly Required Files**. You can select multiple files or dependencies at once and find the impacts or requirements of them all.

For a selected file, check the message in the **Problem Description** column.

- 3 In the dependencies table, check the problem description and project status of dependent files.
- 4 To open the referencing component for editing, right-click a file in the lower table and select **Open**.
- 5 Check the path, where \$ indicates the project root. Check if required files are outside your project root.
- 6 To remove a file from the problem list without adding it to the project, right-click the file and select **Add External File**. The file disappears from the problem list. The next time you run a dependency analysis, this file does not appear in the problem list.

Find Requirements Documents in a Project

In a project, a dependency analysis finds requirements documents linked using the Requirements Management Interface.

- You can view and navigate to and from the linked requirements documents.
- You can create or edit Requirements Management links only if you have Simulink Requirements.

- 1** In a project, in the **Views** pane, select **Dependency Analysis**.
- 2** Click the **Analyze** button.

The Impact graph displays the structure of all analyzed dependencies in the project. Project files that are not detectable dependencies of the analyzed files are not visible in the graph.

- 3** To highlight requirements documents in the graph, in the Dependency Type legend, click **Requirements Link**. Arrows connect requirements documents to the files with the requirement links.
- 4** To find the specific block containing a requirement link, expand the model file in the graph. Click **Expand All** or click the arrows next to the file name. View the arrow connecting the block containing the requirement link to the requirements document file.
- 5** To open a requirements document, double-click the document in the graph.

- “View Linked Requirements in Models and Blocks” on page 12-59

Save, Open, and Compare Dependency Analysis Results

In a project, you can save the results of a dependency analysis. You can view the saved results later, without having to repeat the analysis. You can also save results separately in named files and reload them.

Save, open, and compare dependency analysis results from the **File** section of the **Dependency Analysis** tab.

- To save your results as a `.graphml` file, click **Save As** and choose a file name and location.
- To open saved dependency analysis results, click **Open**.
- To compare results with previously saved results, click **Compare to Saved**. Select a `.graphml` file. Inspect the differences in the comparison report.

You can save reports that include more detailed results by using model dependency analysis. For more information about choosing model or project dependency analysis, see “What Is Dependency Analysis?” on page 18-2.

Export Impact Graph Results to Files or Images

To export impact analysis results, on the **Dependency Analysis** tab, in the **Impact Analysis** section, use the **Export** controls, or use the **Export** context menu on selected files.

Select Files to Export

To export all the files in the current view, check that no files are selected. (Click the graph background to clear the selection on all files.) Click **Export** to display **Files in view: number of files**.

Select a subset of files in the graph to export. Click **Export** to see how many files are selected: **Selected files: number of files**.

Export Files

- To save the selected file paths to a variable, select **Export > Save to Workspace**.
- To open the Custom Task dialog box with the files selected, select **Export > Send to Custom Task**.

- To switch to the Files view with the files selected, select **Export > Show in Files View**.

Export Graph to Image File

To export the Impact graph as an image file for sharing or archiving, you can either:

- Save an image file. On the **Dependency Analysis** tab, in the **File** section, select **Save As > Save As Image**. Use the Save dialog box to specify the name, file type, and location. The default file type is SVG, which supports image scaling.
- Copy the image to the clipboard using the keyboard. You can paste the clipboard contents into other documents.

Export Reloadable Results

To export the impact results to a `.graphml` file that you can reload in a project, click **Save As** and choose a file name and location..

- “Scope of Dependency Analysis” on page 18-37
- “Best Practices for Dependency Analysis” on page 18-40
- “Use the Model Manifest Report” on page 18-41

What Are Model Dependencies?

Each Simulink model requires a set of files to run successfully. These files can include referenced models, data files, S-functions, and other files the model cannot run without. These required files are called model dependencies.

Dependency Analysis Requirements	Tools to Choose
Find required files for an entire project.	Use dependency analysis from the Project. See “Dependency Analysis”.
Perform dependency analysis of a specific model with control of more options.	Use the manifest tools from your model. See “Generate Manifests” on page 18-24. Generate a manifest if you want to: <ul style="list-style-type: none"> • Analyze a model that is not in a project. • Save the list of the model dependencies to a manifest file. • Create a report to identify where dependencies arise. • Control the scope of dependency analysis.

After you generate a manifest for a model to determine its dependencies, you can:

- View the files required by your model in a manifest file.
- Trace dependencies using the report to understand why a particular file or toolbox is required by a model.
- Package the model with its required files into a zip file to send to another Simulink user.
- Compare older and newer manifests for the same model.
- Save a specific version of the model and its required files in a revision control system.

You can also view the libraries and models referenced by your model in a graphical format using the Model Dependency Viewer. See “Model Dependency Viewer” on page 12-54.

Generate Manifests

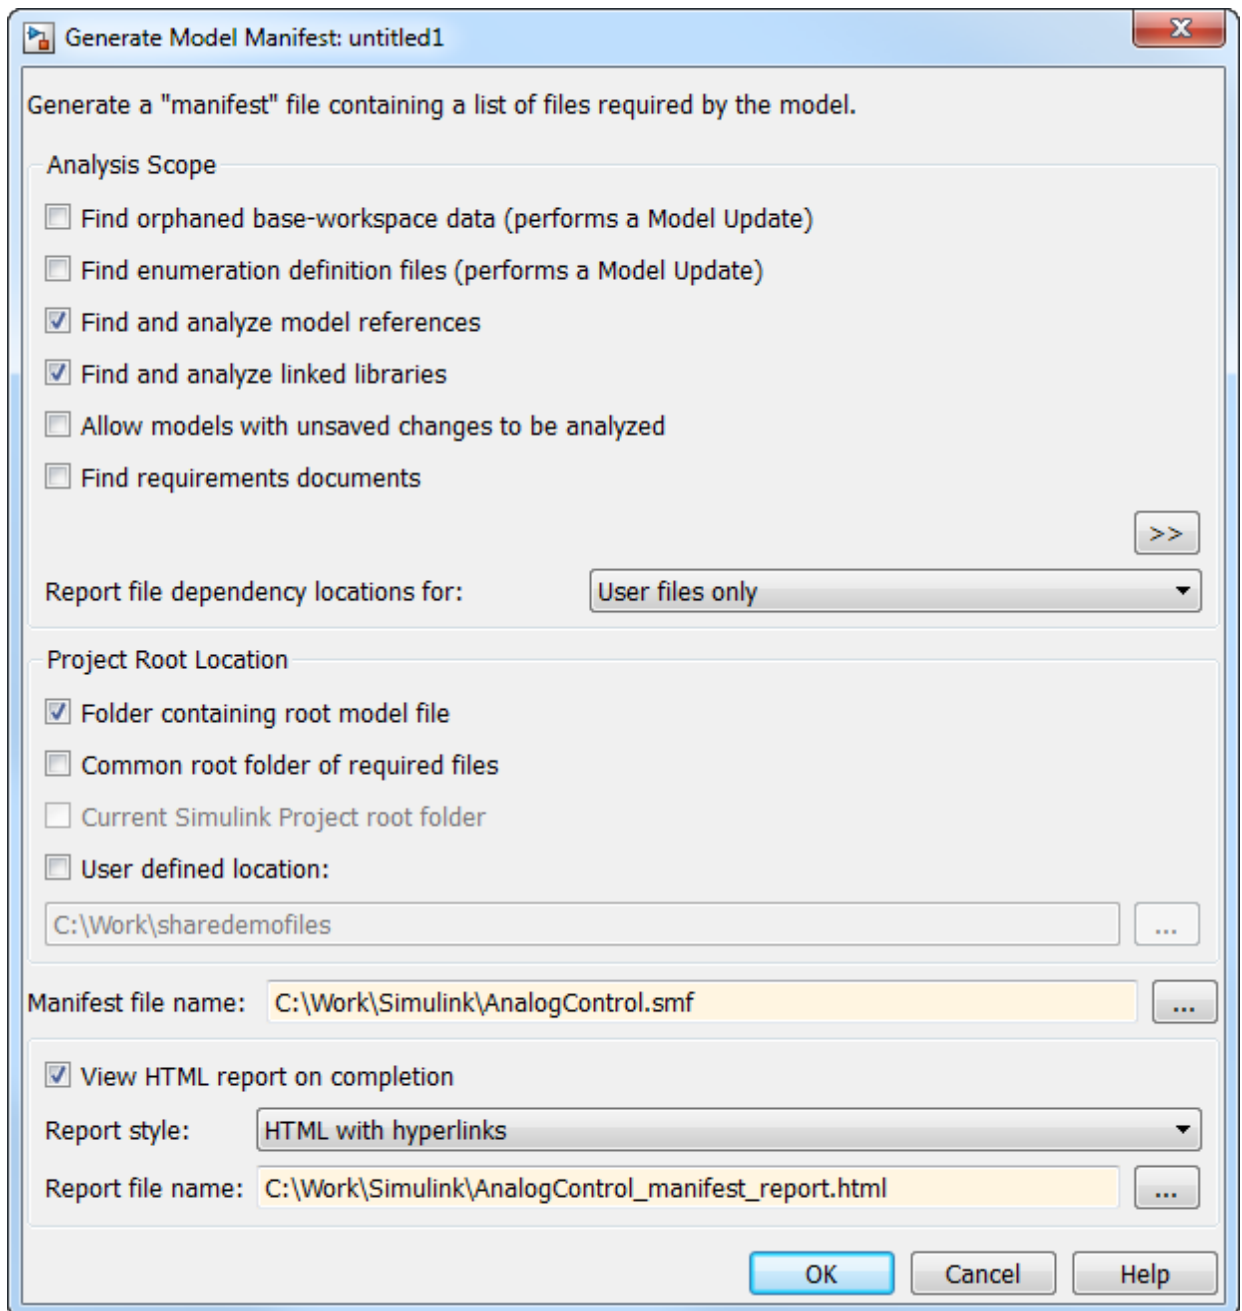

Generating a manifest performs the dependency analysis and saves the list of model dependencies to a manifest file. You must generate the manifest before using any of the other Simulink Manifest Tools.

Note The model dependencies identified in a manifest depend upon the **Analysis Scope** options you specify. For example, performing an analysis without selecting **Find Library Links** might not find all the Simulink blocksets that your model requires, because they are often included in a model as library links. See “Manifest Analysis Scope Options” on page 18-27.

To generate a manifest:

- 1** Select **Analysis > Model Dependencies > Generate Manifest**.

The Generate Model Manifest dialog box appears.

- 2 Click **OK** to generate a manifest and report using the default settings.

Alternatively you can first change the following settings:

- Select the **Analysis scope** check boxes to specify the type of dependencies you want to detect (see “Manifest Analysis Scope Options” on page 18-27).
- Control whether to report file dependency locations by selecting **Report file dependency locations for:**
 - **User files only** (default) — only report locations where dependencies are upon user files. Use this option if you want to understand the interdependencies of your own code and do not care about the locations of dependencies on MathWorks products. This option speeds up report creation and streamlines the report.
 - **All files** — report all locations where dependencies are introduced, including all dependencies on MathWorks products. This is the slowest option and the most verbose report. Use this option if you need to trace all dependencies to understand why a particular file or toolbox is required by a model. If you need to analyze many references, it can be helpful to sort the results by clicking the report column headers.
 - **None** — do not report any dependency locations. This is the fastest option and the most streamlined report. Use this option if you want to discover and package required files and do not require all the information about file references.
- If desired, change the **Project Root Location**. If the model is in a project, you can select **Current project root folder**. Other check box options are: **Folder containing root model file** (the default), **Common root folder of required files**, or **User-defined location** — for this option, enter a path in the edit box, or browse to a location.
- If desired, edit the **Manifest file name** and location in which to save the file.
- Use the check box **View HTML report on completion** to specify if you want to generate a report when you generate the manifest. You can edit the **Report file name** or leave the default, *mymodelname_manifest_report.html*. You can set the **Report style** to Plain HTML or HTML with Hyperlinks.

When you click **OK** Simulink generates a manifest file containing a list of the model dependencies. If you selected **View HTML report on completion**, the Model Manifest Report appears after Simulink generates the manifest. See “Use the Model Manifest Report” on page 18-41 for an example.

The manifest is an XML file with the extension `.smf` located (by default) in the same folder as the model itself.

Manifest Analysis Scope Options

The Simulink Manifest Tools allow you to specify the scope of analysis when generating the manifest. The dependencies identified by the analysis depend upon the scope you specify.

Tip You can select analysis options that perform a Model Update. If Model Update fails you see an error message. Either clear those analysis options to generate a manifest without a Model Update, or try a manual Model Update to find out more about the problem. For example your model might require variables that are not present in the workspace (for example, if a block parameter defines a variable that you forgot to load manually).

The following table describes the Analysis Scope options.

Check Box Option	Description
Find orphaned base workspace data (performs a Model Update)	Searches for base workspace variables the model requires, that are not defined in any file in this Manifest.
Find enumeration definition files (performs a Model Update)	Searches for enumeration definition files. Turn on this option to detect enumerated data types used as part of a bus object definition.
Find and analyze model references	Searches for Model blocks in the model, and identifies any referenced models as dependencies.
Find and analyze linked libraries	Searches for links to library blocks in the model, and identifies any library links as dependencies.
Allow models with unsaved changes to be analyzed	Select this check box only if you want to allow analysis of unsaved changes.

Check Box Option	Description
Find requirements documents	Searches for requirements documents linked using the Requirements Management Interface. Note that requirements links created with IBM Rational DOORS software are not included in manifests. For more information, see “Find Requirements Documents in a Project” on page 18-20.
Click the >> button on the right to show the following advanced analysis options.	
Find S-functions	Searches for S-Function blocks in the model, and identifies S-function files (MATLAB code and C) as dependencies. See the source code item in “Special Cases” on page 18-39.
Analyze model and block callbacks (including Interpreted MATLAB Function blocks)	Searches for file dependencies introduced by the code in Interpreted MATLAB Function blocks, block callbacks, and model callbacks. For more detail on how callbacks are analyzed, see “Code Analysis” on page 18-38.
Find files required for code generation	Searches for file dependencies introduced by Simulink Coder custom code, and Embedded Coder templates. If you do not have a code generation product, this check is off by default, and produces a warning if you select it. This includes analysis of all configuration sets (not just the Active set) and <i>STF_make_rtw_hook</i> functions, and locates system target files and Code Replacement Library definition files (.m or .mat). See also “Required Toolboxes” on page 18-42, and the source code item in “Special Cases” on page 18-39.
Find data files (e.g. in “From File” blocks)	Searches for explicitly referenced data files, such as those in From File blocks, and identifies those files as dependencies. See “Special Cases” on page 18-39.
Analyze Stateflow charts	Searches for file dependencies introduced by using syntax such as <code>ml.mymean(myvariable)</code> in models that use Stateflow.

Check Box Option	Description
Analyze code in MATLAB Functions blocks	Searches for MATLAB Function blocks in the model, and identifies any file dependencies (outside toolboxes) introduced in the code. Toolbox dependencies introduced by a MATLAB Function block are not detected.
Analyze files in “user toolboxes”	Searches for file dependencies introduced by files in user-defined toolboxes. See “Special Cases” on page 18-39.
Analyze MATLAB files	Searches for file dependencies introduced by MATLAB files called from the model. For example, if this option is selected and you have a callback to <code>mycallback.m</code> , then the referenced file <code>mycallback.m</code> is also analyzed for further dependencies. See “Code Analysis” on page 18-38.
Store MATLAB code analysis warnings in manifest	Saves any warnings in the manifest.

See also “Scope of Dependency Analysis” on page 18-37 for more information.

Command-Line Dependency Analysis

- “Check File Dependencies” on page 18-29
- “Check Toolbox Dependencies” on page 18-30

Check File Dependencies

To programmatically check for file dependencies, use the function `dependencies.fileDependencyAnalysis` as follows.

```
[files, missing, depfile, manifestfile] =
dependencies.fileDependencyAnalysis('modelname', 'manifestfile')
```

This returns the following:

- *files* — a cell array of character vectors containing the full-paths of all existing files referenced by the model *modelname*.
- *missing* — a cell array of character vectors containing the names all files that are referenced by the model *modelname*, but cannot be found.

- *depfile* — returns the full path of the user dependencies (.smd) file, if it exists, that stores the names of any files you manually added or excluded. Simulink uses the .smd file to remember your changes the next time you generate a manifest. See “Edit Manifests” on page 18-32.
- *manifestfile* — (optional input) specify the name of the manifest file to create. The suffix .smf is always added to the user-specified name.

If you specify the optional input, *manifestfile*, then the command creates a manifest file with the specified name and path *manifestfile*. *manifestfile* can be a full-path or just a file name (in which case the file is created in the current folder).

If you try this analysis on an example model, it returns an empty list of required files because the standard MathWorks installation includes all the files required for the example models.

Check Toolbox Dependencies

To check which toolboxes are required, use the function `dependencies.toolboxDependencyAnalysis` as follows:

```
[names,dirs] = dependencies.toolboxDependencyAnalysis(files_in)
```

files_in must be a cell array of character vectors containing .m or model files on the MATLAB path. Simulink model names (without file extension) are also allowed.

This returns the following:

- *names* — a cell-array of toolbox names required by the files in *files_in*.
- *dirs* — a cell-array of the toolbox folders.

Note The method `toolboxDependencyAnalysis` looks for toolbox dependencies of the files in *files_in* but does *not* analyze any subsequent dependencies.

If you want to find all detectable toolbox dependencies of your model *and* the files it depends on:

- 1 Call `fileDependencyAnalysis` on your model.

For example:

```
[files, missing, depfile, manifestfile] = dependencies.fileDependencyAnalysis('mymodel')
```

```

files =
    'C:\Work\manifest\foo.m'
    'C:\Work\manifest\mymodel'
missing =
    []
depfile =
    []
manifestfile =
    []

```

- 2 Call `toolboxDependencyAnalysis` on the files output of step 1.

For example:

```
tbxes = dependencies.toolboxDependencyAnalysis(files)
```

```

tbxes =
[1x24 char]    'MATLAB'    'Simulink Coder'    'Simulink'

```

To view long product names examine the `tbxes` cell array as follows:

```
tbxes{:}
```

```

ans =
Image Processing Toolbox

```

```

ans =
MATLAB

```

```

ans =
Simulink Coder

```

```

ans =

```

```

Simulink

```

For command-line dependency analysis, the analysis uses the default settings for analysis scope to determine required toolboxes. For example, if you have code generation products, then the check **Find files required for code generation** is on by default and Simulink Coder is always reported as required. See “Required Toolboxes” on page 18-42 for more examples of how your installed products and analysis scope settings can affect reported toolbox requirements.

Edit Manifests

After you generate a manifest, you can view the list of files identified as dependencies, and manually add or delete files from the list.

To edit the list of required files in a manifest:

- 1 Select **Analysis > Model Dependencies > Edit Manifest Contents**.

Alternatively, if you are viewing a manifest report you can click **Edit** in the top **Actions** box, or you can click **View and Edit Manifest** in the Export Manifest dialog box.

The View and Edit Manifest dialog box appears, showing the latest manifest for the current model.

Note You can open a different manifest by clicking the Browse for manifest file

button . If you have not generated a manifest, select **Generate Manifest** to open the Generate Model Manifest dialog box (see “Generate Manifests” on page 18-24).

- 2 Examine the **Files to be exported** list on the left side of the dialog box. This list shows the files identified as dependencies.

3 To add a file to the manifest:

a Click **Add Files**.

The Add Files to Manifest dialog box opens.

b Select the file you want to add, then click **Open**.

The selected file is added to the **Files to be exported** list.

4 To remove a file from the manifest:

a Select the file you want to remove from the **Files to be exported** list.

b Click the Exclude selected files button .

The selected file is moved to the **Excluded files** list.

Note If you add a file to the manifest and then exclude it, that file is removed from the dialog box (it is not added to the **Excluded files** list). Only files detected by the Simulink Manifest Tools are included in the Excluded files list.

5 If desired, change the **Project Root Location**.

6 Click **Save** to save your changes to the manifest file.

Simulink saves the manifest (.smf) file, and creates a user dependencies (.smd) file that stores the names of any files you manually added or excluded. Simulink uses the .smd file to remember your changes the next time you generate a manifest, so you do not need to repeat manual editing. For example, you might want to exclude source code or include a copyright document every time you generate a manifest for exporting to a customer. The user dependencies (.smd) file has the same name and folder as the model. By default, the user dependencies (.smd) file is also included in the manifest.

Note If the user dependencies (.smd) file is read-only, a warning is displayed when you save the manifest.

7 To view the Model Manifest Report for the updated manifest, click **Show Report**.

An updated Model Manifest Report appears, listing the required files and toolboxes, and details of references to other files. See “Use the Model Manifest Report” on page 18-41 for an example.

- 8 When you are finished editing the manifest, click **OK**.

Compare Manifests

You can compare two manifests to see how the list of model dependencies differs between two models, or between two versions of the same model. You can also compare a manifest with a folder or a ZIP file.

To compare manifests:

- 1 From the Current Folder browser, right-click a manifest file and select **Compare Against > Choose**.

Alternatively, from your model, select **Analysis > Model Dependencies > Compare Manifests**.

The dialog box Select Files or Folders for Comparison appears.

- 2 In the dialog box Select Files or Folders for Comparison, select files to compare, and the comparison type.
 - a Use the drop-down lists or browse to select manifest files to compare.
 - b Select the **Comparison type**. For two manifests you can select:
 - **Simulink manifest comparison** — Select for a manifest file list comparison reporting new, removed, and changed files. The report contains links to open files and compare files that differ. You can use a similar file **List comparison** for comparing a manifest to a folder or a ZIP file.
 - **Simulink manifest comparison (printable)** — Select for a printable Model Manifest Differences Report without links. The report provides details about each manifest file, and lists the differences between the files.
- 3 View the report in the Comparison Tool comparing the file names, dates, and sizes stored in the manifests.

Be aware the details stored in the manifest might differ from the files on disc. If you click a “compare” link in the report, you see warnings if there are problems such as size mismatches, or if the tool cannot find those files on disc.

For more information on the Comparison Tool, see “Compare Files and Folders and Merge Files” (MATLAB) in the MATLAB Data and File Management documentation.

Export Files in a Manifest

You can export copies of the files listed in the manifest to a ZIP file. Exporting the files allows you to package the model with its required files into a single ZIP file, so you can easily send it to another user or save it in a revision control system.

To export your model with its required files:

- 1 Select **Analysis > Model Dependencies > Export Files in Manifest**.

Alternatively, if you are viewing a manifest report you can click **Export** in the top **Actions** box.

The Export Files in Manifest dialog box appears, showing the latest manifest for the current model.

Note You can export a different manifest by clicking the Browse for manifest file

button. If you have not generated a manifest, select **Generate Manifest** to open the Generate Model Manifest dialog box (see “Generate Manifests” on page 18-24).

- 2 If you want to view or edit the manifest before exporting it, click **View and Edit Manifest** to view or change the list of required files. See “Edit Manifests” on page 18-32. When you close the View and Edit Manifest dialog box, you return to the Export Files in Manifest dialog box.
- 3 Click **Validate** to check the manifest. Validation reports information about possible problems such as missing files, warnings, and orphaned base workspace data.
- 4 Enter the ZIP file name to which you want to export the model.
- 5 Select **Preserve folder hierarchy when exporting** if you want to keep folder structure for your exported model and files. Then, select the root folder to use for this structure (usually the same as the **Project Root Location** on the Generate Manifest dialog box).

Note You must select **Preserve folder hierarchy** if you are exporting a model that uses an .m file inside a MATLAB class (to maintain the folder structure of the class), or if the model refers to files in other folders (to ensure the exported files maintain the same relative paths).

- 6 Click **OK**.

The model and its file dependencies are exported to the specified ZIP file.

Scope of Dependency Analysis

The Simulink Manifest Tools identify required files and list them in an XML file called a manifest. When Simulink generates a manifest file, it performs a static analysis on your model, which means that the model does not need to be capable of performing an “update diagram” operation (see “Update Diagram and Run Simulation” on page 1-66). The only exception to this is when you select the analysis option **Find orphaned base workspace data (performs a Model Update)**.

You can specify the type of dependencies you want to detect when you generate the manifest. See “Manifest Analysis Scope Options” on page 18-27.

For more information on what the tool analyzes, refer to the following sections:

- “Analysis Limitations” on page 18-38
- “Code Analysis” on page 18-38
- “Special Cases” on page 18-39

Analysis Limitations

The analysis might not find all files required by your model (for examples, see “Code Analysis” on page 18-38).

The analysis might not report certain blocksets or toolboxes required by a model. You should be aware of this limitation when sending a model to another user. Blocksets that do not introduce dependence on any files (such as Fixed-Point Designer™) cannot be detected. Some SimEvents blocks do not introduce a detectable dependence on SimEvents.

To include dependencies that the analysis cannot detect, you can add additional file dependencies to a manifest file using the View/Edit Manifest Contents option (see “Edit Manifests” on page 18-32).

Code Analysis

When the Simulink dependency analysis encounters MATLAB code, for example in a model or block callback, or in a .m file S-function, the analysis attempts to identify the files it references. If those files contain MATLAB code, *and* the analysis scope option **Analyze MATLAB files** is selected, the referenced files are also analyzed. This function is similar to `matlab.codetools.requiredFilesAndProducts` but with some enhancements:

- Character vectors passed into calls to `eval`, `evalc`, and `evalin` are analyzed.
- File names passed to `load`, `fopen`, `xlsread`, `importdata`, `dlmread`, and `imread` are identified.

Files that are in MathWorks toolboxes are not analyzed.

File names passed to `load`, etc., are identified only if they are literal character vectors, for example:

```
load('mydatafile')  
load mydatafile
```

If you define a file name as a variable and pass that to a function, the file is a hidden dependency. The following example, and anything more complicated, does not identify the dependency because the file name is inside a variable:

```
str = 'mydatafile';
load(str);
```

Similarly, arguments to `eval`, etc., are analyzed only if they are literal character vectors.

The Simulink dependency analysis looks inside MAT-files to find the names of variables to be loaded. This enables them to distinguish reliably between variable names and function names in block callbacks.

If a model depends upon a file for which both `.m` and `.p` files exist, then the manifest reports both, and, if the **Analyze MATLAB files** option is selected, the `.m` file is analyzed.

Special Cases

The following list contains more information about specific cases:

- If your model references a data class created using MATLAB syntax, for example called *MyPackage.MyClass*, all files inside the folder *MyPackage* and its subfolders are added to the manifest.

Warning The analysis adds all files in the class, which includes any source control files such as `.svn` or `.cvs`. You might want to edit the manifest to remove these files.

- A user-defined toolbox must have a properly configured `Contents.m` file. The Simulink Manifest Tools search user-defined toolboxes as follows:
 - If you have a `Contents.m` file in folder *X*, any file inside a subfolder of *X* is considered part of your toolbox.
 - If you have a `Contents.m` file in folder *X/X*, any file inside all subfolders of the “outer” folder *X* is considered part of your toolbox.

For more information on the format of a `Contents.m` file, see `ver`.

- If your S-functions require TLC files, these are detected.
- If you have Simscape, your Simscape components are analyzed. See also “Required Toolboxes” on page 18-42 for other effects of your installed products on manifests.
- If you create a UI using GUIDE and add this to a model callback, then the dependency analysis detects the `.m` and `.fig` file dependencies.

- If you have a dependence on source code, such as .c, .h files, these files are not analyzed at all to find any files that they depend upon. For example, subsequent #include calls inside .h files are not detected. To make such files detectable, you can add them as dependent files to the "header file" section of the Custom Code pane of the Simulink Coder section of the Configuration Parameters dialog box (or specify them with rtwmakecfg). Alternatively, to include dependencies that the analysis cannot detect, you can add additional file dependencies to a manifest file using the View/Edit Manifest Contents option (see "Edit Manifests" on page 18-32).
- Various blocksets and toolboxes can introduce a dependence on a file through their additional source blocks. If the analysis scope option **Find data files (e.g. in "From File" blocks)** is selected, the analysis detects file dependencies introduced by the following blocks:

Product	Blocks
DSP System Toolbox	From Wave File (Obsolete) block (Microsoft Windows operating system only) From Multimedia File block (Windows only)
Computer Vision Toolbox™	Image From File block Read Binary File block
Simulink 3D Animation™	VR Sink block

The option **Find data files** also detects dependencies introduced by setting a "Model Workspace" for a model to either MAT-File or MATLAB Code, and model dependencies specified on the Model Referencing pane of the Configuration Parameters dialog box.

Best Practices for Dependency Analysis

The starting point for dependency analysis is the model itself. Make sure that the model refers to any data files it needs, even if you would normally load these manually. For example, add code to the model's PreLoadFcn to load them automatically, like this example:

```
load mydatafile
load('my_other_data_file.mat')
```

This way, the Simulink Manifest Tools can add them to the manifest. For more detail on callback analysis, see the notes on code analysis (see “Code Analysis” on page 18-38).

More generally, ensure that the model creates or loads any variables it uses, either in model callbacks or in scripts called from model callbacks. This reduces the possibility of the Simulink Manifest Tools confusing variable names with function names when analyzing block callbacks.

If you plan to export the manifest after creating it, ensure that the model does not refer to any files by their absolute paths, for example:

```
load C:\mymodel\mydata\mydatafile.mat
```

Absolute paths can become invalid when you export the model to another machine. If referring to files in other folders, do it by relative path, for example:

```
load mydata\mydatafile.mat
```

Select **Preserve folder hierarchy** when exporting, so that the exported files are in the same locations relative to each other. Also, choose a root folder so that all the files listed in the manifest are inside it. Otherwise, any files outside the root are copied into a new folder called `external` underneath the root, and relative paths to those files become invalid.

If you are exporting a model that uses a `.m` file inside a MATLAB class (in a folder called `@myclass`, for example), you must select the **Preserve folder hierarchy** check box when exporting, to maintain the folder structure of the class.

Always test exported ZIP files by extracting the contents to a new location on your computer and testing the model. Be aware that in some cases required files might be on your path but not in the ZIP file, if your path contains references to folders other than MathWorks toolboxes.

Use the Model Manifest Report

- “Report Sections” on page 18-42
- “Required Toolboxes” on page 18-42
- “Example Model Manifest Report” on page 18-43

Report Sections

If you selected **View HTML report on completion** in the Generate Model Manifest dialog box, the Model Manifest Report appears after Simulink generates the manifest. The report shows:

- Analysis date
- **Actions** pane — Provides links to regenerate, edit, or compare the manifest, and export the files in the manifest to a ZIP file.
- **Model Reference and Library Link Hierarchy** — Links you can click to open models.
- **Files used by this model** — Required files, with paths relative to the project root.

You can sort the results by clicking the report column headers.

- **Toolboxes required by this model.** For details, see “Required Toolboxes” on page 18-42.
- **References in this model** — This section provides details of references to other files so you can identify where dependencies arise. You control the scope of this section with the **Report file dependency locations** options on the Generate Manifest dialog box. You can choose to include references to user files only, all files, or no files. See “Generate Manifests” on page 18-24. Use this section of the report to trace dependencies to understand why a particular file or toolbox is required by a model. If you need to analyze many references, it can be helpful to sort the results by clicking the report column headers.
- **Folders referenced by this model**
- **Orphaned base workspace variables** — If you selected the analysis option **Find orphaned base workspace data**, this section reports any base workspace variables the model requires that are not defined in a file in this manifest.
- **Warnings generated while analyzing MATLAB code** — You can opt out of this section by clearing the **Store MATLAB code analysis warnings in manifest** analysis option.
- **Dependency analysis settings** — Records the details of the analysis scope options.

See the examples shown in “Example Model Manifest Report” on page 18-43.

Required Toolboxes

In the report, the “Toolboxes required by this model” section lists all products required by the model *that the analysis can detect*. Be aware that the analysis might not report

certain blocksets or toolboxes required by a model, e.g., blocksets that do not introduce dependence on any files (such as Fixed-Point Designer) cannot be detected. Some MathWorks files under toolbox/shared can report only requiring MATLAB instead of their associated toolbox.

The results reported can be affected by your analysis scope settings and your installed products. For example:

- If you have code generation products and select the scope option “**Find files required for code generation**”, then:
 - Simulink Coder software is always reported as required.
 - If you also have an .ert system target file selected, then Embedded Coder software is always reported as required.
- If you clear the **Find library links** option, then the analysis cannot find a dependence on, for example, *someBlockSet*, and so no dependence is reported upon the block set.
- If you clear the **Analyze MATLAB files** option, then the analysis cannot find a dependence upon *fuzzy.m*, and so no dependence is reported upon the Fuzzy Logic Toolbox™.

Example Model Manifest Report

You should always check the **Dependency analysis settings** section in the Model Manifest Report to see the scope of analysis settings used to generate it.

Following are portions of a sample report.

Model Manifest Report:mpowertrain

Orphaned base workspace variables

Use the table below to determine what base workspace variables the model requires, that are not defined in a file in this Manifest

Click on a column header to sort the table

Variable Name	Class	Reference Location
manual	logical	mpowertrain/Model Variants (show)
trans_type_auto	Simulink.Variant	mpowertrain/Model Variants (show)
trans_type_manual	Simulink.Variant	mpowertrain/Model Variants (show)

Warnings generated while analyzing MATLAB code

(No warnings were generated)

Dependency analysis settings:

- Detect orphaned workspace variables: **true**
- Find model references: **true**
- Find library links: **true**
- Allow models with unsaved changes to be analyzed: **false**
- Find S-functions: **true**
- Analyze model and block callbacks: **true**
- Find code-generation files: **true**
- Find data files: **true**
- Analyze Stateflow charts: **true**
- Analyze Embedded MATLAB code: **true**
- Find Requirements documents: **false**
- Analyze files in user-defined toolboxes: **true**
- Analyze MATLAB files: **true**
- Reporting of file dependence locations: **user files only**
- Store warnings: **true**

About Source Control with Projects

You can use a project to work with source control. You can perform operations such as update, commit, merge changes, and view revision history directly from the project environment.

In MATLAB, projects have interfaces to:

- Git— See “Set Up Git Source Control” on page 19-20.
- Subversion (SVN) — See “Set Up SVN Source Control” on page 19-11.
- Software Development Kit (SDK) — You can use the SDK to integrate projects with third-party source control tools. See “Write a Source Control Integration with the SDK” on page 19-29.

Tip You can check for updated source control integration downloads on the projects Web page: <https://www.mathworks.com/discovery/simulink-projects.html>

To use source control in your project, use any of the following workflows:

- Add source control to a project. See “Add a Project to Source Control” on page 19-6.
- Retrieve files from an existing repository and create a new project. See “Clone Git Repository or Check Out SVN Repository” on page 19-30.
- Create a new project in a folder already under source control and click **Detect**. See “Create a New Project From a Folder” on page 16-16.
- Make your project publicly available on GitHub. See “Share Project on GitHub” on page 17-48.

When your project is under source control, you can:

- “Clone Git Repository or Check Out SVN Repository” on page 19-30
- “Compare Revisions” on page 19-43
- “Commit Modified Files to Source Control” on page 19-48

Caution Before using source control, you must register model files with your source control tools to avoid corrupting models. See “Register Model Files with Source Control Tools” on page 19-10.

To view an example project under source control, see “Explore Project Tools with the Airframe Project” on page 16-5.

Classic and Distributed Source Control

This diagram represents the classic source control workflow (for example, using SVN).

Benefits of classic source control:

- Locking and user permissions on a per-file basis (e.g., you can enforce locking of model files)
- Central server, reducing local storage needs
- Simple and easy to learn

This diagram represents the distributed source control workflow (for example, using Git).

Benefits of distributed source control:

- Offline working
- Local repository, which provides full history
- Branching
- Multiple remote repositories, enabling large-scale hierarchical access control

To choose classic or distributed source control, consider these tips.

Classic source control can be helpful if:

- You need file locks.
- You are new to source control.

Distributed source control can be helpful if:

- You need to work offline, commit regularly, and need access to the full repository history.
- You need to branch locally.

Add a Project to Source Control

In this section...

“Add a Project to Git Source Control” on page 19-6

“Add a Project to SVN Source Control” on page 19-7

Add a Project to Git Source Control

If you want to add version control to your project files without sharing with another user, it is quickest to create a local Git repository in your sandbox.

- 1 On the Project tab, in the Source Control section, click **Use Source Control**.
- 2 In the Source control information dialog box, click **Add project to source control**.
- 3 In the Add to Source Control dialog box, in the **Source control tool** list, select **Git** to use the Git source control tool provided by the project.
- 4 Click **Convert** to finish adding the project to source control.

Git creates a local repository in your sandbox project root folder. The project runs integrity checks.

- 5 Click **Open Project** to return to your project.

The Project node displays the source control name **Git** and the repository location **Local Repository: *yoursandboxpath***.

- 6 Select the **Modified** files view and click **Commit** to commit the first version of your files to the new repository.

In the dialog box, enter a comment if you want, and click **Submit**.

You need some additional setup steps only if you want to merge branches with Git. See “Install Command-Line Git Client” on page 19-22.

Tip If you want to use Git and share with other users:

- To clone an existing remote Git repository, see “Clone Git Repository or Check Out SVN Repository” on page 19-30.

- To connect an existing project to a remote repository, on the Project tab, in the Source Control section, click **Remote** and specify a single remote repository for the origin branch.
 - To make your project publicly available on GitHub, see “Share Project on GitHub” on page 17-48.
-

Add a Project to SVN Source Control

Caution Before you start, check that your sandbox folder is on a local hard disc. Using a network folder with SVN is slow and unreliable.

This procedure adds a project to the built-in SVN integration that comes with the project. If you want to use a different version of SVN, see “Set Up SVN Source Control” on page 19-11.

- 1 On the Project tab, in the Source Control section, click **Use Source Control**.
- 2 In the Source control information dialog box, click **Add project to source control**.
- 3 In the Add to Source Control dialog box, select SVN as the **Source control tool**.
- 4 Next to **Repository path**, click **Change**.
- 5 In the Specify SVN Repository URL dialog box, select an existing repository or create a new one.
 - To specify an existing repository, click Generate URL from folder  to browse for your repository, paste a URL into the box, or use the list to select a recent repository.
 - To create a new repository, click Create an SVN repository in a folder . Using the file browser, create a folder where you want to create the new repository and click **Select Folder**. Do not place the new repository inside the existing project folder.

The project creates a repository in your folder, and you return to the Specify SVN Repository URL dialog box. The URL of the new repository is in the **Repository URL** box, and the project automatically selects the trunk folder.

Caution Specify file:// URLs and create new repositories for single users only. For multiple users, see “Share a Subversion Repository” on page 19-17.

- 6 Click **Validate** to check the path to the selected repository.

When the path is valid, you can browse the repository folders. For example, select the trunk folder, and verify the selected URL at the bottom of the dialog box, as shown.

- 7 Click **OK** to return to the Add to Source Control dialog box.

If your repository has a file URL, a warning appears that file URLs are for single users. Click **OK** to continue.

- 8 Click **Convert** to finish adding the project to source control.

The project runs integrity checks.

- 9 After the integrity checks run, click **Open Project** to return to your project.

The Project node displays details of the current source control tool and the repository location.

- 10 If you created a new repository, select the **Modified** files view and click **Commit** to commit the first version of your files to the new repository. In the dialog box, enter a comment if you want, and click **Submit**.

Caution Before using source control, you must register model files with your source control tools to avoid corrupting models. See “Register Model Files with Subversion” on page 19-14.

More About

- “About Source Control with Projects” on page 19-2

Register Model Files with Source Control Tools

If you use third-party source control tools, you must register your model file extensions (.mdl and .slx) as binary formats. If you do not, these third-party tools can corrupt your model files when you submit them, by changing end-of-line characters, expanding tokens, substituting keywords, or attempting to automerge. Corruption can occur whether you use the source control tools outside of Simulink or if you try submitting files from a project without first registering your file formats.

Also check that other file extensions are registered as binary to avoid corruption at check-in for files such as .mat, .mlx, .mdl, .slxp, .sldd, .p, MEX-files, .xlsx, .jpg, .pdf, .docx, etc.

For instructions with SVN, see “Register Model Files with Subversion” on page 19-14. You must register model files if you use SVN, including the SVN integration provided by the project.

For instructions with Git, see “Register Model Files with Git” on page 19-23.

Set Up SVN Source Control

In this section...

“Set Up SVN Provided with Projects” on page 19-11

“Set Up Project SVN for SVN Version Already Installed” on page 19-12

“Set Up Project SVN for SVN Version Not Yet Provided with Projects” on page 19-13

“Register Model Files with Subversion” on page 19-14

“Enforce SVN Locking Model Files Before Editing” on page 19-17

“Share a Subversion Repository” on page 19-17

“Manage SVN Externals” on page 19-18

Set Up SVN Provided with Projects

Projects provide SVN for use with Subversion (SVN) sandboxes and repositories at version 1.9. You do not need to install SVN to use this integration because it includes an implementation of SVN.

Note This integration ignores any existing SVN installation.

The project SVN supports secure logins.

To use the version of SVN provided with the project, do one of the following:

- On the MATLAB Home tab, select **New > Project > From SVN**.
- Alternatively, in the start page, select **Project from SVN** to retrieve from source control, or when you add a project to source control, select SVN in the **Source control tool** list

. For instructions, see

- “Add a Project to Source Control” on page 19-6, or
- “Clone Git Repository or Check Out SVN Repository” on page 19-30.

Caution Place your project sandbox folder on a local hard disc. Using a network folder with SVN is slow and unreliable. If you use a Windows network drive, SVN move operations can result in incorrect "not existing" status for files visible in file browsers.

When you create a new sandbox using the project SVN, the new sandbox uses the latest version of SVN provided by the project.

When your project is under source control, you can use these project features:

- "Clone Git Repository or Check Out SVN Repository" on page 19-30
- "Compare Revisions" on page 19-43
- "Commit Modified Files to Source Control" on page 19-48

You can check out from a branch, but the project SVN does not support branch merging. Use an external tool such as TortoiseSVN to perform branch merging. You can use the project tools for comparing and merging by configuring TortoiseSVN to generate an XML comparison report when you perform a diff on model files. See "Merge Simulink Models from the Comparison Report" on page 21-20.

Set Up Project SVN for SVN Version Already Installed

If you want to use projects with an earlier SVN version you already have installed, create a new project in a folder already under SVN source control. The project detects SVN.

For example:

- 1 Create the sandbox using TortoiseSVN from Windows Explorer.
- 2 In MATLAB, create a new project in that folder. The project detects the existing source control. If the sandbox is version 1.6, for example, it remains a version 1.6 sandbox.

Note Before using source control, you must register model files with the tools. See "Register Model Files with Subversion" on page 19-14.

Set Up Project SVN for SVN Version Not Yet Provided with Projects

If you need to use a later version of SVN than 1.9, you can use Command-Line SVN Integration (compatibility mode), but you must also install a command-line SVN client.

Note Select Command-Line SVN Integration (compatibility mode) only if you need to use a later version of SVN than 1.9. Otherwise, use SVN instead, for more features, improved performance, and no need to install an additional command-line SVN client.

Command-line SVN integration communicates with any Subversion (SVN) client that supports the command-line interface.

- 1 Install an SVN client that supports the command-line interface.

Note TortoiseSVN does not support the command-line interface unless you choose the option to install command-line tools. Alternatively, you can continue to use TortoiseSVN from Windows Explorer after installing another SVN client that supports the command-line interface. Ensure that the major version numbers match, for example, both clients are SVN 1.7.

You can find Subversion clients on this Web page:

<https://subversion.apache.org/packages.html>

- 2 In a project, select Command-Line SVN Integration (compatibility mode).

With Command-Line SVN Integration (compatibility mode), if you try to rename a file in a project and the folder name contains an @ character, an error appears because command-line SVN treats all characters after the @ symbol as a peg revision value.

Tip You can check for updated source control integration downloads on the projects Web page: <https://www.mathworks.com/discovery/simulink-projects.html>

Register Model Files with Subversion

You must register model files if you use SVN, including the SVN integration provided by projects.

If you do not register your model file extension as binary, SVN might add annotations to conflicted Simulink files and attempt automerger. This corrupts model files so you cannot load the models in Simulink.

To avoid this problem when using SVN, register file extensions.

- 1 Locate your SVN config file. Look for the file in these locations:
 - C:\Users\myusername\AppData\Roaming\Subversion\config or C:\Documents and Settings\myusername\Application Data\Subversion\config on Windows
 - In ~/.subversion on Linux or Mac OS X
- 2 If you do not find a config file, create a new one. See “Create SVN Config File” on page 19-14.
- 3 If you find an existing config file, you have previously installed SVN. Edit the config file. See “Update Existing SVN Config File” on page 19-15.

Create SVN Config File

- 1 If you do not find an SVN config file, create a text file containing these lines:

```
[miscellany]
enable-auto-props = yes
[auto-props]
*.mdl = svn:mime-type=application/octet-stream
*.mat = svn:mime-type=application/octet-stream
*.slx = svn:mime-type= application/octet-stream
*.mlx = svn:mime-type=application/octet-stream
```

- 2 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as .mat, .mdl, .slxp, .p, MEX-files (.mexa64, .mexmaci64, .mexw64), .xlsx, .jpg, .pdf, .docx, etc. Add a line to the attributes file for each file type you need. Examples:

```
*.mdl = svn:mime-type=application/octet-stream
*.slxp = svn:mime-type=application/octet-stream
```

```
*.sldd = svn:mime-type=application/octet-stream
*.p = svn:mime-type=application/octet-stream
*.mexa64 = svn:mime-type=application/octet-stream
*.mexw64 = svn:mime-type=application/octet-stream
*.mexmaci64 = svn:mime-type=application/octet-stream
*.xlsx = svn:mime-type=application/octet-stream
*.docx = svn:mime-type=application/octet-stream
*.pdf = svn:mime-type=application/octet-stream
*.jpg = svn:mime-type=application/octet-stream
*.png = svn:mime-type=application/octet-stream
```

3 Name the file `config` and save it in the appropriate location:

- `C:\Users\myusername\AppData\Roaming\Subversion\config` or `C:\Documents and Settings\myusername\Application Data\Subversion\config` on Windows
- `~/.subversion` on Linux or Mac OS X

After you create the SVN config file, SVN treats new model files as binary.

If you already have models in repositories, see “Register Models Already in Repositories” on page 19-16.

Update Existing SVN Config File

If you find an existing `config` file, you have previously installed SVN. Edit the `config` file to register files as binary.

- 1** Edit the `config` file in a text editor.
- 2** Locate the `[miscellany]` section, and verify the following line enables auto-props with `yes`:

```
enable-auto-props = yes
```

Ensure that this line is not commented (that is, that it does not start with a `#`). Config files can contain example lines that are commented out. If there is a `#` character at the beginning of the line, delete it.

- 3** Locate the `[auto-props]` section. Ensure that `[auto-props]` is not commented. If there is a `#` character at the beginning, delete it.
- 4** Add the following lines at the end of the `[auto-props]` section:

```
*.mdl = svn:mime-type= application/octet-stream
*.mat = svn:mime-type=application/octet-stream
```

```
*.slx = svn:mime-type= application/octet-stream  
*.mlx = svn:mime-type=application/octet-stream
```

These lines prevent SVN from adding annotations to MATLAB and Simulink files on conflict and from automerging.

- 5 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as `.mat`, `.mdl`, `.slxp`, `.p`, MEX-files (`.mexa64`, `.mexmaci64`, `.mexw64`), `.xlsx`, `.jpg`, `.pdf`, `.docx`, etc. Add a line to the config file for each file type you need.

Examples:

```
*.mdl = svn:mime-type=application/octet-stream  
*.slxp = svn:mime-type=application/octet-stream  
*.sldd = svn:mime-type=application/octet-stream  
*.p = svn:mime-type=application/octet-stream  
*.mexa64 = svn:mime-type=application/octet-stream  
*.mexw64 = svn:mime-type=application/octet-stream  
*.mexmaci64 = svn:mime-type=application/octet-stream  
*.xlsx = svn:mime-type=application/octet-stream  
*.docx = svn:mime-type=application/octet-stream  
*.pdf = svn:mime-type=application/octet-stream  
*.jpg = svn:mime-type=application/octet-stream  
*.png = svn:mime-type=application/octet-stream
```

- 6 Save the config file.

After you create or update the SVN config file, SVN treats new model files as binary.

If you already have models in repositories, register them as described next.

Register Models Already in Repositories

Caution Changing your SVN config file does not affect model files already committed to an SVN repository. If a model is not registered as binary, use `svn propset` to manually register models as binary.

To manually register a file in a repository as binary, use the following command with command-line SVN:

```
svn propset svn:mime-type application/octet-stream modelfilename
```

If you need to install a command-line SVN client, see “Set Up Project SVN for SVN Version Not Yet Provided with Projects” on page 19-13.

Enforce SVN Locking Model Files Before Editing

To ensure users remember to get a lock on model files before editing, you can configure SVN to make specified file extensions read only. To locate your SVN config file, see “Register Model Files with Subversion” on page 19-14.

After this setup, SVN sets model files to read only when you open the project, so you need to select **Source Control > Get File Lock** before you can edit them. Doing so helps prevent editing of models without getting the file lock. When the file has a lock, other users know the file is being edited, and you can avoid merge issues.

- 1 To make SLX files read only, add a property to your SVN config file. Find this line in the [auto-props] section that registers slx files as binary:

```
*.slx = svn:mime-type= application/octet-stream
```

- 2 Add the needs-lock property to the end of the existing slx line, separated by a semicolon, so the line looks like this:

```
*.slx = svn:mime-type=application/octet-stream;svn:needs-lock=yes
```

You can combine properties in any order, but multiple entries (e.g., for slx) must be on a single line separated by semicolons.

- 3 Recreate the sandbox for the config to take effect.
- 4 You need to select **Get File Lock** before you can edit model files. See “Get SVN File Locks” on page 19-39.

If you need to resolve merge issues, see “Resolve Conflicts” on page 19-64.

Share a Subversion Repository

You can specify a repository location using the `file://` protocol. However, Subversion documentation strongly recommends only single users access a repository directly via `file://` URLs. See the Web page:

<http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.choosing.recommendations>

Caution Do not allow multiple users to access a repository directly via `file://` URLs or you risk corrupting the repository. Use `file://` URLs only for single-user repositories.

Be aware of this caution with these workflows:

- If you specify a repository with a `file://` URL, or
- If you use a project to create a repository, this uses the `file://` protocol. Creating new repositories is provided for local single-user access only, for testing and debugging.

Also, accessing a repository via `file://` URLs is slower than using a server.

When you want to share a repository, you need to set up a server. You can use `svnserve` or the Apache SVN module. See the Web page references:

<http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.svnserve>
<http://svnbook.red-bean.com/en/1.7/svn-book.html#svn.serverconfig.httpd>

Standard Repository Structure

Create your repository with the standard `tags`, `trunk`, and `branches` folders, and check out files from `trunk`. The Subversion project recommends this structure. See the Web page:

<https://svn.apache.org/repos/asf/subversion/trunk/doc/user/svn-best-practices.html>

If you use a project to create an SVN repository, it creates the standard repository structure. To enable tagging, the repository must have `trunk/` and `tags/` folders.

After you create a repository with this structure, to add tags to all your project files, on the Project tab, in the Source Control section, click **Tag**. See “Tag and Retrieve Versions of Project Files” on page 19-33.

Manage SVN Externals

To get files into your project from another repository or from a different part of the same repository, use SVN externals.

- 1 In a project, right-click a project folder and select **Source Control > Manage Externals**.
- 2 In the Manage Externals dialog box, click **Add entry**. You can browse to and validate a repository location, specify the relative reference format, specify the subfolder, choose the revision, e.g., the HEAD node, etc.
- 3 After specifying the externals, click **OK**. The project displays the externals definition in the Manage Externals dialog box.

Alternatively, enter or paste an `svn:external` definition in the Manage Externals dialog box. The project applies an SVN version 1.6 compliant externals definition.

- 4 Click **Set** to validate and apply your changes.
- 5 To retrieve the external files, click **Update** to update the sandbox.

If two users modify the `svn:external` for a folder, you can get a conflict. To resolve the conflict, in the All Files View, locate the `.prej` file and examine the conflict details. Open the Manage Externals dialog box and specify the desired `svn:external`, mark the folder conflict resolved, and then commit the changes.

Set Up Git Source Control

In this section...

“Use Git Source Control in Projects” on page 19-20

“About Git Source Control” on page 19-21

“Install Command-Line Git Client” on page 19-22

“Register Model Files with Git” on page 19-23

“Add Git Submodules” on page 19-24

Use Git Source Control in Projects

To use the version of Git provided with projects, when you add a project to source control or retrieve from source control, select **Git** in the **Source control tool** list.

- If you add an existing project to Git source control, you create a local Git repository in that sandbox. You can specify a remote repository later. See “Add a Project to Source Control” on page 19-6
- If you want to clone a remote Git repository to create a project, select **New > Project > From Git** on the MATLAB Home tab. After you specify a remote repository to retrieve from, a local repository is created. You can also pull, fetch, and push changes from and to the remote repository. See “Clone Git Repository or Check Out SVN Repository” on page 19-30.

Note You cannot add empty folders to Git source control. Use **Check Project** instead. See “Pull, Push, and Fetch Files with Git” on page 19-53.

To use a Git server for your remote repository, you can set up your own Apache Git server or use a Git server hosting solution. If you cannot set up a server and must use a remote repository via the file system using the `file:///` protocol, make sure that it is a bare repository with no checked out working copy.

- To make your project publicly available on GitHub, see “Share Project on GitHub” on page 17-48. Sharing adds Git source control to the open project and the project’s remote repository is GitHub.

About Git Source Control

You can manage your models and source code using Gitin projects.

The Git integration with the project provides distributed source control with support for creating and merging branches. Git is a distributed source control tool, so you can commit changes to a local repository and later synchronize with other remote repositories.

Git supports distributed development because every sandbox contains a complete repository. The full revision history of every file is saved locally. This enables working offline, because you do not need to contact remote repositories for every local edit and commit, only when pushing batches of changes. In addition, you can create your own branches and commit local edits. Doing so is fast, and you do not need to merge with other changes on each commit.

Capabilities of Git source control:

- Branch management
- Local full revision history
- Local access that is quicker than remote access
- Offline working
- Tracking of file names and contents separately
- Enforcing of change logs for tracing accountability
- Integration of batches of changes when ready

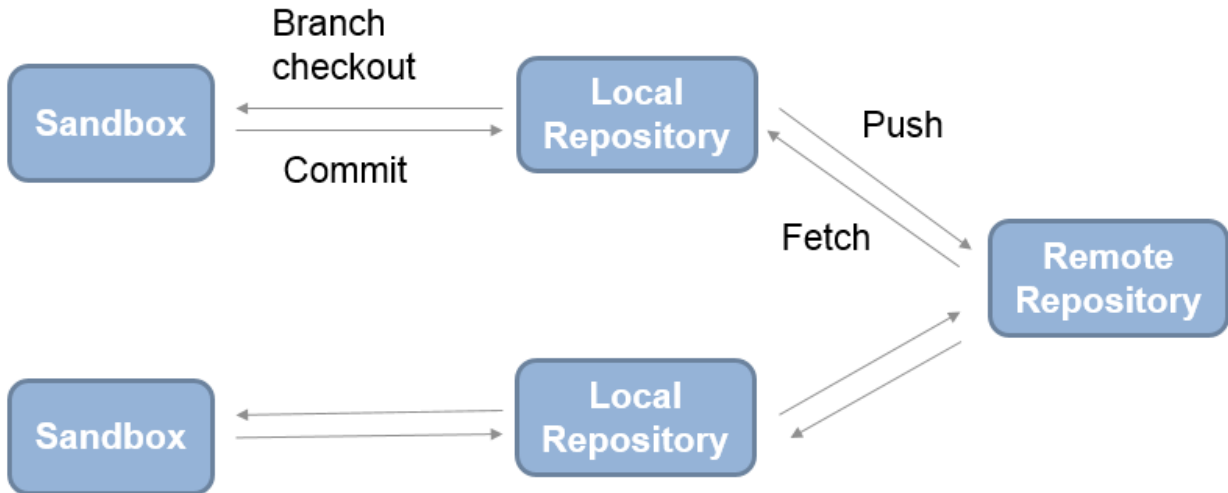

These capabilities do not suit every situation. If your project is not appropriate for offline working or your repository is too large for a full local revision history, for example, Git is not the ideal source control. In addition, if you need to enforce locking of files before editing, Git does not have this ability. In that situation, SVN is the better choice.

When you use Git in a project, you can:

- Create local Git repositories.
- Pull and fetch files from remote Git repositories.
- Create and switch branches.
- Merge branches locally.
- Commit locally.

- Push files to remote Git repositories.

This diagram represents the distributed Git workflow.

Install Command-Line Git Client

If you want to use Git to merge branches in a project, you must also install a command-line Git client that is available systemwide. You can use other Git functionality without any additional installation.

Some clients are not available system wide, including the `mingw32` environment provided by GitHub (**Git Shell** on the **Start** menu). Installing command-line Git makes it available systemwide, and then the project can locate standard ssh keys.

Check if Git is available by using the command `!git` in MATLAB. If Git is not available, install it.

On Windows:

- 1 Download the Git installer and run it. You can find command-line Git at:

<https://msysgit.github.io/>

- 2 In the section on adjusting your PATH, choose the install option to **Use Git from the Windows Command Prompt**. This option adds Git to your PATH variable, so that the project can communicate with Git.
- 3 In the section on configuring the line-ending conversions, choose the option **Checkout as-is, commit as-is** to avoid converting any line endings in files.

On Linux, Git is available for most distributions. Install Git for your distribution. For example, on Debian®, install Git by entering:

```
sudo apt-get install git
```

On Mac, on Mavericks (10.9) or above, try to run `git` from the Terminal. If you do not have Git installed already, it will prompt you to install Xcode Command Line Tools. For more options, see <https://git-scm.com/doc>.

If you are working with long path files, run this command in MATLAB:

```
!git config --global core.longpaths true
```

Caution To avoid corrupting models, before using Git to merge branches, register model files. See “Register Model Files with Git” on page 19-23.

Register Model Files with Git

After you install a command-line Git client, you can prevent Git from corrupting your Simulink models by inserting conflict markers. To do so, edit your `.gitattributes` file to register model files as binary. For details, see:

<https://git-scm.com/docs/gitattributes>

- 1 If you do not already have a `.gitattributes` file in your project root folder, create one by entering in MATLAB:

```
edit .gitattributes
```

- 2 Add these lines to the `.gitattributes` file:

```
*.slx -crlf -diff -merge  
*.mdl -crlf -diff -merge  
*.mat -crlf -diff -merge  
*.mlx -crlf -diff -merge
```

These lines specify not to try automatic line feed, diff, and merge attempts for MATLAB and Simulink files.

- 3 Check for other file types you use in your projects that you also need to register as binary to avoid corruption at check-in. Check for files such as `.mat`, `.mdl`, `.slx`, `.p`, MEX-files (`.mexa64`, `.mexmaci64`, `.mexw64`), `.xlsx`, `.jpg`, `.pdf`, `.docx`, etc. Add a line to the attributes file for each file type you need.

Examples:

```
*.mdl -crlf -diff -merge
*.slx -crlf -diff -merge
*.sldd -crlf -diff -merge
*.p -crlf -diff -merge
*.mexa64 -crlf -diff -merge
*.mexw64 -crlf -diff -merge
*.mexmaci64 -crlf -diff -merge
*.xlsx -crlf -diff -merge
*.docx -crlf -diff -merge
*.pdf -crlf -diff -merge
*.jpg -crlf -diff -merge
*.png -crlf -diff -merge
```

- 4 Restart MATLAB so you can start using the Git client with the project.

After you have installed a command-line Git client and registered your model files as binary, you can use the merging features of Git in projects.

Add Git Submodules

To reuse code from another repository, you can specify Git submodules to include in your project.

To clone an external Git repository as a submodule:

- 1 On the Project tab, in the Source Control section, click **Submodules**.
- 2 In the Submodules dialog box, click the **+** button.
- 3 In the Add Submodule dialog box, in the **Remote** box, specify a repository location. Optionally, click **Validate**.
- 4 In the **Path** box, specify a location for the submodule in your project and click **OK**. The Submodules dialog box displays the status and details of the submodule.

- 5 Check the status message, and click **Close** to return to your project.

Update Submodules

After using **Pull** on the top-level project, check submodules are up to date by clicking Submodules and then click **Update**. If any submodule definition have changed, then the update ensures that the submodule folder contains the correct files. Update applies to all child submodules in the submodule hierarchy.

Use Fetch and Merge with Submodules

When you want to manage a submodule, open the Submodules dialog box.

- 1 To get the latest version of a submodule, in the Submodules dialog box, click **Fetch**.
- 2 After fetching, you must merge. Check the **Status** message in the Submodules dialog box for information about your current branch relative to the remote tracking branch in the repository. When you see the message **Behind**, you need to merge in changes from the repository to your local branch.
- 3 Click **Branches** and merge in the origin changes to your local branch using the Branches dialog box. See “Pull, Fetch, and Merge” on page 19-54.

Use Push to Send Changes to the Submodule Repository

If you make changes in your submodule and want to send changes back to the repository:

- 1 Perform a local commit in the parent project.
- 2 Open the Submodules dialog box and click **Push**.

If you want other project users to obtain your changes in the submodule when they clone the parent project, make sure the index and head match.

- 1 In the Submodules dialog box, check the index and head values. The index points to the head commit at the time you first cloned the submodule, or when you last committed the parent project repository. If the index and head do not match, you must update the index.
- 2 To update the index, commit your changes in the parent project, and then click **Push** in the Submodules dialog box. This action makes the index and head the same.

Disable Source Control

Disabling source control is useful when you are preparing a project to create a template from it, and you want to avoid accidentally committing unwanted changes.

- 1 On the Project tab, in the Source Control section, click the **Details** button for your source control. For example, **SVN Details** or **Git Details**.
- 2 Change the selection from the current source control to **No source control integration**.
- 3 Click **Reload**.

Note Source control tools create files in the project folders (for example, SVN creates an `.svn` folder), so you can put the project back under the same source control only by selecting your previous source control from the list.

- “Add a Project to Source Control” on page 19-6

Change Source Control

Changing source control is useful when you want to create a new local repository for testing and debugging.

- 1 Prepare your project by checking for any updates from the existing source control tool repository and committing any local changes.
- 2 On the **Project** tab, click **Share > Zip Archive** to save a zip file containing the project without any source control information.
- 3 On the **Project** tab, click **New**, and then in the start page, click **Archive** to create a new project from the archived project.
- 4 On the Project tab, in the Source Control section, click **Use Source Control**.
- 5 Click **Add project to source control** and then select a new source control. For details, see “Add a Project to Source Control” on page 19-6.

Tip To avoid accidentally committing changes to the previous source control, delete the original sandbox.

Write a Source Control Integration with the SDK

Tip You can check for updated source control integration downloads on the projects Web page: <https://www.mathworks.com/discovery/simulink-projects.html>

The file exchange provides a Software Development Kit (SDK) that you can use to integrate projects with third-party source control tools. See <https://www.mathworks.com/matlabcentral/fileexchange/61483-source-control-integration-software-development-kit>.

The SDK provides instructions for writing an integration to a source control tool that has a published API you can call from Java®.

You must create a `.jar` file that implements a collection of Java interfaces and a Java Manifest file, that defines a set of required properties.

The SDK provides example source code, Javadoc, and files for validating, building, and testing your source control integration. Build and test your own interfaces using the example as a guide. Then you can use your source control integration with projects. Download the SDK and follow the instructions.

After you write a source control integration, see “Add a Project to Source Control” on page 19-6.

More About

- “About Source Control with Projects” on page 19-2

Clone Git Repository or Check Out SVN Repository

Create a new local copy of a project by retrieving files from source control. You can clone a Git repository, or check out files from an SVN repository, or use another source control integration.

- 1 On the MATLAB Home tab, select **New > Project > From Git** or **From SVN**.

Alternatively, in the Simulinkstart page, click one of the **Project from Git** or **Project from SVN** templates.

- 2 If you know your repository location, you can paste it into the **Repository Path** in the New Project From Source Control dialog box and proceed to step 4.

To browse for and validate the repository path to retrieve files from, click **Change**.

- a In the dialog box, specify the repository URL by entering or pasting a URL into the box, using the list of recent repositories, or by using the **Generate URL from folder** button .
 - b Click **Validate** to check the repository path. If the path is invalid, check the URL against your source control repository browser.
 - c If you see an authentication dialog box for your repository, enter login information to continue.
 - d If necessary, select a deeper folder in the repository tree. With SVN, you might want to check out from `trunk` or a branch folder under `tags`.
 - e When you have finished specifying the URL path you want to retrieve, click **OK**.
- 3 In the New Project From Source Control dialog box, select the working folder where you want to put the retrieved files for your new project, and click **Retrieve**. With SVN, use local folders, because using a network folder is slow.

The source control pane (for example, **Git** or **SVN**) displays messages as the project retrieves the files from source control.

If your repository already contains a project, the project is ready when the tool finishes retrieving files to your selected sandbox folder.

- 4 If your sandbox does not yet contain a project, then a dialog box prompts you to check whether you want to create a project in the folder. To create a project, specify a project name and click **OK**.

The Welcome screen appears to help you set up your new project.

- a** Click **Set Up Project**.
- b** On the next screen, add your project folders to the project path.
- c** On the next screen, specify any startup or shutdown files to automate tasks when you open and close projects. Alternatively, you can set up these files later. To learn more about these setup steps, see “Create a New Project From a Folder” on page 16-16.

Click **Finish**.

The project automatically adds all your files to the project and displays the Files view. For next steps using your new project, try dependency analysis to visualize the structure of your files. See “Run Dependency Analysis” on page 18-4.

Note To update an existing project sandbox from source control, see “Update Revisions of Project Files” on page 19-37.

Troubleshooting

If you encounter errors like `OutOfMemoryError: Java heap space` when cloning big Git repositories, then edit your MATLAB preferences to increase the heap size.

- 1** On the **Home** tab, in the **Environment** section, click **Preferences**.
- 2** Select **MATLAB > General > Java Heap Memory**.
- 3** Move the slider to increase the heap size, and then click **OK**.
- 4** Restart MATLAB.

More About

- “About Source Control with Projects” on page 19-2

Tag and Retrieve Versions of Project Files

With SVN, you can use tags to identify specific revisions of all project files. Not every source control has the concept of tags. To use tags with SVN, you need the standard folder structure in your repository and you need to check out your files from `trunk`. See “Standard Repository Structure” on page 19-18.

- 1 On the Project tab, in the Source Control section, click **Tag**.
- 2 Specify the tag text and click **OK**. The tag is added to every project file.

Errors appear if you do not have a `tags` folder in your repository.

Note You can retrieve a tagged version of your project files from source control, but you cannot tag them again with a new tag. You must check out from `trunk` to create new tags.

To retrieve the tagged version of your project files from source control:

- 1 On the **Project** tab, click **New**, and then in the start page, click **Source Control**.
- 2 Click **Change** to select the Repository Path that you want to retrieve files from.

The Specify Repository URL dialog box opens.

- a Select a recent repository from the **Repository URL** list, or click the **Generate URL from folder** button  to browse for the repository location.
 - b Click **Validate** to show the repository browser.
 - c Expand the `tags` folder in the repository tree, and select the tag version you want.
 - d Click **OK** to continue and return to the new project dialog box.
- 3 Select the local folder to receive the tagged files. You must use an empty project folder. (If you try to retrieve tagged files into an existing project folder, an error appears.)
 - 4 Click **Retrieve**.

Alternatively, you can use labels to apply any metadata to files and manage configurations. You can group and sort by labels, and create batch jobs to export files by label. See “Add Labels to Files” on page 17-24.

With Git, you can switch branches. See “Branch and Merge Files with Git” on page 19-59.

- “Add Labels to Files” on page 17-24
- “Branch and Merge Files with Git” on page 19-59

Refresh Status of Project Files

To check for locally modified project files, on the Project tab, in the Source Control section, click **Refresh**.

Refresh queries the local sandbox state and checks for changes made with another tool outside of MATLAB.

Note For SVN, **Refresh** does not contact the repository. To check the repository for later revisions, use **Check for Modifications** instead. To get the latest revisions, use **Update** instead. See “Check for Modifications” on page 19-36 and “Update Revisions of Project Files” on page 19-37.

The buttons in the Source Control section of the Project tab apply to the whole project.

Refresh refreshes the view of the source control status for all files under `project root`. Clicking **Refresh** updates the information shown in the **Revision** column and the source control status column (for example, **SVN**, or **Git** columns). Hover over the icon to see the tooltip showing the source control status of a file, e.g., **Modified**.

See Also

Related Examples

- “Check for Modifications” on page 19-36
- “Update Revisions of Project Files” on page 19-37
- “Revert Changes” on page 19-50

Check for Modifications

To check the status of individual files for modifications, right-click files in the project and select **Source Control > Check for Modifications**. Use this to find out if the repository version has moved ahead.

With SVN, this option contacts the repository to check for external modifications. The project compares the revision numbers of the local file and the repository version. If the revision number in the repository is larger than that in the local sandbox folder, then the project displays (**not latest**) next to the revision number of the local file.

If your local file is not the latest version, get the latest revisions from the repository by clicking **Update**. See “Update Revisions of Project Files” on page 19-37. You might need to resolve conflicts after updating. See “Resolve Conflicts” on page 19-64 and “Compare Revisions” on page 19-43.

To check for locally modified files, use **Refresh** instead. See “Refresh Status of Project Files” on page 19-35.

See Also

Related Examples

- “Refresh Status of Project Files” on page 19-35

- “Compare Revisions” on page 19-43
- “Revert Changes” on page 19-50

Update Revisions of Project Files

In this section...

“Update Revisions with SVN” on page 19-37

“Update Revisions with Git” on page 19-37

“Update Selected Files” on page 19-38

Update Revisions with SVN

In a project, to get the latest revisions of all project files from the source control repository, click **Update** in the source control section of the project tab.

Use **Update** to get other people’s changes from the repository and find out about any conflicts. If you want to back out local changes, use **Revert Project** instead. See “Discard Local Changes” on page 19-50.

After you update, the project displays a dialog box listing all the files that have changed on disk. You can control this behavior using the project preference **Show changes on source control update**.

When your project uses SVN source control, **Update** calls `svn update` to bring changes from the repository into your working copy. If there are other people’s changes in your modified files, SVN adds conflict markers to the file. SVN preserves your modifications.

Caution Ensure you have registered SLX files as binary with SVN before using **Update**. If you do not, SVN conflict markers can corrupt your SLX file. The project warns you about this when you first click **Update** to ensure you protect your model files. See “Register Model Files with Subversion” on page 19-14.

You must resolve any conflicts before you can commit. See “Resolve Conflicts” on page 19-64.

Update Revisions with Git

If you are using Git source control, click **Pull** in the source control pane.

Caution Ensure you have registered SLX files as binary with Git before using **Pull**. If you do not, conflict markers can corrupt your SLX file. See “Set Up Git Source Control” on page 19-20.

Pull fetches the latest changes and merges them into your current branch. If you are not sure what is going to come in from the repository, use fetch to examine the changes first and then merge the changes manually.

Pull might fail if you have conflicts. With a complicated change you might want to create a branch from the origin, make some compatibility changes, then merge that branch into the main tracking branch. For next steps, see “Pull, Push, and Fetch Files with Git” on page 19-53.

Update Selected Files

To update selected files, right-click and select the **Update** command for the source control system you are using. For example, if you are using SVN, select **Source Control > Update from SVN** to get fresh local copies of the selected files from the repository.

- “Discard Local Changes” on page 19-50

Get SVN File Locks

To ensure users remember to get a lock on model files before editing, you can configure SVN to make model files read only. Follow the steps in “Enforce SVN Locking Model Files Before Editing” on page 19-17. After you configure SVN to make files with certain extensions read only, then users must get a lock on these read-only files before editing.

- 1 In a project, in any Files view, select the files you want to check out.
- 2 Right-click the selected files and select **Source Control > Get File Lock**.

Get File Lock is for SVN. This option does not modify the file in your local sandbox. Git does not have locks.

A lock symbol appears in the SVN source control column. Other users cannot see the lock symbol in their sandboxes, but they cannot get a file lock or check in a change when you have the lock. To view or break locks, click **Locks** on the Project tab.

Note To get a fresh local copy of the file from the repository, select **Update from SVN**.

In the Simulink Editor, if an open model belongs to a project under SVN, you can get a lock by selecting **File > Project > Get File Lock**.

If you see an SVN message reporting a `working copy locked` error, remove stale locks by clicking **SVN Cleanup** in the Source Control section on the Project tab. SVN uses working copy locks internally and they are not the file locks you control using **Get File Lock**.

Manage SVN Repository Locks

To manage global SVN locks for a repository, on the Project tab, in the Source Control section, click **Locks**.

In the SVN Repository Locks dialog box, you can:

- View which users have locks on files.
- Right-click to break locks.
- Group locks by user or file.

- “Enforce SVN Locking Model Files Before Editing” on page 19-17
- “View Modified Files” on page 19-41
- “Commit Modified Files to Source Control” on page 19-48

More About

- “About Source Control with Projects” on page 19-2

View Modified Files

In a project, select the **Modified (number of files)** view. The modified files view is visible only if you are using source control with your project.

If you need to update the modified files list, click **Refresh** in the source control section of the Project tab.

Use the **Modified** files view to review, analyze, label, and commit modified files. Lists of modified files are sometimes called changesets. You can perform the same operations in the Modified files view as you can in other file views. To view changes, see “Compare Revisions” on page 19-43.

Tip In the **Modified** files view, it can be useful to switch to the **List** layout.

You can identify modified or conflicted folder contents using the source control summary status. In the Files views, folders display rolled-up source control status. This makes it easier to locate changes in files, particularly conflicted files. You can hover over the source control status (e.g., the **SVN** or **Git** column) for a folder to view a tooltip displaying how many files inside are modified, conflicted, added or deleted.

Project Definition Files

The files in `resources/project` are project definition files generated by your changes. The project definition files allow you to add metadata to files without checking them out, for example, by creating shortcuts, adding labels, and adding a project description. Project definition files also define the files that are added to your project.

Any changes you make to your project (for example, to shortcuts, labels, categories, or files in the project) generate changes in the `resources/project` folder. These files store the definition of your project in XML files whose format is subject to change.

You do not need to view project definition files directly, except when the source control tool requires a merge. The files are shown so that you know about all the files being committed to the source control system. See “Resolve Conflicts” on page 19-64.

If you want to change project definition file from the type used when the project was created, see `export`.

You can use the project preferences to change the project definition folder for new projects, for example, if you want to revert to folder names for releases before R2019a: `.SimulinkProject` or `_SimulinkProject`.

Compare Revisions

To review changes in modified files in a project, select the **Modified (number of files)** tab.

If you need to update the modified files list, click **Refresh** in the source control section of the Project tab.

To review changes in modified files, right-click selected files in any view in a project and:

- Select **Compare > Compare to Ancestor** to run a comparison with the last checked-out version in the sandbox (SVN) or against the local repository (Git). The Comparison Tool displays a report.
- To compare other revisions of a file, select **Compare > Compare to Revision**. In the Compare to Revisions dialog box, you can view information about who previously committed the file, when they committed it, and the log messages. To view a comparison report, select the revisions you want to compare. You can:
 - Select a revision and click **Compare to Local**.
 - Select two revisions and click **Compare Selected**.

- With SVN, select a revision and you can browse the lower list of files in the change set. Right-click a file in the list to view changes or save revisions..
- To browse the revision history of a file, select **Source Control > Show Revisions**. In the File Revisions dialog box, view information about who previously committed the file, when they committed it, and the log messages. With SVN, select a revision and you can browse the lower list of files in the change set. Right-click a file in the list to view changes or save revisions.
- To browse and compare files within committed SVN change sets, on the Project tab, in the Source Control section, select **Show Log**. In the File Revisions dialog box, select a revision to view a list of modified files. Right-click files in the lower list to view changes or save revisions.

Note In the Simulink Editor, if an open model, library, or chart belongs to a project under source control, you can view changes by selecting **File > Project > Compare to Ancestor** or **Compare to Revision**.

When you compare to a revision or ancestor, the MATLAB Comparison Tool opens a report comparing the modified version of the file in your sandbox with the selected revision or against its ancestor stored in the version control tool.

Comparison type depends on the file you select. If you select a Simulink model, this command runs a Simulink model comparison.

When reviewing changes, you can merge Simulink models from the Comparison Tool report. See “Merge Text Files” on page 19-66 and “Merge Models” on page 19-67.

To examine the dependencies of modified files, see “Perform Impact Analysis” on page 18-6.

More About

- “About Source Control with Projects” on page 19-2

Run Project Checks

In a project, you can run checks from any project view by clicking **Run Checks > Check Project** on the **Project** tab. The project checks can find problems with project integrity such as missing files, unsaved files, or files not under source control.

For details on problems the checks can fix, see “Work with Derived Files in Projects” on page 19-70, “Upgrade Model Files to SLX and Preserve Revision History” on page 17-18, and “Check Dependency Results and Resolve Problems” on page 18-15.

- Click **Check Project** to check the integrity of the project. For example, is everything under source control in the project? Are all project files under source control? A dialog box reports results. You can click for details and follow prompts to fix problems.

For an example showing how the checks can help you, see “Upgrade Model Files to SLX and Preserve Revision History” on page 17-18.

- If you want to check for required files, click **Dependency Analysis** to analyze the dependencies of the modified files.

Use the dependency tools to analyze the structure of your project. See “Perform Impact Analysis” on page 18-6.

Note The files in `resources/project` are project definition files generated by your changes. See “Project Definition Files” on page 19-42.

Commit Modified Files to Source Control

Before you commit modified files, review changes and consider precommit actions. See “Compare Revisions” on page 19-43 and “Run Project Checks” on page 19-46.

- 1 In a project, select the **Modified (number of files)** view.

If you need to update the modified files list, click **Refresh** in the source control section of the Project tab.

- 2 To check in all files in the modified files list, on the Project tab, in the Source Control section, click **Commit**.

If you are using SVN source control, this commits changes to your repository.

If you are using Git source control, this commits to your local repository. To commit to the remote repository, see “Pull and Push” on page 19-53.

- 3 Enter comments in the dialog box if you want, and click **Submit**.
- 4 A message appears if you cannot commit because the repository has moved ahead. Before you can commit the file, you must update its revision up to the current HEAD revision. If you are using SVN source control, click **Update**. If you are using Git source control, click **Pull**. Resolve any conflicts before you commit.

Note You can commit individual files using the context menu, by selecting **Source Control > Commit**. However if you commit individual files, you risk not committing the related project definition files that keep track of your files. Instead, use the **Modified** files view to see all changes, and on the Project tab, click **Commit** to commit all related changes.

Revert Changes

In this section...

“Discard Local Changes” on page 19-50

“Revert a File to a Specified Revision” on page 19-50

“Revert the Project to a Specified Revision” on page 19-51

Discard Local Changes

With SVN, if you want to roll back local changes in a particular file, in a project, right-click the file and select **Source Control > Discard Local Changes and Release Locks** to release locks and revert to the version in the last sandbox update (that is, the last version you synchronized or retrieved from the repository).

In the Simulink Editor, if an open model belongs to a project under source control, you can revert changes by selecting **File > Project > Discard Local Changes and Release Locks**.

To abandon all local changes, in a project select all the files in the **Modified** files list, then right-click and select **Discard Local Changes and Release Locks**.

With Git, right-click a file and select **Source Control > Revert Local Changes**. Git does not have locks. To remove all local changes, click **Branches** in the **Git** pane and click **Revert to Head**.

Revert a File to a Specified Revision

- 1 Right-click a file and select **Source Control > Revert using SVN** or **Source Control > Revert using Git**.
- 2 In the Revert Files dialog box, choose a revision to revert to. Select a revision to view information about the change such as the author, date, log message.

With SVN, select a revision and you can browse the lower list of files in the change set. Right-click a file in the list to view changes or save revisions.

- 3 Click **Revert**.

The project reverts the selected file.

- 4 If you revert a file to an earlier revision and then make changes, you cannot commit the file until you resolve the conflict with the repository history.

With SVN, if you try to commit the file, you see a message that it is out of date. Before you can commit the file, you must update its revision up to the current HEAD revision. click **Update** in the source control section on the Project tab.

The project marks the file as conflicted because you have made changes to an earlier version of the file than the version in the repository.

- 5 With either SVN or Git, to examine conflicts, right-click and select **View Conflicts**.

Decide how to resolve the conflict or to keep your changes to the reverted file. See “Resolve Conflicts” on page 19-64.

- 6 After you have resolved the conflict, mark the conflict resolved, either by using the merge tool or manually by right-clicking the file and selecting **Source Control > Mark Conflict Resolved**.
- 7 Select the **Modified (number of files)** view to check changes, and on the **Project** tab, click **Commit**.

Revert the Project to a Specified Revision

With SVN, inspect the project revision information by clicking **Show Log** in the in Source Control section on the Project tab. In the Log dialog box, each revision in the list is a change set of modified files. Select a revision to view information about the change such as the author, date, log message and the list of modified files.

To revert the project:

- 1 On the Project tab, in the Source Control section, click **Revert Project**.
- 2 In the Revert Files dialog box, choose a revision to revert to.

Each revision in the list is a change set of modified files. Select a revision to view information about the change such as the author, date, and the log message.

With SVN, select a revision and you can browse the lower list of files in the change set. Right-click a file in the list to view changes or save revisions.

- 3 Click **Revert**.

The project displays progress messages in the SVN pane as it restores the project to the state it was in when the selected revision was committed. Depending on the

change set you selected, all files do not necessarily have a particular revision number or matching revision numbers. For example, if you revert a project to revision 20, all files will show their revision numbers when revision 20 was committed (20 or lower).

With Git, you can switch branches. See “Branch and Merge Files with Git” on page 19-59.

Pull, Push, and Fetch Files with Git

In this section...

“Pull and Push” on page 19-53

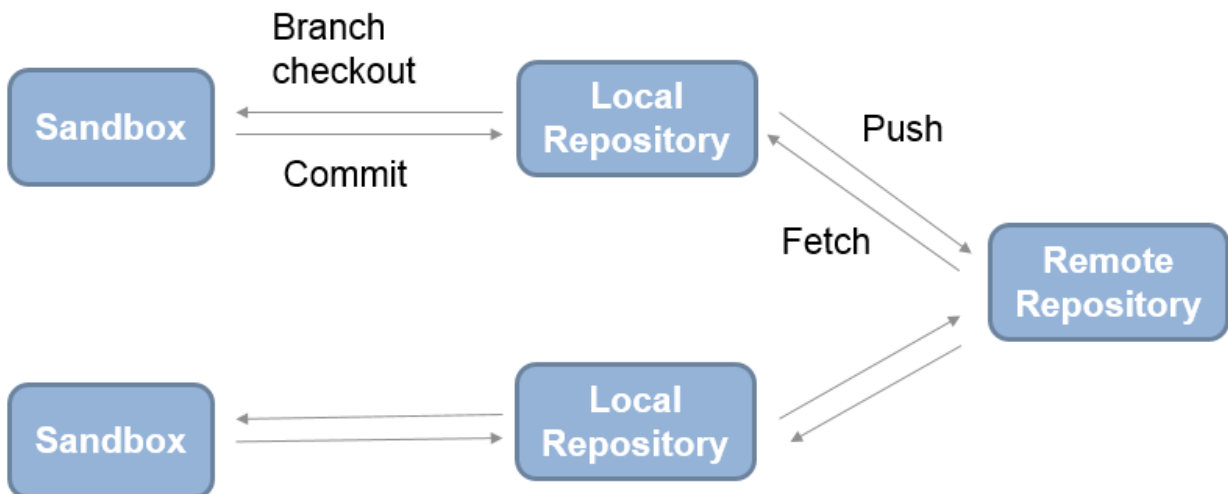

“Pull, Fetch, and Merge” on page 19-54

“Push Empty Folders” on page 19-57

“Use Git Stashes” on page 19-57

Pull and Push

Use this workflow to work with a Git project connected to a remote repository. With Git, there is a two-step workflow: commit local changes, and then push to the remote repository. In a project, the only access to the remote repository is through the **Pull**, **Push**, and **Fetch** buttons. All other actions use the local repository (such as **Check for Modifications**, **Compare to Ancestor**, and **Commit**). This diagram represents the Git workflow.

- 1 To get the latest changes, on the Project tab, in the Source Control section, click **Pull**. Pull fetches the latest changes and merges them into your current branch.

Note Before you can merge, you must install command-line Git on your system path and register model files as binary to prevent Git from inserting conflict markers. See “Install Command-Line Git Client” on page 19-22.

- 2 To create branches to work on, on the Project tab, in the Source Control section, click **Branches**. Create branches in the Branches dialog box, as described in “Branch and Merge Files with Git” on page 19-59.
- 3 When you want to commit changes, select the Modified files view to view files, and on the **Project** tab, click **Commit**. The changes are committed to your current branch in your local repository. Check the **Git** pane for information about the current branch. You see the message **Ahead** when you commit local changes that have moved ahead of the remote tracking branch.

```
Current branch: master
Branch status: SAFE
Ahead of /origin/master
```

- 4 To send your local commits to the remote repository, on the Project tab, in the Source Control section, click **Push**.
- 5 A message appears if you cannot push your changes directly because the repository has moved on. Click **Fetch** to fetch changes from the remote repository. Merge branches and resolve conflicts, and then you can push your changes. See “Pull, Fetch, and Merge” on page 19-54.

Pull, Fetch, and Merge

Use **Fetch** to get changes and merge manually. Use **Pull** instead to fetch the latest changes and merge them into your current branch.

Note Before you can merge branches, you must install command-line Git on your system path and register model files as binary to prevent Git from inserting conflict markers. See “Install Command-Line Git Client” on page 19-22.

Pull fetches the latest changes and merges them into your current branch. If you are not sure what is going to come in from the repository, use fetch instead to examine the changes, and then merge the changes manually.

Pull might fail if you have conflicts. With a complicated change you might want to create a branch from the origin, make some compatibility changes, then merge that branch into the main tracking branch.

To fetch changes from the remote repository, click **Fetch** on the Project tab.

Fetch updates all of the origin branches in the local repository.

Note When you click **Fetch**, your sandbox files are not changed. To see others' changes, you need to merge in the origin changes to your local branches.

Check the Git pane for information about your current branch relative to the remote tracking branch in the repository. When you see the message **Behind**, you need to merge in changes from the repository to your local branch.

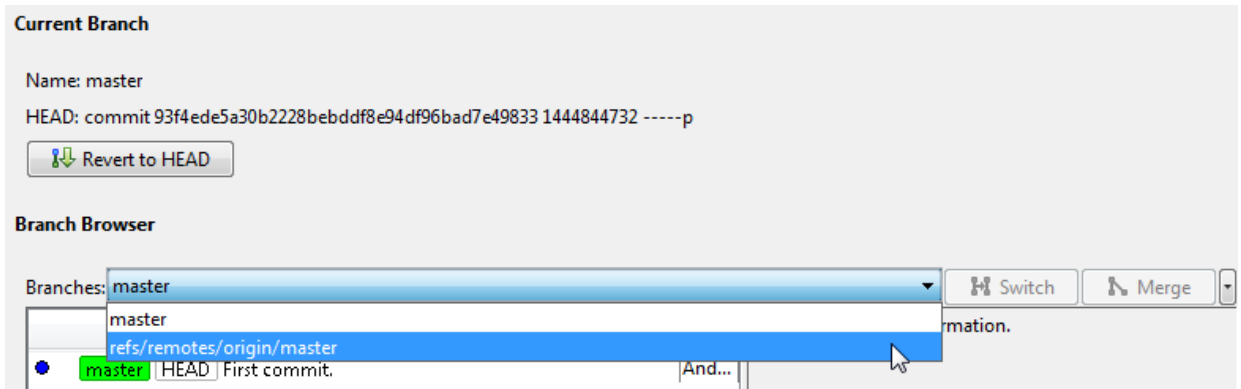

For example, if you are on the master branch and want to get changes from the master branch in the remote repository:

- 1 Click **Fetch**.

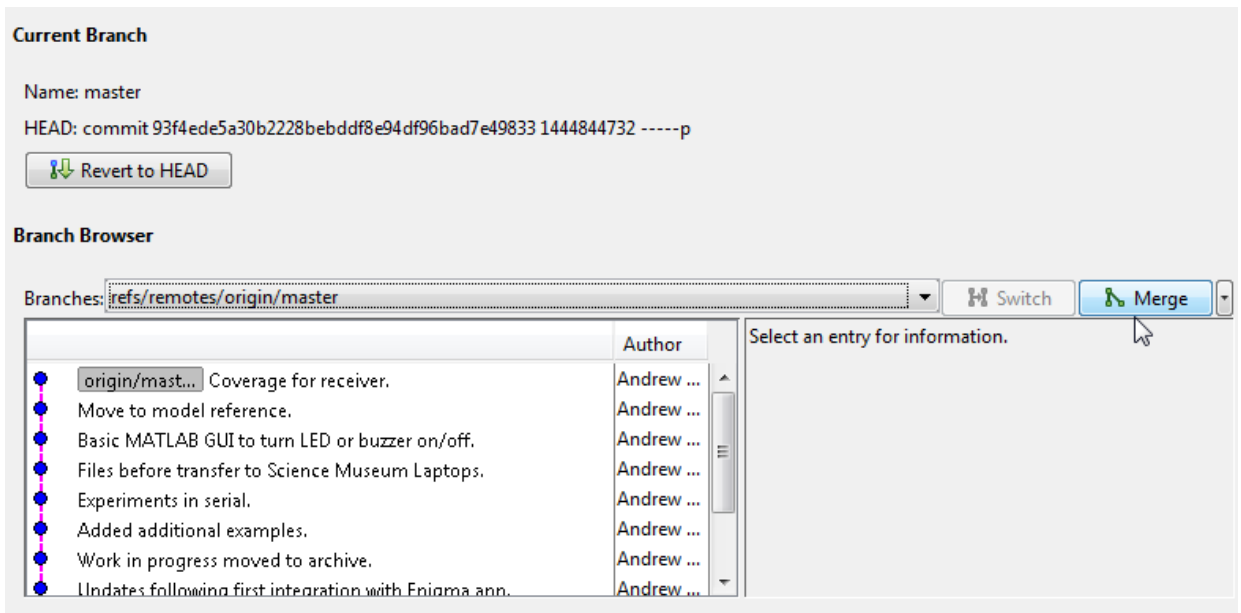

Observe the message in the Git pane, **Behind /origin/master**. You need to merge in the changes from the repository to your local branch, using **Branches**.

```
Current branch: master
Branch status: SAFE
Behind /origin/master
```

- 2 Click **Branches**.
- 3 In the Branches dialog box, in the **Branches** list, select **origin/master**.

- 4 Click **Merge**. This merges the origin branch changes into the master branch in your sandbox.

- 5 Close the Branches dialog box. Observe the message in the Git pane now says **Coincident with /origin/master**. You can now view the changes fetched and merged from the remote repository in your local sandbox files.

When you fetch and merge, you might need to resolve conflicting changes. If the branch merge causes a conflict that Git cannot resolve automatically, an error dialog box reports that automatic merge failed. Resolve the conflicts before proceeding. See “Resolve Conflicts” on page 19-64.

Push Empty Folders

Using Git, you cannot add empty folders to source control, so you cannot select **Push** and then clone an empty folder. You can create an empty folder in a project, but if you push changes and then sync a new sandbox, then the empty folder does not appear in the new sandbox. You can instead run **Check Project** which creates the empty folder for you.

Alternatively, to push empty folders to the repository for other users to sync, create a `gitignore` file in the folder and then push your changes.

Use Git Stashes

Store uncommitted changes for later use by creating a Git stash. Use stashes to:

- Store modified files without committing them.
- Move changes easily to a new branch.
- Browse and examine the changes within a stash.

To create and manage stashes, on the **Project** tab, in the **Source Control** section, click **Stashes**. In the Stashes dialog box:

- To create a stash containing your currently modified files, click **New Stash**.
- To view modified files in a stash, select the stash under **Available Stashes**. Right-click modified files to view changes or save a copy.
- To apply the stash to your current branch and then delete the stash, click **Pop**.
- To apply the stash and keep it, click **Apply**.
- To delete the stash, click **Drop**.

Branch and Merge Files with Git

In this section...

“Create a Branch” on page 19-59

“Switch Branch” on page 19-61

“Compare Branches and Save Copies” on page 19-61

“Merge Branches” on page 19-61

“Revert to Head” on page 19-62

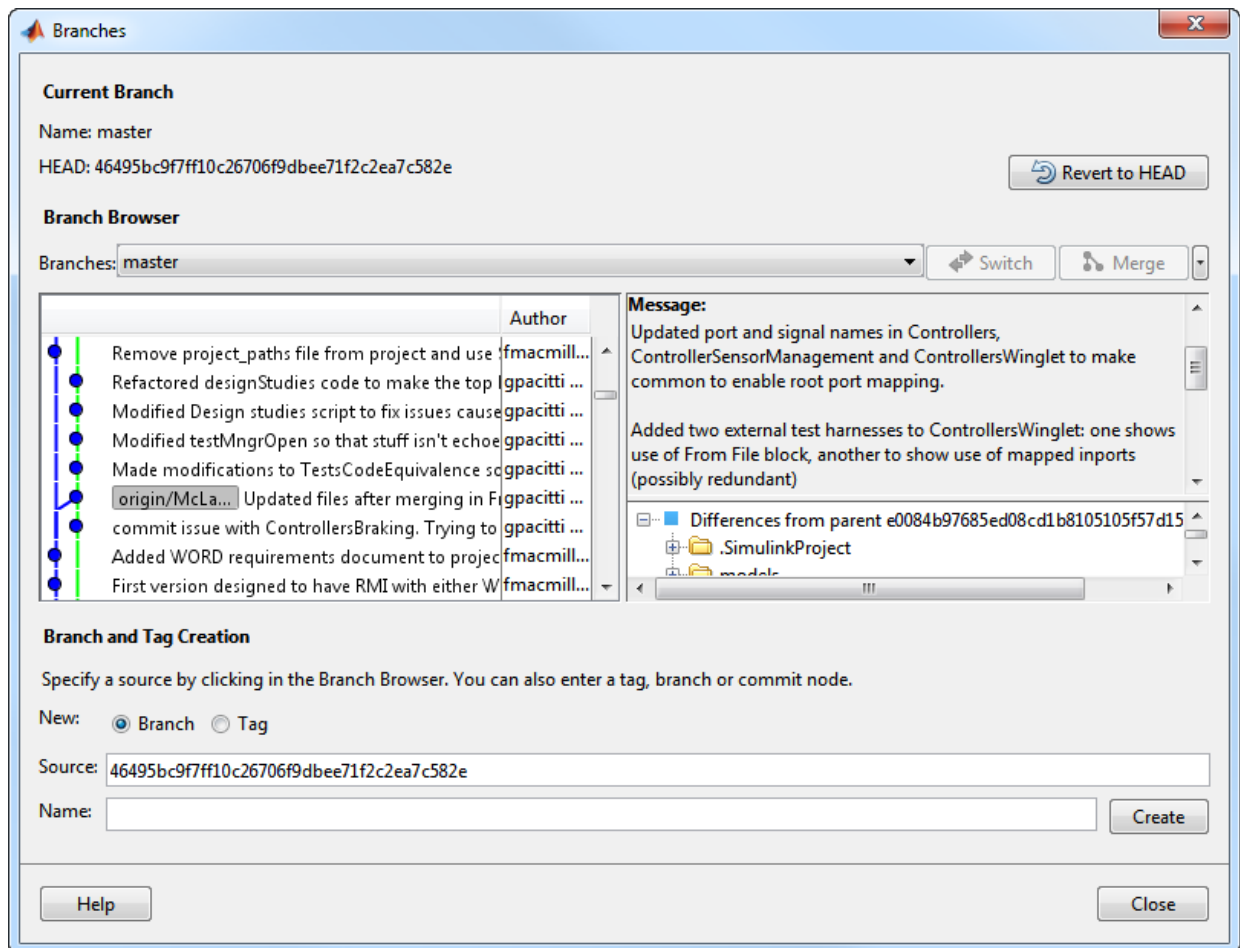

“Delete Branches” on page 19-62

Create a Branch

- 1 In a project using Git source control, click **Branches** on the Project tab. The Branches dialog box appears, where you can view, switch, create, and merge branches.

Tip You can inspect information about each commit node. Select a node in the Branch Browser diagram to view the author, date, commit message, and changed files.

The **Branches** pane in this figure shows an example branch history.

- 2 Select a source for the new branch. Click a node in the Branch Browser diagram, or enter a unique identifier in the Source text box. You can enter a tag, branch name, or a unique prefix of the SHA1 hash (for example, 73c637 to identify a specific commit). Leave the default to create a branch from the head of the current branch.
- 3 Enter a name in the **Branch name** text box and click **Create**.
- 4 To work on the files on your new branch, switch your project to the branch.

In the **Branches** drop-down list, select the branch you want to switch to and click **Switch**.

- 5 Close the Branches dialog box to return to the project and work on the files on your branch.

For next steps, see “Pull, Push, and Fetch Files with Git” on page 19-53.

Switch Branch

- 1 In a project, click **Branches**.
- 2 In the Branches dialog box, select the branch you want to switch to in the **Branches** list and click **Switch**.
- 3 Close the Branches dialog box to return to the project and work on the files on the selected branch.

Compare Branches and Save Copies

In the Branches dialog box, to examine differences from the parent, right-click a file in the tree under **Differences from parent** and select **Show Difference**. The project opens a comparison report.

If you want to examine added or deleted files, or to test how the code ran in previous versions, you can save a copy of the selected or parent files. Right-click a file and select **Save As** or **Save Parent As**.

Merge Branches

Before you can merge branches, you must install command-line Git on your system path and register model files as binary to prevent Git from inserting conflict markers. See “Install Command-Line Git Client” on page 19-22.

Tip After you use **Fetch**, you must merge. See “Pull, Fetch, and Merge” on page 19-54.

To merge any branches:

- 1 In a project, click **Branches**.
- 2 In the Branches dialog box, from the **Branches** drop-down list, select a branch you want to merge into the current branch, and click **Merge**.

- 3 Close the Branches dialog box to return to the project and work on the files on the current branch.

If the branch merge causes a conflict that Git cannot resolve automatically, an error dialog box reports that automatic merge failed. The Branch status in the **Git** pane displays MERGING. Resolve the conflicts before proceeding.

Caution Do not move or delete files outside of MATLAB because this can cause errors on merge.

Keep Your Version

- 1 To keep your version of the file, right-click the file and select **Mark Conflict Resolved**. The Branch status in **Git** pane displays MERGE_RESOLVED. The Modified Files list is empty, because you have not changed any file contents. The local repository index version and your branch version are identical.
- 2 Click **Commit** to commit your change that marks the conflict resolved.

View Conflicts in Branch Versions

If you merge a branch and there is a conflict in a model file, Git marks the file as conflicted and does not modify the contents. Right-click the file and select **View Conflicts**. The project opens a comparison report showing the differences between the file on your branch and the branch you want to merge into. Decide how to resolve the conflict. See “Resolve Conflicts” on page 19-64.

Revert to Head

To remove all local changes, in the Branches dialog box, click **Revert to Head**.

Delete Branches

- 1 In the Branches dialog box, from the **Branches** drop-down list, select a branch you want to delete. You cannot delete the current branch.
- 2 On the far right, click the down arrow and select **Delete Branch**.

Caution You cannot undo deleting a branch.

More About

- “About Source Control with Projects” on page 19-2

Resolve Conflicts

In this section...
“Resolve Conflicts” on page 19-64
“Merge Text Files” on page 19-66
“Merge Models” on page 19-67
“Extract Conflict Markers” on page 19-67

Resolve Conflicts

If you and another user change the same file in different sandboxes or on different branches, a conflict message appears when you try to commit your modified files. Extract conflict markers if necessary, compare the differences causing the conflict, and resolve the conflict.

- 1 Look for conflicted files in the **Modified (*number of files*)** tab.

Identify conflicted folder contents using source control summary status. Folders display rolled-up source control status. This makes it easier to locate changes in files, particularly conflicted files. You can hover over the source control status for a folder to view a tooltip displaying how many files inside are modified, conflicted, added or deleted.

Tip Use the **List** layout to view files without needing to expand folders.

- 2 Check the source control status column (**Git** or **SVN**) for files with a red warning symbol, which indicates a conflict.

Views	All	Project (34)	Modified (6)		Layout: Tree	
	Name	Status	Git	Classification		
Files	.SimulinkProject					
Dependency Analysis	models	✓	!	None		
	AnalogControl.mdl	✓		Upgrade		
	DigitalControl.slx	✓		Design		
	slproject_f14.slx	✓	! (both modified)	Design		
	tests	✓		None		
	f14_airframe_test.m	✓		Test		
	utilities	✓		None		
Labels	clean_up_project.m	✓		Utility		

- 3 Right-click the conflicted file and select **View Conflicts** to compare versions.
- 4 Examine the conflict. The project opens a comparison report showing the differences between the conflicted files.
 - For SVN, the comparison shows the differences between the file and the version of the file in conflict.
 - For Git, the comparison shows the differences between the file on your branch and the branch you want to merge into.
 - For model files, see “Merge Simulink Models from the Comparison Report” on page 21-20.
- 5 Use the comparison report to determine how to resolve the conflict.

To resolve conflicts you can:

- Use the report to merge changes between revisions.
- Decide to overwrite one set of changes with the other.
- Make changes manually from the project by editing files, changing labels, or editing the project description.

For details on using the Comparison Tool to merge changes between revisions, see “Merge Text Files” on page 19-66 and “Merge Models” on page 19-67.

- 6 When you have resolved the changes and want to commit the version in your sandbox, in a project, right-click the file and select **Source Control > Mark Conflict Resolved**. You can use the merge tool to mark the conflict resolved, or you can choose to manually mark the conflict resolved in the project.

For Git, the Branch status in the **Git** pane changes from MERGING to SAFE.

- 7 Select the **Modified (number of files)** tab to check changes. On the **Project** tab, click **Commit**.

Merge Text Files

When comparing text files, you can merge changes from one file to the other. Merging changes is useful when resolving conflicts between different versions of files.

Conflict markers appear in a text comparison report like this:

```
<<<<<<< .mine
```

If your comparison report contains conflict markers, extract them before merging, as described in “Extract Conflict Markers” on page 19-67.

Tip You can merge only from left to right. When comparing to another version in source control, the right file is the version in your sandbox. The left file is either a temporary copy of the previous version or another version causing a conflict (e.g., *filename_theirs*). Observe the file paths of the left and right file at the top of the comparison report. Merge differences from the left (temporary copy) file to the right file to resolve conflicts.

- 1 In the Comparison Tool report, select a difference in the report and click **Merge**. The selected difference is copied from the left file to the right file.

Merged differences display gray row highlighting and a green merge arrow.

```
1 function [len,dims] = lengthofline(hline)      function [len,dims] = lengthofline(hline) 1
```

The merged file name at the top of the report displays the dirty flag (*filename.m**) to show you that the file contains unsaved changes.

- 2 Click **Save Merged File** to save the file on the right. Check the file path of the right file in the comparison report. (To save to a different file, select **Save Merged File >**

Save Merged File As). To resolve conflicts, save the merged file over the conflicted file.

- 3 If you want to inspect the files in the editor, click the line number links in the report.

Note If you make any further changes in the editor, the comparison report does not update to reflect changes and report links can become incorrect.

- 4 After merging to resolve conflicts, mark the conflict resolved and commit the changes, as described in “Resolve Conflicts” on page 19-64.

Merge Models

In the Comparison Tool report, you can merge changes between revisions. For details, see “Merge Simulink Models from the Comparison Report” on page 21-20.

After merging to resolve conflicts, the merge tool can mark the conflict resolved for you, or you can choose to manually mark the conflict resolved. Then commit the changes, as described in “Resolve Conflicts” on page 19-64.

Extract Conflict Markers

- “What Are Conflict Markers?” on page 19-67
- “Extract Conflict Markers” on page 19-68

What Are Conflict Markers?

Source control tools can insert conflict markers in files that you have not registered as binary (e.g., text files). You can use project tools to extract the conflict markers and compare the files causing the conflict. This process helps you to decide how to resolve the conflict.

Caution Register model files with source control tools to prevent them from inserting conflict markers and corrupting models. See “Register Model Files with Source Control Tools” on page 19-10. If your model already contains conflict markers, the project tools can help you to resolve the conflict, but only if you open the model from the project. Opening a model that contains conflict markers from the Current Folder or from a file explorer can fail because Simulink does not recognize conflict markers.

Conflict markers have the following form:

```
<<<<<<["mine" file descriptor]
["mine" file content]
=====
["theirs" file content]
>>>>>>["theirs" file descriptor]
```

If you try to open a file marked conflicted that contains conflict markers, the Conflict Markers Found dialog box opens. Follow the prompts to fix the file by extracting the conflict markers. After you extract the conflict markers, resolve the conflicts as described in “Resolve Conflicts” on page 19-64.

To view the conflict markers, in the Conflict Markers Found dialog box, click **Load File**. Do not try to load model files, because Simulink does not recognize conflict markers. Instead, click **Fix File** to extract the conflict markers.

By default, the project checks only conflicted files for conflict markers. You can change this preference to check all files or no files. Click **Preferences** in the Project tab to change the setting.

Extract Conflict Markers

When you open a conflicted file or select **View Conflicts**, the project checks files for conflict markers and offers to extract the conflict markers. The project checks only conflicted files for conflict markers unless you change your preferences setting.

However, some files that are not marked conflicted can still contain conflict markers. This can happen if you or another user marked a conflict resolved without removing the conflict markers and then committed the file. If you see conflict markers in a file that is not marked conflicted, you can remove the conflict markers.

- 1** In a project, right-click the file and select **Source Control > Extract Conflict Markers to File**.
- 2** Leave the default option to copy the “mine” revision over the conflicted file. Leave the **Compare** check box selected. Click **Extract**.
- 3** Use the Comparison Tool report as usual to continue to resolve the conflict.

Work with Derived Files in Projects

Best practice is to omit derived and temporary files from your project or exclude them from source control. Use **Check Project** in the Precommit Actions pane or the **Project** tab to check the integrity of the project. If you add the `s\prj` folder to a project, the project checks advise you to remove this from the project and offer to make the fix.

Best practice is to exclude derived files, such as `.mex*`, the contents of the `s\prj` folder, `sccprj` folder, or other code generation folders from source control, because they can cause problems. For example:

- With a source control that can do file locking, you can encounter conflicts. If `s\prj` is under source control and you generate code, most of the files under `s\prj` change and become locked. Other users cannot generate code because of file permission errors. The `s\prj` folder is also used for simulation via code generation (for example, with model reference or Stateflow), so locking these files can have an impact on a team. The same problems arise with binaries, such as `.mex*`.
- Deleting `s\prj` is often required. However, deleting `s\prj` causes problems such as “not a working copy” errors if the folder is under some source control tools (for example, SVN).
- If you want to check in the generated code as an artifact of the process, it is common to copy some of the files out of the `s\prj` cache folder and into a separate location that is part of the project. That way, you can delete the temporary cache folder when you need to. See `packNGo` to discover the list of generated code files, and use the project API to add to the project with appropriate metadata.
- The `s\prj` folder can contain many small files. This can affect performance with some source control tools when each of those files is checked to see if it is up-to-date.

Customize External Source Control to Use MATLAB for Diff and Merge

You can customize external source control tools to use the MATLAB Comparison Tool for diff and merge. If you want to compare MATLAB files such as live scripts, MAT, SLX, or MDL files from your source control tool, then you can configure your source control tool to open the MATLAB Comparison Tool.

MATLAB Comparison Tool provides useful merge tools for MathWorks files and is compatible with all popular software configuration management and version control systems.

Set up your source control tool to use MATLAB as the application for diff and merge for the file extensions you want, for example, `.mlx`, `.mat`, `.slx`, or `.mdl`, by following these steps:

- 1 To get the required file paths and set the preference to reuse open MATLAB sessions, run this command in MATLAB:

```
comparisons.ExternalSCMLink.setup()
```

This command sets the MATLAB preference, under **Comparison**, called **Allow external source control tools to use open MATLAB sessions for diffs and merges**.

The command also displays the file paths you will copy and paste into your source control tool setup:

- On Windows:

```
matlabroot\bin\win64\mlDiff.exe
```

```
matlabroot\bin\win64\mlMerge.exe
```

- On Linux:

```
matlabroot/bin/glnxa64/mlDiff
```

```
matlabroot/bin/glnxa64/mlMerge
```

On Mac:

```
matlabroot/bin/maci64/mlDiff
```

```
matlabroot/bin/maci64/mlMerge
```

Where *matlabroot* is replaced with the full path to your installation, for example, C:\Program Files\MATLAB\R2016b.

2 Set up diff.

- a** In the MATLAB Command Window, copy the file path to `mlDiff`, for example, C:\Program Files\MATLAB\R2016b\bin\win64\mlDiff.exe.
- b** In your source control tool, locate the diff setting, and add an entry to specify what to do with a particular file extension (for example, `.slx`). Paste in the file path to `mlDiff` that you copied from the MATLAB Command Window.
- c** After the path to the script, or in the arguments box, add arguments to specify the input files. Look up the argument names specific to your source control tool. Specify the inputs for diffs, in this order: *leftFile*, *rightFile*.

For example, for Tortoise SVN:

```
"C:\Program Files\MATLAB\R2016b\bin\win64\mlDiff.exe" %base %mine
```

For Perforce® P4V:

```
"C:\Program Files\MATLAB\R2016b\bin\win64\mlDiff.exe" %1 %2
```

3 Set up merge.

- a** In the MATLAB Command Window, copy the file path to `mlMerge`.
- b** In your source control tool, locate the merge setting, and add an entry to specify what to do with a particular file extension (for example, `.slx`). Paste in the file path to `mlMerge` that you copied from the MATLAB Command Window.
- c** After the path to the script, or in the arguments box, add arguments to specify the input files. Look up the argument names specific to your source control tool. Specify the inputs for merges, in this order: *base*, *mine*, *theirs*, and *merged* target file.

For example, for Tortoise SVN:

```
"C:\Program Files\MATLAB\R2016b\bin\win64\mlMerge.exe" %base %mine %theirs %merged
```

For Perforce P4V:

```
"C:\Program Files\MATLAB\R2016b\bin\win64\mlMerge.exe" %b %2 %1 %r
```

- 4** After this setup, when you use diff or merge, your external source control tool opens a report in MATLAB Comparison Tool. Use the report to view changes and resolve merges.

Your diff and merge operations use open MATLAB sessions if available, and only open MATLAB when necessary. The comparison only uses the specified MATLAB installation.

Componentization Using Referenced Projects

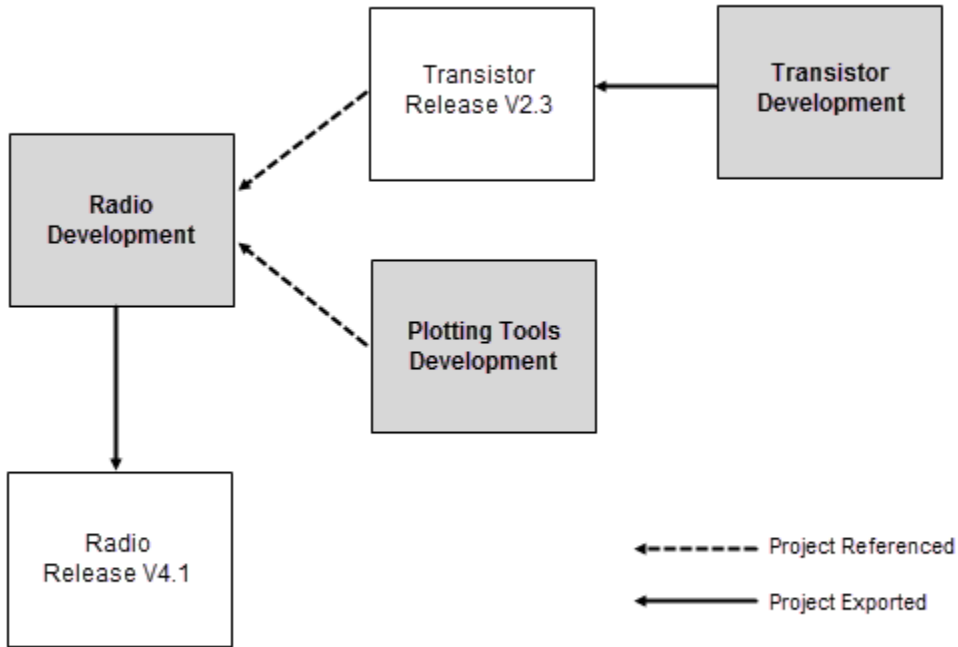

For a large modeling project, organizing the project into components facilitates:

- Component reuse
- Modular, team-based development
- Unit testing
- Independent release of components

Projects supports large-scale project componentization by allowing you to reference other projects from a parent project. A collection of parent and referenced projects constitutes a project reference hierarchy. Project referencing provides these benefits:

- A parent project has access to a referenced project's project paths, entry-point shortcuts, and source control information. For example, from a parent project, you can display the hierarchy of referenced projects. You can select a referenced project and then view, edit, and run files that belong to the referenced project.
- Through a referenced project, your team can develop a component independent of other components.
- In a referenced project, you can test the component separately.
- In a parent project, you can set a checkpoint and then compare the referenced project against the checkpoint to detect any changes.

This project hierarchy illustrates the use of parent and referenced projects as components of a large project.

Through the Transistor Development project, a team independently creates and tests a library of blocks. The team makes the library available to other developers by exporting release versions, for example, version 2.3.

Through the Radio Development project, another team develops and tests the Radio system. This team requires:

- Version 2.3 of the Transistor component. The team sets up the Radio Development project to reference the Transistor Release V2.3 project.
- Tools to plot signals, for example, MATLAB files that are not distributed to customers. The team sets up the Radio Development project to reference the Plotting Tools Development project.

When the Radio system is ready for customers, the team exports a release version, for example, version 4.1.

Add or Remove a Reference to Another Project

Add new components to your project by referencing other projects. The addition of referenced projects creates a project hierarchy. When the Project loads a referenced project in a project hierarchy, it:

- Adds project paths from the referenced project to the MATLAB search path.
- Runs startup shortcuts from the referenced project.

To reference a project:

1

On the Project tab, in the **Environment** section, click .

2 In the Add Reference dialog box, specify settings:

- **Referenced project location** -- Click **Browse** and navigate to the project folder. Then, in the project folder, select the required project (.prj) file.
- **Referenced type** -- If your project hierarchy has a well-defined root relative to your project root, for example, a folder under source control, click **Relative**. If the project you want to reference is in a location accessible to your computers, for example, a network drive, click **Absolute**.
- **Set a checkpoint to detect future changes** -- To create a checkpoint, select the check box. To detect changes, you can compare the referenced project against this checkpoint.

3 Click **Add**. The Project creates a References view that displays the referenced project.

You can reference multiple projects in a hierarchical manner. In the References view, the Project displays the project reference hierarchy as a tree.

To view summary information about a referenced project, in the References tree, select the project.

To view files that belong to the referenced project, click ▼ Show Files.

To remove a referenced project from your project hierarchy, in the References tree, right-click the referenced project and select **Remove Reference**.

- Airframe Project Reference Example

View, Edit, or Run Referenced Project Files

In a project that references other projects, use the References view to see, modify, or run files that belong to the referenced projects.

- 1 In a Project, select the References view.
- 2 In the References tree, select the required project reference.
- 3 Click **Show Files**. The Project displays files and folders from the referenced project.

- 4 Right-click a file, and then, from the context menu, select the required action.

- “Extract a Folder to Create a Referenced Project” on page 20-8
- Airframe Project Reference Example

Extract a Folder to Create a Referenced Project

In a Project, you can partition a large project into components through the use of project references.

Consider the Airframe example project. Suppose you create a folder `Trial` and carry out development work within the folder. You produce:

- Shortcuts to a Simulink library, a MATLAB file, and a Readme document
- Design and source code folders
- Data files

Name ▲	Status
batch_jobs	✓
data	✓
models	✓
reports	✓
src	✓
tests	✓
Trial	✓
DataBaseSourceCode	✓
Design Requirements	✓
ReallyComplicatedSource	✓
buses.mat	✓
DataLoggingLib.slx	✓ ↗
f14_digital_data.mat	✓
plotData.m	✓ ↗
Readme.pdf	✓ ↗
utilities	✓

For easier management, you want to convert the `Trial` folder into a separate component. In addition, you want access to the folder contents, for example, shortcuts to key files. To fulfill these requirements, extract the folder from the project and convert the folder into a referenced project.

- 1 In the Files view, right-click the `Trial` folder and select **Extract to Referenced Project**.
- 2 In the Extract Folder to New Project dialog box, specify these options:

- **New Project Name** — For example, DataLogging.
 - **New Project Location** - For example, C:\Work\DataLogging.
 - **Reference Type** - The default is **Relative** reference. Use the default if you specify the new project location with reference to the current project root. If you specify the full path for the new location, which is, for example, on a network drive, select **Absolute** reference.
- 3 Click **More Options**. If you want to disable any of the default content migration actions, clear the corresponding check box.
 - 4 Click **Extract**.
 - 5 In the two Warning dialog boxes that open, click **OK**.

The folder **Trial** and its contents are removed from the project. On the **Project Shortcuts** tab, the **Referenced Projects** section displays a new DataLogging button.

Manage Referenced Project Changes Using Checkpoints

In a Project, you can create a checkpoint for a referenced project. You can then compare the referenced project against the checkpoint to detect changes.

- 1 In the project that contains the referenced project, select the References view.
- 2 In the References tree, select the referenced project. If a checkpoint does not exist for the project, in the Details view, the **Checkpoint** field displays None.

References	../refs/Signal Multiplier (Relative)
 Wind Gust Library  Signal Multiplier	Name: Signal Multiplier Checkpoint: None Description: This component project provides reusable functionality for amplifying signals.

3

To create a checkpoint, in the Checkpoint section, click . In the Details view, the Checkpoint field displays the timestamp of the check point.

References	../refs/Signal Multiplier (Relative)
 Wind Gust Library  Signal Multiplier	Name: Signal Multiplier Checkpoint: 18 July 2018 15:17:25 Description: This component project provides reusable functionality for amplifying signals.

In future, to detect changes in the referenced project, in the Checkpoint section, click

. The Difference to Checkpoint dialog box shows files that have changed on disk since you created the checkpoint.

To remove the checkpoint, in the Checkpoint section, click .

About Simulink Model Comparison

In this section...
“Creating Model Comparison Reports” on page 21-2
“Examples of Model Comparison” on page 21-3
“Using Model Comparison Reports” on page 21-3
“Select Simulink Models to Compare” on page 21-4

Creating Model Comparison Reports

In Simulink, you can compare Simulink models. Review and merge differences using three-way model merge or two-way model merge.

You can use models from any version of Simulink. Use the comparison report to explore the differences, view the changes highlighted in the original models, and merge differences.

For details, see “Compare Simulink Models” on page 21-7 and “Merge Simulink Models from the Comparison Report” on page 21-20.

You can access the comparison tool from:

- The MATLAB Current Folder browser context menu
- The MATLAB Comparison Tool
- The MATLAB command line
- The Simulink Editor **Analysis** menu
- The Project view

You can use the comparison tool with both model file formats, SLX and MDL. If the selected files are .mdl files, or SLX files saved in a previous version, then the comparison tool first exports the .mdl files to SLX files in a temporary folder, and produces a comparison report based on the SLX files.

For more information on creating reports, see “Select Simulink Models to Compare” on page 21-4.

Examples of Model Comparison

For examples with instructions, see:

- `slxml_compare_merge`
- `slxml_sfcar`
- `slxml_three_way_merge`

For more information on using and understanding the comparison reports, see “Compare Simulink Models” on page 21-7.

Using Model Comparison Reports

You can display comparison reports in the Comparison Tool. In the interactive report, you can click items in the report to display the corresponding items highlighted in the original models.

The comparison report shows a hierarchical view of the portions of the two files that differ. The report does not show sections of the files that are identical.

If the files are identical you see a message reporting there are no differences.

If files have not been saved, you see an error message informing you that you must save modified or newly created models before running a comparison.

Note It might not be possible for the analysis to detect matches between previously corresponding sections of files that have diverged too much.

Change detection is based on a scoring algorithm. Items match if their score is above a threshold. The tool's algorithm uses a comparison pattern that defines the thresholds assigned to particular node types (e.g., block).

For more information on using the report, see “Compare Simulink Models” on page 21-7.

To control highlighting, see “Display Differences in Original Models” on page 21-18.

To merge differences, see “Merge Simulink Models from the Comparison Report” on page 21-20.

For more information about the Comparison Tool, see “Compare Files and Folders and Merge Files” (MATLAB).

Select Simulink Models to Compare

- “Select Files from the Simulink Editor” on page 21-4
- “Select Files from the Current Folder Browser” on page 21-4
- “Select Files from a Project” on page 21-5
- “Select Files from the Comparison Tool” on page 21-5
- “Select Files from the Command Line” on page 21-5
- “Choose a Comparison Type” on page 21-5

To learn what you can do with comparison reports, see “About Simulink Model Comparison” on page 21-2.

Select Files from the Simulink Editor

To compare files using the Simulink Editor:

- 1** Select **Analysis > Compare To...**

The Select Files or Folders for Comparison dialog box opens.

- 2** If the Editor currently displays a model, the current model name and path appear automatically selected in the **First file or folder** edit box. Use the browse buttons to locate and select files for the first and second model files.
- 3** When you click **Compare**, the comparison tool performs the analysis, and displays the resulting report in the Comparison Tool.

Select Files from the Current Folder Browser

To compare two files from the Current Folder browser:

- For two files in the same view, select two files, right-click and select **Compare Selected Files/Folders**.
- Alternatively, you can browse to select the second file to compare:
 - 1** Select a file, right-click and select **Compare Against**
 - 2** Select the second file to compare in the Select Files or Folders for Comparison dialog box.

- 3 For models, leave the default **Comparison type**, Simulink Model Comparison.
- 4 Click **Compare**.

For more information about comparisons of other file types (e.g., text, MAT, or binary) with the Comparison Tool, see “Compare Files and Folders and Merge Files” (MATLAB).

Select Files from a Project

If you have a project using source control, you can create a model comparison report from the Modified Files view of the project. For details, see “Project Management”.

Select Files from the Comparison Tool

To compare files using the Comparison Tool, from the MATLAB Toolstrip, in the **File** section, select the **Compare** button. In the dialog box select files to compare.

Select Files from the Command Line

To compare XML files from the command line, enter

```
visdiff(filename1, filename2)
```

where `filename1` and `filename2` are XML files or Simulink models.

`visdiff` produces a report in the Comparison Tool.

To create an `xmlcomp.Edits` object at the command line without opening the Comparison Tool, enter:

```
Edits = slxmlcomp.compare(modelname_A,modelname_B)
```

See “Export Results to the Workspace” on page 21-28 for information about the `xmlcomp.Edits` object.

Choose a Comparison Type

To change comparison type, either create a new comparison from the Comparison Tool, or use the **Compare Against** option from the Current Folder browser. You can change comparison type in the Select Files or Folders for Comparison dialog box. For example, if you want the MATLAB text differences report for XML or model files, change the comparison type to Text comparison in the dialog before clicking **Compare**. Alternatively, see the `visdiff` function.

- “Change Color Preferences” on page 21-15
- “Save Comparison Results” on page 21-16
- “Examples of Model Comparison” on page 21-16

Navigate the Simulink Model Comparison Report

You can compare models from any version of Simulink. The comparison tool produces a comparison report based on the SLX files, resaved in the current version if necessary. Use the report to explore the differences, view the changes highlighted in the original models, and merge differences.

The Comparison report shows changes only, not the entire file contents. The report shows a hierarchical view of the portions of the files that differ, and does not show sections of the files that are identical. To learn about the report, see “About Simulink Model Comparison” on page 21-2.

To *step through differences*, on the **Comparison** tab, in the **Navigate** section, click **Next** or **Previous**. See “Step Through Changes” on page 21-9.

You can also click to select items in the hierarchical trees and observe the following display features:

- Selected items appear highlighted in a box.
- If the selected item is part of a matched pair it is highlighted in a box in both left and right trees.

- When you select an item, the original model displays and the corresponding item is highlighted. See “Explore Changes in the Original Models” on page 21-9.

Report item highlighting indicates the nature of each difference as follows:

Type of report item	Highlighting	Notes
Modified	Purple	Modified items are matched pairs that differ between the two files. When you select a modified item it is highlighted in a box in both trees. Changed parameters for the selected pair are displayed underneath.
Inserted	Blue	When you select an unmatched item it is highlighted in a box in one tree only.
Deleted	Orange	
Container	None	Rows with no highlighting indicate a container item that contains other modified or unmatched items.

Icons indicate the category of item, for example: model, subsystem, Stateflow machine or chart, block, line, parameter, etc.

To expand or filter the tree view, use the toolstrip for the following functions:

- **Filter** — Use filters to show only the changes you are interested in. By default the report hides all nonfunctional changes, such as repositioning of items. Turn off filters to explore *all* differences including nonfunctional changes. See “Filter Comparison Reports” on page 21-11.
- **Find** — Opens the Find dialog box where you can search for items.
- If you want to swap the files, on the **Comparison** tab, select **Swap Sides**. The report swaps the sides and reruns the comparison. **Refresh** also runs the analysis again.

To create a new report, see “Select Simulink Models to Compare” on page 21-4.

For examples with instructions, see also “Examples of Model Comparison” on page 21-3.

Step Through Changes

On the **Comparison** tab, in the **Navigate** section, when you click the **Next** arrow button (or press the Down key when the report has focus), you step through groups of changes in the report, in the following order:

- 1 The first time you click **Next**, it selects the first changed (purple) or inserted (blue) node.
- 2 Step through the differences with the **Next** button.
 - When selected items have a match in the right tree then they are also highlighted.
 - Next skips white nodes with no color background, if they have no parameter changes underneath. White nodes are parts of the hierarchy that contain no differences.
 - If there is an insertion or deletion with child nodes, **Next** skips the child nodes if they are all also insertions or deletions. For example, if you insert a subsystem, **Next** selects the top subsystem node, then skips all the nodes inside the subsystem (if they are all also insertions) and selects the next difference.
 - **Next** minimizes context switching when highlighting in models. When you click **Next**, the report steps through all differences at the same level of the model, subsystem, or chart, in both left and right trees in the report, before moving to the next level of the report. For example, you step through all differences in a subsystem in the left and right trees, before moving to another subsystem.
- 3 When you have stepped through all changes, **Next** stops at the end.

If you click an item in the report, the **Next/Previous** controls will step through changes from the point you selected.

Explore Changes in the Original Models

When you compare Simulink models, you can choose to display the corresponding items in the original models when you select report items. You can use this highlighting function to explore the changes in the original models. When you select an item, the report highlights the corresponding item in the model.

Control the display by using the **Highlight Now** button and the **Always Highlight in Models** check box.

For details, see “Display Differences in Original Models” on page 21-18.

Merge Differences

To merge, on the **Comparison** tab, click **Merge**. The Target pane appears at the bottom of the report. Use the buttons to select differences to keep in the target. For more information, see “Merge Simulink Models from the Comparison Report” on page 21-20.

Open Child Comparison Reports for Selected Nodes

If additional comparisons are available for particular parameters, you see a **Compare** button to open a report for that pair of nodes. For example, if there are differences in the Model Workspace, you can click **Compare** to open a new report to explore differences in variables.

- You can open a new comparison for parameters when the report cannot display all the details, e.g., long strings or a script.
- If the original models contain MATLAB Function block components, and if differences are found, click the **Compare** button at the end of the MATLAB Function block report items to open new comparisons in the Comparison Tool, showing the text difference reports for the MATLAB Function block components. You can merge differences in MATLAB Function block code from the text comparison report. See “Merge Simulink Models from the Comparison Report” on page 21-20.
- If the original models contain truth tables, and if differences are found:
 - Click the **Compare** button at the end of the MATLAB Function node to see a summary of all changes.
 - Click the `truthtable` node to reverse annotate and display both truth table editors.
 - Click the **Compare** button on the parameter to open a new text comparison showing only Condition table differences.
 - Similarly click the **Compare** button for Action Table to view only Action changes.

Understand the Report Hierarchy and Matching

Note It might not be possible for the analysis to detect matches between previously corresponding sections of files that have diverged too much.

If you cannot see changes you expected to see in the report, turn off filters and see *all* identified changes. See “Filter Comparison Reports” on page 21-11.

Filter Comparison Reports

You can define custom filters to simplify reports and focus on specified elements. You can import and export filters for sharing. Use built-in filters to control display of categories of changes. Turn off filtering to view all identified changes.

To see the available filters, and whether or not they apply to the current report, on the **Comparison** tab, in the **Filter** section, click the down arrow to expand the filter gallery. Click filter names to toggle whether they are applied. In the **Filter** section, click **Show** or **Hide** to control how the filters are applied.

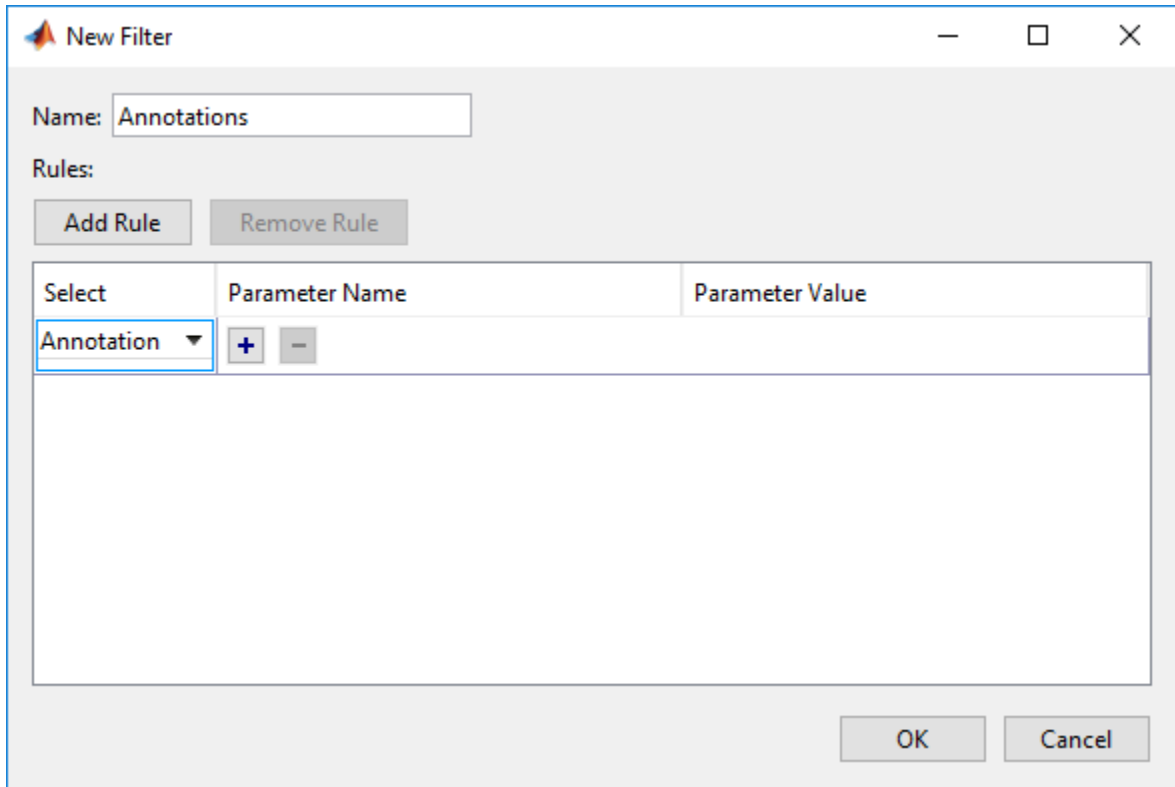

To define a new custom filter:

- 1 On the **Comparison** tab, in the **Filter** section, click **New Filter**.
- 2 In the New Filter dialog box, define one or more rules for your new filter. For example, you can select parameters or blocks of particular types or values. Suggested values depend on the items in your comparison report. Specify a unique name for your filter and click **Apply**.
- 3 To check if your filter applies to the items you expect, enable only the new filter in the filter gallery and then click **Show**. This is often easier than checking that a filter is hiding the changes you expect to see in the report.

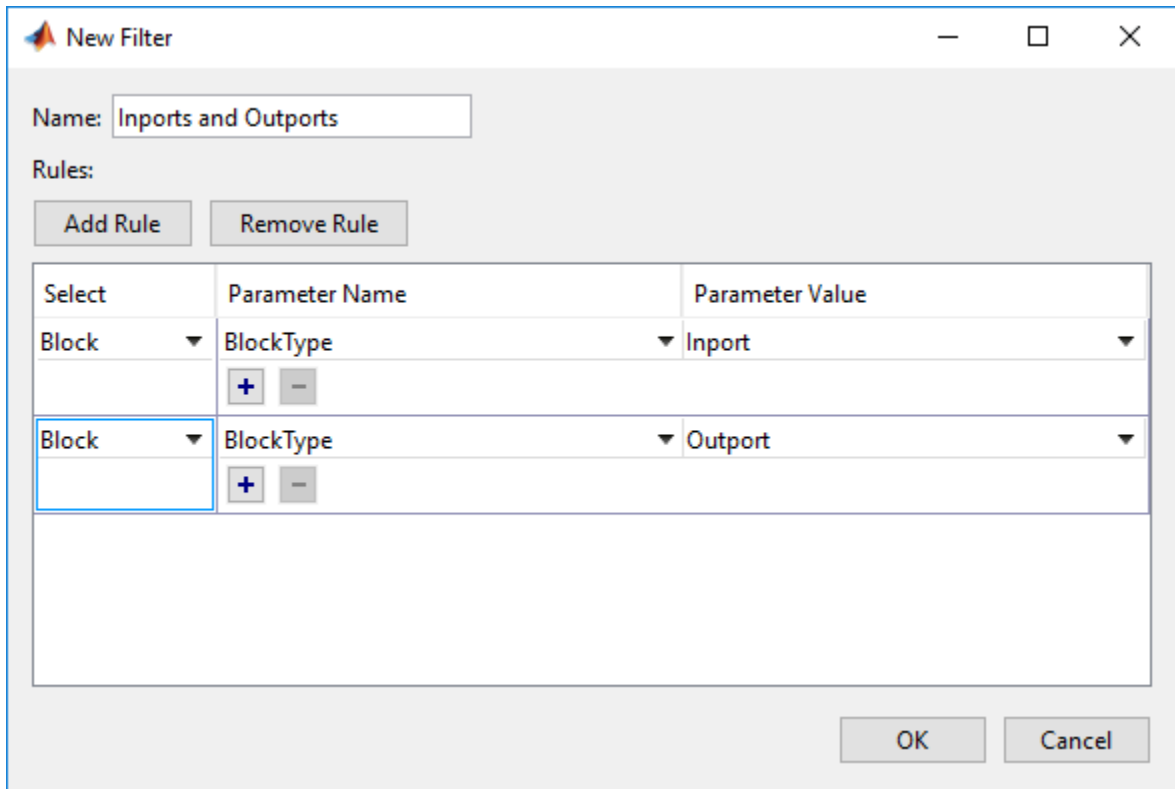

Observe how these custom filters are defined.

Purpose	Select Column	Parameter Name	Parameter Value
Filter out Annotation changes	Annotation	Click the minus button to clear the row.	Leave blank
Filter out Inport and Outport block changes	Block	BlockType	Inport
	To add a row, click Add Rule , then select Block	BlockType	Outport
Filter out sample time parameter changes	Parameter	SampleTime	Any

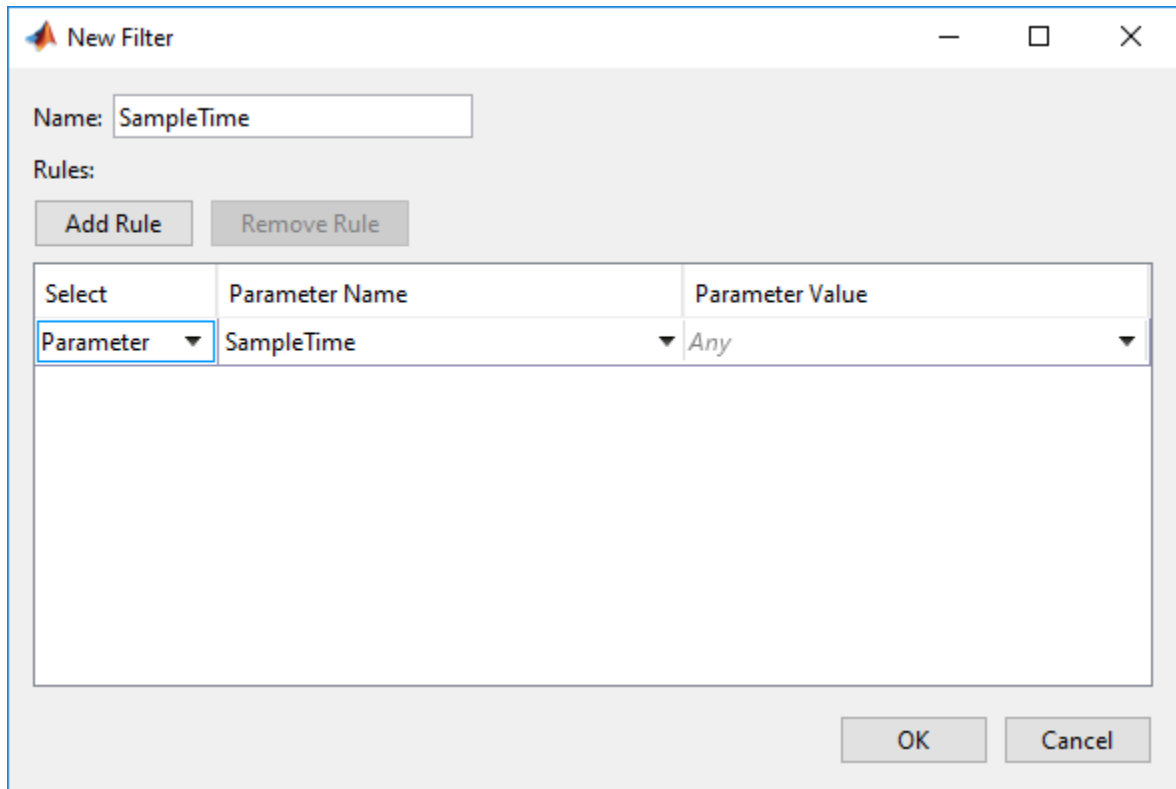

- Annotation changes:

- Inport and Output block changes:

- Sample time parameter changes:

To show all changes, use either of these methods:

- Hide nothing - Click **Hide** and disable all filters in the gallery.
- Show everything - Create a custom filter. In the New Filter dialog box, delete the contents of the first column so it shows **Any**, then remove the rest of the row under **Parameter Name**. Click **Show** and enable the "everything" filter in the gallery.

Use the filters to show only the changes you are interested in. By default the report hides all nonfunctional changes, such as repositioning of items. Turn off filters to explore all differences including nonfunctional changes. Try this if you cannot see changes you expected to see in the report.

Built-in filters include:

- **Lines.** Select all changes to signal lines, including functional changes.
- **Nonfunctional Changes.** The report identifies certain items in the model file as nonfunctional, for example, items representing parameters such as block, system, chart, or label positions; font and color settings for blocks and lines; and system print and display settings.
- **Block Defaults.** Block defaults rarely change and cause longer reports when there are added or deleted blocks. Often the report is simpler when you hide block defaults.

Exceptions

The report does *not* filter out changes to Block and System names, annotations, and Stateflow Notes as nonfunctional, even though changes to these items do not affect the outcome of simulation. The report always displays these changes to facilitate review of code changes, because they can contain important information about users' intentions.

In rare cases, the report filters out changes that can impact the behavior of the design. By default, moves are filtered as nonfunctional, but in these cases moves can change design behavior:

- Moving blocks can in some cases change the execution order.
- In a Stateflow chart, if you move states or junctions so that they intersect, the model fails to simulate.

To view these types of changes in the report, turn off the filter for nonfunctional changes.

Change Color Preferences

You can change and save your diff color preferences for the Comparison tool. You can apply your color preferences to all comparison types.

- 1 On the MATLAB Home tab, click **Preferences**.
- 2 In the Preferences dialog box, under **MATLAB**, click **Comparison**.
- 3 Edit color settings as desired for differences and merges. View the colors in the **Sample** pane.

The **Active Settings** list displays **Default (modified)**.

- 4 To use your modified settings in the comparison, click **Apply** and refresh the comparison report.

- 5 To return to the default color settings, in the Preferences dialog box, click **Reset** and click **Apply**. Refresh the comparison report.
- 6 If you want to save your modified color preferences for use in future MATLAB sessions, click **Save As**. Enter a name for your color settings profile and click **OK**.

After saving settings, you can select them in the **Active Settings** list.

Save Comparison Results

To save your comparison results, use these **Comparison** tab buttons:

- **Publish > HTML or Word** — Open the Save dialog box, where you can choose to save a printable version of the comparison report. See “Save Printable HTML Report” on page 21-28.
- **Publish > Workspace Variable** — Export comparison results to workspace. See “Export Results to the Workspace” on page 21-28.

Alternatively, you can publish a comparison report to a file using the `visdiff` function.

Examples of Model Comparison

For examples with instructions, see:

- `slxml_compare_merge`
- `slxml_sfcar`
- `slxml_three_way_merge`

Display Differences in Original Models

In this section...
“Highlighting in Models” on page 21-18
“Control Highlighting in Models” on page 21-18
“View Changes in Model Configuration Parameters” on page 21-19

Highlighting in Models

When you compare Simulink models, you can choose to display the corresponding items in the original models when you select report items. You can use this highlighting to explore the changes in the original models. When you select an item, the report highlights the corresponding item in the model.

Click a report entry to view the highlighted item (or its parent) in the model:

- If the item occurs in both models, they both appear with highlighting.
- When there is no match in the other model, the report highlights the first matched ancestor to show the context of the missing item.
- If the comparison tool cannot highlight an item directly (e.g., configuration parameters), then it highlights the nearest ancestor of the selected node.

Try highlighting items in original models using the example `slxml_sfc`.

Control Highlighting in Models

To control highlighting in models, in the Comparison Tool, select or clear the check box **Always Highlight in Models**. You can click the **Highlight Now** button to highlight the currently selected report node at any time. This can be useful if you turn off automatic highlighting and only want to display specific nodes.

By default, models display to the right of the comparison report, with the model corresponding to the left side of the report on top, and the right below. If you move or resize the models your position settings are respected by subsequent model highlighting operations within the same session. The tool remembers your window positions.

If you want to preserve window positions across sessions, position the window, and then enter:

```
slxmlcomp.storeWindowPositions
```

This preserves the placement of any Simulink windows, Stateflow windows, and truth table windows.

To stop storing window positions and return to the defaults, enter:

```
slxmlcomp.clearWindowPositions
```

View Changes in Model Configuration Parameters

You can use the report to explore differences in the model Configuration Parameters. If you select a Configuration Parameter item, the report displays the appropriate root node pane, if possible, of both Configuration Parameters dialog boxes.

Parameters display the label text from the dialog controls (or the parameter name if it is command line only), and the parameter values. You can merge selected parameters using merge mode.

Merge Simulink Models from the Comparison Report

In this section...

“Resolve Conflicts Using Three-Way Model Merge” on page 21-20

“Use Three-Way Merge with External Source Control Tools” on page 21-24

“Open Three-Way Merge Without Using Source Control” on page 21-25

“Two-Way Model Merge” on page 21-25

“Merge MATLAB Function Block Code” on page 21-26

Merge tools enable you to:

- Resolve conflicts in model files under source control using three-way merge. Open by selecting **View Conflicts**.
- Merge any two model files using two-way merge. Open by selecting **Compare** context menu items.
- Merge MATLAB Function block code using text comparison reports.

Resolve Conflicts Using Three-Way Model Merge

If you have a conflicted model file under source control in a project or in the Current Folder browser, right-click and select **View Conflicts**. You can resolve the conflicts in the Three-Way Model Merge tool. Examine your local file compared to the conflicting revision and the base ancestor file, and decide which changes to keep. You can resolve the conflict and submit your changes.

- 1 To try an example three-way merge, enter `slxml_three_way_merge`.
- 2 In the project, locate the conflicted model file, right-click and select **View Conflicts**. You can only see **View Conflicts** in the context menu if your file is marked conflicted by the source control.

The Merge tool automatically resolves every difference that it can, and shows the results in the **Target** pane. Review the automerge choices, edit if desired, and decide how to resolve any remaining conflicts.

1 Examine the Merge report columns.

- At the top, **Theirs**, **Base**, and **Mine** columns show the differences in the conflicting revision, your revision, and the base ancestor of both files.
- Underneath, the **Target** shows the local file that you will merge changes into. The Merge tool already automerged the differences it can merge.

2 Examine a difference by clicking **Next** or by clicking a row in the **Theirs**, **Base**, and **Mine** columns.

The merge tool displays two models (or if you selected a configuration setting, you see two model Configuration Parameters dialog boxes). By default, you see **Theirs**

and **Target** models.

- 3 Choose the models to display with the toolbar buttons on the **Merge** tab: **Top Model** or **Bottom Model**. View the models to help you decide what to merge.

Note If you open the merge tool using **View Conflicts**, then the models **Theirs**, **Base**, and **Mine** are temporary files showing the conflicting revisions. Examine them to decide how to merge. The **Target** model is a copy of **Mine** containing the results of your merges in the report.

- 4 Select a version to keep for each change by clicking the buttons in the **Target** pane. You can merge modified, added, or deleted nodes, and you can merge individual

parameters. The Merge tool selects a choice for every difference it could resolve automatically. Review the selections and change them if you want.

Look for warnings in the Conflicts column. Select a button to use **Theirs**, **Base**, or **Mine** for each conflicted item.

Tip Merge blocks before lines, and merge states and junctions before merging transitions. Merge tool then attempts to connect all lines to blocks for you.

- 5 Some differences you must merge manually. In the **Target** pane, look for the manual merge icon in the Conflicts column that shows you must take action.

Make manual changes in the Editor. The comparison report cannot update to show any changes that you make in the Editor, so try to make manual changes after addressing all the simpler merges in the report.

After you have resolved the conflict using the Editor, in the **Target** pane, select the check option to mark the node as complete.

- 6 Examine the summary table to see the number of automatic merges and remaining conflicts you need to resolve.

Resolve remaining 5 changes

Filtered View (3) All Changes (5)

TYPE	UNRESOLVED	RESOLVED
Conflict	1	0
Conflicted manual merge	0	0
Manual merge	2	0
Automatic	0	8
Total	3	8

Check for changes that are filtered out of the current view by looking at the summary table tab titles. The Filtered View and All Changes tab titles show the number of changes. By default the report hides all nonfunctional changes. Turn off active filters to view all identified changes.

- 7 When you are happy with your merge selections and any manual merges in the **Target** file, click **Accept and Close**. This action saves the target file with all your merges and marks the conflicted file resolved in the source control tool.

To save and not mark the conflict resolved, select **Accept and Close > Save and Close**.

To learn more about resolving conflicts in a change list of modified files in a project, see “Resolve Conflicts” on page 19-64.

Use Three-Way Merge with External Source Control Tools

If you are using source control outside of MATLAB, then you can customize external source control tools to open Three-Way Merge (or two-way merge for diffs).

For instructions, see “Customize External Source Control to Use MATLAB for Diff and Merge” on page 19-71.

Open Three-Way Merge Without Using Source Control

If you are not using source control or you want to choose three files to merge, then you can open Three-Way Merge using the function `slxmlcomp.slMerge`. Specify the files to merge, for example:

```
slxmlcomp.slMerge(baseFile, mineFile, theirsFile, targetFile);
```

Three-Way Merge opens, where you can merge the changes in `baseFile`, `mineFile`, and `theirsFile` into the `targetFile`.

Two-Way Model Merge

You can merge two Simulink models from a comparison report. The **Compare** context menu items from a project or the Current Folder browser open a two-way model merge. If you are using source control and want to resolve conflicts using a three-way model merge instead, see “Resolve Conflicts Using Three-Way Model Merge” on page 21-20.

The merge feature enables you to merge two versions of a design modeled in Simulink. You can merge individual parameters, blocks, or entire subsystems. Entire subsystems can only be merged as a whole if they are fully inserted or deleted subsystems.

- 1 On the **Comparison** tab, click **Merge**. The Target pane appears at the bottom of the report.
- 2 Use the same workflow as three-way merge. Use the buttons to select the differences to keep in the target file.

Tip Merge blocks before lines, and merge states and junctions before merging transitions. See “Merging Tips” on page 21-26.

- 3 View the results in the report and the models. Click **Save File**. **Save File** copies the temporary target file over the right file in the comparison and reruns the comparison.
- 4 (Optional) To revert all merge operations, click **Close Merge** without saving the file.
- 5 Inspect your merge changes in the Simulink Editor. If necessary, connect any lines that the software did not connect automatically. The comparison report does not update to show any changes that you make in the Editor.

Merging Tips

- You must merge blocks before lines in the Simulink part of the report. You must merge states and junctions before merging transitions, or the report cannot make the connections.

For an example showing how to merge a change involving multiple nodes, see `slxml_sfcar`.

- Not all parameters can be merged. In this case, only one radio button is shown in the target pane indicating the version that is in the target model.
- For information on merging between models with identical names, see “Comparing Models with Identical Names” on page 21-30.

Merge MATLAB Function Block Code

- 1 To merge differences in MATLAB Function block code, create a comparison report for the parent models.
- 2 Next to the `script` parameter under a MATLAB Function block node in the comparison report, click the **Merge** button. To compare, click the **Compare** button next to the `script` parameter instead.

A new text comparison report opens.

- 3 In the text comparison report, select a difference in the code and click **Merge** to copy the selected difference from the left block to the right block.
- 4 After you finish merging differences, save the parent target model in the Editor.

Export, Print, and Save Model Comparison Results

In this section...
“Save Printable HTML Report” on page 21-28
“Export Results to the Workspace” on page 21-28

Save Printable HTML Report

To save a printable version of a model comparison report,

- 1 On the **Comparison** tab, select **Publish > HTML** or **Word**.

The Save dialog box opens, where you can choose to save a printable version of the model comparison report.

- 2 Select a file name and location to save the report.

The report is a noninteractive document of the differences detected by the algorithm for printing, sharing, or archiving a record of the comparison. If you have applied filters, your filtered results appear in the printable report.

Alternatively, you can publish a comparison report to a file using the `visdiff` function.

Export Results to the Workspace

To export the comparison results to the MATLAB base workspace,

- 1 On the **Comparison** tab, select **Publish > Workspace Variable**.

The Input Variable Name dialog box appears.

- 2 Specify a name for the export object in the dialog and click **OK**. This action exports the results of the XML comparison to an `xmlcomp.Edits` object in the workspace.

The `xmlcomp.Edits` object contains information about the comparison including file names, filters applied, and hierarchical nodes that differ between the two files.

To create an `xmlcomp.Edits` object at the command line without opening the Comparison Tool, enter:

```
Edits = slxmlcomp.compare(modelname_A,modelname_B)
```

Property of <code>xmlcomp.Edits</code>	Description
<code>Filters</code>	Array of filter structure arrays. Each structure has two fields, <code>Name</code> and <code>Value</code> .
<code>LeftFileName</code>	File name of left model.
<code>LeftRoot</code>	<code>xmlcomp.Node</code> object that references the root of the left tree.
<code>RightFileName</code>	File name of right model.
<code>RightRoot</code>	<code>xmlcomp.Node</code> object that references the root of the right tree.
<code>TimeSaved</code>	Time when results exported to the workspace.
<code>Version</code>	MathWorks release-specific version number of <code>xmlcomp.Edits</code> object.

Property of <code>xmlcomp.Node</code>	Description
<code>Children</code>	Array of <code>xmlcomp.Node</code> references to child nodes, if any.
<code>Edited</code>	Boolean — If <code>Edited = true</code> then the node is either inserted (green) or part of a modified matched pair (pink).
<code>Name</code>	Name of node.
<code>Parameters</code>	Array of parameter structure arrays. Each structure has two fields, <code>Name</code> and <code>Value</code> .
<code>Parent</code>	<code>xmlcomp.Node</code> reference to parent node, if any.
<code>Partner</code>	If matched, <code>Partner</code> is an <code>xmlcomp.Node</code> reference to the matched partner node in the other tree. Otherwise empty <code>[]</code> .

`visdiff`

Comparing Models with Identical Names

You can compare model files of the same name. To complete the operation, the comparison tool copies one of the models to a temporary folder, because Simulink cannot have two models of the same name in memory at the same time. The comparison tool creates a read-only copy of one model named *modelName_TEMPORARY_COPY*, and compares the resulting XML files.

Warning When you use highlighting from the report, one of the models displayed is a temporary copy with a new name. The temporary copy is read-only, to avoid making changes that can be lost.

Alternatively, you can run the comparison by renaming or copying one of the files.

If one of the models is open when you try to compare them, a dialog box appears where you can click **Yes** to close the file and proceed, or **No** to abort. You must close open models before the comparison tool can compare two models with the same name. The problem requiring you to close the loaded model is called “shadowed files”. In some cases, another model with the same name might be in memory, but not visible. See “Shadowed Files” on page 15-4 for more information.

If you want to automatically close open models of the same name when comparing them and not see the dialog box again, run these commands:

```
opt = slxmlcomp.options
opt.setCloseSameNameModel(true)
```

This is persistent across MATLAB sessions. To revert to default behavior and be prompted whether or not to close the open model every time, enter:

```
opt = slxmlcomp.options
opt.setCloseSameNameModel(false)
```

If you open a comparison report from a project (for example, using **Compare to Revision**), the project handles files of the same name and does not prompt you to close models.

Work with Referenced Models and Library Links

The model comparison report applies only to the currently selected models, and does not include changes to any referenced models or linked libraries. The comparison report shows only changes in the files selected for comparison.

Tip If you want to examine your whole hierarchy instead, try using a project, where you can examine modified files and dependencies across your whole project, and compare to selected revisions. See “Project Management”.

If you are comparing models that contain referenced models with the same name, then your MATLAB path can affect the results. For example, this can happen if you generate a model comparison report for the current version of your model and a previous baseline. Make sure that your referenced models are not on your MATLAB path before you generate the report.

The reason why results can change is that Simulink records information in the top model about the interface between the top model and the child model. This interface information in the top model enables incremental loading and diagnostic checks without any need to load child models.

When you load a model (for example, to compare) then Simulink refreshes the interface information for referenced models if it can find the child model. Simulink can locate the child model if it is on the path. If another model of the same name is higher on the path, Simulink updates the interface information for that other model before comparing. This can produce entries for interface changes for model reference blocks in the comparison report. Make sure your referenced models are not on your path before you generate the report, to avoid these interface changes in the results. If both model versions are off the path, the interface information in the top model is not refreshed during the comparison process. Instead the cached information is used, resulting in a valid comparison report.

With library links, Simulink does not update the cached interface information when comparing, and so the report correctly captures library interfaces. However with both referenced models and library links, Simulink updates the information when displaying the model. When displaying report items in original models, you may see that Simulink finds another model or library that is higher in the path. To obtain the clearest results, make sure that the models and associated libraries are temporarily removed from the path. By removing the files from the path you will see unresolved library links and

referenced models when you view the original models, but their interfaces will be correct and will correctly align with the comparison report.

Compare Project or Model Templates

In this section...
“Compare Project Templates” on page 21-33
“Compare Model Templates” on page 21-33

Compare Project Templates

You can compare project templates (SLTX files). If you select two project template files to compare, you see a comparison report showing differences in template properties and project metadata. You can open a new report to investigate project file and folder differences.

- Click **Template Properties** to view differences in the Parameters, such as the description or date modified.
- Expand the **Project Metadata** node to view metadata differences such as label changes.
- Next to **Project Files**, click **Compare** to open a folder comparison where you can investigate changed, added, or removed files and folders.

Compare Model Templates

You can compare model templates (SLTX files). If you select two model template files to compare, you see a comparison report showing differences in template properties. You can open a new comparison report to compare the Simulink models.

- Click **Template Properties** to view differences in the Parameters, such as the description or date modified.
- Next to **Model**, click **Compare** to open a Simulink model comparison report where you can investigate differences.

Component-Based Modeling Guidelines

In this section...
“When to Partition a Design” on page 22-2
“When Not to Partition a Design” on page 22-3
“Plan for Componentization in Model Design” on page 22-4
“Guidelines for Component Size and Functionality” on page 22-4
“Choose Components for Team-Based Development” on page 22-9
“Partition an Existing Design” on page 22-11
“Manage Components Using Libraries” on page 22-12

When to Partition a Design

Partition a design when it becomes too complex for one person to know all of the details. Complexity increases with design size and team size, for example,

- Design size and complexity:
 - Thousands of blocks
 - Hundreds of logical decisions
 - Hundreds of inputs and outputs
 - Hundreds of times larger industry examples in some cases
 - Multiple variant configurations of the same functionality
- Team integration:
 - Multiple people working on the design
 - People located in different places
 - People from different companies

Partitioning your design into components helps you to work with large-scale designs. Partitioning a design into components gives modularity to help you reduce complexity, collaborate on development, test and reuse components, and to succeed with large-scale model-based design. Component-based modeling helps:

- Enable efficient and robust system development.

- Reduce overall design complexity by solving smaller problems.
- Gain performance benefits that scale.
- Reuse components across multiple projects.
- Facilitate collaboration
 - Partition algorithms, physical models, and tests. Define architecture in terms of structural and functional partitioning of the design using defined interfaces.
 - Collaborate with teams across organizational boundaries on product development. Teams can elaborate individual components independently to do plant modeling, algorithm design, and developing of test harnesses.
 - Manage design with source control tools.
- Improved iteration, elaboration, and verification workflows
 - Iterate faster via more efficient testing and reuse.
 - Eliminate retesting for unchanged components.
 - Reuse environment models and algorithm designs in different projects.
 - Create variants of designs.
 - Elaborate components independently through well-defined interfaces.
 - Manage design evolution with configuration management tools.

Component-based modeling requires:

- Mechanisms for partitioning models and specifying interfaces
- Tools and processes for managing data, models, and environment

Use the following techniques for component-based modeling.

When Not to Partition a Design

Componentization provides benefits for large-scale designs, but is not needed for small designs. Partitioning your design into components requires design work and can increase time taken to update diagrams. Use separate components only when your design is large enough to benefit from componentization.

To decide whether your design needs partitioning, see the recommendations in “Guidelines for Component Size and Functionality” on page 22-4.

Plan for Componentization in Model Design

After models grow large and complex over time, it is difficult to split them into components to allow multiple engineers to work on them in parallel. Splitting a Simulink model into components is easier if the model is designed for componentization from the start. Designing for componentization in the first place can help you avoid these difficulties:

- If a single engineer develops a model from the bottom up, adding blocks and grouping them into subsystems as the model complexity increases, it is hard to later split the model into components. The subsystems within the model are often “virtual” and nonatomic. When you convert these to atomic subsystems and then to model reference components, you can introduce unwanted algebraic loops that are hard to diagnose and solve.
- Subsystems grown over time do not always represent the best way to partition the model. “Best” here might mean the most useful structure for reusable components in other models, or for generating code that integrates with legacy functionality, or for performing Hardware-in-the-Loop tests, etc.
- If you try to expand to parallel development without componentizing models, it is difficult to share work in teams without time-consuming and error-prone merging of subsystems.

These problems are analogous to taking a large piece of code (C, Java, or MATLAB code) and trying to break it down into a number of separate functions. Significant effort is required and can require extensive modifications to some parts of the code, if the code was not designed to be modular in the first place. The same is true for Simulink models.

Lack of componentization causes common failure modes when trying to place Simulink models into configuration management as they grow and you want more than one engineer to work on it in parallel. The best way to avoid these issues is to design for components from the start. You can use the following features of Simulink to design a model suitable for componentization.

If you already have a design that you want to divide into components, see “Partition an Existing Design” on page 22-11.

Guidelines for Component Size and Functionality

To set up your project for a team to work on, consider the following model architecture guidelines for components. Useful components:

- Have well-defined interface I/O boundaries.
- Perform a defined set of functions (actions), defined by requirements.
- Form part of a larger system.
- Have the “right” size:
 - Large enough to be reusable
 - Small enough to be tested
 - Only one engineer is likely to want to edit each model at a time

The right size can depend on team size. You can have larger components if only one person is working on each, but if you need to share components between several people, you probably need to divide the design into smaller logical pieces. This aids two goals: understanding the design, and reducing file contention and time spent on merging.

Recommendations:

- In most cases, if you have fewer than 100 blocks, do not divide the design into components. Instead, use subsystems if you want to create a visual hierarchy. For example, the example model `vdp` is not large enough to benefit from componentization.
- If you have 500-1000 blocks, consider creating a model reference to contain that component in a separate file. The cost of verification can reduce the size for components. For example, if you have a small component of 100 blocks with high testing costs and frequent changes, consider separating that component into a separate file to make verification easier.

Consider dividing the model based on:

- Physical components (e.g., plant and controller, for code generation)
- Algorithm logic
- Reusability in other models
- Testability, for example, for performing Hardware-in-the-Loop tests
- Sample rate; consider grouping components that have the same sample rate
- Simulation speed; using different solvers for components with different numerical properties can increase simulation speed
- Accessibility to other teams or others on your team.

While you cannot always plan on model size, if you expect multiple people to work on the design, you can benefit from componentization techniques. Consider controlling

configuration management using a project and partitioning the design using Model Reference so that the team can work on separate files concurrently.

Component Size	Recommended Componentization Techniques	Notes
Small <500 blocks	Create visual hierarchy using subsystems.	Small designs do not benefit from dividing into separate files. However, larger teams that cause file contention or high cost of verification can make it worth partitioning smaller components into separate files instead of using subsystems.
Large >500 blocks	Separate components into separate files using Model Reference or Libraries.	For multiple engineers or teams working on a design, best practice is one file per component. To reduce file contention, aim for components in which only one engineer needs to edit each model at a time.
Small <500 blocks, but expected to grow over time	Use atomic subsystems for functional block grouping instead of virtual subsystems. Atomic subsystems are easier to migrate to separate file components later.	If possible, plan your components from the start to avoid migration pain.

If your design or team is large enough to benefit from separating components into separate files, this table summarizes when to apply each technique.

Component Characteristics	Technique	Benefits	Costs
Small, low-level utility functions, reused in many places in a design	Library model containing a single reusable atomic subsystem	<ul style="list-style-type: none"> • Context-dependent: can adapt to various interfaces with different data types, sample time, and dimensions, in different contexts, without changing the design. • Can be reused in other models • Stored as a separate file, can apply version control, but each instance adapts to context of parent model, so generated code can differ in each instance. • To avoid context adaption, if you have an Embedded Coder license, you can specify different function interfaces for a reusable library subsystem and generate code for the library. This technique makes the library and not the model the owner of the code. See “Library-Based Code Generation for Reusable Library Subsystems” (Embedded Coder). 	<ul style="list-style-type: none"> • Cannot use independently to simulate or generate code. Requires a parent model. • Context adaptation not desirable for big components in large-scale models where interfaces are managed and locked down to specific data type and dimension. In these cases, you might not want code generated for the library block to differ in each instance. • Requires link management to avoid problems with broken, disabled, or parameterized links. See “Manage Components Using Libraries” on page 22-12.

Component Characteristics	Technique	Benefits	Costs
Groups of blocks for sharing among users	<p>Library for grouping and storing Simulink blocks</p> <p>Library palette of links to components</p>	<ul style="list-style-type: none"> • Libraries are useful for storing blocks to share among a number of users • To reduce file contention, use library palettes of links to individual components in separate files. Store each component in a model reference file or a single subsystem in a separate library. 	<ul style="list-style-type: none"> • Causes file contention if multiple components reside in a single library file. File contention is a problem only if blocks need frequent updates or multi-user access. Palettes can help. • Requires link management to avoid problems with broken, disabled, or parameterized links. See “Manage Components Using Libraries” on page 22-12.

Component Characteristics	Technique	Benefits	Costs
<p>Top-level components for large-scale models: >500 blocks</p> <p>Large components: starting at ~ 500-5000 blocks for one or a few reusable instances, or smaller if many instances</p> <p>Components at any level of model hierarchy where teams need to work independently</p>	Model Referencing	<ul style="list-style-type: none"> • Components are independent model files and part of a larger model. You can simulate and generate code in the component. • Independent of context—good for large-scale model components where interfaces are managed and locked down. • Stored as a separate file—can apply version control to a component independently of the models that use it. • Possible to use Accelerator mode generated code to reduce memory requirements when loading models and increase simulation speed, compared to subsystems or libraries. Useful for top-level component partitions. 	<p>Performance can reduce slightly when updating a model (update diagram) because each reference model is checked for changes to enable incremental builds. When components are large enough (>500 blocks), update diagram is faster in most cases.</p> <p>See “Partition a Design Using Model Reference” on page 22-11.</p>

Choose Components for Team-Based Development

To perform parallel development, you need component-based modeling. Best practice for successful team-based development is to partition the models within the project so that only one user works on each part at a time. Componentization enables you to avoid or minimize time-consuming merging. To set up your project for work by a team, consider the following model architecture guidelines.

This table compares subsystems, libraries, and model referencing for team-based development.

Modeling Development Process	Subsystems	Libraries	Model Referencing
<p>Team-based development</p>	<p>Not supported</p> <p>For subsystems in a model, Simulink provides no direct interface with source control tools.</p> <p>To create or change a subsystem, you need to open the parent model's file. This can lead to file contention when multiple people want to work on multiple subsystems in a model.</p> <p>Merging subsystems is slow and error prone, so best avoided as a workflow process. However, Simulink provides tools to help you merge subsystems. See "Merge Simulink Models from the Comparison Report" on page 21-20.</p>	<p>Supported, with limitations</p> <p>You can place library files in source control for version control and configuration management. You can use the project to interact with source control.</p> <p>You can maintain one truth, by propagating changes from a single library block to all blocks that link to that library.</p> <p>To reduce file contention, use one subsystem per library.</p> <p>You can link to the same library block from multiple models.</p> <p>You can restrict write access to library components.</p>	<p>Well suited</p> <p>You can place model reference files in source control for version control and configuration management. You can use the project to interact with source control.</p> <p>You save a referenced model in a separate file from the model that references it. Using separate files helps to avoid file contention.</p> <p>You can design, create, simulate, and test a referenced model independently from the model that references it.</p> <p>Simulink does not limit access for changing a model reference.</p>

Most large models use a combination of componentization techniques. No single approach is suitable for the wide range of users of Simulink. The following advice

describes some typical processes to show what you can do with MathWorks tools to perform team-based development.

One File Per Component for Parallel Development

To perform efficient parallel development, break a large model into a number of individual files, so that team members can work independently and you can place each file under revision control. Componentization enables you to avoid or minimize time-consuming merging. To set up your project for work by a team, consider the advice in “Guidelines for Component Size and Functionality” on page 22-4.

A key goal of component-based modeling is to allow parallel development, where different engineers can work on components of a larger system in parallel. You can achieve this if each component is a single file. You can then control and trace the changes in each component using project source control. See “Configuration Management” on page 22-19.

Partition an Existing Design

If you already have a design that you want to divide into components, first decide where to partition the model. Existing subsystems that grow over time are not always the best way to partition the model. Consider dividing the model based on the advice in “Guidelines for Component Size and Functionality” on page 22-4.

Agreeing on an interface is a useful first step in deciding how to break down the functionality of a large system into subcomponents. You can group signals and partition data. See “Interface Design” on page 22-14.

After you decide how to partition your design, Simulink tools can help you divide an existing model into components.

Simulink can help you partition models by converting subsystems to files. You can convert to files using Model Reference or Libraries. See “Guidelines for Component Size and Functionality” on page 22-4 for suggestions on when to apply each technique.

Partition a Design Using Model Reference

Use Model Reference to divide the components into separate files so that the team can work on separate files concurrently. You can also reuse the models in other models. To partition a model using model reference, see “Reference Existing Models” on page 8-17 or “Convert Subsystems to Referenced Models” on page 8-24.

Manage Components Using Libraries

- Use Libraries containing a single subsystem to contain a component in a single file. Use libraries to store blocks you can reuse in models. The linked blocks inherit attributes from the surrounding models, such as data types and sample rate. Using this technique for componentization has the management overhead of library links, described below.
- Use Libraries to reuse blocks in multiple models. Libraries work well for grouping and storing Simulink blocks to share. Best practice for libraries is to use them for storing blocks to share with multiple users, and blocks that are updated infrequently. As a rough guideline, it is appropriate to use a Simulink library if its contents are updated once every few months. If you update it more frequently, then the library is probably being used to perform configuration management. In this case, take care to avoid the common problems described in “Library Link Management” on page 22-12.
- To make library blocks available for reuse while reducing file contention and applying revision control, use library palettes. A palette is a library containing links to other components. If each component is a single subsystem in a separate library, or a model reference file, you can achieve the one-file-per-component best practice for component-based modeling. You can use separate version control for each component, and you can also control the palette.

When you drag a block from the library palette into your model, Simulink follows the link back to the file where the subsystem or model reference is implemented. The models that use the component contain a link to the component and not to the palette.

Library Link Management

Library links can introduce management overhead if you use them for configuration management. Take care to manage:

- Disabled links — Can cause merge conflicts, and failure to update all instances of the same model component. In a hierarchy of links, you can accidentally disable all links without being aware of it, and only restore one link while leaving others disabled.
- Broken links — Accidentally broken links are a hard problem to solve, because, by design, you cannot detect what the broken link linked to previously.
- Parameterized link data — It can be useful to change the value of parameter data, such as the value of a gain within a gain block, without disabling the library link. This generates “link data” for that instance only. However for configuration management this can cause a problem, if you assume all instances are identical, as one now has different properties.

Simulink tools help you manage library links to avoid problems:

- Lock links to prevent editing. See “Lock Links to Blocks in a Library” on page 41-29.
- Use diagnostic options to check library link integrity whenever you save a model. You can set the checks to warn, error, or ignore that a model has disabled or parameterized library links. You select these settings per model. In the Configuration Parameters dialog box, see **Diagnostics > Saving**.

See the diagnostic settings “Block diagram contains disabled library links” and “Block diagram contains parameterized library links”.

- Use Model Advisor checks to report on library link integrity. The advisor checks for disabled and parameterized links within a model. You can use the resulting report as an artifact to check into a configuration management system.

See the Model Advisor checks:

- “Identify disabled library links”
- “Identify parameterized library links”
- “Identify unresolved library links”
- Use the Links Tool to view and restore disabled and edited links. See “Restore Disabled or Parameterized Links” on page 41-31.

Caution These link management tools can detect link problems but cannot prevent editing the wrong files. If this is a problem, then use Model Reference as the partitioning mechanism to avoid the risks associated with disabled, broken, and parameterized links.

Interface Design

In this section...
“Why Interface Definitions Are Important” on page 22-14
“Recommendations for Interface Design” on page 22-14
“Partitioning Data” on page 22-16
“Configure Data Interface for Component” on page 22-16

Why Interface Definitions Are Important

Defining the “interface” of a software component, such as a C or MATLAB code function or a Simulink subsystem, is a key first step before others can use it, for these reasons:

- Agreeing on an interface is a useful first step in deciding how to break down the functionality of a large system into subcomponents.
- After you define interfaces between a number of components, you can develop the components in parallel. If the interface remains stable, then it is easy to integrate those components into a larger system.
- Changing the interface between components is expensive. It requires changes to at least two components (the source and any sinks) and to any test harnesses. It also makes all previous versions of those components incompatible with the current and future versions.

When you need to change an interface, doing so is much easier if the components are stored under configuration management. You can track configurations of compatible component versions to prevent incompatible combinations of components.

Recommendations for Interface Design

Suggestions for defining the interfaces of components for a new project:

- Base the boundaries of the components upon those of the corresponding real systems. This is especially useful when the model contains:
 - Both physical (plant and environment) and control systems
 - Algorithms that run at different rates

- Consider future model elaboration. If you intend to add models of sensors, then put them in from the start as an empty subsystem that passes signals straight through or performs a unit delay and/or name conversion.
- Consider future component reuse.
- Consider using a signal naming convention.
- Use data objects for :
 - Defining component interfaces
 - Precise control over data attributes
- Simplify interface design by grouping signals into buses. Signal buses are well suited for use at the high levels of models, where components often have a large number of signals going in and out, and do not use all the signals available. Using buses can simplify modifying the interface to a component. For example, if you need to add or remove signals used by a component, it can be simpler to modify a bus than to add or remove inports or outports to that component. However, using a bus that crosses model reference boundaries requires using a bus object.

Best practices for using Simulink bus signals and bus objects:

- Make buses virtual, except for model reference component boundaries.
- Use nonvirtual buses when defining interfaces between components. However, this requires associating the bus with a bus object. Bus objects completely define the properties of the signals on a bus, giving an unambiguous interface definition.

Include bus objects in a data dictionary, or save bus objects as a `.mat` or `.m` file, in order to place them under revision control.

- Pass only required signals to each component to reduce costly passing of unnecessary data. Signal buses allow the full set of input and output signals to be defined, but not necessarily used or created.
- Make sure that the interface specifies exactly what the component uses.
- Use a rigorous naming convention for bus objects. Unless you use a data dictionary, bus objects are stored in the base workspace.
- At the lower levels of a model, consider using inports and outports for each signal. At lower levels of a model, where components typically implement algorithms rather than serve as containers for other components, it can increase readability if you use individual inports and outports for components, instead of using signal buses. However, creating interfaces in this way has a greater risk of connection

problems, because it is difficult to check the validity of connections, other than their data type, size, etc.

- To package signals or parameters into structures that correspond to a `struct` type definition that your external C code defines, import the type as a bus object and use the object as a data type for bus signals and MATLAB structures. To create the object, use the `Simulink.importExternalCTypes` function.

Partitioning Data

Explicitly control the scope of data for your components. Some techniques:

- Global parameters — A common approach in the automotive world is to completely separate the problem of parameter storage from model storage. The parameters for a model come from a database of calibration data, and the specific calibration file used becomes part of the configuration. The calibration data is treated as global data, and resides in the base MATLAB workspace. You can migrate base workspace data to a data dictionary for more control.
- Nonglobal parameters — Combining a number of components that somehow store their own parameter data has the risk of parameter name collisions. If you do not use a naming convention for parameters or, alternatively, a list of unique parameter names and definitions, then there is the risk that two components use a parameter with the same name but with different meanings.

Methods for storing local parameter data include:

- Partition data into reference dictionaries for each component.
- With Model Reference, you can use model workspaces.
- Use parameter files (`.m` or `.mat`) and callbacks of the individual Simulink models (e.g., `preload` function).

You can also automatically load required data using project shortcuts.

- Mask workspaces, with or without the use of mask initialization functions.
- For subsystems, you can control the scope of data for a subsystem using the Subsystem Parameters, Permit Hierarchical Resolution dialog box.

Configure Data Interface for Component

Whether you use referenced models or subsystems to break a large system into components, the components can exchange signal data through Inport and Output

blocks. You can explicitly configure design attributes (such as data type and numeric complexity) of the interface to prevent modeling errors and make integrating the components easier.

After you create the Inport and Outport blocks, you can use the Model Data Editor and the interface display to configure the design attributes (such as data type and numeric complexity) of the blocks. Use this technique to view the component interface in its entirety at once and to trace the pieces of the interface to usage points in the internal block algorithm. You can also use this technique to configure the interface of a component before you develop the internal algorithm, in which case the component contains unconnected Inport and Outport blocks.

The example model `sldemo_fuelsys_dd` contains two components which are referenced models:

- A plant component, `sldemo_fuelsys_dd_plant`.
- A controller component, `sldemo_fuelsys_dd_controller`.

Use the Model Data Editor and the interface display to examine and configure the interface of the plant component.

- 1 Open the plant component.

`sldemo_fuelsys_dd_plant`

- 2 Select **Display > Interface**.
- 3 Select **View > Model Data Editor**.

By default, in the Model Data Editor, the **Inports/Outports** tab is selected. Each row in the table represents an Inport or Outport block. By default, the **Change view** drop-down list is set to **Design**.

Tip To view only the Inport and Outport blocks at the root level of the model (by excluding the blocks inside the subsystems), deactivate the **Change Scope** button.

- 4 Use the columns in the Model Data Editor to explicitly configure the design attributes of the interface. For example, specify minimum and maximum values for each Inport and Outport block by using the **Min** and **Max** columns.

To configure code generation settings for the interface of a controller component, in the Model Data Editor, set the **Change view** drop-down list to **Code**.

For more information about using the interface display, see “Trace Connections Using Interface Display” on page 12-67. For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 62-179.

Configuration Management

In this section...

“Manage Designs Using Source Control” on page 22-19

“Determine the Files Used by a Component” on page 22-20

“Manage Model Versions” on page 22-20

“Create Configurations” on page 22-21

Manage Designs Using Source Control

Projects can help you work with configuration management tools for team collaboration. You can use projects to help you manage all the models and associated files for model-based design.

You can control and trace the changes in each component using project source control. Using source control directly from a project provides these benefits:

- Engineers do not have to remember to use two separate tools, avoiding the common mistake of beginning work in Simulink without checking out the required files first.
- You can perform analysis within MATLAB and Simulink to determine the dependencies of files upon each other. Third-party tools are unlikely to understand such dependencies.
- You can compare revisions and use tools to merge models.

If each component is a single file, you can achieve efficient parallel development, where different engineers can work on the different components of a larger system in parallel. Componentization enables you to avoid or minimize time-consuming merging. See “One File Per Component for Parallel Development” on page 22-11. One file per component is not strictly necessary to perform configuration management, but it makes parallel development much easier.

If you break down a model into a number of components, it is easier to reuse those components in different projects. If the components are kept under revision control and configuration management, then you can reuse components in a number of projects simultaneously.

To find out about source control support, see “Source Control in Projects”.

Determine the Files Used by a Component

You can use a project to determine the set of files you need to place under configuration management. You can analyze the set of files that are required for the model to run, such as model references, library links, block and model callbacks (`preload` functions, `init` functions, etc.), S-functions, From Workspace blocks, etc. Any MATLAB code found is also analyzed to determine additional file dependencies. You can use the Simulink manifest tools to report which toolboxes are required by a model, which can be a useful artifact to store.

You can also perform a file dependency analysis of a model programmatically from MATLAB using `dependencies.fileDependencyAnalysis` to get a cell array of paths to required files.

For more information, see “Dependency Analysis”.

Manage Model Versions

Simulink can help you to manage multiple versions of a model.

- Use a project to manage your project files, connect to source control, review modified files, and compare revisions. See “Project Management”.
- Simulink notifies you if a model has changed on disk when updating, simulating, editing, or saving the model. Models can change on disk, for example, with source control operations and multiple users. Control this notification with the Model File Change Notification preference. See “Model File Change Notification” on page 4-67.
- As you edit a model, Simulink generates version information about the model, including a version number, who created and last updated the model, and an optional comments history log. Simulink saves these version properties with the model.
 - Use the Model Properties dialog box to view and edit some of the version information stored in the model and specify history logging.
 - The Model Info block lets you display version information as an annotation block in a model diagram.
- Use `Simulink.MDLInfo` to extract information from a model file without loading the block diagram into memory. You can use `MDLInfo` to query model version and Simulink version, find the names of referenced models without loading the model into memory, and attach arbitrary metadata to your model file.

Create Configurations

You can use a project to work with the revision control parts of the workflow: retrieving files, adding files to source control, checking out files, and committing edited files to source control.

To define configurations of files, you can label a number of files as a new mutually consistent configuration. Other users can get this set of files from the revision control system.

Configurations are different from revisions. Individual components can have revisions that work together only in particular configurations.

Tools for creating configurations in Simulink:

- Variant modeling. See “Variant Systems”.
- Project tools:
 - Label — Label project files. Use labels to apply metadata to files. You can group and sort by labels, label folders for adding to the path using shortcut functions, or create batch jobs to export files by label, for example, to manage files with the label `Diesel`. You cannot retrieve from source control by label, and labels persist across revisions.
 - Revision Log — Use Revert Project to choose a revision to revert to (SVN source control only).
 - Branch — Create branches of file versions, and switch to any branch in the repository (Git source control only).
 - Tag — You can tag all project files (SVN source control only) to identify a particular configuration of a project, and retrieve tagged versions from source control. However, continued development is limited. That is, you cannot tag again, and you must check out from `trunk` to apply tags.
 - Archive — Package all project files in a Zip file that you can create a new project from. However, this packaging removes all source control information, because archiving is for exporting, sharing, and changing to another source control. You can commit the new Zip file to source control.

Study Power Windows

Automobiles use electronics for control operations such as:

- Opening and closing windows and sunroof
- Adjusting mirrors and headlights
- Locking and unlocking doors

These systems are subject to stringent operation constraints. Failures can cause dangerous and possibly life-threatening situations. As a result, careful design and analysis are needed before deployment.

This example focuses on the design of a power window system of an automobile, in particular, the passenger-side window. A critical aspect of this system is that it cannot exert a force of more than 100 N on an object when the window closes. When the system detects such an object, it must lower the window by about 10 cm.

As part of the design process, the example considers:

- Quantitative requirements for the window control system, such as timing and force requirements
- System requirements, captured in activity diagrams
- Data definitions for the signals used in activity diagrams

Other aspects of the design process that this example contains are:

- Managing the components of the system
- Building the model
- Validating the results of system simulation
- Generating code

MathWorks Software Used in This Example

In addition to Simulink, this example uses these additional MathWorks products:

- DSP System Toolbox
- Fixed-Point Designer
- Simscape Multibody

- Simscape Electrical™
- Simscape
- Simulink 3D Animation
- Simulink Real-Time
- Simulink Coverage™
- Stateflow

Quantitative Requirements

Quantitative requirements for the control are:

- The window must fully open and fully close within 4 s.
- If the up is issued for between 200 ms and 1 s, the window must fully open. If the down command is issued for between 200 ms and 1 s, the window must fully close.
- The window must start moving 200 ms after the command is issued.
- The force to detect when an object is present is less than 100 N.
- When closing the window, if an object is in the way, stop closing the window and lower the window by approximately 10 cm.

Capturing Requirements in Activity and Context Diagrams

Activity diagrams help you graphically capture the specification and understand how the system operates. A hierarchical structure helps with analyzing even large systems. At the top level, a context diagram describes the system environment and its interaction with the system under study in terms of data exchange and control operations. Then you can decompose the system into an activity diagram with processes and control specifications (CSPEC).

The processes guide the hierarchical decomposition. You specify each process using another activity diagram or a primitive specification (PSPEC). You can specify a PSPEC in a number of representations with a formal semantic, such as a Simulink block diagram. In addition, context diagrams graphically capture the context of system operation.

Context Diagram: Power Window System

The figure represents the context diagram of a power window system. The square boxes capture the environment, in this case, the driver, passenger, and window. Both the driver and passenger can send commands to the window to move it up and down. The controller

infers the correct command to send to the window actuator (e.g., the driver command has priority over the passenger command). In addition, diagram monitors the state of the window system to establish when the window is fully opened and closed and to detect if there is an object between the window and frame.

The circle (also known as a bubble) represents the power window controller. The circle is the graphical notation for a process. Processes capture the transformation of input data into output data. Primitive process might also generate. CSPECs typically consist of combinational or sequential logic to infer output control signals from input control.

For implementation in the Simulink environment, see “Implementation of Context Diagram: Power Window System” on page 23-35.

Activity Diagram: Power Window Control

The power window control consists of three processes and a CSPEC. Two processes validate the driver and passenger input to ensure that their input is meaningful given the state of the system. For example, if the window is completely opened, the **MOVE DOWN** command does not make sense. The remaining process detects if the window is completely opened or completely closed and if an object is present. The CSPEC takes the

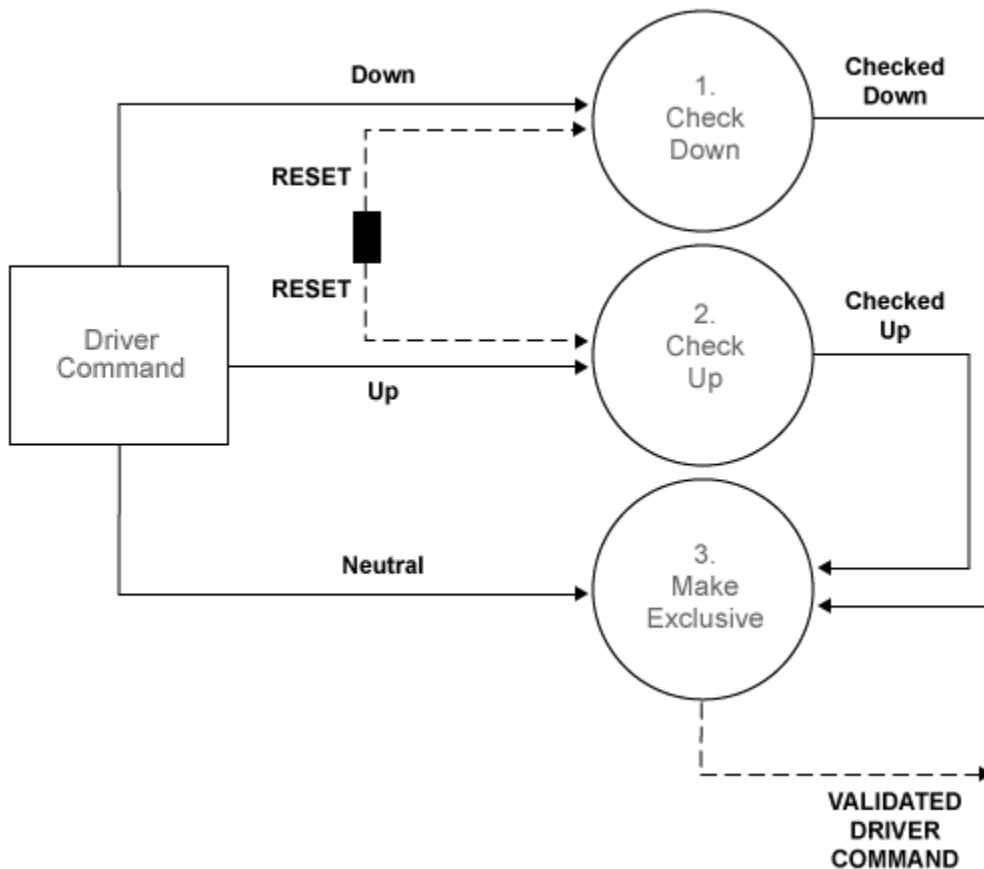

control signals and infers whether to move the window up or down (e.g., if an object is present, the window moves down for about one second or until it reaches an endstop).

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Power Window Control” on page 23-16.

Activity Diagram: Validate Driver

Each process in the VALIDATE DRIVER activity chart is primitive and specified by the following PSPEC. In the MAKE EXCLUSIVE PSPEC, for safety reasons the DOWN command takes precedence over the UP command.

PSPEC 1.1.1: CHECK DOWN
 CHECKED_DOWN = DOWN and not RESET

PSPEC 1.1.2: CHECK UP
 CHECKED_UP = UP and not RESET

PSPEC 1.1.3: MAKE EXCLUSIVE

VALIDATED_DOWN = CHECKED_DOWN

VALIDATED_UP = CHECKED_UP and not CHECKED_DOWN

VALIDATED_NEUTRAL = (NEUTRAL and not (CHECKED_UP and not CHECKED_DOWN))
or not (CHECKED_UP or CHECKED_DOWN)

For implementation in the Simulink environment, see “Implementation of Activity Diagram: Validate” on page 23-37.

Activity Diagram: Validate Passenger

The internals of the VALIDATE PASSENGER process are the same as the VALIDATE DRIVER process. The only difference is the different input and output.

PSPEC 1.2.1: CHECK DOWN

CHECKED_DOWN = DOWN and not RESET

PSPEC 1.2.2: CHECK UP

CHECKED_UP = UP and not RESET

PSPEC 1.2.3: MAKE EXCLUSIVE

VALIDATED_DOWN = CHECKED_DOWN

VALIDATED_UP = CHECKED_UP and not CHECKED_DOWN

VALIDATED_NEUTRAL = (NEUTRAL and not (CHECKED_UP and not CHECKED_DOWN))
or not (CHECKED_UP or CHECKED_DOWN)

For implementation in the Simulink environment, see “Activity Diagram: Validate Passenger” on page 23-8.

Activity Diagram: Detect Obstacle Endstop

The third process in the POWER WINDOW CONTROL activity diagram detects the presence of an obstacle or when the window reaches its top or bottom (ENDSTOP). The detection mechanism is based on the armature current of the window actuator. During normal operation, this current is within certain bounds. When the window reaches its top or bottom, the electromotor draws a large current (more than 15 A or less than -15 A) to try and sustain its angular velocity. Similarly, during normal operation the current is about 2 A or -2 A (depending on whether the window is opening or closing). When there is an object, there is a slight deviation from this value. To keep the window force on the object less than 100 N, the control switches to its emergency operation when it detects a current that is less than -2.5 A. This operations is necessary only when the window is rolling up, which corresponds to a negative current in the particular wiring of this model. The DETECT OBSTACLE ENDSTOP activity diagram embodies this functionality.

CSPEC 1.3: DETECT OBSTACLE ENDSTOP
 RESET = OBSTACLE or ENDSTOP

PSPEC 1.3.1: DETECT ENDSTOP
 ENDSTOP = WINDOW_POSITION > ENDSTOP_MAX

PSPEC 1.3.2: DETECT OBSTACLE
 OBSTACLE = (WINDOW_POSITION > OBSTACLE_MAX) and MOVE_UP for 500 ms

For implementation in the Simulink environment, see "Activity Diagram: Detect Obstacle Endstop" on page 23-10.

Data Definitions

The functional decomposition unambiguously specifies each process by its decomposition or primitive specification (PSPEC). In addition, it must also formally specify the signals in the activity diagrams. Use data definitions for these specifications.

The following tables are data definitions for the signals used in the activity diagrams.

For the associated activity diagram, see “Context Diagram: Power Window System” on page 23-4.

Context Diagram: Power Window System Data Definitions

Signal	Information Type	Continuous/ Discrete	Data Type	Values
DRIVER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
PASSENGER_COMMAND	Data	Discrete	Aggregate	Neutral, up, down
WINDOW_POSITION	Data	Continuous	Real	0 to 0.4 m
MOVE_UP	Control	Discrete	Boolean	'True', 'False'
MOVE_DOWN	Control	Discrete	Boolean	'True', 'False'

For the associated activity diagram, see “Activity Diagram: Power Window Control” on page 23-5.

Activity Diagram: Power Window Control Data Definitions

ENDSTOP_MIN	Data	Constant	Real	0.0 m
ENDSTOP_MAX	Data	Constant	Real	0.4 m
OBSTACLE_MAX	Data	Constant	Real	0.3 m

The model design iterates as we examine more detailed implementations. For information about how the model design iterates as you introduce more detail, see “Iterate on the Design” on page 23-47.

Simulink Power Window Controller Project

MATLAB and Simulink support Model-Based Design for embedded control design, from initial specification to code generation. To organize large projects and share your work with others, use “Project Management”.

The Power Window Control Project example shows how you can use MathWorks tools and the Model-Based Design process to go from concept through implementation for an

automobile power window system. It uses projects to organize the files and other model components.

In addition, this example shows how to link models to system documentation.

Explore the Power Window Controller Project

- 1 To open the Power Window Controller project, in the MATLAB Command Window, type:

```
slexPowerWindowStart
```

Name	Status	SVN	Revision	Classification
configureModel	✓	•		Configuration
data	✓	•		DesignSupport
hmi	✓	•		Visualization
model	✓	•		Design
task	✓	•		Convenience
utilities	✓	•		Configuration

- 2 Explore the project folders. In particular, note the **task** folders. This folder contains scripts that run frequent tasks for a model. For the Power Window Controller Project, these scripts:
 - Set up the model to control window movement on a controller area network (CAN).
 - Set up the model to use the Stateflow and Simulink software to model discrete-event reactive behavior and continuous time behavior, with a low-order plant model.
 - Set up the model with a more detailed plant model that includes power effects in the electrical and mechanical domains. The plant model validates the force exerted by the window on a trapped object.
 - Set up the model with a model that includes other effects that may change the model, such as quantization of the measurements.

Note These scripts also simulate the model. To only configure the model, see the scripts in the **configureModel** folder.

- Use the increase coverage model to generate the model coverage report.

- 3** The **Project Shortcuts** section contains quick-access commands that you can double-click to perform common tasks such as:
- Add projects to MATLAB paths.
 - Perform interactive testing.
 - Validate model testing with model coverage.
 - Open the main model.
 - Simulate the model with various configurations.
 - Generate a model coverage report for increased coverage of the model.
 - Open the model used for increasing model coverage.

Simulink Power Window Controller

- “Implementation of Activity Diagram: Power Window Control” on page 23-16
- “Interactive Testing” on page 23-18
- “Experimental Results from Interactive Testing” on page 23-21
- “Model Coverage” on page 23-30

Implementation of Activity Diagram: Power Window Control

This topic describes the high-level discrete-event control specification for a power window control.

You can model the discrete-event control of the window with a Stateflow chart. A Stateflow chart is a finite state machine with hierarchy and parallelism. This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency. It models the state transitions and accounts for the precedence of driver commands over the passenger commands. It also includes emergency behavior that activates when the software detects an object between the window and the frame while moving up.

The initial Simulink model for the power window control, `slexPowerWindowControl`, is a discrete-event controller that runs at a given sample rate.

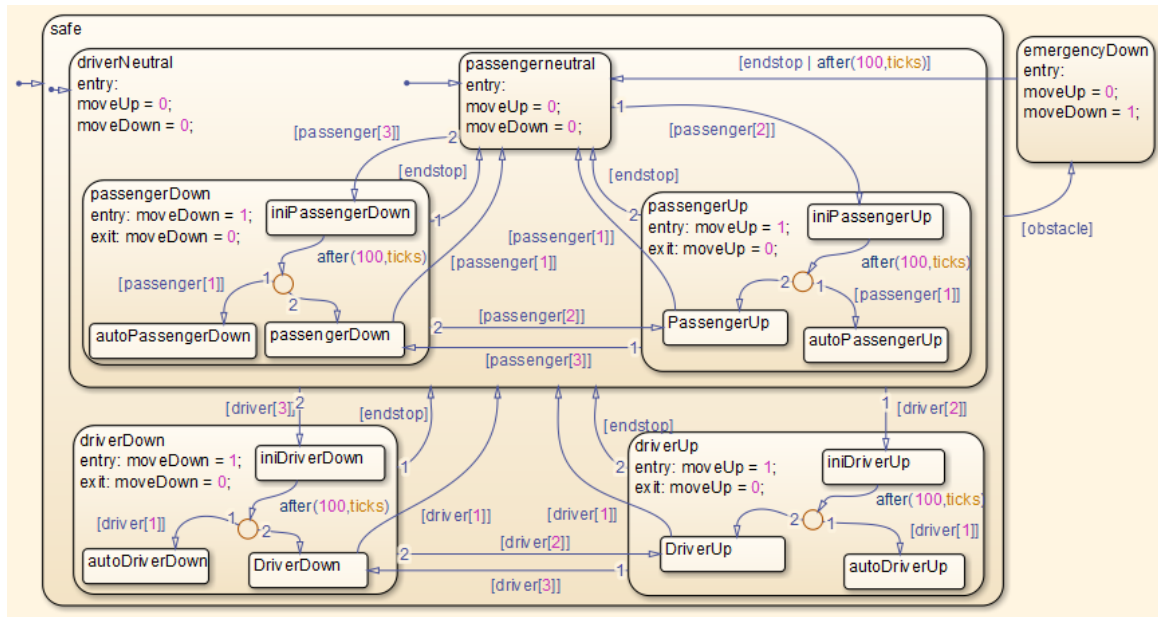

In this implementation, open the power window control subsystem and observe that the Stateflow chart with the discrete-event control forms the CSPEC, represented by the tilted thick bar in the bottom right corner. The `detect_obstacle_endstop` subsystem encapsulate the threshold detection mechanisms.

The discrete-event control is a Stateflow model that extends the state transition diagram notion with hierarchy and parallelism. State changes because of passenger commands are encapsulated in a *super state* that does not correspond to an active driver command.

Consider the control of the passenger window. The passenger or driver can move this window up and down.

This state machine contains the basic states of the power window system: up, auto-up, down, auto-down, rest, and emergency.

Interactive Testing

Control Input

The `slexPowerWindowCntlInteract` model includes this control input as switches. Double-click these switches to manually operate them.

Test the state machine that controls a power window by running the input test vectors and checking that it reaches the desired internal state and generates output. The power window has the following external inputs:

- Passenger input
- Driver input
- Window up or down
- Obstacle in window

Each input consists of a vector with these inputs.

Passenger Input

Element	Description
neutral	Passenger control switch is not depressed.
up	Passenger control switch generates the up signal.
down	Passenger control switch generates the down signal.

Driver Input

Element	Description
neutral	Driver control switch is not depressed.
up	Driver control switch generates the up signal.
down	Driver control switch generates the down signal.

Window Up or Down

Element	Description
0	Window moves freely between top or bottom.
1	Window is stuck at the top or bottom because of physical limitations.

Obstacle in Window

Element	Description
0	Window moves freely between top or bottom.
1	Window has obstacle in the frame.

Generate the passenger and driver input signals by mapping the up and down signals according to this table:

Inputs		Outputs		
up	down	up	down	neutral
0	0	0	0	1
0	1	0	1	0
1	0	1	0	0
1	1	0	0	1

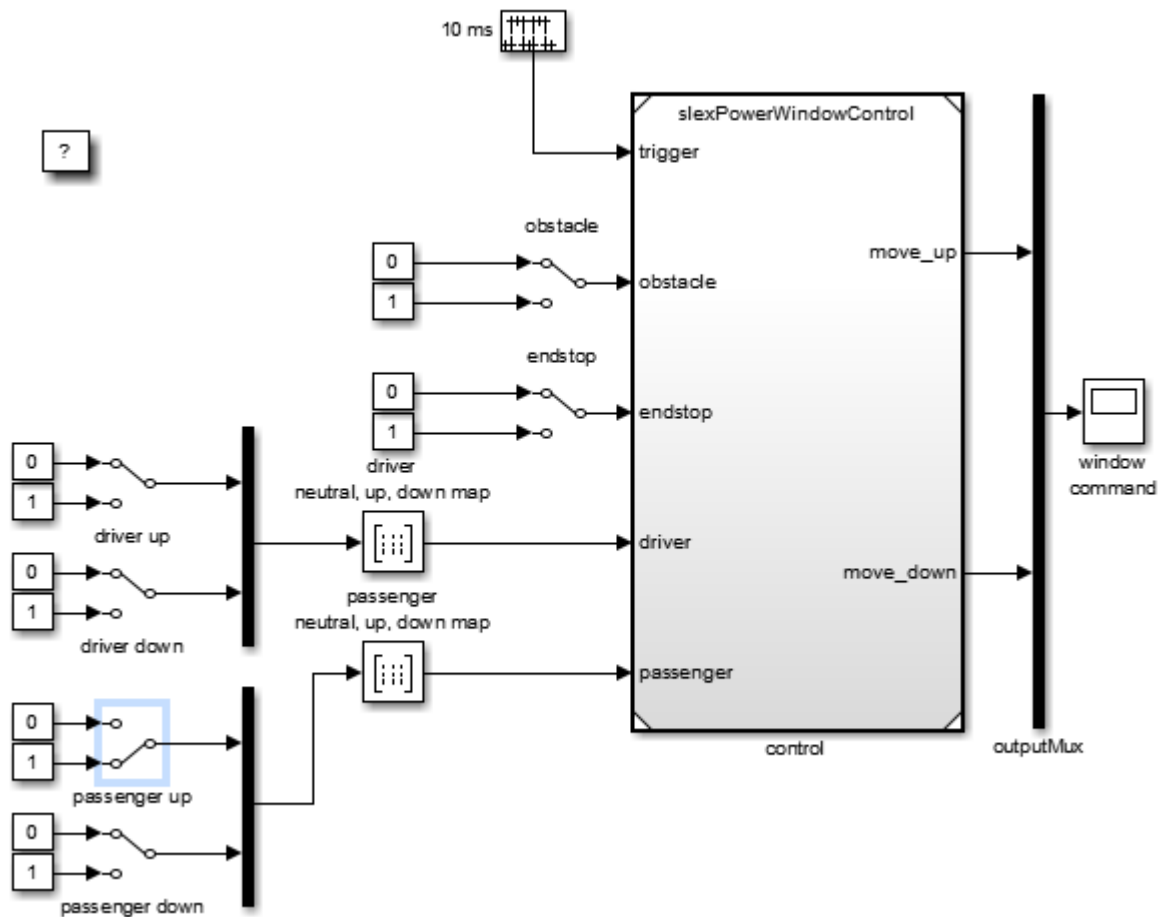

The inputs explicitly generate the `neutral` event from the `up` and `down` events, generated by pressing a power window control switch. The inputs are entered as a truth table in the passenger `neutral, up, down` map and the driver `neutral, up, down` map.

Experimental Results from Interactive Testing

Case 1: Window Up

To observe the state machine behavior:

- 1 Open the `slexPowerWindowCntlInteract` model.
- 2 Run the simulation and then double-click the passenger up switch.

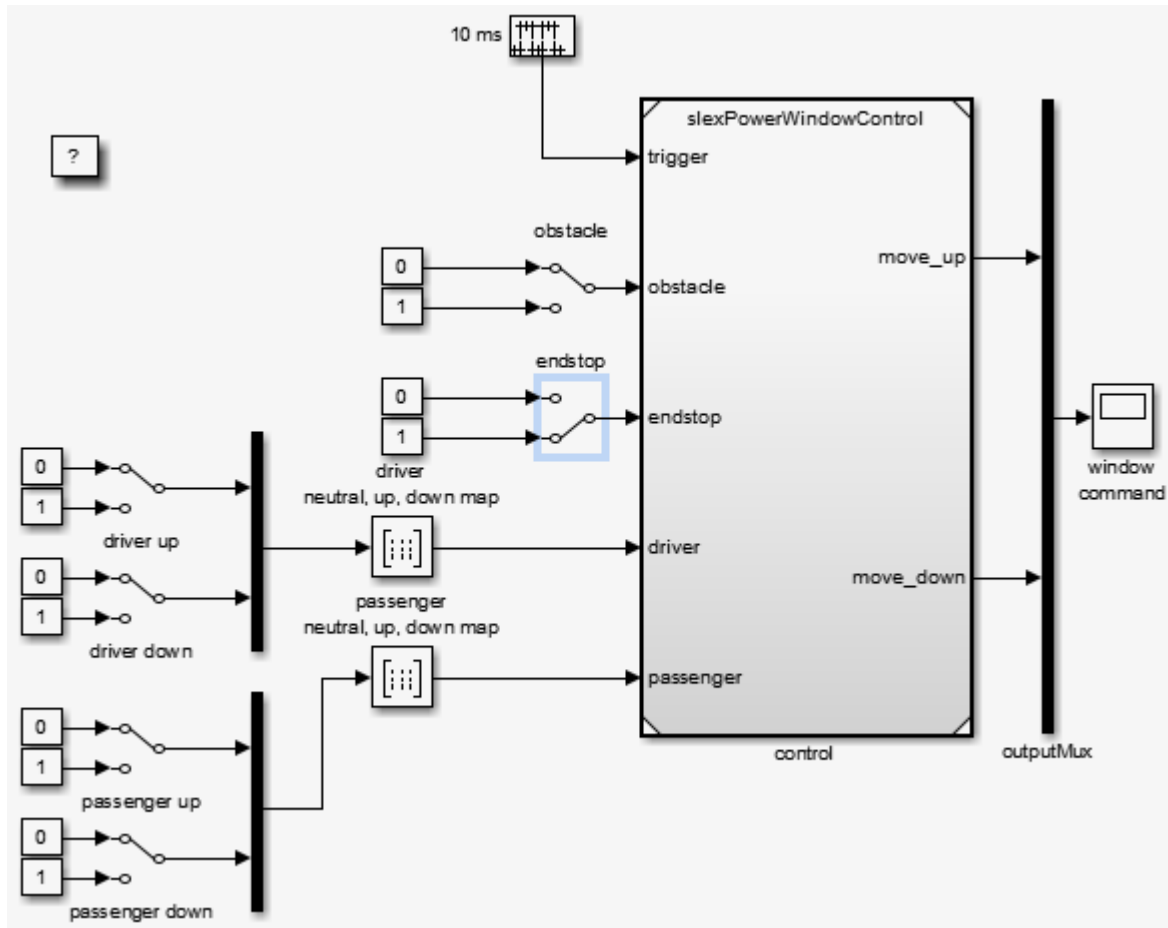

If you press the physical window switch for more than one second, the window moves up until the up switch is released (or the top of the window frame is reached and the endstop event is generated).

- 3 Double-click the selected passenger up switch to release it.

4 Simulate the model.

Setting the endstop switch generates the endstop event.

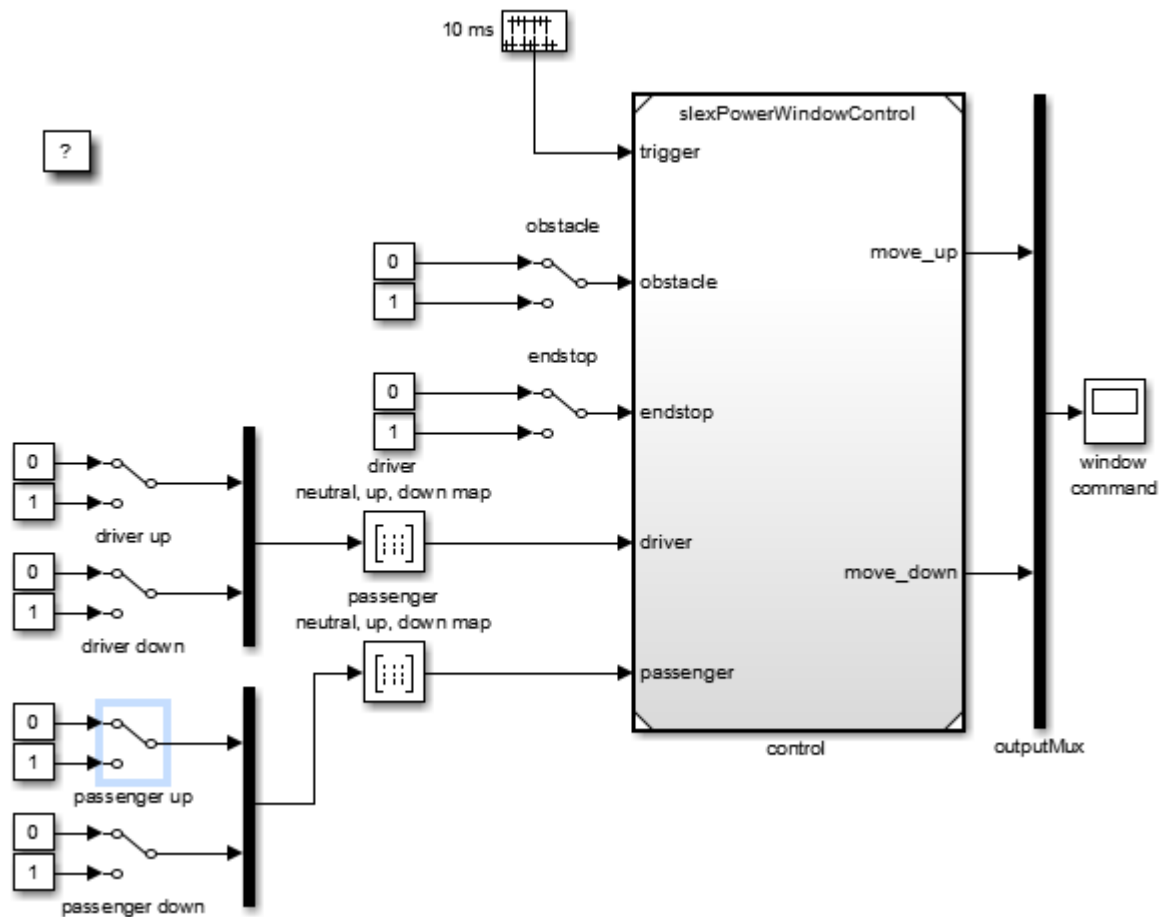

Case 2: Window Auto-Up

If you press the physical passenger window up switch for a short period of time (less than a second), the software activates auto-up behavior and the window continues to move up.

- 1 Press the physical passenger window up switch for a short period of time (less than a second).

Ultimately, the window reaches the top of the frame and the software generates the `endstop` event. This event moves the state machine back to its neutral state.

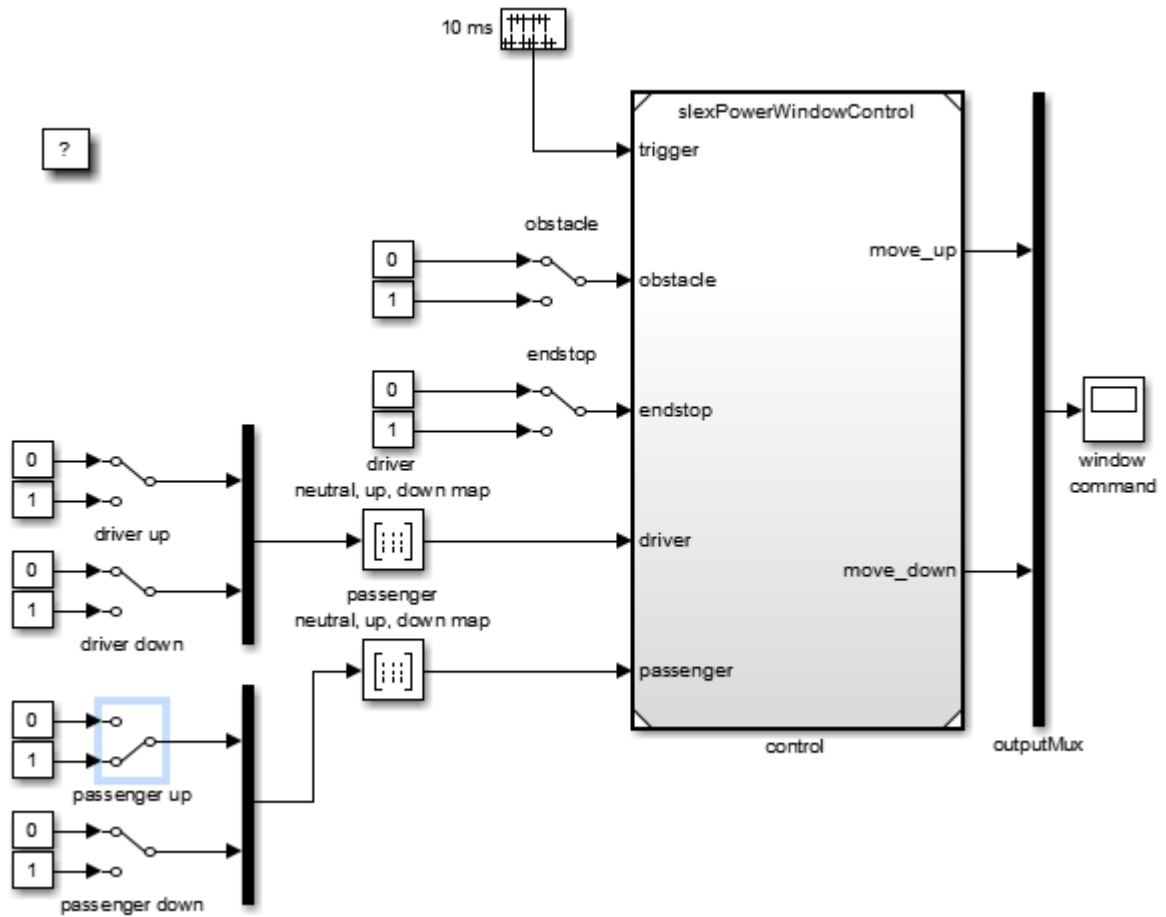

- 2 Simulate the model.

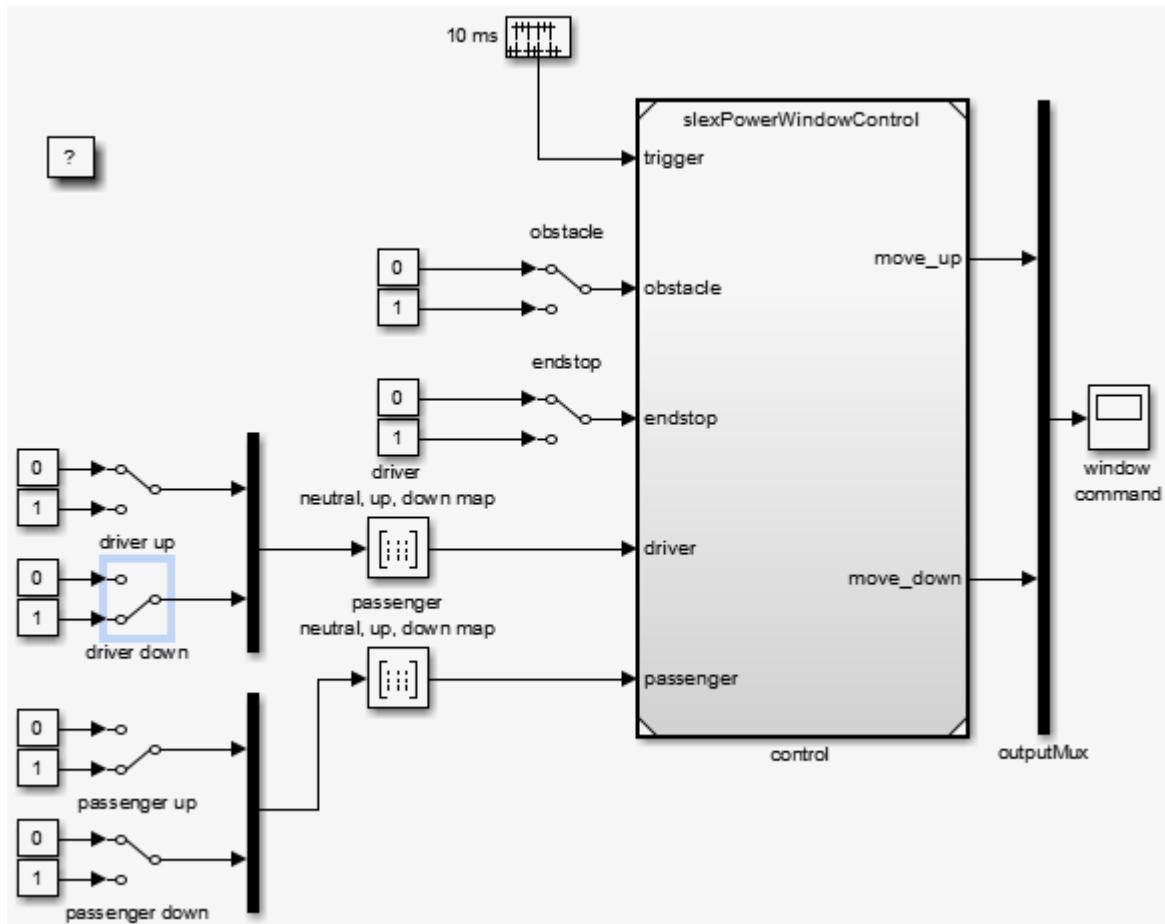

Case 3: Driver-Side Precedence

The driver switch for the passenger window takes precedence over the driver commands. To observe the state machine behavior in this case:

- 1 Run the simulation, and then move the system to the `passenger up` state by double-clicking the passenger window up switch.

2 Double-click the driver down switch.

- 3 Simulate the model.
- 4 Notice how the state machine moves to the driver control part to generate the window down output instead of the window up output.
- 5 Double-click the driver control to driver up. Double-click the driver down switch.

The driver window up state is reached, which generates the window up output again, i.e., $\text{windowUp} = 1$.

- 6 To observe state behavior when an object is between the window and the frame, double-click the obstacle switch.

7 Simulate the model.

On the next sample time, the state machine moves to its **emergencyDown** state to lower the window a few inches. How far the software lowers the window depends on how long the state machine is in the **emergencyDown** state. This behavior is part of the next analysis phase.

If a driver or passenger window switch is still active, the state machine moves into the up or down states upon the next sample time after leaving the emergency state. If the obstacle switch is also still active, the software again activates the emergency state at the next sample time.

Model Coverage

Validation of the Control Subsystem

Validate the discrete-event control of the window using the model coverage tool. This tool helps you determine the extent to which a model test case exercises the conditional branches of the controller. It helps evaluate whether all transitions in the discrete-event control are taken, given the test case, and whether all clauses in a condition that enables a particular transition have become true. Multiple clauses can enable one transition, e.g., the transition from emergency back to neutral occurs when either 100 ticks have occurred or if the endstop is reached.

To achieve full coverage, each clause evaluates to true and false for the test cases used. The percentage of transitions that a test case exercises is called its model coverage. Model coverage is a measure of how thoroughly a test exercises a model.

Using Simulink Coverage software, you can apply the following test to the power window controller.

Position	Step						
	0	1	2	3	4	5	6
Passenger up	0	0	0	0	0	0	0
Passenger down	0	0	0	1	0	1	1
Driver up	0	0	1	0	1	0	1
Driver down	0	1	0	0	1	1	0

With this test, all switches are inactive at time 0. At regular 1 s steps, the state of one or more switches changes. For example, after 1 s, the driver down switch becomes active. To automatically run these input vectors, replace the manual switches by prescribed sequences of input. To see the preconstructed model:

- 1 In the MATLAB Command Window, type:

```
slexPowerWindowCntlCoverage
```

2 Simulate the model to generate the Simulink Coverage coverage report.

For the `slexPowerWindowCntrlCoverage` model, the report reveals that this test handles 100% of the decision outcomes from the driver neutral, up, down map block. However, the test achieves only 50% coverage for the passenger neutral, up, down map block. This coverage means the overall coverage for `slexPowerWindowCntrlCoverage` is 45% while the overall coverage for the `slexPowerWindowControl` model is 42%. A few of the contributing factors for the coverage levels are:

- Passenger up block does not change.
- Endstop and obstacle blocks do not change.

Increase Model Coverage

To increase total coverage to 100%, you need to take into account all possible combinations of driver, passenger, obstacle, and endstop settings. When you are satisfied with the control behavior, you can create the power window system. For more information, see “Create Model Using Model-Based Design” on page 23-35.

This example increases the model coverage for the validation of the discrete-event control of the window. To start, the example uses inputs from `slexPowerWindowCntlCoverage` as a baseline for the model coverage. Next, to further exercise the discrete-event control of the window, it creates more input sets. The spreadsheet file, `inputCntlCoverageIncrease.xlsx`, contains these input sets using one input set per sheet.

In the example, the `slexPowerWindowSpreadsheetGeneration` utility function, which creates a spreadsheet template from the controller model, `slexPowerWindowControl`, creates the `inputCntlCoverageIncrease.xlsx`. In `inputCntlCoverageIncrease.xlsx`, the function uses the block names in the controller model as signal names. `slexPowerWindowSpreadsheetGeneration` defines the sheet names. The `slexWindowSpreadsheetAddInput` utility function populates `inputCntlCoverageIncrease.xlsx` with signal data.

The sheet names of these input sets and their descriptions are:

Sheet Name	Description
Logged	Inputs logged from <code>slexPowerWindowCntlCoverage</code>
LoggedObstacleOffEndStopOn	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with ability to hit endstop
LoggedObstacleOnEndStopOff	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with obstacle in window
LoggedObstacleOnEndStopOn	Inputs logged from <code>slexPowerWindowCntlCoverage</code> with obstacle in window and ability to hit endstop
DriverLoggedPassengerNeutral	Inputs logged from <code>slexPowerWindowCntlCoverage</code> for driver only and passenger takes no action
DriverDownPassengerNeutral	Driver is putting down window and passenger takes no action
DriverUpPassengerNeutral	Driver is putting up window and passenger takes no action

Sheet Name	Description
DriverAutoDownPassengerNeutral	Driver is putting down window for one second (auto-down) and passenger takes no action
DriverAutoUpPassengerNeutral	Driver is putting up window for one second (auto-up) and passenger takes no action
PassengerAutoDownDriverNeutral	Passenger is putting down window for one second (auto-down) and driver takes no action
PassengerAutoUpDriverNeutral	Passenger is putting up window for one second (auto-up) and driver takes no action

To automatically run these input vectors, replace the inputs to the discrete-event control with the From Spreadsheet block using the file, `inputCntlCoverageIncrease.xlsx`. This file contains the multiple input sets. To see the preconstructed model:

- 1 In the MATLAB Command Window, type:
`slexPowerWindowCntlCoverageIncrease`

- 2 To generate the Simulink Coverage coverage report for multiple input set, double click the Run Coverage subsystem in the model.

For the `slxPowerWindowCtrlCoverageIncrease` model, the report reveals that using multiple input sets has successfully raised the overall coverage for the `slxPowerWindowControl` model from 42% to 78%. Coverage levels are less than 100% because of missing input sets for:

- Passenger up state
- Driver up and down states
- Passenger automatic down and automatic up states

Create Model Using Model-Based Design

Why Use Model-Based Design?

In Model-Based Design, a system model is at the center of the development process, from requirements development, through design implementation, and testing. Use Model-Based Design to:

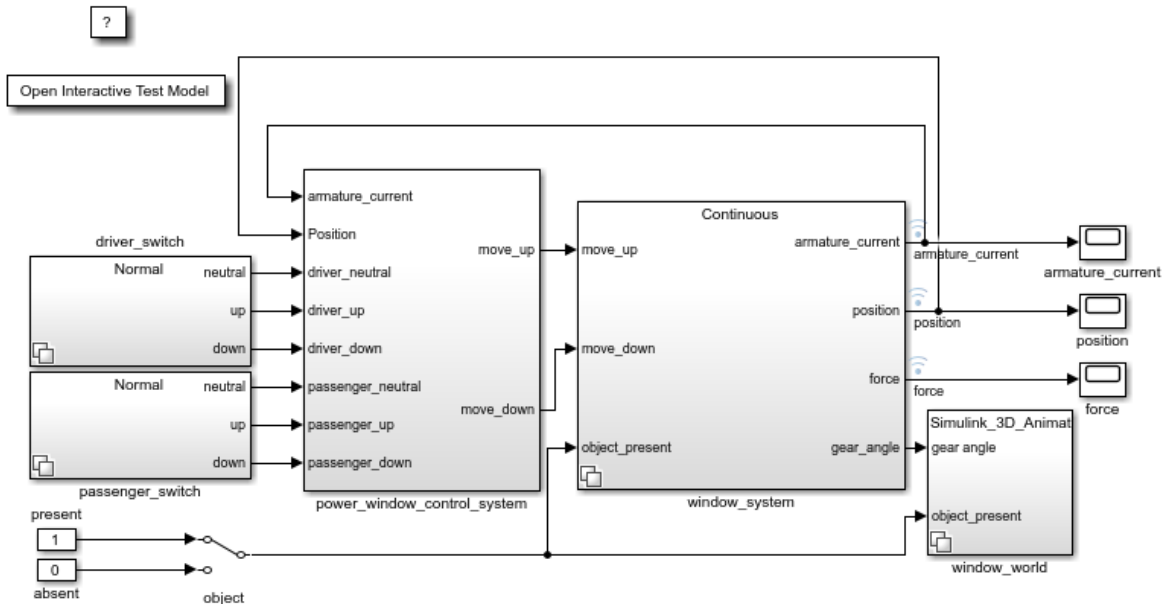

- Use a common design environment across project teams.
- Link designs directly to requirements.
- Integrate testing with design to continuously identify and correct errors.
- Refine algorithms through multidomain simulation.
- Automatically generate embedded software code.
- Develop and reuse test suites.
- Automatically generate documentation for the model.
- Reuse designs to deploy systems across multiple processors and hardware targets.

Implementation of Context Diagram: Power Window System

For requirements presented as a context diagram, see “Context Diagram: Power Window System” on page 23-4.

Create a Simulink model to resemble the context diagram.

- 1 Place the plant behavior into one subsystem.
- 2 Create two subsystems that contain the driver and passenger switches.
- 3 Add a control mechanism to conveniently switch between the presence and absence of the object.
- 4 Put the control in one subsystem.
- 5 Connect the new subsystems.
- 6 To see an implementation of this model, in the MATLAB Command Window, type:
`slexPowerWindowStart`

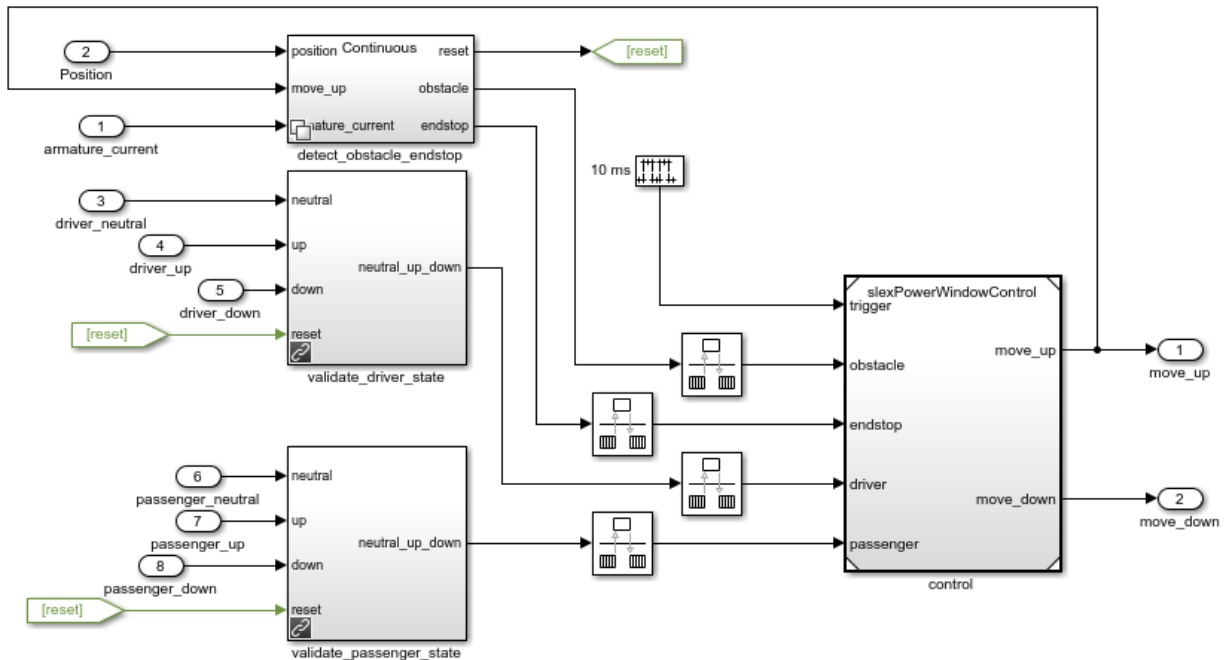

You can use the power window control activity diagram (“Activity Diagram: Power Window Control” on page 23-5) to decompose the power window controller of the context diagram into parts. This diagram shows the input and output signals present in the context diagram for easier tracing to their origins.

Implement Power Window Control System

To satisfy full requirements, the power window control must work with the validation of the driver and passenger inputs and detect the endstop.

For requirements presented as an activity diagram, see “Activity Diagram: Power Window Control” on page 23-5.

Double-click the `slexPowerWindowExample/power_window_control_system` block to open the following subsystem:

Implementation of Activity Diagram: Validate

For requirements presented as activity diagrams, see “Activity Diagram: Validate Driver” on page 23-7 and “Activity Diagram: Validate Passenger” on page 23-8.

The activity diagram adds data validation functionality for the driver and passenger commands to ensure correct operation. For example, when the window reaches the top, the software blocks the up command. The implementation decomposes each validation process in new subsystems. Consider the validation of the driver commands (validation of the passenger commands is similar). Check if the model can execute the up or down commands, according to the following:

- The model allows the down command only when the window is not completely opened.
- The model allows the up command only when the window is not completely closed and no object is detected.

The third activity diagram process checks that the software sends only one of the three commands (neutral, up, down) to the controller. In an actual implementation, both up and down can be simultaneously true (for example, because of switch bouncing effects).

From the power_window_control_system subsystem, this is the validate_driver_state subsystem:

From the power_window_control_system subsystem, this is the validate_passenger_state subsystem:

Implementation of Activity Diagram: Detect Obstacle Endstop

For requirements presented as an activity diagram, see “Activity Diagram: Detect Obstacle Endstop” on page 23-10.

In the `slexPowerWindowExample` model, the `power_window_control_system/detect_obstacle_endstop` block implements this activity diagram in the continuous variant of the Variant Subsystem block. During design iterations, you can add additional variants.

Double-click the `slexPowerWindowExample` model `power_window_control_system/detect_obstacle_endstop/Continuous/verify_position` block:

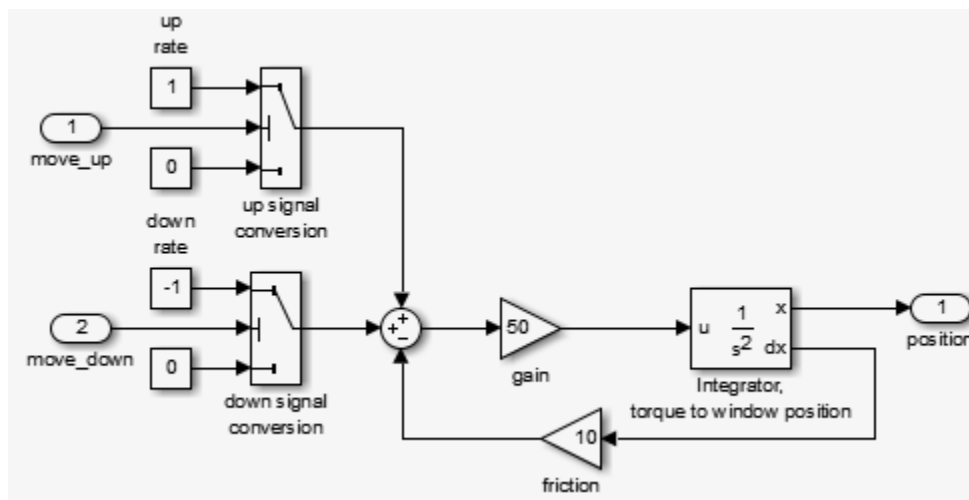

Hybrid Dynamic System: Combine Discrete-Event Control and Continuous Plant

After you have designed and verified the discrete-event control, integrate it with the continuous-time plant behavior. This step is the first iteration of the design with the simplest version of the plant.

In the project, navigate to **Files** and click **Project**. In the **configureModel** folder, run the `slexPowerWindowContinuous` utility to open and initialize the model.

The `window_system` block uses the Variant Subsystem block to allow for varying levels of fidelity in the plant modeling. Double-click the `window_system/Continuous/2nd_order_window_system` block to see the continuous variant.

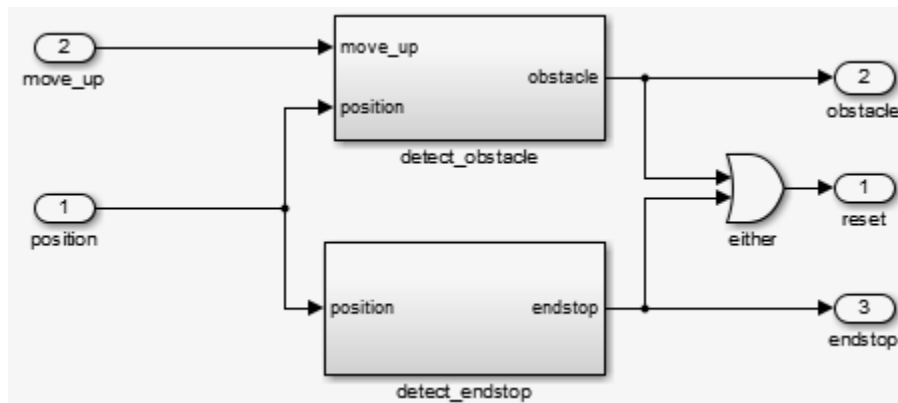

The plant is modeled as a second-order differential equation with step-wise changes in its input:

- When the Stateflow chart generates `windowUp`, the input is 1.
- When the Stateflow chart generates `windowDown`, the input is -1.
- Otherwise, the input is 0.

This phase allows analysis of the interaction between the discrete-event state behavior, its sample rate, and the continuous behavior of the window movement. There are threshold values to generate the window frame top and bottom:

- `endStop`
- Event when an obstacle is present, that is, `obstacle`
- Other events

Double-click the `slexPowerWindowExample` model `power_window_control_system/-detect_obstacle_endstop/Continuous/verify_position` block to see the continuous variant.

When you run the `slexPowerWindowContinuous` `configureModel` utility, the model uses the continuous time solver `ode23` (Bogacki-Shampine).

A structure analysis of a system results in:

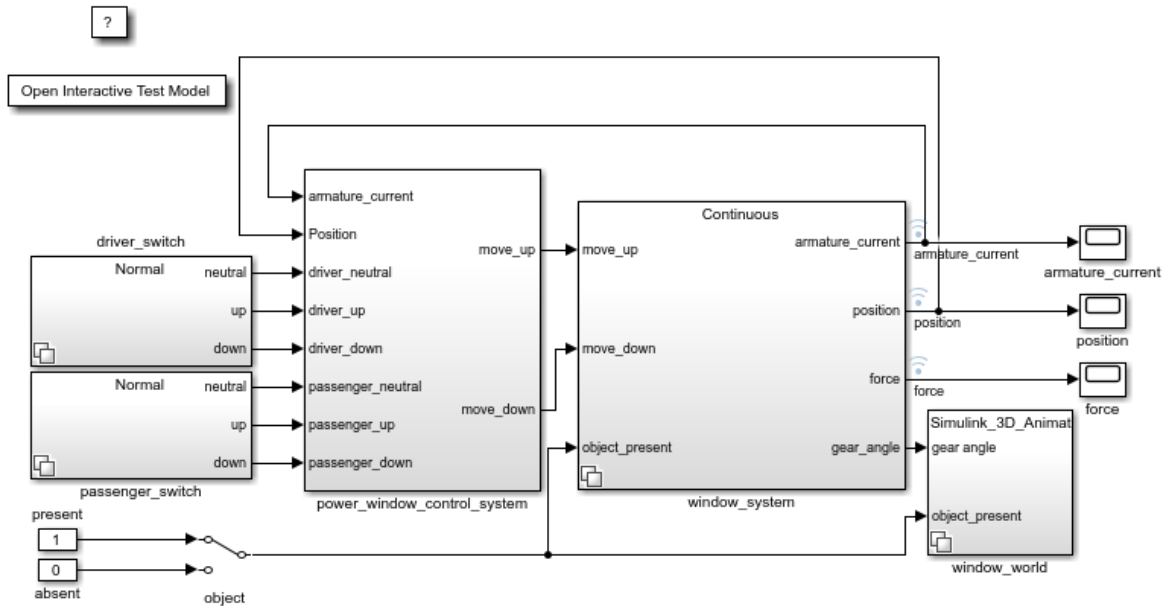

- A functional decomposition of the system
- Data definitions with the specifics of the system signals
- Timing constraints

A structure analysis can also include the implementation architecture (outside the scope of this discussion).

The implementation also adds a control mechanism to conveniently switch between the presence and absence of the object.

Expected Controller Response

To view the window movement, in **Project Shortcuts**, double-click `SimHybridPlantLowOrder`. Alternatively, you can run the task `slexPowerWindowContinuousSim`.

The position scope shows the expected result from the controller. After 30 cm, the model generates the obstacle event and the Stateflow chart moves into its emergencyDown state. In this state, `windowDown` is output until the window lowers by about 10 cm. Because the passenger window up switch is still on, the window starts moving up again and this process repeats. Stop the simulation and open the position scope to observe the oscillating process. In case of an emergency, the discrete-event control rolls down the window approximately 10 cm.

Detailed Modeling of Power Effects

After an initial analysis of the discrete-event control and continuous dynamics, you can use a detailed plant model to evaluate performance in a more realistic situation. It is best to design models at such a level of detail in the power domain, in other words, as energy flows. Several domain-specific MathWorks blocksets can help with this.

To take into account energy flows, add a more detailed variant consisting of power electronics and a multibody system to the `window_system` variant subsystem.

To open the model and explore the more detailed plant variant, in the project, run `configureModel slexPowerWindowPowerEffects`.

Double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system` block.

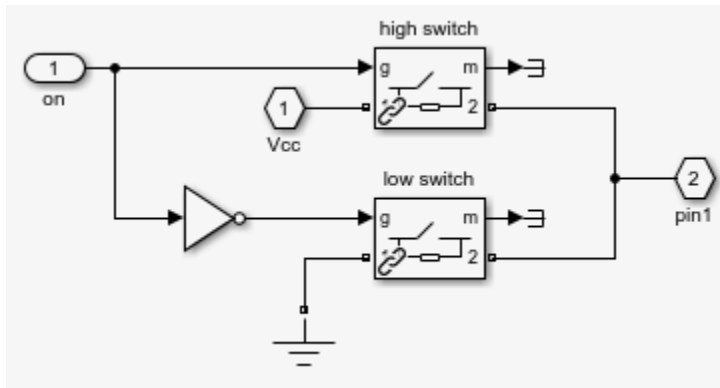

Power Electronics Subsystem

The model must amplify the control signals generated by the discrete-event controller to be powerful enough to drive the DC motor that moves the window.

The amplification modules model this behavior. They show that a switch either connects the DC motor to the battery voltage or ground. By connecting the battery in reverse, the system generates a negative voltage and the window can move up, down, or remain still. The window is always driven at maximum power. In other words, no DC motor controller applies a prescribed velocity.

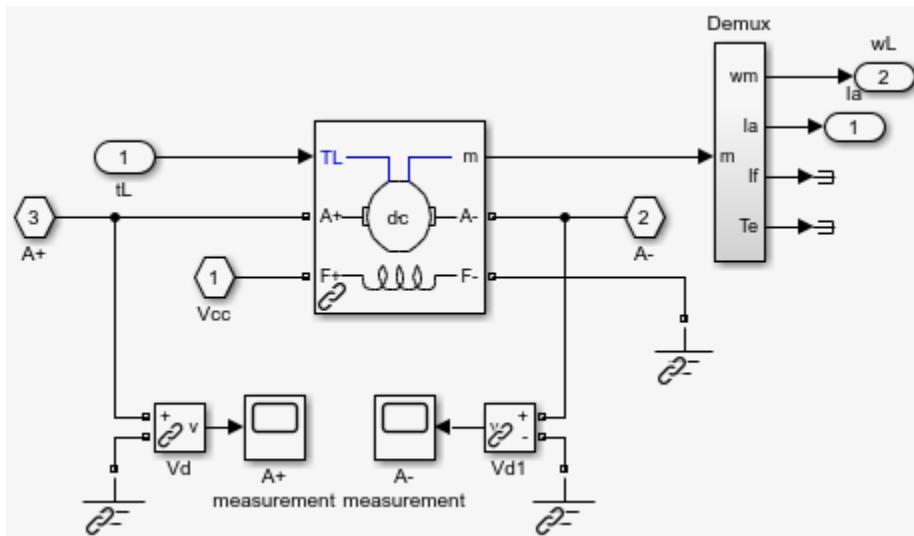

To see the implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/amplification_up` block.

Multibody System

This implementation models the window using Simscape Multibody blocks.

To see the actuator implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/actuator` block.

To see the window implementation, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant` block.

This implementation uses Simscape Multibody blocks for bodies, joints, and actuators. The window model consists of:

- A worm gear
- A lever to move the window holder in the vertical direction

The figure shows how the mechanical parts move.

Iterate on the Design

An important effect of the more detailed implementation is that there is no window position measurement available. Instead, the model measures the DC motor current and

uses it to detect the endstops and to see if an obstacle is present. The next stage of the system design analyzes the control to make sure that it does not cause excessive force when an obstacle is present.

In the original system, the design removes the obstacle and endstop detection based on the window position and replaces it with a current-based implementation. It also connects the process to the controller and position and force measurements. To reflect the different signals used, you must modify the data definition. In addition, observe that, because of power effects, the units are now amps.

PSPEC 1.3.1: DETECT ENDSTOP
 $ENDSTOP = ARMATURE_CURRENT > ENDSTOP_MAX$

PSPEC 1.3.2: DETECT OBSTACLE
 $OBSTACLE = (ARMATURE_CURRENT > OBSTACLE_MAX)$ and MOVE_UP for 500 ms

PSPEC 1.3.3: ABSOLUTE VALUE
 $ABSOLUTE_ARMATURE_CURRENT = abs(ARMATURE_CURRENT)$

This table lists the additional signal for the Context Diagram: Power Window System data definitions.

Context Diagram: Power Window System Data Definition Changes

Signal	Information Type	Continuous/ Discrete	Data Type	Values
ARMATURE_CURRENT	Data	Continuous	Real	-20 to 20 A

This table lists the changed signals for the Activity Diagram: Detect Obstacle Endstop data definitions.

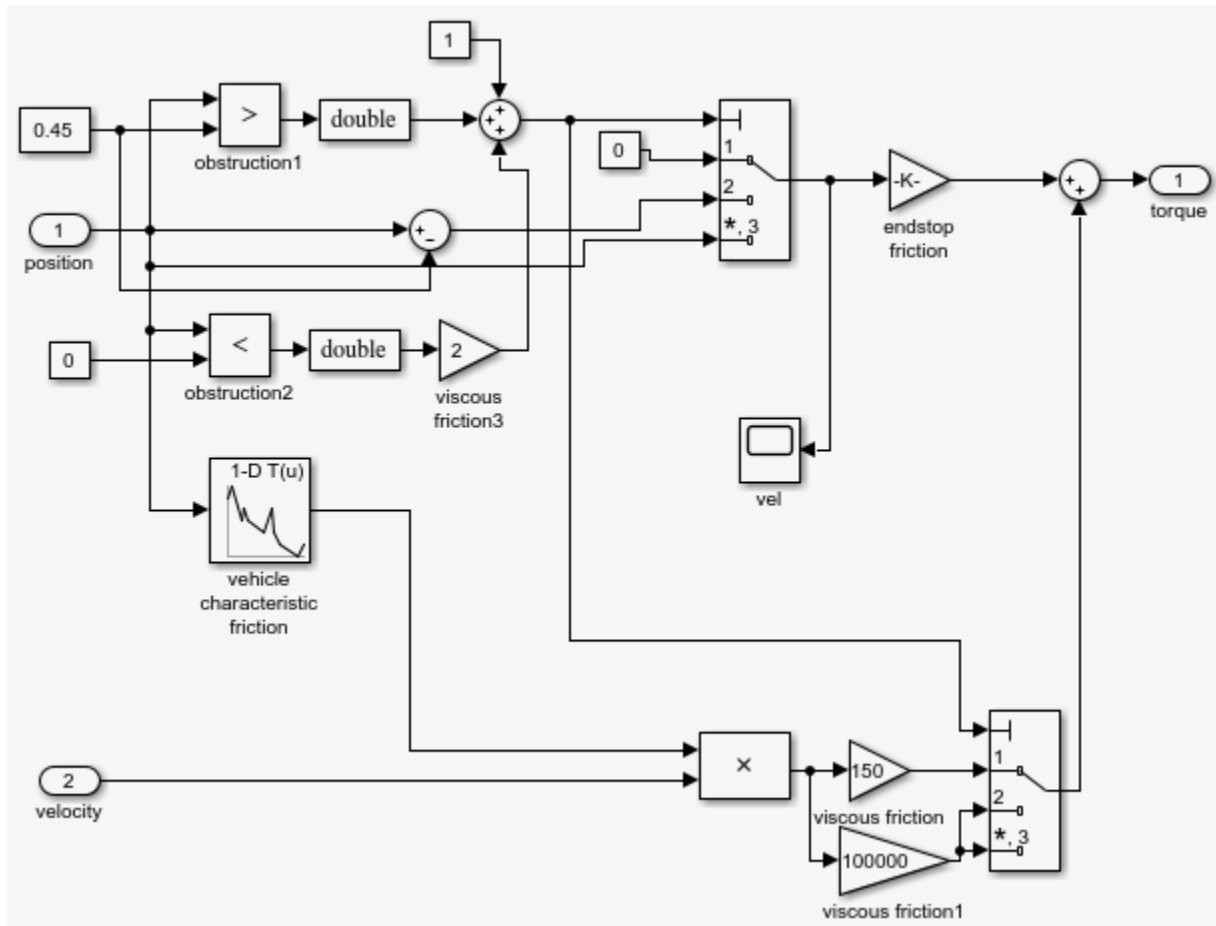

Activity Diagram: Detect Obstacle Endstop Data Definition Changes

Signal	Information Type	Continuous/ Constant	Data Type	Values
ABSOLUTE_ARMATURE_CURRENT	Data	Continuous	Real	0 to 20 A
ENDSTOP_MAX	Data	Constant	Real	15 A
OBSTACLE_MAX	Data	Constant	Real	2.5 A

To see the window subsystem, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant/window` block.

The implementation uses a lookup table and adds noise to allow evaluation of the control robustness. To see the implementation of the friction subsystem, double-click the `slexPowerWindowExample` model `window_system/Power Effects - Visualization/detailed_window_system/plant/window/friction` block.

Control Law Evaluation

The idealized continuous plant allows access to the window position for endStop and obstacle event generation. In the more realistic implementation, the model must generate these events from accessible physical variables. For power window systems, this physical variable is typically the armature current, I_a , of the DC motor that drives the worm gear.

When the window is moving, this current has an approximate value of 2 A. When you switch the window on, the model draws a transient current that can reach a value of

approximately 10 A. When the current exceeds 15 A, the model activates endstop detection. The model draws this current when the angular velocity of the motor is kept at almost 0 despite a positive or negative input voltage.

Detecting the presence of an object is more difficult in this setup. Because safety concerns restrict the window force to no more than 100 N, an armature current much less than 10 A should detect an object. However, this behavior conflicts with the transient values achieved during normal operation.

Implement a control law that disables object detection during achieved transient values. Now, when the system detects an armature current more than 2 A, it considers an object to be present and enters the `emergencyDown` state of the discrete-event control. Open the force scope window (measurements are in newtons) to check that the force exerted remains less than 100 N when an object is present and the window reverses its velocity.

In reality, far more sophisticated control laws are possible and implemented. For example, you can implement neural-network-based learning feedforward control techniques to emulate the friction characteristic of each individual vehicle and changes over time.

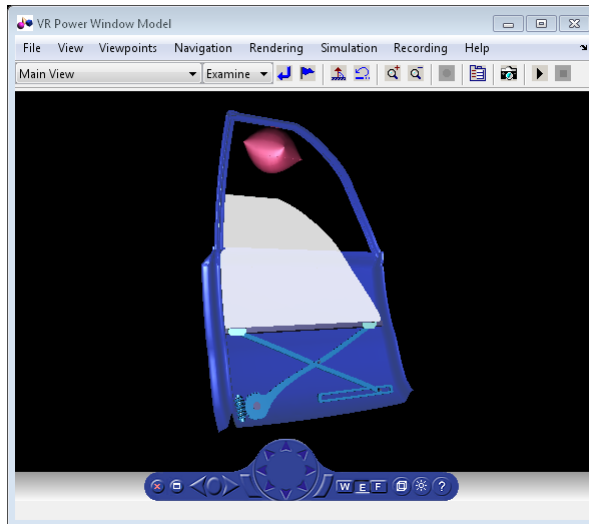

Visualization of the System in Motion

If you have Simulink 3D Animation software installed, you can view the geometrics of the system in motion via a virtual reality world. If the VR Sink block is not yet open, in the `slexPowerWindowExample/window_world/Simulink_3D_Animation View` model, double-click the VR Sink block.

To simulate the model with a stiff solver:

- 1 In a project, run the task, `slexPowerWindowPowerEffectsSim`. This batch job sets the solver to `ode23tb` (stiff/TR-BDF2).
- 2 In the `slexPowerWindowExample` model `passenger_switch/Normal` block, set the passenger up switch to on.
- 3 In the `slexPowerWindowExample` model `driver_switch/Normal` block, set the driver up switch to off.
- 4 Simulate the model.
- 5 Between 10 ms and 1 s in simulation time, switch off the `slexPowerWindowExample/passenger_switch/Normal` block passenger up switch to initiate the auto-up behavior.

- 6 Observe how the window holder starts to move vertically to close the window. When the model encounters the object, it rolls the window down.
- 7 Double-click the `slexPowerWindowExample` model `passenger_switch/Normal` block driver down switch to roll down the window completely and then simulate the model. In this block, at less than one second simulation time, switch off the driver down switch to initiate the auto-down behavior.

- 8 When the window reaches the bottom of the frame, stop the simulation.
- 9 Look at the position measurement (in meters) and at the armature current (I_a) measurement (in amps).

Note The absolute value of the armature current transient during normal behavior does not exceed 10 A. The model detects the obstacle when the absolute value of the armature current required to move the window up exceeds 2.5 A (in fact, it is less than -2.5 A). During normal operation, this is about 2 A. You might have to zoom into the scope to see this measurement. The model detects the window endstop when the absolute value of the armature current exceeds 15 A.

Variation in the armature current during normal operation is due to friction that is included by sensing joint velocities and positions and applying window specific coefficients.

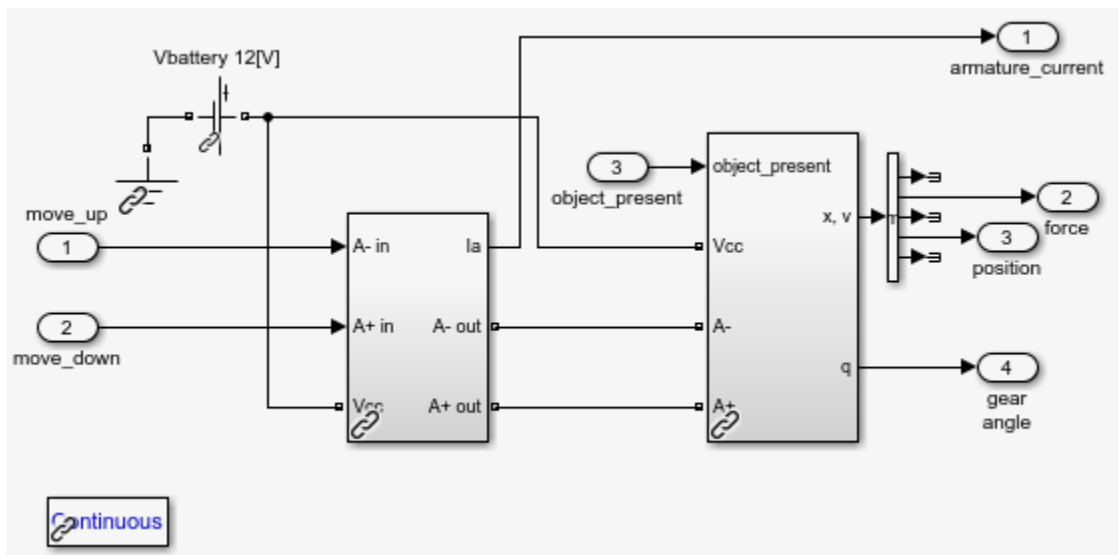

Realistic Armature Measurement

The armature current as used in the power window control is an ideal value that is accessible because of the use of an actuator model. In a more realistic situation, data acquisition components must measure this current value.

To include data acquisition components, add the more realistic measurement variant to the window_system variant subsystem. This realistic measurement variant contains a signal conditioning block in which the current is derived based on a voltage measurement.

To open a model and configure the realistic measurement, in the project, run the configureModel task `slexPowerWindowRealisticArmature`.

To view the contents of the Realistic Armature - Communications Protocol block, double-click the `SlexPowerWindowExample` model `window_system/Realistic Armature - Communications Protocol/detailed_window_system_with_DAQ`.

The measurement voltage is within the range of an analog-to-digital converter (ADC) that discretizes based on a given number of bits. You must scale the resulting value based on the value of the resistor and the range of the ADC.

Include these operations as fixed-point computations. To achieve the necessary resolution with the given range, 16 bits are required instead of 8.

Study the same scenario:

- 1 In the `slexPowerWindowExample/passenger_switch/Normal` block, set the passenger up switch.

- 2 Run the simulation.
- 3 After some time, in the `slexPowerWindowExample/passenger_switch/Normal` block, switch off the passenger up switch.
- 4 When the window has been rolled down, click the `slexPowerWindowExample/passenger_switch/Normal` block driver down switch.
- 5 After some time, switch off the `slexPowerWindowExample/passenger_switch/Normal` block driver down switch.
- 6 When the window reaches the bottom of the frame, stop the simulation.
- 7 Zoom into the `armature_current` scope window and notice the discretized appearance.

Communication Protocols

Similar to the power window output control, hardware must generate the input events. In this case, the hardware is the window control switches in the door and center control panels. Local processors generate these events and then communicate them to the window controller via a CAN bus.

To include these events, add a variant containing input from a CAN bus and switch components that generate the events delivered on the CAN bus to the driver switch and passenger switch variant subsystems. To open the model and configure the CAN communication protocols, run the `configureModel` task, `slexPowerWindowCommunicationProtocolSim`.

To see the implementation of the switch subsystem, double-click the `slexPowerWindowExample/driver_switch/Communication Protocol/driver window control switch` block.

Observe a structure that is very similar to the window control system. This structure contains a:

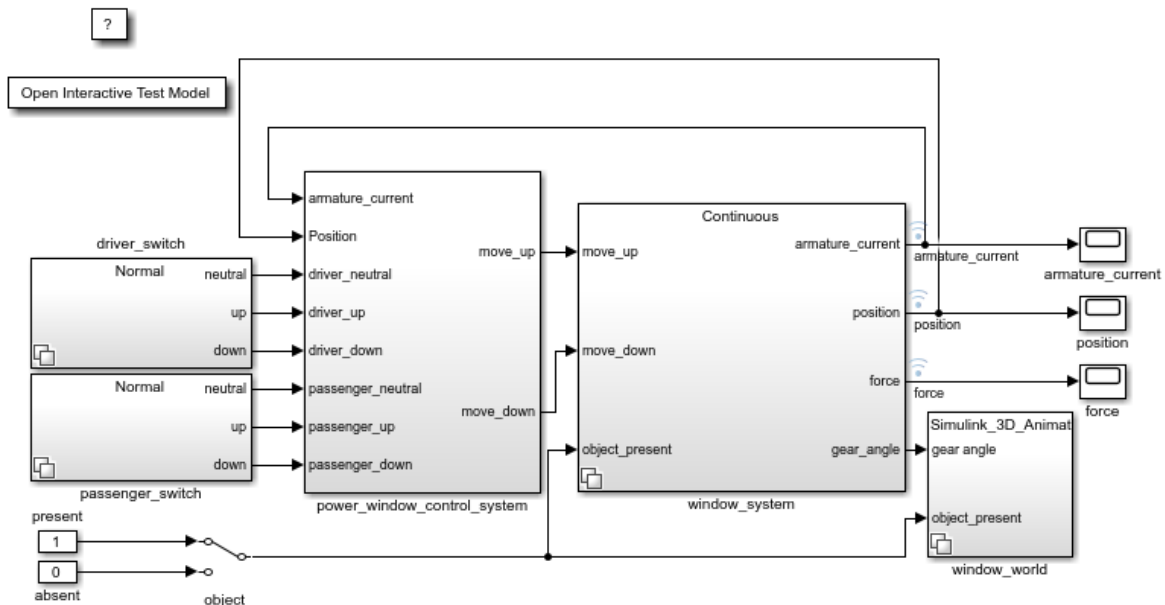

- Plant model that represents the control switch

- Data acquisition subsystem that includes, among other things, signal conditioning components
- Control module to map the commands from the physical switch to logical commands
- CAN module to post the events to the vehicle data bus

You can add communication effects, such as other systems using the CAN bus, and more realism similar to the described phases. Each phase allows analysis of the discrete-event controller in an increasingly realistic situation. When you have enough detail, you can automatically generate controller code for any specific target platform.

Automatic Code Generation for Control Subsystem

You can generate code for the designed control model, `slexPowerWindowExample`.

- 1 Display the sample rates of the controller. In the Simulink Editor, select **Display** > **Sample Time** > **Colors**. Observe that the controller runs at a uniform sample rate.

- 2 Right-click the `power_window_control_system` block and select **C/C++ Code > Build This Subsystem**.

What are Partitions?

Partitions are components of a model that execute independently as atomic tasks. In multi-tasking models, partitions are created from model components. Periodic partitions are scheduled as a function of sample times in a model. In export-function models, the root function-call inputs are defined as partitions. These partitions have a schedule associated with it, which tells what order the partitions execute.

With partitions, you can separate parts of the model which you can explicitly control. You can think of periodic partitions as components that run at specific rates in a model. Aperiodic partitions are components that run at specified hit times. The schedule of these partitions have an impact on simulation and code generation.

The Schedule Editor enables you to partition the model and interact with those partitions. The Schedule Editor shows partitions, the connections between them, and the execution order of the partitions

There are three types of partitions:

Types of Partitions	Image	Description
Implicit		Automatically created by Simulink. Blocks running at the base rate show up as an implicit partition.
Periodic		User-defined partitions from the atomic subsystems and/or model blocks. Periodic partitions can also be defined by export-functions. These partitions execute based on their sample time and thus their execution is periodic.
Aperiodic		Aperiodic partitions are partitions which have no constraints and can be made to execute at any time. Specify the hit times in the Property Inspector of the Schedule Editor, at which you want to run the aperiodic partition.

The blocks running at the base rate in the model is shown as an implicit partition in the Schedule Editor. The base rate is the fastest discrete rate in the model. *D1* denotes the

base rate. *D1* annotation also appears in the Timing Legend. The *D1* partition or implicit partition always remains the first discrete partition in the execution order.

The default partitions that are already present in the model are also implicit partitions.

The partition colors match their rate.

Create Partitions

Partitioning a Model

Partitions are components of a model that execute independently as atomic tasks. In multi-tasking models, partitions are created from model components. Periodic partitions are scheduled as a function of sample times in a model. In export-function models, the root function-call inputs are defined as partitions. These partitions have a schedule associated with it, which tells what order the partitions execute.

With partitions, you can separate parts of the model which you can explicitly control. You can think of periodic partitions as components that run at specific rates in a model. Aperiodic partitions are components that run at specified hit times. The schedule of these partitions have an impact on simulation and code generation.

The Schedule Editor enables you to partition the model and interact with those partitions. The Schedule Editor shows partitions, the connections between them, and the execution order of the partitions

There are three types of partitions:

Types of Partitions	Image	Description
Implicit		Automatically created by Simulink. Blocks running at the base rate show up as an implicit partition.
Periodic		User-defined partitions from the atomic subsystems and/or model blocks. Periodic partitions can also be defined by export-functions. These partitions execute based on their sample time and thus their execution is periodic.

Types of Partitions	Image	Description
Aperiodic		Aperiodic partitions are partitions which have no constraints and can be made to execute at any time. Specify the hit times in the Property Inspector of the Schedule Editor, at which you want to run the aperiodic partition.

The blocks running at the base rate in the model is shown as an implicit partition in the Schedule Editor. The base rate is the fastest discrete rate in the model. *D1* denotes the base rate. *D1* annotation also appears in the Timing Legend. The *D1* partition or implicit partition always remains the first discrete partition in the execution order.

The default partitions that are already present in the model are also implicit partitions.

The partition colors match their rate.

Create Partitions from a Rate-Based Model

Partitioning is enabled only on multitasking, fixed-step solver models. To choose multitasking execution mode, In Solver selection on the Solver pane, select the **Type** to be **Fixed-step**. Select the **Treat each discrete rate as a separate task** check box on the **Solver** pane of the Configuration Parameters dialog box. For more information on multitasking execution mode, see “Time-Based Scheduling and Code Generation” (Embedded Coder).

As a best practice, enable the **Automatically handle rate transition for data transfer** setting in the solver pane. When you check **Automatically handle rate transition for data transfer**, Simulink inserts Rate Transition blocks between blocks when rate transitions are detected. Simulink handles rate transitions for asynchronous and periodic tasks. Simulink adds the hidden blocks configured to ensure data integrity and determinism for data transfers. When you check **Treat each discrete rate as a separate task**, Simulink selects multitasking execution for models operating at different rates. It also specifies that groups of blocks with the same execution priority are processed through each stage of simulation (for example, calculating output and updating states) based on task priority.

To see default partitions in the Schedule Editor, open the Schedule Editor by selecting

View > Schedule Editor, and update the diagram by clicking the  icon on the toolstrip. The default partitions in the model are called implicit partitions. You can also create partitions in the model through an atomic subsystem or a model block.

Create Partitions Using Manage Partitions

In the Schedule Editor, use the **Manage Partitions** panel to create partitions. The changes made in **Manage Partitions** are applied to the model to create partitions after updating the diagram. **Manage Partitions** shows the model hierarchy with the subsystem blocks and model blocks which can be explicitly partitioned.

To create partitions from subsystem blocks, select the subsystems and click the . To create partitions from model blocks, select the model blocks and click . Enter partition names in the column **Partition Name**, and sample times in the column **Sample Time**. Repeat the steps for all the subsystems and model blocks in the model that you want to partition. Update the diagram to see the created partitions in the Schedule Editor. The partitions appear in the graph with their deduced data dependencies and execution order.

The screenshot shows the SCHEDULE EDITOR interface. The main workspace displays a grid with a central block representing a partitioned system. The block is a 2x2 grid of colored squares with corresponding labels and ranges:

0	Cont
[0, 1]	FIM
0.01	D1

The **MANAGE PARTITIONS** panel is highlighted with a red box. It contains a table with the following data:

Block Name	Partition Name	Sample time
Dashboard		
Engine Gas Dynamics		
fuel_rate_control		
airflow_calc		
fuel_calc		

The **EXECUTION ORDER** table on the right shows the following data:

Order	Name	Rate
1	Cont	0
	FIM	[0, 1]
	D1	0.01

The **PROPERTY INSPECTOR** panel at the bottom right shows "Nothing selected".

Note Creating partitions using the **Manage Partitions** panel makes changes to the subsystem or model block parameters.

Following example shows how to configure a model for partitioning and create partitions from using **Manage Partitions** panel in the Schedule Editor.

- 1 Open the model
sldemo_fuelsys

2 Open the Schedule Editor

Open the Schedule Editor from the Simulink **View** menu. To see the default partitions, click **Update Diagram** in the Schedule Editor. Two implicit partitions, created automatically by Simulink are seen in the Schedule Editor.

3 Create partitions

Open the **Manage Partitions** panel. In the panel, expand the `fuel_rate_control` subsystem. Select the `airflow_calc` subsystem and click . To change the default partition name and sample time, click the default name and sample time.

To create a partition for the `fuel_calc` subsystem, select the `fuel_calc` subsystem and click .

The **Manage Partitions** panel gives you the default partition names and sample times.

Update the diagram to see the newly created partitions.

Create Partitions from Atomic Subsystems

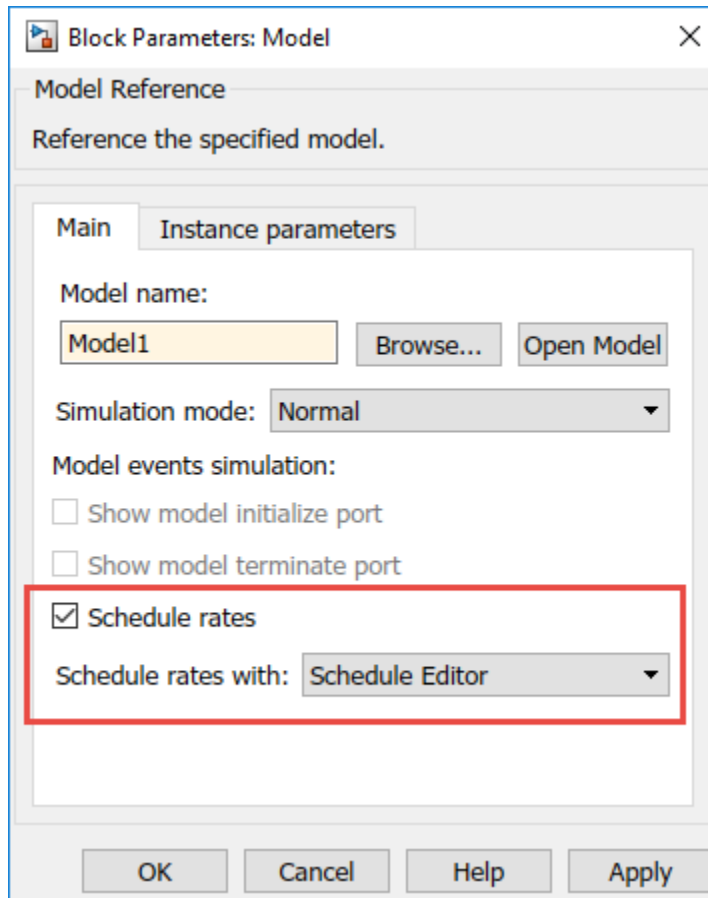

You can partition only an atomic subsystem. An atomic subsystem is treated by Simulink as a unit when determining the execution order of block methods. To create partitions from an atomic subsystem block, go to the Block Parameters dialog box. Select **Periodic partition** from the **Schedule as** drop-down. Give the partition a name and a discrete sample time and click OK. This creates an explicit partition for this block. To see this partition in the Schedule Editor, update the diagram. The partition appears in the graph and in the **Execution Order** with the connections based on the signals in the model.

Create Partitions from Model Block

To create partitions from a Model block, in the **Model events simulation**, select **Schedule rates** and Schedule Editor from the **Schedule rates with** drop-down. When you enable partitioning from a referenced model, partitions are created from all the model blocks present in the referenced model. These partitions are scoped by the model block name. To see this partition in the Schedule Editor, update the diagram. The

partitions appear in the graph and in the **Execution Order** with the connections based on the design of your model.

Export Function Partitions

In export-function models, partitions are created from the function calls present in the model. To create partitions from the function calls in the export-function models, reference the export-function model in a top model. Schedule the Model block using the Schedule Editor through the block parameters. Partitions are then created from the function calls and their execution order is determined by the Schedule Editor.

- Create an export-function model.
- Add a Model block that references the export-function model.
- Set the parameter to use partition the export-function model.

Referencing an export-function model from a Model block allows you to partition the function calls without changing the model itself. To create the model for this example, see “Create Export-Function Model” on page 10-93. Simulink functions in an export-functions models cannot be scheduled, and do not appear as partitions in the Schedule Editor.

- 1 Add a model block to a new Simulink model. In the **Model name** box, enter `export_function_model`. To enable the use of the Schedule Editor, configure the model to be multitasking. Open the Model Configuration Parameters. In **Solver selection** on the **Solver** pane, set the **Type** to Fixed-step. Check the **Treat each discrete rate as a separate task** and **Automatically handle rate transition for data transfer** parameters. Click **OK**. The model is enabled for partitioning.

Note Do not convert a subsystem to create a model because it automatically creates inports.

- 2 Add Outport blocks to the **output_100ms** and **output_10ms** ports for saving simulation data to MATLAB. For this example, in the `export_function_model`, set the sample time of both the function calls to -1.

- 3 Add a Sine Wave block to provide data input. Set **Amplitude** to 2 and **Sample time** to 0.01.
- 4 To partition the function calls of the export function model, in the **Block Parameters** of the model block, select **Schedule Editor** option from the **Schedule Rates with** drop-down menu.
- 5 Open the Schedule Editor and update the diagram to see the function calls as partitions.

The screenshot shows the Schedule Editor interface. The main workspace contains a diagram with three partitions:

- A red partition labeled "0.01 D1" with a red border.
- A blue partition labeled "-1 Model.function_call_1" with a blue border.
- A green partition labeled "-1 Model.function_call_2" with a green border.

An arrow points from the red partition to the green partition. The right-hand side of the interface displays the "EXECUTION ORDER" table:

Order	Name	Rate
1	D1	0.01
2	Model.function_call_1	-1
3	Model.function_call_2	-1

Below the table is the "PROPERTY INSPECTOR" for the selected partition:

Partition	
Name	Model.function_call_1
Rate	-1
Hit Times	<input type="text"/>
Type	Explicit aperiodic partition

Schedule Editor

More About

- “Schedule the Partitions” on page 24-18
- “Generate Code from a Partitioned Model” on page 24-28

Using the Schedule Editor

The Schedule Editor is a scheduling tool that represents the components in the model known as partitions, the data connections between them, and the execution order of those partitions.

Partitions are the components of the model that execute independently as tasks. The data connections between the partitions show the flow of the data between those partitions. The scheduling of these partitions is based on the rates and the events in the model. This schedule is shown in the **Execution Order** table in the Schedule Editor.

Using the Schedule Editor you can:

- Create partitions and specify their execution order
- Edit and analyze the schedule of the executable partitions without disturbing the structure of the model.
- Visualize how Simulink executes partitions

Changes made in the Schedule Editor affect both, simulation and code generation.

Using the Schedule Editor

The Schedule Editor consists of two parts representing two different views of partitions in the model.

- A graph that shows the partitions and the data connections between them.

- A table that shows the order in which the partitions execute.

EXECUTION ORDER			
Order	Name		Rate
1	■ D1	⋮	0.1
2	■ Component.D1	⋮	0.1
3	■ Component.P2	⋮	0.1
4	■ Component.P1	⋮	0.2
5	■ Component.D2	⋮	0.2

Changing one of the views impacts the other.

To use the Schedule Editor, select **View > Schedule Editor**. If the model is already partitioned, you can open the Schedule Editor by clicking the badge, , which appears above the blocks. To see the default partitions present in the model in the

Schedule Editor, update the diagram with  icon, on the toolstrip or by selecting **Ctrl + D**. As you create partitions in the model and update the diagram, partitions appear in the Schedule Editor.

To check how the partitions map to the model, right-click the partitions and select **Show Source**. The Simulink model window appears with every block corresponding to the partition highlighted.

Execution Order

The **Execution Order** shows the order in which the partitions execute. To change the execution order, you can drag and drop the partitions. You can also use the **Up** and **Down** arrows on the toolstrip. Partitions are sorted based on their rates. You can only reorder the partitions with the same rate. Clicking a partition in the **Execution Order**, highlights the corresponding partition in the graph. On changing the execution order, the connections that are affected by this specified change get highlighted.

EXECUTION ORDER		
Order	Name	Rate
1	D1	0.1
3	Component.P2	0.1
2	Component.D1 	0.1
4	Component.D2	0.2
5	Component.P1	0.2

Connections

Connections between the partitions show data dependencies. You can right-click the connections between the partitions to change the constraints on data connections. The different types of connections illustrate how the partitions behave with each other.

The types of connections are:

- **Dependency** - Indicates that the source always runs before the destination. The dependency connection is a solid line.

- **Delay** - Indicates that the destination runs before the source. When the destination runs before the source, a scheduling delay is introduced. The delay connection is a dashed line.

You can put these types of constraints on connections:

- **Allow Delay** - Inserts a delay when required. When you specify this constraint for a connection, Simulink inserts a delay for that connection only when necessary. The unlock icon on the connections signifies an allowed delay. When you select this constraint on a connection, Simulink prefers these connections to be turned into a delay if necessary over other connections.

This constraint is displayed as one of these options.

- **Prevent Delay** - Prevents delay from being inserted in the connection. When you specify this constraint for a connection, Simulink ensures that the connection always remains as a dependency. The lock icon on the connection indicates that the connection is locked to be a dependency and is not changed to a delay.

- “Create Partitions” on page 24-4
- “Schedule the Partitions” on page 24-18
- “Generate Code from a Partitioned Model” on page 24-28

Schedule the Partitions

The two examples walk through the workflow of partitioning a model, scheduling the partitions and analyzing the simulations before and after edit the schedule of the partitions.

Schedule an Export-Function Model Using the Schedule Editor

This example shows how to view and edit the execution order of function-calls in an export-function model using the Schedule Editor. As in all export-function models, the desired functionality is modeled as function-call subsystems. These function-call subsystems define the partitions that are scheduled by the Schedule Editor.

With the Schedule Editor, you can easily view and edit the schedule of the function-calls. The behavior of the system depends on the execution order of these partitions. In this example, we change the execution order and observe its effects on the behavior of the system by simulating the model. To see the impact of editing the schedule on the simulation, we compare the model simulations before and after scheduling.

Create Partitions from Referenced Export-Function Model

To view and edit the schedule of the export-function model, reference the model.

```
open_system('ThrottlePositionControlTop.slx');
```

Schedule an Export-Function Model with the Schedule Editor

Copyright 2018 The MathWorks, Inc.

ThrottlePositionControl is the referenced export-function model. By default, each function has an input port that can be used to trigger these functions. The Schedule Editor automatically handles these ports. To use the Schedule Editor, set the Schedule Rates With parameter to Schedule Editor.

```
set_param('ThrottlePositionControlTop/ThrottleControl', 'ScheduleRatesWith', 'Schedule Editor');
```

Establish a Simulation Baseline

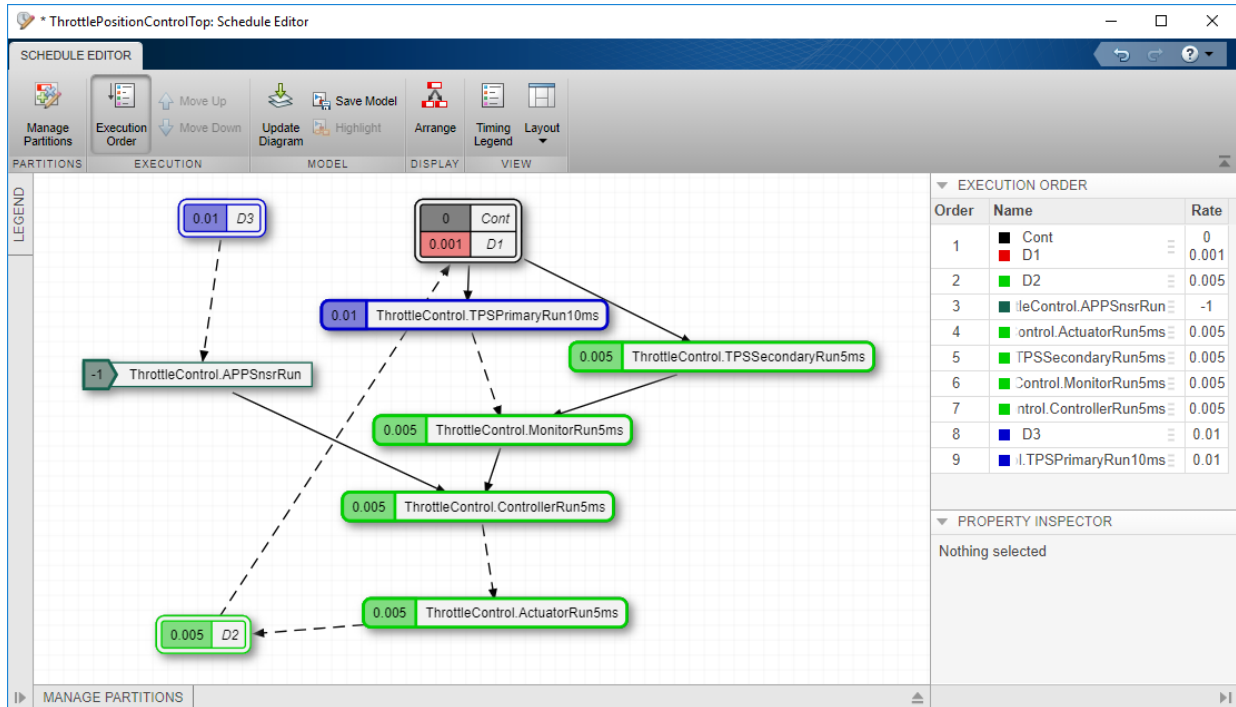

To observe the impact of scheduling on the model behavior, establish a baseline by simulating the model before editing the schedule. Simulate the model.

```
sim('ThrottlePositionControlTop');
```

Open the Schedule Editor

To open the Schedule Editor, go to **View -> Schedule Editor**. In the Schedule Editor, different components of the model are represented as partitions. Update the diagram to

see the partitions. Partitions are the entry-points in the model. The Schedule Editor shows the execution order and data communications of these partitions. The arrows are data connections between the partitions that show the data flow. The dashed lines indicate that there is a delay because the source runs after the destination. The solid lines indicate that there is no delay as the source runs before the destination.

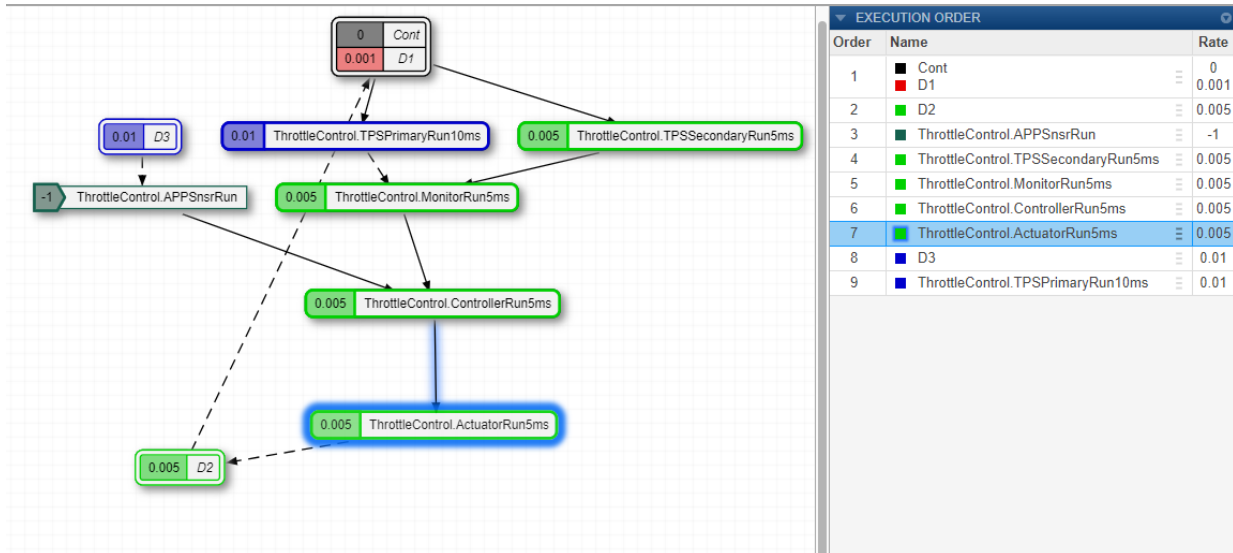

Edit Partition Schedule

The Execution Order shows the order the partitions run in at a given time step. Assume that the execution order of the partitions is in an imperfect state. In this case, to remove the delay, you want to run the `ThrottleComposition.ActuatorRun5ms` partition after the `ThrottleComposition.ControllerRun5ms` partition.

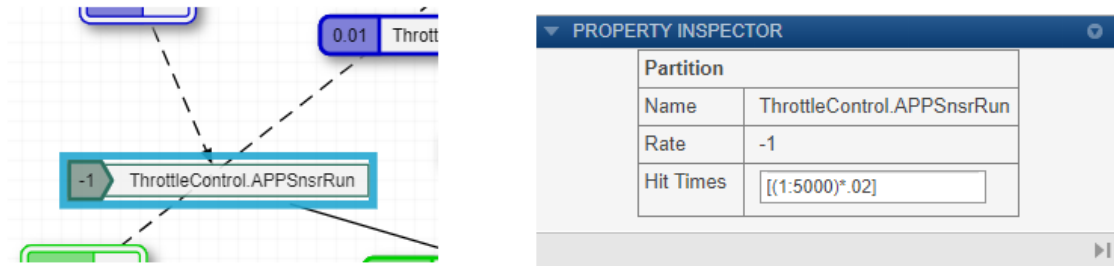

Drag `ThrottleComposition.ActuatorRun5ms` after the `ThrottleComposition.ControllerRun5ms` in the execution order. Observe that the delay between the `ThrottleComposition.ControllerRun5ms` and the `ThrottleComposition.ActuatorRun5ms` partitions changes to a dependency. Observe that now there is no delay between the executions of

ThrottleComposition.ControllerRun5ms and
ThrottleComposition.ActuatorRun5ms.

Schedule the Execution of Aperiodic Partitions

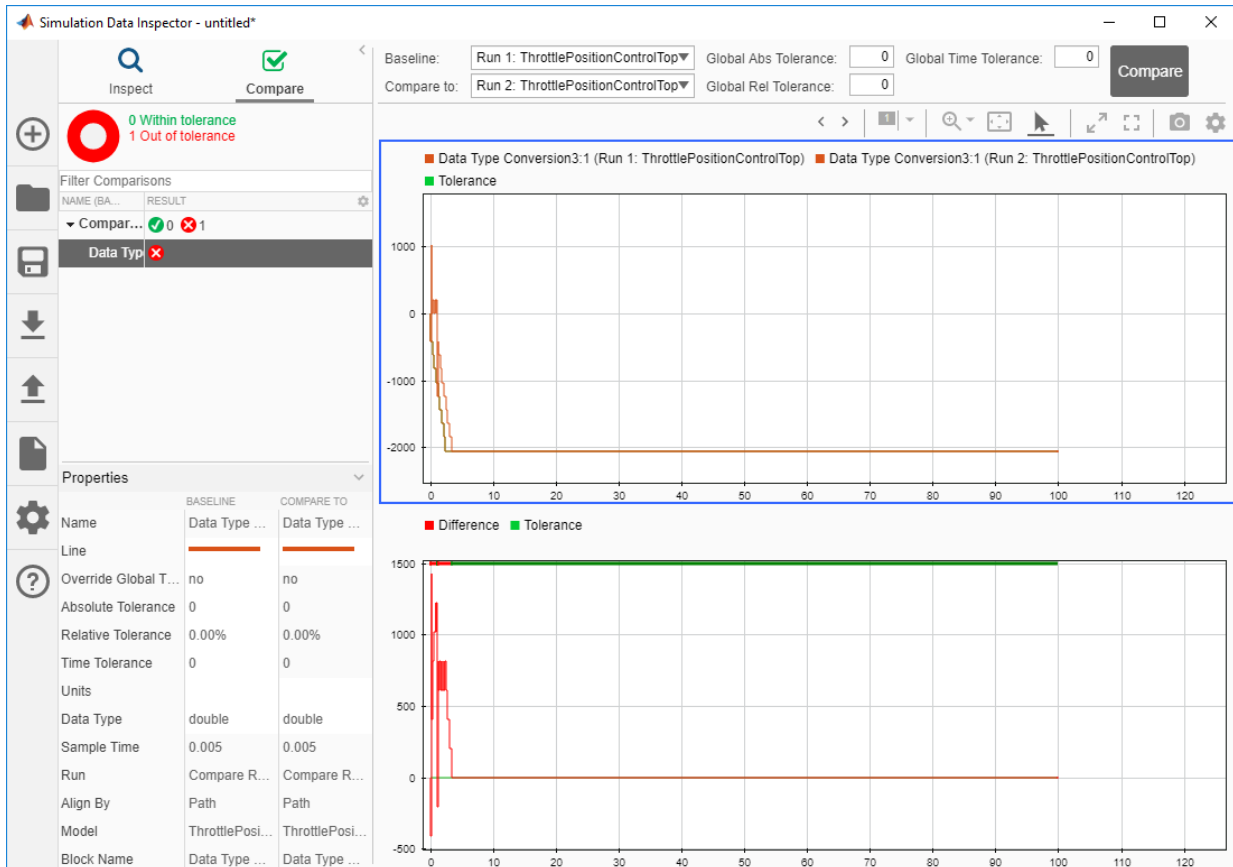

The export-function model contains an unconstrained partition, AccelerationPedalPositionSensor. Suppose you want to schedule an unconstrained partition to simulate as if it were discrete. Schedule AccelerationPedalPositionSensor partition to run at $[0:0.02:100]$ to observe its behavior at different instances of time. Click the unconstrained partition and enter $[(1:5000)*.02]$ for Hit Times in the Property Inspector.

Compare the Runs in Simulation Data Inspector

Now, simulate the model with the changed schedule.

Open the Simulation Data Inspector. Select the two runs and compare. You can see how changing the schedule impacts the model behavior. For more information, see [View Data with the Simulation Data Inspector](#).

Copyright 2018-2019 The MathWorks, Inc.

Schedule a Rate-Based Model Using the Schedule editor

This example shows how to partition a rate-based model using the Schedule Editor. Partitions are the components of the model that can execute independently. In this example, we convert the subsystems into partitions and view and edit their schedule.

With the Schedule Editor, you can easily view and edit the schedule of the partitions. The behavior of the system depends on the execution order of these partitions. In this example, we observe the effects of scheduling this model on the simulation. To see the

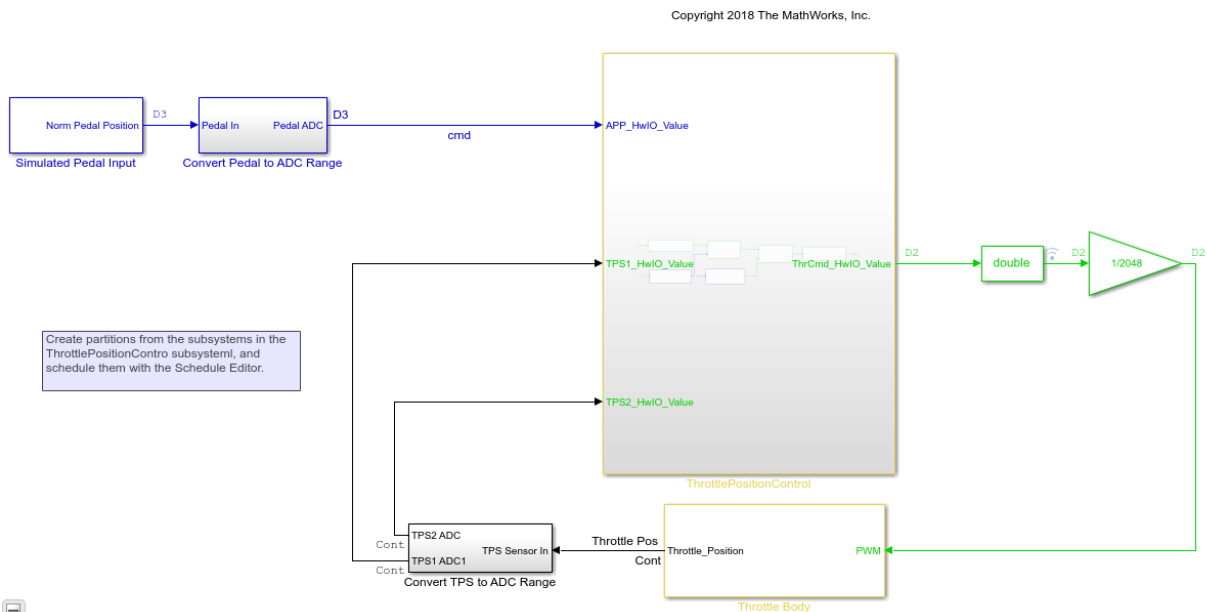

impact of partitioning and scheduling the model, we compare the model simulations before and after creating partitions and scheduling them.

Open the Model and Establish a Simulation Baseline

Open the model of a Throttle Position Control system and simulate it to establish a baseline for comparison

```
open_system('ScheduleEditorWithSubsystemPartitions');
sim('ScheduleEditorWithSubsystemPartitions');
```

Schedule Subsystem Partitions with the Schedule Editor

Open the Schedule Editor and Create Partitions

To open the Schedule Editor, go to **View -> Schedule Editor**. Use **Manage Partitions** to create partitions from the subsystems in your model. Select all the subsystems in ThrottlePositionControl, and click the **Create Partitions** icon on the top of the **Manage Partitions** panel. Specify the names for the partitions and their sample time. Update the diagram to see the partitions in the Schedule Editor.

The arrows are data connections between the partitions that show the data flow. The dashed lines always indicate that there is a delay as the source runs after the destination. The solid lines indicate that there is no delay as the source runs before the destination.

The screenshot shows the SCHEDULE EDITOR interface. The main area displays a graph of partitions and their dependencies. The partitions are represented by colored boxes with their names and sample times. The connections between them are arrows, with solid lines indicating no delay and dashed lines indicating a delay.

The EXECUTION ORDER table is shown on the right side of the interface. It lists the order of execution for each partition at a given time step, along with its name and rate.

Order	Name	Rate
1	Cont	0
2	TPSSecondaryRun5ms	0.005
3	MonitorRun5ms	0.005
4	ControllerRun5ms	0.005
5	ActuatorRun5ms	0.005
6	D2	0.005
7	D3	0.01
8	APPSnsrRun	0.01
9	TPSPPrimaryRun10ms	0.01

The PROPERTY INSPECTOR on the right shows the properties for the selected partition D2:

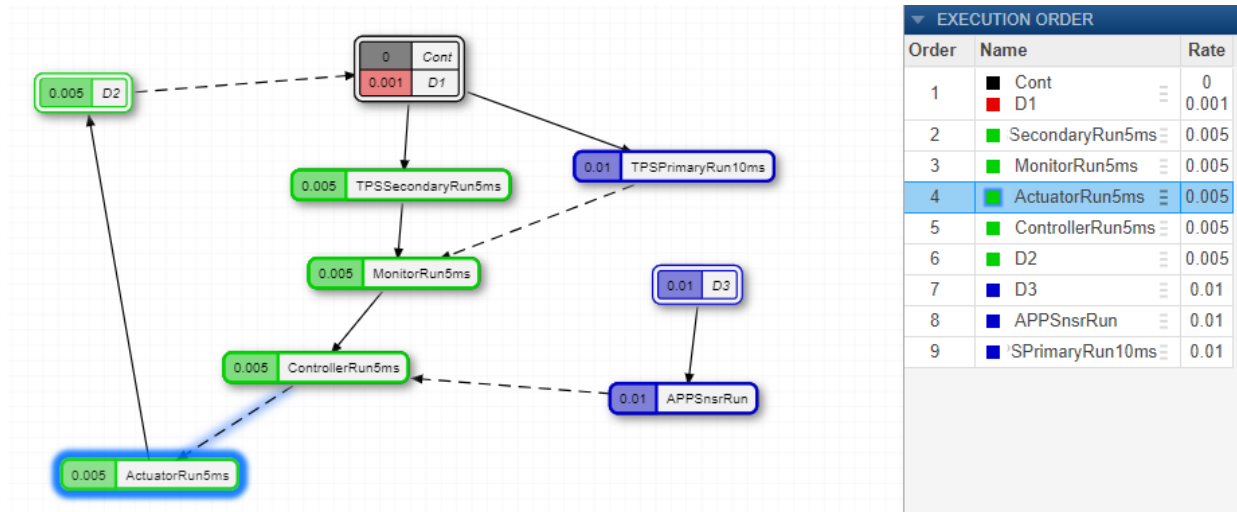

PROPERTY INSPECTOR	
Partition	
Name	D2
Rate	0.005
Type	Implicit periodic partition

The MANAGE PARTITIONS table at the bottom left shows the list of partitions and their sample times:

Block Name	Partition Name	Sample time
Convert Pedal to ADC Range		
Convert TPS to ADC Range		
ThrottlePositionControl		
APPSnsrRun	APPSnsrRun	0.010
ActuatorRun5ms	ActuatorRun5ms	0.005
ControllerRun5ms	ControllerRun5ms	0.005
MonitorRun5ms	MonitorRun5ms	0.005
TPSPPrimaryRun10ms	TPSPPrimaryRun10ms	0.010
TPSSecondaryRun5ms	TPSSecondaryRun5ms	0.005

Edit Partition Schedule

The Execution Order shows the order the partitions run at a given time step. Assume that the execution order of the partitions is in an imperfect state. In this case, you want to run the ActuatorRun5ms partition before the ControllerRun5ms partition. Drag ActuatorRun5ms before the ControllerRun5ms in the execution order. Observe that the dependency between the ControllerRun5ms and the ActuatorRun5ms partitions changes to a delay.

Compare Runs in Simulation Data Inspector

Now, simulate the model with the changed schedule.

Open the Simulation Data Inspector. Select the two runs and compare. You can see how changing the schedule impacts the model behavior. For more information, see View Data with the Simulation Data Inspector.

More About

- “Create Partitions” on page 24-4
- “Generate Code from a Partitioned Model” on page 24-28

Generate Code from a Partitioned Model

Partitioning and scheduling a model has an impact on the order of the function calls in the generated code. Using the Schedule Editor to edit the schedule of a rate-based model or a referenced export-function model, the order of the functions in the generated code depends on the specified schedule in the Schedule Editor. The resulting code shows every partition as an entry point.

Note To use the code generation functionality, Embedded Coder and Simulink Coder are required.

To see the impact of the Schedule Editor on the generated code, use the model that is created in “Create A Rate-Based Model” on page 10-51.

- 1** Open the Schedule Editor from the **View** menu. Use the **Manage Partitions** panel to create partitions for Scheduled Subsystem 1 and Scheduled Subsystem 2 with 0.01 sample time. Update the diagram.
- 2** Change the execution order of the partitions by dragging Scheduled_Subsystem_2 above Scheduled_Subsystem_1.

The screenshot displays the SCHEDULE EDITOR interface. The main workspace shows three blocks on a grid: a red-bordered block labeled '0.01 D1', a blue-bordered block labeled '0.01 Scheduled_Subsystem_2', and a red-bordered block labeled '0.01 Scheduled_Subsystem_1'. The EXECUTION ORDER table on the right lists the execution sequence:

Order	Name	Rate
1	D1	0.01
2	Scheduled_Subsystem_1	0.01
3	Scheduled_Subsystem_2	0.01

The PROPERTY INSPECTOR on the right shows the following details for the selected partition:

Partition	
Name	Scheduled_Subsystem_2
Rate	0.01
Type	Explicit periodic partition

The MANAGE PARTITIONS table at the bottom left shows the following data:

Block Name	Partition Name	Sample time
Scheduled Subsystem 1	Scheduled_Subsystem_1	0.01
Scheduled Subsystem 2	Scheduled_Subsystem_2	0.01

- 3 Generate code for the component model. From the menu, select **Code > C/C++ Code > Build Model**.

In the generated code, the order of the functions depends on the schedule specified in the Schedule Editor.

```

#include "rate_based_model.h"
#include "rate_based_model_private.h"

/* External inputs (root inport signals with default storage) */
ExtU_rate_based_model_T rate_based_model_U;

/* External outputs (root outports fed by signals with default storage) */
ExtY_rate_based_model_T rate_based_model_Y;

/* Real-time model */
RT_MODEL_rate_based_model_T rate_based_model_M;
RT_MODEL_rate_based_model_T *const rate_based_model_M = &rate_based_model_M;

/* Model step function for TID0 */
void rate_based_model_step0(void) /* Sample time: [0.01s, 0.0s] */
{
    /* (no output/update code required) */
}

/* Model step function for TID1 */
void rate_based_model_step1(void) /* Explicit Task: Scheduled_Subsystem_2 */
{
    /* Output: '<Root>/Out2' incorporates:
     * Inport: '<Root>/In2_100ms'
     */
    rate_based_model_Y.Out2 = rate_based_model_U.In2_100ms;
}

/* Model step function for TID2 */
void rate_based_model_step2(void) /* Explicit Task: Scheduled_Subsystem_1 */
{
    /* Output: '<Root>/Out1' incorporates:
     * Inport: '<Root>/In1_10ms'
     */
}

```

24-30

Note Changing the constraints on the connections does impact the generated code. The changes with respect to connections are useful to set preferences about delays and dependencies.

Simulate a Model Interactively

Simulation Basics

You can simulate a model in the Simulink Editor using **Simulation > Run** or the **Run** button  on the toolbar. The **Run** button also appears in tools within the Simulink Editor. You can simulate from any tool that includes the button, such as the Scope viewer.

Before you start a simulation, you can specify options like simulation start time, stop time, and the solver for solving the model. (See “Solver Types” on page 25-6) You specify these options in the Configuration Parameters dialog box, which you can open from the **Simulation** menu or using the **Model Configuration Parameters** button  on the toolbar. These settings are saved with the model in a configuration set. You can create multiple configuration sets for each model and switch between them to see the effects of different settings. See “Configuration Reuse”.

By default, simulations start at 0.0 s and end at 10.0 s.

Note In the Simulink software, time and all related parameters (such as sample times) are implicitly in seconds. If you choose to use a different time unit, scale parameters accordingly.

The **Solver** configuration pane allows you to specify other start and stop times for the currently selected simulation configuration. See “Solver Pane” for more information.

Note Simulation time and actual clock time are not the same. For example, if running a simulation for 10 s usually does not take 10 s as measured on a clock. The amount of time it actually takes to run a simulation depends on many factors including the complexity of the model, the step sizes, and the computer speed.

After you set your model configuration parameters, you can start the simulation. You can pause, resume, and stop simulation using toolbar controls. You can also simulate more than one model at a time, so you can start another simulation while one is running.

During simulation, you cannot make changes to the structure of the model, such as adding or deleting lines or blocks. However, you can make these changes while a simulation is running:

- Modify some configuration parameters, including the stop time and the maximum step size.
- Modify the parameters of a block, as long as you do not cause a change in:
 - Number of states, inputs, or outputs
 - Sample time
 - Number of zero crossings
 - Vector length of any block parameters
 - Length of the internal block work vectors
 - Dimension of any signals

You can also examine the model visually as it simulates. For example, you can click a line to see the signal carried on that line on a Floating Scope or Display block. You can also display port values as a model simulates. See “Display Port Values for Debugging” on page 36-20.

Run, Pause, and Stop a Simulation

To start simulating your model, click the **Run** button . You can pause, resume, or stop a simulation using the corresponding controls on the toolbar.

The model starts simulating at the specified start time and runs until the specified end time. While the simulation is running, information at the bottom of the editor shows the percentage of simulation completed and the current simulation time.

- If an error occurs, simulation stops and a message appears. If a warning condition occurs, simulation completes. In both cases, click the diagnostics link at the bottom of the editor to see the message, which helps you to locate errors.
- Pausing takes effect after the current time step finishes executing. Resuming a paused simulation occurs at the next time step.
- If you stop a simulation, the current time step completes, and then simulation stops.
- If the model outputs to a file or to the workspace, stopping or pausing simulation writes the data.

Use Blocks to Stop or Pause a Simulation

Stop Simulation Using Stop Simulation Blocks

You can use the Stop Simulation block to stop a simulation when the input to the block is nonzero. If the block input is a vector, any nonzero element stops the simulation.

- 1 Add a Stop Simulation block to your model.
- 2 Connect the Stop Simulation block to a signal whose value becomes nonzero at the specified stop time.

For example, this model stops the simulation when the simulation time reaches 10.

Pause Simulation Using Assertion Blocks

You can use an Assertion block to pause the simulation when the input signal to the block is zero. The Assertion block uses the `set_param` command to pause the simulation. See “Run Simulations Programmatically” on page 26-2 for more information on using the `set_param` command to control the execution of a Simulink model.

- 1 Add an Assertion block to your model.
- 2 Connect the Assertion block to a signal whose value becomes zero at the desired pause time.
- 3 In the Assertion block dialog box, clear the **Stop simulation when assertion fails** check box. Enter this command as the value of **Simulation callback when assertion fails**:

```
set_param(bdroot,'SimulationCommand','pause'),  
disp(sprintf('\nSimulation paused.'))
```

This model uses an Assertion block with these settings to pause the simulation when the simulation time reaches 5.

When the simulation pauses, a message appears that shows the time the block paused the simulation.

You can resume the simulation using **Continue** as you can for any paused simulation.

Choose a Solver

In this section...
“Solver Types” on page 25-6
“Compare Solvers” on page 25-7
“Choose a Fixed-Step Solver” on page 25-14
“Choose a Variable-Step Solver” on page 25-18
“Choose a Jacobian Method for an Implicit Solver” on page 25-26

To simulate a dynamic system, you compute its states at successive time steps over a specified time span. This computation uses information provided by a model of the system. Time steps are time intervals when the computation happens. The size of this time interval is called step size. The process of computing the states of a model in this manner is known as solving the model. No single method of solving a model applies to all systems. Simulink provides a set of programs called solvers. Each solver embodies a particular approach to solving a model.

A solver applies a numerical method to solve the set of ordinary differential equations that represent the model. Through this computation, it determines the time of the next simulation step. In the process of solving this initial value problem, the solver also satisfies the accuracy requirements that you specify.

Simulink provides two main types of solvers —fixed-step and variable-step solvers. You can see the solvers under each type in the **Solver** pane of model configuration parameters.

Solver Types

Solvers are broadly classified using these criteria:

- The type of step size used in the computation
 - Fixed-step solvers, as the name suggests, solve the model at fixed step sizes from the beginning to the end of the simulation. You can specify the step size or let the solver choose it. Generally, decreasing the step size increases the accuracy of the results and increases the time required to simulate the system.
 - Variable-step solvers vary the step size during the simulation. They reduce the step size to increase accuracy when the states of a model change rapidly and during

zero-crossing events. They increase the step size to avoid taking unnecessary steps when the states of a model change slowly. Computing the step size adds to the computational overhead at each step. However, it can reduce the total number of steps, and hence the simulation time required to maintain a specified level of accuracy for models with piecewise continuous or rapidly changing states.

- The nature of states in the model
 - Continuous solvers use numerical integration to compute continuous states of a model at the current time step based on the states at previous time steps and the state derivatives. Continuous solvers rely on individual blocks to compute the values of the discrete states of the model at each time step.
 - Discrete solvers are primarily for solving purely discrete models. They compute only the next simulation time step for a model. When they perform this computation, they rely on each block in the model to update its individual discrete state. They do not compute continuous states.

Compare Solvers

When choosing a solver for simulating a model, consider:

- The dynamics of the system
- The stability of the solution
- The speed of computation
- The robustness of the solver

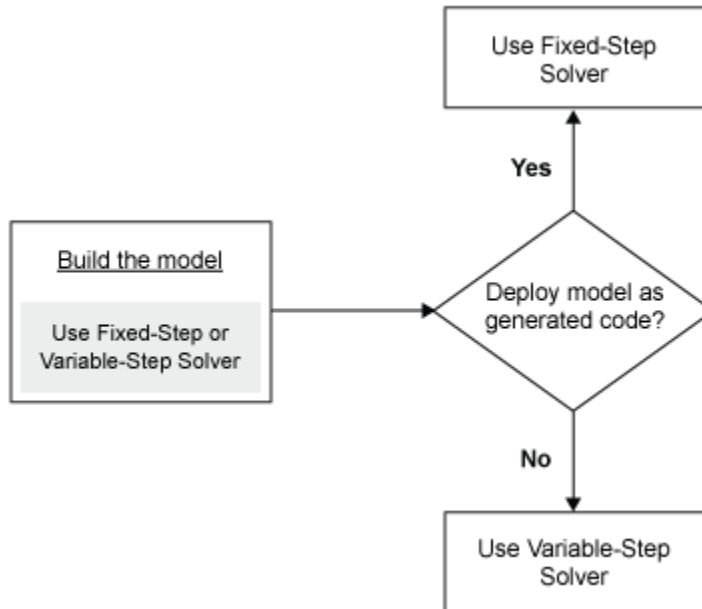

A solver might not completely satisfy all of your requirements, so use an iterative approach when choosing one. Compare simulation results from several solvers and select one that offers the best performance with minimal tradeoffs.

There are two ways to select a solver for your model:

- Use auto solver. New models have their solver selection set to auto solver by default. Auto solver recommends a fixed-step or variable-step solver for your model as well as maximum step size. For more information, see “Use Auto Solver to Select a Solver” on page 25-33
- If you are not satisfied with simulation results using auto solver, select a solver in the **Solver** pane in the model configuration parameters.

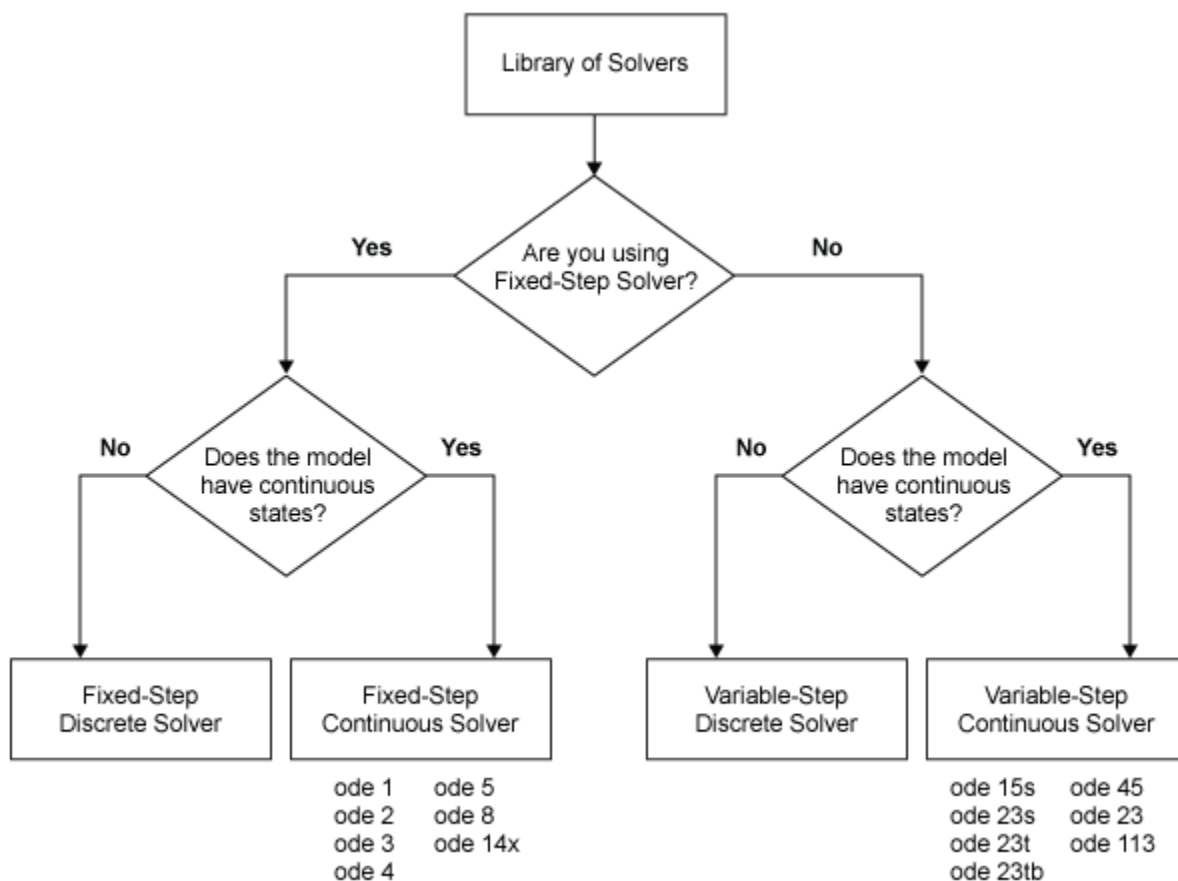

When you build and simulate a model, you can choose the solver based on the dynamics of your model. A variable-step solver is better suited for purely continuous models, like

the dynamics of a mass spring damper system. A fixed-step solver is recommended for a model that contains several switches, like an inverter power system, due to the number of solver resets that would cause a variable-step solver to behave like a fixed-step solver.

When you deploy a model as generated code, you can use only a fixed-step solver. If you select a variable-step solver during simulation, use it to calculate the step size required for the fixed-step solver that you need at deployment.

This chart provides a broad classification of solvers in the Simulink library.

To tailor the selected solver to your model, see “Check and Improve Simulation Accuracy” on page 31-11.

Ideally, the solver you select should:

- Solve the model successfully.
- For variable-step solvers, provide a solution within the tolerance limits you specify.
- Solve the model in a reasonable duration.

A single solver might not meet all of these requirements. Try simulating with several solvers before making a selection.

The Simulink library provides several solvers, all of which can work with the algebraic loop solver. For more information, see “How the Algebraic Loop Solver Works” on page 3-42.

		Discrete	Continuous	Variable-Order
Fixed-Step	Explicit	Not Applicable	“Fixed-Step Continuous Explicit Solvers” on page 25-16	Not Applicable
	Implicit	Not Applicable	“Fixed-Step Continuous Implicit Solvers” on page 25-17	Not Applicable
Variable-Step	Explicit	“Choose a Variable-Step Solver” on page 25-18	“Variable-Step Continuous Explicit Solvers” on page 25-19	“Single-Order Versus Variable-Order Continuous Solvers” on page 25-14
	Implicit		“Variable-Step Continuous Implicit Solvers” on page 25-21	“Single-Order Versus Variable-Order Continuous Solvers” on page 25-14

In the **Solver** pane of model configuration parameters, the Simulink library of solvers is divided into two major types. See “Fixed-Step Versus Variable-Step Solvers” on page 25-10.

You can further categorize the solvers of each type:

- Discrete Versus Continuous Solvers
- Explicit Versus Implicit Continuous Solvers
- One Step Versus Multistep Continuous Solvers
- Single Order Versus Variable Order Continuous Solvers

Fixed-Step Versus Variable-Step Solvers

Fixed-step and variable-step solvers compute the next simulation time as the sum of the current simulation time and the step size. The **Type** control on the **Solver** configuration pane allows you to select the type of solver. With a fixed-step solver, the step size remains constant throughout the simulation. With a variable-step solver, the step size can vary from step to step, depending on the model dynamics. In particular, a variable-step solver increases or reduces the step size to meet the error tolerances that you specify.

The choice between these types depends on how you plan to deploy your model and the model dynamics. If you plan to generate code from your model and run the code on a real-time computer system, choose a fixed-step solver to simulate the model. You cannot map the variable-step size to the real-time clock.

If you do not plan to deploy your model as generated code, the choice between a variable-step and a fixed-step solver depends on the dynamics of your model. A variable-step solver might shorten the simulation time of your model significantly. A variable-step solver allows this saving because, for a given level of accuracy, the solver can dynamically adjust the step size as necessary. This approach reduces the number of steps required. The fixed-step solver must use a single step size throughout the simulation, based on the accuracy requirements. To satisfy these requirements throughout the simulation, the fixed-step solver typically requires a small step.

The `ex_multirate` shows how a variable-step solver can shorten simulation time for a multirate discrete model.

The model generates outputs at two different rates: every 0.5 s and every 0.75 s. To capture both outputs, the fixed-step solver must take a time step every 0.25 s (the *fundamental sample time* for the model).

```
[0.0 0.25 0.5 0.75 1.0 1.25 1.5 ...]
```

By contrast, the variable-step solver has to take a step only when the model generates an output.

```
[0.0 0.5 0.75 1.0 1.5 ...]
```

This scheme significantly reduces the number of time steps required to simulate the model.

Discrete Versus Continuous Solvers

When you select a solver type, you can also select a specific solver. Both sets of solvers include two types: discrete and continuous. Discrete and continuous solvers rely on the model blocks to compute the values of any discrete states. Blocks that define discrete states are responsible for computing the values of those states at each time step. However, unlike discrete solvers, continuous solvers use numerical integration to compute the continuous states that the blocks define. When choosing a solver, determine first whether to use a discrete solver or a continuous solver.

If your model has no continuous states, then Simulink switches to either the fixed-step discrete solver or the variable-step discrete solver. If your model has only continuous states or a mix of continuous and discrete states, choose a continuous solver from the remaining solver choices based on the dynamics of your model. Otherwise, an error occurs.

The solver library contains two discrete solvers—a fixed-step discrete solver and a variable-step discrete solver. The fixed-step solver by default chooses a step size and simulation rate fast enough to track state changes in the fastest block in your model. The variable-step solver adjusts the simulation step size to keep pace with the actual rate of discrete state changes in your model. This adjustment can avoid unnecessary steps and shorten simulation time for multirate models (see “Sample Times in Systems” on page 7-28 for more information.)

Note The fixed-step discrete solvers do not solve for discrete states. Each block calculates its discrete states independently of the solver.

Explicit Versus Implicit Continuous Solvers

You represent an explicit system by the system of equation

$$\dot{x} = f(x)$$

For any given value of x , you can compute \dot{x} by substituting x in $f(x)$ and evaluating the equation.

Equations of the form

$$F(\dot{x}, x) = 0$$

are considered to be implicit. For any given value of x , you must solve this equation to calculate \dot{x} .

A linearly implicit system can be represented by the equation

$$M(x) \cdot \dot{x} = f(x)$$

$M(x)$ is called the mass matrix and $f(x)$ is the forcing function. A system becomes linearly implicit when you use physical modeling blocks in the model.

While you can apply an implicit or explicit continuous solver to solve all these systems, implicit solvers are designed specifically for solving stiff problems. Explicit solvers solve nonstiff problems. An ordinary differential equation problem is said to be stiff if the desired solution varies slowly, but there are closer solutions that vary rapidly. The numerical method must then take small time steps to solve the system. Stiffness is an efficiency issue. The more stiff a system, the longer it takes for the explicit solver to perform a computation. A stiff system has both slowly and quickly varying continuous dynamics.

When compared to explicit solvers, implicit solvers provide greater stability for oscillatory behavior. However, implicit solvers are also computationally more expensive. They generate the Jacobian matrix and solve the set of algebraic equations at every time step using a Newton-like method. To reduce this extra cost, the implicit solvers offer a `Solver Jacobian` method parameter that allows you to improve the simulation performance of implicit solvers. See “Choose a Jacobian Method for an Implicit Solver” on page 25-26 for more information. Implicit solvers are more efficient than explicit solvers for solving a linearly implicit system.

One-Step Versus Multistep Continuous Solvers

The Simulink solver library provides both one-step and multistep solvers. The one-step solvers estimate $Y(t_n)$ using the solution at the immediately preceding time point, $Y(t_{n-1})$, and the values of the derivative at multiple points between t_n and t_{n-1} . These points are minor steps.

Multistep solvers use the results at several preceding time steps to compute the current solution. Simulink provides one explicit multistep solver, `ode113`, and one implicit multistep solver, `ode15s`. Both are variable-step solvers.

Single-Order Versus Variable-Order Continuous Solvers

This distinction is based on the number of orders that the solver uses to solve the system of equation. Two variable-order solvers, `ode15s` and `ode113`, are part of the solver library. They use multiple orders to solve the system of equations. Specifically, the implicit, variable-step `ode15s` solver uses first-order through fifth-order equations, while the explicit, variable-step `ode113` solver uses first-order through thirteenth-order equations. For `ode15s`, you can limit the highest order applied via the `Maximum Order` parameter. For more information, see “Maximum Order” on page 25-22.

Choose a Fixed-Step Solver

Fixed-Step Discrete Solver

The fixed-step discrete solver computes the time of the next simulation step by adding a fixed step size to the current time. The accuracy and the length of time of the resulting simulation depends on the size of the steps taken by the simulation: the smaller the step size, the more accurate the results are but the longer the simulation takes. By default, Simulink chooses the step size or you can choose the step size yourself. If you choose the default setting of `auto`, and if the model has discrete sample times, then Simulink sets the step size to the fundamental sample time of the model. Otherwise, if no discrete rates exist, Simulink sets the size to the result of dividing the difference between the simulation start and stop times by 50.

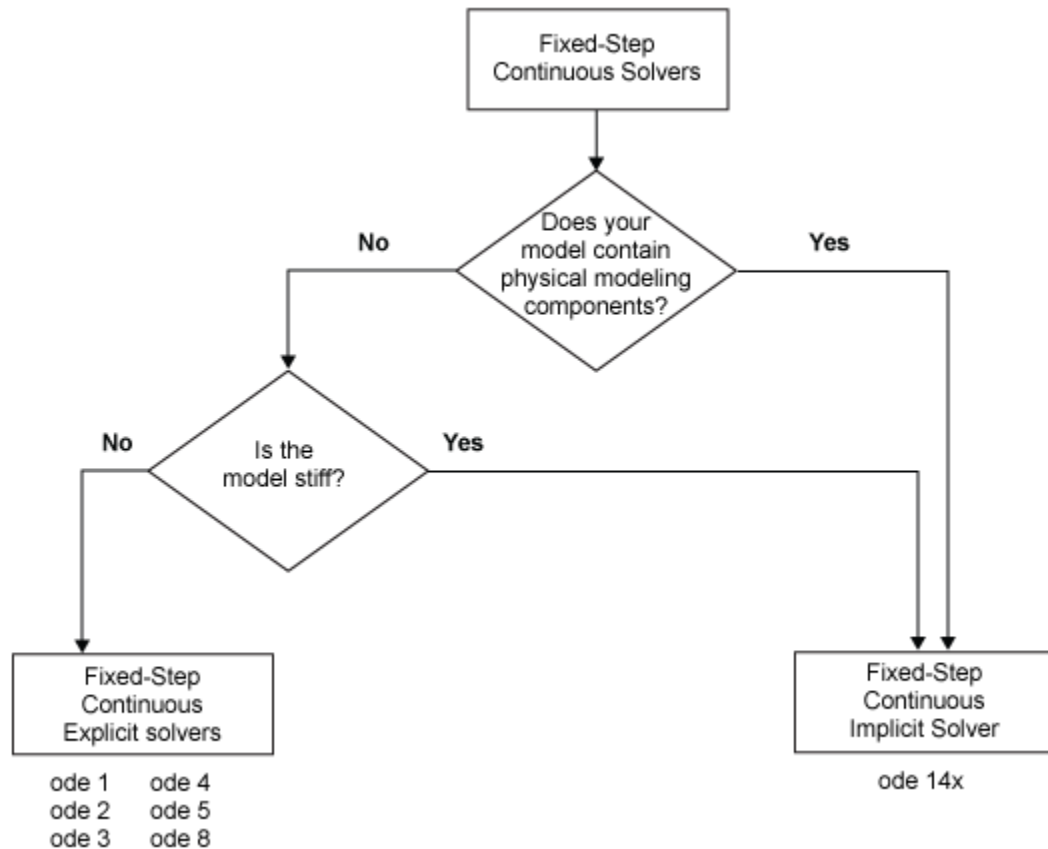

Note If you try to use the fixed-step discrete solver to update or simulate a model that has continuous states, an error message appears. Thus, selecting a fixed-step solver and then updating or simulating a model is a quick way to determine whether the model has continuous states.

Fixed-Step Continuous Solvers

The fixed-step continuous solvers, like the fixed-step discrete solver, compute the next simulation time by adding a fixed-size time step to the current time. For each of these steps, the continuous solvers use numerical integration to compute the values of the continuous states for the model. These values are calculated using the continuous states at the previous time step and the state derivatives at intermediate points (minor steps) between the current and the previous time step.

Note Simulink uses the fixed-step discrete solver for a model that contains no states or only discrete states, even if you specify a fixed-step continuous solver for the model.

Simulink provides two types of fixed-step continuous solvers — explicit and implicit.

The difference between these two types lies in the speed and the stability. An implicit solver requires more computation per step than an explicit solver but is more stable. Therefore, the implicit fixed-step solver that Simulink provides is more adept at solving a stiff system than the fixed-step explicit solvers. For more information, see "Explicit Versus Implicit Continuous Solvers" on page 25-12.

Fixed-Step Continuous Explicit Solvers

Explicit solvers compute the value of a state at the next time step as an explicit function of the current values of both the state and the state derivative. A fixed-step explicit solver is expressed mathematically as:

$$x(n + 1) = x(n) + h * Dx(n)$$

where x is the state, Dx is a solver-dependent function that estimates the state derivative, h is the step size, and n indicates the current time step.

Simulink provides a set of fixed-step continuous explicit solvers. The solvers differ in the specific numerical integration technique that they use to compute the state derivatives of the model. This table lists each solver and the integration technique it uses. The table lists the solvers in order of the computational complexity of the integration methods they use, from the least complex (ode1) to the most complex (ode8).

Solver	Integration Technique	Order of Accuracy
ode1	Euler's Method	First
ode2	Heun's Method	Second
ode3	Bogacki-Shampine Formula	Third
ode4	Fourth-Order Runge-Kutta (RK4) Formula	Fourth
ode5	Dormand-Prince (RK5) Formula	Fifth
ode8	Dormand-Prince RK8(7) Formula	Eighth

None of these solvers has an error control mechanism. Therefore, the accuracy and the duration of a simulation depend directly on the size of the steps taken by the solver. As you decrease the step size, the results become more accurate, but the simulation takes longer. Also, for any given step size, the higher the order of the solver, the more accurate the simulation results.

If you specify a fixed-step solver type for a model, then by default, Simulink selects the FixedStepAuto solver. Auto solver then selects an appropriate fixed-step solver that can handle both continuous and discrete states with moderate computational effort. As with the discrete solver, if the model has discrete rates (sample times), then Simulink sets the step size to the fundamental sample time of the model by default. If the model has no discrete rates, Simulink automatically uses the result of dividing the simulation total duration by 50. Consequently, the solver takes a step at each simulation time at which

Simulink must update the discrete states of the model at its specified sample rates. However, it does not guarantee that the default solver accurately computes the continuous states of a model. Therefore, you may need to choose another solver, a different fixed step size, or both to achieve acceptable accuracy and an acceptable simulation time.

Fixed-Step Continuous Implicit Solvers

An implicit solver computes the state at the next time step as an implicit function of the state at the current time step and the state derivative at the next time step. In other words:

$$x(n + 1) - x(n) - h * Dx(n + 1) = 0$$

Simulink provides one fixed-step implicit solver: `ode14x`. This solver uses a combination of Newton's method and extrapolation from the current value to compute the value of a state at the next time step. You can specify the number of Newton's method iterations and the extrapolation order that the solver uses to compute the next value of a model state (see "Fixed-step size (fundamental sample time)"). The more iterations and the higher the extrapolation order that you select, the greater the accuracy you obtain. However, you simultaneously create a greater computational burden per step size.

How to Choose a Fixed-Step Continuous Solver

Any of the fixed-step continuous solvers in the Simulink product can simulate a model to any desired level of accuracy, given a small enough step size. Unfortunately, it is not possible or practical to decide without trial, the combination of solver and step size that will yield acceptable results for the continuous states in the shortest time. Determining the best solver for a particular model generally requires experimentation.

To select a fixed-step continuous solver,

- 1 Choose error tolerances. For more information, see "Error Tolerances for Variable-Step Solvers" on page 25-24.
- 2 Use one of the variable-step solvers to simulate your model to the level of accuracy that you want. Start with `ode45`. If your model runs slowly, your problem may be stiff and need an implicit solver. The results of this step give a good approximation of the correct simulation results and the appropriate fixed step size.
- 3 Use `ode1` to simulate your model at the default step size for your model. Compare the simulation results for `ode1` with the simulation for the variable-step solver. If the results are the same for the specified level of accuracy, you have found the best fixed-

step solver for your model, namely `ode1`. You arrive at this conclusion because `ode1` is the simplest of the fixed-step solvers and hence yields the shortest simulation time for the current step size.

- 4 If `ode1` does not give satisfactory results, repeat the preceding steps with the other fixed-step solvers until you find one that gives accurate results with the least computational effort. The most efficient way to perform this task is to use a binary search technique:
 - a Try `ode3`.
 - b If `ode3` gives accurate results, try `ode2`. If `ode2` gives accurate results, it is the best solver for your model; otherwise, `ode3` is the best.
 - c If `ode3` does not give accurate results, try `ode5`. If `ode5` gives accurate results, try `ode4`. If `ode4` gives accurate results, select it as the solver for your model; otherwise, select `ode5`.
 - d If `ode5` does not give accurate results, reduce the simulation step size and repeat the preceding process. Continue in this way until you find a solver that solves your model accurately with the least computational effort.

Choose a Variable-Step Solver

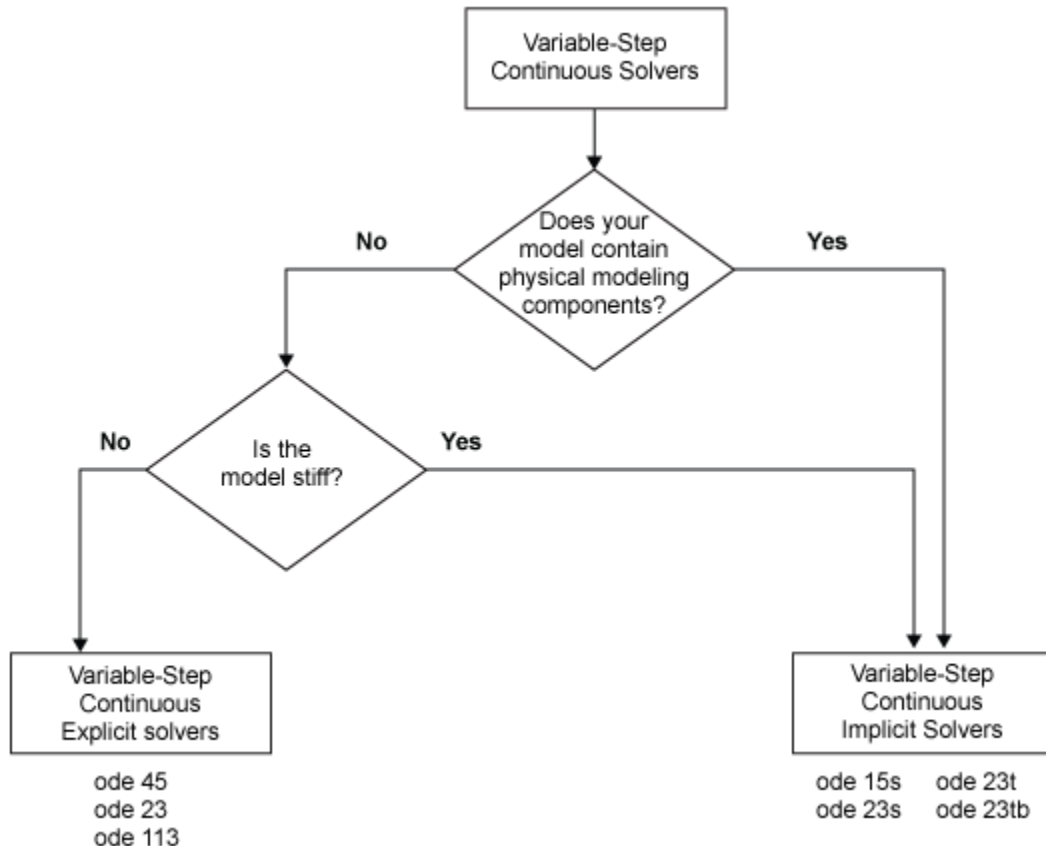

When you set the **Type** control of the **Solver** configuration pane to **Variable-step**, the **Solver** control allows you to choose one of the variable-step solvers. As with fixed-step solvers, the set of variable-step solvers comprises a discrete solver and a subset of continuous solvers. However, unlike the fixed-step solvers, the step size varies dynamically based on the local error.

The choice between the two types of variable-step solvers depends on whether the blocks in your model define states and, if so, the type of states that they define. If your model defines no states or defines only discrete states, select the discrete solver. If a model has no states or only discrete states, Simulink uses the discrete solver to simulate the model even if you specify a continuous solver. If the model has continuous states, the continuous solvers use numerical integration to compute the values of the continuous states at the next time step.

Variable-Step Continuous Solvers

Variable-step solvers dynamically vary the step size during the simulation. Each of these solvers increases or reduces the step size using its local error control to achieve the tolerances that you specify. Computing the step size at each time step adds to the

computational overhead. However, it can reduce the total number of steps, and the simulation time required to maintain a specified level of accuracy.

You can further categorize the variable-step continuous solvers as: one-step or multistep, single-order or variable-order, and explicit or implicit. (See "Compare Solvers" on page 25-7 for more information.)

Variable-Step Continuous Explicit Solvers

The variable-step explicit solvers are designed for nonstiff problems. Simulink provides four such solvers:

- ode45
- ode23
- ode113
- odeN

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Method
ode45	X		Medium	Runge-Kutta, Dormand-Prince (4,5) pair
ode23	X		Low	Runge-Kutta (2,3) pair of Bogacki & Shampine
ode113		X	Variable, Low to High	PECE Implementation of Adams-Bashforth-Moulton
odeN	X		Refer to Order of Accuracy in “Fixed-Step Continuous Explicit Solvers” on page 25-16	Refer to Integration Technique in “Fixed-Step Continuous Explicit Solvers” on page 25-16

ODE Solver	Tips on When to Use
ode45	<p>In general, the ode45 solver is the best to apply as a first try for most problems. This Runge-Kutta (4,5) solver is a fifth-order method that performs a fourth-order estimate of the error. This solver also uses a fourth-order “free” interpolant, which allows for event location and smoother plots.</p> <p>If the ode45 is computationally slow, your problem may be stiff and thus in need of an implicit solver.</p>
ode23	<p>The ode23 can be more efficient than the ode45 solver at crude error tolerances and in the presence of mild stiffness. This solver provides accurate solutions for “free” by applying a cubic Hermite interpolation to the values and slopes computed at the ends of a step.</p>

ODE Solver	Tips on When to Use
ode113	For problems with stringent error tolerances or for computationally intensive problems, the Adams-Bashforth-Moulton PECE solver can be more efficient than ode45.
odeN	The odeN solver uses a nonadaptive Runge-Kutta integration whose order is determined by the Solver order parameter. odeN uses a fixed step size determined by the Max step size parameter, but the step size can be reduced to capture certain solver events, such as zero-crossings and discrete sample hits..

Note A good heuristic for choosing the odeN solver when simulation speed is important:

- The model contains lots of zero-crossings and/or solver resets
- The **Solver Profiler** does not detect any failed steps when profiling the model

Variable-Step Continuous Implicit Solvers

If your problem is stiff, try using one of the variable-step implicit solvers:

- ode15s
- ode23s
- ode23t
- ode23tb

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Solver Reset Method	Max. Order	Method
ode15s		X	Variable, Low to Medium	X	X	Numerical Differentiation Formulas (NDFs)
ode23s	X		Low			Second-order, modified Rosenbrock formula

ODE Solver	One-Step Method	Multistep Method	Order of Accuracy	Solver Reset Method	Max. Order	Method
ode23t	X		Low	X		Trapezoidal rule using a “free” interpolant
ode23tb	X		Low	X		TR-BDF2

Solver Reset Method

For three of the solvers for stiff problems — `ode15s`, `ode23t`, and `ode23tb`— a drop-down menu for the **Solver reset method** appears on the **Solver details** section of the Configuration pane. This parameter controls how the solver treats a reset caused, for example, by a zero-crossing detection. The options allowed are **Fast** and **Robust**. **Fast** specifies that the solver does not recompute the Jacobian for a solver reset, whereas **Robust** specifies that the solver does. Consequently, the **Fast** setting is computationally faster but it may use a small step size in certain cases. To test for such cases, run the simulation with each setting and compare the results. If there is no difference in the results, you can safely use the **Fast** setting and save time. If the results differ significantly, try reducing the step size for the fast simulation.

Maximum Order

For the `ode15s` solver, you can choose the maximum order of the numerical differentiation formulas (NDFs) that the solver applies. Since the `ode15s` uses first-through fifth-order formulas, the **Maximum order** parameter allows you to choose 1 through 5. For a stiff problem, you may want to start with order 2.

Tips for Choosing a Variable-Step Implicit Solver

The following table provides tips relating to the application of variable-step implicit solvers. For an example comparing the behavior of these solvers, see `sldemo_solvers`.

ODE Solver	Tips on When to Use
ode15s	ode15s is a variable-order solver based on the numerical differentiation formulas (NDFs). NDFs are related to, but are more efficient than the backward differentiation formulas (BDFs), which are also known as Gear's method. The ode15s solver numerically generates the Jacobian matrices. If you suspect that a problem is stiff, or if ode45 failed or was highly inefficient, try ode15s. As a rule, start by limiting the maximum order of the NDFs to 2.
ode23s	ode23s is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it can be more efficient than ode15s at crude tolerances. Like ode15s, ode23s numerically generates the Jacobian matrix for you. However, it can solve certain kinds of stiff problems for which ode15s is not effective.
ode23t	The ode23t solver is an implementation of the trapezoidal rule using a "free" interpolant. Use this solver if your model is only moderately stiff and you need a solution without numerical damping. (Energy is not dissipated when you model oscillatory motion.)
ode23tb	ode23tb is an implementation of TR-BDF2, an implicit Runge-Kutta formula with two stages. The first stage is a trapezoidal rule step while the second stage uses a backward differentiation formula of order 2. By construction, the method uses the same iteration matrix in evaluating both stages. Like ode23s, this solver can be more efficient than ode15s at crude tolerances.

Note For a *stiff* problem, solutions can change on a time scale that is very small as compared to the interval of integration, while the solution of interest changes on a much longer time scale. Methods that are not designed for stiff problems are ineffective on intervals where the solution changes slowly because these methods use time steps small enough to resolve the fastest possible change. For more information, see Shampine, L. F., *Numerical Solution of Ordinary Differential Equations*, Chapman & Hall, 1994.

Support for Zero-Crossing Detection

The variable-step discrete and continuous solvers use zero-crossing detection (see "Zero-Crossing Detection" on page 3-24) to handle continuous signals.

Error Tolerances for Variable-Step Solvers

Local Error

The variable-step solvers use standard control techniques to monitor the local error at each time step. During each time step, the solvers compute the state values at the end of the step and determine the *local error*—the estimated error of these state values. They then compare the local error to the *acceptable error*, which is a function of both the relative tolerance (*rtol*) and the absolute tolerance (*atol*). If the local error is greater than the acceptable error for *any one* state, the solver reduces the step size and tries again.

- The *Relative tolerance* measures the error relative to the size of each state. The relative tolerance represents a percentage of the state value. The default, 1e-3, means that the computed state is accurate to within 0.1%.
- *Absolute tolerance* is a threshold error value. This tolerance represents the acceptable error as the value of the measured state approaches zero.

The solvers require the error for the *i*th state, e_i , to satisfy:

$$e_i \leq \max(\text{rtol} \times |x_i|, \text{atol}_i).$$

The following figure shows a plot of a state and the regions in which the relative tolerance and the absolute tolerance determine the acceptable error.

Absolute Tolerances

Your model has a global absolute tolerance that you can set on the Solver pane of the Configuration Parameters dialog box. This tolerance applies to all states in the model. You can specify *auto* or a real scalar. If you specify *auto* (the default), Simulink initially sets the absolute tolerance for each state based on the relative tolerance. If the relative tolerance is larger 1e-3, *abstol* is initialized at 1e-6. However, for *reltol* smaller than 1e-3, *abstol* for the state is initialized at $\text{reltol} * 1e-3$. As the simulation progresses,

the absolute tolerance for each state resets to the maximum value that the state has assumed so far, times the relative tolerance for that state. Thus, if a state changes from 0 to 1 and `reltol` is $1e-3$, `abstol` initializes at $1e-6$ and by the end of the simulation reaches $1e-3$ also. If a state goes from 0 to 1000, then `abstol` changes to 1.

Now, if the state changes from 0 to 1 and `reltol` is set at $1e-4$, then `abstol` initializes at $1e-7$ and by the end of the simulation reaches a value of $1e-4$.

If the computed initial value for the absolute tolerance is not suitable, you can determine an appropriate value yourself. You might have to run a simulation more than once to determine an appropriate value for the absolute tolerance. You can also specify if the absolute tolerance should adapt similar to its `auto` setting by enabling or disabling the `AutoScaleAbsTol` parameter. For more information, see “Auto scale absolute tolerance”.

Several blocks allow you to specify absolute tolerance values for solving the model states that they compute or that determine their output:

- Integrator
- Second-Order Integrator
- Variable Transport Delay
- Transfer Fcn
- State-Space
- Zero-Pole

The absolute tolerance values that you specify for these blocks override the global settings in the Configuration Parameters dialog box. You might want to override the global setting if, for example, the global setting does not provide sufficient error control for all of your model states because they vary widely in magnitude. You can set the block absolute tolerance to:

- `auto`
- `-1` (same as `auto`)
- `positive scalar`
- `real vector` (having a dimension equal to the number of corresponding continuous states in the block)

Tips

If you do choose to set the absolute tolerance, keep in mind that too low of a value causes the solver to take too many steps in the vicinity of near-zero state values. As a result, the simulation is slower.

On the other hand, if you set the absolute tolerance too high, your results can be inaccurate as one or more continuous states in your model approach zero.

Once the simulation is complete, you can verify the accuracy of your results by reducing the absolute tolerance and running the simulation again. If the results of these two simulations are satisfactorily close, then you can feel confident about their accuracy.

Choose a Jacobian Method for an Implicit Solver**The Solver Jacobian**

For implicit solvers, Simulink must compute the *solver Jacobian*, which is a submatrix of the Jacobian matrix associated with the continuous representation of a Simulink model. In general, this continuous representation is of the form:

$$\begin{aligned}\dot{x} &= f(x, t, u) \\ y &= g(x, t, u).\end{aligned}$$

The Jacobian, J , formed from this system of equations is:

$$J = \begin{pmatrix} \frac{\partial f}{\partial x} & \frac{\partial f}{\partial u} \\ \frac{\partial g}{\partial x} & \frac{\partial g}{\partial u} \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix}.$$

In turn, the solver Jacobian is the submatrix, J_x .

$$J_x = A = \frac{\partial f}{\partial x}.$$

Sparsity of Jacobian

For many physical systems, the solver Jacobian J_x is *sparse*, meaning that many of the elements of J_x are zero.

Consider the following system of equations:

$$\dot{x}_1 = f_1(x_1, x_3)$$

$$\dot{x}_2 = f_2(x_2)$$

$$\dot{x}_3 = f_3(x_2).$$

From this system, you can derive a sparsity pattern that reflects the structure of the equations. The pattern, a Boolean matrix, has a 1 for each x_i that appears explicitly on the right-hand side of an equation. Therefore, you attain:

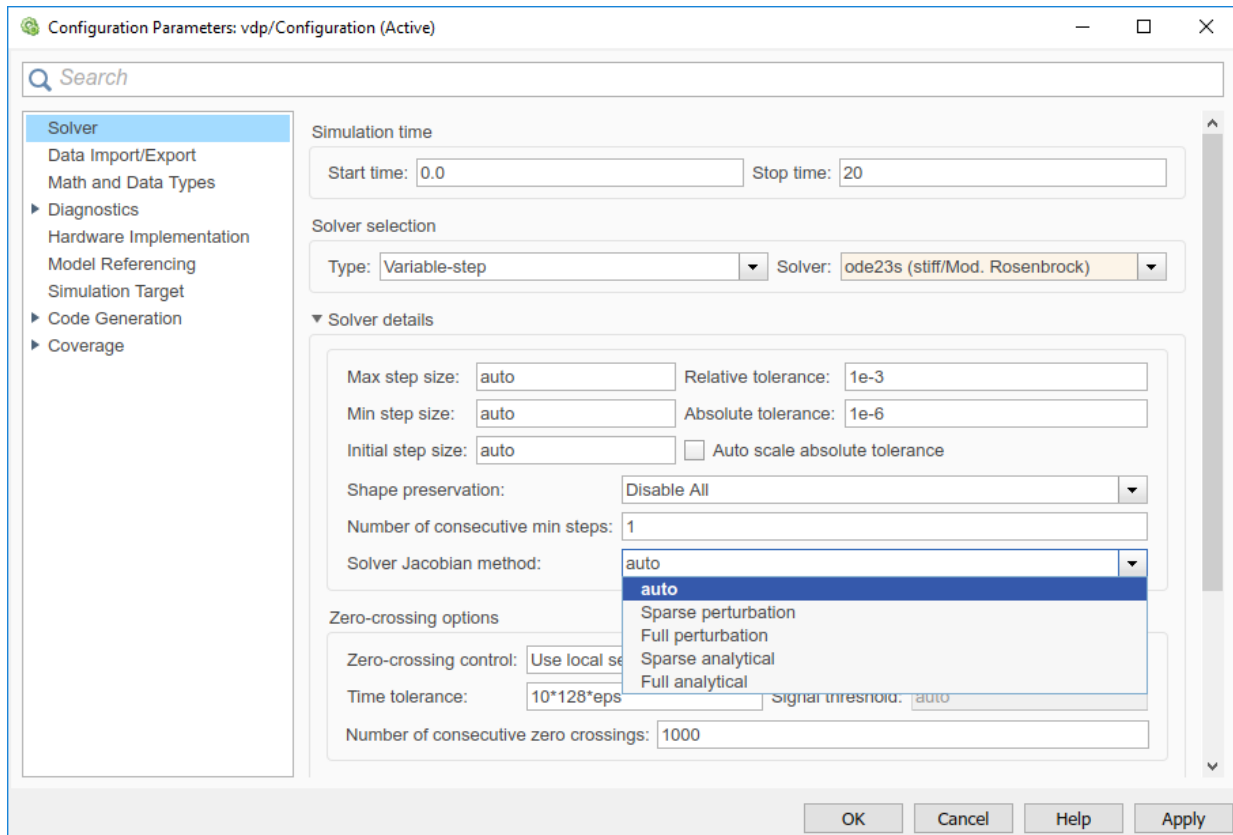

$$J_{x, pattern} = \begin{pmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

As discussed in “Full and Sparse Perturbation Methods” on page 25-30 and “Full and Sparse Analytical Methods” on page 25-31 respectively, the Sparse Perturbation Method and the Sparse Analytical Method may be able to take advantage of this sparsity pattern to reduce the number of computations necessary and improve performance.

Solver Jacobian Methods

When you choose an implicit solver from the **Solver** pane of the configuration parameters dialog box, a parameter called **Solver Jacobian method** and a drop-down menu appear. This menu has five options for computing the solver Jacobian:

- **auto**
- **Sparse perturbation**
- **Full perturbation**
- **Sparse analytical**
- **Full analytical**

Note If you set **Automatic solver parameter selection** to error in the Solver Diagnostics pane, and you choose a different solver method than Simulink, you may receive an error.

Limitations

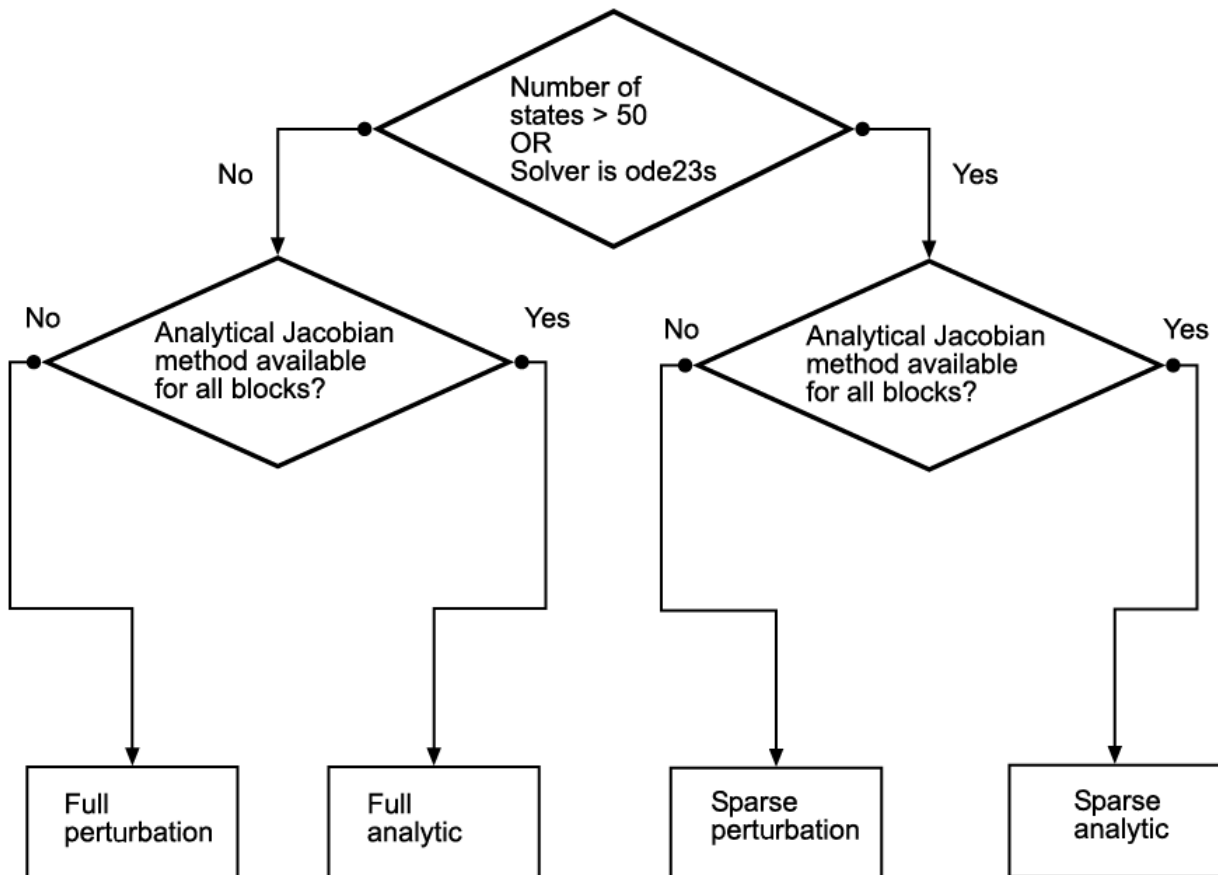

The solver Jacobian methods have the following limitations associated with them.

- If you select an analytical Jacobian method, but one or more blocks in the model do not have an analytical Jacobian, then Simulink applies a perturbation method.

- If you select sparse perturbation and your model contains data store blocks, Simulink applies the full perturbation method.

Heuristic 'auto' Method

The default setting for the Solver Jacobian method is auto. Selecting this choice causes Simulink to perform a heuristic to determine which of the remaining four methods best suits your model. This algorithm is depicted in the following flow chart.

Because sparse methods are beneficial for models having a large number of states, if 50 or more states exist in your model, the heuristic chooses a sparse method. The logic also leads to a sparse method if you specify ode23s because, unlike other implicit solvers,

ode23s generates a new Jacobian at every time step. A sparse analytical or a sparse perturbation method is, therefore, highly advantageous. The heuristic also ensures that the analytical methods are used only if every block in your model can generate an analytical Jacobian.

Full and Sparse Perturbation Methods

The full perturbation method was the standard numerical method that Simulink used to solve a system. For this method, Simulink solves the full set of perturbation equations and uses LAPACK for linear algebraic operations. This method is costly from a computational standpoint, but it remains the recommended method for establishing baseline results.

The sparse perturbation method attempts to improve the run-time performance by taking mathematical advantage of the sparse Jacobian pattern. Returning to the sample system of three equations and three states,

$$\dot{x}_1 = f_1(x_1, x_3)$$

$$\dot{x}_2 = f_2(x_2)$$

$$\dot{x}_3 = f_3(x_2).$$

The solver Jacobian is:

$$J_x = \begin{pmatrix} \frac{\partial f_1}{\partial x_1} & \frac{\partial f_1}{\partial x_2} & \frac{\partial f_1}{\partial x_3} \\ \frac{\partial f_2}{\partial x_1} & \frac{\partial f_2}{\partial x_2} & \frac{\partial f_2}{\partial x_3} \\ \frac{\partial f_3}{\partial x_1} & \frac{\partial f_3}{\partial x_2} & \frac{\partial f_3}{\partial x_3} \end{pmatrix}$$

$$= \begin{pmatrix} \frac{f_1(x_1 + \Delta x_1, x_2, x_3) - f_1}{\Delta x_1} & \frac{f_1(x_1, x_2 + \Delta x_2, x_3) - f_1}{\Delta x_2} & \frac{f_1(x_1, x_2, x_3 + \Delta x_3) - f_1}{\Delta x_3} \\ \frac{f_2(x_1 + \Delta x_1, x_2, x_3) - f_2}{\Delta x_1} & \frac{f_2(x_1, x_2 + \Delta x_2, x_3) - f_2}{\Delta x_2} & \frac{f_2(x_1, x_2, x_3 + \Delta x_3) - f_2}{\Delta x_3} \\ \frac{f_3(x_1 + \Delta x_1, x_2, x_3) - f_3}{\Delta x_1} & \frac{f_3(x_1, x_2 + \Delta x_2, x_3) - f_3}{\Delta x_2} & \frac{f_3(x_1, x_2, x_3 + \Delta x_3) - f_3}{\Delta x_3} \end{pmatrix}$$

It is, therefore, necessary to perturb each of the three states three times and to evaluate the derivative function three times. For a system with n states, this method perturbs the states n times.

By applying the sparsity pattern and perturbing states x_1 and x_2 together, this matrix reduces to:

$$J_x = \begin{pmatrix} \frac{f_1(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_1}{\Delta x_1} & 0 & \frac{f_1(x_1, x_2, x_3 + \Delta x_3) - f_1}{\Delta x_3} \\ 0 & \frac{f_2(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_2}{\Delta x_2} & 0 \\ 0 & \frac{f_3(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3) - f_3}{\Delta x_2} & 0 \end{pmatrix}$$

The solver can now solve columns 1 and 2 in one sweep. While the sparse perturbation method saves significant computation, it also adds overhead to compilation. It might even slow down the simulation if the system does not have a large number of continuous states. A tipping point exists for which you obtain increased performance by applying this method. In general, systems having a large number of continuous states are usually sparse and benefit from the sparse method.

The sparse perturbation method, like the sparse analytical method, uses UMFPACK to perform linear algebraic operations. Also, the sparse perturbation method supports both RSim and Rapid Accelerator mode.

Full and Sparse Analytical Methods

The full and sparse analytical methods attempt to improve performance by calculating the Jacobian using analytical equations rather than the perturbation equations. The sparse analytical method, also uses the sparsity information to accelerate the linear algebraic operations required to solve the ordinary differential equations.

Sparsity Pattern

For details on how to access and interpret the sparsity pattern in MATLAB, see `sldemo_metro`.

Support for Code Generation

While the sparse perturbation method supports RSim, the sparse analytical method does not. Consequently, regardless of which sparse method you select, any generated code uses the sparse perturbation method. This limitation applies to Rapid Accelerator mode as well.

Use Auto Solver to Select a Solver

In this section...

“Use Auto Solver with vdp Model” on page 25-33

“Auto Solver Heuristics” on page 25-34

When you want Simulink to select a solver for simulating the model, use auto solver. Auto solver chooses a suitable solver and sets the maximum step size of the simulation.

For new models, Simulink selects auto solver and sets the type to variable-step by default. For an existing model, you can use auto solver to select a solver.

Use Auto Solver with vdp Model

- 1 Open vdp and click the solver link in the lower-right corner. The **Solver information** pane opens.

- 2 In the pane, click the **View solver settings** button  to open the **Solver** pane of the model configuration parameters.
- 3 Under **Solver selection**, set **Type** to fixed or variable-step according to your preference and set **Solver** to auto.
- 4 When you simulate the model, auto solver selects a fixed-step or variable-step solver according to your preference and calculates the maximum step size it recommends. To see the results, open the **Solver information** pane.

- 5 Click the **Accept suggested settings** button  to apply the recommendations of auto solver. To select different settings, click the **View solver settings** button and make changes in the configuration parameters **Solver** pane.

Auto Solver Heuristics

This chart describes the heuristics of auto solver.

Auto Solver Heuristics

The system has The solver type is		Only discrete states	Continuous states	
			The system is an ordinary differential equation (ODE)	The system has differential algebraic equations (DAE)
Fixed-Step	FixedStepDiscrete		ode3	ode14x
			ode15s	ode45
Variable-Step	VariableStepDiscrete			ode23t

- For Simscape Electrical models, auto solver selects ode23tb. These systems can have circuits with nonlinear models, especially circuit breakers and power electronics. Such nonlinear models require a stiff solver.
- If the number of continuous states in the model exceeds the NumStatesForStiffnessChecking value, auto solver uses ode15s. It does not calculate the stiffness of the model. The default value for this parameter is 1000. You can change this value using set_param.
- If the number of continuous states in the model is less than the NumStatesForStiffnessChecking value, auto solver calculates the stiffness of the model. A model is stiff if the stiffness exceeds the StiffnessThreshold value. The default value for this parameter is 1000. You can change this value using set_param.

Save and Restore Simulation Operating Point

In this section...
“Benefits of Using Operating Point” on page 25-37
“Save an Operating Point” on page 25-38
“Restore Operating Point” on page 25-39

Note In R2019a, the `SimState` object was renamed to `ModelOperatingPoint`.

To effectively design a system, you simulate a model iteratively, so you can analyze the system based on different inputs, boundary conditions, or operating conditions. In many applications, when performing multiple simulations, a startup phase with significant dynamic behavior is common. For example, the cold start takeoff of a gas turbine engine occurs before each set of aircraft maneuvers. In multiple simulations, you ideally:

- 1 Simulate the startup phase once.
- 2 Save the simulation snapshot at the end of the startup phase.
- 3 Use this snapshot as the initial state for each set of conditions or maneuvers.

Use the `ModelOperatingPoint` object to save the snapshot of a simulation. Once you save the snapshot, in future simulations, restore the `ModelOperatingPoint` object and use it to set initial conditions.

The `ModelOperatingPoint` object contains information about:

- Logged states
- State of the solver and execution engine
- Zero-crossing signals for blocks that register zero crossings
- Output values of certain blocks in the model

Simulink analyzes block connections and other information to determine whether it is using the output values effectively as state information.

The `ModelOperatingPoint` object also stores the hidden states of these blocks:

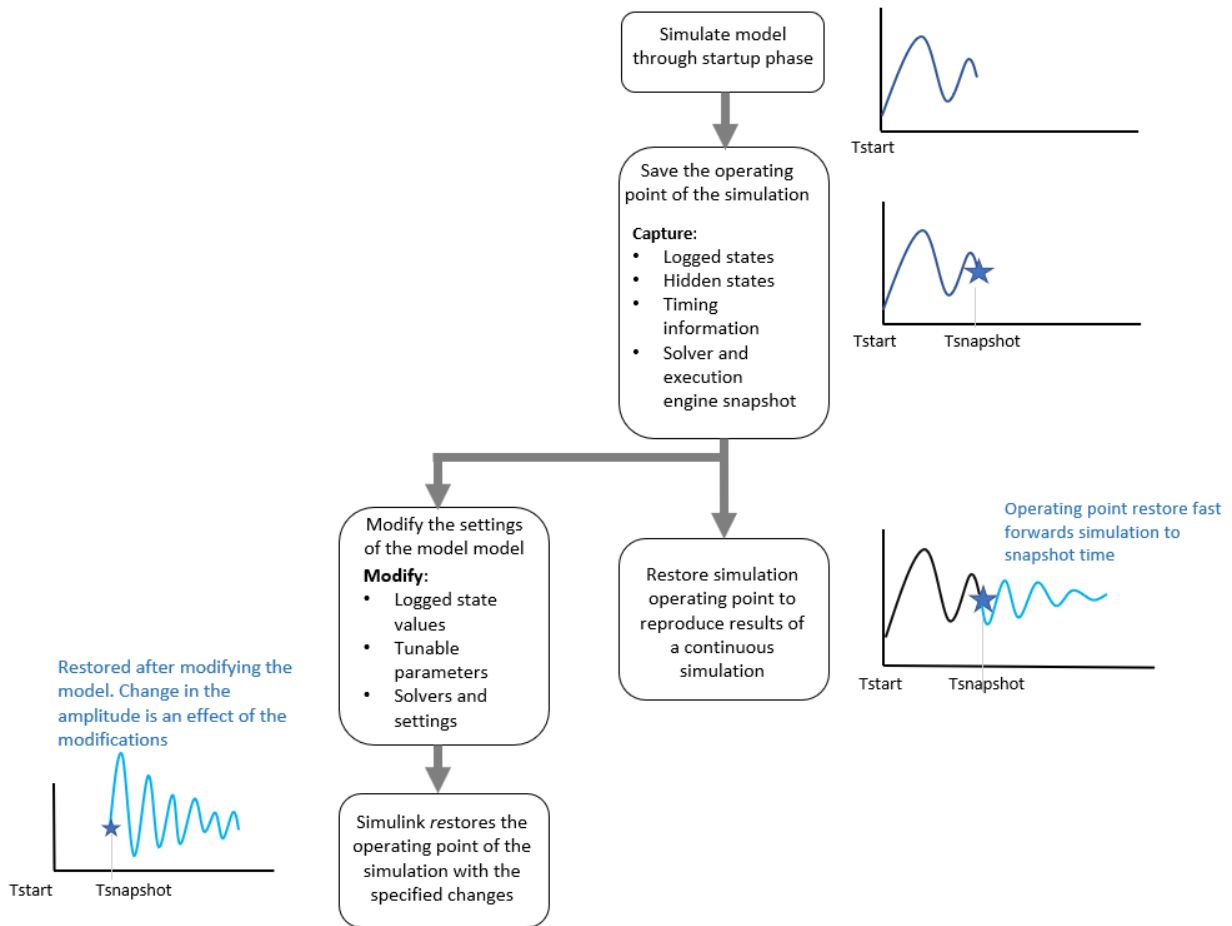

- Transport Delay

- Variable Transport Delay
- From Workspace
- For Each subsystem
- Conditionally executed subsystems
- Stateflow
- MATLAB System
- Simscape Multibody Second Generation

By storing this information, the `ModelOperatingPoint` object ensures that the result of a simulation that starts from the operating point is the same as a simulation that runs from the beginning.

Benefits of Using Operating Point

- When the `ModelOperatingPoint` object saves the snapshot of a simulation, it saves information in addition to the logged states in the model. Restore all of this information to ensure that the simulation matches the uninterrupted simulation. For example, if solver information affected the simulation, then changing the state of a block without using `ModelOperatingPoint` can produce different results.
- You can save several operating points during a simulation, then resume the simulation from any of those operating points.
- The `ModelOperatingPoint` object restores the state of blocks that are typically difficult to restore to a particular state, for example, the Transport delay block. The state of the Transport Delay block is not saved in the structure format or the array format when you log data using the **Final states** configuration parameter.

You can also use the **Final states** option in the Configuration Parameters **Data Import/Export** pane to save a simulation state. However, this option saves only *logged* states—the continuous and discrete states of blocks. These states are only subsets of the complete simulation state of the model. They do not include information about hidden states of blocks, which required for the proper execution of a block.

Save an Operating Point

Save an operating point at the beginning of the final step using one of these options:

- At the final **Stop time**.
- When you interrupt a simulation with the **Pause** or **Stop** button. You can also save an operating point when you pause a simulation using `get_param('modelName', 'CurrentOperatingPoint')`.
- When you use `set_param` or a block, like the Stop block, to stop a simulation.

Interactive Save

- 1 In the Configuration Parameters dialog box, in the **Data Import/Export** pane, select the **Final states** check box. The **Save final Operating Point** check box becomes available.
- 2 Select the **Save final Operating Point** check box.
- 3 In the **Final states** text box, enter a variable name for the `ModelOperatingPoint` object.
- 4 Simulate the model.

Programmatic Save

Use the `sim` command with `set_param`. Set the `SaveOperatingPoint` parameter to `'on'`.

```
fuelsys
set_param('fuelsys', 'SaveFinalState', 'on', 'FinalStateName', ...
'myOperPoint', 'SaveOperatingPoint', 'on');
simOut = sim('fuelsys', 'StopTime', '10')
myoperPoint = simOut.myOperPoint
```

Tip Before you save the operating point, disable the **Block Reduction** parameter in **Configuration Settings > Simulation Target > Advanced Parameters**.

Restore Operating Point

Restore the simulation snapshot using the `ModelOperatingPoint` object after modifying the model. The **Start time** does not change from the value in the simulation that generated the operating point. It is a reference value for all time and time-dependent variables in both the original and the current simulation. For example, a block can save and restore the number of sample time hits that occurred since the beginning of simulation as its `ModelOperatingPoint` object.

Consider a model that you ran from 0 to 100 s and that you now want to run from 100 to 200 s. The **Start time** is 0 s for both the original simulation and for the current simulation. The initial time of the current simulation is 100 s. Also, if the block had 10 sample time hits during the original simulation, Simulink recognizes that the next sample time hit is the 11th, relative to 0, not 100 s.

Note If you change the **Start time** before restoring the `ModelOperatingPoint`, Simulink overwrites the **Start time** with the value saved in the `ModelOperatingPoint`.

Interactive Restore

- 1 In the Configuration Parameters dialog box, in the **Data Import/Export** pane, under **Load from workspace**, select the **Initial state** check box. The text box becomes available.
- 2 Enter the name of the variable containing the `ModelOperatingPoint` in the text box.
- 3 Set the **Stop time** to a value greater than the time at which the operating point was saved.

Programmatic Restore

To configure simulation to restore the operating point that you saved in the example above:

```
set_param('fuelsys','LoadInitialState','on','InitialState',...
'myOperPoint');
myOperPoint = simOut.myOperPoint
```

The `ModelOperatingPoint` object is restored when you simulate the model.

Restore from Different Simulink Versions

You can use `ModelOperatingPoint` objects saved in releases starting with R2010a to restore the `ModelOperatingPoint` of a model. However, this option restores only the logged states of the model. To see the version of Simulink used to save the `ModelOperatingPoint`, examine the **version** parameter of the `ModelOperatingPoint` object.

Simulink detects if the `ModelOperatingPoint` object you provided as the initial state was saved in the current release. By default, Simulink displays an error message if the

`ModelOperatingPoint` was not saved in the current release. You can configure the diagnostic to allow Simulink to display the message as a warning and try to restore as many of the values as possible. To enable this best-effort restoration, in the Configuration Parameters dialog box set the message for **Operating Point object from earlier release** to warning. Previously named `SimState` objects are loaded as `ModelOperatingPoint` objects in 19a.

See Also

More About

- “Operating Point Behavior” on page 25-42

Operating Point Behavior

Learn how you can use operating point with a block, S-functions and model changes.

Change the States of a Block Within Operating Point

- Use `loggedStates` to get or set the states of blocks. If `xout` is the state log that Simulink exports to the workspace, then the `loggedStates` field has the same structure as `xout.signals`.
- You cannot change the states that are not logged. Simulink does not allow this modification as it could cause the state to be inconsistent with the simulation.

S-Functions

You can use APIs for C-MEX and Level-2 MATLAB S-functions to enable S-functions to work with the `ModelOperatingPoint` object. For information on how to implement these APIs within S-functions, see “S-Function Compliance with the `ModelOperatingPoint`”.

S-functions that have `PWork` vectors, which store pointers to data structures but do not declare their operating point compliance level or declare it to be unknown or disallowed do not support operating point. For more information, see “S-Function Compliance with the `ModelOperatingPoint`”.

Model Changes and Operating Point Restore

After saving the operating point of a model, you can change the model and restore an operating point with those changes

- You can rename a model between saving and restoring its operating point.
- The operating point interface checksum is primarily based on the configuration settings in a model and sample times used in the model. You can make some nonstructural changes to the model between saving and restoring an operating point. In the Configuration Parameters dialog box, in the **Diagnostics** pane, use the **Operating point interface checksum mismatch** diagnostic to track such changes. You can then find out if the interface checksum of the restored operating point matches the current interface checksum. See “Operating point interface checksum mismatch”.

You can make the following nonstructural changes to the model without affecting your ability to restore a previously saved operating point:

- Changes to model-level signal logging settings in the “Model Configuration Parameters: Data Import/Export”.
- Logging of specific signals.
- Addition and removal of Scope, Floating Scope and Scope Viewer, To Workspace, To File, and Display blocks.
- Addition and removal of Level-2 MATLAB or C S-Functions that are configured as simulation viewing devices and do not set the operating point compliance to Custom or Disallowed. See “S-Function Compliance with the ModelOperatingPoint” for more information.

Note These modifications may change the number of sample times in the model. This can cause the model's interface checksum to be different from the operating point save and restore checksum. Configure the **Operating point interface checksum mismatch diagnostic** to display a warning (default), error, or none to not compare the checksums.

- You cannot make structural changes to the model between the time you save the operating point and the time you restore the simulation using the operating point. Examples include, adding or removing a block after saving the operating point, changing the sample time of a model, and changing the type of solver from variable-step to fixed-step.
- Mismatches can occur when you try to simulate using a solver that is different from the one that generated the saved operating point. Simulink permits solver changes. For example, you can use the `ode15s` solver to solve the initial stiff portion of a simulation and save the final operating point. You can then continue the simulation with the restored operating point using `ode45`. In other words, this diagnostic helps you see the solver changes but does not signal a problem with the simulation.

Note When you use a variable-step solver with the maximum step size set to `auto`, Simulink uses the maximum step size from the restored `ModelOperatingPoint` object for the new simulation. To ensure that the concatenated operating point trajectory of two simulations matches that of an uninterrupted simulation, specify a value for the maximum step size.

Limitations of Saving and Restoring Operating Point

Note In some cases, saving partial state information avoids some of the limitations of using operating point. For a comparison of the two ways to save state data, see “Comparison of Operating Point and Final State Logging” on page 64-288.

Block Support

The following blocks do not support operating point:

- In the Stack and Queue blocks, the default setting for the **Push full stack** option is **Dynamic reallocation**. This default setting does not support `ModelOperatingPoint` object. Other settings (**Ignore**, **Warning** and **Error**) support `ModelOperatingPoint` object.
- Simscape Multibody First Generation blocks

Simulink tries to save the output of a block as part of an operating point. For S-functions, this happens even if the functions declare that no operating point is required. If the block output is of custom type, Simulink cannot save the operating point and displays an error. For more information about operating point use with S-functions, see “S-Functions” on page 25-42.

Model reference offers partial support for operating point. For details, see “Model Referencing” on page 25-45.

Simulation

- You can use only the normal or the accelerator simulation mode.
- You cannot save operating point in normal mode and restore it in accelerator mode, or vice versa.
- You cannot change the states of certain blocks that are not logged. For more information, see “Change the States of a Block Within Operating Point” on page 25-42.

Code Generation

The operating point feature does not support Simulink Coder or Embedded Coder code generation.

Model Referencing

- You cannot modify logged states of blocks that are inside a referenced model in accelerator mode.
- The following blocks do not support operating point when included in a model referenced in accelerator mode:
 - Level 2 MATLAB S-Function
 - MATLAB System
 - n-D Lookup Table
 - S-Function (with custom operating point or PWork vectors)
 - To File
 - Simscape blocks

For additional information, see “State Information for Referenced Models” on page 64-291.

Model Function

You cannot input the operating point to the model function.

- “Save and Restore Simulation Operating Point” on page 25-36

View Diagnostics

You can view and diagnose errors and warnings generated by your model using the **Diagnostic Viewer**. The **Diagnostic Viewer** displays three types of diagnostic messages: errors, warnings, and information. A model generates these messages during a runtime operation, like model load, simulation, or update diagram.

The diagnostic viewer window is divided into:

- **Toolbar menu:** Displays various commands to help you manage the diagnostic messages. For more information, see “Toolbar” on page 25-47.
- **Diagnostic Message pane:** Displays the error, warning, and information messages. For more information, see “Diagnostic Message Pane” on page 25-47.
- **Suggested Actions:** Displays suggestions and fixes to correct the diagnostic errors and warnings. For more information, see “Suggested Actions” on page 25-51.

Toolbar

To manage the diagnostic messages, use the **Diagnostic Viewer** toolbar.

Button	Action
	Expand or collapse messages
	Save all or latest messages in a log file
	Copy all or latest messages
	Clear all or all but latest messages
	Filter out errors, warning, and information messages
	Group similar type of messages
	Search messages for specific keywords and navigate between messages
	Set maximum number of models to display in tabbed panes and the maximum number of events to display per model

Diagnostic Message Pane

The diagnostic message pane displays the error, warning, and information messages in a tabbed format. These messages are color-coded for distinction and are hierarchical.

A new stage is generated for each successive event, you can save or clear stage. Each stage represents a single event such as model load, update diagram, or simulation.

Different types of diagnostic messages are:

- Information message: Displays the information related to a model load. Information messages are marked as .
- High priority warning: Displays the errors encountered during model load as a high priority warning. Any subsequent operation, like update on the model without

rectifying the high priority warning messages are marked as errors. High priority warnings are marked as .

- Warning: Displays the warnings associated during an operation on a model. Warnings are marked as .
- Error: Displays the errors associated during an operation on a model. Errors are marked as .

Tip To locate the source of error, click the hyperlink in the message. The source of error in the model is highlighted.

Trace Diagnostics Location

Diagnostic Viewer can trace the location of an error so that you can investigate the errors in your model easily. If the error is in a file that is being called from another file, the diagnostics shows up as an expandable stack. You can expand or collapse the stack, as required. Expanding the stack displays information about the file and the line in which the error or warning is located. You can click any of the links to go the error or warning.

Note Tracing the exact location of an error is not applicable for protected files.

Identify Diagnostics from Custom Compilers

Diagnostic viewer can recognize errors and warnings from builds generated by custom compilers. You can specify compiler-specific patterns using the following directives:

```
% Here tool is the buildtool obtained from the toolchain
tool.setDirective ('WarningPattern', 'warning #(\d+):'); %Specifies warning patterns
tool.setDirective ('ErrorPattern', 'error:'); %Specifies error pattern
tool.setDirective ('FileNamePattern', '[^\\s]*\\w+\\. (c|h)'); %Specifies file name pattern
tool.setDirective ('LineNumberPattern', '\\(\\d+\\)'); %Specifies line number pattern
```

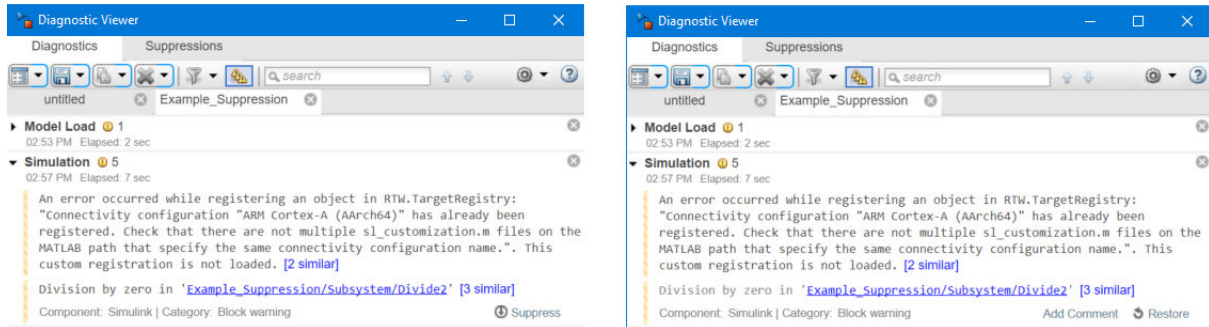

For more information, see the section Create a ToolchainInfo Object in the topic “Register Custom Toolchain and Build Executable” (Simulink Coder).

Suppress Diagnostics

The Diagnostic Viewer provides a **Suppress** button for certain diagnostics. This button allows you to suppress certain numerical diagnostics (for example, overflow, saturation, precision loss) for specific objects in your model. You can also suppress certain errors that have diagnostic level set to error in the **Diagnostics** section of Model Configuration Parameters. You can add a comment for the suppressed diagnostics.

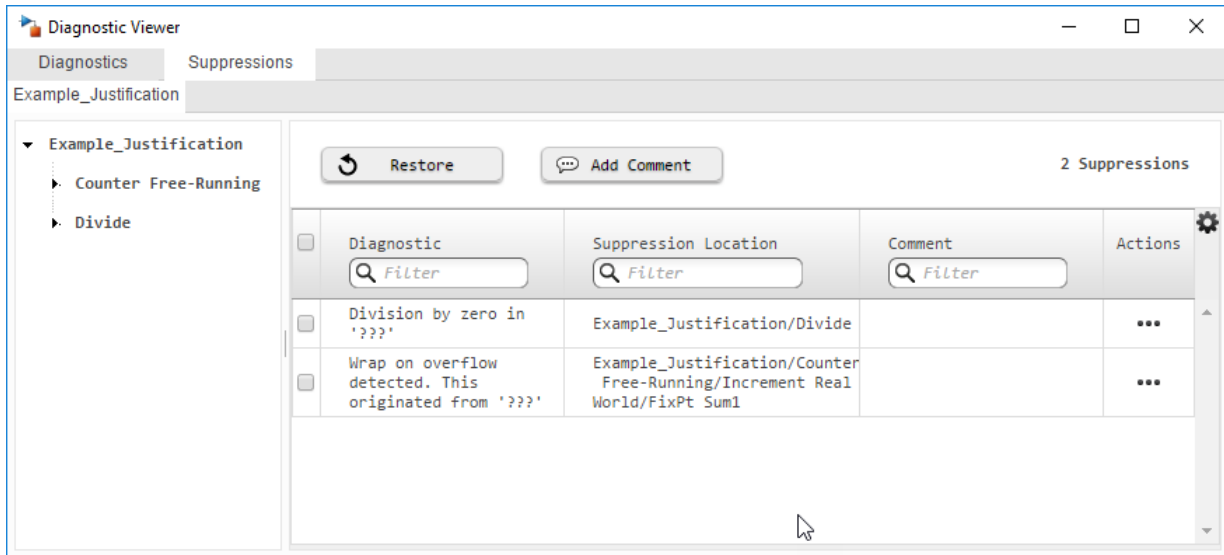

To suppress the diagnostic from the specified source, click the **Suppress** button next to the diagnostic in the Diagnostic Viewer. You can restore the diagnostic from the source by

clicking **Restore**. Diagnostic suppressions are saved with the model and persist across sessions.

The suppressed diagnostics are displayed in the **Suppressions** tab. You can restore the suppressed diagnostics, add or edit comments to the suppressed diagnostic by using the **Restore** and **Add Comment** buttons respectively. Alternatively, you can perform these actions on the suppressed diagnostic by selecting one of the options from the **Actions** menu.

The **Suppression** tab of the Diagnostic Viewer displays the model name in the left pane of the suppressed diagnostics in the right pane in a tabular format. You can use the filter options available in the **Diagnostic**, **Suppression Location**, and the **Comment** columns to filter the diagnostics.

You can move the suppressed diagnostics from block level to subsystem level. You can also control the suppression of diagnostics from the command line. For more information, see “Suppress Diagnostic Messages Programmatically” on page 25-59.

Suggested Actions

Diagnostic viewer provides suggestions and fixes for diagnostic error and warning messages. These suggestions and fixes are provided in the **Suggested Actions** section of diagnostic message pane.

A diagnostic error or warning can have multiple fixes and suggestions. Each fix is associated with a **Fix** button.

You can click the **Fix** button for the most suitable fix to rectify the error automatically. In some cases, you can provide the fix by one of these ways:

- Enter the values in the available edit boxes.
- Select a value from one of the listed values from a combo box.

The **Fix** buttons for a diagnostic error or warning are no longer available after a fix is successfully applied. If a fix was unsuccessful, a failure message is displayed in the **Suggested Actions** section.

Suggestions are provided for errors and warnings that cannot be fixed automatically.

Note The **Suggested Actions** section is available only for the diagnostic errors or warnings that have a predefined fix.

Related Examples

- “Systematic Diagnosis of Errors and Warnings” on page 25-54
- “Customize Diagnostic Messages” on page 25-68
- “Report Diagnostic Messages Programmatically” on page 25-71

Systematic Diagnosis of Errors and Warnings

This example shows how to use the Diagnostic Viewer to identify and locate simulation errors and warnings systematically.

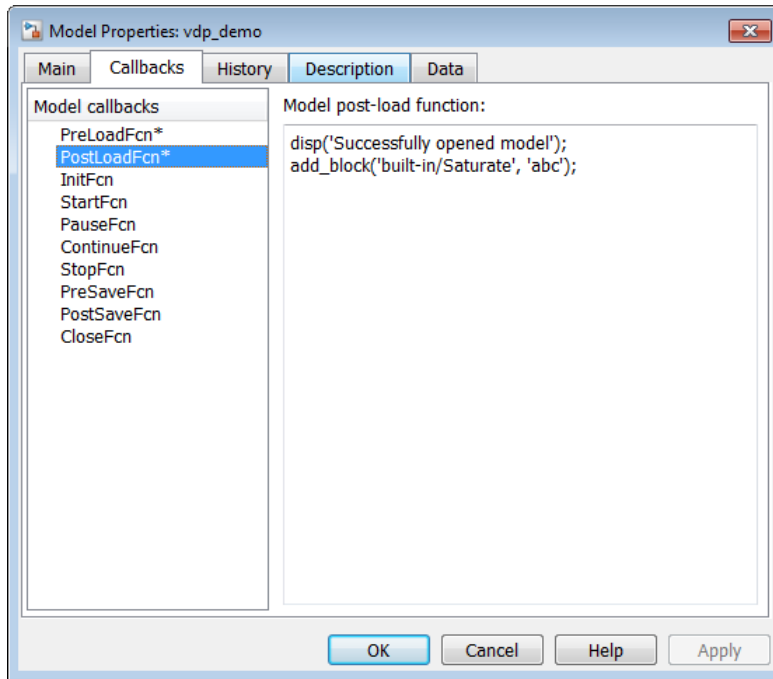

- 1 Open your model.

If your model contains errors related to callback functions, the **Diagnostic Viewer** opens and displays the following errors in **Model Load** stage.

Tip To open the **Diagnostic Viewer** window, click **View > Diagnostic Viewer** or click the view errors or warnings link displayed at the bottom of the Simulink Editor window.

- 2 In the Simulink Editor, click **File > Model Properties > Model Properties**, and examine the callback error.

- 3 After fixing any callback errors, simulate the model to diagnose simulation errors and warnings.

Diagnostic Viewer lists errors and warnings in stages. Each stage in **Diagnostic Viewer** represents a single event such as model load, update diagram, simulation, or build.

- 4 Filter out warnings by clicking  so that you can address errors first.
- 5 To locate the source of the error, click the hyperlink in the message. The model in the source is highlighted. If a block has multiple ports, you can hover over each port to see the port number.

- 6 After fixing all errors, simulate your model again and view the **Diagnostic Viewer** to identify remaining problems.

Note If an error or warning has a predefined fix, the diagnostic message pane displays a **Suggested Actions** section. You can use the **Fix** button provided in this section to rectify the related error or warning. For more information see, “Suggested Actions” on page 25-51.

- 7 If an object in your model generates a warning that you do not want to be notified of, sometimes, you can suppress the warning from the specified source using the **Suppress** button. You can restore the warning from that source using the **Restore** button. For example, if a Counter Free-Running block generates an overflow warning

that is intentional in your design, you can suppress only overflow warnings from this particular block, without sacrificing notification of other overflows in your model.

- 8 To generate code for your model, click **Code > C/C++ Code > Build Model**.

Note If there is a failure during code generation, Diagnostic Viewer provides hyperlinks for easy navigation to the source of the error or warning message.

The screenshot shows the Diagnostic Viewer window with the following content:

Related Examples

- “Customize Diagnostic Messages” on page 25-68

- “Report Diagnostic Messages Programmatically” on page 25-71

Suppress Diagnostic Messages Programmatically

The following examples show how to manage diagnostic suppressions programmatically.

In this section...

“Suppress Diagnostic Messages Programmatically” on page 25-59

“Suppress Diagnostic Messages of a Referenced Model” on page 25-63

Suppress Diagnostic Messages Programmatically

This example shows how to access simulation metadata to manage diagnostic suppressions and to restore diagnostic messages programmatically.

Create a New Folder and Copy Relevant Files

- 1 Create a local working folder, for example, `c:\diagnostic_suppressor_demo`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the `getDiagnosticObjects.m`, `suppressor_script.m`, and `Suppressor_CLI_Demo.slx` files to your local working folder.

The `getDiagnosticObjects.m` function queries the simulation metadata to access diagnostics that were thrown during simulation. The `suppressor_script.m` script contains the commands for suppressing and restoring diagnostics to the `Suppressor_CLI_Demo` model.

`getDiagnosticObjects.m`

```
function y = getDiagnosticObjects(in)
Warningdata = in.getSimulationMetadata.ExecutionInfo.WarningDiagnostics;
Errordata = in.getSimulationMetadata.ExecutionInfo.ErrorDiagnostic;

index = 1;

for i = 1 : numel(Warningdata)
    y(index) = Warningdata(i).Diagnostic;
    index = index + 1;
end
```

```

for i = 1 : numel(Errordata)
    y(index) = Errordata(i).Diagnostic;
    index = index + 1;
end

```

Open and Simulate the Model

Open the model. To access `Simulink.SimulationMetadata`, set the `ReturnWorkspaceOutputs` parameter value to 'on'. Simulate the model.

```

model = 'Suppressor_CLI_Demo';
open_system(model);
set_param(model, 'ReturnWorkspaceOutputs', 'on');
out = sim(model);

```

Fixed-Point to Fixed-Point Conversion

Get Message Identifiers from Simulation Metadata

Find the names of diagnostic message identifiers using the simulation metadata stored in the `MSLDiagnostic` object.

```
if (exist('out', 'var'))
    diag_objects = getDiagnosticObjects(out);
end
```

Several warnings were generated during simulation, including a saturation of the Data Type Converter block. Query the `diag_objects` variable to get more information on the identifiers.

```
diag_objects(5)
```

```
ans =
```

```
MSLDiagnostic with properties:
```

```
    identifier: 'SimulinkFixedPoint:util:Saturationoccurred'
    message: 'Saturation occurred. This originated from 'Suppressor_CLI_Demo/Con...'
    paths: {'Suppressor_CLI_Demo/Convert/FixPt To FixPt3'}
    cause: {}
    stack: [0x1 struct]
```

Suppress Saturation Diagnostic on a Block

Use the `Simulink.suppressDiagnostic` function to suppress the saturation diagnostic on the data type conversion block only. Simulate the model.

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3', ...
    'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

Restore the Saturation Diagnostic

Use the `Simulink.restoreDiagnostic` function to restore the saturation diagnostic of the same block.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt3', ...
    'SimulinkFixedPoint:util:Saturationoccurred');
set_param(model, 'SimulationCommand', 'start');
```

Suppress Multiple Diagnostics on a Source

You can suppress multiple warnings on a single source by creating a cell array of message identifiers. Suppress the precision loss and parameter underflow warnings of the Constant block, one, in the model.

```
diags = {'SimulinkFixedPoint:util:fxpParameterPrecisionLoss', ...
    'SimulinkFixedPoint:util:fxpParameterUnderflow'};
```

```
Simulink.suppressDiagnostic('Suppressor_CLI_Demo/one',diags);  
set_param(model,'SimulationCommand','start');
```

Restore All Diagnostics on a Block

Restore all diagnostics on a specified block using the `Simulink.restoreDiagnostic` function.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/one');  
set_param(model,'SimulationCommand','start');
```

Suppress a Diagnostic on Many Blocks

You can suppress one or more diagnostics on many blocks. For example, use the `find_system` function to create a cell array of all Data Type Converter blocks in a system, and suppress all saturation warnings on the specified blocks.

```
dtc_blocks = find_system('Suppressor_CLI_Demo/Convert',...  
    'BlockType', 'DataTypeConversion');  
Simulink.suppressDiagnostic(dtc_blocks, 'SimulinkFixedPoint:util:Saturationoccurred');  
set_param(model,'SimulationCommand','start');
```

Restore All Diagnostics Inside a Subsystem

You can also use the `Simulink.restoreDiagnostic` function to restore all diagnostics inside a specified subsystem.

```
Simulink.restoreDiagnostic('Suppressor_CLI_Demo/Convert',...  
    'FindAll', 'On');  
set_param(model,'SimulationCommand','start');
```

Add Comments and User Information to a Suppression

A `SuppressedDiagnostic` object contains information on the source of the suppression and the suppressed diagnostic message identifier. You can also include comments, and the name of the user who last modified the suppression.

```
Object = Simulink.SuppressedDiagnostic('Suppressor_CLI_Demo/Convert/FixPt To FixPt1',...  
    'SimulinkFixedPoint:util:Saturationoccurred');  
Object.Comments = 'Reviewed: John Doe';  
Object.LastModifiedBy = 'Joe Schmoe';  
set_param(model,'SimulationCommand','start');
```

Object =

SuppressedDiagnostic with properties:

```

        Source: 'Suppressor_CLI_Demo/Convert/FixPt To FixPt1'
        Id: 'SimulinkFixedPoint:util:Saturationoccurred'
    LastModifiedBy: 'Joe Schmoe'
        Comments: 'Reviewed: John Doe'
    LastModified: '2016-Jun-21 18:23:01'

```

Get Suppression Data

To get suppression data for a certain subsystem or block, use the `Simulink.getSuppressedDiagnostics` function.

```

Object = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo/Convert/FixPt To FixPt1');
set_param(model, 'SimulationCommand', 'start');

```

Restore All Diagnostics on a Model

When a model contains many diagnostic suppressions, and you want to restore all diagnostics to a model, use the `Simulink.getSuppressedDiagnostics` function to return an array `Simulink.SuppressedDiagnostic` objects. Then use the `Simulink.SuppressedDiagnostic.restore` method as you iterate through the array.

```

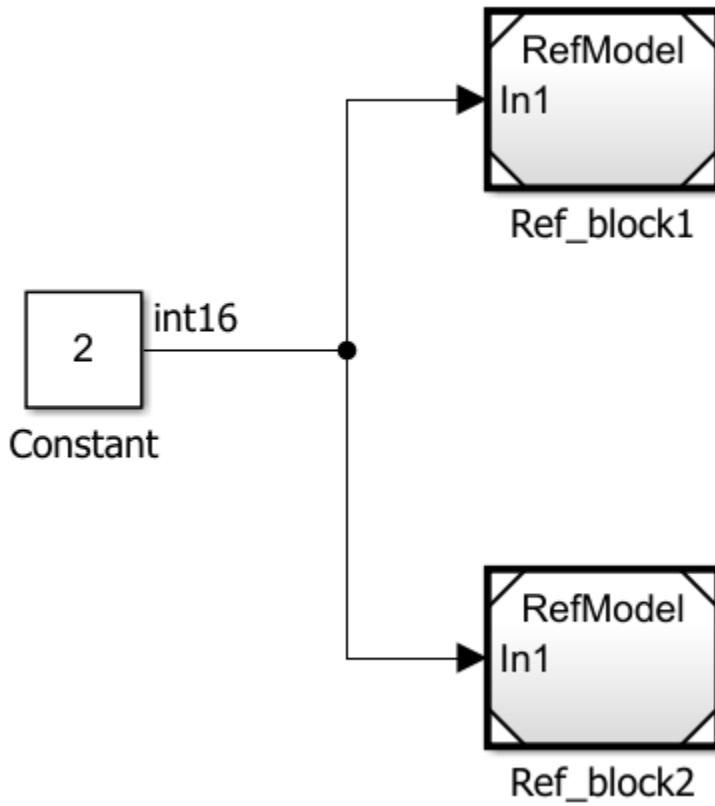

Objects = Simulink.getSuppressedDiagnostics('Suppressor_CLI_Demo');
for iter = 1:numel(Objects)
    restore(Objects(iter));
end
set_param(model, 'SimulationCommand', 'start');

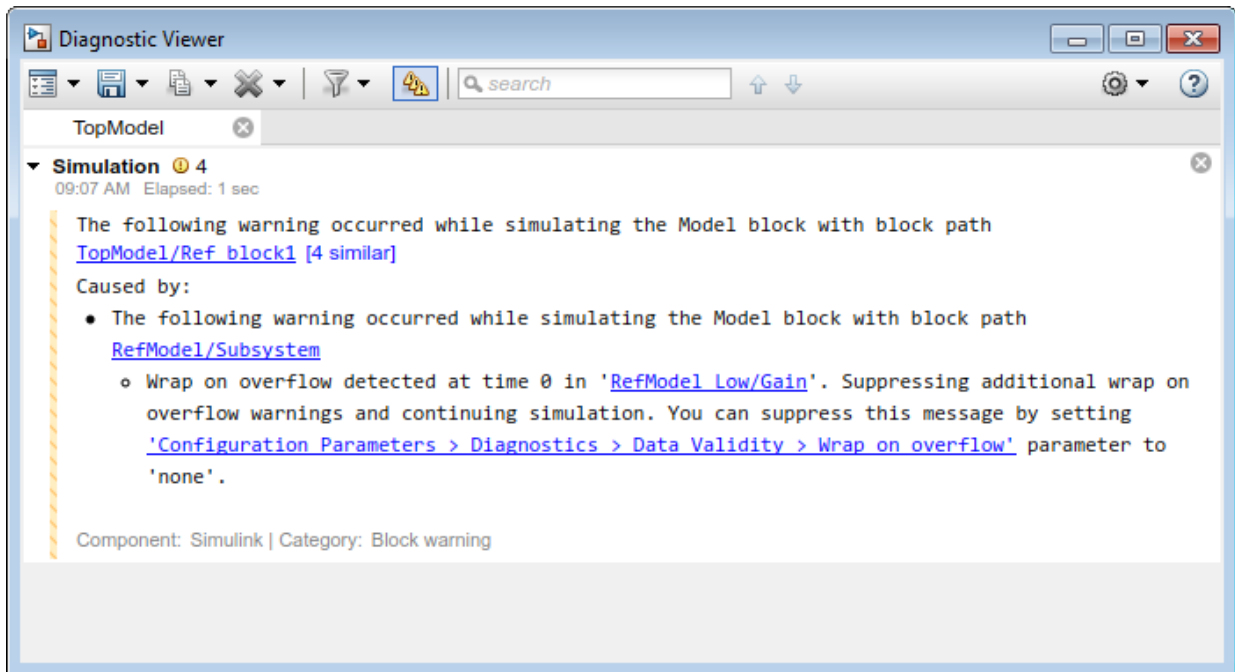

```

Suppress Diagnostic Messages of a Referenced Model

This example shows how to suppress a diagnostic when the diagnostic originates from a referenced model. By accessing the `MSLDiagnostic` object of the specific instance of the warning, you can suppress the warning only for instances when the referenced model is simulated from the specified top model.

This example model contains two instances of the same referenced model, `RefModel`. The model `RefModel` references yet another model, `RefModel_Low`. `RefModel_Low` contains two Gain blocks that each produce a wrap on overflow warning during simulation. Suppress one of the four instances of this warning in the model by accessing the `MSLDiagnostic` object associated with the wrap on overflow warning produced by one of the Gain blocks in the `RefModel_Low` model only when it is referenced by `Ref_block1`.

Open the top model. Simulate the model and store the output in a variable, out.

```
out = sim('TopModel');
```

Access the simulation metadata stored in the `MSLDiagnostic` object.

```
diag = getDiagnosticObjects(out)
```

```
diag =
```

```
1x4 MSLDiagnostic array with properties:
```

```
    identifier  
    message  
    paths  
    cause  
    stack
```

You can view the diagnostics and their causes in the Diagnostic Viewer or at the command-line.

```
for i = 1 : numel(diag)  
    disp(diag(i));  
    disp(diag(i).cause{1});  
end
```

Suppress one of the wrap on overflow warnings from `RefModel_Low` only when it is simulated from `TopModel/Ref_block1` by accessing the specific diagnostic. Simulate the model.

```
Simulink.suppressDiagnostic(diag(1));  
out = sim('TopModel')
```

Access the simulation metadata. This simulation produced only three warnings.

```
diag = getDiagnosticObjects(out)
```

```
diag =
```

```
1x3 MSLDiagnostic array with properties:
```

```
    identifier  
    message  
    paths  
    cause  
    stack
```

Restore the diagnostic to the model.

```
Simulink.restoreDiagnostic(diag(1));
```

Customize Diagnostic Messages

In this section...

“Display Custom Text” on page 25-68

“Create Hyperlinks to Files, Folders, or Blocks” on page 25-69

“Create Programmatic Hyperlinks” on page 25-69

The **Diagnostic Viewer** displays the output of MATLAB error functions executed during simulation.

You can customize simulation error messages in the following ways by using MATLAB error functions in callbacks, S-functions, or MATLAB Function blocks.

Display Custom Text

This example shows how to can customize the MATLAB function `check_signal` to display the text `Signal is negative`.

- 1 Open the MATLAB Function for editing.

- 2 In the MATLAB Editor, create a function to display custom text.

```
function y = check_signal(x)
    if x < 0
        error('Signal is negative');
    else
        y = x;
    end
end
```

- 3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

- 4 To view the following error in **Diagnostic Viewer**, close the debugger.

Create Hyperlinks to Files, Folders, or Blocks

To create hyperlinks to files, folders, or blocks in an error message, include the path to these items within customized text.

Example error message	Hyperlink
<code>error('Error reading data from "C:/Work/designData.mat"')</code>	Opens <code>designData.data</code> in the MATLAB Editor.
<code>error('Could not find data in folder "C:/Work"')</code>	Opens a Command Window and sets <code>C:\Work</code> as the working folder.
<code>error('Error evaluating parameter in block "myModel/Mu"')</code>	Displays the block <code>Mu</code> in model <code>myModel</code> .

Create Programmatic Hyperlinks

This example shows how to can customize the MATLAB function `check_signal` to display a hyperlink to the documentation for `find_system`.

- 1 Open the MATLAB Function for editing.

- 2 In the MATLAB Editor, create a function to display custom text.

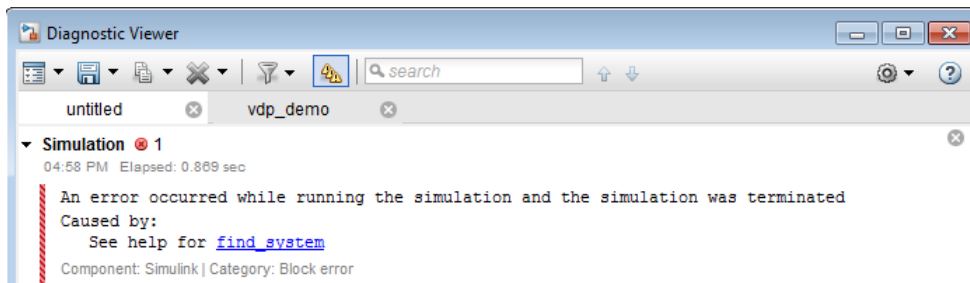

```
function y = check_signal(x)
    if x < 0
```

```
        error('See help for <a href="matlab:doc find_system">find_system</a>');  
    else  
        y = x;  
    end
```

- 3 Simulate the model.

A runtime error appears and you are prompted to start the debugger. Click **OK**.

- 4 To view the following error in **Diagnostic Viewer**, close the debugger.

- “Report Diagnostic Messages Programmatically” on page 25-71

Report Diagnostic Messages Programmatically

The `sldiagviewer` functions enable you to generate, display, and log diagnostic messages in the Diagnostic Viewer.

You can use these functions to report the diagnostic messages programmatically:

- Function to create a stage: `sldiagviewer.createStage`
- Functions to report diagnostic messages:
 - `sldiagviewer.reportError`
 - `sldiagviewer.reportWarning`
 - `sldiagviewer.reportInfo`
- Function to log the diagnostics: `sldiagviewer.diary`

Create Diagnostic Stages

In the Diagnostic Viewer, errors, warnings, and information messages are displayed in groups based on the operation, such as model load, simulation, and build. These groups are called stages. The `sldiagviewer.createStage` function enables you to create stages. You can also create child stages for a stage object. A parent stage object must be active to create a child stage. When you create a stage object, Simulink initializes a stage. When you close the stage object, Simulink ends the stage. If you delete a parent stage object, the corresponding parent and its child stage close in the Diagnostic Viewer. The syntax for creating a stage is:

```
stageObject =  
sldiagviewer.createStage(StageName, 'ModelName', ModelNameValue)
```

In this syntax,

- `StageName` specifies the name of a stage and is a required argument, for example, 'Analysis'.
- Use the 'ModelName', `ModelNameValue` pair to specify the model name of a stage, for example 'ModelName', 'vdp'. All the child stages inherit the model name from their parent.

Example to Create Stage

```
my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');
```

Report Diagnostic Messages

You can use the `sldiagviewer` functions to report error, warning, or information messages in the Diagnostic Viewer. The syntaxes for reporting diagnostic messages are:

- `sldiagviewer.reportError(Message)`: Reports the error messages.
- `sldiagviewer.reportWarning(Message)`: Reports the warnings.
- `sldiagviewer.reportInfo(Message)`: Reports the information messages.

Message describes the error, warning, or build information and is a required argument. Message can have values in these formats:

- String
- `MSLException` or `MException` object

Optionally, you can use the 'Component' argument and its corresponding value in the syntax to specify the component or product that generates the message, for example, 'Simulink' and 'Stateflow'.

Example to Report Diagnostics

```
% Create a Stage to display all the messages
my_stage = sldiagviewer.createStage('Analysis', 'ModelName', 'vdp');

% Catch the error introduced in vdp as an exception.

try
sim('vdp');
catch error
% Report the caught exception as warning

sldiagviewer.reportWarning(error);
end

% Report a custom info message to Diagnostic Viewer
sldiagviewer.reportInfo('My Info message');
```

Log Diagnostic Messages

You can use the `sldiagviewer.diary` function to log the simulation warning, error, and build information to a file. The syntaxes for generating log files are:

- `sldiagviewer.diary`: Intercepts the build information, warnings, and errors transmitted to the Diagnostic Viewer and logs them to a text file `diary.txt` in the current directory.
- `sldiagviewer.diary(filename)`: Toggles the logging state of the text file specified by `filename`.
- `sldiagviewer.diary(toggle)`: Toggles the logging ability. Valid values are 'on' and 'off'. If you have not specified a log file name, the toggle setting applies to the last file name that you specified for logging or to the `diary.txt` file.
- `sldiagviewer.diary(filename, 'UTF-8')`: Specifies the character encoding for the log file.

In this syntax,

- `filename` specifies the file to log the data to.
- `toggle` specifies the logging state 'on' or 'off'.

Log Diagnostic Messages

```
% Start logging build information and simulation warnings and errors to diary.txt
```

```
sldiagviewer.diary
open_system('vdp')
set_param('vdp/Mu', xyz)
set_param('vdp', 'SimulationCommand', 'Start')
% This introduces an error and do UI simulation which you can see in the diary log
```

```
% Open diary.txt to view logs.
```

```
##### Starting build procedure for model: vdp
##### Build procedure for model: 'vdp' aborted due to an error.
%...
```

```
% Set up logging to a specific file
```

```
sldiagviewer.diary('C:\MyLogs\log1.txt') % Make sure you have write permission for this
```

```
% Switch the logging state of a file
```

```
sldiagviewer.diary('C:\MyLogs\log2.txt') % Switch on logging and specify a log file.
open_system('vdp')
set_param('vdp/Mu', xyz)
set_param('vdp', 'SimulationCommand', 'Start')

sldiagviewer.diary('off') % Switch off logging.
open_system('sldemo_fuelsys') % Any operation you do after the previous command will n
rtwbuild('sldemo_fuelsys')

sldiagviewer.diary('on') % Resume logging in the previously specified log file.

% Specify the filename to log to and character encoding to be used
sldiagviewer.diary('C:\MyLogs\log3.txt','UTF-8')
```

Running a Simulation Programmatically

- “Run Simulations Programmatically” on page 26-2
- “Run Parallel Simulations” on page 26-9
- “Using sim function within parfor” on page 26-13
- “Error Handling in Simulink Using MSLErrorException” on page 26-25

Run Simulations Programmatically

You can programmatically simulate a model with the `sim` function, using various techniques to specify parameter values. In addition to simulating a model, you can use the `sim` to enable simulation timeouts, capture simulation errors, and access simulation metadata when your simulation is complete

For an interactive simulation, you can use `set_param` and `get_param`. With `set_param` and `get_param`, you can check the status of a running simulation, control how the simulation works by using block callbacks.

Specify Parameter Name-Value Pairs

This example shows how to programmatically simulate a model, specifying parameters as name-value pairs.

Simulate the `vdp` model with parameter values specified as consecutive name-value pairs.

```
simOut = sim('vdp','SimulationMode','normal','AbsTol','1e-5',...
            'SaveState','on','StateSaveName','xout',...
            'SaveOutput','on','OutputSaveName','yout',...
            'SaveFormat','Dataset');
outputs = simOut.get('yout')
```

```
outputs =
```

```
Simulink.SimulationData.Dataset
Package: Simulink.SimulationData
```

```
Characteristics:
    Name: 'yout'
    Total Elements: 2
```

```
Elements:
    1 : 'x1'
    2 : 'x2'
```

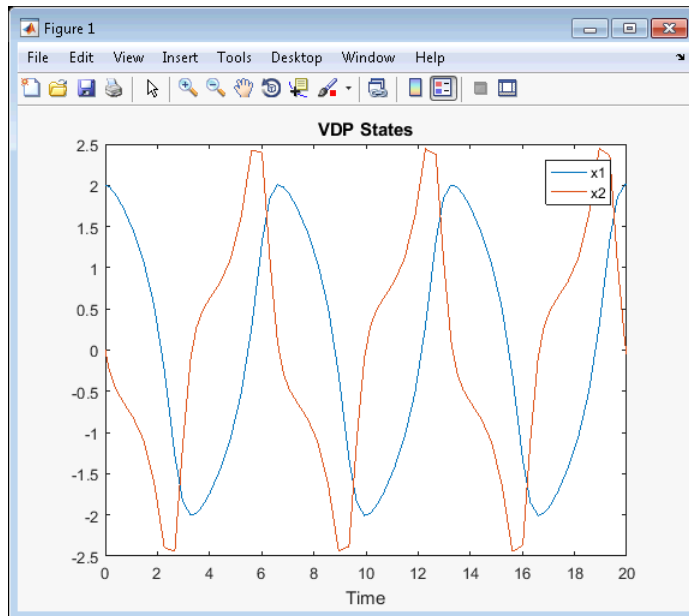

```
-Use get or getElement to access elements by index or name.
-Use addElement or setElement to add or modify elements.
```

You simulate the model in `Normal` mode, specifying an absolute tolerance for solver error. The `sim` function returns `SimOut`, a single `Simulink.SimulationOutput` object that

contains all of the simulation outputs (logged time, states, and signals). The `sim` function *does not* return simulation values to the workspace.

Plot the output signal values against time.

```
x1=(outputs.get('x1').Values);
x2=(outputs.get('x2').Values);
plot(x1); hold on;
plot(x2);
title('VDP States')
xlabel('Time'); legend('x1','x2')
```

Enable Simulation Timeouts

If you are running multiple simulations in a loop and are using a variable-step solver, consider using `sim` with the `timeout` parameter. If, for some reason, a simulation hangs or begins to take unexpectedly small time steps, it will time out. Then, the next simulation can run. Example syntax is shown below.

```
N = 100;
simOut = repmat(Simulink.SimulationOutput, N, 1);
```

```
for i = 1:N
    simOut(i) = sim('vdp', 'timeout', 1000);
end
```

Capture Simulation Errors

If an error causes your simulation to stop, you can see the error in the simulation metadata. In this case, `sim` captures simulation data in the simulation output object up to the time it encounters the error, enabling you to do some debugging of the simulation without rerunning it. To enable this feature, use the `CaptureErrors` parameter with the `sim` function.

Example syntax and resulting output for capturing errors with `sim` is:

```
simOut = sim('my_model', 'CaptureErrors', 'on');
simOut.getSimulationMetadata.ExecutionInfo

ans =

    struct with fields:

        StopEvent: 'DiagnosticError'
        StopEventSource: []
        StopEventDescription: 'Division by zero in 'my_model/Divide''
        ErrorDiagnostic: [1x1 struct]
        WarningDiagnostics: [0x1 struct]
```

Another advantage of this approach is that the simulation error does not also cause `sim` to stop. Therefore, if you are using `sim` in a `for` loop for example, subsequent iterations of the loop will still run.

Access Simulation Metadata

This example shows you how to access simulation metadata once your simulation is complete. You can run any kind of simulation and access its metadata.

This example simulates the model with parameter values specifies as name-value pairs. Run the simulation.

```
simOut = sim('vdp', 'SimulationMode', 'normal', 'AbsTol', '1e-5', ...
    'SaveState', 'on', 'StateSaveName', 'xoutNew', ...
    'SaveOutput', 'on', 'OutputSaveName', 'youtNew', ...
    'SaveFormat', 'StructureWithTime');
```

Access the `ModelInfo` property, which has some basic information about the model and solver.

```
simOut.getSimulationMetadata.ModelInfo
ans =
    struct with fields:
        ModelName: 'vdp'
        ModelVersion: '1.6'
        ModelFilePath: 'C:\MyWork'
        UserID: 'User'
        MachineName: 'MyMachine'
        Platform: 'PCWIN64'
        ModelStructuralChecksum: [4x1 uint32]
        SimulationMode: 'normal'
        StartTime: 0
        StopTime: 20
        SolverInfo: [1x1 struct]
        SimulinkVersion: [1x1 struct]
        LoggingInfo: [1x1 struct]
```

Inspect the solver information.

```
simOut.getSimulationMetadata.ModelInfo.SolverInfo
ans =
    struct with fields:
        Type: 'Variable-Step'
        Solver: 'ode45'
        MaxStepSize: 0.4000
```

Review timing information for your simulation, such as when your simulation started and finished, and the time the simulation took to initialize, execute, and terminate.

```
simOut.getSimulationMetadata.TimingInfo
ans =
    struct with fields:
        WallClockTimestampStart: '2016-06-17 10:26:58.433686'
```

```
WallClockTimestampStop: '2016-06-17 10:26:58.620687'  
InitializationElapsedWallTime: 0.1830  
ExecutionElapsedWallTime: 1.0000e-03  
TerminationElapsedWallTime: 0.0030  
TotalElapsedWallTime: 0.1870
```

Add notes to your simulation.

```
simOut=simOut.setUserString('Results from simulation 1 of 10');  
simOut.getSimulationMetadata
```

ans =

SimulationMetadata with properties:

```
ModelInfo: [1x1 struct]  
TimingInfo: [1x1 struct]  
ExecutionInfo: [1x1 struct]  
UserString: 'Results from simulation 1 of 10'  
UserData: []
```

You can also add your own custom data using the `UserData` property.

Control and Check Status of Simulation

This example shows how to use `set_param` to control and check the status of your simulation. `set_param` allows you to update the variables dynamically as well as write data-logging variables to the workspace.

Start a simulation.

```
set_param('vdp', 'SimulationCommand', 'start')
```

When you start a simulation using `set_param` and the `'start'` argument, you must use the `'stop'` argument to stop it.

Pause, continue, and stop a simulation.

```
set_param('vdp', 'SimulationCommand', 'pause')  
set_param('vdp', 'SimulationCommand', 'continue')  
set_param('vdp', 'SimulationCommand', 'stop')
```

When you use `set_param` to pause or stop a simulation, the commands are requests for such actions and the simulation doesn't execute them immediately. You can use

`set_param` to start a simulation after the stop command and to continue a simulation after the pause command. Simulink first completes uninterruptable work, such as solver steps and other commands that preceded the `set_param` command. Then, simulation starts, pauses, continues or stops as specified by the `set_param` command.

Check the status of a simulation.

```
get_param('vdp','SimulationStatus')
```

The software returns 'stopped', 'initializing', 'running', 'paused', 'compiled', 'updating', 'terminating', or 'external' (used with the Simulink Coder product).

To update the changed workspace variables dynamically while a simulation is running, use the `update` command.

```
set_param('vdp','SimulationCommand','update')
```

Write all data-logging variables to the base workspace.

```
set_param('vdp','SimulationCommand','WriteDataLogs')
```

Automate Simulation Tasks Using Callbacks

A callback executes when you perform various actions on your model, such as starting, pausing, or stopping a simulation. You can use callbacks to execute a MATLAB script or other MATLAB commands. For more information, see “Callbacks for Customized Model Behavior” on page 4-50 and “Block Callback Parameters” on page 4-57.

This example shows how to use the model `StartFcn` callback to automatically execute MATLAB code before the simulation starts.

Write a MATLAB script that finds Scope blocks in your model and opens them in the foreground when you simulate the model. Save the script in the current folder.

```
% openscopes.m
% Brings scopes to forefront at beginning of simulation.

blocks = find_system(bdroot,'BlockType','Scope');

% Finds all of the scope blocks in the top level of your
% model. To find scopes in subsystems, provide the subsystem
% names. Type help find_system for more on this command.
```

```
for i = 1:length(blocks)
    set_param(blocks{i}, 'Open', 'on')
end
```

```
% Loops through all of the scope blocks and brings them
% to the forefront.
```

Set the StartFcn parameter for the model to call the openscopes script.

```
set_param('my_model', 'StartFcn', 'openscopes')
```

Run Parallel Simulations

The `parsim` command allows you to run parallel (simultaneous) Simulink® simulations of your model (design). In this context, parallel runs mean multiple simulations at the same time on different workers. `parsim` makes it easy for you to run the same model with different inputs or different parameter settings in scenarios such as Monte Carlo analyses, parameter sweeps, model testing, experiment design, and model optimization. Running a single simulation in parallel by decomposing the model into smaller components and running those individual pieces simultaneously on multiple workers is currently not supported.

To run the simulations in parallel with `parsim`, you need a Parallel Computing Toolbox for local workers. In addition, you can use MATLAB Parallel Server for multiple computer clusters, clouds, and grids. In the absence of Parallel Computing Toolbox and MATLAB Parallel Server, `parsim` runs the simulations in serial. For more information, see “Parallel Computing Toolbox” and “MATLAB Parallel Server”.

If no parallel pool exists, `parsim` creates a pool from the default cluster profile . To use a cluster other than the default, create a pool with that cluster profile before calling `parsim`.

This example runs multiple simulations in parallel for a set of sweep parameters.

```
% 1) Load model
model = 'sldemo_susp_n_3dof';
load_system(model);

% 2) Set up the sweep parameters
Cf_sweep = 2500*(0.05:0.1:0.95);
numSims = numel(Cf_sweep);

% 3) Create an array of SimulationInput objects and specify the sweep value for each simulation
simIn(1:numSims) = Simulink.SimulationInput(model);
for idx = 1:numSims
    simIn(idx) = simIn(idx).setBlockParameter([model '/Road-Suspension Interaction'], 'Cf', num2str(Cf_sweep(idx)));
end

% 4) Simulate the model
simOut = parsim(simIn)
```

How `parsim` works

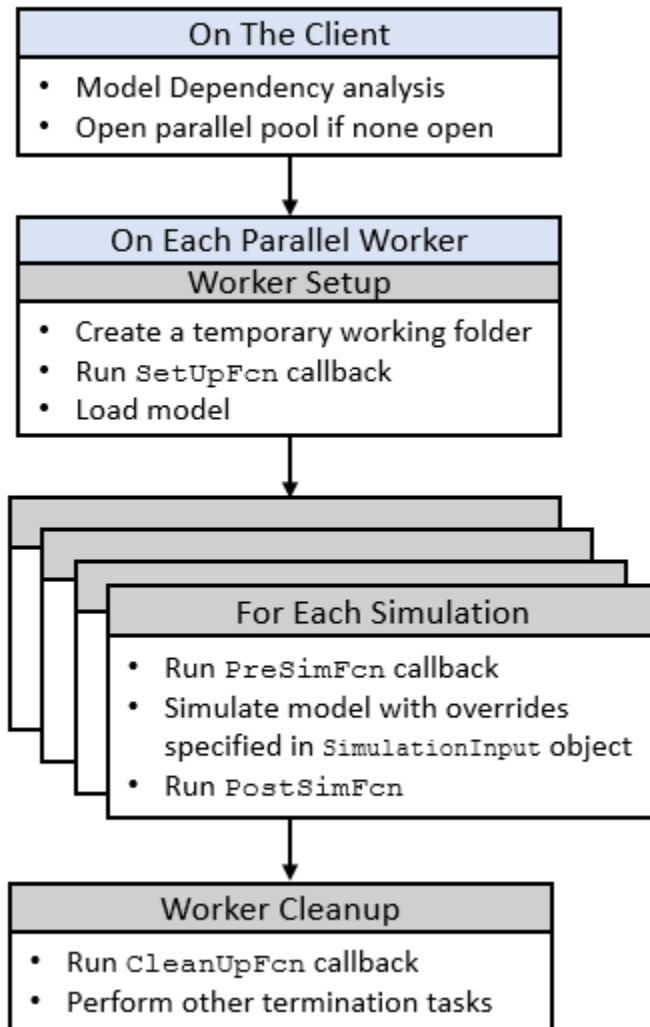

`parsim` runs simulations with different parameters and values based on the `Simulink.SimulationInput` object. Each `SimulationInput` object specifies one

simulation of the model. An array of these objects can be created for multiple simulations. For more information, see “Run Multiple Simulations” on page 27-2.

You can use the following methods and properties on `Simulink.SimulationInput` object:

- `setVariables` - Change variables in base workspace, data dictionary, or model workspace
- `setBlockParameters` - Change block parameters
- `setModelParameters` - Change model parameters
- `setPreSimFcn` - Specify MATLAB functions to run before each simulation for customization and post-processing results on the cluster
- `setPostSimFcn` - Specify MATLAB functions to run after each simulation for customization and post-processing results on the cluster
- `InitialState` - Change the Initial State
- `ExternalInput` - Specify a numerical array, timeseries, or Dataset object as external inputs to the model

This flowchart shows a general sequence of events that occur when `parsim` is executed

Changes to model library blocks can be overwritten when using `parsim`. When models are set up on new workers, model inherits properties directly from the worker library. Use `SetUpFcn` with `parsim` to transfer the model library block changes to the workers.

Using sim function within parfor

Note Using sim function within parfor loop is no longer recommended. For running parallel simulations, use parsim. Please see “Run Parallel Simulations” on page 26-9.

Overview of Calling sim from Within parfor

The `parfor` command allows you to run parallel (simultaneous) Simulink simulations of your model (design). In this context, parallel runs mean multiple model simulations at the same time on different workers. Calling `sim` from within a `parfor` loop often helps for performing multiple simulation runs of the same model for different inputs or for different parameter settings. For example, you can save simulation time performing parameter sweeps and Monte Carlo analyses by running them in parallel. Note that running parallel simulations using `parfor` does not currently support decomposing your model into smaller connected pieces and running the individual pieces simultaneously on multiple workers.

Normal, Accelerator, and Rapid Accelerator simulation modes are supported by `sim` in `parfor`. (See “Choosing a Simulation Mode” on page 35-12 for details on selecting a simulation mode and “Design Your Model for Effective Acceleration” on page 35-18 for optimizing simulation run times.) For other simulation modes, you need to address any workspace access issues and data concurrency issues to produce useful results. Specifically, the simulations need to create separately named output files and workspace variables. Otherwise, each simulation overwrites the same workspace variables and files, or can have collisions trying to write variables and files simultaneously.

For information on code regeneration and parameter handling in Rapid Accelerator mode, see “Parameter Tuning in Rapid Accelerator Mode” on page 35-9.

Also, see `parfor`.

Note If you open models inside a `parfor` statement, close them again using `bdclose all` to avoid leaving temporary files behind.

sim in parfor with Normal Mode

This code fragment shows how you can use `sim` and `parfor` in Normal mode. Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.

```
% 1) Load model and initialize the pool.
model = 'sldemo_susp_n_3dof';
load_system(model);
parpool;

% 2) Set up the iterations that we want to compute.
Cf          = evalin('base', 'Cf');
Cf_sweep    = Cf*(0.05:0.1:0.95);
iterations  = length(Cf_sweep);
simout(iterations) = Simulink.SimulationOutput;

% 3) Need to switch all workers to a separate tempdir in case
% any code is generated for instance for StateFlow, or any other
% file artifacts are created by the model.
spmd
    % Setup tempdir and cd into it
    currDir = pwd;
    addpath(currDir);
    tmpDir = tempname;
    mkdir(tmpDir);
    cd(tmpDir);
    % Load the model on the worker
    load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model '/Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spmd
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
```

```

        close_system(model, 0);
    end

```

```

close_system(model, 0);
delete(gcf('nocreate'));

```

sim in parfor with Normal Mode and MATLAB Parallel Server Software

This code fragment is identical to the one in “sim in parfor with Normal Mode” on page 26-14

. Modify it as follows for using `sim` and `parfor` in Normal mode:

- In item 1, modify the `parpool` command as follows to create an object and use it to call a cluster name.

```

p = parpool('clusterProfile');
% 'clusterProfile' is the name of the distributed cluster

```

- In item 1, find files on which the model depends and attach those files to the model for distribution to cluster workers on remote machines.

```

files = dependencies.fileDependencyAnalysis(modelName);
p.addAttachedFiles(files);

```

- If you do not have a MATLAB Parallel Server cluster, use your local cluster. For more information, see “Discover Clusters and Use Cluster Profiles” (Parallel Computing Toolbox).

Start your cluster before running the code.

```

% 1) Load model and initialize the pool.
model = 'sldemo_suspn_3dof';
load_system(model);
parpool;

```

```

% 2) Set up the iterations that we want to compute.
Cf
    = evalin('base', 'Cf');
Cf_sweep
    = Cf*(0.05:0.1:0.95);
iterations
    = length(Cf_sweep);
simout(iterations)
    = Simulink.SimulationOutput;

```

```

% 3) Need to switch all workers to a separate tempdir in case
% any code is generated for instance for StateFlow, or any other
% file artifacts are created by the model.
spmd

```

```
% Setup tempdir and cd into it
addpath(pwd);
currDir = pwd;
addpath(currDir);
tmpDir = tempname;
mkdir(tmpDir);
cd(tmpDir);
% Load the model on the worker
load_system(model);
end

% 4) Loop over the number of iterations and perform the
% computation for different parameter values.
parfor idx=1:iterations
    set_param([model 'Road-Suspension Interaction'],'MaskValues',...
        {'Kf',num2str(Cf_sweep(idx)),'Kr','Cr'});
    simout(idx) = sim(model, 'SimulationMode', 'normal');
end

% 5) Switch all of the workers back to their original folder.
spmd
    cd(currDir);
    rmdir(tmpDir,'s');
    rmpath(currDir);
    close_system(model, 0);
end

close_system(model, 0);
delete(gcp('nocreate'));
```

sim in parfor with Rapid Accelerator Mode

Running Rapid Accelerator simulations in `parfor` combines speed with automatic distribution of a prebuilt executable to the `parfor` workers. As a result, this mode eliminates duplication of the update diagram phase.

To run parallel simulations in Rapid Accelerator simulation mode using the `sim` and `parfor` commands:

- Configure the model to run in Rapid Accelerator simulation mode.
- Save changes to your model before simulating in `parfor`. The saved copy of your model is distributed to parallel workers when simulating in `parfor`.
- Ensure that the Rapid Accelerator target is already built and up to date.
